In many ways, a Darlington configuration behaves like a single transistor where:

- the current gains ( $H_{fe}$ ) of the individual transistors it is composed of are multiplied together and,
- the B-E voltage drops of the individual transistors it is composed of are added together.

Darlington's are used where drive is limited and the high gain - typically over 1,000 - is needed. Frequency response is not usually that great, however.

C  
o  
|

Testing with a VOM or DMM is basically similar to that of normal bipolar transistors except that in the forward direction, B-E will measure higher than a normal transistor on a VOM (but not open and 1.2 to 1.4 V on a DMM's diode test range due to the pair of junctions in series. Note, 1.2 V may be too high for some DMMs and thus a good Darlington may test open - confirm that the open circuit reading on your DMM is higher than 1.4 V or check with a known good Darlington.

## Testing Digital or Bias Resistor Transistors

Occasionally you may find a transistor that includes an internal bias resistor network attached to the base and emitter so that it can be driven directly from a digital (e.g., TTL) source. These may be used in consumer electronic equipment where space is critical or for no good reason other than to make it difficult to locate a suitable replacement device!

The addition of R1 makes testing with a multimeter other than for shorts more difficult. With a VOM, you should see a difference in the B-E and B-C junctions in the forward and reverse directions. However, a DMM will probably read open across all pairs of terminals.

## Testing Unijunction and Programmable Unijunction Transistors

Unijunction Transistors (UJTs) and Programmable Unijunction Transistors (PUTs) are used in similar sorts of circuits though the UJT is all but extinct. They both exhibit a negative resistance characteristic and can be used easily in low

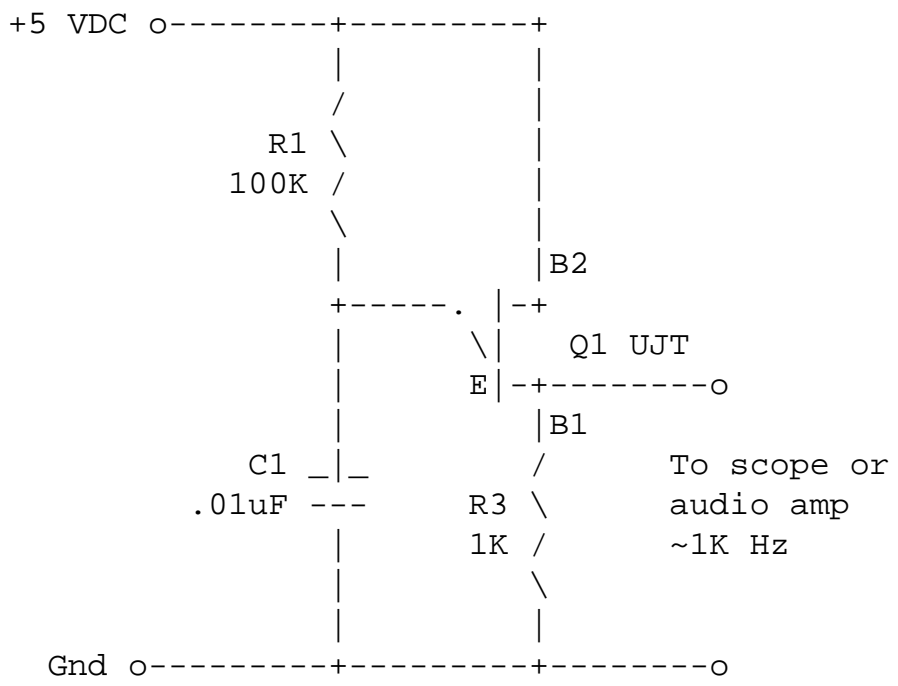

to medium frequency free running relaxation oscillators and other trigger type circuits.

- The UJT goes into heavy conduction from E to B1 when E becomes more positive than a critical trigger voltage,  $V_t = n * V_{bb} + .6$ . (n, the 'intrinsic standoff voltage' is typically about .6). It continues to conduct until the emitter current drops below some minimum 'valley current' value. Sounds sort of like a thyristor, right? :)
- The PUT is even more like a thyristor: The PUT in that the triggering takes place when the G becomes more positive than the A (probably plus a diode drop, .6 V) so that the threshold voltage can now be set with a voltage divider feeding the anode. Then, current flows from the G to the K terminal. Note that its leads are even labeled like an SCR but it behaves sort of backwards!

For an initial test, check between B1 and B2 (UJT) or A and K (PUT) with an ohmmeter. The resistance should be the same in both directions and typically a few K ohms or more. A short or wildly different readings would indicate a bad device.

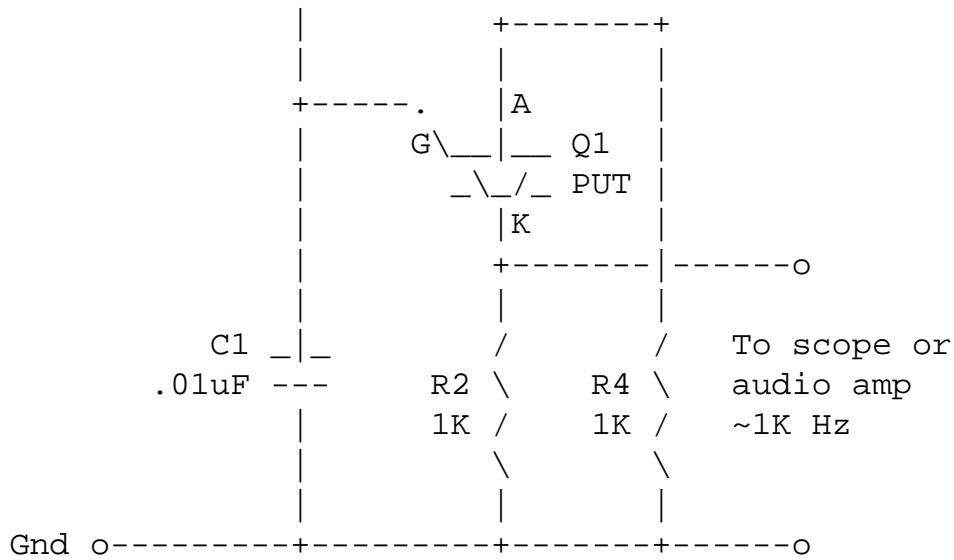

This doesn't prove that the device is good - only that it isn't blown up. A more complete test requires a simple circuit and some means of detecting an audio output signal.

For the UJT:

For the PUT (Programmable Unijunction Transistor), an additional voltage divider (R3 and R4) is needed to set the threshold:

(From: Spehro Pefhany (speff@interlog.com).)

A PUT is essentially an SCR with a large reverse gate breakdown voltage (G can be more positive than A by maybe 40 V) and a sensitive gate. When the voltage at A exceeds the voltage at G by a diode drop, and assuming enough voltage from A to K, the SCR turns on (conducts from A to K) and stays that way until the current drops below the holding current (typically around 100 uA, but it drops with increasing resistance in series with the gate).

Symbol and example:

If you connect your meter from A to K, it should measure open both ways. If you connect the positive lead (which may be red or black, depending on the meter design) to A and the negative lead to K, and then momentarily short G to K it should change to a relatively low resistance reading (meter dependent). It will most likely stay latched when the G lead is returned to being open, because the meter measuring current will exceed the "holding current" of the PUT (called "valley current" in PUT specs).

If your meter has a "diode" range (in the ohms group), using that would assure there is enough open-circuit voltage to make this work, but it works this way in the half-dozen or so meters I have checked, using reasonable ohms ranges.

Measurements between A and G, with K open, should be similar to a silicon diode (fairly low in one direction, open in the other). Between G and K, with A open, should be open in both directions.

PUTs are pretty sensitive (less than 1 uA trigger current) so be sure to keep fingers away from the G lead.

# Thyristors - SCRs and Triacs

## What are Thyristors

Thyristors are used to control power in numerous applications including light dimmers and motor speed controls, solid state relays, some microwave ovens, photocopiers, traction motors for electric locomotives and electric cars, power inverters for transmission of electric power over long distances, frequency converters, other DC-DC or DC-AC or AC-AC inverters, AC-DC regulated power supplies, and many other applications where efficient power control is required.

A Silicon Controlled Rectifier is one type of thyristor used where the power to be controlled is unidirectional. The Triac is a thyristor used where AC power is to be controlled. (There are exceptions in both cases but for this simple discussion these can be ignored).

Both types are normally off but may be triggered on by a low current pulse to an input called the Gate. Once triggered on, they remain on until the current flowing through the main terminals of the device drops below a hold value which is very close to zero. It is usually not possible (at least not easy) to turn thyristors off while current is flowing. However, there are special types called Gate Turnoff Thyristors which enable this type of control as well.

Both SCRs and Triacs are 4 layer PNPN structures.

## How Does a Thyristor Work?

The usual way an SCR is described is with an analogy to a pair of cross connected transistors - one is NPN and the other is PNP. The base of the NPN is connected to the collector of the PNP and the base of the PNP is connected to the collector of the NPN.

If we connect the positive terminal of a supply to say, a light bulb, and then to the emitter of the PNP transistor and its return to the emitter of the NPN transistor, no current will flow as long as the breakdown voltage ratings of the transistor are not exceeded because there is no base current to either transistor. However, if we provide some current to the base of the NPN (IG(+).)ransistor, it will turn on and provide current to the base of the PNP transistor which will turn on providing more current to the NPN transistor. The entire structure is now in the solid on state and will stay that way even when the input to the NPN's base is removed - until the power supply goes to zero and the load current goes below the hold value.

The same scenario is true if we reverse the power supply and use the IG(-) input for the trigger.

A Triac works in a basically similar manner except that the polarity of the Gate can be either + or - during either half cycle of an AC cycle.

For a light dimmer or motor speed control, for example, the exact time when the thyristor is triggered relative to the zero crossings of the AC power is used to determine the power level. Trigger the thyristor early in the cycle and the load is driven a high power. Trigger the thyristor late in the cycle and there is only a small amount of power delivered to the load. The thermal or mechanical inertia is generally counted to smooth out the power and results in smooth continuous operation (i.e., a light bulb controlled by a dimmer does not flicker.)

The advantage of thyristors over simple variable resistors is that they (ideally) dissipate very little power as they are either fully on or fully off.

There are a wide variety of other types of thyristor and thyristor-like devices. In particular, are diacs and sidacs which have no gate input but simply turn on when a specified threshold voltage is exceeded across their main terminals. See the section: [Testing Diacs and Sidacs](#). These are often used to trigger other thyristors in phase control applications.

For more information on thyristors, see Horowitz and Hill or any thyristor databook.

## Testing SCRs and Triacs

- For SCRs, the gate to cathode should test like a diode (which it is) on a multimeter. The anode to cathode and gate to anode junctions should read open.
- For triacs, the gate to main terminal 2 (MT2) should test like a diode junction in both directions. MT1 to MT2 and gate to MT1 junctions should read open.
- For diacs and sidacs, there is no gate terminal - resistance should be infinite in both directions. For more complete testing, see the section: [Testing Diacs and Sidacs](#).

Note: Some thyristors will have a low G-K/MT2 resistance but it should not read as a short.

The real test is quite simple but will require a low voltage DC power supply and two resistors. For triacs, a negative output from the supply is desirable as well to test the triggering when the gate is negative).

R1 will be used to limit current through the device and R2 will be used to limit current to the gate. A 12 VDC supply of at least 200 mA capacity with a 100 ohm 2 W resistor for R1 and 1 K 1/4 W resistor for R2 should work for most small to medium power SCRs. Check the 'minimum gate current' and 'holding current' specs to be sure. For larger devices, R1 and/or R2 may need to be smaller.

1. Connect the supply as shown.
2. Trigger the gate from the positive of the supply through the current limiting resistor (R2) and see that the DUT turns on stays on when the gate is disconnected.
3. Open the circuit to the anode (with the gate connected to the cathode) again reconnect the anode resistor. The DUT should now be off again.
  - For triacs, repeat steps (2) and (3) with R2 supplied from a negative voltage.
  - For diacs, testing must be at full rated voltage. See the section: [Testing Diacs and Sidacs](#).

If the device passes these tests, it is behaving properly and is probably functional. However, without applying full voltage or current, there is no way of knowing if it will meet all specifications.

You can replace the DC supply with a low voltage power transformer (say, 12 VAC). Use a scope to monitor the voltage across the DUT or R1. Then, when the gate is connected to R2, you should see the voltage across the DUT drop to nearly zero when it switches on part way through the positive cycle. This phase will be determined by the voltage and value of R2. It should remain off for the entire negative cycle (SCRs only) with the gate connected and remain off all the time with the gate connected to the cathode.

(From: T. O. Prellwitz (timilen@halcyon.com).)

If you have a semiconductor curve tracer you can configure a small audio transformer circuit to drive the gate. I did this with my B&K and it works well. The secondary should provide enough voltage to drive the gate of the SCR and the negative swing of the AC will cycle the scr off while the positive phase turns it on. I drive the transformer with an audio generator. Hope this offers some ideas.

## Testing Diacs and Sidacs

Diacs and Sidacs are thyristors without any gate terminal. They depend on the leakage current to switch them on once the voltage across the device exceeds their specified ratings. With an ohmmeter, they can be tested only for shorts. Resistance should be infinite in both directions.

However, you can test a diac or sidac with a resistor, variable power supply (you will need at least the rating of the device), and a DMM. Hook them in series and monitor across the device. With care, your variable supply can be a Variac, 1N4007, and 1 uF, 200 V capacitor. Use a 47 K resistor to limit the current:

**CAUTION:** this is not isolated from the power line. Use an isolation transformer for safety. If the DUT is rated more than about 180 V, you will need to use a doubler and higher voltage capacitor but testing is otherwise similar.

As you increase the input, the voltage on the DUT will track it until the rated voltage at which point it will drop abruptly to zero and stay there until the voltage is reduced below its holding current. Repeat with the opposite polarity.

With a scope it is even easier as you can use an AC supply directly (remove D1 and C1) and observe that the DUT will turn on at the proper voltage on both polarities of the AC waveform and stay on until the voltage crosses 0.

Use an isolation transformer for safety.

## Thyristors Driving Inductive Loads

"I am trying to turn on a triac which is driving an inductive load (solenoid) using a digital signal without using an opto triac. I get limited success."

(From: Jeroen Stessen (Jeroen.Stessen@philips.com).)

It is soooo easy: just use a DC current to drive the gate of the triac. Even the polarity of the current doesn't matter, although most triacs are more sensitive for a negative input current (flowing out of the gate to a negative supply). A large triac may require some 50 mA.

There will be some applications where there is no 50 mA supply available. That's where you would want to drive with short pulses. But these pulses would have to occur around the expected instant of the zero-crossing of the load current, which is a bit tricky with an inductive load.

As an alternative you could look for a more sensitive triac, for not too large load currents there are types down to 5 mA or so. If you have 50 mA of DC to spare, go for it, it will work.

By the way, never switch an inductive load like a power transformer ON at the zero crossing of the mains voltage. That's guaranteed to drive the transformer into saturation and create the worst possible current transient. Try and switch on at maximum mains voltage, at +/- 90 degrees delay. Do not use a voltage differentiator to generate +90 degrees phase shift, as it will be too sensitive to mains disturbances. Instead, use a double integrator to give 2 \* -45 degrees and a low-pass filter. Using only 1 integrator to approach -90 degrees gives too much attenuation of the voltage, hence 2 are recommended.

## Burning Up of Thyristors

(From: Neill Means (means@expert.cc.purdue.edu).)

Any thyristor will have a maximum change in current vs change in time  $dI/dt$ . If this is exceeded, then current flowing through the thyristor will find the path of least resistance through the silicon. Unfortunately, for us, this can be thought of as a molecular sized lightning bolt streaking through the doped layers of silicon - finding the path of least resistance from individual molecule to individual molecule. This soon results in an 'avalanche' of electrons streaming through a very small path and this process feeds on itself until the thyristor dies. This whole process probably takes only microseconds to happen.

I don't know if fast blow fuses will help this situation if the current changes too rapidly. A fuse is a very analog device with mass and it seems like it would be a slow, lumbering giant compared to almost instantaneous current change.

The solution for this problem? I am guessing putting an appropriately sized inductor in series with the light bulb, but just be sure to add the correct over voltage snubbing network. The inductor will keep the current from changing too rapidly.

-

## Additional Semiconductor Tests

### Identifying Unknown Bipolar Transistors

The type (NPN or PNP) and lead arrangement of unmarked transistors can be determined using a multimeter based on similar considerations. This, again, assumes the back-to-back diode model. The collector and emitter can then be identified based on the fact that the doping for the B-E junction is always much higher than for the B-C junction. Therefore, the forward voltage drop will be very slightly higher - this will show up as a couple of mV (sometimes more) difference on a DMM's diode-test scale or a slightly higher resistance on an analog VOM.

To determine the lead arrangement, label the pins on the unknown device 1, 2, and 3. Put the positive probe (as determined above) of your multimeter on pin 1. Now, measure the resistance (VOM) or diode drop (DMM) to the other two pins. If the positive probe is on the base of a good NPN transistor, you should get low resistance readings or a low diode drop to the other two leads. The B-C resistance or diode drop will be just slightly lower than the B-E reading.

If one or both measurements to the other two pins is high, put the positive probe on pin 2 and try again. If still no cigar, try pin 3.

If this still doesn't work, you may have a PNP transistor - repeat with the negative probe as the common pin.

If none of the six combinations yields a pair of low readings - or if more than one combination results in a pair of low readings, your transistor is likely bad - or it is not a bipolar transistor!

As noted, some power transistors have built in base resistors or damper diodes and will confuse these measurements. However, the lead arrangement of these types of transistors is usually self evident (standard TO3, TOP3, or TO220 cases). There are also some transistors with series base resistors which may prove confusing. There are relatively rare, however.

Voltage ratings are more difficult and require a low current variable DC power supply with a maximum voltage

output greater than the expected (or desired) breakdown rating of the transistors being tested. A fixed DC supply with a suitable potentiometer is also satisfactory. For tests up to 100 V, a 100K ohm pot would be satisfactory. Put a current limiting resistor of about 100 K ohms in series with the output. For higher voltage transistors, use an appropriate power supply and increase the value of the potentiometer (if used) and current limiting resistor. It should be possible to determine approximate values for Breakdown Voltages such as:

BVcbo - collector to base, emitter open. BVceo - collector to emitter, base open. BVces - collector to emitter, base shorted to emitter. BVebo - emitter to base, collector open.

Apply your variable voltage across the appropriate leads and monitor at the transistor with your VOM or DMM. The breakover point should be easily detectable. The current limiting resistor should prevent damage to the part from power dissipated in the reverse biased junction.

This approach also works for signal, rectifier, zener diodes, and other similar devices.

## Luke's Comments on Junction Voltage Drops and Doping

(From: Luke Enriquez VK3DLE (ecsclfe@lux.latrobe.edu.au).)

The B-C junction voltage drop is always very slightly lower than the E-B junction drop. The drop is given by the equation:

$$V_{drop} = V_t * \ln ( N_a * N_d / n_i^2 )$$

where:

$$V_t = kT/q = 26 \text{ mV at } 300 \text{ degrees K}$$

$n_i$  = intrinsic carrier concentration in a pure sample of silicon  
( $n_i = 1.5 * 10^{10} \text{ cm}^{-3}$  at 300 deg K for silicon)

$N_d$  = doping density atoms/cm<sup>3</sup> in the n-type material

$N_a$  = doping density atoms/cm<sup>3</sup> in the p-type material

This equation means that if the doping density at the Base-Emitter junction is higher than the Base-Collector junction, the Vdrop of the Base-Emitter junction will be higher than that of the Base-Collector junction.

This has been confirmed below on a selection of common transistors using an El-cheapo DMM:

Transistor	B-C Voltage	B-E Voltage
TIP3055	0.640	0.642
TIP2955	0.668	0.668
BD140	0.697	0.699
2N2369A	0.682	0.710
PN3563	0.752	0.753
BC108	0.715	0.716

**CAUTION:** Do not hold the transistor under test in your hand. For every degree the transistor increases in temperature, the Base-Emitter Diode Drop (commonly called  $V_{be}$ ) decreases by 2 mV. This is a significant amount when determining the B-E and B-C junctions.

## Lance's Method for Determining C and E on an Unmarked Bipolar Transistor

(Slightly edited for readability --- sam)

(From: Lance (cast@iafrica.com).)

Using an analog (VOM - a DMM will not work), on its highest resistance range I test across the collector and the emitter one way and then change the leads around. The reading that is lower reading is the one to note (the one with the most leakage on a uA meter). Sometimes the needle only just barely moves. For a PNP the positive lead is on the emitter and for a NPN the positive lead is on the collector. Now you know the base collector and emitter, this has helped me work out how a circuit works by finding the legs of the working transistors and then repairing it. I found this in a very old mag more than fifteen years ago. If I can't remember which way is what I use a known transistor. I then find out the hard way. (Note: for a VOM, the polarities of the leads are often opposite of the color code as noted above --- sam).

## Testing MOSFETs

(From: Paul Mathews (optoeng@whidbey.com).)

1. Verify gate has infinite resistance to both drain and source. Exception: FETs with protection circuitry may act like there is a zener shunting GS, i.e., diode drop for gate reverse bias, ~20V breakdown in fwd bias.
2. Connect gate to source. Drain to source should act like a diode.
3. Forward bias GS with ~5 V. DS in forward bias should measure very low ohms. In reverse bias, it will still act like a diode.

The usual failure mode: GS short AND DS short. In other words, everything connected together.

(From: Richard Torrens (4qd@argonet.co.uk).)

A lot of common multimeters have a diode range: you can use this to measure a MOSFET out of circuit and get a good idea of whether it is OK. Meter negative on the source, you should get no reading (open circuit) on the drain. Not on the gate but if you measure the drain AFTER measuring the gate you will find it conducts. A finger between source and gate will bleed away the charge and the MOSFET stops conducting.

You really need a 'scope to check the drive circuit. What it does will depend on the circuit configuration, whether there is current limiting etc.

(From: E. Wolsner (interser@algonet.se).)

My way of testing a power MOSFET is indeed simple and normally sufficient:

One ohmmeter is connected to the drain and the source, measuring the resistance between drain and source, which

should be very high. Another ohmmeter is connected between gate and source. This ohm-meter should have a high resistance capability (maybe 20 M ohms) and thus have a relatively high test voltage (more than 5 volts). Now this voltage, when connected with the proper polarity, will turn the mosfet on, which will be indicated by the first ohm-meter. It will show zero resistance. To turn the transistor off, you reverse the gate-source voltage, and the drain-source ohm-meter will again indicate high resistance.

(Portions from: Egon Wolsner (interser@algonet.se).)

The multimeter must be able to provide at least 5 volts output on the resistance measuring range (this usually means that a DMM will not work). If it does, here is the procedure:

First you measure the resistance between the drain and source terminals, it should be infinity. Then connect the plus to the gate and the minus to the source pin. That should turn the MOSFET on. Then you measure the resistance between the drain and source pins, which should verify that the resistance is indeed near zero. (The gate capacitance will hold the device in the on-state long enough for this test.) Turn the mosfet off by shorting the gate and source pins (for a n-channel MOSFET)

(From: Bruce (reglarnavy@aol.com).)

You can get a pretty good idea about the condition of a MOSFET with some quick & simple bench tests. The first thing you can do with a meter is measure the parasitic substrate diode that connects the drain to the source. In an NMOS part, this diode's cathode will be at the drain, and the anode at the source. It will meter out similar to any conventional diode in both fwd / reverse directions. You can see this diode in the schematic representation of the FET in some databooks and a few schematics. The FET should show infinite resistance, gate - source and gate - drain. If it does not, then the gate oxide may be blown.

A second simple test can be done with a meter and a 9 V battery. First, short the gate to the source to discharge any stored charge there. Then put your meter on ohms and connect it across the drain - source. It should measure as an open. Briefly connect the 9 V across the gate (+) to source (-) , again, NMOS polarities, and the meter resistance should fall to a very low resistance, on the order of an ohm or less. Removing the battery will not change the reading, because in a good FET, Ciss will remain charged for a long time and keep the FET on. Most FETs come on at  $V_{gs}=2$  volts or so.

If these two tests work, then the FET is off to a good start. Substituting a power supply and a proper load resistor for the meter, and a variable voltage (a pot across the 9v will work) for the  $V_{gs}$  supply, in the aforementioned test, will obviously be a more realistic test, and will also let you measure  $V_{ds}$ ,  $I_d$ , etc.

**BEWARE ESD WITH FETS!** Wear a wrist strap, keep the parts away from insulators like plastics, and make sure your soldering iron tips are grounded. If you do not have any of the black ESD foam to keep your parts in, then look around for an anti-static bag that once may have contained a computer board, SIMMs, etc.

## Testing LEDs

Electrically, LEDs (and IR emitting diodes, strictly speaking called IREDs) behave like ordinary diodes except that their forward voltage drop is higher.

Typical values are:

IR: 1.2 V, Red: 1.85 V, Yellow: 2 V, Green: 2.15 V. The new blue LEDs will be somewhat higher (perhaps 3 V).

These voltages are at reasonable forward current. Depending on the actual technology (i.e., compounds like GaAsP, GaP, GaAsP/GaP, GaAlAs, etc.), actual voltages can vary quite a bit. For example, the forward voltage drop of red LEDs may range at least from 1.50 V to 2.10 V. Therefore, LED voltage drop is not a reliable test of color though multiple samples of similar LEDs should be very close. Obviously, if the device is good, it will also be emitting light when driven in this way if the current is high enough.

So, test for short and open with a multimeter (but it must be able to supply more than the forward voltage drop to show a non-open condition).

An LED can be weak and still pass the electrical tests so checking for output is still necessary.

Therefore, if these tests don't find a problem, drive the LED from a DC supply and appropriate current limiting resistor. For the IR types, you will need a suitable IR detector. See the document: "Notes on the Troubleshooting and Repair of Hand Held Remote Controls" for a variety of options.

## Testing Opto-Isolators and Photo-Interrupters

Both these classes of components are basically similar: a light source (usually an IR LED) and photodetector together in a single package.

- The opto-isolator will be totally sealed with adequate separation between the two parts to provide the specified isolation voltage rating.
- The photo-interrupter (and similar devices) will provide a beam path that can be blocked or otherwise modified by external means.

For both types, the photodetector can be a photodiode, phototransistor, photothyristor, or other more complex device or circuit.

Refer to an optoelectronics databook or the catalog of a large electronics distributor for specific pinouts and specifications.

Assuming a photodiode or phototransistor type (most common), these can be tested for basic functionality pretty easily:

Wire up a test circuit as follows:

Depressing S1 should result in the Output dropping from +5 V to close to 0 V. For monitoring on a scope, drive the LED with a pulse generator and current limiting resistor instead of S1. With a photo-interrupter type, blocking or adding a reflector to the optical path (as appropriate) should result in similar behavior.

## Testing Thermistors

There are two types of thermistors:

- Positive Temperature Coefficient (PTC) types have a resistance that increases with increasing temperature.
- Negative Temperature Coefficient (NTC) types have a resistance that decreases with increasing temperature.

For a small thermistor, put an ohmmeter on it and heat it up with a blow dryer, heat gun, or the tip of a soldering iron - the resistance should change smoothly (up or down depending on whether it is PTC or NTC type). If the resistance changes erratically, or goes to infinity or zero, the device is bad. However, you will need specifications, temperature measuring sensors, etc. to really determine if it is operating correctly.

## Testing Thermo-Electric (Peltier) Devices

While these are often called Thermo-Electric Coolers (TECs), they are equally good (or poor) at heating. The typical TEC uses a series connected string of thermocouple-like junctions sandwiched between a pair of ceramic plates. They are generally specified in terms of maximum temperature difference (typically between 60 to 70 °C); maximum current, voltage, and power dissipation; and physical dimensions.

Most problems will be obvious - like the entire thing was smashed by your pet elephant or melted down due to applying too much power. :) However, a hairline crack in one of the interior junctions could be undetectable without testing.

The best way to test a TEC is to apply a controlled current and monitor the voltage across the device as a function of current and measure the temperature difference between the hot and cold surfaces. Then, compare the readings with the device's specifications. If these aren't known, it may be possible to match up your device with one of similar dimensions. One major supplier is [Melcore](#).

Testing for continuity can be done with an ohmmeter but really only if the temperature of the two sides is exactly equal - otherwise there will be a voltage offset (the junctions also generate voltage when a temperature difference is present - and this can also serve as a test of sorts).

The I-V characteristics should be fairly linear over a relatively wide range of current within the device's specified operating range. However, the voltage for a given current does vary slightly with the temperature difference between the hot and cold surfaces.

# Miscellaneous Information

## Differences Between Ordinary, Fast Recovery, and Schottky Diodes

When the polarity reverses on a diode, it takes finite time for the charge carriers to be cleared from the area of the junction. During this time, reverse current flows. For high frequency applications - i.e., switching power supplies, horizontal deflection circuits, etc. - a normal diode would act more like a short circuit and result in poor performance or even burn out.

There are a variety of alternatives: fast, super-fast, ultra-fast (and so forth) recovery diodes, schottky diodes, and others that must be used in high frequency signal, switching, and power supply circuits:

Thus, if you find a bad diode in a piece of electronic equipment, don't assume it is just an ordinary diode because the case looks the same. Replacing a fast recovery diode with a 1N4007 will very likely just result in more confusion. A proper device must be used even for testing. In most cases, a faster part can be substituted without problems. However, there are occasional situations where the specific characteristics of a slow part (a reverse pulse due to its long recovery time or high capacitance) are depended upon for the circuit to operation properly!

(From: John Popelish (jpopelish@rica.net).)

Fast recovery diodes have a little gold added to the silicon (and perhaps other process changes) that make the minority carriers (holes in n type and electrons in p type sides of the junction) have shorter lifetimes, so that in addition to sweeping them out by applied voltage, the carriers spontaneously disappear. This makes the diodes turn off faster. Other tricks help the diodes to turn off with less of a snap, to reduce high frequency noise generation. These changes usually compromise other properties of the diode, like reverse leakage, forward drop or breakdown voltage, so there are lots of different combinations of trade-offs.

Schottky diodes are really just half diodes. A metal intimately bonded to a p type semiconductor. Holes have a zero lifetime in metal, so the minority lifetime is just about zero for schottky diodes. They also have about half a diode drop in the forward direction, and so are twice as efficient even for low frequency rectification. The trade off here is that they can only be made to handle low reverse voltages and even there, they have more reverse leakage than junction diodes.

Motorola published a diode handbook that goes into a lot more detail on these things and I recommend it.

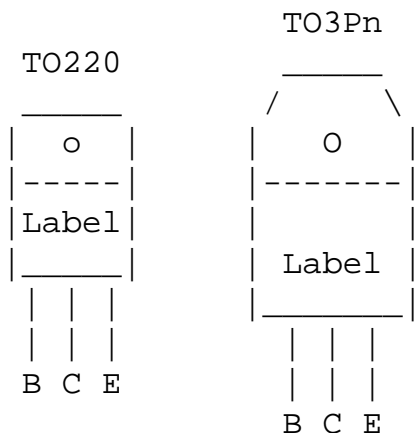

## Horizontal Output Transistor Pinouts

You will nearly always find one of two types of horizontal output transistors in TVs and monitors:

- Metal can - TO3 package:

- Plastic tab - Mostly these will be the TO3Pn (n = several suffixes) package but some B/W TVs and mono monitors or video display terminals may use HOTs in the smaller TO220 package:

View from front (label side).

B = Base, E = Emitter, C = Collector.

If there is an exposed metal tab, that is the Collector as well.

Some other transistor types use the same pinout (TO66 for metal can, TO218 and TO220 for plastic tab) but not all. However, for horizontal output transistors, these pinouts should be valid.

Note that those with a built in damper diode may read around 50 ohms between B and E (near 0 on the diode test range) - this is normal as long as the resistance is not really low like under 10 ohms.

## Difference Between Normal and 'R' Marked Parts

"Does anyone know the difference between transistor BDY58R and BDY58 (if any at all)?"

(From: Paul Grohe (grohe@galaxy.nsc.com).)

Yep! We "hit our head" on this one while diagnosing a sick scope.

Electrically, the parts are exactly the same. The "R" stands for 'reverse'. The 'R' pinout is a mirror image of the normal one.

Top view of 'normal' SOT

Top view of 'R' SOT

This makes layout of high-frequency pairs easier because traces do not have to cross over one another, and the layout is 'cleaner' but bites you if you are unaware!

## Testing Zener Diodes

The following applies to both testing of zeners for failure and determining the ratings of an unknown device. Zeners

most often fail short or open with short probably more likely. However, it is also possible, though a lot less common, for the zener voltage to change (almost always to a lower voltage) and/or for the shape of the I-V curve to change dramatically (e.g., become less sharp cornered).

With a VOM, a good zener diode should read like a normal diode in the forward direction and open in the reverse direction unless the VOM applies more than the zener voltage for the device. A DMM on its diode test range may read the actual zener voltage if it is very low (e.g., a couple V) but will read open otherwise. The most common failure would be for the device to short - read 0.0 ohms in both directions. Then, it is definitely dead. :)

Some zeners are marked with a JEDEC (1N) part number, others with a couple of colored bands (e.g., for 18 V, brown/gray), or a house number or house color code.

You can easily test a zener and identify its voltage rating with a DC power supply, resistor, and multimeter. You will need a power supply (a DC wall adapter or AC wall adapter with a rectifier and filter capacitor is fine) greater than the highest zener voltage you want to test. Select a resistor that will limit current to a few mA. For example, for zeners up to about 20 V, you can use:

This same approach applies to other devices that exhibit a similar behavior such as the B-E junction of a bipolar transistor.

## Testing MOVs

MOVs are used mostly for surge suppression in power strips and the front-ends of the power supplies of TVs, VCRs, and other consumer electronic equipment. They are those brightly colored things that look like Epoxy dipped capacitors. At least, that's what they look like when new. A common failure mode is for the MOV to be totally obliterated by a surge or from old age. Then testing is not needed! :)

They are supposed to be located beyond the line fuse (though possibly not always). In this case, where the line fuse blows but there is no visible damage to the MOV(s), the simplest test may be to just temporarily remove the MOV(s) and see if your problem goes away.

A multimeter can be used to test for leakage (there should be none) but the best option is to remove the device. Since the proper functioning of the equipment doesn't depend on any MOVs (in 99.9999 percent of the cases - the exception being where the MOV is used as a high voltage triggering device or something like that rather than a surge suppressor), remove the MOV(s), test the equipment, and just replace the MOV(s) if in doubt.

(From: Brad Thompson (Brad\_Thompson@pop.valley.net).)

Usually, the manufacturers specify a maximum leakage current (usually one milliampere) at a AC specified voltage. You'd need a Variac adjustable AC source, an isolation transformer (for safety), an AC voltmeter and an AC milliammeter to make the measurement.

An MOV works as follows: It's essentially a batch of metallic-oxide grains separated by insulating layers. Repeated voltage surges break down the insulating layers, lowering the overall resistance and eventually causing the device to draw too much current and trip whatever overcurrent protection is inherent in the system.

I've seen MOVs exuding tiny metallic "teardrops" through their epoxy coatings, which remained bright and shiny. These devices needed replacement!

(From: Kevin Carney (carneyke@us.ibm.com).)

This is not a valid test for breakdown voltage but these devices read a few megohms when damaged. The new replacements read open on my meter that has a 20 Megohm range of a DMM.

## Introduction to Curve Tracers

### Curve Tracer Design

A curve tracer is a piece of test equipment or an add-on to an oscilloscope which provides a graphical display of the V-I (or other parameters) of an electronic component. The design of a curve tracer is simple in principle (description here for bipolar transistors):

For the horizontal (collector supply) you need a variable ramp generator. If your scope has a sweep output, then you can derive it from this - if you are not interested in frequency response, an audio amplifier may be adequate with a volume control to adjust the amplitude.

For the base drive you need a programmable current source capable of putting out a series of constant currents for the base drive. Here, a counter driving a D/A set up for a current output mode. Use the trigger output or sweep output of the scope to increment the counter so that it sequences through a set of say, 10 current settings.

Then, you need some way of sensing collector current to drive the vertical channel - a small series resistor in the emitter circuit, for example.

For simple diode tests, you can just use a variable AC voltage source like a variable isolation transformer (with a current limiting resistor) across the diode. The X (horizontal) input of the scope goes across the device under test. The Y (vertical) input of the scope goes across the current limiting resistor or a separate series current sense resistor. See the section: [Quick and Dirty Curve Tracer](#).

Then, you can jazz it up with microprocessor controlled on-screen display.

Curve tracers can be big expensive things (e.g., multi-\$K) or little add-ons to regular scopes. Here one company selling a curve tracer kit or assembled. I have no idea how good it is but check out [Gootee Systems](#) for more info.

Popular Electronics, May 1999, has complete plans for a "Semiconductor Tester" which can handle NPN and PNP bipolar transistors, JFETs and MOSFETs, all sorts of diodes including zeners, and a variety of other devices. This is

basically a curve tracer adapter for an oscilloscope. With a little ingenuity, it can be enhanced to test virtually all the semiconductors discussed in this document.

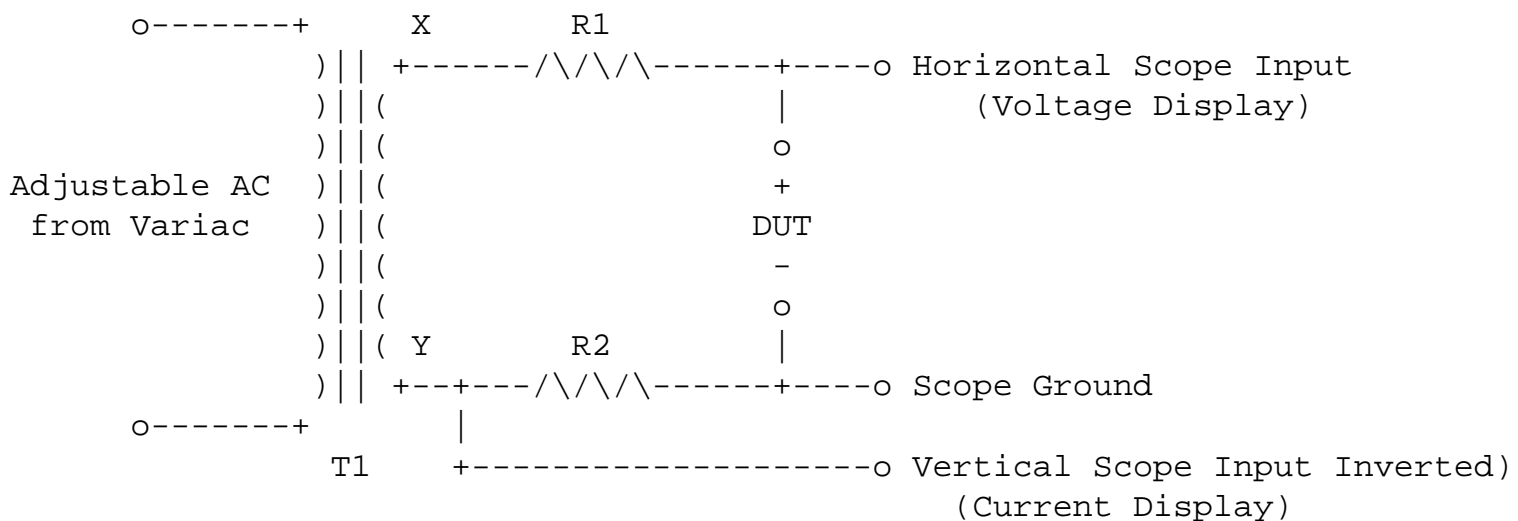

Therefore, if you want a sophisticated piece of test equipment, one of these would be suitable. Or, get yourself a used Tektronix 575 curve tracer. This will do just about everything you could possibly want (including the testing of vacuum tubes with the addition of a bit of external circuitry.)

However, to just test 2 terminal devices - or to just get a feel for device characteristics, there are much simpler, cheaper, alternatives.

## Quick and Dirty Curve Tracer

I threw the following circuit together in about 10 minutes. With minor modifications, it is capable of displaying V-I curves for diodes, zeners, transistors, thyristors, resistors, capacitors, inductors, etc.

I used a 12 VAC transformer just because it was handy. You can use anything you like as long as you understand the safety implications of higher voltages and make sure the components you use can withstand the power that might be dissipated in them if the Device Under Test (DUT) is a dead short. In addition, it is bad form to blow out the DUT while testing it! A signal generator driving a small audio transformer could also be used if it is desired to test components at frequencies other than 60 (or 50) Hz.

**CAUTION:** turn down the intensity of the scope so the spot is just barely visible so that when there is no input, you don't end up drilling a hole in the face of the CRT!

- R1: Current limiting and phase shift control. I used 500 ohms which works well for small signal semiconductors and capacitors around 1 uF.
- R2: Current sense. I used 10 ohms and put the scope on the one of the .1, .2, or .5 V/cm ranges.
- T1: Small power transformer. I used the 12 VAC wall wart from an obsolete modem. This will supply a voltage of up to about 17 V peak to your DUT.

For higher power or higher voltage devices, substitute a suitable larger transformer.

Modify these (selector switches might be nice) for your needs. A Variac provides a convenient method of adjusting the voltage applied to the DUT.

- Zener diodes - the result will be exactly like the picture in your textbook. Try this with a 5 or 6 V zener to confirm that your rig is working.
- Resistors - the display should be a straight diagonal line. You should be able to compute their value from the ratio of V to I.
- Capacitors - you should see the phase shift between voltage and current resulting in an ellipse (though you will probably have to adjust the scale factors to obtain a usable display with typical capacitor values).
- Bipolar transistors - a source of (DC) base current is needed. You can be fancy or simple. For a simple source, I used a variable 0 to 15 V power supply and a current limiting resistor. Since we know that the voltage drop across the B-E junction is fairly constant at around .7 V (for silicon), the output of the supply can be calibrated in terms of base current.
- SCRs - connect a suitable resistor in series with a diode or two (or a diac) between the gate and DUT+ (so that gate current is included in the V-I curve). When the threshold current is exceeded, the device should turn on and remain on until the zero crossing. With the reverse polarity, the device should remain off. For triacs, use diodes in parallel in both directions or a diac. A triac should trigger on both polarities of the AC waveform.

### In-Circuit Tester

The following is along the same lines as the "Quick and Dirty Curve Tracer" but is suitable for in-circuit testing as the current and voltage are limited to safe values for most devices (less than 1 VAC and than 1 mAAC respectively).

The very complicated circuit is shown in: [curve.gif](#) and below in ASCII.

CAUTION: Use at your own risk. I cannot absolutely guarantee that there won't be certain devices in use today that didn't exist in 1975 that might be unhappy with this approach.

(From: Wern Thiel (wern@zoo.toronto.edu).)

In the August 1975 issue of Popular Electronics author Lou Garner wrote in a story called "A simple On-Board Tester" about this fairly simple piece of test equipment.

The device can be used with any type of oscilloscope and consists of a 6 volt filament transformer, three 1/4 watt resistors and two test probes. Half of the filament voltage is applied to a voltage divider consisting of 220 ohm and 100 ohm resistors, yielding 1 volt ac on top of the 1 K ohm resistor. This voltage can be applied to any component or combination of components across which the test leads are placed. The current is limited to one milliampere by the 1 K ohm resistor.

The voltage across the probes is connected to the horizontal input of a scope while the voltage across the 1 K ohm resistor as a result of the current through it is connected to the vertical input.

What we see on the scope is a voltage across a component under test versus the current through the component:

Resistors:	Open	Horizontal line.
	10 K	10 degree.
	1 K	45 degree.
	0	Vertical line.

Capacitor:	.1 uF	Shallow ellipse.
	2.6 uF	Circle.
	50. uF	Narrow vertical.

Transformer:	Ellipse depending on impedance.
--------------	---------------------------------

Diodes (Germanium):	Right angle display.
---------------------	----------------------

Diodes (Silicon):	Right angle one side longer (any leakage showing less sharp angle).
-------------------	--

Transistors:	Test as two diodes (B to E and B to C).
--------------	---

Integrated Circuits:	Input for gates and counters show a certain signature display.
----------------------	--

Outputs display a different signature.

A short will show a vertical line.

An open will show a horizontal line

In circuit testing is done with \*no\* power applied to the equipment under test.

With some experience one is able to test components in and out of circuit and troubleshoot without danger of a damage to components.

## Testing Vacuum Tubes (or FETs) on a Bipolar Curve Tracer

A transistor curve tracer can be easily adapted to test vacuum tubes (OK, valves for those of you on the other side of the lake) if it has an adequate voltage range for the collector (now plate) drive and independent control of base and collector polarity. All that is needed is to add a separate transformer to power the tube's filament(s) and a resistor to convert base current to voltage.

For FETs, just leave off the transformer.

(From: Michael Covington (mcovingt@ai.uga.edu).)

Get an old Tektronix 575 (mine cost \$25 at a hamfest). That is a transistor curve tracer that goes back to the 1950s and goes up to 200 volts.

It doesn't have FET settings, but you can control the 'base' and 'collector' polarity independently. So what you do is put a 1 K resistor from 'base' to ground, so that you can read milliamps as volts. Then put a positive-going voltage on the 'collector' and a negative-going current into the 'base'.

For tubes, emitter, collector, and base are cathode, plate, and grid, respectively. Naturally you also need a filament supply; I use a lab-type DC supply because it's handy and can't introduce hum.

I also test FETs that way (without the filament supply, of course). Then, emitter, collector, and base become source, drain, and gate respectively.

## Chapter 2) Introduction

---

### 2.1) CRT FAQ

This document contains a collection of information relating to CRT (picture tube) construction, characteristics, problems, maintenance, troubleshooting, and repair from the TV and Monitor Repair FAQs and other sources.

Most new CRT related information resulting from `sci.electronics.repair`, `comp.sys.ibm.pc.hardware.video`, or other newsgroups will be included here rather than those other documents. In the future, I may replace the 'CRT Basics' chapter of those documents with a link to this one instead.

Related documents I have written:

- \* Safety Guidelines for High Voltage and/or Line Powered Equipment.
- \* Notes on the Troubleshooting and Repair of Computer and Video Monitors.
- \* Notes on the Troubleshooting and Repair of Television Sets.
- \* Performance Testing of Computer and Video Monitors.
- \* Notes on Approaches to using Fixed Frequency Monitors on PCs.

Special thanks to Bob Myers (`myers@fc.hp.com`) and Jeroen Stessen (`Jeroen.Stessen@ehv.ce.philips.com`) for their contributions to this document through their newsgroup postings and private email.

As always, comments, corrections, and additions are welcome.

---

# Chapter 3) General CRT Construction and Characteristics

---

## 3.1) Why is the CRT still dominant?

Currently, most TVs and computer monitors are still based on the Cathode Ray Tube (CRT) as the display device. However, many hand-held TVs, portable equipment, laptop computers, and the screens inside video projectors now use flat panel technology, mostly Liquid Crystal Displays - LCDs. These are a lot less bulky than CRTs, use less power, and have better geometry - but suffer from certain flaws.

First, the picture quality in terms of gray scale, color, and brightness is generally inferior to a decent analog monitor. The number of distinct shades of gray or distinct colors is a lot more limited. They are generally not as responsive as CRTs when it comes to real-time video which is becoming increasingly important with multimedia computers. Brightness is generally not as good as a decent CRT display. And last but not least, the cost is still much much higher due both to the increased complexity of flat panel technology and lower production volumes (though this is certainly increasing dramatically). It is really hard to beat the simplicity of the shadow mask CRT. For example, a decent quality active matrix color LCD panel may add \$1000 to the cost of a notebook computer compared to \$200 for a VGA monitor. More of these panels go into the dumpster than make it to product do to manufacturing imperfections.

A variety of technologies are currently competing for use in the flat panel displays of the future. Among these are advanced LCD, plasma discharge, and field emission displays. Only time will tell which, if any survives to become **the** picture-on-the-wall or notepad display - at reasonable cost.

At least one company is about to introduce a 42 inch diagonal HDTV format flat plasma panel multisystem color TV/monitor which will accept input from almost any video or computer source. Its price at introduction will be more than that of a typical new automobile - about \$15,000! :-). Thus, at first, such sets will find their way into business conference rooms and mansions rather than your home theater but prices will drop over time.

Projection - large screen - TVs and monitors, on the other hand, may be able to take advantage of a novel development in integrated micromachining - the Texas Instruments Inc. Digital Micromirror Device (DMD). This is basically an integrated circuit with a tiltable micromirror for each pixel fabricated on top of a static memory - RAM - cell. This technology would permit nearly

any size projection display to be produced and would therefore be applicable to high resolution computer monitors as well as HDTV. Since a reflective medium is used in this device, the light source can be as bright as needed. Commercial products based on the DMD are beginning to appear.

---

## Chapter 4) Color CRT Basics

---

### 4.1) Color CRT construction

For an introductory on-line article about (mostly) CRTs, see: [High Tech Tubes](#), Popular Mechanics, April 1997.

All the color CRTs found in TVs and computer and video monitors utilize a shadow mask or aperture grill a fraction of an inch (1/2" typical) behind the phosphor screen to direct the electron beams for the red, green, and blue video signals to the proper phosphor dots. Since the electron beams for the R, G, and B phosphors originate from slightly different positions (individual electron guns for each) and thus arrive at slightly different angles, only the proper phosphors are excited when the purity is properly adjusted and the necessary magnetic field free region is maintained inside the CRT. Note that purity determines that the correct video signal excites the proper color while convergence determines the geometric alignment of the 3 colors. Both are affected by magnetic fields. Bad purity results in mottled or incorrect colors. Bad convergence results in color fringing at edges of characters or graphics.

The shadow mask consists of a thin steel or InVar (a ferrous alloy) with a fine array of holes - one for each trio of phosphor dots - positioned about 1/2 inch behind the surface of the phosphor screen. With some CRTs, the phosphors are arranged in triangular formations called triads with each of the color dots at the apex of the triangle. With many TVs and some monitors, they are arranged as vertical slots with the phosphors for the 3 colors next to one another.

An aperture grille, used exclusively in Sony Trinitrons (and now their clones as well), replaces the shadow mask with an array of finely tensioned vertical wires. Along with other characteristics of the aperture grille approach, this permits a somewhat higher possible brightness to be achieved and is more immune to other problems like line induced moire and purity changes due to local heating causing distortion (doming) of the shadow mask.

However, there are some disadvantages of the aperture grille design:

\* Weight - a heavy support structure must be provided for the tensioned wires (like a piano frame).

- \* Price (proportional to weight).
- \* Always a cylindrical screen (this may be considered an advantage depending on your preference).
- \* Visible stabilizing wires which may be objectionable or unacceptable for certain applications.

Apparently, there is no known way around the need to keep the fine wires from vibrating or changing position due to mechanical shock in high resolution tubes and thus all Trinitron monitors require 1, 2, or 3 stabilizing wires (depending on tube size) across the screen which can be seen as very fine lines on bright images. Some people find these wires to be objectionable and for some critical applications, they may be unacceptable (e.g., medical diagnosis).

---

## 4.2) Assembly of color CRTs

(Portions from: Jeroen H. Stessen (Jeroen.Stessen@ehv.ce.philips.com)).

The following is a greatly simplified description of the general process of color (shadow or slot mask) CRT construction. Trinitrons should be basically similar.

The screen and envelope glass pieces are molded separately and then glued (Epoxyed?) together as one of the last steps of assembly prior to the baking and evacuation. (You will note this seam if you examine the envelope of a color CRT near the front.)

The shadow mask is manufactured through a photo etching process. No, there are no workers responsible for punching all those holes! Since a position error of even a tiny fraction of a mm would result in purity errors, each shadow mask is unique for its faceplate. They are not interchangeable. To facilitate the following steps, it can easily be mounted and removed (essentially clicked in place) during tube production. Registration pins assure precise alignment.

- \* For each of the phosphor colours (and optional black matrix) one phosphor layer is deposited followed by one photoresist layer.

At least one manufacturer adds some steps for the Superbright tubes. They put 3 different colour filters between the glass and the phosphor. In terms of contrast that tube is a definite killer.

- \* The shadow mask for that CRT (unique) is then mounted - clicked in place.
- \* An intense point source of light is mounted at the location of the effective center of deflection for the electron gun associated with that phosphor.
- \* The photoresist is exposed to light.
- \* The shadow mask is removed and the excess resist (not exposed to light) and

phosphor is washed away.

These steps are repeated for the red, green, and blue phosphors, and the optional (but very common) black matrix surround.

Using the shadow mask repeatedly in this manner guarantees close registration. How else would you lay down a million individual dots in exactly the right place - paint by numbers? :-).

Then, an aluminum overcoat is deposited over the phosphor/black matrix. This has several functions:

- \* Provide the return path for the electron beam - connected to the EHT 2nd anode.
- \* Reduces backscattering or secondary emission. Electrons that bounce back from either the shadow mask or the screen may hit a phosphor elsewhere and thus cause unwanted white light. That reduces contrast and colour purity.
- \* A side benefit is that it blocks negative ions from residual air molecules from hitting the phosphors. These might result in an unsightly blemish in the center of the screen since they are much heavier (many thousands of times the mass) than electrons and are not deflected very much. (This was a problem in the early days of CRT production but apparently not with present high vacuums and getters to clean up whatever is left.)

The shadow mask is then mounted for a final time and the faceplate, envelope (with its electron gun assembly already fused to it) are mated. At this point, it is ready for the final baking and evacuation.

The tube is evacuated through the thin stem that is located in the middle of the socket. That takes several hours at the vacuum pumps. The stem is then sealed by heating and melting.

The getter - part of the electron gun assembly - is then 'activated' via induction heating from a coil external to the neck of the CRT. This vaporizes and deposits a highly active metal on the interior of the glass of the neck. The getter material adsorbs much of any remaining gas molecules left over from the evacuation of the tube. The getter material is normally silvery - if it changes to red or milky white, the tube is probably gassy or up to air.

When the tube is ready it is matched with a deflection coil that provides optimum purity. It takes some ingenuity to get a good match between using a light for exposure which matches the behaviour of the future electron optical system, in order to get good purity.

Amazingly, this basic process has not changed in any fundamental way since the invention of the shadow mask CRT!

However, Computer Aided Design (CAD) has had a major impact on the design of the electron optics. The working of the electron gun and deflection system is now much more predictable thanks to advanced computer simulation. This has reduced the number of active correction circuits for focus, geometry and convergence to almost zero.

---

## 4.3) Color CRT resolution - focus and dot/slot/line pitch

The ability to display fine detail involves many factors including the resolution of the video source, video bandwidth, sharpness of the electron beam(s), and the dot/slot/line pitch (color only) of the CRT.

The CRT is primarily responsible for the latter two.

The focus or sharpness of the spot or spots that scan across the screen is a function of the design of the electron gun(s) in the CRT and the values of the various voltages which drive them. Focus may be adjusted but excellent focus everywhere on the screen is generally not possible.

Sharp focus is a difficult objective - the negatively charged electrons repel each other and provide an inherent defocusing action. However, increasingly sharp focus would not be of value beyond a certain point as the ultimate resolution of a color CRT is limited by the spacing - the pitch - of the color phosphor elements. (For monochrome displays and black-and-white TVs, CRT resolution is limited primarily by the electron beam focus.)

One of three approaches are used to ensure that only the proper electron beam strikes each color phosphor. All perform the same function:

Dot mask - the phosphor screen consists of triads of R, G, and B, circular dots in a triangular arrangement. The shadow mask is a steel or InVar sheet filled with holes - one for triad. The dot mask has been used since the early days of color TV and is still popular today. The electron guns are also arranged in a triangular configuration.

Slot mask - the phosphor screen consists of triples of vertically elongated R, G, and B, stripes (actually, these are usually full vertical stripes interrupted by narrow gaps). The shadow mask is a steel or InVar sheet filled with slots - one for each triple. Ideally, the metal between the slots vertically is as thin as possible to maintain the structural stability of the slot mask sheet. This type of tube seems to be very popular in TVs but also shows up in some computer monitors. The electron guns are in line which makes some of the setup adjustments less critical compared to the dot mask CRT.

Aperture grille - the phosphor screen consists of triples of vertical R, G, and B, lines running the full height of the screen. The aperture grille is a series of tensioned steel wires running vertically behind the phosphor stripes - one for each triple. The aperture grille - until recently under patent protection and therefore only available in the Trinitron from Sony - is found in both TVs and monitors. The electron guns are also in line.

The pitch of a color CRT refers to the spacing of phosphor triads or triples. For dot mask CRTs, this parameter is relevant in both the horizontal and vertical direction. For slot mask and aperture grille CRTs, the pitch is only relevant in the horizontal direction.

Dot pitches as small as .22mm are found in high resolution CRTs. Very inexpensive 14" monitors - often bundled with a 'low ball' PC system - may

have a dot pitch as poor as .39 mm. This is useless for any resolution greater than VGA. Common SVGA monitors use a typical dot pitch of .28 mm. TVs due to their lower resolution have pitches (depending on screen size) as high as .75 mm - or more.

Obviously, with smaller screens and higher desired video source resolutions, CRT pitch becomes increasingly important. However, it isn't a simple relationship like the size of a pixel should be larger than the size of a dot triad or triple, for example. Focus is important. All other factors being equal, a smaller pitch is generally preferred and you will likely be disappointed if the pitch is larger than a pixel. As the pixel size approaches the phosphor triad or triple size, Moire becomes more likely. However, the only truly reliable way to determine whether Moire will be a problem with your monitor is to test it at the resolutions you intend to use.

---

## 4.4) Magnetic interference and shielding

When color CRTs must be operated in areas where the magnetic field causes unacceptable purity errors or distortion (either static or dynamic depending on whether the source is constant (as with the magnet in an MRI scanner or MegaBase(tm) loudspeaker) or changing (as with nearby motors, transformers, or even other monitors), there are several options (besides relocating):

- \* Passive shielding - soft magnetic materials (those that are easily magnetized and don't retain their magnetism) can effectively block modest strength magnetic fields. The best known of these for shielding purposes is called 'Mu-Metal', an alloy of 76% nickel, 17% iron, 5% copper, and 2% chromium. (Nelson and Parker, A.L.Physics).

Advantages: simple (at least in principle), doesn't care if conditions change (within specified field strength limits). Mu-metal can be very effective if used properly - but see below.

Disadvantages: expensive and often ugly. The cost of a complete functional but not aesthetic enclosure for use of a color monitor near an MRI scanner was about \$2,000 a couple of years ago when we needed to provide this for one of our customers.

- \* Active compensation - a set of coils is energized with exactly the correct currents to cancel the effects of the interfering fields.

Advantages: can be built inside the monitor using small coils in some cases.

Disadvantages: must be engineered for each situation. Change almost anything and it will no longer be effective even if feedback is used. Complex in practice since interfering field geometry is often not well behaved.

- \* Shielding can also sometimes be introduced at the source. See the document: ["Notes on the Troubleshooting and Repair of Audio Equipment and other Miscellaneous Stuff"](#), specifically, the section: "Comments on speaker

shielding"

Advantages: will reduce interference for all monitors in the vicinity.

Disadvantages: shielding location may not be readily accessible. Geometry offending device may not lend itself to a reasonable size or shape shield.

(From: Tony Williams (tonyw@ledelec.demon.co.uk)).

You can buy commercial Mu-metal screening cans and yes they are a complete enclosure, with small holes for the I/O wires.

Mu-metal is very expensive and not easy to work but will solder, especially with acid flux.

I suggest you try a dummy run first with some mild steel to get the design sorted and to test if it looks worth it.

You never know your luck, mild steel may do the job anyway and you may not want to deal with mu-metal (--- sam):

"Just got my 10' sheet of mu-metal delivered today. It came very well packaged sandwiched between two pieces of wood so that it would not bend during shipment."

(From: James P. Meyer (jimbob@acpub.duke.edu)).

One of the reasons it came so well packaged was the fact that the magnetic properties are degraded if the material is bent or stressed in any way. Once you fabricate anything out of the mu-metal, you have to go through a high temperature annealing process to remove the stress and restore its full magnetic properties. If you don't do that, you are no better off with Mu-metal than you would be with tin-can stock.

---

## 4.5) Dot pitch of TV CRTs

Computer monitor specifications always include the dot pitch of the CRT. However, this information is rarely available for TVs. Why? The quick answer is that since TVs are always used at the same scan rate (except for multisystem international TVs), this information is not nearly as important for TVs as for high resolution multiscan computer monitors.

In general, the dot/slot/line pitch of TV CRTs is very large compared to even mediocre computer monitors. Here are some typical values which I measured very precisely (!! ) by putting a machinest's scale against the screen. These are all slot mask type CRTs:

- \* 13" GE - .60 mm.
- \* 19" Samsung - .75 mm.
- \* 25" RCA - .9 mm.

Therefore, you can forget about trying to use one of these CRTs for your 1280x1024 high resolution PC or workstation. The dot/stripe pitch needed for 1280 pixels on a 25" tube would be about .3-.4 mm maximum. The pixels are about .35 mm. Typical high resolution CRTs for high resolution computer monitors have a dot/stripe pitch of .25 to .28 mm (I have heard of numbers as low as .22 mm in commercially available monitors).

---

## 4.6) A discussion of issues relating to monitor and CRT resolution

Many factors influence the effective resolution of a monitor but the CRT dot or slot mask or aperture grill is the ultimate limit (though it may still be possible to use a monitor at a resolution which exceeds the that of the CRT). However, as the pixel spacing approaches that of the CRT, moire effects are likely to be more of a problem.

(From: Bob Niland (rjn@csn.net)).

Dot pitch is the major component in the actual resolution of the monitor. Most monitor vendors quote the highest resolution signal their monitor will sync to irrespective of whether or not the tube can resolve it. Indeed, it often cannot resolve the highest (and even second highest) claimed display resolution.

(From: Bob Myers (myers@fc.hp.com)).

Very true. On the other hand, things may not be quite as bad as what the numbers appear to say, sometimes.

(From: Bob Niland (rjn@csn.net)).

It's no accident that monitor size is specified in inches, and dot pitch in mm. The vendors don't want to make it easy for you to know what the geometry of their phosphor triads actually is, i.e. how many RGB dot triplets there are across and down the screen."

(From: Bob Myers (myers@fc.hp.com)).

Well, I wouldn't want to accuse the tube industry of deception. Expressing diagonal sizes in inches comes from long-standing tradition. Expressing pitch in millimeters is actually a relatively new practice in comparison, and isn't too unusual when you realize that most tube manufacturers - esp. those in the Far East - actually spec their tube diagonals in metric terms. For instance, Matsushita (Panasonic) has listed their "15 inch visual" color CRTs as "420xxxx" models, 420 being the overall diagonal in mm (16.54")

(From: Bob Niland (rjn@csn.net)).

Here's how to figure it out. You need first to know:

1. The diagonal 'active picture' area (APD). If the vendor fails to specify

this, subtract 1 inch from the advertised monitor size. I.e. a '21 inch' monitor will usually have about a 20-inch usable diagonal picture area. ('PC Inches' versus 'real inches' is a topic for another time. :-)

2. You need the horizontal dot pitch (HDP). The vertical and horizontal are often different (with the vertical being a smaller number). If you have been given only one number, it's probably the diagonal, and is misleading, but it is all we have to work with.

(From: Bob Myers (myers@fc.hp.com)).

Trinitron (aperture grille) tubes will never have the pitch specified as a diagonal measurement, since they have vertical stripes of phosphor. Conventional (flat-square) models will, and probably the safest conversion between diagonal and horizontal for these is to multiply by the cosine of 30 degrees (0.866), unless you know for sure the angle to horizontal at which the diagonal measurement was made. (It varies for different tube designs.) See the section: "[How to compute effective dot pitch](#)".

(From: Bob Niland (rjn@csn.net)).

3. The monitor aspect ratio (AR). This is 4:3 (or 1.33:1) for any CRT you are likely to be using.

To calculate useful horizontal resolution:

- \* Multiply the APD by .80 (4:3 tube).

This is the Active Picture Horizontal size (APH) in inches.

- \* Multiply APH by 25.4.

This is the APH in mm (APHmm).

- \* Divide the APHmm by the HDP.

This is the useful horizontal resolution of the monitor.

Notice that this number probably does not precisely match any common (640, 800, 1024, 1152, 1280 or 1600) resolution in use, and that it is probably \*less\* than what the vendor claimed.

I use a Hitachi AccuVue UX4921D (aka HM-4921-D/A-HT01) 21-inch monitor. It is a claimed 1600x1200 monitor, and having a .22 horizontal dot pitch, actually has over 1800 phosphor triads across the screen. This is rare. Most large monitors usually have 1280 or fewer triads across the screen.

(From: Bob Myers (myers@fc.hp.com)).

Here is where some words of explanation are in order.

What many people fail to realize is that the phosphor triads of the screen \*do not\* correspond to pixels in the image; they are not kept in alignment with the image pixels/lines/whatever, nor is there any reason for them to be. The phosphor dot pitch IS a limiting factor in resolution, but we need to look a little further to determine whether or not a given tube will be usable for a given format (what most people mistakenly call a "resolution".)

The true resolution capabilities of a CRT are limited primarily by the dot pitch AND the spot size. For practically all CRTs and monitors in the PC market, the spot size is considerably larger than the dot pitch - up to 2X or so at the corners, if the tube is at or near its specification limits. This doesn't necessarily cause a problem with the image quality, however, since you aren't really resolving individual "pixels" in any case - what you need to resolve are the \*differences\* between adjacent pixels, or pixel/line pairs. And, oddly enough, it doesn't take a dot pitch of equal or greater size than a logical pixel to do this to most people's satisfaction. In fact, display types sometimes talk about a 'Resolution/Addressability Ratio', or RAR, which is in effect the ratio of the actual size of a spot on the display to the size of a "logical" pixel in the image. And for best perceived appearance, this is generally going to be GREATER than 1:1 - say, 1.5:1 or even 2:1. (Too high, and the image is blurred; but too low, and the image takes on a grainy appearance that most people find objectionable.)

Bob is absolutely correct in stating that most displays, when run at the highest support addressability or format (or, if you insist, "resolution") wind up with the "pixel size" being smaller than the dot pitch. But what is also correct, if somewhat counterintuitive, is that this is OK, and can still result in an image that will be acceptable (and even perceived as 'sharp') to the user.

You can certainly exceed the resolution capabilities of a tube and/or monitor (monitors differ from simple tubes by also having a video amp to worry about!). For instance, you probably won't be really happy with 1600 x 1200 on a 17" 0.28 mm CRT. But 1280 x 1024 on an 0.31 mm 20-21" tube can look very good, even though the numbers don't appear to work out.

(From: Bob Niland (rjn@csn.net)).

While not stated above, I would speculate that this is due to various human visual system factors, particularly that humans have more visual acuity in luminance (B&W) than in chrominance (color). If a CRT can actually illuminate less than a full phosphor triad, its luminance resolution can exceed the dot pitch. There will be some color fringing, but the eye may not notice.

(From: Bob Myers (myers@fc.hp.com)).

That's a good bit of it. Whether or not you're going to be satisfied with a given dot pitch versus addressability ("resolution") basically has to do with what you think "resolve" means.

