[Perpetual motion or science - have a look](#) | 8 comments (8 topical, editorial)

Re: Perpetual motion or science - have a look ([none / 0](#)) (#2)  
by kell on Thu Jan 1st, 2004 at 03:53:47 PM MST  
([User Info](#))

They don't make claims of perpetual motion. They do claim to get more gas with less current than predicted by theory that no one has questioned for more than a hundred years or examined narrowly in this particular experimental context insofar as I am aware... and the empirical trumps the theoretical. If you're a scientist.

Also, even if they were to claim that the hydrolyzer would run on its own heat output (which they don't), that's still not "perpetual motion". It isn't a closed system.

[My Mini Geni isn't working very good](#) | 18 comments (18 topical, editorial)

Re: My Mini Geni isn't working very good ([none / 0](#)) (#11)  
by kell on Tue Dec 30th, 2003 at 09:38:00 PM MST ([User Info](#))

For each bunch of little mags fighting each other you've got a distorted multipolar field with flux lines going every which way. I think you'll do better with cheap ceramic magnets of the right size, so you know the flux lines will cut the coils where and when you want them to.

Re: My Mini Geni isn't working very good ([none / 0](#)) (#12)

<http://www.dplusv.com/Photo-03.html>

I did 6 of the little Ed/Windstuff magnets on a smaller version of this motor. Didn't change a thing but machined the armature down to fit the magnets.

It dose cogg hard but I'm seeing 60 watts at 500 rpm. Just try getting 60 watts from a solar panel for 6 bux.

I was reading somewhere on the board that , lining up magnets like this created a magnetic field that was the same as a bar magnet with the poles on the sides. That's why I built it this way.

Is this right or not, Many of Zubbly's designs are similar to this approach.

big gap..... ([none / 0](#)) (#16)

by Norm on Wed Dec 31st, 2003 at 12:51:12 PM MST

([User Info](#))

After taking a real close look at the pictures and especially the last ones ,I think I have the solution...a couple of the ones that replied and said about the gap were on the right track especially Electric Ed where he also referred to the width of the magnets to the width of the coil or something like that, so I'll be back with the solution as soon as I draw a couple of illustrations on one of your pictures. OK? Norm

Re: big gap..... ([none / 0](#)) (#17)

by Norm on Wed Dec 31st, 2003 at 02:48:13 PM MST

([User Info](#))

Okay...on the next one you get like this(this would be an alternative for someone with only simple handtools)after carefully unwinding each coil.....cut each pole straight down as on the red line, when you are finished it will look something like the first picture. Now center a block of wood as thick as the laminate and scribe the radius of the rotor and cut the ends of each pole off accordingly take a large half-round file and file the curve to allow clearance of the rotor. Then rewind the coils and put em back. This is far from ideal but it should work. The better way would be as Jerry suggested....Hope this helps....Have Fun! (:>) Norm.

Re: big gap..... ([none / 0](#)) (#18)  
by Harry Luubovv on Wed Dec 31st,  
2003 at 08:30:05 PM MST  
([User Info](#))

Ok Woofer,

Why not try using square magnets to line up one after another instead of round ones ? because the rounds do give trouble to the magnetic paths, that is, pulling and distorting the flux path. Square ones should behave more "Squarely" in this regard, no pun intended. :-

Love experimenters !  
Luubovv

[Magnetic Brushes for Axial Flux Path](#) | 8 comments (8 topical, editorial)

Re: Magnetic Brushes for Axial Flux Path ([none / 0](#)) (#3)  
by [kell](#) on Tue Dec 30th, 2003 at 09:26:32 PM MST ([User Info](#))

You'll make your brushes out of some ferromagnetic material to increase permeability in the coils? Silicon steel, soft iron, ferrite, powdered iron, whatever... I can just see a ferromagnetic brush glomming onto the first mag it touches, not just cogging but mechanically locking up your genny. In other words, your brushes would have to be made of something that is not attracted to magnets. But what?

Anybody out there know: Is there some non-ferromagnetic high-permeability material?

Re: Magnetic Brushes for Axial Flux Path ([none / 0](#)) (#4)  
by [drdongle](#) on Wed Dec 31st, 2003 at 05:26:23 AM MST ([User Info](#))

Excellent point, the brushes would have to pass or channel the field but not be affected by it, can't be done.

Dr.D

[QUESTION ON MAGNETS](#) | 3 comments (3 topical, 0 editorial)

Re: QUESTION ON MAGNETS ([none / 0](#)) ([#2](#))  
by kell on Mon Dec 29th, 2003 at 07:07:12 PM MST  
([User Info](#))

What do you mean "soft material?" It has to be something that a magnet will attract, which for all practical purposes means iron or steel.

No magnet exerts the same amount of force regardless of distance. All magnets exert less force at greater distance, and you get to a point where the attraction is so small you can't even measure it, let alone make use of it. Also: four feet is way too far. If you're talking about permanent magnets you could never hope to get your hands on a permanent magnet strong enough to exert useful force at four feet. Electromagnets are another matter... if you've got the dollars to build on an industrial scale.

Also, just for the sake of argument, if you could find a permanent magnet that strong you would be risking permanent injury or death just handling it around everyday objects. Get between it and a hunk of steel and it would crush you.

Or maybe I just misunderstood your post.

Re: QUESTION ON MAGNETS ([none / 0](#)) ([#3](#))  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Mon Dec 29th, 2003 at 07:23:10 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Kell is right, you won't find a magnet, electric or permanent that will have a force that you describe. If your looking for a magnet that has a large field, your looking for a ceramic magnet. I have some ring magnets that will affect a TV from 4 ft away. They are 8 inches in diameter with a 4 inch hole and are 3/4" thick. They aren't real strong in the sense a neo is but the field size is impressive.

Have Fun!  
Ed

[Can I see sulfation on battery plates?](#) | 7 comments (7 topical, editorial)

Re: Can I see sulfation on battery plates? ([none / 0](#)) (#4)  
by [kell](#) on Mon Dec 29th, 2003 at 06:39:54 PM MST ([User Info](#))

There was a charging circuit posted here a while ago that is supposed to help freshen up a sulfated battery. I don't know how to post diagrams but I'll describe the circuit. You need a full bridge rectifier rated for at least a couple hundred volts peak inverse voltage. Basically you are running rectified line power (120 v) into the battery, but you limit current by simply feeding the ac into the bridge through a capacitor. The capacitor should have a voltage rating of at least a couple hundred volts. The capacitance determines the current. For a fairly big battery you could go for a few dozen uF (microfarads)... it's not an exact thing; just monitor current and voltage. Attach the dc output of the bridge to the battery. Keep an eye on the battery voltage so you don't overcharge it. You can do a couple of discharge/recharge cycles. The cap needs to be non-polarized. There's also a way to use polarized capacitors and diodes to pass ac, but I won't go into that here.

In effect this is a constant-current high voltage pulse charger, so the monitoring is important because it will overcharge your battery if you don't watch it.

Re: Can I see sulfation on battery plates? ([none / 0](#)) (#4)  
by [kell](#) on Mon Dec 29th, 2003 at 06:39:54 PM MST ([User Info](#))

There was a charging circuit posted here a while ago that is supposed to help freshen up a sulfated battery. I don't know how to post diagrams but I'll describe the circuit. You need a full bridge rectifier rated for at least a couple hundred volts peak inverse voltage. Basically you are running rectified line power (120 v) into the battery, but you limit current by simply feeding the ac into the bridge through a capacitor. The capacitor should have a voltage rating of at least a couple hundred volts. The capacitance determines the current. For a fairly big battery you could go for a few dozen uF (microfarads)... it's not an exact thing; just monitor current and voltage. Attach the dc output of the bridge to the battery. Keep an eye on the battery voltage so you don't overcharge it. You can do a couple of discharge/recharge cycles. The cap needs to be non-polarized. There's also a way to use polarized capacitors and diodes to pass ac, but I won't go into that here.

In effect this is a constant-current high voltage pulse charger, so the monitoring is important because it will overcharge your battery if you don't watch it.

([User Info](#))

I wonder why you intend to do this test. Do you want to see how much wind load your tower will take? Wind loading exerts external forces. The proposed test exerts internal forces.

The test you described could give you some idea how much sheer weight the tower would support, since the cable will exert a downward force on the tower at its uppermost point, as would a massive mill of some sort. But what mill is so heavy and tower so weak as to buckle in such a way?

A heavy mill poses a risk by making your tower more vulnerable to tipping!

Weakness will likely manifest itself where the sections of tower join and at the base. A tipping tower exerts the most moment (torque) at its base. Like a big lever.

The closest thing to copy wind loading and tipping would entail erecting the tower, attaching a cable to the tower somewhere between the middle and the top and pulling in a horizontal direction, insofar as possible.

Hello,  
New to this site, but i'll throw this in. Surplus Center has hand pumps with small oil tanks attached. i think they were used to lift the cabs of transfer trucks. seems they were around \$150. you might try one of the "power pak" sets used for auto body work (northern or harbor freight) Are you near a community college? they might have one or a hydraulics lab with pump and gauges. might be a good project for the class. forgive my spelling.

Maybe it consumes the metals... somebody came up with an engine that runs by oxidizing aluminum. The aluminum sits in a container of water, and there's some way they use the energy released by oxidizing the aluminum to hydrolyze the water, then burn the hydrogen to run the engine. After a while you have a bucket of aluminum oxide sludge. As you may know, refining (reducing) aluminum takes huge amounts of energy, so there's a lot of energy in an aluminum ingot -- I think twenty pounds drives a car 500 miles, or something like that.

[pass magnet inside the coils ?](#) | 4 comments (4 topical, editorial)

Re: pass magnet inside the coils ? ([none / 0](#)) (#2)  
by kell on Sun Dec 28th, 2003 at 09:06:01 AM MST  
([User Info](#))

Amethyste, do a search for "linear alternator." Some of the posts are kind of jokey, some are speculative... people that want significant power haven't been building linear alternators because they would have to reciprocate (back and forth, like pistons). Much harder to engineer than something that spins.

The flashlights that you shake to charge them have a magnet on a spring that bounces back and forth inside a coil, from what I've heard.

Long term you want to float; that's even less than a trickle charge. I'd check with an ammeter.

by [kell](#) on Sat Dec 27th, 2003 at 08:17:18 AM MST  
([User Info](#))

"Seafoam" is the same stuff as "Deep Creep" but a little cheaper because the Seafoam doesn't come in an aerosol can. If you're a penny-pincher like me you can just pour Seafoam into a bottle with a squirt atomizer and squirt it into your carb, instead of paying for the aerosol version.

It's also used as an additive for gas tank and crankcase. I get mine at NAPA.

In a car engine you may have to change the spark plugs after dosing the carb. It will make your car smoke like a wet campfire.

[Using different kinds of magnets on same rotor](#) | 17 comments (17 topical, editorial)

Re: Using different kinds of magnets on same rotor  
([none / 0](#)) (#15)  
by kell on Sun Dec 21st, 2003 at 07:43:29 PM MST  
([User Info](#))

Consider the moment the coils pass between magnets. Flux lines extend from the north pole of one magnet to the south pole of the adjacent one just as they extend from the north pole of a single magnet to its own south pole. The coil will see that. So doesn't it make sense that the north and south poles of two adjacent magnets should measure the same distance apart as the north and south poles of a single magnet, in order to optimize the functioning of your generator?

Try dangling a needle on a thread to find the exact point a pole is located at. Measure the distance between the north and south poles of one of your magnets. That should be the distance, center to center, for you to mount the magnets. You may have to adjust the distance from the center of rotation of your ring of magnets in order to make it all come out even because, in this case, you are dealing with a fixed magnet spacing. That may be why some people succeeded with HD mags and some didn't -- it might be kind of a crapshoot whether the poles are spaced evenly even if the magnets themselves are spaced evenly. Another reason all your magnets should be the same.

[Using different kinds of magnets on same rotor](#) | 17 comments (17 topical, editorial)

Re: Using different kinds of magnets on same rotor  
([none / 0](#)) (#15)  
by [kell](#) on Sun Dec 21st, 2003 at 07:43:29 PM MST  
([User Info](#))

Consider the moment the coils pass between magnets. Flux lines extend from the north pole of one magnet to the south pole of the adjacent one just as they extend from the north pole of a single magnet to its own south pole. The coil will see that. So doesn't it make sense that the north and south poles of two adjacent magnets should measure the same distance apart as the north and south poles of a single magnet, in order to optimize the functioning of your generator?

Try dangling a needle on a thread to find the exact point a pole is located at. Measure the distance between the north and south poles of one of your magnets. That should be the distance, center to center, for you to mount the magnets. You may have to adjust the distance from the center of rotation of your ring of magnets in order to make it all come out even because, in this case, you are dealing with a fixed magnet spacing. That may be why some people succeeded with HD mags and some didn't -- it might be kind of a crapshoot whether the poles are spaced evenly even if the magnets themselves are spaced evenly. Another reason all your magnets should be the same.

[Question for Charged.](#) | 25 comments (25 topical, editorial)

Re: Question for Charged. (none / 0) (#18)  
by kell on Sat Dec 20th, 2003 at 06:42:42 PM MST  
([User Info](#))

Is there any way the batteries could overcharge, and how do you regulate them?

Re: Question for Charged. (none / 0) (#19)  
by wooferhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on

([User Info](#))  
<http://timmythy.home.mindspring.com/timmy.htm>

How do you know when the batteries are fully charged ?  
How do you divert the load when you determine that the batteries are charged ?

} = - W o o f - = {

Re: Question for Charged. (none / 0) (#20)  
by charged on Sun Dec 21st, 2003 at  
08:46:34 AM MST  
([User Info](#))

Ok, here's a cryptic response for you to ponder. First I'll give you a small experiment, then I'll give you a good off-loading method.

Set up a SMALL cap-discharge charging system as a TEST-BED. Start with something small like a motorcycle battery.

Use a 100ma 12v transformer feeding a large capacitance through a single rectifier (half-wave). Make sure the caps are rated for a minimum of 35v.

This way you have a good experimental input-power control mechanism.

You should end up with about 25v MAX in the caps if you don't discharge them.

Now, set up your TRIAC/TRANSISTOR discharge circuit between the caps and the battery with a 5v zener between the triac gate and the cap positive. High voltage bipolar transistors are better than mosfets for this

5 minute interval.  
Note: You may cloak yourself from appearing here in your Display Preferences.

application. A good IGBT is even better. For a slightly more advanced control system, use a 555 with an opto-coupled output to drive the triac gate. This way you can set your discharge voltage by changing the pulse-rate. Adjust the pulse-rate while monitoring the battery voltage. Set the 555 to work from about 1.5hz up to 50hz or so, roughly. Start with fast pulses and work your way down in frequency.

Monitor the battery electrolyte temperature during charging compared to the ambient air temperature. You might be suprised at what you see.

Anyway, let the system run until you see the battery outgassing. Make note of the battery voltage at this point. Also make note of the battery temperature at this point.

Now, take a measurement of the specific gravity of the electrolyte. Do an extended load test on the battery to deplete it. Then recharge. Note the TIME it takes for recharging. Do your load test again. Repeat this process about 10 times and you might be very suprised.

In a nutshell, your batteries will behave differently under capacitive charging than they do with direct generator connection. All the "rules" of battery charging that have been written are based on MISMATCHED IMPEDANCE, STEADY-CURRENT charging systems that directly couple the inductive generator output to the ionic charging of the batteries.

Even systems that "pulse" the inductive source directly against the battery cannot do what a capacitive discharge can do.

Essentially, use and ACOUSTIC charge controller to monitor for bubbling inside the batteries. That is the REAL indicator that the bank has reached peak charge. For a larger bank, your weakest battery will bubble first. Put the monitor there.

Your monitor should be wired to a solid-state relay to divert discharges to the following load assembly:

Ok, OFFLOADING is EASY PICKINS!

It's just a matter of making sure that the caps never get dropped below generator voltage so that the inductive spikes are the only thing coming in on the line.

Cut out 1'x1' plates from 1/16" sheet steel. Stainless is preferred. For a 12v minimum cap voltage system, use 10 plates.

Mount them in a stack using 3/8" teflon standoffs in-between. You'll end up with what looks like a stack of square pancakes with little plastic spacers to keep them from touching eachother. Each plate is electrically isolated from the next. Weld a couple of peices of steel wire to the top and bottom plates on the stack. Hold the stack together with a non-conductive

clamping assembly from either end.

Dangle this down about 10" from the bottom of a 55 gallon drum filled with tap water.

The two steel wires should be sticking up out of the water. Nothing should be making electrical contact with the drum surfaces.

This is a gassing H<sub>2</sub>/O<sub>2</sub> load for your discharge circuit. It will build up a scum layer on top of the water from minerals and such. Who cares. Just use a toilet float to keep the drum full of water. Simple stuff.

A small fan and ventilator tube can be attached to the top of the drum to discard the gasses outside the house. Don't try to pressurize this mixture since it WILL detonate at pressures exceeding 35psi.

Dangerous toys:  
For more fun, fill balloons with the mixed gas and ignite them with a 10ft "matchstick". Make sure you're wearing earplugs and safety goggles!

Yikes. I almost forgot something!!!  
Shame on me.

Make a light alkaline solution in the barrel using lye (red devil drain cleaner). Or for those who are more skiddish, use baking soda and push the solution to saturation.

This makes the water a bit more conductive.

DON'T USE SALT. It causes chlorine gas release. You don't want that.

Re: Test Results ([none / 0](#)) ([#12](#))  
by kell on Sat Dec 13th, 2003 at 04:49:43 PM MST  
([User Info](#))

I looked at one website where a guy made a tesla coil using MOSFETs. He did it so that the MOSFETs would turn on and off when they weren't conducting. Very efficient.

People burn up transistors all the time in inductive applications... That's why IGBT's are so useful. They are designed expressly for firing a coil (automotive). When I converted my old bike over from points to a homebrew solid-state setup, I ordered my IGBT's and hall effect sensors from Newark.com. I mounted a shutter disc on a bushing and slid it down over the points cam, with a set screw to hold it. I put little quarter inch neos pressed into holes in an aluminum plate above the disc, and mounted the hall sensors on the plate the points used to be on. The usual wiring scheme is to have a pull-up resistor to bias the transistor or transistors ON. When the shutter disc spins it intermittently allows the hall unit to see the magnetic field and, when it does, the hall unit shunts current to ground, turning off the transistor... shutting off current to the coil. This is when the spark fires. I think you could use a related setup for this charging circuit you're talking about. You could also wire in a voltage regulation circuit to turn the transistor off when necessary. Might even be able to work out a way to use a voltage regulator from a car alternator so you don't have to do a lot of circuit building. Instead of regulating voltage at the output of a charging system, they are designed to turn on and off the field coils (depending on the voltage measured across the battery), so you could just use it instead to control the transistor.

You don't have to use the hall effect units if it feels to complicated. A mechanical switch to turn the transistor on and off would work fine without arcing because the gate current is truly negligible with MOSFETs and IGBTs.

Re: Test Results ([none / 0](#)) ([#9](#))  
by kell on Fri Dec 12th, 2003 at 07:36:02 PM MST  
([User Info](#))

IGBT's (insulated gate bipolar transistors) used in ignitions have built-in protection in the form of avalanche diodes to clamp overvoltage spikes, and unlike SCR's they turn off when you release the gate. The gate on an IGBT acts just like a MOSFET gate.

They're a good alternative to mechanical switching. You can use a hall effect sensor and a magnet attached to a shaft or flywheel, or use a shutter disc that interrupts the field of a stationary magnet.

Re: Test Results ([none / 0](#)) ([#11](#))  
by charged on Sat Dec 13th, 2003 at 09:17:49 AM MST  
([User Info](#))

This guy's as sharp as a tack. :)

First, SCR's definitely not the best way, in THIS application. They can float "on" longer than the commutator signal and cause genny-capacitor-load connection overlaps.

You can use mosfets, bipolar transistors, IGBT's, etc..., as long as the reverse voltage tolerance is high enough. I've destroyed many transistors that were rated too low for this system.

It's pretty strange to see a 25v capacitor discharge into a 12v battery pop the guts out of a 150v transistor. 200v rating is about minimum. Make sure the "on" state resistance of your transistor is very low.

Anyone not familiar with paralleling semiconductors to lower switching resistance and increasing amp tolerance should dig around the web a little and learn how to do it.

Capacitive discharge is much more "kinetic" than a sinewave system. It's also MUCH more effective for battery charging.

Imagine, all of Tesla's patent designs on "radiant" energy had to be done with purely mechanical switching. What could he produce with access to today's semiconductors?

I suspect that the problems you describe with blowing transistors was more of a problem with a limited current handling ability than with voltage.

Dr.D

by charged on Mon Dec 15th, 2003 at  
04:13:12 PM MST  
([User Info](#))

Nope. The voltage peaks when breaking the circuit were popping them. I solved it when I went to higher voltage rated components.

Current is easy. That's just a matter of wiring a suitable number of parallel transistors. They were still popping. That's what threw me a little at first. I was building WAY over the wattage required and still frying the parts.

Breaking the current flow off has some strange (and useful) effects.

Were you able to observe these "transients" that blew the transistors? Your comment leads me to think that it was inductive "kick" that produced them. If so it would be a simple matter to add a limiting circuit ( zeners, and or a triac) to clip these spikes to a safe level.

Dr.D

Jon;

Sorry, but I have absolutely no idea what it is you are asking. Can you be a little more specific?

Cheers.

TomW

([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Woofers;

You said:

The magnets are quite small and are probably the problem. They are 1/4 x 1/4 Disk Neodymium and are rated N38. They are grouped in sets of three with epoxy glue & tie wraps, the **same polarity pointing out in each set.**

Way back in alternators 101 we learned that the poles need to alternate N S N S N S etc.

That and the other drawbacks noted will produce a poor alternator.

Cheers.

TomW

Thanks TomW

let me quote what you quoted and add the rest of the paragraph...

--Quote-----

They are grouped in sets of three with epoxy glue & tie wraps, the same polarity pointing out in each set. 12 groups are glued around the rotor alternating North-South all the way around.  
-----

Perhaps I could have described this more clearly. As they say "A picture is worth a 1000 words" so here's a pic

The mags are grouped in sets of 3. Each set has all North or all South pointing out. putting the magnets together this way is very difficult as the mags are trying to run away from each other and flip around and stuff. Then these Sets are glued to the stator in alternating groups.

- set of 3 Norths
- set of 3 Souths
- set of 3 Norths
- set of 3 Souths
- etc.

} = - W o o f - = {

Ed;

First let me say that nearly anything is possible but not everything is practical.

We have discussed reciprocating style generators before and while it seems it could be done that they would be fairly inefficient. Maybe a search of this site for comments with "linear alternator" or "reciprocating" in comments would turn up the discussion I found several but the link posting feature on the board seems broken so I didn't put the link in here. I seem to recall that the lack of movement on the end of each stroke when the shaft reverses direction would be a source of lost mechanical power. Just off the top of my head before my coffee.

Oh, and welcome to the board.

Cheers.

Ed;

actually you can get to 110 using toes.

for every 10 on fingers curl one toe when all toes are curled its 100 then you still got the 10 fingers .

Cheers.

[Converting Amps to 0 - 10 volts for data acquisition](#) | 2 comments  
(2 topical, editorial)

Re: Converting Amps to 0 - 10 volts... ([none / 0](#)) ([#1](#))  
by TomW on Thu Dec 18th, 2003 at 08:06:41 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

dconn;

I am doing some data logging using a PC and a RS232 meter. What I do is use optoisolators to drive relays off the parallel port set up as dpdt switches to select the source i want to sample this eliminates the common ground problems. JimU set me up with some perl scripts to read the meter output and translate to graphs. Sounds like a totally different approach from yours. There are probably one chip solutions to your problem but it seems you could simply use your low voltages to drive a transistor biased for 10X amplification or whatever you need to transform low voltage to higher values.

More details of exactly what you are using [software / hardware] would make answering the question easier.

Just off the top of my head.

Cheers.

by TomW on Tue Dec 16th, 2003 at 01:04:20 PM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Dave B;

Uh, as far as I know no one can edit a comment once it is posted.

What I did notice last nite was like 2 seconds after I posted my comment trying to explain caps your comment was there. Not sure how you could have replied before it was actually posted? Perhaps a glitch in the board software? I regularly preview my comments several times before I actually hit "post" and that comment took awhile before I felt it was ready to post. Perhaps it served you up one of my previews?

Anyway, sorry for any confusion and you are correct series caps work like parallel resistors as far as value is concerned.

Cheers.

TomW

Thanks Tom, weird stuff happening I guess. I remember fighting with the AC circuits in school and how much fun the LC combinations can be. I dabble in audio and crossover/cabinet design and have a "magic box" of caps, coils and pots I built for dialing in 2 and 3 way crossovers for different drivers. Now that is alot more fun than class ever was. Too much fun and not enough time, next project, carving a 12' diameter 3 blade set for my alternator. Thanks for the reply. Dave B.

Hey Dave

Have you ever built a 12 per octive 5k hi pass  
exover for tweeters plus a small incandescent  
lightbulb in siries with the + input side of the  
exover.

We build and sell these at my car stereo store.  
Primarily for our more out of control customers.

This crossover format is also used comercially  
but we prefur to build our own.  
The addition of the bulb deals nicely with  
exssesive power and distortion very nicely with  
no colorization or SQ degridation. In short save  
your tweeters but and sounds good to.

<http://www.madbbs.com/users/bruggelog>

Jerry,

I built small 2 ways (5" full range & 1"  
soft dome tweeters) sealed enclosures 20  
years ago that used moocho power to  
sound great so I designed a very small pc  
board that was a single LED used as an  
adjustable peak power indicator. This was  
for show and/or as a warning to blowing  
things up depending on the level it was  
set. This was a simple rectifier, transistor,  
pot, LED circuit and was mounted behind  
the grille with just the LED showing. Many  
of these are still cranking in bars and cars  
(pat on the back). The attached photo  
shows my variable 12db-6db 2 or 3 way  
crossover. It has independent driver  
control and A-B comparison of 2 separate  
crossovers dialed in. I personalized alot of  
older speaker sysyems with this for those  
tired or worn out rock & roll ears out there  
and if out of the tweaking range it's pretty  
easy to customize new systems so there is  
headroom in the upper and lower range  
depending on the individuals listening  
tastes. We could talk for hours on this fun  
stuff I'm sure. This is a diversified group  
for sure, I'm glad to have found it. Dave

B.

Dave B;

Uh, as far as I know no one can edit a comment once it is posted.

What I did notice last nite was like 2 seconds after I posted my comment trying to explain caps your comment was there. Not sure how you could have replied before it was actually posted? Perhaps a glitch in the board software? I regularly preview my comments several times before I actually hit "post" and that comment took awhile before I felt it was ready to post. Perhaps it served you up one of my previews?

Anyway, sorry for any confusion and you are correct series caps work like parallel resistors as far as value is concerned.

Cheers.

TomW

I think this would be a good subject to pursue.

It seems that a lot of us aren't clear what kind of capacitor to use on various circuits like how do you use them where, why, when what size etc. Norm.

Re: A good one for Renewable Energy FAQ's...Capaci ([none / 0](#)) (#2) by Dave B on Mon Dec 15th, 2003 at 11:27:07 PM MST ([User Info](#)) <http://www.madbbs.com/users/bruggelog>

Seems like I remember caps. to add opposite of resistors. 2 Caps. in parallel add (100mf + 100mf) = 200mf and 2 caps. in series (of the same value) would equal 1/2 of the value of one of the caps. or 50mf. I could be wrong, if so let me know, it's been along time since school days. Dave B.

Re: A good one for Renewable Energy FAQ's...Capaci ([none / 0](#)) (#3) by TomW on Mon Dec 15th, 2003 at 11:40:58 PM MST ([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Norm;

Well, I am no capacitor expert but the basics are pretty simple:

Capacitors add in capacitance [microfarads] when in parallel. So 2 40 volt 100 microfarad caps in parallel will net the equivalent of a 40 volt 200 microfarad cap.

Capacitors add in voltage rating when in series. that same pair of 40 volt 100 microfarad caps in series will yield an equivalent of an 80 volt 50 microfarad cap. 2 equal value caps in series yield 1/2 the capacitance rating. For multiple caps in series it is the inverse of the sum of the inverses of the cap values.

Within reason you can series / parallel many caps to get a value you require.

Thats the capacitors in a nutshell but it can be a very involved process understanding how they work in A.C. circuits and with RF signals.

Cheers.

Issues with pictures and graphics; ([none / 0](#)) (#4)  
by TomW on Tue Dec 16th, 2003 at 12:17:40 PM MST  
([User Info](#)) <http://oneota.net/~earthsourcespowr/>

JB;

There have been lots of ongoing issues with pictures and diagrams on the board.

Several people have uploaded such huge pictures [file size] that they exceed their storage quota. Some have deleted some of them to get more space for their next set of uploads. To the best of my knowledge none of the admins have removed any uploaded files. Once the files are removed by the user they are no longer available for display on the board. Frankly it is almost exclusively a user problem not a board problem. It is very inconsiderate to post a picture that is much bigger than 200 or 300 kilobytes to a forum like this but some of our users regularly post several 900 kilobyte plus sized pictures and diagrams in comments & stories. One recent comment had over 3 megabytes of diagrams from one user and that takes a very long time to download for a dialup user.

Others link to external pictures they have hosted other places. In that case there could be any number of reasons they do not display that I can't begin to explain here.

Here is my suggestion for you:

When you see something you like you should simply download it to your own computer and then it will be available to you any time.

How you do that depends on your operating system and your browser.

Cheers.

TomW

Have you considered a ban on BMP files as they are probably the real problem. If everyone stored their diagrams as GIFs and their photos as JPEGs wouldn't the problem go away.

Unless you have a very old computer, there are programs installed with the operating system that can do the conversion.

Martin.

Capacitors add in capacitance [microfarads] when in parallel. So 2 40 volt 100 microfarad caps in parallel will net the equivalent of a 40 volt 200 microfarad cap.

Capacitors add in voltage rating when in series. that same pair of 40 volt 100 microfarad caps in series will yield an equivalent of an 80 volt 50 microfarad cap. 2 equal value caps in series yield 1/2 the capacitance rating. For multiple caps in series it is the inverse of the sum of the inverses of the cap values.

Within reason you can series / parallel many caps to get a value you require.

Thats the capacitors in a nutshell but it can be a very involved process understanding how they work in A.C. circuits and with RF signals.

Cheers.

Instead of 'post a comment', I think I need to reply to that particular post, so it will follow that particular posting?

Yes, indeed to get it to look like a response to a specific comment you need to click "reply to this".

"Post Comment" simply sticks it in with the rest of the comments and then it displays according to how the users preferences are set. You certainly are not the only one who has been confused by this feature.

Cheers.

## Stovetop Heating Elements

By [bruce1](#), Section [Homebrewed Electricity](#)

Posted on Fri Dec 12th, 2003 at 11:41:53 AM MST

[Wind](#)

Whats inside of them?

I'm unwinding the round stovetop heating elements into straight pieces, cutting them off at shorter lengths to make a heating element to draw down batteries during testing. What inside those elements? The outside is just metal, there is a very thin wire inside, and its all encased in this whitish stuff. Is it just ceramic? I dont want to be playing with an asbestos sort of material.

Thanks, Bruce

I am surprised they held together as you unwound them! I would have thought they would have split or bronek or something!

That is interesting. . .

I believe it's magnesium oxide.

There is a type of electrical wiring cable called Mineral Insulated Cable (Tradenname - Pyrotenax) that uses magnesium oxide as an insulating material. It is used where a fire resistant wiring method is required.

[http://www.sesco-ge.com/pd\\_pyrotenax.htm](http://www.sesco-ge.com/pd_pyrotenax.htm)

hi bruce

it is probably magnesium oxide. havent looked up the msd but think it is pretty inert.

i wouldnt put it on your cornflakes just to be safe. the wire is nickel chome trade name nichrome. can buy it online easily enough. it is expensive but still cheaper than new resistors.

bob

Re: Stovetop Heating Elements ([none / 0](#)) (#4)  
by bruce1 on Fri Dec 12th, 2003 at 03:37:06 PM MST  
([User Info](#))

No, they unwound into one long rod, or at least these did. I hacked them into roughly 6" pieces, pulled the wire out of them about 1" on each side, attached all the wires on each side to a scrap steel bar, hooked a wire to each bar, put an ammeter inline between the battery and one bar, and hooked it to the battery. With 5 of those pieces in there, it draws 18A @12vdc. They are about the right length so that they each draw significant amperage, about 3.5A, but yet they do not glow red and get too terribly hot.

My last comment may have come across wrong. I didnt say 'no' to the people saying it was magnesium oxide, I was replying to an earlier post that someone was surprised the stove elements didnt break up. I was saying 'no', as in 'they did not break into pieces, they unrolled rather well'. Instead of 'post a comment', I think I need to reply to that particular post, so it will follow that particular posting? I'm sorry if it came across wrong.

Anyway, thanks all for the replies. I feel better knowing its not some nasty toxic granulars.

Thanks, Bruce

[DC motor to PM Gen](#) | 6 comments (6 topical, editorial)

Re: DC motor to PM Gen ([none / 0](#)) ([#1](#))  
 by TomW on Sat Dec 13th, 2003 at 10:26:16 AM MST  
 ([User Info](#)) <http://oneota.net/~earthsourcepowr/>

acenergydfw;

I, too, thought a golf cart motor would make a decent generator. Wrong. At least in my case the motor is a series wound DC motor. This means it uses a field coil to create the magnetic field it uses to create the electrical energy. Very problematic for several reasons not limited to figuring out how to energize the field windings only when its spinning.

Just right off the top of my head. I think this has been discussed a time or two before. Maybe a search of this site for "golf cart motor" will yield more in depth detail on the [dis]advantages of using one. Mine is a Harley Davidson and others may be designed different.

Cheers.

Yes the series wound field, which I want to replace with permanent magnets, if only I could find some NIB arcs that are curved with an ID of 4.3125" thickness of .5" and 3" long and width depending on how many poles I wanted it to be. It appears from what I've seen searching, something like this would be very cost prohibitive. Sorry I didn't do a thorough search of the site, just thought I'd toss this out there.

Wonder why they aren't PM motors? Maybe it's an older type motor and the newer ones have PM's ?Well at least you've got a nice little motor that you can use to power something once you have a windmill to charge some batteries to run it...would run a nice little scooter for around town or an electric riding mower....Norm.

## [DC motor to PM Gen](#)

By [acenergydfw](#), Section [Homebrewed Electricity](#)

Posted on Sat Dec 13th, 2003 at 09:47:42 AM MST

[Wind](#)

Need advice from the board.

I've been toying with wind power ideas for years but have never attempted any projects. I have 23yrs experience in the UPS business as a tech/fe and have been recently playing with PM motors as generators. I understand the mechanical drawbacks of them and the advantages of PM alts, but I have free a 2.1hp, 36v motor from a golf cart I am considering making a ginny out of. The stator is currently 4 pole, the commutator has 64 contacts and 4 brushes. I'm figuring that these brushes are fairly common and they can be replaced relatively easily so I would like to try replacing the EMs in the stator with PMs. The other ratings on the motor are 2800rpm and 51a. Will increasing the # of poles give any increase in voltage or will this be limited by the armature windings? Other specs are: Armature core 3"l X 4.25"dia, Stator cores 3"l x 2.25"w x .5" thick, Case is 6.75"dia x 10"l. The shaft is .75 and has a flywheel and brake, the output to the differential was with a splined shaft and it does have bearings. I'll try to up-load a picture. It appears to be in there now.

TIA  
mel

Re: DC motor to PM Gen ([none / 0](#)) (#5)  
by Chuck on Mon Dec 15th, 2003 at 10:10:02 AM MST  
([User Info](#)) <http://www.greeleynet.com/~cmorrison>

There are limitations to what you can do without rewinding the coils. While you can add magnets to your heart's content, if it doesn't match the winding on the armature, you'll probably not be able to generate anything. An armature designed for 4 poles will only work (well) with 4 poles.

What you have is set up for 36v at 2800 rpm. Since this is usually a linear relationship, if you want to get 12 volt charging from it, you'll still be looking at 933 rpm just to get 12 volts, assuming it acts similarly with PM's as it does with coils.

You can see my attempts at doing this at :  
<http://www.greeleynet.com/~cmorrison/WindMachine.html>

Re: Alt rotor Questions : magnets ([none / 0](#)) (#7)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Fri Dec 12th, 2003 at 12:20:52 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

By laying them out the way iFred explained works well also but the field doesn't extend out as far as pushing them together. By allowing them to spread apart will match the field of the magnet. In turn open up the area of the field. On a dual rotor system with a fairly large gap it would be better to butt them together. Where'as a laminated stator may better use the area of the magnetic field as opposed to the concentration. It all works well in the right places.

iFred tends to think outside the normal, this is usually where new things are found. I for one like unusual and creative thinking... the stranger the better! I'd like to say I think in similar terms but there are so many rules that are in the back of my head that sometimes makes it difficult. Like a cup overflowing... there is no more room to add more... sometimes we need to empty our cup in order to get more.

More fun than my cup will hold!  
Ed

no reason, just have not enough time for more research.

ifred;

So what ever happened with your magnetic interruptor research?

Very curious why you just stopped talking about it?

Cheers.

TomW

Dr. D;

A possible substitute might be a piece of copper tube soldered to the cable with the end flattened and the proper hole drilled in it. Add some shrink tube if you want or some tape and you can duplicate almost any ring connector for very cheap.

Most of my battery interconnects are done this way but with larger cable and tube for ends. Basically free from the copper pipe I have salvaged over the years.

Cheers.

erne;

Hi I dont know how to post a comment, help apriciated.

Well, erne, its as easy as [easier really] posting a story.

At the bottom of every story there is a "Post Comment" link. If you are logged in and click on that it pulls up a page where you can post a comment. Once you have that page your comment gets typed into the text window much like when posting a story. Same thing when you wish to respond to a comment except then it is a link titled "Reply to This".

Cheers.

Google search for calframo fan they are a bit more sophisticated than a thermocouple and use a peltier device to run it. Ours has been spinning on our stove for 3 years or more.

Cheers.

## [Fisher and Paykel Tests](#)

By [TomW](#), Section [Diaries](#)

Posted on Tue Sep 23rd, 2003 at 04:10:50 PM  
MST

[TomW's Diary](#)

### Fisher and Paykel Smart Drive motor Tests

Well, folks, I got myself a nice F&P Smart Drive motor through my vast connections online.

I looked at lots of info on them. Well "lots" is relative since there is not a whole lot published about them just yet.

It is a radial design. Mine has 42 coils of 1.6 mm wire [thats .062 in inches or about #16]. Its 3 phase with 14 coils per phase. The coils have 42 wraps each in two layers. The rotor has 14 of what appear to be ferrite or ceramic magnets.

This picture shows the unit the way it came via UPS.

I studied it awhile and did some preliminary tests once I figured out how to assemble it. Stock it has way too much resistance in the phases for RE use. I got a box of terminal blocks like these below on EbaY to break out the coils so I could wire them as needed to get the right output levels.

Thats not my stator its a picture I found someplace online.  
Mine currently looks very similar.

After thinking about it awhile I decided to split the coils  
out into pairs. This gave me individual pairs that were .3  
ohms by my meter[s].

I built a test jig to hold the bearing assembly so I could  
test a coil pair in the drillpress at known RPMs. Following is  
the data I have so far:

One coil pair connected to a 35 amp bridge:

210 RPM:

No load

AC volts into bridge: 3.4 VAC

DC volts out of bridge: 2.9 VDC

1 ohm load on DC side of bridge:

AC volts into bridge: 3.1 VAC

DC volts out of bridge: 1.4 VDC

Amps into 1 ohm: 1.5 Amps DC.

305 RPM:

No load

AC volts into bridge: 5.4 VAC

DC volts out of bridge: 5.0 VDC

1 ohm load on DC side of bridge:

AC volts into bridge: 4.5 VAC

DC volts out of bridge: 2.5 VDC

Amps into 1 ohm: 2.7 Amps DC.

450 RPM:

No load

AC volts into bridge: 7.55 VAC

DC volts out of bridge: 7.0 VDC

1 ohm load on DC side of bridge:

AC volts into bridge: 5.6 VAC

DC volts out of bridge: 3.4 VDC

Amps into 1 ohm: 3.5 Amps DC.

900 RPM:

No load

AC volts into bridge: 14.3 VAC

DC volts out of bridge: 14.7 VDC

1 ohm load on DC side of bridge:

AC volts into bridge: 7.0 VAC

DC volts out of bridge: 5.0 VDC

Amps into 1 ohm: 5.5 Amps DC.

Remember, this is one pair of coils in one phase. There are 14 coils in 3 phases in this motor. It is reasonable to assume the voltage out for one phase times 7 will equal the phase output voltage if connected in series. Of course the current for an entire phase will not be more than the current from one coil.

Thats it for just now but I will update this as I get more data so check back if interested.

Cheers.

TomW

([User Info](#))

Hi,

We tested these units about a year ago. There are 3 units in the series. I call them 100S, 80S and 60S. This relate to the approx' wire diameter in mm, 1.0mm, 0.8mm, 0.6mm. The picture is one of our my realier tries. We do it very differently today, you can make a annular copper ring and solder all the connections on, then cover in hot glue and do the necx annular ring. It is much tidier and quicker.

IF you want a copy of the test results I have then all on an excel file, just send me an email.

We get all the unit that FSP remove on their recycling line. Currently several hundred in stock. WeE sell them for around US\$150 delivered to your door including a manual on how to reconnect them. Ww include a new shaft and bearing assembly and it is machnied and fitted into a box section for easy mounting. For and extra \$50 we sell a de-cogged version which is made by machining the stator so that it is suitable for wind turbines. We have a 48 v model with a 1.5m prop upto 650 Watts aty the moment.

Regards

Michael

[TomW's Diary](#)

DanB sent me this set of blades to play with.

This shows them pretty much as shipped except for the arbor I bolted to the hub.

That hub tube is one foot long and the center is 3/4 inch diameter with a keyway in it. I bolted a 5/8th inch arbor to it using a piece of rubber hose to shim between the bolt part of the arbor and the center hole on the hub tube.

The blade stub mounting tube is 4.125 inches long and 1.060 inches diameter. The thickest part of the root airfoil is .450 inches and the root is 4.125 inches wide. The tip is 2 inches wide and .270 inches at its thickest. Total blade diameter is 7 feet 8 inches. The drop at the root is 1.25 inches which calculates out to 16 degrees of pitch with tips running flat.

Not sure what anyone else calls these but I have dubbed them The Fylon Blades

Too late today for much beyond the specs but I'll try to paint them tomorrow and stick them on a tape drive mill I have on my garage. We are in our lowest wind time of the year and in a low wind area anyway so I'm not expecting much until fall but will get them up anyway.

Oh, and after being painted and with an arbor installed the weigh in at slightly less than 4.5 #

Cheers.

TomW

Hey Tom,

Where do you get your arbors from?

Thanks,

DaveR

Arbors: ([none / 0](#)) ([#2](#))  
by TomW on Sat Jul 19th, 2003 at 09:33:53 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

DaveR;

Well I got 1 from the local hardware store. They could not order more so I got 5 more from harbor freight.

The 5/8th inch one is here:

<http://www.harborfreight.com/cpi/ctaf/Displayitem.taf?itemnumber=46623>

The 1/2 inch one is here:

<http://www.harborfreight.com/cpi/ctaf/Displayitem.taf?itemnumber=46622>

And \$1.99 each from them and \$5 from hardware store. But after handling and shipping I think they were about \$4 each from harbor freight.

Cheers.

TomW

### Counter Rotating Dual Pinwheel Tapedrive Genny

Front view sitting on the bench fully assembled except for wiring and a tail.

Tape Drive Motor mounting and pivot detail. Yes that is an aluminum 4 foot level.

Rear of pinwheel assembly showing the support pieces of aluminum strap.

More detail of pivot assembly attachment.

The far side which is just the same as the near side. The pinwheels rotate clockwise on the right hand one and counter clockwise on the left handed one. The side boom is 4 feet wide total with the pinwheels approximately 42 inches center to center.

Just one of the pinwheels close up.

Hopefully tomorrow I'll get the motors wired in series, a tail on it and up on the pole.

Cheers.

TomW

Demetri;

I think mostly because they use counter rotating shafts to keep things from getting harmonic vibration. Like in motorcycle engines and I believe props on opposite sides of a plane rotate opposite directions.

But then again, its always about the learning and I thought it would be cool.

It unscrewed one of the props due to the installer [me] not double checking nuts on the arbor. The CCW prop unscrewed itself very soon after the wind got up and I had to take it down. I was seeing some fair volts considering it was likely only half working.

Its currently on the bench getting put back together and I think in the end it will be a fair little unit.

Cheers.

[Ponder This. \[very off topic\]](#)

By [TomW](#), Section [Diaries](#)

Posted on Tue Jun 24th, 2003 at 05:16:59 AM

[TomW's Diary](#)

This whole anonymous hero thing points to consider:

Fellow board members:

Yes members, not the web wanderers seeking attention!

Just a few points I would like to share with you to hopefully assist you in seeing this "problem" for what it is.

Before, on the old board we had lots of non registered user posts and most were at least on topic with very few flame wars and personal attacks. The occasional piece of SPAM slipped onto the board but overall it was quite manageable.

Then we got featured in HomePower Magazine shortly after that we got mentioned on [HTTP://Slashdot.org](http://Slashdot.org) and by now I am fairly sure we are on the list of Scoop sites.

The trend I see is that we have gotten exposure from our success and that has drawn the lunatic fringe of web wanderers willing to disrupt any community type board simply for the attention it gets them. These people could care less for our passion for home brewed power but many intersperse their diatribe with cool pictures or snippets of ideas that do pertain to the community. The true reason for their [often unsigned] stories and comments has little or nothing to do with our stated purpose.

I submit that many have pulled this same stunt on many boards across the web. I, personally, have seen it on several boards. The pattern is unmistakable.

New people show up with a chip on their shoulder or at least a great desire to argue, generally off topic.

The community tries accommodation.

It does not work.

The argumentative newcomer claims censorship and call people Nazis.

The term Free Speech is thrown around without the necessary modifier responsible.

It causes a huge upheaval in the community and often the community loses good people who just don't want to hear it or be involved.

If allowed to continue the board becomes unusable to those who actually want the information it provides.

Bottom line is:

Lets not let this happen here.

by TomW on Tue Jun 24th, 2003 at 10:27:35 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Norm;

Since you are me [according to some] seems redundant to reply to you but here we go:

By the way what does that mean by Norm(on soon)

I think it simply means that the timestamp is not set because you have not posted the comment or story. I could be wrong but its in the spot that would hold the date the comment was posted after you squeeze the trigger on it.

And thank you for your ongoing support in face of these disturbances. I could just as easily [oh, hell, it would be easier] let them win but while I can turn the other cheek at some point you run out and get tired of it.

You may have noticed I generally do not respond to any Anonymous posts lately which has kept me from commenting on some good stories, etc.

Hopefully we are back on an even keel with just normal disagreement over who has created the most watts feeding in, whose is bigger, better etc.

Cheers.

by Brian on Tue Jun 24th, 2003 at 05:30:15 PM MST  
([User Info](#))

I agree Tom. I'm sure you remember me as another Tom as well :-). After all the hub-bub here I decided to just ignore it as well. As others have said, it's not easy at times but it helps keep things under control. In my opinion you're doing a good job looking out for the best interests of the board. I look forward to the abolishment of the anonymous hero posts!! Have a good one, Brian.

by Larsanderss ([larsanderss@brevet.nu](mailto:larsanderss@brevet.nu)) on Thu Jun  
26th, 2003 at 01:01:07 PM MST  
([User Info](#))

I seem to know to few words in english to say what i want..... I agree with You and am trying to ignore (not to be ignorant ??) stupidities and such. Like a lot of other people (i think) i want it all to go on in the nice and funny way without the flaming things.  
Thanks a lot to all who keep this going.

And at the end i must tell the world that my hot air solar experiment made a new record of 56°C (probably a lot of °F, who knows ??) in the air being blown into my washing machine room in the basement the other day. Just need to increase the size of the collector an the fan to have it going as something more than a experiment. This is one my wife actually likes.

Good evening

Lars A

Re: Ponder This. [very off topic] ([none / 0](#)) (#7)  
by hvirtane on Mon Jun 30th, 2003 at 07:57:17 AM MST  
([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

I think that everybody, who posts here is looking for some kind of attention.  
Otherwise they wouldn't post at all?  
What is off limits depends on the opinions of different people.

While I'm thinking that some kind play, who makes more watts of magnets doesn't make much harm...  
I think that for developing new things limiting everything to that kind of game... will not kick much new out.

I agree that it is not an easy task to admin this kind of board.

One way to put things easy and simple would be to limit the discussion on the things, which have already been done and working.

But for visionary people that doesn't make much sense.  
Many good ideas have remained very theoretical for long times, before somebody had the resources and the interest to prove them.  
I think that visionary people, who are not doing much in practice are for these discussions important, too.

American culture is a very competitive and aggressive culture, so it is the case in my country, too.

Everybody can see, that too much competition is doing too much harm. It leads into violence easily. Concerning discussions it leads into flame wars easily. Often 'the winners' are suffering most.

I've got to know so many kinds of people that I'm tolerating quite a lot of rude behaviour, too. My English language ability is limited, so I can tolerate a lot in English. I just don't care, if people get stupid by their speaking. There are many kinds of language cultures, too. For example in India their English is often very polite even if their real behavior is very rude.

I just wanted to say that this kind of things need many kinds of people to be done.

Hannu Virtanen  
hvirtane@cc.jyu.fi

Re: Ponder This. [very off topic] ([none / 0](#)) ([#8](#))  
by John on Tue Jul 1st, 2003 at 03:35:23 AM MST  
([User Info](#))

I totally disagree with your first statement. What I see here is that most posts are:

- 1.) Asking for information,
- and,
- 2.) Freely giving information out of a sincere desire to provide accurate information to anyone who wants it.

So why do I post messages here? It certainly is not because I want attention, but rather it is to share information that I have accumulated through my life time. While I can not speak for others, I believe that many other posters feel the same way.

I'm not trying to start an argument, I just don't like being lumped into the category of "everybody".

Let's keep the knowledge flowing!

([User Info](#)) <http://www.cc.jyu.fi/~hvirtane/cooker/>

I agree with this that the main posts are:

- 
- 1.) Asking for information,
  - and,
  - 2.) Freely giving information out of a sincere desire to provide accurate information to anyone who wants it.
- 

But people, who post them want these messages to be read as well?

It is mainly a question of the definition of the concepts, if this is seeking 'attention'. My use of the English language is of course different of that of yours.

-----

I understand, I think, quite well the idea of the original author of this discussion. He is telling than in his opinion some of the users had 'a wrong attitude'.

That some users in his opinion are just trying to make themselves to be 'well-known'? And that they know too little to speak about the matters?

I think that concerning the cases, which I've seen it is not really true. I've seen that there have been many kinds of people, who post here. Some of them are young, some of them are a little bit older.

Some of them want to know something, which is already known, some of them want to invent even something new. Some of them are defending some quite crazy ideas strongly, some of them very sceptical about almost all.

I've been quite a long time involved in the fields of education. Sometimes doing research, sometimes teaching. Sometimes teaching young people, sometimes teaching old people, sometimes both of them at the same time. In my philosophy classes there have been at the same time people 75 years old and 16 years old. Some of them priests, some of them farmers, some of them school-teachers, some of them school boys. It isn't always so easy.

I've realized that different people, if we can find a way they can cooperate can do together a very good job. They can find really many viewpoints at the problems to be there for solving. I've realized that there is really many kinds of 'knowledge', which can be valuable.

I agree that administrating a website like this is a very difficult job. I've been administrating some systems myself.

In my opinion these people here administrating this site have been doing a very good job. They have found creative solutions for problems. I agree that 'Quarantine zone' is a good idea.

My opinion is that sometimes the most valuable ideas are coming out the mouths of people, who are considered to be quite crazy by conservative people. How more conservative people here can tolerate them,

I don't know, because I don't know the more conservative people here well.

I repeat here the text I've written once already:  
maybe most of the writings of Newton were about astrology, but his science wasn't that bad.  
Please don't think that everything coming from the computers of some people, who sometimes write something, which isn't so good, is stupid.

- Hannu Virtanen

I seem to know to few words in english to say what i want..... I agree with You and am trying to ignore (not to be ignorant ??) stupidities and such. Like a lot of other people (i think) i want it all to go on in the nice and funny way without the flaming things. Thanks a lot to all who keep this going.

And at the end i must tell the world that my hot air solar experiment made a new record of 56°C (probably a lot of °F, who knows ??) in the air being blown into my washing machine room in the basement the other day. Just need to increase the size of the collector an the fan to have it going as something more than a experiment. This is one my wife actually likes.

Good evening

Lars A

([User Info](#)) <http://oneota.net/~earthsourcespowr/>

Norm;

Since you are me [according to some] seems redundant to reply to you but here we go:

By the way what does that mean by Norm(on soon)

I think it simply means that the timestamp is not set because you have not posted the comment or story. I could be wrong but its in the spot that would hold the date the comment was posted after you squeeze the trigger on it.

And thank you for your ongoing support in face of these disturbances. I could just as easily [oh, hell, it would be easier] let them win but while I can turn the other cheek at some point you run out and get tired of it.

You may have noticed I generally do not respond to any Anonymous posts lately which has kept me from commenting on some good stories, etc.

Hopefully we are back on an even keel with just normal disagreement over who has created the most watts feeding in, whose is bigger, better etc.

Cheers.

TomW

I agree Tom. I'm sure you remember me as another Tom as well :-). After all the hub-bub here I decided to just ignore it as well. As others have said, it's not easy at times but it helps keep things under control. In my opinion you're doing a good job looking out for the best interests of the board. I look forward to the abolishment of the anonymous hero posts!! Have a good one, Brian.

Re: Ponder This. [very off topic] ([none / 0](#)) (#8)  
by John on Tue Jul 1st, 2003 at 03:35:23 AM MST  
([User Info](#))

I totally disagree with your first statement. What I see here is that most posts are:

- 1.) Asking for information, and,
- 2.) Freely giving information out of a sincere desire to provide accurate information to anyone who wants it.

So why do I post messages here? It certainly is not because I want attention, but rather it is to share information that I have accumulated through my life time. While I can not speak for others, I believe that many other posters feel the same way.

I'm not trying to start an argument, I just don't like being lumped into the category of "everybody".

Let's keep the knowledge flowing!

### [Diaries... What are they good for...](#)

By [TomW](#), Section [Diaries](#)

Posted on Fri Jun 20th, 2003 at 04:01:39 AM MST [TomW's Diary](#)

Absolutely Nothin.. Unless you use them that is...

I know a lot of folks on the board are still getting used to this new place we have here. I have visited a lot of Scoop sites over the years so I am used to it as a web log.

Tonight I just want to pose the question:

Why don't more of you folks use the diary area?

Its a good place to post your most recent thoughts and pictures of your windmill or cat or whatever you like. If you have been reading these diary entries of mine you know I mostly share my experiments successful or not in these entries. I also have posted a lot of the data I collected here off the main page where some folks may never see it.

So I am encouraging those of you who may feel their story is not suitable for the main discussion area to post that stuff to your diary. Questions, comments, ideas, whatever you want. It is a great place to submit your thoughts and things that may not "fit" the front page.

Personally, I prefer posting to my diary rather than the front page and if you want to follow what I am doing this is the place to do it.

Cheers.

TomW

[Diaries... What are they good for...](#) | 3 comments (3 topical, 0 editorial)

Re: Diaries... What are they good for... ([none / 0](#)) (#1)  
by Junkie ([madscientist@blownup.com](mailto:madscientist@blownup.com)) on Fri Jun 20th, 2003 at 08:21:45 AM MST  
([User Info](#)) <http://www.akuma.dsl.pipex.com/chris>

When I come here I just look at the 'front page' that shows all the recent postings. I don't see any reason to post in a diary since thats just another section, same as all the others like 'Homebrewed electricity'. And a diary post will get lost the same way as all the other posts do so I dont see any reason to post a diary, unless its off topic ? -Chris

I find it quite refreshing to come to this section and discover that we're all here to have fun sharing our successes and failures....laughing with each about our stupid mistakes...like me gluing in a starter magnet upside down (well...I thought they came in pairs! one north pole and one south pole! and some of us have dogs. then some of us have kids and wives that don't seem to understand making windmills that do something useful ( why don't you make cute little windmills like the neighbors have?We already have electricity!) Havin' fun in NE Ohio! (:>) Norm.

Tom, since ADMIN call this a diary area, I would have thought that it would work like a physical diary. Each person was one diary page and they post what they are up to at the moment.

I personally think that the post that DanB has been doing with the building of the new windmill should go here while anything that is a question should go on the discussion side of the board.

If I kept a real physical diary, I would expect someone else other than me to put entries in it. Now other people may have comments, questions or just bravos about anything posted in someone else's diary but that, I think, should be kept physically separate from the diary itself.

Now to keep things practical, when you select someones diary, there should be a limit on how far back it fetches on one page but something could be worked out.

Look at the weblogs (blogs) model. That's how I would like to see the diaries work.

Martin.

When I come here I just look at the 'front page' that shows all the recent postings. I don't see any reason to post in a diary since thats just another section, same as all the others like 'Homebrewed electricity'. And a diary post will get lost the same way as all the other posts do so I dont see any reason to post a diary, unless its off topic ? -Chris

### [Crossflow VAWT tinkering](#)

By [TomW](#), Section [Diaries](#)

Posted on Mon Jun 16th, 2003 at 08:29:15 AM MST [TomW's Diary](#)

I slapped this together over the last couple of days...

Above we see the frontal view showing the main components. Two 30 volt tape drive motors [TDM] as a top and bottom generator-bearing combination. Rough sawn oak frame with plywood wing ribs and 4 mm corrugated plastic skin.

This is a closeup of the high tech TDM mounting setup.

Here you can see the 5/8th tdm shaft to 3/4" pvc coupling i made by sawing 2 cuts into the PVC and shoving the motor shaft into it with a shim of plastic flex tubing and clamping it with good old hose clamps.

I learned a lot while putting this together. For one thing the plastic does not conform well one way but does OK the other. One side is much smoother than the other. PVC is cheap and easy to work with but too flexible for a final unit.

It has an alignment issue with the 2 motor / bearings which I will look into today.

Its dimensions on the wing are 2 foot diameter by 2 foot tall. I know it needs multiple wings to self start and that is the plan eventually. Typical for me this is a mockup and test of the basic idea and to find building pitfalls before trying a full size 3 wing unit.

Cheers.

TomW

([User Info](#))

Hi TomW,

Are the motors wired in series to get up to charging voltage? I mean it seems a VAWT would be spinning way too slow, or am I missing something?

I've been playing around with the idea of a VAWT for some time, but getting an RPM high enough to make useable electricity seems to be a quest.

Just curious,  
RogerAS

"Put the bunny back in the box!"

Re: Crossflow VAWT tinkering ([none / 0](#)) (#2)  
by TomW on Mon Jun 16th, 2003 at 09:29:07 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Roger;

Well those motors are just bearings now. Not wired at all. However, my plan is to wire them in series in the real unit. Furthermore I have a pair of 40 volt TDMs and they have 2 sets of brushes in parallel that are 90 degrees apart on the commutator. I was toying with the idea of rigging the 2 sets of brushes in series internally to get more volts per rpm per TDM and perhaps series the outputs of those.

These TDMs do get to charge volts about 300 RPM so it is within the realm of reality to get them going fast enough to charge with a small diameter and tall vawt.

My wind situation is so poor that I have decided that HAWTs are never going to work for me here so I have shifted from HAWT to VAWT research. There is a guy from France "trentman" who constructed the full size one from picoturbines plans and he has gotten good output from the purpose built genny on it. His is 4 feet in diameter and 6 feet tall or more. Maybe I can convince him to post about it here.

Pictures of his are available online too:

<http://op.servepics.com/cgi-bin/album.pl?album=trentman>

More info on the wing construction is available in a PDF I got from Picoturbine.com:

<http://www.picoturbine.com/pt250-blade-plan10A.pdf>

Cheers.

TomW,

I'm in the same boat with low wind speeds. Except for a few months in winter we in the Ozarks are breeze challenged!:-)

I have 6 of those plastic 55 gallon drums and a good set of pillow block bearings. Since I'm blessed with an abundance of tall straight hardwoods I think I could easily build a tower. One thing that has me sorta confused is the plates the wing (drum) halves are mounted to. How does one assure the flatness? I mean without really stiff material wouldn't the whole thing wobble pretty bad?

Anyway, I'm really interested in this project. Keep us posted!

<http://oneota.net/~earthsourcepowr/>

Roger;

If you mean the ribs that the skin is attached to I think stiffness may be an issue but once secured the skin stiffens it a lot. I used a snug hole and cross pinned the wings to the "drive" shaft through the plywood wing ribs with screws.

The original picoturbine plans call for 4 angle brackets per rib to connect it to the shaft. I just pinned it and i think its plenty strong enough for a 2 foot unit.

You need to realize that as size increase stress on components go up exponentially too.

Cheers.

TomW

Hi,

there are good books available concerning Savonius rotors made of drums.

One of the best is:  
Savonius Rotor Construction.  
J.A.Kozlowski.  
VITA USA.  
1977. 0-86619-062-7.

Available from  
<http://www.vita.org>

'PicoTurbine Deluxe Windmill Plans' text is a good one. Available from  
<http://www.picoturbine.com>.

A single set of 55 gal drum halves will give you good torque, but will be a little slow on RPM's. One of the main factors that affect rpms on a savonius is the aspect ratio (height/width). A tall skinny savonius will go a lot faster than a short square one of the same frontal area. Of course, if you stack three drums, your aspect ratio also goes up proportionally.

If you guys come up with a good low wind design, I'd think real hard about building one, as Indiana is also wind challenged.

Best Regards,

troy

**More fooling around with different small blade stuff follows**

When I'm not spending my time disrupting the smooth flow of dissenting opinions here on OtherPower I actually do get in some wind power related testing and experimenting. Heres the latest unsuccessful skirmish using 4 inch cedar lap siding:

Thats 4 inch cedar lap siding mounted at 23 degrees to the hub with a bit of rounding on the leading edge. No taper and 3 feet per blade and about 6.5 feet total prop diameter.

While it spins in a very light breeze it is another blade setup that lacks top end for charging.

Once again this is actually my buddy Lanes thing. He had been looking at a Bergey 1KW mill [XL. 1 I think] and he was curious about its apparent lack of twist. He tossed these on one of my old JerryBlade hubs to see if it worked at all. And, like I mentioned, they work at some level but have low and limited rpm.

Can anyone explain just how Bergey makes those blades work? I have never seen them myself yet but Lane says they have no twist and what looks to be a constant profile.

Cheers.

([User Info](#))

Glad to know you haven't been entirely sucked into the vortex of board politics.

In a driven rotor (as opposed to a propeller) lack of twist will make the rotor hard to start with a good top end, or poor at the top end with good starting characteristics.

Or they can split the difference and get so so starting with so so top end, and definitely not as good as a set of twisted blades.

Unless of course it's some variable pitch hub or one of those magic blades that are thin in just the right places so that as wind speed goes up, they deform into a better attitude.

Good luck and especially, keep having fun.

troy

Always love to see a experment. I think the big problem with this blade is the 23 degree angle more than anything. Jerrys blades are now something in the area of half that and they work really well. 23 degree is great for start up but have too much drag to go very fast.

Re: Just because we had to know.. ([none / 0](#)) (#3)  
by Norm on Sat Jun 14th, 2003 at 03:56:43 PM MST  
([User Info](#))

Do you suppose you could use a reinforcing metal strap the length of each blade about 3" wide and 3/16 thick or whatever it takes, where you could twist the strap enough where it would stay twisted at the proper angle when you screwed or bolted it to the wood siding? (Actually there are a few good woodworkers out there that know how to twist and bend wood like it were plastic!) I've always thought myself that it was a lot of work to just shape a prop, let alone put a twist in it as you go along, It wouldn't have to be so thick in the first place, if you could twist it afterwards.Norm.

Steam Bending ([none / 0](#)) (#4)  
by TomW on Sun Jun 15th, 2003 at 04:38:37 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Norm;

I looked into steam bending and it might be a way to go except for the little fact that softwoods do not accept steam bending according to my research.

Tests on some pine I had on hand show that for boards that thickness about a half hour in live steam softens them enough to get a nice twist. All well and good. However, after sitting awhile after they dry the boards straighten back to near the original shape.

I did not really expect these to actually work and it was just more "what if..?" stuff.

One day I need to just get something that works for my crazy wind situation. Here I think that means a VAWT and thats my current project to get a clone of the picoturbine crossflow Vawt working using a couple tape drive motors as top and bottom bearings.

Cheers.

The wood has to be clamped in position and slightly overtwisted (trial and error to determine the correct amount, just like everything else in this crazy, but fun game!)then it has to remain clamped until dry, I suppose, to be truthful I'm just drawing a logical conclusion from what I've read no experience except from watching some of my plywood squares that I had get wet and seen them twist into all kinds of unwanted shapes! ### [Yet another Pinwheel.](#)

By [TomW](#), Section [Diaries](#)

Posted on Wed Jun 4th, 2003 at 12:28:40 AM MST

[TomW's Diary](#)

Well Lane was here again and after a fun day yesterday we had to try another pinwheel spinner.

Thats a 6 foot diameter blade on a 40 volt tape drive motor. It spins in very light breezes but seems lame at any high speed but no real wind to test it either. Rule #1

These 2 are shots of our high tech, mobile test facility.

Bottom line is it starts easy runs slow and is too flimsy. We had a good time and it was a learning experience and we have ideas on a 3 foot or so 2 blade pinwheel.

Heres an mpeg file of it actually ripping along at 3 or 4 rpm:

<http://www.otherpower.com/images/scimages/4/MOV01653.MPG>

Cheers.

TomW

On to another design? ([none / 0](#)) ([#1](#))

by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Wed Jun 4th, 2003 at 04:43:00 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

I never took the pinwheel to such heights. The main reason they slow turning is because of the bulky leading edge. This causes lots of drag. If this could be worked down a bit it might make a reasonably efficient prop. One idea that came to mind ( never tried it ) was to install an aluminum tube for the main structure of the wing and wrap the aluminum sheet around the tube forming a less bulky leading edge and adding structure to the wing. Sort of forming a "," shape(comma shape- you know what it looks like if you write it). They would be vulnerable to stress cracking which there are a few of those on mine. I get antsy to build another one so if it made a couple years use without any problems there would be another in it's place shortly after. I like to see new idea's good bad or indifferent... I especially like to see the really strange ones... I have a few of those

Lots of Fun!

Ed

R&D ([none / 0](#)) ([#2](#))

by TomW on Wed Jun 4th, 2003 at 06:37:47 PM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Ed;

Reck n Destroy.

Well, that 2 blade one did not survive the night with the awesome 8 or 9 mph gusts we had.

Way too much flex and it actually folded forward on itself and had developed several stress cracks around rivets. A couple of spots had problems from being against a square edge a known problem I think.

I'm looking at several other options including an actual formed wing shape with foam injected but im kinda slow with limited ability and none in metal working. Plus that gets away from "pinwheel" and into "formed metal blade" territory.

The most successful version so far is the standard 4 blade pinwheel shape. I'm thinking on a way to do 3 blades. Its mostly the fun and anything learned is icing on the cake.

Cheers.

Foam injection sounds interesting, I've cut a few sections of foam with a homemade cutter ( basically an "E" string off a guitar stretched between a couple dowels and a battery). Cuts some nice airfoils. Keep us posted on the foam injection stuff... sounds fun!

Withdrawl's... getting weak... need... windpower..

Have Fun!

A couple of weeks ago I was thinking about the aerodynamics of a pinwheel and the feasibility of using it to drive a generator and here it is ...I should have known it's probably just a coincidence...but still seems weird, well anyhow, I'm thinking with reinforcing along the edges some epoxy and a lot of pop rivets it would really fly! Great job ! Real neat!  
Norm.

### [Aluminum Sheet Pinwheel](#)

By [TomW](#), Section [Diaries](#)

Posted on Mon Jun 2nd, 2003 at 05:53:05 PM  
MST

[TomW's Diary](#)

My friend Lane [Pythos for you IRC folks] stopped out and slapped together this pinwheel that we attached to an ac fan motor for a bearing.

---

The material is .008 inch thick [yes 8 thousandths] aluminum sheet that is 2 feet by 3 feet. He cut one sheet down to 2 foot square and cut and folded it into a pinwheel that he attached to the motor.

Here it is. The pinwheel measures about 34 inches tip to tip on the points.

Here is Lane doing duty as a tower. This thing actually spins up pretty well and seems to zip right along.

This was simply a prototype "will it work?" exercise. The only support is a 1 & 1/8 inch diameter quarter inch plywood disc behind the center. This allows a lot of flex and the blade was tending to rub on the mounting hardware for the motor. It had a tendency to rotate from any air movement including walking with it in the air.

As you can see one of the "wings" got pretty distorted right away but we know what the problem is and have a solution.

Maybe more another day.

Cheers.

Tips on the pinwheel ([none / 0](#)) (#1)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Mon Jun 2nd,  
2003 at 07:01:59 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Hi Tom,

Here are some tips on keeping it going. I built one 3 years ago and found it to be quite flimbsy. I added a square piece behind the pinwheel and riveted it together. Added 2 large fender washers to the front mount. Make a crease in the trailing edge of each blade ( bend it at about 3 or 4 degrees ) about 3/4 inch in.

So far mine has been up for 3 years and has been through some pretty heavy storms with 60+ mph winds. It has a threaded rod through a piece of tubing that has been greased twice now... its still going. I've attached it to a couple generators and a few homemade alternaotors for testing and you'd be surprised at the power you will get from it. Mine came out to 27 inches tip to tip. It will make 50 watts in a 30 mph wind... not super efficient but its torky. Mine runs at a TSR of just over 2... I'll have to get a picture of the old wreck. Lots of Fun!!!