The fact that we don't generally have the same spatial acuity for color - in other words, you won't really see small details based on differences in color alone, there has to be a difference in brightness - is a big part of this. And you will be able to see such variations acceptably even when the size of the logical pixel is somewhat under the dot pitch size. When this occurs, you don't get constant color pixels - you don't even get constant \*luminance\* pixels - but you do perceive acceptable levels of detail to call the image 'sharp'.

---

## 4.7) How to compute effective dot pitch

We always see CRTs specified in terms of dot pitch but what does this mean with respect to actual useful horizontal and vertical dot pitch?

The usual arrangement of phosphor dots on the screen of a dot mask type CRT is shown below:

```

  B R G B R G B R G B R G B R
  R G B R G B R G B R G B R G B   Magnified ->
  B R G B R G B R G B R G B R
  R G B R G B R G B R G B R G B
                                     R --- G --- B --- R
                                     /   |
                                     /   |
                                     G --- R +- B --- G --- R

```

(Portions from: Jac Jamar (jamar@comp.snads.philips.nl)).

For a dot mask type CRT, normally the nominal pitch (also called the Hexagonal Pitch or HexP) is defined as the distance between one phosphor dot to the next same colored one in the 'hexagonal' direction (i.e. in the direction 30 degrees above the horizontal).

The calculations below follow from simple geometry:

\* The Vertical Dot Pitch (VDP) will be equal to:  $\text{HexP} * 1/2$ .

\* The Same Color Horizontal Dot Pitch (SCHDP) will be:

$$\text{SCHDP} = \text{HexP} * \text{sqrt}(3) \quad (\text{sqrt}(3) = 1.732 \text{ or } 2 * \cos(30 \text{ degrees}))$$

This is the distance between one phosphor dot and the next dot of the same color on the same horizontal line.

\* The Horizontal Dot Pitch (HDP) is the distance between adjacent columns of same color dots. This is equal to:  $\text{SCHDP} * 1/2$ .

\* The distance between adjacent dots of different colors or Closest Dot Spacing (CDS) is equal to:  $\text{SCHDP} * 1/3$ . A landing error of this magnitude (due to improper manufacture, adjustment, inadequate degauss, external fields, or doming) may completely shift the color from what it is supposed to be to one of the other primary colors.

So, for a 0.28 mm dot pitch CRT, VDP = .14 mm, SCHDP = .485 mm, HDP = .242 mm, and CDS = .16 mm.

---

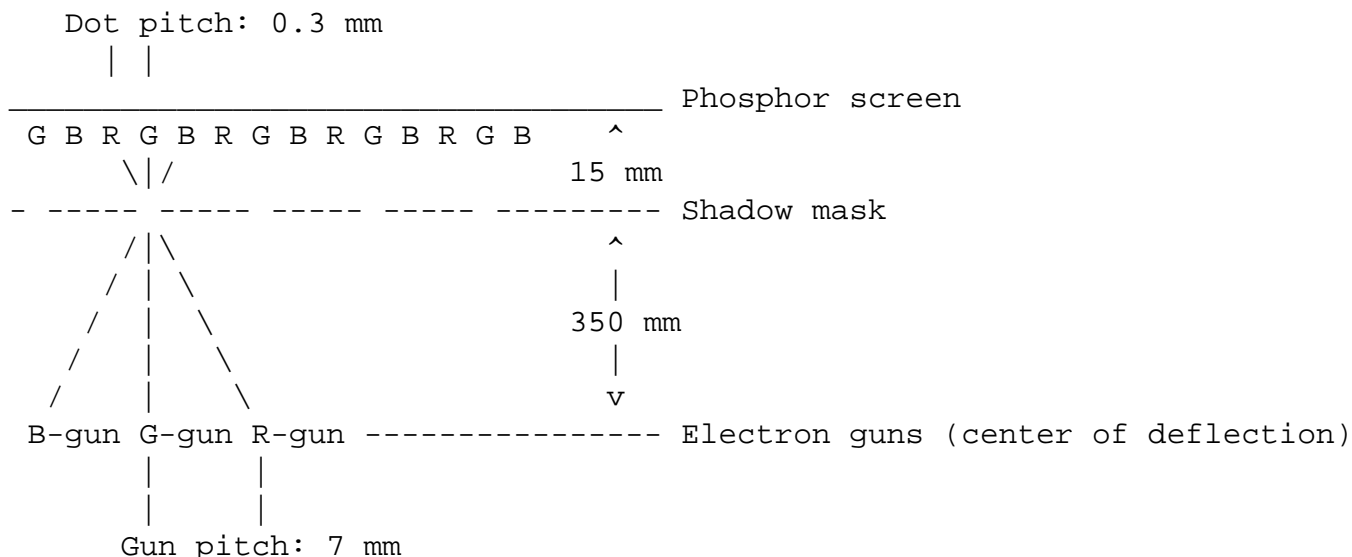

## 4.8) How far is the shadow mask from the phosphor screen?

(Portions from: Jeroen H. Stessen (Jeroen.Stessen@ehv.ce.philips.com)).

This is simple geometry - similar triangles (at least for a good approximation).

It is easy to do the calculations based on the distance between the electron

guns and the horizontal stripe pitch of the CRT (assuming slot mask or Trinitron - just a little more trouble for dot mask to convert the dot pitch).

(Cool diagram based on efforts of Jeroem Stessen.)

Be aware that both face-plate and shadow-mask are curved and that the radius of curvature is much larger than the distance to the guns. The screen is relatively flat. This too has consequences for the calculation. Oh, heck.

At the center of the screen, we have:

$$\frac{\text{Distance between E-guns (R-G)}}{\text{Distance from deflection center to mask}} = \frac{\text{Slot pitch (R-G)}}{\text{Mask to screen}}$$

For a typical 25 inch TV CRT with a .9 mm slot pitch (.3 mm between adjacent stripes) and 7 mm between adjacent guns we have a ratio of about 23:1.

For a distance of 350 mm between the center of deflection and mask, this gives us about 15 mm (~.6 inches) between the mask and the screen.

## 4.9) How is the shadow mask mounted inside the CRT?

(Portions from: Jeroen H. Stessen (Jeroen.Stessen@ehv.ce.philips.com)).

The shadow mask is mounted in a diaphragm. The diaphragm is mounted to the inside of the tube with 4 metal springs. In the old days these were bimetal springs. They have an important role for colour purity: they allow the mask to move forward as it expands due to self-heating.

Remember: it must dissipate a lot of power and there is no cool air in there...

During production the mask is mounted and removed many times to allow for etching of the phosphors. A point light source is precisely positioned at the deflection center of each gun in-turn to expose the photoresist used in laying down the phosphor dots. (I know, you thought they were painted on

one spot at a time! :-)

The mask is never fastened permanently, only clicked in to place just prior to having the envelope glued to the front assembly.

As no two masks are identical, each tube is always paired with its own mask.

(From: David Moisan (dmoisan@shore.net)).

From pictures I've seen, the best way to describe the shadow mask is that it is like a picture inside its frame: The glass face is the frame and the mask is the picture it holds, so to speak. The mask is carefully designed in a frame of its own, with spring clips around the edges, so that it won't distort under the heating it gets from the electron beams (not to mention during manufacturing). There's also a magnetic shield around the inside of the bell in some tubes.

---

## 4.10) Leaded glass and CRT coatings

"Is it really true that they put lead in the CRT glass for X-ray shielding? What is the transparent conductive coating on the front of the CRT made of?"

(From: Bob Myers (myers@fc.hp.com)).

First - yes, the glass is leaded (or contains other "impurities") to reduce emissions. In short, it's not just straight sand. :-)

There are various proprietary formulas used to make the faceplate coating, which often acts both as a conductive layer to reduce low-frequency electric fields and as a glare-reduction layer, but one of the most popular materials for making a transparent conductive layer is indium-tin oxide, a.k.a. "ITO". Such transparent conductors are also used in LCDs and other flat-panel technologies - at least the top layer of electrodes (row or column lines) has to be transparent! As conductors go, these things aren't THAT conductive - the age of see-through power lines or Star Trek's "transparent aluminum" is not upon us (and for certain theoretical reasons CAN'T be) - but they get the job done.

---

## 4.11) CRT fine tuning

Once the CRT is sealed, baked, evacuated, etc., the job is not yet done!

(From: Jeroen H. Stessen (Jeroen.Stessen@ehv.ce.philips.com)).

They still need to match the finished tube with a deflection coil that will give adequate purity performance and then they need to fiddle with magnets (multipole rings around the neck and sometimes other magnets all over the

cone) to improve it further. And even then many tubes need active correction for convergence and/or geometry.

Only after all that correction can you call the yield high. (But you should see their scrap yard, good thing that glass recycles well...)

---

## 4.12) Why do TVs overscan?

(The following includes material from:

Jeroen Stessen (Jeroen.Stessen@ehv.ce.philips.com)).

TVs are always set up to generate a picture which is 10-15 percent large than the visible face of the CRT. Why?

In the early days of TV, this was probably done to make the design easier. Component tolerances and power line voltage fluctuations would be masked even if they caused changes in picture size.

There certainly is almost no reason today to have any more than a couple of percent overscan. Most modern TVs have very well regulated power supplies and component values do not really drift much.

Computer monitors, for example, are usually set up for no overscan at all so that the entire image is visible.

We are constantly reminded of that, now that we are building TV's with VGA inputs (PD5029C1 in the USA, US\$ 2000). This mixed application has overscan in TV mode and underscan in VGA mode. Geometry adjustment is quite critical if you see border-on-border.

Unfortunately, TV's may be good but VCR's certainly are not. If you have too little overscan and then put the VCR in any feature mode (like picture search) then one (black) picture edge may become visible. Bad form. Viewers do not like this.

While design considerations may have been the original reason for overscan, now it has become accepted as a de facto standard, and broadcasters are counting on the overscan being a certain percentage. One wonders whether it will ever change or whether this really matters.

I suppose when we have true flat panel digitally addressed displays, we might have 0% overscan.

At the Japan Electronics Show all the signs are pointed toward flat panel displays so maybe I will not have to hold your breath for much longer.

Physically, as with an LCD display on a laptop computer, there will be 0% overscan (no need to build the extra pixels) but that doesn't mean that all 480 lines will be visible.

---

## 4.13) Why is the shadow mask or aperture grill made of a magnetic material?

(From: Jeroen Stessen (Jeroen.Stessen@ehv.ce.philips.com)).

The question often arises: Well, if magnetization and the need for degauss is a problem, why not make the shadow mask or aperture grille from something that is non-magnetic?

The shadow mask *must* be made of magnetic material! This may seem to be undesirable or counterintuitive but read on:

Together with the internal shielding hood it forms sort of a closed space in which it is attempted to achieve a field-free space. The purpose of degaussing is *not* to demagnetize the metal, but to create a magnetization that compensates for the earth's magnetic field. The *sum* of the two fields must be near zero! Degaussing coils create a strong alternating magnetic field that gradually decays to zero. The effect is that the present earth magnetic field is "frozen" into the magnetic shielding and the field inside the shielding will be (almost) zero. Non-zero field will cause colour purity errors.

Now you will understand why a CRT must be degaussed again after it has been moved relative to the earth's magnetic field. This will also explain why expensive computer monitors on a swivel pedestal have a manual degaussing button, you must press it every time after you have rotated the monitor.

The axial component of the magnetic field is harder to compensate by means of degaussing. Better compensation may be achieved by means of a "rotation coil" (around the neck or around the screen), this requires an adjustment that depends on local magnetic field. CRT's for moving vehicles (like military airplanes) may be equipped with 6 coils to achieve zero magnetic field in all directions. They use magnetic field sensors and active compensation, thus they don't need any degaussing function. This is too expensive for consumer equipment.

---

## 4.14) Northern/Southern Hemisphere corrections and adjustments

The vertical component of the earth's magnetic field varies in intensity and polarity (N/S) as one moves from the North pole over the equator and to the South pole. It is maximum at the poles and decreases to zero at the equator. The total strength is not large - after all it is less than the total magnitude of the earth's magnetic field of about .5 Gauss

(.00005 Tesla). However, it is enough to affect the trajectory of the electron beam(s) slightly.

For monochrome monitors and B/W TVs, this will result only in a slight shift in position or rotation of the picture depending on the orientation of the CRT with respect to the earth's magnetic field. For the most part such effects will not be significant enough to be objectionable.

However, for high resolution color monitors and even some color TVs, the result of transporting the unit from the hemisphere from which it was manufactured or set up to a location in the opposite hemisphere may be uncorrectable purity problems or excessive sensitivity to local magnetic fields.

Note that it is quite possible that you will never encounter any of these problems. The extent to which your particular monitor or TV is affected depends on many factors - many of which you have no control over.

(From: Bob Myers (myers@fc.hp.com)).

For many monitors - especially the larger sizes, such as 21" - there is a subtle difference in the CRT itself which may mean that a unit with the wrong tube could NOT be adjusted to be within specifications when used in the 'wrong' hemisphere.

(From: Jeroen Stessen (Jeroen.Stessen@ehv.ce.philips.com)).

There are two types of adjustments:

- \* The passive ones that are done in the picture tube factory and
- \* The active ones that are done by the setmaker a/o the customer.

In the factory inside the neck of every (Philips) tube a metal ring is permanently magnetized to create a multipole correction field. Then each tube is matched with a deflection yoke to achieve optimum colour purity. It is possible that a couple of yokes must be tried in succession. This matching is done under specific ambient magnetic field conditions. On oriental tubes you will often see little permanent magnets added to achieve further fine correction of landing and/or convergence. When the tube is within landing specification it is shipped to the setmaker.

Depending on the sophistication of the circuitry in the (television or monitor) set, the setmaker can adjust geometry and sometimes convergence (if there is a set of convergence coils present). If there is a rotation coil present then this may also improve the landing a bit.

In the 'digital monitors' there are flexible waveform generators to adjust the corrections. There may be further adjustments possible for the uniformity of the colour point and brightness. This gives a place-dependent modulation of the 3 beam currents, it does nothing to improve the landing.

The most expensive monitors (large screen, fine phosphor pitch, very critical on landing) may have active magnetic field compensation in all 3 directions with electronic magnetic field sensors for automatic adjustment. These monitors should be mostly insensitive to the earth magnetic field. (This technology was originally invented for the use of CRT displays on board of jet fighter planes, which tend to turn relative to the earth...)

All other monitors will degrade picture quality when the degaussing is not able to completely compensate for the earth magnetic field. With a tube built for the wrong hemisphere it is possible that the effect of the vertical component of the earth magnetic field will give a residual landing error. This can not be corrected by turning any of the available adjustments, digital or not. Re-alignment might become a very costly job.

---

## 4.15) Tubes for all Nations

(From: Jeroen Stessen (Jeroen.Stessen@ehv.ce.philips.com))

CRT Manufacturers actually make different versions of their tubes for TV's for the northern and southern hemisphere, and sometimes a 3rd neutral type. These are so-to-say precorrected for the uncompensated field. (Note that the term 'tube' here includes much of the convergence hardware as well - not just what is inside the glass.)

I remember when we exported projection televisions from Belgium to Australia, a couple of years ago. They all had to be opened on arrival to re-adjust the rotation settings on the convergence panel, due to the different magnetic field in Australia. Projection TV's don't have degaussing (there is nothing to degauss), and the customer can only adjust red and blue shift, not rotation.

Our CRT application group has a "magnetic cage". This is a wooden cube (approx. 2 meter long sides) with copper coils around each of the 6 surfaces. With this they can simulate the earth magnetic field for every place on earth (as indicated on a map on the wall).

During production and adjustment of the tube, the beam landing is optimized for the field condition in which it will be used later. There may be different tube specifications for north, south and equator ("neutral"). If you choose to use it in different conditions then the landing reserve will be diminished and you will suffer sooner from colour purity errors. I'm not so sure if the convergence would be a primary problem, maybe yes.

With a dotted shadow mask, also the horizontal component of the field matters, which is bad because it also depends on which direction you orient the display. This too will eat away from your landing reserve. How critical it all is depends on tube size (bigger is worse) and on dot pitch (smaller is worse). Workstation monitors are most critical.

Using a Helmholtz cage you can test or optimize for a particular place on earth. The most expensive monitors come with their own built-in Helmholtz cage and magnetic sensors to always create a field-free space.

Another interesting bit of trivia:

B&O (Bang & Olufsen of Danmark) use Philips picture tubes in their beautifully designed cabinets. In order to facilitate a more narrow styling they decided to mount the tube upside-down, so they don't need safety clearance for the EHT

on top. As a consequence they needed a southern-hemisphere tube for the northern hemisphere! So here is a hint for a solution to you all...

(From the editor).

In light of the above discussion, the following makes perfect sense:

(From: Nigel Morgan (nigel@wycombe.demon.co.uk)).

When I was in the TV trade some 20 years ago, I was introduced to a model with a PYE badge on which differed in one significant detail: on all TV sets I'd seen to that date the tube had the blue gun uppermost and the EHT connector at the top of the tube. Thorn TV sets mounted the tube upside-down for some reason so that the EHT connector was at the bottom along with the blue gun, but these PYE sets had the blue gun at the bottom, but the EHT connector was at the top! When I asked about this, I was told that the tubes used in the PYE sets were 'Southern Hemisphere tubes. I never could decide whether this was genuine or BS!

(From: Terry DeWick (dewickt@esper.com)).

The magnetic field for South America is about 0 to -100 mG while the U.S. runs 400 to 500 mG (milli Gauss). For a CRT to set up correctly the gun is offset 1 to 1.5 mm left of center for the 500mG field and 1 mm to the right for 0 mG this way the purity will be centered and the yoke tilt will be centered making setup easy during production. A North American CRT can be set up in South America but there is a chance that it will not set up well with excessive purity correction and or wedging set to the extremes.

Best direction to face a Monitor?

-----  
One would think that the magnetic field of the earth is inconsequential compared to what is used to drive a CRT. While the reasons this is not true should be obvious from other sections of this document, some would still call worrying about such issues as the direction of the monitor nonsense.

(From: Bob Myers (myers@fc.hp.com)).

No, it's not nonsense. The fields generated by the deflection coils, etc., ARE much greater in magnitude than the Earth's field, but they're AC fields. The DC offset of these fields is relatively small, and the Earth's field (also DC) IS sufficient to cause a visible shift in the position of the raster and affect the beam landing, etc.. This is why, for instance, there ARE often problems when trying to use a "Northern hemisphere" monitor in the Southern hemisphere.

Having said that, however, this isn't really something the average user needs to worry about. In the detailed specs for any monitor, there generally ARE a set of specific ambient conditions under which certain performance specs are intended to be checked. These usually include the ambient magnetic fields (which also tells you what magnetic environment was used at the factory for adjustment), and the orientation of the monitor within those fields. For the vast majority of monitors, the specified ambient conditions simulate average magnetic fields in the U.S. or Europe (which are very similar), and the monitor is specified as facing east or west within those fields. Strictly speaking, one has to establish those conditions (and so match the factory

adjustment environment) in order to evaluate the monitor for compliance with these specifications.

Monitors are aligned in whatever field the manufacturer (or large OEM customer) SPECIFIES. This USUALLY involves an east or west alignment, as this results in no field component in the CRT's Z-axis (the axis "down the throat" of the CRT, perpendicular to the center of the screen).

However, this doesn't necessarily mean that optimum performance at YOUR location will be obtained with the unit facing east or west, as local fields can vary considerably from the specified nominal field. The field identified in the specs is just that - it is part of the conditions under which those specifications are to be checked.

But the \*specific\* conditions for a given installation can vary considerably from the nominal, and so the only advice I can give the individual user is that if you're happy with the performance, don't worry about it. If you DO think that a local DC field (the Earth's field or any other) is causing a problem, THEN try to move or rotate the unit to see if you can find a better orientation or location. Of course, \*AC\* fields, such as those from a nearby power line or electrical equipment, are something else entirely.

---

## 4.16) Ways around North/South or other sensitivity to magnetic fields?

(From: Jeroen Stessen (Jeroen.Stessen@ehv.ce.philips.com))

They use magnetic field compensation for the professional types. This is too expensive for us mortals, so we get a CRT that has been optimized for one field condition only: North, South or Neutral. Not all displays are CRTs. LCDs for instance are not sensitive to the earth magnetic field. And not all CRTs use a shadow mask for colour selection. For instance, in Tektronix colour oscilloscope they use a white CRT with a colour LCD shutter in front of it. That too would not be affected too much by the earth magnetic field.

You see, plenty of ways out for aircraft, ships, and the Space Shuttle.

---

## 4.17) Addition comments/summary on Northern/Southern hemisphere issues

(From: Jeroen Stessen (Jeroen.Stessen@ehv.ce.philips.com))

\* The vertical component of the earth magnetic field varies as a function of latitude, particularly between hemispheres a vertical magnetic field will influence the color purity of a CRT.

- \* The magnetic shielding of a CRT will, after degaussing, not provide complete compensation for the vertical field, especially for the space between shadow mask and screen.
- \* That's why manufacturers produce different displays for different hemispheres: northern, southern and neutral. They do this by adjusting for optimum purity in a simulated magnetic field.

Where you have a TV or monitor that was manufactured for a different location, your options (apart from tossing it) are:

- \* Re-adjust the purity, this involves moving the deflection coil, adjustment magnets, adding more magnets, etcetera. This is a big job and success would not be guaranteed.
- \* Simulate a southern hemisphere location by creating a vertical magnetic field around the TV, put two big multi-turn wire loops (Helmholtz coils) above and below the TV and run a DC current through them. Might be expensive and certainly would provide a 'different' look!
- \* Replace the picture tube with a northern hemisphere type, this is very expensive.
- \* Mount the picture tube upside-down inside the TV cabinet. Then reverse the wires for the line (H) and field (V) deflection to put the picture correct side up again.

For this case, you might have some problems with:

- The mounting nuts for the tube are hard to reach and may have left thread (look carefully before turning!)
- The wires to the inverted picture tube panel being too short, they can probably be easily extended.
- The distance between high-voltage anode connection and the chassis (circuits) being too short (safety!)
- Condensation dripping into the anode contact.

Bang & Olufsen once made a compact style television where they wanted the anode contact to be away from the top of the cabinet, so the back cover could fit tighter. So they mounted the tube upside-down. Consequently they had to order southern hemisphere tubes for a northern hemisphere TV set. That works, of course.

---

## 4.18) Principles of purity and convergence adjustment

Purity involves bending all 3 of the beams so that they cross the space between shadow mask and screen at the proper angle and will land at a different place on the phosphors. Convergence involves adjusting the aim of

1 or 2 of the beams at a different angle so that they all land at the same place on the screen.

Dynamic convergence circuitry is now virtually non-existent, except in high resolution monitor tubes and in Sony Trinitron tubes (they require a very basic horizontal convergence). All other tubes have the convergence correction built into the design of the tube and the coil. Sony has chosen a different trade-off between price and performance (which includes also sharpness).

Most CRTs have a series - usually 3 pairs - of ring magnets mounted on the neck near the socket end. These are used for part of the purity adjustment and static convergence. (Coarse purity is set by the position of the yoke and dynamic convergence is set by the tilt of the yoke.) These rings consist of multi-pole magnets which due to their field configuration are able to affect the electron beams from the 3 guns in different ways.

(Some CRTs employ internal structures that are premagnetized at the factory and cannot be adjusted in the field - though perhaps auxiliary magnet rings could be added if the original magnetization were lost for reasons we won't go into :-). This type of CRT will be obvious as there will be no adjustable rings to mess screw up!)

The relative orientation of the rings in a pair affect the strength of the effect.

In a nutshell, the electron guns in most modern CRTs are arranged in-line. For example: GRB. Some of the ring adjustments are designed to affect them all while others pretty much leave the center gun's beam alone and only affect the outer ones. Various options then exist depending on the magnetic field configuration.

The three sets of ring magnets are shown below along with the position of the red (R), green (G), and blue (B) electron beams passing through them. Each is actually a pair of rings which may be moved relative to one-another to control the strength of the magnetic field. When the tabs are adjacent, the fields from the two rings nearly cancel and the rings then have no effect. Two typical orientations are shown (N and S are the poles of the ring magnets):

Orientation 1:

Orientation 2:

S	S	N	N
2-pole	4-pole	6-pole	
(purity)	(red-blue)	(red/blue-green)	
90 Degrees	45 Degrees	30 Degrees	

(My apologies if I have the direction of deflection reversed - I can never remember the right hand rule for electrons moving in magnetic fields!)

\* The 2-pole purity rings move the set of RGB beams more or less together to fine tune the position of the center of deflection.

The field lines go generally across (at the orientation shown) between the N and S poles.

Orientation 1, the RGB beams will be raised.

Orientation 2, the RGB beams will be moved to the right.

\* The 4-pole red-blue rings move the R and B beams relative to the G beam but leave the G beam alone.

The field lines go generally between adjacent N and S poles. On opposite sides of the rings, the polarity/direction of the lines oppose and thus tend to move the R and B beams in opposite directions. The G beam in the center does not experience any deflection from the 4-pole ring magnets since all the fields tend to cancel.

Orientation 1: The R beam will move up and the B beam will move down relative to G.

Orientation 2: The R beam will move up and to the right and the B beam will move down and to the left relative to G.

\* The 6-pole red/blue-green rings move the RB beams with relative to the G beam but leave the G beam alone.

The field lines go generally between adjacent N and S poles. On opposite sides of the rings, the polarity/direction of the lines are the same and thus tend to affect the R and B beams in the same direction. The G beam in the center does not experience any deflection from the 6-pole ring magnets since all the fields tend to cancel.

Orientation 1: The R and B beams will move up relative to G.

Orientation 2: The R and B beams will move up and to the right relative to G.

For purity to be perfect (or as good as possible), the electron beams must originate from the same effective center of deflection as used in originally laying down the phosphors. Moving the yoke forward and backward on the neck of the CRT can precisely set the deflection center along the axis of the neck. However, slight transverse errors may still exist due to imperfections in the yoke windings or positions of the electron guns. This is affected slightly by the earth's magnetic field as well. The purity magnet rings are those closest to the yoke and provide the means for moving the electron beams very slightly to compensate.

The adjustment procedures generally use the red gun for the setting purity.

Intuitively, one would think this should be the center (green) gun. However, since the red beam current is the highest (red phosphor is least sensitive), problems are likely to show up first with the red purity so it is used for the adjustment. In any case, it is a good idea to check all three guns for proper purity and tweak if needed before moving on to convergence.

In an in-line gun, the green gun is always in the middle. The only reason for adjusting purity with the red beam is because it gives the greatest sensitivity:

(From: Jeroen H. Stessen (Jeroen.Stessen@ehv.ce.philips.com)).

- \* The red beam current usually has the largest amplitude.
- \* A landing error of the red beam gives the best visible discoloration (much better than green, better than blue).
- \* This makes the landing of the red beam the most critical.

---

## 4.19) CRTs with no purity or static convergence rings

I have a late model TV with a 13 inch tube with no static purity or convergence rings. I don't get to see that many modern tubes so this was a bit of a surprise or maybe I just hadn't noticed before on small CRTs if they didn't have purity/convergence problems. I do see it has wrapping of a rubber-ferrite-permalloy type material where the ring assembly would go. I assume that this is magnetized selectively at the factory to adjust purity/convergence? The yoke has the usual position and tilt adjustments. This one was an RCA/GE CRT.

What this means is that if you were to accidentally bring a strong permanent magnet near the base of the CRT or a strong degaussing coil, there is a slight possibility of totally messing up this compensation requiring replacement of the CRT. I don't know how possible this is without really working at it!

(From: Jeroen H. Stessen (Jeroen.Stessen@ehv.ce.philips.com)).

Since eternity, Philips CRTs have not had external multipole magnet rings around the neck. There is an iron ring inside the neck, at the end of the electron gun assembly. This ring is permanently magnetized in the factory by a strong outside magnetic field at a later stage of the production. Further responsibility for purity, convergence and geometry is in the design of the coil windings distribution and some metal parts. Final purity adjustment is achieved by matching a tube with a coil and then shifting and tilting the coil slightly. This explains why Philips CRTs are always sold as a matched combination of tube and coil, contrary to some other brands.

---

## 4.20) Projection set convergence adjustment principles

(From: Jeroen H. Stessen (Jeroen.Stessen@ehv.ce.philips.com)).

CRT projection displays require much convergence correction, especially since the 3 tubes aim at the screen under different angles. Generally the green Horizontal convergence coil is not driven because that is a geometry correction which is taken care of by the horizontal deflection circuit. The 3 vertical convergence coils usually also take care of vertical geometry correction (N-S correction) because the vertical deflection circuit is generally a standard direct-view type. Add to that a severe keystone correction for the Red and Blue tubes.

The convergence waveforms used to be generated from an analog polynomial generator. The components are then weighted and summed to form a Taylor polynomial. Consider the adjustment of horizontal convergence, then typical polynomial components are:

1 (shift),  
x (amplitude),  
x<sup>2</sup> (linearity),  
y (rotation or tilt),  
y<sup>2</sup> (bow),  
x\*y (keystone),  
x<sup>2</sup>\*y (dunno if it's used)  
x\*y<sup>2</sup> (pin-cushion),  
x<sup>3</sup> (side linearity)  
x\*y<sup>4</sup> (corner pin-cushion)

Adjusting convergence is a highly iterative (read: costly) process because each potentiometer tends to influence the whole screen. Also, this method is not easily extendible to higher order adjustments for more accuracy. That's why better waveform generators have been designed, like digital look-up tables with D/A converters (which are quite expensive) and spline-like waveform generators (which are cheap and easy to adjust, the Philips design is called Convergence Spline Processor, it's digital too).

---

## 4.21) What is doming?

The shadow or slot mask inside the CRT is a thin sheet of steel or InVar positioned a half an inch or so behind the phosphor screen. The flatter the screen, the more susceptible it will be to thermal expansion effects: With individual phosphor dots spaced as little as .13 mm apart (for a .22 mm dot pitch CRT), it doesn't take much inaccuracy in their position to result in a noticeable effect. (See the section: "[How to compute effective dot pitch](#)".) As a result, high resolution CRTs tend to be more susceptible to doming problems.

(Portions from: Jac Jamar (jamar@comp.snads.philips.com)).

1. Doming is a deformation of the shadow mask or its support structure caused

by heating and subsequent expansion in bright (high beam current) areas of the picture. This causes a shift in position of the finely spaced holes or slots in the mask. The result will be color purity problems - discoloration and brightness variations. For a .28 mm dot pitch CRT, a change of only .14 mm in the position of a hole or slot can totally shift the display from one of the primary colors to another.

2. InVar shadow masks can sustain a significantly higher current density than steel shadow masks (by as much as 3:1) without noticeable problems.

Trinitrons are more resistant to local doming effects as long as the wires are under enough tension. However, expansion of the suspension components can still result in doming with an overall bright picture.

3. The onset and disappearance of color purity problems will generally lag the cause due to the thermal mass of the affected components. For local heating resulting from picture highlights, this will be only a few seconds since the thermal mass of a small area of the mask is not that great. However, for effects having to do with expansion of the suspension or support structure, it may take up to 30 minutes to reach equilibrium.
4. The orientation of the TV or monitor with respect to the earth's magnetic field and even whether the CRT was set up for the Northern or Southern hemispheres may affect the resulting color shift. Thus, the picture may tend toward yellow while the monitor is facing one way and blue when rotated 180 degrees on its base (even if degaussed at each position).
5. Reducing the brightness/contrast or setting the brightness limiter will prevent doming but may result in an unacceptably dark picture.
6. Shadow mask doming in itself is not something that becomes defective and has to be repaired. It is a characteristic of the CRT assembly. However, shifts in the position of purity adjustments can result in increased sensitivity to slight doming.

Purity problems resulting in discoloration and/or brightness variations are due to mislanding of the microscopic electron beams (the electron beams after the mask) on the red/green/blue phosphor stripes or dots. The mislanding is in general caused by:

- \* Influences of ambient magnetic fields (such as the earth magnetic field).
- \* Shadow mask doming.
- \* Tolerances occurring in the production of CRTs.
- \* Less than optimal setup of the purity adjustments (yoke position, rings on CRT neck, etc).

Only when the sum of these influences exceeds the 'guardband' provided in the CRT design, discoloration (or brightness variations) becomes visible.

If discoloration complaints arise, this will normally not be due to changes in doming behaviour, but to changes in shielding against magnetic fields.

The ambient magnetic fields are shielded by means of iron components inside (or sometimes outside) the tube, which have to be 'degaussed' to give good

shielding. For this in a set degaussing coils and circuits are provided. A discolouration complaint will thus often be due to insufficient degaussing.

\* TV sets and monitors which are kept in 'stand-by' mode for a long time may never be degaussed adequately because the degaussing circuit may only operate for a short time after the unit is switched on from cold - whether this is so with your unit depends on the design). In this case, they can pick up magnetic fields from magnets moved nearby or other equipment.

The solution in this case is to switch the TV or monitor completely off or pull the plug if in doubt, let it cool down for half an hour or longer and switch it on again. If necessary this procedure can be repeated a few times (I had to do this at home once when my children had been playing with magnets). For monitors with degauss buttons, you can usually hear a hum when the degauss is activated.

\* Similarly, if the orientation of a unit with respect to the earth's magnetic field is changed, it requires degaussing. So if you put your TV in another corner of the room or rotate your computer monitor on its tilt-swivel base, you have to activate its degauss circuitry (by letting it cool down or in the case of a high-end monitor, using its degauss button) or degauss it manually (see the section: "[Degaussing \(demagnetizing\) a CRT](#)").

\* The PTC resistor (thermistor or posistor) in the degaussing circuit can become defective. This prevents proper degaussing after switch-on.

Since lower resolution CRTs are used for most TVs compared to similar size computer monitors, doming would not be nearly as much of a problem if they were both run at similar brightness (energy density) levels. However, TVs are very often used at higher brightness levels resulting in more of a thermal load on the mask which offsets the lower resolution.

---

## 4.22) Why are there fine lines across my Trinitron monitor or TV?

These are not a defect - they are a 'feature'.

All Trinitron (or clone) CRTs - tubes that use an aperture grille - require 1, 2, or 3 very fine wires across the screen to stabilize the array of vertical wires in the aperture grille. Without these, the display would be very sensitive to any shock or vibration and result in visible shimmering or rippling. (In fact, even with these stabilizing wires, you can usually see this shimmering if you whack a Trinitron monitor.) The lines you see are the shadows cast by these fine wires.

The number of wires depends on the size of the screen. Below 15" there is usually a single wire; between 15" and 21" there are usually 2 wires; above 21" there may be 3 wires.

Only you can decide if this deficiency is serious enough to avoid the use of a Trinitron based monitor. Some people never get used to the fine

lines but many really like the generally high quality of Trinitron based displays and eventually totally ignore them.

---

## 4.23) Differences between Trinitron and Diamondtron CRTs

(From: Bill Nott (BNott@Bangate.compaq.com)).

Mitsubishi makes the Diamondtron under license from Sony - the subtle differences (according to Mitsubishi) are improvements in the electron gun design for spot uniformity over the CRT face. Also, for the time being, Mitsubishi has tried to introduce Diamondtron tubes in sizes which are not available as Trinitrons - to keep from directly competing, and (ostensibly) to address niches which other sizes can't address.

In order to properly evaluate a monitor, one must consider more than the tube alone - as many readers know, Trinitrons are finding their way into various manufacturer's sets, but they don't all perform the same. In today's market, it's quite possible to find a dot mask design which performs as well as (or better in some cases) the aperture grill design - IMHO every critical monitor purchase should be made by personally examining the monitor to be bought, under the intended application(s).

(BTW, all color tubes use 3 guns, including the Trinitron. Sony used to talk about a "unitized gun", but that only refers to the cathode structure. It's classical use of a misleading term to gain market awareness (looks like it works).)

---

## 4.24) So what does it mean to have a Trinitron CRT?

Trinitron is a CRT technology developed by Sony. The patent has recently expired and therefore other manufacturers are free to offer similar CRTs. The CRT uses a set of fine vertical wires called an aperture grill instead of a steel shadow mask to separate the R, G, and B electron beams and force them to strike only the appropriate colored phosphors. This in conjunction with an in-line set of electron guns is supposed to provide a brighter image with simpler convergence and purity adjustments. It should be brighter because the percentage of open space of the aperture grill is higher than that of a shadow mask. Other adjustments should be less critical in the vertical direction. In addition, since there is no imposed structure in the vertical direction, undesirable moire patterns caused by scan line pitch compared with the shadow mask dot pitch should be eliminated.

You can recognize a Trinitron tube by the fact that the picture is made up of fine vertical stripes of red, green, and blue rather than dots or slots. The shadow mask in all other kinds of common CRTs are made up of either dots (nearly all good non-Trinitron computer monitors) or slots

(many television sets). The Trinitron equivalent is called an aperture grill and is made of around a thousand vertical wires under tension a fraction of an inch behind the glass faceplate with its phosphor stripes.

Since the aperture grill wires run the full height of the tube, there are 1 or 2 stabilizing wires to minimize vibration and distortion of the aperture grill. These may be seen by looking closely 1/3 and/or 2/3 of the way down the tube. The larger size tubes will have 2 while those under 17 inch (I think) will only have a single wire. Many have complained about these or asked if they are defects - no they are apparently needed.

You can be sure that Sony would have eliminated them if it were possible.

Another noticeable characteristic of Trinitrons is the nearly cylindrical faceplate. The radius in the vertical direction is very large compared to the horizontal. This is both a requirement and a feature. Since the aperture grill wires are under tension, they cannot follow the curve of the glass as a normal shadow mask may. Therefore, the glass must be flat or nearly flat in the vertical direction. As a selling point, this is also an attractive shape.

In the final analysis, the ultimate image quality on a monitor depends as much on other factors as on the CRT. There are many fine monitors that do not use Trinitrons as well as many not-so-great monitors which do use Trinitron tubes.

---

## 4.25) Comparison of CRT types

"Could someone please help to elucidate the comparative advantages of each technology? I know how they work but do not know which is advantageous and why."

(From: Jeroen Stessen (Jeroen.Stessen@ehv.ce.philips.com)).

Trinitron is Sony technology. The shadow mask (called the aperture grille) consists of vertical wires under tension. The mask is always straight in the vertical direction and curved in the horizontal direction, thus the shape is a cylinder. The tube surface is also cylindrical, which causes some strange effects, particularly funny mirror reflections of yourself. Because the wires are under a lot of tension, the internal tube structure must be very strong and thus relatively heavy. Because the glass surface is cylindrical instead of spherical, the glass must be thicker and heavier too, to withstand atmospheric pressure.

Heavier always equates to more expensive!

The electron gun construction is also different: there are still 3 guns (not one as some may think but the 3 guns share one main lens. (The assembly of focusing grids is called a lens, in analogy to the optical principle.) There are still 3 cathodes and 3 GIs, as usual. The large diameter lens has the advantage of less spherical aberration (and thus a sharper spot) but the disadvantage of large physical length which means a deeper cabinet.

In the deflection coil design another compromise is found between spot quality, purity and convergence. As a result horizontal convergence must be helped by an auxiliary dynamic convergence waveform (on an extra convergence coil?). This adds to cost and can occasionally give an interesting failure of the horizontal convergence.

The best non-Trinitron (or clone) CRTs use a conventional shadow mask made of Invar - originally Matsushita technology; Philips uses it too. The shadow mask is of the standard shape (spherical metal plate with holes in it) but it is made of a special alloy with a 7 times lower coefficient of thermal expansion than regular iron. This allows a brighter picture with less purity errors.

The problem with regular shadow masks is 'doming'. Due to the inherent principle of shadow masks, 2/3 or more of all beam energy is dissipated in the mask. Where static bright objects are displayed, it heats up several hundred degrees. This causes thermal expansion, with local warping of the mask. The holes in the mask move to a different place and the projections of the electron beams will land on the wrong colours: purity errors. The use of invar allows about 3 times more beam current for the same purity errors. See the section: "[What is doming?](#)".

Combating purity errors is a necessity due to 2 trends:

- \* Flatter picture tubes: flatter shadow masks are more sensitive to doming
- \* Darker (glass) picture tubes: this gives more contrast but more beam current is needed for enough brightness

The trinitron aperture grill shadow mask is inherently insensitive to doming as long as the tension in the wires remains positive. If the wires become too long then they become more sensitive to microphony (try tap the cabinet...). The vertical wires are connected in several places by thin horizontal wires. Some people complain about seeing faint shadows of these wires.

To summarize: Trinitron monitors are probably heavier, larger, more expensive, maybe better on purity, and maybe better on focus than other monitors, with or without invar shadow masks. There are excellent monitors other than Trinitron too... I suppose the Coke-Pepsi comparison is true.

---

## 4.26) Some history of in-line gun CRTs

(From: Thomas Maggio (staccato@gate.net)).

GE's first set was a 10 or 11 inch "PortaColor" TV which, to the best of my memory, was introduced in the mid-60s. It was a tube chassis that made use of space saving Compactron multifunction tubes. A solid state version followed some years later I believe. If I remember correctly, the color circuit used a novel method to generate the local 3.58 MHz color signal: it used the recovered color burst to 'ring' a series crystal to produce a continuous carrier. I remember reading about all this in one of the late great

"Radio-Electronics" Annual Color TV issues that I looked forward to each year back then as color TVs were dynamically evolving from many US companies.

The GE CRT did indeed use 3 in-line guns aimed at a conventional shadow mask triad phosphor screen. This simplified convergence and the CRT neck components needed. Sony uses one gun with a large common cathode to emit 3 electron beams which focus through a single large electrostatic 'lens' instead of 3 smaller ones like the GE and others used.

One last stroll down memory lane: Does anyone remember the forerunner of the Sony Trinitron? It began as the "Lawrence Tube" (named after its U.S. inventor Dr. Lawrence) then was demonstrated as the "Chromatron" (I think Paramount had some stake in it then). I don't know how the concept became Sony's property so if anyone can corroborate or correct any of my recollections, I would enjoy hearing about it. Thanks.

(From: Andy Cuffe (baltimora@psu.edu)).

I read about Sony's development of the Trinitron. Apparently Sony actually manufactured a 17" TV with a Chromatron CRT in the early 60's. It was only sold in Japan and used a very unreliable tube chassis. According to the book they all ended up being returned and Sony lost a lot of money on it. Later Sony took ideas from the GE in-line tube and the Chromatron to invent the Trinitron. They used the 3 in-line cathodes of the GE tube with the vertical phosphor stripe screen of the chromatron. The common focusing lens was a way to stay as close as possible to the single electron gun design of the chromatron. The tone of the book suggested that Sony bet the whole company on the success of the Trinitron. Apparently they were very close to licensing the shadow mask design from RCA because of the amount of money they were losing by developing their own color CRT. If anyone is interested I think the title of the book was "Sony Vision". It also had chapters on the Betamax and the development of the first solid state TV.

---

## 4.27) Why are indirectly heated cathodes used in CRTs

Here are three reasons:

1. The cathode can be made of and/or coated with a material optimal for emitting electrons without regard to its performance as a heater.
  2. The separate cathode and filament can be electrically isolated so that the filament voltage and cathode drive signal, if any, do not interfere.
  3. The cathode can have an optimal shape for the application. This would be particularly significant for CRTs. The spot on the screen is a reduced focused image of the effective shape of the emitting portion of the cathode.
-

# Chapter 5) Maintenance and Repair

---

## 5.1) SAFETY

TVs and computer or video monitors are among the more dangerous of consumer electronics equipment when it comes to servicing. (Microwave ovens are probably the most hazardous due to high voltage at flesh frying and cardiac arresting high power.)

There are two areas which have particularly nasty electrical dangers: the non-isolated line power supply and the CRT high voltage.

Major parts of nearly all modern TVs and many computer monitors are directly connected to the AC line - there is no power transformer to provide the essential barrier for safety and to minimize the risk of equipment damage. In the majority of designs, the live parts of the TV or monitor are limited to the AC input and line filter, degauss circuit, bridge rectifier and main filter capacitor(s), low voltage (B+) regulator (if any), horizontal output transistor and primary side of the flyback (LOPT) transformer, and parts of the startup circuit and standby power supply. The flyback generates most of the other voltages used in the unit and provides an isolation barrier so that the signal circuits are not line connected and safer.

Since a bridge rectifier is generally used in the power supply, both directions of the polarized plug result in dangerous conditions and an isolation transformer really should be used - to protect you, your test equipment, and the TV, from serious damage. Some TVs do not have any isolation barrier whatsoever - the entire chassis is live. These are particularly nasty.

The high voltage to the CRT, while 200 times greater than the line input, is not nearly as dangerous for several reasons. First, it is present in a very limited area of the TV or monitor - from the output of the flyback to the CRT anode via the fat red wire and suction cup connector. If you don't need to remove the mainboard or replace the flyback or CRT, then leave it alone and it should not bite. Furthermore, while the shock from the HV can be quite painful due to the capacitance of the CRT envelope, it is not nearly as likely to be lethal since the current available from the line connected power supply is much greater.

---

## 5.2) Safe discharging of capacitors in TVs and video monitors

It is essential - for your safety and to prevent damage to the device under test as well as your test equipment - that large or high voltage capacitors be fully discharged before measurements are made, soldering is attempted, or the circuitry is touched in any way. Some of the large filter capacitors commonly found in line operated equipment store a potentially lethal charge.

This doesn't mean that every one of the 250 capacitors in your TV need to be discharged every time you power off and want to make a measurement. However, the large main filter capacitors and other capacitors in the power supplies should be checked and discharged if any significant voltage is found after powering off (or before any testing - some capacitors (like the high voltage of the CRT in a TV or video monitor) will retain a dangerous or at least painful charge for days or longer!)

The technique I recommend is to use a high wattage resistor of about 100 ohms/V of the working voltage of the capacitor. This will prevent the arc-welding associated with screwdriver discharge but will have a short enough time constant so that the capacitor will drop to a low voltage in at most a few seconds (dependent of course on the RC time constant and its original voltage).

Then check with a voltmeter to be double sure. Better yet, monitor while discharging (not needed for the CRT - discharge is nearly instantaneous even with multi-M ohm resistor).

Obviously, make sure that you are well insulated!

- \* For the main capacitors in a switching power supply which might be 100 uF at 350 V this would mean a 5K 10W resistor.  $RC = .5$  second.  $5RC = 2.5$  seconds. A lower wattage resistor can be used since the total energy is not that great. If you want to be more high tech, you can build the capacitor discharge circuit outlined in the companion document: "Testing capacitors with a multimeter and safe discharge". This provides a visible indication of remaining charge and polarity.
- \* For the CRT, use a high wattage (not for power but to hold off the high voltage which could jump across a tiny 1/4 watt job) resistor of a few M ohms discharged to the chassis ground connected to the outside of the CRT - NOT SIGNAL GROUND ON THE MAIN BOARD as you may damage sensitive circuitry. The time constant is very short - a ms or so. However, repeat a few times to be sure. (Using a shorting clip lead may not be a bad idea as well while working on the equipment - there have been too many stories of painful experiences from charge developing for whatever reasons ready to bite when the HV lead is reconnected.) Note that if you are touching the little board on the neck of the CRT, you may want to discharge the HV even if you are not disconnecting the fat red wire - the focus and screen (G2) voltages on that board are derived from the CRT HV.

WARNING: Most common resistors - even 5 W jobs - are rated for only a few hundred volts and are not suitable for the 25KV or more found in modern TVs and monitors. Alternatives to a long string of regular resistors are a high voltage probe or a known good focus/screen divider network. However, note that the discharge time constant with these may be a few seconds. Also see the section: "[Additional information on discharging CRTs](#)".

If you are not going to be removing the CRT anode connection, replacing

the flyback, or going near the components on the little board on the neck of the CRT, I would just stay away from the fat red wire and what it is connected to including the focus and screen wires. Repeatedly shoving a screwdriver under the anode cap risks scratching the CRT envelope which is something you really do not want to do.

Again, always double check with a reliable voltmeter!T

Reasons to use a resistor and not a screwdriver to discharge capacitors:

1. It will not destroy screwdrivers and capacitor terminals.
2. It will not damage the capacitor (due to the current pulse).
3. It will reduce your spouse's stress level in not having to hear those scary snaps and crackles.

---

## 5.3) Preventive maintenance - care and cleaning

Preventive maintenance for a monitor is pretty simple - just keep the case clean and free of obstructions. Clean the CRT screen with a soft cloth just dampened with water and mild detergent or isopropyl alcohol. This will avoid damage to normal as well as antireflection coated glass. DO NOT use anything so wet that liquid may seep inside of the monitor around the edge of the CRT. You could end up with a very expensive repair bill when the liquid decides to short out the main circuit board lurking just below. Then dry thoroughly. Use the CRT sprays sold in computer stores if you like but again, make sure none can seep inside. If you have not cleaned the screen for quite a while, you will be amazed at the amount of black grime that collects due to the static buildup from the CRT high voltage supply.

In really dusty situations, periodically vacuuming inside the case and the use of contact cleaner for the controls might be a good idea but realistically, you will not do this so don't worry about it.

---

## 5.4) Degaussing (demagnetizing) a CRT

Degaussing may be required if there are color purity problems with the display. On rare occasions, there may be geometric distortion caused by magnetic fields as well without color problems. The CRT can get magnetized:

- \* if the TV or monitor is moved or even just rotated.
- \* if there has been a lightning strike nearby. A friend of mine had a lightning strike near his house which produced all of the

effects of the EMP from a nuclear bomb.

- \* If a permanent magnet was brought near the screen (e.g., kid's magnet or megawatt stereo speakers).
- \* If some piece of electrical or electronic equipment with unshielded magnetic fields is in the vicinity of the TV or monitor.

Degaussing should be the first thing attempted whenever color purity problems are detected. As noted below, first try the internal degauss circuits of the TV or monitor by power cycling a few times (on for a minute, off for 30 minutes, on for a minute, etc.) If this does not help or does not completely cure the problem, then you can try manually degaussing.

Commercial CRT Degaussers are available from parts distributors like MCM Electronics and consist of a hundred or so turns of magnet wire in a 6-12 inch coil. They include a line cord and momentary switch. You flip on the switch, and bring the coil to within several inches of the screen face. Then you slowly draw the center of the coil toward one edge of the screen and trace the perimeter of the screen face. Then return to the original position of the coil being flat against the center of the screen. Next, slowly decrease the field to zero by backing straight up across the room as you hold the coil. When you are farther than 5 feet away you can release the line switch.

The key word here is **\*\* slow \*\***. Go too fast and you will freeze the instantaneous intensity of the 50/60 Hz AC magnetic field variation into the ferrous components of the CRT and may make the problem worse.

It looks really cool to do this while the CRT is powered. The kids will love the color effects.

Bulk tape erasers, tape head degaussers, open frame transformers, and the "ass-end" of a weller soldering gun can be used as CRT demagnetizers but it just takes a little longer. (Be careful not to scratch the screen face with anything sharp.) It is imperative to have the CRT running when using these whimpier approaches, so that you can see where there are still impurities. Never release the power switch until you're 4 or 5 feet away from the screen or you'll have to start over.

I've never known of anything being damaged by excess manual degaussing though I would recommend keeping really powerful bulk tape erasers turned degaussers a couple of inches from the CRT.

If an AC degaussing coil or substitute is unavailable, I have even done degaussed with a permanent magnet but this is not recommended since it is more likely to make the problem worse than better. However, if the display is unusable as is, then using a small magnet can do no harm. (Don't use a 20 pound speaker or magnetron magnet as you may rip the shadow mask right out of the CRT - well at least distort it beyond repair. What I have in mind is something about as powerful as a refrigerator magnet.)

Keep degaussing fields away from magnetic media. It is a good idea to avoid degaussing in a room with floppies or back-up tapes. When removing media from a room remember to check desk drawers and manuals for stray floppies, too.

It is unlikely that you could actually affect magnetic media but better safe than sorry. Of the devices mentioned above, only a bulk eraser or strong permanent magnet are likely to have any effect - and then only when at extremely close range (direct contact with media container).

All color CRTs include a built-in degaussing coil wrapped around the perimeter of the CRT face. These are activated each time the CRT is powered up cold by a 3 terminal thermister device or other control circuitry. This is why it is often suggested that color purity problems may go away "in a few days". It isn't a matter of time; it's the number of cold power ups that causes it. It takes about 15 minutes of the power being off for each cool down cycle. These built-in coils with thermal control are never as effective as external coils.

---

## 5.5) How often to degauss

Some monitor manufacturers specifically warn about excessive use of degauss, most likely as a result of overstressing components in the degauss circuitry which are designed (cheaply) for only infrequent use. In particular, there is often a thermister that dissipates significant power for the second or two that the degauss is active. Also, the large coil around the CRT is not rated for continuous operation and may overheat.

If one or two activations of the degauss button do not clear up the color problems, manual degaussing using an external coil may be needed or the monitor may need internal purity/color adjustments. Or, you may have just installed your megawatt stereo speakers next to the monitor!

You should only need to degauss if you see color purity problems on your CRT. Otherwise it is unnecessary. The reasons it only works the first time is that the degauss timing is controlled by a thermister which heats up and cuts off the current. If you push the button twice in a row, that thermister is still hot and so little happens.

One word of clarification: In order for the degauss operation to be effective, the AC current in the coil must approach zero before the circuit cuts out. The circuit to accomplish this often involves a thermister to gradually decrease the current (over a matter of several seconds), and in better monitors, a relay to totally cut off the current after a certain delay. If the current was turned off suddenly, you would likely be left with a more magnetized CRT. There are time delay elements involved which prevent multiple degauss operations in succession. Whether this is by design or accident, it does prevent the degauss coil - which is usually grossly undersized for continuous operation - to cool.

---

## 5.6) Ultra cheap degaussing coil

Next time you scrap a computer monitor (or tv), save the degaussing coil (coil of wire, usually wrapped in black tape or plastic) mounted around the front of the tube. To adapt it for degaussing sets, wrap it into a smaller coil, maybe 4"-6". To limit the current to something reasonable, put it in series with a light bulb (60-100W). You need AC current to degauss, so just put the bulb in series with the coil and use the your local 120V outlet. BE VERY CAREFUL that you actually wired it in series, and that everything is properly insulated before you plug it in (A fuse would be a real good idea too!!)

A few circles over the affected area will usually do it. Note that it will also make your screen go crazy for a little bit, but this will fade out within a minute or so.

Just a couple of points for emphasis:

1. The coil as removed from the TV is not designed for continuous operation across the line as indicated above. In fact, it will go up in a mass of smoke without the light bulb to limit the current. The poor TV from which this organ was salvaged included additional circuitry to ramp the current to 0 in a few seconds after power is turned on.
2. Reducing the coil size by a factor of 2 or 3 will increase the intensity of the magnetic field which is important since we are limiting the current with the light bulb to a value lower than the TV used. You don't need to unwind all the magnet wire, just bend the entire assembly into a smaller coil. Just make sure that the current is always flowing in the same direction (clockwise or counterclockwise) around the coil.
3. Insulate everything very thoroughly with electrical tape. A pushbutton momentary switch rated for 2 amps at 115 volts AC would be useful so that you do not need to depend on the wall plug to turn it on and off.

---

## 5.7) Bob Myers notes on degaussing

A couple of comments: first of all, it makes no difference whatsoever if the display is on while it's being degaussed. (Oh, some people DO like to watch the psychedelic light show, but it really doesn't help anything for it to be on.) Actually, there is a very minor case to be made for degaussing while OFF, at least for the Trinitron and similar tubes. (The field of an external degauss coil CAN cause the grille wires to move slightly, and they're a bit more flexible when hot - so it is conceivable, although certainly unlikely, that you're running a higher risk of causing the grille wires to touch or cross and become damaged.)

Secondly, a good practice for degaussing is to slowly back away from

the monitor after giving the screen a good going over. Once you're about 5-6' away, turn the coil so it's a right angles to the CRT faceplate (which minimizes the field the monitor is seeing), and THEN turn to coil off. This is to reduce the possibility of the field transient caused by switching the coil off from leaving you once again with a magnetized monitor.

The last point is to make sure that you DON'T leave the coil on too long. These things are basically just big coils of wire with a line cord attached, and are not designed to be left on for extended periods of time - they can overheat. (I like the kind with the pushbutton "on" switch, which turns off as soon as I release the button. That way, I can never go off and leave the coil energized.)

Oh, one more thing - make sure your wallet is in a safe place. You know all those credit cards and things with the nice magnetic stripe on them? :-)

(Actually, I've got a good story about that last. I was teaching a group of field service engineers how to do this once, and being the Big Deal Out of Town Expert, made VERY sure to place my wallet on a shelf far away from the action. Unfortunately, Mr. Big Deal Out of Town Expert was staying in a hotel which used those neat little magnetic-card gadgets instead of a "real" key. Ever try to explain to a desk clerk how it was that, not only would your keycard NOT let you into your room, it was no longer anything that their system would even recognize as a key? :-))

---

## 5.8) Can a really strong magnet permanently damage the CRT?

Even a magnet that can suspend your weight may still not have much range as they usually have metal pole pieces that concentrate the flux and work well only with a matching flat steel plate.

The only thing in the guts of a TV or monitor (that is accessible from outside the cabinet) that can be damaged permanently is the shadow or slot mask of the CRT. If the magnet is strong enough to distort it, the CRT will be ruined. Even manual degaussing with a similarly powerful degaussing coil will then not totally clear up color purity problems. The shadow or slot mask is a very thin perforated steel or InVar sheet about 1/2 inch behind the glass of the CRT screen - which is itself about 1 inch thick or more. So, even up against the screen, your magnet is still at least 1-1/2 inches from the shadow mask. It would take a mighty powerful magnet to distort it.

For Trinitron (or clone) CRTs with aperture grilles - tensioned fine wires in place of a shadow or slot mask, the force required would be even greater.

No way to know without trying it :-).

(From: Jeff Mangas (jeff@edldisplays.com)).

I work in a small monitor factory and some time ago we were using some very strong degaussing wands to remove magnetism from some of our chassis. We found that this caused a weakening of the shadow mask and it would take only a small shock/vibration to break the mask loose. We are not 100% sure that it was the degaussing that caused the problem but we only used these strong wands for a short time (lost several tubes while using them) and have not had any problems before or since.

---

## 5.9) Detailed purity and static convergence adjustment procedure

Also see the adjustment information in the document: "[Notes on the Troubleshooting and Repair of Computer and Video Monitors](#)" (or Television Sets).

(From: Alan McKinnon (alan.mck@pixie.co.za)).

The rearmost pair of magnets (seem from the service position behind the set in other words furthest from you nearest the front of the tube) affects purity. More on this later. The middle and front magnets are for convergence and work on pairs of colours. The effects can most easily be seen on a cross hatch test pattern (10 or so horizontal lines, 15 or so vertical lines).

But first, purity:

Without getting into the details of what happens inside the guns, I assume you need to know how to do the adjustments. You need some means of generating an evenly red screen. An (expensive) pattern generator is the preferred method. Fiddle the rear purity rings to distort the screen by bringing green and blue blobs into it. You will note that the magnets can be adjusted by moving both together, and moving them apart relative to each other. The best advice here is: adjust slowly and observe what happens. Once you have the screen evenly red, move on to convergence, which is the trick of getting the red green and blue beams to coincide on the screen to produce white, with the minimum of colour shadowing.

With a cross hatch pattern on screen, you can see easily how convergence works, and how the magnets affect the picture. Each tube type is different in exactly how this is done, but the general idea is that one set of magnets affects two specific colours only, moving them apart and bringing them nearer, while leaving the third colour alone. The other set of magnets takes the colours affected by the other set, and moves them together relative to the third colour. Also, moving a pair of magnets together adjusts the colours in one direction (vert or horiz) while moving the magnets apart adjusts the other direction. With all things in life, there is some overlap, so you need to look carefully and see what happens mostly - the adjustments are not cut and dried. Oh, and they are interactive to some degree. Keep checking purity after you do convergence. All of this is best shown with a picture, the colours are arbitrary, you may well find the details do not apply to your tv, but the

basic principles will. These initial convergence adjustments apply only to the centre of the screen by the way, the edges are done elsewhere:

Rotating one set of magnets together might move red and blue together till they coincide vertically:

And moving them apart relative to each other might move red and blue together horizontally:

Moving the other set of magnets together might take the red and blue pair and move them to coincide with the green, vertically:

And moving them apart relative to each other might move the red and blue pair and move them to coincide with green horizontally:

Once the convergence is perfect in the centre of the screen (called static convergence) it's time to handle the edges and corners (called dynamic convergence for historical reasons). This is done by physically moving the entire yoke that is clamped around the tube neck with the deflection coil on it. It is anchored in place by a collar on the tube neck, loosen this slightly, but not enough so that the yoke can move backwards. It is also held in place by rubber wedges glued or taped down. Take the wedges out. By gripping the yoke and levering it up and down, left and right, you will change the convergence in the corners. The effects don't work as you might at first suppose - moving the yoke left affects the lower right corner, this type of thing. Get the dynamic convergence right and stuff the wedges back under the yoke to hold it precisely in place and glue them back down. The recheck purity.

There you have it. Easy as pie. Some folk would have you believe no-one in their right minds adjusts these things. Well, balls. Someone did it at the factory, and they did it the way I just described. All you need is the right tools (pattern generator), patience, and time.

---

## 5.10) Tony's notes on setting convergence on older delta gun CRTs

(From: ard12@eng.cam.ac.uk (A.R. Duell))

The older delta-gun tubes (3 guns in a triangle, not in a line) can give **\*\*excellent\*\*** pictures, with very good convergence, provided:

1. You've set those 20-or-so presets correctly - a right pain as they interact to some extent.
2. The CRT is set up in the final position - this type of tube is more sensitive to external fields than the PIL type.

Both my delta-gun sets (a B&O 3200 chassis and a Barco CDCT2/51) have very clearly set out and labeled convergence panels, and you don't need a service manual to do them. The instructions in the Barco manual are something like:

"Apply crosshatch, and adjust the controls on the convergence board in the numbered order to converge the picture. The diagrams by each control show the effect".

Here's a very quick guide to delta gun convergence where the settings are done using various adjustments on the neck of the CRT (if you don't have a service manual but do know what each control does, and where they all are - otherwise, follow the instructions in the service manual --- sam):

1. Apply a white crosshatch or dot pattern to the set. Don't try and converge on anything else - you'll go insane. It's useful to be able to switch between those 2 patterns.
2. Before you start, set the height, width, linearity, pincushion, etc. They will interact with the convergence. Also check PSU voltages, and the EHT voltage if it's adjustable. That's where you do need a service manual, I guess.
3. Turn off the blue gun using the A1 switch, and use the red and green static radial controls to get a yellow crosshatch in the middle of the screen. These controls may be electrical presets, or may be movable magnets on the radial convergence yoke (the Y-shaped thing behind the deflection yoke).
4. Turn on the blue gun and use the 2 blue static controls (radial and lateral) to align the blue and yellow crosshatches at the center of the screen. Some manufacturers recommend turning off the green gun when doing this, and aligning red with blue (using *only* the blue controls, of course), but I prefer to align blue with yellow, as it gives a check on the overall convergence of the tube.
5. Turn off the blue gun again. Now the fun starts - dynamic convergence. The first adjustments align the red and green crosshatches near the edges -

I normally do the top and bottom first. There will be 2 controls for this, either a top and a bottom, or a shift and a linearity. The second type is a \*pain\* to do, as it's not uncommon for it to affect the static convergence.

6. Getting the red and green verticals aligned near the edges is a similar process.
7. You now have (hopefully) a yellow crosshatch over the entire screen.
8. Now to align the blue. This is a lot worse, although the principle is the same. Turn on the blue gun again, and check the static (center) convergence
9. To align the blue lines with the yellow ones, you'll find not only shift controls, but also slope controls. Use the shift controls to align the centers of the lines and the slope controls to get the endpoints right. These interact to some extent. You'll need to fiddle with the controls for a bit to work out what they do, even if you have the manual.

The convergence over the entire screen should now be good....

A word of warning here... The purity is set by ring magnets on almost all colour CRTs, but on PIL tubes, there are other ring magnets as well - like static convergence. Make sure you know what you are adjusting.

---

## 5.11) Jerry's comments on convergence and other advanced adjustments

(From: Jerry G. (jerryg@total.net)).

Convergence alignment is not something you can do yourself unless you have the proper calibration instruments and skills. It takes lots of experience and time. There are published specs for most of the good monitors. Most of the time they are as follows:

There is the 'A area', 'B area', and 'C area'. On a 15 inch monitor the A area would be a diameter of about 4 inches. The B area would be about 7.5 inches. The C area would be the outside areas including the corners. These numbers are approximate. There are actually standard specs for these areas. They are expressed in percentage of screen viewing area. Therefore the inches would vary with the CRT size.

The higher the price (quality) of the monitor CRT, yoke, and scanning control circuits, the tighter the convergence can be aligned by the technician. For the A area on a good monitor, the maximum error should not exceed 0.1 mm. For the B area it should not exceed more than about 0.25 mm. And for the C area, it can be allowed up to about 0.3 mm. Most of the monitors that I have repaired, seen, and used did not meet these specs unless they were rather expensive. With these specs there would not be any real visible misconvergence unless you put your nose very close to the screen... A lot of

the ones in the medium price range they were about 0.15 mm error in the A area, about 0.4 in the B and greater than in the C area. This also annoys me because I am very critical.

If one has the skills and test gear he or she can do a better job on most monitors. It is a question of the time involved. To see the convergence errors a grating or crosshatch pattern is used. A full raster color generator is required for the purity adjustments as well. This is necessary to align the landing points of the CRT guns. The exact center reference and purity adjustments are done with the ring magnets on the CRT neck. The yoke position angle adjustments are also done for the side and top-bottom skewing as well. Everything interacts!

The corners are done with various sorts of slip or edge magnets. As for corner convergence skewing, button magnets are used. The color purity will be effected as you go, and must be also corrected. These adjustments interact on one another, and the processes continues until the convergence and purity are good at the same time...!

I don't recommend the amateur or hobbieist, or even the do-it-yourselfer to attempt this alignment procedure. The test gear would exceed the cost of a really good monitor anyways...!!! And without the proper skills required, he or she would only make it worse anyways...

As for purity specs, the color change from any corner to any corner must not exceed an error of more than 200 degrees Kelvin. The error in the B area should not exceed 300 degrees kelvin. This applies to a white raster. Most of the monitors I see don't get better than about 300 degrees Kelvin. And some are even 1000 out! The purity errors are best checked with a full Red raster using 100 % saturation. Then the other color vector angles are checked with cyan, and then magenta. The color temperature stability should be the same in all aspects.

A color spectrometer should be used to judge this error factor. As far as the eye is concerned, it will see a purity error of more than about 500 degrees Kelvin if the person knows what to look for...

When changing the CRT, this alignment must be done completely. Most shops do not even employ people who are skilled to a proper alignment, or don't even own the instruments to do it right, and the poor customer get back a monitor that is not in specs...!

---

## 5.12) Monitor tune-up?

(The following from: Bob Myers (myers@fc.hp.com)).

Most manufacturers will quote an MTBF (Mean Time Before Failure) of somewhere in the 30,000 to 60,000 hour range, EXCLUSIVE OF the CRT. The typical CRT, without an extended-life cathode, is usually good for 10,000 to 15,000 hours before it reaches half of its initial brightness. Note that, if you leave your monitor on all the time, a year is just about

8,000 hours.