Ed

Thanks, Ed ([none / 0](#)) (#2)  
by TomW on Tue Jun 3rd, 2003 at 06:38:29 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Ed;

Thanks for the feedback. I was going to try a paint can lid as a stiffener for the backside of the pinwheel mostly because I have one around.

Just curious what material and thickness yours is built from? And by "crease" you mean like the little bends they put in ductwork to stiffen the sides of a plenum? I've seen them do those with a screwdriver and "score" the piece of sheetmetal in an X shape.

Cheers.

TomW

Pinwheel ([none / 0](#)) (#3)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Tue Jun  
3rd, 2003 at 08:17:15 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Here is a picture of the pinwheel

<http://www.otherpower.com/images/scimages/15/front.JPG>

<http://www.otherpower.com/images/scimages/15/back.JPG>

I couldn't figure out how to do the IMG SCR thing so hopefully you can click on the links

The back shows the aluminum plate I used as a stiffener and the front shows the crease in the trailing edge as well as the washers in the center. It was a fun project... quick and simple

Ed;

Funny how the simplest things can actually work.

We were thinking of a 2 blade version but it has not clarified itself just how to do it.

Thanks for the pictures.

Cheers.

## [JerryBlade modifications and Tape Drive Motors](#)

By [TomW](#), Section [Diaries](#)

[TomW's Diary](#)

Posted on Sun May 25th, 2003 at 04:51:43 PM MST

Another installment in the TDM genny saga.

This is the hub. It consists of a 5/8th motor Arbor adaptor: a piece of 1/8th inch 2 inch wide aluminum strap about 6 inches long. and 2 jerryblades. The root angle is 23 degrees and they are 48 inches in diameter.

This shows the shape i cut into the original blades:

- [TomW's Diary](#)

Preliminary results are that these run faster at a given windspeed over the stock JerryBlade or either of the other 2 mods I have tried.

The entire blade and hub assembly weighs 1.5 pounds which I like.

Cheers.

TomW

New Blade Mods ([none / 0](#)) (#1)  
by Jerry on Sun May 25th, 2003 at 11:25:05 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Tom I'll try this again? I had thought about trying something like what you done in this new mod just never found the time. I was thinking about a gentle sweep from the tip and the out to the trailing edge. Kinda of an arch rather than straight back then over but I've never tryed it and it sounds like your works very well. Could you give us some dementions? size and shap of tip,width at severall station and at what point to cut over to the trailing edge? PS Tom thanks for your help getting me going here. JK TAS Jerry

Observations ([none / 0](#)) (#3)  
by TomW on Mon May 26th, 2003 at 10:39:47 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Jerry;

So glad we could get you on the new board I know I really appreciate your input on a regular basis.

Right now its all by observation and my observations are that it runs faster than either stock or mike modded but its still rough with no knife edge on that trailing edge. I'll measure it later on for the precise dimensions of the cuts.

It was just what looked good and I free handed the first one with a razor knife and just copied it on the second.

The measurements from memory are 1.5" wide at tip with leading edge left stock. I started that radius from the root about 7" out from the point on the root section edge the radius is smooth from there to 1/2 the width of the blade at like 14 inches. then tapered to 1.5 inches on the tip.

I am fairly certain that the trailing edge being rough is impeding performance some. I don't have accurate measurement gear hooked up but we have reported 8 mph winds and mounted on my truck in the field putting out 20 volts from that 30 volt tape drive motor and will do 4 amps into a short before it slows down to a crawl. Diameter is 48" and they weigh 1.5 pounds including the arbor.

I am confident that dressing the trailing edge to a

knife edge would improve performance a lot because it wooshes while spinning. A slight radius on the tips might improve performance also.

Still got 8 blades to play with to see if these thinner blades can be gotten up to higher rpms for these tape drive motors at lower wind speeds.

Have you tried cutting these blades with a hot wire cutter or other means besides saw and razor knife?

Cheers.

[Online Rights the myth](#)

By [TomW](#), Section [Diaries](#)

Posted on Mon May 12th, 2003 at 08:33:42 AM MST

[TomW's Diary](#)

Ok I'm just going to address this whole censorship and "rights" thing here once so any morons or understanding challenged folks in the group should read very carefully.

Assuming you were born and raised in the USA you have grown up with a right to free speech. That right is not without limitations. You may not invoke this "right" to slander another person, yell fire in a crowded theater, stand on a street corner shouting profanity, etc. Your right to free speech is by necessity a right to responsible speech.

Also, as with any right, your rights end where mine begin.

However your freedom of speech does not apply beyond public spaces. Once you enter a private dwelling or place of business the owner of that place may enforce any rules or regulations they desire regulating behaviour or speech they feel appropriate.

Now here is the part some do not seem to understand:

The internet, and most of its component parts are operated on private equipment. bandwidth and finances. Guess what? Your freedom of speech does not exist on the internet beyond the level it is granted by the owners of the resource you are using.

So, as surprising as it may be to some, those who run this place have an absolute right to allow or disallow anything they want be it reasonable in our eyes or not. Right, wrong or indifferent thats how it is. Lucky for all of us this board is run by even tempered, laid back folks.

Well thats how it really is please feel free to show where I am wrong.

Cheers.

"censorship" ([none / 0](#)) (#3)  
by troy on Mon May 12th, 2003 at 04:05:04 PM MST  
([User Info](#))

Dear Tom and admin,

I really value this board for all the expertise, wisdom and humor that everyone supplies as a group. In my humble opinion, the admin has shown a great balance between allowing for the occasion interesting off topic or controversial post, but still willing to draw the line in the sand when people (not pointing any fingers at anybody in particular) get wacko.

I'm not sure if everyone realizes how good this discussion board is. There are lots of them out there that are not well regulated/edited, and it's painful to participate for very long.

Keep up the terrifically good work,

troy

"censorship" ([none / 0](#)) ([#3](#))  
by troy on Mon May 12th, 2003 at 04:05:04 PM MST  
([User Info](#))

Dear Tom and admin,

I really value this board for all the expertise, wisdom and humor that everyone supplies as a group. In my humble opinion, the admin has shown a great balance between allowing for the occasion interesting off topic or controversial post, but still willing to draw the line in the sand when people (not pointing any fingers at anybody in particular) get wacko.

I'm not sure if everyone realizes how good this discussion board is. There are lots of them out there that are not well regulated/edited, and it's painful to participate for very long.

Keep up the terrifically good work,

troy

Heartily Agree, and well spoken, Tom! ([none / 0](#)) (#8) by xeroid ([centurion27@lycos.com](mailto:centurion27@lycos.com)) on Thu Jun 5th, 2003 at 10:43:40 AM MST ([User Info](#))

I really appreciate your intelligent and clear explanation of freedom of speech, in it's proper context. Too many people "claim" that right in order to belch out profanity, ignorance and nonsense. Thanks for setting the record straight, Tom.

Regards,

Xeroid.

Couldn't have said it better, Tom. ([none / 0](#)) (#4)  
by Electric Ed on Mon May 12th, 2003 at 09:08:03 PM  
MST  
([User Info](#)) <http://www.electric-ed.com>

I agree 100% with Tom and the others on this.

I have seen other discussion boards taken over by the "lunatic fringe" and hope this is not what we are seeing the beginning of here.

Ed

## [Jerry Blades a Tape Drive Motor means a mill in a day.](#)

By [TomW](#), Section [Diaries](#)

[TomW's Diary](#)

Posted on Sat Apr 12th, 2003 at 02:54:12 PM MST

This is my latest quickie project. I started on it yesterday and its spinning today in what the wind map says is a 6 mph breeze.

---

### Parts needed:

3 Mike Modded JerryBlades.

some aluminum scrap.

1. 8" aluminum pulley.
1. 30 volt Ametek Tape Drive Motor [TDM].
1. 3/4 inch floor flange.
1. 6 inch 3/4 pipe nipple.
2. 4 inch muffler clamps

a small pile of 10-24 screws and washers / nuts.

TDM ([none / 0](#)) (#1)

by [wiredup](#) on Tue Apr 15th, 2003 at 12:41:56 PM MST  
([User Info](#))

hi tom are you able to keep 12 volt batteries charged up and at what wind speed does it take.thanks

Charge rates ([none / 0](#)) (#2)

by [TomW](#) on Wed Apr 16th, 2003 at 10:14:23 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Wiredup;

Well I don't have an anemometer so everything is by what wind maps say was happening,

I can get 6 volt "trickle" charge at around 9 mph winds. Thats around 250 milliamps or so [.25 Amps].

In gusts reportedly to 28 MPH I was seeing bursts up into the 3 to 5 amp range into fairly charged up [12.5 volts] 400 AH of batteries @ 12 volts. It seems to be able to sustain a steady amp+ in around 15 MPH.

It is no powerhouse but it seems to do OK all things considered, price, effort, location, etc.

This particular mill is mostly "proof of concept" type stuff and I have been more concerned with mechanical function than logging charge rates.

Yesterday my improvised balancing scheme of duct taped lead bullets to the pulley shucked a weight and went violently out of balance in the 45 mph gusts we had. I shut her down, locked the prop and this morning brought it into the shop. No damage but it sounded like a jackhammer when it was unbalanced. I will be tweaking it for some other issues like pivot point balance and rebalancing the blades in a more permanent fashion today.

Output Amps VS RPM data on these motors is in one of my other diary entries if interested.

Cheers.

TomW

by no1redraidersfan on Fri Apr 25th, 2003 at 01:26:52 PM MST  
([User Info](#))

Do you have any suggestions on how to make a wind power generator out of raw materials, but I get the motor and gears. The fan blade is 18 inches diameter and the axis of rotation is 11 to 12 inches above table level. Please help me and if you have any web sites or suggestions (would be better) this would be great for school project not high budget. Its for a school project so not as big as yours. Thanks joe

Liked the website there Tom! Some real good hands on YE going on! Your idea of the Uncoil was intriguing, I see what you mean. I recall seeing something vaguely similar in some old patents. Let me know and I will get them to you in PDF format.

Peace,

TS out

Thanks. ([none / 0](#)) ([#6](#))  
by TomW on Wed Apr 30th, 2003 at 10:00:35 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

TS;

Thanks for the compliment on my site! It is falling behind lately as I am doing more and documenting less with nice weather.

As far as the uncoil goes its one of those "looks good on paper" things that doesn't really work as expected. Marty over on IRC did some tests and it did not give much if any improvement over standard coils in his tests. I can't find the link just now but if i find it i'll post it for you.

Cheers.

TomW

## [Tape Drive Motor Data](#)

By [TomW](#), Section [Diaries](#)

Posted on Thu Apr 3rd, 2003 at 07:57:19 AM MST

[TomW's Diary](#)

Well I seem to be in a go through my notes mode on this windy rainy day. So I am posting some more output data I have compiled.

I bought a pair of 30 volt Ametek Tape Drive Motors [TDM] from Silicon Salvage in California. \$20 each, plus shipping, of course.

Shortly after I got them I ran output tests on one and built a quickie mill with the other.

I chucked the motor into my drill press and ran it thru a stud mount diode to 220 AH of 12 volt batteries that were at 12.9 volts.

RPM	Open Volts	Amps	Watts into 12.9 volts
210.	9.8V	0	0W
305.	13.5V	< 1A	< 12W
450.	18.2V	1.0A	13W
530.	24.6V	2.2A	28.4W
900.	41.0V	3.6A	46.4W

I didn't test above 900 RPM.

These are nice, compact motors with a 5/8" shaft and are sealed and have extremely nice bearings in them.

add a tail boom a tail a prop and a diode and you have a mill capable of up to 40 watts at attainable rpm.

Cheers.

TomW

([User Info](#))

hi tom i have removed the stock magnets and replaced them with 4 #29s nearly doubled yhe volts have you ever done anything like that.if so would you post results. thanks

no, I have not ([none / 0](#)) ([#2](#))

by TomW on Wed Apr 16th, 2003 at 12:24:55 PM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

However, We have discussed this over on IRC more than once. I am just better off putting together off the shelf parts to do non standard things than mechanically modifying things.

I believe JimU is going to do it one of these days.

Did you realise the #29 is no longer available?

Cheers.

([User Info](#))

hi tom didnt know about the #29s glade i got 10 extra. there is no mods needed, they go right in where the old ones come outi didnt even glue mine down they held so tight and matched the curve so well. i may try the 50 volt next. have fun and thanks for all the info. P.S. those cup you have on things you keep.well they look a little to full to be catchin any wind, haha.

NEW.. 40 Volt TDM Data ([none / 0](#)) (#7)  
by TomW on Thu Apr 24th, 2003 at 08:54:28 AM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Got my 40 volt TDMs in yesterday. Chucked one in the drillpress for some tests. Here are the results:

Nominal 12 volt charging into 440 AH of batteries @12.1 volts

RPM Open Volts Amps into 12.1V Watts

210.	7.5V	0	0W
305.	11.4V	0A	0W
450.	16V	1A	~12W
530.	22V	3.1A	~37W
900.	28V	5.2A	~63W

Nominal 6 volt charging into 220 AH of batteries @6.05 volts

RPM Open Volts Amps into 6.05V Watts

210.	7.5V	.25A	1.5W
305.	11.4V	1.25A	7.5W
450.	16V	3A	~18W
530.	22V	5.4A	~32W
900.	28V	7A	~42W

Well these numbers are quite interesting. I expected higher voltages at lower rpm but that was not the case.

What appears to be the case is it produces better current lower in the range and actually outperforms the 30 volt motors for 6 volt charging and has a better top end performance curve. It looks to be producing 25% more than the 30 volt motor @ 900 rpm!

Cheers.

### [Treadmill Motor Data](#)

By [TomW](#), Section [Diaries](#)

Posted on Thu Apr 3rd, 2003 at 06:59:26 AM MST

[TomW's Diary](#)

I bought one of those BG Micro Treadmill Motors some time ago for like \$20. I didn't get a chance to do any testing with it til earlier this week.

---

This is what I found by chucking it into my drillpress.

Into 440 AH of 12 volt batteries that were @ 11.9 volts:

RPM, Open Volts, Amps

210. , 4.63V     0A  
305. , 7.2V,     0A  
530. , 13.3V,    2A  
900. , 18.0V,    3.9A

All in all about the same output curve as a 30 volt Tape Drive Motor [TDM] for the same money but with an open frame motor and that funky worm drive shaft. The TDM seems better suited to outside life and has a standard 5/8 shaft.

I'll be posting the Tape Drive Motor Data I have soon too so keep looking back in.

Cheers.

TomW

## [Some fresh blade pics to look at](#)

By [TomW](#), Section [Diaries](#)

[TomW's Diary](#)

Posted on Sun Mar 30th, 2003 at 10:50:17 AM MST

Been working with bobn over on IRC designing and carving a 3 blade prop for my Tape Drive Motor gennies.

These are made from 64" of 1X6 pine for each 30" blade. Thats one 30", one 22" and one 12" piece stacked as shown in ther raw blank on one side in the pics.

I'll comment them at a later time but for now some raw pics to laugh at:

New to the site, did you ever try drawing a pattern for your blades on a 45 gallon drum and cutting them out .A guy out of Peterborough Ontario told me this years ago.By gaging the thickness of the barrel you control the weight and apparently they have the almost perfect pitch.

## [Step by Step Photo Uploading /Use on OP](#)

By [TomW](#), Section [Rants & Opinion](#)

[Scoop](#)

Posted on Sun Mar 30th, 2003 at 08:19:33 AM MST

I try to demystify photo uploading and use.

First and foremost log in

Then on the right in one of those textboxes there should be one with your nickname [username] in it. In that box is an option "Your Photo Uploads".

Click on "Your Photo Uploads" and then you can follow the directions to uploiad the photo or file to your upload area.

Ok now the photo is uploaded to an area on the www.fieldlines.com server where anyone can access it from the internet.

All fine and good.

Finally we get to actually use that photo in a posting.

From the front page or perhaps others on the right again select "Submit Posting" from the menu.

Once that page loads you should see a box on the right for "user Files". Use the pulldown menu to select which of your files to use click the button to insert it into the message.

Simple as that.

Much easier to do than explain. Cheers. TomW

[Wind](#)

Posted on Thu Mar 20th, 2003 at 08:40:58 AM MST

I have a fairly large [and growing] pile of salvaged components such as relays, FETs, diodes, transformers and bridge rectifiers.

Lots of stuff that has useful life in it eventually gets disposed of because i cannot use it all myself. I also get some used sealed lead acid batteries in the smaller sizes that become available sporatically.

I would be happy to send these supplies to folks who would actually use them for the cost of shipping.

The stock changes as items come in and go out. There would be no guarantee other than the parts will be shipped.

I can look for specific items in my salvage stream too.

Respond here if interested.

Sorry but i will be limiting this offer to active members of the OP board.

What state do you live in?  
Be blessed! Gary

shipping? ([none / 0](#)) (#4)

by Gorilla Boy ([No Spam/gwmorris@fgisp.com](mailto:No_Spam/gwmorris@fgisp.com)) on Mon Mar 31st, 2003 at 08:20:16 PM MST  
([User Info](#)) <http://www.livetheword.info>

I was asking because of the shipping. I live in East Texas and would drive a ways (100-150 miles) if it was worth it (shipping less or more). Gary

[Can I charge a sealed lead acid with this?](#) | 5 comments (5 topical, editorial)

Re: Can I charge a sealed lead acid with this? ([1.00 / 1](#)) (#1)  
by Andrew ([andrew@lookingglass.com](mailto:andrew@lookingglass.com)) on Thu Aug 21st, 2003 at 04:48:51 PM MST  
([User Info](#))

Probably,  
1 amp is pretty large for a 17ah. It should work. Do two things before trying. First, get a voltmeter and measure the output of the charger. It should be between 13.6 and 14 volts. Second, Is your charger current controlled? If it is, your in luck, but if not, I would not leave the battery unattended during charging. Sometimes they can force the charger much more than just an amp out.

-Andrew

Wow!  
Very nice.  
I would like to exchange some emails with you sometime. I like your ideas about current based chargers. If you have the time could you send me an email at [gar4772@hotmail.com](mailto:gar4772@hotmail.com).  
I would like to hear your opinions on other aspects of battery recovery and pulsed charging.

Thanks!!!

Below is a description of a very simple solar collector from the company that produces them. I also have a pdf. file showing the detailed breakdown of the unit if interested...

**- ADVANCED HOMEBUILT AIR-BASED SOLAR COLLECTOR - BUILDING INSTRUCTIONS**

**OVERVIEW**

The instructions below are for a homebuilt version of Sol-Air Company's air-based SHVC (Solar Heating and Ventilation Cooling) system (description at bottom). Our commercial version differs from the homebuilt in having an internal air-handler (the AutoVent automatic mode-switching control), and a proprietary absorber material that has somewhat higher surface area and selective properties.

**Homebuilt Solar Collector Output**

Like its commercial cousin, this homebuilt unit produces more energy for the money by far than other forms of solar utilization, including PV and solar DHW systems. The output for a 20 square foot unit is approximately 5,000,000 Btu per year, equal to approx. 50 gallons of heating oil (or 50 Therms of natural gas). This output is produced primarily in the spring and fall, with a decided dead spot in the middle of a cold winter.

**Mounting**

The collector is mounted vertically on the outside wall (the rule that tilt = latitude is for another type - DHW collectors, which need year-round input). The lower sun angle in winter reduces the performance penalty, and the avoidance of summertime sun is an important factor in increasing system life. Another advantage gained is ease of installation.

**House connection**

Air passes into and out of the collector through a manifold which connects it to the inside of the house. Instead of using the collector to replace a window, plan to install your homebuilt collector with the manifold passing through a hole in the wall, (you can install it beneath a window, or with the manifold passing across the window sill of a slider-type of window). That way, you will have two solar devices, the collector and the window.

**WINDOW COMPARISON**

Gain from a solar collector, as with a window, is directly proportional to

glazed area; it occurs for 5-6 hours on sunny days. Both a window and a solar collector "leak" some of the energy taken in, but there is a net gain during collecting hours on a good day. The difference between a solar collector and a window is that the window leaks energy 24 hours a day, while the solar collector leaks energy only during those 5-6 hours. People with "passive solar" homes must play an active role in reducing nighttime losses. During non-collecting hours, an active solar collector loses virtually no energy, without manual intervention. A solar collector is a large no-loss window with a virtual window plug that self-installs, whether you're home or not.

#### What's a Window Plug?

While windows have greater losses, these can be reduced if you manually insulate them at night, with "window plugs" that you make from 1" blue Styrofoam, edged with wood strips (3/4" x 1", ripped from a 1x4). Each night, or right when you come home from work, you plug your windows. As you put a window plug in, you feel immediately warmer - right now. You can put them behind a couch or door during the day. Plug north windows all winter if you like.

#### Build a Window Plug:

The monetary payback period for window plugs varies from instant (if you have spare time and materials) to six months. In winter, they have an immediate effect on room comfort.

To make one, tack together a rectangular frame of the 3/4" x 1" wood, to fit the inside of your window frame. Use one nail at each corner, through the end of one piece into the end grain of the next). Brace the frame with diagonal pieces of wood while it's in the window; remove it, lay it on top of the Styrofoam on the floor, and mark inside the wood with a pointy marker pen. Leave 1/16" clearance all the way around (1/8" overall). Use a very sharp, very thin knife to cut the foam.

Double 6" long fabric strips into loops to aid removal from the window. Slip the foam into the frame, with a loop in the joint at each side near the top. First use dots of hot glue, then sawdust-thickened wood glue.

Cover one or both sides with Contac shelf paper, muslin in glue, wallpaper, etc.

For all-winter window plugs, prevent condensation by installing 3M V-seal on the edges: Make the plugs 1/8" undersize (insert corrugated cardboard underneath and on one side of the frame as you build it in the window.

Sand and prime the wood edges with shellac before you apply the V-seal.

Cut the V-seal strips to meet nicely at the corners.

Now is also the time to caulk drafts around the window trim.

## COLLECTOR FEATURES

### The Absorber

The most important characteristic for an air-cooled absorber is super-high surface area. For your home-built unit, the best solar absorber is 1" thick furnace filter media, painted flat black and located in a reflective cavity. Furnace filter media presents a surface area to the air flow that is about 50 times the filter's face area. This is a higher surface area, by an order of magnitude, than that of conventional metal absorbers, whether finned, rippled, dimpled, or screen type. The sun shines on the filter fibers which get very hot; the heat is transferred to the air passing through the filter, taking advantage of intimate contact and good turbulence.

The "inside out" outer-surface heat exchange of this type absorber means that fibers transfer their heat to the air coolant directly at or immediately adjacent to the directly sun-lit sites at which the heat is generated. Dividing the material into small fibers produces an extremely short internal path - through the fiber material - from a sunlit fiber site to an adjacent shaded site.

### Low Cost Absorber Material

A virtual doubling of the heat transfer surface area is presented via a conduction path length of one fiber diameter. Because the "doubled-area path length" is extremely short, non-metallic material may be used without any performance penalty - a significant material-cost savings. Material note: I have used both glass fiber and polyester fiber furnace filter media as a solar collector absorber for 18 years without observing significant material degradation. As a pro-active precaution, observe the "Operation Caveat" stated below.

### Low Cost Design

A liquid-cooled collector cannot take advantage of this type absorber construction, which is very light. The low weight of the absorber produces a cascade of weight and cost savings in the support structure of the collector.

### Absorber Efficiency

The absorber's high efficiency produces a low operating temperature. A collector built to these specifications was tested at Western Michigan University's Energy Learning Center - no longer operating, I understand - using the ASHRAE 93-77 procedure, yielding a greater than 72% maximum theoretical efficiency. This was the highest efficiency air collector they ever tested; it bettered all liquid collectors but one, which it virtually equaled. I know of no other non-concentrating air collector, Conserval's SolarWall included, with better full-system efficiency.

You will want furnace filter media that comes in roll form so you can customize the size and shape of the collector. See a Grainger industrial supply catalog, item 4WZ72 (roll, 36" W. x 90 ft.; 1" thick); other widths are available there. You could go to an HVAC contractor and ask them to cut you the lengths you need. Use hi-temp stove paint, and spray it at a  
45

degree angle (a "glancing" angle) from both sides, so little of the paint passes through.

#### The Reflective Cavity Enhances The Absorber

The foil-faced inside surface of the collector is left reflective (not painted black) so the black filter fibers do all the absorbing. Sunlight that passes unabsorbed from the front direction is reflected back to the absorber for another pass, doubling the effectiveness of the absorber.

--

#### MAKING THE SOLAR COLLECTOR

Build the collector case of 1" foil-faced isocyanurate (urethane) foam-board. A good final case size is 46" x 64" (the case-back is 43-1/2" x 61-1/2"). The depth of the collector case is 6". With the back material being 1" thick, this leaves 5" for air passages. The sides are 6" wide, and they overlap the edges of the back.

Use urethane construction adhesive for all joints. On heat-exposed joints

like the case-side/case-back joint, protect the joint with a fillet of silicone adhesive at the inside of the case. Apply the silicone adhesive after the urethane adhesive has set (24 hours). Use spots of hot glue to

hold temporary right-angled pieces of foam-board at three places on each

side, to keep the sides straight and to hold them square to the back while

the urethane adhesive sets overnight.

Both urethane adhesive and silicone adhesive use water (humidity) to initiate curing; speed curing by spraying a tiny bit of plain water on the edges of the seams after you put the pieces together.

To provide a surface that will hold the mounting bracket screws, glue 1/4"

plywood pieces, 6" wide and full length (short sides can overlap long sides,

or the reverse), on the sides only - no plywood is needed on the back.

You

can also use luan underlayment plywood. It's slightly lighter, thinner and

cheaper, but it's a less "green" material. Glue the pieces on the four sides of the case with a single 3"-wide wavy line of urethane adhesive.

There's no need to use 3/8" plywood - it just adds weight. Even though it

would give you a chance to screw-fasten the plastic glazing, using screws

doesn't produce an even line of pressure on the edge of the glazing, only a

point pressure at each screw. You're going to cover the case with an aluminum sheathing, so use the even pressure of the corner bend of the

aluminum sheathing to pull the glazing against the edge of the case more

evenly.

Cut an 11-1/2" square hole, centered side-to-side, in the back wall of the

case; the upper edge of the hole is 3" from the outside top surface.

#### Bend the Aluminum Sheathing

To make the box weather resistant, you need an aluminum outside skin, or

sheathing. The dimensions are shown in the illustration. Make up the pieces before you install the glazing, so you can install them

immediately

after, thus holding the glazing in place.

You can do the case sheathing two ways. You could use pre-painted

#### aluminum

coil-stock (house trim material). But, the material is too thick to bend by hand, so you should have the bends made by a siding company on their trim brake. Plain aluminum flashing is satisfactory, just be sure to apply a car wax to the aluminum. Aluminum flashing can be bent by hand over the edge of a piece of plywood. Press and slide your hand along the length of the bend, "milking" it a few degrees at a time. Protect your working hand with a leather glove, and hold an old towel to press onto the work. Back up the aluminum with a backup block - a length of 1" x 3-1/2" pine ripped from a straight 2x4. Set the backup block on edge on top of the aluminum, right at the edge of the plywood, and apply a clamp at each end. Use the same backup block to make the 1/2" x 1" x 1-1/2" aluminum flashing angles to cap the edges of the inner "C" baffle. For the slight amount of over-bend specified, bend the aluminum as far as you can clamped, then unclamp it and work in some more bend by hand.

Also the flow of air through the case is guided by a "C"-shaped baffle, for which you will need two 4-foot-long pieces of aluminum cap-angle to cover the raw edges of the baffle. The dimensions are shown in the illustration.

Last, make ten aluminum flashing mounting-rail pieces, 1"x1" x 4 feet long, legs a 90 degree angle.

#### Install the "C"-shaped baffle

The center leg of the "C" baffle runs across the 11-1/2" square hole in the upper back wall of the case. The "C"-shaped baffle is glued with urethane adhesive to the inside of the case, oriented with its center horizontal, at the top, and with the two legs descending, parallel to each other. The upper passage of the manifold is above the center leg of the "C", and the lower passage is below. There is 6" vertical dimension of the hole below the center leg of the "C", and 4-1/2" above. The distance between the descending legs is 12".

Fillet all of the inside collector joints, including all around the "C" baffle, with silicone adhesive. Cap the baffle with the aluminum cap-angle you bent up earlier using a 3/8" bead of silicone inside the angle.

#### Install the Absorber Mounting-Rails

The filter absorber sits on mounting-rails aligned on a diagonal to the air flow. Air enters the collector between the absorber and the glazing. As it moves through the collector toward the outlet, the diagonal absorber placement forces air to pass through the absorber to the back side, away from the glazing. The diagonal progression starts with the absorber near to the back wall at the inlet, and moves near to the glazing at the outlet; the

progression continues all along the air flow path. This keeps the hottest air away from the glazing, reduces conductive heat loss, and increases efficiency.

Use the 1"x1" angles of aluminum flashing that you bent up earlier as mounting-rails. Install each mounting-rail so the leg touching the collector is oriented toward the back wall. Use dots of hot glue a foot apart to hold the mounting-rails in place temporarily; then run a continuous fillet of silicone adhesive along the joint between the angle and the collector wall.

#### Install the Mounting-Rails

Install horizontal mounting-rails at the top and bottom inside surfaces of the collector. Use two or your pre-bent angles pieces, overlapped by an inch, to make up the needed length. Stop the rails 3/8" short of the adjoining surfaces. The top mounting-rail has its absorber-mounting-surface spaced 1-1/2" from the glazing plane. The bottom mounting-rail has its absorber-mounting-surface spaced 2" from the back wall (3" from the glazing plane).

Install diagonal rails beginning at the inside of each "C" leg starting below the fan; at this end, the absorber-mounting-surface is spaced 1/2" from the back wall of the collector. The rails run in a straight line to overlap the rail at the bottom of the collector; that is, they run at a slight angle away from the back wall down each "C" leg, continuing past the bottoms of the "C" legs to overlap the bottom rail. Snip a small piece from the back leg of the angles so they can overlap the bottom rail.

Moving to the side bays, install diagonal mounting rails at the sides of each bay, so the rails make a continuous straight line from the bottom rail to the top rail. Again, snip a small piece from the back leg of the angles so they can overlap the bottom and top rails.

Where the four central rails of the collector cross open space, snip the back leg of each rail near the "C" baffle and fold the rail flat. This allows air to travel unimpeded between the center bay and the side bays.

#### Install the Absorbers

With the exception of the fan/intake shroud area, the entire face of the collector is covered with filter-media absorber sitting on mounting-rails. In preparation for installing the absorber, cut the pieces you will need to size, and paint them from both sides with hi-temp stove paint from a spray can, holding it at a 45 degree angle to the face of the. Work quickly, covering first the back, then the front; favor the front with the most paint. Use nearly the entire spray can, leaving enough to paint the fan shroud. At the very end, just before you put on the glazing, use the last of the paint to touch up where needed.

Working one foot at a time, glue the absorber to the mounting-rails in a continuous bead of silicone adhesive, again using occasional dots of hot glue as a temporary aid.

#### Install the Fan

Install your collector fan (Grainger, 4WT48 70 cfm, or 4WT47 105 cfm)

and a pre-set snap-disc cooling thermostat (Grainger 2E245, close at 110 degF, open at 90 degF) in a shroud of aluminum flashing or house trim.

Make a one-piece fan-and-solar-thermostat inlet shroud, or you can use a two-piece shroud. One piece, to mount the fan, is an 11-7/8" x 6" pan with 1" flanges on top and bottom (make from 11-7/8" x 8" material); it has a 4-3/4" hole at its center and a 3/8" hole at one side to pass the thermostat leads out from the collector. Mount the fan over the hole with 1/8" x 1/4" pop rivets and a fillet of silicone adhesive, and bond the assembly in place with silicone adhesive vertically in the intake, at the back wall of the collector. Make sure the fan's air-direction arrow points into the collector.

The other shroud piece is also mounted with silicone adhesive. It has a 1" horizontal leg, a 4" 45 degree surface to mount the thermostat facing the sun and to redirect the incoming air downward, and a descending 3" leg.

Mount the thermostat through a hole the size of a quarter, and fasten it with pop rivets. Bond the thermostat shroud in place so the vertical leg is spaced 1/2" away from the plane of the glazing. Pass the thermostat leads through the 3/8" hole in the fan mounting plate. Wire the fan and the thermostat in series - tie one lead from the fan to one lead from the thermostat with a #14 wiring nut, and finish with an 8" length of electrical tape. Seal the thermostat wire hole with silicone adhesive. The remaining unattached leads, one from the fan and one from the thermostat, will be wired to the power cord leads at final installation.

#### Touch-up

Use the rest of your spray paint to paint the inlet shroud (paint the nose of the thermostat) and touch up the absorber.

#### Install the Glazing

The glazing can be Plexiglas (acrylic), which does well in this application because of the vertical angle and the efficient (low) temperature at which this collector runs, or another material of your choice (Kalwall). Polycarbonate (TwinWall, etc.) is strong, but may yellow. Cut the glazing to size to match the inside line of the plywood. Install the glazing with 1/8" pop rivets (1/4" grip range), spaced every 8" along the baffles.

Install pop rivets through the glazing every 8" along the "C" baffle. Put four rivets across the center of the "C" baffle.

Lift the glazing edge slightly and put a 5/16" bead of silicone adhesive around the collector sides where the glazing will sit. Place the silicone adhesive bead near the inside edge of the surface, so that as you allow the glazing to rest on it, the adhesive squeeze-out just reaches the inside of the collector.

#### Install the Aluminum Sheathing

Press the aluminum sheathing in place using an aid made from two 2-foot-long

1. x 1-1/2's glued together to make a 90 degree angle. As you do, install
1. /8" pop rivets through the sheathing into the plywood, all around the sides

of the collector, located 1" from the front edge, and every 8".

Install the sheathing angle all around the rear of the collector with 1/8" pop rivets into the plywood spaced, located 1" from the rear edge, every 8".

Working on each side on turn, tip the collector up on the side on a flat work table, to help ensure the sheathing edge is straight and cannot slip toward the side. Install 1/8" pop rivets, through the bend line where the sheathing touches the glazing (drill these holes through both sheathing and glazing). Rivet around the collector face on the contact line using a 12" spacing.

#### Dress and Fill the Glazing Joint

Use a gentle leather-glove touch to adjust the gap where the edge of the aluminum sheathing "returns" away from the glazing. The gap should be at least 1/4". Completely fill the gap with silicone, and finish it the joint with a spoon. Allow the fillet to extend 1/4" out onto the face of the glazing. Don't try to clean up until the silicone cures.

This seal design is tough and won't be broken by shock or expansion from temperature change.

#### The Manifold

The collector connects to the house via a manifold box made using the same construction materials and gluing method you used for the case - a urethane foam-board box with an outer layer of plywood around the sides. It also has a sheathing of aluminum flashing, made from a 9" x 1-1/2" angle, 60" long (this allows an overlap). The 14" square, 9" long, two-way, over-and-under manifold connects to the house through the wall or across the window sill.

You can use plywood on just the top and bottom, or on all four sides of the manifold. The manifold is divided by a foam-board "center divider" into a lower intake and an upper exhaust passage (back to the house). The lower passage is 6" high, the top is 4-1/2" high.

On the upper surface inside the upper passage, 1" away from the front face, install an 11" length of 1" x 1" flashing angle. Use hot glue dots and silicone adhesive. Face the angle legs away from the front face. This will act as a stop and support the edge of the inlet/outlet filter. Do the same at the lower surface inside the lower passage. Cut an 11-1/2" square piece of furnace filter to use for an inlet/outlet filter. The filter will span the center divider of the manifold, and rest against the 1" x 1" stops.

Install a Grainger 2W050 three-wire power cord up through a 3/8" hole in the bottom front edge of the manifold; make an overhand knot for a strain relief. Put a ring terminal on the green ground wire. When you make

the final installation, fasten the ring terminal to the fan shroud with a 3/16" aluminum pop rivet. Note: You could install an additional room temperature thermostat (open on temperature rise) in the inlet to disable the fan on rising room temperature; this would partially limit warm weather output. But the unit will still thermosyphon slowly. To fully prevent the unit from heating in summer, without damaging it, you will have to cover it with a cloth or plywood cover. Do not close or stop up the manifold openings without also covering the collector, as this would cause very high collector temperatures and consequent material damage.

The grilles for the manifold should be split, to eliminate heat cross-over.

Don't choose moveable-louver grilles. You could use perforated metal.

The best and cheapest pre-made grilles are white painted steel, available from Hart and Cooley through your local HVAC supplier. Order one #672-steel-white, 12 x 4 for the upper air passage, and one #672-steel-white, 12 x 6 for the lower passage. These are approximately 13-3/4" long, and 5-3/4" high for the 12 x 4, 7-3/4" high for the 12 x 6.

There are two mounting holes in the grilles (one at each side). Use urethane adhesive to glue a block of wood into the foam-board to accept a screw at each mounting hole location. Install the grilles with the bottom grille's louvers angled down, and the top grille's louvers angled up, to help prevent air from crossing over from outlet to inlet (short-circuiting).

The hot outlet air tends to segregate itself by rising away.

## INSTALLATION

### Plan the Installation

My preferred installation method is to cut a 14-3/8" square hole through the wall between studs (assuming a 14" square manifold). Or, if you choose, a sliding window installation is an option. Just pre-mount the manifold to the collector the day before with urethane adhesive. Give the adhesive a full 24 hours to cure. Prop the collector in place with the manifold coming across the window sill. If you have a storm sash, seal that one first. Shut the sash on the manifold and block off the gaps with 1" urethane foam-board - the same foam-board used to make the collector. Trim the foam-board edges with aluminum foil tape. Next do the same to the inside sash. Caulk only the joints at the bottom and sides of the foam-board. Use peel-and-stick foam strips on the underside of the sliding sashes so you can open them when needed. Install a security catch on the inside sash if desired.

### Preparation

In preparation for installation, make (4) brackets of 1/8" x 3/4" flat aluminum bar, 9" long, bent to give a 6" and a 3" leg. Use a 3/16" drill for #10 stainless pan head screws. Drill (3) holes in the 6" leg, (2) holes

in the 3" leg. Put (3) #10 x 3/4" stainless screws through the 6" leg into the collector, and (2) #10 x 1-1/2" stainless screws through the 3" leg into the building. Use one bracket near each corner of the collector.

### Begin the Installation

#### Wall installation:

Cut a 14-3/8" square hole through the wall between studs (assuming a 14" square manifold). Make a small hole in the center of where you think you'd like the hole to be. Probe with a coat hanger to find the studs.

#### Measure

the manifold and mark lines for a hole 3/8" bigger than the manifold dimensions. Cut the inside wall board with a utility knife. Stuff the insulation from the hole into the wall cavity. Square from the inside hole

over to the outside wall, and drill holes at the corners to the outside. From the outside mark the lines, check the dimensions, and make them plumb and square. Use a saw to cut the hole.

#### Sliding Window installation:

Pre-mount the manifold to the collector the day before with urethane adhesive. Give the adhesive a full 24 hours to cure. Prop the collector in place with the manifold coming across the window sill. If you have a storm sash, seal that one first. Shut the sash on the manifold and block off the gaps with 1" urethane foam-board - the same foam-board used to make the collector. Trim the foam-board edges with aluminum foil tape. Next do the same to the inside sash. Caulk only the joints at the bottom and sides of the foam-board. Use peel-and-stick foam strips on the underside of the sliding sashes so you can open them when needed. Install a security catch on the inside sash if desired.

#### Flash the Hole

Next, line the hole with a piece of aluminum flashing. This will be flush with the inside wall surface, with 3" wide ears bent to sit against the outside wall. To make this, cut a piece of flashing 60" long, and 3" wider than the wall thickness. Make a 90 degree, 3" wide bend down the length of the piece. Make cuts through the 3" leg, to allow you to wrap it around the outside of your 14" square manifold, making 90 degree bends at the four manifold corners. Set the manifold aside to attach to the collector later, from inside the house. Staple the pre-bent flashing into place in the hole, putting some staples inside the hole and at least four in each outside ear. Caulk under the ears (don't neglect the corners) with silicone adhesive.

#### Pre-Mount the upper Brackets

Mount the upper two mounting brackets to the collector (use (3) #10 x 3/4" stainless screws). Take care to locate the brackets so the collector will be spaced about 9/16" away from the wall (or from the clapboard bottom edges, if you have clapboards; and locate the brackets so they fall just

under a clapboard edge).

Before you place the collector against the wall, press sticky-back foam seal strips (3/16" thick x 1-1/2" wide, the type used to mount camper caps onto pickup trucks) to the back of the collector around the 11-1/2" square manifold hole. Space the foam strips 1-3/4" away from the hole edge. Build up three layers of the strips, so the seal is 9/16" thick.

Prop the collector in position

Now use short pieces of 2x6, on edge, as braces under the collector to raise it to the right height on the wall (so the foam seal rests on the flashing ears). Use a long 2x4 as a brace to keep the top brackets of the collector against the house. Use a level to get the collector plumb. Now take the manifold inside the house. To check whether the collector is aligned with the hole, insert the manifold into the hole and check that the center divider lines up with the "C" baffle in the collector case. Readjust everything until it's plumb and aligned. Outside, fasten the upper collector brackets first, then install the lower ones (keep the collector vertical, viewed from both ways. From the inside, with the manifold removed, use silicone adhesive to caulk around the perimeter of the hole against the foam seal. Completely fill the space between the collector and the flashing.

Install the Manifold

To install the manifold, lay a generous 1/2" bead of urethane adhesive around the manifold rear edges and across the center divider. Place it in the hole, and press it onto the collector. It should stay there by itself, or you can wedge it in position to cure overnight. You can immediately caulk the gap around the manifold at the inside wall with siliconized latex caulk. For a finished look, trim with quarter-round or picture frame molding.

Operation Caveat

As stated earlier, to fully stop the unit from thermosyphoning in summer without damaging the unit (due to high stagnation temperatures), you must cover it, not simply close or stop up the manifold openings. Do not close or stop up the manifold openings without covering the collector, as this will cause very high temperature and material damage.

The worst of the "new collector" smell is gone in a few hours (silicone curing smells like vinegar) and will disappear in a day or two.

To Make Larger Arrays

In scaling up, keep these points in mind:

1. The geometry shown in the accompanying illustration permits daytime thermosyphoning, and discourages nighttime thermosyphoning (the descending and rising legs of the flow circuit are both at outside temperature at night, and are of nearly equal height). If you change to a different flow layout, you may need an anti-backdraft damper.

A manifolded array would use collectors 4 feet wide by any height, and divided into left and right (rising and descending) halves by a vertical baffle, with the halves interconnected at top or bottom by a gap in the baffle, with the filter element mounted on "rails" in each half, on one long diagonal from inlet to outlet.

2. With more than 25 square feet (one good-size collector per room), room overheating becomes a concern in warm/hot weather. You will want large size, automatic or manual collector vents (without these you will need to cover the collectors in summer). In addition to collector vents (top and bottom), you may still have to cover the outlets manually in the hottest weather, and make sure the collector temperatures do not climb too high.

(This is why I invented the AutoVent control. This is what makes an SHVC (Solar Heating and Ventilation Cooling) system. It integrates two three-way valves (one at the inlet, one at the outlet), and four ports (an inlet/outlet pair at both the interior and the exterior) into a drop-in control module.)

3. A large array manifolded with a single fan should be segmented into areas (separate collectors) with a parallel-flow circuit. You might need to restrict the higher-flow collectors to get the array balanced.

You could use "in-at-the-bottom, out-at-the-bottom" collectors manifolded in parallel. These could be served by a split over-and-under manifold duct located at floor level on the inside wall, that might not be too intrusive. It might be three to four inches thick out from the wall, by two feet in height. The bottom 12 inches would be the intake manifold, with an intake grille located at one side of the room; the lower part would be divided from the top 12 inches, the outlet manifold, with a grille at the other side of the room. Or, there could be small outlet grilles located all along the top of the outlet duct and small intake grilles located all along the intake duct.

In this scheme, the entry and exit connections to the collector are all located low in the collector. This arrangement tends to thermosyphon at night, in either direction unpredictably; it will need a positive manual damper, or a timed electro-mechanical damper, that prevents nighttime flow in either direction.

An alternative scheme that needs no damper is to place the over-and-under manifold duct near the ceiling, serving "in-at-the-top, out-at-the-top" collectors manifolded in parallel. There would be an auxiliary inlet duct connecting to the inlet half of the split over-and-under manifold. It would descend to the floor at one side of the room. there would be an auxiliary outlet duct connecting to the outlet half of the manifold, descending to the floor at the other side of the room (i.e. one descending duct at the left side and one descending duct at the right side of the room, at the corners against the outside wall). The reason for the descending ducts inside the room is to receive the coolest inlet air and distribute heated air low in the room.

In this scheme, the entry and exit connections to the collector are located high in the collector. So, the descending and rising outside legs of the flow circuit are both at outside temperature at night, the inside descending

and rising legs are at inside temperature, and all are of nearly equal height, so you don't need any damper.

HAPPY BUILDING!

--

Sol-Air Company makes the SHVC solar system, the world's only modular solar comfort system. In a single wall-mounted module, it provides space-heating in cold weather, ventilation cooling in warm weather, and both cool-air conservation and system safety in hot weather - all done automatically. The SHVC system offers a realistic payback and a 20-year+ working life. Its year-round capability distinguishes it from the seasonal "air panel" or "hot air collector". Its patented control shifts automatically between four operating modes, hands-off, year-round. The system is packaged for easy installation.

As the room temperature rises in warm weather, Sol-Air's AutoVent(tm) adaptive air handling control initiates room ventilation. In hot weather, the system acts conservatively by sealing the house, power-venting the collector with outside air to prevent collector damage. It thus conserves cool inside air, and even allows conventional A/C to operate normally.

You don't cover the system manually to prevent overheating, or uncover it to resume heating. The system returns to the solar heating mode automatically as the weather changes. Our breakthrough Transorber(tm) solar absorber gives the system a maximum efficiency greater than 72% - the SHVC solar system provides energy, comfort and safety, automatically and efficiently, all year!

Below is a description of a very simple solar collector from the company that produces them. I also have a pdf. file showing the detailed breakdown of the unit if interested...

**- ADVANCED HOMEBUILT AIR-BASED SOLAR COLLECTOR - BUILDING INSTRUCTIONS**

**OVERVIEW**

The instructions below are for a homebuilt version of Sol-Air Company's air-based SHVC (Solar Heating and Ventilation Cooling) system (description at bottom). Our commercial version differs from the homebuilt in having an internal air-handler (the AutoVent automatic mode-switching control), and a proprietary absorber material that has somewhat higher surface area and selective properties.

**Homebuilt Solar Collector Output**

Like its commercial cousin, this homebuilt unit produces more energy for the money by far than other forms of solar utilization, including PV and solar DHW systems. The output for a 20 square foot unit is approximately 5,000,000 Btu per year, equal to approx. 50 gallons of heating oil (or 50 Therms of natural gas). This output is produced primarily in the spring and fall, with a decided dead spot in the middle of a cold winter.

**Mounting**

The collector is mounted vertically on the outside wall (the rule that tilt = latitude is for another type - DHW collectors, which need year-round input). The lower sun angle in winter reduces the performance penalty, and the avoidance of summertime sun is an important factor in increasing system life. Another advantage gained is ease of installation.

**House connection**

Air passes into and out of the collector through a manifold which connects it to the inside of the house. Instead of using the collector to replace a window, plan to install your homebuilt collector with the manifold passing through a hole in the wall, (you can install it beneath a window, or with the manifold passing across the window sill of a slider-type of window). That way, you will have two solar devices, the collector and the window.

**WINDOW COMPARISON**

Gain from a solar collector, as with a window, is directly proportional to

glazed area; it occurs for 5-6 hours on sunny days. Both a window and a solar collector "leak" some of the energy taken in, but there is a net gain during collecting hours on a good day. The difference between a solar collector and a window is that the window leaks energy 24 hours a day, while the solar collector leaks energy only during those 5-6 hours. People with "passive solar" homes must play an active role in reducing nighttime losses. During non-collecting hours, an active solar collector loses virtually no energy, without manual intervention. A solar collector is a large no-loss window with a virtual window plug that self-installs, whether you're home or not.

#### What's a Window Plug?

While windows have greater losses, these can be reduced if you manually insulate them at night, with "window plugs" that you make from 1" blue Styrofoam, edged with wood strips (3/4" x 1", ripped from a 1x4). Each night, or right when you come home from work, you plug your windows. As you put a window plug in, you feel immediately warmer - right now. You can put them behind a couch or door during the day. Plug north windows all winter if you like.

#### Build a Window Plug:

The monetary payback period for window plugs varies from instant (if you have spare time and materials) to six months. In winter, they have an immediate effect on room comfort.

To make one, tack together a rectangular frame of the 3/4" x 1" wood, to fit the inside of your window frame. Use one nail at each corner, through the end of one piece into the end grain of the next). Brace the frame with diagonal pieces of wood while it's in the window; remove it, lay it on top of the Styrofoam on the floor, and mark inside the wood with a pointy marker pen. Leave 1/16" clearance all the way around (1/8" overall). Use a very sharp, very thin knife to cut the foam.

Double 6" long fabric strips into loops to aid removal from the window. Slip the foam into the frame, with a loop in the joint at each side near the top. First use dots of hot glue, then sawdust-thickened wood glue.

Cover one or both sides with Contac shelf paper, muslin in glue, wallpaper, etc.

For all-winter window plugs, prevent condensation by installing 3M V-seal on the edges: Make the plugs 1/8" undersize (insert corrugated cardboard underneath and on one side of the frame as you build it in the window.

Sand and prime the wood edges with shellac before you apply the V-seal. Cut the V-seal strips to meet nicely at the corners.

Now is also the time to caulk drafts around the window trim.

## COLLECTOR FEATURES

### The Absorber

The most important characteristic for an air-cooled absorber is super-high surface area. For your home-built unit, the best solar absorber is 1" thick furnace filter media, painted flat black and located in a reflective cavity. Furnace filter media presents a surface area to the air flow that is about 50 times the filter's face area. This is a higher surface area, by an order of magnitude, than that of conventional metal absorbers, whether finned, rippled, dimpled, or screen type. The sun shines on the filter fibers which get very hot; the heat is transferred to the air passing through the filter, taking advantage of intimate contact and good turbulence.

The "inside out" outer-surface heat exchange of this type absorber means that fibers transfer their heat to the air coolant directly at or immediately adjacent to the directly sun-lit sites at which the heat is generated. Dividing the material into small fibers produces an extremely short internal path - through the fiber material - from a sunlit fiber site to an adjacent shaded site.

### Low Cost Absorber Material

A virtual doubling of the heat transfer surface area is presented via a conduction path length of one fiber diameter. Because the "doubled-area path length" is extremely short, non-metallic material may be used without any performance penalty - a significant material-cost savings. Material note: I have used both glass fiber and polyester fiber furnace filter media as a solar collector absorber for 18 years without observing significant material degradation. As a pro-active precaution, observe the "Operation Caveat" stated below.

### Low Cost Design

A liquid-cooled collector cannot take advantage of this type absorber construction, which is very light. The low weight of the absorber produces a cascade of weight and cost savings in the support structure of the collector.

### Absorber Efficiency

The absorber's high efficiency produces a low operating temperature. A collector built to these specifications was tested at Western Michigan University's Energy Learning Center - no longer operating, I understand - using the ASHRAE 93-77 procedure, yielding a greater than 72% maximum theoretical efficiency. This was the highest efficiency air collector they ever tested; it bettered all liquid collectors but one, which it virtually equaled. I know of no other non-concentrating air collector, Conserval's SolarWall included, with better full-system efficiency.

You will want furnace filter media that comes in roll form so you can customize the size and shape of the collector. See a Grainger industrial supply catalog, item 4WZ72 (roll, 36" W. x 90 ft.; 1" thick); other widths are available there. You could go to an HVAC contractor and ask them to cut you the lengths you need. Use hi-temp stove paint, and spray it at a  
45

degree angle (a "glancing" angle) from both sides, so little of the paint passes through.

#### The Reflective Cavity Enhances The Absorber

The foil-faced inside surface of the collector is left reflective (not painted black) so the black filter fibers do all the absorbing. Sunlight that passes unabsorbed from the front direction is reflected back to the absorber for another pass, doubling the effectiveness of the absorber.

--

#### MAKING THE SOLAR COLLECTOR

Build the collector case of 1" foil-faced isocyanurate (urethane) foam-board. A good final case size is 46" x 64" (the case-back is 43-1/2" x 61-1/2"). The depth of the collector case is 6". With the back material being 1" thick, this leaves 5" for air passages. The sides are 6" wide, and they overlap the edges of the back.

Use urethane construction adhesive for all joints. On heat-exposed joints

like the case-side/case-back joint, protect the joint with a fillet of silicone adhesive at the inside of the case. Apply the silicone adhesive after the urethane adhesive has set (24 hours). Use spots of hot glue to

hold temporary right-angled pieces of foam-board at three places on each side, to keep the sides straight and to hold them square to the back while

the urethane adhesive sets overnight.

Both urethane adhesive and silicone adhesive use water (humidity) to initiate curing; speed curing by spraying a tiny bit of plain water on the edges of the seams after you put the pieces together.

To provide a surface that will hold the mounting bracket screws, glue 1/4"

plywood pieces, 6" wide and full length (short sides can overlap long sides, or the reverse), on the sides only - no plywood is needed on the back.

You can also use luan underlayment plywood. It's slightly lighter, thinner and cheaper, but it's a less "green" material. Glue the pieces on the four sides of the case with a single 3"-wide wavy line of urethane adhesive.

There's no need to use 3/8" plywood - it just adds weight. Even though it would give you a chance to screw-fasten the plastic glazing, using screws doesn't produce an even line of pressure on the edge of the glazing, only a point pressure at each screw. You're going to cover the case with an aluminum sheathing, so use the even pressure of the corner bend of the aluminum sheathing to pull the glazing against the edge of the case more evenly.

Cut an 11-1/2" square hole, centered side-to-side, in the back wall of the case; the upper edge of the hole is 3" from the outside top surface.

#### Bend the Aluminum Sheathing

To make the box weather resistant, you need an aluminum outside skin, or sheathing. The dimensions are shown in the illustration. Make up the pieces before you install the glazing, so you can install them immediately after, thus holding the glazing in place.

You can do the case sheathing two ways. You could use pre-painted

#### aluminum

coil-stock (house trim material). But, the material is too thick to bend by hand, so you should have the bends made by a siding company on their trim brake. Plain aluminum flashing is satisfactory, just be sure to apply a car wax to the aluminum. Aluminum flashing can be bent by hand over the edge of a piece of plywood. Press and slide your hand along the length of the bend, "milking" it a few degrees at a time. Protect your working hand with a leather glove, and hold an old towel to press onto the work. Back up the aluminum with a backup block - a length of 1" x 3-1/2" pine ripped from a straight 2x4. Set the backup block on edge on top of the aluminum, right at the edge of the plywood, and apply a clamp at each end. Use the same backup block to make the 1/2" x 1" x 1-1/2" aluminum flashing angles to cap the edges of the inner "C" baffle. For the slight amount of over-bend specified, bend the aluminum as far as you can clamped, then unclamp it and work in some more bend by hand.

Also the flow of air through the case is guided by a "C"-shaped baffle, for which you will need two 4-foot-long pieces of aluminum cap-angle to cover the raw edges of the baffle. The dimensions are shown in the illustration.

Last, make ten aluminum flashing mounting-rail pieces, 1"x1" x 4 feet long, legs a 90 degree angle.

#### Install the "C"-shaped baffle

The center leg of the "C" baffle runs across the 11-1/2" square hole in the upper back wall of the case. The "C"-shaped baffle is glued with urethane adhesive to the inside of the case, oriented with its center horizontal, at the top, and with the two legs descending, parallel to each other. The upper passage of the manifold is above the center leg of the "C", and the lower passage is below. There is 6" vertical dimension of the hole below the center leg of the "C", and 4-1/2" above. The distance between the descending legs is 12".

Fillet all of the inside collector joints, including all around the "C" baffle, with silicone adhesive. Cap the baffle with the aluminum cap-angle you bent up earlier using a 3/8" bead of silicone inside the angle.

#### Install the Absorber Mounting-Rails

The filter absorber sits on mounting-rails aligned on a diagonal to the air flow. Air enters the collector between the absorber and the glazing. As it moves through the collector toward the outlet, the diagonal absorber placement forces air to pass through the absorber to the back side, away from the glazing. The diagonal progression starts with the absorber near to the back wall at the inlet, and moves near to the glazing at the outlet; the

progression continues all along the air flow path. This keeps the hottest air away from the glazing, reduces conductive heat loss, and increases efficiency.

Use the 1"x1" angles of aluminum flashing that you bent up earlier as mounting-rails. Install each mounting-rail so the leg touching the collector is oriented toward the back wall. Use dots of hot glue a foot apart to hold the mounting-rails in place temporarily; then run a continuous fillet of silicone adhesive along the joint between the angle and the collector wall.

#### Install the Mounting-Rails

Install horizontal mounting-rails at the top and bottom inside surfaces of the collector. Use two or your pre-bent angles pieces, overlapped by an inch, to make up the needed length. Stop the rails 3/8" short of the adjoining surfaces. The top mounting-rail has its absorber-mounting-surface spaced 1-1/2" from the glazing plane. The bottom mounting-rail has its absorber-mounting-surface spaced 2" from the back wall (3" from the glazing plane).

Install diagonal rails beginning at the inside of each "C" leg starting below the fan; at this end, the absorber-mounting-surface is spaced 1/2" from the back wall of the collector. The rails run in a straight line to overlap the rail at the bottom of the collector; that is, they run at a slight angle away from the back wall down each "C" leg, continuing past the bottoms of the "C" legs to overlap the bottom rail. Snip a small piece from the back leg of the angles so they can overlap the bottom rail.

Moving to the side bays, install diagonal mounting rails at the sides of each bay, so the rails make a continuous straight line from the bottom rail to the top rail. Again, snip a small piece from the back leg of the angles so they can overlap the bottom and top rails.

Where the four central rails of the collector cross open space, snip the back leg of each rail near the "C" baffle and fold the rail flat. This allows air to travel unimpeded between the center bay and the side bays.

#### Install the Absorbers

With the exception of the fan/intake shroud area, the entire face of the collector is covered with filter-media absorber sitting on mounting-rails. In preparation for installing the absorber, cut the pieces you will need to size, and paint them from both sides with hi-temp stove paint from a spray can, holding it at a 45 degree angle to the face of the. Work quickly, covering first the back, then the front; favor the front with the most paint. Use nearly the entire spray can, leaving enough to paint the fan shroud. At the very end, just before you put on the glazing, use the last of the paint to touch up where needed.

Working one foot at a time, glue the absorber to the mounting-rails in a continuous bead of silicone adhesive, again using occasional dots of hot glue as a temporary aid.

#### Install the Fan

Install your collector fan (Grainger, 4WT48 70 cfm, or 4WT47 105 cfm)

and a pre-set snap-disc cooling thermostat (Grainger 2E245, close at 110 degF, open at 90 degF) in a shroud of aluminum flashing or house trim.

Make a one-piece fan-and-solar-thermostat inlet shroud, or you can use a two-piece shroud. One piece, to mount the fan, is an 11-7/8" x 6" pan with 1" flanges on top and bottom (make from 11-7/8" x 8" material); it has a 4-3/4" hole at its center and a 3/8" hole at one side to pass the thermostat leads out from the collector. Mount the fan over the hole with 1/8" x 1/4" pop rivets and a fillet of silicone adhesive, and bond the assembly in place with silicone adhesive vertically in the intake, at the back wall of the collector. Make sure the fan's air-direction arrow points into the collector.

The other shroud piece is also mounted with silicone adhesive. It has a 1" horizontal leg, a 4" 45 degree surface to mount the thermostat facing the sun and to redirect the incoming air downward, and a descending 3" leg.

Mount the thermostat through a hole the size of a quarter, and fasten it with pop rivets. Bond the thermostat shroud in place so the vertical leg is spaced 1/2" away from the plane of the glazing. Pass the thermostat leads through the 3/8" hole in the fan mounting plate. Wire the fan and the thermostat in series - tie one lead from the fan to one lead from the thermostat with a #14 wiring nut, and finish with an 8" length of electrical tape. Seal the thermostat wire hole with silicone adhesive. The remaining unattached leads, one from the fan and one from the thermostat, will be wired to the power cord leads at final installation.

#### Touch-up

Use the rest of your spray paint to paint the inlet shroud (paint the nose of the thermostat) and touch up the absorber.

#### Install the Glazing

The glazing can be Plexiglas (acrylic), which does well in this application because of the vertical angle and the efficient (low) temperature at which this collector runs, or another material of your choice (Kalwall). Polycarbonate (TwinWall, etc.) is strong, but may yellow. Cut the glazing to size to match the inside line of the plywood. Install the glazing with 1/8" pop rivets (1/4" grip range), spaced every 8" along the baffles.

Install pop rivets through the glazing every 8" along the "C" baffle. Put four rivets across the center of the "C" baffle.

Lift the glazing edge slightly and put a 5/16" bead of silicone adhesive around the collector sides where the glazing will sit. Place the silicone adhesive bead near the inside edge of the surface, so that as you allow the glazing to rest on it, the adhesive squeeze-out just reaches the inside of the collector.

#### Install the Aluminum Sheathing

Press the aluminum sheathing in place using an aid made from two 2-foot-long

1. x 1-1/2's glued together to make a 90 degree angle. As you do, install
1. /8" pop rivets through the sheathing into the plywood, all around the sides

of the collector, located 1" from the front edge, and every 8".

Install the sheathing angle all around the rear of the collector with 1/8" pop rivets into the plywood spaced, located 1" from the rear edge, every 8".

Working on each side on turn, tip the collector up on the side on a flat work table, to help ensure the sheathing edge is straight and cannot slip toward the side. Install 1/8" pop rivets, through the bend line where the sheathing touches the glazing (drill these holes through both sheathing and glazing). Rivet around the collector face on the contact line using a 12" spacing.

#### Dress and Fill the Glazing Joint

Use a gentle leather-glove touch to adjust the gap where the edge of the aluminum sheathing "returns" away from the glazing. The gap should be at least 1/4". Completely fill the gap with silicone, and finish it the joint with a spoon. Allow the fillet to extend 1/4" out onto the face of the glazing. Don't try to clean up until the silicone cures.

This seal design is tough and won't be broken by shock or expansion from temperature change.

#### The Manifold

The collector connects to the house via a manifold box made using the same construction materials and gluing method you used for the case - a urethane foam-board box with an outer layer of plywood around the sides. It also has a sheathing of aluminum flashing, made from a 9" x 1-1/2" angle, 60" long (this allows an overlap). The 14" square, 9" long, two-way, over-and-under manifold connects to the house through the wall or across the window sill.

You can use plywood on just the top and bottom, or on all four sides of the manifold. The manifold is divided by a foam-board "center divider" into a lower intake and an upper exhaust passage (back to the house). The lower passage is 6" high, the top is 4-1/2" high.

On the upper surface inside the upper passage, 1" away from the front face, install an 11" length of 1" x 1" flashing angle. Use hot glue dots and silicone adhesive. Face the angle legs away from the front face. This will act as a stop and support the edge of the inlet/outlet filter. Do the same at the lower surface inside the lower passage. Cut an 11-1/2" square piece of furnace filter to use for an inlet/outlet filter. The filter will span the center divider of the manifold, and rest against the 1" x 1" stops.

Install a Grainger 2W050 three-wire power cord up through a 3/8" hole in the bottom front edge of the manifold; make an overhand knot for a strain relief. Put a ring terminal on the green ground wire. When you make

the final installation, fasten the ring terminal to the fan shroud with a 3/16" aluminum pop rivet. Note: You could install an additional room temperature thermostat (open on temperature rise) in the inlet to disable the fan on rising room temperature; this would partially limit warm weather output. But the unit will still thermosyphon slowly. To fully prevent the unit from heating in summer, without damaging it, you will have to cover it with a cloth or plywood cover. Do not close or stop up the manifold openings without also covering the collector, as this would cause very high collector temperatures and consequent material damage.

The grilles for the manifold should be split, to eliminate heat cross-over.

Don't choose moveable-louver grilles. You could use perforated metal.

The best and cheapest pre-made grilles are white painted steel, available from Hart and Cooley through your local HVAC supplier. Order one #672-steel-white, 12 x 4 for the upper air passage, and one #672-steel-white, 12 x 6 for the lower passage. These are approximately 13-3/4" long, and 5-3/4" high for the 12 x 4, 7-3/4" high for the 12 x 6.

There are two mounting holes in the grilles (one at each side). Use urethane adhesive to glue a block of wood into the foam-board to accept a screw at each mounting hole location. Install the grilles with the bottom grille's louvers angled down, and the top grille's louvers angled up, to help prevent air from crossing over from outlet to inlet (short-circuiting).

The hot outlet air tends to segregate itself by rising away.

## INSTALLATION

### Plan the Installation

My preferred installation method is to cut a 14-3/8" square hole through the wall between studs (assuming a 14" square manifold). Or, if you choose, a sliding window installation is an option. Just pre-mount the manifold to the collector the day before with urethane adhesive. Give the adhesive a full 24 hours to cure. Prop the collector in place with the manifold coming across the window sill. If you have a storm sash, seal that one first. Shut the sash on the manifold and block off the gaps with 1" urethane foam-board - the same foam-board used to make the collector. Trim the foam-board edges with aluminum foil tape. Next do the same to the inside sash. Caulk only the joints at the bottom and sides of the foam-board. Use peel-and-stick foam strips on the underside of the sliding sashes so you can open them when needed. Install a security catch on the inside sash if desired.

### Preparation

In preparation for installation, make (4) brackets of 1/8" x 3/4" flat aluminum bar, 9" long, bent to give a 6" and a 3" leg. Use a 3/16" drill for #10 stainless pan head screws. Drill (3) holes in the 6" leg, (2) holes

in the 3" leg. Put (3) #10 x 3/4" stainless screws through the 6" leg into the collector, and (2) #10 x 1-1/2" stainless screws through the 3" leg into the building. Use one bracket near each corner of the collector.

### Begin the Installation

#### Wall installation:

Cut a 14-3/8" square hole through the wall between studs (assuming a 14" square manifold). Make a small hole in the center of where you think you'd like the hole to be. Probe with a coat hanger to find the studs.

#### Measure

the manifold and mark lines for a hole 3/8" bigger than the manifold dimensions. Cut the inside wall board with a utility knife. Stuff the insulation from the hole into the wall cavity. Square from the inside hole

over to the outside wall, and drill holes at the corners to the outside. From the outside mark the lines, check the dimensions, and make them plumb and square. Use a saw to cut the hole.

#### Sliding Window installation:

Pre-mount the manifold to the collector the day before with urethane adhesive. Give the adhesive a full 24 hours to cure. Prop the collector in place with the manifold coming across the window sill. If you have a storm sash, seal that one first. Shut the sash on the manifold and block off the gaps with 1" urethane foam-board - the same foam-board used to make the collector. Trim the foam-board edges with aluminum foil tape. Next do the same to the inside sash. Caulk only the joints at the bottom and sides of the foam-board. Use peel-and-stick foam strips on the underside of the sliding sashes so you can open them when needed. Install a security catch on the inside sash if desired.

#### Flash the Hole

Next, line the hole with a piece of aluminum flashing. This will be flush with the inside wall surface, with 3" wide ears bent to sit against the outside wall. To make this, cut a piece of flashing 60" long, and 3" wider than the wall thickness. Make a 90 degree, 3" wide bend down the length of the piece. Make cuts through the 3" leg, to allow you to wrap it around the outside of your 14" square manifold, making 90 degree bends at the four manifold corners. Set the manifold aside to attach to the collector later, from inside the house. Staple the pre-bent flashing into place in the hole, putting some staples inside the hole and at least four in each outside ear. Caulk under the ears (don't neglect the corners) with silicone adhesive.

#### Pre-Mount the upper Brackets

Mount the upper two mounting brackets to the collector (use (3) #10 x 3/4" stainless screws). Take care to locate the brackets so the collector will be spaced about 9/16" away from the wall (or from the clapboard bottom edges, if you have clapboards; and locate the brackets so they fall just

under a clapboard edge).

Before you place the collector against the wall, press sticky-back foam seal strips (3/16" thick x 1-1/2" wide, the type used to mount camper caps onto pickup trucks) to the back of the collector around the 11-1/2" square manifold hole. Space the foam strips 1-3/4" away from the hole edge. Build up three layers of the strips, so the seal is 9/16" thick.

Prop the collector in position

Now use short pieces of 2x6, on edge, as braces under the collector to raise it to the right height on the wall (so the foam seal rests on the flashing ears). Use a long 2x4 as a brace to keep the top brackets of the collector against the house. Use a level to get the collector plumb. Now take the manifold inside the house. To check whether the collector is aligned with the hole, insert the manifold into the hole and check that the center divider lines up with the "C" baffle in the collector case. Readjust everything until it's plumb and aligned. Outside, fasten the upper collector brackets first, then install the lower ones (keep the collector vertical, viewed from both ways. From the inside, with the manifold removed, use silicone adhesive to caulk around the perimeter of the hole against the foam seal. Completely fill the space between the collector and the flashing.

Install the Manifold

To install the manifold, lay a generous 1/2" bead of urethane adhesive around the manifold rear edges and across the center divider. Place it in the hole, and press it onto the collector. It should stay there by itself, or you can wedge it in position to cure overnight. You can immediately caulk the gap around the manifold at the inside wall with siliconized latex caulk. For a finished look, trim with quarter-round or picture frame molding.

Operation Caveat

As stated earlier, to fully stop the unit from thermosyphoning in summer without damaging the unit (due to high stagnation temperatures), you must cover it, not simply close or stop up the manifold openings. Do not close or stop up the manifold openings without covering the collector, as this will cause very high temperature and material damage.

The worst of the "new collector" smell is gone in a few hours (silicone curing smells like vinegar) and will disappear in a day or two.

To Make Larger Arrays

In scaling up, keep these points in mind:

1. The geometry shown in the accompanying illustration permits daytime thermosyphoning, and discourages nighttime thermosyphoning (the descending and rising legs of the flow circuit are both at outside temperature at night, and are of nearly equal height). If you change to a different flow layout, you may need an anti-backdraft damper.

A manifolded array would use collectors 4 feet wide by any height, and divided into left and right (rising and descending) halves by a vertical baffle, with the halves interconnected at top or bottom by a gap in the baffle, with the filter element mounted on "rails" in each half, on one long diagonal from inlet to outlet.

2. With more than 25 square feet (one good-size collector per room), room overheating becomes a concern in warm/hot weather. You will want large size, automatic or manual collector vents (without these you will need to cover the collectors in summer). In addition to collector vents (top and bottom), you may still have to cover the outlets manually in the hottest weather, and make sure the collector temperatures do not climb too high.

(This is why I invented the AutoVent control. This is what makes an SHVC (Solar Heating and Ventilation Cooling) system. It integrates two three-way valves (one at the inlet, one at the outlet), and four ports (an inlet/outlet pair at both the interior and the exterior) into a drop-in control module.)

3. A large array manifolded with a single fan should be segmented into areas (separate collectors) with a parallel-flow circuit. You might need to restrict the higher-flow collectors to get the array balanced.

You could use "in-at-the-bottom, out-at-the-bottom" collectors manifolded in parallel. These could be served by a split over-and-under manifold duct located at floor level on the inside wall, that might not be too intrusive. It might be three to four inches thick out from the wall, by two feet in height. The bottom 12 inches would be the intake manifold, with an intake grille located at one side of the room; the lower part would be divided from the top 12 inches, the outlet manifold, with a grille at the other side of the room. Or, there could be small outlet grilles located all along the top of the outlet duct and small intake grilles located all along the intake duct.

In this scheme, the entry and exit connections to the collector are all located low in the collector. This arrangement tends to thermosyphon at night, in either direction unpredictably; it will need a positive manual damper, or a timed electro-mechanical damper, that prevents nighttime flow in either direction.

An alternative scheme that needs no damper is to place the over-and-under manifold duct near the ceiling, serving "in-at-the-top, out-at-the-top" collectors manifolded in parallel. There would be an auxiliary inlet duct connecting to the inlet half of the split over-and-under manifold. It would descend to the floor at one side of the room. there would be an auxiliary outlet duct connecting to the outlet half of the manifold, descending to the floor at the other side of the room (i.e. one descending duct at the left side and one descending duct at the right side of the room, at the corners against the outside wall). The reason for the descending ducts inside the room is to receive the coolest inlet air and distribute heated air low in the room.

In this scheme, the entry and exit connections to the collector are located high in the collector. So, the descending and rising outside legs of the flow circuit are both at outside temperature at night, the inside descending

and rising legs are at inside temperature, and all are of nearly equal height, so you don't need any damper.

HAPPY BUILDING!

--

Sol-Air Company makes the SHVC solar system, the world's only modular solar comfort system. In a single wall-mounted module, it provides space-heating in cold weather, ventilation cooling in warm weather, and both cool-air conservation and system safety in hot weather - all done automatically. The SHVC system offers a realistic payback and a 20-year+ working life. Its year-round capability distinguishes it from the seasonal "air panel" or "hot air collector". Its patented control shifts automatically between four operating modes, hands-off, year-round. The system is packaged for easy installation.

As the room temperature rises in warm weather, Sol-Air's AutoVent(tm) adaptive air handling control initiates room ventilation. In hot weather, the system acts conservatively by sealing the house, power-venting the collector with outside air to prevent collector damage. It thus conserves cool inside air, and even allows conventional A/C to operate normally.

You don't cover the system manually to prevent overheating, or uncover it to resume heating. The system returns to the solar heating mode automatically as the weather changes. Our breakthrough Transorber(tm) solar absorber gives the system a maximum efficiency greater than 72% - the SHVC solar system provides energy, comfort and safety, automatically and efficiently, all year!

The old board is seriously flawed with a crappy search setup and its going to simply burst from the load.

## ENGINEERS SOLVE PROBLEMS

### Activity 5 - Student Reading: Long May It Wave

As an engineer you must design a flagpole that will withstand the forces of nature. Figure 1 shows two of the important forces: the force of the wind acting on the flag ( $F_1$ ) and the force of the wind acting on the combination of the flag and flagpole ( $F_2$ ).

Figure 1

Given:

Elevation of site - 4000 ft

Ambient temperature - 45 degrees F

Air density in  $\text{lb}/\text{ft}^3$  at 45 degrees F - 0.0679 lb per  $\text{ft}^3$

Wind velocity - 60 miles per hour, or 5280 feet per minute, or 88 feet per second

Density of concrete - 130  $\text{lb}/\text{ft}^3$

#### EQUATIONS TO USE

Surface area for object: length times width ( $l \times w$ ) in same units

Moment: force in pounds times lever arms in feet

Volume: length times width times height in same units

#### DEFINITIONS

##### Center of mass.

Point at which a force acts upon a body. The flagpole is one body with a length and width. The flag is another body, and it, too, has length and width. The flag has width because of the wind playing on the fabric, causing it

to ripple. The width of the ripple is the width of the flag (as seen from above, not on the flat surface). The large area of the flag is parallel to the direction of the wind flow.

A wind force acts at the middle of the area of each body. The force that acts upon the flag ( $F_1$  in Figure 1) is different from the force that acts upon the flagpole ( $F_2$  in Figure 1). These forces are given in the problem. (Engineers have formulas for computing the size of these forces, but the formulas are too complicated for us to use here.)

### **Moment of force.**

A force applied to a body may produce rotation about some axis. You can easily see this if you push against an open door. Try pushing a door at the handle, at the center, and right at the hinge. The further out from the hinge you push, the less force you need to move the door. The effectiveness of a force in setting a body in rotation is known as the moment of force. It is measured by the product of the force times the length of the lever arm (here, the distance outward from the hinge.)

In order for a body to remain stationary, the moments must be equal and opposite.

### **Fulcrum.**

The support or point of support on which a lever turns in raising or moving something. On a door that's open and free to swing, the fulcrum is the hinge.

### **THE PROBLEM:**

Figure 1 shows the two forces acting upon their separate centers of area. The moment equals the forces that are acting upon the center of their areas times the distance from the base to the center of each area. There are two parts to the problem: The first is to determine the moment of force of the flag and flagpole together. The second is to make sure that the moment of force of the base is the same as that of the flag and flagpole, in order to balance the two forces.

### **STEP 1.**

Figure the moment, or force of rotation, of the flag and flagpole, which must also equal the moment of the base. Thus  $M_1$  must equal  $M_2$ , as shows in Figure 2.

Figure 2

Thus, the moment of force of the flag and flagpole,  $(28 \text{ feet} \times F_1) + (15 \text{ ft.} \times F_2)$ , 22,832 ft-lb, must also be the moment of force of the base.

### STEP 2.

We know that the moment of force of the base ( $M_2$ ) must be 22,832 ft-lb. We are given two measures of the base, the length and width, which give us the area of the base of the block. We need to find how deep the block must be in order to balance the moment of force of the flagpole. The moment of force of the base will be the total weight of the base times the distance from the fulcrum to the base's center.

Figure 3

Remember that the density of concrete is 130 lb per cubic foot. The weight of the base will be the volume of the base times the density of concrete in pounds per cubic foot.

$$M_1 = M_2$$

$$\text{vol}_1 = (\text{length})(\text{width})(\text{height})$$

$$= 4 \cdot 4 \cdot (x) = (16x) \text{ ft}^3$$

$$w_1 = (16x)(130) = (2080x) \text{ lb}$$

$$M_1 = (2080x) \left( \frac{4}{2} \right) = (4160x) \text{ ft-lb}$$

Moment of base = moment of flagpole

$$(4160x) \text{ ft-lb} = 22,832 \text{ ft-lb}$$

$$x = \underline{5.5 \text{ ft}}$$

Therefore, the base must be at least 5.5 feet deep in order to balance a flagpole as described.

(note: lb = pounds; ft = feet)

Since you asked...

These are 1/2 of the 2880 AH of telco type batteries I have in the shed. There are two 24v strings in the shed. The other 1/2 is identical and located to the left of the photographer. They're about 2 feet deep and stack about 3 ft high and 4 feet wide per string. 3000 lbs per.

These are also ones that are "not recommended" for RE use. I think the main reason people shy away from them is they don't like to be deep cycled. IMHO if you have enough amp hours available, you don't have to deep cycle them.

My guess is that an mppt charger is required to get close to rated output. Even then it doesn't really make it.

I have 630 watts (rated) of panels. Even with a good mppt charger, the most I've seen go into the battery is 18.x amps @28 volts, just over 500 watts (dead of winter at noon). This would make each 105 watt panel actually 83.3 watts. Better than the example you give, but still \$4.81/watt instead of \$3.81/watt.

oh well...

Hi Rob,

I picked up the batteries in Denver from a guy who was disposing of them for US West. Last I spoke with him it looked like he had made arrangements to have the rest (about 10 48v strings !) sold in mid november. If you are interested, contact me off list and I can make sure they're gone (or not). (See my web site for my email address)

Yes, it was Surplus Center of Lincoln, Neb. They might have sold them by now too.

I'm curious if the ones I (and Matt) have are the same type as you ask about. The ones we have are SLAs, but are specifically VRLA, or Valve Regulated Lead Acid. These are the type that Surplus Center was showing on their mail out flyer. They are huge in size, weight and capacity (1440 amp hours) and were made originally for telcos. They use a calcium paste on the plates rather than antimony that is used in most liquid lead acid type batts and should not be drawn down below 50% if you want them to last. They were designed to last 20 years and I'm hoping with care, they will.

I've been using my original set (12 2v cells strung for 24v) for the past couple years with 600 watts (rated) of solar panels and occasional wind from my homemade gennies. I use a c-40 for the wind and a Solar Boost 3048 for the PV. There is temperature compensation on both units as I don't have a constant temp where the battery is.

There are other SLAs that are completely sealed, including some car batteries. It would depend on the make and specific type as to how good they might be in RE applications.

The main thing about using SLAs, as DanF said, is to not abuse them. Never overcharge them as you would when equalizing a liquid lead acid battery, and try not to draw them down too low. Having said that, I've read a study done by East Penn (makers of the VRLA telco batts <http://www.eastpenn-deka.com/>) which shows no discernable degradation of performance after several hundred complete discharge cycles, but I don't know if I really trust tests done in idealized conditions.

([User Info](#)) <http://www.greeleynet.com/~cmorrison>

I'm curious if the ones I (and Matt) have are the same type as you ask about. The ones we have are SLAs, but are specifically VRLA, or Valve Regulated Lead Acid. These are the type that Surplus Center was showing on their mail out flyer. They are huge in size, weight and capacity (1440 amp hours) and were made originally for telcos. They use a calcium paste on the plates rather than antimony that is used in most liquid lead acid type batts and should not be drawn down below 50% if you want them to last. They were designed to last 20 years and I'm hoping with care, they will.

I've been using my original set (12 2v cells strung for 24v) for the past couple years with 600 watts (rated) of solar panels and occasional wind from my homemade gennies. I use a c-40 for the wind and a Solar Boost 3048 for the PV. There is temperature compensation on both units as I don't have a constant temp where the battery is.

There are other SLAs that are completely sealed, including some car batteries. It would depend on the make and specific type as to how good they might be in RE applications.

The main thing about using SLAs, as DanF said, is to not abuse them. Never overcharge them as you would when equalizing a liquid lead acid battery, and try not to draw them down too low. Having said that, I've read a study done by East Penn (makers of the VRLA telco batts <http://www.eastpenn-deka.com/>) which shows no discernable degradation of performance after several hundred complete discharge cycles, but I don't know if I really trust tests done in idealized conditions.

3060Ah would only be if you're drawing at 2 volts with all the cells in parallel. Otherwise, it remains 510Ah, but at the voltage of the string of cells.

Bruce is asking about testing the cells to see if they're any good. I'd suggest finding out who manufactured them and get the specs and charging/testing instructions from them if possible. Otherwise, find someone who makes a similar battery (like trojan) and go by their recommendations.

([User Info](#))

figure out the Ah rating for each cell.. let that determine for a load test  
for example a 2v 200Ah cell has a 4 hour discharge to 1.75v rating of 48A  
so putting a 48A load on that cell should drop ot's voltage to 1.75 after about 4 hours

also you can charge them and check specific gravity to get an indication

## [High wind postmortum](#)

By [Chuck](#), Section [Homebrewed Electricity](#)

Posted on Mon Sep 15th, 2003 at 10:52:45 AM MST

[Wind](#)

windmill rides out 70 mph winds, mostly...

This weekend we had a pretty strong front come through our part of Colorado. While I didn't have an anemometer set up, I would agree with the weather people (this time) who mentioned gusts of 70mph. For a while it seemed like it was pretty sustained winds of around 50 mph.

Since I had installed a number of untested "features" on the windmill, I decided to leave it running and test them in strong winds. Afterwards I lowered the tower and examined the results. This is what I found:

1. The Pipes furling system. I had been concerned that the furling system didn't seem to do much, but that was in rather low wind, below 30mph. In the strong wind it furling well. In fact it maxed out several times while I watched it, so it does indeed furl nicely when it should.
2. 3 blade, 7' diameter rotor. I had carved these up a few months ago using fir and gluing a 1" board and a 2" board together to get enough depth for the root section twist. I used the newer type polyurethane glue for the first time. I didn't see any stress lines showing on the painted surfaces and so it appears to have held together well at pretty high rpms.
3. The 24v 194rpm DC motor as generator. I've wondered what output I could really get out of this. With my current setup it appears the answer is at least 20 amps (27 volts, so 540 watts) when the wind is really going. So far the bearings are holding up.
4. The slip rings. Here is where it fell apart. Watching the ammeter during the storm I was seeing surges to 20 + amps and then down to 0. I know the rotor was moving fast, so I was confused until I examined the slip rings. I had a joint in each ring which was slightly uneven. At some point in the evening, one joint was lined up with a brush, which straddled the (small) gap and started sparking. The heat build up in the brush melted the plastic brush holder and very effectively glued the brush into position. The ring next to the joint was heavily carbonized and some of the copper ring was melted near the joint. I used two brushes per ring. One ring getting glued off the ring shouldn't have killed output, but it did. The other brush on that ring was a little stiff in it's holder, and could have been off the ring at times. It did have a lot of carbon build up on that side of the ring too, but I didn't see any other melted copper. The other brushes appeared to have no problems.

I believe the slip ring unit would have worked fine if...

a) a thin copper lining surrounded the brushes in the plastic holder. This would make them slide easier and keep hot plastic from adhering to the brush. Leads from a lining to the terminals might have helped keep the

resistance down and the heat lower.

b) a jointless ring had been used. I was unable to find a copper or brass pipe the right size or I would have done this in the first place. A smoothed over solder joint may have helped.

Next project ...

I have a set of two thin nylon blades (8' diameter) to try out. It should be fun to see how these work on the 24v-164rpm motor. I'm concerned about startup with only two blades and also the oft mentioned yaw jerkiness two blades are reported to have. Until I beef up the slip rings, I'll go with dangle wiring to test this one out.

Performance testing at the outer envelope is often very informative, if perhaps destructive. Thank you for sharing this valuable insight. I love polyurathane based wood glue, eg gorilla glue. I am still a bit cautious about slip rings, though if you come up with a bulletproof design, I could be a convert.

Best regards,

troy

Hi,

Great report!

Now for your brushes;  
I have an old AC generator that has brush holders made of bakelite that seem as though they would work for your application. I would look into motor rewind shops in your area and see if they have something similar you can adapt to your needs. Heck, I've been thinking of turning this into a PMA and if you want I'll send them to you. The generator won't every be used as it was again, so either send me email at [rogeras@cei.net](mailto:rogeras@cei.net) or respond to this.

RogerAS

Hi Roger,

Thanks for the offer. Bakelite would certainly stop the melting plastic issue. It would be nice to make the whole assembly out of it if it was easily available as a raw material.

I do have a motor shop nearby and I'll probably check them out for some metal holders. They might have some of the integrated roll spring kind which would be fun to play with. I prefer metal so the holder can help transfer current.

My main concern here is not so much to have something for my own use, but to come up with a bullet proof design that anyone can make easily if they want to go with slip rings.

I have a freind in town who makes his own "very rare auto electric parts"... from bakelite. I don't think it's too difficult, I think it can be done in a normal oven - but searching for info on Google I've found very little.. although I did find several places that supply the materials.

I'm curious about working with it - it could have some applications.

([User Info](#)) <http://www.fludan.com>

Hi I found this in one of my books (bakelite), please take a look below (hope it is legible)

#### 14.5b Preparation of plastics

**Bakelite.** Developed by L. H. Baekeland in the first decade of this century, Bakelite is one of the oldest of the commercial phenolic plastics. It is easy to make a black plastic similar to Bakelite. Simultaneously pour 100 cc of a saturated solution of aniline hydrochloride and 100 cc of 40 per cent formaldehyde solution (commercial formalin) into a 300-cc or larger beaker; stir with a glass rod. At first students will find that a thick dark brown mass forms. When this is allowed to harden, a black plastic similar to Bakelite is formed. While it is still viscous, it can be poured into a child's sand mold.

True Bakelite, a phenol-formaldehyde resin, is somewhat more complicated to prepare (Fig. 14-12). Combine 50 grams of pure phenol (carbolic acid—*caution*) with 80 grams of formalin in a Pyrex or metal beaker. Heat in a water bath until the phenol crystals melt and the liquid turns clear. Then add half a gram of solid sodium hydroxide and continue heating slowly. After a time students should find that the mixture thickens. If the rate of thickening is too slow, add an additional small quantity of sodium hydroxide.

14.5b / ORGANIC CHEMISTRY 291

Fig. 14-13 Phenol-formaldehyde resin made from liquid phenol, formalin and ammonium hydroxide heated in a flask fitted with a reflux condenser.

When the substance becomes viscous, quickly pour it into a mold.

In some classes you may want students to prepare this variation. Into a dry beaker place 10 g resorcinol, 2 cc sodium hydroxide (10 per cent), and 10 cc 37 per cent formaldehyde. Set the beaker in a water bath (Fig. 14-12) at 50° C and stir until the crystals dissolve. Raise the temperature of the bath to 70° C (no higher) and keep the solution in the bath. After 10 minutes remove the beaker and let it cool. Remove the plastic disk from the beaker.

*Note:* Many plastics can be colored by the addition of an aniline dye to the still-liquid plastic. Students may also produce a marbled effect by mixing dyed batches of plastics.

Hope this will help

Frank

revisions ([none / 0](#)) ([#7](#))  
by Chuck on Mon Sep 15th, 2003 at 12:52:39 PM MST  
([User Info](#)) <http://www.greeleynet.com/~cmorrison>

After a 70mph storm and a failure of the slip rings shown above, I have a few revisions for this design to deal with higher amperage. The failure was due to sparking near the ring joint, resulting in a melting of the ring and the plastic brush holder melting onto the brush, siezing it in place.

1. Use solid copper rings if possible. The use of copper sheet may be OK if you can solder the joint and sand it smooth with the curve of the ring. Size can be a problem getting appropriate copper pipe for the rings.
2. A metal sleeve between the plastic holder and the brush will keep changes to the plastic from affecting the brush's ability to move. Assuming things get too hot. A thin copper sheet might suffice for this.
3. Larger wires on the brushes should reduce the resistance and thus the heat buildup in the brushes. This unit was passing over 20 amps when it failed.

## [Making a slip ring connector](#)

By [Chuck](#), Section [Diaries](#)

Posted on Fri Jul 18th, 2003 at 11:22:02 AM MST

[Chuck's Diary](#)

**Building a slip ring and brush assembly for wind generators**

I've never liked the idea of letting a wire dangle directly from a wind generator, twisting as the wind shifts direction and requiring occasional untangling. A few weeks ago I purchased some old wincharger tower stubs at an auction (\$5 each). These both had ring assemblies on them and one had the original (sized) generator in place. They gave me an opportunity to seriously look into slip ring designs and how to get them to work in a homebrewed system.

The following is a quick look at how I used readily available plumbing parts to make a usable slip ring and brush assembly.

The parts:

Most of the parts are shown above. All were purchased at a local hardware store. What is missing above, and shown in a photo further down, is a sheet of copper and some electrical connectors. Missing from all photos is a small brush spring holder made from a cardboard tampon inserter.

The Brush Assembly:

The largest part is a 1 1/4" (ID) to 3" (ID) plastic pipe adapter. This has holes drilled into it and threaded to accept four smaller threaded pipe adapters (not sure of the size right now, but I think it may be 3/8"ID by 3/4"ID) which are screwed into it. These are offset by ~3/4", in pairs, to match the placement of the rings.

Each of these four adapters has a cap for each end. The inner cap is drilled out so as to fit the brush that will go through it. The larger, outside cap is drilled to size for a brass screw. Above you see the larger cap already assembled with brass screw, brass washer and rubber washer already in place.

The Brushes were the largest I could find at the hardware store. The smaller part of the 4 adapters is chiseled out (1/4" chisel) to fit the brush size and shape as shown below. This can be laborious, but using the brushes themselves to size the holes is a great help. The carbon on the brushes rubs off on the high spots of the slot showing

- [Chuck's Diary](#)

you where to trim down more.

The following shows how the pieces fit together to hold the brushes against the ring assembly. It is preferable to have some kind of holder for the springs, which will flop about in the larger cap area. I used 5/8" sections of a super sized tampx applicator. These applicators consist of two concentric cardboard tubes. Using both extended allows the rather long springs to be easily placed in the caps and they slide together as the cap is tightened. The larger tube also fits snugly in the rubber washer and guides the spring end of the brush into strong, direct contact with the brass washer and screw end for a good connection. Without the spring holders, the brushes don't have a secure and consistent push against the rings.

The alternator/generator leads attach to the screws on the brush assembly. The opposing brushes should be linked together so two brushes carry each side of the circuit. For a 3 phase assembly, you would need to add a ring and offset another set of brushes.

The ring assembly:

The ring assembly starts out with a plastic plumbing joint. I used a 2" ID piece and eventually glued a smaller joint inside it to reduce the inside diameter to closer fit my tower mast.

It's not necessary, but I turned slots into the outside of the joint piece so there would be a plastic ridge between the two rings. These slots and the smaller inside joint are visible in the top photo.

For the rings themselves I cut 3/4" strips of copper sheet which I wrapped around the joint piece and then glued to the joint. I used a hand saw to cut a slot in each side to accept the ends of the copper sheet. I left about an inch extra length on each side of the copper strip after pulling it tight through the slots. I then cut shorter copper strips and bent them in half fitting them over the existing extra lengths of ring inside the joint piece. These become the attachment points for the wire going down the tower. The upper attachment strips are longer and to the full length of the joint plus an inch or two. I filed down the inner ridge of the joint where this longer strip goes through. Inserting the smaller joint exerts a clamping force on these strips and some epoxy makes it permanent.

On the ends of these strips I attached some brass electrical connectors. This adds rigidity to the strips so they don't short out against the tower or an opposing ring. I angled these out for the same reason.

This whole excersize was to to get a good connection for my peculiar wind turbine setup. The top (smaller) end of the brush assembly attaches to my wind generator. The ring assembly attaches to the mast of my tower, a Rohn 25G. I think this basic concept can be used all sorts of places for an inexpensive rotating power takeoff with just enough modification to fit the existing application.

Re: Making a slip ring connector ([none / 0](#)) (#1)  
by DanB on Fri Jul 18th, 2003 at 12:09:29 PM MST  
([User Info](#))

Thats nice Chuck! Probably not an issue, but my concern would just be... the possibility of high current overheating it. Probably not an issue, especially at higher voltages, but it would be interesting to bench test the assembly with the highest possible current you'd expect from the turbine for a while and see if things heat up at all. I get surprised sometimes how even big chunks of carbon get pretty hot under fairly low current.

Someone on this board suggested using the brushes from Automobile starter motors... they seem like some kind of copper/graphite substance (or something) -but they take higher current.

I like my "dangling wire" :-) but it might be a problem if I had to leave it for an extended period of time.

Thanks for the cool pictures and good ideas! Be fun to see how it works... bet it works fine.

Re: Making a slip ring connector ([none / 0](#)) (#2)  
by Chuck on Fri Jul 18th, 2003 at 01:35:26 PM MST  
([User Info](#)) <http://www.greeleynet.com/~cmorrison>

Dan,

Thanks for the comments.

Yes, high current is an issue I'm very concerned with, especially with plastic brush holders (I've seen plastic brush holders melted in motors). That's one reason I went with 2 brushes for each side of the circuit. It would be easy enough to make it 3 or 4 per side if need be, or just find higher capacity brushes like you suggest.

I have a 24 volt system and don't expect this generator to put out much over 20 or 30 amps, about 10 - 15 amps per brush. Still might be too much, I don't know, but I should find out soon.

Chuck

How much resistance? ([none / 0](#)) (#3)  
by TomW on Fri Jul 18th, 2003 at 02:08:33 PM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Nice writeup, Chuck.

One question comes to mind first. How much resistance across the commutator / brush assembly?

I ask because the loss through that setup might be considerable if the resistance is much at all.

Those  $I^2 R$  losses are hard to beat.

Just with round numbers if its .1 ohm per brush pair you will see 90 watts lost in each pair of brushes at 30 amps output.  $[.1 * [30 * 30]]$  or  $.1 * 900$ .

Just curious.

Cheers.

TomW

Of course it is easier to suggest improvements to someone's inspiration than to come up with something yourself... First, Good job and fine looking craftsmanship.

I think one could use a short section of "hard copper pipe" or even just one of the little solder connectors for the slip rings. I believe there would be less to fail.

Ron

Re: Making a slip ring connector ([none / 0](#)) (#5)  
by Chuck on Mon Jul 21st, 2003 at 10:51:52 AM MST  
([User Info](#)) <http://www.greeleynet.com/~cmorrison>

Thanks Tom and Ron for the comments,

Tom, I'll have to try to measure the resistance on the whole assembly and see what it is.

Interesting thing about that formula, it doesn't hurt you as much at higher voltages.

For 12v:

10. amps - loose 10 watts out of 120 or 12%.
20. amps - loose 40 watts out of 240 or 16%.
30. amps - loose 90 watts out of 360 or 25%.

For 24v:

10. amps - loose 10 watts out of 240 or 4%.
20. amps - loose 40 watts out of 480 or 8%.
30. amps - loose 90 watts out of 720 or 12.5%.

For 48v:

10. amps - loose 10 watts out of 480 or 2%.
20. amps - loose 40 watts out of 960 or 4%.
30. amps - loose 90 watts out of 1440 or 6%

It makes one seriously consider higher voltage systems.

Ron, Yes, the copper pipe is a better solution in some ways. I originally did build a

prototype that used copper pipe, but I found that I couldn't get it in the size I needed for this setup from local sources. Even 2" was difficult to come by and I needed an odd size above that.

Winchargers relied on rings that weren't appreciably thicker than the copper sheeting I used, and that was for a 6 volt system. The only real difference is the joint, which I don't like. But sometimes you compromise to get something done.

Chuck

Hi Guys

I've been flying gennys now for about 5 years without slip rings. Just send the wire down the mast. I've never had a twist problem.

If its good enough for Hugh its good enough for me.  
Anyway I don't want to loose any power I've tryed so hard to get.

I'll be putting up a genny this winter with most of its wire exposed. This will have about 30 feet of wire visable. This will be a good chance to see what hapens to wire without slip rings. May take some befor and after pics. It will be a good study.

JK TAS Jerry

revisions ([none / 0](#)) (#7)  
by Chuck on Mon Sep 15th, 2003 at 12:52:39 PM MST  
([User Info](#)) <http://www.greeleynet.com/~cmorrison>

After a 70mph storm and a failure of the slip rings shown above, I have a few revisions for this design to deal with higher amperage. The failure was due to sparking near the ring joint, resulting in a melting of the ring and the plastic brush holder melting onto the brush, siezing it in place.

1. Use solid copper rings if possible. The use of copper sheet may be OK if you can solder the joint and sand it smooth with the curve of the ring. Size can be a problem getting appropriate copper pipe for the rings.
2. A metal sleeve between the plastic holder and the brush will keep changes to the plastic from affecting the brush's ability to move. Assuming things get too hot. A thin copper sheet might suffice for this.
3. Larger wires on the brushes should reduce the resistance and thus the heat buildup in the brushes. This unit was passing over 20 amps when it failed.

Chuck

Welcome to the board. You have the right books to start things off with.

As far as wiring from the generator down the tower goes... Most folks here seem to go the route of letting the wires dangle and if they need to, they occasionally unhook them and untangle them.

A few others of us try various slip ring implimentations to avoid the possible problems you mention. See my diary on slip rings here:  
<http://www.fieldlines.com/story/2003/7/18/11222/7109>

This slip ring config has been working ok for the last several months, although it doesn't have to pass more than 20 amps. I intend to beef up the brushes when the next one goes up to handle 50 amps or so.

Nothing is a panacea though. There are issues with slip rings as well, losses due to resistance, weathering issues and others related to the increased complexity of the system. It takes more time to create and add this to your system.

Chuck

## Wind Tower Wiring

By [N2Everythg](#), Section [Homebrewed Electricity](#)  
 Posted on Tue Sep 9th, 2003 at 12:59:38 PM MST

[Wind](#)

huh?

Newbie here. I've been lurking so far. Thanks for your patience.

Did a search of the board as well as a quick skim of my newly arrived copies of Axial Flux Plans and Windpower workshop and couldn't find a quick answer. I've been wondering.....

How do you keep the wiring coming from the generator and leading down the tower from twisting into a knot as the wind generator pivots into the wind (again, and again and again) ?

It seems as though as the wiring would possibly twist in circles until it either torqued the connectors or snapped. Am I way off base here or is there some wiring method that I havn't found yet.

I'm in a location that the wind frequently shifts E->W then W->E on a regular basis. Sometimes several times a day. If it is in the books could someone point the way or is there an easy answer?

Thanks for your replys and I appreciate all the info that I have gleaned from the board so far.

N2

([User Info](#))

If your going to just let the wires wind up... try using a steel cable.. shorter than your wire from the mill.... it will hit tension first... before your wire dose.... stoping the mill from spinning that way any more... then it should just naturally un-wind its self....

Re: Wind Tower Wiring ([none / 0](#)) (#3)  
by iFred ([retrodude123@yahoo.com](mailto:retrodude123@yahoo.com)) on Tue Sep 9th, 2003 at 11:43:27 PM MST  
([User Info](#)) <http://www.internetfred.com>

I use a simple metal slot in the poles, They only allow the jenny to turn a total of 360 deg, before having to turn the other way. A simple cable can also do this. Basically a stop. It turns till it hits the stop then has no choice but to turn the other way.

Re: Wind Tower Wiring ([none / 0](#)) (#4)  
by scoraigwind ([magnet@scoraigwind.co.uk](mailto:magnet@scoraigwind.co.uk)) on Wed Sep 10th, 2003 at 12:51:37 AM MST  
([User Info](#)) <http://www.scoraigwind.co.uk>

On most sites, the simplest and most reliable solution is to drop the wires down the middle of the tower pipe, through the bearing. Use thick, single wires, with tough insulation and make them long enough to accommodate a bit of winding up. Watch out for places where they can rub/wear on the sides of the pipe.

On some sites this will twist up quite fast. You can fit a plug and socket to unwind it or you can make sliprings. (Do a good job or dont bother).

I do not recommend you restrain the machine from yawing if it has a side-facing furling system (furling tail). The restraint will interact with the furling system to give you very low output or overspeed depending on the direction of the cumulative twisting action.

Hugh Piggott <http://www.scoraigwind.co.uk>

Re: Wind Tower Wiring ([none / 0](#)) (#5)  
by Reno on Thu Sep 11th, 2003 at 08:10:57 PM MST  
([User Info](#))

What I did was use the industrial type wire not sure what its called but it has plastic outer wound steel then rubber inners then the wires. Using two wires can get it with any amount of conductors you want. The portion coming through the support pole (top of tower) I cut away the plastic outer and the wound steel. At the genny I clamped the wire down so it hangs straight no bend. When you turn the genny one full turn and let it go it spins back because the wire winds like a spring. This is in fact a function of the rubber not the conductor inside the rubber.

## [battery connections](#)

By [Chuck](#), Section [Diaries](#)

Posted on Mon Aug 11th, 2003 at 10:52:55 AM MST

[Chuck's Diary](#)

Battery connections for unigy 2 batteries

The photo below shows the battery connection pattern for the Deka Unigy II batteries. They mount in steel racks, 3 cells across and stack upwards depending on voltage required. Shown is a 3000 lb. 24 volt, 1440 AH (over 8 hrs) system with four racks installed. Each white faced (and one black face) box is a 2.2v cell with six terminals. It's difficult to tell from the photo which sets of terminals are positive and which are negative, but the large chrome plate on the right is positive, the other is negative. Since they are connected in series, It should be fairly easy to follow the sequence of pos. & neg. on the cells.

These are lead-cadmium based absorbed mat, Valve Regulated Lead Acid (VRLA) batteries and not technically deep cycle. To keep the 20 year life expectancy, they should be floated at 2.25 volts per cell at a temperature of 77 deg. F. Variations of temperature should be compensated for and most good charge controllers are available with this feature. They should NEVER be equalized. It's also not a good idea (for longevity) to draw below 80% of full.

In the normal course of purchasing new RE equipment, Batteries of this type would not be a cost effective use of tight funds. However, there are enough telecom companies closing down operations that these sometimes become available in like new condition and relatively cheap prices.

## [pipes part 2](#)

By [Chuck](#), Section [Diaries](#)

Posted on Mon Aug 4th, 2003 at 11:54:00 AM MST

[Chuck's Diary](#)

Definately not sexy

---

In my previous diary on the pipe furling system, I didn't show the generator mounting. This caused some confusion which I wanted to fix here. The photos below might help. They show two different attachment methods, but It is certainly possible to postulate others, especially for use with axial brake disk style alternators.

- [Chuck's Diary](#)

Above is a view of my original generator attachment scheme viewed from the front, windward side. Note the 1/4" bolts securing the pipes on the left side.

Here the generator is attached off to the right side of the mast facing the viewer. Possible adjustments are the length of the nipple between the "T" joint and the floor flange, the angle of the generator relative to the tower (Blades parallel to the tower or tilted up a bit), and the thickness of the support block, in this case a 2x6. Due to the fact that my generator is 8" in diameter, this scheme means the generator shaft is a full 8" + from the center of the mast, which gives the wind on the rotor more leverage for furling than I want. It also puts the full weight of the generator (almost 100 lbs including the hub and rotor weight) too far from the mast for my taste.

Above is the other version. In this the elbow positions the support platform above the "T" joint and off to the right roughly 4 inches from the mast center. This is closer to where I want the center of the rotor. If at some later point I want to experiment with different positions, I can easily drill out a new 2x6 and move the generator in or out from the mast (left or right in the picture).

This placement of the generator mount leads to several possibilities in useage and support options. It could be rotated forward to support an axial alternator design instead of the motor mount style. It is an easy modification to use 1/8" thick steel strapping as additional support from the support platform to the locking bolts on the "T" joint. This would further reduce the possibility of the pipes shifting position. Since the generator mount platform (the 2x6) is an inch or so above the "T" joint, a shim could be placed

between the two pieces to relieve the strain on the elbow joint.

For the truly paranoid, the joints can be super-glued and the pipes could be filled with epoxy or fibreglass resin after the locking bolts are installed.

This shows a simple motor mount. A floor flange bolted to a 2x6 bolted to a motor mount. The motor/generator, omitted from these photos so the support details can be seen clearly, bolts to the opposite side of the 2x6 as the flange. The flange bolts are recessed so as to allow the motor to mount flush to the 2x6. The outline of the motor mount can be seen on the following photo.

This mounting apparatus is not sleek and sexy, but it is adjustable and with proper locking precautions should give a wind generator the support it needs to stay up and running with the wind for many years. Of course, who wants that when you can take it down and readjust it so easily ?

Chuck

That's very nice, chuck.

One thing you need to watch is the tendency of pipe to shear off at the threads. Use good thick pipe throughout if the loads are high, especially if there is any vibration.  
Hugh Piggott <http://www.scoraigwind.co.uk>

Thanks Hugh,

I couldn't agree more.

I haven't tested this enough to have any idea of how much stress it can take or for how long, but I'm sure the winds of eastern Colorado are going to be up to the challenge of testing it for me.

I see two options for strengthening these potential weak spots and I'm sure there are others as well.

1. Bolting on steel support straps to resist twisting at the joints. There are already bolts there, so adding the straps should be little extra work. At the very least these straps could keep the generator from falling off the tower if shearing did occur. I like this idea from a safety standpoint.
2. A fibreglass fill in the pipes and joints themselves to further strengthen the whole unit and increase shear strength. I don't know if imbedding steel rods in the fibreglass would help much, but it could be done easily as well.

Either or both of these steps can be done after the angles have been adjusted to one's liking. Not elegant perhaps, and it increases the complexity somewhat, but hopefully it would get the job done.

Hi Hannu,

The Generator I'll be testing this with at first is the same one I rebuilt and showed on my web site. It weighs a good 40 or 50 lbs by itself. It is shown with a prototype support system (lots of wood pieces) in the photo below.

That's very nice, chuck.

One thing you need to watch is the tendency of pipe to shear off at the threads. Use good thick pipe throughout if the loads are high, especially if there is any vibration.  
 Hugh Piggott <http://www.scoraigwind.co.uk>

Thanks Hugh,

I couldn't agree more.

I haven't tested this enough to have any idea of how much stress it can take or for how long, but I'm sure the winds of eastern Colorado are going to be up to the challenge of testing it for me.

I see two options for strengthening these potential weak spots and I'm sure there are others as well.

1. Bolting on steel support straps to resist twisting at the joints. There are already bolts there, so adding the straps should be little extra work. At the very least these straps could keep the generator from falling off the tower if shearing did occur. I like this idea from a safety standpoint.
2. A fibreglass fill in the pipes and joints themselves to further strengthen the whole unit and increase shear strength. I don't know if imbedding steel rods in the fibreglass would help much, but it could be done easily as well.

Either or both of these steps can be done after the angles have been adjusted to one's liking. Not elegant perhaps, and it increases the complexity somewhat, but hopefully it would get the job done.

Chuck

[Chuck's Diary](#)

Non-welded furling assembly

One drawback to some of the best plans available for wind generators is a requirement for welding. I agree that this is a great way to build a sturdy platform, but many of us don't have the required tools or skills to pull it off. I've puzzled over the problem for a while now and this weekend I put some form to some of my ideas.

The idea is to create a side furling mechanism using readily available parts without having to resort to welding. Furthermore, I wanted something adjustable since I wanted to experiment with getting the right angles. The readily available parts are 1 1/4" black water pipe 45 degree and 90 degree elbows, two "T" joints, some reducers (1 1/4" to 1/2"), a 3/8"x6" black pipe with caps and a few 1/4" bolts. The tail boom is 4 feet of 3/4" square tube and there is some 1/8"x3/4" flat galvanized bar stock.

The first view shows how it looks from above. This shows the positions of the 45 and 90 degree elbows. Note that none of these photos show the 1/4" bolts inserted through the joints required to keep them from unscrewing from the weight of the tail.

The next view is from the side where the generator attaches to the hole on the left of the photo. I use a floor flange for this... I'll try later to get some photos of the whole assembly. My camera was low on batteries this weekend.

- [Chuck's Diary](#)

Here is a close up of the bearing assembly. It's a 1 1/4" T pipe with reducers at each end to reduce the opening for a 1/2" pipe. This fits a 3/8" pipe quite nicely. A few 5/8" washers give it a larger bearing surface and reduces slop. Holes drilled through the caps allow 1/4" bolt connections to bar stock which holds the tail boom. The bar stock is twisted to give the tail it's vertical orientation. The hole drilled in the main "T" is intended for a thin nylon rope which can be used to pull the tail in a locked furlled position. The smooth bearing surface isn't in place in the photo.

And finally the whole thing showing the tail. The bolts locking the joints into position are not shown on any of these photos. I did that after the camera batteries gave out. It's easy to envision though. Each joint has a 1/4" hole drilled completely through the large collar and a 1/4" bolt is inserted through it with a lock washer and bolt. Super glue or loctite finishes the locking of the joints. I didn't get a chance to raise the unit yet as the new blades haven't been balanced yet and I wanted to beef up my tower raising gear first. More to follow...

Chuck, It looks like a pretty ingenious idea. I'm not sure how you plan to mount the generator/alternator but the way it sounds you plan to mount it center of the mast mount ( the hole on the left). This will make the gen/alt centered and the furling tail will have no effect. The gen/alt has to be mounted offset from the center of the pole pivot. You may have already figured this out but its just an observation of how it was explained. Minor detail in any case.... good work... let us know how it works out

Have Fun  
Ed

Re: pipe based furling mechanism ([none / 0](#)) (#3)  
by Chuck on Tue Jul 29th, 2003 at 09:09:59 AM MST  
([User Info](#)) <http://www.greeleynet.com/~cmorrison>

Hi Ed,

I guess the pictures and/or text are misleading. The "T" over the mast is oriented horizontally. The generator is mounted on a floor flange that is on the opposite side of the "T" from the tail assembly (flange mounted vertically). Generator on one side, tail on the other, mast inbetween them.

The closest to mast center I seem to be able to get it this way is with the prop centered at 8 inches to the left of the mast (looking from behind), while the tail is on the right. I have had this machine up before with a different tail arrangement and it worked fine. Too good actually as it furlled earlier than I wanted it to. This is probably due to the 8" off center distance. Since I can't really change that (it's a big generator) I'll have to deal with tail weight, length, angle etc. to get it to furl efficiently.

If the "T" was mounted vertically it would be as you mention with the generator on top and you could stick a tail out the rear. But of course it wouldn't be a furling setup. Envisioning this brings up some intriguing possibilities though...A dual tail arrangement could be very easy to set up this way... Much simpler, although most folks don't like the looks of a dual tail... You could also use a platform on top that allows the generator to be adjusted various distances from mast center...

Thanks Ed, a totally different angle I hadn't considered.

Chuck

Tilt up triangular tower conversion ?

Anyone out there converted a triangular (Rohn) or other guyed tower for tilt up with gin pole etc ? I'm looking at 60-90' and it's either that or climb it, I'm not so sure about that. Thanks, Dave B.

[Tilt up triangular tower conversion ?](#) | 6 comments (6 topical, 0 editorial)

My thoughts ([none / 0](#)) ([#1](#))

by [wdyasq](#) on Sat Nov 8th, 2003 at 06:26:08 AM MST  
([User Info](#))

src="http://www.otherpower.com/images/scimages/284/twr\_hinge.jpg"  
width=80%>

One could use almost any style tower. I would use a worm gear type winch to raise and lower to keep everything undercontrol.

Here's what I want to do. Thinking of 30' on the lower tower and 60 - 70 feet overall height without guys.

([User Info](#)) <http://www.madbbs.com/users/bruggelog>

Thinking of the simple gin pole idea and hinged base. I think Rohn may have some of this hardware available already so I'm searching it out. I agree with the worm drive for a winch, it's some serious leverage at that height and weight. Anyone with any more ideas or experience with tilt towers and or conversions I welcome your comments. Thank you, Dave B.

heres som pics of mine rebar for the concrete needs to be welded on the bottom yet. have to wait till spring before i can pour so its just bolted down to the patio out back as a test tower for now its pivoted on two legs with the third at 90 degrees to them. a long piece of one inch pipe slipped into this third leg will function as a gin pole as it is winched up. after it drops out it can be removed. as the tower comes over center and settles in a short piece of pipe will lock the third leg down. then tighten guys up. the hinge should control the side to side motion. three guys planned. it will be fairley short at only 40 feet. cant wait till spring.

by Dave B on Sun Nov 9th, 2003 at 11:17:37 AM MST  
([User Info](#)) <http://www.madbbs.com/users/bruggelog>

Beautiful. That's exactly what I had in mind, maybe on a bit of a larger scale but that's it. I'm looking for a commercially available base to fit my tower or have someone with plenty of welding experience fabricate one for me. What make is your tower and what will be on top in the Spring ? Thank you for your photos, I had been sketching things out but now I can show someone the idea. Fun stuff. Dave B

Maybe in the US but not here. It has one element with points to connect 2 hot wires. I have a clothes driver from the US and it has 2 connections for each phase and a ground and a separate neutral but the hot water heater I bought here in Brazil only has the 2 hot wires and nothing for ground or neutral.

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

I broke alot of my plastic blades in the begining.

Then I started using thin aluminum sheet metal as a support. Thin aluminum on both sides. Not so many broke. I then moved the screws further away from the edge and used 1 inch fender washers along with the aluminum.

That was it. i've tested this combo to 68 mph with no breakage. At 40 mph have seen 80 amps from a 49 inch 4 blade set.

So keep researching the power is there even on the low end also, a few amps at 5 mph. So they do start early to.

I was thinking aluminum pipe for the 4 or 5 inch material? Maybe the sheet aluminum for the big stuff?

And at least Toms remidy at a minimum. JK TAS  
Jerry

gotta love em, but!!!

---

they really need to be reinforced for higher winds the nice wind storm that went through the usa this week stole the blade portion of my 4 ft prop so far I have only found 2 pieces one about 50 ft the other about 100 ft havent located the other 2 yet still searching lol

[pvc blades](#) | 10 comments (10 topical, 0 editorial)

Re: pvc blades ([none / 0](#)) (#1)  
 by woofhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Fri Nov 14th, 2003 at 02:48:02 PM MST  
[\(User Info\)](#) <http://timmythy.home.mindspring.com/timmy.htm>

When I put the plans upfor PVC Props, everyone had questions about how strong they are. I thought the plades would be plenty strong but I forgot that all of those forces are coming down to a single point, the bolt.

Reno had suggested to cut two identical blades then glue and screw them together. I thought it was a good idea for getting thickness for forming an airfoil with. But for stiffening the whole blade, I don't think it's nessesary. But something should be added to the bolt area.

I was thinking about cutting two smaller versions like in the drawing above, then gluing and screwing that all together. This would triple the thickness in the areas that are getting the most stress.

BrianK , exactly how did the blades break ???

BrianK;

I think a light aluminum strap "spar" behind that thing would have spread that stress out and perhaps kept it from fracturing.

This pinwheel is made from aluminum sheet that is thinner than an aluminum pop can so i used spars on that to help stiffen it and stop them from bending back from the wind. This pic was taken before i pop riveted the spar to the pinwheel but you can see the concept.

I did something very similar on the jerryblades on tape drive motors:

Both have worked well and the strap was cheap and a couple of pop rivets to secure the blade to the spar about half way out on the blade.

Cheers,

TomW

BrianK;

Yeah I think it couldn't hurt much beyond a touch of drag.

As someone else mentioned anytime you have a couple of lines come together like that you should drill a hole at the intersection and make your cuts into the hole. The hole redirects the stress around it rather than into the solid piece.

Actually, the spar should be rounded too as well as not have any sharp edges.

Cheers,

TomW

([User Info](#))

Brian K, I can't see from the "parts" pic but could I suggest making sure there are no sharp angles. By that I mean where the centreline meets the circle/hub on Woof's drawing relieve that point by drilling a hole and cutting too that hole.

In the pic of Tom's pinwheel he appears to have a small hole at the hub where the fold begins.

PVC is more prone to breaking when its cold, so that may be a factor.

regards Allan

Have any of you guys considered using large diameter metal conduit to reinforce this type of blade?

Seems like it would hold up, though it would be much heavier. And it would be harder to fabricate - though not impossible. It's shape already matches the pvc stuff you're using. I'd think that using it for the highest stress areas would be a good match.

But what do I know?

Bach On

- I'm just as happy as if I had good sense! -

Re: pvc blades ([none / 0](#)) (#10)  
by woofhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Sat Nov 15th, 2003 at 04:17:04 PM MST  
([User Info](#)) <http://timmythy.home.mindspring.com/timmy.htm>

If I used metal conduit for the blades. Then I would'nt need the PVC Pipe anymore.

BrianK;

Yeah I think it couldn't hurt much beyond a touch of drag.

As someone else mentioned anytime you have a couple of lines come together like that you should drill a hole at the intersection and make your cuts into the hole. The hole redirects the stress around it rather than into the solid piece.

Actually, the spar should be rounded too as well as not have any sharp edges.

Cheers,

TomW

([User Info](#)) <http://oneota.net/~earthsourcepowr/>

BrianK;

I think a light aluminum strap "spar" behind that thing would have spread that stress out and perhaps kept it from fracturing.

This pinwheel is made from aluminum sheet that is thinner than an aluminum pop can so i used spars on that to help stiffen it and stop them from bending back from the wind. This pic was taken before i pop riveted the spar to the pinwheel but you can see the concept.

I did something very similar on the jerryblades on tape drive motors:

Both have worked well and the strap was cheap and a couple of pop rivets to secure the blade to the spar about

half way out on the blade.

Cheers,

TomW

I made one of the plastic props awhile back I really like it and I think it may be just as easy as cutting the angle line on the opposite side of the center line to make it turn the other way.

## [Blade position and sweep](#)

By [Kemper73](#), Section [Homebrewed Electricity](#)

Posted on Tue Nov 4th, 2003 at 08:13:25 AM MST

[Wind](#)

I'm about to start my first turbine but have a couple of questions

Hi everyone, I have learned alot about PM generators and wind turbines by reading this board,, I do have a couple of very important question which I have not been able to find the answer for easily..

1. - should the leading edge be straight, swept forward or swept backward for best efficiency?
2. - should the leading edge of the blade be forward, neutral or trailing from the pivot of the turbine?

The reason I ask is because I am looking at the single piece plastic pipe props. They appear to have a backward swept leading edge that is forward of the pivot point. Plus I have also seen pictures of turbines that seem to have a straight leading edge, that is centered on the pivot axis..

Here is a picture of what I am talking about

I am considering building a single piece plastic pipe turbine or a 3 blade plastic pipe turbine. I have started making some good cad drawings of the props if people are intersted.

Thanks

Jeff

Re: Blade position and sweep ([none / 0](#)) (#1)  
by woofhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Tue Nov 4th, 2003 at 09:22:36 PM MST  
([User Info](#)) <http://timmythy.home.mindspring.com/timmy.htm>

Me and zubby have been playing with single piece PVC Pipe Props. I was messing around last week and came up with a 4 blade PVC prop. It works great even in super gentle breezes without a load. Here's a link...

<http://www.fieldlines.com/story/2003/10/29/17144/245>

Here is the diagrams that I'm working off of ...

I like the design because it's really easy to control the angles of the blade from the Base of the blade through to the tip. The leading edge is the angled cut from the side of the circle in the middle to the tip, the trailing edge is the centerline cut. The reverse of what you are mentioning in your question above.

Re: Blade position and sweep ([none / 0](#)) (#2)  
by Kemper73 on Wed Nov 5th, 2003 at 04:02:38 PM MST  
([User Info](#))

Yeah,, well that is where I got the question from. From the picture you show, it has a backwards sweeping blade and the blade is forward of the centerline axis,,

I'm just trying to see what would be the difference in having forward sweeping and behind the centerline axis.

I know I can't make it in a single piece, But maybe I will be able to try to make a 2 piece blade soon.

Thanks

Jeff

([User Info](#)) <http://timmythy.home.mindspring.com/timmy.htm>

I may not understand your question then.

What do you mean by "Backward Sweeping" ?

If you want to spin the opposite way then just reverse the diagram that I posted.

If to want the centerline cut to face into the wind, I think it would give you a lot less power.

in this picture . . .

The head of the bolt in the center is facing into the wind, and the shaft of the bolt goes to the generator on the downwind side.

I'm playing around with a stock GM alt I have it producing 30+ volts dc with at the present time set up on a real crude setup runnig it with a 1/2 hp motor with a 3 in. pully. the only thong done so far is the fact that the voltage reg is bypassed full 12 volt feed.

dont know if this helps or not.

## [HOMEADE CHARGER QUESTIONS](#)

By [halfcrazy](#), Section [Remote Living](#)

Posted on Tue Oct 28th, 2003 at 07:19:38 PM MST [Batteries](#)

if i have a 24 vdc battery bank what are my options for making a gm alternator charger? i know it only puts out 12vdc so that is my dilema.

[HOMEADE CHARGER QUESTIONS](#) | 6 comments (6 topical, 0 editorial)

Re: HOMEADE CHARGER QUESTIONS ([none / 0](#)) ([#1](#))  
by [zmoz](#) on Tue Oct 28th, 2003 at 07:32:59 PM MST  
([User Info](#))

Two alternators? :) They make 24v alternators for big trucks and things...you could use one of those. Also you could probably buy/make a regulator to get 24v at less amperage than at 12v. I know people turn alternators into welders and use considerably more than 12v.

Re: HOMEADE CHARGER QUESTIONS ([none / 0](#)) ([#3](#))  
by [Jerry](#) on Tue Oct 28th, 2003 at 09:52:45 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Halfcrazy  
I'm building a stock 12 volt GM alt for a hydro system.

I've replaced the stock rotor and coil with an armature from a garbage disposal motor fitted with 14 neo magnets 1/2 X 1/4 X 1 inch.

At 900 rpm in my lathe its porducing 11 amps at 26.25 volts. I changed the stock 3 phase wiring from Y. I seperated the 3 phases. I used a fullwave bridge diode on each phase on the dc out put of each diode I connected a 67,000UF/50 volt electrolytic capacitor. Now I have 3 seperate dc supplys. I've wired these in siries. This wireing scheam makes much higher voltage than the stock Y or star conection.

If your powering this from a gas engine or hydro and you only need 10 amps it should work fine. However there is no voltage regulator so some form of charge control is nessasery. If for wind and 12 volt it should work ok. This is basicly an upgraded 12 volt Hornet.

JK TAS Jerry

([User Info](#))

Well, If it`s for use as a wind generator, then chances are it needs to be re-wound to operate a lower speeds, so You`d just have to make sure when you re-wind it that it produces enough voltage for 24 volt charging.

If it`s not for wind use (ie, gas gen) then get a second alternator of the same type and wire them in series and drive together from the same belt (or sprocket and chain or whatever). I don`t know if that would really work practically, but it would worth looking into. :)

Cya,  
Chris

Re: HOMEADE CHARGER QUESTIONS ([none / 0](#)) (#4)  
by jubalearly on Wed Oct 29th, 2003 at 10:34:29 AM MST  
([User Info](#))

They used to make those devices that would allow you to run 120v universal (AC or DC) motors using your automobile alternator. Those things really did work, sort of, for drills & such. As long as you didn't mind it being run on 70v - 100v @ about 300hz. Primarily they bypassed the regulator. They also required running the engine at high speed (4000 RPM?), or about 10,000 - 12,000 RPM at the alternator.

So, a 12v alternator can be made to output 24vdc, but not efficiently. It is really better to get one rewound for 24v. Better is a truck alternator originally built for 24vdc. Your local junkyard or alternator shop (rebuilder) may have a 'used' 24v at a reasonable price. The best approach is a new 48v winding with PM rotor (some new 2004 autos may have these alternators) to get 24v at lower speeds.

apparently permanent magnet alternators can be wound for different voltage ranges. [hydrogenappliances.com](#) shows several different voltage models for example.

## speaker magnets

By [BrianK](#), Section [Homebrewed Electricity](#)  
 Posted on Wed Oct 29th, 2003 at 09:17:24 AM MST [Magnetism](#)  
 are they good?

Will they work for a rotor type gen?

[speaker magnets](#) | 3 comments (3 topical, 0 editorial)

Re: speaker magnets ([none / 0](#)) ([#1](#))  
 by woofhound ([timmythy@mindspring.com](mailto:timmythy@mindspring.com)) on Wed Oct 29th, 2003 at 09:25:21 AM MST  
[\(User Info\)](#)  
<http://timmythy.home.mindspring.com/timmy.htm>

It's hard to get them out of the enclosure without breaking them. It's hard to get enough of them that are the same size. They are large and would require large coils with lots of wire, and very large rotors. Generally they are not strong like the neodymium magnets which give the most output.

However the speaker itself can be used to make electricity as it is...

Hi Woof,

I followed your link. very interesting I must say. I especially was intrigued with the suggestion, to utilize the exhaust power pulses, of an small IC gasoline engine. If the engine is running about 2000 rpm, then the freq will be about between, 15 and 30hz.

-JW

I also have a 30kw that has parallel abilities adjustable freq.timing lights and all could that gen be able to do this task easier?

Re: spin the meter backwards ([none / 0](#)) ([#8](#))  
by troy on Sat Nov 1st, 2003 at 06:59:42 AM MST  
([User Info](#))

Nope, not unless it's specifically designed to intertie with the grid. Good frequency control is one thing, and matching the utility frequency and phase is something completely different.

Sorry again...

troy

[\(User Info\)](#)  
<http://timmythy.home.mindspring.com/timmy.htm>

While I was home for lunch today I mounted the 4 blader pictured above onto the top of a piece of pipe (without any kind of load) and set it outside where the wind goes around the house. I was surprised that it started when the wind blew the least little bit, and in the 10mph gusts, it was spinnin' so fast you could'nt see it. Now I'm look at all the construction sites for bigger pipe.

I think much of the good response from these blades has to do with the cup shape that the pipe offers.

This cup shape would be rather difficult to make in a wood blade.

My plastic blades have a slight cup and I believe in part this is why at only 49 inches total tip to tip I've seen 1200 watts from these blades.

Here are the good attributes. 23 degrees at the root to almost flat at the tip and a tapering cup from root to tip. There is also a slight rise in the trailing edge from the root and peaking about 1/3 towards the tip at this point this rise and the cup flatten out towards the tip.

I had one of these blades on a GARBOGEN on a 3 foot stand today in my parking lot. In a 10 mph breeze the blades were a blur.

([User Info](#))

Despite my crude drawing. You probably could do this....

The N.C. contact would be you state changer.

The lower limit switch would unlatch the whole deal.

Cya,  
Chris

[Question for Charged.](#) | 25 comments (25 topical, editorial)

Re: Question for Charged. ([none / 0](#)) (#6)  
by laskey on Wed Dec 17th, 2003 at 07:28:18 PM MST  
([User Info](#))

Yes, I think you're right. While the battery will provide self regulation in an infinite bus DC situation. I'd be concerned about pulses that are too high, since this system looks like it negates the self regulation of the battery. It's like throwing a pail of water into a pool. You don't want the pail to get too big, or the pool to small.

Another thing to watch out for is the firing frequency of the the triac (they're not designed to go terrifically high), you wouldn't want your triac to not switch off.

Here's a question...why are you using a triac anyway, you only want to pass a current one way. That sounds like a job for an SCR to me. The circuit proposed has a Zenner in it which when reversed biased would conduct like a regular diode. A constant .7V across a triac gate "might" meet the reverse turnon condition of the triac in an electrically noisy environment.

... Meaning, that when the gen is stopped, and the battery voltage is atleast .7v above the capacitors. The triac "MAY" (perhaps better said "can") lock on in the reverse direction, and discharge the battery into the caps until they reach the battery voltage. SCR..Think about it.

I think that an advantage of this charging method is that you probably would never have to desulfate your battery bank with all those nice pulses all the time.

Cya,  
Chris

If you can get the scr to turn off! in order for that to happen the holding current needs to go quite low (usually 5ma ), it may or may not work, I will try that as I am currently building this to see how it works in the real world.

another advantage to this setup would be recovering energy slowly, like on a small genny I have, it makes a high enough voltage but not enough current to charge a battery with. using this setup I can 'pool' energy into the caps slowly and then dump it into the batteries where before i had no way to get any charge into them.

Re: Question for Charged. ([none / 0](#)) ([#15](#))  
by Budgreen on Fri Dec 19th, 2003 at  
12:53:23 PM MST  
([User Info](#))

actually I was wrong here.. grinding my gears back to basic electronics 2 things need to happen for the scr to turn off.

1. ) the gate current needs to drop below holding.. most cases < 5mA
2. ) the voltage coming in must drop below about .7v

therefore an scr based circuit will never turn off unless the caps are discharged below .7v and with incoming power will not happen. (plus I also tested it to be sure)

Re: Question for Charged. ([none / 0](#)) ([#16](#))  
by charged on Fri Dec 19th, 2003 at  
02:56:25 PM MST  
([User Info](#))

I must apologize for not being VERY clear about exactly WHAT will be charging the capacitor bank.

Unfortunately, I have explained SOME of the system without filling in all the holes. Some of those holes are pretty important.

There are TWO METHODS for charging this capacitor bank.

1. Use PURELY INDUCTIVE power transfer in the system.
2. Use an isolated FLIP-FLOP charging controller on either side of the capacitor bank. That happens to be a recently patented large-scale charging system. Not mine. I believe that you are allowed, under patent law, to build one for

YOURSELF, but not as a commercial venture. Anyway.....

For a steady-current generator as the source, the flip-flop alternately floats the capacitor bank between the incoming generator power and the battery bank. Just make sure the two don't overlap.

The triac discharge circuit works just fine. I have two running right now with a small inductive charging system on the caps.

If you have a monster capacitor bank and a heavy parallel transistor bank to apply the discharge, the pulse duration into the batteries is super short.

In any case, the triac/transistor arrangement is not for universal application, to be sure. A proper long-term system installation would be fully digital controlled.

([User Info](#))

A Battery Charger is designed to operate at 60Hz. Running it outside of that frequency will cause all kinds of nasty side-effects. Most of which are heat related.

A cheap battery charger is usually little more than a slightly refined equivalent of your wind gen set-up anyway. Power source, and bridge rectification, maybe a smoothing capacitor. A more expensive one will have a voltage detector circuit that will shut the thing off when the battery is charged.

I agree with the posts above. You want to do your own battery charging.

Generally speaking, a transformer operated equipment will have no problem operated at line frequencies other than its own designed frequency.

Ciao

Re: static electricity shocks ([none / 0](#)) (#36)  
by laskey on Mon Nov 17th, 2003 at 07:28:58 AM MST  
([User Info](#))

I went to the manufacture's website, and while my spanish (I pretty sure it was spanish) isn't all that great (actually it's terrible), but a product table is still a product table.

Their 2500 watt electric water heater is indeed 220. Which means it has to be 2-phase.

And that means, you have a bad element, but if I understand the language correctly... you have a 3 year warranty.

Drain the tank, remove the element, take it back, and have it replaced.

Look around that website, you understand the language better than I do, there may just be installation instructions.

Cya,  
Chris

Re: static electricity shocks ([none / 0](#)) (#45)  
by storrence on Mon Nov 17th, 2003 at 01:00:28 PM MST  
([User Info](#))

Is it possible to visually see if an element is bad once I pull it? It's new so what would I be looking for for verification? The only manual that came with it was a sticker on the side of the tank that is now turned against the wall so difficult to see. I will check their site.

I remember that when we ordered it they asked if we wanted 220 or 110 which I guess here is really 126\*2 (should it be called 152V) and 126+neutral. But it only has 1 element and some body here said a 220V has 2 elements in the US. Well I don't see why 1 element wouldn't work if you put 1 phase on each terminal and grounded it. In our case we have some defect but otherwise it seems it doesn't need 2 elements to be a 220v at least not down here.

I'm curious why you say because it's 220v it has to be 2 phase? Aren't the 220V hot water heaters in the states single phase 220v?

I don't understand why you removed the cross braces.  
Isn't that what gives these types of towers their strength?

Cya,  
Chris

Re: Strengthening a tv tower ([none / 0](#)) (#2)  
by Reno on Mon Nov 17th, 2003 at 06:05:52 PM MST  
([User Info](#))

the 2x10 bracing is for the horizontal loads.  
I would have liked to find a tower with triangular bracing but all I could find was two with the cross bracing. The cross bracing could not be left on as it was because there is no room. If they are to be reused they would have to be mounted inside both layers of steel. The tower is stiff and once attached to the hinged mount it should add rigidity to the gin pole which is doing all the flexing  
I intend on doing a weight test once it is ready should be able to lift 2 people easily.

Posted on Sun Nov 16th, 2003 at 03:34:02 PM MST

[Wind](#)

none

Here are a few modifications I made to a tv tower that require you only have a drill and a grinder and a saw. I added supports made from 2x10 pressure treated wood. I then got a second arial tower and removes all the cross braces

except the last one at the top the tow towers were bolted together at the joints the bolts went through all three layers.

With the 2x 10 braces I was able to lift 180 lbs with it see pics

([User Info](#))

I don't understand why you removed the cross braces.  
Isn't that what gives these types of towers their strength?

Cya,  
Chris

Re: Strengthening a tv tower ([none / 0](#)) (#2)  
by Reno on Mon Nov 17th, 2003 at 06:05:52 PM  
MST  
([User Info](#))

the 2x10 bracing is for the horizontal loads.  
I would have liked to find a tower with triangular  
bracing  
but all I could find was two with the cross bracing.  
The cross bracing could not be left on as it was  
because  
there is no room. If they are to be reused they would  
have  
to be mounted inside both layers of steel.  
The tower is stiff and once attached to the hinged  
mount  
it should add rigidity to the gin pole which is doing all  
the flexing  
I intend on doing a weight test once it is ready  
should be able to lift  
2 people easily.

You may have a decayed anode rod or something like that. The heater is in need of inspection by an electrician at any rate. It is very dangerous to have a live hot water heater casing, especially if you have copper pipes.

I have PVC but I agree it's dangerous. It's difficult to get an electrician to my location and even if I did, they would not consider it dangerous. You have no idea how they are with electricy here. Many people just connect wires directly to the overhead street lines so they don't have to pay but that's another story. Since I'm not so courageous to take this risk, is there any tests I can do to confirm I have a problem and what the problem would be? I have a multimeter.

I don't believe the casing is completely hot because it would have tripped the 30amp breaker when I had it's casing connected to ground.

I assume that if it's running it's got heat to spare, and if it's in dump mode he's probably dumping to heaters which will keep it warm in there. Am I right?

Re: Thermostats for solar heating panels ([none / 0](#)) (#9)  
by pexring on Fri Nov 14th, 2003 at 12:08:05 PM MST ([User Info](#))

Great link. I can build, wire and plumb a house without even looking at a book. Yet my knowledge of this type of electronics is minimal. This website should sell this type of thermostat where I could simply run a wire inside the solar panel and adjust the dial on the wall.

Today I had another thought. Why not just buy an ordinary mercury-type thermostat and put it inside the panel. Set the t-stat on a/c so it kicks on when the temp reaches about 80. Then it would never shut off until it got cold again. With my solar panel on the wall, I could reach in through the intake vent and adjust the dial if necessary. Crude, but it may just work!

Otherwise, I'd possibly pay someone to build and send me one that worked.

Mark

You could put up a bank of lights on the tower to burn off the excess, and that way you could see if your battery bank is full.

But honestly, I like the winter heating, and summer cooling idea. I suppose your shed roof is good. Maybe just use the extra to pump water onto the shed roof... maybe that would cool it off a bit in the summer?

Cya,  
Chris

[Heat exchanger for a residential clothes dryer?](#) | 20 comments (20 topical, editorial)

Re: Heat exchanger and spinner ([none / 0](#)) ([#14](#))  
by laskey on Sun Nov 9th, 2003 at 09:03:54 PM MST  
([User Info](#))

Now I know this is getting low-tech, but I went to my local Canadian Tire store and found two different products for about 15 bucks (Canadian, each). One is a box you put in your dryer exhaust vent line that acts like a switch closing off the outside line and blowing through a lint trap (which you have to clean with each use) marked with the cryptic settings of summer and winter. The other is a thing for houses that have no dryer vent (and can't have one for some reason) it goes on the end of the dryer vent hose and is like a vented bowl filled with water (I guess to catch the lint) and you have to clean it with each use as well.

I was thinking of getting one (the box switch thingy), but there is only two of us, and we only do laundry once a week. It wouldn't solve my basement heating problems. I need a little bit of heat all the time... Not alot for a couple of hours a week.

I'm still thinking about what I could do with that dryer heat.

Cya,  
Chris

[Multiple generators](#) | 10 comments (10 topical, editorial)

Re: Multiple generators ([none / 0](#)) ([#4](#))  
 by laskey on Sun Nov 9th, 2003 at 08:46:28 PM MST  
[\(User Info\)](#)

You're right its called "infinite bus" synchronization. The grid is so large an powerful that the generators conform to the Grid, because they can be "forced" into sync by the grid, the main problem for you would be if the grid went down. In free running mode those two gens would fight each other and likely do damage to each other. You'd be well off to build yourself a synching setup so that you can match them to the grid and each other.

As a side note, the "infinite bus" effect is exactly the same reason that a non-grid-tie inverter will explode if you hook it straight to the grid. Inverters don't normally have the ability to synch to the grid, and if you try to force them something will burn out.

Cya,  
 Chris

[Are the diodes correct](#) | 20 comments (20 topical, 0 editorial)

Re: Are the diodes correct ([none / 0](#)) (#6)  
by laskey on Fri Nov 7th, 2003 at 07:20:42 PM MST  
([User Info](#))

I don` t think so. What you really want to do place a diode in the positive line after the caps, and eliminate the other ones. After all what do you want to do with a diode anyway... stop current from flowing backward through it to something important. You probably don` t want your batteries charging those Caps.

I don` t think you need to isolate the batteries from each other with anything other than fuses (in case of a failure).