The only "tuneup" that a monitor should need, exclusive of adjustments needed following replacement of a failed component, would be video amplifier and/or CRT biasing adjustments to compensate for the aging of the tube. These are usually done only if you're using the thing in an application where exact color/brightness matching is important. Regular degaussing of the unit may be needed, of course, but I'm not considering that a "tuneup" or adjustment.

---

## 5.13) Checking the age of the CRT

So you have this great deal on a used TV or monitor. How can you tell if the picture tube is about to die on you?

(From: Andy Cuffe (baltimora@psu.edu)).

The best way to tell is to look at the picture quality. There is no way to tell the exact number of hours. Also, the life of CRTs varies quite a bit. some will go down hill much faster than others.

- \* It should be sharply focused over the entire screen and all 3 colors should be equally sharp.
- \* Set the picture brightness and color to maximum. If you see any bleeding or smearing to the right of bright objects don't buy it.
- \* When you first turn it on the picture should look normal in well under a minute. If it is dim, tinted, or blurry for more than a minute or two the CRT is getting weak.
- \* A B/W picture should not be tinted.
- \* The picture should have decent brightness with the picture at about mid range.

Apart from that, if the overall picture is good the CRT is fine. CRTs usually fail very slowly. Even if it's starting to show it's age it probably has several years left.

(Portions from: Jerry G. (jerryg50@hotmail.com)).

You cannot tell the hours used by just looking or even measuring a tube. A tube can go at any time. There are no hour counters!

Turn on the unit and see if there is any unusual bleeding of the image in the picture at high contrast levels. When turning the brightness up and down, the color temperature should not change, only the brightness. When turning the contrast up and down, the focus at the center should also be very stable. It may change only a little bit. When turning on the set, the color temperature should be stable within about 3 to 5 minutes.

Look at the colors in the corners to see if the purity is good. Bad purity can be attributed to a miss-adjusted yoke assembly, to a bad shadow mask.

To know the manufacture date of the unit, it is usually on the back with the model and serial number. Most TV sets are on about 5 to 8 hours a day if it is a family TV. If it is a bedroom TV the hours may be 1/2 that amount. Monitors may be on 24 hours a day - or much less.

A good way to know if the emission of the CRT is up to specs is to get a CRT analyzer and measure the gun emission. Some service centers own one.

---

## 5.14) Brightening an old CRT

If performing adjustments of the internal background and/or screen controls still results in a dark picture even after a long warmup period (and the controls are having an effect - they are not faulty), the CRT may simply be near the end of its useful life. In the old days of TVs with short lived CRTs, the CRT brightener was a common item (sold in every corner drugstore, it seemed!).

First confirm that the filaments are running at the correct voltage - there could be a marginal connection or bad resistor or capacitor in the filament power supply. Since this is usually derived from the flyback, it may not be possible to measure the (pulsed high frequency) voltage with a DMM but a service manual will probably have a waveform or other test. A visual examination is not a bad way to determine if the filaments are hot enough. They should be a fairly bright orange to yellow color. A dim red or almost dark filament is probably not getting its quota of electrons. It is not the CRT since all three filaments are wired in parallel and for all three to be defective is very unlikely.

If possible, confirm that the video output levels are correct. For cathode driven CRTs, too high a bias voltage will result in a darker than normal picture.

CRT brighteners are available from parts suppliers like MCM Electronics. Some of these are designed as isolation transformers as well to deal with heater-to-cathode shorts.

You can try making a brightener. Caution: this may shorten the life of the CRT - possibly quite dramatically (like it will blow in a couple of seconds or minutes). However, if the monitor or TV is otherwise destined for the scrap heap, it is worth a try.

The approach is simple: you are going to increase the voltage to the filaments of the electron guns making them run hotter. Hopefully, just hotter enough to increase the brightness without blowing them out.

Voltage for the CRT filament is usually obtained from a couple of turns on the flyback transformer. Adding an extra turn will increase the voltage and thus the current making the filaments run hotter. This will also shorten the CRT life - perhaps rather drastically. However, if the monitor

was headed for the dumpster anyhow, you have nothing to lose. You can just add a turn to an existing winding or make your own separate filament winding as outlined in the section: "[Providing isolation for a CRT H-K short](#)".

In some monitors, there is a separate filament supply on the mainboard - this should be obvious once you trace the filament wires from the video driver board). In this case, it still may be possible to increase this output or substitute another supply but a schematic will be required.

There are also commercial CRT rejuvenators that supposedly zap the cathodes of the electron guns. A TV or monitor service center may be able to provide this service, though it is, at best, a short term fix.

---

## 5.15) CRT rejuvenation

Where one or more electron guns in the CRT have deteriorated due to wear and tear, it is sometimes possible to give them a new, but possibly, temporary lease on life through rejuvenation using a special piece of CRT service equipment.

(From: Gary Klechowicz (klechowi@execpc.com)).

When I rejuvenate a tube I inform the customer that there is no warranty on the job. Rejuvenating a CRT is like when Clatuu was brought back to life by Gort in "The Day The Earth Stood Still". When asked "How long will you live"? he replied: "no one knows".

I use a Sencore Beam Builder. If your tube is just moderately dim and blurry but still shows good cut off threshold, I would just use the auto restore mode on the beam builder rather than using the restore button. If the tube is really bad with little or no cutoff threshold, then the rejuvenator is needed but that has less than a 50% chance of fixing the tube and in many cases the tube gets worse to trashed in the process.

---

## 5.16) More comments on CRT rejuvenation

(From: Ren Tescher (ren@rap.ucar.edu)).

Reduced emission (dim picture) can occur when the cathode/filament has used up most of the electrons it can emit to the screen. Or, a 'crust' may have formed on the thoriated emitter material that can be 'boiled off' to expose more electrons.

A rejuvenator or restorer generally hits the cathode/filament with a higher than normal current to accomplish this.

But, while a rejuvenator gives the cathode/filament a 'blast' of power, a

restorer can slowly increase the temperature while monitoring beam current on one of the grids.

So generally a rejuvenator was a 'do or die' unit and a restorer could give only what was needed to accomplish increased emission. But these definitions have always been blurred by advertising hype.

The early restorers, such as my REM, had the operator watch the grid current on a meter(s) to determine when emission was sufficient. I suppose newer units have a PIC chip or some other logic to do the job.

(From: Terry DeWick (dewickt@esper.com)).

I use a hand held Tesla coil to all pins for about 5 seconds. Then, follow up with rejuvenator for a quick check and cleanup if needed. Tesla coil is type the neon sign people use for testing. 95% or better luck - saved a lot of out of warranty Zeniths from big repair bills or junk pile.

---

## 5.17) CRT age resulting in dark picture

Where circuit problems have been ruled out:

(From: Jeroen Stessen (Jeroen.Stessen@ehv.ce.philips.com)).

Most probably the cathodes have worn out. The emission material on the surface slowly becomes inactive. Usually you see one colour go first, then the others. At the same time you will observe a loss in sharpness, because a larger cathode area is being used, giving a bigger spot.

Rejuvenating is done by applying a (too) high filament voltage, in order to bring new emission material to the surface. It will not work for long and there is the risk of burning the filament wire for good. It may be worth a try, though.

Other wear mechanisms are:

- \* Glass browning (generally only for projection tubes).
- \* Phosphor aging (life time is defined by efficiency < 50%).
- \* Vacuum leaks (generally cause EHT flashover, audible).

Then again, it may also be that for some mysterious reason your VG2 voltage has dropped below spec. A too high VG2 voltage will cause a smaller cathode area to be used, leading to a sharper picture but accelerated cathode wear.

---

## 5.18) Shorts in a CRT

Occasionally, small conductive flakes or whiskers present since the day of

manufacture manage to make their way into a location where they short out adjacent elements in the CRT electron guns. Symptoms may be intermittent or only show up when the TV or monitor is cold or warm or in-between. Some possible locations are listed below:

- \* Heater to cathode (H-K). The cathode for the affected gun will be pulled to the heater (filament) bias voltage - most often 0 V (signal ground). In this case, one color will be full on with retrace lines. Where the heater is biased at some other voltage, other symptoms are possible like reduced brightness and/or contrast for that color. This is probably the most common location for a short to occur.
- \* Cathode to control grid (K-G1). Since the G1 electrodes for all the guns are connected together, this will affect not only the color of the guilty cathode but the others as well. The result may be a very bright overloaded \*negative\* picture with little, none, or messed up colors.
- \* Control grid to screen (G1-G2). Depending on circuitry can result in any degree of washed out or dark picture.
- \* Screen to focus (G2-F). Screen (G2) and focus voltage will be the same and the controls on the flyback will interact. Result will be a fuzzy white raster with retrace lines and little or very low contrast picture. Symptoms will be similar to those of a flyback with breakdown in the focus/screen divider network.
- \* Focus to high voltage (F-HV). High voltage will be pulled down - probably arcing at the focus spark gaps/other protective devices. Line fuse and/or HOT may blow.
- \* Other locations between electron gun elements as feed wires.

Replacing the CRT may be required but there are a variety of 'techniques' that can often be used to salvage a TV that would otherwise end up in the dump since replacing a CRT is rarely cost effective:

1. Isolation - this will usually work for H-K shorts as long as only one gun is involved.
2. Blowing out the short with a capacitor - depending on what is causing the short, this may be successful but will require some experimentation.
3. Placing the CRT (TV or monitor) face down on a soft blanket and gently tapping the neck to dislodge the contamination. Depending on the location of the short, one side or the other might be better as well.

A combination of (2) and (3) may be required for intermittent shorts which don't appear until under power. See the sections below for additional details. However, for shorts involving the focus and high voltage elements, even a sharp edge can result in arcing even if there is no actual short. There is no remedy for these types of faults.

---

## 5.19) Providing isolation for a CRT H-K short

This procedure will substitute a winding of your own for the one that is built in to the flyback to isolate the shorted filament from the ground or voltage reference. Note that if you have a schematic and can determine where to disconnect the ground or voltage reference connection to the filament winding, try this instead.

The flyback is the thing with the fat red wire coming out of it (and perhaps a couple of others going to the CRT board or it is near this component if your set has a separate tripler) and may have a couple of controls for focus and screen. It should have some exposed parts with a ferrite core about 1/2-3/4" diameter.

The filament of the CRT is the internal heater for each gun - it is what glows orange when the set is on. What has happened is that a part of the fine wire of the bad color's filament (assuming this is indeed your problem) has shorted to the cathode - the part that actually emits the electrons. Normally, the heater circuit is grounded or tied to a reference voltage so when it shorts to the cathode, the cathode voltage level is pulled to ground or this reference.

You will need some well insulated wire, fairly thick (say #18-22). Find a spot on the flyback where you can stick this around the core. Wrap two turns around the core and solder to the CRT filament pins after cutting the connections to the original filament source (scribe the traces on the board to break them). Make sure you do not accidentally disconnect anything else.

This winding should cause the filaments to glow about the same brightness as before but now isolated from ground. If they are too dim, put another turn on the flyback to boost the voltage. (Don't go overboard as you may blow the filament totally if you put too many turns on the core - you then toss the TV or monitor.)

Route the wires so that there is no chance of them getting near the high voltage or any sharp metal edges etc. Your picture quality may be a tad lower than it was before because of the added stray capacitance of the filament wiring being attached to the the (formerly bad) video signal, but hey, something is better than nothing.

---

## 5.20) Rescuing a shorted CRT

If the short is filament-cathode (H-K), you don't want to use the following approach since you may blow out the filament in the process. If this is the case, you may be able to float the filament and live with the short (see the document: "[Notes on the Troubleshooting and Repair of Television Sets](#)").

Shorts in the CRT that are between directly accessible electrodes can be dealt with in a more direct way than for H-K shorts. At this point you have nothing to lose. A shorted CRT is not terribly useful.

If the short is between two directly accessible electrodes like cathode-grid,

then as a last resort, you might try zapping it with a charged capacitor.

Unplug the CRT socket!

Start with a relatively small capacitor - say a few uF at a couple hundred volts. Check to see if the short is blown after each zap - few may be needed. Increase the capacitance if you feel lucky but have had little success with the small capacitor.

If the fault is intermittent, you will, of course, need to catch the CRT with the socket disconnected and the short still present. Try some gentle tapping if necessary. If you do this with the charged capacitor across the suspect electrode, you **\*\*will\*\*** know when the short occurs!

---

## 5.21) Determining if your CRT is up to air

"I have a Compuadd monitor that's completely blank. The high voltage is very low and there's flashing inside the neck of the picture tube. I believe there may be a small hairline crack in the neck of the picture tube. I suspect that a crack has compromised the vacuum in the tube and that's what is causing the flashing and the low voltage. Is that possible, and if so, is there anything that can be done other than junking it?"

If there is a crack, then everything else is possible. However, these rarely develop on their own.

Look around the neck of the CRT for a coating - the getter. If it has turned white or red, your CRT is history. If it is still silver, the vacuum is intact and your arcing may be due to a bad flyback putting excessive voltage on the screen or focus electrode or a CRT that is bad in other ways. There are supposed to be external protection spark gaps, etc. for this but may not always work.

Sorry, junking it is probably the only realistic solution. Unless you find a cheap used CRT, the expense is not worth it. Even then, adjustments may be quite involved.

---

## 5.22) Scratches or other damage to the CRT face

It is generally difficult to accidentally scratch the face of the screen but accidents do happen. The way the manufacturer would repair it is to replace the CRT. If the scratch is the result of shipping damage, file a claim with the shipping company. If it is a factory defect, get it repaired or replaced under warranty.

Barely visible scratches can be removed with jeweler's rouge or similar ultra-fine abrasive unless the CRT has an antireflective or textured surface.

Jeweler's rouge is the same stuff that is used in the final polishing of lenses and mirrors so it makes for a fine finish. However, any kind of scratch deep enough to be felt will not yield to this approach.

For larger scratches, one would normally start out with a coarser abrasive like 300 grit and work toward successively finer sizes - 600, 1200, etc. - with the final polishing being done with the rouge. However, realistically, this isn't really a viable approach for a CRT faceplate. It takes a lot of grinding to remove enough material to smooth out a scratch and you are more likely to mess things up than to improve matters.

If the CRT has an antireflective coating or textured surface, it will almost certainly be best to leave the scratch alone. Any type of polishing *\*will\** remove affect the appearance in the vicinity and leave you with a big unsightly blob. This will be much more objectionable than a slight scratch.

The types of fillers sold in auto parts stores for repairing auto windshields may reduce the visibility of any scratches but DO NOT restore the integrity of the glass.

I don't quite know whether this is better or worse than the disease but it might be worth trying:

(From: Cooper@Hub.ofthe.NET).

"I may have come across an easy fix for those who have scratched glass on the monitor face. I am currently using window film as an adhering material to cover and conceal the scratches. This looks much better and enables me to continue usage of the monitor without the aggravating distortion."

---

## 5.23) Risks from CRT scratches?

A really deep long scratch or gouge on the CRT face should be considered a serious safety hazard as it may reduce the structural integrity and increase the risk of implosion. However, you would likely need a hammer and chisel or diamond tipped tool to make scratches that deep. It is very unlikely that such scratches could come from any reasonable normal use. Dropping it from a cliff, deliberate use of a glass cutter, the use of a really really BIG hammer, or 12 gauge shotgun, might perhaps be sufficient.

This is more of a concern for modern CRTs that usually have 'integral implosion protection' - that steel rimband around the outside near the front. Older CRTs used either (1) a separate safety shield - that laminated glass plate in front of your grandmom's TV - or (2) a second contoured glass panel bonded to the actual tube face. In both of these cases, the second panel is protective and cosmetic but is not part of the structure of the CRT. Therefore, any damage to it does not significantly compromise the tube. In the case of modern CRTs, the steel band in conjunction with the basic tube envelope is used to maintain the integrity of the overall CRT. In addition should implosion occur as a result of catastrophic damage, the rimband will reduce the range

and velocity of flying debris.

Also see the section: "[CRT implosion risk?](#)".

BTW, scratches in the CRT have absolutely no effect on X-ray emission. X-rays are blocked long before they come anywhere near the surface and glass has very little effect on their direction. Any scratch deep enough to have any detectable effect on X-ray emission (actually, it would need to be an inch deep gouge) would have caused the tube to implode.

---

## Chapter 6) Items of Interest

---

### 6.1) Information on CRTs

(From: David Moisan (dmoisan@shore.net)).

I've seen a few such pictures and I was fortunate enough to find a book on color CRTs that explained quite a few things:

Color Television Picture Tubes"  
Morell, Law, Ramberg, Harold  
ISBN 0-12-022151-0.

I'm not sure if its still in print but you might check out your local university library.)

If you are lucky enough to see "The Secret Life of Machines" on The Learning Channel (or was, last time I saw it), there's an episode on the secret life of the TV. It's excellent! The creator and presenter, Tim Hunkin, has a weird sense of humor but he's very well informed and quite gifted in the way he demonstrates difficult-to-explain concepts. In the opening scene, he showed off a TV that he sawed in half, showing the CRT construction very clearly. (He must have let the air into the tube, then used a diamond saw to cut it; that's the only way it could be done without glass everywhere!)

(Of course, he may not \*actually\* have cut a TV in half - manufacturers no doubt maintain props of this sort!)

---

### 6.2) CRT aspect ratio

Nearly all modern CRTs have a 4:3 aspect ratio (H:V). Of course, with HDTV, 16:9 will probably become standard but CRTs may be obsolete by then!

(From: Bob Myers (myers@fc.hp.com)).

The physical shape of the tubes themselves came through this evolution, but the aspect ratio assumed for the original transmission format specs WAS 4:3, as driven by Hollywood. Where did you think the shape of the masks came from?

The desired 4:3 aspect ratio standard was known right from the start, and the early TV designers DID realize that the use of round tubes to display this was a literal case of a "square peg in a round hole". Rectangular CRTs for TV use had been developed as early as 1939, with the first American rectangular tube to enter production in late 1949.

(See Peter Keller's very excellent "The Cathode Ray Tube: Technology, History, and Applications" for all the details.)

---

## 6.3) How to read CRT part numbers

More than you ever wanted to know (but still not that useful)!

(From: Jeff Roberts (jroberts@axionet.com)).

The following information comes from the Sencore CR7000 Manual

The tube number is broken down in to 5 parts:

Example: M / 36 / KME / 20 / XX

Part 1 = Tube Type:

A or W = TV picture tube.

M = Monitor tubes (differ in the size and pitch of the phosphor dots).

P = Projection tube.

D = Electrostatic deflection.

Part 2 = Minimum viewable diagonal. Measurement is in cm. (1 inch = 2.54 cm).

Part 3 = Family Number - Tubes Within a particular family have specific mechanical and electrical characteristics.

These letters are assigned alphabetically beginning with "AAA", followed by "AAB", "AAC", etc.

Tubes with the same sequence of letters are identical as far as their setup for the Sencore CR7000.

The letter sequences are grouped according to the country they are manufactured in.

Part 4 = Member of Family - This one or two digit number specifies a

particular member within a family.

A different number is assigned to tubes within the same family that have different neck diameters, for example. Single digit member #s = monochrome, double digit members = Color tubes.

Part 5 = Phosphor Type.

---

## 6.4) CRT substitution

"I have an RCA TV model # f20700dg that has a bad crt #A51ABU14X what I would like to know is can I replace it with a #A51AGC14X."

(From: Tech 7 (gscivi@aol.com)).

Perhaps you need to know why the #'s are different?

The A is for the grade of the tube (AA is all new, B is rebuilt etc), the 51 is size in cm, the ABU is gun type, the 14 is # of elements used (pins), and the X is for phosphor type. Since the gun type is different in your two tubes, I would not spend the time to sub the tube without first check the voltages on the old one, get a schematic of set for new one, compare the parameters and then decide.

---

## 6.5) Why do CRTs use red, green, and blue rather than red, yellow, blue?

So you were taught in grade school that any color could be made up of red, yellow, and blue paint. Why are these not used in CRTs?

Nearly any color that we can perceive can be made from some combination of primary colors. There are two types - additive and subtractive.

RGB are primary additive colors - anything that emits light will use these.

The three types of cone (color) receptors in the retina of the human eye have peaks (roughly) sensitive to these primary colors.

Those red, yellow, and blue primaries you used to create your works of art should actually not have been red, yellow, blue but rather magenta, yellow, cyan - close but no cigar. Red, yellow, and blue are approximations good enough for basic painting or printing but are not capable of reproducing the widest range of colors.

CMY (cyan, magenta, yellow) are subtractive colors. Printing processes and color photography use these because layers of ink or dye absorb light. Basically, each of CMY removes a single color from (RGB).

- \* Cyan = (green+blue) and is the complement of red.
- \* Magenta = (red+blue) and is the complement of green.
- \* Yellow = (red+green) and is the complement of blue.

The phosphors used in CRTs are not necessarily optimal - that is why some monitors or TVs may appear to have better color rendition than others.

---

## 6.6) Why does the intensity appear so non-uniform in bright areas?

Actually, the intensity variation is likely to be even worse than you might think - possibly as much as 2:1 from the center to the corners. In most cases you do not notice it. With large deflection angle tubes, fewer electrons make it to phosphor dots near the edge of the screen. It is simple geometry.

(From: Bob Myers (myers@fc.hp.com)).

It is extremely difficult for any CRT display to maintain perfect brightness and color uniformity across the entire image. Just the geometry of the thing - the change distance from the gun to the screen as the beam is scanned, the changing spot size and shape, etc. - makes this nearly impossible, and there can also be variations in the phosphor screen, the thickness of the faceplate, etc.. Typical brightness-uniformity specs are that the brightness won't drop to less than 70% or so of the center value (usually the brightest spot on the screen).

On color tubes, the lack of perfect brightness uniformity is aggravated by the lack of perfect *color* uniformity and purity. What appear to be "dark spots" on a solid gray image may actually be beam mislanding (color purity) problems, which may to some degree be remedied by degaussing the monitor.

Again, *some* variation is normal; if you think you're seeing too much, you can try degaussing the thing and seeing if that helps. If it doesn't, then the question is whether or not the product meets its published specs, and that is something you'll have to discuss with the manufacturer or distributor.

---

## 6.7) Contrast ratio of CRTs

(From: Don Stauffer (stauffer@htc.honeywell.com)).

Apparently CRTs have made quite an increase lately. Years ago when I looked into it, CRTs were not much better than about 20:1. Now, folks are claiming well over 40:1.

One thing to watch, though. The phosphor has two decay curves, a rapid one followed by a slow one. A change in scene can lower contrast ratio of a bar chart that appears in a region that was a large white area.

(From: Steve Eckhardt (skeckhardt@mmm.com)).

This comment makes me curious about the claims made by manufacturers of video projectors. Visually, their images have lots of resolution but mediocre contrast at large scale. A video monitor looks a lot better in contrast. The manufacturers, however, claim contrast ratios of 100:1 or better.

Are the numbers simply marketing hyperbole or have I missed something interesting?

There are several methods for arriving at the advertised numbers for contrast. One is to simply advertise the number for the imager and ignore the degradation due to the rest of the system. Another is to measure the illuminance of a white screen compared to a black screen. The best way is to use the ANSI method and advertise ANSI contrast, which is the practice at 3M. We really do sell projectors that achieve 100:1 contrast when measured by the ANSI standard. This is, however, a relatively recent achievement. LCD projectors are improving at a rapid rate.

CRT projectors are an alternate technology that I know little about, but they have characteristics that allow them to produce very high localized contrast. This can make displays and projectors based on CRT's look superior to anything an LCD can produce.

(From: Don Stauffer (stauffer@htc.honeywell.com)).

One big problem with LCD displays, projection or otherwise, is view angle. In order to cut off the light completely, polarization needs to be controlled to a couple of degrees. The LCD works by affecting the rotation, so many degrees per unit distance through the crystal. But the total path through the crystal depends on view angle. So max contrast may be only over a small field angle. Now, games can be played with this in projection optics, but it is hard.

---

## 6.8) CRT deflection angle

What does this mean? What is the difference between a 110 degree tube and a 90 degree tube?

This is the maximum angle the beam makes with respect to the gun axis to fill the screen.

\* All other factors being equal, a 110 degree tube is shorter than a 90 degree tube. This is the principle advantage of higher deflection angle CRTs.

\* High deflection angles means higher deflection power for a given accelerating (2nd anode) voltage.

\* Higher deflection angle CRTs are more difficult to converge and maintain focus, purity, and uniform brightness across the screen. Reducing geometric errors is more challenging. Yoke design is also trickier.

In the early days, 60 degrees was considered high tech. 110 degrees is about the practical limit for TV CRTs now. Give me a 90 degree CRT any day. Monitor tubes are usually 90 degrees.

---

## 6.9) About the quality of monitor focus

"I have 2 identical monitors. One is razor sharp from edge to edge. The other is blurred at the corners- not from convergence problems, but just plain out of focus. In this monitor, the focus adjustment on the flyback can improve the focus at the edges, but then the center of the screen becomes worse..My question is : Is this a problem in the electronics and presumably a fixable flaw or is it caused by variance in the picture tube itself and not correctable ? Or is it some other issue?"

(From: Bob Myers (myers@fc.hp.com)).

The adjustment on the flyback sets the "static" focus voltage, which is a DC voltage applied to the focus electrode in the CRT. However, a single fixed focus voltage will not give you the best focus across the whole CRT screen, for the simple reason that the distance from the gun to the screen is different at the screen center than it is in the corners. (The beam SHAPE is basically different in the corners, too, since the beam strikes the screen at an angle there, but that's another story.) To compensate for this, most monitors include at least some form of "dynamic" focus, which varies the focus voltage as the image is scanned. The controls for the dynamic focus adjustment will be located elsewhere in the monitor, and will probably have at LEAST three adjustments which may to some degree interact with one another. Your best bet, short of having a service tech adjust it for you, would be to get the service manual for the unit in question.

It is also possible that the dynamic focus circuitry has failed, leaving only the static focus adjust.

As always, DO NOT attempt any servicing of a CRT display unless you are familiar with the correct procedures for SAFELY working on high-voltage equipment. The voltages in even the smallest CRT monitor can be lethal.

---

## 6.10) Comments on color purity, set orientation, and doming

"The problem with my TV is that bright parts of the picture change color. For example, white areas may shift towards yellow or blue depending on the

orientation of the set.

What are the possible causes of doming? I have noticed that the magnitude of the doming effect varies with TV orientation even after degaussing several times at the new orientation. Does this help identify the cause of the doming in my case?"

(Portions from: Jeroen Stessen (Jeroen.Stessen@ehv.ce.philips.com)).

The problem with regular shadow masks is 'doming'. Due to the inherent principle of shadow masks, 2/3 or more of all beam energy is dissipated in the mask. Where static bright objects are displayed, it heats up several hundred degrees. This causes thermal expansion, with local warping of the mask. The holes in the mask move to a different place and the projections of the electron beams will land on the wrong colours: purity errors. The use of invar allows about 3 times more beam current for the same purity errors.

Both local doming and magnetic fields compete for the remaining landing reserve. Due to improper degaussing, the doming problem may be more visible. And applying a tube designed for the wrong hemisphere may very well increase the doming complaints. It is possible to deliberately offset the nominal landing in order to get more doming reserve (the shift due to doming is always to the outside of the tube). You would do this using spoiler magnets put in the right places.

Permanently setting the contrast lower is not a real cure because the customer might not like such a dark picture. A better picture tube (Invar shadow mask) *is* a good cure (in most cases) but there is the cost price increase. (This is mainly due to the fact that Invar metal is harder to etch.)

Also see the section: "[What is doming?](#)".

---

## 6.11) Difference in color rendition between CRTs

(From: Jeroen H. Stessen (Jeroen.Stessen@ehv.ce.philips.com)).

There can be several reasons why primary colours (especially red) may look different between picture tube brands:

1. Different phosphor composition. In the beginning everybody was looking for the phosphors with the highest luminous efficiency. Nowadays with the trend to avoid heavy metals, particularly cadmium, in consumer products the composition had to be changed. This shifts the colour point.
2. Back scattering. Not all electrons that hit the shadow mask are absorbed. In fact, a quite high percentage is scattered back into the empty space between gun and mask. If they bounce back again from internal metal parts, then they may find their way to the screen and activate an arbitrary phosphor element. This increases the black level and reduces saturation of the primary colours. Red turns a bit towards orange. Even with good phosphors, large area colours will be less than perfect.

Triple-CRT projection TVs do not have this problem, fantastic red!

3. Colour filters. Toshiba has developed a process where they put individual colour filters between glass and phosphor. This makes the black much better and also improves the colour points when unwanted spectral lines are suppressed.
  4. There can also be differences with respect to the NTSC system, like wrong matrix from YUV to RGB. The definition in the Japanese NTSC system differs from the USA NTSC system and the signal processing should take that into account.
- 

## 6.12) Purple blob - or worse

Have you tried demagnetizing it? Try powering it off for a half hour, then on. Repeat a couple of times. This should activate the internal degausser. See the section: "[Degaussing \(demagnetizing\) a CRT](#)".

Is there any chance that someone waved a magnet near the tube? Remove it and/or move any items like monster speakers away from the set.

Was your kid experimenting with nuclear explosives - an EMP would magnetize the CRT. Nearby lightning strikes may have a similar effect.

If demagnetizing does not help, then it is possible that something shifted on the CRT - there are a variety of little magnets that are stuck on at the time of manufacture to adjust purity. There are also service adjustments but it is unlikely (though not impossible) that these would have shifted suddenly. This may be a task for a service shop but you can try your hand at it if you get the Sams' Photofact or service manual - don't attempt purity adjustments without one.

If the monitor or TV was dropped, then the internal shadow mask of the CRT may have become distorted or popped loose and you now have a hundred pound paper weight. If the discoloration is slight, some carefully placed 'refrigerator' magnets around the periphery of the tube might help. See the section: "[Magnet fix for purity problems - if duct tape works, use it!](#)".

It is even possible that this is a 'feature' complements of the manufacturer. If certain components like transformers and loudspeakers are of inferior design and/or are located too close to the CRT, they could have an effect on purity. Even if you did not notice the problem when the set was new, it might always have been marginal and now a discoloration is visible due to slight changes or movement of components over time.

---

## 6.13) Magnet fix for purity problems - if duct tape works, use it!

The approach below will work for slight discoloration that cannot be eliminated through degaussing. However, performing the standard purity adjustments would be the preferred solution. On the other hand, the magnets may be quick and easy. And, where CRT has suffered internal distortion or dislocation of the shadow mask, adjustments may not be enough.

In any case, first, relocate those megablaster loudspeakers and that MRI scanner with the superconducting magnets.

The addition of some moderate strength magnets carefully placed to reduce or eliminate purity problems due to a distorted or dislocated shadow mask may be enough to make the TV usable - if not perfect. The type of magnets you want are sold as 'refrigerator magnets' and the like for sticking up notes on steel surfaces. These will be made of ferrite material (without any steel) and will be disks or rectangles. Experiment with placement using masking tape to hold them in place temporarily. Degauss periodically to evaluate the status of your efforts. Then, make the 'repair' permanent using duct tape or silicone sealer or other household adhesive.

Depending on the severity of the purity problem, you may need quite a few magnets! However, don't get carried away and use BIG speaker or magnetron magnets - you will make the problems worse.

Also note that unless the magnets are placed near the front of the CRT, very significant geometric distortion of the picture will occur - which may be a cure worse than the disease.

WARNING: Don't get carried away while positioning the magnets - you will be near some pretty nasty voltages!

(From: Mr. Caldwell (jcaldwel@iquest.net)).

I ended up with the old 'stuck on a desert island trick':

I duck taped 2 Radio Shack magnets on the case, in such a way as to pull the beam back!!!!

A \$2 solution to a \$200 problem. My friend is happy as heck.

RCA sells magnets to correct corner convergence, they are shaped like chevrons and you stick them in the 'right' spot on the rear of the CRT.

---

## 6.14) Contour lines on high resolution monitors - Moire

These fall into the category of wavy lines, contour lines, or light and dark bands even in areas of constant brightness. These may be almost as fine as the dot pitch on the CRT or 1 or 2 cm or larger and changing across the screen. If they are more or less fixed on the screen and stable, then they are not likely to be outside interference or internal power supply problems. (However, if the patterns are locked to the image, then there

could be a problem with the video board.)

One cause of these lines is moire (interference patterns) between the raster and the dot structure of the CRT. Ironically, the better the focus on the tube, the worse this is likely to be. Trinitrons, which do not have a vertical dot structure should be immune to interference of this sort from the raster lines (but not from the horizontal pixel structure).

You can test for moire by slowly adjusting the vertical size. If it is moire, you should see the pattern change in location and spatial frequency as slight changes are made to size. Changes to vertical position will move the patterns without altering their structure - but they will not remain locked to the moving image.

If they are due to the raster line structure - your focus is too good - the patterns will remain essentially fixed in position on the face of the CRT for horizontal size and position adjustments - the patterns will remain fixed under the changing image.

How to eliminate it? If moire is your problem, then there may be no easy answer. For a given resolution and size, it will either be a problem or not. You can try changing size and resolution - moire is a function of geometry. Ironically, I have a monitor which is nicer in this respect at 1024x768 interlaced than at 800x600 non-interlaced.

Some monitors have a 'Moire Reduction Mode' switch, control, or mode. This may or may not be of help. One way to do this is - you guessed it - reduce the sharpness of the beam spot and make the picture fuzzier! You might find the cure worse than the disease.

Another cause of similar problems is bad video cable termination creating reflections and ghosting which under certain conditions can be so severe as to mimic Moire effects. This is unlikely to occur in all colors with a VGA display since the termination is internal to the monitor and individual resistors are used for each color (RGB).

I think it is ironic that some people will end up returning otherwise superb monitors because of moire - when in many cases this is an indication of most excellent focus - something many people strive for! You can always get rid of it - the converse is not necessarily true!

---

## 6.15) Moire and shadow mask dot pitch

(From: myers@fc.hp.com (Bob Myers)).

The density of the holes in the shadow mask set an upper limit on the resolution supported by that monitor. Lower resolutions work just fine; there is no need to have the logical pixels in the image line up with the physical holes in the mask (nor is there any mechanism to make this happen), and so you can think of this as the "larger pixels" of the lower-res image simply covering more than one hole or slot in the mask.

As the effective size of the pixels in the image approach the spacing of the mask holes, individual pixels are no longer guaranteed to cover enough phosphor dots on the screen to ensure that they are constant color or constant luminance, but an image will still be displayed which ON AVERAGE (over a reasonably large area) looks OK. Actually, the specified "top end" format ("resolution") for most monitors usually is at or slightly beyond this point - the effective pixel size is somewhat UNDER the dot pitch.

---

## 6.16) Isolated spots on display

These could be a problem with the video source - bad pixels in the video card's frame buffer or bad spots on a camcorder's CCD, for example. Or, they could be dirt or dead phosphor areas in the CRT. Except for problems with the on-screen character generator, it is unlikely that the monitor's circuitry would be generating isolated spots.

You can easily distinguish between video problems and CRT problems - missing pixels due to the video source will move on the screen as you change raster position. CRT defects will remain stationary relative to the screen and will generally be much more sharply delineated as well.

There is a specification for the number and size of acceptable CRT blemishes so you may have to whine a bit to convince the vendor to provide a replacement monitor under warranty.

---

## 6.17) Disposing of dead TVs or monitors (CRTs and charged HV capacitors)

I don't know what the law says, but for safety, here is my recommendation:

Treat the CRT with respect - the implosion hazard should not be minimized. A large CRT will have over 10 tons of air pressure attempting to crush it. Wear eye protection whenever dealing with the CRT. Handle the CRT by the front - not the neck or thin funnel shaped envelope. Don't just toss it in the garbage - it is a significant hazard. The vacuum can be safely released (Let out? Sucked in? What does one do with an unwanted vacuum?) without spectacular effects by breaking the glass seal in the center of the CRT socket (may be hidden by the indexing plastic of the socket). Cover the entire CRT with a heavy blanket when doing this for additional protection. Once the vacuum is gone, it is just a big glass bottle though there may be some moderately hazardous materials in the phosphor coatings and of course, the glass and shadow mask will have many sharp edges if it is broken.

In addition, there could be a nice surprise awaiting anyone disconnecting the high voltage wire - that CRT capacitance can hold a charge for quite a while. Since it is being scrapped, a screwdriver under the suction cap HV connector

should suffice.

The main power supply filter caps should have discharged on their own after any reasonable length of time (measured in terms of minutes, not days or years).

Of course around here, TVs and monitors (well, wishful thinking as I have yet to see a decent monitor on the curb) are just tossed intact which is fortunate for scavengers like me who would not be happy at all with pre-safed equipment of this type!

(From: Jeroen Stessen (Jeroen.Stessen@ehv.ce.philips.com)).

We have a procedure for disposing of used CRT's. The vacuum must be broken to avoid future implosion, like when it will be crushed by the dumpster truck press. That's NOT funny! One method is to punch or drill a small hole in the anode contact, which is made of a soft metal. But take care of the electrical discharge of the aquadag capacitance first!!!

The other method is to break the stem in the centre of the socket pins. This is the stem through which the tube was pumped empty during manufacturing. It breaks off easily (after you have removed the plastic part around the pins).

You want to avoid making too large holes, like for example from chopping off the entire neck in one blow with a hammer.

---

## 6.18) CRT implosion risk?

Also see the section: "[Disposing of dead TVs or monitors \(CRTs and charged HV capacitors\)](#)".

(From: Jeroen Stessen (Jeroen.Stessen@ehv.ce.philips.com)).

I have checked with our CRT expert and he thinks that any 'normal' type of scratch does not pose any danger. Usual disclaimer applies ... (what is 'normal'?)

The front of the tube is much thicker and stronger than the rear. It has to be, to withstand the air pressure, because the curvature radius is so much larger. You won't break it by throwing a slipper at it. The neck is in fact very easy to break, usually without causing injuries to anyone.

Normally, if the tube should implode, the rimband (the tensioned steel band around the rim of all modern CRTs of any size) prevents the glass from flying outward too far. Every tube type has to pass tests in which it is deliberately imploded and it is checked whether any large shrapnel flies too far out.

What *is* very dangerous is a CRT with its rimband missing, or a CRT which never had a decent rimband in the first place (like some dubious Russian-made samples we once saw). Such a tube should not be handled at all. NEVER ever attempt to remove the rimband for any reason!

I just saw a picture tube that was broken due to dropping the (entire) TV on one corner. In the cone (the backside) there are open cracks of some 3 feet length in total. Nevertheless all the glass is still in its original place and it looks as if no glass has flown outward. The faceplate is still intact. So in this case nobody would have got hurt. I remember reading about Americans (who else?) who tried to shoot CRT's with smaller rifles, with little or no success.

Does this comfort you? Get out the shotgun and have a go at it!

Or, perhaps, the following:

(From: Ren Tescher (ren@rap.ucar.edu)).

Our 6 month old 20" SGI color monitor (model GDM-20D11) lost a fight with a fork lift. The case is intact, the CRT probably still has a vacuum, but the outer layer of glass on the screen is shattered.

---

## 6.19) Purpose of a separate CRT faceplate

The surface of the screen you see is most often part of the CRT envelope. In this case, there should be a tensioned steel band - a rimband - around the edge of the CRT near the front. The rimband is essential to assure the structural integrity of the CRT envelope against the immense forces due to the air pressure attempting to crush it. In the event of a catastrophic event, the rimband will also reduce the range and velocity of any debris. This is called 'integral implosion protection' by some manufacturers.

Warning: A CRT that is supposed to have a rimband but where it is missing or damaged is a serious hazard since the possibility of implosion is greatly increased and the effects of such an implosion will be more severe. However, such a situation is virtually impossible to occur on its own since the rimband is part of the mounting bracket assembly. Don't be tempted to remove the rimband for any reason!

In some cases, there will be a separate faceplate. Older TVs usually had either a totally separate laminated glass plate in front of the CRT or a contoured glass panel bonded (glued) to the CRT itself. Part of its purpose is protective. It would prevent damage to the CRT in the event of a blow from a thrown object like an ashtray or shoe! In addition, it would contain the debris in the unlikely event of an implosion resulting from some really catastrophic event.

However, the separate or bonded glass plate can also be used for cosmetic purposes to:

- \* Improve contrast in a bright light by using a tinted glass.
- \* Reduce reflection by using an anti-reflection coating.
- \* Iron out the bumps by using a glass plate smoother than the CRT.

- \* Give the impression of a flatter display by using a glass plate with a larger radius of curvature than the CRT itself.
  - \* Give the impression of a Sony Trinitron by using a cylindrical (plastic) plate in front of a real-flat rear-projection screen.
- 

## 6.20) Picture tube disassembly for demonstration purposes

"I am interested in using a dead CRT for a display at our science center on how things work and know about the safety issues. Also, I would really like to cut one (or parts of one) open, so it would be great to know what other things to worry about or what tools to use."

(Portions from: Jeroen H. Stessen (Jeroen.Stessen@ehv.ce.philips.com)).

Back in the TV-lab we have an unassembled picture tube for that purpose. Most convenient!

- \* First, make sure that the electrical capacitance of the CRT is properly discharged. Pull the mains plug. Connect a wire to the outer aquadag. Then push it under the anode cap and make a good short-circuit. Remove the anode cap and EHT wire.
- \* Next you want to break the vacuum. This is my preferred method:
  - Use a sharp object or a drill to punch a small hole in the anode contact. It's made of really soft metal, probably copper. It takes several minutes for the air to fill the entire tube. In the mean time you can have some fun putting your finger over the hole. No, that's not harmful.
  - The other way to break the vacuum is via the thin tube that was used to pump the air out of the tube. That is located in the middle of the socket at the end of the neck. Remove the plastic part around the pins and break the little tube by hitting it with e.g. the tip of a screwdriver (+hammer). If you score it with a fine triangular file, it will crack off cleanly.

I like this method less, for fear of breaking too much glass.

- \* You might also want to cut off the neck for easier manipulation and study of the electron gun parts. Use a glass cutting saw if one is available. Else, score totally around the neck with a fine triangular file or glass cutter and then it should snap fairly cleanly.

Don't just chop off the neck - especially if you have not released the vacuum. Aside from the danger of flying bits of glass, you get a very characteristic dirty spot on the front of the screen, it looks as if the phosphor layer has been blown away from the faceplate by the strong inrush of air. Or maybe it was the shadow mask being blown against the faceplate. Very tell-tale and spoils your nice display.

- \* The deflection coils (and purity/convergence magnet assembly, if used) are also easily removed. Loosen the clamps and twist and slide them off of the

neck. It's best to find an old tube where the coils have not been potted (against the noise they tend to make). Then you can see them very well.

\* The difficult part will be to cut the connection between faceplate and funnel. Normally the two parts are glued together. I think it will require a glass cutting saw to get the tube open again.

You want to separate it just behind the faceplate or else there will not be enough space to grab and remove the shadow mask. That's just clicked into place, very easy to unclick.

"I would assume the phosphors are a problem... Any things I need to know about chemical hazards?"

Old tubes had environmentally unfriendly phosphors, containing heavy metals such as cadmium and some rare earths. Nothing immediately toxic but the long-term effects are not healthy either. Modern tubes should at least have cadmium-free phosphor. But the phosphor is covered with a metal layer, so normally it would not even be exposed. Just don't touch it.

"Or that we would need to bond a cover over the exposed interior components both for safety and to keep them intact?"

Obviously, you will want to prevent the curious from being injured by sharp metal parts but nothing will fall apart (assuming your original disassembly was not overly violent). The internal magnetic screen is attached to the shadow mask, which is clicked into metal parts at the face plate. The whole assembly removes easily.

Have fun, this is going to be a wonderful demonstration of a very practical application of some heavy \*physics\*.

---

## **6.21) Picture tube implosion - but your really need to work at it!**

As noted elsewhere in this document, picture tube implosion is a hazard but under normal conditions, quite unlikely.

(From: Dan Evens (dan.evens@hydro.on.ca)).

In high school, our electronics teacher did a demo for each class. He saved out an old black-and-white tube for each class and set up a place to break it. Put the tube on the ground by a brick wall, with a hammer suspended on a wire from the top of the wall. Did it on the driveway so that the glass would be easier to pick up. The tube was placed image-side down.

First he pulled the hammer back about 20 feet and just let it go. It bounced off the tube. This was to show that such tubes are pretty tough. Then he pulled the hammer back and gave it a pretty good shove, turning his back to the tube and moving quickly away from it. (Let's face it, the guy could probably have found a safer way to do this.)

Palm sized chunks of glass flew 50 feet. The noise was quite impressive. The thickness of the image plate of the tube was also quite impressive. Kind of looked like a porthole on a submarine. This was from the tube of a small black-and-white TV, about 14 inches or so. One of the larger colour models might be a LOT more violent.

If I was handling these things in such a way as to have the possibility of dropping one, I'd insist on body armor and face protection. And if it involves a picture tube, I insist on competent trained professionals for service.

---

## 6.22) Lifespans of Monitors

(From: Bob Myers (myers@fc.hp.com)).

Most manufacturers will quote an MTBF (Mean Time Before Failure) of somewhere in the 30,000 to 60,000 hour range, EXCLUSIVE OF the CRT. The typical CRT, without an extended-life cathode, is usually good for 10,000 to 15,000 hours before it reaches half of its initial brightness. Note that, if you leave your monitor on all the time, a year is just about 8,000 hours.

The only 'tune-up' that a monitor should need, exclusive of adjustments needed following replacement of a failed component, would be video amplifier and/or CRT biasing adjustments to compensate for the aging of the tube. These are usually done only if you're using the thing in an application where exact color/brightness matching is important. Regular degaussing of the unit may be needed, of course, but I'm not considering that a tune-up or adjustment.

---

## 6.23) Monitor life, energy conservation, and laziness

A common misconception about the care and feeding of computer monitors is that they should be left on all the time. While there are some advantages to this, there are many more disadvantages:

1. CRT Life: The life of a monitor is determined by the life of the CRT. The CRT is by far the most expensive single part and it is usually not worth repairing a monitor in which the CRT requires replacement. The brightness half-life of a CRT is usually about 10-15 K hours of on time independent of what is being displayed on the screen. 10 K hours is only a little more than a year. By not turning the monitor off at night, you are reducing the life of the monitor by a factor of 2-3. Screen savers do not make any substantial difference especially with modern displays using X-Windows or MS Windows where the screen layout is not fixed. With video display terminals, the text always came up in the

same position and eventually burned impressions into the screen phosphor.

2. Component life: The heat generated inside a monitor tends to dry out parts like electrolytic capacitors thus shortening their life. These effects are particularly severe at night during the summer when the air conditioning may be off but it is still a consideration year around.
3. Safety: While electronic equipment designed and manufactured in accordance with the National Electrical Codes is very safe, there is always a small risk of catastrophic failure resulting in a fire. With no one around, even with sprinklers and smoke alarms, such an failure could be much more disasterous.
4. Energy use: While modern monitors use a lot less energy than their older cousins, the aggregate energy usage is not something to be ignored. A typical monitor uses between 60 and 200 Watts. Thus at a \$.10 per KWH electric rate such a monitor will cost between \$48 and \$160 a year for electricity. During the night, 1/2 to 2/3 of this is wasted for every monitor that is left on. If air conditioning is on during the night, then there is the additional energy usage needed to remove this heat as well - probably about half the cost of the electricity to run the monitor.

The popular rationalization for what is most often just laziness is that power-on is a stressful time for any electronic device and reducing the number of power cycles will prolong the life of the monitor. With a properly designed monitor, this is rarely an issue. Can you recall the last time a monitor blew up when it was turned on? The other argument, which has more basis in reality is that the thermal cycling resulting from turning a monitor on and off will shorten its life. It is true that such thermal stress can contribute to various kinds of failures due to bad solder connections. However, these can be easily repaired and do not effect the monitor's heart - the CRT. You wouldn't leave your TV on 24 hours a day, would you?

Also see the section: "[Thernal cycling and component life](#)".

Some of the newest ('green') monitors have energy conserving capabilities. However, it is necessary for the software to trigger these power reduction or power down modes. Few monitors in actual use and fewer workstations or PCs are set up to support these features. If you have such a monitor and computer to support it, by all means set up the necessary power off/power down timers. However, using the power saving modes of a 'green' PC with an older monitor can potentially cause damage since some of the modes disable the sync signals. A 'green' monitor which can detect a blank screen and use this as a trigger can easily be used with a screen saver which can be set to display a blank screen - on any PC or workstation.

Even if the monitor does not support power saving modes, a blank screen or dark picture will reduce stress on the CRT and power supply. Electronic components will run cooler and last longer.

Please make it a habit to turn your monitors off at night. This will extend the life of the monitor (and your investment) and is good for the environment as well. For workstations, there are good reasons to leave the system unit on all the time. However, the monitor should be turned off using its power switch. For PCs, my recommendation is that the entire unit be turned off at

night since the boot process is very quick and PCs are generally not required to be accessible over a network 24 hours a day.

---

## 6.24) Thermal cycling and component life

(From: Bob Myers (myers@fc.hp.com)).

In a CRT monitor, the shortest-lived component BY FAR is the CRT itself, and it ages (more properly, the cathode is aging) as long as the heater is on and the tube is under bias. Most monitors don't get around to turning the heater down or off until they enter the DPMS "suspend" or "off" modes. (And no, screen-savers do NOT help here - the tube is still on and the cathode is aging.)

Other factors - simply having the circuits hot and powered up in general means that they're aging. Clearly, they're NOT aging when they're off. This needs to be balanced against the thermal-cycling sort of stresses that you mention which happen during power cycling, and this is why I recommend shutting off only when you're going to be away for an extended period, such as overnight. This is, of course, most important for those components which have clear heat-related aging, but most do to some extent. Esp. vulnerable are things like electrolytic caps, for obvious reasons.

The bottom line is that nothing is ever going to last forever, and trying to maximize the life of the product is an exercise in making tradeoffs between various aging/failure mechanisms.

---

## 6.25) Why are prices of video monitors so high compared to similarly sized TVs?

How come I can buy a 32" Sony Trinitron TV set for \$800, but when it comes to buying a monitor for my PC, \$1400 only gets me a no-name 20" tube?

Why can't a giant like Sony produce a PC monitor anywhere close in cost to an equivalently sized TV set?

(Some of this from: Mike Stewart (mstewart@whale.st.usm.edu)).

There are several significant factors being overlooked here:

1. Economy of scale. There are still \*many\* more TV sets being sold than computer monitors. Manufacturers order TV chipsets in much larger quantities. This drives down the price.
2. Resolution. NTSC TV signals aren't even VGA resolution. Try getting that 32" Sony Trinitron XBR to give you 1280x1024. A computer monitor has a

CRT with a resolution about 2 to 3 times that of a TV of similar size in both horizontal and vertical directions. The beam is also more sharply focused.

3. Refresh rates. NTSC TV signals come at one refresh rate, period. You either watch broadcast NTSC at 59.94Hz (interlaced), or you don't watch it at all. No nice, clean 72Hz NI display on there. (NOTE: This only refers to the 99+% of TV playback equipment that contains no line-doubling circuitry. That's fair, as you'll pay a good bit more for a non-interlaced, line-doubled NTSC picture than the previous poster was complaining about, anyway.)

Therefore, a auto-scan monitor needs more sophisticated deflection and power supply circuitry. It must run at much higher scan rates and this complicates the circuitry as well.

5. Geometry. The precision of a good computer monitor is much greater than any TV. The sides will be parallel and square. Adjustments are provided to eliminate pincushion, keystone, and trapezoid distortions.
6. Stability. The image on a high quality computer monitor is rock solid and does not shift position or change size as components warm up, or the power line voltage fluctuates, etc.

---

## 6.26) Problems with designing a combination TV and computer monitor

(The following is from: Bob Myers (myers@fc.hp.com)).

It's possible, and has been done (for instance, Toshiba has one product and offerings from other companies are available or are on the way). But such designs ARE compromises, and won't give the best performance possible in either application.

There is a fundamental difference between CRTs designed for TV use, and those used in computer monitors. It's a brightness/resolution tradeoff - TV tubes are run about 3X or so the brightness of a typical computer monitor, but sacrifice the ability to use small spot sizes and fine dot pitches to do this. You don't see very many color tubes running at 100 - 150 fL brightness and still using an 0.28 mm pitch!

---

## 6.27) CRT replacement worth it?

The sad fact is that even if you can obtain a new CRT you won't have the proper set up for getting proper alignment and convergence. They generally use various permanent magnet glued to the perimeter of the yoke to set the geometry of the

raster. It takes a special factory jig to do this step or really great persistence and patience. However, if you have the time and will resist punching a hole in the new CRT before you finish, by all means.

Also, consider the cost of a new CRT may be more than half the cost of the monitor when it was new.

Replacing a monochrome CRT is a snap in comparison.

A better (or at least less stressful) approach is to locate a monitor that died due to a circuit problem and salvage the CRT including the yoke and all the other magical magnets and coils.

(From: Andy Cuffe (baltimora@psu.edu)).

I have found that most 15" monitors use compatible CRTs. I just put the CRT from an old Gateway2000 with analog controls into a nice 2 year old monitor. As long as the yokes and CRT sockets are similar it should work fine. Don't try to swap the yokes or you will never get it converged.

---

## 6.28) Rebuilt CRTs

(From: B. K. Richardson (rchvid7@flash.net)).

Try Hawkeye. They have been giving us good service for at least 15 years. Their rebuilds are covered by warranty.

\* Hawk-Eye Picture Tube Mfg., Inc.  
724 Scott Avenue, Des Moines, IA. 50309-5052  
Phone: 515-288-8567  
Fax: 515-288-8568

Suppliers of standard & high resolution color and monochrome picture tubes.

---

## 6.29) Shipping damage why monitors are like basketballs

(From: Stephen Swann (swann@panix.com)).

Monitors are more prone to shipping damage than most other computer components, and it doesn't help that they typically pass through several people's hands (several stages of shipping) before they get to you: factory -> distribution center -> vendor -> you.

And from what I've seen first hand of shipping practices (I put in a couple of months working in a distribution warehouse during college), you can safely assume that each stage of shipping is roughly the equivalent of your monitor being dropped down a flight of stairs.

You wouldn't \*believe\* the abuse that UPS and FedEx can subject packages to. In fact, putting a \*FRAGILE\* sign on the side of the box is about the equivalent of writing "KICK ME" on it. I remember receiving packages marked "FRAGILE" where the (originally cubical) cardboard boxes had been smashed into shapeless cardboard "bags", and it took us 20 minutes to figure out what the contents of the box had originally been. ("What are all these shards?" "I think it was some kind of vase" "No, it was some kind of lamp." "Where's the bulb socket, then?" "How about this squashed piece of aluminum?" "Yeah, you're right, but where's the cord then?" etc). :-) Shipping guys would think nothing of dropping "fragile" boxes from waist-high onto a concrete floor - safe in the knowledge that the package had passed through so many hands that the damage could never possibly be traced back to them. "Blameless is Guiltless" should be the motto of these folks.

Basically, what I'm saying is that if 1 monitor in 3 arrives arrives in workable condition, you should be surprised that even that one monitor survived.

---

## 6.30) What is Aquadag?

You may see the term 'Aquadag' referring the the black paint covering the outside of most of the funnel section of the CRT.

(From: Nicholas Bodley (nbodley@tiac.net)).

Aquadag used to be a trademark of Acheson Colloids [Corp.?], I think around Niagara Falls or Buffalo, NY. It was one of many "-dag" colloidal graphites; they also made Oildag, Gredag (grease), and Alcoholdag, as I recall. Unfortunately, it's probably sold in 55-gallon drums minimum. I hope you can find smaller quantities. Are there any CRT rebuild shops around the USA? See the Thomas Catalog (ThomCat) in a library to find Acheson.

I am pretty sure there's nothing magic about the graphite. If you can find some reasonably-priced nickel-flake or copper-flake paint (be sure it's conductive!), you might have an affordable (?) coating. How about plain metal foil, maybe even ordinary aluminum foil? You surely don't need current-carrying capacity; you would need a decent adhesive, though. How to make sure you have continuity between pieces, I'm not so sure; shoot for really tight crimps that deform the metal and are gas-tight. (This might, however, be quite unnecessary.)

---

## 6.31) Additional information on discharging CRTs

You may hear that it is only safe to discharge from the Ultor to the Dag. So, what the @\$% are they talking about? :-).

(From: Asimov (mike.ross@juxta.mnet.pubnix.ten)).

'Dag' is short for Aquadag. It is a type of paint made of a graphite pigment which is conductive. It is painted onto the inside and outside of picture tubes to form the 2 plates of a high voltage filter capacitor using the glass in between as dielectric. This capacitor is between .005uF and .01uF in value. This seems like very little capacity but it can store a substantial charge with 25,000 volts applied.

The outside "dag" is always connected to the circuit chassis ground via a series of springs, clips, and wires around the picture tube. The high voltage or "Ultor" terminal must be discharged to chassis ground before working on the circuit especially with older TV's which didn't use a voltage divider to derive the focus potential or newer TV's with a defective open divider.

---

## 6.32) What does it take to be a picture tube rebuilder, really?

(From: Charles Godard (cgodard@iamerica.net)).

Back in the late 50's A Tech friend of mine built a picture tube rebuilding plant from scratch. He made a living with it for a few years selling rebuilt b&w tubes. Everybody around said he sold the best rebuilt tubes that you could get. He said the secret was in the good vacuum pump and that he used and the amount of time that he pumped down the tube.

He always said that a tube could be made to last practically forever if you could get a high enough vacuum on it. The only real money he put into his plant was in the pump.

A few years ago he retired and brought the whole thing down to my shop for storage. It was a marvel to behold. The cooker was an old upright deep freeze with a pyrex pie plate for a window. The lathe where he welded the tube necks onto the tube was built of scraps of angle iron with a washing machine motor. The device that he used to cut the necks off of the tube was a model railroad controller with a homemade foot pedal and a couple of whittled down broomsticks with metal tips shaped so that you could easily fold the nichrome wire around the tube neck. He said it was the only transformer he could find, at the time, that would hold up to heat the wire hot enough to cut the neck off of the tube. It was very low voltage but would supply hi current.

He said he had the most trouble when designing the inductance heater but finally got it built with the help of a local genius who had built one of our local TV station's nearly from scratch back in the 50's.

In addition to the tube plant, he also designed and got a patent on a cotton picker. I've got a copy of his patent on display in my shop. Some of us only half believed him for years, when he said he had the patent, but when he died,

we searched the shop and found his patent papers hidden away in a file cabinet of old Sams Photofacts.

We found the contract where he sold the rights to build and market the picker for a \$500 per picker royalty. The guy he sold it to took the patent and went to a nearby state, borrowed \$200,000 from the bank with the Patent as collateral then skipped the country. My friend never got anything from his invention, and some of his design ideas were later stolen and incorporated into some one of the big name picker manufacture's products.

Those old guys were something else. They could start with a few old scraps and build something worthwhile and useful.

Speaking of patent's, I've also seen the original patent for the hinges RCA used to hold up the tops on the old console stereo's. I made a service call a few years ago, and the guy's widow showed me the patent and his original prototype hinges. The only thing is, they took the idea from the patent and redesigned it so they wouldn't have to pay our local guy for the hinges. RCA's redesign didn't work as well as his original, but was recognizable as his original with only a couple of changes. RCA 'did him' about the same way they 'did' Philo Farnsworth.

When I get a slack spell, I'll try the inductance heater to see if it still works. If it does, I try it on the tubes and let you know. I believe you called it a Tesla coil?

WARNING: Read, understand, and follow the recommendations in the document: "[Safety Guidelines for High Voltage and/or Line Powered Equipment](#)" before attempting any TV or monitor repairs.

---

## 2.2) Scope of this document

TVs and most computer and video monitors depend on the use of similar (at least in concept) circuit configurations to generate several outputs:

- \* Current waveform required in the deflection yoke coils of the CRT for linear sweep of the electron beam to create a high quality (geometry and linearity) picture. This is close to a sawtooth but not quite.
- \* CRT High voltage (20 to 30 KV or more) required to accelerate the electron beam and provide high brightness and sharp focus, as well as other related voltages - focus and screen (G2).
- \* Various auxiliary power and signals for other subsystems of the equipment (low voltage, CRT filament, feedback, etc.).

This document addresses the basic principles of operation of these types of deflection systems. While most people with any familiarity with TV or monitor operation or repair have some vague idea of how these circuits work (probably just enough to be dangerous), many are incorrect or at least very incomplete.

Most of this information applies to the horizontal deflection which operates at the higher frequency in a raster scan display (except for peculiar rotated portrait formats where the functions of the horizontal and vertical scan are interchanged).

Equipment which utilizes this circuitry includes TV (direct view as well 3-CRT and light valve projection types), computer and video monitors, tube based video cameras (e.g., vidicon), and other magnetically deflected CRT devices.

Vertical deflection circuits are much less complex due to the lower scan rate (e.g., 50 to 120 Hz V as compared to 15.734 KHz H for an NTSC TV or up to 120 KHz or more for a high resolution computer monitor). Most of the control and output drive circuitry is contained in a special vertical chip in modern equipment.

---

## **Chapter 3) Horizontal Deflection System Fundamentals**

---

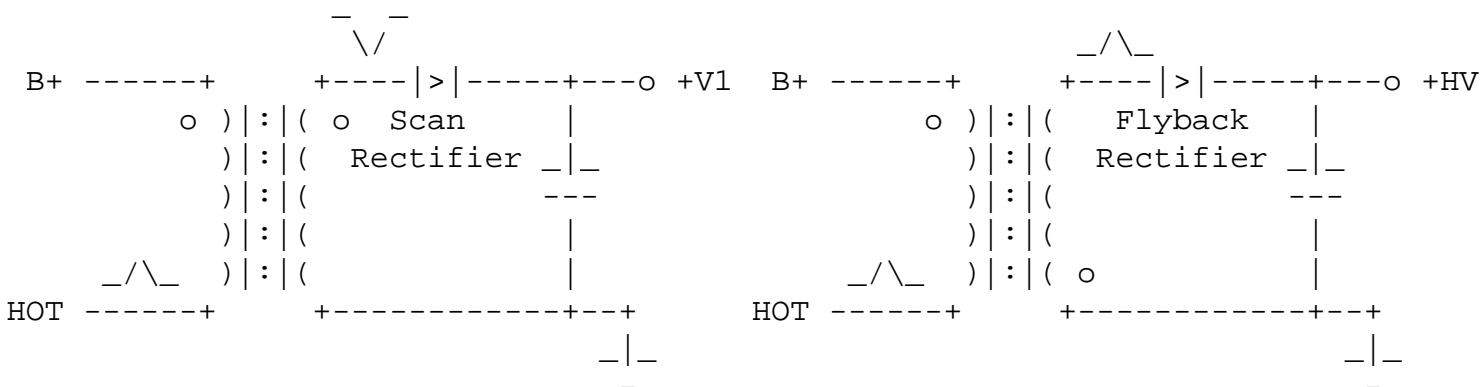

### **3.1) How does the horizontal deflection circuit work?**

Although there are many variations, the basic operation of the horizontal deflection/high voltage power supplies in most TVs, monitors, and other CRT

displays is very similar.

Since the flyback is constructed with an air gap in the core, it behaves more like an inductor than a transformer as far as the primary drive is concerned.

There are scan rectifiers and the coupling factor with the primary is decent. But they make no use of the stored magnetic energy, they load the primary directly during the scan part. They do not cause an increase of the stored magnetic energy so a heavy load is not a problem. The flyback rectifiers (especially the EHT) draw from the stored magnetic energy. When the secondary load increases, also the magnetisation current will increase. Ultimately this will cause saturation of the ferrite core. Excess beam current is a common cause for this and should be avoided by the beam current limiter. The advantage of a flyback rectifier is that it provides 7 times more volts per winding than a scan rectifier.

Here, V1 is just a typical example of an auxiliary supply derived from a scan rectifier and HV is the best known example of the use of a flyback rectifier.

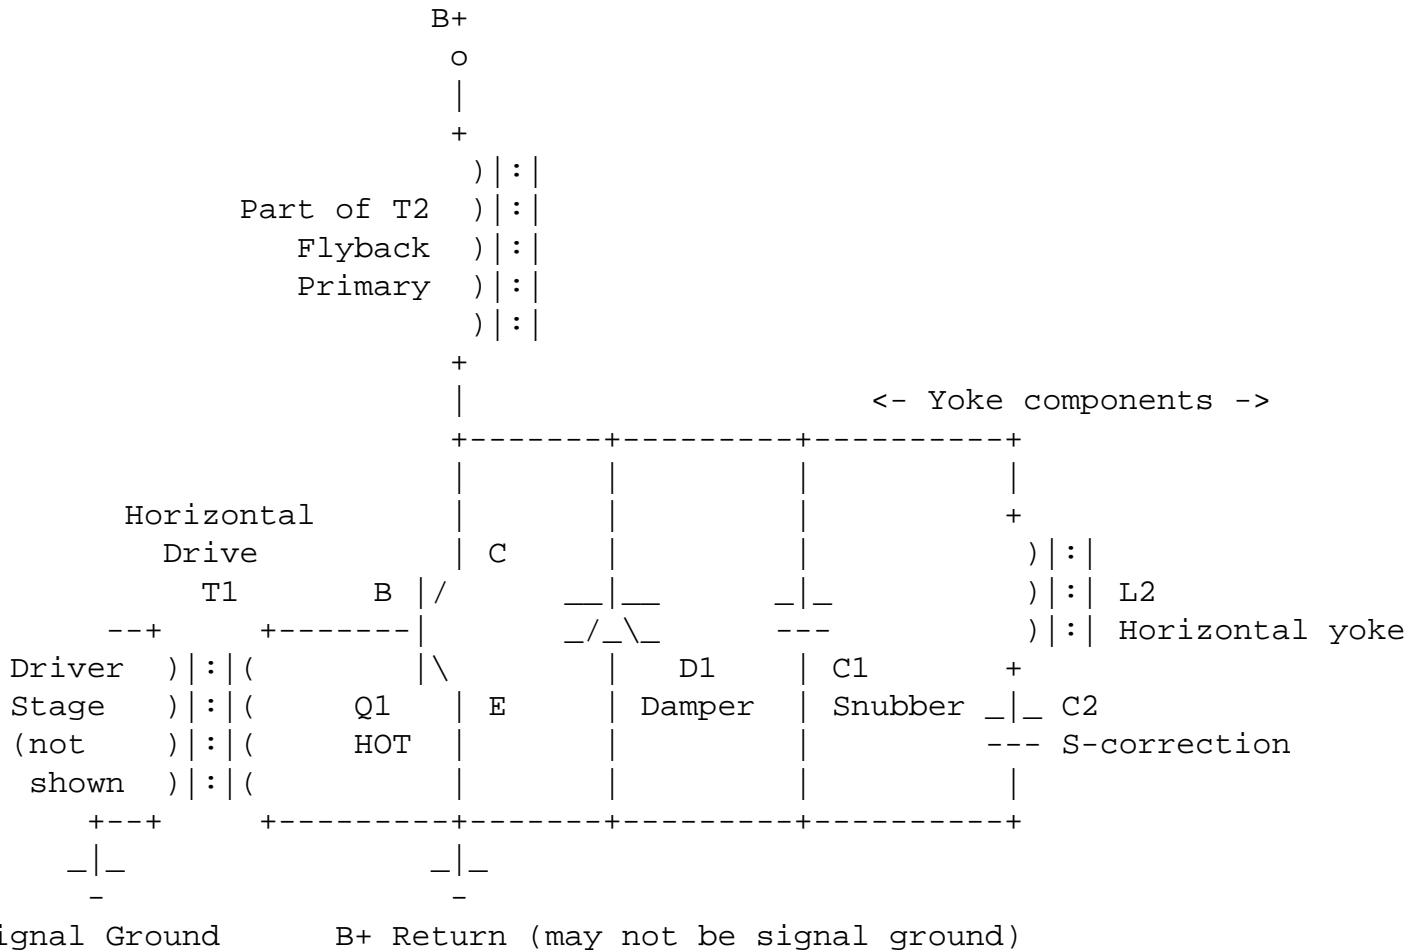

For understanding the working of the deflection circuit regard the flyback transformer as an inductor. The airgap stores energy, some of which may be tapped off during flyback by secondary rectifiers (e.g., vertical deflection, signal circuits, and high voltage supplies) and non-rectified loads (e.g., filament supply) but these have hardly any influence on the basic working principles.

The scenario described below is only true in the steady state - the first few scans are different because the picture tube capacitance is still discharged. This represents a short-circuit at the secondary side of the flyback. It prevents proper demagnetizing, hence the core will go into saturation (unless special soft-start measures have been taken, like a VB supply that comes up slowly). Generally, a hard start of the line deflection circuit represents a very heavy load on the HOT. This will happen after a picture tube flashover or if the B+ is connected suddenly (due to intermittent contact) and can mean instant death to the HOT due to secondary breakdown.

## 3.2) Basic deflection circuit operation

The following description is only the basics. For more information, see the article by David Sharples in "Electronics World", June 1996.

A very simplified circuit is shown below - many components needed to create a practical design have been omitted for clarity. First concentrate only the portion of the schematic shown below to the left of the yoke components:

The current in the flyback primary and collector of the HOT are \*not\* equal. The horizontal deflection yoke, damper diode, HOT collector, snubber HV capacitor(s), and flyback primary all connect to the same point. We begin our adventure at the end of the scan - retrace - when the flyback period begins:

1. At the end of scan, current is flowing through the flyback primary to the HOT, Q1. At the start of the flyback period, Q1 turns off. (This must be done in a controlled manner - not just a hard shutoff to minimize stresses on the HOT - but that is another story). Since current in an inductor (the primary of the flyback has inductance) cannot change instantaneously, the current is diverted into the snubber capacitor, C1. The inductance of the flyback primary (T2) and C1 forms a resonant circuit so that the voltage climbs on C1 as the current goes down. At its peak, this voltage will be 1000 V to 1500 V.
2. C1 now begins to discharge in reverse through the primary of T2 (back into the B+ supply - the filter capacitor will stabilize the B+ output) until its voltage (also C-E of the HOT) reaches 0.
3. If there were no damper diode (D1), this voltage would go negative and continue to oscillate as a damped sinusoid due to the resonant circuit formed by T2 and C1 (and the other components). However, D1 turns on as

the voltage goes negative and diverts the current through it clamping the voltage near 0 ( $-V_f$  for the diode).

Note that the damper diode D1 may have been built into the HOT T2 in the case of an inexpensive or small screen TV that does not have any circuitry for E/W correction.

Steps (1) to (3) have accomplished the flyback function of quickly and cleanly reversing the current in T2 (and, as we will see, the deflection yoke as well). The full flyback (and yoke current) are now flowing through the forward biased damper diode, D1.

4. At the beginning of scan, the damper diode (forward biased) carries the bulk of the current from the yoke and flyback. The nearly constant voltage of the B+ across T2 results in a linear ramp of current now through the damper diode since it is still negative and decreasing in magnitude.
5. At approximately mid-scan, the current passes through zero and changes polarity from minus to plus. As it does so, the damper diode cuts off and the HOT picks up the current (with a voltage drop of  $+V_{CEsat}$ ). Current is now flowing out of the B+ supply.

The base-drive to the HOT must have been switched on before this point! Timing is not very critical as long as it happens between the end of the flyback and the zero crossing of the summed current. The location of the zero crossing depends on the secondary load, notably the beam current. Larger beam current requires that the HOT be switched on earlier. The designer has to do some optimizing here...

6. During the second half of the scan, the HOT current ramps up approximately linearly. This is again due to the nearly constant voltage of B+ across the inductance of the flyback primary.
7. Near the end of scan, the HOT turns off and the cycle repeats.

The HOT has a storage time between 3 us and 7 us, thus the base-drive is switched off earlier, in a controlled way to properly remove the charge carriers from the collector region in the HOT. The peak amplitude of the base current and the way it is decreased determine the ultimate dissipation in the HOT and are thus subject of heavy optimization. This is hampered by the fact that there is much spread in HOT parameters.

Thus, the current in the flyback (ignoring the yoke components) is a nearly perfect sawtooth. The ramp portion is quite linear due to the essentially constant B+ across the flyback primary inductance. The current waveform can be easily viewed on an oscilloscope with a high frequency current probe. See the section: "[Probing TV and monitor yoke signals](#)".

The voltage across the C-E of the HOT is a half sinusoid pulse during the flyback (scan retrace) period and close to zero at all other times ( $-V_f$  of the damper diode during the first half of scan;  $+V_{CEsat}$  for the HOT during second half of scan).

Caution: without a proper high frequency high voltage probe, it is not possible

or safe to observe this point on an oscilloscope with full B+. However, where the equipment can be run on a Variac, this clean pulse waveform can be observed at very reduced B+. Excessive ringing or other corruption would indicate a problem in the flyback, yoke, or elsewhere.

Normally you would use a 100:1 probe suitable for 2 kV peak. You could always make your own voltage divider out of a couple of suitable resistors and use a regular 10:1 or 1:1 probe. Beware that also the capacitive division ratio must be correct because the line frequency is high enough to make it relevant.

The current through Q1+D1 is several amperes peak-peak. There's a lot of power circulating here, making this a \*dangerous\* circuit in every way!

---

## 3.3) The deflection yoke connection

So, you ask: "Why can't the yoke just be placed in series or parallel with the flyback primary?"

There are several reasons including:

- \* The desired yoke current is not quite a sawtooth but includes two major corrections: S and E/W (described below). These cannot be applied easily with such a configuration.
- \* The flyback also generates the HV and secondary output voltages and the primary current might then be affected by these and change as a function of beam current (picture brightness) or audio level (although feeding the audio amplifiers from LOT windings is not common anymore).

Note that some TVs and monitors cut off power to the horizontal deflection circuits if the yoke connector is removed. This is a separate interlock and not a result of the B+ flowing through the yoke. Its purpose is to protect the circuitry and the CRT. With no deflection, the very bright spot in the center of the screen would quickly turn into a very dark permanent unsightly blemish. With appropriate precautions to avoid this costly situation, it is possible to power a monitor or TV with the yoke winding(s) disconnected to determine if a defective yoke is messing up the deflection system operation. See the documents: "[Notes on the Troubleshooting and Repair of Computer and Video Monitors](#)" (or "...Television Sets") for additional information.

The yoke is placed across the C-E of the H0T in series with a capacitor (S-correction) and other components which in effect form a variable power supply (analogous to the constant B+) which is used to compensate for the various problems of scanning a nearly flat screen.

---

## 3.4) What are S and E/W or N/S correction?

These terms actually refer to the various corrections to deal with what is normally called scan linearity and pincushion distortion. Most larger TVs and nearly all high quality monitors will have various user and internal controls to optimize the corrections for each scan rate (multiscan monitors).

Because the screen of most CRTs is relatively flat (even those not advertised as flat) and the electron gun is relatively close, any picture tube will naturally have serious linearity problems and pincushion distortion if there were no corrections applied. Near the \*edges\* and \*corners\* of the screen the spot will move faster because the same angular speed translates to a larger linear speed. This is simple trigonometry.

---

## 3.5) S-correction circuit operation

The first correction to apply, in both directions, is S-correction. By simply putting a capacitor in series with each coil, the sawtooth waveform is modified into a slightly sine-wave shape (the top and bottom are somewhat squashed). This reduces the scanning speed near the edges. Linearity over the two main axis should now be good.

When we add in the yoke components (only the horizontal deflection coil and S-correction capacitor or S-cap are actually shown above) conditions are only slightly more complex:

First, consider what would happen if instead of the S-cap, the yoke were connected to B+ like the flyback. In this case, the total current would divide between the flyback primary and the yoke. It would still be a sawtooth as described above. Of course, component values would need to be changed to provide the proper resonant circuit behavior.

That's called 'tuning of the flyback capacitor', to achieve the proper duration of the flyback pulse, matching the blanking time of the video signal, and to achieve the proper peak flyback voltage, matching the Vces specification of the HOT with a reserve of about 20%.

That's two conditions, requiring two degrees of design freedom. There are 3 freedoms: supply voltage, flyback capacitor and yoke inductance.

With the S-cap and yoke wired as shown above, the inductance of the yoke and S-cap form a low pass filter such that voltage on the S-cap will be a smoothed version of the pulses on the HOT collector (similar in effect to the B+ feeding the flyback but not a constant value). The average value of the S-cap voltage will be positive.

The S-capacitor together with the yoke inductance forms a resonant circuit whose frequency is tuned lower than the line frequency. It has the effect

of modifying the sawtooth current into a sine-wave shape. This is called 'S-correction'. It reduces the scanning speed at the left and right edges of the screen.

The value of the S-cap can be selected so that the voltage varies in such a way as to squash the current sawtooth by the appropriate amount to largely compensate for the fact that the electron beam scans a greater distance with respect to deflection angle near the edges of the screen.

Think of it this way: When the scan begins, the yoke current is at the maximum value in the direction to charge the S-cap. The voltage across the S-cap is causing the current to decrease but the S-cap is also gaining charge so the rate of decrease is increasing. At the time the current passes through 0, the S-cap is charged to its maximum. The current now reverses direction retracing its steps. Got that! :-). This is another example of a portion of a resonant circuit. The voltage on the S-cap is varying by just the right amount to compensate for the geometry error.

For multiscan monitors, S-caps must be selected for each scan range since the timing varies with scan rate. These are only approximate corrections but good enough for most purposes. MOSFET or relay circuits take care that for each range of scanning frequencies the correct combination of S-correction capacitors is selected.

As an example, consider a multiscan monitor which supports VGA (31.4 KHz, 800x600 at 56 Kz (35 KHz), and 800x600 at 60 Hz (38 KHz):

For good geometry between 31, 35 and 38 kHz, two discrete values for the S-cap is barely enough. Actually a 3rd value optimized for 35 kHz would be better. If there is only one S-cap and it is optimized for 38 kHz, then at 31 kHz you will be using a too large angle of the sine (of the resonant frequency between the S-cap C and the deflection coil inductance). Possibly even > 180 degrees, making the current fold back. Apart from an obvious geometric distortion, there is also increased risk of HOT failure because you're operating too close to the resonant frequency.

---

## 3.6) N/S and E/W correction circuit operation

Then remain the N/S and E/W errors, meaning that near the corners the scanning speed is still too large.

To a large extent the N/S errors can be corrected by a suitable coil design. For smaller tubes (90 to 100 degrees types) this is also possible for E/W errors. For larger tubes (110 degrees) or high quality tubes, electronic E/W correction is required. This is the well-known pin-cushion.

E/W correction is modulation (which implies multiplication) as a function of vertical beam position. The amplitude of the horizontal deflection current is modulated with a parabola waveform which is derived from the vertical deflection circuit. This squeezes the top and bottom lines back into the left

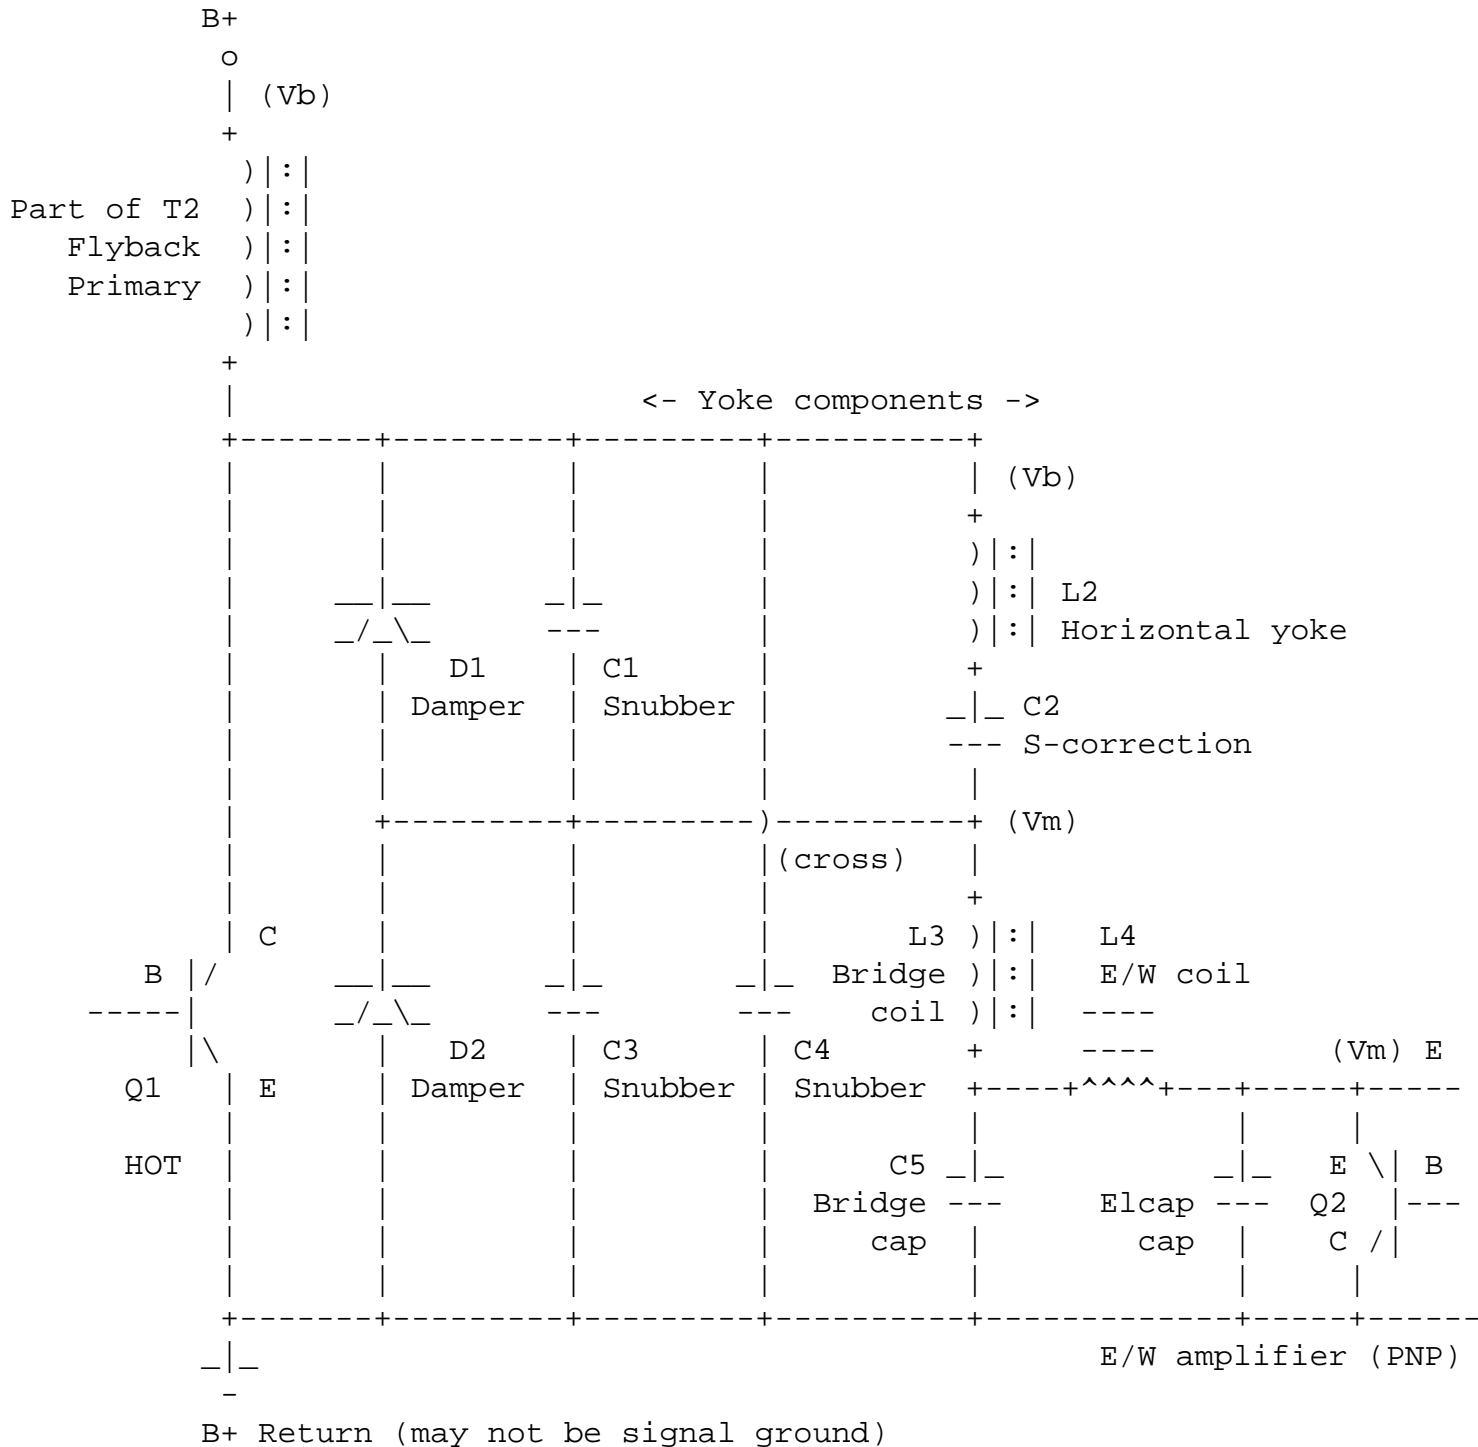

and right screen borders.

N/S correction (if any) is a method of injection - addition of a high frequency waveform (harmonics of the line frequency) to the low-frequency field-deflection waveform.

This requires costly nasty circuitry which is better avoided.

This is how the diode modulator for E/W correction works:

The deflection supply B+ gives a constant voltage Vb. At the output of the E/W amplifier there is a variable voltage Vm. Because there can not be an average voltage over any coil, the average voltage over the deflection circuit (L2 + C2) is Vb-Vm. The scanning width is proportional with this voltage Vb-Vm. By modulating Vm as a field-frequency parabola which is higher for the top and bottom lines it is achieved that the

scanning width is reduced for the corners of the screen.

The required field-parabola waveform is derived from the field deflection circuit. Amplitude and DC-level are adjustable, for correcting pin-cushion distortion and setting the screen width. EHT is *\*not\** influenced !

The E/W amplifier usually has a PNP emitter follower only, because it must only sink current and dissipate a bit of power. The coils L3 and L4 take care that the E/W amplifier sees no line-frequency.

The "bridge" components L3 and C5 resemble the deflection coil with its S-correction capacitor and carry the large amplitude alternating current. L3+C5 are tuned to approximately the same frequency as L2+C2.

C1, C3 and C4 must be tuned so that EHT is independent of  $V_m$  and peak voltage over D2+C2 is high enough but not too high when Q2 is off. C4 is usually a small ceramic capacitor of approx. 1 nF mounted close to the HOT Q1, it also suppresses EMI. Flyback capacitors are critical components. Wrong types may overheat and burn. Bad contacts here or elsewhere in the deflection circuit may arc and also cause fire.

There are many variants to this circuit, e.g. for dynamic S-correction. Multi-sync monitors need added circuitry to make the EHT independent of the line frequency (if there is not a separate EHT supply, that is).

If the E/W modulator fails then you will see that the top and bottom lines will be much too wide. There are several parts that could have failed. It's usually not too difficult to find why there's no parabola. If you have partial loss of E/W modulation, notably in the extreme corners, then you should suspect the tuning of the 3 flyback capacitors that belong to the diode modulator circuit. That's a specialist job...

---

## 3.7) S-correction problems

- \* An open S-cap will result in no horizontal deflection - a vertical line.
- \* A shorted S-cap will likely load down the B+ possibly resulting in a blown fuse or other power supply components.
- \* An S-cap that changed value (or in the case of a multiscan monitor, selected to be the wrong value) will result in distortion at the left and right sides of the screen:
  - Too low: picture will be squashed towards edges.
  - Too high: picture will be stretched towards edges.

Note that this is not the same as what is commonly called linearity which would likely affect only one side or gradually change across the screen.

---

## 3.8) Horizontal linearity correction

Since there is non-zero resistance associated with the components (mainly coil losses) in the yoke circuit (yoke winding, ESR of S-cap, etc.) the world is not quite as ideal as one would hope. Without compensation, this resistance would result in non-linearity of the picture - it would tend to be squashed on the right side as the resistance saps energy from the yoke circuit.

The waveform becomes a damped sinewave, which will be 'undamped' by restoring energy during the flyback.

One way to deal with this is to add a magnetically biased saturable inductor in series with the horizontal deflection yoke. This is called the linearity coil.

Its core is magnetically biased near the point of saturation such that the inductance decreases with increasing current and this helps to stretch the right hand side of the scan. In other words, during the scan the coil saturates so that the inductance decreases. At the end of scan there is practically no voltage left over the linearity coil so that the deflection coil gets maximum voltage.

---

## 3.9) E/W correction problems

The common name for the adjustments is likely to be 'Pincushion Amp' and 'Pincushion Phase'. They are controlling the E/W correction circuits.

Pincushion Amp adjusts the amplitude of the correction signal.

Pincushion Phase adjusts where the correction is applied on the vertical scan.

- \* Failure of the E/W correction circuit will result in very noticeable pincushioning distortion of the vertical edges.
- \* Excessive E/W correction will result in barrel distortion of the vertical edges.
- \* A bad power supply derived from the flyback could also result in similar symptoms due to ripple or lack of power to the pincushion circuitry.

---

## 3.10) Differences between N/S and E/W correction implementation

While the desired effects are symmetric - modulate the amplitude of one component of the deflection circuit (H or V) by the other (V or H), the implementations will differ substantially. The reasons should be obvious: The line frequency is much higher than the field frequency.

E/W correction is easy: the lower frequency modulates the higher frequency. This reduces to simple amplitude modulation. Well, simple in principle. The line circuit is a high-energy circuit. For this purpose the diode modulator circuit has been invented. It allows an energy exchange between the line deflection circuit and a pseudo deflection circuit.

N/S correction is difficult: the higher frequency modulates the lower frequency. It *can* be done with sort-of amplitude modulation by using a 'transductor'. This is not a transformer but a component with 2 coils and a saturable core where the (line frequency) current through 1 coil modulates the inductance of the other coil. If there are tuned parts in the circuit then the correction will be highly sensitive to line frequency variations.

It can also be done with a regular transformer, by injecting a strong signal (from an amplifier) with line frequency components into the field deflection circuit.

Either way, it's an expensive solution which should be avoided by designing the deflection coils in such a way that the picture tube needs no active N/S correction.

---

## 3.11) EHT (high voltage) generation

The EHT is generated from a flyback rectifier on a secondary winding of the line transformer with many many turns of very thin wire. Because the flyback pulse is so narrow, the rectifier diode will conduct only a short time. Thus the peak current in the winding will be quite high, resulting in a significant voltage drop when loaded. The internal impedance of the EHT source is in the order of 1 MOhm, so with a load of e.g. 1 mA the EHT will drop 1000 V = -3%. Usually the EHT voltage is far from stable, 10% drop is quite normal.

If the EHT voltage drops, then the electrons will be accelerated less and will move through the deflection field at a lower velocity. As a result they will be easier to deflect by the magnetic field, and the picture size will grow. Without special measures, brighter pictures will be larger. The measure is to feed some EHT information or beam current information to the deflection circuits, reducing the deflection current amplitude a bit for bright pictures. For horizontal deflection this is done by the E/W modulator. This is called anti-breathing.

Sets with raster correction free picture tubes don't have an E/W modulator. There the correction may be done by means of a power resistor in series with the B+ supply. A large beam current causes more power consumption, this lowers the B+ supply voltage and thus

reduces the line deflection current. That also reduces the EHT even further, but the deflection current has a stronger effect on the picture width than the EHT. Better methods exist too.

The EHT information is also used to protect the flyback transformer from overload. As the load increases, the average primary current rises. Ultimately it may reach a level where the transformer core may go into saturation. This causes large peak currents in the HOT which might lead to destruction. To prevent this, some EHT information is fed to the contrast controller, to automatically reduce the picture brightness whenever the white content is too much. This is called the average beam current limiter.

A failure in the video path, like a video output amplifier stuck at 0 V, causes a high beam current that will not react to the contrast controller. In that case the beam current limiter will not work and the set should switch off automatically, usually within a few seconds after applying power. When the cathodes heat up, you'll see an even picture with diagonal retrace lines and then it will switch off.

---

## 3.12) The difference between the ideal and the real

Don't expect to find the circuits shown above staring you in the face when you get your Sams' Photofact or service manual. There are a semi-infinite number of variations on this basic theme. Some of them will, to put it mildly, appear quite obscure (or to put it more positively, creative) at first.

You may see all sorts of additional passive components as well as transformers for generating additional voltages not provided by the flyback. There may be diodes in places you would think would be impossible. Therefore, to really understand even approximately how each design works may require some head scratching but the basic operation of them all seems to be very similar.

---

# Chapter 4) Horizontal Output Transistors

---

## 4.1) Storage time of HOTs

Storage time differs between transistor types, there's parameter spread within a type (lower hFE gain gives shorter storage time and v.v.) and

it depends on load (higher beam current or larger deflection amplitude due to E/W modulation gives shorter storage time).

Variations in storage time would translate into horizontal position errors of the picture. That's why the base-drive to the HOT is generated by a PLL that measures the phase of the output of the HOT, which is the flyback pulse at the collector. This PLL is called the PHI-2. It keeps a constant phase relation between the sync at the input and the flyback pulse. As a result, you will see the base-drive pulse shifting in time as a function of HOT load, this is normal.

Most deflection processors generate a base-drive pulse with a constant duty-cycle. This means that also the switch-on moment of the HOT will vary with the load. This makes it extra difficult to optimize the base-drive because there is only a limited time interval where the HOT may be switched on and that interval is shorter with high beam current load. On-time is typically between 50% and 55%, depending on the IC.

The feedback of the flyback pulse to the PHI-2 PLL is not perfect because the shape of the pulse distorts as a function of beam current. This will give a dynamic geometry error. It is compensated by feeding a certain amount of EHT information to the PLL.

---

## **4.2) Why are nearly all horizontal drivers circuits transformer coupled?**

One (probably secondary) reason is that this provides one of the isolation barriers between a line-connected HOT and flyback primary and the signal circuits of the TV.

A more important rationale is that a transformer is nice easy way of impedance matching the horizontal driver circuit (100s to 1000s of ohms) to the few ohm input impedance of the horizontal output transistor base which requires upwards of several amps for proper drive. A typical driver transformer may be in the 5-10:1 turns ratio representing 25-100:1 impedance ratio.

A byproduct of all this is that it is unlikely for a faulty driver stage to kill the HOT. Unlikely but not impossible.

---

## **4.3) Additional information on horizontal driver circuits**

Usually, the primary voltage is \*constant\* when the driver transistor is ON and thus the HOT is OFF. Then when the driver switches OFF, the stored magnetic

energy switches the HOT to ON.

This is called non-simultaneous base drive, which is most common. The primary voltage that you see then is mostly a transformed version of the secondary voltage, over the series base impedance. The voltage at HOT=ON is not forced from the primary side.

Usually the "cold" side of the primary of the driver transformer is connected via a power resistor and filtering electrolytic capacitor to the B+. The R determines the average voltage and thus the base drive current. Higher R means less base drive and vice-versa. Varying the value of this resistor is the first choice for minimizing the power dissipated in the HOT.

The filtered DC voltage at the cold side is (typically) a little over  $1/2 * V(B+)$ . Then when the driver switches off the voltage at the hot side (of the primary) will be higher, but typically not higher than  $V(B+)$ . But how high exactly is a coincidence.

---

## 4.4) Horizontal output transistors keep blowing (or excessively hot)

Unfortunately, these sorts of problems are often difficult to definitively diagnose and repair and will often involve expensive component swapping.

You have just replaced an obviously blown (shorted) horizontal output transistor (HOT) and an hour (or a minute) later the same symptoms appear. Or, you notice that the new HOT is hotter than expected:

Would the next logical step be a new flyback (LOPT)? Not necessarily.

If the set performed normally until it died, there are other possible causes. However, it could be the flyback failing under load or when it warms up. I would expect some warning though - like the picture shrinks for a few seconds before the poof.

Other possible causes:

1. Improper drive to horizontal output transistor (HOT).

- \* A too weak drive (or a HOT with a too low  $H_{fe}$ ) causes  $V_{ce(sat)}$  to be too large, giving conduction losses.
- \* A too strong drive (or a HOT with a too high  $H_{fe}$ ) causes it to switch off too slowly, giving switching losses.

Base drive should be optimized to balance between these 2 losses. Check driver and HOT base circuit components. Dried up capacitors, open resistors or chokes, bad connections, or a driver transformer with shorted windings can all affect drive waveforms.

2. Excessive voltage on HOT collector - check low voltage regulator (and line voltage if this is a field repair), if any.
3. Defective safety/flyback capacitors or damper diode around HOT. (Though this usually results in instant destruction with little heating).
4. New transistor not mounted properly to heat sink - probably needs mica washer and heat sink compound.
5. Replacement transistor not correct or inferior cross reference. Sometimes, the horizontal deflection is designed based on the quirks of a particular transistor. Substitutes may not work reliably.

Well, you can always *\*try\** to optimize the base drive by changing the value of the power resistor that feeds the drive circuit at the primary of the drive transformer. But you're on your own here! Clearly label what you have done or else your name will be mud if the unit ever needs to be repaired by someone else in the future.

The HOT should not run hot if properly mounted to the heat sink (using heatsink compound). It should not be too hot to touch (CAREFUL - don't touch with power on - it is at over a hundred volts with nasty multihundred volt spikes and line connected - discharge power supply filter caps first after unplugging). If it is scorching hot after a few minutes, then you need to check the other possibilities.

It is also possible that a defective flyback - perhaps one shorted turn - would not cause an immediate failure and only affect the picture slightly. This would be unusual, however. See the document: "[Testing of Flyback \(LOPT\) Transformers](#)".

Note that running the set with a series light bulb may allow the HOT to survive long enough for you to gather some of the information needed to identify the bad component.

---

## 4.5) Why are there so many different HOTs?

I find it fascinating (ok, well at least interesting) that after 20 years of designing totally solid state TVs and monitors, HOTs have not become jelly bean parts. Why does every new design insist on a unique HOT? I don't believe this is simply due to increased requirements like wider deflection angles or (for computer monitors) higher scan rates.

Actually there is still some progress going on :-).

TV's for Europe DO get higher scan rates, you know. Our entire high-end range runs on 31250 Hz. Sets with VGA capability often run even higher. 100 Hz HDTV was supposed to run on 62500 Hz but that is a big technological problem as you might imagine.

Larger screen sizes (32" 16:9, 33" 4:3) do tend to have less sensitive deflection coils, so the peak-peak amps go up. Combined with the higher scan rate this often means that some new transistor must be found, even if it is only a higher rated selection from an existing type. There is also 1700 V Vce types next to the regular 1500 V.

And in USA it is known that setmakers (like ourselves) have standard transistors marked with a different type number, to prevent repairmen from putting in just any would-be replacement type. For a fact, it IS risky to put in the wrong replacement, the faulty drive conditions may destroy it early. So try and avoid this.

To comfort you, the BU508 is still widely used!

---

## 4.6) Varieties of BU508 HOTs

(From: J. G. Simpson (ccjs@cse.bris.ac.uk)).

BU508 series seem to come in a number of variants, I haven't sorted out the specification for each listed variant, but have found that it's worth trying replacements by different manufacturers. Also if the device is on a grounded piece of metal as heatsink try adding another radiator (twisted vane is my preference). Some TV manufacturers introduce post production mods to change resistance values to provide more drive into the base, this may be in the base or emitter. Scope the waveform for parasitic high frequency oscillation and check that the waveform looks clean. Check voltage rails, supply and derived, and that the set is not over scanning. Check all the components around the horizontal output stage, it may be the manufacturer. had a duff batch of some component (often a capacitor that goes OC) that keeps failing which then stresses the BU508.

---

## 4.7) Is there a standard HOT transistor for monitors?

"Anyone like to comment on BU508's, they should be to the same spec. and born equal. My experience has been that different manufacturers BU508's behave differently. One make will fry and last about 3 weeks, put in a different make, no circuit change, and it runs cool, and is still running 3 years later. Price doesn't seem to be a guide, a \$1 one may run cool and have no mfr. code, a branded one cost more and run hot."

Yes, here you have the problem exactly!

There is such a thing as component spread. Base drive must be optimized for the whole range of gain within a type. That range can be so large that at the limits of the spread the dissipation can still be too large. The reason is

that the device with the largest gain will be overdriven, causing a tail in the current at switch-off, whereas the device with the smallest gain will be underdriven, causing it not to saturate enough. Each condition can be easily viewed on the 'scope. By varying the base drive you can minimize dissipation.

Normally one base drive is set for the entire population, accepting the variation in dissipation and its upper limit. Sometimes the variation is so large that this will not be acceptable. But this is unlikely for a BU508 in a 16 kHz application. Substituting it with a similar type from a different brand with different parameter spread may indeed cause it to dissipate too much and thus fail early. This has nothing to do with price or quality, just with a different optimum base drive. If base drive has been optimized for a brand with low parameter spread then it can be that the heatsink may have correctly been selected smaller...

Since you live in the UK, you should definitely read David Sharples' article in Electronics World (was it June 1996?). He literally optimizes base drive for a living.

---

## 4.8) Why do apparently similar or better HOTs sometimes run hot and blow?

It is often surprising that replacing a horizontal output transistor with one that has overall better specifications does not work out - it may run hot and fail.

There is more to characterizing a transistor than just maximum voltage, current, and power dissipation.

One important parameter is current gain: Too low a gain for a particular operating point may result in incomplete turn-on during scan resulting in high dissipation. You want the transistor to be in the fully saturated state. A larger HOT is more likely to have a lower current gain.

If you read the app notes put out by the manufacturers like Motorola you will also find that fast turn off based drive (negative step) is actually not what you want since this traps excess carriers in the high resistivity collector region which leads to continued conduction and heating. The ideal waveform also provides adequate drive during scan but not excessive overdrive and is thus an increasing ramp to account for the increasing collector current during scan.

Characteristics like this are not dealt with by the basic specs but can differ substantially among otherwise similar transistors.

Also see the section: "[Horizontal output transistor specs and substitution](#)".

---

## 4.9) Horizontal output transistors blowing at random intervals

The HOT may last a few months or years but then blow again.

These are among the hardest problems to locate. It could even be some peculiar combination of user cockpit error - customer abuse - that you will never identify. Yes, this should not happen with a properly designed monitor. However, a combination of mode switching, loss of sync during bootup, running on the edge of acceptable scan rates, and frequent power cycles, could test the monitor in ways never dreamed of by the designers. It may take only one scan line that is too long to blow the HOT.

---

## 4.10) Horizontal output transistor specs and substitution

Refer the article on deflection circuit design by David Sharples (Electronics World & Wireless World, June 1996).

Every line transistor has its own requirements for:

- \* Amount of base drive current, especially the  $I_b$  at end-of-scan.
- \* Waveform of base drive current (rising, steady, falling)
- \* Speed of reduction base drive current at switch-off.

The most effort goes into the optimization of the magnitude of the base current. The problem is: gain spread. There used to be other spread factors influencing the dynamic transistor parameters but these have been mostly eliminated by better process control at P.S.. You have to find \*one\* optimum drive so that neither the high-gain nor the low-gain type will dissipate too much.

Overdriving causes a slow switch-off behaviour, some collector current keeps flowing during the beginning of the flyback and will cause dissipation.

Underdriving causes bad saturation, the collector voltage will start to rise before the flyback should start. This too causes dissipation. Either condition is easily observed with an oscilloscope, a current probe and a 1:100 voltage probe (be sure to calibrate it for HF !).

The dissipation as a function of the base drive current is a more-or-less parabolic function with a global minimum. The minimum will be different for high-gain and low-gain types. By measuring the curves for both extreme types and combining them, an optimum drive for the random type will be found, with a figure for the worst-case dissipation.

All this will only be true if you insert a device which is a member of the population spread for which you optimized the base drive. If you just insert a random other device (different type, same type but different brand, same

type and brand but much older/newer batch) then all bets are off. Dissipation may be way too high, with early failure as a result (and possibly a distorted picture geometry due to excess damping of the waveform).

It is certainly not possible to substitute a standard HOT (BU508) in place of a more advanced type (in >> 15 kHz applications like monitor). It is also a very bad idea to substitute a BU508 in place of a much lighter type like a BUT11 (used in <= 17" sets). It will fail!

With horizontal output transistors, it is *\*not\** true that 'bigger is better'. If you substitute a heavier transistor (more amps, more volts, more watts, faster switching, whatever) for a lighter one, then there is a very big chance that it will fail earlier, not later. The reason is that the drive conditions will now be wrong (most likely underdrive) and the transistor will overheat from too high conduction losses ( $I_c * V_{ce,sat}$ ). So do yourselves a favour and get a correct replacement type.

---

## 4.11) What is this diode across my HOT?

It is called a damper diode and is essential to proper operation of the TV's or monitor's horizontal deflection as well as to the continued life and happiness of the HOT. Using an HOT with an internal damper is ok even if there is a separate one in the circuit. The other way around (leaving it out entirely) will likely result in instant - i.e., single scan - destruction of the HOT. This is because in modern deflection system designs, the damper carries the horizontal yoke current for a significant portion of the scan. If it is not present, the HOT will be forced to try to eat this current - in reverse - across C-E.

The damper is a special high voltage fast recovery type of diode - a 1N400x type will not work in its place.

BTW, many of these HOTs have a D after the part number to indicate that they have the internal damper and include a B-E resistor (which may confuse transistor testing) of about 50 ohms. However, the D is not a sure indication of an internal damper - nor is its absence an indication of a lack thereof. The entire part number must be checked to be sure.

---

## 4.12) What is this funny capacitor (or capacitors) across my HOT?

These may go by the name flyback, high voltage, snubber, or deflection capacitors. When the HOT is shut off, the current flowing in the inductance of the flyback primary and horizontal deflection yoke cannot be stopped

instantly. These capacitors provide a place for this current to go and is part of a tuned circuit (in combination with the flyback and yoke) which needed to accomplish the flyback function.

If this capacitor is open or missing, excessive flyback voltage will result probably killing the HOT. If the HOT does not fail, the result will likely be greatly increased high voltage. Should the X-ray protection circuitry not shut down the deflection, there could be internal or external arcing and/or destruction of components like the flyback or tripler.

For proper operation and continued safety, only proper exact replacements should be used for these parts.

---

## 4.13) Brief comments on testing the HOT

For a TV with no blown fuses that will not start, here are two quicky checks to see if the HOT is good and has power and drive:

- \* HOT tests - check across each pair of pins for shorts (preferably removed from the circuit board). No junction should measure less than 50 ohms or so. Lower readings almost certainly indicate a bad HOT. If in-circuit, however, the reading between base and emitter will be near zero due to the secondary of the driver transformer. See the document: "Testing Diodes and Bipolar Transistors with a DMM or VOM". Don't be confused by internal damper diodes and B-E resistors.
- \* Power - measure across the collector to emitter with a multimeter (with the HOT removed or if there is no deflection, this is safe with it in place). There should be solid B+ - typically about 100 to 160 V (115 VAC sets - possibly higher for 220 VAC sets). If this is missing, iether there is a problem with the power supply or the emitter fusable resistor has blown (probably in addition to the HOT) and there is no return.
- \* Drive: put an oscilloscope on the base - there should be pulses around .7 V for most of the scan (~50 microseconds) and probably going negative a couple volts at least for retrace (~12 microseconds). If drive is weak or missing, determine how startup is implemented as there may be a problem in the startup power supply or deflection IC.

WARNING: use an isolation transformer for the oscilloscope tests (and whenever you are probing a TV in general)!!! This part of the circuit, in particular, is usually line connected. See the document: "[Safety Guidelines for High Voltage and/or Line Powered Equipment](#)".

---

## 4.14) Saga on swapping of horizontal output transistors

(From: Malik (M.Dad@mmu.ac.uk)).

The prologue:

I have in for repair a Tatung monitor model CM14UAE. Originally it was dead this fault was quickly remedied by replacing the line output transistor which was 'dead short', causing the power supply to shut down.

Now the transistor I replaced seems to get a hell of a lot hotter than it should, when it gets to a certain temperature after about half an hour the width begins to collapse at which point I quickly switched off. If I switched off for a few seconds and back on again I would get the width back but again it quickly began to collapse.

Things you need to know:

The LOP stage is independent from the EHT transformer. i.e. there is a separate transformer for the EHT (and A1 supplies etc) with its own transistor and a separate line output only transformer with its own transistor.

I have also tried substituting the efficiency diode, still no joy. I have also replaced the EW transistor and its driver.

To me it seems that the transistor is not being switched properly, although the waveforms do look ok.

Original line output device 2SC3893A, which I replaced with a BU508DF (European equivalent according to the books. I also tried a 2SC3883 which used for the same job in other SVGA monitors. Both give the same problem,

I will be trying to get the original transistor in case this is the problem but I don't think it will make a difference.

And the conclusion:

Anyway after all that headache I finally received through the post the original 2SC3893A. I fitted this and left the monitor on test. Sigh of relief, the problem has gone away.

It seems the timing on this device differs from all the others I tried. The transistor runs at a reasonable temperature even after a few hours use.

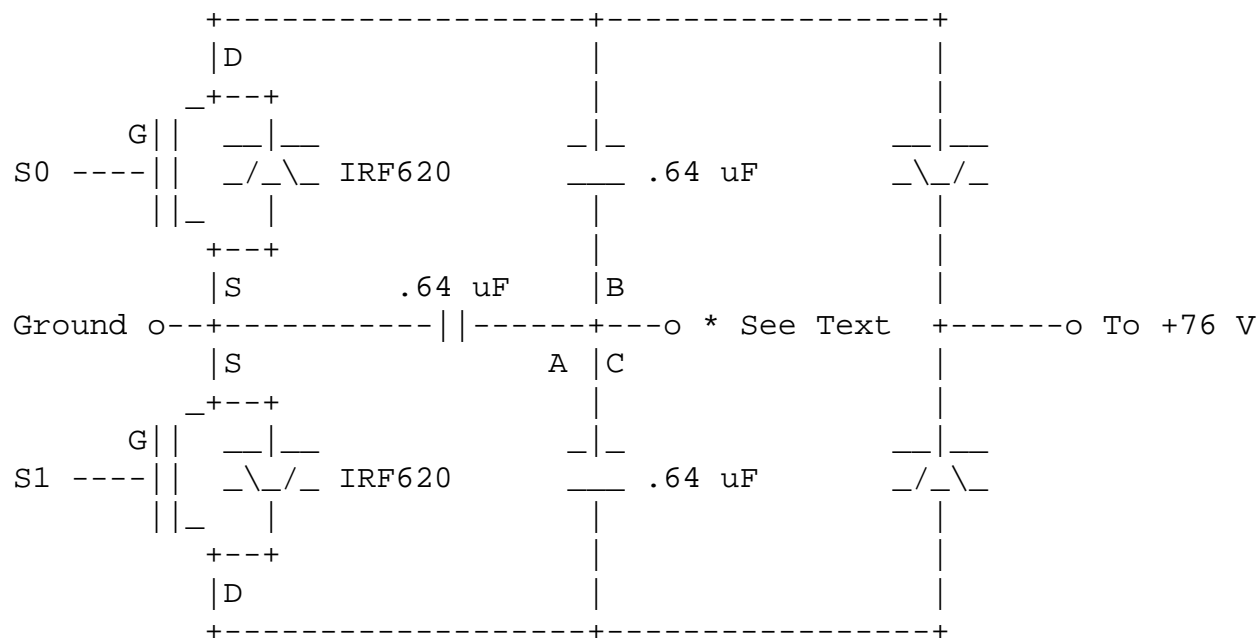

The moral of this story is, use original line output transistors. Unless you are 100% sure the replacement works in its place. Don't rely too much on equivalent books, these should be used as a guide. The book I looked at specified the BU508DF as a direct replacement for a 2SC3893A, but as I know now it doesn't work properly.

The HOT should not run too hot to touch. If the replacement sizzles, it won't last long and is probably deficient in some specification. If the monitor or TV appears to work normally otherwise, try an exact replacement HOT if available before swapping other expensive parts like the flyback (LOPT). For testing, however, a substitute can usually be used - with a

## 4.15) S-correction circuits on multi-scan monitors

(Quoted text from a curious but frustrated tinkerer/technician.)

"Hi there. Recently, I've encountered this circuit (or ones similar to it) several times in VGA monitors and I'd like to know what it's purpose is.

The IRF620's are N channel Enhancement Mode MOSFETs.

\* The connection at this point is to the HOT collector via the horizontal deflection yoke (HDY), width, and linearity coils."

You will probably find that 0, 1, or 2 of the MOSFETs will be turned on (S0, S1 set to ground or +15 V (typical) depending on the scan rate. This would introduce varying amounts of S-correction (E/W) depending on the horizontal scan rate.

The diodes are probably for clamping and protection. The MOSFETs are used as switches. You, in effect, get 1, 2, or 3 x .64 uF between the yoke return (the point marked '\*') and ground.

This circuit is from an auto-scan computer monitor where it switches the effective S-correction capacitor to one of 3 possible values depending on scan rate.

Note that this approach is used both in multi-scan and auto-scan monitors. The multi-scan (largely obsolete technology though still used in some specific applications) has two or more discrete line frequencies and the auto-scan has a whole range of available frequencies. You would not guess this from the

discrete switching of the S-correction capacitors. Obviously, the S-correction is optimized only for 3 frequencies and approximated for all others. This is generally good enough (even) for auto-scan.

The internal diodes anti-parallel to the MOSFET (A to S, K to D) are important to set the DC voltage over the extra S-capacitors to a reasonable value before they are first switched in. At lower line frequencies the extra capacitors are permanently switched on.

For each given scan frequency there is only one correct value for the S-correction capacitor. If you limit your circuit to only 3 discrete values (like 0.64, 1.28 and 1.92 uF) then the horizontal geometry can be optimized for only 3 scan frequencies.

Somewhere between these 3 frequencies there will be 2 switch-over points where more S-correction capacitance is added by the switches. Generally, around these border frequencies the geometry will be worst (because whatever the position of the switch, there will be an error one way or the other) and it would be wise to switch over near some little-used frequencies and thus optimize for the much-used frequencies like 31, 38, 48 and 64 kHz. For the other scan frequencies, the geometry will then be only approximately correct. Luckily, S-correction is not very critical.

For any given scan frequency, the position of the MOSFET switches is constant: either on or off. These are not used in a switched mode.

There *will* be one or two other MOSFET switches that switch at a line scan rate in order to take care of the correct dependency of the (average) supply voltage and E/W voltage in function of the scan frequency.

There is a difference in the horizontal deflection circuit of a TV versus an auto-scan monitor. In the diode bridge of a TV, the deflection circuit is in the upper half of the bridge and the "bridge circuit" is in the lower half of the circuit. The E/W amplifier *sinks* current from the centre node (and dissipates). The VB supply voltage is constant.

In the diode bridge of a auto-scan monitor, the deflection circuit is in the lower half of the bridge. This makes the S-correction capacitor grounded and thus easier variable (without need for level shifters, opto-couplers, etc). The E/W amplifier *sources* current into the centre node. The VB supply voltage is made variable, linearly proportional to the line frequency, by means of a switched-mode down-converter topology. The same topology is also used for the E/W amplifier, which now actually delivers power to the circuit. With this topology you can have a constant (even regulated) EHT and a constant deflection current amplitude, independent of the line frequency.

"In another similar monitor, this circuit had completely self-destructed and taken out a few other things too (fire). The monitor shuts down immediately unless the HOT is disabled or connections A, B, and C are *all* broken (no other combination works). It almost seems like it's used to accommodate or change the horizontal frequency for different video modes. For some reason, the monitor is now powering up so seems like it might be an intermittent short somewhere."

By disconnecting A,B,C you effectively take the deflection coil (HDY) out

of the circuit. By disabling the line transistor (HOT) there remains only DC voltage over the bridge- and S-correction capacitors. Either way there is no voltage over the HDY. I would suspect a short or arcing in the deflection coil. Just a wild guess, though.

There is enough energy present in the deflection circuit (also in the HDY) to create a very nice fire, let there be no doubt about that. A loose contact in series with this circuit is potentially fatal.

Typical HOTs as used in monitors  
-----

(From an engineer at Philips).

14", SVGA (38 kHz)	A-types: BU2508AF, 2SC4830, 2SC5148.
	D-types: BU2508DF, 2SC4762, 2SC4916, 2SC5149, 2SC4291, 2SC5250.
15", XVGA (64 kHz)	A-types: BU2520AF, BU2522AF, 2SC3885A, 2SC3886A, 2SC4757, 2SC4758, 2SC5129, 2SC4438, 2SC4770, 2SC4743, 2SC5067, 2SC5207, 2SC5251, 2SC5002.
	D-types: BU2520DF, 2SC3892A, 2SC3893A, 2SC4531, 2SC4763, 2SC4124, 2SC4769, 2SC5296, 2SC4742, 2SC4744, 2SC4927, 2SC5003.

(A=no damper, D=built in damper diode).

For designs with larger screen sizes (and higher frequencies) the device selection is not so straightforward as some designs split the horizontal deflection and EHT stages.

In nearly all the above cases, the devices will plug-in substitute for each other within category.

Continuous dissipation is hardly ever the cause of failure (never for Philips devices). Failure is usually due to some infrequent transient condition. For multi-frequency monitor designs 1991-1994 mode-change was/is a big killer. When repairs are made it is wise to cycle through a mode-change sequence. Delays of about 1 min. between changes should be used, shorter delays can cook the device.

\* As a rule, once an engineer has a bad experience with mode change he takes greater care in the small-signal circuitry of his next design. This has led to mode change, in general, becoming more benign in the last couple of years. However, in Taiwan & Korea there is a high turn round of engineering staff and some, shall we say, less than perfect designs do still reach production.

\* To "cook" a device by mode changing would take at least 30 mins. of continuous changing with a delay of about 20 seconds between each change.

\* If a device fails during such a sequence the old, but rather uncooth, spit test is good indicator of why a device fails. That is, a drop of spit on the HOT immediately after failure can tell us a lot: if it sizzles then the device has probably cooked, if it doesn't then the

device failed instantly after one stressful cycle. Frontiers of technology it is isn't but it is a useful technique.

- \* If you do get fails which haven't been caused by the HOT "cooking" I have no easy solution, sorry !
- \* Winfield Hill's comments reflect the experiences of many. School physics teaches that bipolar's are current driven and MOSFET's are voltage driven. In practice, of course, this is a gross over-simplification. A MOSFET in deflection would, as we say in the north of England, have to be a "bloody big bugger". For example, a 1500V MOSFET that behaved as a BU2508 would have to be nearly twice the size and at least twice the price. Getting 10V on all the gate cells of such a big chip requires a lot of charge to be injected (ie current) and then removed (reverse current); much like a bipolar drive.

---

## 4.16) Why MOSFETs are not generally used for HOTs

One would think that with a MOSFET's high impedance voltage drive and other desirable characteristics, they would have displaced bipolar transistors for horizontal deflection circuits. Why not?

True, a MOSFET is much much much easier to drive. In modern switched-mode power supplies they reign, rightfully so. They are effective and rugged.

\*But\* in line deflection things are not so easy. I'll give you 4 reasons:

1. The flyback pulse is regularly 1200 V peak, allowing for margins you need a 1500 V device. There are few or no FETs available for that. In a small set, a 1000 or 1200 V device may be usable. With effort, the deflection circuit impedance may be re-scaled for greater current and lower voltage.
2. The conduction losses ( $V_{ds} = I_d * R_{ds}$ ) of a FET are quite high, this not only is wasteful dissipation but it also affects the linearity of the picture (it's a damped sine-wave, going slower and slower).
3. For the same power losses a FET needs a much bigger silicon area, also FETs are made in a more advanced process, with IC-like features, this translates directly into greater cost! They are several times more expensive.
4. A FET has no storage time, hence it has no storage-time modulation, which is a disadvantage because that would help to improve the natural stability of the control of the phase of the line deflection.

And these are just some major reasons, there are minors too. We have looked into it time and again and still the bipolar wins!

---

## 4.17) Universal HOT replacement for TVs?

Warning: as noted elsewhere in this document, the following approach is much less likely to work with long term (or even more than a few millisecond) reliability in high performance computer monitors.

(From: Chris Jardine (cjardine@wctc.net)).

I shouldn't say this, but, the TV repair shop I worked for a number of years ago stocked 1 universal Horizontal Output Transistor 2SC1308K or NTE238. This worked in almost every set out there that used a transistor and not SCR's (RCA, etc.). This may not be the best way of substituting, but, these 2 part numbers seem to have fairly high gain, power capability, voltage ratings, current ratings, etc. These characteristics made it a good substitute and when you buy 100 at a time you would get a really good price.

This may not work in your case, but, my \$.02

---

## 4.18) Optimizing base drive for HOTs

It is interesting that the problem of base drive optimization receives a fair bit of attention, either for allowing a (non-compatible) replacement HOT to survive or for rebuilding a fixed frequency monitor to a different scan frequency. I wish there was an easy way to teach the average hobbyist a method to do this himself.

The recipe itself isn't all to difficult: mostly we change the value of the power resistor that feeds the line drive circuit until the temperature of the HOT heatsink is at minimum. Too much basedrive current increases the switching losses, too little basedrive current increases the conduction losses. The optimum is somewhere in the middle. All you need is a handful of power resistors and a thermometer on the heatsink.

If you need to optimize for a general HOT type (as opposed to one single sample) then you kindly ask the manufacturer to provide some limit case samples (lowest and highest hFE found) and find a basedrive that satisfies both extremes. Of course you must select a slightly larger heatsink. So far so good. The difficult bit is when you find that you need to change other components in the drive circuit as well, like the spread inductance of the driver transformer, a damping resistor, a duty cycle of a drive signal etc. And of course you may find that the HOT you planned to use is entirely unsuitable for this application ...

Anyway, it's never a case of just 'drive it hard'.

---

## 4.19) Testing of replacement HOTs

The following is useful both to confirm that a substitute replacement HOT is suitable and that no other circuit problems are still present. However, single scan line anomalies (particularly when changing channels and/or where reception is poor with a TV or when switching scan rates and/or when no or incorrect sync is present with a monitor) resulting in excessive voltage across the HOT and instant failure are still possible and will not result in an HOT running excessively hot.

(From: Raymond Carlsen (rrcc@u.washington.edu)).

After installing a replacement HOT in a TV set or monitor, I like to check the temperature for awhile to make sure the substitute is a good match and that there are no other problems such as a weak H drive signal. The input current is just not a good enough indicator. I have been using a WCF (well calibrated finger) for years. For me, the rule of thumb, quite literally, is: if you can not hold your finger on it, it's running too hot, and will probably fail prematurely. Touching the case of the transistor or heat sink is tricky....

Metal case transistors will be connected to the collector and have a healthy pulse (>1,200 V peak!) and even with plastic case tab transistors, the tab will be at this potential. It is best to do this only after the power is off and the B+ has discharged. In addition, the HOT may be hot enough to burn you.

A better method is the use of an indoor/outdoor thermometer. I bought one recently from Radio Shack for about \$15 (63-1009). It has a plastic 'probe' on the end of a 10' cable as the outdoor sensor. With a large alligator clip, I just clamp the sensor to the heat sink near the transistor and set up the digital display near the TV set to monitor the temperature. The last TV I used it on was a 27" Sanyo that had a shorted H. output and an open B+ resistor. Replacement parts brought the set back to life and the flyback pulse looked OK, but the transistor was getting hot within 5 minutes... up to 130 degrees before I shut it down and started looking for the cause. I found a 1 uF 160 volt cap in the driver circuit that was open. After replacing the cap, I fired up the set again and monitored the heat sink as before. This time, the temperature slowly rose to about 115 degrees and stayed there. I ran the set all day and noticed little variation in the measurement. Test equipment doesn't have to cost a fortune.

---

## 4.20) Oscillation or ringing at HOT base?

"Could this be happening because I'm using the wrong HOT?"

At these relatively low frequencies your scope probe is probably not suspect, although you should keep loops small and not underestimate the effect of high dV/dt inside the line transformer.

First, how do we know if the oscillations were already there with the original HOT ? I suppose you have never measured that ...

Second, it is NEVER a good idea to replace a HOT with just any other type because there can be significant differences which are not at all visible in the spec. Even for specialists it's quite difficult to optimize the drive conditions for a new HOT type. You're on your own here.

Third, some oscillations are normal because the inductance of the base drive transformer does form part of a damped resonant circuit. Usually these oscillations show after switching OFF the HOT and they can be a problem if the negative  $V_{be}$  is insufficient during the flyback pulse and the transistor might be turned back on, which would kill it. As a rule of thumb,  $V_{be}$  should be -2 V during flyback, but there are exceptions. Depending on the HOT type, some damping resistor may have to be applied. I've never heard of oscillations during HOT ON.

If the collector waveforms (V and I) seem OK and the HOT does not overheat then maybe you shouldn't worry too much. But do check at high beam current too (max. brightness on a white picture) because then the HOT must be switched on earlier to provide the magnetizing current to the line transformer too.

(From: Alan McKinnon (a.mckinnon@pixie.co.za)).

I've run into this kind of thing several times recently on different sets, this is what I've found:

1. Do you have a damper resistor (about 30 or so ohms) across B-E of the HOT. It can go open circuit, causing weird stuff.
2. Check the supply feed resistor into the transformer of the line drive circuit. These can go hgh, especially if it's a high value resistor dropping a supply of 120 odd volts down to 30 or so.
3. Check all small resistors and caps in the line drive circuit, take them out and measure them, in circuit readings are funny in this area.
4. Try a new drive transformer.

---

## 4.21) Why do some monitors fail if driven at the wrong horizontal frequency?

I think it *should* not have failed. It is the purpose of the deflection processor to guard that the line deflection never runs at a forbidden frequency. It is possible that such protection is not good enough, that when the PLL is not in lock it might generate a very irregular line drive. That can prove to be immediately fatal to a line transistor. All it takes is one line length that is too long, followed by a flyback pulse that is too high, and it's all over. Second breakdown, terminal.

Trying a too high line frequency is usually not harmful, generally your EHT will be too low and your deflection current amplitude too. The HOT might eventually die from overheating due to bad drive conditions, but otherwise any decent monitor should be able to withstand it. In the better cases it simply refuses to sync on an illegal frequency.

1. While increasing the frequency of the horizontal drive \*all other factors being equal\* should not result in HOT death, all other factors are not always equal. The sync circuits may select an improper set of voltages, the drive waveform (as mentioned) may be insufficient, etc.
2. The sync may lock to a submultiple so the drive may be at 1/2 H resulting in a too long on-time and poof.

As noted, this can be a one shot affair - absolutely no warning. My recommendation remains to attempt if at all possible to obtain the specs for any monitor you intend to use.

---

## 4.22) Changing scan rate on fixed frequency monitor

Here is a discussion about modifying a monitor to run at other scan rates than for which it was originally designed (in this case, a lower one):

"I would like to convert IBM XGA2 (39.4 KHz JH) monitors (9515, 9518) to work at VGA (31.4 KHz H) rates.

I have the schematics, and with datasheets/application notes from chipmakers' websites altering the scan-frequencies and the mode-switching logic has been relatively straightforward.

That's as regards the 'small-signal' bits (and frame output), to leave a 39.4 KHz scan for 75 fps graphics and provide 31.5 KHz for the 400-line DOS text (VGA startup) mode, and 350-line graphics.

\*But\* the HOTs blow up at 31.5 kHz: after a while in the first of a number of 9515s, almost instantly in 9518. The corpses and heatsinks are very hot, as in 'high temperature' as well as function :-("

Blowing up the HOT after minutes is due to bad base drive, or (much more rare) due to LOT core saturation. Blowing up a HOT immediately is due to too high collector pulse.

"The base drive looks fine on a 'scope as regards holding the HOTs (or now an experimentally-substituted forward diode) firmly saturated for the longer 'on' time, and then sharply/cleanly turning them off."

There's more to a good base drive than just 'looking fine' on a scope. The aim is to minimize the dissipation in the HOT. This requires just the right amount of base current and reducing it in a particular manner at the end of each line. (A process that we call 'de-holing', removing all the holes from the

high-impedance collector region, this must not go too fast.)

\* Too little base drive current will cause the collector voltage to start rising too early, before the beam has reached the right end of the screen. The HOT goes out of saturation too early, causing dissipation.

\* Too much base drive current will cause the collector current to reduce too slowly during the beginning of flyback. The HOT goes out of saturation too late, also causing dissipation.

Usually for lower line frequency you need a bit more base drive.

"I have only a rather vague mental picture of how a LOPT works. I think that, as a load on the HOT, it is almost purely inductive from turn-on (though not from the EHT-generating turn-off)."

If there are secondary scan-voltage rectifiers then they add to the load during (beam) scan. Otherwise it is always inductive. During flyback, the flyback capacitor and the secondary flyback rectifiers cause the characteristic flyback pulse shape.

"Hence I suppose that the longer 'on' period allows the current to increase to a higher (and destructive) level."

Not the higher current in itself is destructive, but the increased magnetic energy is. During flyback,  $1/2 * L * I^2$  is converted to  $1/2 * C * V^2$  in the flyback capacitor. More energy means more voltage over the HOT. Over 1500 V peak it will be destroyed immediately.

"If magnetic saturation were to be reached, it would even look more like a dead short than an inductance."

That's true, but it occurs mainly due to excess beam current. Secondary flyback load causes the primary scan current to rise.

"My questions are twofold: (1) how correct is my understanding?"

Fair enough. You can get a fair idea by running simulations with ideal circuit models. But to understand what happens inside a HOT you need very advanced models. Which don't even exist (yet)!

"(2) More to the point, what solution is there?"

You're doing a good job guessing. I'll let you continue.

"One that springs to mind is to reduce the voltage of the HOT's supply, something like proportionally to the increase in 'on' time, so that the peak current is back to what it is at the higher frequency."

Exactly. Peak current and more importantly peak voltage, because then also the EHT will be kept constant.

"This would be a non-trivial task, both to provide a second voltage (at quite high current) and to switch between them."

Maybe not trivial but a lot easier than you think.

"Though some multi-frequency monitors have such multiple (switched) supplies, I don't think all do: what alternatives can be adopted? How does one calculate in this area, or is it (unfortunately) a matter of having LOPTs intended for the purpose?"

The LOPT must be optimized for the higher line frequency and the corresponding short flyback duration. For lower line frequencies, you want to reduce the B+ voltage so that it is proportional to the line time. This is in fact very easy if you use a switched-mode down-converter (is that called a 'buck'?) and you make the on-time of the switch \*constant\*. Now the line frequency may be varied over a wide and continuous range. This gives near constant EHT too.

On other monitors, a voltage determined by the detected scan rate is returned to the power supply in place of the usual zener reference to adjust its output.

You can use an extra filter coil to provide constant B+ to the line deflection circuit or you can use the LOPT primary for that. There are some subtle problems with which I will not bother you.

It may be necessary to reduce base drive current for line frequencies beyond a certain value.

The 'only' other thing left to do is to keep geometry correct for the various display modes. Mainly by switching in more or less S-correction capacitance (using FETs or even relays).

Don't assume that you will be able to re-invent the multi-scan monitor on your own. I think you will find that you have insufficient resources to do that.

Honestly.

---

## 4.23) Yoke and interlocks

"I was asked a question today that I never thought of much before. If you remove the yoke (unplug it) from a TV or monitor is the high voltage still present and if so can this cause damage to the set. Thanks"

The answer is an unqualified maybe on all counts.

Some have an interlock so you lose power to the deflection/set if the yoke is unplugged - found that out on a Magnavox chassis that would not do anything without the yoke connections.

Those that continue to have power may result in damage - at the very least, if the HV is present, you will be drilling a hole in the center of the screen since deflection will be absent. The horizontal deflection will be detuned possibly resulting in overheating, excess HV, etc.

If you do try this, I recommend using a Variac and carefully monitoring the CRT for presense of a very bright spot (which will turn into a very dark spot quite quickly) as well as an excessively hot HOT.

BTW, disconnecting the yoke may be desirable to troubleshoot a horizontal deflection/high voltage if the yoke is suspect. If the yoke is loading the deflection output due to shorted turns, disconnecting it may allow high voltage to come up - just go slow and nothing will blow.

(From: Stefan Huebner (Stefan\_Huebner@rookie.fido.de)).

Some yoke plugs have a jumper wire to remove +B from the flyback when pulling it. But this may still damage the SMPS since they are not all build for running without a minimum load. Some yoke plugs only have the four yoke wires connected; in those sets HV will build up when the plug is pulled and you may even destroy something in the flyback area (most likely the HOT) because the horizontal deflection yoke is an essential part of the flyback circuitry (exception: some monitors, for example Eizo, which have separate HOTs for the flyback and the horizontal yoke).

---

## 4.24) Why the yoke is needed to keep the horizontal deflection system happy

If you unplug the yoke (even if there is no interlock), while the system may still work to some extent, performance will be poor. High voltage will be reduced and parts may overheat (and possibly blow up).

\* One reason to do this at all is as a quick test to determine if the yoke is defective. While the resulting waveforms will not be totally correct, they should be much better than with a shorted yoke installed and there may be enough HV to get a spot on the screen. Caution: It may be quite bright. See the document: "[Notes on the Troubleshooting and Repair of Television Sets](#)" or "[Notes on the Troubleshooting and Repair of Computer and Video Monitors](#)" for more info and precautions.

\* Another more fun reason is if it is desired to use the flyback subsystem of a defunct TV, monitor, or computer terminal as a stand-alone high voltage power supply - but details are left as an exercise for the highly motivated (and cautious!) student. See the document: "[Salvaging Interesting Gadgets, Components, and Subsystems](#)" for more details.

WARNING: High voltages and possibly line voltage present at HOT, yoke, flyback outputs, and elsewhere!

(From: Jeroen Stessen (Jeroen.Stessen@ehv.ce.philips.com)).

Of course, just removing the yoke doesn't work. The flyback capacitor is tuned for the presence of both inductances: line transformer and deflection coil. If you remove the deflection coil then the remaining primary transformer inductance is about 5 times as large. So, rule-of-thumb, you would have to decrease the flyback capacitor by a factor of approximate 5. But that's not all:

Without the deflection coil, a lot less current runs through the horizontal output transistor. So, in all likelihood, it will now be overdriven. So you need to reduce the basedrive. But that's not all:

If you remove the picture tube capacitance and the deflection coil then all peak energy demand must be delivered from the primary winding of the line transformer. Even the shortest peak load will cause saturation. The parallel deflection coil will at least lend some temporary energy, and the picture tube capacitance does an even better job. A good high-voltage source without the benefit of a deflection coil is more expensive...