Cya,  
Chris

[ [Parent](#) ]

Re: Are the diodes correct ([none / 0](#)) (#7)  
by Reno on Fri Nov 7th, 2003 at 08:47:36 PM MST  
([User Info](#))

I am under the impression that you should not mix different batteries in a bank ie. age, voltage..... This Marine battery is a couple of years old and some time gets pulled down pretty good also usually sits all winter. The 6 Volt bateries are brand new bought for my genny. So to combine the two I assumed that keeping them from drawing from each other with the use of diodes would be the solution. Come spring time the 12V goes back in the boat. Am I wrong in the believe not to mix batteries, I learned that here.

Hi Guys

I'm in an industry where large value caps are used every day. As an example one of our sterero demo vehickles has 10 farrad of caps on board. The other 16 farrad onboard. That is 16 million UF.

In both demo cars the caps are hard wired to batteries. they are allways together. The first vehickle is my daily driver 1995 chevy Astro van. We also have 4 batteries and a stock alternator inthis van. prior to this this system was in a 85 S-10. The S-10 is now my wind test truck.

Befor these 2 it was a 1977 full size chevy van. The alt was stock in in this van also. We campained this demo van for 10 years. We had 22 car batteries and 60 caps onboard this van. BTW this van was featured in the LOW RIDER mag.

My point is. Connect your caps directly to your batteries. Ever tryed to connect a dicharged cap to a voltage source. depending on state of discharge there will be anywhere from no spark to a huge spark depending also on the value in MF of the cap.

If the cap has a large enough value and is discharged at the moment of connection the cap apears as a ded short to the voltage supply in this case a wind genny. wind gennies have a hard time with startup when working into a ded short.

The benifit of the cap is still the same when connect directly to the battery. However the cap is never discharged and dose not cause a stall condition for the genny. All the caps benifit to the genny is still there.

In car audio capacitor are refured to as stiffning caps. We most frequently here complaints about customers lights dimming at night when the audio system are pounding out bass responce. The bass frequecies range from 30 hz to 100 hz.

Oddly enough our invertors are operating at 60 hz. Although these invertors have pulswidth modulated power supplys and are highly regulated the power supply puls load on the batts is at 60 hz. Caps can store and release energy many times faster than batteries. Hence when caps are added to batteries where these frequecies are involved preformance is greatly inhanced. BTW car audio amps also have the same type power supplies as invertors. When we add caps to car audio systems, most of the time the lights stop blinking. Voltage is stableized. The car audio Ind. suggest 100,00 UF for every 100 watts RMS of amp power.

If it were me I'd use only the diode of the genny and no more. If the genny is a brush type perminet magnet motor then just one diode. If its a PMA then what ever diode configuration it is designed with.

I would not seperate the batteries. I never do and never have in the 27 years i've been doing high power car audio.

Flooded lead acid batteries work fine at 14.4 volts. Thats the voltage we measure in almost every car we test in some we see 13.8 so in that range is good. This dosen't matter if its the smallest Honda battery or one were testing in a big rig. I think this is because the flooded lead acid battery cell, just one

has a chemical rest voltage of 2.1 and very comfortable with 2.4 while charging. It doesn't seem to matter the physical size of the cell. We use a 2 volt hysteresis cell on our test bench to add 2 volt to our 12 volt supply. this cell is 5X5X 16 inches tall and rest at 2.1 and charges at 2.4 same as each cell in the small garden tractor battery. So you can apply the same 13.8 volts across the honda battery or the two 6 volt golf cart batteries in series. If you want these 2 battery systems to be charged from the same charging source (wind generator) use a battery isolator just as you would do in the old PU with the camper on the back. The generator must still charge both batteries but the batteries are totally independent from each other. All a battery isolator is is 2 diodes in a pretty blue heat sink.

Voltage from the alternator flows each diode towards its battery. The diodes anodes are tied together and are connected to the alternator or in this case the generator. the cathodes are separate and each one goes to its one battery.

The ONE thing of utmost importance is fusing. We are subject to liability in car audio installations. To protect our butt and the customers as well. We never connect

any accessory to a battery without a fuse unless you like fires. A standard car battery can light up some heavy gauge power wire like a christmas tree. We always tell our customers fuses are cheaper than cars. In this case maybe houses. The battery isolator or 2 diode will have that nasty .5 volt drop. It doesn't sound like much but I worked hard to make this voltage and I don't want to give any up.

Sorry if I went long on this one guys. It's what I do all day on this one.

I don't think I made the cap ded short thing clear. If you connect the caps directly to the dc output of the genny and then follow that with isolation doides. The voltage can fall to ZERO accross the caps because they will be isolated from the batteries. This fall to ZERO can ocure if enough time elapes while the genny is stoped ( no wind). When it trys to start up again the caps will appear as a ded short. This can't happen with caps in perelell with the batteries.

([User Info](#))

I don` t think so. What you really want to do place a diode in the positive line after the caps, and eliminate the other ones. After all what do you want to do with a diode anyway... stop current from flowing backward through it to something important. You probably don` t want your batteries charging those Caps.

I don` t think you need to isolate the batteries from each other with anything other than fuses (in case of a failure).

Cya,  
Chris

[Wind](#)

none

I want to connect my 12V marine battery to the wind generator during the winter so as not to mix the two types of batteries I want to separate the two.

Have I left out any diodes thanks in advance

Reno;

From that drawing it looks to me like your 2 diodes between the + post of the 6V battery and the inverter are basically wired reverse polarity to each other and will pass current both directions effectively eliminating any isolation. I could be seeing it wrong or missing something, however.

Cheers.

TomW

by wpowokal on Fri Nov 7th, 2003 at 03:27:51 PM MST  
([User Info](#))

Reno I agree with Tom.  
The first diode after the caps blocks the power from motoring  
the generator.

Leave out the lower left diode and line.

Remove the diode to the 6v battery and place it forward biased  
in the line to the 12v and inverter. This will isolate the two  
batteries, the 12v in this case will be charged to around 0.6v  
less than the 6v pair, but when supplying load they will both be  
on an equal voltage footing.

regards Allan

Re: Are the diodes correct ([none / 0](#)) (#3)  
by drdongle on Fri Nov 7th, 2003 at 03:50:31 PM MST  
([User Info](#))

Good analysis of the problem, but just to put my 2 cents worth  
the first diode from the caps is not required and in fact lowers  
available voltage by .6 volts which may under low wind  
conditions reduce the voltage for charging.

Dr.D

Re: Are the diodes correct ([none / 0](#)) (#4)  
by Reno on Fri Nov 7th, 2003 at 03:57:27 PM MST  
([User Info](#))

Ok i see the first one is redundant  
thanks. so your saying leave the other two.  
I cannot see how the inverter can draw from both  
batteries 6v & 12V without the two caps to isolate  
them. Is this what you mean.

I am under the impression that you should not mix different batteries in a bank ie. age, voltage..... This Marine battery is a couple of years old and some time gets pulled down pretty good also usually sits all winter. The 6 Volt bateries are brand new bought for my genny. So to combine the two I assumed that keeping them from drawing from each other with the use of diodes would be the solution. Come spring time the 12V goes back in the boat. Am I wrong in the believe not to mix batteries, I learned that here.

([User Info](#))

You schematic still has two errors on it. It shows a connection between the + terminal of the 12 volt battery and the + terminal of the left most 6 volt battery. this defeats the diodes as they are actually wired in parallel. The only way to provide isolation is to have 4 diodes, two from the capacitor bank, one to each battery and a second two, from each battery to the inverter. In an ideal situation each battery group could drive it's own inverter, eliminating the second set of diodes and providing redundancy, on second thought keep one inverter but add an auto switch over relay to change it from one battery to the other when the charge drops to a predetermined level.  
This one of the reasons you should avoid mixing battery types.

Dr.D

Re: Are the diodes correct ([none / 0](#))  
(#12)  
by RobC on Sat Nov 8th, 2003 at 08:44:44  
AM MST  
([User Info](#))

Question? Why even bother with capacitors.  
Well maybe a small one to smooth the ripple from the bridge rectifier other than that in this appication I don't see the need. As far as seperating types of batterys I put my gell cells in one bank  
deep cycles in another used truck batterys in another. My plan is to have a dedicated inverter on each bank that way if my old truck batterys die its no big deal. However that brings us back to original question how to charge all of them at the same time.  
I think in this case one diode per battery bank would do the trick.  
RobC

[ [Parent](#) ]

Re: Are the diodes correct ([none / 0](#)) (#13)  
by RobC on Sat Nov 8th, 2003 at 08:57:12 AM MST  
([User Info](#))

Hey Jerry your big caps would certainly help a small bank of batterys handle an inverter with a large surge capacity. You need to get us catalog of parts and pieces that we can buy from you.

[ [Parent](#) ]

Re: Are the diodes correct ([none / 0](#)) (#14)  
by Reno on Sat Nov 8th, 2003 at 09:37:36 AM MST  
([User Info](#))

Ok  
If i may pick your brain  
Since you seem to be charging different batteries.  
You use a diode on each battery bank but the only difference is you have spererate inverters for each bank  
Am I understanding this correctly

[ [Parent](#) ]

Re: Are the diodes correct ([none / 0](#)) (#15)  
by Reno on Sat Nov 8th, 2003 at 10:11:07 AM MST  
([User Info](#))

OK this has to be it  
I cleaned it up easier to follow

Re: Are the diodes correct ([none / 0](#)) (#16)  
by drdongle on Sat Nov 8th, 2003 at 10:31:31 AM MST  
([User Info](#))

You almost have it, take the right hand horizontal diode and move the anode lead to the + terminal on the left most 6 v battery.

Dr.D

Re: Are the diodes correct ([none / 0](#)) (#20)  
by Jerry on Sat Nov 8th, 2003 at 10:12:38 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Scott you are our hero.  
this last one is the correct schematic. The only thing I would change. I would connect the caps directly to the inverter. The caps are still isolated from the batteries and can still cause genny stall after the genny has been idle long enough for the caps to discharge.

Caps connected directly to the inverter will have a constant voltage supply. Although this voltage will be .5 volts lower than battery voltage and 1 volt lower than genny voltage.

Re: Sine wave inverter ([none / 0](#)) ([#9](#))  
by Budgreen on Tue Nov 4th, 2003 at 10:57:35 AM MST  
([User Info](#))

it could be fairly hard and not worth the time.. most inverter ups systems that have non-square wave outputs normally use a microprocessor to create the waveforms and do the rest of the inverter control. if you could read the software off it and recode it would be very possible but quite time consuming :)

on another note you could start and make a dc-dc converter first say 24vin 170v out.. pwm controlled, take a recitfied 170v out and run it to an H-bridge, controll the H bridge with a 10-25khz pwm signal modulated by a 60hz stable sine wave, then filter the output of the H-bridge to remove the 10-25khz pwm frequency and your left with a nice sine wave output at a high efficiency.

I have been trying to come up with a good dc-dc converter information to try and design a 24v-170v converter (that in itself is easy, just getting it to put out 10-20A is the hard part) so if anyone could help in this arena I may have schematics available by the end of the year :)

Re: Rectifier usage ([none / 0](#)) ([#4](#))  
by laskey on Fri Oct 31st, 2003 at 01:38:00 PM MST  
([User Info](#))

If you've really got AC coming in from the gen you want a bridge rectifier rated for your maximum voltage and maximum current, any thing else and you run the risk of burning it out. Remember, a bridge rectifier has dideoes pointing both directions for each half of the AC cycle, so using one in a DC application is the electrical equivalent of using nothing at all.

If you've really got DC coming from the gen then you'll only need a single rectifier, and the same voltage and current rules apply.

Cya,  
Chris

Mmmmm... I don` t think your tape drives are actually producing DC (I could be wrong here), so you` d probably want bridge rectifiers before transmission (as it were).

Laskey;

The Ametecs I have experience with [30V, 40V and 50V] all produce DC voltage via a commutator and brushes.

Cheers.

TomW

Re: HOMEADE CHARGER QUESTIONS ([none / 0](#)) ([#2](#))  
by laskey on Tue Oct 28th, 2003 at 07:38:48 PM MST  
([User Info](#))

Well, If it`s for use as a wind generator, then chances are it needs to be re-wound to operate a lower speeds, so You`d just have to make sure when you re-wind it that it produces enough voltage for 24 volt charging.

If it`s not for wind use (ie, gas gen) then get a second alternator of the same type and wire them in series and drive together from the same belt (or sprocket and chain or whatever). I don`t know if that would really work practically, but it would worth looking into. :)

Cya,  
Chris

[When under load is the coil equal to the magnet in terms of uhhh power?](#) | 11 comments (11 topical, 0 editorial)

Re: ([none / 0](#)) ([#10](#))  
by laskey on Mon Oct 20th, 2003 at 06:47:03 PM MST  
([User Info](#))

You're not getting a free lunch.

Here's what happens. The permanent magnet is like a starter. The actual power is generated by the rotation of the wind mill. The magnet of any amount (as long as there is some) starts a current flowing in the stator coils. Some of the current generated, then feeds the field coils which brings up the magnetic field, generating more current in the stator coils, and up and up the magnetic field goes until you are at operating capacity. Remember, it's the rotation of the windmill (thus the wind) that is generating power. In the case of a PMG the magnet are rotated by the wind. It's the magnetic flux pass through the stator coils that causes the current to flow. More magnetic field, more current flowing.

The problem with wind gens is that they don't operate at a constant speed, and generation output, so with field coils you end up with a fluctuating magnetic field which isn't good if they were all by them selves.

Cya,  
Chris

## [When under load is the coil equal to the magnet in terms of uhhh power?](#)

By [headhunter](#), Section [Weird Science](#) [Magnetism](#)

Posted on Sat Oct 18th, 2003 at 08:04:19 PM MST

When under load is the coil equal to the magnet in terms of uhhh power?

As a coil is powered up, is that coil equal to the magnet (in terms of strength), or will it always be less?

I'm assuming it would be less.

[When under load is the coil equal to the magnet in terms of uhhh power?](#) | 11 comments (11 topical, 0 editorial)

Re: When under load is the coil equal to the magne  
([none / 0](#)) (#1)  
by [laskey](#) on Sat Oct 18th, 2003 at 08:29:44 PM MST  
([User Info](#))

That`s kind of a loaded question. It depend on the coil... how it`s coiled, what it`s coiled around, how many turns, the size of the wire, all that determines the magnetic flux density (how strong a magnet it is). Electro magnets (coils of wire with current flowing through them) properly made are always capable of higher flux densities than permanent magnets... ALWAYS. That`s why electric company`s grid-tied alternators always have electro-magnetic field coils instead of magnets.

Why don`t wind gens use field coils if they`re so great... because when you use them it takes some power to make power. If your alternator is a megawatt, and it uses 1000 watts to work, then it`s no problem you still have 999 kilowatts left. If your wind gen is 2000 watts, and it takes 1000 watts to work... well that`s not as good is it.

Cya,  
Chris

Re: When under load is the coil equal to the magne  
([none / 0](#)) (#3)  
by [kww](#) on Sun Oct 19th, 2003 at 08:56:09 AM MST  
([User Info](#))

But wouldn't a car alternator be impractical if that's the case? Wouldn't a 2000 watt windmill need maybe 10-100 watts to energize the coils sufficiently?  
Kevin

Hi Kevin, you are correct, wound fields are typically designed to use ~ 5% of full load power. The trouble is that 2000 watt wind turbine produces a lar ge % of its annual energy at 200 watts and less.

Ok just to confirm what ya said. If I had a generator with permanent magnets, as i spin this generator (and say the coils are done to perfection or the best possible), the coils, once under load would be more powerful than the permanent magnets that charged em up?

Correct?

Re: ([none / 0](#)) (#6)  
by laskey on Sun Oct 19th, 2003 at 07:53:44 PM MST  
([User Info](#))

It's a case of increasing return with increasing magnetic density. As you generate more power you will have more power available to generate more power with.

I've always wondered if you could use a hybrid design of a standard PMG with field coils to get a low speed starting, but higher output wind turbine, at running speed. It would be cool to see if it really practically did do better than just a regular PMG.

([User Info](#))

Hi Chris,

Your idea is a valid one. There were some high end gennies in the old days that had two permanent magnet gennie made electricity to energize the field coils of the "real" gennie which actually produced the usable electricity.

The faster the wind blows, the more magnetic flux you get in the field coils. This sort of automatically matches the gennie to the blade size. And I think Jerry has suggested that you could use two separate windmills, using the PMA to drive the field coils of the main gennie.

There are some efficiency advantages to this method, but they are fairly complex to build. I think www.homepower.com recently ran an article about how they work.

Best regards.

troy

([User Info](#))

I understand that you can make more power with stronger magnets, but what i was asking is can the coil(under load), when charged ever be stronger than the magnet that charged it in the first place.

heres what i mean:

Re:oil equal to the magnet in terms of uhhh power?  
([none / 0](#)) (#8)  
by wpowokal on Mon Oct 20th, 2003 at 06:11:34 AM MST  
([User Info](#))

Simply, there is no such thing as a free lunch.  
More complex, there are at least 3 voltages generated in a generator, but simply no you do not get more out than you put in.

Just my humble opinion.

regards Allan

Re: ([none / 0](#)) (#9)  
by headhunter on Mon Oct 20th, 2003 at 11:28:48 AM MST  
([User Info](#))

I know there is no free lunch, just confirming that the coil generates an equal or less magnetic force than that which charges it.

Re: ([none / 0](#)) (#10)

[When under load is the coil equal to the magnet in terms of uhhh power?](#) | 11 comments (11 topical, editorial)

Re: When under load is the coil equal to the magne ([none / 0](#)) (#1)  
by laskey on Sat Oct 18th, 2003 at 08:29:44 PM MST  
([User Info](#))

That`s kind of a loaded question. It depend on the coil... how it`s coiled, what it`s coiled around, how many turns, the size of the wire, all that determines the magnetic flux density (how strong a magnet it is). Electro magnets (coils of wire with current flowing through them) properly made are always capable of higher flux densities than permanent magnets... ALWAYS. That`s why electric company`s grid-tied alternators always have electro-magnetic field coils instead of magnets.

Why don`t wind gens use field coils if they`re so great... because when you use them it takes some power to make power. If your alternator is a megawatt, and it uses 1000 watts to work, then it`s no problem you still have 999 kilowatts left. If your wind gen is 2000 watts, and it takes 1000 watts to work... well that`s not as good is it.

Cya,  
Chris

([User Info](#))

But wouldn't a car alternator be impractical if that's the case? Wouldn't a 2000 watt windmill need maybe 10-100 watts to energize the coils sufficiently?  
Kevin

Hi Kevin, you are correct, wound fields are typically designed to use ~ 5% of full load power. The trouble is that 2000 watt wind turbine produces a large % of its annual energy at 200 watts and less.

[Measuring Volts + Amps](#) | 2 comments (2 topical, editorial)

Re: Measuring Volts + Amps ([none / 0](#)) (#2)  
by laskey on Sat Oct 18th, 2003 at 08:12:22 PM MST  
([User Info](#))

Yep that`s it.

You should put in a fuse (in series) that matches or is less than your ampmeter`s maximum ability to read. So that if something happens you don`t damage the meter. Most meters aren`t fused on their high current range. Which is probably what you`ll be on since a 25W 12V bulb will draw just over 2 Amps. If you`ve got a gen capable of more than 25 watts, then consider putting some more bulbs in parallel to get a bigger load to see how much you can draw. Just remember not to blow up your ampmeter in the process (they can only take what they`re rate for).

Cya,  
Chris

## [Measuring Volts + Amps](#)

By [Insomnian](#), Section [Homebrewed Electricity](#)

Posted on Sat Oct 18th, 2003 at 07:21:50 PM MST [Alternators](#)

Series or parallel for measuring volts/amps

Which is the proper way to measure volts and amps?

I have hooked my rectifier to a few coils (still on the lathe for testing). I then attached a 12V (25W) car bulb to the + & - terminals of the rectifier, as a test load. The bulb lights well at 450 RPM from two coils. To measure volts should the multimeter probes be in series with the bulb or parallel? Also when I measure for amps, should it be series or parallel for the probes/bulb.

Thanks for any info.

[diminishing returns on stator heating](#) | 4 comments (4 topical, editorial)

Re: deminishing returns on stator heating ([none / 0](#)) (#2)  
by laskey on Sat Oct 18th, 2003 at 07:57:32 PM MST ([User Info](#))

Hey guys, it`s a moot point with a wind gen. Your heat only goes up when you generate more power, you only generate more power when there is more wind, meaning you have higher cooling already. It doesn`t get any better without using your generated enegy to run a cooling system.

The text book says you only need go beyond forced air cooling in alternators larger than 10 Megawatts. (that`s a cost:benefit ratio type thing)

You are of course right about the 40-50 degree rise above ambient temp, but you have to do one of two things to get that in a wind gen. 1) Have some really, really, really, fast winds (without, of course, having your gen been torn apart by the winds.) or 2) really design your gen badly.

Whatever stator heating you may experience should be well offset, by the large number of British thermal units of air that the driving wind can remove from your stator.

Cya,  
Chris

by bob golding ([yubba at clara dot net](#)) on Sun Oct 19th, 2003 at 02:38:56 AM MST ([User Info](#))

thx guys that is what i thought. the reason i asked is that i am thinking of putting the alternator on the ground to keep the weight down and therefore will lose the cooling effect from being up in air where the cooling air is. i think i will just put it in a big enough box that it wont matter and use thermal cutouts in the windings as used in microwave oven transformers and motors.

cheers  
bob

## [diminishing returns on stator heating](#)

By [bob golding](#), Section [Homebrewed Electricity](#) [Alternators](#)

Posted on Sat Oct 18th, 2003 at 12:18:52 PM MST

hi all does anyone know the point at which trying to cool a stator

becomes uneconomic in terms of energy usage. i know you can get magnet wire that runs up to high temperatures but when does it become counter productive? i know this violates the K.I.S.S principle but that aside does anyone know?

having lots and lots of fun not enough hours in the day

bob

by [zubbly](#) on Sat Oct 18th, 2003 at 05:24:37 PM MST ([User Info](#))

hello Bob. i think you could use the same rating as on electric motors. generally 40-50 degree rise above the ambient surrounding temperature. hope this helps.

zubbly

([User Info](#))

Removing the generator from the 'cooling air' will also remove it from the wind. In other words, the amount of power you can generate on the ground is much less than a higher mount could give you. And that is true even when there are no obstructions - any obstructions make it worse.

The temperature that you can run the stator depends on what the insulation can take. Most magnet wire has class H insulation but the epoxy used in addition is usually class F, limited to a maximum temperature of ambient (40 deg C)+ 100 deg. (avg.) C rise - actually an internal maximum temperature of 150C. I wouldn't want it that hot. You should have plenty of cooling air provided you do not exceed the amperage rating of your winding.

[multiple frequency on same ac line](#) | 11 comments (11 topical, editorial)

Re: multiple frequency on same ac line ([none / 0](#)) (#10)  
by laskey on Sat Oct 18th, 2003 at 07:32:08 PM MST ([User Info](#))

Yes, When you add multiple frequencies together you get strange results. If two alternators are exactly in phase at the same frequency then they add together as twice as much voltage, if they are exactly 180 degrees out of phase at the same frequency then when you add then you get nothing, they cancel each other. Being different frequencies (and varying frequencies) you get some kind of strange middle ground that`s not reliable.

When we are taking about the Grid, then alternators are forced to the right frequency by what`s called the infinite bus. Meaning the grid is so large and powerful that it forces alternators running on it to run at it`s frequency. In a smaller setup the alternators wired together will fight each other until they reach a middle ground. If they are all the same size this might not be bad, as they would all kinda smooth each other out, and find a happy middle ground. The big problem is if you have different sized Alternators, as one may very well be using it`s generated enegry to drive other ones like motors, and such.

Cya,  
Chris

Signweld,

The simple answer is, yes, they will fight each other. An easy solution would be to rectify the output of each individual alternator and then parallel the D.C. outputs into your power transmission wire.

Matt

Re: multiple frequency on same ac line ([none / 0](#)) ([#2](#))  
by [laskey](#) on Thu Oct 16th, 2003 at 05:40:30 PM MST  
([User Info](#))

Yep Your right. Because they aren't synchronous, they will un-relibly fight each other.

The problem with DC into the house is that you need huge wire to run long distances. If you've got a long way to go, consider having a battery/inverter shack at a central point then run 3 phase to the shack from each gen and then have your batteries and inverter there and then run single phase AC to your house.

Cya,  
Chris

I agree with the other two comments posted, they interfere, best to convert everything to DC.. As for the wire, the bigger the better #2 guage is good for about 150 to 200 ft. Also the higher the voltage and lower the current the lesser the losses. Do the recification on site and filter later, caps will freeze like batteries, unless kept above freezing like a nice warm house or shack!

Good Luck!  
ifred.

I can accept that it wont work. But does anybody know why" Is it the 2 different voltages that are not compatible, or the fact that you have 2 diferent frequencys.

I dont mean to dispute anyone, Im just curious. I know you can carry a AC frequency signal over a DC signal in electronics, and the electric co. runs high frequency communications over thier transmission lines ( dont know if its same voltage as line voltage) and your all telling me to run seperate 3ph AC lines to my batteries and then thru the rectifiers (I assume seperate rectifiers for each alternators output lines) and use these somewhat different and varying DC voltages to my common battery bank. So its OK to have several different voltages on same line to batteries after rectified? Maybe its the different AC voltages that are not compatible?

still confused, but I know to heed from other's experiances.

As one of your source AC voltages is rising +Positive and another of your source AC voltages is coming up to it's -Negative point. If these two sources are connected together the voltages will cancel out, or in my opinion "evaporate". This will happen whether you connect them together in series or parallel.

Yes, When you add multiple frequencies together you get strange results. If two alternators are exactly in phase at the same frequency then they add together as twice as much voltage, if they are exactly 180 degrees out of phase at the same frequency then when you add them you get nothing, they cancel each other. Being different frequencies (and varying frequencies) you get some kind of strange middle ground that`s not reliable.

When we are talking about the Grid, then alternators are forced to the right frequency by what`s called the infinite bus. Meaning the grid is so large and powerful that it forces alternators running on it to run at it`s frequency.

In a smaller setup the alternators wired together will fight each other until they reach a middle ground. If they are all the same size this might not be bad, as they would all kinda smooth each other out, and find a happy middle ground. The big problem is if you have different sized Alternators, as one may very well be using it`s generated enegy to drive other ones like motors, and such.

The other problem is that one windturbie will load up the other in this situation... as one turned, it would actually be trying to motor the other one! This would always be happening, so the machines would always have a load on them and theyd have a rough time starting up Id think. Id just rectify them at the bottom of the tower.

I looked at some caps, I found that some of the higher voltage types can withstand minus -40 deg c. So, depends on the cap.. So, if you can rectify and filter your alt would be perfect.

Re: multiple frequency on same ac line ([none / 0](#)) (#11)  
by charged on Fri Nov 14th, 2003 at 09:10:07 AM MST  
([User Info](#))

Here's a weird but moderately simple solution.

Use half-wave rectification (1 heavy-current diode) on each output winding on the alternator. Charge a large capacitor (100,000uf+) with this output. Place a single protector diode in reverse-bias mode across the capacitor.

Do this to each alternator. Then, connect the three capacitors in series. The capacitors render the "out-of-phase" relationships of the three alternators moot.

This will give you a higher voltage DC. The protector diodes prevent the capacitors from ever getting a catastrophic reversed charge condition should one of the alternators fail.

Because of the half-wave rectification (adiabatic cap charging method) and the series wiring of the capacitors, you'll have more than 4x the original working voltage which will transfer with greater efficiency.

Here's the magical "teslian" component to the system. (diagram below)

Get a single heavy-current inductor (microwave oven transformer primary), a couple of power transistors and a couple of 555 timer circuits set to 50% duty.

The two switches in the following diagram represent the two power transistors being driven by two 555 pulse generators.

The capacitor at the battery bank should be 1F or larger and able to handle the incoming voltage plus a little.

The inductor and c.e.m.f. recovery diode are hooked up close to the triple capacitor bank at the source. Adjust the pulse rate so that the inductor is driven to about 80% saturation with each pulse (only a sawtooth, not a flat DC line on the scope). The combined inductance of the transformer winding and the long wire will probably end up in the 50-60hz range for a standard oven transformer.

The transistor and pulse circuit inside the house can be run at a relatively high frequency at 50% duty.

Mosfets are preferred over bipolar transistors since they don't present any voltage drop.

The large 1F receiver capacitance being fed with the "buck converter" pulse at the source will very efficiently step-down the high voltage and allow you to directly charge the batteries at their preferred voltage level. No transformers required.

For a more detailed explanation of basic capacitive DC-DC conversion check this out.

[http://www.maxim-ic.com/appnotes.cfm/appnote\\_number/710/ln/en](http://www.maxim-ic.com/appnotes.cfm/appnote_number/710/ln/en)

It's not just for application in "little chips". It works just fine at the macroscopic level too.

Enjoy!

figure 1

The two switches represent two heavy-current transistors or mosfets rated for at least 200v.

figure 2

Each of the three capacitors on the left of figure 1 is wired to it's respective alternator as shown in figure 2.

Re: How efficient is an auto alternator? ([none / 0](#)) (#4)  
by laskey on Wed Oct 8th, 2003 at 06:43:43 AM MST ([User Info](#))

Cumbustion engines are terrible for efficiency. the theoretical max for your 5HP motor is 3730 watts. Now you drive a 55Amp 24Volt alternator with it... so your system is capable for producing 1320watts.  $1320/3720 = .353$  which means your system is 35.3% efficient at it's theoretical maximum. And that doesn't take into account the stored energy in the gas which will make your efficiency even worse. gas gen is really not the way to efficiency.

### [How efficient is an auto alternator?](#)

By [zmoz](#), Section [Homebrewed Electricity](#)  
Posted on Tue Oct 7th, 2003 at 09:22:18 PM MST [Alternators](#)  
**How efficient is an auto alternator?**

Can somebody tell me aproximately how efficient an auto alternator is? I mean...if I had one powered by a 3hp engine, what is the max watts I could produce?

[How efficient is an auto alternator?](#) | 13 comments (13 topical, 0 editorial)

Re: How efficient is an auto alternator? ([none / 0](#))  
(#1)  
by [wpowokal](#) on Wed Oct 8th, 2003 at 12:10:22 AM MST  
([User Info](#))

Zmos,

While I don't know how efficient auto alternators actually are your question is more relevent to other parameters.

I have a 55a Bosh 24v alternator connected to a 5hp motor 2.5" motor pully with 2" alternator pully. This allows the engine to drive it at full load. I have tried larger pullies to reduce motor revs but that is the best combination.

It is possible to use a regulator on the alternator to reduce initial current to what the engine can accomodate, Homepower has published a good one of these. With such a regulator I believe a three HP motor would drive such an alternator, 3HP is 2.25 kw, in my case 55a @ 24v = 1.32kw. Homepower also have published an artical on such a motor alternator conversion.

So in sumary its relevent pully size v motor speed and therefore power.

regards Allan

Actually, I'm not trying to run an alternator off of a small engine...I just used that as an example. What I want to know, is how much HP is wasted. I'm actually planning on wiring up a switch in my truck that will turn off the alternator when I want a little extra power. I'm trying to figure out aproximately how much of a HP increase that will give me. Are they something like 80% efficient? More? Less?

Thanks :)

([User Info](#)) <http://www.geocities.com/za2bb/>

Your horsepower gain would be 3/5 of 5/8 of bugger all. ;-)

Seriously, once you've started your engine the amps produced by your alternator will be high for a few minutes until your starter battery is brought back to full charge, then drop to maybe half an amp. Your electric fan generally only gets switched on by the thermostat when the vehicle is stationary or moving slowly, in most vehicles once you're doing 20mph or so there's more than enough airflow through the radiator and the fan isn't really needed.

Go for it if you like, but I suspect that the performance boost would only be noticeable on the dyno. If you're just looking at doing a few runs down the drag strip then you'd be better off pulling the alternator out altogether, fitting a 4ah battery to power the ignition and starting it via jumper leads - that way you'll gain the little bit of power and lose some weight at the same time. ;-)

BTH

I doubt you will notice any power gains at all, 1HP = 746(?)watts or thereabout, so that would be around 62A@12v I highly doubt you constntly pull 62 amps from the alterntor :)

([#5](#))

by jubalearly on Wed Oct 8th, 2003 at 09:44:03 AM MST

([User Info](#))

Automobile alternators are only about 60% efficient at full load. At lower loads it is even less efficient because the rotor current doesn't drop off much. I figure rotor current at about 10% of output between 50% and 100% output. Below 50% load I just figure 5 amps rotor current. So changing to permanent magnets gives you 5-10 amps FREE energy! (this is the only kind of free energy I believe in).

Re: How efficient is an auto alternator? ([none / 0](#))

([#6](#))

by zmoz on Wed Oct 8th, 2003 at 11:53:08 AM MST

([User Info](#))

Geez...I thought it would be alot better than 60%! That really could make a big difference for me, I have replaced my belt driven fan with an electric one, so that puts more load on the alternator at all times than usual.

Re: How efficient is an auto alternator? ([none / 0](#)) ([#11](#))

by jubalearly on Thu Oct 9th, 2003 at 01:39:49 PM MST

([User Info](#))

What's your worry? Are you looking for better gas mileage or more power? You aren't going to gain enough to make turning the alternator off worthwhile.

The new car designs (2005? 2006?) are supposed to gain about 8% by turning the entire engine off while sitting at a red light (and other methods). They will have more efficient alternators - mostly so that they can get more power for electrical goodies.

The .6 efficiencies includes friction & windage, core, and winding losses in the alternator but not belt losses:

$$\begin{aligned} 105 \text{ amps} \times 14\text{v} &= 1470 \text{ watts} \\ 1470 / 746 &= 1.97\text{HP} \\ 1.97\text{HP} / .60 &= 3.28\text{HP} \end{aligned}$$

The above are assuming the maximum output for (assumed) 105a alternator. Belt losses would put you a little over 4HP.

But you are not likely to require full output. Also, your electric fan doesn't run all of the time, assuming you have a thermostat on it. Even so it probably takes  $13.8\text{v} \times 20\text{a} = 276\text{w}$ , or about .37HP compared to 6-10HP for a belt driven fan. You can save more HP just by correctly adjusting the air in your tires.

You have to make all kinds of assumptions to estimate fuel mileage based on a HP savings. Using .5lb. fuel per HP per hr., 4HP works out to .4 gal/hr. At 60 MPH that would mean you went 60 miles using .4 gal. So you would be saving between 1/10th - 1/8th mpg by eliminating this load. And you still have to charge the battery, somehow, sometime.

Re: How efficient is an auto alternator?  
([none / 0](#)) ([#13](#))  
by zmoz on Thu Oct 9th, 2003 at 05:18:16 PM MST  
([User Info](#))

I'm not doing this for fuel mileage. As I said below, the engine is already modified in alot of other ways and is going to be even further. Every little bit of HP helps. It's not like I'm going to be driving around like this, it's only going to be for starting off at a light or doing a 1/4 mile run. Also, my electric fan runs at all times.

Back when I was much younger - and a dollar would buy about 4 gallons of gas, someone decided they would put a cut-off switch on the A/C hooked to the vacuum of the engine. This was quite an engine. And, with the roller-cam, did not find 9k RPM an unusual sight. BTW, \$0.09 of that 4 for a \$1 gas was tax.

As I remember, the run was over when the vacuum switch allowed the AC to come back on. However, parts not designed for the operation made new ventilation openings on the hood. This also mandated replacement of many parts associated with the accessory options on the vehicle. We never found out how much time was cutoff of a 1/4 mile by this method.

It was amusing - IF you were not the one paying for the repairs.

Ron

PS: Thanks for the memory jog...

Re: How efficient is an auto alternator? ([none / 0](#)) (#8)  
by Demetri ([corvettemach1@yahoo.com](mailto:corvettemach1@yahoo.com)) on Wed Oct 8th, 2003 at 09:26:18 PM MST  
([User Info](#))

From what I understand, most of the power lost to an alternator (when not under heavy load) is in the friction of the belt driving the thing, even if you have a serpentine belt. I think you'd find that your ignition runs so much better on the full 14.7 volts vs. 12.7 that the extra power loss is worth the problem. Then again, there are dragsters that don't have alternators nor magneto ignitions, and do just fine. I'd look somewhere else to free up power. And even easier than freeing up or creating power is reducing weight..... What kind of vehicle?

Demetri

by troy on Thu Oct 9th, 2003 at 12:41:52 PM MST  
([User Info](#))

Some time ago, I think www.homepower.com ran a short article about a woman who unhooked her alternator completely and screwed one of those flexible solar panels to the roof. She didn't do a lot of night driving so headlights weren't a concern, and if memory serves me correctly, she gained 3 mpg.

Best regards,

troy

This is in a Jeep Cherokee...and I'm in the process of alot of other mods as well. Stroked to 4.7 liters from the original 4, headers, lots of porting, ect. There might be a supercharger sometime in the future too. :) When I'm done I should be able to blow the doors off of a stock sports car and get ~26mpg, with a vehicle weighing 2 tons and having the aerodynamics of a bus.

In this set up I'd use a Bridge Rectifier before it goes into the Caps. That way you are sure you have all positive going waveforms going into the caps so you can use big honking Electrolytic Caps without fear of them exploding, and you've got an AC genny there so a blocking diode would waste half your voltage. A bridge will flip the negative half-cycle over to positive for you and can then be used for charging as well.

Blocking didoes only work well on DC set-ups, and you should always use one to protect your electronics.

Cya,  
Chris

[Wind](#)

[not smooth](#)

Been working flat out, or as much as allowed on my latest wind genny which is a motor conversion (induction). I have just got it flying today and it works fairly well considering i used ceramic magnets. But heres the big question, im using a analogue amp meter of an old battery charger. When i had my first genny up the needle would rise and fall according wind speed but now with this latest genny the needle appears to vibrate or bounce, i would say more like vibrate. Now im thinking its down to the fact that this genny hits charging voltage almost as soon as it starts to spin and its pulsing dc at its very worst. Its a 2 phase motor start and run and ive tryed both windings on there own and its still has that vibration look to the meter. Would i be better trying a faster better prop or using capacitors to smooth the dc out? Any comments mucho aprecitado, the motor is on my site under wind but it aint updated just yet thats to come.....sean

I looked at your pictures and I thing the think going on here is that 4 magnets is not enough. You have got two sets of windings, but they deliver different voltages at the same speed so when the magnetic field has passed away from one set of windings and is approaching the other the voltage does not rise as high so you get a dip in your meter then it goes back up when it reaches the high windings again. Your meter is not fast as that happens but does show it. I say hell, take out the armature, cut 4 more slots into it, fill them with magnets, and then your frequency should be fast enough your meter will not show it. The advantage is you get more power. if you do not want to do that then I say capacitors, lots and lots of capacitors, or a big in-line inductor.

Cya,  
Chris

I suspect that the out put frequency from your new generator is higher that that from the old one and the meter is reflecting that. try a filter or smoothing capacitor on the generator out put before it goes through the meter ( select one that is at least twice the voltage that will be delivered from the genny). For example 1000 Uf at 50 volts if the genny puts out 24V tops. If you have to fudge things always fudge up in value not down, so that in this example a 100 volt capacitor would be a better choice than a 35 volter.

Dr.D

Re: not smooth ([none / 0](#)) (#7)  
by jubalearly on Mon Sep 22nd, 2003 at 09:30:32 AM MST  
([User Info](#))

I think you would be pleasantly surprised how much even a small capacitor would improve your output. Rule of thumb is about 1000 microfarads per amp output. But even a couple of hundred mf will work noticeably better. If you look at an AC waveform (sinewave) you will see that it spends a lot of time lower than the charging voltage.

A capacitor will hold the voltage up for at least part of that time and increase the charging at NO COST. Well, actually it tends to pull the peak voltage down, but that usually doesn't hurt anything. Adding an 880uf capacitor to a battery charger usually makes it charge at about 130%, or about 3 hours instead of 4, in my experience.....

Alcohol non-toxic? Why don't you just dump big bricks of salt in there?

Just because it's non-toxic, doesn't stop it from being a total environmental disaster.

The air bubble thing might work. It's been known to keep harbours ice free and things like that, but it's only going to work if the stream is fast enough not to freeze solid.

Cya,  
Chris

I have an azimuth tray on a small tower for a large 8' satellite dish (you know the old big ones sold by Channel master). This could be used if you were to build some controller hardware. I was originally planning to use this for 4 120W Kyocera panels I have. I was thinking I could even use the original actuator. All I would have to do is make it follow the sun and reset to its original position at night. This can be done by using photo transistors placed inside of a tube as to only make the sensor receive light when its actually pointed at the sun +/- 15 degrees. If you place one sensor on either side of the panels, A comparator can be used to control the circuitry to move the actuator until both sensors have an equal amount of light hitting them (the panels then would be pointed into the sun directly. The circuitry would have to know when one sensor loses light to move the panel again to equalize the light and keep it facing the sun. This happens over and over again throughout the day till the sun sets and then when there is no more light hitting the sensors, it will reset the actuator to its starting location for the next morning. This is just a thought. :-) have fun!!

RoyR

I would think it would be more cost effective to make it time based....

But to make it track the sun.. i use this on my setup  
<http://www.redrok.com/electron.htm#paypalled3kitus>

takes a bit of tinkering to gt it to work properly... bu tit does work for me.

Re: Solar Tracker Homebrew ([none / 0](#)) ([#4](#))  
by hydrosun on Wed Aug 6th, 2003 at 10:18:13 PM MST  
([User Info](#))

I once used a car window motor to turn the platform for my solar cooker. I rigged a circuit with two photo diodes and the comparitor was a 555 chip which turned on for 1/2 second and moved the platform toward the west. It would stop until triggered again when the sun had move far enough. I had a switch that hit part of the frame at the farthest limit, that shut off the circuit. I had to manually reset it to the east for the next morning. I could have eventually work out a time delay after the switch was triggered for it to automatically turn to the east.

I'm now using the redrok.com circuit to move my solar array. After the original actuator from a satellite dish froze up I bought a replacement on ebay for \$46 including shipping. It's working fine. I've set up an identical system for someone else. The reason I went with this circuit instead of my own is this has the automatic return to the east and for \$36 it's not worth my time to try to replicate.

[formatted re-post of more on ferrous cores...](#) | 10 comments (10 topical, editorial)

Re: formatted re-post of more on ferrous cores...  
 (none / 0) (#9)  
 by Jerry on Sat Jan 3rd, 2004 at 10:09:42 PM MST  
 (User Info) <http://www.dplusv.com/Photo-03.html>

Ok guys now you've went a done it again. And just when I thought i had to many ideas and projects you go and add another one. This board is addictive and dangerus. OK so heres my next progect idea. My brother use to work for Mead paper Corp. you know those folks that make spieral note books and stuff like that. He use to bring me large carboard tubes. We make sub woofer inclosers at the car stereo store. Some of these tubes still had a very nice varnish coated soft steel wire they used to make the spiroll spring things. However its nice and straight on these big rolls. I still have a few 100 feet. Magnets realy like this stuff. So I'm going to wind some coils with copper and this stuff in perelell. I have a zilion speaker magnets so I'll wind the coils same size and shape as the speaker magnets. This will get the magnets very close to the laminations (Mead wire) and copper coils at the same time. Very small gap. Thanks so much for this idea. I guess better get ahold of Mead or = to see about more of the soft and candy coated steel wire? JK TAS Jerry

Re: formatted re-post of more on ferrous cores... (none / 0) (#10)  
 by bill541 on Sun Jan 4th, 2004 at 07:16:41 PM MST  
 (User Info)

I would have to agree with Ed on this one. The steel wire will make an inductor, not unlike your copper wire does. This steel inductor will have voltage induced on it, so it must be insulated from itself just as the copper magnet wire is. If you could wind a full layer of the steel wire and bond it to itself so that it did not form and inductor, then I think you would get it to work. Otherwise it should be insulated steel wire. You may be able to wind the coil so that the copper insulated wire always keeps the steel wire separated, but you would need to put a layer of insulating material between each winding layer... Just my thoughts, Bill

Ok guys now you've went a done it again. And just when I thought i had to many ideas and projects you go and add another one. This board is addictive and dangerus. OK so heres my next progect idea. My brother use to work for Mead paper Corp. you know those folks that make spieral note books and stuff like that. He use to bring me large carboard tubes. We make sub woofer inclosers at the car stereo store. Some of these tubes still had a very nice varnish coated soft steel wire they used to make the spiroll spring things. However its nice and straight on these big rolls. I still have a few 100 feet. Magnets realy like this stuff. So I'm going to wind some coils with copper and this stuff in perelell. I have a zilion speaker magnets so I'll wind the coils same size and shape as the speaker magnets. This will get the magnets very close to the laminations (Mead wire) and copper coils at the same time. Very small gap. Thanks so much for this idea. I guess better get ahold of Mead or = to see about more of the soft and candy coated steel wire? JK TAS Jerry

PS. Thanks to Reno, Bsparky and Dualsporter I didn't mean to not thank you guys to. And another ? for you guys. I use an audio generator at work. These things are small and work from 9 v to 15 v. They have square, tryangle and sign wave output from 1 HZ to 1 meg HZ. I guess that would be 60 pulses per min. Could I use this unit to sequence the FETs instead of the 30 pulses per min. flasher unit. You know make this hole thing solid state? JK TAS Jerry

Thanks Budgreen. I'm using a 13.8 volt 3 amp regulated power supply to supply power for the 12 volt flasher unit and the Bosch relay. I would very much like to remove the Bosch relay and replace it with an FET. What FET would I use if I increase voltage to 100 and amperge to 50? Or is that combination not doable or recimended? I did the load test on the battery today. Its a 10 second test and the tester said the battery is a good 770 cold cranking battery. I was surprizes because Optima calls this battery a 750 CCA battery. And this was after burning the end off that old screwdriver a few times. (REDNECK battery tester burning the end off old screwdrivers.) Looking forward to the schimatic. I'll try to hook up the 100 amp relays inplace of the 40 amp Bosch tommorow. This will be to see if I can bring the other Optima battery back to life. Thanks again Budgreen and Charged. You guys are an insperation. JK TAS Jerry

Hi Dualsporter I'm not sure if gell batteries have sludge that settels to the bottom. I've opened one up and the gell guu stuff seems prety stiff. I has a pie dough consistancy but its almost clear. Can't see how much stteling could happin? This is 24 hrs latter and the voltage is still 12.6 v and it still burns the end off the old screwdriver. I hope this works this good on the other battery. JK TAS Jerry

Sorry if I left that out Bob. The power supply is 21 volts DC. I'll be trying higher voltage caps and higher power supply voltage. But first i must upgrade the relays. JK TAS  
Jerry

At 21v you're at just about optimum. For desulfating you can use smaller capacitors at higher voltage(100v) for short periods. This "cracks" the sulfate barrier. THEN you discharge to help dissolve the crystals in an orderly manner. Once you fully discharge, then start applying you're standard 21v pulsing.

You might want to build a dedicated charger with two voltage settings specifically for desulfating/reclaiming old batteries. That way you can scavenge batteries here and there and see if they'll come back to life. Some will, some won't, so what.

Hi John. Could you describe your blades. Size at the root, size at the tip, any twist, how thick, profile, cup, leading edge, degrees of attack tip and root, trailing edge and how many? I've not built a working disc genny yet. Although I've started a couple. I have mostly been doing AC motor conversions. I have seen 1200 watts from my 22 inch plastic blades (49 inches tip to tip) so at least that part is similar to yours? JK TAS Jerry

 ([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Reno Yep this is just playing with caps for fun. Since I have a zillion caps I'll be trying higher voltages and higher UF also. What I really need to do is get the solid state swiching thing working. But I like the idea of charging the caps to 20 to 60 volts or higher and then dumping that voltage onto the 12 volt batteries. I guess you could do the same with 24v or 48v also. The battery never got even slightly warm and the charger stayed prety cool also. The caps were cold. I think however the relay was taking a beeting. This is were solid state swiching would help. Reno your right about helping the genny in low wind. And then maybe swich over to normal genny operation when the wind speed gose up? Atleast this will help the genny to make some power in low wind. JK TAS Jerry

Re: 144,000 pulses and counting. ([none / 0](#)) (#8)  
 by dualsporter on Fri Jan 2nd, 2004 at 12:15:23 AM MST  
 ([User Info](#))

Experimenting for fun is good. Pulse circuits are very entertaining. In your case it sounds like you have all the parts setting around which is the perfect situation for playing with an idea any time you want. That's got to be great. I don't have enough room to be able to collect much "stuff".

The life expectancy of any component (relay, SCR, etc.) is directly related to loading. The more energy it has to move, the shorter it's life. (The candle that burns twice as bright, burns half as long.) Things also pretty much work the other way around too. If a component is surviving well beyond it's rated life, then it's not being required to move a heavy energy load. It's also possible you just have a very good quality relay that has not yet met it's rated life expectancy.

Designing and building a circuit to last for 40 years of non-stop operation is not a problem as long as it is designed with an appropriate margin of safety for the components.

The interesting question is how well this circuit

transfers energy from your mill as compared to just running a heavy cable and sending low voltage.

A standard heavy copper cable system is somewhat expensive. For that reason, if the pulse concept only moves energy, maybe 2/3 as efficiently as copper cable, it might still have merit because of the comparative prices of the two systems. That's why knowing how well the pulse system transfers energy is the key bit of information someone needs to have before deciding whether it is worth investing in for their final, permanent system.

Also knowing the circuit's efficiency is what tells you if it's worth investing in even for a "starter" circuit for your mill. (followed by switching over to standard cables when wind speed is up) The fact that it's not loading your mill and allowing it to start up in low wind should be telling you something. (The loading on the mill is a direct relationship to how much energy it's trying to move.) "Does the little bit of energy it moves in a low wind condition justify purchasing the parts required?" Also, if it's not loading the mill significantly in lower wind conditions it probably won't in higher wind conditions either setting you up for a runaway self-destruct.

Regarding pulse charging your batteries... Pulse charging borderline batteries does rejuvenate them somewhat. The higher voltage spikes blast the sulfate bridges shorting the plates together. These sulfate bridges form in the sulfate sludge at the bottom of the battery that forms when they are allowed to set uncharged for extended periods of time. The bridges will begin to set up again within a short period of time because the pulse charge does not destroy the sulfate. It just moves it temporarily. It's possible, if you could remove the sludge layer, your battery's life would be pretty much restored.

For all experiments, if it was fun, it was worth the investment.

Dualsporter

Hi Dualsporter I'm not sure if gell batteries have sludge that settels to the bottom. I've opened one up and the gell guu stuff seems prety stiff. I has a pie dough consistancy but its almost clear. Can't see how much stteling could happin? This is 24 hrs latter and the voltage is still 12.6 v and it still burns the end off the old screwdriver. I hope this works this good on the other battery. JK TAS Jerry

Hi Reno Yep this is just playing with caps for fun. Since I have a zillion caps I'll be trying higher voltages and higher UF also. What I really need to do is get the solid state swiching thing working. But I like the idea of charging the caps to 20 to 60 volts or higher and then dumping that voltage onto the 12 volt batteries. I guess you could do the same with 24v or 48v also. The battery never got even slightly warm and the charger stayed pretty cool also. The caps were cold. I think however the relay was taking a beating. This is were solid state swiching would help. Reno your right about helping the genny in low wind. And then maybe swich over to normal genny operation when the wind speed gose up? Atleast this will help the genny to make some power in low wind. JK TAS Jerry

The 80 hr test was for Relay longevity. I wanted to see how the relays held up in continuous duty. Also the battery I was charging appeared to be no good. That is after charging it in a normal fashion it would lose voltage in just a few hrs. Its been holding 12.67 for 1 1/2 days now. I haven't done a load test yet. But it did burn the end off an old screw driver and after a short time the voltage was still at 12.6. I don't know what the pulse charging did but the battery seems to be back to full capacity. I have a 125 amp load tester at the store shop so I'll load it down tomorrow and see if the battery is still good. I hooked up the other battery it was worse than I thought. It was down to 2.5 volts and the 40 Bosch relay stop working after a couple hrs. I'm going to replace the Bosch with some 100 amp relays and place some 2 uf/ 400 volt mylar caps across their terminals to stop the arcing and pitting. I'll see how long they last. If they hold up this system might just bring this other battery back to life also. Hey Charged could you explain again how this pulse charge helped this otherwise junk battery? If it did? Or maybe this battery wasn't junk? I da no? I guess I'll find out with the really dead battery? JK TAS Jerry

Jerry about the supply voltage ac or dc? Look for it on your Cap pulse testing posting. Maybe I've miss it.  
 Bob

Sorry if I left that out Bob. The power supply is 21 volts DC. I'll be trying higher voltage caps and higher power supply voltage. But first i must upgrade the relays. JK TAS Jerry

At 21v you're at just about optimum. For desulfating you can use smaller capacitors at higher voltage(100v) for short periods. This "cracks" the sulfate barrier. THEN you discharge to help dissolve the crystals in an orderly manner. Once you fully discharge, then start applying you're standard 21v pulsing.

You might want to build a dedicated charger with two voltage settings specifically for desulfating/reclaiming old batteries. That way you can scavenge batteries here and there and see if they'll come back to life. Some will, some won't, so what.

Re: My Mini Geni isn't working very good ([none / 0](#)) (#14)

by Jerry on Wed Dec 31st, 2003 at 08:30:03 AM MST ([User Info](#)) <http://www.dplusv.com/Photo-03.html>

I did 6 of the little Ed/Windstuff magnets on a smaller version of this motor. Didn't change a thing but machined the armature down to fit the magnets.

It dose cog hard but I'm seeing 60 watts at 500 rpm. Just try getting 60 watts from a solar panel for 6 bux.

Hi Bill

Very nice drawing. It looks as though this design would reduce cogging a bunch.

I'm not sure what effects there would be on flux path or efficiencies? your drawing is now resembling an ac motor. Coils and narrow slots. Very efficient and reduces cogging. But dose away the need for curved magnets.

I do hope you build and test your idea. JK TAS Jerry

I guess next time I test I should use the peak hold button?  
I was in a hurry last night. The desulphating thing sounds like another plus.

I'm thinking this system may help low powered gennies or gennies that have low wind startup problems?

peak hold feature would just lock the highest reading on the screen :)

this would be like a sample system that keeps a running check of the voltage peaks

Ed,  
Thanks again for all the help. I'll start crunching some numbers and post my results to further narrow in on the blade design. I sure appreciate all the trial & error out there behind your experience that has saved me much time. Believe me if I had the time I would like nothing more than to help pave the way for others through experimenting. I'll keep in mind you will have the steel also, I'm already thinking about maybe bigger and better, that's what happens when you're addicted. Thanks, Dave B.

PS and you want to talk about narrow gap. I set my gap at 1/16 inch but it could be 1/32 inch. Because of the motor lamination efficiency I've done 1/2 inch gaps with surprizing output.

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

The only problem I see is sevier cogging. When the magnet is centered over the steel spool it will be very hard to move it.

This is a very efficient way though to increase magnetic flux through the coils. This is why I prefur ac motor conversion. The ac motors I most commonly convert have 36 slots so its very easy to move the magnets past these narrow slots. AND you want to talk about awsome laminations. Motors have the best steel lamination posable and your coils are allready wound.

Some people say the small diameter of the motor is a limiting factor but as deminstrated above the increased output more than compensates for this. This is why I see charging start at 5 mph on motor conversions whith 49 inch tip to tip blades.

WE gave up on the curved neo,s way to soon. JK TAS Jerry

Re: Miniature Axial Flux Generator Experiments ([none / 0](#)) (#10)  
by bill541 on Sun Dec 28th, 2003 at 05:12:07 PM MST  
([User Info](#))

Thanks Jerry,

I didn't really think about cogging being much of a problem, but it sure could be in low winds. It might turn into a magnetic brake of sorts.

What do you think of the following solution? The red indicates more ferrous material.

By providing a few more paths for the flux when the cores are off center of the magnets, wouldn't this smooth things out? The trick would be to balance the flux out so that there was an even pull at every degree of rotation.

This may be easier to provide on a rectangular magnet set up. This way you would only need pie shaped pieces around the perimeter.

-Bill-

Hi Bill

Very nice drawing. It looks as though this design would reduce cogging a bunch.

I'm not sure what effects there would be on flux path or efficiencies? your drawing is now resembling an ac motor. Coils and narrow slots. Very efficient and reduces cogging But dose away the need for curved magnets.

I do hope you build and test your idea. JK

([User Info](#))

To smooth things out use a gap in the spacing of one magnet or use an odd number of magnets.  
This looks very much like a standard alternator with the exception of the ferrites.  
RobD

Hi Charged and all happy holidays.

Charged what would be a recommended value for the diode across the caps and the polarity of the diode in relation to the caps. I'm referring to the shottky across each 1 farad cap.

Speaking of caps I took a brief inventory of some of my caps. These were the caps that I could reach or find in my messy shop without renting a backhoe to dig them out.

Cap value in UF price each	voltage/surge V.	count	
2,200 uf	400v/475v	1	\$10
400 uf	350v/v?	1	\$10
60 uf	350v/v?	12	\$1
100 uf	350v/v?	9	\$1
4,500 uf \$6.50	200v/250v	4	
2,000 uf	200v/250v	14	\$5
1,400 uf	200v/v?	1	\$3
1,000 uf \$2.50	200v/v?	4	
640 uf	200v/v?	3	\$2
500 uf	200v/v?	2	\$2
7,300 uf \$6.50	150v/175v	4	
1000 uf	150v/v?	14	\$3
15,000 uf \$7.50	100v/v?	240	
40,000 uf \$10	90v/110v	40	
26,000 uf	75v/95v	40	\$10
12,000 uf \$6.50	75v/100v	10	

This is a sample list I have many more in voltage down to 6.3v and uf from a few 100 to 650,000 uf plus the 1 farad 24v special at \$59.95. Some of these are take outs and

Hi Hank  
Well it took me 2 days but I got the 200 lb genny in the test truck.  
That was a scary addventure?

Charging started at 10 mph at 5 amps, at 15 it hit 10 amps at 25 mph the amp meter was showing 20 amps.

The blade was a littel out of balance so i'm going to try a diferant blade.  
This blade was my plastic blades at 5 1/2 ft tip to tip.

I'm going to try a smaller blade. One of my 49 inchers.  
Thanks for your help I'll keep working on it.

[pipe genny with servo motor](#) | 4 comments (4 topical, 0 editorial)

Re: pipe genny with servo motor ([none / 0](#)) ([#1](#))  
by Jerry on Wed Dec 17th, 2003 at 08:57:28 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Bill

Looks like a real hevvy duty genny do you know how much it weighs?

I used the same motor to build a genny for a sail boat. I think this guy was crazy cause the sail boat was small and he was sailing from Oregon to Mexico.

I built him the genny. It weighed 24 lbs. He returned and said it was too heavy for his small sail boat. I'm thinking your going out in the ocean and a 24 lb genny is too heavy. I wouldn't go any where in that boat and for sure not to sea.

So I did my best to lightin it up. It ended up at 18 lbs and pretty rugged too.

I used 2 of my Jerry blades 49 inches tip to tip. These blades are \$15 each. They weigh 9 oz. each. plus homemade hub and yaw system. The blades handled 68 mph winds just fine. No furling on this genny. In high winds its making over 360 watts and seems to work great.

I'm flying 3 of these small gennies on my shop. They sure are cheap and easy.

All the yaw and tail boom and wing stuff was less than \$25 and light as a feather.

Since this genny is so light I fly them on 1.5" EMT electrical conduit. The big box home improvement stores sell this conduit for around \$7 for a 10 ft pice.

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Bill

Looks like a real hevvy duty genny do you know how much it weighs?

I used the same motor to build a genny for a sail boat. I think this guy was crazy cause the sail boat was small and he was sailing from Oregon to Mexico.

I built him the genny. It weighed 24 lbs. He returned and said it was too heavy for his small sail boat. I'm thinking your going out in the ocean and a 24 lb genny is too heavy. I wouldn't go any where in that boat and for sure not to sea.

So I did my best to lightin it up. It ended up at 18 lbs and pretty rugged too.

I used 2 of my Jerry blades 49 inches tip to tip. These blades are \$15 each. They weigh 9 oz. each. plus homemade hub and yaw system. The blades handled 68 mph winds just fine. No furling on this genny. In high winds its making over 360 watts and seems to work great.

I'm flying 3 of these small gennies on my shop. They sure are cheap and easy.

All the yaw and tail boom and wing stuff was less than \$25 and light as a feather.

Since this genny is so light I fly them on 1.5" EMT electrical conduit. The big box home improvement stores sell this conduit for around \$7 for a 10 ft piece.

Hi Charged YoudaMan

The 1 puls per second sound great for a manual relay swither im going to try.

We sell a heavy duty electronic flasher that is progarable for 1 puls per second or 1 puls every 2 seconds. It draws very little curent and I may either use it to trip larger relays or solid state devices. Just expirementing here?

Re: Question for Charged. ([none / 0](#)) ([#9](#))  
by Budgreen on Thu Dec 18th, 2003 at 06:42:49 AM MST  
([User Info](#))

if you are going to 1 pulse per second, do not use a relay, they do have ratings such as 1,000,000 cycles at half load or similar, if you discharge a cap through it I can gaurentee that it will not last, you will end up with melted,fused,or burnt contacts.

I would suggest setting up your pulsing circuit to trigger a FET to dump the load. these are usually very cheap, last quite awhile and can be paralleled quite easily.

Hi Bob  
The price all depends on the UF and voltage of the caps.

To day we got a deal and here it is.

20 volt with 24 volt surge 1 farrad caps \$59.95 plus shipping and hadeling.

This as thet say while supply last. If you don't mind these are a kinda pail yellow and if you don't like the color just peal of the plastic jacket and they are aluminum color.

Just let me know the UF/volt rating you want and I'll get you the price. I have many big caps starting at \$5.

PS.  
Another thought I had has to do with the curved neo magnets. You told Norm to use magnets of the same pole.

AC motor conversion consideration?

The old #29 curved neo is hard to find in NS pairs but they are still available ungaranteed pairs. This means if you buy 10 they may all be Ns. With the system you've discribed this would not matter. You could treet each pole as an indeividual coil and puls charge caps from each pole. Or would the common lamination of the poles cause phase cancelation? More thinking?

Hey Dave  
Have you ever built a 12 per octive 5k hi pass exover for tweeters plus a small incandesent lightbulb in siries with the + input side of the exover.

We build and sell these at my car stereo store. Primarily for our more out of control customers.

This crossover format is also used comercially but we prefur to build our own.  
The addition of the bulb deals nicely with exssesive power and distortion very nicely with no colorization or SQ degridation. In short save your tweeters but and sounds good to.

Jerry,  
I built small 2 ways (5" full range & 1" soft dome tweeters) sealed enclosures 20 years ago that used moocho power to sound great so I designed a very small pc board that was a single LED used as an adjustable peak power indicator. This was for show and/or as a warning to blowing things up depending on the level it was set. This was a simple rectifier, transistor, pot, LED circuit and was mounted behind the grille with just the LED showing. Many of these are still cranking in bars and cars (pat on the back). The attached photo shows my variable 12db-6db 2 or 3 way crossover. It has independent driver control and A-B comparison of 2 separate crossovers dialed in. I personalized alot of older speaker sysyems with this for those tired or worn out rock & roll ears out there and if out of the tweaking range it's pretty easy to customize new systems so there is headroom in the upper and lower range depending on the

Hey Thanks Ed.

I built a small lamination wyinding machine. There are 3 spools. 1 to supply the lamination (plummers tape), 1 to supply masking tape and the 3rd to roll these 2 up on.

I do have lots of the glue at the stereo shop. May try that next time?

[Help with Alternator modification](#) | 9 comments (9 topical, editorial)

Re: Help with Alternator modification ([none / 0](#)) ([#8](#))  
by Jerry on Mon Dec 15th, 2003 at 11:08:02 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

I have 4 of the TDMs flying using my blades. The most I've seen from these gennies is 364 watts each. This was in a very strong wind. However my \$550 SW-403 is rated 400 watts at 28.8 mph.

My 4 TDM gennies cost me \$200 to totally equip and fly produce 850 watts at 28.8 mph and they start charging at 5 mph and never make any noise. My 403 starts at 13 mph and is very noisy.

The most I've seen out of the 403 is 600 watts at 50 mph. These TDM gennies will poroduce almost 1500 watts under those coditions.

What I'm saying is don't overlook the TDM genny

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

I have 4 of the TDMs flying using my blades. The most I've seen from these gennies is 364 watts each. This was in a very strong wind. However my \$550 SW-403 is rated 400 watts at 28.8 mph.

My 4 TDM gennies cost me \$200 to totally equip and fly produce 850 watts at 28.8 mph and they start charging at 5 mph and never make any noise. My 403 starts at 13 mph and is very noisy.

The most I've seen out of the 403 is 600 watts at 50 mph. These TDM gennies will produce almost 1500 watts under those conditions.

What I'm saying is don't overlook the TDM genny

[Alternators](#)

No Juice from my alternator

Hello,  
This is my first post to this board. I'm sure you guys are going to have my answer.

I'm building a gennie.

I have purchased an alternator on ebay for my prototypes.  
I'm getting no juice.

<http://cgi.ebay.com/ebaymotors/ws/eBayISAPI.dll?ViewItem&item=2446139113>

It has four connections on the back a)ground b)positive and c,d)a two prong connector.

From what I've read on this board I need to supply 12v to the two prong connector to charge the windings. Is this correct?

The posts I have read however say I have to do this to an unmodified alternator. So How do I modify/override it to not need this 12v. at the prongs.

Thanks in advance  
Steve

([User Info](#))

First of all an auto alternator is a less than ideal device to use for a wind system as they generally require a very high RPM to deliver any usable power, this leads to belts, pulleys and such complicating the device and reducing efficiency. That being said an auto alternator requires that the field coil ( on the armature) to be "excited" by a DC voltage from a regulator. The regulator is also connected to the main 12 buss from the alternators output to the battery. It provides a start up voltage to the field coil so the alternators start to produce an out put. when that output reaches a predetermined voltage ( generally about 13.8 V) the current to the field is leveled off so as to keep the the output constant ( in theory), in reality the voltage may reach 18 V in the typical vehicle. Many of the folks here have replaced the field coil and field poles with Neodymium magnets so as to eliminate the whole coil/ regulator issue. Some even go so far as to rewind the 3 phase stator coils to produce a higher voltage output at lower speed. I know that this doesn't solve the problem but at least you know your options.

Dr.D

Thanks for the response,

I've been trying to keep my costs down and thus bought this \$10 alternator.

Problem is I have a room full of cheap stuff, alternators, 8ft wind mills, Bike dynamos of all flavors and ages, whirlygigs, ceramic and neodymium magnets (having a blast with the neo's buy the way). Looks like I've spent \$100+ on garbage.

What should I be using? I don't have the patience or the expertese to actually build and alternator. I bought the Neo's for perpetually motion experiments, or at least 99% efficiency. (We'll See, HA HA)

How about the Ametek's tape drive motors I see on Ebay all the time.

I'm sure your going to laugh but I have a ceiling fan bolted onto and alternator outside and have attached the 8ft windmill blades as well. Its a Blazing NewEngland winter outside and its holding up, but no Juice and many wasted hours from what your telling me. (yes I know, I'll probably be pulling one of these blade out of my neighbors windows tomorrow).

Back to the topic, What should I invest in for a Motor/ Generator/ Dynamo.

Thanks Again.

Steve

P.S.

On The Lighter side

Have you guys seen this page, from what I've read on this board your gonna love it.

The Museum of Unworkable Devices

([User Info](#))

The tape drive motors are an excellent way to get started, so much is already done for you. Basically just add blades and a yaw bearing. In fact my first one is is a TDM which I'm trying to finish up, and get flying soon. I can highly recommend Jerrys blades, you can't beat the price \$10.00 each or \$15 for the modded units.

Don't through out your treasure yet, you may yet find a use for some of it.

Dr.D

This might help you to understand the difficulties you might encounter with modifying an alternator....[http://www.windstuffnow.com/main/gm\\_alt\\_mod.htm](http://www.windstuffnow.com/main/gm_alt_mod.htm) to get juice from your alternator in its present state you have to connect the + wire to the field now when you turn the alternator the slight residual magnetism will cause it to gradually self-excite the field (this may or may not work with yours) if this doesn't work someone on the board does know exactly what you have and how to hook it up. Also as it is some individuals take the simplest way out and employ a chain drive to gear it up. Good luck with your project you're starting out on a fun filled adventure! Norm.

Amazed,  
Aside from the useful info, this looks almost exactly like the alternator I  
have.  
I knew I cam to the right place.  
Thanks,  
Steve

Take a look at the technical articles on this page:

<http://www.duboismarketing.com/>

This looks like one of the older Delco alternators & should be just like the 37 amp one on the otherpower page. I believe this style went up to 55 amps, then the newer 10SI (internal regulator) went up to 65 amps, IIRC. But most of the parts will interchange.

Hi Bob

I've mentioned here B-4 that I will sell you guys car stereo stuff cheaper. This is easy for me since I've owned and operated my own store since 1986. I started as an installer in 1976 I've been involved with audio & electronics since 1958.

Now that I've patted myself on the back heres the deal. That \$180 1 farrad cap you mentioned. I'll sell that to my wind freinds here for \$75 + shipping & hadling.

Plus I have I have a 1000 or 2 of caps with voltages and UFs all over the map. Many of these start at \$5 depending on UF and voltage rating. All or computer grade, many are take outs.

Thanks Zubbly  
I understand the time thing. It is a raer commodity. I think the text is still there where you originally posted it. I will refer to it when I try this magnet style of motor conversion.

Again thanks very much for taking the time. Right now I'm winding coils for my small disc alt. 100 turns of #20 wire on a 1/2 X 1 inch form to match the 12 small neos I'm using. I'm using unmodifide plumers tape as lamination. Disc is 5 inches in dia.

I don't expect much from this little alt all though I would like to see 100 watts at least. Maybe around 750 rpm?

Now I'm speculating on how to glue down the laminations?