If you *must* get rid of the 'ugly' deflection coil, then you may want to replace it with an equivalent 'pretty' coil. But:

- \* It must be able to carry the peak current without saturation (a deflection coil has such a huge air gap that it can not possibly ever saturate, but a smaller coil can).
- \* It must have a low enough dissipation so you might have to wind it with litz-like wire (multi-stranded isolated), do not underestimate the losses in high-frequency coils, mostly due to skin- and proximity-effect.
- \* Yes, it can be done, good luck.

And you might want to add a discrete high-voltage capacitor. How to isolate the wiring (corona discharge!) is left as an exercise to the reader... (We pot them in convenient blocks).

---

## 4.25) Probing TV and monitor yoke signals

Due to the particular nature of the signals on the deflection yoke, special techniques must be used to safely view them on a scope. Note that the following also applies to some extent to deflection signals in tube-type video cameras and other similar devices as well.

You cannot put a ground clip on either pole of the line yoke, because one side carries the flyback pulses which are approx. 1000 V<sub>pp</sub> and the other side carries the S-correction voltage which may be 100 V average with a (?) 50 V<sub>pp</sub> line parabola. Both signals are at line frequency (15.75 kHz and up). You need a 100:1 oscilloscope probe for the 1000 V<sub>pp</sub> signal! The field coil carries lower voltages (order of 50 V<sub>pp</sub> max) and at field frequency (50 to 120 Hz).

Usually you connect the scope ground to a large heatsink, unless that carries a warning label that it is not grounded... ALWAYS check first to identify a proper ground and use an isolation transformer for safety since even this may not be the same as the power line ground.

If you have a current probe for your scope, this can be used to monitor the various current waveforms. I have used my Tektronix current probe to view the

yoke current on TVs. The rendition of the horizontal deflection current waveform is quite good. However, the vertical suffers from severe distortion due to the low frequency cutoff of this probe.

You can build a not-very-fantastic (but quite usable) current probe using a split ferrite core of the type used on keyboard and monitor cables (preferably one that snaps together). The following will work:

- \* Wrap seven turns of insulated wire around one half of the core.
- \* Solder a 2.2 ohm resistor across the two leads to act as a load.
- \* Connect to the vertical input of your scope via a coaxial cable or probe.

You can experiment with the number of turns and load resistor value for best results.

To use your fabulous device, insert one and only one of the current carrying wires inside the ferrite core and clamp the two halves together.

For a typical TV horizontal deflection yoke, this results in about a .3 V p-p signal. The shape was similar to that from my (originally) expensive Tektronix current probe. Enjoy the show! Due to its uncompensated design, this simple probe will not work well (if at all) for low frequency signals.

---

## 4.26) Tweaking the deflection rates in a fixed frequency monitor

Pulling a fixed frequency monitor by more than a few percent will likely be a problem. I know this is not the answer you were looking for but getting a new inexpensive video card may be a better solution.

If not, you are looking for an adjustment called horizontal oscillator, horizontal frequency, or horizontal hold. If you do tweak, mark everything beforehand just in case you need to get back to the original settings. There is some risk - changing it too far may result in damage either immediate or down the road - I have no idea.

---

## 4.27) Breathing compensation

Breathing is a change in picture size caused by a variation of the EHT voltage due to varying beam current loading. The EHT has a typical output impedance of (approx.) 1 M Ohm. Average beam current varies between 0 and 2 mA, so the voltage drops by 2 kV (from 30 kV), or worse. At lower EHT, the electron beam is easier to deflect, so the picture size will increase.

Brighter picture -> higher beam current -> lower EHT -> larger picture.

That's the law of physics.

The breathing can be compensated by decreasing the deflection current amplitude as a function of the beam current. A voltage called "EHT-info" is generated from the beam current as delivered by the line transformer. This is fed to the deflection circuit for feed-forward correction. For horizontal deflection this means feeding it to the East-West modulator.

And here's the catch for you Americans: many USA sets don't have an East-West modulator! Most picture tubes (for the USA) with 90 or 100 degrees deflection don't need (much) pin-cushion correction, so there is no fundamental need for the East-West modulator and so there is also no correction possibility for the anti-breathing. There are other options for corrections, like creating a deliberate higher output impedance for the V+ deflection supply etc., but these are passive measures which will lack accuracy.

Sets with 110 degrees deflection angle (common in Europe) will need active East-West correction and should also perform adequate anti-breathing. Although that is still difficult enough, I should know...

The LD/DVD "Video Essentials" contains test pictures to check your breathing performance. It advises you a simple counter-measure: reduce the beam current by lowering the contrast setting ! This will also improve the sharpness (less spot blooming) and increase the lifetime of the picture tube (less burn-in of the phosphors). But you need to darken the room because the picture will obviously be much darker... (<http://www.videoessentials.com/> )

2. There is no charge except to cover the costs of copying.

---

# Chapter 2) Introduction

---

## 2.1) Scope of this document

Problems with bad solder connections, mostly in and around the tuner are very common with several series of late model (e.g., CTC175-187 and higher chassis) RCA/GE/Proscan TVs. Ignoring these erratic and intermittent problems can lead to serious damage including failure of the EEPROM and possibly other expensive

ICs. Therefore, it is essential to deal with the solder connections as soon as these symptoms appear. The repairs are straightforward though perhaps tedious. Thompson may reimburse for reasonable cost of repairs.

Also, some LXI TVs may actually be of RCA/GE manufacture: LXI is sold by Sears. If the model number starts with 274.something it is an RCA CTC176/7 or 187 chassis. (pwhite4@aol.com (PWhite4)).

Sometimes, similar symptoms are the result of bad solder connections elsewhere on these chassis. Check around the pins of large components like power transistors, power resistors, transformers, etc. However, since problems with the tuner soldering are so common, this is usually the place to start.

Note that many other RCA chassis as well as other manufacturer's TVs are also susceptible to similar symptoms with similar causes.

Some of the common symptoms include:

- \* Random power cycling. It may come on in the middle of the night!
- \* Picture shifts or changes size vertically or horizontally.
- \* Picture turns to snow or shows other reception problems.
- \* Picture turns to random display of time or other data.
- \* Noisy or muted sound, volume buttons have no effect.
- \* Remote has no or unexpected effect.

The articles in this document have been compiled over the last few months from postings on the USENET newsgroup sci.electronics.repair.

Contributions are welcome to increase the coverage of this set of notes as well as those for the very similar set of problems and solutions for late model Sony TVs: "[Sony TV Tuner and IF Solder Connection Problems](#)". (Symptoms are very similar and repair requires removing and resoldering connections inside the tuner and IF boxes. Unfortunately, at least on some models, removing these modules is a real treat!)

Proper attributions will be made for all providers of solutions. I apologize if I have incorrectly referenced you or left your name off. I will be happy to make any necessary corrections in the next revision. Please email me with any additional sections. I would very much like to improve the details of the repair procedure if possible.

Corrections and additions to any specific symptom or solution are also welcome.

I have no connection with Thompson Electronics or any other manufacturer of consumer electronics. These articles have been included unedited except for some spelling, grammar, and format cleanup.

---

## Chapter 3) Solder Connection Problems and

# Solutions

---

## 3.1) Symptoms of cracked solder connections

Here are some typical sets of symptoms resulting from bad solder connections in and around the tuner of these late model TVs:

"I have a 26" RCA television with a "squeezed" vertical and "snowy" picture, at its worst times it also shuts off and on again. This problem is occurring 50% of the time, I noticed that tapping the panel where the 75ohm and rca connectors are attached will realign it temporarily. Is this a symptom of the "solder cracking I read about in RCA's or a bad EEPROM and if it is a bad EEPROM why does a smack offer a quick fix and why is it shutting off and on?"

"This picture is short vertical about 1/2 inch at top and two inches at the bottom. Anyone seen this problem on this chassis. Is it possibly related to all the bad solder joints in the tuner area?"

"I have an RCA TV with the following symptoms:

- \* The audio will suddenly switch to maximum volume.
- \* The volume buttons on the TV and the remote control have no effect on the volume during this time.
- \* If the blaring condition occurs and I attempt to adjust the volume very low, then when the condition returns to normal, the volume comes back at this very low volume. So the signal to adjust the volume must be received by the controller while the speaker is blaring.
- \* If I use the remote to mute the volume a slight diminishing in the volume can be noticed, but the mute is not accomplished.
- \* If I cycle power, the problem persists, unless I leave the unit off for a while (sometimes 30 seconds, sometimes a few minutes) before turning it back on.
- \* If I adjust the volume to minimum and turn on the muting, just using my stereo for sound from the VCR, the TV will still begin to blare in short burst and then eventually come on and remain at full volume."

"My parents' RCA TV has lost some volume, and is now barely audible when on full volume. The controls are all electronic and on screen. Is this a known problem with RCAs, and could there perhaps be a pot I could adjust inside to 'boost' the volume?"

"I have a GE 31" (about 3 years old) where the picture moves down the tube, like a DC offset is present. The top of the picture is down about 1/3 from the top of the screen and the bottom of the picture compresses. Occasionally, the picture turns to snow. If I turn off the power and back on, it temporarily cures the problem. Could these symptoms also be caused by poor tuner connections?"

"I have the SAME TV, and mine is about 1/5 off. Some channels also have lots of Snow etc."

"I tried using a VCR as a tuner & running the signal in through the RCA plugs in the back. Same difference. I still experience the same problems. Does this rule out the turner?"

"I am having the following problem with the TV:

- \* The screen will go black and display: 1:5P A-- (the "P" is sometimes an "8" or possibly a "B")
- \* the screen will suddenly go from showing a picture to show nothing but "snow". There is no sound, the remote control won't shut it off, the power button on the set won't shut it off, it has to be shut down by unplugging it.
- \* When it is plugged back in it will sometimes come back on without pushing the power button or using the remote, screen shows nothing but snow, no sound.
- \* Sometimes when it is plugged back in it works normally (won't come on until you push the power button or use the remote), it then acts normally except there is no sound until you use the remote or the buttons on the set to adjust the sound."

"My RCA XL-100 TV has begun to develop a life of its own -- it intermittently goes crazy."

"My two and a half year old GE 25" set started having troubles with the picture shrinking from top to bottom, losing signal strength (snow) and now shifting of the picture off the bottom of the screen. This would occur usually right after turning it on, and sometimes could be cured by turning off the set and turning it back on again. Lately it has been getting worse so I took it in for repair. Lo and behold, there were several GE and RCA sets there that had similar complaints. All ended up needing an "S-kit" from GE, an item apparently supplied to the repair center for free from GE. I needed a crystal as well. This sounds like some kind of widespread problem that maybe should be looked at as if it is an unwritten warranty? Anyone care to comment?"

"I have a 27" GE Model 27GT610. About a year ago a problem started to develop. It would take turning it on 2-3 times before the picture came up. Initially all I would get was a black screen and static on the speakers as if it wasn't on a broadcast channel. Over the last year it

has progressed to taking me 20-30 minutes to get the picture to come on. I suspect it might be a corroding startup relay but am unsure. Does anyone have a part# and component# that could point me in the right direction? Any other suggestions would also be appreciated. Thanks, btw I already have the FAQ.

"I have a 2 year old RCA XL100 television. It has worked just fine up until the last 2 or 3 weeks. I now have severe problems with it and am hoping that someone who reads this posting will recognize the symptoms and help steer me in the right direction to fix the damned thing! I know of another person who had the exact same model and 2 years after he bought it, it started acting up in the same way, so I assume this is a well documented problem that I'm seeing...

When the set is turned on, the "reception" on some cable channels is terrible, but others are fine. Turning off and on again fixes those channels, but within a few seconds, the reception goes bad again. There is a time display function and a mute function on the TV. When I press a button, the channel displays in the upper right corner. Likewise in the lower left corner with mute. When the TV is misbehaving, these words "walk" down on the set. The MUTE word goes so far that it's unreadable since only the tops of the letters show. Turning off and then back on temporarily solves the problem. Whenever this phenomenon occurs, the top of the picture gets "squashed" down and a black band appears at the top of the screen. When I look at CNN, the sportsticker at the bottom is almost unreadable and it appears that the lower part of the picture is forced into the non-viewable area of the screen. If I struggle through these problems for an hour or so, then everything is almost back to normal, but the problems do appear intermittently. When I switch over to the VCR tuner, my reception problems are solved, but I still get the screen "walking" behavior, so it looks to be more that the tuner chip (unless that also controls these extra functions). Does anybody know about this problem??? Is it just a bad chip or component that I can replace? What should I do about it? (I'm a EE and am quite capable of fixing simple soldering problems and such myself). Before I take it to a repair shop or buy a new one, I'd like to see if I can fix this one... in a word... HELP!"

"I have an RCA FMR70ER TV that only works when the room temperature is warm. If the temperature is cool the TV will never turn on .

"The problem tends to show up after the TV has been on for a few minutes. The picture will appear to have signal problems (i.e. a snowy picture), and then the top line of the picture will begin to dip down, until it is approximately 25% of the way down the tube. There is just black above it. When its really bad, the picture will be just snow, the top will drop down almost half, and there will be a very bright band at the bottom of the screen. Now, one way to remedy this problem is to shut the TV off, and then back on again. Sometimes this will 'reboot' the TV and the picture is fine. Sometimes it doesn't work.

The problem is beginning to become more persistent and annoying!"

"I have a General Electric 21" (or 23"...can't remember) colour remote control television. It's about two and a half years old.

The problem we're having is that the picture is 'dropping' off the bottom of the screen. This sometimes happens shortly after turning the TV on, or sometimes not for some time after turning the TV on. What happens is that the whole picture seems to move down a bit on the screen, then it moves a little further, then before you know it, there's about a couple of inches of black at the top of the screen, above the picture. You can't see the bottom of the picture because it is now below the bottom of the screen (i.e. the picture doesn't just shrink). Sometimes a bright white line will appear at the very bottom of the screen, and after a snapping sound the picture will jump back up (sometimes back to the top, sometimes just part of the way up). Then it happens all over again, kind of random. If you turn the TV off, wait a few seconds, then turn it back on, most of the time (not always) the picture will start out back at the top of the screen as it should."

"2 year old ge has tuner problem. Some channels part snowy others very snowy. Sometimes don't work at all. But, only on some channels.( Vertical is not shrinking). Any case histories?"

"I have a CTC177 that instead of the two relay clicks of the degaussing circuit will click 6-8 times when it is first turned on. Signal was coming from U3101 - changed IC, no change in problem. Works fine once it's warmed up, anyone else have this problem?"

"I have a weird problem, or at least I have never seen it before. I have a GE colour television that when it is initially turned on the lower channels are not existent (snowy) and the upper channels are crystal clear. When the TV has been on for about half an hour, all the channels are crystal clear."

"I had/have the same problem w/ an RCA CTC175. Picture shrunk down to letterbox size. When i was going to check the joints, I turned it on (hasn't been used in a couple weeks), to see if the picture came in full size, but to my surprise i had no picture. When i say no picture i mean it's like my cable has been disconnected. After a little fiddling here and there i came up with the following.

\* Cable box hooked - no picture on any channel.

\* Straight cable to TV - only cable channels 54, 55, 64, & 76 (nice and clear).

Should i go ahead and resolder the tuner connections and see what happens or does it sound like the microprocessor may be out?"

"I have a GE TV 25GT543, CTC187AA chassis with a vertical intermittent where a whack on the side fixes it. Is this 'the resolder under and around the tuner' fix? Is there anyway to tell exactly which connection is really the bad one rather than randomly resoldering everything within sight? I like the feeling

I get when I know that I have really found the source of the problem rather hope I got it....."

"Volume and channel OSD shifted off to the right so that channels are not visible. Closed captioning and customer menus shifted to the left. Tuner shield was done about a year ago and is ok. Problem occurred after a power surge that caused C7 the main filter capacitor to fail. Otherwise the set seems to work fine. Horizontal and vertical sync pulses are present on pins 26 and 27 of the micro."

---

## 3.2) General repair considerations

Caution: See the document: "[Troubleshooting and Repair of Consumer Electronics Equipment](#)" before attempting to repair or replace the tuner module. You *\*must\** have proper soldering equipment and desoldering tools. Attempting to remove, solder, or replace the modules(s) without these *\*will\** result in a mess and a very expensive bill when you finally take your TV to a professional.

Someone brought me a TV to look at. After a little prodding, it was learned that he had lent it to a friend and it died after six months or so. The 'friend' then attempted to replace the tuner module based on the description on a refused estimate from a TV service shop. He did not have proper soldering equipment - perhaps only a Weller 100 W soldering gun. Needless to say, the TV did not work - nearly every pad on the PC board under the tuner had been destroyed. I had to run wires from the pins on the tuner to the their destinations on the mainboard. It was not fun. Luckily, no permanent damage was done but it could have easily been a lot worse.

---

## 3.3) About that special RCA solder and soldering of the tuner in general

There seems to be some disagreement on whether to use the 'special RCA solder' or not:

(From: Charles Godard (cgodard@iamerica.net)).

The solder RCA recommends doesn't flow properly. The only returns I've had after doing this repair have been because of using their solder. The best way to do the job is to use regular 60-40 lead tin and apply the right amount of heat with a controlled heat solder gun. Too much heat and you peel the board, not enough and it won't stick or will crack again.

I first flux the joint's with rosin solder paste. I clean my tip before starting, and a couple of times during the job. Again, I use a controlled heat solder gun.

This seems like a simple job because it is 'simply' soldering. Don't be fooled. I've been at this business for twenty years and am an expert at soldering. Of the first dozen or so of these sets that I worked on, I had a couple of solder spills that cost me a couple of extra hours to locate because I didn't realize I had made a spill and assumed another problem. Another hazard is that if you are not skilled and attentive, you may loose one of the small resistors or capacitors from the board. If you find it, then you've got to figure out where to put it back. :> If you flex this board you may cause a crack on a resistor or capacitor lead that could be very difficult to find.

In addition to all that, there are some hidden joint's that won't be apparent to even a skilled technician the first time he does the job. (The stuff in the middle :)

If you are a trained technician and do soldering regularly and have a controlled heat gun, and are used to working with these flimsy consumer type circuit boards, then you can probably do it with no problem. There are some jobs that are suited for do-it-yourselfers and I don't hesitate to tell a guy if I think he can do it and save a few bucks. This is not a job I would recommend for the average guy to tackle. I can think of very few solder job's I've ever done that require more skill and attention than this one.

Sorry, I'm sure that's not what you wanted to hear. However, next time you have a problem, just ask. I may have an easy fix for you, and will be glad to give it if I do.

---

## 3.4) Descriptions of the solutions

Here are some of the responses - many from experienced techs who fix (too) many of these sets:

(From: J. Caldwell).

Following the instructions packed with the service bulletin will allow a proper job to be performed. Overheating the board substrate and surrounding components will cause future and horrible failures.

The connection will NOT look shiny but shouldn't look bubbly or crinked, the solder will only flow if you use the special solder paste, rosin core solder will cause it to corrode oddly so clean all rosin core off the board.

A standard Weller station does the job quite well and experience has shown me that the full repair with jumpers and the special solder (as the bulletin

states) is the best thing to do for reliability and customer satisfaction. I was mistaken in earlier ramblings.

(From: (JohnSon) johntrum@netonecom.net)).

This sounds like the typical shield/pcb solder joint problems that RCA has had made famous with their CTC175/177 chassis. It's a common problem. We have fixed literally "tons" of them. I'm guessing it would be this series of chassis because you also mentioned the EEPROM.

The symptoms you mentioned are all associated with these bad solder connections and there are even more symptoms that can appear from this same problem. No video, color drop, etc. are other common symptoms. Just get your solder iron hot and do a good job soldering ALL bad connections related to the shield areas and you'll be in business again. You'll still just have a "new model" RCA, but, the symptoms you describe should go away. If you catch it while it is in the "smack" condition, you shouldn't need any parts. If you wait until it dies completely, you could be looking at an IC or EEPROM replacement. You DON'T want to replace the EEPROM, trust me!

(From: Jaclyn (lambert@sos.net)).

Possibly.. :) Once you think you've got all the solder connections done - you've only just begun. Also check for cracks on the pads surrounding the tuner grounds. Oh, you might want to order an extra pound of solder before you begin....

(From: Louis A. Iannotta (bouncer@nauticom.net))

The problem is bad solder connections under the tuner shield. The bad connections cause false signals to the EEPROM which cause the reduced vertical height. RCA just recently has issued a bulletin and a kit to repair the connections with a special "elastic" solder which isn't supposed to crack under temperature fluctuations.

(From: Chuck (Nordic@osuunx.ucc.okstate.edu)).

I would open the tuner control module and solder all the posts that are around the periphery of the board. Also on rare occasions, the solder connections break on the main board jack that the plug from the tuner control module attaches to. Resolder them also. Good luck.

(From: JohnSon (johntrum@netonecom.net)).

I am sure you are probably talking about the "infamous" Thompson (the RCA/GE owners) bad solder joint chassis'. They started with the CTC175/176/177 and from what I see they have continued on up through the CTC187 at least and maybe further. You can confirm your chassis number by checking inside the back of the set or on the back of the set sometimes. These sets have a variety of symptoms accompanying the bad solder joints. The two you listed are only a couple. When repairing these sets, all of the trouble areas should be repaired at

that time. You will be just asking for more problems if you don't. If you are very technically minded, you may be able to repair this yourself. If not, you could try a local repair shop. I have heard repair prices for this range from \$50.00 to \$140.00. I don't have any idea what the shops are doing to repair them for \$50.00, but, I suspect they may be just going in and soldering the obvious bad joint, at the time. As I mentioned, this would only be a temporary repair at best. The majority of the problems are under the shield of the "built into the board tuner", but, there are others also. I know our charge to repair them, complete, runs about \$100.00. (lots of soldering to do the job right.) If you decide you need further info, post what model and chassis number you are working on. If it is the problem that I think it is, I can tell you, from our complete repairs, we have never had a recall on these chassis for this same trouble and we have literally repaired tons of these things.

(From: Kevin (giddy@ac.dal.ca)).

In RCA/GE chassis CTC-175,176,177, There is a common problem with bad solder on the tuner shields and around the microprocessor shield.

The symptom is usually intermittant snowy picture and reduced vertical height. Please do not be misled into trying to troubleshoot the vertical section as you may be wasting your time. Often you can confirm if this is your problem by grabbing the RF input connector firmly and wiggling it while observing the picture.

Thomson seemed to have solved the problem around the end of 1993.

I have done lots of these.

(From: BELJAN E (lvpy67c@ix.netcom.com)).

It is the CTC series chassis and the tuner solder joints break. You should take the set in as soon as the problem develops to avoid permanently damaging the set. The S-kit is most likely the repair kit for the GE series (S stands for solder) it has special flexible solder that will keep the tuner from going again.

(From: Marlin (mister-m@ix.netcom.com)).

Yea! These RCA/GE all are having the problem of loose grounds. They are mostly around the Micro and Tuner grounds. If your having problems with the picture becoming snowy you may have to remove the tuner shield and do those also.

The intermitten power on and off may also be around T4401 Flyback Transformer. Check or resolder this area also.

(From: Mark Paladino (paladino@frontiernet.net)).

I'm not familiar with this model in particular but the symptoms you describe may be similar to another well documented RCA tuner problem.

That problem involves tv's of about the same vintage and after a year or so develop symptoms similar to what you describe. The solution to those maladies is resoldering all of the tuner shield connections where the shield connects to the pc board. I have accomplished the "fix" on several RCA TVs of that vintage with similar tuner symptoms and in each instance was able to completely correct the problems and restore the tv to workable condition.

(From: Mr. Caldwell (jcaldwel@iquest.net)).

It is not a picture tube. Why is it that some people think that the picture tube is bad when the set has a snowy picture?

It's solder connection in the tuner, the tuner is not replaceable it is part of the mother board. Call RCA and ask them if they will foot the bill. If not call an authorized repair center and get an estimate.

(From: Lawrence E. Manion (MANION.L.E@worldnet.att.net)).

Get the problem fixed now or the connections will cause enough noise on the microprocessor that it will eventually 'deprogram' the EEPROM and you'll need that replaced and it's quite expensive as this part holds \*all\* adjustments. There are only 2 or 3 controls that are manually aligned.

I have fixed many, many TV's with this problem. It is common to all RCA, GE, LXI model. The problem is easy to fix, but its hard to get the area ready for repair. To those that are brave remove the back, pull out the chassis, (some plugs must be removed so mark as needed) turn the mother board over. Now find the metal can near the cable connection. Their will be 4 solder connections, remove (its harder than it look) then remove shield to expose inner tuner area. You will need to solder all ground inside and around the shield mound you removed, and the connection that was unsoldered from the shield. Now solder any connections that looks bad including surface mounded components i.e.: transistors, IC, and the cable input connections. reassemble in reverse order then your problem will be gone. Be careful not to bridge any connections that is NOT connected a good mag light is a must!

I normally charge \$70 labor for this job takes about an hour of work and 8 hours of playing time to confirm the problem is fixed. Only one out of 20-30 TV's required parts.

(From: John F. Reeves (jreeves@uwf.edu)).

On the CTC175 family of chassis, the tuner shield soldering job must be performed before any other troubleshooting can be done as this procedure will correct many such symptoms. the tuner shield on the bottom of the board must be removed and resoldering around the shield structure should be done. There are four posts that need to be resoldered, and check for any other suspicious looking connections. There are other circuits to check also. Give the entire board a good look. When that is done, see if there is any change in your symptom. These chassis also have a service menu that can accessed by pressing and holding the menu button then

momentarily pressing the power and volume up buttons. CAUTION!!!  
If you are not familiar with these procedure DO NOT MESS WITH IT!!!  
You can really foul up your set. This procedure is included in the  
service manual.

(From: Paul White (pwhite4@aol.com)).

I advise resoldering the chassis, all ground and shield lugs that feed  
through the board, especially around and under the tuner shield. If you  
can't do this take it to a shop and tell them the symptom and that it needs  
resoldering, if they don't know what you are talking about take it  
somewhere else. If you wait to long the problem will get worse and will  
damage IC u3201, the EEPROM IC, which means a complete alignment of this  
IC. Most techs will fudge these settings and may be ok but don't wait  
till that occurs for your own benefit.

(From: Bill A. (Lucy27@ix.netcom.com)).

Yup!! Actually, the whole tuner shield/microprocessor shield grounds all are  
poorly soldered. You can sometimes with the naked eye or magnifier see some  
of the loose connections, but if you solder just a few now you will be back in  
there in a month or less guaranteed. So just do the whole solder job. It is  
actually a much better repair and you can rest easier at night knowing that  
you resolved the problem rather than patching it.

The 'classic' problem is prone to the CTC175 through CTC187 chassis. I'm also  
seeing the same problem on the newer generation CTC178 through CTC189 chassis.  
Instead of RCA redesigning their 'On-Board' tuners, they would rather re-design  
the solder thats been around for hundred years give or take. Good Luck!!!

---

## 3.5) Detailed solder/shield repair procedure

(From: Mr. Paul (jcaldwel@iquest.net)).

RCA now offers a 'kit' to repair these, the only thing in the kit that is of  
any use is the paper template that shows exactly where to solder. But I'll  
give it a shot:

First under a bright light, after removing the bottom shield look for solder  
splashes or components that may have been desoldered by heat.

Kind of short....view from bottom with RF connector toward top:

X	
X	< < Bad connections in lower right < corner causes vertical bounce.

Two X's will cause a snowy pix, they are posts from the shield that are supposed to poke through the bottom but don't quite make it. A small round pad that may look like a test pad or that has a component lead poking through the board are good points to solder.

Also when you remove the board in some sets the leads on a filter to the left of the deflection/color/etc. IC can be bent and short, usually resulting in a snowy pix or just snow. (View from bottom, IC is below tuner, filter is to left, has three in-line pins.

(From: Ken Bouchard (bouchard@ime.net)).

On all of these RCA chassis, with the 'sandwich' type tuners, the shield must be removed, and then carefully solder everything you can see on the top and bottom of the tuner. Then re-install shields and solder them in as many places as you can as well.

A special solder (very very expensive) is sold to the repair centers, that has an elasticity to it to allow a correct fix for this problem. However, you can get away with just normal soldering in most cases, to cure the problems.

I cured our set of all of this, by soldering and soldering.... Most of it has to do with grounds that pass through the tuner, as well as 0 ohm jumpers and such that have bad soldering....

The connections that are bad, are feed-through holes as well as all connections around the perimeter of the tuner can. Each feed-through can be spotted and rca supplies you with a mask. There are about 15-20 connections in all. RCA has a fix for this, which uses a very special (\$700 a pound) solder which has elasticity to it. That and the solder mask helps to make a fast repair. Also look about for ends of any chip components that were poorly soldered. Got to have a fine point tip, or your likely to short something out in your effort to repair.

Be advised that there are many surface mount transistors, chip caps, and resistors that are in the tuner, so you will need a fine point low wattage or temperature controlled soldering iron for these.

(From: Tech 7 (gscivi@aol.com)).

You don't really need a template! Just solder the shield all the way around, and at each point where it comes through the chassis. (this is easily observed by removing the top shield cover as well). and instead of adding jumpers, I simply solder each corner of the bottom shield to the pc board. Jumpers work just as well, so if you want to follow the instructions of the people who didn't make it right in the first place, be my guest. A close inspection will also reveal the locations to solder. And resolder the upc shield too!

---

## 3.6) Still doesn't help?

"I need some help with this GE tv. Its a 1993 vintage model 27GT613 with a chassis number of CTC177BH."

I resoldered the tuner shield and connections. However, when I powered it to check to see if I had resolved the intermittent tuner situation I found that I receive stations 2-13 with much snow in the picture."

(From: Nice address (jbc@blkbox.com)).

If you are sure that you did not make a mistake in soldering, check the RF coils. The coils are small wires through the PC board in the tuner section. I have seen a few cases where the wire was probably not clean when soldered. You may have to scrape each wire and solder it again. A bad MIXER coil may cause snow on some channels and be ok on others. EEPROM alignment will not solve the problem.

---

# Chapter 4) EEPROM Information, Problems, and Solutions

---

## 4.1) Bad EEPROM

Almost any problem can be due to a bad EEPROM since it contains the 'boot' information needed to set up all the TV's subsystems. These include reception, raster, picture, menu, closed captioning, color, sound, and other symptoms. The most common cause are the bad tuner solder connections discussed elsewhere in this document. However, EEPROMs can and do fail on their own.

Where the TV has died totally - particularly after having had prior problems caused by bad solder connections - the EEPROM may be corrupted so totally that the set cannot even 'boot':

If you have an oscilloscope, monitor the DATA line from the EEPROM when you turn the set on. Normally data should appear for a short time and then

disappear. If there is a continuous stream of data on the DATA line, the EEPROM is probably corrupted. (For the CTC177, it is U3201, pin 6 if you don't have a schematic.)

Replacement EEPROMs are now available from:

- \* Dalbani (1-800-325-2264) for over 150 different RCA/GE chassis between CTC175 and CTC187. About \$3 in singles.
- \* TV Man (tvman@mindspring.com)). I now have all Thompson, RCA, and GE EEPROMs in stock. Web: <http://www.mindspring.com/~tvman/>.

"I have a GE model 25GT505 that suddenly developed a problem. Here's what happened:

For 2 years the set has worked fine. Went on vacation for two weeks - house at 63 degrees. Used TV for 3 hours one night with no problems. Next morning, picture is bad as follows:

Picture is as wide as the screen but the vertical height is compressed. Picture starts about 1/3 of the way down the tube and extends to about 1/3 of the way up from the bottom. Furthermore, the bottom traces seem to be overlaid resulting in brighter than normal lines."

(From: DCAVS (dcavs@aol.com)).

This is a common problem for all GE, RCA, ProScan televisions of a variety of chassis. It is due to a design and manufacturing flaw. You should call RCA Customer Relations at 317-587-4151 and take it to a Thompson Authorized Service Center. (Thompson Electronics of France owns the names, RCA, GE, and ProScan for Televisions. ) Thompson has been sending their customers \$75.00 for carry in service and \$95.00 for in-home service. This amount should cover the bill as any technician who knows what they are doing should be able to complete the repairs quickly. There is a small chance that the data in the EEPROM IC that stores all the setup data has become corrupted. In this case the set needs to be reprogrammed to operate correctly. This is a time consuming process and can have a great affect on the quality of reception.

---

## 4.2) Verifying that the EEPROM is bad

"I have a dead RCA CTC175 chassis in my shop that I have traced down to a bad EEPROM. The tuner shield solder connections were repaired, but how do I read the EEPROM contents when the set can't be fired up? We have done a number of these EEPROM change outs, but never with a dead set."

The following applies specifically to the GE model 31GT657 but the general approach (with appropriate changes in chip IDs and pins) applies to many

other models:

(From: seabulls@unlimited.net).

If you do have troubleshooting experience, scope pins 5 and 6 of U3201 when the set is first plugged in to see if data is being exchanged momentarily. If the data continues on and on, then the eeprom is bad. If data occurs for just a moment then settles into a steady 4.8V, then troubleshoot the horizontal drive circuitry, and if there is no data and no 5V on pin 8, then troubleshoot U4101 and the 1.5meg resistor off pin 4 (I think) for open. As Hank pointed out, you could have a blown fuse and shorted flyback although they are unlikely on this chassis. If you do have a blown fuse, U4101 is most likely shorted and the 140V rectifier is probably shorted too (CR4106 I think is the location). The flyback, while possible, is the last thing I would try.

(From: Videotek (dmcdonal@Direct.CA)).

You are right, it is probably the EEPROM. When you install the new one, the set should fire up, but the horizontal sync will likely be out. Just enter the service menu, and reprogram the eeprom. There are about 80 parameters that need to be set. To verify that it IS the EEPROM, scope the data line on the EEPROM, and plug the set in. If you see a burst of data, and then nothing then the EEPROM is OK. If you see continual data, then the EEPROM is bad, as the CPU is trying to find it, and the eeprom is not responding. If no burst of data, then check your power supply.

Everything from soup to nuts can be blamed on that blasted EEPROM. No audio, no vertical, no color. All bad eeprom. I have changed hundreds, and have 3 sets in my shop now waiting for their turn to my bench.

---

## 4.3) EEPROM organization

(From: Mr. Caldwell (jccaldwel@iquest.net)).

There are three sections to the EEPROM:

- \* The factory identification section is where the generic microprocessor gets the data on what chassis it is in. If this get's scrambled the set might think it's a PTV or other size set or has a different type of audio system, etc. This is only alterable by a device that can directly write to the eeprom and cannot be modified by the TV (except when something goes wrong) or the technician without knowing the data and having an I2C eeprom programmer.
- \* The factory adjustment section is that part that stores technician alterable settings such as horizontal hold, stereo alignments, etc. and can be adjusted by entering a code and then using the remote or chipper checker from Thompson.

\* The Customer adjustment section holds all customer controls and is adjustable in normal use of the set.

Since this chip is an I2C bus memory chip it should be quit easy to buy one of each chip from RCA and pull out the chassis coding for each chip then buy the IC in bulk at 1.00 a pop. It's an interesting chip anyway and worth experimenting on.

I think Phillips has such a programmer available since I2C is there baby.

BTW, you should get the FULL 'service' model number and FULL chassis number when ordering parts. Having the service model number makes it easy to look up the full chassis number, you only need the full chassis number to actually get the eeprom but some parts require the 'service' model number.

The service model number is the model number in smaller print on the back that has 3 or more extra digits on the end.

---

## **4.4) Difference in EEPROM contents depending on model**

(From: Matthew L. Kruckeberg (MKRUCKEBERG@pol.org)).

Various configurations require various EEPROMs. Stereo/Mono, AV jacks/no AV jacks, PIP/no PIP, linear power supply/switch mode power supply, pincushion circuitry/no pincushion circuitry, hotel set/consumer set, and the screen size are all variables stored in the section of the EEPROM not accessible from the on screen menu. There also at least 2 different microprocessors. The early sets were produced without closed captioning and require a different micro. I agree that there is a lot of confusion caused by the variety of EEPROMS and the lack of properly trained techs to service these sets. I have seen quite a few butcher jobs to the tuner shields, wrong EEPROMs installed, and incorrect or no realignment of the EEPROM values. Unfortunately there are many people who think they are qualified to service these units just because they claim to know how to solder. When in doubt about the correct EEPROM check with the local RCA parts distributor with a chassis number or better yet buy a manual.

---

## **4.5) Comments on EEPROMs**

(From: Raymond Carlsen (rrcc@u.washington.edu)).

There are dozens of different models, each with different functions supported

by "instructions" in that EEPROM. You could buy one of each (chip) and clone them with a burner, but unless you have hundreds of sets to repair, it wouldn't make sense to go to all that trouble. There are now quite a few after-market sources for those EEPROMS. The specific one for the chassis you're working on must be installed or the set will not work properly.

Some of the 'programming' of the chip must be done *after* it is installed, by the tech, such as the tuner setup adjustments. Each tuner is of course different and so requires tuning. Other factory-programmed EEPROM data cannot be changed by the tech during setup... that's the basic reason the EEPROM must be replaced when the tuner grounds corrupt the data.

Rather than start from scratch each time the chip must be changed, the tuner settings can be 'copied' from the old chip (Note: not always possible), i.e. readings written down on paper and then entered into the new chip during the setup adjustments. After you've done the tuner resoldering, install a socket for the EEPROM. Unplug the TV, install the replacement chip and power up the set. With the set still plugged in (but turned off, of course), remove the chip and install the "bad" one and copy the "parameters". Put the replacement back in and enter the values you copied down. The set should now work properly. I've been able to do that on all but one set I've worked on. You will not find that information in the RCA service literature. It's essentially a workaround, dreamed up by a tech to save time. Bless that one!

Lastly, don't get me started on why Thomson treats it's servicers like [censored]. Chipper Check... Nipper Net... all paid for by techs who can barely afford the coffee they're drinking. Who needs it? You *must* buy RCA's test fixtures and software to service and do even simple adjustments on the new sets! I pass. If that's leading edge.....

---

## 4.6) EEPROM part numbers

"I have a GE 27 inch stereo TV (model 27GT613, chassis CTC177BH) on which I just repaired the tuner shield cracked solder connections."

(From: Michael D. Long (longm@tusmp004.allied.com)).

A friend of mine who repairs machines said it was the EEPROM before he even scrolled done to see that you had had a repair tech look at it. He also has told me that to replace the eeprom you need to get the correct eeprom from RCA and prior to removal all of the factory settings need to be recorded from service menu(he doesn't remember exactly how to get to it without a tv in front of him--check a sam's photofact for details--you can also get the correct part number from that too.

(From: "Nice address" (jbc@blkbox.com)).

Do not trust Sam's photofact for the correct part number. There are

about 14 different part numbers for CTC177. They may all use the 24C02 but the default values are different.

Hey, NAP uses a 24C01 and they charge about \$25 for it. Has anyone built the I2C programmer yet?

(From: YonyMar (yonymar@aol.com)).

Your problem could be caused by a bad EEPROM. First you need to get the correct replacement EEPROM. The letters at the chassis will get you the correct part number, i.e. CTC177XX. Before you remove the old EEPROM enter the software service mode and copy down all the settings so you can write them into the new EEPROM. I would suggest using a socket also.

---

## 4.7) Article on EEPROM problems and servicing

The July 1997 issue of "Electronic Servicing & Technology" magazine has an article "Servicing EEPROM problems in RCA televisions", by Bob Rose. (Editor: Nils Conrad Persson (CPersedit@aol.com), Sales: Electronic Servicing & Technology, 76 N. Broadway, Hicksville, NY 11801, 1-516-681-2922. Editorial office: PO BOX 12487, Overland Park, KS 66212 1-913-492-4857.

ES&T has also had articles on CTC17x servicing and of course all sorts of other repair of consumer electronics in general. While not something you will find on the newsstand, you might be able to get a peak at one if you snuggle up to your local electronics repair shop :-).

(From: Ted Gondert (vcrepair@bbs.industry.net)).

The article is good with some useful information. There is a chart with average values to use for setup/alignment of the new EEPROM. Compared the printed numbers to what I wrote down from RCA CTC175A that was repaired by replacing the EEPROM using a socket and switching the old for new EEPROM after turning on the set to read the old parameters. Then setting the new ic to match. His numbers are close, so maybe TV would work about the same, just set new EEPROM to the average values in the chart.

The article also explained cure for the no sound problem caused by the speakers being muted by pin 29 on microprocessor high. That can be fixed by removing resistor R1915 in the muting transistor circuit, etc., as mentioned on the sci.electronics.repair newsgroup many times. But, he said RCA doesn't approve of it and recommends this technique:

1. Disconnect AC from chassis by unplugging the set.
2. Unsolder pin 8 of EEPROM (and isolate from pad).
3. Use a pick to short pin 8 to the pad, temporarily restoring B+.
4. Plug in set and turn it on.
5. Remove the pick and therefore the short circuit (to the pad).

6. Use the menu function to select speaker on-off.
7. Turn speaker back on.
8. Unplug set and resolder pin 8.

I haven't tried it but sounds interesting. Wonder if some other EEPROM problems can be cured that way? ;-).

---

## 4.8) EEPROM trick for GE CTC177 Problem

Restore defaults I assume.

From: jcaldwel@iquest.net (Mr. Caldwell)

Trick # 722

- \* Press and hold menu then press power and then press volume +
- \* Release menu
- \* Press menu (vertical will collapse don't panic)
- \* Press menu
- \* Press power

You may have restored the eeprom, it's worked for me with some very weird problems with the eeprom where I'd normally have replaced the eeprom.

Note: You need the FULL chassis number and failing that the FULL model number to get the correct eeprom.

The full chassis number may be on the back of the set but it is always inside and, it begins with CTC get all the digits after it. I.e CTC177AE CTC177BA CTC177BA2 etc etc

The generic number on the eeprom will only get you an un-factory programmed eeprom that will not work or work \*very\* strange.

The full model is the 'Service Model' in small print near the large print model number. There are several digits after it that point to the correct chassis number and thus the correct eeprom number.

---

## 4.9) Getting into programming mode on dead set

Where the set does not come on at all or shuts down immediately, the following MAY get you going. WARNING: If the shutdown is actually being caused by excessive HV, this could result in a dangerous and/or destructive situation!

(From: Wes Black (wesmike@aol.com)).

On the "T" Chip solder a temporary jumper from terminal 26 to ground this will bypass the HV shutdown circuitry. You should be able to fire the set up and enter into the program mode. When finished be sure to remove the jumper. This procedure has worked many times for me. Oh Ya!! don't forget to resolder the tuner section first.

(From: J. Caldwell (jcaldwel@iquest.net)).

Setting the horizontal frequency to low (by accident or from corrupted EEPROM) may cause the TV to shutdown or give the with the appearance of being dead.

To fix this is you need to check the value of the main 'critical safety capacitor' a.k.a 'redundant capacitor' a.k.a 'tuning capacitor' This is a larger blue capacitor that is connected from the collector of the horizontal output, it can be connected to ground in smaller sets or is run through the pincushion circuit to ground.

Once you have the RCA part number order one, solder this in parallel to the existing capacitor and the set will fire up and not activate the high voltage shutdown circuit. You can enter the factory setup, reset the horizontal frequency for a stable picture, turn the set off and remove this added capacitor.

I've used this sporadically only to be able to copy down all the other values in an EEPROM since if this happens on it's own it's a good idea to replace the EEPROM. This is not needed if you have the RCA signal generator for these newer chassis.

(From: Tech 7 (gscivi@aol.com)).

Don't let the set run too long with the shunt capacitor either! This does work however, and is even the suggested method by RCA itself! After a number of these badly machined chassis, I have learned to count the service menu items in the event this very symptom crosses my bench. (once the resoldering has been accomplished, there is no need to replace the eeprom!) ; Clip shunt cap to horizontal output, turn set on (full AC), enter service mode, press Volume Up 76 times, Channel Up once, you are now in the horiz oscillator adjustment parameter. Volume up/down will adjust the oscillator to near sync. As soon as you see two or three slanted sync bars shut the set down, remove the shunt capacitor and try the set again. Isn't this fun?!

---

## 4.10) In circuit EEPROM reprogramming

In many cases, while the contents of the EEPROM have been corrupted by write errors caused by bad solder connections, the actual chip is undamaged and

really does not need to be replaced.

The following isn't something you could likely justify for one repair but if you have a motel full of RCAs, it could easily pay for itself and then some in saved time and money! Note: I have not tested this software/device so I do not have any first hand knowledge of its performance.

The hardware interface schematic is free from the Web site or you can buy it preassembled.

(From: Jim Lawnichak (tvdr@mail.emeraldnet.net)).

If you get the chance, stop by <http://www.emeraldnet.net/~tvdr> and take a look at Quick Clip. The program eliminates most tuner alignments and repairs the EEPROM while its still in the set.

---

## 4.11) EEPROM and audio problems

(From: Paul R Gendreau Jr. (tvman@biddeford.com)).

The 175/6/7 (and more) chassis has a SPEAKER MUTE feature for those chassis that sport speaker output jacks, and the speaker mute is also used during the POWER ON or POWER OFF functions. Even if your model doesn't have the jacks - the software and hardware to mute the speakers exists! When the EEPROM data is being corrupted by the poor solder connections - one piece of data that can become corrupted is the bit that is set to turn the SPEAKER MUTE circuit on. Since the on screen display for that model has no menu feature to allow the customer (or technician) to turn the speakers back on - you cannot correct the data in the EEPROM without an EEPROM programmer. There are some servicers that are using EEPROM programmers to access the data.

A easy and cost effective work around is to disable the speaker mute circuit in hardware. This involves the removal of a diode or a surface mounted device (SMD) transistor - what part to remove depends of the chassis involved. If Q903 is present on the foil side of the board - remove it. If Q903 is not there, then CR1953, a diode, will be present on the component side of the board and it should be removed. Only one component, not both, will be in a given TV. Removal of whichever of these 2 is present will disable the speaker mute circuit. If the rest of the EEPROM data is OK or can be corrected by the on screen menu then this procedure will save the replacement cost of the EEPROM (less than \$5.00 wholesale) and the tedious job of performing about 100 alignments to the tuning system which is \*REQUIRED\* after EEPROM replacement.

On the negative side: The customer will find a difference in the way the TV operates! The software in the TV mutes the speakers during POWER ON or POWER OFF functions. This make both of those functions very quite.

With the speaker mute circuit disabled there will be a small burst of noise during both of those functions. The level of the noise is not objectionable - but it will be a cause of concern for customers that are not forewarned. I would guess that over 80% of our customers choose the modification and subsequent cost savings rather than have the EEPROM replaced.

(From: Woodie Morris (bwmorris@bellatlantic.net)).

Here's what I do:

- \* If it's a stereo model, short Q903 emitter to base. (surface mounted)
- \* If mono, cut or remove CR1953.

---

## 4.12) EEPROM notes

(From: Darren (fatal@net.bluemoon.net)).

For the RCA series CTC chassis that have been produced in say the past 6 or 7 years, there is a 4 pin IC near the front of the chassis..... that is the EEPROM. Every chassis has letters such as CTC175 A or K or E2 etc. When you call for this part you need to know the exact letters of the chassis, because the programming in the eeprom differs for every chassis. I have a complete list of all eeproms to chassis part numbers. The info on the ic is useless. The majority of the EEPROMs run about \$4 to 6 which is not all that much. We stock all RCA EEPROMs.

How do you know when your RCA needs a new EEPROM? The two most common reasons are: no power (TV will not turn on) or no audio.

Yes, sometimes the TA audio chip goes bad, or the fat flameproof resistor that feeds the main voltage to that IC burns up, or solder loosens from the board.

When you determine you need a new EEPROM, and you put it in, audio should come back. But if it does not and you know the audio IC is good, chances are you may have zapped the IC or the new one is defective. These EEPROMs are extremely sensitive. To determine if it is the EEPROM, you need to desolder a pin on the main IC and apply a 4.6 volt source to it to see if it will bring audio back. I don't have the schematic handy so I cannot tell you which pin that it is but that is a definite way to determine a bad ic due to an EEPROM.

Once you replace the EEPROM, you need to reprogram the set. off of the main menu you have to put the TV into service mode. If you were smart (and the TV was not in shutdown) you copied all the codes from the old EEPROM, so you know the settings for the new one. Knowing these codes is extremely important! There are something like 50 main options 100 more just for the tuner set-up. Get the service manual!

---

## 4.13) Work-Arounds to sound muting problem due to bad EEPROM

"Yes, please send me a more complete diagram and the EEPROM work-arounds as I see that the no-audio problem has come up a couple of times on the sci.electronics.repair newsgroup. BTW, how exactly does a bad EEPROM result in no audio?"

(From tvman@biddeford.com).

The 175/6/7 (and more) chassis has a SPEAKER MUTE feature for those chassis that sport speaker output jacks, and the speaker mute is also used during the POWER ON or POWER OFF functions. Even if your model doesn't have the jacks - the software and hardware to mute the speakers exists! When the EEPROM data is being corrupted by the poor solder connections - one piece of data that can become corrupted is the bit that is set to turn the SPEAKER MUTE circuit on. Since the on screen display for that model has no menu feature to allow the customer (or technician) to turn the speakers back on - you cannot correct the data in the EEPROM without a an EEPROM programmer. There are some servicers that are using EEPROM programmers to access the data.

A easy and cost effective work around is to disable the speaker mute circuit in hardware. This involves the removal of a diode or a surface mounted device (SMD) transistor - what part to remove depends of the chassis involved. If Q903 is present on the foil side of the board - remove it. If Q903 is not there, then CR1953, a diode, will be present on the component side of the board and it should be removed. Only one component, not both, will be in a given TV. Removal of whichever of these 2 is present will disable the speaker mute circuit. If the rest of the EEPROM data is OK or can be corrected by the on screen menu then this procedure will save the replacement cost of the EEPROM (less than \$5.00 wholesale) and the tedious job of performing about 100 alignments to the tuning system which is *\*REQUIRED\** after EEPROM replacement.

On the negative side: The customer will find a difference in the way the TV operates! The software in the TV mutes the speakers during POWER ON or POWER OFF functions. This make both of those functions very quite. With the speaker mute circuit disabled there will be a small burst of noise during both of those functions. The level of the noise is not objectionable - but it will be a cause of concern for customers that are not forwarned. I would guess that over 80% of our customers choose the modification and subsequent cost savings rather than have the EEPROM replaced.

---

## 4.14) Comments on alignment after EEPROM replacement

The EEPROM data is different for the CTC175, CTC176, CTC177 and up chassis. For correct EEPROM alignments, access to the service data is required! You can install an EEPROM IC and only adjust the first dozen settings, which deal with picture color and size, and this might result in a pretty good picture. But the TV will be far from correct in operation! Keep in mind that the tuner alignments are all set to mid-range when you install the new EEPROM. The tuner is therefore far out of alignment and requires full alignment! Proper alignment requires 3 things:

1. The correct service information for the chassis involved.
2. A signal generator capable of generating a signal on all cable channels.
3. A digital volt meter.

While items 1 and 3 are either inexpensive or common, the signal generator is neither!

For any problems you might have, I recommend that you find a FACTORY AUTHORIZED SERVICE CENTER for the brand you want repaired. There are several reasons for this suggestion. The primary reason is that only a FACTORY AUTHORIZED SERVICE CENTER has the service manual, technical support and access to original specification parts that should make the service of your product effective. In addition, only a FACTORY AUTHORIZED SERVICE CENTER will have knowledge of common problems which may occur in your model and may have suggestions from the manufacturer as to the best solution for those problems.

Call the manufacturer to locate your nearest FACTORY AUTHORIZED SERVICE CENTER, or check your local Yellow Pages. Then call ahead to confirm that the service center is authorized not only for the brand of product you need serviced but for the specific type of product (for example, a Sharp FACTORY AUTHORIZED SERVICE CENTER may not repair Sharp CD players).

If your product is less than 2 years old and you have concerns regarding early product failure, product quality, or repair problems, then you should direct those concerns to the manufacturer. Many manufacturers are eager to assist you if you take the time to call or write. If you do contact the manufacturer, it is important to have ready the model number, serial number and purchase date of your product. Many times they cannot assist you without that information.

If you need to have a product repaired within the terms of the

manufacturers warranty and you do not have your bill of sale (proof of purchase) then all is not lost! Most companies are prepared to send you a PROOF OF PURCHASE DOCUMENT if you call them with the model number, serial number and what you feel is the purchase date. This can take some time to obtain. If the FACTORY AUTHORIZED SERVICE CENTER you'll use has a fax number - ask the manufacturer to fax the letter to the service center. This will speed the repair along.

(From: Matthew L. Kruckeberg(MKRUCKEBERG@pol.org)).

Alignment is a must for proper operation. You will need a service manual for the instructions which should be available from your RCA distributor. You will also need a RF signal generator capable of generating the entire tuning range on the set (up through cable channels 120+). RCA sells one under the part number TAG-001 for about \$200. There are about 150 parameter that will need to be aligned. With a lot of practice I have gotten the time down to about 45 minutes but the first ones became afternoon projects. Unless you plan on doing a lot of them you may be better off cutting your losses and referring the job to a shop with the needed equipment and experience.

---

## 4.15) Tuner alignment problems

"This RCA CTC175 came in with dead set diagnosis, as usual the problems was the EEPROM. I installed a new one and the set came on, but the new EEPROM came with the parameters set at default, and in some channels I had poor reception. When I get into the service mode I can adjust this parameters (100 and further) of the electronic tuner and I achieved a good reception changing this parameters. The problem is that, as far as I know, the way to save these parameters is pressing power, but when I restarted the set, got poor reception again. When I checked the parameters, the new data was there, at least in the display, but it has no effect in the reception. I think the procedure to save this parameters is not the correct."

(From: Dogcatcher (Dogcatch@ix.netcom.com)).

The correct procedure for aligning the tuner parameters is with a special piece of gear that you can purchase from RCA called a 'TAG001' generator. According to the manual once you adjust any of the tuning parameters you must align all. It is true, I've tried to "tweak" them in myself and you think it looks clear but when you turn the unit off or change the channel it is snowy again. I really suggest you check with RCA or a distributor and do it right.

(From: PWhite4 (pwhite4@aol.com)).

Pressing the power button is how you write your settings to memory. You are saving the parameters correctly. I have noticed on the CTC175 chassis that the settings for several of the parameters above 100 can affect the reception

of the different bands in the tuner. 2 through 6 or 7 through 13 etc. can become snowy and clear as you adjust. If you don't have the RCA Tuner Alignment Generator (TAG) you just have to fudge until you get all the tuning bands acceptable. This is very time consuming and frustrating.

---

## 4.16) EEPROM replacement tricks

(From: Raymond Carlsen (rrcc@u.washington.edu)).

Hopefully you saved the old chip. If so, you can use it to put the original values back for the tuner (assuming a snowy picture was not one of the original problems). There are no "ball park" values. Install a socket for the EEPROM. Fire up the set with the new chip, then power it down. Without unplugging it from the AC outlet, remove the new chip and put the old one back in. Turn on the set and run the menu and copy down \*all\* the parameters for the tuner. Turn the set off again and install the new chip. Put in the values you copied down and exit. Power down and unplug the set for a few minutes. Now, fire it up again and see if it works. You may have to reset some of the operational parameters like height and RGB values, but the tuner should be OK. I've used this technique several times with very good results. It saves having to start from scratch. The trick is that some of the values in the EEPROM are sent to the micro when the set is plugged in, and others when the set is turned on. That's the reason you don't unplug it to swap chips. It's a bit of a gamble with the new chip, but worth it for the time it saves. Good luck.

(From: n3evg@aol.com)

Next time you're faced with a RCA/GE dead set due to shot EEPROM from bad tuner grounds and connections...and worried that you can't dump the contents of the bad EEPROM to reset the tuning alignment and other parameters, do this:

Remove the "bad" chip and solder an 8 pin dip socket in its place. Now take the new chip, plug it in the socket, plug in the set and turn it on. If all goes well and the set comes on (make sure you have already had all the solder connections repaired in the tuner before this of course) turn the set off and Without unplugging the set! Remove the new EEPROM and replace the original in its place. Turn the set on and enter the programming menu and proceed to copy down the contents of each of the memory registers. Do all of the tuning channels regardless of how many stations you are receiving. After you have completed, you can now replace the bad eeprom with the new one and program each of the registers. When finished, I then turn the TV off, unplug it wait a few seconds, plug it back in and make sure everything held. Sometimes I have to redo the horizontal hold and RGB registers.

(From: jcaldwel@iquest.net (Mr. Caldwell)).

- \* Pull plug!
- \* Get an 8 pin socket and remove the new IC and reinstall the old IC in the socket (I'm hoping it's not zapped).
- \* Plug set in and turn on.
- \* Enter the access code to get the numbers out of the old EEPROM and copy them down (all entries - even channels you aren't using --- sam).
- \* Pull Plug.
- \* Put new IC in socket and copy in the numbers you wrote down.

Now enter all the numbers from the old IC into the new IC and see if problem is solved. If not, I've forgotten which numbers are for the sound but since you copied the new IC's numbers you should have no problem when you read the service literature or someone here tells you what they are .

Also pull the shield from the bottom of the tuner and resolder the grounds or expect to keep doing this.

If you zapped the old IC then use the TV for target practice with a high powered rifle, I suggest .308 with a soft-point :-). Just kidding, you should probably get it professionally aligned.

Unless you are willing to purchase the equipment needed to perform the tuner alignment and preserve your sanity or some kind repair shop owner who lurks here will accept the chassis you send them for repair.

---

## Chapter 5) Setup Information

---

### 5.1) Setup menus for the uninitiated

"There are some secret codes on this GE TV. I had a Circuit City guy here before, and he held down the power-key or something & fiddled with the other keys during startup. Its almost like a computer's BIOS... Wild! Is this list available to mere mortals?"

---

## 5.2) Setup for CTC175/176/177

(From: yonymar@aol.com).

The following is the setup procedure for the Thomson CTC 175/176/177 chassis.

Software setup procedure:

1. Press and hold Menu button, press Power, then Vol+.
2. Two displays appear at the right and left of center. Use the Vol+ button to step the right display to # V76 (Group 1 setup V76).
3. Press Ch+ or CH- button to access parameter.
4. Press Vol+ or Vol- buttons to change software value.

Group 1, V76 Service Adjustment Parameters

Parameter (Ch+/-)	Parameter Value (Vol+/- to change)	Range
00	Security pass # for Service Adjustment.	Must set to 76. May not advance until value set.
01	Horz freerun freq	00-31
02	Horz phase	00-15
03	Width (27/31 )	00-15
04	Pin amp (27/31 )	00-07
05	Vert center	00-15
06	Vert height	00-31
07	Red bias	00-127
08	Green bias	00-127
09	Blue bias	00-127
10	Red drive	00-63
11	Green drive	00-63
12	Blue drive	00-63
13	Security pass # for Chassis Adjustment.	Must set to 77. May not advance to higher param. until value set

Group 2, V77 Chassis Alignment Parameters

Parameter (Ch+/-), Value (Vol+/-).

14 to 24.

25 Security pass # for Tuner Adjustment (Must set to 78)

Group 3, V78 Electronic Tuner Alignment Parameters

Parameter (Ch+/-), Value (Vol+/-)

100 to 156.

Or more specifically:

(From: Glenn Watkins (blueribb@comcat.com)).

To access the second level of the service menu, first press and hold MENU. Then tap the POWER and then the VOLUME UP buttons. You should see 4 zeros. Press VOLUME UP until the right zeros read '76'. You are now in the first level. Now press CHANNEL UP until you get to 13. Now press VOLUME UP again to '77' on the right zeros.

You are now in the second level.

Thomson has a CTC 175/176/177 Technical Training Manual which has all this information. Get a copy!

(From: P White4 (pwhite4@aol.com)).

If this set has the RCA CTC195/197 chassis you will need a lap top computer and the RCA chipper check software to adjust the digital convergence beyond the 25 steps in the set up menu. RCA is forcing the software on us in this chassis and any beyond it.

---

## 5.3) CTC175 CTC176 CTC177 EEPROM addresses and comments

(From: J. Dow).

The contents of address 0x00 of a CTC175/176/177 chassis V-line EEPROM is:

bit 0 : 1=speakers enabled 0=disabled  
bit 1 : 1=tone high 0=normal  
bit 2 : 1=air 0=cable  
bit 3 : 1=autocolor enabled 0=disabled  
bit 4 : 1=closed captioning enabled 0=disabled  
bit 5 : unused  
bit 6 : unused  
bit 7 : unused

The contents of address 0x00 of a CTC175/176/177 chassis W-line (with ST-9 micro) EEPROM is:

bit 0 : 1=speakers enabled 0=disabled  
bit 1 : 1=tone high 0=normal  
bit 2 : 1=air 0=cable  
bit 3 : 1=autocolor enabled 0=disabled  
bit 4 : 1=closed captioning enabled 0=disabled

bit 5 : 1=alarm enabled (4K EEPROM only)  
bit 6 : unused  
bit 7 : 1=adjust/setup menus disabled (commercial sets only)

Now it's pretty clear, if the very first bit of your EEPROM gets cleared, the sound is gone. So, before you touch anything else, try writing 0x0F to address 0x00.

If you're familiar with I2C, you know, address zero (and subsequent addresses if you're really unlucky) can be cleared easily by accident if one keeps the data (SDA) low and bangs the clock (SCL) long enough.

On early sets, crazy things like that happen when the micro loses ground due to an intermittent tuner shield contact. Newer sets have the micro grounded thru other paths; nevertheless, EEPROM corruption is not completely eliminated.

The EEPROM has a bunch of chassis dependent setup as well. Losing the channel list and labels is only an inconvenience, but losing the tuner setup can make the TV worthless if you can't realign the tuner. Losing some other values, such as hor. freq., B+ voltage, etc. can make the set blow the fuse....

The EEPROM map varies, even for the same chassis due to revisions. EEPROMs are *\*not\** interchangeable! A factory new EEPROM does *\*not\** have any correct alignment values: it's only good enough to start up!

No TV made by Thomson(GE/RCA/ProScan) has ever had a non-volatile memory built into the microcontroller. Some sets have more than one EEPROM. Some ancient AccuScan boat anchors have the channel list in the *\*remote\** and not the *\*TV\** set.

Once I had the pleasure of aligning a couple of hundred chassis in a couple of days; The defaults were grossly incorrect for tuner settings; failing minimum gain, tilt and out-of-band rejection specs. Some channels wouldn't come in at all, and a few sets wouldn't sync up.

If you don't understand how the micro works and what's in the EEPROM, it's all black magic and you'll be cussing and replacing chips at random. If you know the game, you can fix a number of things without ever having to solder or buy a component!

---

## 5.4) GE/RCA CTC177AF tuner alignment

(From: J. Dow).

Tuning voltages for channels: 2,6,14,17,18,13,34,37,48,50,51,57,63,76,83,93, 110,117, and 125 are stored in the EEPROM. Primary, secondary and single tuned. Three values per channel. Every chassis is different because of

individual variations in manufacture, coil knifing, etc. So the factory default middle values are no good for any particular set.

You may try to copy the data from the old EEPROM from 0x54 through 0x8C into the new one. If that doesn't help, you really have to realign the set.

If you have the factory ATE rig it's less than 4 minutes.

If you have the service rig (TAG001 or similar), it can be half an hour or more.

The procedure is described in the service manual.

You need a VHF/UHF signal generator at least; a spectrum analyzer is also very handy but not essential. You also need a lot of patience if you're doing it by hand and not software.

---

## Chapter 6) Miscellaneous Problems

---

### 6.1) Bad buttons?

(From: Zapper (zap@mhv.net)).

I have run into at least 6 sets of the CTC177 family with bad channel up/down switches. One switch would get 'leaky'...stick on I guess. Everybody that I talk to has not seen this except for me.

---

### 6.2) Lost sound after repairs?

(From: mandacat@ix.netcom.com).

I've had two RCA (Thompson) Chassis with intermittent vertical problems. The fix was to install jumpers to carry the ground through all points on the PCB.

The interesting thing in troubleshooting this intermittent (prior to learning the cause) was that you would typically resolder what you thought was suspicious solder connections (grounds and components to the PCB). Now to the point. One of the sets I worked on lost sound AFTER the repair. I found

out that if the set didn't have an 'Internal speaker off' option, one connection on the sound module was not soldered at the factory. I soldered it when I was re-soldering connections and I lost sound! If you have the schematic, I think its Pin 3 on the TDA7263 Sound Module which is not connected at the factory on sets that do not have the internal speaker off feature. Very Interesting! Another way to re-enable the sound would be to lift R1915 (you can cut it on the top of the chassis) from the collector of Q1903 (Transistor is always turned on for the case mentioned above).

---

## 6.3) The ultimate in trapezoid distortion on CTC177?

"The raster is full height and is centered, but narrow at the top (less than half the width of the screen) and nearly full width at the bottom. The image is extremely distorted with gross convergence error at the sides.

With the vertical drive connector removed from the yoke, the display consists of the red line sloped down from left to right, the green line roughly horizontal and the blue line sloped upward from left to right. The three lines cross approximately in the middle of the screen. The ends of the lines fit the shape that the raster has when the vertical yoke connector is in place. That is, the upper ends of the lines are closer together than the bottom ends. A rough diagram of this display may be viewed at

All waveforms associated with the horizontal output, vertical output and high voltage transformer (T4401) appear as depicted on the service notes."

My first thought was mechanical - the yoke is grossly tilted on the neck of the tube - the TV was dropped or something. This would result in both trapezoidal distortion and convergence problems (probably purity as well).

Another possibility is that a portion of the horizontal yoke windings (the upper half, in this case) have opened due to bad connections or a break in the wire. This would mean that the R, G, B electron beams would see less deflection at the top than the bottom and could conceivably result in the severe convergence problems as well.

A short between H and V windings of the yoke is not a likely cause as this would result in much more severe (if that is possible) problems (including much smoke).

I do not know whether EEPROM problems could result in this but considering that so much is controlled digitally these days, I would not discount it as a possibility. Width and Height are digitally controlled so that some peculiar failure in an LSI chip or the EEPROM might be possible.

First, eliminate the more likely possibilities unless you have an EEPROM to swap and quickly confirm.

The November issue of Electronic Servicing reviews the 175 and the 177. It appears that the EEPROM in these sets can cause a great deal of weird problems. It goes into great detail and gives some circuit diagrams of these sets.

---

## **Chapter 7) Service Information, Costs, Reliability**

---

### **7.1) Source for Thomson (RCA/GE/Proscan) television receiver service manuals**

(From: Michael Caplan (cy173@freenet.carleton.ca)).

The following has always worked for me:

TCE Publications  
10003 Bunsen Way  
Louisville, KY 40299  
Phone: 502-491-8110

---

### **7.2) Solder and EEPROM repair costs**

"I live in New Haven, CT and my local RCA/GE repair center tells me that a repair for this problem will cost about 145\$???. Everyone who has responded to this post says under \$100. Am I being taken to the cleaners????????? That would really piss me off."

(From: Paul R Gendreau Jr. (tvman@biddeford.com)).

We are an RCA/GE factory authorized service center. (You should have this work done by an authorized service center because we are the ONLY people who understand where all the problems are with this TV!) Our rate for this job is \$77.00. Furthermore, if the TV is less than 2 years old it would be a good idea for you to call RCA/GE (same company). Call consumer affairs at 1-317-587-4151. Explain how you feel about the cost of repair and the set

not being very old. The numbers of posts in this group referring to this problem confirms that there is a PROBLEM. Ask them to reimburse you for part of the cost.

RCA/GE/Thomson is a good company and has always been willing to address complaints from consumers.

---

## 7.3) That special RCA solder

From: Raymond Carlsen

I understand it is a different Tin/Lead formulation with Gallium added to both lower the melting point and make it more flexible after it hardens. With regards the melting point, as people have pointed out here, you have to get it up to at least 800 degrees to make it flow properly. Well, yes and no. I get the best results With a Weller PTC station and a PTE8 (800 degree screwdriver tip), which I think is the biggest physical size tip made for that iron. That's the clue... use a big tip and solder quickly. Use the edge of the tip for the areas close to SMDs. The large mass heats the metal quickly so you don't have to cook the board.

(From: Charles Godard (cgodard@iamerica.net)).

I've done hundreds of these sets and since the first few when we didn't know about all the 43-46 (depending on how you count) joints, have NEVER had one come back and NEVER expect to see one back. If one ever does come back, I'll fix it for free! Guaranteed!

I've had a few from other shops and from refurbish shops that were not properly soldered. But, if done right with 60-40, they will not come back!

We have been soldering grounds containing various mixes of metals ever since the PC boards first came out. Soldering grounds is nothing new. The same requirements hold now as always did. Flux + Clean joint + proper heat will make a good joint! Every time!

Of the ones that I've seen lately that have come from the refurb shops, the same problem exist. They didn't heat the NEW solder to the flow temp and it still didn't make a good joint. Even with the NEW solder, they still can't get it right.

Is there anything wrong with using the new solder? NO

Is is a waste of resources? YES

Why would it work? It is a gimmick to make the tech heat the ground connection to the proper temp to make the solder bond to the ground. It requires a higher temp to flow the NEW solder. In the process, the temp of the ground

metal is heated enough to accept the bond.

Why would TCE recommend the new solder? It's called CYA (Cover Your A\*\*). There's got to be an excuse for their continuing to sell so many of the units with a manufacturing defect. This is an excuse because they can't figure out how to fix the problem on the assembly line without spending mega bucks.

Do I care? No it makes me mega bucks.

What causes the problem in the manufacturing plant? The solder bath does not heat the grounds to the proper temp.

If the manufacturing process heated the grounds to the proper temp, would there be any problem with the finished product? NO

Is the original solder in the solder bath sufficient to make a good ground if proper heat is applied? YES

Then why would there be any need to change the specifications for the solder applied to the board on a refurb job instead of instructing the tech to heat the joint to the proper temp to flow the solder? CYA

If the original solder in the solder bath is not sufficiently flexible to make a good ground, then is there a defect in engineering or the manufacturing process? YES

Why don't they just put the new solder in the solder bath? Because the temp required to flow the new solder would peel the board.

Why don't they just heat the solder bath hot enough to make the grounds bond with the solder? Because a temp that high would peel the board.

Why do they do it this way? Because it is a cheap process.

Is there any need to use the new solder? NO, just heat the grounds until the solder flows.

Will the joint hold if 60-40 is used? YES, just as they have always held ever since we first started working with PC boards if solder is properly flowed, various metals notwithstanding.

---

## 7.4) Thomson Consumer Electronics Saga

(From: Gregg Lansley (gregglns@ix.netcom.com)).

The good news is that Thomson Consumer Electronics has recently released a repair kit for the 175/177 chassis. The bad news is, as far as I've been able to determine, that this kit appears to be limited, as yet, to Thomson authorized service dealers, which I ain't.

My supplier, Andrews Electronics in California, doesn't stock it and doesn't know when/if they will. The stock number is S-Kit-1. I've only seen a copy of the instruction sheet that comes with it, but it consists of solder and paste flux (enough for 10 repairs) and a template. The key seems to be the solder. To quote from the instruction sheet:

The special solder supplied in the kit is *\*not\** a rosin-core solder. Paste flux must be used to get the solder to flow. The solder included in the kit remains elastic when cool to prevent joints from breaking due to thermal expansion.

There. Now, you know everything I know!

"I guess that's good news for the RCA/GE group (Thompson), but, unfortunately it took them over 2 years to correct the problem. They should have had a factory recall on these tv's and made their customers happy or at least "happier" than they are now! Instead, I have found, they won't even honor their extended warranty in several cases. I just fixed one of these tvs for a lady that had exactly that problem. Her extended warranty is good to January 1988. She called Thompson when she started having problems with the tv. They gave her a list of about 3 or 4 "authorized service centers" for the RCA/GE tvs. She spent the better part of 2 hours on long distance calls and to her surprise, they would not honor the warranty as stated. The warranty states that they will provide IN HOME service for any tv that is 19" or larger. She has a 20" tv and when she called the closest warranty center, they told her they did not travel that far for repairs. The distance was approximately 75 miles for the closest "service center" that they referred her to. She got the same answer from the other places they offered. They said they would fix it if she brought it in, but, this lady is elderly and obviously her mother is older. She got this tv for her mother, with the extended warranty, so she could eliminate the problem of having to haul it somewhere if she had a problem."

Typically, these days, the customer is expected to bring in sets of that size. However, if in home service was a condition of the warranty, then it seems to me a service call should have been made. Look closely at the warranty, however, and see if there's some fine print that allowed them to get out of making such a distant service call. Remember, these documents are written by lawyers!

"Her reasoning was that it was a GE and they are a "GOOD TV"

"We bring good things to life"!

Foiled *\*her\**! In my opinion, those sets are crap. For that matter, what about "RCA"? For years, they were a better color TV than GE. How many consumers really know that today, RCA = GE? Don't own one, don't want one. But how does the average would-be purchaser know this?

I noticed these things beginning to come in, with the same type of problems, about a year ago. Not till I began reading this group did I realize how common the RCA/GE failure is. I don't think a week goes by without somebody posting about the CTC175/177. In fact, I've saved several of the posts on the subject. Now, if a customer stops by with one, and expresses disgust at the set's needing repair at such an early date, I just bring them over to the computer and let them read a few of these posts. The one that sticks in my mind was made last spring. Somebody posted of an odd problem they'd been having with a late model RCA or GE, and whoever replied said something like, "Oh, you must have a CTC 175/177. Hehehehehe!"

"And the company would back up any claim they gave in writing! Right?? WRONG!! She was so disgusted after she attempted to get them to repair it that she called me back and said to come and pick it up, fix it, and she would just pay for it. She was not messing around any more with them. So, on top of buying the tv and paying for the extended warranty, she now has an additional charge for my repair bill. I'm sure she won't be purchasing another Thompson product.. ever!! This tv was purchased brand new in January 1995."

Barely more than a year old. Unfortunately, that's fairly typical for the RCA/GE with that problem. In fact, I have to go look at one today, same problem description, about the same age; a 27" floor model.

"I'm also sure she is not the only customer who has experienced these similar problems. Don't get me wrong, I don't think this mishap will put a company the size of Thompson out of business or anything close to that, but, I'm sure it hasn't helped their public image at all."

Oh, I don't think it's even registered with the public. You'd think that you'd read of this dismal repair record in a publication like Consumer Reports, but they are silent on the matter. Makes you wonder how much the magazine is worth....

"I know they sold a ton of these sets that will still need repairs in the future too!"

Yeah, we'll have work for some time to come.

"I just think their announcement is just too little, too late. I'm sorry for rambling on, but, some of these companies and their greed just get me a little pissed off."

Don't blame you. I think you're absolutely right. Although maybe there is just a bit of corporate honesty showing here; the RCA symbol is, after all, a \*dog\*! ;-)

---

## 7.5) In defense of Thomson Consumer Electronics

At least here are a couple of people's experiences:

(From: Daryl Smith (darsmith@spk.hp.com)).

Thomson Consumer Electronics has been good about taking care of this problem, despite the TV's being out of the warranty period, in my case, anyway.

There is a 1-800 number to call Thomson Consumer Electronics about this problem. My 2 year old 31" GE TV had the same problem. I called, they sent an acknowledgement letter, I had the set repaired (~\$90), I sent a copy of the repair bill along with the letter back to Thomson, and they reimbursed me the full cost of the repair. I don't have the number with me right now, but if you can't locate it elsewhere, I will dig it up at home. I had it repaired in late May and the reimbursement check came last week. You will also need to send them a copy of the original sales receipt for the TV. Good luck.

(BTW, they originally said they would pay up to \$75 toward the repair labor + the full cost of any required parts, but the check came back for the full \$90 it cost to have the set fixed, so I'm not complaining. Maybe it was for the extra effort to get a 31" set hauled down to and back from the shop [it must be a factory authorized shop].)

(From smaher@freyja.solano.cc.ca.us).

I like many others have faced the solder problem. I bought my 27" RCA, Model F273S1WN, television on January 9, 1995, and paid for a two year extended warranty. With the extended warranty, my labor was covered until April 9, 1997.

I first experienced video and sound problems in August 1996 while the television was still on warranty. I had almost the identical symptoms as stated in section 1.2 of your article.

I brought the set in for repair and was immediately informed that I needed a part to repair the problem. After three weeks, I got my television back, and it worked fine until April 17, 1997 (eight days after the warranty expired).

I again brought the set to the same repair company. This time I was told that all the solder connections had to be resoldered at a cost of \$115.00. Since my television had the same symptoms as it had the first time it went bad, I asked if they just fixed the same problem again.

The repair company could not find any paperwork of the previous repair so I called the warranty company and they stated to me the the repair done in August 1996, and the problem was soldering not a part replacement.

I called RCA at (317) 415-4151 and stated that I felt I should not have to pay for repairs even though my warranty had expired. They agreed to

reimburse me for \$85.00 of the cost of the repair.

(From: Dave Fredricks (fred@rea-alp.com)).

If you have to, there is a 900 number supplied by Thomson. Yes it is \$2.50 a minute, but if you can clear customer for the bill at least the set is fixed and you get the money. They have been pretty helpful when I have had to use them on a dog unit.

---

## 7.6) Reliability of repaired sets and new models

Since these are manufacturing problems and not electronic design faults, the long term reliability of these RCA/GE chassis with properly repaired solder connections should be excellent.

However, not everyone shares this opinion:

"How far to the landfill? I expect these TVs to be problems for years to come. Cut your losses now!"

(From: Bert Christensen (bert.christensen@rose.com)).

My experience with these sets has been that once the grounds are repaired they are quite trouble free. I would much rather have a set with one or two easily repaired faults than one with different faults everywhere like the Zenith System series.

(From: Mick DeMaria (bmvid@snet.net)).

For what its worth. We are an authorized TCE service center in the central CT area. TCE has been giving customers special authorization. Letters for tuner-skit repairs in the amount of \$75.00 for carry in, and an extra \$20 for in-home on 31" and larger sets. The customer is expected to pay the difference. So far if the s-kit instructions are followed, we have only had one or two repeat failures out of at least 500 repairs done to specs. in the TCE bulletin. Many authorized servicers in this area seem to think the jumpers and special are just BS. I can't say for sure but TCE's procedure seems to work.

---

## 7.7) Would you buy one of these sets?

(From: Mr. Caldwell (jcaldwel@iquest.net)).

I would buy an RCA/GE TV. The problems with the solder connections have been solved on the newer chassis. Once the connections have been fixed on the problem sets there is no other common problem. If you yell at RCA they have been paying for the repair.

(From: Mr. Caldwell (jcaldwel@iquest.net)).

I would, the problem with the solder connections has been fixed in the newer chassis. Once the connections have been fixed on the problem sets there is no other common problem. If you yell at RCA they've have been paying for the repair.

(From: Bert Shristensen (bert.christensen@rose.com)).

My experience with these sets is that once the grounds are repaired they are quite trouble free. I would much rather have a set with one or two easily repaired faults than one with different faults everywhere like the Zenith System series.

(From: Leon Thomas (lthomas@bcn.net)).

I live in Mass. and have sold and repaired hundreds of the ctcl75/6/7 chassis. If a technician is called when these problems are first noticed I would call it a minor repair. If the repair is done properly, it WON'T happen again. The most you should be charged for this repair (no parts changed) is around \$70.00. I have never had to do a second repair on the same set. I do not recommend anyone without experience touch these chassis. You can mess up the tuner very badly if you touch the soldering iron to one of the many surface mounted components. Pay the \$70 and have it done right. I even let people watch me fix this problem to show them what it was. What you have to realize is RCA has made a terrific set with a minor bug. These chassis, in my mind, are the best on the market once they have been repaired. The new chassis they produce now ctcl89 is a great improvement. Basically the same design with no bugs. I have sold many of these sets and have had not one return!

---

## 7.8) Getting service/reimbursement 1

"Just got off the phone with Thomson. I was "authorized" to receive \$75 for the repair, plus \$20 for travel to my house. My local repair shop quoted \$110, if I brought it to them. So if I can't talk them down much, I may tackle the repair myself. I'm a EE, which isn't saying much, but I work with many talented techs who can help get the job done."

(From: Siva Subramaniam (SubraS@cat.com)).

The same thing happened to my GE 25" TV. I was told it is a problem with bad solder near the tuner. This problem is very prevalent and GE (Thompson Electronics rather) is aware of it. My TV was out of warranty

too, but when I called GE at 317-415-4151 and complained about it, they offered to assist me in taking care of the problem. They paid \$75 in labor and all parts charges. They even set me up with an authorized service center locally and paid them directly. I did not even have to get anything reimbursed. I had to pay \$90.00 for labor (\$15.00 out of my pocket), and the unit now works fine. Even though the quality of GE TV was bad (this solder problem), I laud their customer service. I hope you could get taken care of in a similar way.

(From: algba@ix.netcom.com)).

If you call that # and find that you get nowhere, call it back another day and talk to a different person and you will probably get satisfactory results. I've told this to many customers that didn't get results on the first call and they had success on the next call.

(From: Colin Fisher (gomark06@aol.com)).

Call them at the

- A) Beginning of a month and quarter (best)
- B) Beginning of the month (least)
- C) Beginning of the quarter (next best)

Why?....that's when many corps dole out budgets.....

(From: Dave (moonwolf@fundy.net)).

We just had our 3 year old GE TV serviced for a problem with the tuner shielding. The tech had to resolder the shield. Even though our warranty just ran out, it was honored. The tech said this was a common problem with GE & RCA - the board heating up and cracking the solder joints. He also touched up a couple of other areas in the vicinity as 'preventive maintenance', he said.

It's back to working fine now.

(From: Gary Ferris (grferris@voyager.net)).

Thomson Consumer Electronics' US headquarters is in Indianapolis, IN. I have found them relatively accommodating if a product is 1 or 2 years old. Any older an they tend to take a harder line (which is not unreasonable). Many other manufacturers have "silent recalls" for products that develop problems in a significant percentage of the same model. These will usually last for 6 months to a year and service centers are reimbursed for the repair as if under normal warranty. Two examples are Gold Star with the infamous reel sensor failure and Sharp with Hi-Fi audio crackling. Both of these were covered for one year.

---

## 7.9) Getting service/reimbursement 2

"I am trying to decide if I should attempt to repair this myself or take it to the shop. While I have am a degreed EE (who actually has his own lab bench), this only serves to remind me of how much I actually don't know about TV repair. From reading the above information, it seems that there are no component leads that need resoldering, only the shield connections. Is my perception accurate? Are all of these spots easy to access? Is the template in the repair kit helpful/accurate? Can a do-it-yourselfer get the template? Is it really necessary to use the "elastic" solder? (Got to admit - I've never seen elastic solder - wonder if that's a marketing ploy to try and convince you that you'll never have to repair cracked joints three years from now.

(Responses from: Matt Kruckeberg (mkruckeberg@pol.org)).

If your are skilled in soldering you may be able to do it yourself. Be advised that the traces and components under the shield are fairly small and subject to damage and detuning. The template provided is accurate. As to the reliability of the repair only time will tell. I have had no reoccurrences on the units serviced with standard solder 3 years ago before the "elastic" solder kit and jumper wire instruction set was made available.

"Because of the above uncertainties, I would prefer to have a professional do the repair. However, I want Thomson/GE to pay for it. It appears as though there is an obvious design/manufacturing flaw. My company would recall/repair its product if this happened. So I feel Thomson/GE should also. It's the principle of the situation. But, from this web page, it seems as only RCA is reimbursing their customers for the repair, not GE. Does anybody know a phone number where I can call and complain to Thomson/GE? Has anybody heard of any successes in getting GE to pay for it? Does it have to be a GE authorized repair center? Any help is appreciated."

Good luck. Thomson Consumer Electronics the parent company of RCA and GE televisions has been quite difficult to deal with regarding this problem. I have had them tell customers that I did not know what I was talking about and denying that a problem exists. This after sending out 3 service bulletins on the problem. I even received a letter and phone call from the field service manager stating that such information was not to be released to the general public. The phone number I have for TCE customer relations is 1-317-415-4151. Be prepared for busy signals and a wait on hold. Officially the work is to be done by an authorized service center but I have heard of cases of reimbursement for work done by non authorized servicers, generally in rural areas where an authorized servicer is not locally available. I would suggest having the work done by an authorized servicer since they should have the needed solder, training, and experience. The good news is that these sets have been very reliable otherwise.

---

## 7.10) Getting service/reimbursement 3

(From: Steve Backi (backis@rjrt.com)).

I have an RCA 27" TV with a CTC 177 chassis. This set was manufactured in June 93, and I purchased it in September of 93. A couple of months ago, I started experiencing problems with the set, i.e: snowy picture, picture compressed, picking up other channels. Typical problems associated with CTC175/176/177 chassis. I telephoned several repair shops. Each one of them was very familiar with the problem. I took it to one shop in the area. He charged \$115 for the repair. \$85 for the solder problem and \$30 for additional EEPROM configurations. Based on estimates I seen, this seemed like a fair price.

My repair man gave me the telephone number of Thompson Consumer Electronics, and asked that I request partial reimbursement for the repairs. This is where the fun begins. I first spoke with a customer service rep(Patrice) who would not give me her last name. She stated that she was not aware of any problems. I asked for the supervisor's name. After a brief conference with the supervisor, (I suppose), she gave me the name Ryan Brown. She also said because the set was older than 3 years, I was not entitled to any refund. She hung up before I could get further explanation. I telephoned back, and asked for Ryan Brown. Mr. Kevin Johnson answered my call. He very rudely said he was unaware of any problems despite what every repair person I spoke with and the hundreds of responses on the internet.

While he did say he would not offer any type reimbursement, he was willing to offer a certificate towards the next RCA/GE/ProScan TV purchase. I told him, I will no longer be purchasing any brands manufactured by Thompson Consumer Electronics, because in my opinion, they do not stand behind their products. I will no longer purchase those brands, and I urge consumers not to purchase those products. I suspect that the reason towards my bitterness, is that I own two other Sony TV's, and a Mitsubishi, which are at least 12 years old, and they perform flawlessly.

---

## 7.11) Getting service/reimbursement 4

(From: Karen Justice (Karen.Justice@PSS.Boeing.Com)).

We had the misfortune of buying a 35" RCA TV in September 1995. We chose the RCA based on a Consumer Guide rating that indicated it to be a "best buy". We paid over \$1200 for the television. Within 8 months, we were experiencing the "shrinking picture" problem. I believe the manufacturer's warranty was 90 days on labor and 1 year on parts. I called the authorized service dealers in our area as well as several others and learned that the estimate for the repair was typically more than \$200. No repair shop was able to tell me that it was a known problem and that I should contact the

manufacturer to see if they could offer any type of assistance. I went with a non-authorized dealer close to home who charged me \$138 to fix the "vertical output system". Of that amount, \$30 was for pick-up/delivery and the rest for labor. The TV worked fine after spending the \$138.

Well, less than two years later, the same problem is occurring again. It just so happened that last month's Consumer Report magazine (my subscription hasn't expired) indicated that Thompson Electronics recognized a defect with the TV's and suggested that the Customer Service number be called. So, after numerous long distance phone calls (the first time I was told I needed the exact date of purchase, since I couldn't recall if I bought it on 9/5/95 or 9/6/95, and to call back). I can't imagine that the one day made any difference, but I verified the date, called back and eventually got through. They said they do NOT admit to the televisions having a problem. However, since the TV is relatively new and I have already had one out of pocket expense, they would give me a "special warranty". They said that I am "lucky" to get this, since I had a non-authorized repairman look at it originally. They agreed to pay for all parts and up to \$80 for labor, if I went to an authorized service center. They recommended Martha Lake Electronics. I called Martha Lake and learned they have a "flat rate minimum" charge for large TVs and won't even begin to look at the TV for less than \$225 and it could go up from there! Pickup/delivery is another \$110 at Martha Lake (which is about two miles from my house). So, I contacted the other authorized repair service and he said he could probably do it for \$150 plus \$40 for pickup/delivery. I called Thompson back to let them know that the amount they are authorizing doesn't even come close to covering the cost of the repair. They were unwilling to negotiate a different amount. They gave me the names of other authorized service centers in other cities within a 30 mile radius that I could call for comparison. They said they had mailed out my authorization on April 29, but I told them I never received it. They checked and for some reason it didn't get sent. After another long distance call of probably 20 minutes they said they would send another authorization today.

Needless to say, I am thoroughly disgusted. I am mad at Consumer Reports for recommending a TV as a "best buy" which was built by a manufacturer that had a running history of a known defect. I am mad at the authorized service dealers who didn't mention the problem to me when I first called in June 1996 when I could have perhaps negotiated with Thompson Electronics to pay for at least part of the repair. I am mad at the repair service dealers who appear to be charging customers much more than they should for this repair (all other information in your article on the internet said that all the repair associated with this problem should easily be accomplished for \$99 or less). They tell me it is a "major repair" to do the soldering. I am mad at Thompson Electronics for not authorizing full repair of my television, since it is a recognized problem (in your article, someone indicated they should even authorize a recall).

The one thing I did learn is that I will never buy another RCA (or GE) product again and I will no longer use the Consumer Guide recommendations upon which to base my buying decisions. So maybe I made a one time purchasing mistake, but they have lost my business forever, which in the

end, could be even costlier for them.

(a week or so passed)

Since I wrote the note, other problems are occurring with the television (we can't turn it off - other than unplugging it, and the picture is nearly obliterated now with "snow"). By the way, I got a letter from Thompson Electronics on Friday, May 8 (dated April 29), authorizing the repairs/labor (up to \$80). I have All Area Servicing coming this morning to fix it (they said they should be able to do the repairs at our house). The "house call" is \$54.95 and the repair will be another \$100 plus tax. They say that once a complete soldering job is done that the TV's seem to work fine. I certainly hope so. I don't look forward to facing another \$150 bill in another two years. Thanks for listening!

---

# Chapter 2) Introduction

---

## 2.1) Scope of this document

Problems with bad solder connections, mostly in and around the tuner and IF boxes are very common with several series of late model Sony TVs. The repairs are straightforward though perhaps tedious and on some models, removing the tuner and IF boxes from the mainboard can be real fun.

Some of the common symptoms include:

- \* Picture turns to snow or shows other reception problems.
- \* Inability to tune blocks of channels.
- \* Channels change randomly as if TV doesn't like what you are watching.
- \* Loss of picture - just raster and high pitched whine.
- \* Noisy or muted sound, volume buttons have no effect.
- \* Controls have no or unexpected affect (console or remote).

Note that many other manufacturer's TVs are also susceptible to similar symptoms with similar causes.

The articles in this document have been compiled over the last few months from postings on the USENET newsgroup sci.electronics.repair.

Contributions are welcome to increase the coverage of this set of notes as well as those for the very similar set of problems and solutions for late model RCA and GE TVs: "RCA/GE TV (CTC175/176/177) Solder Connection and EEPROM Problems".

Proper attributions will be made for all providers of solutions. I apologize if I have incorrectly referenced you or left your name off. I will be happy to make any necessary corrections in the next revision. Please email me with any additional sections. I would very much like to improve the details of the repair procedure if possible.

Corrections and additions to any specific symptom or solution are also welcome.

I have no connection with Sony Electronics or any other manufacturer of consumer electronics. These articles have been included unedited except for some spelling, grammar, and format cleanup.

---

# Chapter 3) Solder Connection Problems and Solutions

---

## 3.1) Symptoms of cracked solder connections

Here are some typical sets of symptoms resulting from bad solder connections in and around the tuner of this series of late model TVs. Most of these problems are characterized by erratic behavior of one form or another. However, total failure of reception is possible:

"I have a two-year old Sony Trinitron TV. When it is turned on, picture perfect. But it can only last about 30 mins, then it looks like it has difficulty to receive signal. On its hardly seen screen, you can see all channel display only one TV station signal (I am using cable). After I turn it off for a while and turn it on again, I got good picture again. The time it last depends on the time I turn it off. Occasionally, if it past the first 30 mins, it seems it will be good forever."

"I have a Sony KV-27TS20 tv that upon power up will drift back and forth from a clear picture to a whining static fill mess. This happen for about five minutes then the clear picture stays."

"My Sony 27" (Model KV-2782R) is having a problem with the tuner (I think). When the TV comes on, I have no control over any of the functions. The channel changer, display controls, TV/Video selector all have no effect on the TV. I can, however, see the source (VCR/Laserdisc) that is plugged in to my Video 1 jack, but the picture is very dark."

"I have these 2 practically identical (at least on the outside) 13" TVs, and they both have the same problem: they act like if someone was messing with the antenna - the picture comes and goes, or just 'jumps' vertically every couple of seconds, the sound sometimes goes away too (turns into just noise). On the KV-1395 the problem sometimes stops - either the picture is already good at power-up or it just acts up for about 20 seconds and tunes in, the other one is totally unwatchable.

I assume that this is a common problem with these and some other Sony TVs - I remember long time ago someone had posted repair tips on Sony tuners, but I could not find them on the FAQ sites."

One more detail: At power on both the TVs cycle through channels 2-6, with no picture on screen. You have to select a channel for the picture

to come on. Is this normal with these models?"

"I'm having a problem with my KV27XBR55 (mines in the XBR series). I realize now that the problem started many months ago when I heard the sound degrading (I thought the sub-woofer had blown). But after moving recently the sound got very bad just before the picture dropped out too.

If I unplugged the set for a while (minutes to hours) it would work for several minutes to several hours after plugging it back in. And... (forgive me! :) a well place thump on the cabinet could get either some video/audio static or actually restore the picture and sound.

I thought the jarring of the move may have loosened some circuit boards or connectors, so I opened the back and reseated every card/connector I could easily reach. That seemed to work but the next day it died again.

When it's having its "problem" I can get a picture by selecting a video input (like the VCR) but no sound."

"This TV works fine for a few minutes, but after warming up it demonstrates a tuner problem. When a channel is switched to, it will take ~5 seconds to lock into the station. Then it will not stay locked in, but instead drift to an adjacent channel for the audio.

I have been reading here for several months, and based on other postings of similar problems, thought I could try to fix this. I read the pertinent parts of Sam's FAQs, and I photocopied parts of the Sams' Photofacts.

The photo of the A-Board shows one tuner box, while I have a box labeled RF-AGC [IFB-450M 1-464-598-11 AE7C20] and Tuner [1-463-603-13 BTP-201 D7011BY]. Adjusting the blue turn knob in the top of the RF-AGC did not improve the problem. I have not adjusted the white turn knob that is in the RF-AGC box. It is difficult to get to because of the proximity of the adjacent Tuner box.

My questions are:

- \* Should I adjust the knob inside the RF-AGC?
- \* Should I solder out the Tuner box and replace it?
- \* Should I solder out the RF-AGC and replace it?
- \* What will a tuner and/or RF-AGC cost and where can I get one?

I admit to being a novice, but I have enjoyed reading the troubleshooting advice that is discussed here. Although I could take this to a shop, I would like to try and fix it myself."

Do not touch any of the adjustments! Problems that happen suddenly or have significant consequences are rarely due to adjustments drifting!

None of the modules need replacing but if you screw up :-)) the IF is about \$90 and the tuner is about \$100. Resoldering all suspect joints will cure your problems.

"Would like to know if any users have discover why the tuner or TV signal fails to work until the set has been on for about 10 minutes. This problem shows up on the VHF channels - the UHF channels will work. A number of the same vintage sets are starting to show the same problem. Any suggestions would be most welcome."

"I turn it on, and after 5 minutess, it goes to static. I can't even play a tape in the VCR (which the signal runs through first)."

"I have a 4 year old SONY TV with a trinitron tube. When the TV is switched on, it does not receive a few station. For some stations it just snows, on others it shows a very distorted view of some other channel. The problem goes off automatically after 4-5 minutes and then there is no problem as long as the TV is on. The lower frequency channels take the longest time to come back. It is a cable ready TV and when we are viewing cable, the lower channels have the same problem. Most of the time the higher band cable stations are ok from the start.

We are thinking that it may be a problem with the tuner. It does not look like heating problem as the problem is there only during the startup. Can it be a problem of the tuner PLL? or is it something simpler?"

This may be an actual electronic problem but would still recommend doing the resoldering first.

"Does anyone know how I can go about fixing a tuner problem with the Sony TV? The tv signal will come in and out, the signal will come in only for about 30 seconds and is gone for about 15 mins. I have checked all electrical cables, cable TV and antenna cables too.

I have tried contacting Sony, they seem don't care about their consumer services. I have emailed them and contacted their Sony Store dealers, and they would only say it would best to buy a new Sony. I personally will not buy another Sony every again.

"I have a Sony 32" console type TV and the model number is KV-32TW75. The TV set is about three years old. It worked perfect until few month ago. When the set is direct connected to antenna through the UHF/VHF terminal, it worked perfect for about 1 minute then lost all the signals and had no picture. Then I connected the antenna to a VCR first, and connected both the UHF/VHF and video output from the VCR to the TV, it worked all the time. I thought maybe the signal was weak, by turning on the VCR may increase the signal so I didn't pay that much attention. Yesterday it started getting very poor picture quality. I disconnected the video input it got no picture at all. With the video input connected, it doesn't make any difference with or without the UHF/VHF input connected and the picture quality is way low. By connecting only the VCR UHF/VHF output to another TV (this one is a 19" sony with no video input terminal), the picture is perfect. Anyone have any idea what cause this problem and how can I fix it? Thanks in advance.

"This small electronically tuned Sony (Sony KV-13TR14) has this problem:

after about a minute of power on, picture snaps to another (cable) channel for an indeterminate amount of time and then snaps back to the original channel where it operates okay for periods of time (a few seconds to a minute or so). This goes on for several minutes then usually stops and doesn't happen again until the set is turned off, etc.

The local cable company told me that this model Sony had "a bad 'board' grounding problem" or some similar 'grounding' flaw.

I wrote to Sony asking if they were aware of a manufacturing problem with this model and they replied no.

Of course its out of warranty and there's the judgment of taking to the repair store or just buying new.

I'd sure like to repair this myself and any help greatly appreciated."

"I have two Sony TVs that seem to have tuner problems.

The first one is a 13" TV about 4 years old. After about 1 hour of use, the VHF channels go away and all I get is a scanning type picture and a high pitched whine. The UHF and Video input still work. (I do not have cable.) Turning the set off for a while will fix the problem. Also, the TV has the problem faster when it is hot out.

The next one is a 27" TV about 5 years old. When I first turn it on, it works fine for 1 minute or so. Then the VHF channels start to dissapper in the same way as the other TV. This starts at channel 9 (the top VHF station) and works its way down. The problem only affected channels 9 and 7 but not 4 and 2 go out too. After 5 or so minutes they are all back. UHF and Video input still work.

Would you suggest re-soldering the tuner modules for these TVs?"

"I'm wondering how easy it is to replace a tuner module for my 13" Sony. Repair shop said that it is a very expensive part and is very difficult to replace. I'm skeptical about the expense because the same shop replaced a tuner module on another tv I had and they listed the part as \$5. If it's easy, any ideas about where I can find a replacement part?

A replacement tuner for a Sony 13" tv is a little expensive. I would suggest that you check the solder connections in the IF block before investing in a new tuner."

---

## 3.2) General repair considerations

Caution: See the document: "[Troubleshooting and Repair of Consumer Electronics Equipment](#)" before attempting to repair or replace the tuner module. You *\*must\** have proper soldering equipment and desoldering tools. Attempting to remove, solder, or replace the modules(s) without these *\*will\** result in a mess and a very expensive bill when you finally take your TV to a professional.

Someone brought me a TV to look at. After a little prodding, it was learned that he had lent it to a friend and it died after six months or so. The 'friend' then attempted to replace the tuner module based on the description on a refused estimate from a TV service shop. He did not have proper soldering equipment - perhaps only a Weller 100W soldering gun. Needless to say, the TV did not work - nearly every pad on the PC board under the tuner had been destroyed. I had to run wires from the pins on the tuner to the their destinations on the mainboard. It was not fun. Luckily, no permanent damage was done but it could have easily been a lot worse.

You need to remove the two metal boxes (if there are two - one is the tuner and the other is the IF). On some sets like the 13 inch models, these are readily accessible once the rear cover is removed. On some 19" sets, the pins that need to be desoldered to remove the modules are partially blocked by the plastic bottom frame that holds the mainboard.

Once these are pulled, snap off the *\*bottom\** shield of each and go over all solder connections - both through-hole and surface mount. You may be able to pinpoint some hairline cracks. The pins that go to the mainboard on the tuner and a coil on the IF module seems to be popular locations for problems. Also check the solder connections to the metal case shield and the fingers that need to make contact when the cover is snapped in place.

Don't touch any of the top-side components. Take care not to introduce any solder bridges or overheat anything. However, you may need more than a 15 watt iron to adequately heat some of the (shield) connections.

---

## 3.3) Descriptions of the solutions

Here are some of the responses - many from experienced techs who fix (too) many of these sets:

(From: Davetech (dnesbitt4@ vcom.is.net)).

If that is the one with an IF (VIF?) module beside the tuner, shoot some freeze spray into the module while it is playing. I had a Sony last week that turned out to have a bad solder joint in that module, and freezing it pinpointed it. It too, was "searching" through the channel.

(From: Gary Klechowicz (klechowi@execpc.com)).

On Sony TV/monitors of the early 90s there were problems with solder connections in the AGC module. This module was a solder-on board enclosed in a metal box very much like the tuner. There were tunable coils inside and one or two of the legs from the coils would crack free from the circuit. This caused a gray screen effect but also caused the audio to drop out as well. This may be a similar problem. Look for any delay line modules. They are in small plastic cases sometimes orange colored and solder edgewise onto the main board. Inspect the solder connections there as well. If I remember right there was a delay line that had three legs and one of the solder connections would crack and you loose things like low level B & W. That would cause your problem.

(From: Jeff Rigby (jeffg2@ix.netcom.com)).

If a sound and picture problem then look for bad connections in the tuner and the IF module. The IF module generally has bad connections at the pin connections for the Coils (IF, AFT, Disc). The tuner has bad grounds on the outer edge of the tuner board. This problem is generally temperature related=> it will work when cold or hot but in one condition or another will give problems.

As a check, with the back off and the set operating lightly tap the IF can and the tuner and see if the picture or sound changes.

Sound *\*only\** problems are usually due to surface mount caps on the MPX decoder board.

Video only problems are a surface mount capitor problem in the comb filter board.

Both of the above are temperature related and usually get better as they heat up.

(From: Tom Cat (kanduit@juno.com)).

Remove IF 450, solder connections around AFT coil... and any other connection that looks bad... (very common problem).

(From: Mr. Caldwell (jcaldwel@iquest.net)).

Open the IF assembly and resolder the coils, tuner should not need resoldering but if the problem persists you can resolder the ground connection in it if it does.

(From: Brian Leeman (bryboe@mint.net)).

I have run into a few of these...

In every case it has been due to one of the grounding "fan" leads that runs from the PCB to the metal case having a cold joint.

It has always been the lead that fastens to the top of the case directly to the left of the AGC trimmer (looking at the trace side).

These problems are gravy for techs, but it is a shame how poorly Sony executes the manufacture of their consumer electronics. Talk about mass produced junk...

Sorry for the rant, but if you work on this stuff, you have to agree!!

(From: Mister M. (mister-m@ix.netcom.com)).

You should start by checking for these symptoms. If the signal goes to snow then tap on the tuner to see if the signal returns. If it does then proceed to pull the tuner out and pop the shield to solder all grounds around the perimeter of the tuner. (being very careful with the solder splashing). If your signal seems to drift out and come back not snow but a smeared picture or a detuned like symptom then pull out you IF201 if block pop the shield and look for a AFT coil. Resolder and your back in business.

(From: Viawest (viawest@azstarnet.com)).

Invariably, the Sony KV-13TR14 and most of the ones near it are famous, and plagued with bad solder joints. be very careful not to cause any solder bridges when resoldering the pc board. you must remove the shields from the tuner assembly to accomplish this repair. By the way, check the rest of the board \*before\* tearing your tuner apart. Sometimes it is a bad spot other than in the tuner itself - usually the power supply.

(From: Raymond Carlsen (rrcc@u.washington.edu)).

It sounds like you're describing the classic "tuner with bad solder connections". You'll have to remove the tuner and pop the covers. Resolder all the grounds around the outside of the little PC board. Also solder the ground tabs where the metal can pokes through and grounds the foil in half a dozen spots around the middle of the board. Look at the top side of the board to see where the metal goes through the PC. Work carefully! Don't get any solder "bridges" in there. Use a large enough (and hot enough) iron that will fully heat the connections without having to heat them for too long a time, but not so large a tip that will cause bridging. Re-install the tuner and pull the little can next to it. The PC connections that run from the board to the chassis need to be gone over. Resolder any connections that look flaky. Re-install that sub-board and you're done. That should take care of it. I've never had to do one twice.

---

## 3.4) Successes from non-techs

(From: Bill Somrak (cooncat@ncweb.com)).

Well, thanks to all those that suggested that I look at the I.F. assembly for poor grounds and soldering.

I pulled the unit from the main board last night, removed the tin covers on both sides. On the side with the coils and chips in it, there wasn't much to be done, so I left that pretty much alone. The other side was mostly surface mounted stuff. I didn't see anything that was grossly under soldered. Several joints looked "cold". All I did was touch up as many ground connections as I could .. re-solder the cold looking ones, re-do the two chips. I also bent out the little tabs that are on the covers of both sides of the unit .. these tabs apparently make contact with ground spots on the unit. After all this I resoldered the unit back onto the main board .. crossed my fingers, plugged the set back in and powered it up.

Success! No matter what channel I tuned to, the set came on (with picture) instantly. I powered it down several times to let it cool down again, and tried the experiment over and over ... never a failure. So, this morning, before going to work, I put the cover back on the 13" Sony and its working as well as the day I got it (1991). I did note that this is the ONLY Sony that I've had problems with. It was assembled in Mexico (strike 1???), and the I.F. tuner was made in Korea (strike 2????). I wonder if other's have found "non-Japanese" made Sonys to have less than the expected reliability?

---

## Chapter 4) Miscellaneous Problems

---

### 4.1) Erratic picture and sound

"At start-up, picture comes on OK, then goes dark - loud Crash-Boom sounds from set. After turning off - letting sit - on -- repeats -- several times, seems to stabilize, stay on, and function Ok. I'd appreciate any advice so I know if the repairman has a clue."

This may be tuner/IF related but other bad connections could be involved.

(From: Mr. Caldwell (jcaldwel@iquest.net)).

What should be done anyway:

- \* Resolder all the TO220 package regulators on the main board.
- \* Resolder the Horizontal Output Transformer.
- \* Remove open and resolder the IF pack coils.
- \* Remove the power supply itself and resolder the output diodes.

There is a capacitor in the power supply that's caused some problems,

it's the 22V/27V line I think, a 1000uf@25v or 1000@50v. I've just been replacing it with a 1000uf@50v.

If you do all of this you should not have much else to worry about with this TV.

---

## 4.2) Noisy audio

"I bought a Sony TV (model KV-27TS27) in 1992 and had some problem with the tuner right after the warranty expired but fortunately my Visa card's extended warranty covered some of the repair cost. Now the sound is getting very noisy and I suspect the audio module is not working properly. The TV is not covered by any warranty and I'd like to take care of it myself. I wonder if any one out there knows where I can order an audio module for my Sony TV."

(From: Mr. Caldwell (jcaldwel@iquest.net)).

The MPX 'IC' is a custom mini ceramic PCB with components masked onto it. It is easy to spot and as it is a DIP but you can see the components on the 1" x 1" ceramic 'board'. Capacitors on this board leak and cause a failure in the audio. It will do all sorts of weirdness and then fail.

Call Sony and politely gripe.

---

## 4.3) Intermittent audio

"My Sony KV-32TS20 television (4 yrs. old) has developed an audio problem. The stereo LED no longer lights up and I get intermittent popping/crackling along with the audio. I have tried switching between mono and stereo and the audio sounds the same in either mode (sounds like mono in both modes to me). This set had the infamous Sony tuner solder joint problem in the past which was resolved by resoldering the tuner to main ckt. board connections. Now I resoldered the audio section solder joints on the main circuit board but the audio problem remains."

(From: Mr. Caldwell (jcaldwel@iquest.net)).

Defective IC on audio pcb. Little green part with tiny caps on it smack in the middle of the board with the a/v jacks on it. It's a ceramic PCB, about 1" square and it will have corrosion because the capacitors start leaking.

---

## 4.4) Periodic audio noise

"I have a SONY KV A2522U (U.K.) TV. About every hour or so it gives out, through the R. hand speaker, a very loud thunder like noise. (and just as loud) Even when the volume is set low? If I tap the set with my hand the noise stops. Telling me it's a loose connection?"

(From: Steven Turner (steven.turner@amigabee.org.uk)).

Very common fault this. Locate the Metal heat sink running front to back resolder all the IC pins on the heat sink. That will fix it.

---

## 4.5) Intermittent picture

(From: John de Rooy (solaris@dds.nl)).

A few months ago someone gave me a Sony 27'' kve2911d television, which was repaired by Sony about 8 months ago. The set came up ok with sound and stereo LEDs but no picture at all. After warming up about 15 minutes the picture returned and stayed until switching off.

I talked to a Sony technician about this case and told him the set was already repaired by them 8 months ago for a lot of money and asked for help. While I think the Sony service is very poor by luck this time he told me about the bad solder connections from the tuner and IF boards.

I was very happy with this information and started taking off the cover for a check! But bad luck! Sony already had resoldered every connection of the tuner and IF boards. After a long time trying to locate the problem (only 15 minutes a day to measure!), I found out the problem was on the small CRT board located on the neck of the CRT. I resoldered the entire crt board (10 minutes of work) and the set has been OK since then.

---

# Chapter 5) Service Information, Costs, Reliability

---

## 5.1) Getting out-of-warranty repairs

If you are not inclined to tackle these sorts of repairs for whatever reason, you may still have recourse with Sony. If pressed, they will often cover at least part of the cost of the repair.

(From: Mr. Caldwell (jccaldwel@iquest.net)).

Call Sony Customer Service and explain the problem to them and see if they may cover parts. It's more than likely the tuner and while it can be resoldered and repaired in most cases you can do nothing wrong by asking Sony to cover some of the costs. A 3 year TV isn't that old.

Call Sony and see if they'll pay for the parts and then call a Sony service center and get an estimate and THEN tell them you've got authorization for the part from Sony. ;-)

---

## 5.2) Warning about Sony tuner repair on certain models

(From: Gary Warner (warner1@airmail.net)).

Lately I caused myself a lot of grief quite innocently. I thought it might stop a problem before it happens to share this:

On a Sony KV-27S15 I needed to replace the tuner. The tuner is on the "A Board". Looks easy enough to get out but, one end of the board won't clear a metal frame that runs across the center of the main PCB. It's only a small part of the frame and was easily bent out of the way. Unknown to me, bending the frame caused the "solder land" that's under the frame where I bent it, to twist and cause an open connection all around the land. After replacing the tuner and the "A Board" I plugged the unit up, turned it on and POW, the power supply and the horizontal output were all bad.

After a day of troubleshooting I found that the crack had opened the only ground reference for the "feed back" loop of the transformer in the power supply (pin 12 of T603). The power supply lost it's ability to regulate and it ran at "full throttle".

What an embarrassment for me as this was an in-home tuner replacement and now I "Blew up the set". Anyway, everything is okay and the customer understood when I explained all this to them. It was one of those hard lessons that I thought some of you could appreciate and might avoid yourselves.

BTW, the tuner was bad like the tuners in the JVC's, where it intermittently

looses the tuning but it's not a physical (connection) or thermal problem. My guess was the PLL IC was checking out. Until now, this model was free of any tuner problems for me.

---

## 5.3) Sony service bulletins

(From: Lynn H. Blakely (lynns@arkansas.net)).

I thought you should know about the service bulletin #203R3. This covers a lot of different models. It shows where to solder the grounds and they have a new cover to replace the original one for the tuner. Also, many of these and similar models have sound problems these can be repaired many times by replacing the SBX1637-11 module. The Sony part #8-746-371-20.

# Introduction

## Scope of This Document

Note: This document replaces the individual sections in each of major repair guides.

A number of organizations have compiled databases covering thousands of common problems with VCRs, TVs, computer monitors, and other electronic equipment. Most charge for their information but a few, accessible via the Internet, are either free or have a very minimal monthly or per-case fee. In other cases, a limited but still useful subset of the for-fee database is freely available.

A tech-tips database is a collection of problems and solutions accumulated by the organization providing the information or other sources based on actual repair experiences and case histories. Since the identical failures often occur at some point in a large percentage of a given model or product line, checking out a tech-tips database may quickly identify your problem and solution.

In that case, you can greatly simplify your troubleshooting or at least confirm a diagnosis before ordering parts. My only reservation with respect to tech-tips databases in general - this has nothing to do with any one in particular - is that symptoms can sometimes be deceiving and a solution that works in one instance may not apply to your specific problem. Therefore, an understanding of the hows and whys of the equipment along with some good old fashioned testing is highly desirable to minimize the risk of replacing parts that turn out not to be bad.

The other disadvantage - at least from one point of view - is that you do not learn much by just following a procedure developed by others. There is no explanation of how the original diagnosis was determined or what may have caused the failure in the first place. Nor is there likely to be any list of other components that may have been affected by overstress and may fail in the future. Replacing Q701 and C725 may get your equipment going again but this will not help you to repair a different model in the future.

One alternative to tech-tips databases is to search via [Google Groups](#) (formerly Deja.com/Dejanews) for postings with keywords matching your model and problem and the USENET newsgroup [sci.electronics.repair](#). See the document: [Troubleshooting of Consumer Electronic Equipment](#) for more information.

## Safety

The people who compile tech-tips databases assume you know what you are doing, at least to the extent of taking appropriate precautions to minimize the possibility of bodily harm and equipment damage. Before going inside any piece of electronic equipment, make sure you understand and follow the guidelines in the document: [Notes on Safety](#). If you are at all unsure of your understanding of this safety info, take the equipment to a professional for repair or buy a new one. Your life is more valuable than the few dollars you might save by doing it yourself!

-

## List of On-Line Tech-Tips Databases

- Here are some tech-tips sites for computer monitors, TVs, and VCRs:
  - [Anatekcorp Tech Forum](#) (Free)
  - [Repair World](#) (\$8/month)
  - [Electronic Repair Tips Home Page](#) (Free, somewhat limited)
  - [Electronics Info](#) (free large text files)
  - [Fletcher's Site](#) (Free)
  - [Golden Rule Electronics](#) (Free, limited)
  
- A related site has many links to TV tech-tips by model:
  - [Golden Rule Electronics Alta.vista TV Repair Page](#) (free, many links)
  
- Here is one for TVs, VCRs, camcorders, and audio. There is also some specific info on RCA EEPROM contents and Sony service tips. It includes a technical forum (discussion group) and is currently free but is not as comprehensive as some of the others:
  - [Technician's Desk Reference](#)
  
- Here is a site from which you should be able to download a fully operational version of a database with over 115,000 tips for TVs, VCRs, camcorders monitors, microwave ovens, audio equipment, and more. It will work for 14 days and can be purchased and registered during this time. There are versions for both Windows (WinSTIPS) and DOS (SVCTIPS). This from KDTV - Indiana Wholesale Electronics:
  - [WinSTIPS and SVCTIPS Page](#)

They also offer [ServiceTalk](#), an on-line discussion group for electronics repair professionals. This members-only forum has access to a subset of WinSTIPS (about 17,000 tips).

- Here are a couple of comprehensive tech-tips databases just for VCRs that are currently free:
  - [Fixer - VCR Repair Instruction](#) (Quite extensive)
  - [Vidcam](#) (Australia, but has USA models as well)
  
- These have quite a bit of info for TVs. Some may be free but others require a relatively small charge (up to \$25) or a monthly or other membership fee. However, this may include a personal reply from a technician experienced with your monitor so it could be well worth it:
  - [Dogcatcher's Tech Tip Site](#)
  - [Shop Helper](#)

- [TV Technical Assistance](#)
- The following is a site with tech-tips and other services relating to TVs and VCRs. This is a UK site but may include U.S.A. models as well.
  - [TV and VCR On-line Fault Finder \(UK\)](#)
- The following are just for monitors:
  - [KMR Technical Services Tech Support](#) (\$19.95 charge)
  - [ADCC](#) (Tech-tips of the month and 'ask a wizard' options)
- The Resolve Monitor Tech-Tips database is a diskette that is priced out of the reach of most hobbyists. However, a reduced shareware version may be downloaded from a number of web sites. Go to <http://www.filez.com/> and look for res16sw.zip.
- The next one includes tips on some of the most common monitor problems.
  - [Al's Monitor Repair Database](#) (Collection of tips various sources.)
- The following is specifically for microwave ovens. In addition to a large database of specific repairs, there is a great deal of useful information and links to other sites:
  - [MicroTech Home Page](#) (Everything you always wanted to know about microwave ovens)
- The following site (from Russia with...) appears to be in its infancy but looks promising with information, some actual schematics, links, repair case studies, chip identification for some models, etc.:
  - [Electronics Repair](#)
- The site below has a repair tips file that can be downloaded. Tony ([tonytech@my-deja.com](mailto:tonytech@my-deja.com)) is starting a non-profit repair tips database which should grow with time as people contribute to it:
  - [Tony's Freeware Repair Tip Program](#)

Don't get excited (as he says), the download has only 25 tips. However, with any sort of cooperation, this could grow into something very useful.

These types of sites seem to come and go so it is worth checking them out from time-to-time even if you don't have a pressing need. If possible, download and archive any useful information for use on a rainy day in the future. Some also include many useful links in addition to the tech-tips info so are worth investigating out even if you don't have a specific symptom to deal with!

## DISCLAIMER

Some of the contact information and summary of products may be out of date as I don't place orders that often. In general, the range of offerings increases with time so it is best to check with the company's Web site and/or request a catalog. However, I won't be responsible if you miss an opportunity to buy your favorite horizontal output transistor because the listing below didn't include HOTs as a line item! Corrections are welcome.

# Introduction

## Scope of This Document

Note: This document replaces the individual sections in each of major repair guides.

The following sections provide contact info and/or links to companies specializing in service parts (as opposed to general electronics distributors).

For general electronic components like resistors and capacitors, most electronics distributors will have a sufficient variety at reasonable cost. Even Radio Shack can be considered in a pinch.

However, for modern electronic equipment repairs, places like Digikey, Allied, and Newark do not have the a variety of Japanese semiconductors like ICs and transistors or any components like flyback transformers or degauss Posistors.

The companies below are good sources for consumer electronics replacement parts, especially for VCRs, TVs, and other audio and video equipment:

I have used those in the first section personally. In general, I have been quite satisfied with their quality and reliability. I do not have personal experience with the others but in general, they get listed here as a result of a recommendations from satisfied customers via email or on the USENET newsgroup [sci.electronics.repair](mailto:sci.electronics.repair).

## Service Parts Suppliers I (Sam) Have Used

- [MCM Electronics](#)

U.S. Voice: 1-800-543-4330

U.S. Fax: 1-513-434-6959

Web: <http://www.mcmelectronics.com/>

VCR parts, Japanese semiconductors, tools, test equipment, audio, consumer electronics including microwave oven parts and electric range elements, etc.

- [Dalbani](#)

U.S. Voice: 1-800-325-2264

Int. Voice: 1-305-716-0947

U.S. Fax: 1-305-594-6588

Int. Fax: 1-305-716-9719

Web: <http://www.dalbani.com/>

Excellent Japanese semiconductor source, VCR parts, other consumer electronics, car stereo, CATV).

- Premium Parts

U.S. Voice: 1-800-558-9572

U.S. Fax: 1-800-887-2727

Very complete VCR parts, some tools, adapter cables, other replacement parts.

- [Computer Component Source](#)

U.S. Voice: 1-800-356-1227

U.S. Fax: 1-800-926-2062

Int. Voice: 1-516-496-8780

Int. Fax: 1-516-496-8784

Web: <http://www.ccs-sales.com/>

Mostly computer monitor replacement parts. Also, some electronic components including semiconductors.

- 
- Back to [Major Service Parts Suppliers Table of Contents](#).

## Other Service Parts Suppliers

These companies have been recommended but I do not have personal experience with them. The following are good sources for consumer electronics replacement parts, especially for VCRs, TVs, and other audio and video equipment. Catalogs are a must. (The first 4 I have used and have been satisfied with service and selection. The others have been recommended by others.)

- [Global Micro Parts](#), 1-800-325-8488, <http://www.allapplianceparts.com/>.

They specialize in microwave oven parts, but also carry some other major appliance parts.

- Cititronix/Panson, U.S. Phone: 1-800-846-2484, U.S. Fax: 1-800-726-0142.

JC Penney, JVC, Kenwood, Maganvox, Service parts for: Fisher, GE, Hitachi, Panasonic, Philco, Philips, Quasar, RCA, Sanyo, Sharp, Sony, Sylvania, Technics, Zenith.

- [Electro Dynamics, Inc.](#), 135 Eileen Way, Syosset, N.Y. 11791-9022, Phone: 1-800-426-6423, Web: <http://www.edi-sales.com/>.

- [Electronic Parts Center](#), Phone: 1-800-501-9888, Fax: 1-626-285-6873, Web: <http://home.earthlink.net/~epcs/>.

Includes many popular CD pickups at reasonable prices.

- [Electronix](#), 313 W. Main St., Fairborn, OH 45324-5036. Phone: 937-878-1828, Web: <http://www.electronix.com/>.

- Electronic Warehouse Corp., 1-800-221-0424.
- Fox International, 1-800-321-6993.
- MAT Electronics: 400 Pike Road, Huntingdon Valley, PA 19006-1610, Phone: 1-800-628-1118.
- [Parts Express](#), 340 E. First St, Dayton, OH 45429, Phone: 1-800-338-0531, Fax: 1-513-222-4644, Web: <http://www.parts-express.com/>.
- RNJ Electronics: 805 Albany Ave., P.O. Box 528, Lindenhurst, New York 11757, Phone: 1-800-645-5833.
- Tritronics: 1306 Continental Drive, Abingdon, MD 21009-2334. Phone: 1-800-638-3328.

Also see the extensive mail order lists at:

- [List of Mail Order Electronics Companies](#)
- [AF4K's List of Parts Suppliers](#)

Also see the document: "Troubleshooting of Consumer Electronic Equipment" for additional parts sources as well as the equipment specific supplier lists at the end of each Repair Guide. The chapter: "Laser and Parts Sources" of "Sam's Laser FAQ" also includes extensive lists of new and surplus electronics supplies that may be useful.

---

## 2. Personal Safety

Read the associated document: "Safety Guidelines for High Voltage and/or line power equipment" before attempting to work with high voltage systems. High

voltage can jump amazing distances when you least expect it. The direct or indirect consequences of this can ruin your entire day or a whole lot more.

---

### 3. Basic Considerations

Warning: DMMs may not be particularly forgiving of voltages on their inputs exceeding their specifications. Autoranging DMMs may be even more likely to blowout as they are selecting the correct range - if there even is one. Depending on your electrical and mechanical components, the chance of excess voltage due to arcover, leakage, or component breakdown may be a major consideration. My analog VOM has survived many close encounters with HV. You should not assume the same for the typical low cost or even expensive DMM. There is a reason for the high cost of commercial HV probes - these kinds of factors are incorporated (hopefully) in their design.

A simple high voltage probe for a DMM or VOM may be constructed from a pair of resistors. This is suitable for DC measurements but without compensation, will have a unknown AC response due to the very high impedance and stray capacitance forming a filter - low pass or high pass depending on the amount of stray capacitance and input capacitance of your meter or scope. However, this simple design is sufficient for the majority of consumer electronics work which are mostly DC measurements. I have not characterized the AC response of this probe design. However, if there is AC riding on your high voltage, it may mess up your readings if there is no compensation provided as it may act as a high pass filter.

To design the voltage divider, the input impedance of the meter must be taken into account. There is a minor but significant difference between DMMs and VOMs.

DMM: Z-in is usually constant, often 10 M ohms.

VOM: Z-in is the voltage range (full scale) times the ohms/volt rating of the meter.

Here is the basic circuit:

R1 together with R2//R3 form a voltage divider where R3 is the internal

resistance of the DMM or VOM on the scale for which the probe is designed.

While R2 is not strictly needed, it is recommended that it be included and approximately equal to the Z-in of the meter on the scale you will be using. The reason to include R2 is to insure that high voltage never can reach the meter. The ground clip should be securely connected to the metal chassis of the device being tested - the frame of a microwave oven or CRT grounding/mounting strap of a TV or monitor - before it is powered up. Both R1 and R2 should be located in the probe head.

The only difficult part is locating a suitable resistor for R1 that has high enough resistance and physically is long enough such that arcover is avoided. One company that comes to mind has a name something like Victoreen - they make/made radiation measuring instruments among other things that require really high value resistors. It can be constructed from several equal lower value resistors in series if they are all approximately the same size. Another possibility is salvaging the focus divider networks from dead flybacks or TV/monitor voltage multiplier assemblies. Even if the unit was discarded as being faulty, where there are no internal shorts in the HV rectifier or resistive network itself, the entire unit can be used intact.

In addition to basic safety precautions when working around high voltages, some form of equipment protection should be considered in provide an arcover path to ground should there be arcing over the surface of the resistor as well as if the resistor should somehow decrease in value. There is no telling what can happen under less than ideal damp or dirty conditions.

A 'corona', 'arc', or 'discharge' ring could be placed around the resistor near the low voltage end securely connected to the ground cable. The idea is that any arcing over the surface should find this as its destination before obliterating your meter.

A variety of devices could be placed across R2 to limit the maximum voltage present in the event of a breakdown. Suitable devices include neon light bulbs (NE2s without resistors); zener, avalanche, or ordinary diodes; or other semiconductor junction devices. Traditional surge suppressors like MOVs and Tranzorbs may work but their off-state impedance may be too low compared to R2). The neon bulb is good since its impedance is essentially infinite until its breakdown of 90 volts or so is reached. In some cases, these devices will be destroyed (semiconductors may short) but they will have served their protective function and are a small price to pay to protect you and your meter.

---

## 4. Frequency Response Considerations

Probe compensation similar to that used on oscilloscope probes can be implemented. However, the determination of the capacitor values is beyond the

scope of this note. To put it simply, the ratio of the capacitance  $C1:C2$  (where  $C1$  is across  $R1$  and  $C2$  is across  $R2//R3$ ) needs to be equal to the ratio of  $R2//R3$  to  $R1$  (or equivalently, to the inverse of the voltage divider ratio).  $C2$  includes the stray capacitance and input capacitance of the meter or scope probe. The capacitor across  $R1$  would need to sustain the HV so that is another complication. Since a 10x scope probe usually has an input impedance of 10 M, the same design as used for the DMM would work with a scope. Although I have not pursued this issue, it sounds like based on the ratio (1000:1 would mean that  $C1$  would need to be extremely small, probably smaller than the stray capacitance of the  $R1$  and the associated wire) you would need to add a capacitance for  $C2$  and that there will be enough stray capacitance such that no physical  $C1$  will be needed.

If you are only interested in DC measurements, putting a .1 uF capacitor across  $R2$  should smooth out any 50/60 Hz or higher frequency ripple.

The implementation of full probe compensation is left as an exercise for the motivated student.

Design example: 50,000 V maximum using a 10 M ohm Z-in DMM.

-----

By my rule above, I will select  $R2$  to be 10 M ohms. Fine adjustment of calibration could be made by making  $R2$  out of a combination of a fixed resistor and a multiturn pot.

To minimally load the circuit under test,  $R1$  should be as high as practical. Practical here means (1) low enough so that leakage over its surface is not a problem, (2) low enough that a reasonable voltage can be developed across  $R2//R3$ , and high enough so that loading of equipment being tested will not change the readings by more than a few percent.

$R2//R3$  is 5 M ohm. Selecting  $R1$  to be 5,000 M ohm will give a 1000:1 ratio so that 50,000 volts will read out as 50 V on the DMM. 5,000 M ohm is high enough that loading of a 250 M ohm focus network should not be an issue (5%). 1000:1 is a nice easy to remember ratio. You could go to something higher if loading is still a concern but then leakage current over the surface of  $R1$  becomes an even greater concern. Even 5,000 M ohm is about as close to an open circuit as you can get - any contamination whatsoever will change the calibration significantly. You may find that using a 1,000 M ohm resistor will result in less of a problem and accept the circuit loading that this value implies.

Design example: 50,000 V maximum using a 30K/V VOM.

-----

This is a little more complicated because you need to pick a range and then calculate the Z-in for that range. for example, for the 100 V range of a 30K/V VOM, the Z-in will be 3 M ohms. For the same 5,000 M ohm  $R1$  and 10 M ohm  $R2$ , you would get a reading of 23 V (roughly) on the 100 V scale for a 50 KV input. The divide ratio in this case is about 218.

It is a simple matter to determine a scale and an  $R2$  such that the actual high

voltage measurement is easily calculated from the meter reading. What you want is the ratio of R1 to R2//R3 to be a nice round number. Note that switching ranges will produce some peculiar behavior due to this current division between R2 and R3. A unique R2 must be selected for each range of interest. You are already using nearly the maximum sensitivity of the meter and switching to a lower range will only slightly change the position of the needle unless you construct a range switch box as shown below.

## 5. Calibration

Unless you have a calibrated HV supply, a working TV for which you have the service manual makes a good starting point. The proper high voltage is usually specified to within 5-10%. If you have a line-transformer based HV supply (e.g., neon sign transformer, rectifier, capacitor), then this would be pretty accurate based on your power line voltage. For a DMM with a constant input resistance, you can use a low voltage (like a few hundred V) on a lower range and extrapolate for the HV range. However, for a VOM, you cannot use this technique since changing ranges also changes the parallel resistance of R2//R3. You are already using nearly the full sensitivity of the meter.

## 6. Sample Circuit

I have constructed a high voltage probe from the surplus bleeder resistor from a defunct video terminal. For the probe tip, I used a discarded probe from a VOM. The resistor and probe tip were mounted inside an insulating plastic tube with R2 included at its base. A ground cable with an alligator clip provided the connection to the chassis. A second pair of wires with banana plugs connected to the meter via a switchbox which could select between a DMM or a couple of different scales on a VOM. Potting the entire HV head is a good idea to minimize the possibility of arcover. Remember that 50,000 V can jump several inches (2 inches in dry air approximately). See above text for other suggestions on equipment/you protection (which is not shown).

This circuit uses only a 203 M ohm high voltage resistor. Since the internal resistance of a typical focus divider network is 200-300 M ohm, this probe would obviously load such a circuit excessively.

SW1 - SPDT Center Off Toggle Switch.  
 All resistors except R1 are 1/4 watt 2%.

50,000 V maximum based on the particular R1 I had laying around. 1000:1 voltage division.

SW1-1 = Radio Shack DMM on 3, 30, or 300 V scale (10 M Zin).  
 SW1-2 = VOM, 25 V scale (30K ohms/V, 750 K Zin).  
 SW1-3 = VOM, 100 V scale (30K ohms/V, 3 M Zin).

## 7. General construction comments

(From: Duane C. Johnson (redrok@pclink.com)).

1. When you make the resistor strings make sure that the maximum voltage rating of the resistors is not exceeded. Most resistors have a maximum rating of 200 volts. In this case I would not exceed 100 volts per resistor.
2. Don't place the scope directly in series with the higher resistors. The first resistor should be in parallel with the scope and and ground or the scope chasis.

This detail is important for safety reasons. If the connection to the scope becomes disconnected then their will not be a dangerous shock hazard as would be the case if the scope was in series.

(From: Larry G. Nelson Sr. (nr@ma.ultranet.com)).

You can do this with a high voltage resistor divider network. That is what is in a high voltage probe you would buy. This can be very dangerous to you and your equipment in the event of a failure. Please be very careful. I suggest a

fuse at the probe input and an MOV across the resistor to ground that will connect to the scope and use a plexiglass tube to put it all in to contain the bits if anything blows up.

(From: Kevin Astir (kferguson@aquilagroup.com)).

With respect to preventing high voltage arcing and corona, *\*do not\** use RTV.

Places that carry the GC line will have some 'anti corona discharge dope' often called 'Q-dope'. This is *\*the\** stuff to use at HV. You can clean it off with acetone when you discover that you didn't clean flux off good enough and have an arc underneath. Epoxy and RTV have no such advantage, and RTV releases corrosive acid while curing to boot.

Heed the warnings of other respondents WRT resistor voltage. As they said 100 V per for garden variety resistors will yield a safe margin. 200V is typical max rating.

There are special HV resistors (up to 10 KV or so) made, available into the G Ohm range. I don't know of a hobbieist source however. If you know anyone who works in nuclear instrumentation field they may be able to snag one for you. (HV used as detector and PMT bias in radiation detectors). This is what will be inside "real" HV probe from Fluke, or Tektronix.

Finally, I have a lot of experience, and am fairly blase around HV, but in addition to "normal" 115V AC rules, (no rings, one hand in pocket, etc.) I *\*never\** work on HV stuff (not even a TV or hi-pot test) alone. And, I make sure the 'observer' knows CPR, even if I have to wait 2 days to fix TV, so girlfriend can 'help'.

---

## 8. High voltage probe frequency response

(From: Winfield Hill (hill@rowland.org)).

You can calculate this for yourself. The parasitic lead-to-lead capacitance of a typical small resistor is 0.05 to 0.2pF. The capacitance from the *\*middle\** of the resistor and from any connection node between series resistors, to ground, may range from 1pF to 5pF or more depending upon your choice of a sheilding scheme. Longer glass resistors intended for high voltages have lower lead-to-lead capacitance, but higher distributed parallel capacitance.

As a worst case, imagine a 1000 M ohm probe made with a 2-inch long resistor. To start, place the capacitance to ground from the midpoint. If you assume 5pF of parallel capacitance, you'll see you're in trouble even at 60Hz!