I'll post after testing this little toy. JK TAS Jerry

[quote]"Now I'm speculating on how to glue down the laminations?"

Try spraying both sides of the metal strip with spray-on contact cement. It insulates the laminations as well as holding them together.

Electric Ed

Hey Thanks Ed.

I built a small lamination wyinding machine.  
There are 3 spools. 1 to supply the lamination  
(plummers tape), 1 to supply masking tape and  
the 3rd to roll these 2 up on.

I do have lots of the glue at the stereo shop.  
May try that next time?

JK TAS Jerry

### [Switching power supply experiment.](#)

By [Jerry](#), Section [Homebrewed Electricity](#)

Posted on Sun Dec 7th, 2003 at 11:15:08 PM MST [Alternators](#)

Pedle power + shiching supply voltage range test.

This idea was kicked around here a while back. I don't think anyone has tryed it yet?  
I did tonight.

Varible voltage source, pedle powered pma. This pma is a 3/4 hp, 1075 rpm, 6 pole, 120 volt ac, 10 amp furnace blower motor. It has been fitted with 6 old # 29 curved neo magnets. This unit has done 1200 watts as a wind genny but not on the exersize bike.

I've hit about 150 watts on the bike. No load I can pedle 0 to 160 volts. Did a 142 volts with a 100 watt light bulb. My grandson was pedling today and we drilled a 1/2 hole in a pice of 3/4 in. plywood with a big 1/2 drill plugged into the bike.

Tonights expirement was with a high speed switching power supply. I purchased this supply from All Electronics for \$8.50. It has 3 voltage outputs.

- 3. volts at 25 amps
- 5. volts at 15 amps
- 12. volts at 1 amp

I used a 25 watt 12 volt bulb as a load and connected it to the 5 volt tap. The bulb drew to many amps for the 12 volt tap and it was bright enough for this experiment.

I started pedeling and tracking the ac voltage going into the supply. I went up in 5 volt increments. At 65 volts the bulb lit. I kept pedeling up to 146 volts. The bulbs brightness did not change. These power supplies are highly regulated.

Conclusion at this point. This may be a way to generate a regulated power source with varying wind speed. I it could posable bypass battery use during adiqute wind speed do to the high level of regulation. Depending on wind genny wattage, power supplies amperage and load amperage rquierment.

This supply says each voltage output can be vairyed. 5 volt range is 4.95 to 5.25 volts at 15 amps. If 3 supplies were wired in sories the voltage could be 14.85 volts at 15 amps. You could do sories perelell supllies for higher amperage

These supplies come in much higher amperage. I have cofigured 9 of the big supplies at my stereo store. We use this supply for demos and benching. It produses 15 volts at 1120 amps, thats 16,800 watts and we use every bit of it.

This would work very well with 3 phase also. the outputs are very well isolated from the ac input. Another thing I notice there was no load untill voltage was high enough to turn the power supply on.

Before I tried this supply I connect a normal battery charger to the pma. There was severe load and cogging from the get go. I think this is because the frequency of the pma is very low at startup and the transformer presented a very low impedance load until a higher frequency was reached.

That's what is so nice about the high speed switching power supply. There is virtually no load on the genny until it spins up to turnon voltage. This lets the genny startup easier. And helps it reach turnon voltage sooner.

Another plus, small wire with long runs are possible. I'll be trying 3 power supplies on a 3 phase motor conversion. There's most likely a good voltage combination for battery charging as well.

Another use could be. Use this system only while your away from home. Adjust the voltage to a safe point for your batteries and not worry about over charging. Then go back to the possibly more powerful charging system when you return home. The input voltage on this supply is listed at 100v to 240 v. These supplies simply change the line voltage to dc so frequency is not critical. you could maybe even power them with dc if the polarity was correct? Not sure about that one though.

Sorry about rambling on here.

Any other thoughts here. Good or bad lets hear it.

JK TAS Jerry

by Jerry on Sun Dec 7th, 2003 at 11:56:35 PM MST ([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Just a note. The input amperage on this supply is listed at 2.1 amps. Not bad consumption for the output it's rated.

Sure you can run DC into it. If the supply has a full bridge (four diodes) at its input, it won't even matter what polarity.

JT Tas Jerry:

By the way: Human power, long term, is defined as a 75 watts source with about 150-200 watts short time power peaks.

For wind mills that have high variable generated voltage, a converter is the ideal case, basically like yours.

The Switching power supplies, most of them that have wide AC voltage range ( 85 to 240 AC ) are designed to operate at high voltage -- 230 to 340 volts DC.

So the input has a switch ( some are automatic) for voltage range 120 or 230 input AC Voltage.

This AC voltage is then doubled rectified for the low range or and for the high range, full wave rectified and filtered then the high frequency converter does the rest.

For this type of converter to operate with the wind mill several things are needed>

The best is to have a converter with PFC ( Power Factor Correction) to accept all the voltage range directly without problems, and if you can furnish DC or rectified DC single or 3 phases ( 230 to 360 volts DC).

Mouser and/or Digikey may sell some of those chargers at low price, like a non-PFC converter, 250 watts for around 80 USA dollars. ( for single 12, 24 & 48 outputs)

The system should, as well, have a Controller for overvoltage and over-RPM protection to present a dump load to the generator, the best is a duty cycle controller to present a variable load to the generator to maintain accurate regulated output voltage under wide wind and load variations.

This duty Cycle controller, that I have designed is just a power MOSFET with a Mosfet driver and a LM339 that produces a triangular low frequency ( ~ 200 Hertz) and a comparator to duty cycle the MosFet ON/OFF times.

In some cases an amplifier is needed to insure proper operation

Regards

Nando

I keep trying hope this pix works?

To many steps? I must be forgetting. If this works Its a pix of the 200 LB DC pm motor/pma. It came from Boeing Aircraft. It is 24 inches long and 9 inches in diameter. Weighs 185 lb. After adding the mouting base, tail wing and boon, yaw bearing and 8 blade prop it will weigh over 200 lbs. its fun to spin by hand and lite up a 100 watt bulb. I have a big 48 volt battery bank. JK TAS Jerry

I've been wondering, since I've never had a motor/generator near that big to try it out on....would it be easier to 'pedal power' something like this to charge a battery? It could be 1:1 ratio chain drive using something like your flywheel exercise bicycle...yeah I know it would be kind of overkill but just out of curiosity....Well maybe not quite that big big...but big enough to put out some charging current at 80-90 rpm 1:1 ratio...foot power?

Oh sorry BIG goof this time. This is a picture of my pump power supply. Or some would call it my mechanical inverter.

There are 2 two HP dc motors. One on each side of a 5500 watt 240 ac generator. This was powered by 20 12 volt batteries. They went bad last winter and I've not replaced them yet. This combo runs my well pump great. No load 260 volts and while pumping 242 volts. Just right.

JK TAS Jerry

Hi Dr D

I'm not to good with this computer stuff and i goofed last night.

There is a brief description in a post just above somewhere.

I couldn't aford the big inverter that could run my well pump in emergency power outs.

This was my sollution. If power goes out we would use watter spairingly. And this power source will cover are needs. I do have a 5500 Generac gas gen if power is out long term.

It was also one of those , can I do this, kinda things.

I have a few of these 2 hp dc motors left if someone is in need. They are Magnatek. I bought surplus locally.

I don't think the surplus guy knew what he had. When I called Magnatek the factory guy said these are \$1000 motors. I'm asking \$100 each.

Its amazing how 2 two HP dc motors can easley replace a 10 hp gas motor.

JK TAS Jerry

This is a response to the drill question below.

The post rules thing said I used to many words in my title. I say what title this is a response. Any way.

I do this mod or conversion all the time. Works great. Dc motors can tolerate more voltage than their name plate states. You'll get a stronger drill.

JK TAS Jerry

([User Info](#))

when you post a response the title of the post becomes the "subject" of the response and can be changed in the box under your name when you post a response.

when a story has a long title sometimes it causes problems with responses and you need to shorten it or change it to something shorter when you reply

10 years ago I bought an old craftsman 6 volt cordless with built in batteries which soon died. I pulled the batteries and ran a cord out to plug into my 12 volt house system. Used it for years for light duty work. It just ran faster than with the batteries. If the gearing can handle the load and you don't push it harder than before the only problem would be heat in the motor coils. I didn't have to worry about how much the voltage dropped in the long cord and thin extension cord because I could lose half the voltage and still use the drill.

### [More Lamination Dialog?](#)

By [Jerry](#), Section [Homebrewed Electricity](#)  
Posted on Wed Nov 26th, 2003 at 10:40:45 PM MST [Alternators](#)  
I asked this ? on the old board. Time to ask again?

Now that the disc alt group has advanced to the dual rotor this ? about lamination may not be as pertinent. However I have yet to finish my first disc alt/pma and the first few I'll build will most likely have lamination.

You see I'm a year or 2 behind in disc alt building.

? about car ignition coils? wrecking yards must have tons of these things in a pile out back somewhere that they will never sale?

I've taken several apart and they have lamination material about 1/2 to 3/4 inch wide and 4 to 5 inches long. Thin metal strips. I'm sure you could form a circle of this stuff as you would a continuous strip of metal and this has to be the best possible lamination material.

BIG QUESTION question. Is the oil in these old coils PCB. If it is then you don't want to mess with this stuff.

Does anyone know if these things are poison or not?

I found a few that don't use any oil at all they were just dry inside. Lot of wire in there to. easy to unroll.

JK TAS Jerry

Hi Jerry.

A couple years ago I had a bunch and can also get hold of a lot of these coils, I remember the oil that was in them, I do not believe that there were pcb's in them, I did do extensive google search and nothing popped up. Mostly what I do remember was that pcb's were found in larger transformers used in street lighting, you might also find them in old neon sign transformers and most of that looked like liquid black tar, very dark in color. As for the wire, there is lot's of #20 I think for the primary and #30 for the secondary, very easy to remove the windings. Good resource for wire now that you mention it. maybe others could shed some light on the pcb issue, I'm interested in this question as well.

On PCBs ([none / 0](#)) (#2)  
by wdyasq on Thu Nov 27th, 2003 at 06:18:41 AM MST  
([User Info](#))

One would think there is a particular year where PCB's were banned from use. If one used a coil built after that year, one should be OK. BUT, car companies had a lot of exemptions from enviromental rules so that may not be true.

Ron

Identifying PCBs ([none / 0](#)) (#3)  
by ADMIN ([admin@otherpower.com](mailto:admin@otherpower.com)) on Thu Nov 27th, 2003 at 09:24:21 AM MST  
([User Info](#))

From a university of toronto website.....might help. Looks like you only need to worry about anything made before 1980, and only high voltage transformers. The part about ballast capacitors in old flourescent lights was new to me though.  
\*\*\*\*\*

#### 4.2 TRANSFORMERS

Since the 1930's, a generic fluid called "askarel" containing 40-70% PCBs were used in high voltage transformers. Commercial Aroclors were blended with trichlorobenzene. Askarel is the genetic term used to identify the combination of Aroclor and trichlorobenzene. A typical Askarel transformer may contain 30-40% PCBs and as high as 65%. Contaminated mineral oil usually contains < 1% PCBs.

PCB-contaminated transformers can usually be distinguished by the nameplate on the transformer located on the outside casing. If the following brand names appears on the nameplate, the transformer contains PCBs:

TABLE 1: TRADE NAMES OF PCB-CONTAMINATED TRANSFORMERS

Apirolio [Italian]	Kaneclor [Japan]
Aroclor	Montar
Asbestol	NoFlamol
Chorextol	Phenoclor [France]
Chorinol	Pydraul
Clophen [German]	Pyralene
Diaclor	Pyroclor
DK (decachlorodiphenyl) [Italy]	Saf-T-Kuhl
Dykanol	Santotherm FR [Japan]
Elemex	Sorol
Eucarel	Therminol FR

Fenclor [Italy]

Hyvol

Inerteen

In addition, the "Type Number" also indicates if the transformer contains PCBs. Any Type Number beginning with "L" indicates that the transformer is PCB-contaminated. Some Type Numbers are: LFAF, LFAN, LFWN, LNAF, LNP, LNS, LNW, and LNWN.

#### 4.3 CAPACITORS

Almost every capacitor manufactured between 1930-1980 contains PCB dielectric liquids. Capacitors in electrical equipment vary in sizes from ice cubes to larger than refrigerators. Capacitors are classified as large when they contain > 0.5 kg of PCBs. Small capacitors are generally associated with electronic or lighting equipment. Fluorescent light ballasts also contain capacitors. Light ballasts are discussed below.

Capacitors may be found in a variety of locations within a building for example connected to A.C. motors > 30 hp wired to the electrical terminals. A capacitor often can be recognized by the letters KVAR stamped on its nameplate. Capacitors may vary in size from 5 KVAR to 200 KVAR range. Capacitors are hermetically sealed to reduce leakage. Unless clearly indicated on the equipment, or the date of purchase can be confirmed to be after 1980, most capacitors in use must be assumed to be contaminated with PCBs unless tests have verified their absence.

##### 4.3.1. BALLASTS

Fluorescent light fixtures may contain several ballasts. Fluorescent lighting ballasts are easily identifiable containing PCBs or non PCB. The small capacitors inside the ballasts are contaminated with high levels of PCB liquid if they were manufactured prior to 1980. At the University over the years, these ballasts have been used from a wide variety of manufacturers. The Office of Environmental Health and Safety maintains a list of models from various manufacturers that are PCB-contaminated.

## [Peddle Power](#)

By [Jerry](#), Section [Homebrewed Electricity](#)

Posted on Mon Nov 24th, 2003 at 10:57:11 PM MST [Alternators](#)

Here are some early results from an exsersizes bike conversion.

I don't know what brand it is. It was headed for the dumpster. I saved it. It has a very heavy very well balanced flywhell. The flywheel is 16 inches in diameter. Its 1.5 inches thick. Its all solid steel and very heavy.

I machined a gruve in the flywheel to accept a V-belt. The peddle sproket is 8.5 in. dia. the chain sproket on the flywheel 3 in. dia. The belt pully on the PMA is 7 in. dia.

PMA is a 3/4 hp furnace blower motor, 1075 rpm, 6 pole, 9 amps single phase. I'm curenly only using the run windings. I may use the starts also latter.

I've insatlld 6 of the old # 29 curved neo magnets on the armature.

No load its easy to crank out 160 volts. I conected a 100 watt incandesent bulb and for a short burst I can pump 140 volts accross that bulb. The bulb gets very bright and I get very pooped very fast. I did out do my 12 year old grandsun. He topped out at 119 volts. But he didn't have any akes or pains after that exabition. I'm still sore.

I will try to count rpm. I think I can see how many rpm the pma dose for 1 peddle revolution? and do the math for 120 volts. The flywhell realy smooths out peddle pulses.

Hey DanF how many hamster power am I worth? But they can go all day I'm only good for a few mins.

JK TAS Jerry

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Norm

I read brifly through David Buchers page. He stated "maybe" the average human can peddle between 40 to 120 rpm.

I just looked at the peddle to pma gear ratio on my bike. Its aprox. 8 to 1. If Davids #s are right the rpm range on this bike of mine would be 320 rpm to 960 rpm?

However I was geting 140 volts with a 100 watt plus load from a motor/pma rated 1075 rpm as a motor.

How could I deturmin the rpm of the pma? Could I measure the frequency and do some math? Its a 6 pole with 6 magnets. All 6 poles are wired in siries, stock wireing.

woud I have to seperate and measure on just one coil?

This has got my curiosity going now?

JK TAS Jerry

considering the windmill without use of batteries, a flywheel gives me an idea. My first thought was to to store the winds energy by filling a tank of water. Ha - a spinning tank of water that winds up on a cable too. Missoula Montana has a lot of bikes! Partly because people are too poor to drive and because its flat in the valley. Get rid of the car and stay in shape:)

Re: Peddle Power ([none / 0](#)) (#3)  
by RobD on Wed Nov 26th, 2003 at 03:37:09 PM MST  
([User Info](#))

Ladies and gentlemen, I give you BobFlex.  
This is my computer and TV riding bike and SLA battery charger. I made the Alternator out of old magnets and oil burner casing parts. It will put out decent power. The bike was a throw away but it has a good heavy flywheel. It does 'cog' a little at low rpm so the next one I'll skew the magnets.

RobD

### [10th Genny flying](#)

By [Jerry](#), Section [Homebrewed Electricity](#)

Posted on Sun Nov 23rd, 2003 at 08:53:34 AM MST

[Wind](#)

Put up the 10 genny.

We now have 10 genny's on the roof of my stereo store shop roof.

I had hoped to have 20 up there by now. However last sommer kept me to busy. We are charging 2 systems, a 12 volt and a 156 volt system for lites, heat and power tools.

Maybe I should post some pix of these two.

JK TAS Jerry

Hi Jerry:  
Can you describe that 156 volt system you are charging for lights, tools and heating please? How it works?  
Thanks

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Tahino  
It just turned out that way. I freind of mine is a retiered electronic transportation enginier. He designed electric things that move. He has a hybred vehicle gas/electric of his own design. This van had 12 very large 12 volt batteries. The are about the size of 2 six volt golf cart batteries.  
He was given a grant from Optima Battery Co. They fixed him up with some large deep cycle gell batteries.

I bought his old batteries real cheap. I got 13 of them, thats what he had. I use 12 of them in my 48 volt home system for a while till I picked up 22 aircraft batteries. they are 24 volt.

I decided to take all 13 of the old big ones to my store/shop. We wired them in sories. We've tapped of at 130 volts for our power tools. All of our power tools with high rpm motors with brushes work very well at 130 volts dc. This includes big shopvac, drills, chop saw, skill saw, router, rotozip and a few more I

can't remember. Also a few incandescent bulbs.

These power tool run faster, stronger, much smoother. We've decided even if we wern't do the wind power thing that we would make dc volts for these tools. We're spoiled now.

The 156 volt tapp gose to a 240 volt electric furnace. this furnace has three 5000 watt elemets. We can swich on 1,2 or 3 of them. I'll be chaging the blower motor to dc soon but for now we use the ac blower motor.

Its amazing how much heat this thing makes at just 156 volts. We only run it for 1/2 hr. to 45 min. just to warm the shop up in the morn. After that we still have plenty of power left all day for the tools.

I only have 4 gennys on this battery bank so far. fist 2 batts are on one genny the next 1 batt. has 1 genny the next 2 have a genny and the next 3 I've got my 48 volt SW-403. I've got my 48 volt 403 charging at 36 volts. I dosen't do much at 48 v. it does a little better at 36 but its still prety lazy compaired to the homebrew stuff.

The other system uses 14 six volt golf cart batteries wired as a 12 volt bank. I have 5 gennies chagreing this group right now. We've seen 150 amps comming into this bank on very windy days. Thats awsome cause we use this bank for are shop lights. We have 60 four ft. florecents that are power by a 2500 watt square wave inveter.

We also use at the same time from this system a small bench grinder and a small drillpress. We also run test equipment and charge our Makita's.

We're going to take the 220 v. ac motor (grid powered) of our air compresor and replace it with a 2 hp 100 volt dc motor and power it from the 156 volt bank.

Our goal is to power out install bays/shop from the wind as much as possible. Hopefully everyday. To do this I want to build and put on the roof 10 more gennys. Also icrease the battery banks. Double or triple there size.

We have kept the store operational during power outages. This while our business neighbors were in the dark.

They only think your crazy when the powers on. When its off they are envious.

Right now I'm building stuff for other people so its hard to get these projects going

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Cevonk

I may have answered your question in my previous post. We are trying to get the shop prortion of our store as grid free as possible. Not there yet but we have ran the shop for several hrs grid free a few times. Just depends how generus the wind has been. Thats why we need more genny's and batteries.

I forgot to mention above. When all the lights are on in the shop the inverter is drawing 120 amps so on those very windy days when the genny's are delivering 150 amps we are 30 amps ahead of the game. I'm confident that after we add batts/gens the shop will be grid free. But wow we suck up alot of power in that shop. We also powewr up several multy 1000 watt demo systems from this power also.

### [Yaw Bearing pix](#)

By [Jerry](#), Section [Homebrewed Electricity](#)

Posted on Wed Nov 12th, 2003 at 10:09:26 AM MST

[Alternators](#)

Yaw bearing and genny mount pix.

Thought I'd try a few more pix. If this doesn't work Kurt may have to help me again. I'm trying to learn this pix posting thing.

The picture is the mounting brackets, base, yaw bearing and complete Garbogen. This system will work on other types of genny/alt also. I'll be using this system on my small disc genny also.

This bearing is very smooth and turns very easy. With the set screws the genny is locked securely to the mast and the wires go down the center of the bearing and mast.

The thick base is 1.25 inch thick plexi but I've used metal and I'm building one now from some left over composite decking material. This stuff is a combination of wood fiber and plastic mix. It won't crack, split, peel, rot, or twist.

I'll be using it instead of plywood for disc genny project. Its very strong and needs no coatings for weather protection. Neat stuff, cuts like wood.

Hi Jerry,

from some left over composit decking material. This stuff is a combination of wood fiber and plastic mix. It won't crack, split, peel, rot, or twist.

Would you happen to know what this stuff is called or maybe someone else reading this? Been wanting to make a few things out of something just a little more durable than particle board like a flywheel for an pedal powered generator for instance and the base....etc. Don't worry so much about pic size...for anyone that really is interested in reading your posting there are ways...for instance I just drag n drop stuff like that onto a html editor...size the pics to what the author probably had in mind...and save it to a special folder on my hard drive. I know the frustration of computers tho' I have a nephew...I knew him as an 8yr.old brat....now he's 22 or so and troubleshoots my computer goes to DOS and types something in and fixes it easier than I can say WOW! How'd you do that?(>) Norm.

by Jerry on Thu Nov 13th, 2003 at 09:33:30 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Norm

Ya its called Choice Deck. I got mine at lowes. This matereal comes in a few diferant widths and thicknesses. The scrap i made a genny base out of was a 1 X 6 ".

I've got some 1 X 12" scraps also. I spent most of this last sommer building this deck. Thats why I'm so behind on wind projects. This deck measures 22 ft X 24 ft. with a roof and a lower area with a roof measuring 20 ft X 24 ft.

There are sevealr brands making this compisitiom matereal. I've been told its made of wood fiber and recycled plastic milk jugs or plastic Wall Mart bags.

Today I tryed another bearing. This one is not a pivoting flange bearing. It was just a bearing with no housing. The outer diameter of the race

measured 3 1/8 inch and the bore is the same as the bearing in the above pix. I cut a hole into a pice of Choice Deck 3 1/8 in. and presed the bearing in. There is a narrow stop type snap ring on the outer bearing race for mounting purpuses. I pressed the bearing in till it hit this stop. I'll make a small metal retainer ring to keep this in place.

This bearing can't pivot and its realy smaller and lighter and cheaper than the big pivoting flange bearing of the same diameter. I think this is it. Any way this is what i'll be doing for yaw bearings and genny mounts.

I'll try to get some pix. The only draw back is its not as prety as the flange bearing and plexi but it is cheaper and lighter. Might even be stronger.

by RobC on Wed Nov 12th, 2003 at 08:19:42 PM MST  
([User Info](#))

Nice job Jerry. Only one thing bothers me this bearing looks like a self aligning type which means that the bearing can move wherever it wants to in its housing possibly allowing the blades to srike the the tower. But I could be wrong let me know. As usual great work. I hope to drive by your shop one of these days. Maybe with a little luck.  
RobC

Re: Yaw Bearing pix ([none / 0](#)) ([#4](#))  
by Jerry on Wed Nov 12th, 2003 at 11:16:33 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Rob C.  
Are you in the Salem area?

The bearing can pivot and if I let it do that it would be a problem.  
This is why I use 1 1/8 inch thick plexi. This bearing accepts 1.5 inch diameter EMT conduit. I have a hole saw blade that cuts a hole just the right size to let the conduit spin free. There is a hole in the plexi that the mast (1.5" EMT) slides into after passing through the bearing. This stops the bearing from pivoting. I grease the hole in the plexi with a generus glob of copper never size. I've got several gennies using this yaw system. They've been through several storms, the bearings yaw so easy and don't loose alignment. There was one more picture that didn't come through on my post and the top one came out blurry. It was supozed to come out last? I'll try to post pix of this yaw system when I put it on my small disc alt.

[Six inch disc](#)

By [Jerry](#), Section [Homebrewed Electricity](#)  
 Posted on Tue Nov 11th, 2003 at 10:27:09 PM MST [Alternators](#)  
 Six inch disc with neo's

Hope this works. Trying to post pics of a 6 inch disc with 8 small neo's made from speaker backing plate. I have a few 8" backing plates also. I will try making slightly larger disc alt if this one works. The disc is 3/8" thick. The pole piece in the center is 1.5" diameter. This disc had a 1/2" vent hole. I enlarged it to 5/8" and tapped it on the side for a shaft set screw. These things are very thick and strong.

JK TAS Jerry

[editor's note, by kurt] i fixed your pics jerry

I got the lamination metal from Ed. Now just got to figure out what to do for coils. These magnets are 1/4" X 1/2" X 1" Neo's. The lamination metal will also be 1 inch wide when inplace.

I plan on a 48 inch 3 blade for this one. OH ya 8 magnets 8 coils single phase. Its my first disc alt.

<http://www.dplusv.com/Photo-03.html>

Hi Troy

I don't think this one will match up to the GARBOGEN but I've wanted to do a disc alt for a long time.

It all started when I saw DanB's first units. Since I've been so slow the desing of the disc alt has been improving almost weekly. If I keep letting all the others do the research I'll save a bunch of time saved.

I think the AX-300 is the 6 inch DanB did with the gear. If I remember right I think it did around 200 watts? Correct me Dan if I'm wrong?

Ofcourse I would like to better Dan's #s a little. Must be a chalinge thing. If it works then on to the bigger units.

I'm still shooting for 2 KW out of my plstic blades? On the bigger genny.

## [Poured Stator ?](#)

By [Jerry](#), Section [Homebrewed Electricity](#)

Posted on Mon Nov 10th, 2003 at 11:02:25 PM MST

Poured Stator ? for I-fred and Ed/winstuff

[Alternators](#)

I-Fred.

How did you make the form to poure the stator? How is this project comming? How is the efficientcy of your poured stator?

Ed

You said in your report on your web page that the efficientcy wasc down abit on your poured stator. How dose this difer from I-Freds?

I've notice that I-Freds stator most resembles an AC induction motor. This type of stator may have benifits from both the disc design as well as AC motor coverision.

I see the higher pole and magnet count as one over the AC motor.

And I see a reduced air-gap problem of the disc alt since the coils are imbebed within the laminations and therefor more involved with the magnetic circut.

Give me your thoughts guys cause I realy like the looks of these things and want to try one.

JK TAS Jerry

Re: Poured Stator ? ([none / 0](#)) ([#1](#))

by [windstuffnow](#) ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Tue Nov 11th, 2003 at 06:07:07 AM MST

([User Info](#)) <http://www.windstuffnow.com/main>

Hi Jerry,

I believe iFreds is using a non metallic version as I posted some time back for the dual rotor alternator. My attempt that's posted on my site was for a "quickie" laminated stator by adding iron powder to the plastic mix. The end result is very inefficient. It does make it very easy to put together a slotted stator but there are alot of losses. The steel laminates either using 1018 strips to form a stator and either slotting them or laying coils over them is far better than the poured iron powder.

The silicon steel is far superior. For a quickie project the poured core unit is quite fun, quick and simple and you can usually put an alternator together in a day or two using the poured methods.

Have Fun

Ed

by Jerry on Tue Nov 11th, 2003 at 09:46:59 AM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Thanks Ed

I noticed your design and iFred's are different. I was thinking of using the steel lamination as normal and pouring the iron/epoxy mix on the steel.

The idea here is to have the good performance of the steel and use the mix as a medium as a path for the flux to follow. This to enhance the flux strength in what otherwise is just open air, the gap between the coils and the laminations. Surely the iron mix will be more conductive to the magnetic flux than air would be. I see the iron past mix as a much better path than just air.

I would use iFred's design and simply mold the stator on top of the steel laminations. The holes for the coils would just touch the top of the steel.

If this worked the gap could be wider with more wire with the mix in the gap. Also the magnets could be placed very close to this hybrid stator.

Just a thought? Could be all wrong?

JK TAS Jerry

([User Info](#)) <http://www.windstuffnow.com/main>

If your coils are going to be thin it may be better to simply pour the plastic and either drill or machine the plastic on top of the steel core. I think the iron powder will lower the efficiency. You could drill the steel for the coils similar to my original idea of drilling a plastic form for the dual rotor machine. This works quite well although it takes a bit more time

This is one of the cores from the 2500 watt machine I did last summer. It has a plastic overlay on the silicon steel and the plastic was machined to hold the wires in place...

Hi Jerry.  
My stator core is a composite of 90% iron grindings and 10% fiberglass resin. Ed is correct, you would get much much more output from thin metal laminations then from a poured core form, however there is major fun that comes from putting together a pour core mold. The intial tests show that it is working well, and I beleive it could be enhanced further, which I am attempting to do. I beleive with embedding some laminations into the pour code as well (esp; in the poles) the output could go much higher. I am presently working on a 13 inch disk with this idea as well.

Take a look at the wood form that I make on this page of my web site. I used wood dowels and a simple form.  
<http://www.internetfred.com/newgen/newgen.html>  
this produced the mold.

The idea for the poured core form came from Ed, I got it from him. He's a master at building things!! Amazing some of the stuff he comes up with.

My suggestions on to building one are, increase the width of the core and thus longer wire per pole. Longer and more magnets, thinner poles. larger slots for more wire.

Good Luck!

I bought some from a "Teacher Center" but later robbed them from the local brake shops. They have tons of shavings and their more than happy to let you have them.

Have Fun  
Ed

A local brake shop, when they grind the breaks it leaves a nice grinding power material, I semi clean it and sift it. I wear a mask for this because it might contain some hazerdous materials, but it's just a percation. They have lots and are more then willing to give it.

iFred did you just pull the wood dowls out after the resin set or did you drill them out? What was the outside form in your mold. OH the inside to? I would think if you kept the slots narrow were you slip the coil wire through, the cogging would not be to bad?

Did you wind the coils first and then drop them in place or did you wind in place around each pole or did you do wave winding? I think thats 3 ?

Thanks guys.

JK TAS Jerry

Hi Jerry

Glad I can help and answer your questions.

The bottom of the form is plywood, to this I glued a paper template that was filled with guidelines 22.7 deg apart. to the outside of the mold I cut some sheet metal (duct metal) and wrapped it around wood base and used some wood screws to hold everything in place. (i used some duct tape in the bottom to prevent spillage. The center was also made of wood. I then gave this part of the mold a coat of varnish.

When I finished the build, I cut the dowels to a single length, then I sanded them (ends) individually to fit for each position. I did this 32 times, once for each dowel. I then marked each position on the dowels, just in case. I then greased everything down very well including each dowel individually. Everything was a tight fit, it's critical to get a tight fit.

I measured everything and mixed the iron grindings and resins together, had to work quickly.. ... (resin went around and under the dowels when packed in slightly, but not enough to jar the dowels(the tight fit-:)). Also: To prevent bubbles and stuff I continually shook, rotated and gently slapped down the mold to make sure the stuff got into all areas of the mold. and continued to pack as much as possible up to the top of the third layer of the mold. The third layer tells where to end.

When completed the dowels popped out with very little problems, only one gave me an problem and I had to drill it out. But all in all the dowels came out smooth. Next I used my dermal to cut out the centers in the top between the poles. The slots where narrow to allow the wire to go through and just a little extra. Dermal with a cutting blade works great on this material!

The cogging is minimal. I used a metal plate made of multi sheets (not suggested) of sheet metal (in order to get thickness). I am still experimenting but I have 32 mags x 3 for width. YUP! you read correct.. 3 magnets per pole in length! 96 small mags 1/2 x 1/8 each.. Got a ton of them, don't ask ;-)

I wound each wire around each pole by hand, 25 times per pole. Man my fingers where killing me, I was shaking after doing 15 poles! LOL... Oh and... they where tightly wound and pressed into each pole with a peice of small hardwood I carved so i could fit in the most wire as I was winding each pole. It's very tighly wound ;->

Hope this helps!!

[Alternators](#)

What can I expect from this stepper?

Hi Group

I was at the scrap metal place today. Looking for some mast pipe for my 200 lb PMA/genny.

I found this little stepper motor. Paid \$5.

Specs amps 4, .75 ohms, 2 phase, 1.8 degrees/step. It has 8 wires comming out. It has 8 coils inside so I think 2 coils in sories so 2 wires for each 2 coils?

It about 3.5 inches long and 3 inches dia. The shaft is 5/8 inch long.

What kinda power could I expect at say 500 rpm?

Never had one of these motors. Its realy clean with very nice bearings. Very well built. I could see why the big ones make nice gennys. The coils look identicle to the GE ECM motors pictured on airheads.

Thanks Tommy L

I'm surprized Mike did't round the tip of his blades as he did in the Mike mod Jerry blades.

He said his stepper motor was rated 4 amps and so is mine. He didn't say how many phases.

I'm going to use 2 of my plastic blades and then compair results with Mike,s genny.

Well I ran the little stepper in the lathe. 500, 900 and 1600 rpm. No load saw 14.7, 25.6 and 47.6 volts. But I could only get about 1/2 amp out of this motor.

I think the magnets used in these must be ceramics. I'm thinking of a neo upgrade.

Jerry;

It may just be the wire size is far too small to pump more than an amp or so.

I want to pass on that I upgraded a 30 volt Ametek to neos with very little increase in amps out but with a slight voltage increase. In other words it was a huge pain in the posterior to reassemble it with neos for a dismal return in power plus it cogged a LOT more. It just seems like adding more flux would increase power but it did not work that way with the Ametek tape drive motor. I think it was at the limits of its windings current ability as stock from the factory

Just my experience and your experience may vary.

Cheers.

TomW

AM MST  
([User Info](#))  
<http://www.dplusv.com/Photo-03.html>

Hi Norm

Ya that armature is actully a little smaller than  
the GM alt. Just a little machineing and the  
little magnets drop into the groove. I used  
some thick wall plastic pipe of the same dia. as  
the armature to make the little spacers. I  
screwed these little spacers down with little  
stainless steel wood screws and the glude the  
magnets on.

The GM alt has a 17 MM dia. shaft. This  
armature has a 5/8 in. shaft. This makes it  
easier to find standerd pulllys and hubs and  
such.

Hornet has used a sigle large doughnut shaped  
neo magnet in there GM alt PMAs.  
I think they looked at my pictures on aireheads  
of this one and copyyed it in there new style alt  
PMA.

I think this is a cheaper conversion. I makes  
more power but it dose cog more.

Hornet claims low cogging but in the same add they say it needs a bigger prop to get started.

I use the fronts of 2 GM alts because you can replace the bearings to mach the new armature in the front part but not the back part of the GM alt.

This alt with these mods, some wireing changes and some caps will make a few hundred watts with a direct mouted blade at around 4 ft.

JK TAS Jerry

## [Lamination ?](#)

By [Jerry](#), Section [Homebrewed Electricity](#)  
 Posted on Sat Nov 1st, 2003 at 08:43:30 AM MST [Alternators](#)  
 Yet another lamination ?

For a couple of small low budget disc alts I'm going to use metel plumers tape as lamination matereal. This stuff is soft so I don't think it will have a magnetic memory?

Will the holes in this stuff hinder its preformance as a lamination? I plan on using masking tape as an insulator as I roll it to reduce eddy currents.

[\(User Info\)](#)

Hi Jerry - I think it would work allright....

Not ideal though, you'd see a big improvment if you used old transformer laminates or something. I used cold rolled steel for a while....

I did a test once and these were approx the results.  
 Basicly I built up a 1/2" thick block of diff. steel material and rubbed a Neo magnet on it to get an idea how bad hystoresis losses might be.

Bandsaw blades would retain a magnetic field density of around 110 Gauss!

Plumbers strapping would retains about 25 Gauss.

The cold rolled sheet metal I was using would retain about 13 Gauss.

Transformer laminates would retain about 7 Gauss.

Ive not tried that silicon steel from Ed at [Windstuffnow.com](#).

From the softness of the plumbers strapping I was a bit surprised just how good a permanent magnet it was. I wonder if perhaps it was the galvanized coating that sets up magnetic domains or something.... I believe rust can also setup magnetic domains to a small degree.

Regarding your question about the holes... I don't think they would affect things significantly. I suspect it would work allright with the plumbers strap, but there would be some drag, probably 3X more iron losses at least than if you used good silicon steel.

## [Blade ?](#)

By [Jerry](#), Section [Homebrewed Electricity](#)

Posted on Sat Nov 1st, 2003 at 12:19:38 AM MST

[Wind](#)

Blade count and size ?

OK blade Gurus help me out here.

I machined the blade hub tonight for my 200 lb PM dc motor. This is the one that lights a 50 watt 120v bulb with a hand spin of the shaft. shaft 1 3/8 inches dia.

I'm going to use it for 48 volt charging. I have a power pole 24 ft tall nothing on this pole. I've a freind works for a utility CO. this pole is possioned around trees and out buildings but most times the wind will come through a channel between all these obstacles. This pole is fairly fat and I don't want to take this monster up high. Since low rpm works well on the pm motor I'm thinking a very high tourque low rpm blade. The location some what demands a low wind blade also.

I'm building an 8 blade 6 and 1/2 ft. tip to tip. The blades will be pitched at 25 degrees at the root and just a couple degrees at the tip.

What diamiter 2 or 3 blade dose this blade equal. 10 foot, 12 foot or does it work that way?

JK TAS Jerry

[Blade ?](#) | 4 comments (4 topical, 0 editorial)

Re: BLade ? ([none / 0](#)) (#1)

by scoraigwind ([magnet@scoraigwind.co.uk](mailto:magnet@scoraigwind.co.uk)) on Sat Nov 1st, 2003 at 02:46:06 AM MST

([User Info](#)) <http://www.scoraigwind.co.uk>

The power you can get will depend on the diameter, not the number of blades.

More blades will give you more torque, but less speed.

Small diameter gives more speed and less torque and less power. For example your 6.5' diameter will catch only 42% of the power that a 10' diameter rotor will catch. If it is a standards shape (scaled down), then it will give about 27% of the torque of the larger blade. But if you use more, wider blades you can correct this to an extent.

When designing blades I usually look at the cut in speed of the alternator at the desired voltage. I then aim to build a blade that will be very happy at this rpm at about 7mph windspeed (3 metres per second).

You don't give us much help as far as the cut in speed goes. If the blade tips are slender (2" wide) then tip speed ratio could be about 5.5. Circumference is about 6.2 metres. Tip speed is about  $3 \times 5.5 = 16.5$  metres per second at cut-in. That's 160 rpm ( $16.5 \times 60 / 6.2$ )

Does that makes sense?

on Sun Nov 2nd, 2003 at 05:23:05 AM MST  
([User Info](#)) <http://www.scoraigwind.co.uk>

You can get a bit more torque by adding blades (provided you get the angles right) but not more power. You can get much more torque and power by increasing the diameter of the rotor (scaling it up).

If you double the diameter you get four times the power and 8 times the torque.

Yes, I will be coming back to Washington state (Guemes island) next year to run another workshop course. April 12-17, 2004

Contact [ian.woofenden@homepower.com](mailto:ian.woofenden@homepower.com) for details of how to come.

I have put pictures of my previous courses at <http://www.scoraigwind.co.uk/buildyo>

I'd be very interested to learn more about how you make the blades. I saw lots of pics on the airhead site but not much discussion. It would be great if you could share some of your experiences with the group at Guemes Island.

<http://www.dplusv.com/Photo-03.html>

Thanks Hugh

I'm not sure if I can make the trip but I will send a set of blades up any way.

Not sure how you could test them they are set up on a hub that fits most ac motor shafts. any where from 1/4 inch to 3/4 inch shaft. I'll send a 3 blade in the 4 foot size.

I think this would be good for that small 48 inch genny you guys built last time. If you had some hub design specs I could posably do a one off for your next seminar up there.

I may be able to stop by for one day to discus the hole story behind and preformance details for the plastic blades.

Only if this does not interfear with your workshop.

Jerry

### [Blades for sale](#)

By [Jerry](#), Section [Classifieds](#)

Posted on Thu Oct 30th, 2003 at 11:02:27 PM MST

[Wind](#)

Blades \$10 to \$15 each.

These are the blades used on the 1200 watt GARBOGEN. I've used these blades on tape drive motors, ac motor to pma conversions, direct mount car alts. Many peple on OPs board have used these blades with excelant results.

These are my plastic blades. Here are some specs. Stock unmodifide blade. 22 3/4 inches long tip to root Part of this is a 2X2 in. mounting tab, 5 inches wide at the root, 3 1/2 in. wide at the tip, 5/16 inch thick at the root, 1/8 in. thick at the tip. Blade should be mounted 21 to 23 degrees pitch at the root. This will make the blade almost flat at the tip. The blade has a slight cup at the root that ends at a 1/3 rd point towards the tip. Blade has a twist from root to tip.

Best preformance is had with the Mike mods. To do this I use a pence and draw a 2 in. diam. circle at the tip starting at the tip and the leading edge. On the trailing edge of the circle I draw a line to extend to a point 11 inches from the tip to the trailing edge. Then sand a knife edge around the tip and down the new trailing edge.

This makes the blade very fast and quiet.

VERY IMPORTANT OR THEY WILL BREAK. Use aluminumsheet metal to form a support from the very edge of the mounting tab 6 inches toward the tip. This is what I call the sanwich trick. The blade is the bologna and the alumiun is the bread. Then I use #10 stainless steel machine screws and 1/2 fender washer. On the tip end keep these 1 inch away from all sides.

Stock blades \$10 each Mike mod blades \$15 each. PS I've made blades as small as 46 inches to as large as 62 inches and 2,3,4,7 blades.

E-mail me at [audiosourcesalem@aol.com](mailto:audiosourcesalem@aol.com) Thanks Jerry

Jerry, I took the liberty of adding this pic I got from Mike on the modification. Stock on the left moded on the right. TomW

Thanks TomW

Your awsum dood. I wish I was more computer savy? I thought I was just posting on the clasifides. I didn't want to post this add here. I didn't think this was the right place to sell stuff. Anyway thanks a bunch for the help Tom.

Jerry;

Well we don't really have any "rules" as such for classified ads but they do display on the front page by default.

We have had a few where the account to post the ad was made immediately before it was posted and those type get set to display only on the classifieds page[s].

Long term members such as you get a lot more slack on the classifieds than those that apparently just join to post an ad.

As always, I am here to help. I wish I was more construction savvy but I'm better with these silly computers and dreaming up bizarre ways to do stuff than wrenches and building things.

And, by the way, glad to see you are using caps for that added voltage bump on mills. I bet you get some monsters in the car audio business.

Cheers.

Hi TomW

YA, We sell lots of 1 farrad caps 1,000,000UF/ 20 volt at \$99.95 ea. I'll sell these caps to OP board members for \$75. They come in red, blue, yellow, silver, green.

We also have 1.5 farrad, 2.5, 35 and 100 farrad caps. WE have a vehicle that holds the NW IASCA SPL record at 168.8 DB. This truck has 54,000 watts onboard. Lots of caps lots of batteries.

I also have caps in the  
6,10,12,15,18,20,25,30,35,40,50,60,75,80,90,100,110,150,200,250,300,400  
volt range with UF rating from 1 UF to 1 farrad. Cap prices from \$2 to \$100 depending on volts/UF rating. Have some non pollar caps as well also some large oil filds, motor start ,motor runs and ect.

Yep caps make a diferance. JK TAS Jerry

PS we also have plenty of gold distribution blocks, fuse blocks and holders, power wire from 10 ga. to 4/0 ga., split loom many sizes. All kinds of car stereo install hardware that realy works great for RE installs.

All this stuff shure is handy for our small wind genny farm on our store roof.

I guse I should make a list and post here and give all my RE buddies here the brotherinlaw discount. That is if its ok with the ADMIN and I don't step on any toes.

Thanks again Tom. Jerry

([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Jerry;

I see no problem with listing your stuff at all.

Thats what classy fried ads are for. Giving our users a place to list stuff they have to sell to others in this RE thing that can supply a need. Especially if there is a discount to be had.

Lots of folks need blades and those high value caps don't exactly grow on trees and good connectors are nice to have available.

Another thought is go ahead and make up a list of stuff you have to sell send it to me and I will make a webpage out of it we can stick somewhere people can get to it online. Then include a link in your signature like the airheads link i did for you.

Cheers.

TomW

long bars (1.00 / 1) (#1)  
by troy on Fri Sep 19th, 2003 at 09:43:00 AM MST  
([User Info](#))

As noted by others (Rodger maybe...) the long bar magnet idea will probably work fine if the entire top face of the magnet is a single pole (N or S) and probably won't work at all if one end of the bar is N and the other end S.

Clamping/gluing magnets cheek to cheek like that can be something of a trick. You may need to glue them one at a time until the glue completely sets up for each one.

Best regards and have fun!

troy

OK well lets try it again? HI Richard. I've had a thought about this curved magnet problem. There are curved ceramic magnets galor in pm motors. Many have 2 but you need 4. And ceramics are weak. This might be a little better than ceramics? Take a thick wall steel tube the same diamter as your motors armature. Since your motor is 4 pole. Cut this tube into 4 pices like a pie. cut it so there is a gap between the pices. Glue the magnets to the under side of the tubing pices then glue the magnets to the greatly redused in size armature. This would get the flux closer to the laminations and cover the pole more thouroughly. There will be a reduction in flux travel. But the 2 surfaces will be better mated together and hopefully overcome some of the square surface losses.

([User Info](#)) <http://www.madbbs.com/users/bruggelog>

Jerry,

You beat me to the punch, I hope you don't mind me riding along with a similar request to the "blade experts". I need as much torque (power) as I can get from 0-400 rpm up to 30 mph from a 12' diameter 3 blade set. This looks like about tsr-7. Is the blade design program geared more toward "high speed efficiency" or would this be the best all around design for torque also ? I plan to heat water direct with my variable load controller NO BATTERIES. Thanks Jerry and to anyone who responds on this subject. Dave B.

by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Mon Dec 29th, 2003 at 09:09:45 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Dave,

It's difficult to match the full torque range because of the cubed power coming through the blade at different wind speeds. It would probably be best to match the average winds in your area. For instance we have a relatively low average 6-12mph I typically set them up to perform best in that range. We quite often have higher winds in the range of 12 - 20 mph so anything extra is a bonus although they tend to drop efficiency as wind increases.

The blade designer program will work with all efficiencies, simply change the efficiency number in the efficiency box. I use an overall efficiency based on the alternator and expected blade efficiency so if your expecting say a 40% blade and a 70% alternator then the number to plug in would be (.4 x .7 = .28) 28% overall.

Have Fun  
Ed

Great job Jerry Can i assume you a producing AC and the pulse charge circuit is after the rectifier(s). keep the info coming. Would this idea of Charges be usable as a low wind device and when the wind is strong it can be taken out of circuit or would the high voltage cap bank have to be designed for the highest input foreseeable.

I think Jerry is doing an experiment. Of course it must be scaleable to be of use but the preliminary results look good. If we can turn thaose 5 and 10 mph winds into stored energy that would be great. I know my mill without the resistance of the battery spins up past charging voltage no problem.

Hi Reno Yep this is just playing with caps for fun. Since I have a zillion caps I'll be trying higher voltages and higher UF also. What I really need to do is get the solid state swiching thing working. But I like the idea of charging the caps to 20 to 60 volts or higher and then dumping that voltage onto the 12 volt batteries. I guess you could do the same with 24v or 48v also. The battery never got even slightly warm and the charger stayed pretty cool also. The caps were cold. I think however the relay was taking a beating. This is were solid state swiching would help. Reno your right about helping the genny in low wind. And then maybe swich over to normal genny operation when the wind speed gose up? Atleast this will help the genny to make some power in low wind. JK TAS Jerry

Re: 144,000 pulses and counting. ([none / 0](#)) (#8)  
by dualsporter on Fri Jan 2nd, 2004 at 12:15:23 AM MST  
([User Info](#))

Experimenting for fun is good. Pulse circuits are very entertaining. In your case it sounds like you have all the parts setting around which is the perfect situation for playing with an idea any time you want. That's got to be great. I don't have enough room to be able to collect much "stuff".

The life expectancy of any component (relay, SCR, etc.) is directly related to loading. The more energy it has to move, the shorter it's life. (The candle that burns twice as bright, burns half as long.) Things also pretty much work the other way around too. If a component is surviving well beyond it's rated life, then it's not being required to move a heavy energy load. It's also possible you just have a very good quality relay that has not yet met it's rated life expectancy.

Designing and building a circuit to last for 40 years of non-stop operation is not a problem as long as it is designed with an appropriate margin of safety for the components.

The interesting question is how well this circuit transfers energy from your mill as compared to just running a heavy cable and sending low voltage.

A standard heavy copper cable system is somewhat expensive. For that reason, if the pulse concept only moves energy, maybe 2/3 as efficiently as copper cable, it might still have merit because of the comparative prices of the two systems. That's why knowing how well the pulse system transfers energy is the key bit of information someone needs to have before deciding whether it is worth investing in for their final, permanent system.

Also knowing the circuit's efficiency is what tells you if it's worth investing in even for a "starter" circuit for your mill. (followed by switching over to standard cables when wind speed is up) The fact that it's not loading your mill and allowing it to start up in low wind should be telling you something. (The loading on the mill is a direct relationship to how much energy it's trying to move.) "Does the little bit of energy it moves in a low wind condition justify purchasing the parts required?" Also, if it's not loading the mill significantly in lower wind conditions it probably won't in higher wind conditions either setting you up for a runaway self-destruct.

Regarding pulse charging your batteries... Pulse charging borderline batteries does rejuvenate them somewhat. The higher voltage spikes blast the sulfate bridges shorting the plates together. These sulfate bridges form in the sulfate sludge at the bottom of the battery that forms when they are allowed to set uncharged for extended periods of time. The bridges will begin to set up again within a short period of time because the pulse charge does not destroy the sulfate. It just moves it temporarily. It's possible, if you could remove the sludge layer, your battery's life would be pretty much restored.

For all experiments, if it was fun, it was worth the investment.

Hi Dualsporter I'm not sure if gell batteries have sludge that settels to the bottom. I've opened one up and the gell guu stuff seems prety stiff. I has a pie dough consistancy but its almost clear. Can't see how much stteling could happin? This is 24 hrs latter and the voltage is still 12.6 v and it still burns the end off the old screwdriver. I hope this works this good on the other battery. Re: 144,000 pulses and counting. ([none / 0](#)) (#6)  
by Jerry on Thu Jan 1st, 2004 at 09:31:47 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

The 80 hr test was for Relay longevity. I wanted to see how the relays held up in continuous duty. Also the battery I was charging appeared to be no good. That is after charging it in a normal fashion it would lose voltage in just a few hrs. It's been holding 12.67 for 1 1/2 days now. I haven't done a load test yet. But it did burn the end off an old screw driver and after a short time the voltage was still at 12.6. I don't know what the pulse charging did but the battery seems to be back to full capacity. I have a 125 amp load tester at the store shop so I'll load it down tomorrow and see if the battery is still good. I hooked up the other battery it was worse than I thought. It was down to 2.5 volts and the 40 Bosch relay stop working after a couple hrs. I'm going to replace the Bosch with some 100 amp relays and place some 2 uf/ 400 volt mylar caps across their terminals to stop the arcing and pitting. I'll see how long they last. If they hold up this system might just bring this other battery back to life also. Hey Charged could you explain again how this pulse charge helped this otherwise junk battery? If it did? Or maybe this battery wasn't junk? I da no? I guess I'll find out with the really dead battery? JK TAS Jerry

At 21v you're at just about optimum. For desulfating you can use smaller capacitors at higher voltage(100v) for short periods. This "cracks" the sulfate barrier. THEN you discharge to help dissolve the crystals in an orderly manner. Once you fully discharge, then start applying you're standard 21v pulsing.

You might want to build a dedicated charger with two voltage settings specifically for desulfating/reclaiming old batteries. That way you can scavenge batteries here and there and see if they'll come back to life. Some will, some won't, so what.

Re: 144,000 pulses and counting. ([none / 0](#)) (#5)  
by Reno on Thu Jan 1st, 2004 at 05:13:26 PM MST  
([User Info](#))

I think Jerry is doing an experiment. Of course it must be scaleable to be of use but the preliminary results look good. If we can turn thaose 5 and 10 mph winds into stored energy that would be great. I know my mill without the resistance of the battery spins up past charging voltage no problem.

([User Info](#))

here is also something to check, when you start the next battery pulsing take a voltage reading of the pulses at the battery, I would imagine them to be a higher voltage untill the battery starts to reach a full charge then being around 14.5v. the relays should last upwards of 1 million pulses if the pulse is not near the full current rating of the relay but I would suggest a FET to do the switching, if you let me know what kind of voltage/current source you have available to trigger the relay I could draw up a very simple fet switch for you to use. FET's are much cheaper than relays in the long run unless you have an unlimited supply of course.

Thanks Budgreen. I'm using a 13.8 volt 3 amp regulated power supply to supply power for the 12 volt flasher unit and the Bosch relay. I would very much like to remove the Bosch relay and replace it with an FET. What FET would I use if I increase voltage to 100 and amperge to 50? Or is that combination not doable or recimended? I did the load test on the battery today. Its a 10 second test and the tester said the battery is a good 770 cold cranking battery. I was surprizes because Optima calls this battery a 750 CCA battery. And this was after burning the end off that old screwdriver a few times. (REDNECK battery tester burning the end off old screwdrivers.) Looking forward to the schimatic. I'll try to hook up the 100 amp relays inplace of the 40 amp Bosch tommorow. This will be to see if I can bring the other Optima battery back to life. Thanks again Budgreen and Charged. You guys are an insperation. JK TAS Jerry

PS. Thanks to Reno, Bsparky and Dualsporter I didn't mean to not thank you guys to. And another ? for you guys. I use an audio generator at work. These things are small and work from 9 v to 15 v. They have square, tryangle and sign wave output from 1 HZ to 1 meg HZ. I guess that would be 60 pulses per min. Could I use this unit to sequence the FETs instead of the 30 pulses per min. flasher unit. You know make this hole thing solid state? JK

well done jerry, as i said in a previous post i will hold off on the caps until you have done some more tests. sounds excellent so far. keep up the good work. might be able to do a deal on some very cheap igbt's. will ask the guy if he has any left. not too sure about exporting electronics to the states anymore, those homeland security guys are real paranoid about imports.

([User Info](#))

you could also construct a peak reading volt meter to watch the batteries voltage if you so please, I will be doing this to test the merits of pulse voltage change vs. state of charge when I have some free time.  
from what I understand when you use a desulphator (similar to this setup of pulse charging) the batteries will start out with a high pulse voltage and gradually return to normal. If a dead battery has a higher internal resistance than a charged battery (not sure) this would be a very usefull circuit.

I guess next time I test I should use the peak hold button? I was in a hurry last night. The desulphating thing sounds like another plus.

I'm thinking this system may help low powered gennies or gennies that have low wind startup problems?

peak hold feature would just lock the highest reading on the screen :)

this would be like a sample system that keeps a running check of the voltage peaks

I don't think I'll invest in anything powered by vacuum energy just yet.

[quote] (emphasis mine)  
"Toulouse - Nov 25, 2003

New results from a study of distant galaxy clusters, observed as they were when the universe was only half as old as it is today, lead to some surprising conclusions. The observations were obtained by the European Space Agency's (ESA) satellite XMM in the context of an international collaboration involving researchers from two laboratories (the Laboratoire d'Astrophysique and the Centre d'Etude Spatiale des Rayonnements (CESR) at the Observatoire Midi-Pyrénées (OMP) in Toulouse, the Institut d'Astrophysique Spatiale (IAS) in Paris, the Collège de France, the Service d'Astrophysique (SAp) in Saclay, and the ESA center ESTEC in Holland. The scientific interpretation of these observations will soon appear as a letter in Astronomy and Astrophysics. The observations indicate that the abundance of X-ray luminous galaxy clusters was much lower at this ancient epoch, which suggests that the matter density of the Universe is significantly larger than what has been commonly assumed since the observations of the cosmic background radiation reported by NASA's WMAP satellite. This new result could call into question the need for vacuum energy!  
In any case, the results indicate that certain basic assumptions adopted by cosmologists will have to be modified: If galaxy clusters behave as commonly assumed, then one must abandon the ideal of a universe dominated by vacuum energy -- a radical change relative to recent ideas in the field; otherwise, one will have to understand the physical processes operating to make galaxy clusters more complicated objects than expected."

"Investment" was not why I provided the link. What he has there is an excellent description of the two disparate energy flows between an external circuit and the ion flow inside the battery. Electrons are many orders of magnitude faster than ions.

I tend to go with empirical data (up close) rather than magazine articles that reflect only the opinions of people that have never seen what I'm looking at. By basing my own experiments on other people's system claims I've verified enough "odd" processes to realize that the "best mousetrap" isn't usually on the shelf at Wal-mart.

Commercial obstruction? Maybe. Who knows for sure?

Drop one of those "magazine physicists" in the middle of the Adirondack mountains with nothing but a bowie knife and see how well they survive, alone in the woods, for two weeks. They're mostly self-aggrandizing paper-pushers that spend their lives patting each other on the back and collecting elitest awards. They have no practical skills. I know quite a few engineers where I work that are just the same. School made them all-knowing and flawless in their perceptions. ;) They're also so well paid that they gladly fork over every penny they must to the power company without batting an eyelash. Wealth can offer false-security and it almost always breeds intellectual decadence.

What I'm saying here is that REGARDLESS of where this energy comes from the enters the system, it DOES enter. Why do the ions keep moving in a charge mode between capacitive pulses? Don't know for sure. But, they do it anyway, regardless of the operator's disbelief.

Electrical engineering texts have never been updated to reflect current known processes in quantum mechanics. It's not that the texts are "wrong", as such. It's just that they are sorely incomplete.

<http://www.cheniere.org/techpapers/vanflandern.htm>

These flaws in standard EM theory are already being exploited by quite a few people. Many of these processes have been patented. The real comedy is that most "learned" people just pass them by, saying "That won't work", instead of simply building something to find the truth.

There are those that disparage what they cannot understand. There are those that learn the basics and never do anything with it. And then there are those that don't worry as much about WHY something works, they just build it and use it, learning the "why" as they go.

That last sentence most closely reflects my philosophy.

hi jerry i am thinking of doing the same thing. how much do you charge for big caps? i havent really looked very hard yet but new they cost a fortune. i am in the UK so postage is a bit of an issue. as regards the relay i would go for solid state everytime. not a high duty cycle and very easy on the relays. can get them used quite cheaply and much more reliable. they either work or they dont. if they stop just plug another one in. solid state relays and triacs go up to 3000 amps or so.

bob

Re: Question for Charged. (none / 0) (#2)  
by bob golding ([yubba at clara dot net](#)) on Wed Dec 17th, 2003 at 06:58:55 AM MST  
([User Info](#))

hi jerry i am thinking of doing the same thing. how much do you charge for big caps? i havent really looked very hard yet but new they cost a fortune. i am in the UK so postage is a bit of an issue. as regards the relay i would go for solid state everytime. not a high duty cycle and very easy on the relays. can get them used quite cheaply and much more reliable. they either work or they dont. if they stop just plug another one in. solid state relays and triacs go up to 3000 amps or so.

bob

Re: Question for Charged. (none / 0) (#7)

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Bob

The price all depends on the UF and voltage of the caps.

To day we got a deal and here it is.

20 volt with 24 volt surge 1 farrad caps \$59.95 plus shipping and hadeling.

This as thet say while supply last. If you don't mind these are a kinda pail yellow and if you don't like the color just peal of the plastic jacket and they are aluminum color.

Just let me know the UF/volt rating you want and I'll get you the price. I have many big caps starting at \$5.

JK TAS Jerry

Re: Question for Charged. ([none / 0](#)) ([#3](#))  
by charged on Wed Dec 17th, 2003 at 07:47:04 AM MST  
([User Info](#))

This is about the simplest method I've worked with. The key with this particular circuit is that the LOAD (your battery bank) must have a very low impedance for it to work right. It just so happens that your battery-bank is such a load. Go figure.

Get yourself a HEAVY CURRENT TRIAC and a good 5v zener diode. Use about a 400v rating, minimum. The sudden on-rush does some funny things, in electrostatic terms, when the capacitor bank voltage faces off with the battery voltage. Stick with HV components.

Connect the triac between the capacitor positive and the battery positive.

Connect the zener ANODE to the TRIAC GATE and the zener CATHODE to the capacitor positive.

Now, whenever you capacitor bank reaches 5v above battery voltage, the TRIAC switches on the dumps the charge into the bank in a very sudden burst of high current. Your capacitors have nearly zero internal resistance and the battery bank is also nearly zero (for our purposes). The only bottlenecks are the wires and the TRIAC itself. The lower the on-state resistance of the TRIAC the shorter the pulse duration will be.

Make sure all the leads between the cap bank and the battery bank are very heavy gauge so that each pulse duration will be as short as possible and as high a current as possible.

If your TRIAC starts sticking in the "ON" position, it means that your cap bank needs more capacitance, OR the wires you chosen to use are not heavy enough. Or maybe both.

Since you know the amount of charge (coulombs) that is contained in a 5v pulse from your known capacitance, you can make pretty accurate rough estimates of the incoming power by watching the pulse rate. Just put a high-impedance analog volt meter across the cap bank. Don't skimp. Make it pretty.

A 1 Farad bank at 5v is 5 Coulombs. At 1 pulse per second, that's 5 amps average input current. 10 pps would be 50amps, and so on. The frequency will vary based on the amount of generator power coming in.

The best part of this setup is that you never need to screw around with energy-wasting regulators between your generators and your batteries. Sudden-discharge capacitive pulse charging usually keeps the batteries ICE COLD while they charge. Just keep an eye on the electrolyte levels and you'll be fine.

Re: Question for Charged. ([none / 0](#)) (#4)  
by charged on Wed Dec 17th, 2003 at 11:15:07 AM  
MST  
([User Info](#))

Ok, here's a simple circuit that will allow you to use your local Radio Shack triac and a good power mosfet or a bipolar transistor. This will prevent the triac from having to handle any major current directly.

The gate-source resistance will vary, depending on the triac power dissipation limitations. The power mosfet will be handling almost all of the current once the triac turns on and the mosfet gate goes positive.

With the Radio shack triac (#276-1000), use a 10ohm, 5watt resistor between the gate and source leads of the mosfet.

You can parallel more mosfets for greater current handling. All the drain leads are directly paralleled AND all the gate leads are directly paralleled. BUT, EACH mosfet source get's a non-inductive .05ohm resistor (digikey TBH25PR050J-ND). This will prevent overcurrent in any single mosfet in the array.

You CAN do it with just the single mosfet if you purchase one of sufficient overall wattage handling capability. Get one rated for at least 200v and VERY LOW on-state resistance.

DO NOT USE A LOWER VOLTAGE TRANSISTOR BY ADDING TRANSIENT SUPPRESSION. The batteries like the transients too! Don't deprive them of what they love so dearly.

Hi Charged YoudaMan

The 1 puls per second sound great for a manual relay swither im going to try.

We sell a heavy duty electronic flasher that is progarable for 1 puls per second or 1 puls every 2 seconds.

It draws very little curent and I may either use it to trip larger relays or solid state devices. Just expirementing here?

JK TAS Jerry

if you are going to 1 pulse per second, do not use a relay, they do have ratings such as 1,000,000 cycles at half load or similar, if you discharge a cap through it I can gaurentee that it will not last, you will end up with melted,fused,or burnt contacts.

I would suggest setting up your pulsing circuit to trigger a FET to dump the load. these are usually very cheap, last quite awhile and can be paralleled quite easily.

Re: Question for Charged. ([none / 0](#)) (#5)  
by Budgreen on Wed Dec 17th, 2003 at 02:03:52 PM MST  
([User Info](#))

ok, I understand the principal of this quite well, but I have one point to make regarding the mosfets. The mosfets (if paralleled) should not hog current as a bipolar device would, so the 1 resistor across all of them should suffice with the proper wattage. I also have a question, why 5v above battery voltage? just because it's a common zener rating? it would seem that pulse charging a 13.8v system at 18.8v could do damage, or am I missing something.

If you can get the scr to turn off! in order for that to happen the holding current needs to go quite low (usually 5ma ), it may or may not work, I will try that as I am currently building this to see how it works in the real world.

another advantage to this setup would be recovering energy slowly, like on a small genny I have, it makes a high enough voltage but not enough current to charge a battery with. using this setup I can 'pool' energy into the caps slowly and then dump it into the batteries where before i had no way to get any charge into them.

([User Info](#))

actually I was wrong here.. grinding my gears back to basic electronics 2 things need to happen for the scr to turn off.

1. ) the gate current needs to drop below holding.. most cases < 5mA
2. ) the voltage comming in must drop below about .7v

therefore an scr based circuit will never turn off unless the caps are discharged below .7v and with incomming power will not happen. (plus I also tested it to be sure)

I must apologize for not being VERY clear about exactly WHAT will be charging the capacitor bank.

Unfortunately, I have explained SOME of the system without filling in all the holes. Some of those holes are pretty important.

There are TWO METHODS for charging this capacitor bank.

1. Use PURELY INDUCTIVE power transfer in the system.
2. Use an isolated FLIP-FLOP charging controller on either side of the capacitor bank. That happens to be a recently patented large-scale charging system. Not mine. I believe that you are allowed, under patent law, to build one for YOURSELF, but not as a commercial venture. Anyway.....

For a steady-current generator as the source, the flip-flop alternately floats the capacitor bank between the incoming generator power and the battery bank. Just make sure the two don't overlap.

The triac discharge circuit works just fine. I have two running right now with a small inductive charging system on the caps.

If you have a monster capacitor bank and a heavy parallel transistor bank to apply the discharge, the pulse duration into the batteries is super short.

In any case, the triac/transistor arrangement is not for universal application, to be sure. A proper long-term system installation would be fully digital controlled.

yes, triac good SCR bad :)

this is becoming a large thread and getting full of all kinds of usefull info we could probably make a faq just on power transfer =)

actually I was wrong here.. grinding my gears back to basic electronics 2 things need to hppen for the scr to turn off.

1. ) the gate current needs to drop below holding.. most cases < 5mA
2. ) the voltage comming in must drop below about .7v therefore an scr based circuit will never turn off unless the caps are discharged below .7v and with incomming power will not happen. (plus I also tested it to be sure)

[Question for Charged.](#) | 25 comments (25 topical, editorial)

Re: Question for Charged. ([none / 0](#)) (#11)  
by charged on Thu Dec 18th, 2003 at 08:30:16 AM MST  
([User Info](#))

First, using a cacitive discharge is COMPLETELY DIFFERENT than using a steady current charging system. I may have overlooked some generator source info in this thread because I'm getting issues crossed (in my head) with other similar threads.

Here's some simple DC-DC circuit info. It works just fine inside small IC's and it also works GREAT up here in the land of big power transfer.

[http://www.maxim-ic.com/appnotes.cfm/appnote\\_number/710/ln/en](http://www.maxim-ic.com/appnotes.cfm/appnote_number/710/ln/en)

Look at figure 5 on that webpage, "Inverting topology".

The transformer chosen should be able to handle a full generator current pulse without flinching.

Scavenge a couple of microwave oven transformers. Remove the two windings and put both primary windings on the same core. Now you have a 1:1 transformer.

This is HOW TO handle your generator AT THE TOWER or AT THE GENERATOR SOURCE, wherever it may be. The only difference that I would apply would be a full-wave bridge across the inverting x-former secondary. The transformer should be a 1:1 HEAVY DUTY isolation transformer. The transformer, rectifier and pulse-width controller are at the generator tower. Set the pulse width to about 80% of the field moment of the transformer. All the genny power goes into that transformer circuit. The capacitor portion of the circuit is IN THE HOUSE at the battery bank. The very first capacitor on the wire should be an HV photoflash capacitor of about 1000uf or so. This takes the highest voltage peaks without damage. Then run a heavy twin-lead from that cap to the large bank.

This turns all your generator power into transient or "radiant" spikes with little or no current component. Your line losses between generator and house will virtually disappear since you've changed all the power into "transient" pulses before it goes down the lines. The caps at the house receive and translate the spikes back to usable current. This step-charges the capacitor bank.

A 5v pulse is NOT going to hurt your batteries.

I run my discharges at about 20v above battery voltage with no problems at all.

Take a much closer look at that simple zener/triac/mosfet circuit.

1. The voltage on the cap bank rises to 5v above battery.
2. The zener begins to conduct.
3. The "threshold" gate current is reached and the TRIAC conducts. The maximum current is determined by the resistor between the mos gate and source leads.
4. The mosfet gate goes positive and it switches on FULLY. The mosfet "ON" state is a PURE RESISTANCE. The TRIAC current drops to 0 the instant(well, almost) that the mosfet begins to

conduct, shutting the triac off.

Follow me here.

The cap bank will charge in a ramp fashion and then the mosfet DUMPS the built-up charge into the battery in a tiny fraction of a second. The larger the cap bank, the longer the ramp-charging time.

The discharge pulse-width is only a tiny fraction of the ramp time when you are using enough capacitance. There will be no "floating on-state" of the triac in this configuration.

right. as I have just built it and am playing with it now :)

the trick seems to be getting a large enough cap bank to pulse the batteries with and having it charge somewhat slowly, I don't have a large bank here at work, but with some small caps and a power supply it appears to work correctly but once it turns on the power from the supply is enough to keep it on (no ramp up of the cap) turns on about 5.5v above the batt voltage and dumped 15A at 14.5 volts into it, gotta wait till I can get home and throw it on the big caps.

only problem I could see is if the genny is making enough power to keep the caps charged thus keeping he circuit on. if not built to withstand your full current output could end up in a molten pile ;)

[ [Parent](#) ]

Re: Question for Charged. ([none / 0](#)) ([#13](#))  
by charged on Fri Dec 19th, 2003 at 07:38:30 AM MST  
([User Info](#))

Yup. But, I did say this was a "simple" circuit. heh. A LARGE capacitance and a very LOW IMPEDANCE discharge circuit are the keys. The total capacitance would be over-engineered for the system ahead of time.

In my utopian world, all wind machines would be reconfigured to operate as 1:1 "magneto" systems. HV inductive impulses are the only thing that is used. You can literally run a single wire to the house and use a 6' copper ground spike on both ends as the second lead. Inductive discharge power transfer is FAR superior to standard AC or DC generator output. THIS is why Tesla said, in his autobiography, that he considered all of this AC systems to be a FAILURE. His later impulse systems were much better. BUT, he'd already gotten everyone using AC, essentially burying himself commercially. Then the systems were simply forgotten. Look at the patents after 1890.

I'm working on a wind generator design that has all this built in so that you don't need to have any heavy transformers and such out at your tower. If I get it worked out to my satisfaction, I'll post the plans for everyone to play with.

Here's the basic gist of how this operates. Those skilled in the art of pulse-width-modulation will be able to whip up a test unit, post haste.

Tesla loved using capacitance on both ends of his impulse systems.

Put a LARGE capacitance across the genny output RIGHT AT the tower. If it's an AC machine, use a high-current full-wave bridge and then the capacitors.

Use a simple pulse-width modulator to control a heavy IGBT to pulse the capacitor into the primary of a HEAVY CURRENT 1:1 transformer. First, turn the pulse frequency down and then widen the pulse-width until you JUST start to see a DC line at the end of the ramp pulse. Then back off to about 80% of the ramp, so that no pure DC can flow. Now, turn up the frequency until you have a 50% duty-cycle. This is what I consider the optimum setting.

The transformer SECONDARY now gets a 1kv full-wave bridge rectifier. The negative output is fed into a deep earth ground. The positive goes down the long-wire to the house.

The PWM uses very little power. You can use a couple of 555 timers to build it. There are schematics all over the place for that chip. Put a 9v regulator and a 1000uf across the power leads, then power it from the capacitor bank at the tower. Use an opto-isolator between the PWM and the IGBT.

Whenever the generator puts out enough power to run the PWM, the system will start transferring power to the house as a buzzing HV spike train.

OK, back to the house.

Where the wire meets the house, drive another deep earth ground rod. Put a 400v 1500uf capacitor(s) between the wire and the ground connection. Run your jumpers from this capacitor down to the large cap bank.

The inductive spikes will collect in a 1:1 POWER ratio with the generator. BUT, the system now has the capability to go much higher than the straight generator voltage, as needed.

Make sure your BATTERY bank is configured to be AT or ABOVE the normal generator voltage output. If you pull the house capacitors LOWER than the normal generator voltage, you'll start to see CURRENT on the wire from the generator, instead of just the radiant (impulse RF???) spikes. You don't want CURRENT since it defeats the purpose of this system.

## DC-DC Converter Tutorial

*Switching regulators offer higher efficiency than linear regulators. In addition, they can step-up, step-down and invert the input voltage. This article outlines the different types of switching regulators used in DC-DC conversion. It also reviews and compares the various control techniques for these converters.*

### ALSO SEE:

- [Building a Power Supply That Works](#)
- [Power Supply Cookbook](#)

## What Is a Switching Regulator?

A switching regulator is a circuit that uses an inductor, a transformer, or a capacitor as an energy-storage element to transfer energy from input to output in discrete packets. Feedback circuitry regulates the energy transfer to maintain a constant voltage within the load limits of the circuit.

The basic circuit can be configured to step up (boost), step down (buck), or invert output voltage with respect to input voltage.

## Why Use a Switching Regulator?

For battery management, the only other choice is a linear regulator. Linear regulators only step down, and efficiency is equivalent to the output voltage divided by the input voltage. On the other hand, switching regulators operate by passing energy in discrete packets over a low-resistance switch, so they can step up, step down, and invert. In addition, they offer higher efficiency than linear regulators.

Using a transformer as the energy-storage element also allows the output voltage to be electrically isolated from the input voltage.

The one disadvantage of the switching regulator is noise. Any time you move charge in discrete packets, you create noise or ripple. But the noise can often be minimized using specific control techniques and through careful component selection.

## Charge Phase

A basic boost configuration is depicted in Figure 1. Assuming that the switch has been open

for a long time, the voltage across the capacitor is equal to the input voltage. During the charge phase, when the switch closes the input voltage is impressed across the inductor and the diode prevents the capacitor from discharging to ground. Because the input voltage is DC, current through the inductor rises linearly with time at a rate that is proportional to the input voltage divided by the inductance. The energy stored in the inductor for the duration shown is equal to one-half the inductance times the square of the peak current.

Figure 1. Charge phase: When the switch closes, current ramps up through the inductor.

## Discharge Phase

Figure 2 shows the discharge phase. When the switch opens again, the voltage across the inductor changes instantaneously to whatever is required to maintain current flow, because the inductor current can't change instantly. In order for current to continue flowing, the inductor voltage must change enough to forward-bias the diode. The voltage on top of the switch (at the diode anode) is equal to a diode forward voltage ( $V_D$ ) above the voltage on the capacitor, and the voltage across the inductor actually switches polarity relative to the charge phase. In this initial cycle,  $V_{\text{switch}}$  is equal to  $V_{\text{IN}}$  plus  $V_D$ . If we assume that the capacitor is relatively large such that the  $dV/dt$  for the resulting inductor peak current is negligibly small, then  $V_{\text{OUT}}$  remains relatively constant during the second half of the cycle. As  $V_{\text{switch}}$  remains at a diode drop above  $V_{\text{OUT}}$ , the voltage across the inductor also remains relatively constant. This results in a linear  $di/dt$  opposite in polarity from the charge phase and proportional to the inductor voltage divided by the inductance,  $-V_D$  over  $L$  in this initial cycle.

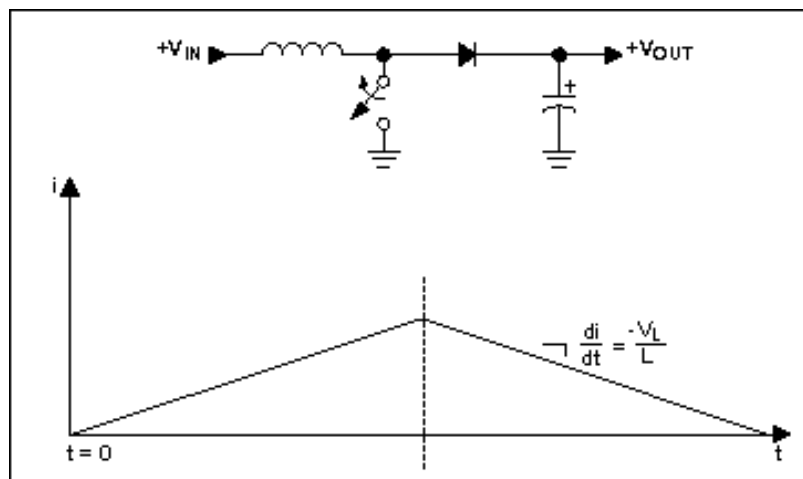

Figure 2. Discharge phase: When the switch opens, current flows to the load.

If we continue this process over and over, the voltage across the capacitor ( $V_{OUT}$ ) will rise with every cycle. If we then employ some feedback and control (see Figure 7), the output voltage can be regulated at any value within the breakdown tolerance of the selected components.

If we take the same basic elements and rearrange their positions, we can create the other configurations such as the buck converter topology (see Figure 3). Here, when the switch closes, the voltage across the inductor is equal to  $V_{IN}$  minus  $V_{OUT}$ . Initially this is  $V_{IN}$ , because  $V_{OUT}$  is zero at startup. Current will ramp up linearly, as in the boost case (Figure 4), and flow into the output capacitor. When the switch opens, the voltage across it will change instantaneously to allow current to flow through the diode and the inductor, and into the output capacitor. Because energy is gated to the output capacitor in each half of the cycle, the buck topology typically offers the greatest efficiency.

Figure 3. Buck converter topology

Figure 4. Simple boost converter

Keeping the switch in the same place and swapping the inductor and diode positions in the circuit yields the inverting topology (Figure 5). When the switch closes,  $V_{IN}$  is impressed across the inductor and the current ramps up as before. When the switch opens again, the current wants to continue to flow in the same direction. Thus, it flows through the diode and charges the output capacitor in the reverse direction, creating an output voltage with the opposite polarity to the input voltage.

Figure 5. Inverting topology

Using a transformer, you can realize boost, buck, or inverting topologies and isolate the output voltage from the input voltage. The circuit shown in Figure 6 is a boost transformer flyback topology.

Figure 6. Transformer flyback topology

## Control Techniques

Popular control techniques include *pulse-frequency modulation*, where the switch is cycled at a 50% duty cycle until the output voltage comes into regulation; *current-limited pulse-frequency modulation*, where the charge cycle terminates when a predetermined peak inductor current is reached; and *pulse-width modulation*, where the switch frequency is constant and the duty cycle varies with the load. Each of these control techniques has advantages and disadvantages.

Clocked pulse-frequency modulation, or PFM, is the simplest control technique. With this method, when the output voltage is below the regulation point the control circuit gates a free-running oscillator to the switch. The inductive charge pumping action boosts the output voltage back up to the regulation point. However, the inductor selection is complicated, the peak-to-peak voltage ripple can be quite high, and the noise/ripple spectrum will vary greatly with the load.

Current-limited pulse-frequency modulation is similar to standard PFM; but instead of using a 50% duty cycle oscillator, this control scheme employs a peak inductor current limit and a one shot. As soon as the output voltage goes out of regulation, the switch turns on until the inductor current reaches the programmed current limit, usually set with a current sense resistor in the inductor-current path. Once the inductor current reaches the programmed limit, the switch turns off for a time constant set by an internal one shot, generally on the order of a microsecond. At the end of the one-shot time constant, the feedback circuit compares  $V_{OUT}$  to the regulation voltage and either turns the switch on again if  $V_{OUT}$  remains out of regulation or holds the switch off until  $V_{OUT}$  falls out of regulation. Because the inductor peak current is fixed, this control scheme makes inductor selection easier; you only need to size the inductor core to meet the fixed limit. Also, because the peak current is fixed, the peak-to-peak ripple is reduced over the standard PFM, although the noise spectrum still varies with the load.

Figure 7. Adding feedback and control

The pulse-width modulation, or PWM, control technique maintains a constant switching frequency and varies the ratio of charge cycle to discharge cycle as the load varies. This technique affords high efficiency over a wide load range. In addition, because the switching frequency is fixed, the noise spectrum is relatively narrow, allowing simple low-pass filter techniques to greatly reduce the peak-to-peak voltage ripple. For this same reason, PWM is

popular with telecom applications where noise interference is of concern.

Figure 8 shows an example of the clocked PFM control scheme.  $V_{OUT}$  is fed back through a voltage divider to one input of a comparator whose other input is connected to a reference voltage. When the divided-down  $V_{OUT}$  falls below  $V_{REF}$ , the comparator gates the square-wave oscillator to the switch. This causes it to rapidly open and close, storing energy in the inductor and transferring it to the output capacitor in each cycle.

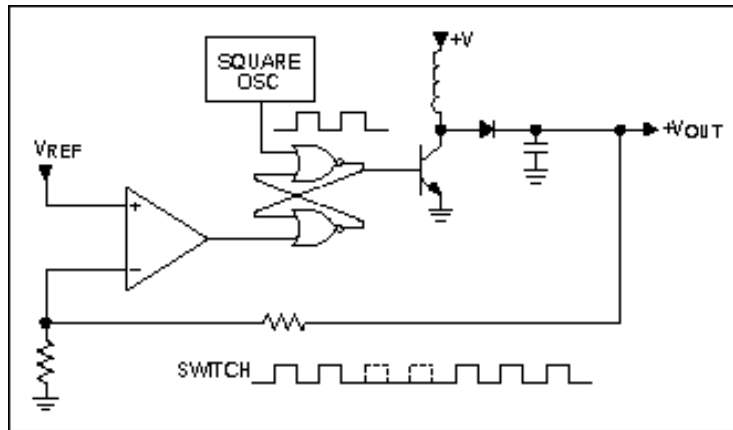

Figure 8. Clocked pulse-frequency modulation

The current-limited minimum-off-time PFM scheme, depicted in Figure 9, is a bit more complicated. As with the clocked PFM,  $V_{OUT}$  is fed back through a voltage divider to one input of a comparator whose other input is connected to a reference. The output of this comparator controls the trigger of a one-shot multivibrator. Another comparator looks at the peak inductor current as a voltage across a current sense resistor in the source of the N-channel MOSFET switch. When the output is out of regulation, the SR flip-flop turns the NMOS switch on until the voltage across the current sense resistor is equal to the reference voltage. The flip-flop resets, turning off the NMOS switch, the one-shot timer is triggered, and the switch remains off for the duration of the one shot, usually 1 microsecond. If the output voltage limiting comparator is still indicating an out-of-regulation condition, the flip-flop sets again and the cycle repeats itself.

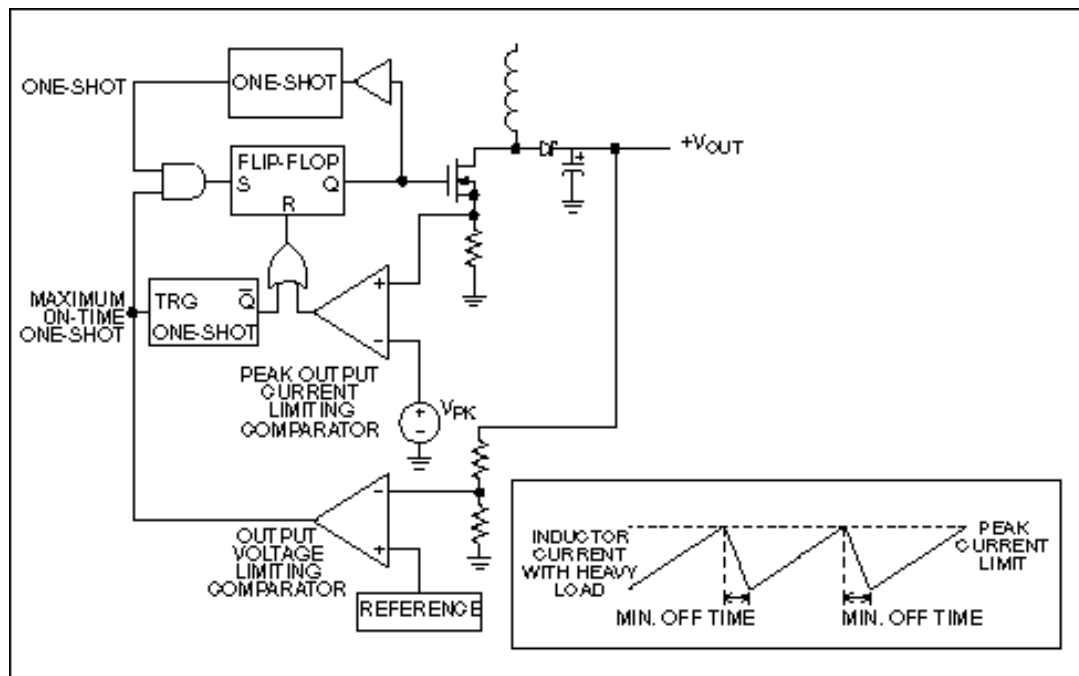

Figure 9. Current-limited minimum-off-time pulse-frequency modulation

Pulse-width modulation comes in a couple of different flavors. In voltage-mode PWM, shown in Figure 10, the divided-down output voltage is fed to an amplifier whose output is the difference between a voltage reference and the divided-down output voltage. This "error voltage" sets the threshold of a comparator whose other input is connected to a ramp generator. The output of the comparator drives the main switch. On a cycle-by-cycle basis, the greater the error voltage, the higher the comparator threshold on the comparator, and the longer the switch is held on. As the switch is held on longer, the peak current in the inductor is allowed to climb higher, storing more energy to serve the load and maintain regulation.

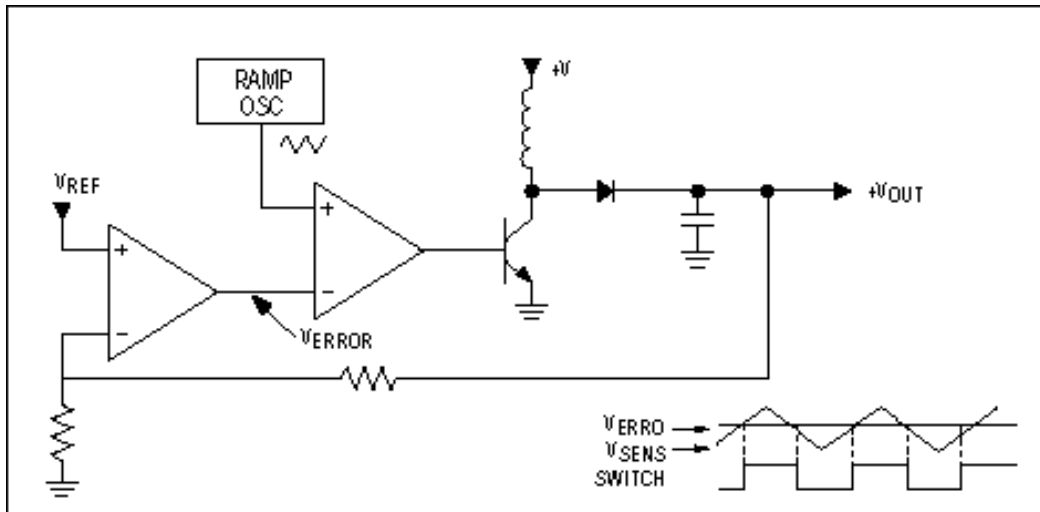

Figure 10. Voltage-mode pulse-width modulation

Current-mode pulse-width modulation (Figure 11) works in a similar fashion but with a key difference. As with the voltage-mode PWM, the divided-down  $V_{OUT}$  is fed to a different amplifier whose output is the difference between the fed-back  $V_{OUT}$  and a voltage reference. However, instead of setting the threshold on a ramp generator, this scheme employs a current sense resistor to sense the inductor current and flip-flop to control the switch. With each cycle, the switch is turned on by a pulse oscillator and the current in the inductor ramps up to the threshold set by the error voltage. This control scheme tends to be a bit easier to stabilize than the voltage-mode PWM.

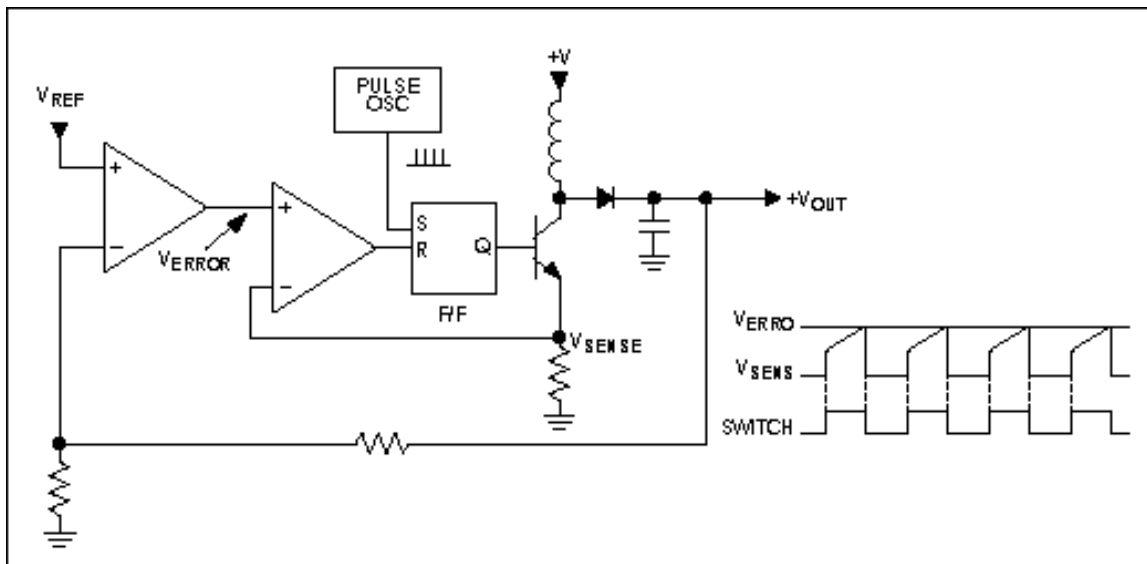

Figure 11. Current-mode pulse-width modulation

In striving for maximum efficiency, one of the largest power-loss factors to consider is that through the diode. The power dissipated is simply the forward voltage drop multiplied by the current going through it. This power dissipation (loss) reduces overall efficiency. To minimize

this loss, most DC-DC switching regulator circuits use Schottky-type diodes whose relatively low forward voltage drop and high speed minimize losses. However, for maximum efficiency, you can use a switch in place of the diode. This is known as "synchronous rectification" (see Figures 12 and 13). The synchronous rectifier switch is open when the main switch is closed, and the same is true conversely. To prevent "crowbar" current that would flow if both switches were closed at the same time, the switching scheme must be break-before-make. Because of this, the diode is still required to conduct the first bit of current during the interval between the opening of the main switch and the closing of the synchronous rectifier switch.

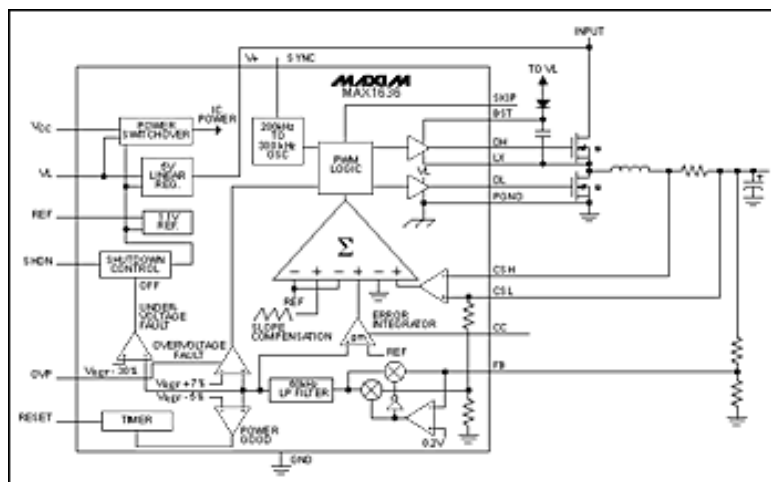

Figure 12. Synchronous rectification

[Click to view larger image](#)

Figure 13. Example: Synchronous rectified buck regulator

Another variant of PWM is the Idle-Mode™ PWM scheme (Figure 14). This technique combines the best of PFM's efficiency at light loads and PWM's efficiency and low-noise characteristics at higher loads. Thus, at light loads it acts similar to a PFM, skipping pulses as necessary, and at higher loads it acts as a PWM, affording the maximum efficiency over the widest possible load range.

Figure 14. Idle Mode™ PWM

In Figure 15, we see that the efficiency with Idle-Mode PWM is greater than 90% with V+ = 6V from 20mA or to just over 5A!

Figure 15. Efficiency with Idle Mode

right. as I have just built it and am playing with it now :)

the trick seems to be getting a large enough cap bank to pulse the batteries with and having it charge somewhat slowly, I don't have a large bank here at work, but with some small caps and a power supply it appears to work correctly but once it turns on the power from the supply is enough to keep it on (no ramp up of the cap) turns on about 5.5v above the batt voltage and dumped 15A at 14.5 volts into it, gotta wait till I can get home and throw it on the big caps.

only problem I could see is if the genny is making enough power to keep the caps charged thus keeping he circuit on. if not built to withstand your full current output could end up in a molten pile ;)

Yup. But, I did say this was a "simple" circuit. heh. A LARGE capacitance and a very LOW IMPEDANCE discharge circuit are the keys. The total capacitance would be over-engineered for the system ahead of time.

In my utopian world, all wind machines would be reconfigured to operate as 1:1 "magneto" systems. HV inductive impulses are the only thing that is used. You can literally run a single wire to the house and use a 6' copper ground spike on both ends as the second lead. Inductive discharge power transfer is FAR superior to standard AC or DC generator output. THIS is why Tesla said, in his autobiography, that he considered all of this AC systems to be a FAILURE. His later impulse systems were much better. BUT, he'd already gotten everyone using AC, essentially burying himself commercially. Then the systems were simply forgotten. Look at the patents after 1890.

I'm working on a wind generator design that has all this built in so that you don't need to have any heavy transformers and such out at your tower. If I get it worked out to my satisfaction, I'll post the plans for everyone to play with.

Here's the basic gist of how this operates. Those

skilled in the art of pulse-width-modulation will be able to whip up a test unit, post haste.

Tesla loved using capacitance on both ends of his impulse systems.

Put a LARGE capacitance across the genny output RIGHT AT the tower. If it's an AC machine, use a high-current full-wave bridge and then the capacitors.

Use a simple pulse-width modulator to control a heavy IGBT to pulse the capacitor into the primary of a HEAVY CURRENT 1:1 transformer. First, turn the pulse frequency down and then widen the pulse-width until you JUST start to see a DC line at the end of the ramp pulse. Then back off to about 80% of the ramp, so that no pure DC can flow. Now, turn up the frequency until you have a 50% duty-cycle. This is what I consider the optimum setting.

The transformer SECONDARY now gets a 1kv full-wave bridge rectifier. The negative output is fed into a deep earth ground. The positive goes down the long-wire to the house.

The PWM uses very little power. You can use a couple of 555 timers to build it. There are schematics all over the place for that chip. Put a 9v regulator and a 1000uf across the power leads, then power it from the capacitor bank at the tower. Use an opto-isolator between the PWM and the IGBT.

Whenever the generator puts out enough power to run the PWM, the system will start transferring power to the house as a buzzing HV spike train.

OK, back to the house.

Where the wire meets the house, drive another deep earth ground rod. Put a 400v 1500uf capacitor(s) between the wire and the ground connection. Run your jumpers from this capacitor down to the large cap bank.

The inductive spikes will collect in a 1:1 POWER ratio with the generator. BUT, the system now has the capability to go much higher than the straight generator voltage, as needed.

Make sure your BATTERY bank is configured to be AT or ABOVE the normal generator voltage output. If you pull the house capacitors LOWER than the normal generator voltage, you'll start to see CURRENT on the wire from the generator, instead of just the radiant (impulse RF???) spikes. You don't want CURRENT since it defeats the purpose of this system.

Re: Question for Charged. (none / 0) (#14)  
by charged on Fri Dec 19th, 2003 at 10:27:06 AM MST  
([User Info](#))

Another tidbit on the TRIAC/TRANSISTOR pulse circuit.

You could also use a solid-state pulse circuit to drive the triac gate at whatever rate you choose. You can even set up a few separate pulse-circuit pathways. One goes DIRECTLY to the battery from the caps. The other(s) can be wired with a WORKING LOAD in series between the cap bank and the batteries.

The capacitor bank can be used to drive certain types of loads DIRECTLY. BUT, you must place the load IN SERIES with the POSITIVE BATTERY BANK TERMINAL.

This prevents the capacitor bank from falling any lower than battery voltage, thus preventing heavy current-loading of your otherwise pristine incoming radiant pulses.

The discharge will simply be SLOWER, because the load resistance SLOWS DOWN the CHARGE TRANSFER.

Remember, your battery bank is a super-low impedance. You can drive heating elements, lights, DC motors, whatever, just by firing a controlled pulse-train from the caps, through the load, and through the batteries. This also ABSORBS load inefficiency since there is still REAL CURRENT pushed through the batteries in CHARGE MODE while the load is being powered.

Try it. Charge a large electrolytic cap to 25v. Discharge it into a 12v battery IN SERIES with a 12v signal-lamp bulb. Put an ammeter in series also. The discharge is SLOWER. But, all the charge above the battery voltage still passes through the battery as a charging current.

You just powered a bulb with Tesla's "radiant" energy and imparted some charge to your batteries at the same time. This is analogous to the way a reactive load works against an AC signal. The same process can work on DC circuits in this specific arrangement.

Enjoy!

Another tidbit on the TRIAC/TRANSISTOR pulse circuit.

You could also use a solid-state pulse circuit to drive the triac gate at whatever rate you choose. You can even set up a few separate pulse-circuit pathways. One goes DIRECTLY to the battery from the caps. The other(s) can be wired with a WORKING LOAD in series between the cap bank and the batteries.

The capacitor bank can be used to drive certain types of loads DIRECTLY. BUT, you must place the load IN SERIES with the POSITIVE BATTERY BANK TERMINAL.

This prevents the capacitor bank from falling any lower than battery voltage, thus preventing heavy current-loading of your otherwise pristine incoming radiant pulses.

The discharge will simply be SLOWER, because the load resistance SLOWS DOWN the CHARGE TRANSFER.

Remember, your battery bank is a super-low impedance. You can drive heating elements, lights, DC motors, whatever, just by firing a controlled pulse-train from the caps, through the load, and through the batteries. This also ABSORBS load inefficiency since there is still REAL CURRENT pushed through the batteries in CHARGE MODE while the load is being powered.

Try it. Charge a large electrolytic cap to 25v. Discharge it into a 12v battery IN SERIES with a 12v signal-lamp bulb. Put an ammeter in series also. The discharge is SLOWER. But, all the charge above the battery voltage still passes through the battery as a charging current.

You just powered a bulb with Tesla's "radiant" energy and imparted some charge to your batteries at the same time. This is analogous to the way a reactive load works against an AC signal. The same process can work on DC circuits in this specific arrangement.

Enjoy!

([User Info](#))

Ok, here's a cryptic response for you to ponder. First I'll give you a small experiment, then I'll give you a good off-loading method.

Set up a SMALL cap-discharge charging system as a TEST-BED. Start with something small like a motorcycle battery.

Use a 100ma 12v transformer feeding a large capacitance through a single rectifier (half-wave). Make sure the caps are rated for a minimum of 35v.

This way you have a good experimental input-power control mechanism.

You should end up with about 25v MAX in the caps if you don't discharge them.

Now, set up your TRIAC/TRANSISTOR discharge circuit between the caps and the battery with a 5v zener between the triac gate and the cap positive. High voltage bipolar transistors are better then mosfets for this application. A good IGBT is even better.

For a slightly more advanced control system, use a 555 with an opto-coupled output to drive the triac gate. This way you can set your discharge voltage by changing the pulse-rate. Adjust the pulse-rate while monitoring the battery voltage. Set the 555 to work from about 1.5hz up to 50hz or so, roughly. Start with fast pulses and work your way down in frequency.

Monitor the battery electrolyte temperature during charging compared to the ambient air temperature. You might be suprised at what you see.

Anyway, let the system run until you see the battery outgassing. Make note of the battery voltage at this point. Also make note of the battery temperature at this point.

Now, take a measurement of the specific gravity of the electrolyte. Do an extended load test on the battery to deplete it. Then recharge. Note the TIME it takes for recharging. Do your load test again. Repeat this process about 10 times and you might be very suprised.

In a nutshell, your batteries will behave differently under capacitive charging than they do with direct generator connection. All the "rules" of battery charging that have been written are based on MISMATCHED IMPEDANCE, STEADY-CURRENT charging systems that directly couple the inductive generator output to the ionic charging of the batteries.

Even systems that "pulse" the inductive source directly against the battery cannot do what a capacitive discharge can do.

5 minute interval.

Note: You may cloak yourself from appearing here in your Display Preferences.

Essentially, use an ACOUSTIC charge controller to monitor for bubbling inside the batteries. That is the REAL indicator that the bank has reached peak charge. For a larger bank, your weakest battery will bubble first. Put the monitor there.

Your monitor should be wired to a solid-state relay to divert discharges to the following load assembly:

Ok, OFFLOADING is EASY PICKINS!

It's just a matter of making sure that the caps never get dropped below generator voltage so that the inductive spikes are the only thing coming in on the line.

Cut out 1'x1' plates from 1/16" sheet steel. Stainless is preferred. For a 12v minimum cap voltage system, use 10 plates.

Mount them in a stack using 3/8" teflon standoffs in-between. You'll end up with what looks like a stack of square pancakes with little plastic spacers to keep them from touching each other. Each plate is electrically isolated from the next. Weld a couple of pieces of steel wire to the top and bottom plates on the stack. Hold the stack together with a non-conductive clamping assembly from either end.

Dangle this down about 10" from the bottom of a 55 gallon drum filled with tap water.

The two steel wires should be sticking up out of the water. Nothing should be making electrical contact with the drum surfaces.

This is a gassing H<sub>2</sub>/O<sub>2</sub> load for your discharge circuit. It will build up a scum layer on top of the water from minerals and such. Who cares. Just use a toilet float to keep the drum full of water. Simple stuff.

A small fan and ventilator tube can be attached to the top of the drum to discard the gasses outside the house. Don't try to pressurize this mixture since it WILL detonate at pressures exceeding 35psi.

Dangerous toys:  
For more fun, fill balloons with the mixed gas and ignite them with a 10ft "matchstick". Make sure you're wearing earplugs and safety goggles!

Yikes. I almost forgot something!!! Shame on me.

Make a light alkaline solution in the barrel using lye (red devil drain cleaner). Or for those who are more skiddish, use baking soda and push the solution to saturation.

This makes the water a bit more conductive.

DON'T USE SALT. It causes chlorine gas release. You don't want that.

I posted this in another thread.

[4 component load control system](#)

Thought I should post it here too.

A cautionary note about this type of energy transfer.

Accurately measuring energy actually being transferred with this kind of circuit is difficult. DC ammeters are not capable of correctly measuring pulsed currents and an AC ammeter is calibrated to a 60 cycle, true sine current and would return an incorrect reading.

The only proper method is via an oscilloscope across an appropriate current shunt and is a little subjective as to how to read it. The energy in a pulse is interpreted as the "area" above/below the zero threshold and contained within the displayed waveform. (inside the trace) Pulsed energy delivery systems are notorious for getting people excited about what actually is a less than stellar performance.

True energy transfer is measured not just in "watts" but in "watt time". (WattSeconds, KilowattHours, etc.) Kevin (kww - from previously mentioned thread) made note that his triac can handle 6 amps at 400 volts for a wattage of 2400 watts. My question would then be "What is the duration of that pulse and how often does it refire?" A 2400 watt pulse that lasts only 10 milliseconds (typical heavy current squarewave pulse) is only 24 wattseconds. If this circuit were pulsing once per second, the time averaged energy transfer would only be 24 watts.

Also, the 400 volts of the specified pulse is only the peak instantaneous voltage of the pulse and is preceded and followed by the ramping voltages which compose the majority of the pulse. These ramping voltages are obviously lower and therefore these areas of the pulse carry wattage that is correspondingly lower.

Just a couple of notes of caution regarding getting overly excited before the numbers are in. I admit that the concept of transferring full mill energy via a small gauge feed line has me interested.

Ok, I give basic empiracal results the most credibility when it comes to system analysis. Relatively static "before" and "after" readings are all that count, in a practical sense.

Here's the basics of how I've tested the system for power transmission. This is not the test for flyback efficiency. It's ONLY to prove the transmission efficiency of this process. Nothing more. Flyback efficiency is another issue based on transformer engineering. In a nutshell, whip up a GOOD 1:1 transformer that can handle the FULL current of your generator through it's primary and you'll have the best results.

I start out with the basic driver and a current source. I put a VERY large capacitance across the driver circuit and the LARGE inductance in series between the battery and that capacitor. My analog ammeter goes in series between the battery positive and the inductor. The scope shows a slight ripple down in the mv range. My digital VOM also shows a slight AC ripple in the mv range. The analog meter just reads a steady current when the flyback is operating.

With just a short lead, a 12" #18 alligator jumper pair, I charge a 400,000uf capacitor bank from the flyback emf.

Using a 10v zener triggered triac that drives a power transistor base in a darlington type arrangement, The cap discharges into another 12v battery at about 22v, plus or minus a little depending on the actual battery voltage.

This is a 4 Coulomb discharge (10v x .4F). By counting the number of discharges per second, you get your baseline for what's coming out of the flyback.

NEXT, run about 500 ft of #24 twin-lead out in a big loop.

Disconnect the short jumpers and connect the flyback to one end of the twin-lead. Connect your cap to the other end.

The cap charges as the same rate, UNLESS you discharge the caps to a voltage LOWER than the primary source voltage. Then you're below the 1:1 emf ceiling and you're drawing more primary current. You CAN

lower this ceiling by putting more turns on the primary and fewer turns on the secondary.

If you discharge the caps to 0v, it takes a while for them to come up to battery voltage (resistance on the line to the current). Once they've reached that point, the charging speeds up again.

This is Tesla's post-1890 methodology. He declared his own AC systems to be a failure because of the later discoveries dealing with short-duration UNIDIRECTIONAL impulses.

Many have treated his later inventions as some sort of insane mystical enterprise. In fact, the impulse power transmission methods work very well, once you understand how to apply them. Tesla patented the processes. But, he didn't include a full tutorial in his patents. Someone else explained to me how to apply it. I, in turn, hand it over to the home-power crowd. Hopefully, someone will get some use out of it.

There's the full autobiography text. Good reading for those interested in what floated through Tesla's mind.

## My Inventions The Autobiography of Nikola Tesla

---

### Introduction

Nikola Tesla was born in Croatia (then part of Austria-Hungary) on July 9, 1856, and died January 7, 1943. He was the electrical engineer who invented the AC (alternating current) induction motor, which made the universal transmission and distribution of electricity possible. Tesla began his studies in physics and mathematics at Graz Polytechnic, and then took philosophy at the University of Prague. He worked as an electrical engineer in Budapest, Hungary, and subsequently in France and Germany. In 1888 his discovery that a magnetic field could be made to rotate if two coils at right angles are supplied with AC current 90° out of phase made possible the invention of the AC induction motor. The major advantage of this motor being its brush less operation, which many at the time believed impossible.

Tesla moved to the United States in 1884, where he worked for Thomas Edison who quickly became a rival Edison being an advocate of the inferior DC power transmission system. During this time, Tesla was commissioned with the design of the AC generators installed at Niagara Falls. George Westinghouse purchased the patents to his induction motor, and made it the basis of the Westinghouse power system which still underlies the modern electrical power industry today. He also did notable research on high-voltage electricity and wireless communication; at one point creating an earthquake which shook the ground for several miles around his New York laboratory. He also devised a system which anticipated worldwide wireless communications, fax machines, radar, radio- guided missiles and aircraft.

Nikola Tesla is the true unsung prophet of the electronic age; without whom our radio, auto ignition, telephone, alternating current power generation and transmission, radio and television would all have been

impossible. Yet his life and times have vanished largely from public access. This autobiography is released to remedy this situation.

---

## Table of Contents

- [Chapter 1—Early Life](#)
  - [Chapter 2—Extraordinary Experiences](#)
  - [Chapter 3—The Rotary Magnetic Field](#)
  - [Chapter 4—Tesla Coil and Transformer](#)
  - [Chapter 5—The Influences That Shape Our Destiny](#)
  - [Chapter 6—The Magnifying Transmitter](#)
- 

### Purchase These Books By Nikola Tesla

- **My Inventions: The Autobiography of Nikola Tesla** - Author: Nikola Tesla, Ben Johnston (Editor)

Tesla's autobiography, the text of which is included in these pages, is available in paperback. This autobiography was originally printed as a series of six magazine articles in "The Electrical Experimenter" magazine. This edition is complete with illustrations.

[CLICK HERE to purchase this Paperback edition of "My Inventions"](#)

- **Colorado Springs Notes 1899-1900** - Author: Nikola Tesla

This reprint of Tesla's working journal during the period of his Colorado experiments provides insight into his thought processes and methods of working.

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Thanks Zubbly

I'll be making considerations of what magnet arrangement to use. I like what you did with the small magnets and the cage thing. I'm not sure I'm skilled enough to try that however. I do like the idea of low cogging. Have you considered a prop for this one. I'm sure it will be larger than the props I've been building.

This motor is quite abit lighter than my 200 lb. genny so the yaw bearing system shouldn't be to hard to build?

I've got the yaw system together for the 200 lb. genny but wieghting for free time and a break in the weather to put it up. It will be a heavy chalange.

Would you conider building a cage for my 7.5 hp motor if I shipped you the armature?

E-mail me with your descusion on this last ? Thanks.

Hi Jerry!

sorry i did not post the pics you wanted yet. i shall get it done this weekend.

i am flattered that you would consider having me build your rotor for you. as it is i am extremely pressed for time for my own projects, as well as getting time for the family things. at this time Jerry, i would not be able to consider it. however, i will try to get a post up for you giving all the detail on just exactly how to do it.

it does not take a lot of skill. i have ironed out all the bugs ofdoing it and will gladly share all the info with you. i know you can do it!

have fun-zubbly

There is a local aircraft service center here. I guess the FAA will only allow so many HRs on aircraft batteries. I've done some house trading with a guy how know a guy. One of those things. They are rated 42 amp hrs at 24 volts. They are 85 lbs each.

How do you water those batteries? They look very tightly packed to me. Are they sealed?

They are a sealed gell cell. They were used in helicopters. Because of this they are very rigid and reliable. The guy I got these from siad the first time he saw one a guy was welding with it. I belive that cause when I acceadentially shorted the termanels there was quite a fire ball.

I think some folks here have said this type of battery is not good for RE use but I got them cheap and they've been working great for me.

well, here we go (beware dialup)  
to many batteries

to few racks

these racks will hold 24 of the 60 cells I have, each is rated at 2v200AH so the total in my basement when i finish getting it hooked up will be 24v@400Ah

## My Solar Power System

The switchboard consists of a charge controller (yellow box), inverter (blue box) and a Real Big Switch.

Half of the battery bank.

The whole battery bank - 1100Ah at 24V. Total weight ~ 1500kg.

The solar panels on my roof. There are 2 more to come, for a total of 560 Watts.

The rear of the solar panels, showing my homebrew rack. The timber is to prevent scratches on the colourbond roofing.

Nice Exide Faure-X collection! (I thought I was the only guy using them!)

That's a nice shelving system too. I've been thinking about how to arrange mine once I move, and you've given me a few ideas. ;-)

Hi Ted  
You and Charged are responsible for my trying this. After seeing your posts.  
I have a few hundred of these little transformers. They are audio isolatin trans. with a 1 to 1 ratio. When both coils are siriased it measures 2 ohm,s DC. I cut the laminations so there are a "T". I place the top of the "T" in the round slot where normally a circle of lamination matereal would go. This alowed the "T" part to almost tuch. I filled the small void between each "T" with JB Weld. It has steel in it so it bridged the magnetic gap between transformers. The cogging was bad until rpm was up.

Jerry

Here is a inductor coil I found at a Ham swap meet I got 32 of them at 50 cents each.

The guy that I got them from said they were for speaker cross overs.

I tested one with eight neos 3/4 by3/4 by1/4 on the 6 inch face plate on my lathe.

I got 3.4 voltes at 138 rpm with a 1/4 inch air gap. This is as slow as the lathe would go.

Cogging has been my main worry for not going any farther than this the tool post that I had clamped the coil in had some play in it and shook like the devil.

Keep them flying

Hi Old F

Yes these are subwoofer crossover coils. We don't use these at our stereo shop because you loose 36 watts out of 100 watts in this coil. We do use them as part of a hipass xover for midrange speakers some times however. I have these also.

Dan B did an expiriment with a simular coil arrangement befor he discovered the disc alt. I think preformance was poor however so the idea was not persude.

I'm getting the same voltage from the small disc alt no load per coil but very low amperage. In thirory it should have worked but in reality I'm moveing on to the normal laminations and coils. I am however going to use small gage wire and do a diode bridge for each coil.

Its that large # of small things working together?

JK TAS Jerry

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Old F  
Yes these are subwoofer crossover coils. We don't use these at our stereo shop because you loose 36 watts out of 100 watts in this coil. We do use them as part of a hipass xover for midrange speakers some times however. I have these also.

Dan B did an expiriment with a simular coil arangement befor he discovered the disc alt. I think preformance was poor however so the idea was not persude.

I'm getting the same voltage from the small disc alt no load per coil but very low amperage. In thirory it should have worked but in reality I'm moveing on to the normal laminations and coils. I am however going to use small gage wire and do a diode bridge for each coil. Its that large # of small things working together?

JK TAS Jerry

Just a note. The input amperage on this supply is listed at 2.1 amps. Not bad consumption for the out put its rated.

by [kell](#) on Mon Dec 8th, 2003 at 11:22:27 AM MST ([User Info](#))

Sure you can run DC into it. If the supply has a full bridge (four diodes) at its input, it won't even matter what polarity.

Re: Switching power supply experiment. ([none / 0](#)) (#7)  
by Nando on Sun Dec 28th, 2003 at 02:20:17 PM MST ([User Info](#))

JT Tas Jerry:  
By the way: Human power, long term, is defined as a 75 watts source with about 150-200 watts short time power peaks.

For wind mills that have high variable generated voltage, a converter is the ideal case, basically like yours.

The Switching power supplies, most of them that have wide AC voltage range ( 85 to 240 AC )are designed to operate at high voltage -- 230 to 340 volts DC.

So the input has a switch ( some are automatic) for voltage range 120 or 230 input AC Voltage.

This AC voltage is then doubled rectified for the low range or and for the high range, full wave rectified and filtered then the high frequency converter does the rest.

For this type of converter to operate with the wind mill several things are needed>

The best is to have a converter with PFC ( Power Factor Correction) to accept all the voltage range directly without problems, and if you can furnish DC or rectified DC single or 3 phases ( 230 to 360 volts DC).

Mouser and/or Digikey may sell some of those chargers at low price, like a non-PFC converter, 250 watts for around 80 USA dollars. ( for single 12, 24 & 48 outputs)

The system should, as well, have a Controller for overvoltage and over-RPM protection to present a dump load to the generator, the best is a duty cycle controller to present a variable load to the generator to maintain accurate regulaed output voltage under wide wind and load variations.

This duty Cycle controller, that I have designed is just a power MOSFET with a Mosfet driver and a LM339 that produces a triangular low frequency ( ~ 200 Hertz) and a comparator to duty cycle the MosFet ON/OFF times. In some cases an amplifier is needed to insure proper operation

Regards

Nando

So the input has a switch ( some are automatic) for voltage range 120 or 230 input AC Voltage.

This AC voltage is then doubled rectified for the low range or and for the high range, full wave rectified and filtered then the high frequency converter does the rest.

For this type of converter to operate with the wind mill several things are needed>

The best is to have a converter with PFC ( Power Factor Correction) to accept all the voltage range directly without problems, and if you can furnish DC or rectified DC single or 3 phases ( 230 to 360 volts DC).

Mouser and/or Digikey may sell some of those chargers at low price, like a non-PFC converter, 250 watts for around 80 USA dollars. ( for single 12, 24 & 48 outputs)

The system should, as well, have a Controller for overvoltage and over-RPM protection to present a dump load to the generator, the best is a duty cycle controller to present a variable load to the generator to maintain accurate regulaed output voltage under wide wind and load variations.

This duty Cycle controller, that I have designed is just a power MOSFET with a Mosfet driver and a LM339 that produces a triangular low frequency ( ~ 200 Hertz) and a comparator to duty cycle the MosFet ON/OFF times. In some cases an amplifier is needed to insure proper operation

Regards

Nando

I've been wondering, since I've never had a motor/generator near that big to try it out on....would it be easier to 'pedal power' something like this to charge a battery? It could be 1:1 ratio chain drive using something like your flywheel exercise bicycle...yeah I know it would be kind of overkill but just out of curiosity....Well maybe not quite that big big...but big enough to put out some charging current at 80-90 rpm 1:1 ratio...foot power?

Oh sorry BIG goof this time. This is a picture of my pump power supply. Or some would call it my mechanical inverter.

There are 2 two HP dc motors. One on each side of a 5500 watt 240 ac generator. This was powered by 20 12 volt batteries. They went bad last winter and I've not replaced them yet. This combo runs my well pump great. No load 260 volts and while pumping 242 volts. Just right.

Hi Dr D

I'm not to good with this computer stuff and i goofed last night.

There is a brief description in a post just above somewhere.

I couldn't aford the big inverter that could run my well pump in emergency power outs.

This was my sollution. If power goes out we would use watter spairingly. And this power source will cover are needs. I do have a 5500 Generac gas gen if power is out long term.

It was also one of those , can I do this, kinda things.

I have a few of these 2 hp dc motors left if someone is in need. They are Magnatek. I bought surplus locally.

I don't think the surplus guy knew what he had. When I called Magnatek the factory guy said these are \$1000 motors. I'm asking \$100 each.

Its amazing how 2 two HP dc motors can easley replace a 10 hp gas motor.

Jerry;

Great pics. I fixed things up hope all the pics are there you wanted.

Your biggest problem posting for proper size is you must hit the enter key after you finish typing the text and before you click that add photo button. It ensures the pic is on its own line and works like a charm.

Cheers.

TomW

when you post a response the title of the post becomes the "subject" of the response and can be changed in the box under your name when you post a response.

when a story has a long title sometimes it causes problems with responses and you need to shorten it or change it to something shorter when you reply

10 years ago I bought an old craftsman 6 volt cordless with built in batteries which soon died. I pulled the batteries and ran a cord out to plug into my 12 volt house system. Used it for years for light duty work. It just ran faster than with the batteries. If the gearing can handle the load and you don't push it harder than before the only problem would be heat in the motor coils. I didn't have to worry about how much the voltage dropped in the long cord and thin extension cord because I could lose half the voltage and still use the drill.

Hi Jerry.

A couple years ago I had a bunch and can also get hold of a lot of these coils, I remember the oil that was in them, I do not beleive that there where pcb's in them, I did do extensive google search and nothing popped up. Mostly what I do remember was that pcb's where found in larger transformers used in street lighting, you might also find them in old neon sign transformers and most of that looked like liquid black tar, very dark in color. As for the wire, there is lot's of #20 I think for the primary and #30 for the secondary, very easy to remove the windings. Good resource for wire now that you mention it. maybe others could shed some light on the pcb issue, I'm interested in this question as well.

On PCBs ([none / 0](#)) ([#2](#))  
by wdyasq on Thu Nov 27th, 2003 at 06:18:41 AM MST  
([User Info](#))

One would think there is a particular year where PCB's were banned from use. If one used a coil built after that year, one should be OK. BUT, car companies had a lot of exemptions from enviromental rules so that may not be true.

Ron

Identifying PCBs ([none / 0](#)) ([#3](#))  
 by ADMIN ([admin@otherpower.com](mailto:admin@otherpower.com)) on Thu Nov 27th, 2003 at 09:24:21 AM MST  
 ([User Info](#))

From a university of toronto website.....might help. Looks like you only need to worry about anything made before 1980, and only high voltage transformers. The part about ballast capacitors in old flourescent lights was new to me though.

\*\*\*\*\*

#### 4.2 TRANSFORMERS

Since the 1930's, a generic fluid called "askarel" containing 40-70% PCBs were used in high voltage transformers. Commercial Aroclors were blended with trichlorobenzene. Askarel is the genetic term used to identify the combination of Aroclor and trichlorobenzene. A typical Askarel transformer may contain 30-40% PCBs and as high as 65%. Contaminated mineral oil usually contains < 1% PCBs.

PCB-contaminated transformers can usually be distinguished by the nameplate on the transformer located on the outside casing. If the following brand names appears on the nameplate, the transformer contains PCBs:

TABLE 1: TRADE NAMES OF PCB-CONTAMINATED TRANSFORMERS

Apirolio [Italian]	Kaneclor [Japan]
Aroclor	Montar
Asbestol	NoFlamol
Chorextol	Phenoclor [France]
Chorinol	Pydraul
Clophen [German]	Pyralene
Diaclor	Pyroclor
DK (decachlorodiphenyl) [Italy]	Saf-T-Kuhl
Dykanol	Santotherm FR [Japan]
Elemex	Sorol
Eucarel	Therminol FR
Fenclor [Italy]	
Hyvol	
Inerteen	

In addition, the "Type Number" also indicates if the

transformer contains PCBs. Any Type Number beginning with "L" indicates that the transformer is PCB-contaminated. Some Type Numbers are: LFAF, LFAN, LFWN, LNAF, LNP, LNS, LNW, and LNWN.

#### 4.3 CAPACITORS

Almost every capacitor manufactured between 1930-1980 contains PCB dielectric liquids. Capacitors in electrical equipment vary in sizes from ice cubes to larger than refrigerators. Capacitors are classified as large when they contain > 0.5 kg of PCBs. Small capacitors are generally associated with electronic or lighting equipment. Fluorescent light ballasts also contain capacitors. Light ballasts are discussed below.

Capacitors may be found in a variety of locations within a building for example connected to A.C. motors > 30 hp wired to the electrical terminals. A capacitor often can be recognized by the letters KVAR stamped on its nameplate. Capacitors may vary in size from 5 KVAR to 200 KVAR range. Capacitors are hermetically sealed to reduce leakage. Unless clearly indicated on the equipment, or the date of purchase can be confirmed to be after 1980, most capacitors in use must be assumed to be contaminated with PCBs unless tests have verified their absence.

##### 4.3.1. BALLASTS

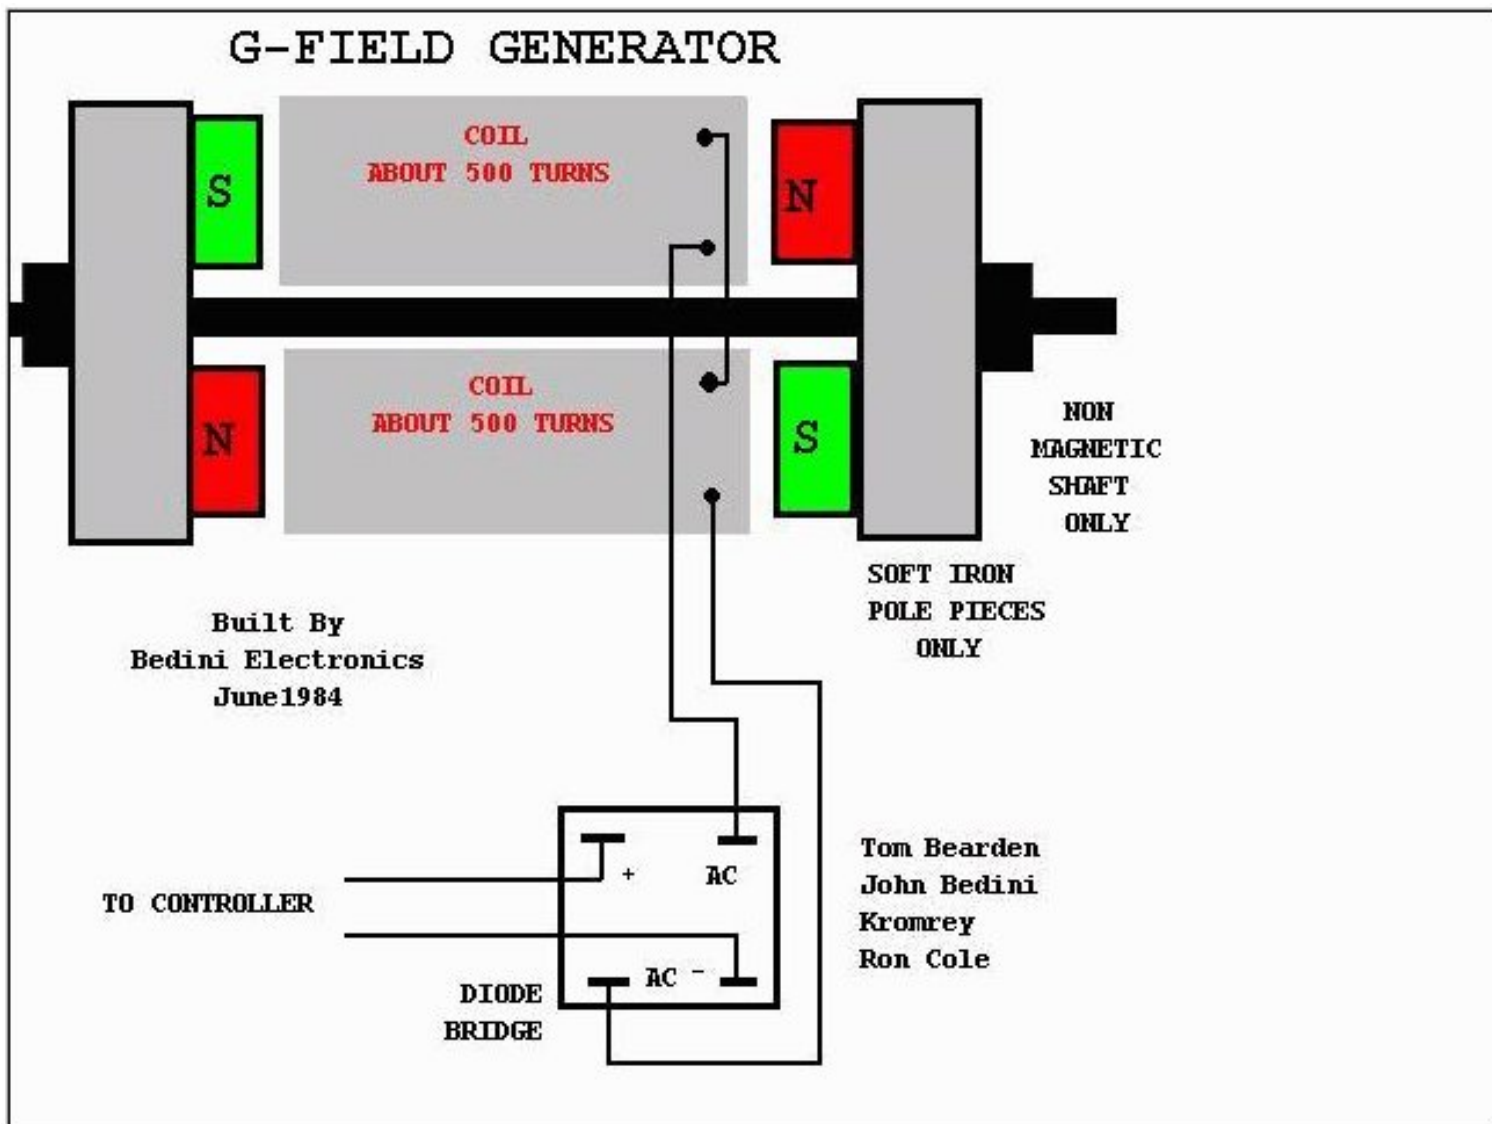

Fluorescent light fixtures may contain several ballasts. Fluorescent lighting ballasts are easily identifiable containing PCBs or non PCB. The small capacitors inside the ballasts are contaminated with high levels of PCB liquid if they were manufactured prior to 1980. At the University over the years, these ballasts have been used from a wide variety of manufacturers. The Office of Environmental Health and Safety maintains a list of models from various manufacturers that are PCB-contaminated.

Identifying PCBs ([none / 0](#)) ([#3](#))  
 by ADMIN ([admin@otherpower.com](mailto:admin@otherpower.com)) on Thu Nov 27th, 2003 at 09:24:21 AM MST  
 ([User Info](#))

From a university of toronto website.....might help. Looks like you only need to worry about anything made before 1980, and only high voltage transformers. The part about ballast capacitors in old flourescent lights was new to me though.

\*\*\*\*\*

#### 4.2 TRANSFORMERS

Since the 1930's, a generic fluid called "askarel" containing 40-70% PCBs were used in high voltage transformers. Commercial Aroclors were blended with trichlorobenzene. Askarel is the genetic term used to identify the combination of Aroclor and trichlorobenzene. A typical Askarel transformer may contain 30-40% PCBs and as high as 65%. Contaminated mineral oil usually contains < 1% PCBs.

PCB-contaminated transformers can usually be distinguished by the nameplate on the transformer located on the outside casing. If the following brand names appears on the nameplate, the transformer contains PCBs:

TABLE 1: TRADE NAMES OF PCB-CONTAMINATED TRANSFORMERS

Apirolio [Italian]	Kaneclor [Japan]
Aroclor	Montar
Asbestol	NoFlamol
Chorextol	Phenoclor [France]
Chorinol	Pydraul
Clophen [German]	Pyralene
Diaclor	Pyroclor
DK (decachlorodiphenyl) [Italy]	Saf-T-Kuhl
Dykanol	Santotherm FR [Japan]
Elemex	Sorol
Eucarel	Therminol FR
Fenclor [Italy]	
Hyvol	
Inerteen	

In addition, the "Type Number" also indicates if the

Hi Norm  
 I read brifly through David Buchers page. He stated "maybe" the average human can peddle between 40 to 120 rpm.

I just looked at the peddle to pma gear ratio on my bike. Its aprox. 8 to 1. If Davids #s are right the rpm range on this bike of mine would be 320 rpm to 960 rpm?

However I was geting 140 volts with a 100 watt plus load from a motor/pma rated 1075 rpm as a motor.

How could I deturmin the rpm of the pma? Could I measure the frequency and do some math? Its a 6 pole with 6 magnets. All 6 poles are wired in saries, stock wireing.  
 woud I have to seperate and measure on just one coil?

This has got my curiosity going now?

JK TAS Jerry

# David Butcher

Have you ever wished you could create useful power solely with your own body? To be able to travel, move heavy loads, perform machine work, and generate electricity with your legs, arms, etc? I went beyond wishing. I imagined, designed, and built what I needed to achieve my dreams.

---

Note: My ex employer, [Novell](#), has eliminated my position, Director of Web Marketing and Corporate Webmaster. I am actively looking for a job which would combine those talents with the creative engineering approach embodied in the projects found on this page. My [resume \(MS Word version\)](#) spells it out. In the meantime, I may finally have some time to update this page, and perhaps even to bring some of the projects back to life. Never abandon your dreams.

I have always been a mad scientist at heart. Three projects from the past that I am particularly fond of are a [pedal generator](#), a [pedal-powered "pickup truck"](#) and a [pedal-powered canoe](#).

My most recent project is a [Micro Solar Lighting System](#).

I have a voice synthesizer waiting to help you say 'Hi' if you like.

And on very rare occasions, you can [see me](#).

A [Datsun Roadster Fuse Box Diagram](#) is here in a small (9k) postscript file.

If you have a Datsun Roadster, you may be interested in the details of [rebuilding the heater](#), a project I finished in the summer of 1995. In 1996, I tackled the [SU Carburetors](#). My latest project (1997) was to [enhance the ignition system](#) before the cold weather sets in. With summer on the way, you may be interested in the [cooling system enhancements](#) I designed.

I recently replaced the wheel bearings in the left front hub of the roadster. If you would like a write-up of the activity, please mail davidbu"at"www.los-gatos.ca.us and ask. If enough people write I will create the write-up.

This is my [Datsun Theft Deterrent System](#).

In the summer of 2000, we decided to go green, and we signed up for both [Green Mountain Energy](#) and [Corbin Motors Sparrow #95](#), an electric vehicle. The Sparrow is here and it is a blast! If you like reading about other folk's experiences with things, you may enjoy my [Sparrow diary](#).

Of course, my autobiography would not be complete without mentioning ["hal"](#), a program I wrote in 1983 and ported to the WWW.

P.S. My wife owned [Nine Lives](#), one of the first "Electronic Storefronts" on the Internet. The physical store is now closed, and I am in the process of archiving the online store.

And last but not least, here are some totally obscure pages:

[Connecting my Linux system to DSL.](#)

[Radio Shack Model P Video Repair.](#)

[The world's first solar calculator, which I invented.](#)

[Faster UNIX Bourne Shell Scripts.](#)

[A Linux or Unix shell script for printing Avery 5266 labels.](#)

[A Music Link and Resource page for Linux users.](#)

[Magazine Sales Scams to Avoid](#)

considering the windmill without use of batteries, a flywheel gives me an idea. My first thought was to store the winds energy by filling a tank of water. Ha - a spinning tank of water that winds up on a cable too. Missoula Montana has a lot of bikes! Partly because people are too poor to drive and because its flat in the valley. Get rid of the car and stay in shape:)

Ladies and gentlemen, I give you BobFlex.  
This is my computer and TV riding bike and SLA battery charger. I made the Alternator out of old magnets and oil burner casing parts. It will put out decent power. The bike was a throw away but it has a good heavy flywheel. It does 'cog' a little at low rpm so the next one I'll skew the magnets.

Re: 10th Genny flying ([none / 0](#)) ([#1](#))  
by Tahino on Sun Nov 23rd, 2003 at 09:41:06 AM MST  
([User Info](#))

Hi Jerry:  
Can you describe that 156 volt system you are charging for lights, tools and heating please? How it works?  
Thanks

Re: 10th Genny flying ([none / 0](#)) ([#3](#))  
by Jerry on Sun Nov 23rd, 2003 at 10:13:56 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Hi Tahino  
It just turned out that way. I freind of mine is a retired electronic transportation engineer. He designed electric things that move. He has a hybrid vehicle gas/electric of his own design. This van had 12 very large 12 volt batteries. They are about the size of 2 six volt golf cart batteries. He was given a grant from Optima Battery Co. They fixed him up with some large deep cycle gell batteries.

I bought his old batteries real cheap. I got 13 of them, that's what he had. I use 12 of them in my 48 volt home system for a while till I picked up 22 aircraft batteries. they are 24 volt.

I decided to take all 13 of the old big ones to my store/shop. We wired them in series. We've tapped off at 130 volts for our power tools. All of our power tools with high rpm motors with brushes work very well at 130 volts dc. This includes big shopvac, drills, chop saw, skill saw, router, rotozip and a few more I can't remember. Also a few incandescent bulbs.

These power tools run faster, stronger, much smoother. We've decided even if we weren't doing the wind power thing that we would make dc volts for these tools. We're spoiled now.

The 156 volt tap goes to a 240 volt electric furnace. this furnace has three 5000 watt elements. We can switch on 1, 2 or 3 of them. I'll be changing the blower motor to dc soon but for now we use the ac blower motor.

It's amazing how much heat this thing makes at just 156 volts. We only run it for 1/2 hr. to 45 min. just to warm the shop up in the morn. After that we still have plenty of power left all day for the tools.

5 minute interval.  
Note: You may cloak yourself from appearing here in your Display Preferences.

I only have 4 gennys on this battery bank so far. fist 2 batts are on one genny the next 1 batt. has 1 genny the next 2 have a genny and the next 3 I've got my 48 volt SW-403. I've got my 48 volt 403 charging at 36 volts. I dosen't do much at 48 v. it does a little better at 36 but its still prety lazy compaired to the homebrew stuff.

The other system uses 14 six volt golf cart batteries wired as a 12 volt bank. I have 5 gennies chagreing this group right now. We've seen 150 amps comming into this bank on very windy days. Thats awsome cause we use this bank for are shop lights. We have 60 four ft. florecents that are power by a 2500 watt square wave inveter.

We also use at the same time from this system a small bench grinder and a small drillpress. We also run test equipment and charge our Makita's.

We're going to take the 220 v. ac motor (grid powered) of our air compresor and replace it with a 2 hp 100 volt dc motor and power it from the 156 volt bank.

Our goal is to power out install bays/shop from the wind as much as possible. Hopefully everyday. To do this I want to build and put on the roof 10 more gennys. Also icrease the battery banks. Double or triple there size.

We have kept the store operational during power outages. This while our business neighbors were in the dark.

They only think your crazy when the powers on. When its off they are envious.

Right now I'm building stuff for other people so its hard to get these projects going

JK TAS Jerry

Boy, talk about "walking the walk"! :-)

Congratulations!

What portion of your electrical needs do these generators satisfy?

Hi Cevonk

I may have answered your question in my previus post. We are trying to get the shop prortion of our store as grid free as posible. Not there yet but we have ran the shop for several hrs grid free a few times. Just depends how generus the wind has been. Thats why we need more genny's and batteries.

I forgot to mention above. When all the lights are on in the shop the inverter is drawing 120 amps so on those very windy days when the genny's are delivering 150 amps we are 30 amps ahead of the game. I'm confident that after we add batts/gens the shop will be grid free. But wow we suck up alot of power in that shop. We also powewr up several multy 1000 watt demo systems from this power also.

Re: Turns Counter ([none / 0](#)) (#4)  
 by NJ JOHN on Wed Nov 19th, 2003 at 06:45:56 AM MST  
 ([User Info](#))

Hi  
 New to this board and this is my first comment. Here's a way I made a counter/tach with a Dollar Store calculator. What I did was soldered 2 wires to the leads going to the EQUAL key and the other ends to an earphone jack and mounted this to the case of the calculator. To make a sensor I connected a normally open micro switch (or magnetic switch) through a toggle switch in parallel with a normally open pushbutton switch. This was then wired to a jack.

To use this setup just plug the jack in when needed and remove when being used as a calculator.

To use as a counter just turn on the calculator enter + 1 on the keypad and each time the switch is closed the calculator increases by 1 until you reach your desired count. If you put in a starting number and enter - 1 on the keyboard and when the display reads -1 you have completed your count.

To use as a tach open the toggle switch and push the push button switch for 15 seconds then multiply by 4 for RPM.

I hope this helps.

John

OK Kurt or Tom help me out here. I'm going by the instruction but it still doesn't work but I don't mind if you guys do all my pix posting for me. However I'm sure you have better things to do.

To bad these things only work for computer savy people. I'll keep being a pest till I figure it out. Sorry I'm so slow at learning this stuff. If you want to know how hard it is for me just take 6 marbles and stack them one on top the other.

Hi Jerry,

from some left over composit decking material. This stuff is a combination of wood fiber and plastic mix. It won't crack, split, peel, rot, or twist.

Would you happen to know what this stuff is called or maybe someone else reading this? Been wanting to make a few things out of something just a little more durable than particle board like a flywheel for an pedal powered generator for instance and the base....etc.