\* HV probes with usable high frequency response may have cleverly arranged sheilds which can be connected to ground, the attenuated signal output,

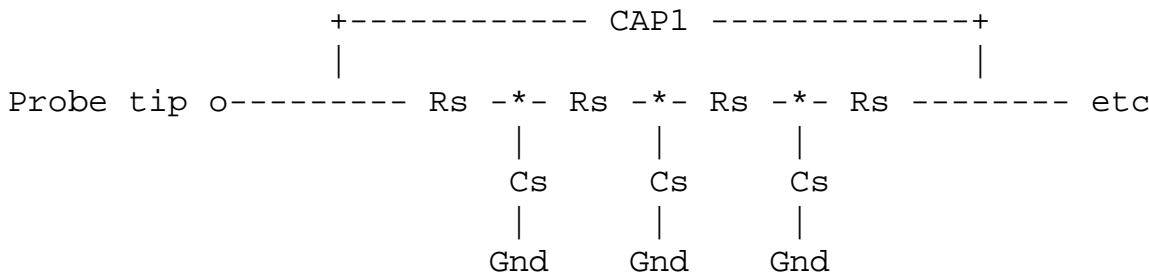

and the input. Some shields may overlap and may be adjustable, to provide an adjustable capacitive divider that can swamp the remaining effects of the resistor's capacitance.

- \* These probes can be very accurate at DC and high frequencies, but the skill of the designer is tested in the transition between resistive and capacitive divider action. They can be very badly behaved in this transition region. Basically the "center" of the resistor experiences a bypass to ground (a severe dip in gain) or due to other HF components, a severe peak in gain. This can easily be 50% and cover a decade. Typically it'll happen at 20 to 100 KHz.

One solution invokes the capacitance from a few carefully-placed concentric sleeves connected to the input and the signal output, plus an overall shield or guard connected to ground.

- \* Poorly designed probes can suffer from mid- or high-frequency errors and from severe pickup sensitivity to nearby rapidly-changing voltages. For example, I've seen probes that provide an output even when the measuring tip is grounded!

The classic low-voltage probe architecture of a pair pf RCs doesn't work for HV scope probes, unless (1) you're willing to have an overly high capacitive loading, or (2) you don't care about mid-frequency or pulse-shape response accuracy. This is because the RES1 value will be very high, 100M or more likely 1000 M ohms, and physically long and large. So the real circuit is like:

Because the Rs are so high, the probe becomes a good antenna, and a shield is mandantory. Therefore the Cs "stray" capacitance is higher than you might think. I think you see the problem.

One solution is to make C1 very large, but it's just a matter of specs - if you want 1% performance over the whole range, C1 is a severe load. There is a good overall solution, which I think is fairly clever (after thinking of it, I discovered the experts had beat me to it!).

---

## 9. High voltage probes for AC measurements

(From Winfield Hill (hill@rowland.org)).

The usual method is simply to use a capacitive divider, a small 1 kV capacitor, etc., or make the HV capacitor yourself for really high voltages, like 5 to 20 kV, use an air neutralizing capacitor, etc.

Say for example, its a 3pF capacitor. With shields. With another more conventional capacitor, say 3000pF for the bottom of the attenuator, followed with a voltage buffer if desired, and you've got a nice wideband 1000:1 HV probe installed in the system, good for mucho kV.

---

## 10. Commercial high voltage probes

(From: Frank Miles (fpm@u.washington.edu)).

Both Tektronix and Hewlett Packard sell HV probes rated at 5kV and up. Bandwidths are (at least) into the 100kHz area, probably more. I imagine there are others.

The older Tek probes even had ports to refill with now-banned chemicals. The newer ones don't, but are more expensive.

Frequency response is a significant concern. Designing and manufacturing a decent HV probe is definitely non-trivial if you need flat frequency response. Many parts have significant voltage coefficients, too, as well as breakdown voltages.

(From Winfield Hill (hill@rowland.org)).

A significant part of the design effort (and cost) deals with, the problem of how to go smoothly from a resistive divider at low frequencies, to a capacitive divider at high frequencies, while keeping a constant attenuation value at mid-frequencies. This isn't easy. Consider for example, that an overall shield is clearly needed and must properly prevent the high-Z end of the probe from simply acting as an antenna (as some HV probes do! i.e. ground the tip of the probe and \*still\* see large signals at the output). This shield acts as a capacitance to ground for the HV resistor, routing some of the high-frequency current which is supposed to go to the output, to ground. Hence at some middle frequency there's a dip! This is solved in various ways - with shields connected to the probe tip (but inside the ground), capacitors bypassing the resistor, special resistor construction, etc. Most solutions can just as easily cause a region with a response hump, as well as a dip, or even both. BTW, these problems are much harder if one seeks to make a probe with very low capacitive loading and high frequency response. The Tek P6015A probe is 3pF, and you'll also note it has a veritable raft of response adjustments on the scope-input end.

Much of the cost of the probe is knowing how to do all this!

Incidentally, a low-cost intermediate-range HV probe is the Fluke PM9100, which is a 4kV 100:1 probe with a 200MHz bandwidth. Also the Tek P5100 is rated to 2.5kV. Most of these probes also have a derating above some d frequency.

Most of this mess you can avoid entirely by not attempting to make the probe measure DC (or at least not the whole frequency range).

## 2. Introduction

The purpose of this document is to help reduce the clutter in landfills :-).

Many dead appliances, and consumer electronic and computer equipment contain parts and subassemblies which are not only neat and interesting, but useful for various experiments and projects.

- \* I bet you tossed that big heavy slow 5-1/4" hard drive in the garbage when you upgraded, didn't you? Admit it! Did you know that if it was a high performance drive, it contained several of the most powerful permanent magnets you would ever be likely to find anywhere? And, they would have been free!
- \* That big old microwave oven? Too bad. More magnets, nice high voltage power transformer, rectifier, capacitor. Electronic or mechanical timer, fans, other motors, etc.
- \* What about that dot matrix printer? Too bad - at least two stepper motors, a nice power supply, and various other electronic and mechanical components.
- \* More steppers in floppy drives. Also, probably a regulated speed pancake motor.
- \* Old TV or monitor? Another mistake. The high voltage power supply was probably good for 12 to 30 KVDC at 1 or 2 mA. This is useful for many high voltage experiments, plasma globes, negative ion and ozone generators, bug disintegrators, starters for really LARGE HeNe lasers, etc.

There will be several types of information:

1. Where to obtain a particular type of part like a powerful magnet.
2. What dead consumer electronics, computer equipment, and appliances yield in the way of useful parts.
3. Unconventional uses for subsystems or common replacement parts or modules from such equipment.

---

## 3. Place to obtain sacrificial equipment

So, where do you find the equipment from which to remove parts other than your basement, your attic, or those of your relatives or friends? Consider garage, yard, tag, estate, and other sales; thrift stores (which may even have a 'free' table); junk, salvage, and surplus yards (including those run by the Department of Defense!), the town dump and other landfills if they let you take things away, trash rooms of high rise apartment complexes, the curb on

pickup day, college campuses around the end of the Spring term, and any other place where perfectly good equipment gets tossed in this throw-away society!

Of course, don't overlook high tech flea markets as well as ham and computer fests. Regular flea markets are usually overpriced (where do you think they get the stuff??) but sometimes you will be able to negotiate a great price because they have no idea of what they are selling!

Yes, we are a strange bunch :-).

---

## 4. DISCLAIMER

The devices, equipment, circuits, and other gadgets described in this document may be dangerous. Much of it deals with potentially lethal voltages. Getting electrocuted could ruin your whole day. For really high voltage equipment, also see: [Tesla Coils Safety Information](#).

We will not be responsible for damage to equipment, your ego, blown parts, county wide power outages, spontaneously generated mini (or larger) black holes, planetary disruptions, or personal injury that may result from the use of this material.

---

## 5. Neat magnets

Two excellent sources of magnets are described below. These are at least as strong as the more well known speaker types, possibly much stronger, and generally easier to remove:

1. Microwave oven magnetron tubes. Go to your local appliance repair shop and ask - they just toss bad ones. Each one has two ring shaped ferrite magnets about 2-1/4" in diameter with a 7/8" hole, magnetized N-S on the faces.

Surplus places typically charge \$3 to \$6 each for one of these magnets.

Note: A few older magnetrons used AlNiCo magnet assemblies or even possibly electromagnets which are not nearly as interesting. However, you probably won't see any of these.

2. Large hard disk drives - especially full height 5-1/4" high performance types - e.g., Seagate WREN series or Micropolous boat anchors (the rare earth magnets in these are wicked). The magnets in small drives are even stronger but are, well, much smaller :-). A typical size for a large drive is about 1" x 1-1/4" by 1/2". Since almost no one wants such large slow drives anymore, they are often found at swap meets or yard sales for next to nothing.

Surplus places may charge \$12 or more for ONE of the magnets from a large disk drive (there are typically 2 to 6 such magnets in a disk drive)!

For some things to do with these neat magnets, see: [Neodymiumarium](#).

Caution: Both these types are powerful and will squash flesh as they suck all the bits off of your magnetic media! I am not kidding about the part about squashed flesh - with some you actually need a small crowbar to pry the assembly apart!

You will find that some of these magnets are painted. This provides some resistance to chipping though this material may be on the verge of flaking off or has already done so in spots. In any case, I further recommend that you add additional layers of a tough enamel (e.g., Rustoleum) or the plastic/rubber dip used to coat tool handles. Otherwise, chipping damage (at least) will result all too easily and the chips are just as powerful as the rest of the magnet.

Disclaimer: I will not be responsible when your spouse or parents come home to find the microwave or PC missing some key components and as dead as a brick!

---

## 6. Other sources of fairly strong magnets

3. Spent laser printer toner cartridges where the entire developer assembly is part of the cartridge (e.g., EPS-2 for Canon engines). These include a page-width ferrite magnet. However, expect to make a mess disassembling the cartridge as there will still be considerable toner remaining inside.

WARNING: The toner is a possible health hazard. A good dust mask should be used while working on these. Also, do not vacuum what remains - static can set off a dust explosion - use wet rags or paper towels to clean up the mess! The coating on the photosensitive drum may also be a hazardous material.

4. Loudspeakers.

\* Smaller or older speakers use AlNiCo type magnets which are usually in the form of a cylinder (about as tall as it is wide). AlNiCo is an extremely hard metal alloy.

AlNiCo magnets are not as powerful as ferrite or rare earth types and are easily demagnetized (but just as easily remagnetized). Passing a stack of these through the center hole of a strong ferrite magnet will increase their strength dramatically - until they are separated from each other!

\* Modern loudspeakers use ring shaped ceramic ferrite magnets (similar to those in a microwave oven magnetron - see the section: "[Neat magnets](#)"). glued to the pole piece (yoke) assembly within which the voice coil moves. The ferrite is extremely hard but very brittle so care must be used to extract these from the yoke assembly - see the section: "[Disassembling](#)

[Loudspeakers to get at the magnets](#)".

5. Permanent magnet stepper and servo motors. These will use ferrite or rare earth magnets usually in strange shapes. Note: Removing the magnets may result in partial demagnetization (reduction in magnetic strength) as the rotor is part of the magnetic circuit. Therefore, I do not recommend this source. There is generally no practical way of remagnetizing the strange shapes involved.
6. Optical (laser) pickups from CD players, CDRom drives, and other optical data storage devices. These may have some very tiny, but strong, rare earth magnets in the focus and tracking actuator. However, it seems a shame to sacrifice a the beautiful mechanics in such a device just to get the magnets! Caution: Tiny magnets even more fragile than bigger ones!

---

## 7. Disassembling loudspeakers to get at the magnets

For small speakers with AlNiCo type magnets (the magnets usually look like metal cylinders), careful prying with a sturdy screwdriver will usually break the adhesive bond and/or free them from the yoke assembly. Note: Use the proper tool for the job - not your dad's prized screwdrivers!) Unlike the ceramic magnets described below, AlNiCo types are metal and quite sturdy.

(From: Arie de Muynck (ademu@pi.net)).

For the normal black ceramic ring shaped magnets (and likely for some Ticonal 'iron colored') the trick is: heat the complete assembly slowly using a paint-stripper gun, or in an oven (thermal, not microwave!). The glue will weaken and with a screwdriver you can SLOWLY work them loose. Protect your fingers with an old cloth. Never apply too much force, the ceramic would chip or break.

Do not overheat them above the so-called Curie temperature or the magnet will loose it's power irreversibly. That temp depends on the material but should be way above the 120 C or so to soften the glue. If you want to experiment with this effect: use a piece of iron attracted towards a magnet, heat the iron with a flame and above a rather sharply defined temperature it will not be attracted anymore. The effect is used in some Weller soldering irons to stabilize the temp.

Note that the force of a bare ceramic magnet is not as strong as you might expect, the magnetic lines of the large area of the ring have to be bundled and guided through iron to a narrow gap to provide a proper magnetic field.

---

## 8. Scripto lighters and gas grill ignitors

Some types of disposable lighters contain a piezo electric element (instead of a flint and wheel) which generates a spark to ignite the Butane gas. Pressing down on the activator drives an escapement which results in a bar hitting the piezo element.

The result is several thousand volts on demand with its output available at a couple of terminals. This can be used to trigger xenon tubes or even to start helium neon lasers (with the addition of a pair of high voltage diodes to form a charge pump). Or as a prod for small cattle, but I didn't say that :-). For a discussion of the HeNe laser application, see the document: "Lasers: Safety, Info, Links, Parts; Diode, HeNe, Ar/Kr Ion Lasers".

Detaching the piezo assembly only requires bending back and removing the sheet metal shroud at the top of the lighter. The entire piezo unit then just pops out.

Gas grill ignitors are similar - and even more powerful. These are available as replacement parts at your local home center or appliance store. (Don't steal the one from the family gas grill - your dad won't be happy.)

---

## 9. Dangerous (or useful) parts in a dead microwave oven

A microwave oven with its power cord cut or removed AND its high voltage capacitor safely discharged is an inanimate object. There are no particularly hazardous parts inside. Of course, heavy transformers can smash your feet and sharp sheet metal can cut flesh. And, the magnets in the magnetron may erase your diskettes or mess up the colors on your TV.

Some may feel there is nothing of interest inside a microwave oven. I would counter that anything unfamiliar can be of immense educational value to children of all ages. With appropriate supervision, an investigation of the inside of a deceased microwave oven can be very interesting.

However, before you cannibalize your old oven, consider that many of the parts are interchangeable and may be useful should your \*new\* oven ever need repair!

For the hobbist, there are, in fact, some useful devices inside:

- \* Motors - cooling fan and turntable (if used). These usually operate on 115 VAC but some may use low voltage DC. They can easily be adapted to other uses.

- \* Controller and touchpad - digital timer, relay and/or triac control of the AC power. See the section: "[Using the control panel from defunct microwave oven as an electronic timer](#)".

- \* Interlock switches - 3 or more high current microswitches.

- \* Heavy duty power cord, fuse holder, thermal protector, other miscellaneous parts.
- \* High voltage components (VERY DANGEROUS if powered) - HV transformer (1,500 to 2,500 VRMS, .5 A), HV rectifier (12,000 PRV, .5 A), and HV capacitor (approximately 1 uF, up to 2,500 VAC, perhaps 3,000 V peak).
- \* Magnetron - there are some nifty powerful magnets as part of the assembly. Take appropriate precautions to protect your credit cards, diskettes, and mechanical wristwatches. See the section: "[Neat magnets](#)" and the document: "Notes on the Troubleshooting and Repair of Microwave Ovens for more info.

DOUBLE WARNING: Do not even think about powering the magnetron once you have removed any parts or altered anything mechanical in the oven. Dangerous microwave leakage is possible.

---

## 10. Using the control panel from defunct microwave oven as an electronic timer

It is usually possible to remove just the touchpad and controller board to use as a stand-alone timer with a switched output. Be careful when disconnecting the touchpanel as the printed flex cable is fragile. With many models, the touchpanel (membrane touchpad) needs to be peeled off of the front plastic panel or the entire assembly can be removed intact.

The output will control a 10-15 A AC load using its built in relay or triac (though these may be mounted separately in the oven). Note that power on a microwave oven is regulated by slow pulse width modulation - order of a 30 second cycle if this matters. If it uses a triac, the triac is NOT phase angle controlled - just switched on or off.

---

## 11. Useful parts in a non-working VCR

- \* Motors: 1 to 6 motors of various types. Mostly these are cheap DC permanent magnet motors but the main capstan motor may be a high quality brushless type with electronic control on-board. The video drum motor is likely three phase with its own controller.
- \* Power supply: Outputs various voltages and may be used intact but will always contain useful components like transistors and diodes, transformer(s), and large capacitors.
- \* Tuner. Whether you can make this work without the rest of the VCR is problematic but worth a try.

- \* RF modulator. This usually accepts a DC voltage for power, a control voltage to select TV/VCR, and will output on channel 3 or 4.
- \* Miscellaneous electronic components including crystals, delay lines, video and audio ICs, pots, connectors, etc.

What can you build with it? One can never tell! :-).

---

## 12. High voltage power supplies from dead equipment

- \* TVs, monitors, and computer terminals all contain a source of high voltage for the CRT. Depending on the particular model, up to 30 KVDC or more at 1 to 2 mA will be available assuming the deflection/HV subsystem of your sacrificial equipment is in operating condition. However, you cannot (or at least should not) just string HV wires from the back of the family's 35 inch TV to your lab :-).

- How much circuitry you actually need (and what you will have to add) depends on design but figure on the mainboard with the deflection drive and flyback, and probably the yoke (to keep the system properly tuned though this may not be essential).

Some capacitance on the HV output may be needed as well (though the ones I have tried were happy enough with just the stray capacitance of the wiring). Originally, the CRT envelope provided this capacitance.

See the section: "[Why the yoke is needed to keep the horizontal deflection system happy](#)".

- Power will either be the AC line (WARNING: Very dangerous) or a DC supply (typically 12 to 24 VDC). They will usually operate on somewhat lower input voltages with correspondingly reduced output.
- A 555 timer based oscillator or other horizontal sync source may be needed as well if the system doesn't free-run at close to the normal horizontal scan rate. This is probably easier where the guts came from a monitor or terminal (since a separate TTL compatible horizontal drive input is likely to be available) but it should be possible to fake out a TV as well.
- Depending on design, these may require signals like 'HV Enable' and/or a feedback or reference voltage to operate properly.
- Small B/W TVs, mono computer monitors, and computer terminals will provide about 12 to 15 KV.
- Large B/W TVs and Color TVs and monitors will provide 15 to 30 KV. Even more from projection sets!

- Some larger high performance color monitors may have a separate self contained HV module. One particular type (found in a 19 inch workstation monitor) is rated at 25 KV, 1.1 mA (and produces several other voltages) from a 26 VDC, 2.5 A power supply. However, by tweaking some internal pots, over 30 KV is available. See the section: "[High voltage power supply module from Monitronix EZ series monitors](#)" for one example.

One key advantage of using predesigned circuitry is that you are less likely to destroy power transistors and other expensive parts - and I have blown my unfair share :-).

See the section: "[Sam's super-starter\(tm\)](#)" for a specific example of this kludge, um, err, approach for starting large HeNe laser tubes :-).

\* The high voltage power supplies from plasma globes, electrostatic dust precipitators, photocopiers and laser printers, bug zappers, negative ion and ozone generators, electric fences, cattle prods, electric chairs, and other 'common' equipment may be pressed into service for your applications.

Since these HV generators are not combined with anything else, they are likely to be self contained modules and very easily used by themselves.

However, available current from some of these sources is generally less than from TVs or monitors. Details are left to the highly motivated student :-).

- Plasma globes: Pulsed (not rectified or filtered) 10 to 15 KV.
- Electrostatic dust precipitators: 5 to 10 KVDC.
- Photocopiers and laser printers: Two outputs at 5 or 6 KVDC.
- Bug zappers: 10 KV???

Caution: Since these power supplies were designed for a specific purpose under specific operating conditions, their behavior when confronted with overloads or short circuits on the output will depend on their design. It may not be pretty - as in they may blow up! Take care to avoid such events and/or add suitable protection in the form of fast acting fuses and current limiting to the switching transistor.

Note about X-rays: Improper use of these sorts of devices may result in shock or electrocution, but at least you will not be irradiated at the same time unless you connect them to a something which includes a vacuum. In order to produce measurable X-ray radiation, electrons must be accelerated to high velocity and strike a heavy metal target. A high vacuum such as in a CRT or other vacuum tube (valve) is best but there may be some X-ray production from a low pressure gas filled tube. There is virtually none in sparks or arcs at normal atmospheric pressure. However, there will be UV and ozone which are both hazardous.

---

## 13. Sam's super-starter(tm)

This would be called a kludge by some, a Rube Goldberg by others. But, hey, as still others would say: "If it works, use it!". The original application was for starting LARGE HeNe laser tubes but there can be many other uses.

The entire horizontal deflection and high voltage sections of a long obsolete and lonely ASCII video display terminal were pressed into service for starting larger HeNe tubes. A source of about 12 VDC at 1.5 A is needed for power and a 555 timer based oscillator is needed to provide the fake horizontal sync:

- \* The deflection circuitry was all on one corner of relatively small board (about 3 x 6 inches). The flyback transformer is a plug-in unit. I left the other circuitry (vertical, video) in place since it is not powered by the same supply and therefore is pretty inert. However, if you want to recycle the parts.....
- \* The horizontal deflection yoke is needed to 'tune' the system - performance is much better with it installed. This wart looks a bit strange but is the easiest way to avoid modifying the design. See the section: "[Why the yoke is needed to keep the horizontal deflection system happy](#)" for more info.
- \* Horizontal drive is provided by a 555 timer in astable mode running at about 16 KHz (the original horizontal deflection rate of the terminal). A 10K ohm pot allows me to fine tune this for maximum HV output.

Well, it turns out there was an unused spot on the board ready made for this circuit (well almost, at least there was a pattern for a spare 8 pin DIP! So, once the thing was basically working, I built the oscillator onto the board to reduce the clutter!

- \* Power requirements are modest - 10 to 15 VDC at just over 1 A. Over this range, the output varies between about 10 and 15 KV (what a coincidence!). Input down to about 5 VDC produces correspondingly reduced output but the circuit is not particularly stable over this lower range of voltages.)

I guarantee that "[Sam's super-starter\(tm\)](#)" - or its big brother, "Sam's hyper-starter(tm)" using parts from a color TV or monitor - will start ANY HeNe tube that can possibly be started! These also make nice self contained HV sources for other experiments :-).

---

## 14. Why the yoke is needed to keep the horizontal deflection system happy

If you unplug the yoke (even if there is no interlock), while the system may still work to some extent but performance will be poor. High voltage will be reduced and parts may overheat (and possibly blow up).

(From: Jeroen Stessen (Jeroen.Stessen@ehv.ce.philips.com)).

Of course that doesn't work. The flyback capacitor is tuned for the presence

of both inductances: line transformer and deflection coil. If you remove the deflection coil then the remaining primary transformer inductance is about 5 times as large. So, rule-of-thumb, you would have to decrease the flyback capacitor by a factor of approximate 5. But that's not all:

Without the deflection coil, a lot less current runs through the horizontal output transistor. So, in all likelihood, it will now be overdriven. So you need to reduce the base drive. But that's not all:

If you remove the picture tube capacitance and the deflection coil then all peak energy demand must be delivered from the primary winding of the line transformer. Even the shortest peak load will cause saturation. The parallel deflection coil will at least lend some temporary energy, and the picture tube capacitance does an even better job. A good high-voltage source without the benefit of a deflection coil is more expensive...

If you *must* get rid of the 'ugly' deflection coil, then you may want to replace it with an equivalent 'pretty' coil. But:

- \* It must be able to carry the peak current without saturation (a deflection coil has such a huge air gap that it can not possibly ever saturate, but a smaller coil can).
- \* It must have a low enough dissipation so you might have to wind it with litz-like wire (multi-stranded isolated), do not underestimate the losses in high-frequency coils, mostly due to skin- and proximity-effect.
- \* Yes, it can be done, good luck.

And you might want to add a discrete high-voltage capacitor. How to isolate the wiring (corona discharge!) is left as an exercise to the reader... (We pot them in convenient blocks).

---

## 15. High voltage power supply module from Monitronix EZ series monitors

This is a self contained module (separate from the deflection circuitry) which makes it very convenient for your HV projects.

It is fully enclosed in an aluminum case about 1-7/8" x 6" x 5" with a 9 pin connector for the low voltage wiring and thick red wires with HV connectors - suction cup and Alden type - for the CRT 2nd anode and focus voltage respectively.

Manufacturer: Toyo, Corp., Japan

Model: HVP-1208A1-26L.

Input: 26 V, 2.5 A max.

Output: 25 KVDC, 1.1 mA

Focus, 4.5 to 7.65 KVDC, 15 uA  
G2, 200 to 1000 VDC, 5 uA  
-200 VDC, .5 mA

There are 8 pins installed on the 9 pin connector of which 6 were used. I wonder if the other 2 have any function other than spacing off the G2 voltage.

Pin 1: -200 VDC (-184 VDC measured)	White or yellow
Pin 2: V+ in 26 VDC, 2.5 A max.	Green or brown
Pin 3: Power Gnd	Black
Pin 4: Shield Gnd	Bare or black
Pin 5: NC	
Pin 6: NC	
Pin 7: Enable (low) TTL	Orange
Pin 8: NC	
Pin 9: G2 (+200 to +1000 VDC)	Red

I assume the NCs are truly not connected to anything and simply serve as clearance for the up to 1000 V G2.

In addition to the Focus and G2 pots, there is an unmarked adjustment accessible via a hole in the case. At first, this appeared to have no effect on any output.

When I opened the case, 2 additional pots come into view. While I do not really know their exact function, by advancing them clockwise, the HV could be boosted significantly. With both fully clockwise, the externally accessible control will vary the HV between about 27 and 32 KVDC regulated (only HV probe meter load).

---

## 16. High voltage transformers

\* Neon sign or luminous tube transformers (same thing): 10 to 15 KV at 15 to 60 mA, current limited. Some may be higher. There are also smaller ones.

Current limited means that the transformer will deliver the rated current ( $I_o$ ) into a short circuit and produce the rated voltage ( $V_o$ ) with no load. This is somewhat similar to being in series with a resistor equal to  $V_o/I_o$  but implemented as a loose magnetic coupling so there is no additional power dissipation. (It isn't really this straightforward but will serve as a first approximation.) Therefore, a short circuit on the output will not

blow a fuse or trip a breaker.

Sources: Your local sign shop, demolition company, or salvage yard. New: \$100 or more. Used: \$5 to \$50 or free.

WARNING: Though current limited, the available current from neon sign transformers - especially the larger ones - is far into the range where lethal consequences are likely under the wrong circumstances.

- \* Oil burner ignition transformers: 8 to 10 KV at 10 to 25 mA, current limited. (See description for neon sign transformers, above.)

Sources: Your local HVAC contractor probably for the asking as they are thrown out along with old oil burners when they are replaced. However, you will probably have to take the entire icky smelling disgusting burner assembly as part of the deal :-). However, there is will be a nice motor and small oil pump in there as well ;-).

WARNING: Though current limited, the available current from oil burner ignition transformers is still more than enough to kill under the wrong circumstances.

Both neon sign and oil burner ignition transformer generally have centertapped secondaries connected to the case - which MUST be grounded (via a three wire cord and properly wired outlet) for SAFETY. Therefore, it is generally not possible to construct a totally isolated HV power supplie with these devices.

- \* Microwave oven transformers: 1.5 to 3 KV at .25 to .5 AMPS.

Sources: Dead microwave ovens (the transformer is rarely the problem). Try your local appliance repair shop. However, you will probably have to cart away the entire oven - but other useful parts inside :-). See the section: "[Dangerous \(or useful\) parts in a dead microwave oven](#)".

WARNING: The electrocution danger from microwave oven transformers cannot be overemphasized. They are not current limited, and even if they were, could be instantly lethal given the least excuse for a suitable path through your body since the rated current is a substantial fraction of an AMP at several thousand volts. Normally, one end of the high voltage secondary is bonded to the core - which must be grounded for safety. However, it may be possible to disconnect this and construct an isolated HV power supply (which will be only marginally less dangerous).

- \* Automotive ignition coils: 25 to 75 KV (depending on model) at low current.

Sources: Your 1997 Honda. Just kidding :-). Auto repair shops or parts stores, salvage yards.

WARNING: While unlikely to be lethal, the HV output of an ignition coil can still result in a seriously unpleasant shock and possible collateral damage.

- \* Flyback transformers from TVs, monitors, computer terminals, or other HV power supplies. Little teeny ones in CRT based camcorder viewfinders and older Watchman TVs. Output from less than 3 KV to over 30 KV at 1 to 2 mA depending on model. Most include a high voltage rectifier though some may use an external one or voltage multiplier (also a useful and neat device).

For many hobbyist uses, the only portion of the flyback that is important will be the high voltage winding (and rectifier, if present). It is a simple matter to add your own drive and feedback windings on the flyback core. This eliminates the uncertainty of determining the number of turns and wire size for the existing windings.

Sources: CRT based equipment tossed for failures NOT caused by a defective flyback. However, sometimes even a bad flyback can be used for HV projects. This will be the case if the problem is:

- Shorted primary windings. With some flybacks, the primary windings are on a separate bobbin and can be removed. Even when buried, they can sometimes be extracted without affecting the HV winding (just don't lose the HV return!).
- External arcing due to cracks or pin-holes. Try coating with RTV silicone or HV sealer (allow ample time to dry completely). Plastic electrical tape may work temporarily at least. Note: Try to get the type of RTV that is non-acidic. The normal kind (that smells like vinegar when curing) may be corrosive to the wiring. However, I haven't seen problems with this.
- Breakdown in focus/screen network. This section may be removable with a hacksaw or small chisel! Then, insulate the exposed HV terminals as above.
- Shorted HV rectifier (rare). Just add an external HV rectifier if needed.

If you really want AC, this is an advantage! In fact, it might be possible to deliberately short the HV rectifier where you want an AC source by passing excessive (DC) current through it and/or violating its PIV rating (but that may be tough as other parts are likely to fail first!).

- Broken or cracked core. Substitute the core from another flyback or glue or clamp the pieces together (broken edges in close contact). Don't lose the mylar/plastic spacers and replace them (if needed) when the repair is complete!

No one actually buys flyback transformers for experimentation!

WARNING: Flyback transformers are capable of producing shocking experiences. However, when run at high frequencies, your first hint of bodily damage may be via your sense of smell - from burning flesh. Keep clear!

Note: Ignition coils and flyback transformers can generate very high voltages but must be driven by a pulsed or high frequency drive circuit. These cannot be plugged into the wall socket directly!

Also see the section: "[Driving automotive ignition coils and similar devices](#)".

---

## 17. Driving automotive ignition coils and similar devices

"I have some questions about automotive ignition coils. I'm referring to the cylindrical "universal" type which has two 12 V terminals and one HV terminal in the center of the cap.

What is the typical peak output voltage and current?

What is the maximum average power input that such a coil can tolerate? I'm aware that the cross-sectional area of a transformer core dictates power handling capability. Judging from the skinny core in a spark coil, I'd place the maximum continuous duty input at around 50 watts. Am I in the ball park on this?

Is there an optimum pulse rate?

Do ignition coils employ any sort of current limiting?

Do "high-performance" coils with 45-75kv outputs offer significant increases in output power, or just higher voltage?"

(From: jfreitag@gso.sun1.gso.uri.edu (John Freitag)).

First, be aware that the coil does not act as a transformer as such, even so called "Hot Coils" have only a 1:100 turns ratio which would give only 1,200 volts from a transformer. If you were to energize the coil with an AC voltage like you would with a transformer this is what you would get. An automobile ignition is more properly referred to as an "induction coil" Its output voltage is defined, not by the turns ratio but rather by the differential equation:

$$V = L di/dt$$

where:

V is the output voltage

L is the inductance in Henrys

di/dt is the rate of change of current flow as the field collapses in the coil.

V into an open circuit, will essentially rise until a spark jumps. When the air ionizes and the spark occurs the remaining energy in the coil sustains the spark.

Hot coils have a heavier primary so that they can pass more current, hence a higher di/dt.

The maximum pulse rate is determined by the time taken for the current to build when the points close (due to L it rises slowly until it reaches a steady state) and the time for the field to collapse when the points open. (the voltage to generate the spark occurs only after the points open and the field is collapsing)

I have never thought about the power in the spark but I suppose it would be:

$P = (L di/dt)^2 / R$  where P is the power in watts and R is the total resistance of the coil secondary, the plug wire and the ionized spark

gap. (Some Professor of EE is welcome to comment here).

As for current limiting, many coils employ a series resistor in the primary which limits current and is shorted out during starting.

(From: Mark Kinsler (kinsler@froggy.frognet.net)).

I use a 12 volt battery and it works pretty well. Probably the best high voltage power supply for careless amateurs is the one I designed, which could be found on my Web page if I knew how to do schematics but I don't. But it's simple enough.

I've been driving my old 12 V coil (bought as a replacement for the one in my Econoline but never used) through a buzzer-type interrupter made from an old relay. I put a capacitor across the contacts for good luck, and for the most part it works pretty well. It'll give me about a 1/2" spark, which is all I need for my illegal spark transmitter and the spark plug in my famous "One Stroke Engine" demonstration. However, it yields some amusing effects, to wit: blue sparks dancing around on the battery lead and the battery itself, extremely strange noises, copious production of ozone, and the occasional puff of smoke. I have the whole mess mounted inside a plastic 2-liter cola bottle. On the advice of my friend Dewey King, who restores old gas engines from oil rigs, I've purchased a Chrysler ballast resistor to put in series with the battery and thus keep the coil healthy.

All you need to do is make a trip to the local auto junkyard:

Buy a used but fairly viable car battery, an old-fashioned ignition coil (i.e., before electronic ignition came out in the '70's), an ignition condenser (capacitor) from out of a dead distributor, and the heaviest 12 volt spdt relay you can get from Radio Shack. DPDT is okay, too.

1. Figure out how to connect the relay so it buzzes.
2. Connect the capacitor across the contacts
3. Connect the primary winding of the ignition coil in parallel with the relay coil.

If you do this right, the relay contacts will give a pulsating current through the ignition coil primary. You'll get a several hundred Hz, 12,000 V between the secondary (the central tower of the coil) and ground. It'll give you a big surprise but it won't kill you unless you're pretty determined to do yourself in.

I've found that only a car battery has sufficiently low internal resistance to run the thing: my big old bench power supply won't do it. So keep a trickle charger on the battery. It seems capable of giving a 3 cm or so arc depending on conditions.

(From: Pamela Hughes (phughes@omnilinx.net)).

I did something like that only it plugged into the wall. Don't remember the circuit but it was a 33 uF, 630 VAC mercury vapor ballast cap connected to a rectifier in a linear fashion (much like using a cap for an AC resistor only the rectifier prevented bidirectional current flow...). This was connected to an 800 V, 6 A SCR and a neon lamp for a diac in a trigger circuit. Adjusted

the trigger point so the scr would fire at a certain point in the AC cycle and discharge the cap through the primary of an ignition coil. If you adjusted the trigger point right, you could get about 3" to 4" sparks. Connected that to a 40 KV TV rectifier and a cap made from a window and some aluminum foil and to a 2" spark gap. Wouldn't fire unless something was placed in the spark gap, but then it went off with a bang that would put any bug zapper to shame.

BTW, I took the ignition coil apart, disconnected the common lead connecting the primary and secondary and then used the secondary and core for a giant sense coil for monitoring changes in magnetic fields... thing would make the volt meter jump if you brought a magnet anywhere close to it, but mostly it just fluctuated with atmospheric effects like lightning.

(From: Pierre Joubert joubertp@icon.co.za)).

1. Use a monostable-based circuit which gives the maximum 'on' time for current in the coil. As revs go up, many older systems produce reduced spark energy simply because the rate of rise of current in the coil prevents full current from being reached before the current has to be switched off.
2. Use one of the coils which is designed to operate normally with a series resistance, which is conventionally bypassed during cranking to help get a better spark on the reduced battery voltage. But instead, limit the current in the coil to a safe value by setting a current limit around the switch transistor. This prevents the coil overheating (which it would if you used it without the resistor in a conventional system.
3. Look around for the 'best' coil you can find; you might find a better match to your needs by using a coil from a different model or even make of car. If you know the R and approximate L you can model the current buildup and estimate the energy available. Generally the more energy the better, assuming that the transformation ratios of most coils are roughly the same, which was true way back when.

---

## 18. Mark's comments on high voltage lab conditions

(From: Mark Kinsler (kinsler@frognet.net)).

So how do you make your high-voltage laboratory safe? Well, you just assume that anything you build is likely to catch fire and/or arc over, and design your lab space accordingly. Stay out of the way of capacitor strings, though when these blow up the shrapnel is generally pretty harmless. I've gotten stung by exploding carbon resistors, but again, it's no big deal if you're well away from them. In general, take the same precautions with high-voltage or high-current components that you would with small fireworks: avoid flammable environments and stay well away from them. If all else fails, take the stuff outside.

My advisor at Mississippi State University observed that if you never damage any equipment and you don't have fairly catastrophic failures, you're probably not doing any research. That helped justify the 6" crater I blew in the concrete lab floor (a record that still stands--his crater was only 4", though there were several of them produced at once.)

---

## 19. Cheap sources of magnet wire

It has been suggested that transformers, inductors, and TV/monitor deflection coils are inexpensive or free sources of magnet wire. This may be OK for antennas or similar applications where the insulation isn't critical. However, unwinding those coils may result in damaged insulation as the wire is peeled apart since they tend to be impregnated with varnish. This makes the wire unsuitable for winding new coils. Unless, you have a way of dissolving the varnish without destroying the insulation, the risk of a random shorted turn or two (or many) buried beneath several thousand nice separate ones isn't worth it!

However, a nice source of fine magnet wire is relays and solenoids - many have very fine wire - #40 for example - and miles of it (well thousands of feet at least). These are very often not varnished so they unwind easily (just don't let them unwind all over your junk drawer!).

---

## 20. Plasma globes

A 'plasma globe' is one of those things sold at Radio Shack and gift shops which have a glass sphere containing a partial vacuum sitting on a power supply base which is a high frequency inverter. The pressure is such that the discharge tends to take place in streamers rather than as a diffuse glow. The resulting display is supposed to be neat, nifty, interesting, etc. When you place your hand(s) on the globe, the patterns of the discharge inside change.

Recent Sci-Fi movies and TV series seem to have latched onto plasma globes as high-tech replacements for the old-fashioned Jacobs Ladder :-). (E.g., certain episodes of "Star Trek the Next Generator" and "Star Trek Voyager".)

One such product is called "Eye of the Storm".

It should be possible to construct these gadgets with salvaged flyback transformers, power transistors, and a few other miscellaneous parts using a large clear light bulb - good or bad, doesn't matter - for the discharge globe (However, I don't know how good these actually are for this purpose).

Of course, purists will insist on fabricating their own globe (and official ones can also be purchased at exorbitant prices as well).

As far as I know, these will work with just regular air (though the expensive ones no doubt have fancy and very noble gasses!) and the vacuum is not that high so a refrigeration compressor should be fine.

See [The Electronic Bell Jar](#) vacuum technology articles for info on using refrigeration compressors as vacuum pumps.

However, since large clear light bulbs may also be satisfactory (though I don't know which ones to recommend), there is may be no need to mess with a vacuum equipment :-). And, of course, you have a wide selection of inexpensive types to use for experiments, and dropping one or blowing it up isn't a disaster!

Excitation is usually from a high frequency flyback transformer based inverter producing 12 to 15 KV AC at around 10 kHz. Its HV terminal attaches to the internal (center) electrode of the globe or light bulb. The HV return is grounded. Ionization of the gas mixture results from the current flowing due to capacitive coupling through the glass.

For a power source, either the "[Simple High Voltage Generator](#)" or "[Adjustable High Voltage Power Supply](#)" would be suitable. See the document: "Various and Diagrams" for circuit ideas.

However, note that its output must be AC so there must not be any internal HV rectifier in the flyback transformer (which may be hard to find these days since most flybacks have internal rectifiers). (If a flyback with an internal rectifier is used, the globe will just charge up like a capacitor which is pretty boring after a few milliseconds!)

(Portions from: Steve Quest (Squest@mariner.cris.com)).

A \$20 air conditioner repair hand-pump is fine. If the colors of plain air are not 'pretty' enough, let me recommend what is used in commercial units: a mixture of low pressure argon and neon. If you want to be extra fancy, try all the inert gasses, or a mixture of them all, helium, neon, argon, krypton, xenon, radon. :) Of course, radon may not be safe/legal, or even available. You could just toss a chunk of radium into the globe, it will generate the daughter isotope Rn(222) thus slowly, over time, enhance the color of the gas mixture. Just a thought.

The power supply needs to be dielectrically isolated (using the glass as the dielectric), otherwise you'd have direct emission from the metal, and it would be more of a light bulb than streaks of color. Plus, people touching it would feel a tingle while the dielectrically isolated is less likely to shock. What this means is that a direct connection to the filament lead wires is not that great as you really want glass in between the driving source the center as well as the outside globe.

\* If you are making your own 'globe', one way to do this is to fuse a glass test tube into the center and coat its interior with conductive paint. This then becomes the center electrode.

\* For a light bulb (which isn't really recommended anyhow), you can try to use the filament directly or cut the lead wires as close to the glass as possible and insulate them with RTV or HV putty. Then coat the remainder of the interior of the glass filament support structure with conductive paint to use as the center electrode.

If you cannot locate a suitable flyback, wind your own. Tesla-style air core transformers work. :)

## 2. Performance testing of monitors

This document provides a guide to the testing of computer and video monitors for functional characteristics like color purity, convergence, geometry, focus, resolution, Moire, switching between scan rates (where applicable), and acoustic noise.

**WARNING:** No monitor is perfect. Running these tests on your monitor or one you are considering may make you aware of deficiencies you never realized were even possible. You may never be happy with any monitor for the rest of your life!

Note: the intent of these tests is **\*\*not\*\*** to evaluate or calibrate a monitor for photometric accuracy. Rather they are for functional testing of the monitor's performance.

Obviously, the ideal situation is to be able to perform these sorts of tests before purchase. With a small customer oriented store, this may be possible. However, the best that can be done when ordering by mail is to examine a similar model in a store for gross characteristics and then do a thorough test when your monitor arrives.

---

## 3. Comments on monitor performance and sample-to-sample variations

(From: Will Nott (bnott@barngate.compaq.com)).

As with every piece of machinery built in mass production, monitors have performance specifications which define tolerances on performance, as well as operational limits. This has always been the case for monitors, and, in fact, front of screen performance specifications have not changed appreciably over the last ten years. Other items, such as for video & scan rate capabilities have changed, but those items do not appreciably affect the front of screen issues which most users find disappointing.

Most users never see the detailed specifications which the manufacturer works to, but may see a sub-set intended to "feature" the product's strong and/or competitive points. There are some variables which may be compensated for with more sophisticated circuits, but that usually results in higher product cost (**\*not\*** necessarily sales price; see below). There are other variables which are subject to normal state of the art production tolerances, and because of

this, some units will actually come off the line looking better than others, even though they all meet spec.

For an example, misconvergence is a variable subject to production tolerances, and practically all monitors have similar spec's, even though most people would not like to settle for a unit which is at the limit of the spec. The typical spec. is 0.3 mm in the area within a circle equal to the height of the image, and 0.4 mm outside that area. That is actually more than the theoretical pixel size on a 14" monitor, and hardly anyone will want to use a display with that performance. However, the spec. allows such variations to exist.

An example of a feature which can be affected by additional circuit sophistication is Geometry, or line straightness - each manufacturer has specifications to meet, but here some units may allow as much as 6 mm of non-straightness, where other units may have the ability of being adjusted to a straightness of less than 1mm.

So, what the user runs into are variations of two kinds:

1. Normal manufacturing tolerances explain differences that may be expected among various examples of the same brand & model monitor.
2. Differences in design (circuits) which provide the possibility of adjusting out other kinds of distortion explain differences between different brands and models.

Of course, this probably has very little correlation with the price at which the product is being offered, because of other competing factors in the marketing game, so it's not really fair (although we all are likely to do it) to expect a more expensive product to perform better - maybe that company is doing better at "charging what the traffic will bear". That's why it's always advisable (within practical limits) to try and understand the spec's, and to try and examine the actual unit which you will be taking home, not a showroom example.

---

## 4. Basic monitor performance criteria

The following are among those characteristics of a monitor that should be evaluated:

- \* Screen size and general appearance.
- \* Brightness and uniformity, purity and color saturation.
- \* Stability.
- \* Convergence.
- \* Edge geometry.
- \* Linearity.
- \* Tilt.
- \* Size and position control range.
- \* Ghosting or trailing streaks.

- \* Sharpness.
- \* Moire.
- \* Scan rate switching.
- \* Acoustic noise - buzzing and whining.

For monochrome monitors, use the appropriate subset of these tests. The descriptions below usually assume an auto-scan SVGA type of monitor. Modify accordingly for fixed scan computer monitors and studio video monitors.

Note: we use the term 'auto-scan' to describe a monitor which accepts a wide (and possibly continuous) range of scan rates. Usually, this refers mostly to the horizontal frequency as the vertical refresh rate is quite flexible on many monitors of all types. Fixed scan or fixed frequency monitors are designed to work with a single scan rate (though a 5% or so variation may actually be accepted). Multi-scan monitors sync at two or more distinct scan rates. While not very common anymore, multi-scan monitors may still be found in some specific applications.

CAUTION: since there is no risk-free way of evaluating the actual scan rate limits of a monitor, this is not an objective of these tests. It is assumed that the specifications of both the video source/card and the monitor are known and that supported scan rates are not exceeded. Some monitors will operate perfectly happily at well beyond the specified range or will shut down without damage. Others will simply blow up instantly and require expensive repairs.

Note: throughout this document, we use the term 'raster' to refer to the entire extent of the scanned portion of the screen and the terms 'picture', 'image'. or 'display', to refer to the actual presentation content.

---

## 5. Test patterns

Three kinds of test patterns will be needed:

1. Solid, saturated primary colors (R,G,B) and combinations of these (Y,C,M,W). These will be used for brightness and color purity tests. Total black will also be required to set background level and evaluate black level retention.
2. White cross hatch, fine dot, alternating vertical and horizontal line patterns and bounding box outline. These will be used for convergence, geometry, size, and position, focus, and Moire tests.
3. High quality graphic or photographic image for general color appearance and overall aesthetic tests. If no suitable material is available, a Windows desktop with a vibrant color scheme (computer monitors) or an outdoor scene on a sunny day (studio video monitors) may be used.

For computer monitors, software programs are available to conveniently generate the required test patterns. However, an application like Windows Paint in conjunction with a picture with vibrant colors can be used to

create anything that is needed. It just will not be quite as easy to switch between patterns. Video cards like those from ATI come with a software Install program which provides a bounding box pattern and at all (PC DOS/Windows) resolutions and scan rates.

Test pattern generators for TV monitors are readily available and relatively inexpensive. However, a camcorder viewing appropriate printed material or a prerecorded tape can be used in a pinch.

---

## 6. Testing

Before starting the series of tests, allow the monitor to warm up for at least 1/2 hour and make sure it is completely degaussed (see the document: "[Notes on the Troubleshooting and Repair of Computer and Video Monitors](#)" for details on degaussing techniques. Power the monitor up in the physical orientation you will be using it (front-back facing North-South if you do not know how your setup will be arranged) and don't rotate it on its tilt swivel base after degaussing and for the duration of these tests. Make sure the monitor is not near any sources of electromagnetic interference (i.e., other powered monitors, loudspeakers, motors, transformers, etc.). Subdued lighting is best.

Use only the original video cable that came with the monitor or high quality BNC cables as appropriate. If you have a choice, opt for a BNC cable - the quality at higher scan rates will be noticeably better. Do not use any extension cables, any video switch boxes, or excessively long BNC cables.

Obviously, if you can do any of this in a store at all, then you may not quite have the luxury to fully control your environment!

Note that for an auto-scan monitor, all tests should ideally be performed at several points including the extremes upper and lower limits of each scan range. Most aspects of a auto-scan monitor's performance are affected by scan rate.

Unless otherwise noted, all controls are those available to the user.

For each test, adjust the size and position controls so that the raster fills as much of the screen as possible or as appropriate for the particular test.

---

## 7. Screen size and general appearance

Screen dimensions are normally measured diagonally - corner to corner.

So you thought you were buying a 17 inch monitor, right? Wrong. A monitor that is advertised as 17" (or 15" or 21") will rarely give you anything near that viewable size. The specification is of the CRT - including what is covered up by the front bezel and not considering the actual maximum size picture that may be possible in all scan modes.

Easily, 1.5 to 2 inches of your valuable diagonal screen real estate may be lost to marketing hype. As a result, you might find as much as a 20% difference in usable screen area between monitors which claim to be the same size. This is like buying a 17" monitor and getting one that is only 15"!

At certain scan rates, it may not be possible to get a picture corner to corner so even more usable area will be lost. Check out the section: "[Size and position control range](#)".

Some advertisements now include actual viewable screen size. Hopefully, this will become a universal practice but I will not hold my breath.

Other aspects of the monitor to check out:

- \* Screen curvature - some are curved, others are nearly flat, Trinitrons are cylindrical. For the most part, this is strictly a matter of preference. However, if you intend to photograph (still or video) off the screen, a flatter screen (all other factors being equal like geometric accuracy) will result in less distortion.
- \* Screen surface finish - this may be highly polished resulting in annoying reflections or dull (flat) which if excessively graining will decrease the crispness of the display. A highly polished surface with an anti-reflective coating (see below) is probably best.
- \* Antireflective and/or black (smoked) glass - usually, a CRT with a dark appearance will produce a higher contrast picture but possibly at the expense of overall brightness. Antireflective coatings like on camera lenses help also but are easily smudged and may be damaged by excessive cleaning.
- \* Convenience of the user controls. Digital controls are nice in that the settings for each resolution and scan rate are stored in memory. However, knobs are much easier to adjust in many cases. I prefer knobs for at least brightness and contrast.
- \* The aesthetics of the case. While this is usually unimportant from a performance point of view, it could be of great significance to your happiness. However, I know of some incredibly ugly monitors with great performance!

---

## 8. Brightness and screen uniformity, purity and color saturation

Display a black - totally blank screen (but don't just pull the video cable as the monitor will be running with the normal voltages and signals) so that the raster is just barely visible. This adjustment should be possible but as noted below, not all monitors have totally independent brightness and contrast controls - you may need to bring up contrast a bit also.

The raster should be of uniform intensity and neutral gray. If it is not of uniform intensity or has hum bars - full width areas of varying brightness - or full height vertical rippled areas, the monitor's power supplies may be defective or of poor design. The only way to be sure is to compare several samples of the same model.

If the raster is not a neutral gray but has a tint, the color balance may need to be adjusted. See the section: "[Brightness and screen uniformity, purity and color saturation](#)".

Make sure you can actually set the brightness for total black (turn out the lights and check). If not, you will never have truly dark shadow areas in your display. Blacks will never be black and the display will always look a washed out. This may be adjustable internally.

However, inability or difficulty in adjusting for a totally or nearly black raster and vibrant bright display - or if the background brightness shifts as the picture content changes - may indicate a deficiency or defect in the black level retention circuitry. Since video signals are usually AC coupled, a clamping circuit is needed to set the black reference. If this does not work correctly or is poorly designed, the black level may shift depending on the picture content. Modern monitors should be nearly perfect in this regard. This problem is still seen in some cheap TVs, however.

Now set brightness to make the raster just disappear. Set the contrast control all the way up. Display a pure red (R) full intensity raster. The entire screen should be a pure, fairly uniform fully saturated red. There should not be any areas that are not pure red. Repeat with the other two primaries - green (G) and blue (B). Follow this up with tests of pairs of primaries resulting in yellow (R+G), cyan (G+B). and magenta (R+B). Again, these should result in pure vibrant colors.

Finally, display a pure white full intensity screen. The raster should be pure white. There should be no patches of discoloration. It may be a warm white (somewhat redish) or a cool white (somewhat bluish) but not objectionably so. Some monitors permit this color 'temperature' to be adjusted by the user (e.g., NEC AccuColor models like the 4FG or 5FG). If the screen is noticeably colored and there are no user adjustments, then the internal video gain controls need attention - see the section: "[Brightness and screen uniformity, purity and color saturation](#)".

Note that the term 'vibrant' here is a subjective term but relates to the boldness, saturation, and, well, zappiness! However, this is affected both by the choice of spectral output of the primary color phosphors and to your perception. For a given CRT, the phosphors set the spectral characteristics of the display. Expensive studio monitors can be ordered with a specific CRT to suit the needs of the video standard. This is rarely an option with computer monitors. You probably do not have

control over your visual perception (but do take off those autocompensating sun glasses!) In other words, your mileage may vary.

If any of these tests detect a problem, the color purity may need to be adjusted. (By you or by a professional as appropriate). A brand new monitor should not have purity problems unless it is near a source of magnetic fields like a loudspeaker or MRI scanner.

The pure white screen can also be used to evaluate the brightness uniformity of the CRT. Don't expect perfection. The actual quantitative measured brightness may vary quite a bit even with a high quality monitor. The corners and edges may be noticeably darker than the center even on the low deflection angle CRTs used in high performance monitors. With the high deflection angle CRTs in TVs and cheap monitors, this may be even worse.

However, local significantly darker or brighter areas could indicate defects in the CRT dot/slot mask or aperture grille or phosphor screen which should not be tolerated.

Should you see color or uniformity problems at full intensity, try turning down the contrast control. If the uniformity improves after a few seconds, the shadowmask in the CRT may be heating and deforming. This is not unusual with color monitors. One of the advantages of an InVar shadowmask is that it is less prone to these problems, however.

Also note if there is a brightness limiter circuit that is kicking in with the full white screen. As you turn up the contrast, is there a point where further increase has no effect on the intensity of the display or where the intensity actually decreases? These brightness limiters are designed to maintain the beam current at supposedly safe levels to minimize X-ray generation and/or to minimize the shadowmask heating effects. Is the maximum brightness adequate for your needs and viewing enjoyment?

Using the full white screen, adjust the contrast and brightness controls through their full range. The size of the raster should not change noticeably. A significant change in size - more than 1 or 2 percent - would indicate poor power supply regulation.

Examine the entire screen closely for blemishes both in the surface finish and for dead spots.

If you see any dead or darker spots, confirm that these are not due to the video source: if they are CRT defects, they will not move as you adjust the position controls.

There is a specification for the number and size of acceptable CRT blemishes so you may have to whine a bit to convince the vendor to provide a replacement monitor under warranty. Before the purchase is the time to find these.

---

## 9. Stability

Display a picture having a complete range of colors and intensities.

At refresh rates beyond 70-75 Hz, even a very bright display should appear rock solid. Turn off any fluorescent lights (whose possible flicker at twice the power line frequency can confuse the test) and examine the screen closely. There should be no shimmering, wiggling, jittering, or dark or light flashes. Any of these would indicate either (1) external electromagnetic interference or (2) a poorly designed or defective power supply in the monitor. It is also possible, though less likely, that the incoming AC power is noisy but modern monitors generally do a decent job of filtering the power lines to eliminate most of this.

---

## 10. Convergence

Ideally, all three electron beams in a color CRT should be precisely coincident at every point on the screen. While this is never quite achieved, the degree of convergence even at the corners is generally quite impressive - less than .5 mm for many moderately priced monitors.

Display a white crosshatch pattern with boxes about 1/2 inch square. IF you do not have this, use a white-on-black graphics or text screen with a lot of fine detail - small fonts or intricate patterns.

The lines should appear white without excessive color fringing. The individual primary colors should not be visible at a normal viewing distance. First, examine the center. This should be nearly perfect. If your monitor has any user adjustable convergence controls, set these for best center convergence. Convergence will be worst in the corners but even there, it should not be objectionable.

A serious convergence problem in the center of the screen is definitely an indication of a defective monitor or one that needs internal adjustments. Slightly poorer convergence at the corners may be within specifications. A new monitor with significant convergence problems should be rejected.

---

## 11. Edge geometry

Display a bounding box image - one that extends to the very edge of the raster on all sides.

Adjust any user pincushion controls (amplitude and phase) for minimum distortion along the vertical edges. Amplitude moves the sides in and out. Phase sets where, vertically, this effect takes place. If there are any other user controls that affect raster shape, optimize these for a perfectly

rectangular display.

Now, examine all edges for curves, wiggles, dips, keystoneing, or trapezoidal deviations from a perfect rectangle. These are all considered defects in the geometry of the raster. These will likely be more pronounced at high scan rates - near the limits of the specifications for the monitor. In particular, you may see a wiggle or wave on the left and right edges near the top of the screen which will be come more pronounced as you approach the highest scan rate (this is a deflection problem, however, not strictly a CRT geometry problem).

During manufacture, various magnets are strategically glued around the CRT or carefully positioned on rotating swivels on the deflection yoke frame or elsewhere. You need to decide if any remaining errors in geometry are acceptable or not because improving upon these settings is not something that is easy or fun to do - by you or a professional! As noted, if the geometry becomes noticeably inferior at high scan rates, this indicates a problem in the deflection circuitry - adjustments will probably not help. Consider another monitor if you intend to run at these rates.

---

## 12. Linearity

Display a crosshatch pattern of roughly 1/2" spaced lines. Take a tape measure and compare the exact spacing of vertical lines in the left, middle, and right areas of the screen. Do the same for the horizontal lines in the top, middle, and bottom of the screen. Modern monitors should have very little variation - probably undetectable using a tape measure.

Linearity may or may not be adjustable.

---

## 13. Tilt

Inspect the bounding box for tilt - is it perfectly aligned with the cosmetic bezel of the CRT? If the monitor has a tilt control, see if it will compensate. Few do. The only way to correct tilt on monitors without a tilt adjustment is to rotate the deflection yoke or entire CRT - not recommended. If the degree of tilt bothers you in the slightest and you are a perfectionist, reject the monitor or insist that the tilt be corrected - and be present if possible to make sure that the adjustment is done to your satisfaction.

---

# 14. Size and position control range

Determine if the size and position controls have enough of an range to fill the screen totally (for computer monitors) or (possibly in conjunction with an underscan switch) allow for a suitable reduced raster size (studio video monitors).

For computer monitors, these tests may need to be done in conjunction with the video card you will be using and the software setup program for that video card. Ideally, all size and position adjustments can be done in software with the monitor's controls left at their center (default) setting. However, this is not always the case.

Some people want their computer monitors to extend to or past the edges of the CRT. Many monitors may leave a large border around the picture particularly at higher scan rates. Test at the resolutions and scan rates you expect to use. Obviously, a monitor that will not fill the screen is shortchanging you in terms of how much screen size you purchased!

Often, slightly reducing the scan rate at a given resolution will allow for a larger picture. This is one alternative if the flicker is not objectionable.

---

# 15. Ghosting or trailing streaks

Display a picture with a large number of high contrast vertical edges - a Windows desktop with many open folders, for example.

Vertical edges should be crisp and clear. Examine these for smearing, ghosting, or trailing darker or lighter lines. Any deficiencies will be most evident at high scan rates since these require the most bandwidth from the video card, cables, and monitor. Also, any ringing, undershoot, or overshoot, will extend for a longer space following the edge.

Without substituting video cards, cables, and monitors, it is not usually possible to determine which is the limiting factor.

The most common cause of these types of problems are inferior, defective, or excessively long cables; use of cable extensions or video switch boxes, or improper termination if there are termination options on the monitor.

Full brightness vertical edges should not smear or bloom to the right - possibly with a color change. This is due to the internal video gain controls being set too high and may be correctable but possibly with a reduction in maximum brightness.

There should also be no trailing lines to the right of long bright or

dark horizontal areas. Similarly, the edges of the raster should not bulge out where the picture is very bright. These types of problems would indicate problems with the power supplies or just poor design.

---

## 16. Sharpness

Display a white screen at the highest resolution and scan rate your system is capable of (or the highest you ever anticipate using). See if you are able to make out the individual scan lines. Turn down the brightness - this will decrease the effective spot size and make the scan lines more visible.

Display a fine dot pattern. The individual dots should be tiny, crisp, and fairly symmetric. If the spot size changes drastically with brightness, focus may need to be adjusted or the monitor's power supplies or CRT may be mediocre or defective.

Note that it is not always best to have super sharp focus as long as the spot size is small enough. A slightly defocused spot will result in a smoother display and less likelihood of Moire effects.

---

## 17. Moire

Moire is caused by interference - beating - between the picture or raster and the phosphor dots or lines that make up the display. Technically, it is an aliasing artifact due to the relative sampling rates of these two structures.

There are several causes of Moire. The following will address two of these: scan line Moire and pixel Moire.

Try these tests with any 'Moire reducing modes' both off and on. However, the use of such 'features' may reduce the quality of the display in other ways like reducing sharpness or stability.

Display a solid white screen at mid brightness. Look for patterns that look similar to contour lines on topographic maps. Adjust the vertical size and position controls to see if these move around or change their severity and spacing. Repeat with a display of alternating black and white horizontal lines.

Now, display a pattern consisting of alternating black and white vertical lines at the maximum possible frequency (alternating dark and light pixels for a computer display - make sure your software is not doing any dithering). Look for serious contour lines in this display. Adjust the horizontal size

and position controls to see how these affect any Moire.

Try these tests at multiple resolutions including the highest you will ever use. However, the highest may not necessarily be the worst with respect to Moire.

Other than using any 'Moire reducing mode' provided by the monitor, there may not be anything you can do to reduce the severity of Moire other than running at resolutions which do not exhibit a serious problem.

Nonetheless, I think it is ironic that some people will end up returning otherwise superb monitors because of moire - when in many cases this is an indication of most excellent focus - something many people strive for! You can always get rid of it - the converse is not necessarily true!

---

## 18. Scan rate switching

When running Windows or DOS with a auto-scan monitor, switching scan rates may be done quite frequently. Some monitors take longer than others to perform this switchover. There may be clicks (due to relays) and other sounds. Better monitors will blank the video until the new scan rate has stabilized. On cheaper monitors, you may see the image as it locks in. Some monitors are very quick. Others can take several seconds - an eternity if you are doing this frequently. Try switching between scan rates at the limits of each scan range as this will be the toughest situation. While it is hard to pin down what makes for a suitable outcome of this test (unless there is an actual failure to properly sync), a monitor that appears to be struggling or which doesn't always make it may be trying to tell you something.

Note: there have been some monitors that blow up - fail completely and require expensive repairs - simply as a result of the video card initialization at boot time due to its power on self test when the video signal may be unspecified and driving the monitor at an invalid scan rate. However, this is not likely to be a problem with any modern auto-scan monitor.

---

## 19. Acoustic noise

Ideally, a monitor is seen and not heard. However, there are a variety of components inside that can vibrate and this may be quite annoying in a quiet room or late at night. A buzz may originate from the switching power supply or vertical deflection components. A high pitched whine, squeal, or twittering may originate from the switching power supply, flyback (LOPT) transformer, or horizontal deflection components. Some people aren't bothered by these sounds at all or cannot hear them. Others will be driven stark raving bonkers.

Listen carefully through the grille in the cover for any indication - even momentary - of annoying sounds. Try all scan rates - very often various resonances will only occur at particular horizontal or vertical scan frequencies. Even with high quality monitors, these problems sometimes occur erratically and no quick test will identify such faults. Obviously, doing this in a quiet location is best.

Note that any decreasing hum or buzz that may be heard at power-on is due to the internal degaussing coil and is usually normal and unavoidable.

---

## 20. Final evaluation

If after these tests, you determine that your monitor or the one you are considering is perfect - let me know as this is extremely unlikely. More likely is that you found a number of deficiencies. If this is a monitor you are considering purchasing, you need to decide if the benefits outweigh the defects. For certain problems like color balance, the vendor may work with you to tweak the needed internal controls. Alternatively, using the information contained in the document: "[Notes on the Troubleshooting and Repair of Computer and Video Monitors](#)", you may decide that you will be able to take care of the problem yourself. However, for problems like severe misconvergence, uncorrectable pincushioning, serious Moire, or audible buzz, there may be no easy solution and searching for another monitor may be the only option. If you inherited the monitor or are getting a really good deal, then many of these problems can probably be dealt with but with some risk that significant improvement may not be possible.

---

## 21. Checking the age of the CRT

So you have this great deal on a used TV or monitor. How can you tell if the picture tube is about to die on you?

(From: Andy Cuffe (baltimora@psu.edu)).

The best way to tell is to look at the picture quality. There is no way to tell the exact number of hours. Also, the life of CRTs varies quite a bit. some will go down hill much faster than others.

- \* It should be sharply focused over the entire screen and all 3 colors should be equally sharp.
- \* Set the picture brightness and color to maximum. If you see any bleeding or smearing to the right of bright objects don't buy it.
- \* When you first turn it on the picture should look normal in well under a

minute. If it is dim, tinted, or blurry for more than a minute or two the CRT is getting weak.

\* A B/W picture should not be tinted.

\* The picture should have decent brightness with the picture at about mid range.

Apart from that, if the overall picture is good the CRT is fine. CRTs usually fail very slowly. Even if it's starting to show it's age it probably has several years left.

(Portions from: Jerry G. (jerryg50@hotmail.com)).

You cannot tell the hours used by just looking or even measuring a tube. A tube can go at any time. There are no hour counters!

Turn on the unit and see if there is any unusual bleeding of the image in the picture at high contrast levels. When turning the brightness up and down, the color temperature should not change, only the brightness. When turning the contrast up and down, the focus at the center should also be very stable. It may change only a little bit. When turning on the set, the color temperature should be stable within about 3 to 5 minutes.

Look at the colors in the corners to see if the purity is good. Bad purity can be attributed to a miss-adjusted yoke assembly, to a bad shadow mask.

To know the manufacture date of the unit, it is usually on the back with the model and serial number. Most TV sets are on about 5 to 8 hours a day if it is a family TV. If it is a bedroom TV the hours may be 1/2 that amount. Monitors may be on 24 hours a day - or much less.

A good way to know if the emission of the CRT is up to specs is to get a CRT analyzer and measure the gun emission. Some service centers own one.

---

## 22. Monitor testing programs

There are a variety of PC compatible software programs for testing of SVGA computer monitors. These display various test patterns and color charts which are appropriate for the procedures discussed in this document.

Here are a few pointers:

- The monitor test program "NTest" from the [Nokia Download Page](#) is very often recommended on the [comp.sys.ibm.pc.hardware.video](#) Newsgroup.
  - [Nokia Ntest Monitor Test](#).
- (From: Bert Christensen (rosewood@interlog.com).)

"Screen Test" is a program for those who repair monitors. It has color bar, gray scale, purity, dot, crosshatch, and linearity patterns. It is available for downloading from Rosewood Software at:

- [Screen Test](#).
- [ComputerCraft](#) provides a shareware program for testing monitors and video cards. I have not tested it but as they say: "If you are aware of the dangers, Monitors 1.01 is a powerful tool." See the section: [WARNING and DISCLAIMER](#) for some of these. This shareware program can also test video cards for characteristics and graphic modes
  - [Monitors 1.01](#).

(From: Mark E. Nikl (markn3@infoave.net).)

In the download section of the Web site, there is a file called monitors. It will give you all the test patterns and setups for gray scales, HV regulation, tell you about you video card and much more. I just ran across it the other day. You can even set up the pincushion and lots more.