Don't worry so much about pic size...for anyone that really is interested in reading your posting there are ways...for instance I just drag n drop stuff like that onto a html editor...size the pics to what the author probably had in mind...and save it to a special folder on my hard drive. I know the frustration of computers tho' I have a nephew...I knew him as an 8yr.old brat....now he's 22 or so and troubleshoots my computer goes to DOS and types something in and fixes it easier than I can say WOW! How'd you do that?(>) Norm.

<http://www.dplusv.com/Photo-03.html>

Hi Norm

Ya its called Choice Deck. I got mine at lowes. This matereal comes in a few diferant widths and thicknesses. The scrap i made a genny base out of was a 1 X 6 ".

I've got some 1 X 12" scraps also. I spent most of this last sommer building this deck. Thats why I'm so behind on wind projects. This deck measures 22 ft X 24 ft. with a roof and a lower area with a roof measuring 20 ft X 24 ft.

There are seveal brands making this compisition matereal. I've been told its made of wood fiber and recycled plastic milk jugs or plastic Wall Mart bags.

Today I tryed another bearing. This one is not a pivoting flange bearing. It was just a bearing with no housing. The outer diameter of the race measured 3 1/8 inch and the bore is the same as the bearing in the above pix. I cut a hole into a pice of Choice Deck 3 1/8 in. and presed the bearing in. There is a narrow stop type snap ring on the outer bearing race for mounting purposes. I pressed the bearing in till it hit this stop. I'll make a small metal retainer ring to keep this in place.

This bearing can't pivot and its realy smaller and lighter and cheaper than the big pivoting flange bearing of the same diameter. I think this is it. Any way this is what i'll be doing for

yaw bearings and genny mounts.

I'll try to get some pix. The only draw back is its not as prety as the flange bearing and plexi but it is cheaper and lighter. Might even be stronger.

JK TAS Jerry

Ya its called Choice Deck. I got mine at lowes. This matereal comes in a few diferant widths and thicknesses. The scrap i made a genny base out of was a 1 X 6 ".

I've got some 1 X 12" scraps also. I spent most of this last sommer building this deck. Thats why I'm so behind on wind projects. This deck measures 22 ft X 24 ft. with a roof and a lower area with a roof measuring 20 ft X 24 ft.

There are sevealr brands making this compisitiom matereal. I've been told its made of wood fiber and recycled plastic milk jugs or plastic Wall Mart bags.

Today I tryed another bearing. This one is not a pivoting flange bearing. It was just a bearing with no housing. The outer diameter of the race measured 3 1/8 inch and the bore is the same as the bearing in the above pix. I cut a hole into a pice of Choice Deck 3 1/8 in. and presed the bearing in. There is a narrow stop type snap ring on the outer bearing race for mounting purposes. I pressed the bearing in till it hit this stop. I'll make a small metal retainer ring to keep this in place.

This bearing can't pivot and its realy smaller and lighter and cheaper than the big pivoting flange bearing of the same diameter. I think this is it. Any way this is what i'll be doing for yaw bearings and genny mounts.

I'll try to get some pix. The only draw back is its not as prety as the flange bearing and plexi but it is cheaper and lighter. Might even be stronger.

JK TAS Jerry

Nice job Jerry. Only one thing bothers me this bearing looks like a self aligning type which means that the bearing can move wherever it wants to in its housing possibly allowing the blades to strike the tower. But I could be wrong let me know. As usual great work. I hope to drive by your shop one of these days. Maybe with a little luck.  
RobC

Hi Rob C.  
Are you in the Salem area?

The bearing can pivot and if I let it do that it would be a problem.  
This is why I use 1 1/8 inch thick plexi. This bearing accepts 1.5 inch diameter EMT conduit. I have a hole saw blade that cuts a hole just the right size to let the conduit spin free. There is a hole in the plexi that the mast (1.5" EMT) slides into after passing through the bearing. This stops the bearing from pivoting. I grease the hole in the plexi with a generous glob of copper never size. I've got several gennies using this yaw system. They've been through several storms, the bearings yaw so easy and don't loose alignment. There was one more picture that didn't come through on my post and the top one came out blurry. It was supozed to come out last? I'll try to post pix of this yaw system when I put it on my small disc alt.

Jerry we live here in southwest Idaho but we may make it out to the coast next year if we I would like to swing by.  
Ater I made my comment about the bearing I realized what you were doing. Boy, do I feel dumb. Anyway, talk to you later.

Thanks Kurt

I wish I had some one to do my home work for my when I was in school. Oh but then I wouldn't learn nuthin.

I'll keep tryin to post pix. I may learn some day but if your there to bail me out we shouldn't miss any.

PS this pic is a 3 phase conversion, 48 volt.

The heat sink on the back of this one is from a GM car alt. It is the diode package. Small premade and its a 6 pack, a 3 phase diode pkg.

I got the lamination metal from Ed. Now just got to figure out what to do for coils. These magnets are 1/4" X 1/2" X 1" Neo's. The lamination metal will also be 1 inch wide when inplace.  
I plan on a 48 inch 3 blade for this one. OH ya 8 magnets 8 coils single phase. Its my first disc alt.

Hi Troy

I don't think this one will match up to the GARBOGEN but I've wanted to do a disc alt for a long time.

It all started when I saw DanB's first units. Since I've been so slow the desing of the disc alt has been improving almost weekly. If I keep letting all the others do the research I'll save a bunch of time saved.

I think the AX-300 is the 6 inch DanB did with the gear. If I remember right I think it did around 200 watts? Correct me Dan if I'm wrong?

Ofcourse I would like to better Dan's #s a little. Must be a chalinge thing. If it works then on to the bigger units.

I'm still shooting for 2 KW out of my plstic blades? On the bigger genny.

JK TAS Jerry

[Poured Stator ?](#) | 16 comments (16 topical, editorial)

Re: Poured Stator ? (none / 0) (#1)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Tue Nov 11th, 2003 at 06:07:07 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

Hi Jerry,

I believe iFred's is using a non metallic version as I posted some time back for the dual rotor alternator. My attempt that's posted on my site was for a "quickie" laminated stator by adding iron powder to the plastic mix. The end result is very inefficient. It does make it very easy to put together a slotted stator but there are a lot of losses. The steel laminates either using 1018 strips to form a stator and either slotting them or laying coils over them is far better than the poured iron powder. The silicon steel is far superior. For a quickie project the poured core unit is quite fun, quick and simple and you can usually put an alternator together in a day or two using the poured methods.

Have Fun  
Ed

Re: Poured Stator ? ([none / 0](#)) (#2)  
by Jerry on Tue Nov 11th, 2003 at 09:46:59 AM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Thanks Ed

I noticed your design and iFred's are different. I was thinking of using the steel lamination as normal and pouring the iron/epoxy mix on the steel.

The idea here is to have the good performance of the steel and use the mix as a medium as a path for the flux to follow. This to enhance the flux strength in what otherwise is just open air, the gap between the coils and the laminations. Surely the iron mix will be more conductive to the magnetic flux than air would be. I see the iron past mix as a much better path than just air.

I would use iFred's design and simply mold the stator on top of the steel laminations. The holes for the coils would just touch the top of the steel.

If this worked the gap could be wider with more wire with the mix in the gap. Also the magnets could be placed very close to this hybrid stator.

Just a thought? Could be all wrong?

JK TAS Jerry

If your coils are going to be thin it may be better to simply pour the plastic and either drill or machine the plastic on top of the steel core. I think the iron powder will lower the efficiency. You could drill the steel for the coils similar to my original idea of drilling a plastic form for the dual rotor machine. This works quite well although it takes a bit more time

This is one of the cores from the 2500 watt machine I did last summer. It has a plastic overlay on the silicon steel and the plastic was machined to hold the wires in place...

([User Info](#)) <http://www.windstuffnow.com/main>

I tried to do a search on the unit as I posted it sometime ago but couldn't find it. It was actually suppose to be a higher wattage but fell short of my goal. It was meant to produce 1000 watts at a very low rpm and up to 5kw. It ended up being around 1/2 of my intended goal. Its in the corner waiting for some alterations. Here are the pics I posted from before....

Hey Ed where would one find silicon steel.  
I was thinking if a mandrel was made of steel lams  
and then the mag wire wound around it then mounted to the mold  
Then resin poured around everything.

Hi Reno,  
I usually keep a little bit in stock for my own projects but occasionally I get  
requests for some. Let me know what size ( OD and ID ) and I'll see if I have  
enough to fill your needs.

Have Fun  
Ed

This to enhance the flux strength in what otherwise is just open air, the gap between the coils and the laminations. Surely the iron mix will be more conductive to the magnetic flux than air would be. I see the iron past mix as a much better path than just air.

I would use iFred's design and simply mold the stator on top of the steel laminations. The holes for the coils would just touch the top of the steel.

If this worked the gap could be wider with more wire with the mix in the gap. Also the magnets could be placed very close to this hybrid stator.

Just a thought? Could be all wrong?

JK TAS Jerry

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Thanks Ed

I noticed your design and iFred's are different. I was thinking of using the steel lamination as normal and pouring the iron/epoxy mix on the steel.

The idea here is to have the good performance of the steel and use the mix as a medium as a path for the flux to follow. This to enhance the flux strength in what otherwise is just open air, the gap between the coils and the laminations. Surely the iron mix will be more conductive to the magnetic flux than air would be. I see the iron past mix as a much better path than just air.

I would use iFred's design and simply mold the stator on top of the steel laminations. The holes for the coils would just touch the top of the steel.

If this worked the gap could be wider with more wire with the mix in the gap. Also the magnets could be placed very close to this hybrid stator.

Just a thought? Could be all wrong?

If your coils are going to be thin it may be better to simply pour the plastic and either drill or machine the plastic on top of the steel core. I think the iron powder will lower the efficiency. You could drill the steel for the coils similar to my original idea of drilling a plastic form for the dual rotor machine. This works quite well although it takes a bit more time

This is one of the cores from the 2500 watt machine I did last summer. It has a plastic overlay on the silicon steel and the plastic was machined to hold the wires in place...

I tried to do a search on the unit as I posted it sometime ago but couldn't find it. It was actually suppose to be a higher wattage but fell short of my goal. It was meant to produce 1000 watts at a very low rpm and up to 5kw. It ended up being around 1/2 of my intended goal. Its in the corner waiting for some alterations. Here are the pics I posted from before....

Hey Ed where would one find silicon steel.  
I was thinking if a mandrel was made of steel lams  
and then the mag wire wound around it then mounted to  
the mold  
Then resin poured around everything.

Hi Reno,  
I usually keep a little bit in stock for my own  
projects but occasionally I get requests for some.  
Let me know what size ( OD and ID ) and I'll see if I  
have enough to fill your needs.

Have Fun  
Ed

Hi Jerry.

My stator core is a composite of 90% iron grindings and 10% fiberglass resin. Ed is correct, you would get much much more output from thin metal laminations then from a poured core form, however there is major fun that comes from putting together a pour core mold. The intial tests show that it is working well, and I beleive it could be enhanced further, which I am attempting to do. I beleive with embedding some laminations into the pour code as well (esp; in the poles) the output could go much higher. I am presently working on a 13 inch disk with this idea as well.

Take a look at the wood form that I make on this page of my web site. I used wood dowels and a simple form. <http://www.internetfred.com/newgen/newgen.html> this produced the mold.

The idea for the poured core form came from Ed, I got it from him. He's a master at building things!! Amazing some of the stuff he comes up with.

My suggestions on to building one are, increase the width of the core and thus longer wire per pole. Longer and more magnets, thinner poles. larger slots for more wire.

Good Luck!

A local brake shop, when they grind the breaks it leaves a nice grinding power material, I semi clean it and sift it. I wear a mask for this because it might contain some hazerdous materials, but it's just a percation. They have lots and are more then willing to give it.

To Ed.

I gotta tell you Ed, I have been reading allot of electrical power technology books lately, and some of your designs on the mathematics end are pretty close to near specs on the practical side. Your good dude! real good! Keep it up, or I'll catch up soon...LOL

above all....Have FUN!!  
And have a GREAT DAY!

iFred did you just pull the wood dowls out after the resin set or did you drill them out? What was the outside form in your mold. OH the inside to? I would think if you kept the slots narrow were you slip the coil wire through, the cogging would not be to bad?

Did you wind the coils first and then drop them in place or did you wind in place around each pole or did you do wave winding? I think thats 3 ?

Thanks guys.

JK TAS Jerry

Re: Poured Stator ? ([none / 0](#)) (#12)

by iFred ([retrodude123@yahoo.com](mailto:retrodude123@yahoo.com)) on Tue Nov 11th, 2003 at 11:22:22 PM MST

([User Info](#)) <http://www.internetfred.com>

Hi Jerry

Glad I can help and answer your questions.

The bottom of the form is plywood, to this I glued a paper template that was filled with guidelines 22.7 deg apart. to the outside of the mold I cut some sheet metal (duct metal) and wrapped it around wood base and used some wood screws to hold everything in place. (i used some duct tape in the bottom to prevent spillage. The center was also made of wood. I then gave this part of the mold a coat of varnish.

When I finished the build, I cut the dowels to a single length, then I sanded them (ends) individually to fit for each position. I did this 32 times, once for each dowel. I then marked each position on the dowels, just in case. I then greased everything down very well including each dowel individually. Everything was a tight fit, it's critical to get a tight fit.

I measured everything and mixed the iron grindings and resins together, had to work quickly.. ... (resin went around and under the dowels when packed in slightly, but not enough to jar the dowels(the tight fit-:)). Also: To prevent bubbles and stuff I continually shook, rotated and gently slapped down the mold to make sure the stuff got into all areas of the mold. and continued to pack as much as possible up to the top of the third layer of the mold. The third layer tells where to end.

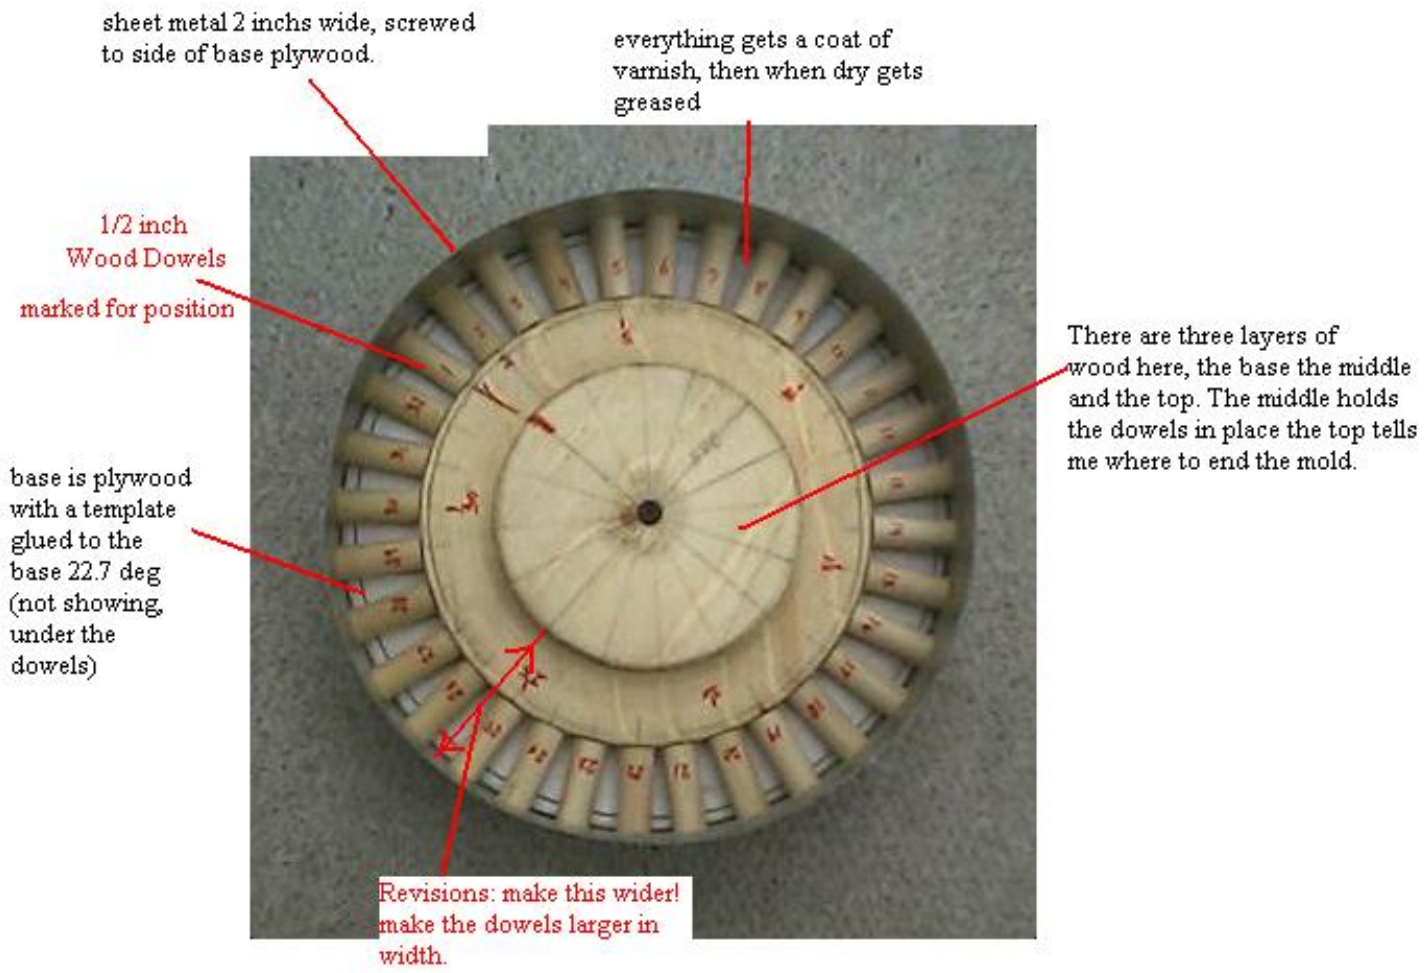

When completed the dowels popped out with very little problems, only one gave me an problem and I had to drill it out. But all in all the dowels came out smooth. Next I used my dermal to cut out the centers in the top between the poles. The slots where narrow to allow the wire to go through and just a little extra. Dermal with a cutting blade works great on this material!

The cogging is minimal. I used a metal plate made of multi sheets (not suggested) of sheet metal (in order to get thickness). I am still experimenting but I have 32 mags x 3 for width. YUP! you read correct.. 3 magnets per pole in length! 96 small mags 1/2 x 1/8 each.. Got a ton of them, don't ask ;-)

I wound each wire around each pole by hand, 25 times per pole. Man my fingers where killing me, I was shaking after doing 15 poles! LOL... Oh and... they where tightly wound and pressed into each pole with a peice of small hardwood I carved so i could fit in the most wire as I was winding each pole. It's very tighly wound ;->

Hope this helps!!

by Jerry on Thu Nov 13th, 2003 at 10:19:42 PM MST  
([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Thanks iFred

This helps a buch.

I thought someone mentioned on this board about a powdered iron food suppliment use to feed young pigs and you can get it at the farm store.

Is there any truth to this? JK TAS Jerry

([User Info](#)) <http://www.dplusv.com/Photo-03.html>

iFred did you just pull the wood dowls out after the resin set or did you drill them out? What was the outside form in your mold. OH the inside to? I would think if you kept the slots narrow were you slip the coil wire through, the cogging would not be to bad?

Did you wind the coils first and then drop them in place or did you wind in place around each pole or did you do wave winding? I think thats 3 ?

Thanks guys.

JK TAS Jerry

Hi Jerry

Glad I can help and answer your questions.

The bottom of the form is plywood, to this I glued a paper template that was filled with guidelines 22.7 deg apart. to the outside of the mold I cut some sheet metal (duct metal) and wrapped it around wood base and used some wood screws to hold everything in place. (i used some duct tape in the bottom to prevent spillage. The center was also made of wood. I then gave this part of the mold a coat of varnish.

When I finished the build, I cut the dowels to a single length, then I sanded them (ends) individually to fit for each position. I did this 32 times, once for each dowel. I then marked each position on the dowels, just in case. I then greased everything down very well including each dowel individually. Everything was a tight fit, it's critical to get a tight fit.

I measured everything and mixed the iron grindings and resins together, had to work quickly.. ... (resin went around and under the dowels when packed in slightly, but not enough to jar the dowels(the tight fit-:)). Also: To prevent bubbles and stuff I continually shook, rotated and gently slapped down the mold to make sure the stuff got into all areas of the mold. and continued to pack as much as possible up to the top of the third layer of the mold. The third layer tells where to end.

When completed the dowels popped out with very little problems, only one gave me an problem and I had to drill it out. But all in all the dowels came out smooth. Next I used my dermal to cut out the centers in the top between the poles. The slots were narrow to allow the wire to go through and just a little extra. Dermal with a cutting blade works great on this material!

The cogging is minimal. I used a metal plate made of multi sheets (not suggested) of sheet metal (in order to get thickness). I am still experimenting but I have 32 mags x 3 for width. YUP! you read correct.. 3 magnets per pole in length! 96 small mags 1/2 x 1/8 each.. Got a ton of them, don't ask ;-)

I wound each wire around each pole by hand, 25 times per pole. Man my fingers were killing me, I was shaking after doing 15 poles! LOL... Oh and... they were tightly wound and pressed into each pole with a piece of small hardwood I carved so i could fit in the most wire as I was winding each pole. It's very tightly wound ;->

Hope this helps!!

sheet metal 2 inchs wide, screwed to side of base plywood.

everything gets a coat of varnish, then when dry gets greased

1/2 inch Wood Dowels  
marked for position

base is plywood with a template glued to the base 22.7 deg (not showing under the dowels)

There are three layers of wood here, the base the middle and the top. The middle holds the dowels in place the top tells me where to end the mold.

Revisions: make this wider!  
make the dowels larger in width.

I always thought stainless steel mixing bowls made nice, inexpensive... nifty looking nose cones! They're rolled over on the side, so they are easy to screw/bolt down. (just a thought..)

Hi Dan  
I thought of this and my wife caught me checking out her bowls in the kitchen.  
Needless to say she didn't approve of the idea. I did see a nice wok type fry pan at the thrift store but didn't buy it. When I went back it was gone. Haven't seen one there since.

So the Wok is gone?  
Did you check back in the kitchen to see if your wife was gone?

Seriously though - I've seen nice big 14" (I'm sure they make 16") mixing bowls at wallmart for pretty cheap, might be worth checking if there's one in the area.

by Norm on Wed Nov 5th, 2003 at 05:59:25  
PM MST  
([User Info](#))

Yeah Dan that's were I've seen them too.  
Or just make a cone from a sheet of  
aluminum...easy..cut a circle about 22 inches  
in diameter cut to center then overlap the  
edges....Or since you have a lathe just spin a  
bowl from a heavy sheet of aluminum into a

wood blank??

Jerry also when I put these pics on the  
board I changed were it says 80% to 40% to  
make them smaller than original. (:>) Norm.

<http://www.dplusv.com/Photo-03.html>

Well Norm the one on the right looks  
like something Madona or Dolly could  
use.

Dan I'll check Wally world and the thrift  
store again. I think however I'll just fly  
it flat for now.

I finished it today look pretty good. I'll  
try to get a pix on the board soon?

([User Info](#))

Hi Dan,  
Do you think the bowl or cone would give an  
improvement in performance for a down wind  
machine? Maybe more stress on the tower  
during times of max. furling. Btw, I may put  
a thing on this next turbine I'm  
building(more than half way there :-)  
to smooth the airflow after it goes around the  
pole. It may be hard to do though since it's  
got to turn with the turbine.  
Kevin

Re: Big fat hub ? ([none / 0](#)) (#8)  
by DanB on Wed Nov 5th, 2003 at  
08:28:11 PM MST  
([User Info](#))

Kevin - I doubt a nose cone makes a  
noticeable difference. In theory... it  
probably increases performance, but I  
would think its minimal...

Hard to know for sure!

Hi Dan  
I thought of this and my wife caught me checking out her bowls in the kitchen.  
Needless to say she didn't approve of the idea. I did see a nice wok type fry pan at the thrift store but didn't buy it.  
When i went back it was gone. Havn't seen one there since.

So the Wok is gone?  
Did you check back in the kitchen to see if your wife was gone?

Seriously though - Ive seen nice big 14" (Im sure they make 16") mixing bowls at wallmart for pretty cheap, might be worth checking if theres one in the area.

Yeah Dan that's were I've seen them too. Or just make a cone from a sheet of aluminum...easy..cut a circle about 22 inches in diameter cut to center then overlap the edges....Or since you have a lathe just spin a bowl from a heavy sheet of aluminum into a

wood blank??

Jerry also when I put these pics on the board I changed were it says 80% to 40% to make them smaller than original. (:>) Norm.

Well Norm the one on the right looks like something Madona or Dolly could use.

Dan I'll check Wally world and the thrift store again. I think however I'll just fly it flat for now.

I finished it today look pretty good. I'll try to get a pix on the board soon?

Hi Dan,  
Do you think the bowl or cone would give an improvement in performance for a down wind machine? Maybe more stress on the tower during times of max. furling. Btw, I may put a thing on this next turbine I'm building (more than half way there :-)) to smooth the airflow after it goes around the pole. It may be hard to do though since it's got to turn with the turbine.

Kevin - I doubt a nose cone makes a noticable differance.  
In theory... it probably increass performance, but I would think its minimal....

Hard to know for sure!

Hi zubbly  
I'm using a short power pole. Its about 20 feet tall. It is the lower portion of a taller pole.  
A power co. freind brought it over for me a installed it about 7 ft into the ground. Its fat I think about 12 inches at the gound and 10 inches at the top were I'll add 4 ft. of heavy mast above the pole. The mast its self will be about 10 ft. long.  
It all looks very strong. We also put in a 40 footer about 50 ft away. Also have a 45 foot tree with all the limes removed and I'm installing a 40 foot free standing tower with a liitle crankup genny mount that goes up some tracks on the side. I have some 15 and 20 mast secured to my shop also. Can you say small wind farm?

Since we are on the subject of towers, does anyone have any links to building an octahedral tower? I seem to remember these from back in the 70's and if memory serves me, were inexpensive to build and erect. Getting closer to putting up my first generator...

Thanks Tommy L

I'm surprized Mike did't round the tip of his blades as he did in the Mike mod Jerry blades.

He said his stepper motor was rated 4 amps and so is mine. He didn't say how many phases.

I'm going to use 2 of my plastic blades and then compair results with Mike,s genny.

Well I ran the little stepper in the lathe. 500, 900 and 1600 rpm. No load saw 14.7, 25.6 and 47.6 volts. But I could only get about 1/2 amp out of this motor.

I think the magnets used in these must be ceramics. I'm thinking of a neo upgrade.

Re: Stepper motor ? ([none / 0](#)) (#4)  
by TomW on Fri Nov 7th, 2003 at 07:49:27 AM MST  
([User Info](#))  
<http://oneota.net/~earthsourcepowr/>

Jerry;

It may just be the wire size is far too small to pump more than an amp or so.

I want to pass on that I upgraded a 30 volt Ametek to neos with very little increase in amps out but with a slight voltage increase. In other words it was a huge pain in the posterior to reassemble it with neos for a dismal return in power plus it cogged a LOT more. It just seems like adding more flux would increase power but it did not work that way with the Ametek tape drive motor. I think it was at the limits of its windings current ability as stock from the factory

Just my experience and your experience may vary.

Cheers.

TomW

# ANOTHER SMALL WIND GENERATOR

MADE FROM A LARGE STEPPER MOTOR AND PLASTIC BLADES

---

With the success of the "Microwind" genny made from a surplus NEMA 34 stepper motor, a prop from a trashed 20" box fan and some pipe fittings, I wanted to scale the design up to produce a bit more power, yet still retain the simplicity and the storm survival ability of the little genny.

After months of searching, I found a much larger surplus stepper motor. This one has the same diameter, shaft and flange dimensions, but is about twice as long. In addition, the shaft comes out of both ends, which brings up the possibility of coupling several together to be driven from a single prop. While the small stepper had one amp coils, the larger one has coils rated for four amps each. By using a bridge rectifier on each phase and connecting the DC outputs in parallel, this one should produce several times the power of the original Microwind.

I first thought about carving a set of wooden blades, but I ran across some scrap plastic pieces that were nearly the correct size, weight and shape. These were routed cutouts from a large plastic bin, and were curved in such a way as to form a somewhat undercambered airfoil. I cut a set of three

tapered blades from this material and used a rotary file to thin the trailing edge. Since these were scrap cutouts from a molded plastic part, each piece had a vent hole in the center. Being small, it shouldn't hurt anything. Each blade is 21" long, 4 1/2" wide at the root, and 2 3/4" wide at the tip.

I found a scrap of heavy gauge steel about 1 1/2" wide, and cut it into three equal strips about 7 inches long. These I sandwiched between two very large washers. A bolt and nut squished the washers together, capturing the steel strips. Once they were perfectly aligned, I welded them all together, forming a solid three-blade hub.

I bored a short piece of 1" aluminum barstock to fit the stepper motor shaft and added two #10 setscrews, then turned the piece around and counterbored it halfway, then tapped it for a 7/16" x 14 screw. While it was in the lathe, I turned a step on the O.D. to fit the hole in the washers. The step is a bit shorter than the width of the hub, so the center screw will draw it down tight and square.

The aluminum piece wouldn't fit all the way through the hub, since the three steel strips had actually stuck through a little way into the hole in the washers (the bolt was smaller than the hole.) Rather than file them away, I instead filed three small flats on the aluminum piece. This way it could not rotate inside the hub... simpler than cutting a keyway!

The three steel strips were marked and drilled, then tapped for three 1/4"-20 screws in each one to mount the blades. At this time I also scribed a line an inch out from the washer across each one. Each strip was then clamped in the vice at this line, and using a large crescent wrench I twisted each one to the proper blade angle, sighting it with another line drawn across the top of the vice with magic marker.

The blades were mounted on the hub using three 1/4"-20 bolts and washers for each one. Since the hub itself is tapped, once the bolts were drawn down very tight, a nut was threaded on to the back side of each bolt and tightened down to lock everything together.

Once the blades were installed, I mounted the hub onto one of the large stepper motors and took it out into the back yard. Shortly we had a small gust of wind, and as soon as I felt it on my face the genny started to rotate. It seems to start in a fairly low windspeed, and once spinning it maintained it's rotation quite well. With some of the larger gusts, it picked up quite a bit of speed. Since I can rotate it by hand and light a good-sized 12 volt bulb with each phase, it looks like this thing will produce some power once it's up in the air.

---

Since we've been known to get some storms around here with winds in excess of 85 mph, I thought it would be a good idea to reinforce the hub to prevent it from bending backwards. Rather than using a 7/16" bolt to secure the hub, I cut a piece of threaded rod and tightened it into the adapter. I then used a nut to secure the hub, leaving a few inches of rod sticking out. This gave me a point to attach three support rods from the center back to the outermost bolt on each blade. Before fastening the rods, I bent the arms of the hub slightly forward. This "rake" will allow the blades to flex a bit in high winds without risk of hitting the mast.

Here it is, up on the shop roof. To the right is the original Microwind prototype, fastened to the vent pipe where it's been adding it's share to the station batteries for over a year now. I've seen an amp out of the little guy, and I hope the bigger version will do much better.

This side view shows the forward rake of the blades. This should allow plenty of room for flexing in extreme weather.

---

The mini genny is an ongoing project. Now that it's up, naturally we have winds of less than 2 mph predicted for the next several days. Once we see some real wind, it won't take long to see what it's going to do. I expect to do some experimenting with the blade pitch to get the right angle to get as much out of the stepper motor as possible. Adjustment is a matter of putting the hub in the vice and twisting each arm with a very large wrench. So far, it seems to start in very light winds, and in a few light gusts shortly after it went up, it lit a 12 volt trailer light easily. Since these were very light gusts, this is a good sign... it should spin up much faster once the wind picks up. I'll post more data here as the project unfolds.

---

### UPDATE!

Once we got some gusty winds peaking around 15 to 18 mph, I took some measurements on the new wind generator. It starts easily, and when feeding power to a battery through a blocking diode, it would begin charging somewhere around 10 mph. At higher windspeeds the RPM and the current would increase, but not as fast as I had hoped. Since the plastic blanks were straight, I had no twist to the blades, and I suspect that under load, the tips were stalling at the higher wind speeds.

I brought the rotor down and trimmed some taper to the leading edge of the blades. Since the shape is undercambered, this did two things... first, it made the airfoil thinner at the tips. Second, it also made the airfoil fly at a lower angle of attack, adding a bit of "twist" to the blade.

The result is a bit more speed in the gusts. As I write this we're having winds with gusts up over

20 mph, and I'm seeing an easy 1 to 1 1/2 amps going into the batteries on the average, more in the strongest peaks. This is certainly not bad for a little NEMA 34 stepper motor. I have a feeling that it will do better in some real wind, at least as long as it holds together.

The biggest thing it needs now is good, clear, unobstructed wind. Once I'm sure it's doing what I want it to do, I'll move it from the shop roof to the top of one of the towers.

---

Thanks Tommy L

I'm surprized Mike did't round the tip of his blades as he did in the Mike mod Jerry blades.

He said his stepper motor was rated 4 amps and so is mine. He didn't say how many phases.

I'm going to use 2 of my plastic blades and then compair results with Mike,s genny.

Well I ran the little stepper in the lathe. 500, 900 and 1600 rpm. No load saw 14.7, 25.6 and 47.6 volts. But I could only get about 1/2 amp out of this motor.

I think the magnets used in these must be ceramics. I'm thinking of a neo upgrade.

5 minute interval.

Note: You may cloak yourself from appearing here in your Display Preferences.

Jerry;

It may just be the wire size is far too small to pump more than an amp or so.

I want to pass on that I upgraded a 30 volt Ametek to neos with very little increase in amps out but with a slight voltage increase. In other words it was a huge pain in the posterior to reassemble it with neos for a dismal return in power plus it clogged a LOT more. It just seems like adding more flux would increase power but it did not work that way with the Ametek tape drive motor. I think it was at the limits of its windings current ability as stock from the factory

Just my experience and your experience may vary.

Cheers.

TomW

Hi Guys

On Oct 5th I tried to post a pic. and it didn't work.  
Norm answered back and made some helpfull sugjestions.  
Thanks Norm.

Then Electric Ed, Tom W, Norm again, zubbly, ADMIN,  
Woof and John talked in lingham about sizing.

They were speaking that Chinese again. The closest  
translation book I have is Tazmainion. So please bear with  
me until I get the hang of it.

You may see a few big pictures from me for awhile. You  
goota crawl befor you can walk.

Glad to see you're getting the hang of it...you  
mean that armature actually fits into an altenator?  
probably have to machine it down just a little? That is  
a pretty picture with the red background. We'll have  
to talk a little more about pic's one of these days,  
and I'm glad to have been of help. (:>) Norm.

Hi Norm

Ya that armature is actully a little smaller than the GM alt. Just a little machineing and the little magnets drop into the groove. I used some thick wall plastic pipe of the same dia. as the armature to make the little spacers. I screwed these little spacers down with little stainless steel wood screws and the glude the magnets on.

The GM alt has a 17 MM dia. shaft. This armature has a 5/8 in. shaft. This makes it easier to find standerd pullys and hubs and such.

Hornet has used a sigle large doughnut shaped neo magnet in there GM alt PMAs. I think they looked at my pictures on aireheads of this one and copyed it in there new style alt PMA.

I think this is a cheaper conversion. I makes more power but it dose cog more.

Hornet claims low cogging but in the same add they say it needs a bigger prop to get started.

I use the fronts of 2 GM alts because you can replace the bearings to mach the new armature in the front part but not the back part of the GM alt.

This alt with these mods, some wireing changes and some caps will make a few hundred watts with a direct mouted blade at around 4 ft.

JK TAS Jerry

I screwed these little spacers down with little stainless steel wood screws and the glue the magnets on.

The GM alt has a 17 MM dia. shaft. This armature has a 5/8 in. shaft. This makes it easier to find standard pulleys and hubs and such.

Hornet has used a single large doughnut shaped neodymium magnet in their GM alt PMAs. I think they looked at my pictures on airheads of this one and copied it in their new style alt PMA. I think this is a cheaper conversion. It makes more power but it does cog more.

Hornet claims low cogging but in the same add they say it needs a bigger prop to get started.

I use the fronts of 2 GM alts because you can replace the bearings to match the new armature in the front part but not the back part of the GM alt.

This alt with these mods, some wiring changes and some caps will make a few hundred watts with a direct mounted blade at around 4 ft.

JK TAS Jerry

Hi Norm

Ya that armature is actually a little smaller than the GM alt. Just a little machineing and the little magnets drop into the groove. I used some thick wall plastic pipe of the same dia. as the armature to make the little spacers. I screwed these little spacers down with little stainless steel wood screws and the glue the magnets on.

The GM alt has a 17 MM dia. shaft. This armature has a 5/8 in. shaft. This makes it easier to find standard pulleys and hubs and such.

Hornet has used a single large doughnut shaped neo magnet in there GM alt PMAs.

I think they looked at my pictures on airheads of this one and copied it in there new style alt PMA.

I think this is a cheaper conversion. It makes more power but it dose cog more.

Hornet claims low cogging but in the same add they say it needs a bigger prop to get started.

I use the fronts of 2 GM alts because you can replace the bearings to match the new armature in the front part but not the back part of the GM alt.

This alt with these mods, some wiring changes and some caps will make a few hundred watts with a direct mounted blade at around 4 ft.

Hi Jerry - I think it would work allright....

Not ideal though, you'd see a big improvment if you used old transformer laminates or something. I used cold rolled steel for a while....

I did a test once and these were approx the results.  
Basicy I built up a 1/2" thick block of diff. steel material and rubbed a Neo magnet on it to get an idea how bad hystoresis losses might be.

Bandsaw blades would retain a magnetic field density of around 110 Gauss!

Plumbers strapping would retains about 25 Gauss.

The cold rolled sheet metal I was using would retain about 13 Gauss.

Transformer laminates would retain about 7 Gauss.

Ive not tried that silicon steel from Ed at Windstuffnow.com.

From the softness of the plumbers strapping I was a bit surprised just how good a permanent magnet it was. I wonder if perhaps it was the galvanized coating that sets up magnetic domains or something.... I believe rust can also setup magnetic domains to a small degree.

Regarding your question about the holes... I don't think they would affect things significantly. I suspect it would work allright with the plumbers strap, but there would be some drag, probably 3X more iron losses at least than if you used good silicon steel.

[Blade ?](#) | 4 comments (4 topical, editorial)

Re: BLade ? (none / 0) (#1)  
by scoraigwind ([magnet@scoraigwind.co.uk](mailto:magnet@scoraigwind.co.uk)) on Sat Nov 1st, 2003 at 02:46:06 AM MST  
([User Info](#)) <http://www.scoraigwind.co.uk>

The power you can get will depend on the diameter, not the number of blades.

More blades will give you more torque, but less speed.

Small diameter gives more speed and less torque and less power. For example your 6.5' diameter will catch only 42% of the power that a 10' diameter rotor will catch. If it is a standards shape (scaled down), then it will give about 27% of the torque of the larger blade. But if you use more, wider blades you can correct this to an extent.

When designing blades I usually look at the cut in speed of the alternator at the desired voltage. I then aim to build a blade that will be very happy at this rpm at about 7mph windspeed (3 metres per second).

You don't give us much help as far as the cut in speed goes. If the blade tips are slender (2" wide) then tip speed ratio could be about 5.5. Circumference is about 6.2 metres. Tip speed is about  $3 \times 5.5 = 16.5$  metres per second at cut-in. That's 160 rpm ( $16.5 \times 60/6.2$ )

Does that makes sense?

 ([User Info](#)) <http://www.dplusv.com/Photo-03.html>

Thanks Hugh  
 I know this thing won't need much rpm but it will need alot of tourque.

Off topic here but are you doing a work shop in Washington state next spring?

Would like you to see and evaluate the plastic blades. I'm working on a new 3 blade. I've got high hopes for this one. If this is out of line I understand no problem. Just curius?

Re: BLade ? ([none / 0](#)) (#3)  
by scoraigwind ([magnet@scoraigwind.co.uk](mailto:magnet@scoraigwind.co.uk))  
on Sun Nov 2nd, 2003 at 05:23:05 AM MST  
([User Info](#)) <http://www.scoraigwind.co.uk>

You can get a bit more torque by adding blades (provided you get the angles right) but not more power. You can get much more torque and power by increasing the diameter of the rotor (scaling it up).

If you double the diameter you get four times the power and 8 times the torque.

Yes, I will be coming back to Washington state (Guemes island) next year to run another workshop course. April 12-17, 2004

Contact [ian.woofenden@homepower.com](mailto:ian.woofenden@homepower.com) for details of how to come.

I have put pictures of my previous courses at <http://www.scoraigwind.co.uk/buildyo>

I'd be very interested to learn more about how you make the blades. I saw lots of pics on the airhead site but not much discussion. It would be great if you could share some of your experiences with the group at Guemes Island.

Thanks Hugh  
I'm not sure if I can make the trip but I will send a set of blades up any way.

Not sure how you could test them they are set up on a hub that fits most ac motor shafts. any where from 1/4 inch to 3/4 inch shaft. I'll send a 3 blade in the 4 foot size.

I think this would be good for that small 48 inch genny you guys built last time. If you had some hub design specs I could posably do a one off for your next seminar up there.

I may be able to stop by for one day to discus the hole story behind and preformance details for the plastic blades.

Only if this does not interfear with your workshop.

Jerry

by scoraigwind ([magnet@scoraigwind.co.uk](mailto:magnet@scoraigwind.co.uk)) on Sun Nov 2nd, 2003 at 05:23:05 AM MST  
([User Info](#)) <http://www.scoraigwind.co.uk>

You can get a bit more torque by adding blades (provided you get the angles right) but not more power. You can get much more torque and power by increasing the diameter of the rotor (scaling it up).

If you double the diameter you get four times the power and 8 times the torque.

Yes, I will be coming back to Washington state (Guemes island) next year to run another workshop course. April 12-17, 2004

Contact [ian.woofenden@homepower.com](mailto:ian.woofenden@homepower.com) for details of how to come.

I have put pictures of my previous courses at <http://www.scoraigwind.co.uk/buildyo>

I'd be very interested to learn more about how you make the blades. I saw lots of pics on the airhead site but not much discussion. It would be great if you could share some of your experiences with the group at Guemes Island.

# "How to build a wind turbine"

## Workshop courses

with **Hugh Piggott**

### Upcoming courses:

Next year

[Four Winds in Edinburgh 15th March 2004 \(already filling up fast\)](#)

[SEI on Guemes Island in Washington USA April 12-17 2004 \(\\$600 for tuition\)](#)

[Scoraig 8-15 May 2004](#)

[LILI?](#)

workshop [course notes](#) for sale (July edition)

### Some **previous courses** photo pages:

2001	<a href="#">Scoraig Aug 2001</a> 	<a href="#">SEI Guemes Island WA USA Oct 2001</a> 	
2002	<a href="#">Scoraig May 02</a> 		<a href="#">CAT October 2002</a> 
2003	<a href="#">Scoraig May 03</a> 	<a href="#">SEI Guemes Island WA USA April 2003</a> 	<a href="#">CAT October 2003</a>  <a href="#">Four Winds Edinburgh February 03</a> 

Each day, a modest amount of theoretical introduction will lead to workshop sessions with opportunities to gain hands-on experience of carving wooden blades, winding coils and fitting magnets into purpose built alternators for windpower, wiring, fabrication, erection and all aspects which can be covered as time allows.

A complete wind turbine will be built from scratch and erected. Full drawings are provided as part of the course.

I should stress that these courses are to teach you **how to build** a wind generator, so please do not expect that you will go home with a completed wind generator.

[More info](#)

---

**"Thank you for an incredibly exciting and interesting course. It really taught me and revised for me a whole number of things, from aerodynamic physics to welding and I hope that in the not to distant future we shall have a wind turbine up... "**

---

[Scoraig](#) 8-15 May 2004

The cost of the Scoraig course is £500 per head, including accommodation at Shanti Griha. Concessionary rates may be negotiable. There may also be space for partners/friends to stay at [Shanti Griha](#) during but not partaking of the course.

This will be the fourth year we hold a course here on Scoraig at the Shanti Griha site. The courses are small (about 7-8 people) but lively and successful. We always complete one wind turbine during the project, and make progress in the construction of others. The main project is a 2.4 metres diameter wind turbine with wooden blades and a permanent magnet alternator. Output is about 500 watts electrical.

To book a place on the scoraig course, please send me [Hugh Piggott](#) a deposit of £100 at

Hugh Piggott  
Scoraig  
Dundonnell  
Ross shire  
IV23 2RE

Keep in touch closer to the time to arrange for car-sharing from nearby railway stations. I will meet you with a boat and take you across to Scoraig from Badluarach jetty. I shall also take your gear to Shanti Griha by quad bike and trailer. Meanwhile you can walk the two miles and enjoy the views of many small wind turbines along the way.

There is no shop on Scoraig so you are recommended to bring supplies of personal luxuries such as beer

or tobacco to last you out. Weather clothing including rubber boots are a good idea even though you will probably not need them. Depending on the season there may already be some small biting insects called midges which drive some people wild. You may wish to bring repellent of some sort.

When driving to Scoraig, take the A9 to Inverness, then follow signs towards Ullapool. Follow the Ullapool road as far as Braemore junction and turn left for Dundonnell. (**Do not** turn left onto the A832 Gairloch road at Garve - wait until **Braemore** where you see the sign for Dundonnell.) After Dundonnell, watch out for signs to Badluarach, and take a right turn down to the jetty.

---

## [Four Winds Inspiration Centre](#)

Edinburgh 15th March 2004 (date to be fixed soon)  
£300.00 per place. Six day course  
[to book a place - e mail \(click here\)](#)

or Telephone/Fax:  
0131~332~2229

---

# Purpose of the Build your own wind turbine workshop courses :

To inspire, empower, and inform participants who wish to build small wind turbines. To cater for people from all backgrounds, age-groups, nationalities, and educational levels. To provide some basic theoretical understanding, and to develop the necessary workshop skills and confidence to enable participants to undertake small wind turbine construction projects safely.

Course at [Liverpool](#)

[in 2000.](#)

## Scope of workshop course - goal and objectives:

A six day course in which the participants learn as much as they are personally capable of learning about small wind turbine design and construction. Each day, a modest amount of theoretical introduction will lead to workshop sessions with opportunities to gain hands-on experience of carving wooden blades, winding coils and fitting magnets into purpose built alternators for windpower, wiring, fabrication, erection and all aspects which can be covered as time allows. Participants who bring their own ideas and materials to the course will be welcomed and given assistance where possible.

We would hope to complete one wind turbine during the project, and make progress in the construction of others. Where participants have brought the materials, they will be able to take the complete (or partially complete) components (blades, alternators..) home with them. Other work in progress will remain on site for use in future courses.

# Scoraig Wind Electric

## COURSES AT CAT IN WALES

I help to teach more general windpower courses at CAT in Wales once or twice each year.

They include some self build material and also wind system design, gridlinked systems, theory of wind engineering etc... for all comers.

The next course takes place in MARCH 2004.

For details [click here](#).

To book please contact Laura Snowball in the Courses Office.

Tel. +44 (0)1654 705981

Fax. +44 (0)1654 703605

Jerry;

Well we don't really have any "rules" as such for classified ads but they do display on the front page by default.

We have had a few where the account to post the ad was made immediately before it was posted and those type get set to display only on the classifieds page[s].

Long term members such as you get a lot more slack on the classifieds than those that apparently just join to post an ad.

As always, I am here to help. I wish I was more construction savvy but I'm better with these silly computers and dreaming up bizarre ways to do stuff than wrenches and building things.

And, by the way, glad to see you are using caps for that added voltage bump on mills. I bet you get some monsters in the car audio business.

Cheers.

TomW

Hi TomW

YA, We sell lots of 1 farrad caps 1,000,000UF/ 20 volt at \$99.95 ea. I'll sell these caps to OP board members for \$75. They come in red, blue, yellow, silver, green.

We also have 1.5 farrad, 2.5, 35 and 100 farrad caps. WE have a vehicle that holds the NW IASCA SPL record at 168.8 DB. This truck has 54,000 watts onboard. Lots of caps lots of batteries.

I also have caps in the

6,10,12,15,18,20,25,30,35,40,50,60,75,80,90,100,110,150,200,250,300,400 volt range with UF rating from 1 UF to 1 farrad. Cap prices from \$2 to \$100 depending on volts/UF rating. Have some non pollar caps as well also some large oil filds, motor start ,motor runs and ect.

Yep caps make a diferance. JK TAS Jerry

PS we also have plenty of gold distribution blocks, fuse blocks and holders, power wire from 10 ga. to 4/0 ga., split loom many sizes. All kinds of car stereo install hardware that realy works great for RE installs.

All this stuff shure is handy for our small wind genny farm on our store roof.

I guse I should make a list and post here and give all my RE buddies here the brotherinlaw discount. That is if its ok with the ADMIN and I don't step on any toes.

Thanks again Tom. Jerry

[Airheads Page](#)

Re: To Jerry ([none / 0](#)) (#5)  
by TomW on Fri Oct 31st, 2003 at 11:37:17 PM MST  
([User Info](#)) <http://oneota.net/~earthsourcepowr/>

Jerry;

I see no problem with listing your stuff at all.

Thats what classy fried ads are for. Giving our users a place to list stuff they have to sell to others in this RE thing that can supply a need. Especially if there is a discount to be had.

Lots of folks need blades and those high value caps don't exactly grow on trees and good connectors are nice to have available.

Another thought is go ahead and make up a list of stuff you have to sell send it to me and I will make a webpage out of it we can stick somewhere people can get to it online. Then include a link in your signature like the airheads link i did for you.

Cheers.

Jerry;

I see no problem with listing your stuff at all.

Thats what classy fried ads are for. Giving our users a place to list stuff they have to sell to others in this RE thing that can supply a need. Especially if there is a discount to be had.

Lots of folks need blades and those high value caps don't exactly grow on trees and good connectors are nice to have available.

Another thought is go ahead and make up a list of stuff you have to sell send it to me and I will make a webpage out of it we can stick somewhere people can get to it online. Then include a link in your signature like the airheads link i did for you.

Cheers.

TomW

Jerry;

Well we don't really have any "rules" as such for classified ads but they do display on the front page by default.

We have had a few where the account to post the ad was made immediately before it was posted and those type get set to display only on the classifieds page[s].

Long term members such as you get a lot more slack on the classifieds than those that apparently just join to post an ad.

As always, I am here to help. I wish I was more construction savvy but I'm better with these silly computers and dreaming up bizarre ways to do stuff than wrenches and building things.

And, by the way, glad to see you are using caps for that added voltage bump on mills. I bet you get some monsters in the car audio business.

Cheers.

Hi TomW

YA, We sell lots of 1 farrad caps 1,000,000UF/ 20 volt at \$99.95 ea. I'll sell these caps to OP board members for \$75. They come in red, blue, yellow, silver, green.

We also have 1.5 farrad, 2.5, 35 and 100 farrad caps. WE have a vehicle that holds the NW IASCA SPL record at 168.8 DB. This truck has 54,000 watts onboard. Lots of caps lots of batteries.

I aslo have caps in the 6, 10, 12, 15, 18, 20, 25, 30, 35, 40, 50, 60, 75, 80, 90, 100, 110, 150, 200, 250, 300, 400 volt range with UF rating from 1 UF to 1 farrad. Cap prices from \$2 to \$100 depending on volts/UF rating. Have some non pollar caps as well also some large oil filds, motor start ,motor runs and ect.

Yep caps make a diferance. JK TAS Jerry

PS we also have plenty of gold distribution blocks, fuse blocks and holders, power wire from 10 ga. to 4/0 ga., split loom many sizes. All kinds of car stereo install hardware that realy works great for RE installs.

All this stuff shure is handy for our small wind genny farm on our store roof.

I guse I should make a list and post here and give all my RE buddies here the brotherinlaw discount. That is if its ok with the ADMIN and I don't step on any toes.

Thanks again Tom. Jerry

Thank you Ed for the great info. We have a wide range of wind here in Western NY but all charts say around 12mph annual average. Sustained winds of 20+ are very common during the winter so it's tough to guess at my design for my application. If this wasn't my first one I'd have a better feel for the specs. I have no easy way to physically measure the power or torque needed under load while I'm testing, pony brake is out. I'm going by feel and guess and just wondered if I'm better off going with more torque and sacrifice some speed, I know I can't have my cake and eat it too. This is great fun, you sold me the silicon steel a while back and I may be in the market again, I'm hooked.  
Dave B.

([User Info](#)) <http://www.windstuffnow.com/main>

Dave,

You can usually guesstimate reasonably well if you have a tested output on your machine. I usually make a chart for the rpm range and calculated output for the alternator. This way you have more of a calculated "guess" instead of pulling numbers out of the air and hoping for the best. Once you know your approx alternator output at a given rpm then it makes it much easier to match a blade with that performance.

As an example say your test showed your alternator was making 12 volts at 100 rpm. The resistance of the stator was say 1 ohm to make it simple, and the charging voltage was 12 volts

$$100 \text{ rpm} / 12 = 8.33 \text{ rpm per volt}$$

So at 200 rpm we can calculate what the output might be without any losses...

$$200 \text{ rpm} / 8.33 = 24 \text{ volts open (no load)}$$

Charging to a 12V battery would yeild..

$$(24 \text{ volts open} - 12 \text{ volts charging}) / 1 \text{ ohm} = 12 \text{amps}$$

You can chart this at any rpm, I use a spread sheet to make it simple

5 minute interval.

Note: You may cloak yourself from appearing here in your Display Preferences.

RPM	Open volts	Amps	Watts
200.	24	12	144
300.	36	24	288
400.	48	36	432

And so on...

Then you can easily go on to matching a prop to perform in the range of your wind from there.

Have Fun...

I have a new shipment of silicon coming in soon, I was going to pick it up but its a 5 hour drive and I didn't have the time to spend on the road. Its going to be trucked in instead. I'll have about 500 lbs of silicon available shortly and some sample rolls which I'll list in a few days...

Ed

Ed,  
Thanks again for all the help. I'll start crunching some numbers and post my results to further narrow in on the blade design. I sure appreciate all the trial & error out there behind your experience that has saved me much time. Believe me if I had the time I would like nothing more than to help pave the way for others through experimenting. I'll keep in mind you will have the steel also, I'm already thinking about maybe bigger and better, that's what happens when you're adicted. Thanks, Dave B.

[HomeBuilt Float Switch - What about low level cutoff?](#) | 3 comments  
(3 topical, editorial)

Re: HomeBuilt Float Switch - What about low level  
([none / 0](#)) (#3)  
by ADMIN ([admin@otherpower.com](mailto:admin@otherpower.com)) on Sat Dec 13th,  
2003 at 11:50:21 AM MST  
([User Info](#))

The hall effect sensor and flipflop are a great idea - BUT in my location I've had outdoor electronics fail so many different times from lightning that I hesitate to use them for a critical application like a float switch.....if it failed and I didn't notice, the pump could burn out. I also worry about the extremely harsh, condensing environment -- tho I suppose the entire thing could be potted in epoxy.

However, I think my next electronics project is going to be a water system status panel. The challenge is that the house is 480 feet from the spring. I think I have enough wire in place to make a system monitor that will show -- pump running or not, status of both float switches, and a sensor at the cistern to show that water is actually flowing.

DAN

([User Info](#))

Perfectly appropriate posting for here.

I did have a prototype of this low-level switch working at one time. I didn't want to have the reed switch submerged, OR the magnet (some concerns about possible contamination of the water by epoxy, or Neodymium if the magnet coating failed). So I used a rod with a magnet on it that extended above the water level inside a PVC tube, and a reed switch on the side of the tube. When the water level dropped, the magnet lowered to next to the reed switch and closed it, and both were still above the water line. There was an extension of the bottom of the rod, too -- long enough that the magnet could not travel down past the reed switch and accidentally turn the pump back on again, and so that it could not stick to the switch.

In any case, my problem was ice....the upper level of my well rings is still an icy environment and the water vapor condensed in the tube and froze, causing failure--clogged the whole tube with hoarfrost. I did not find a way around this, other than the possibility of re-building my whole spring house with more space and more insulation. So the project was never written up for our web pages.

In any case -- SJE Rhombus sent us new replacement float switches, one for low level and one for high. That's my next project -- installing them. Time will tell how well they work.

Hope that answers your question.

Cheers  
DANF

### ["WindPower" generator plans](#)

By [johnjach](#), Section [Homebrewed Electricity](#)

Posted on Mon Dec 8th, 2003 at 10:13:28 AM MST

[Wind](#)

Is this power output possible?

Plans for a "WindPower" wind generator are available from [www.lookout2000.com](#).

This is a homebrew generator with a 6' dia. 2-bladed prop geared down to a 12V, 60 amp GM alternator. They are claiming an output of 720 watts in a 20 mph wind.

Is this realistic?

Thanks for your help.

Re: "WindPower" generator plans ([none / 0](#)) (#1)  
by [windstuffnow](#) ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Mon Dec 8th, 2003 at 10:28:33 AM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

I didn't see the unit...The site you posted brings me to some web hosting site. On the possibility of making that much power with a 6 ft blade... That comes out to about 63% overall which means they beat the betz and are using an alternator of 100% efficiency.

The best I got from my set up with a 6ft blade and a 60 amp alternator with a modified rotor using neo's was around 320 watts in a 20 mph wind. I thought that was pretty good at the time but still only comes out to around 28% overall efficiency.

Can you repost the site? I'd like to take a look at the unit...

Have Fun

Ed

Re: "WindPower" generator plans ([none / 0](#)) (#2)  
by [johnjach](#) on Mon Dec 8th, 2003 at 10:41:29 AM MST  
([User Info](#))

So sorry Ed, the complete website is [www.lookout2000.com/windpower/](#)

I'll look forward to your comments. Another DIY unit using an unmodified car alternator is the "Dragonfly" listed on the site list of Otherpower. What do you think of that one?

Thanks. JJ.

The Dragonfly, to me, looks like about the best you could do with a car alternator....that's why we linked to him. He's also been in business quite a while. We've all discussed the limitations of car alternators and gearing in wind turbines here.....all I can say is that at least the Dragonfly has wood blades and a furling system. I doubt that low wind performance is very good, but at least the machine probably won't blow up. And, the builder advises scheduled maintenance. Another plus, I liked his attitude about maintenance. And it appears he mostly sells for marine users, where 20mph is fairly common....I can't think of a car alternator machine I've seen that starts up below 20 mph.

As for the WindPower machine (I first saw it on Ebay) -- sheet metal blades sound really scary to me. And there's no furling. Sounds like metal fatigue waiting to happen. Maybe OK in the mojave desert where the builder is located, but I think it would blow up here.

Nuff said.

([User Info](#)) <http://www.windstuffnow.com/main>

I'd have to say Dan's right about the blades... I'm not real comfortable with metal blades at all. The dragonfly looks like a stout little unit. My attempts of using the alternator out of the box were less than satisfying but the modified rotor unit worked fairly well. I still prefer building my own alternator for whatever project I'm working on. I purchased the plans for the dragonfly some time ago out of curiosity but never built one.

I would say if your going to build any type of turbine use good judgement on the strength and durability of the spinning mass....

Have Fun but play safe!

Ed

Wind power plant outputs have been exaggerated by  
dealers/designers in the past. Generally I expect 1/2 of the  
stated maximum rated output (at 20 mph).

Re: "WindPower" generator plans ([none / 0](#)) (#5)  
by desertratjack on Mon Dec 8th, 2003 at 11:52:25 AM MST  
([User Info](#))

I looked at the site mentioned. I enjoyed it and will look more  
at it in the future. (He's located about 50 miles south of me).  
What I read was 500 watts at 30MPH. Half of this at 20 MPH  
(250 watts) sounds about right. I'd be glad to visit him and  
attempt to verify his figures.

Here is an example of proper documentation of windmill output.

I saw that too in the latest issue, and will be ordering it.

Quite a few years back, Mother Earth News was turned into a rich yuppie outdoor magazine, with articles about helicopter salmon fishing in New Zealand and such; I cancelled my subscription then. They lost thousands of subscribers from this, and many staffers. Some of the ex-staffers and readers went on to start Back Home Magazine, to which I have been a contributing author twice now. That's actually my house on the cover of the latest issue of Back Home, with the remote communications article ;~) I do highly recommend Back Home....lots of organic gardening, home cooking, home business success stories, livestock tips, renewable energy, homesteading info....

Then someone at TMEN realized that, hmmm, maybe this was a bad idea. The new TMEN magazine is more back to the roots of the original. My only complaint is they don't run much about renewable energy systems anymore.

In fact, there's not even much about homebrew RE systems anywhere anymore, not even in Home Power.....they seem to focus on mostly big, expensive commercial systems now. It's a void we are considering trying to fill. Just a thought for now, but who knows?

Cheers!  
DANF

([User Info](#))

If that 23V rating is for open-circuit voltage, it's already just fine for charging a 12v battery.

"remote living" here IS an appropriate place for this kind of question. And home grain production is still done by the very most remote and/or hardcore homesteaders.

I think I've seen info on home-built threshing machines in older issues of The Mother Earth News, and possibly an issue of Back Home. The latest issue of TMEN has a photo of a homesteader threshing by hand, and she is not looking particularly pleased about the whole process. I can see why you want to build a machine!

[SLA batts](#) | 5 comments (5 topical, editorial)

Re: SLA batts ([none / 0](#)) ([#2](#))  
 by ADMIN ([admin@otherpower.com](mailto:admin@otherpower.com)) on Mon Dec 1st, 2003 at 08:49:18 AM MST  
[\(User Info\)](#)

Forcefield magnet magnate MattB has about 3000 a/h of surplus SLAs from ChuckM installed at his place -- they went online a couple weeks ago. So far so good! We'll see how they perform, but my opinion is that if the SLAs are in good shape when you get them, and you use the proper regulator (in his case a c-40 set for SLAs) to prevent overcharging, they are probably just great. We've seen lots of dead SLAs, but I think they were murdered by the owners....you can't just add distilled water, so it's critical to not overcharge and boil them.

His SLAs were mounted in steel racks, horizontally. There are 4 racks, and each weighs about 800 lbs. We used an engine hoist to unload them from Chuck's truck into Matts. Matt stated that he used a variety of Mankind's most basic tools to unload them and get them up the hill to their spot underneath his house -- the lever, the fulcrum, the wheel, and the chainsaw :-)

DANF

PS -- the chainsaw was used to widen the doorway so they would fit thru!

PPS -- we'll try and get some pics posted.

[\(User Info\)](#)

Good Dan,  
 You crack us up here with your sense of humor!

Where did Matt get his batts?  
 I looked for the Surplus Center batts. Are they Surplus Center o Nebraska? I couldn't find them there.

Hi Rob,

I picked up the batteries in Denver from a guy who was disposing of them for US West. Last I spoke with him it looked like he had made arrangements to have the rest (about 10 48v strings !) sold in mid november. If you are interested, contact me off list and I can make sure they're gone (or not). (See my web site for my email address)

Yes, it was Surplus Center of Lincoln, Neb. They might have sold them by now too.

Chuck

Forcefield magnet magnate MattB has about 3000 a/h of surplus SLAs from ChuckM installed at his place -- they went online a couple weeks ago. So far so good! We'll see how they perform, but my opinion is that if the SLAs are in good shape when you get them, and you use the proper regulator (in his case a c-40 set for SLAs) to prevent overcharging, they are probably just great. We've seen lots of dead SLAs, but I think they were murdered by the owners....you can't just add distilled water, so it's critical to not overcharge and boil them.  
His SLAs were mounted in steel racks, horizontally. There are 4 racks, and each weighs about 800 lbs. We used an engine hoist to unload them from Chuck's truck into Matts. Matt stated that he used a variety of Mankind's most basic tools to unload them and get them up the hill to their spot underneath his house -- the lever, the fulcrum, the wheel, and the chainsaw :-)

DANF

PS -- the chainsaw was used to widen the doorway so they would fit thru!

PPS -- we'll try and get some pics posted.

We will have that data for you soon!

The key thing seems to be getting the drag on the wheel from the coils and magnets just enough for max power output, but not so much that Skippy refuses to run because it's all uphill too steep.

We shall see....

Yep, I thinking a strip of corrugated cardboard for traction.

OR -- maybe little tiny track shoes and a possible Nike endorsement? The front of a Wheaties box? Next I might try feeding him on wheaties just to see....

Hello DANF,  
Good idea, but i´m thinking of Material which is used to cover a running circle in a Stadium for Lightathletics - just to make it more convinient for your Powerrunner.  
This should be inside of the Wheel. lol  
Thomas

We ruled out bumping up the posts with new comments to the top-- there would be too many older posts on the front page many mornings.

Instead, we are working on an op that displays only new stuff wherever you deploy it. The programmer we use for all this is real busy, so we'll have to wait for a bit. We'll also have him alphabetize the FAQs by topic and within topics.

It'll happen, please be patient!

## [Our Beautiful 1967 Jeep Fire Engine](#)

By [ADMIN](#), Section [Diaries](#)

[ADMIN's Diary](#)

Posted on Sun Sep 21st, 2003 at 11:20:39 AM MST

When you live next door to DanB, you'd BETTER have a fire engine handy!

---

This gorgeous old girl belongs to the Rist Canyon Volunteer Fire Dept., Larimer County Colorado. Our response area is huge; it's a one-hour drive at code 3 (lights and siren) from our east border to our west border. Therefore we have 5 stations....none are manned. The old girl resides at DanF's house since we don't have a "physical" station way up here on the west border of our area.

She's a 1967 Jeep M-715 cargo truck with 38K miles on her. 4WD with high and low range -- and low range is REALLY LOW. She runs a 232 Tornado engine, and was converted to 12v from 24v in the early 1970s. She is outfitted with a modern BB4 fire pump, 250 gallon water tank, booster line reel, and full complement of hose line and tools. RCVFD built the pump system, and it is designed to drain back for winter use -- she can be fully drained and winterized in under 15 minutes, and can draft up a full tank of water again in about 10 minutes. She was originally owned by Larimer County Search and Rescue, and they gave her the nicely-fabricated metal cab and utility bed to replace the old cloth top and flatbed.

She is registered with the county as a Type 6X wildland engine, Rist Canyon Engine 651. She's lovingly referred to as our "slow response pumper" -- she doesn't move very fast, the "Armstrong" power steering gives the driver an upper-body workout, and she will rattle your bones on a rough road, but she also can travel to remote areas where our more modern trucks (like Ford F-550s) fear to tread.

She's one of 3 Jeep M-715s in active service with our department, and she's the only one of the 3 that's classified as a "first out" engine--so she rolls on all fire, medical and rescue calls in our Area 5.

## [Wind -- How do I regulate voltage from my windmill to my battery bank?](#)

By [ADMIN](#), Section [Renewable Energy FAQ](#) [Wind](#)

Posted on Tue Nov 4th, 2003 at 12:43:45 PM MST

The batteries actually regulate themselves, UNTIL they get full. At that point you must start diverting power to a Dump Load.

Many people ask how you can connect an alternator or generator that puts out 30v (into an open circuit) to a battery bank that's only 12v without frying the batteries. The batteries actually regulate themselves and pull the generator voltage down to their charging voltage, UNTIL they get full. Then the power needs to be diverted somewhere else. That is the job of a diversion charge controller and the dump load it sends power to.

Dump loads can be as simple as turning on more lights in your house when it's windy and your battery bank is full. Electric heatings elements are often used. Many people buy or build an automatic diversion charge controller that senses your battery bank voltage and turns heating elements or other loads on to dump power.

Homemade units:

<http://www.bioelectrifier.com/charge.htm>

<http://www.homepower.com/files/shuntregulator18.pdf>

Some commercial units can operate as dump load controllers, for example:

<http://www.xantrex.com/products/product.asp?did=191>

(note -- they can be set to function as a solar charge controller or as a wind dump load controller, but not both at the same time.)

Some good discussion on diversion charge controllers and dump loads:

[Wind -- Can I use a car voltage regulator to regulate my wind generator?](#)

[Wind](#)

By [ADMIN](#), Section [Renewable Energy FAQ](#)  
Posted on Tue Nov 4th, 2003 at 12:24:53 PM MST  
No, vehicle voltage regulators are built to perform a completely different function.

Car alternators use spinning electromagnets in the armature to induce current into the coils of the stator and charge your car's battery and/or run your headlights, etc. Your car's voltage regulator is designed to change how much power it puts into the alternator's electromagnets and thus change how powerful the magnetic field is, and therefore how much power it generates. When your car is using lots of power, the voltage regulator increases the power to the magnetic field and the alternator loads up and makes more power. When the battery is full, the voltage regulator reduces power to the electromagnets, letting the alternator spin more freely and make less power.

With any kind of wind turbine, when the batteries get full during a windstorm, you MUST keep the wind turbine loaded up--otherwise it will freewheel, overspeed and blow up. A car voltage regulator would perform the opposite function...it unloads the alternator when the batteries fill.

With a permanent magnet alternator, your battery bank is an integral part of the electrical circuit and regulates the voltage on it's own -- UNTIL the batteries get full. At that point you need to divert power to a Dump Load.

See these FAQs for "How do I regulate my windmill?" for more details on regulation, dump loads, shunt regulators, etc.

Good voltage regulator discussion here:

## [Wind -- Can I use a car alternator to build a wind generator?](#)

By [ADMIN](#), Section [Renewable Energy FAQ](#)

Posted on Tue Nov 4th, 2003 at 12:09:21 PM MST

[Wind](#)

You could...but they are poorly-suited for the task, requiring high rpms to make power, and have other problems.

You could do it, but car alternators need to spin much too fast to be direct-driven by a windmill. You'll need pulleys and gears to get the rpms up above 1000, whereas a homebuilt PM alternator can cut in at only 110 rpm and rarely exceeds 500 rpm (ideally). There are major friction losses involved in gearing the machine up, and these losses come right off the top and seriously hurt your low-wind performance. It's possible to rewind a car alternator with thinner wire to improve low cut-in speed, but the other problems still remain and it's complicated to do. The electromagnetic field in a car alternator also uses up power. There are also brushes that wear out, and the bearings are not designed for thrust loads. These facts all make a good case for building your own permanent magnet (PM) alternator instead of adapting a car alternator.

We have more details about selecting an alternator or generator for a wind turbine on our site here:  
[http://www.otherpower.com/otherpower\\_wind\\_alternators.html](http://www.otherpower.com/otherpower_wind_alternators.html)

Some discussion on this board about using car alternators for wind power and the relationship inside them between coil wire size, voltage and amperage:

### [Hugh Piggott's Axial Flux Alternator Windmills Plans in stock](#)

By [ADMIN](#), Section [Site News](#)

Posted on Fri Aug 29th, 2003 at 03:04:29 PM MST

[Wind](#)

The latest version of the wind turbines Hugh is building in his seminars....

This is the same mill the Dans helped build at Hugh's seminar on Guemes Island, WA, April 2003. 8-foot diameter, dual-magnet-rotor machine, with details on building the 4-foot version too. Nicely detailed and dimensioned CAD drawings, charts, and photos. All the information, details and measurements you need to build an axial-flux wind turbine. Hugh's focus is on slow, gentle, heavy and reliable machines that stand up to extreme conditions.

[http://www.wondermagnets.com/cgi-bin/edatcat/WMSstore.pl?user\\_action=detail&catalogno=1502](http://www.wondermagnets.com/cgi-bin/edatcat/WMSstore.pl?user_action=detail&catalogno=1502)

([User Info](#))

? But how accurate is it????

Re: Bicycle Speedometer Anemometers ([none / 0](#)) ([#2](#))  
by ADMIN ([admin@otherpower.com](mailto:admin@otherpower.com)) on Thu Aug 14th, 2003 at 01:02:03  
PM MST  
([User Info](#))

Pretty darn good accuracy. It does not respond as fast to gusts as my analog anemometer, since the refresh rate on the bike speedometer is only once per second. But when calibrated off my truck using both GPS and speedometer (GPS showed the truck speedometer is on within 1 mph) it's right on the money. And it matches right up with my Easter Egg anemometer.

CHeers

## [New Product -- Anemometer Cup and Hub Assembly](#)

By [ADMIN](#), Section [Site News](#)

Posted on Wed Jul 16th, 2003 at 09:10:54 AM MST

[Wind](#)

Takes care of the tedious part of anemometer building -- fabricating and balancing the cups and hub!

A really nice unit made of durable Polycarbonate (Lexan®). Mounting, glueing and balancing those durn Easter Eggs was a pain in the butt. With this thing, you just press the cups into the hub and are ready to rock n roll.

[http://www.wondermagnets.com/cgi-bin/edatcat/WMSstore.pl?user\\_action=detail&catalogno=4201](http://www.wondermagnets.com/cgi-bin/edatcat/WMSstore.pl?user_action=detail&catalogno=4201)

### CATALOG COPY

\*\*\*\*\*

A quick and easy way to build your own anemometer! A windspeed meter is essential both for evaluating a site for wind power potential, and for measuring the performance of your wind turbine. The most tedious part of building our Easter Egg Anemometer was fabricating and balancing the cup assembly. This product makes that easy! You can use it for any design, including bicycle speedometer versions.

The 3 cups and the hub are made from extremely durable black polycarbonate plastic (Lexan®). They ship unassembled, and the cups simply press fit very firmly into the hub -- no glue is needed. In both of the anemometers we built with these cups, no balancing was needed. There is a 3/32 inch diameter reinforced hole in the exact center of the hub to make fitting your own shaft,

hi

do you think that i can make something like this but bigger and put it on a dc motor and use it as a wind gen ????

Re: New Product -- Anemometer Cup and Hub Assembly ([none / 0](#)) ([#4](#))  
by troy on Thu Jul 17th, 2003 at 12:41:53 PM MST  
([User Info](#))

You sure can. It's called a drag machine because it uses drag and not lift like a "propellor" based mill. Drag machines are generally pretty good on torque and pretty bad on rpm. Plus the tip of the rotor (like the cup on the anemometer) can never go faster than the ambient wind speed, which is much much different than a machine with a prop. The tip speed on a prop will run anything from 3 to 10 times faster than the ambient wind speed.

A Savonius rotor is another example of a common drag machine.

Best regards,

troy

Yeeee-hah, DanB and DanF are taking off for the drive to Seattle this morning.....

, to attend Hugh Piggott's wind generator building seminar. We are both loaded down with cameras, and We plan to put together some detailed webpages about our experiences. And I convinced DanB that we should take my 1999 Ford Ranger instead of his 1931 Model A .... Neither of us will have any internet access for all of next week, but everything will be running normally at our shipping office, retail store and Ebay operations...those folks don't get to go :- ( Anyway, if you have ordering questions or problems, as usual send them to ff@wondermagnet.com Cheers, and have fun...we will be! DANF DANB

[formatted re-post of more on ferrous cores...](#) | 10 comments (10 topical, editorial)

Re: formatted re-post of more on ferrous cores...  
([none / 0](#)) ([#1](#))  
by Reno on Thu Jan 1st, 2004 at 08:55:45 AM MST  
([User Info](#))

Happy new year to you and all. Couple of questions How did you decide how much metal to use did you consider placing the layers of metal between windings of mag wire Will you try to see if it is scaleable in other words less copper same amount of production. This could be a good weight reducer, money saver, space reducer..... Great job I am hoping to start my coil testing but am stilling trying to locate a backing plate for my mags (needs to be cut special) My first design was going to be the metal copper metal idea.

Ted(Monte350c),

I'm glad somebody else is interested in this too. If more than one person can get positive results, then there may be something to this. I like your idea of the spiral laminations, that is a good way to make a round form out of flat stock. I think the silicon steel mostly comes in the form of flat stock.

It looks like the inside diameter of your coils are the same as the outside diameter of your magnets. I wonder if the diameter differences could account for the differences in gain between your setup and mine?

In the tests I'm running, the finished coil diameters are the same as the magnet diameters. I also found by having a metal disk on the ends of the coils helped as well (the spool shape). The disks I used were just mild steel washers and I swagged them to the ends of the center tube. Basically flaring the ends of the tubing to hold the washers in place.

I'm wondering if you placed metal discs on the ends of the coil you have if there would be any change in output.

Keep us posted on your tests!

Happy New Years!

-Bill-

Ted, Those results are impressive and after some research I think I am starting to understand it a little better. I found out that permeability is the resistance to magnet flux (U). Higher numbers are good and conduct more flux. Air, wood, and plastic are approx = 1, iron = 5000, and silicon steel 40,000. If the magnetic circuit can be approximated or crudely represented by a simple circuit  $v=I*R$  where I is the flux than lowering the total resistance is a good thing. More flux should mean higher voltage. I have been considering a concept to bridge the air gaps in the circuit. If total R is the combined resistance of two air gaps and the conductor in the center we want to minimize it. If 3 resistors are in series then I believe we add the sum to compute total R. If any one of them is a large number the system resistance will be high and bring the flux across the system down. I just posted a picture in the MY PHOTO UPLOAD section that shows a magnetic brush concept. I have explained the picture in my last Magnetic Brush post. I have read your and Bill541 work and think it is well done. I would really like to get your perspective on this addition.  
 Regards, Steve M

Hi guys,

Still recovering from New Year's...

I like the brush concept - but what about trying to put the brushes on the magnets instead? Perhaps some kind of fine hardened steel wire like a brush.

I'm still doing more playing around with various coil formats. I'll post more when I've tested a few. Sure wish Santa had brought me a lathe - maybe next year!

Ted.

([User Info](#))

Get a roll of soft-steel MIG welding wire or just plain 'ol mechanics wire from the hardware store. Wrap the mechanics wire right along with the copper wire as you make your winding. Start winding on a 3/8" dowel and work your way out. This integrates the ferrous material right into the coil and virtually zeros out the eddy-current losses.

Re: formatted re-post of more on ferrous cores... ([none / 0](#)) (#7)  
by Electric Ed on Fri Jan 2nd, 2004 at 03:03:52 PM MST  
([User Info](#)) <http://www.electric-ed.com>

Better do this with a coil that you don't value very highly. There will be voltage induced into the iron wire, and if the turns are not insulated from each other, short circuits will exist where adjacent turns come in contact.

Current will flow in these "shorted" coils, producing hot spots, similar to what happens in a motor winding that has partially shorted coils.

Electric Ed

Ok guys now you've went a done it again. And just when I thought i had to many ideas and projects you go and add another one. This board is addictive and dangerus. OK so heres my next project idea. My brother use to work for Mead paper Corp. you know those folks that make spieral note books and stuff like that. He use to bring me large carboard tubes. We make sub woofer inclosers at the car stereo store. Some of these tubes still had a very nice varnish coated soft steel wire they used to make the spiroll spring things. However its nice and straight on these big rolls. I still have a few 100 feet. Magnets realy like this

stuff. So I'm going to wind some coils with copper and this stuff in perelell. I have a zilion speaker magnets so I'll wind the coils same size and shape as the speaker magnets. This will get the magnets very close to the laminations (Mead wire) and copper coils at the same time. Very small gap. Thanks so much for this idea. I guess better get ahold of Mead or = to see about more of the soft and candy coated steel wire? JK TAS Jerry

I would have to agree with Ed on this one. The steel wire will make an inductor, not unlike your copper wire does. This steel inductor will have voltage induced on it, so it must be insulated from itself just as the copper magnet wire is. If you could wind a full layer of the steel wire and bond it to itself so that it did not form and inductor, then I think you would get it to work. Otherwise it should be insulated steel wire. You may be able to wind the coil so that the copper insulated wire always keeps the steel wire separated, but you would need to put a layer of insulating material between each winding layer... Just my thoughts, Bill

Jon..

I own several motorcycles, and have no idea what a stator and amp are..

Now, my 87 Harley Softail has a 30 amp PM alternator on it, which contains a stator and a rotor , using ceramic magnets. Mebbe this is what you are talking about?

If so, not good for wind because of the HI RPMs required for output. I have heard of some success with the rewinding of Harley alternators used to generate some power in wind. You also state 6 volt .. again, still unsure what you are talking about with "amp" , but 6 volt alternators are not a viable option

by JB on Wed Dec 31st, 2003 at  
03:23:11 PM MST  
([User Info](#))

you might get a little power with one off  
a outboard engine or a real big kohler etc  
if you could get the right curved magnets  
to match. Usually the stock flywheel  
magnets are too weak I got a pm motor  
flying out here that was wound a lot like  
a motorcycle stator that puts out about  
120 watts. JB

you might get a little power with one off a outboard engine or a real big kohler etc if you could get the right curved magnets to match. Usually the stock flywheel magnets are too weak I got a pm motor flying out here that was wound a lot like a motorcycle stator that puts out about 120 watts. JB

[My Mini Geni isn't working very good](#) | 18 comments (18 topical, editorial)

Re: My Mini Geni isn't working very good ([none / 0](#)) (#1)  
by Electric Ed on Tue Dec 30th, 2003 at 03:14:02 PM MST  
([User Info](#)) <http://www.electric-ed.com>

From the photos, the coil "span" appears to be somewhat less than the magnet pole center-to-center distance. I suspect that there may be some voltage cancelling happening.

Also, there appears that there is no stator iron, which would create a very inefficient magnetic circuit.

Electric Ed

([User Info](#))  
<http://timmythy.home.mindspring.com/timmy.htm>

When I was testing, I was only using 1 coil at a time. For the picture I just stuck those two coils in there so folks could see how I planned to place them. There will be 12 coils and 12 magnets and they will line up to each other 1 to 1.

The ring around the outside is the laminate material from the original fan motor. I was sure that would work for the stator iron.

I should point out that I cut the slots out of the original fan stator, leaving me with an almost perfect circle of laminates.

([User Info](#))

I've got the same thing (even the same hacksaw, but yellow handle) get another junk fan motor (you know they're not that scarce) and start all over again, but don't cut the laminates, this time grind down the armature enough to allow for some of those small magnets that Ed on Windstuffnow has (99 cents each so they won't break you) Have Fun ( :>) Norm

Re: My Mini Geni isn't working very good ([none / 0](#)) (#2)  
by [cevonk \(cevonk\(atsignhere\)aol.com\)](#) on Tue Dec 30th, 2003 at 03:24:08 PM MST ([User Info](#))

Very interesting project! Getting things to work on a small scale is sometimes harder than on a large scale. If the magnets are 1/4" in diameter and 1/4" thick, it looks as if the field airgap between the magnets and the outside stator is about 3/4". With larger magnets, say 1/2" thick, that would work out to an airgap of 1 1/2", which would probably be a serious drawback.

It's neat to see the ideas that you are working on!

([User Info](#))  
<http://timmythy.home.mindspring.com/timmy.htm>

It's hard to tell the scale from the photos, but the airgap from the end of the magnet to the laminates is slightly over 1/2 inch. was planning on making coils at 3/8 inch thick.

Re: My Mini Geni isn't working very good ([none / 0](#)) (#4)  
by Norm on Tue Dec 30th, 2003 at 03:43:51 PM MST ([User Info](#))

What happens if you just run the output of one coil thru one small 1 amp diode? or even try measuring the ac voltage? ,,or check the voltage of the battery...then check the voltage of the battery thru the rectifier...you should be getting some kind of voltage ac or dc? even .001 volt? Hope this helps until you get a more expert advice....Like Zuck perhaps? Maybe with a different arrangement of magnets ( :>) Norm.

Re: My Mini Geni isn't working very good ([none / 0](#)) (#5)  
by JB on Tue Dec 30th, 2003 at 04:34:52 PM MST ([User Info](#))

I did a little 1/6 hp motor something like that last week. it was a small 6 pole 7.8 amp 1000 rpm ac motor and had only 6 coils in series. They looked about 17 or 18 gauge. i put 6 of the 1/2 by 2 by 1/4 neos on it skewed ns ns ns. It still cogs pretty good. I wasnt terribly impressed with my results but it did show 4 amps 15.5 volts on the dc side of the bridge rectifier on my meter at 400 rpm and 5.3 amps 24 volts dc at 770rpm I think if i had doubled the magnets amd made them 1/2 thick I would have been able to bring the charging voltage down considerably. JB

I did try to test the straight AC voltage, but after I disconnected everything I realized that it was'nt hooked up properly. I'll try again in the morning.

Also I did consider testing using a single diode, but the wife wanted the vacuum cleaner fixed so I went on to the higher priority project at the time.  
Thanx

I think you'll do better with cheap ceramic magnets of the right size, so you know the flux lines will cut the coils where and when you want them to.  
I agree ...something like Ed has would have been a lot less fuss and bother:

by Jerry on Wed Dec 31st, 2003 at 08:30:03 AM MST ([User Info](#)) <http://www.dplusv.com/Photo-03.html>

I did 6 of the little Ed/Windstuff magnets on a smaller version of this motor. Didn't change a thing but machined the armature down to fit the magnets.

It dose cogg hard but I'm seeing 60 watts at 500 rpm. Just try getting 60 watts from a solar panel for 6 bux.

JK TAS Jerry

big gap..... (none / 0) (#16)  
by Norm on Wed Dec 31st, 2003 at 12:51:12 PM MST  
([User Info](#))

After taking a real close look at the pictures and especially the last ones ,I think I have the solution...a couple of the ones that replied and said about the gap were on the right track especially Electric Ed where he also referred to the width of the magnets to the width of the coil or something like that, so I'll be back with the solution as soon as I draw a couple of illustrations on one of your pictures. OK? Norm

Okay....on the next one you get like this(this would be an alternative for someone with only simple handtools)after carefully unwinding each coil.....cut each pole straight down as on the red line, when you are finished it will look something like the first picture. Now center a block of wood as thick as the laminate and scribe the radius of the rotor and cut the ends of each pole off accordingly take a large half-round file and file the curve to allow clearance of the rotor. Then rewind the coils and put em back. This is far from ideal but it should work. The better

Ok Woofer,

Why not try using square magnets to line up one after another instead of round ones ? because the rounds do give trouble to the magnetic paths, that is, pulling and distorting the flux path. Square ones should behave more "Squarely" in this regard, no pun intended. :-

Love experimenters !

Hi John. Could you discribe your blades. Size at the root, size at the tip, any twist, how thick, profile, cup, leading edge, degrees of attac tip and root, trailing edge and how many? I've not built a working disc genny yet. Although I've started a couple. I have mostly been doing AC motor conversions. I have seen 1200 watts from my 22 inch plastic blades (49 inches tip to tip) so at least that part is similar to yours? JK TAS Jerry

I think this might work if U use a pendulum lke on a clock ,it swings back & forth and never moves from the centre, might be worth a try.

Re: Is this possible? ([none / 0](#)) ([#3](#))  
by Dave B on Sat Dec 27th, 2003 at 11:28:58 PM MST  
([User Info](#)) <http://www.madbbs.com/users/bruggelog>

Look up linear motors. I used to work on very large disk drives that used a linear motor for the read / write heads. It used a chrome etched scale with electronic reading head for indexing the distance moved in or out. The "motor" probably weighed 20 lbs itself and had incredibly fast precise movement. A very large electromagnet coil surrounding the "piston" linear rotor I'll call it and was mounted on rails with ball bearings just like you mention. Wish I had kept a couple of these for just such experiments. If you find one be very careful experimenting, these could clip your fingers off very easily ! Dave

Hi Yo, Pardon me if I appear to be bad when I do not agree with you :-). But I think the idea is a waste of time first off, a reciprocating coil/magnet device would induce too much vibration for the blades. Remember an internal combustion engine has good rubber mounts when it has piston(s) going up and down. Still, there are vibration that you can feel while sitting in the car. But those engines would absolutely indeed need something (Piston) to go up and down because of the function of the fuel system --the fuel needed to be expanded and exploded in order to create powers and so we need top-dead-center position which is the best position to allow the explosions to happen. But this idea again if applied to generator of sorts, would mean wasted power as someone already mentioned, that when the magnet or whatever travels to the top dead center position, it stops for some moments before reversing direction. Hence, you get the lost of energy and wind energy can be too precious to lose this way. Besides again, we would have to have some forms of a crank, or at least a cam device in order for that going-up-and-down thing to motion up and down, this arrangement is an additional source for wasted energy. I could think of many other negative areas for the reciprocating idea but I stop here and want to just briefly mention the difference between reciprocating action and linear one. Linear one is the most efficient type of motions since it has no repeated action loss, meaning, something goes forever straight-on forward, NOT REVOLVING around and around !! But we cannot apply this linear

technology to some generators because a generator is always something affixed stationarily. But if applied to moving vehicles or vessels, then the linear idea I think is the ideal medium for future transportation propulsion folks. In fact, I can remember still in my failing head that we already have this form of motions for some thirty odd years ! I remember some monorail systems did indeed use linear electro induction theory to move forward back from that time ! And some of those vehicles indeed do not use real rolling bearings neither, they use magnetic powers to float the vehicles above the metal track, so the friction loss is about near zero much like hovercrafts sort of. We did also have other in-plant vehicles moving this way etc etc. However, this gives me an idea, if we can somehow make a continuous "Tube" which is actually a loop of magnet wires and we allow a magnet (Which is magnetically coupled to the blades hub by a spinning disk with magnets affixed to it) to travel inside around and around and at the same time having the magnet inside to float off the wire tube, we can then cut down friction to zero and this will enhance greatly to precious wind power uses I think. But the only obstacle here is, how do we devise some magnets to travel and floats inside a tube of wires without touching the sidewall ? This is the only question in my head folks ! Perhaps we can have the a real tube made of plastic to covering the wires and have the inside of this tubing vacuum filled and have some form of fluids to float the magnet. But this fluid still would not create zero friction. But perhaps then we can use laser beams to float the magnet, this is possible. Think on folks ... but I think we are getting too high tech here, I will have to come down from the sky you would have to say ..... ! Hey last, I am not a scientist honestly, I am someone just like you, who tends to like to fiddle with things just to find out ..... so as a fellow human being, I can be wrong too in areas folks ..... hey ! ! Ciao ! Luubovv.

MST  
([User Info](#))

Thanks for the comments. What I was actually thinking is probably a goofy idea. I was thinking of what would happen if I were to make a thirty foot or more long string of coils vertically and then use the turbine to haul up the magnet "rotors" which would be dropped down the string of coils (using gravity as the force) one after the other and loop back up again.

And thank's for the welcome Tom!

Ed P

Hi Ed,

Don't worry about the goofy ideas, we are all here just to goof one way or another. So lets see if I can goof along longer. I understand your idea, it would be like one round circle standing up vertically, with some benches all around, and this thing turns around and around vertically, and we are the ones who sit in those benches, like what we see in the carnivals ! This will be a true linear motor if you made the circle large enough so that the arrangement will not be seen as a circle anymore. So the magents and the coils are actually crossing paths one vertically and the other horizontally. Or we can say that the coils stay on the inside of the revolving magnet circle. I like the part about letting gravity help move down the magnets on the return side. This actually would be a noval idea, we are not just letting the wind doing the job for us, but now we are utilizing gravity at the same time, and to think about it, the magnets are naturally heavy so there are going to be great momentum to help the down push motion, and the down motion is really the same effect as the up motion for the other side of the circle ! ! ! But sadly one hitch, because by the same token, the weigh of the magnets when first going up, will balance away the gains from the down momentum.

Happy New Year.  
Luubovv.

Hi Ed,

Don't worry about the goofy ideas, we are all here just to goof one way or another. So lets see if I can goof along longer. I understand your idea, it would be like one round circle standing up vertically, with some benches all around, and this thing turns around and around vertically, and we are the ones who sit in those benches, like what we see in the carnivals ! This will be a true linear motor if you made the circle large enough so that the arrangement will not be seen as a circle anymore. So the magents and the coils are actually crossing paths one vertically and the other horizontally. Or we can say that the coils stay on the inside of the revolving magnet circle. I like the part about letting gravity help move down the magnets on the return side. This actually would be a noval idea, we are not just letting the wind doing the job for us, but now we are utilizing gravity at the same time, and to think about it, the magnets are naturally heavy so there are going to be great momentum to help the down push motion, and the down motion is really the same effect as the up motion for the other side of the circle ! ! ! But sadly one hitch, because by the same token, the weigh of the magnets when first going up, will balance away the gains from the down momentum.

Happy New Year.  
Luubovv.

## BRUSHLESS 24VDC MOTOR W/ SPEED CONTROL (USED)

[Larger Picture Available](#)

Powerful 24Vdc motor with built-in speed control. Removed from electric scooters, these motor/speed control assemblies provide smooth acceleration from 165 to 2880 RPM (no load). No load rating: 2880 RPM @ 24 Vdc @ 0.70 Amps. With a load these motors may draw 15 Amps or more. We estimate them to be about 300 Watts. The speed control is in a potted assembly inside the motor housing. Motor dimensions: 5" diameter x 2.63". 5/16" diameter x 1" long shaft. A removable .5" diameter collar, which was part of the drive mechanism, covers the shaft. The control and power leads have been cut to a length of 3." There are two power leads and six control leads. A 100K linear potentiometer (not included) is required to connect to three of the control leads. Two other leads are a kill switch. The purpose of the remaining lead is unknown. Motors are tested and guaranteed functional. Hook-up diagram supplied.  
CAT# DCM-221

Your Price: \$26.00 each

In stock, ships within 24-48 hours.

Correction

12/16/2003

Reviewer: A viewer from Winfield, KS US

My face is red, but..... In fairness to All Electronics and people who read my first review, I need to comment again. Having ordered two more motors before discovering the no-load current increase I mentioned, I immediately tested the next two and they seemed to be fine. Problem is, I also test the first motors again, and wasn't able to reproduce the same results as before. Nor can I explain why at this time. All I can say is try them for yourself. Thanks

Was this review helpful to you?  YES  NO

More comments

12/12/2003

Reviewer: A viewer from Winfield, KS US

Having purchased 2 of these motors and reading Ron's review, I decided to do some testing of my own. (I just checked to see that they ran when I first recieved them) I'm in agreement with Ron's analysis. The current into the (white) control wire tracks the applied voltage at 100 microamp per volt, suggesting an input impedance of 10K ohm. The 100k pot works as a speed control with or without the black lead, indicating it is functioning as a current controlling device. I found the control range to be the same, about 1.7 to 4+ volts. Unfortunately during my testing I found that the no load current, while starting around 0.7 amp began to increase after the motor ran for a period of time, until it exceeded the current limiting of my bench supply (3amp). At full RPM this was a couple of minutes, at a more moderate RPM (1000?) about 10-15 minutes. I tried this on a power supply with more current capacity (15amp) and found that it only became worse. I stopped at 5 amp because I was convinced if the motor was not thermally protected, it would lock up and self-destruct. Both motors I have do the same thing, making them more or less useless. Bad design, bad bearings, or what I don't know. Unfortunately I didn't take the time to check them better when I first recieved them.

more info you'll need - please read!

12/06/2003

Reviewer: Ron Chinnery from Independence, MO USA

First, it's a great deal. However, the hookup drawing supplied needs some correction/additions. The small Black wire should not be used as part of the POT hookup for speed control. That wire appears to be an Output, possibly an open collector output for status of some sort. It is floating open at all times, in all conditions as far as I've been able to tell to this point. (if you figure it out, post it here!) The small Green and Blue wires are Ground, common with the large Black DC Power wire. Use one of these wires for the POT ground, if you need it. The small Red wire outputs a non-regulated DC voltage of less-than the supplied Input DC voltage. I'm not too keen on using this for the +V source for the POT, because it varied a lot with motor load. The Brown wire, when connected to Ground, does indeed disable the motor. In addition, it also reduces the "idle" current consumption to around 40mA. In a typical application, you would not want to use a switch in series with the main DC power to the motor, since it draws such high current. With the current drain reduced to 40mA, you don't really have to worry about the controller draining your batteries. The "speed control" input wire (the small White wire) requires a range of 1.7V to 4.2V to cover the entire speed control range. Personally, I would insert a 10K resistor in series with the White wire, to be sure you don't over-current that input. Once you exceed about 5V on that input, the current (on the White wire) starts to climb fast... leading me to believe the original design had a limit on the control voltage of maybe 5V or so. I also found that using a capacitor of 10uF/50V on this input helped get rid of some (apparently) high input-impedance issues... noise. The controller is an "open loop" design, no speed regulation was employed. :( One of the 2 units I got sounds like it has bad bearings, the other is fine... that's the risk with "used/surplus" motors. Weight: 3lb 10oz Have fun!

Thanks drdongle, I kind of suspected that. I just couldn't get the tesla coil picture out of my head...: =) It occured to me later the metal tower would always be a better ground. If these props work as advertised the RPM should be significantly higher. Put that together with iFred's many thin coil design and I got a bit nervous.....

My aim was to minimize line losses to the house of course.

Now I'm off to find some carbon fiber poles and little props.....

What would he use as a power source? You might be able to find some hobby motors. One could power the other one, which would actually produce the electricity. He might be able to build a shell around one to make it look like a diesel engine.

Frankly, it seems like a stretch (at least to me) to make it functional. Without a miniature diesel engine, it can't actually be authentic. You'd also need motors for each of the wheels. But, hey! What do I know? Maybe he could try some of the more exclusive hobby shops - especially those that deal with model trains. Good luck!

([User Info](#))

Ed,  
I am interested. How do we go about getting together on pricing etc.? will this be offered on windstuffnow?  
Firefly

Re: Silicon steel ([none / 0](#)) (#3)  
by windstuffnow ([elenz@windstuffnow.com](mailto:elenz@windstuffnow.com)) on Tue Dec 23rd, 2003 at 03:00:01 PM MST  
([User Info](#)) <http://www.windstuffnow.com/main>

If you interested in the 1/2" silicon the formula to find weight is:

$$(OD^2 - ID^2) \times .7854 \times .134 = \text{lbs}$$

This is for the 1/2" stuff, the 3/4" will have a different conversion, I'll know when I get it here.

The cost of the stuff is \$4.00 per lb. for either

You can email me with any specifics.

I'm thinking of putting it on my site but in specific size rolls instead of winding each one specific for an application. So there will most likely be 5 or 10lb rolls as a standard.

Have Fun  
Ed

[Really thin coils.](#) | 5 comments (5 topical, editorial)

Re: Really thin coils. (none / 0) (#2)  
by Bach On on Tue Dec 23rd, 2003 at 04:48:16 AM MST  
([User Info](#)) [change AT: bach\\_on AT hotmail.com](#)

Dan,

Thanks for the response. I've tried 1 by wood as the core for my coils. I've also tried dowels. The quarter inch thick wood seems a better thickness. I might even try to plane that down to something like 3/16 of an inch.

I suspect my post was not clear. I'm talking about two different steps. First, using the plexiglass as a mold for the nine individual coils.

After molding and setting the coils in whatever glue/resin to hold them together, that plexi and wood would be removed and probably discarded. Pure copper would remain.

Then there would be one thickness of plexiglass to which my nine coils would be glued. This should leave me with a stator in the range of 3/8 to 7/16 inches thick.

A difficulty I always seem to have is that my fiberglass molded stators often vary in thickness. This often forces me to have a wider gap to accomodate the less than "plumb" and uniformly level surfaces. I just haven't found the right process to end up with a level molded surface. The plexiglass should be uniformly level, while adding minimally to the thickness.

The plexiglass I have is about an 1/8 of an inch thick.

Bach On,

If I were trying to build the thinnest and strongest stator for the thickness, I would make the front and back plates of high-tensile epoxy resin and 'S-glass' or carbon-fiber cloth first. These thin laminates would be made on a piece of waxed plate glass and made with as little resin as it took to soak the cloth. All excess would be pulled off or I might vacuum bag it with 'peal-ply'.

I would then make my coils and sandwich them between the two skins I had just made. Spacer blocks would keep the skins at a constant thickness and squeeze out the excess resin.

The resulting product would have the structural material as separated as possible. The 'skins' would likely be less than .030 inches each.

But, there is an old saying -Go ahead, it's not my cow.-

Why dont you try to explain what you are trying to do, I mean, the final product; it may be better, this way, for someone to understand what you are trying to do, this way you may get a lot of more practical help.

([User Info](#))

Hi guys,

Don't forget, it is important to use clamping-down method while epoxying the sandwich. This will keep the stator thinner and the clamps can be adjusted to get an even thickness ALL AROUND the stator disc as you can squeeze the coils down (Unless you already have the coils wound in high density, which is not so easy to do in homemade situations). That too, you won't even have to fabricate spaces. Using 4 or even 6 clamps around the disc can get must precise height adjustments than using the "Lazy" 3 clamps. With 3 clamps, sometimes you might think you got it under control but when the resin or epoxy is dried and you opened the clamps, you would find the uneven thickness still. (Sorry for the outburst "Lazy", did not mean to contradict others. Just wanted to update ideas. Get the drift ? :-)

Smile,  
Harry Luubovv.

[Progressive winding alternator](#) | 5 comments (5 topical, editorial)

Re: Progressive winding alternator ([none / 0](#)) (#5)  
 by Harry Luubovv on Tue Dec 30th, 2003 at 10:12:30 AM MST  
 ([User Info](#))

Hi Windstuff Ed,

I think your "Progressive Coil" idea is innovative thinking, and I like innovative thinking. I had such a thought also once, but only briefly though because nevertheless (Pardon my ignorance Ed), I think, the various sizes of wires will sum back up to the same output figures as if you used an averaged 3 sizes of wires. If we literally did this experiment it can prove out itself. Because I think it is the matter of total copper and the spaces available for the copper to set in, that makes the difference aside from ..... yes, the only way to optimize outputs for high-low winds situations could only be by switching between parallel and series connections. Another matter I think Ed, in both series or parallel situations, the larger sized wires would be dragged down of its output by the smaller sized wires. One thing I've learn in electronics is never to parallel nor to series two different sizes of wires coils unless you are sure that the smallest of wires alone can handle at least half of the current produced in 2 coils situation, or one third the capacity in 3 coils situations, 1/4 cap in 4 coils situation, etc etc ! But in a windgen, we can never be sure of this because we do not control the speed of the mills, the wind does.

Please correct me if I am wrong !

Cheers,  
 Harry Luubovv.

i dont know personally but if you look at the tesla coil list pupman.com or the tesla coil web ring you might find someone. i know there are a few tesla coilers in oz who might be able to help. lot of simularities between this list and the tesla list.

[Net metering with a generator??](#) | 3 comments (3 topical, 0 editorial)

Re: Net metering with a generator?? ([none / 0](#)) ([#1](#))  
by wpowokal on Sun Dec 21st, 2003 at 05:18:47 AM MST  
([User Info](#))

This begs the question of why would you want to!

However the least one would need for the generators well being is the facility to synchronise to the system frequency. This ensures your generator is closed to the system in phase at zero volts. A very small generator could be simply crashed onto the system and come into sync, probably without much harm.

Then there is the problem of voltage, the power factor of the grid (inductive or capacitive), frequency (should the system frequency drop your generator may try to supply the whole of uncle Sam)

Then the legality of a system outage, linesman working and your generator electrocuting them. (thus the features of grid interactive inverters)

Allan

I agree with Allan,

It most likely is doable on a small scale, but why bother. It can be feasible to make homebrew power at 2 cents per kwh, but chances are, you most likely won't produce enough power over-time to "contribute" to the grid. Also a good point is the line-mans safety...

If somehow you have managed to assemble a substantial, micro power plant, that can produce 60kw continious 24/7, at 2 cents per kwh, including overhead(equip cost) and fuel cost and will conform to EPA emmissions standards(btw- corn burners do meet these standards). then most likely the local utility will advise you how to do this properly (your results may vary :)

with wind power this is becoming much more popular "ie" wind farms. generally the problems of "freq-sync" to the grid are lessend by stable battery banks and grid-interactive inverters.

back to the original question- use the search feature "of this site" for a -VAR- or VAR power controller. this

is part of how you can sync to the grid with a mechanical gen-set. but these systems are difficult to manage(and expensive) and you must consult with the utility comp. to do it right.

I was thinking that a synchronous inverter would be the safest off the shelf solution, in that you would take the power you generated and use it to charge a battery bank, or for greater efficiency, an ultra-capacitor bank, and set the inverter(s) to deliver power to the grid when the supply voltage reached a preset level. This would be doable with a trace sw series or similar inverter. You would of course lose some energy in the conversion/charging necessary to provide the right charging voltage for your battery bank. The Inverter would be UL listed for grid connection, and therefore reasonably safe. As for the economics of such a connection, I suspect that with depreciation of the equipment, it would be a money loser. Good Luck.

[Using different kinds of magnets on same rotor](#) | 17 comments (17 topical, editorial)

Re: Using different kinds of magnets on same rotor ([none / 0](#)) (#2)  
by [Sponge](#) on Sun Dec 21st, 2003 at 02:27:44 AM MST ([User Info](#))

Im working myself on a harrdisk magnet rotor, this week I'm going to try my test setup for it.

As you might have noticed.. magnets come in all sorts and sizes.. liek this picture demonstrates. I took it yesterday night, bit unsharp:

(clickable)

My current amount of proper magnets:

(clickable)

I have not yet made laminates. I can't find any decent info about it. The only metal I can find overhere is 10mm wide, 1mm in height and 1m long. (or a 16mm wide version).

I'm not sure if that is bad, good, or semi good. The only strips I can find are aluminium...

Oh, I forgot: Does anyone think the material from a "cookie box" (like where my magnets are on, at the top picture) would be a nice amination material? :) It's thin.. :)

Also, right here:

<http://www.fieldlines.com/story/2003/10/15/102538/69>

Someone is telling about his HD magnet windmill (somewhere in center of the page), but the guy doesn't have a nemail adres unfortunately.

Regards,  
Almar

Im working myself on a harddisk magnet rotor, this week I'm going to try my test setup for it.

As you might have noticed.. magnets come in all sorts and sizes.. liek this picture demonstrates. I took it yesterday night, bit unsharp:

(clickable)

My current amount of proper magnets:

(clickable)

I have not yet made laminates. I can't find any decent info about it. The only metal I can find overhere is 10mm wide, 1mm in height and 1m long. (or a 16mm wide version). I'm not sure if

that is bad, good, or semi good. The only strips I can find are aluminium...

Oh, I forgot: Does anyone think the material from a "cookie box" (like where my magnets are on, at the top picture) would be a nice amination material? :) It's thin.. :)

Also, right here:

<http://www.fieldlines.com/story/2003/10/15/102538/69>

Someone is telling about his HD magnet windmill (somewhere in center of the page), but the guy doesn't have a nemail adres unfortunatly.

Try this site

[http://www.otherpower.com/otherpower\\_experiments.html](http://www.otherpower.com/otherpower_experiments.html)

There is a lot of info there on various genny's.

The Volvo 240 and the "Ward Mill" will discuss laminates.

Have fun

I have to say that I've seen alot of your comments on the rest of the discussion board and I usually have the same questions as you do. Are you not worried by Hanks advice about the dual poles on the hard drive magnets? It seems to me that others have used them with some success. I also hear you saying, "over here" a lot. Where is that?  
Thanks,

Jeremy

Well, ChrisW (the post I mentioned above) got it working right. Although someone else that I mailed failed on his "harddisk magnet" windmill.

"Over here" is the Nothern part of The Netherlands, always windy, 100+ windmills visible with "the naked eye" (on a small hill :-).

Thanks for the advice,

The part I find confusing about laminates is firstly, what kind of metal to use (which I think I understand more about from your comment) and secondly, are the strips wound in a coil or are they concentric rings insulated completely from eachother? I would also love an example of a product or thing in everyday life that is made of this metal. I suppose I'm ignorant to what low-carbon or silcon steel is. It sounds so specialized, but perhaps it is an everyday metal I come across all the time. Thanks again for the insight.

Jeremy

by [Hank](#) on Sun Dec 21st, 2003 at 09:43:02 AM MST ([User Info](#))

Jeremy,

Low carbon steel is probably the cheapest steel. Probably used in making cars. You may also find it in a Auto Body supply shop. It's soft and easy to work. You can also call a steel supply shop and ask about it. Key here is "low carbon" and that's what I would recommend as being the most cost effective.

The strips are concentric rings insulated from each other. I used masking tape on one side for the insulation.

The pic here shows my stator. If you look carefully behind the coils in the center you will see the laminates. The width of all the laminates should be at least the size of your magnets and they serve the purpose of focusing and completing the magnetic circuit.

by [Sponge](#) on Sun Dec 21st, 2003 at 10:30:10 AM MST  
([User Info](#))

btw, staying on topic, I have tried various coils today..and right now, the power output of one coil - currently without laminates - is still a bit disappointing I think. I get about 0.3v with one coil (circular, and wide), spinning my mill as fast as I can. So I'm wondering a bit if I could improve my coil:

Note: Right now you see various magnets. This was just quicky for testing if it was a magnet problem for the low output. For my "real" setup, check out picture above!

Since this is my first windmill, I have no idea how those coils exactly work, even after reading all sites I could find :)

All my magnets look like:

Anyone can tell me what the best size would be? :)

Regards,  
Sponge

Re: Using different kinds of magnets on same rotor ([none / 0](#)) ([#10](#))  
by DanB on Sun Dec 21st, 2003 at 11:59:23 AM MST  
([User Info](#))

Yes, I would try what Electric Ed suggests below. I think your coil is way too large... at most, it should be the size of a single magnet there, so that the OD of the coil is not larger than two poles (1 magnet).

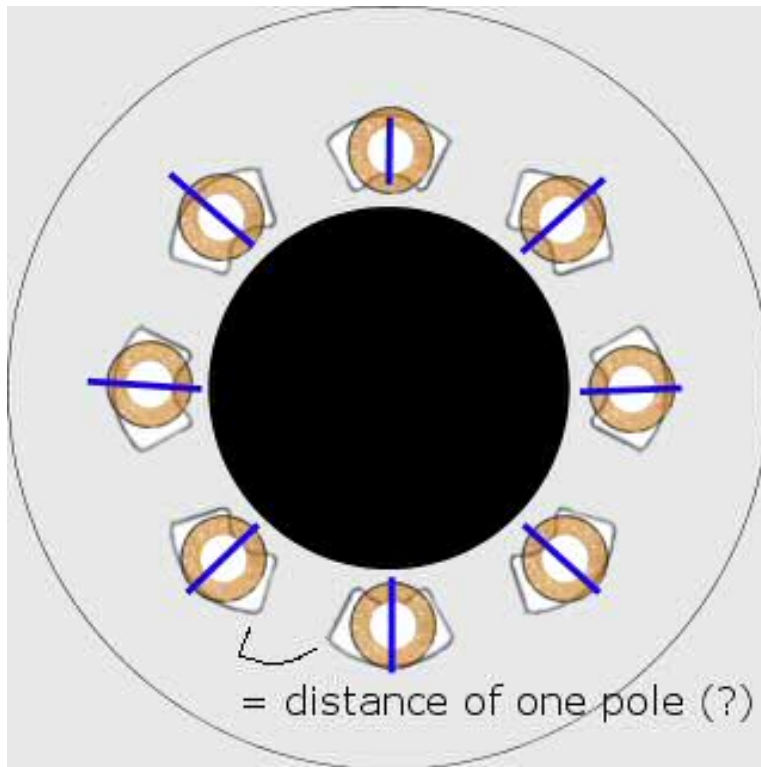

Id also try to keep the coil pretty thin - if you use laminates, i believe there becomes a point of diminishing return when the airgap is thicker than thne magnets. So if you can stack your magnets up to say... 1/4" thick - try to keep the airgap (distance from magnet to laminates) not much more than that...

It sounds a bit funny - but I think perhaps youd get better results if you could break those hard drive magnets in half so that there was a bit of seperation between the poles.

Re: Using different kinds of magnets on same rotor ([none / 0](#)) ([#11](#))  
by [Sponge](#) on Sun Dec 21st, 2003 at 01:20:01 PM MST  
([User Info](#))

Thanks, a bit like this?

I don't like breaking the magnets in two, actually :)

Regards,  
Sponge

[ [Parent](#) ]

Re: Using different kinds of magnets on same rotor ([none / 0](#)) ([#12](#))  
by Hank on Sun Dec 21st, 2003 at 02:14:13 PM MST  
([User Info](#))

You may want to make your coils look more like Ed showed, sort of rectangular. You want the magnets crossing the wire at a right angles (90 deg.) not parallel. So the hole in the center should be larger than your magnets are wide and the magnets should just cross the legs of the coil.

[ [Parent](#) ]

Re: Using different kinds of magnets on same rotor ([none / 0](#)) ([#13](#))  
by [Sponge](#) on Sun Dec 21st, 2003 at 02:45:13 PM MST  
([User Info](#))

Yeah, I tried rectangular before, but somehow the circular one gave more output :). But I guess it was my first "flat" coil. So, if I understand correctly, it should be like this? (or more like the bottom coil?).

With one magnet per pole, it's easier to be sure than with these HD magnets :)  
So.. just checking :) (And I think there are more people looking for answers like these in the future too :- ) !)

Regards,  
Almar

[ [Parent](#) ]

Re: Using different kinds of magnets on same rotor ([none / 0](#)) ([#14](#))  
by Hank on Sun Dec 21st, 2003 at 06:07:22 PM MST  
([User Info](#))

Yes that's more like it. NOT like the bottom one it's to large. Also I think you might want to make the legs a bit longer so the whole magnet can be seen thru the hole in the center of the coil.

Magnets passing parallel with the coil windings don't produce power. This is a waste of potential power.

The coils don't have to be perfectly rectangular, you may want to make them a bit trapazoidal to sort of fit to the shape of your magnets. Perhaps similar to the pic I have above in an earlier thread.

[ [Parent](#) ]

Re: Using different kinds of magnets on same rotor ([none / 0](#)) ([#16](#))  
by DanB on Mon Dec 22nd, 2003 at 08:27:57 AM MST  
([User Info](#))

I think thats close... the best bet is experiment I suppose. Id try the coils slightly larger. If it were me, If you're not going to break the magnets, then Id try to run them close together so the poles are as equally spaced as possible.

Thanks, a bit like this?

I don't like breaking the magnets in two, actually :)

Regards,  
Sponge

Re: Using different kinds of magnets on same rotor ([none / 0](#)) (#12)  
by [Hank](#) on Sun Dec 21st, 2003 at 02:14:13 PM MST ([User Info](#))

You may want to make your coils look more like Ed showed, sort of rectangular. You want the magnets crossing the wire at a right angles (90 deg.) not parallel. So the hole in the center should be larger then your magnets are wide and the magnets should just cross the legs of the coil.

[ [Parent](#) ]

Re: Using different kinds of magnets on same rotor ([none / 0](#)) ([#13](#))  
by Sponge on Sun Dec 21st, 2003 at 02:45:13 PM MST  
([User Info](#))

Yeah, I tried rectangular before, but somehow the circular one gave more output :). But I guess it was my first "flat" coil. So, if I understand correctly, it should be like this? (or more like the bottom coil?).

With one magnet per pole, it's easier to be sure than with these HD magnets :) So.. just checking :) (And I think there are more people looking for answers like these in the future too :- ) !)

Re: Using different kinds of magnets on same rotor ([none / 0](#)) ([#14](#))  
by Hank on Sun Dec 21st, 2003 at 06:07:22 PM MST  
([User Info](#))

Yes that's more like it. NOT like the bottom one it's to large. Also I think you might want to make the legs a bit longer so the whole magnet can be seen thru the hole in the center of the coil.

Magnets passing parallel with the coil windings don't produce power. This is a waste of potential power.

The coils don't have to be perfectly rectangular, you may want to make them a bit trapazoidal to sort of fit to the shape of your magnets. Perhaps similar to the pic I have above in an earlier thread.

[ [Parent](#) ]

Re: Using different kinds of magnets on same rotor ([none / 0](#)) ([#16](#))  
by DanB on Mon Dec 22nd, 2003 at 08:27:57 AM MST  
([User Info](#))

I think thats close... the best bet is experiment I suppose. Id try the coils slightly larger. If it were me, If you're not going to break the magnets, then Id try to run them close together so the poles are as equally spaced as possible.

# Phase changes

Transitions between solid, liquid, and gaseous phases typically involve large amounts of energy compared to the [specific heat](#). If heat were added at a constant rate to a mass of ice to take it through its phase changes to liquid water and then to steam, the energies required to accomplish the phase changes (called the latent [heat of fusion](#) and latent [heat of vaporization](#)) would lead to plateaus in the temperature vs time graph.

[Temperature scales](#) | [Water phase changes](#) | [Boiling point](#)

[Water](#)

[Phase change concepts](#)

# Why is the Potential Energy Negative?

In discussing the energy of the [phase changes in water](#), we found that the potential energy is treated as a negative quantity. An analogy with a mechanical system with [gravitational potential energy](#) and [kinetic energy](#) might be helpful in understanding the logic of a negative energy quantity. You are always free to choose the zero of potential energy, and it seems logical to choose the [zero of potential energy](#) such that a free molecule at rest has zero energy. A bound particle at rest then has negative potential energy.

A marble sits on a table with zero mechanical energy - that is, its kinetic energy is zero and, being supported, its potential energy is also zero.

If the marble now tips over the edge and rolls down into the depression, it will have negative PE, positive KE and the total mechanical energy will still be zero.

But if the marble is stopped at the bottom of the depression, it will have just the negative potential energy and will be trapped in a "bound state".

Positive kinetic energy of molecular motion

Zero energy

Negative potential energy from intermolecular attractive forces.

**Particles in bound states are said to have negative energy compared to free particles .**

The intermolecular attractive forces between water molecules hold them together in the liquid or solid state. This means they have negative potential energy with respect to free molecules. and that the negative potential energy exceeds the positive kinetic energy so that they are in a negative energy "bound state".

# Details of Heating Water

It is known that 100 calories of energy must be added to raise the temperature of one gram of water from 0° to 100°C. Part of that energy increases the kinetic energy of the molecules, and some adds to the [potential energy](#).

The sizes of the blocks which represent the kinetic energy of the molecules at 0°C and 100°C provide a visual illustration of the meaning of [temperature](#) and the nature of the absolute or [Kelvin temperature scale](#). From the definition of [kinetic temperature](#), the size of the block is seen to be proportional to temperature, and the ratios of the heights of the KE blocks is the ratio of the temperatures. But the kinetic temperature is inherently the absolute temperature, so that the ratio of the heights of the blocks is 373K/273K. So the absolute temperature is actually proportional to the translational kinetic energy of the molecules, while the Celsius temperatures are just chosen for convenience.

[Go Back](#)

[Index](#)

[Phase change concepts](#)

# Some energy details related to heating water

In the process of [heating water](#) from from 0 to 100 C, 100 calories of energy must be added. Part of that energy increases the kinetic energy of the molecules, and some adds to the [potential energy](#). To assess the amount added to kinetic energy, the molecular speeds at the two temperatures may be evaluated with the [Boltzmann speed distribution](#).

$$v_{\text{rms}} = 615 \text{ m/sec at } 0^\circ\text{C for H}_2\text{O}$$

$$\begin{aligned} \text{K.E./mole} &= \left(\frac{1}{2}\right)(18 \text{ amu/molecule})(615 \text{ m/sec})^2 \\ &\quad \times (6.02 \times 10^{23} \text{ molecules/mole})(1.66 \times 10^{-27} \text{ kg/amu}) \end{aligned}$$

$$\text{K.E./mole} = 3400 \text{ J/mole} = 45 \text{ cal/gm at } 0^\circ\text{C}$$

At 100°C the corresponding translational K.E. is:

$$45 \text{ cal/gm} \times \frac{373\text{K}}{273\text{K}} = 61.7 \text{ cal/gm}$$

The net gain in kinetic energy is then 16.7 calories/gram when the water is heated from 0 to 100 C. The remainder of the energy goes into weakening the attractive forces between the water molecules. This weakening of the intermolecular forces manifests itself in the reduction of the [surface tension](#) of water as it is heated.

In the process of vaporization of water, a large amount of energy must be added to overcome the remaining cohesive forces between the molecules and an additional amount of energy goes into [PdV work](#) to expand the gas from its very small liquid volume to the volume occupied by the resulting vapor.

PdV work during vaporization at 100°C:

$$\begin{aligned} &\frac{(1.013 \times 10^5 \text{ N/m}^2)(22.4 \times 373/273 \times 10^3 \text{ cm}^3/\text{mole})}{(18 \text{ gm/mole})(10^6 \text{ cm}^3/\text{m}^3)} \\ &= 172 \text{ J/gm} = 41 \text{ cal/gm} \end{aligned}$$

If the [heat of vaporization](#) of water at 100°C is 539 calories, then subtracting the 41 calorie work component suggests that the actual binding energy of the water molecules at 100°C is 539-41=498 calories.

## Why is the heat of vaporization more at body temperature?

An interesting feature of the process of [cooling the human body](#) by evaporation is that the heat extracted by the evaporation of a gram of perspiration from the human skin at body temperature (37°C) is quoted in physiology books as 580 calories/gm rather than the

[Index](#)

[Phase change concepts](#)

nominal 540 calories/gm at the normal boiling point. The question is, why is it larger at body temperature?

The main part of the answer is that the binding energy of the water molecules is greater at that lower temperature, and it therefore takes more energy to break them apart into the gaseous state. The change in the heat of vaporization can be roughly calculated using what we know from the [specific heat](#) of water, 1 calorie/gm °C. It takes 37 calories to heat a gram of water from 0°C to 37°C, but the change in the kinetic energy is much less than that:

$$\text{K.E./mole} = 3400 \text{ J/mole} = 45 \text{ cal/gm at } 0^\circ\text{C}$$

At 37°C the corresponding translational K.E. is:

$$45 \text{ cal/gm} \times \frac{310\text{K}}{273\text{K}} = 51.1 \text{ cal/gm}$$

The energy contributed to weakening the bonds is then  $37 - 6.1 = 30.9 \text{ cal}$

It was shown above that the kinetic energy of the water molecules only increases by  $61.7 - 45 = 16.7$  calories/gm when the water is heated from zero to 100°C but we know it takes 100 calories to do that heating. Therefore the contribution to weakening the water bonds is 83.3 calories/gm. Using the result for water at 37°C it is evident that 52.4 calories of additional energy must be supplied at 37°C to vaporize the water.

There is one additional element in modeling the heat of vaporization at body temperature - the PdV work required to expand the water into its gaseous form is slightly less at 37°C. By analogy with the work calculation above, that work is found to be 34.2 calories/gm, 6.8 calories/gm less than at 100°C.

This model then suggests a heat of vaporization at 37°C:

$$\text{Body temperature heat of vaporization} = 539 \text{ cal/gm} + 52.4 \text{ cal/gm} - 6.8 \text{ cal/gm} = 585 \text{ cal/gm.}$$

So this simple model agrees fairly well with the quoted 580 cal/gm.

[Water phase changes](#)

[Water](#)

## BUILD A SIMPLE

# CHARGE CONTROLLER

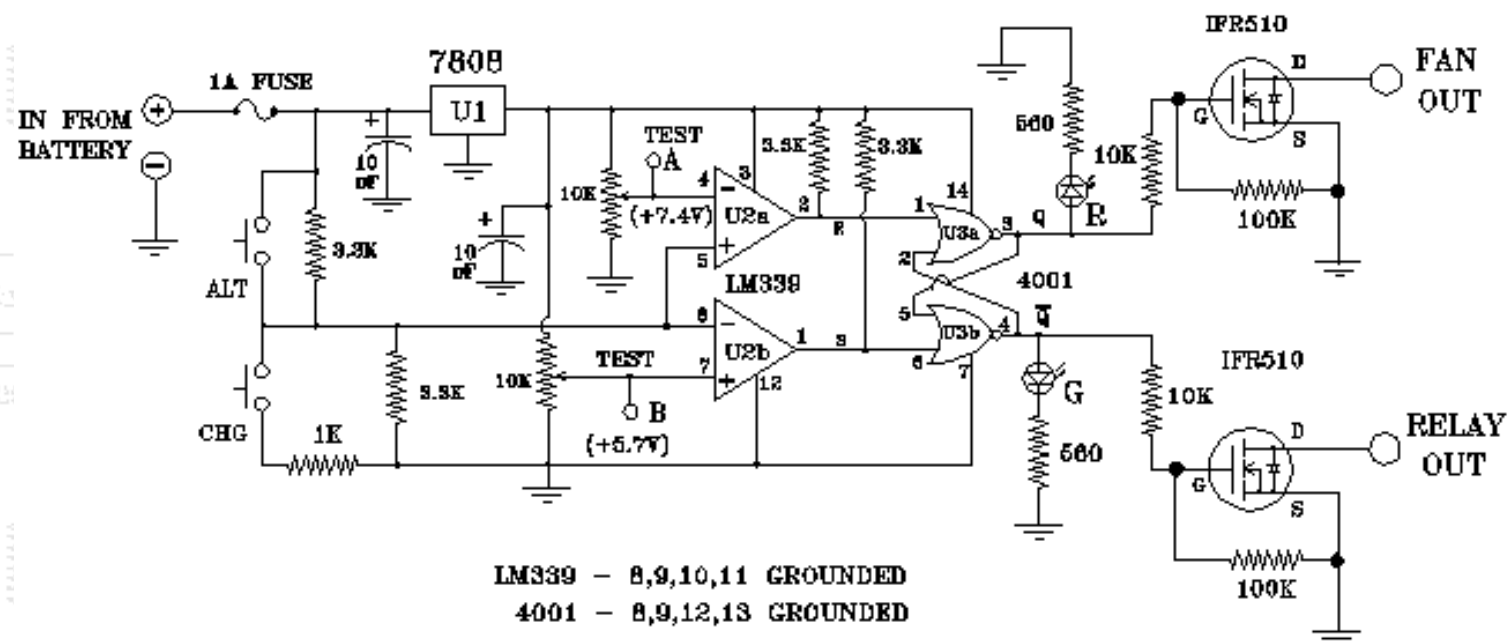

## FOR WIND AND SOLAR POWER SYSTEMS

Once our wind generators and solar panels were up and running, the next obvious requirement was some sort of charge controller, since continuous overcharging would boil the electrolyte dry and ruin the expensive battery bank. Several small controllers came bundled with the solar panels, but they were totally unsuitable for wind power use.

Charge controllers intended for solar panels work by monitoring the battery voltage, and once it reaches full charge, the controller simply shorts the solar panel leads together. This doesn't harm the solar panels, but it does waste whatever power they're generating. The energy ends up heating the transistors in the controller.

This type of controller is not ideal for a wind generator, since shorting the output of the genny while it's spinning at high speed will generate a huge current spike, possibly destroying the controller and perhaps even the generator in the process. On the other hand, simply unhooking the generator from the batteries is not a good idea either, since with no load on it, the generator might overspeed in a strong wind and destroy itself.

The ideal solution is to charge the batteries until they reach a full charge, then switch to an alternate load where the energy can be safely handled. While we're at it, this energy should be used for some useful purpose, such as supplementing a water heater or powering a peltier-junction refrigerator, but in a pinch, a bank of 12 volt light bulbs will do.

The above schematic shows the simple charge controller circuit. The incoming battery voltage is divided in half by a pair of 3.3K resistors, so the trip points are adjusted to one-half the desired levels. The actual trip points will depend on your particular batteries, but a good starting point is 14.5 volts for full-charge, and 11.8 volts for discharged. In this case, the trim pots should be adjusted to read 7.25 volts at TP-A and 5.9 volts at TP-B. You will probably need to monitor your battery voltage through several charge - discharge cycles to determine the perfect trip points for your system.

The outputs of the controller are latched, and drive a pair of IFR510 power FETs, which serve as relay

the battery terminal voltage, so each source contributes whatever current it's capable of producing. Each blocking diode has to be sized for the current that source can generate. The negative lead from each source is connected to ground.

Here's the hookup as it's working here. As long as the batteries are charging I can see the red LED glowing. As soon as the trip voltage is reached, the red LED goes out and the green one comes on, and the power is shunted to the alternate load. This way, no power is wasted.

[BACK](#)

# Homebrew

## Shunt Regulator

Chris Greacen

Wind, hydro and photovoltaic panels can sometimes produce more electricity than our batteries can store. Overcharging batteries increases water loss in the electrolyte, decrease battery life; and is potentially more dangerous. Under charge, the voltage of a fully charged battery system can rise to levels which will fry 12 Volt electronics (including some inverters) attached to the system.

There are two basic kinds of regulators: series regulators and shunt regulators. Both regulators have a sensing circuit which regulates current flow into batteries when the voltage exceeds a threshold level. Series regulators work by switching off current from the

charging source (panels, etc) when the voltage climbs too high. With the charging source disconnected like this the battery voltage sinks to its standing voltage (lower than its voltage under charge). Series regulators are simple, but they have two disadvantages: first, not all power potentially produced by the power source is used. When the load is switched off, generators used in hydro or wind systems can spin more quickly than they are designed for and destroy themselves. This does not apply to solar cells - running PVs open circuit, or short circuit for that matter, does no harm.

Shunt regulators work by diverting the power from the batteries into some other load. In effect they waste electricity, but wasting electricity is much better than overcharging batteries - or destroying electronics. Of course if you do have a way to put those electrons to a good use, by all means do it - run the washing machine or vacuum cleaner.

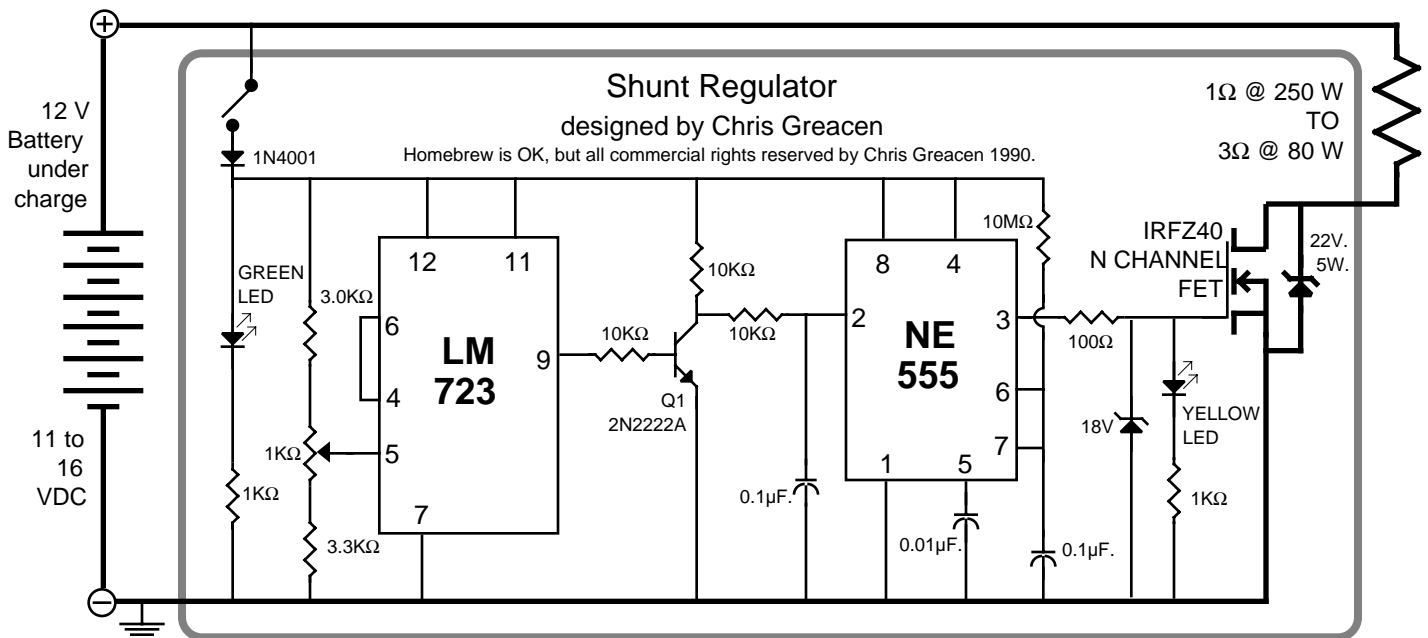

What follows is a working, simple shunt regulator. With a proper load, this shunt regulator can regulate up to 15 Amps (more than 3 Kyocera J-48 PV panels on a very sunny day).

### How it Works

The threshold voltage is determined by the potentiometer on the voltage divider into pin 5 of the 723 (refer to the schematic). When this voltage exceeds the 723's internal reference voltage (pin 6), pin 9 goes high saturating Q1. The 10kΩ resistor and 0.1μF capacitor assure that the power FET does not make the ON-OFF-ON transition too fast. When the capacitor on pin 2 is discharged to 1/3 Vcc the 555 is triggered and pin 3 stays high for a time period determined by the resistor to Vcc and capacitor to ground on pins 6 and 7: time ≈ 1.1RC ≈ 1.1 seconds. Pin 3 feeds the gate of the FET, protected against over voltage (Vgatemax= 20 Volts) by an 18 Volt zener. When the gate goes high the FET conducts, sending full current through the shunt load. A 5 Watt, 22 Volt zener diode protects against voltage spikes from inductive loads. The two LEDs help see what the electronics are doing. The green LED is on whenever power is on. The amber LED lights whenever the regulator is diverting power to the load.

### Construction and use information

In the schematic dark lines indicate high current carrying wires. To avoid overheating on these use 16 gauge or larger wire. For a load

by Andrew ([andrew@lookingglass.com](mailto:andrew@lookingglass.com)) on  
Mon Jul 21st, 2003 at 02:29:15 PM MST  
([User Info](#))

I did somewhat the same for a heating element load...

I used the rods from a water heater...

Each measuring 2.2 ohms...

Put them in parallel across a board

I made a bar that was attached to some all thread...

The bar would slide across the resistive rods to determine the right resistance (think of a really big potentiometer)

And to get the right load, I would simply turn the all thread in a direction...

Like 120v it would be the farthest away, and 12v it would be pretty close to the top...

Get it?

The bar is acting like like the other end of the circuit...

And when it is closer to the opposite side, the resistance will be lower, meaning more load....

-Andrew

I suggest using high wattage power resistors since reliability of the load is the primary consideration. Using a bunch of car tail lights in parallel would also provide a good load since chances are excellent they will not burn out at once. Here is an example for determining resistance and wattage. Suppose the maximum current I wanted to regulate was 15 Amps at 15 Volts. Since  $R = V/I$  we need a resistance of  $15 \text{ Volts}/15 \text{ Amps} = 1.0 \Omega$ . Wattage is given by  $P = IV$ .  $P = 15 \text{ Amps} * 15 \text{ Volts} = 225 \text{ Watts}$ . To be safe, I'd use 250 Watts. When hooking up your regulator make sure the system's voltage is

below 16 VDC since the NE555 is rated at a maximum 16 Volts. The regulator will regulate voltages from 12.0 to 15.8 Volts. When hooking up your shunt regulator it is a good idea to hook up the load first and make sure there are no short circuits.

Please help!

I'm planning to build a three phase alternator windmill. I'm thinking of using the diode rectifier from a Chevy alternator. One question, how can I regulate the voltage? I dont understand how the voltage regulator in the Chevy alternator works and how I can adapte it for my use? I'm also looking for information on how to build the furling system.I looked and did a search, and couldn't find enough information on how to build it. Thanks in advance. Mike

Hi Mike -

You need not regulate the voltage, the batteries will do that for you. You may want a charge controller which will put a load on either the windmill, or the batteries once the batteries are full charged to prevent overcharging.

Regarding the furling system.... at this point I cannot think of a detailed description on the web. (I'm sure there is one out there). Hugh Piggott's is great, I'd go to his website and either buy his plans, or get his book "Windpower Workshop" - it's all very helpful.

There was some discussion about this recently:  
<http://www.fieldlines.com/story/2003/7/9/21444/13286>

Re: Need help on how to regulate voltage ([none / 0](#)) ([#2](#))  
by [troy](#) on Fri Jul 18th, 2003 at 09:55:56 AM MST  
([User Info](#))

As far as voltage regulation, that depends on what you're doing with the juice. If you're charging a decent sized battery bank, the batteries will draw down the output voltage of the mill to the battery level. If you have an extremely high voltage mill (say over 50 volts at speed) and a 12 volt battery bank, you might run into problems. But if your mill makes voltage more in the 15-30 volt range, no problem. You don't have to regulate the voltage at all.

However, your batteries will eventually get charged, and then you have to switch the current to a dump load, a heater or light bulbs or whatever, appropriate for the voltage and current. There are commercial units to do the switching or some home brew designs that you could build if you're handy with a soldering gun.

So if you could give a bit more info on what you're doing with your system, we can be more helpful.

Best regards,

troy

Re: Need help on how to regulate voltage ([none / 0](#)) ([#3](#))

([User Info](#))

What do you mean by voltage regulation ? What is the difference from voltage rectification ? As I understand it vorage rectification is the process of making AC vorage become DC voltage. While voltage regulation is the process of controlling the voltage so It will show little or no voltage variation. Just to clarify the termilogy used here, I am francophone so maybe you guys use different terminolgy.

There are two types of common voltage regulation designs- series & shunt. The precision series type that is commonly used in a regulated linear type DC power supply maintains a preset voltage irregardless of the load (current) & burns off the over-voltage (voltage above the preset output voltage) in the form of heat. The shunt type simply loads the output down to the desired voltage level, but usually requires a series resistor as well.

Unless your battery storage is undersized with regard to your generator output, you do not need a voltage regulator. The beauty of a battery system is it will draw a variable load during charging & maintain approximately 10% regulation. One does not need a precision regulator. Once the batteries are fully charged, a resistive load bank can be switched in circuit to drawdown the excessive voltage & prevent overcharging the batteries. A good resistor bank is a 24vdc hot water heater. Some electric commercial water heaters that are fast recovery type makes use of a lot of heater elements. These heaters are rated for either 480 or 240 vac & most are 3-phase. One could use either 240 volt or the best are 120 volt elements & rewire the water heater to single phase. If an elements is 1000 watts at 120 volts, at 24 volts it will draw 200 watts. If you have 6 elements, that is a 1200 watt load. If 12 elements are used, that is a 2400 watt load.

I am new to this power generation for the home owner business, but have built large power generation plants. Others can point you to some load shedding type devices to achieve your needs. I am modeling my system to use that commercial hot water heater. Summers have less wind vs the winter where I live. If I have a situation of excessive hot water during the winter, I will divert it to heating my house. I doubt this issue will arise during the summer. I also will build my own controller to like mil-spec standard for ultra high reliability. (I have designed for NASA once).

Hmm.

If an elements is 1000 watts at 120 volts, at 24 volts it will draw 40 watts. The current and voltage both go down so you only get 1/25 the power out.

Power = Vsquared /R

Resistance per ohms law of a 1000 watt @ 120vac heater (resistor) is 14.4 ohms. At 24 volts, the 14.4 ohm element would draw 1.66 amps. 1.66 amps times 6 elements is say 10 amps. 24 volts x 10 amps is 240 watts. I miss calculated. Tnx for the correction. I will use lower resistance elements to get to the 1200 watt load.

Dear Jimbob and others,

Here's a source with specifications and prices for ready made low voltage heating elements for water heater. Convert away!

Best regards,

troy

Use one or more of these elements as a diversion load with Trace C35, C40, C60, TC60 controllers. They fit most standard water heaters with screw-in elements. An adapter is used for the square flange type element. The dual 12/24 element has two separate 25 elements. It can be wired for 25 amps or 50 amps at 14.5 volts or 25 amps at 29 volts. The dual 24/48 volt element has two separate 30 amp elements. It can be wired for 30 or 60 amps at 29 volts or 30 amps at 58 volts. Order enough elements with a total current draw greater than your charging system's maximum output, but no more than about 75% the maximum amp rating of controller. 150 watt hours will raise 1 gallon of water about 60°. D380 12/24 volt Dual 25 amp 3 lbs \$65