- SONERA Technologies markets a set of programs called "DisplayMate" available for DOS and Windows/Win95. This is supposed to guide you through the monitor testing and setup process with a series of test pattern 'slides'. I have not tried it so I cannot comment on its utility.

A demo version with a few test patterns, more information on their products, and some video tech tips, and some test patters are available at:

- [Display Mate Home Page and Demo](#).
- [Test Patters](#).

A subset of these test patterns is available courtesy of PC Magazine at:

<http://www8.zdnet.com/pcmag/features/monitors/test/>. I don't know how long this will be available but for now, it is really easy to use and doesn't require that you even exit Windows. You may use it on 640 x 480, 800 x 600, 1024 x 768 screen resolution or windows of these size. Test patterns are provided for color rendition, horizontal resolution, dot/cross hatch, and more. The images files may be downloaded and saved as well.

## 3. Introduction

So, you have got the deal of a lifetime - a brand spanking new (or at least low mileage) high resolution 21" computer monitor that came from a DEC Alpha Workstation - or a Sun or HP - or Macintosh. Or, perhaps an IBM9517 which you were told has a super sharp bright picture. The cost to you: \$1 or you haul it away. Is this really and truly a good deal if you use a PC?

Questions like this come up all the time on `comp.sys.ibm.pc.hardware.video`.

These are either fixed frequency monitors or incompatible with the common VGA/SVGA 'standards' in some other ways.

A fixed frequency monitor is designed to operate at a single scan rate which usually means a single resolution such as 1280x1024. (Strictly speaking, the horizontal resolution is determined by the number of pixels sent on each scan line by the video card but this is a detail.) PCs running DOS, Windows 3.1, WFWG3.11, and Win95 generally require the monitor to run at multiple scan rates - one for each corresponding resolution. For example, boot at 640x400, VGA at 640x480, Windows at 1024x768 - and each one may have a correspondingly different horizontal and vertical scan rate. (Some workstation monitors are actually dual frequency but this does not really help since neither of the supported scan rates are what a PC wants.)

Monitors like the IBM9517 are not fixed frequency but are XGA compatible. This was an IBM abortion and not compatible with VGA/SVGA even for booting your PC.

These types of monitors are generally manufactured by the best names in the industry such as Hitachi, Mitsubishi, Philips, Sony, etc. - and are thus often of very high quality. The specifications of these monitors may exceed those of any but the very top-of-the-line monitors used on PCs. The original cost of these monitors was probably much higher than an equivalently sized PC monitor as well. They become available as high

performance workstations (whose technology advances nearly as quickly as that of PCs) are decommissioned or upgraded. The cost to you now is usually very low since they just take up space and you know how bean counters at big companies like to have all their beans lined up in a nice neat row :-)

Some fixed frequency monitors may be from Apple Macintosh computers as well.

It would be nice if all you needed was a cable to use one of these beauties on a PC. Unfortunately, there is often much more involved in making these freebie monitors conveniently usable on a PC under DOS, Windows, or Win95. Note that some of these comments - a la scan rates - may not apply to systems like Linux if scan rate switching is not required.

Note: just because a monitor has BNC connectors (or does not have a VGA/SVGA connector or cable) does not necessarily mean that it is a fixed frequency monitor and therefore a problem. Many top quality monitors only have BNC connectors and might be fully compatible with most video cards running PC/DOS/Windows. The only way to be sure is to obtain the detailed video, sync, and scan rate specifications.

---

## 4. Problems with fixed frequency monitors on PCs

While workstation monitors look like PC monitors - they have a CRT and a power cord, after all - there are generally significant differences that prevent these from being a 'drop in' solution.

The following are the principle difficulties in using a fixed frequency monitor on a PC:

- \* Scan rates. PCs particularly with DOS/Windows/Win95 may require a number of different resolutions and scan rates during any work or play session. Workstations use one scan rate and resolution at all times including during boot. That is why the monitors are called fixed frequency. The video source must match the parameters of the monitor within a few percent, not enough variance for typical PC applications.
- \* Sync. PC VGA and SVGA video cards generate separate horizontal and vertical sync signals. Some may be programmable to generate what is known as composite sync. Workstation monitors may require composite sync or sync-on-green (this will be explained later). They rarely use separate H and V sync like a PC. Many PC video cards can only provide separate syncs. Some workstation monitors are already set up for various sync schemes but not all.
- \* Video connectors. PCs nearly always have a miniature DB15 VGA/SVGA type connector. Workstation monitors may use separate BNC connectors (3, 4, or 5 depending on sync options), a 13W3 Sun style connector, or something

totally non-standard.

- \* Plug-and-play. The newest PCs and video cards expect to determine the capabilities of your monitor (to a greater or lesser extent) by either reading the monitor sense lines on the VGA connector or interrogating the ACCESS.bus. Neither of these will be present by default with a workstation monitor. The PC may come up in glorious black and white or refuse to operate in all modes.

---

## 5. Scan rate issues

A workstation runs at a fixed resolution and scan rate. All software is written to interface to the screen via a windowing system like X-Windows. PCs, on the other hand, must be able to drive a monitor at several quite different resolutions and scan rates:

- \* DOS - 640 x 400 default boot screen.
- \* DOS programs - 640 x 400 (EGA compatible), 640 x 480 (basic VGA), etc. (Note: CGA resolutions like 320x200 are emulated by modern video cards by running at 640x400 (for this example) and replicating pixels and lines.)
- \* Windows/Win95 - 640x480, 800x600, 1024x768, 1280x1024, 1600x1200 etc. depending on your hardware and software. Normally, the highest resolution that the video card/monitor combination supports with good quality will be used most often. Some options like a larger desktop than the physical display with dynamic resolution switching require multiple scan rates, however.

Therefore, a fixed frequency monitor driven from a typical video card (e.g., ATI GPT) has a problem. For a typical workstation monitor with a resolution of 1280x1024 operating at 78 KHz horizontal scan rate and 72 Hz vertical scan rate (fixed frequency), you only have one option - and that precludes the display of the DOS boot messages or running DOS applications or games.

Note: for the remainder of this document, I use the term 'Windows' to refer to MS Windows 3.1, WFWG 3.11, and Win95 interchangeably.

If all you run is Windows - never any DOS games or other applications that require you to suspend to a full screen DOS shell or run in native DOS mode - then you can always use a second VGA monitor for booting and then just switch over to the high resolution monitor once Windows comes up. Or, just assume your system **\*\*will\*\*** come up and forgo a display until the Windows desktop appears.

Unfortunately, there are a lot of DOS applications still used so this not a solution for everyone.

However, if you mostly use your PC for Autocad or Lotus, then this is a perfectly reasonable option if you have a suitable video card. (However, read on).

---

## 6. Sync options - separate, composite, sync-on-green, sync polarity

In order for the monitor to display a picture, it must know where the lines and frames begin. The synchronization signals - sync for short - are pulses sent for each line (horizontal sync) and each frame (vertical sync). There are 3 common schemes for doing this:

1. Separate horizontal and vertical sync signals. Individual wires are used for the H and V sync. This is the scheme that has been used for most PC video cards including MGA, EGA, VGA, and SVGA. It makes for easier hardware - particularly in the monitor.
2. Composite sync signal. The H and V syncs are logically combined (usually either OR or XOR) and sent on a single wire. This is used by Macintosh computers and Sun workstations, for example. Basically, it saves a wire.
3. Sync-on-green. The composite sync signal from (2) is combined with the green video signal (it actually goes on the bottom, from 0 to .3 V or so). The Red and Blue video signals usually do not have sync added to them but this is not always the case. Note that theoretically, (1) or (2) are best as there is no interaction between the digital sync signals and analog video signals but in practice, the difference is usually undetectable.

The users manual for your monitor will identify which options the monitor supports. OK, so you don't have a users manual:

For monitors with BNC connectors, it may be possible to determine capabilities by counting them:

- \* 3 BNCs - Sync-on-green only (Red, Green+Sync, Blue).
- \* 4 BNCs - Composite sync (R,G,B,CS) and possibly sync-on-green.
- \* 5 BNCs - Separate syncs (R,G,B,HS,VS) and possibly composite or sync-on-green as well.

Monitors with a 13W3 connector will generally accept composite sync though the other options may be possibilities as well.

Some video cards (like the ATI GUP, GPT, and others) can be programmed in their SETUP or INSTALL program (or possibly from a command line option) to generate composite sync on the H or V sync wire. These will then work (at least with respect to sync) with a monitor requiring either separate or composite syncs. A few high-end cards can generate sync-on-green as well.

Sync polarity (whether the pulses are negative or positive going) may be an issue depending on the design of the monitor. However, most suitable video cards can be programmed for either polarity.

Therefore, depending on your video card, the sync issue may be a non-issue.

Otherwise, an adapter will be needed. Unfortunately, this is not just a cable as circuitry is required to combine the signals. If you are electronically handy, it is a simple matter to construct a suitable circuit but if you are not, this may be a show-stopper unless you can locate a commercial product. Note that the term 'electronically handy' means a bit more than knowing how to read the resistor color code. The circuits are very simple. However, for the adapter to work well at the very high video bandwidths of the typical (1280x1024) display, you must use the proper 75 ohm coax and connectors, and assemble the circuitry itself in a shielded metal box, if possible. Otherwise, there could be degradation of the displayed video - ghosting, ringing, and less than optimal image sharpness. If you will be making a cable from scratch, there will be some precision (very tiny pins) crimping or soldering needed to construct the VGA and/or 13W3 (typically) connectors as well.

---

## 7. Connectors

Most common are BNCs - individual coax connectors for each signal - and 13W3 which combines 3 coax and 10 normal signal pins in a single shell. Except for some really strange custom connectors, adapters are available:

- \* VGA to 3, 4, or 5 BNC (might as well get the 5 BNC as the increased cost may not be that great and it is the most flexible should you come across another 'bargain').
  - \* VGA to 13W3. (e.g., Sun monitor).
  - \* VGA to MAC (regular DB15). (e.g., Macinstosh monitor).
- 

## 8. Plug-and-play

When your PC boots, it may interrogate the monitor to determine what its capabilities are. With BNC or 13W3 connectors, the needed signals are generally not present. Some manufacturers are addressing this by providing little widget boxes that plug in as part of an adapter cable to provide these signals but these are not common at the present time. Therefore, you may need to take steps in hardware or software to get around this deficiency.

---

## 9. Alternatives to the dumpster

Perhaps that deal-of-the-century doesn't sound so great at this point. Don't give up yet. There are several possibilities.

- \* High-end video cards with compatible scan rates. As noted above, for use with applications that run entirely in windows and/or at a single resolution and scan rate. A separate monitor (or no monitor in case you trust your setup) is used for booting.
- \* Special fixed frequency monitor video cards. These emulate VGA and SVGA video cards as far as the PC's software is concerned but drive the monitor at a fixed (high) resolution and scan rate even when booting (in most cases).

---

## 10. Then again, maybe it will work

Having been told by all the experts that his monitor was fixed frequency and a pain to use:

(From: Malik (psxplic@malik.eng.net)).

Against all odds i thought what the hell and tried it anyway... And hey, presto! it works perfectly, no problems.

I had to feed a vertical sync into the monitor which would not have been possible because the feed for this was not present on the plug. However it was possible to remove one of the unwanted wires in the RGB lead and reconnect it to the unused Vsync input.

It appears Sony just fit the appropriate lead/connectors to the monitor depending on its purpose then badge it for Sun, etc.

The model number is GDM 17E20 its absolutely a superb monitor... If you can get one I suggest you do.

I know there is a 17E10 and 17E11 that are older.... the situation maybe the same with these.

---

## 11. High-end video cards

If you already have an investment in a good video card (not a \$29 K-Mart special), then this may be a possibility.

- \* Advantages: you may already have one and it will be good for a PC compatible multiscan monitor in the future.
- \* Disadvantages: Not usable for booting and DOS applications. It may not be capable of generating composite sync or sync-on-green (if needed) without an adapter.
- \* Information sources:

The Fixed frequency monitor FAQ and Sync-on-green FAQ are available at:

<http://www.repairfaq.org/>

Some other sites with information and links relating to fixed frequency monitors:

<http://saturn.tlug.org/sunstuff/ffmonitor.html>

<http://rugmd0.chem.rug.nl/~everdij/hitachi.html>

<http://www.midcoast.com/jp/sun/2.html>

<http://www.devo.com/video/>

<http://www.sunhelp.com/>

The `Comp.sys.ibm.pc.hardware.video` FAQ is available at:

<http://www.heartlab.rri.uwo.ca/videofaq.html>

The FAQ has received `news.answers` approval, so it should be archived at `rtfm.mit.edu` and all mirrors, as well as in `news.answers` and `comp.answers`.

- \* The following company sells various inexpensive fixed frequency monitors and video cards. I have not dealt with them so I have no idea of their quality or customer service.

---

## 12. Fixed frequency monitor cards

These are special video cards. You remove and mothball your current video card (if you already have one) and replace it with one of these. You then install the special video drivers (where required) supplied with the card.

Some models appear to be quite competitive in terms of graphics performance (Windows accelerated, etc.) so these may represent an attractive alternative even for high performance applications like Autocad.

After specifying the monitor type and/or scan rate parameters for your monitor, the behavior of the card should be essentially transparent to your software. That is, programs think they are talking to a VGA/SVGA card but

the output of the card drives your fixed frequency workstation monitor properly at all times - including booting, DOS games, Windows, etc.

- \* Advantages: full DOS/Windows, possibly high performance (some models claim Windows accelerated video performance), drop-in solution (no adapters, circuits, cables, etc.).
- \* Disadvantages: cost if you already have an expensive video card, possible lack of wide or long term support (these are not exactly Fortune-500 companies).
- \* Information: Mirage and Photon appear to be the most well known of the companies providing fixed frequency video cards. However, the FAQ lists several others as well. The order of these entries is somewhat arbitrary and may change without prior notice :-). In other words, it doesn't represent any sort of recommendation.

## 14. Check and dirty way to display lower resolutions on fixed frequency monitor

(From: Karl Ivar Dahl (karld@asgard.ifi.uio.no)).

I have a SONY GDM 1961 (a.k.a. VRT 19-HA) fixed frequency (sync-on-green) monitor. This monitor displays 1280x1024, but I have recently been able to tweak it to display 1024x768, 800x600, and 640x480!

So now I can play Quake full screen under NT and Linux :-)

The clue is to reduce the visible resolution and add the missing pixels to the front and back porch. The image of course doesn't fill the entire screen, but it's a *lot* better than having none at all.

I have made a page with my experiences with making a fixed-sync monitor work on linux, NT and win95 to help others with access to these extraordinarily cheap and large workstation monitors:

\* <http://www.geocities.com/SiliconValley/Foothills/4467/fixedsync.html>

---

## 15. Steve's experience with a special video card

As noted below, this is an experience with one particular video card - I don't even know which one or how old it was. Thus, these comments should only be used as an indication of what kinds of questions to ask when selecting a card and the possible problems you may encounter.

(From: Steven Leinwand (steve\_leinwand@hp.com)).

It is true that the most expensive solution (a special video card) is usually the best solution. I bought one a while back, and in the interest of 'truth in advertising' let me describe some of the drawbacks you will experience. In all fairness, I will mention that I haven't tried all the video boards out there, and am basing my comments entirely on my experience. Your mileage may vary.

Fixed frequency monitors like those commonly supplied with Sun workstations cannot change video modes like multiscan monitors. In order to get them to work in DOS modes, video card vendors like Mirage and Photon modify the VGA bios on their cards to 'emulate' \*some\* DOS modes at a fixed scan frequency. This works well in \*some\* modes, works poorly in others, and doesn't work at all in some.

These BIOS mods interfered with motherboard timing on two VLB motherboards. I tested it with four video cards, the problem was the VGA BIOS). Video wouldn't sync after warm-booting. I had to shut the machine off, and wait about 10 minutes. In all fairness, I have not heard of similar problems on ISA and/or PCI cards, so that problem may be on that vendor's VLB boards only.

It usually works best in Windows, where the display is always in the same graphics mode, and mode switching isn't an issue. It works for \*some\* DOS programs, depending on what video mode they try to put the display in. It works poorest on games, which seem to insist on using weird and/or undocumented VGA video modes. At least half my games either wouldn't work, or their image was so small, as to negate any benefit of having a large monitor.

\*\* Modes less than the monitor resolution will usually be displayed at 1/2 the screen size of the monitor \*\*

This was a surprise to me, and was never mentioned in any of the ads for video boards. I've been told this is a fact of physics, and cannot be overcome in fixed frequency monitors. (Editor's note: it can be overcome using a scan converter but this is much more complex than a BIOS change! See the "[Notes on Video Conversion](#)" document for further information on scan converters.)

I finally sold both monitor and video card, bit the bullet, and bought a 17" SVGA monitor and card. If I didn't have the VGA BIOS timing problems with the VLB version, I might have been able to re-use the video card, but was tired of the hassle. Since I got the monitor for free (obsolete product destined for the dumpster), it wasn't that bad. My advice is ask detailed questions before you buy, get a money-back guarantee, and test with all your applications. If you can't live with the results, exercise your guarantee.

Also check out support capabilities. One of those vendors I mentioned was very responsive and helpful. The other one started out awful, but made some progress in responsiveness over time.

---

## 16. IBM6091 monitor information

(From: Richard Shima (RShima@att.net)).

The IBM (Sony?) display 6091-19 is a 5-BNC type, and is, indeed, a fixed frequency type. Therefore, you'll need certain special modes available in a display adapter to accommodate it, beside the correct cable, of course.

Take a look at the following site for some interesting info relating to 6091 modes and video cards:

<http://www.lysator.liu.se/~jonass/6091.html> (IBM6091 info)

Also, if you like, go to the following IBM Web site for specific monitor features & technical specs covering your 6091:

[http://www.nz.pc.ibm.com/support/a03e\\_1de2.html](http://www.nz.pc.ibm.com/support/a03e_1de2.html)

I'm pretty certain that IBM 6091 was actually made by Sony, and, in their better displays, they still use the 5-BNC (separate signal) video cable, i.e., on their current SE series, etc. I'm certain you could buy a Sony (or other) replacement cable that would do the job, tying your display to a PC-type 15-pin VGA/SVGA "D" video connector, once you know you have a video card that will support it.

---

## 17. Using IBM 6091 monitor on PC

(From: Wayne Rothermich (wayne@utilicom.com))

I had to learn what signals my IBM 6091 monitor wanted versus what signals my video card provided by experimenting with a scope and a pulse generator for a day or so. In my case, the monitor wanted inverted polarity on the horizontal sync line. I found that I could provide this by triggering a lab pulse generator from the video card's horizontal sync output, and using the resulting (inverted) pulse to sync the monitor. Fortunately, the timing jitter in the pulse generator was low enough that no horizontal jitter was noticeable on the display.

I used the monitor this (rather nerdy) way for a while, and then I noticed a small ad in Nuts and Volts magazine for a moderate cost (\$200) translating video card made by a company called Ming. I ordered one, and it turned out to be a modified (new video BIOS chip, a few wire jumpers) Jaton 58P card, which uses the Tseng Labs ET6000 chip.

This has proven to be a good solution to my fixed frequency monitor problem.

I ran comparative benchmarks using the Landmark PCPRO test program, and the speed of this card - when writing to video RAM - is similar to other high performance (Matrox Millenium 2, Diamond Stealth 3D 2000), cards I have tested recently. Ming makes cards for several different fixed frequency monitors, so they could be a viable choice for many of your readers. You can check their web page at <http://www.riverside.quik.com/ming> for more details.

---

## 18. Modifying an IBM9517 XGA monitor for SVGA operation

(From Arnoud van der Wel (a.p.vanderwel@student.utwente.nl)).

Well, I did this to two of them about a year ago. Of course I wrote down what I did, so I'll try to reconstruct for you what I did.

There are two modifications, one is the H-FREQ control, the other is the H SHIFT VGA control.

To boot, you need it to display the standard 31.5 KHz VGA text mode.

Turning the H FREQ pot (on the rear edge of the PCB) will eventually give you a display, but it is off-screen to the right. You then adjust the H SHIFT VGA pot (on the right of the PCB) and find that this pot has insufficient range to center the display. The H FREQ pot is 4.7K from the factory. It is in series with an 18K SMD resistor on the solder side of the PCB. I found that I had to turn the 4.7K pot to max resistance to move the display to the left, so I removed the 18K resistor and the 4.7K pot, and replaced them with a 22K resistor and a 10K pot.

I was then able to center the display for text mode. The only problem is that the horizontal linearity in text mode is now off. The letters near the right of the screen are narrower than elsewhere. The problem is not serious (a casual observer does not see it) so I can live with that. Moreover, I never use text mode anyway (except during booting and for BIOS setup, etc.) The 320\*200 mode (games) also works correctly after this modification.

Now, we want it to sync to higher refresh rates, specifically, 1024\*768. That is the mode I adjusted it for. All the 1024\*768 parameters are separately adjustable from the ones for the other modes, except the H FREQ. The pots that govern this mode are all labeled "4,5", meaning, I presume, that they govern the operation of what the monitor manufacturer calls mode 4 and mode 5. I found these to coincide with H frequencies of over approximately 50 KHz.

I found that by tweaking the H freq, I could get the text mode to be all right, \*or\* the 1024 mode, but not both at the same time. (BTW, I run 1024 with a pixel clock of 77 MHz, H freq. of 57.63, and V freq. of 68.13 Hz. I don't know what the specs for this monitor are, so I thought it was prudent to stay on the low side.)

This solved monitor number one, and oddly enough, when I did monitor number two. I was able to get it working after installing only mod number one. A little help from the VGA card (Diamond Speedstar if I remember correctly) did the rest. So maybe you are in luck and need only one mod. A flexible VGA card definitely helps. (Or good setup-software for the VGA card.)

When you are turning all the little presets, be careful not to short the wipers to the chassis... use a plastic tool! The wipers are not insulated from the screwdriver slots. You can easily destroy some of the SMD transistors by doing that. That's what I did, and I had some VERY lucky guesswork in unsoldering them and replacing them by normal transistors (that is what I tend to do when I find a dead SMD transistor...)

These are beautiful monitors and well worth modifying. Fortunately, not a lot of people are able to do this, and this means that they are available rather cheaply. :)

---

## 19. SVGA to Sun/Sony GDM1960

(From: Flupke ut Warns (P.O.Langemeijer@student.utwente.nl)).

The most important thing is to get the sync pin(s) connected and the horizontal scan rate as close to the required value.

There is much more info and links at:

\* <http://www.geocities.com/SiliconValley/Foothills/4467/fixedsync.html>

---

## 20. SVGA to Sun fixed frequency monitor - complete solution

Here is a success story for the Sun 21" fixed frequency color monitor.

0. The only active part in the circuit is a 74HCT86 quad XOR chip. Only one XOR gate is used - to combine H and V sync. All the other signals are wired through to the monitor (using RG59, 75 ohm coax for each of the RGB videos.)

(From: Ken Jones (k.jones@coastlight.com)).

Disclaimer: I will not be responsible for any damage to your monitor or ego that might be caused by the use of this circuit.

I don't know if this works with all VGA Cards. I've tested this with my Matrox Millenium and Mystique VGA Card, and it worked well. But there is a tricky

part!!! For all those, who are trying this circuit with their Matrox Card, be sure to accomplish the following steps:

1. Buy all the needed hardware parts - 74HCT86 (TTL-XOR), 0.1uF Capacitor, Print, HF-Box - and assemble it. I use a small HF-Box, to eliminate interference problems. Be sure to make all wires as short as possible!
2. In Win95, go to the Display Properties:
  - \* Select MGA-Monitor Panel.
  - \* Choose a Monitor which can Display 1152x864. (Hitachi CM2111 for example)
  - \* Select this Monitor, and press 'Properties'.
  - \* Now select 1152x864x256 or 1152x864x65535 (as you like) and press 'Apply'.
  - \* Select the MGA-Settings Panel and increase the Display-Area to 1152x864 too. Press 'Apply' and reboot Win95.

Now, your Monitor could work. If not, (as it happened to me...) do the following:

3. Go to the Display-Properties again:
  - \* Select MGA-Monitor Panel.
  - \* There is a Button named 'TEST!'. (First it was grayed out). Press it. (What for?.. Well, read on)
  - \* A Monitor Test-Pattern should appear, nothing special, but there is a small Button, called 'DETAILS'. This is the key for all...
  - \* Press 'DETAILS' and a new form appears. Now you can choose Sync-Negotiation, Vertical, and Horizontal, Refresh-Rates, etc, etc... (AHA!)
  - \* Set all you need to get your Monitor running. (In my case i changed the horizontal-refresh-rate to 71kHz)

---

## 21. Sony GDM-1961 Fixed Frequency Monitor on PC

The site below documents in great detail the connection of the Sony GDM-1961 to a running Linux, Win3.1, and Win95. The information should be of use for other monitors as well.

\* <http://www.geocities.com/SiliconValley/Foothills/4467/fixedsync.html>

---

# 22. Sun 365-1335 or Sony GDM20E20 monitor on PC

(From: Anders Stenkvist (Anders.Stenkvist@uab.ericsson.se)).

I just wanted to share some info about a Sun monitor I recently acquired. It's one of the new 20" multisync monitors you get together with Ultras with part number 365-1335 or GDM 20E20 made by Sony. Searching the net told me it should be possible to connect it to my PC but gave no info on how. So, armed with a screwdriver, an soldering iron and a lot of curiosity a started to investigate my new monitor, and after some iterations I got the following "new" pinout of the 13W3 connector.

Analogue: 13W3 connector:

The monitor works with a PC driver from sony named "SONY multiscan 20se" and is able to do at least 1280x1024 @ 75Hz, that's at least what my video card is capable of.

Looking inside it I also found markings for one of the PC-monitor buses used for autoconfig but I have not bothered to get that to work. Any info on that would be appreciated but it does work nicely without it.

---

---

## Chapter 2) Introduction

Questions relating to various aspects of converting one video format (like PC SVGA) to another (like NTSC) are very common.

Most of the articles in this document have been compiled over the last two years based on replies from myself and others to postings on the USENET newsgroups comp.sys.ibm.pc.hardware.video and those of the sci.electronics hierarchy. I apologize if your response is not here - it could have been that I missed the posting and will welcome contributions.

As always, comments, suggestions, and corrections are welcome.

---

## Chapter 3) Conversion from TV to RGB

---

### 3.1) Viewing NTSC TV on a VGA/SVGA monitor

Depending on the monitor, you may need a lot of electronics. VGA uses a 31.47 KHz horizontal scanning frequency - twice NTSC.

1. If it is auto-scan and goes down to 15 KHz horizontal, then you need an NTSC to RGB converter. There are chips from companies like Sony, Signetics, and others that will do this without too much pain.
2. If it will not sync at 15.734 KHz, you will need a real time digital scan converter consisting of a video digitizer and a full frame buffer with suitably fast I/O, For the special case of basic VGA, a subset of this called a line doubler or scan doubler will get you a picture but it will

not be very good since it is not possible to achieve the correct type of interleaving of even and odd video fields. See the section: "[What is a scan doubler?](#)".

For PAL (625/50) the relevant resolution is closer to 800x600.

There are boards for your PC that will take NTSC/PAL and put it into a window.

What you may find in the end is that your \$150 TV gives you a better picture.

(The following from: Stan Rohrer )

For cards as well that take NTSC and put it into a window on your PO:

Check in the PC mail-order catalogs and your local PC parts outlets. There are a number of TV boards and frame grabber boards that do what you want. Prices start (I think) around \$150. Professional level conversion boxes soar above there somewhere.

I've just started investigating such devices. PC Zone (800-258-2088 for orders/catalog) and MicroWarehouse (800-367-7080) carry Computer Eyes and TelevEyes by Digital Vision. Prices here range from \$300 to \$600 with the highest reported to include genlock and overlay capability.

PC Zone has an AITech TV board for \$150. I don't know if it will take NTSC video input or not. One of the guys I work with just bought an (unknown brand) TV board that takes NTSC but he doesn't have it installed yet.

---

## 3.2) TV to fixed frequency monitor

The hardware needed to watch TV on a typical high resolution fixed frequency monitor would cost more than a nice large TV. In two words, forget it! In addition to decoding the NTSC/PAL to RGB, the scan rates are SO different that the only hope would be to build a full blown scan converter.

---

## 3.3) TV to MGA

"How hard would it be to make my amber Hercules monitor display the output from my VCR? the VCR has a RCA video output and a coaxial RF output and I want to use the monitor as an orange TV."

This is almost certainly not worth the effort as the monitor accepts TTL (2 bits) and can display at most 4 gray (well, amber) levels without extensive modifications. In addition, the scan rates differ substantially between NTSC or PAL and the Hercules standard. As noted below and elsewhere in this

document, a CGA monitor with a composite video input would be a better choice.

(From: Jerry Penner (jpenner@sentex.net)).

You want to connect a Herc Mono TTL monitor to a composite video signal? Can you say 'Big Waste of Time and Effort'? If you want a black and orange or black and green TV screen, connect your RCA video output on your VCR to the input of a composite CGA monitor. These monitors were used on Sanyo MBC computers, and early Apple clones as well as some XT's. Colour composite CGA monitors used to be used on C-64 and Vic-20 computers. Their usefulness as TV/game monitors is legendary, and you'll be lucky to find a used one for under CDN\$80.

---

## 3.4) TV to CGA

"I have a RGB CGA monitor and would like to use it to display a composite or S-video signal from a VCR. I was wondering if anyone knows how to accomplish this or knows of any economical products that will be able to do this. Any info on S-video pinouts would also be greatly appreciated."

Is it strictly CGA? If so, that is TTL and you can forget about displaying VCR S-video without extensive and not worth-it modifications. Some CGA monitors have composite inputs or analog RGB inputs. With analog RGB inputs, you need an NTSC to RGB converter. These can be built with a single chip and some discrete components. There are probably converter boxes available as well. If it accepts composite, then just use the normal video out from your VCR. S-video won't gain you anything unless the monitor has separate Y and C inputs as well.

I have a Magnavox CM8762-074T RGB Color Monitor which accepts both CGA TTL and NTSC color composite video inputs. Locating monitors of this type may be an alternative to video format conversion. These may be available for next to nothing as the owners have upgraded and are often not interested in (or aware of) their present utility. They are often of relatively high quality and display a very nice picture since their original intended resolution is similar to that of NTSC. I use the Magnavox CM8762-074T for testing of VCRs and other baseband video sources.

---

## Chapter 4) PC VGA/SVGA Conversion

Note: for the purposes of these discussion, the terms 'VGA' and 'SVGA' are used somewhat interchangeably. However, strictly speaking:

\* VGA refers to the basic original IBM VGA standard of 640 x 480 at 60 Hz.

\* SVGA refers to scan rates greater than and including the basic VGA rate.

---

## 4.1) VGA to TTL (MGA, CGA, EGA)

Both the signal format and scan rates are incompatible. Therefore, simple conversion between analog VGA/SVGA and any of the TTL formats - Mono, CGA, and EGA - is generally not realistically possible.

Some (mostly older high-end) monitors will accept multiple input types like VGA, EGA, and composite. Two examples are the Mitsubishi AUM1371/81 and the Tatung CM1495. These can select between VGA and EGA input and the Mitsubishi will also accept composite (NTSC) video.

---

## 4.2) VGA to CGA 1

For the general case of desiring to drive a true CGA-TTL monitor from a VGA card, there are three options:

1. Replace the monitor with a VGA monitor.
2. Replace the video card with a CGA card if you can find one.
3. Completely redesign the CGA monitor to accept the VGA scan rate and analog video input. Neither of these is easy or necessarily even possible and the resolution of the CRT may be inadequate in any case.

If the monitor accepts analog RGB, it may be possible to program your VGA card to put out the CGA (15.734 KHz) horizontal scan rate to be compatible with a CGA monitor of this type. Your hardware and software may or may not support this easily or at all.

If it's a true CGA monitor, there simply is no practical way to use it with a VGA card. Period. If it's one of the original multisyncs that happens to work with CGA, then there's some hope. However, these weren't so common: Sony 1302, Mitsubishi AUM1381 or Diamond Scan, plus a few others). In this case, you just need the proper cable and the appropriate switch settings for the monitor.

---

## 4.3) VGA to CGA 2

"We are trying to upgrade our print servers and have a lot of CGA monitors

and a lot of PS2 computers with VGA cards. We don't need more than 2 colors (mono) but when we make an adapter to connect the R to R, G to G, B to B, H to H, V to V, Ground to Ground and the rest NC we don't really get what is wanted.

Well, what happens is that the display is quite acceptable other than the fact that there are two of everything on the screen indicating timing problems. Covering the right side of the screen with a sheet of paper works to cure the problem but a more acceptable solution is needed.

Adjustments to the monitor frequency, width, phase, H-hold, etc. don't help."

This is not surprising as the horizontal scan rates for VGA and CGA differ by about a factor of two. This is much too large change for the monitor to accommodate.

Note that CGA outputs TTL level signals (0 to 3-5V) and VGA outputs analog levels (.7 V p-p). Therefore, what you have done may not work in any case if the monitor expects strictly a TTL input. However, your monitor must be compatible with the VGA levels.

The monitor would have to sync at double its normal scan rate for the picture to properly fill the screen. First, it would be difficult to modify the monitor for such a substantial change in horizontal scan rate. Second, and more importantly, any such change could compromise the safety - stressing the monitor's circuitry - increasing the risk of failure and the possible fire hazard. Therefore, I would not recommend even making the attempt unless you are quite knowledgeable in the design of monitor deflection circuits and power supplies.

One other option other than replacing the video card or the monitor would be to determine if your PC is capable of putting out CGA scan rate video. Many video cards do have this capability not so much for CGA as for NTSC/PAL compatibility. However, some programming or use of special video drivers (software) may be required.

Alternatively, you may be able to find an inexpensive card that would be able to provide the correct timing or even some old CGA cards that no one wants anymore. Also, monochrome video rates are 18.43 KHz. If you can find some MGA cards, you may be able to tweek the monitor that far.

Actually, for your intended application, painting over one half of the screen isn't such a bad idea. :-)

---

## 4.4) VGA to TTL

The following applies with minor changes (scan rates, number of bits) to MGA, CGA, EGA, and most other TTL video signal formats as well.

"I am trying to use an old Sony monitor, (PVM-1342Q), which only accepts a

CGA video signal through a 9 pin connector. My output is SVGA via a HD15 pin connector. Any suggestions on pin assignments or existing converters to do the job?"

Assuming the monitor is actually CGA, it is probably not worth it. CGA is TTL and SVGA is analog - you would need a converter and then only end up with CGA's 8 colors or whatever.

The scan rates differ by a significant factor. If you can program your VGA card for the monitor's horizontal scan rate (around 15.734 Hz - similar to NTSC in the case of CGA), then the remaining problem is converting from analog to TTL. This will require some high speed comparators and logic.

---

## 4.5) VGA to fixed frequency monitor (3, 4, or 5 BNC connectors)

Questions about this specific problem are among the most common as low cost fixed frequency monitors become available when their workstation hosts are decommissioned due to the march of progress.

You will have to obtain the specs to have any idea of whether what you want to do is possible. These are very often high resolution with a typical horizontal scan rate of 64 KHz.

There are several issues:

1. Video compatibility - here is the one area where you are likely fine - your monitor is probably compatible with VGA analog video levels - .7 V p-p.
2. Scan rate - your horizontal and vertical refresh rate. I would expect that the monitor is not auto-scan and probably not compatible with VGA or SVGA. Please check the specs if you have them or post a message so that someone else can identify it. You need to know its horizontal and vertical scan frequency range.

If it is fixed frequency, you will be able to use it only in your high resolution (probably) applications. Booting the PC will require a normal VGA monitor for the messages to be seen.

Assuming you are willing to use something else to boot and only run at a single resolution, then the last hurdle is sync:

3. Sync. You have 5, 4, or 3 BNC (coax) connectors on the back of the monitor.

\* 5 BNC connectors - this means that your likely have separate horizontal and vertical (H and V) sync inputs - just what your VGA card wants. In this case, as far as sync is concerned at least, all you need is a VGA-to-5 BNC cable.

- \* 4 BNC connectors - this means that your monitor requires composite sync. The H and V sync signals must be combined into one TTL level signal. Some cards like those from ATI will probably drive it with just a VGA to 4 BNC cable since they can be programmed to generate composite sync with no additional hardware. (Actually, get a VGA to 5 BNC - you just won't use one of the syncs and this may come in handy at a later time).

You need to determine what its expected H and V rates are to see if they fall within the range of the video card. Some internal twiddling may be possible depending on the monitor. Also, the software size adjustment in the ATI Install program also affect rates so that adds another couple of degrees of freedom.

If you need to combine the H and V sync, a TTL gate, single transistor circuit, or sometimes just a couple of resistors will do it.

For example, if you are able to program your video card for negative sync polarity, then an AND gate (which will act as an OR for negative logic) should do it. For positive sync polarity, a NOR gate or NPN transistor will work. It is also possible to build an auto-polarity switching circuit to accommodate any combination of positive and negative sync polarities. In some cases, just using a resistor in series with each sync line will be enough.

- \* 3 BNC Connectors - these monitors need what is known as 'sync-on-green'. This will require some circuitry to combine the H+V+video into one signal. The circuitry is quite simple if you are electronically handy. Commercial boxes to do this are also available.

(From: Exar (exar@aol.com)).

For any type of video converters call ALTINEX,INC. in California 714-524-5400 they make a device that will combine sync, separate sync, put it on Green, shift image left or right. Product name is DA1910SX. I have several of them for my PC, MAC SGI and SUN.

See the documents: "Fixed Frequency Monitor FAQ" and "Sync-On-Green PC Video FAQ" for details.

Some monitors have the required circuitry to accept separate sync internally that is not brought out for a particular model. In this case, some careful exploration may reveal hidden treasures.

So, check your scan rate. If that is not compatible, then you will need a new display board anyway. If it is compatible, then you will just need the sync combiner. Then there is the problem of booting DOS or Windows - these usually want 640x400 at boot.

There are video cards designed for just this purpose. Whether the investment is worth it compared with a new PC compatible monitor is questionable IMO.

See the document: "Notes on Approaches to Using Fixed Frequency Monitors on PCs" for additional information and names of companies who manufacture the special video adapters.

---

## 4.6) VGA to Apple RGB

"Is there any way to modify an Apple 12-inch RGB color monitor so that it can display 640x480 (instead of 512x384)?

Has anyone ever managed to do this? Any opinions on whether or not it is possible?"

I assume you want VGA resolution - 31.4 KHz horizontal.

This would require changing the horizontal scan rate by a large amount and is unlikely to be easily accomplished without extensive modifications to the monitor's circuitry. This should not even be attempted unless you are knowledgeable in the design of monitor deflection circuits and power supplies.

For other Apple (MacIntosh) monitors, see the section: "[VGA to fixed frequency monitor \(3, 4, or 5 BNC connectors\)](#)" as most of these run at a fixed frequency. For example, the Mac II rate is 35.0 KHz H and 66.67 Hz V.

---

## 4.7) VGA monitor on Sun Sparc

(From: jnz@southwind.net).

Most any multisync "VGA" style monitor will work with the GX, TX or CG3/CG6 frame buffers on a Sun Sparc. Commercial 13W3 cables and adapters are available or you could get the instructions from a couple of places on the net.

I use my ViewSonic 17s on both Macs and Suns.

You should have a copy of Birdsall's Sun FAQ and you may wish to join the Suns-at-Home mail list, for all Sun self-maintainers. Use a search engine for these and they should vector you to the cable pinouts as well.

---

## 4.8) VGA to Sun/Sony GDM1960

(From: Flupke ut Warns (P.O.Langemeijer@student.utwente.nl)).

The most important thing is to get the sync pin(s) connected and the horizontal scan rate as close to the required value.

There is much more info and links at:

\* <http://www.ifi.uio.no/~karld/fixedsync.html>

---

## 4.9) VGA to composite video

Realize that no matter what you do, the quality you get on the TV/VCR is not going to be anywhere near what you see on the computer screen. You must keep this in mind when designing layouts, selecting text fonts and font sizes, etc. The new video cards with on-board NTSC/PAL output should be better than your average cheap converter but don't expect miracles.

"I need a bit of advice on converting VGA or SVGA to output suitable for a color composite monitor and/or a regular NTSC standard television. I have seen add on cards or outboard boxes that will convert VGA to standard TV but I am not sure if this will have the same effect on a Color Composite Monitor. You see I am wondering if it would be more cost effective to keep my old Apple Color Composite Monitor and buy the necessary hardware to convert VGA output from my IBM clone or to just go ahead and buy a bottom end 14" VGA monitor? Can I even get true 24 bit 800 x 600 color performance out of a TV or a color composite monitor?"

A color composite monitor may be somewhat better than a good TV but it is still limited by the NTSC standard - mainly horizontal resolution but color rendition as well. There is no way to get even basic VGA performance (640 x 480) from a TV or composite monitor.

You are much better off getting a bottom-end SVGA monitor for your PC. As noted, the resolution of a TV or composite monitor is not even good enough to do justice to VGA (640x480) when using the composite video input. Direct RGB can be better but the pitch of the CRT relatively coarse dot or slot mask or aperture grill is then likely to be the limiting factor. A composite monitor or TV will give you approximately 480-490 lines vertically but 10 to 15 percent of these may be hidden by the CRT bezel due to overscan. However, horizontal resolution is much worse. You will be lucky to get half the VGA resolution (300 to 350 lines). For SVGA, there is simply no way to display 800 x 600 without expensive scan conversion on such a tube and you will not be able to read text or display clear graphics. In addition, since the composite monitor or TV is interlaced, there will be annoying flicker of graphics with thin horizontal lines.

Save your pennies - prices for basic monitors are dropping. Your Apple monitor may work fine on your VCR, however.

---

## 4.10) VGA to grayscale composite monitor

This will only work if you can program the video card to produce a compatible resolution and scan rate.

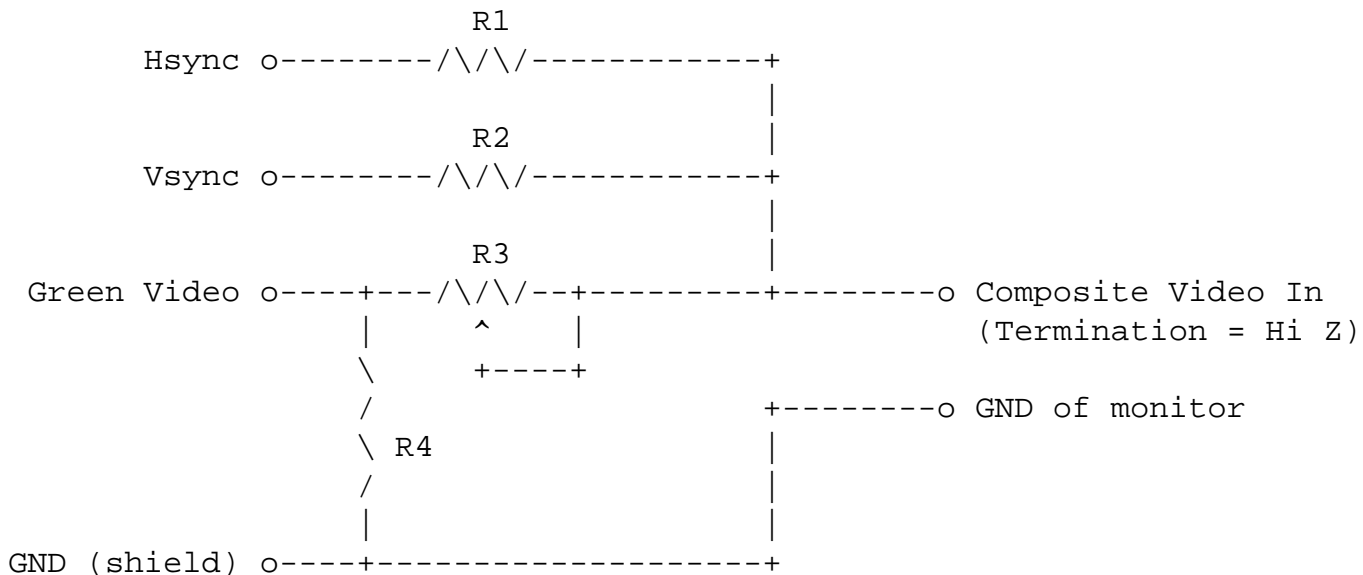

If you would like to experiment, here is a really simple circuit that may work well enough for combining Hsync, Vsync, and one of the VGA color signals, say green, into a composite video.

If the monitor sense lines on the VGA connector are tied MS1 (pin 12) = GND, MS0 (pin 11) = no connect, then some programs will default to monochrome and use a reasonable color map. I don't know how you will get a reasonable mapping to monochrome for the others.

All you will need are 4 resistors.

I am calling your connector on the monitor 'Composite Video In'.

- \* Hsync through 500-1K ohm (R1) to Composite Video In.
- \* Vsync through 500-1K ohm (R2) to Composite Video In.
- \* Green Video through 200 ohm (R3 - variable) to Composite Video In.
- \* Green Video side of R3 to Ground through an 82 ohm (R4) resistor.
- \* Tie this ground to the BNC or RCA connector ground.

It is essential that all this be built as close to the monitor as possible for best signal quality.

Set monitor video termination for Hi-Z. R4 provides the cable termination to minimize reflections and ghosting of the green video signal.

Set your video card for negative sync polarity.

You may need to tweak these values for best results. This will depend on your actual signals. The variable R3 may provide enough range for this.

## 4.11) VGA to NTSC or PAL

"I am interested in converting a signal from my video card to a signal that can be taken into the video in on my vcr. I realize that it is not going to be easy. Still I would appreciate how to do it."

You are correct - this is not easy.

1. You need to convert RGB to NTSC or PAL - there are single chips for this. Try Sony, Philips, Motorola, and others. These will combine the R, G, B, Hsync, and Vsync into a single composite video signal using a minimum of additional components. The same part can usually do either NTSC or PAL by changing a jumper and possibly some of the external components.

For example:

(From: Brian B

"In the July 1996 issue of Electronics Now, a MC1377P (Motorola) is used to convert RGB to NTSC/PAL. The chip can be purchased through the Newark catalog. This chip is very easy to use and should make your circuit simple."

Some other possibilities may be: ADV7175/ADV7176, UPC1352 (ECG/NTE1416).

2. You need to match the horizontal scan rate to NTSC (15.734 KHz) or PAL (15.625 KHz). Even basic VGA is roughly twice this - 31.4 KHz. If your video card can be programmed to put out interlaced NTSC or PAL rate video then this is easy. If not, it is more difficult. If you want to use any higher resolution than basic VGA (640x480) for a 60 Hz system or 800x600 for a 50 Hz system, it is a very non-trivial problem requiring a scan converter which includes a video A-D, full frame store, interpolator, readout timing, and video D-A. Unless you are an experienced digital and analog designer, you really really do not want to tackle this.

For the special case of VGA to NTSC or PAL, you may be able to get away with something less than a full blown scan converter. See the section: "[What is a scan divider?](#)".

You can also buy little boxes to do this. Quality is general not great as you are seriously limited by NTSC/PAL and the VCR.

(From: Tomi Holger Engdahl (then@neppari.cs.hut.fi)).

There is all sorts of information relevant to video at:

<http://www.hut.fi/~then/electronics/video.html>

There is collection of links to RGB to NTSC/PAL converter and other video chips at:

<http://www.hut.fi/~then/electronics/video.html#chips>

For more detail on this, check my circuit and related software at

<http://www.hut.fi/~then/circuits/vga2tv/>

Probably the most complete VGA to TV conversion pages in the web can be found at:

<http://www.hut.fi/Misc/Electronics/circuits/vga2tv/index.html>.

There you can find schematics, drivers, tips, ideas, documents, links to commercial products and much more. It does not have everything you need but it is a good start. Going to composite video or RF is more complicated as there are three composite video standard NTSC, PAL and SECAM in use in the world and there are also some small differences in modifications of those used in different countries) which is the reason why there are not much of this kind of project. VGA to TV conversion is not simple technology either (the circuit can be simple but there are quite many things to consider when designing such circuit).

Homebuilt circuit persons should take a look at:

<http://www.hut.fi/Misc/Electronics/circuits/vga2tv/index.html>

There you can find my design of VGA to TV converter which outputs RGBS signals suitable for TV SCART RGB input (I have also designed one with composite video output, but that's for a commercial application). At the same page you can find a PAL composite video output version of the circuit designed by Paulo Coelho.

For introduction to scan conversion, check

<http://www.extron.com/>

Specifically:

<http://www.extron.com/product/scanconv.html>

Flickering is a problems always when yu do graphics to TV systems. The graphics material must be designed so that flicker is not noticeable or the scan converter box must include some kind of filtering to do the job.

NTSC/PAL system limit the bandwidth which makes picture to loose some details. The picture is usually even worse than that, because of the cheap video encoding chips used in many converters.

(From: Bill Sloman (sloman@sci.kun.nl)).

Try the Analog Devices AD721 and AD722. When I used the AD720, I had to add a National Semiconductor LM1881 sync separator, and black-level clamps on the red, green and blue inputs to get the right DC levels.

Check them out at <http://www.analog.com>

(From: Leon Heller (leon@lfheller.demon.co.uk)).

Raytheon has a chip which produces broadcast quality PAL/NTSC from VGA.

I think that Harris does one, as well.

---

## 4.12) VGA to TV (NTSC) converter boxes, adapters, and boards

(From: Kevin Centanni (kpc@panix.com)).

There are a couple of VGA-to-TV converter boxes that also output an NTSC RGB signal. I own one from UMAX - I think it's called the TV-Mini. I bought it from Global Computer Supplies for about \$175. I also think that MicroWarehouse sells this product. There's a model sold by AVer also that has RGB out... but it's over \$300.

The UMAX TV-Mini is a small box that plugs into your VGA card... it also has a female VGA connector on it so you can display images on your computer monitor and television monitor at the same time. The TV-Mini is powered by the PC's keyboard connector. It has an RCA jack for composite NTSC, an S-Video jack for s-video output and a Mini-8-DIN for RGB output... if you go to UMAX's web page, they'll talk about how the TV-Mini comes with an RGB SCART cable (SCART is a strange looking connector that's used on many European televisions) - but it doesn't come with this cable.

I was able to build a small adapter cable with some parts from Digi-Key. The TV-Mini manual provides the Mini-9-DIN pinouts.

(From: Jerry G. (jerryg@total.net)).

I have played around with a few. The ones in the upper \$300 to \$400 are not too bad. You will get a reasonable picture. I found the cheap ones are extremely poor.

The best way to do it is with a video display card that has it built in. These cards are expensive because the scan rate must be changed. There is a lot of high speed ram and processing involved to do it right.

It is not a question of movement involved. It is a question of scan rate conversion that makes things complex. With this conversion there is the requirement of some complex quantizing to also convert the characters to match as well. In a lower priced card that I have seen good results is the ATI card with the NTSC output. I don't know the price of the card, but it is not cheap...! There is a Targa card that is excellent, but the price is too high unless you are in the business... But like I said, the higher the price, I found the pictures get better.

Also, the bandwidth for the fonts, and data coming through the conversion is extremely wide. It is wider than off of a conventional TV broadcast, or what comes out of a VCR. The TV set that you use must have a Video Component

input, and be able to handle at least 600 lines resolution or better. If not, you will be cutting the performance of the signal right at the end! If your TV has S-VHS capability, get the card with that option. It is better than using encoded NTSC or PAL. The S-VHS mode keeps the color information separate for processing. This allows for a better signal to noise in the luminance signal, thus rendering cleaner pictures.

Please note, that you will never get the same picture out of a TV video monitor as your computer monitor. They are based on very different processing and CRT design. There are VGA Monitor projectors on the market, and I would consider renting one for the casual use. It will certainly do a much better job. This is what I recommend and do for my clients. Don't even think about buying such a projector unless you have a lot of use for it. They are extremely expensive, and require periodic maintenance.

(From: E. Abel (EugeneA1@worldnet.att.net)).

I've used an ATI 3D Expression+ PC2TV. The S-Video output is not bad, although text is really not very crisp.

Surprisingly, the TV output from the Canopus Pure 3D card is much better. Text is actually readable. (this is on a 27" Sony trinitron TV.) The Canopus card uses a Chrontel chip to do the conversion.

Of course, at \$190 the card is a little pricy.

---

## 4.13) Questions and answers on VGA to NTSC considerations

This dialog resulted from the desire to construct a VGA to NTSC converter to output PC video to a TV or VCR.

"I managed to construct a VGA to RGB converter so far, so I'm almost halfway there, all I believe I need now is an RGB to NTSC converter circuit, although i was trying to avoid the cost of buying one they sell in the PC catalogs."

Can you program your video card to output 15,734 Hz H interlaced scan? If so, you will have a lot less hassle.

"I figure the odds are in my favor by creating one myself, and as far as I know, no harm could come to my computer by attempting it since the VGA/RGB is and output only and not and I/O. Now since I already managed to convert my VGA to RGB, hopefully you might be able to answer some specific questions for me?"

"1. Is there a minimum & maximum resolution for a TV , or does that depend on the size of the TV?"

If you mean resolvable spots on the TV screen, realistically, it is about half VGA horizontally and perhaps a little more than half vertically or about 320x300 give or take.

If you mean scan lines, that is pretty much fixed at 525 total interlaced 2:1 at 60/30 Hz (625 at 50/25 Hz for PAL 50 Hz systems) with about 420 (540) actually visible on a typical TV. TV's are not auto-scan - they are designed to run at a single scan rate.

Therefore, even displaying easily viewable VGA resolution will be tough. A TV with an S-video input may do somewhat better.

(Remember when you had at most 40 characters across on a Commodore?)

"2. Assuming the construction of this circuit would only allow a maximum output from my VGA card, what resolution would that be? 640x480 or 800x600 (I have no expectations of anything higher)"

As noted, for a regular TV, you can send it 640x480 but it will be somewhat fussy. 800x600 is really out of the question. A high quality TV-monitor might do VGA ok. The actual number of lines on a TV is, of course, only about 480 active with perhaps only 420 visible due to the CRT bezel. Unlike an auto-scan monitor, you don't get easy control of this and no control of the number of lines.

"3. Finally, taking into consideration the limitations of such a device, I only intend for this to be used for full motion video playback, as my current video capture card, as well as all other cards currently on the market, lack the ability to output the video back to the original source (i.e. a VCR or camcorder).

Unfortunately, even expensive solutions are still limited by NTSC. However, since your playback is often at reduced resolution (e.g., MPEG) to begin with, this may be acceptable.

(From: FoulDragon (fouldragon@aol.com)).

I'll warn you: You can get a box that will make your PC display on a TV, but it will not be worth your while. We use them at our school, they cost from US \$100 and up, and the picture, even on a good TV is very poor. If you can afford one of those boxes, buy a used VGA [even monochrome] and use that as you will be much happier.

(From: Terry Lin (tlin@servtech.com)).

I find that with the ATI PC2TV, on a S-Video hookup on a Sony XBR, the image quality is pretty decent. The flicker removal makes even a full white screen easy to look at (provided you have the contrast turned down, which should be done on every set). I have seen what poor external boxes can do, they give me headaches with the flicker and blurriness. Just make sure your setup is right before evaluating the entire PC to TV monitor thing.

---

## 4.14) Notes on VGA to RGB conversion

(From: Jon Jenkins (jenkinsj@ozy.dec.com)).

I use standard 74HC 14pin DIP gates available from any electronics store. I use a 14 pin DIP socket originally so that I could change gate types (OR/XOR/AND) easily. 74HC86 (XOR) works just great with the VR320 (I am using it now can also use OR, don't understand why ??).

The VN10KM is a small signal N channel enhancement mode MOSFET also available from most electronics store.

If the video card you are using is a standard VGA output (I'm using a diamond stealth 64 VRAM):

Pin 1: Red video  
Pin 2: Green video  
Pin 3: Blue video  
Pin 4: Monitor ID bit 2  
Pin 5: Ground  
Pin 6: Red return  
Pin 7: Green return  
Pin 8: Blue return  
Pin 9: NC  
Pin 10: Sync return  
Pin 11: Monitor ID bit 0  
Pin 12: Monitor Id bit 1  
Pin 13: H sync  
Pin 14: V sync  
Pin 15: NC

I join all the "returns" together with the ground on the small PCB and use that as a common ground for the RGB cable to the monitor. You can use separate if you want to but you should join the green return and sync returns together. I did find some small shadowing if I didn't group them all together.

Just a note, when you set up your video card in Windows (or Win95) set it to 1280x1024x72|66 or whatever is closest. I use a VR260 (1024x864) at 1027x768@66Hz (check with your manual DA or D4 are 72Hz) your VGA will not like this frequency so either disconnect it quickly or before you actually set the video card to this mode (i.e. put the OK as the active control in Windows and then connect the VR320 and hit return) My diamond setup gives me 10 seconds to do this adjustment When you exit you will probably have to select the 1280x1024 mode with your old VGA connected again and from then on every time you start Windows you will be able to view it in "big" colour mode. Note the vr320 will not work in DOS mode as it is not an auto-scan monitor so all you see when you boot up is garbage until Windows starts, I put "win" in my autoexec.bat file.

Note there is a danger here: I had set up the monitor and for some reason it did not work so I couldn't see what was going on: my old VGA wouldn't work and the VR wouldn't work either so I had to find the cards .ini files and edit by hand to get back to usable video!!

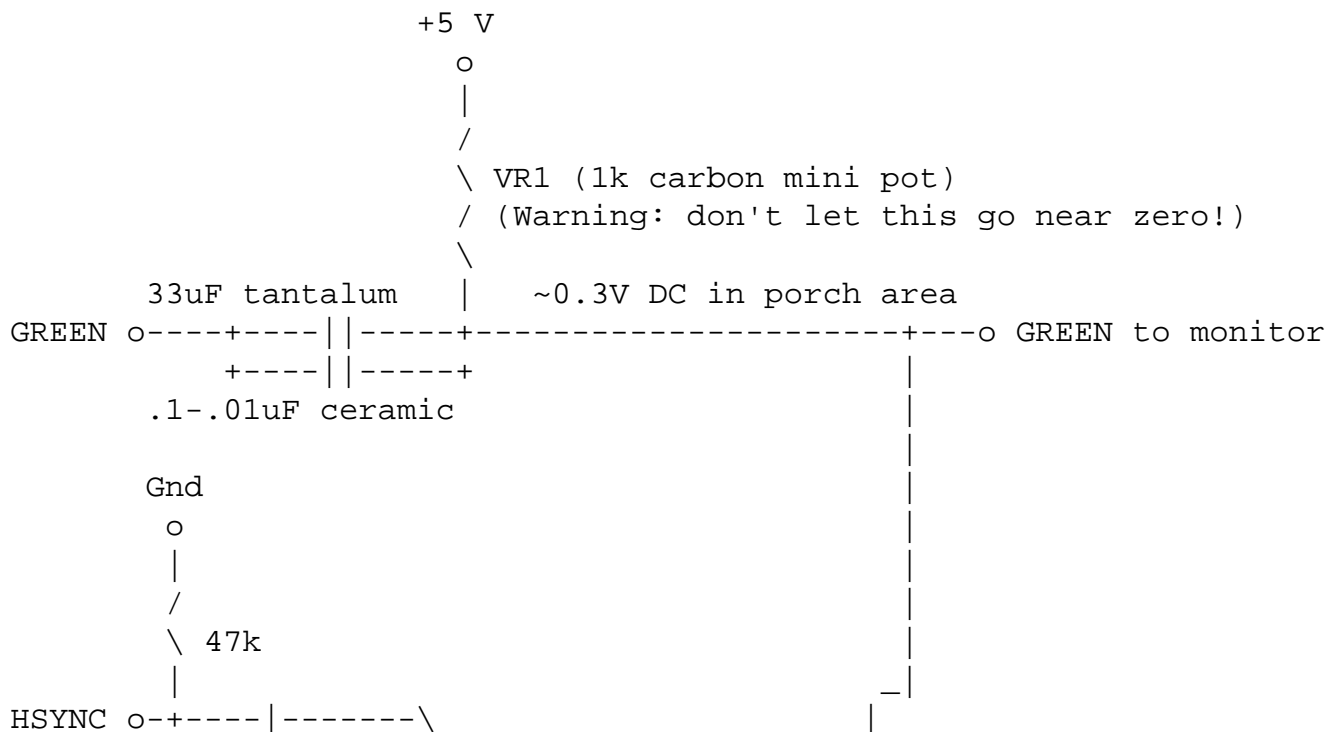

For FreeBSD/XF86 the lines are:

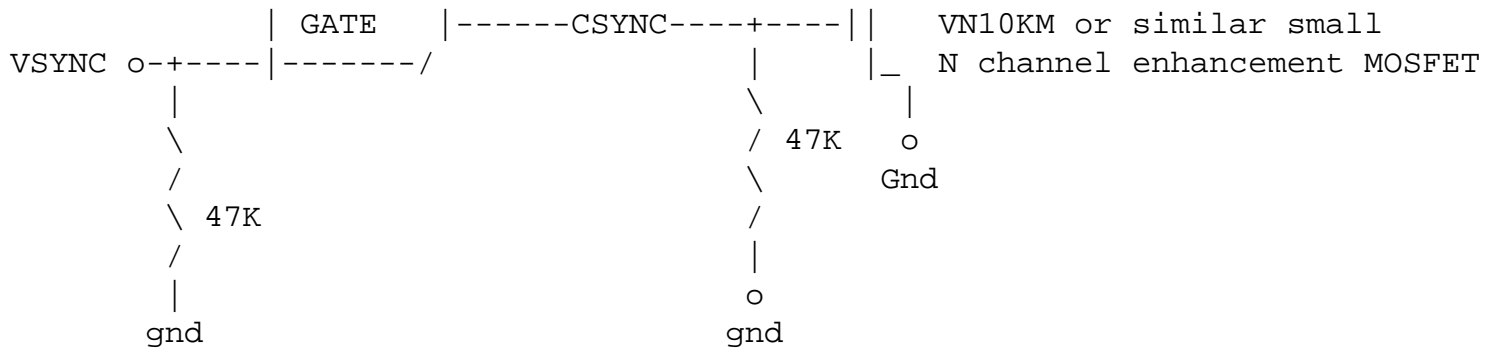

```
#VR260 monitor is 70MHz 1024x864
#VR320/319 monitor is 130MHz 1280x1024
Modeline
  "1280x1024" 130.81 1280 1312 1472 1696 1024 1027 1030 1063 +hsync +vsync
Modeline
  "1024x864" 69.2 1024 1040 1168 1272 864 864 867 904 +hsync +vsync
```

The circuit to do this is as follows:

Notes:

1. You may be dealing with 135MHz square waves so there are lots of high frequency stuff around; use good RF practices.
2. The coupling capacitors are a safeguard to start with. I don't use them because they caused shadowing around sharp colour changes (the old RC effect).
3. Use the XOR gate first as a test but you may need other gates to actually get it working.
4. An oscilloscope will be handy for final adjustment.
5. Make the device is as close as possible to the video outlet on the VGA card.
6. Take the 5V from the PC power supply inside the box. I just hooked one of the spare connectors which I also use for an external fan (Pentiums being the heaters they are!). Make sure (check it again!!) (and again!!!) you don't get the 12V one!!
7. You must use a VN10KM or other small signal N-channel enhancement mode MOSFET. Others will not work!!

HSYNC, VSYNC and CSYNC are grounded with 47k carbon resistors

Gate type=LS or HC types, HC preferred:

- \* OR: for -ve logic sync and no hsync during vsync.
- \* NAND: for +ve logic sync and no hsync during vsync.
- \* XOR: for -ve or +ve logic sync and hsync during vsync.

Capacitors are optional, I don't use them.

Use XOR gate with DEC monitors and as a first shot with others, then OR gate then NAND gate.

Get an oscilloscope and adjust porch levels to 0.3V and 0 level (sync level) to 0.0V

## 4.15) TTL to VGA/analog

This requires matching the scan rates and implementing a suitable digital to analog converter to take the TTL data and produce analog signals.

A scan converter can be used on the analog signals once they are generated to adapt the video to your monitor. However, I don't know if scan converters with suitable input and/or output capabilities exist.

The digital to analog conversion can be done with a few resistors if you are not terribly fussy about the quality. For example, the following circuit should be able to generate a reasonable VGA signal from a 2 bit input (e.g., MGA or one of the EGA color channels):

Ground o-----+-----o Monitor Ground

This assumes the H and V sync are separate signals. If this is not the case, these will need to be combined into this signal (at least one of the channels) as well.

I have not tested this circuit. Using low value pullups on the TTL signals (say 220 ohms) should help improve the high level consistency.

---

## 4.16) VGA to Amiga 1024

From: jcaldwel@iquest.net (Mr. Caldwell)

It is a CGA frequency only monitor. It has an 8 pin analog jack on the back and may have a 5 pin ttl jack and ttl to analog converter inside for standard CGA, you can use a cable for the analog plug to a 9 pin d plug for MCGA and get 320 x 200 by 16 Million colors. Some IBM cards will put out the correct frequency and analog signal, most won't. I used an ATI Wonder VGA card that would work correctly \*if\* manually configured.

Otherwise you need a VGA to NTSC converter. See the section: "[VGA to NTSC or PAL](#)" for more information.

---

## 4.17) VGA to NTSC/PAL chip

"I am trying to build a circuit to convert the RGB output of a video game to my large screen TV.

(From: Leon Heller (Leon@lfheller.demon.co.uk)).

If the game outputs VGA, Raytheon has a chip, the TMC2360, which converts it to broadcast quality PAL/NTSC video.

---

## 4.18) VGA to Mac (monitor) conversion

I have no idea of what this gadget actually does but it may be worth checking out:

(From: James Willcox (jwillcox@spitfire.net)).

Boca makes an adapter. I have one and it works fine. It has little switches on it to select resolution and refresh rate.

---

## Chapter 5) TV to PC VGA/SVGA

---

### 5.1) NTSC to CGA

"Does anyone know how to convert a video out signal into a signal usable by a CGA monitor (RGB + H and V sync)?"

If your CGA monitor is TTL, then it may not be possible, at least not without modifications to the monitor. You need to convert from NTSC to RGB. There are single chips (with a few external components) solutions to this. Try Sony, Philips/Signetix, and Analog Devices (I think) as well as others. These take NTSC (or PAL) and output RGB and sync. CGA is not analog (continuous range of video values). It is TTL with Red, Green, and Blue signals as well as a separate Intensity signal. Unless your CGA monitor can take analog video (.7 V p-p) inputs, you will still only be able to get 8 or 16 colors - not a normal TV picture. (And even for that, you will need external circuitry to convert the analog output of the decoder chip to TTL.)

However, some CGA monitors have internal NTSC composite inputs and in that case, it is simply a matter of flipping the appropriate switch.

---

### 5.2) Composite video (NTSC/PAL) to RGB

Several companies provide single chip solutions requiring only the addition of a few discrete components to convert NTSC or PAL to RGB and H+V or C sync. Some have options for YIQ, S-Video, and other formats at the input or output in as well.

Check out the web sites or databooks of Sony, Philips, Brooktree, Motorola, Linear Technology, etc.

For example, Motorola offers the MC44011. The datasheet can be found at:  
<http://design-net.com/books/dl128/gifs/mc44011rev1f.1.gif>.

This part can be used without an external delay line (for PAL to RGB) but a delay is recommended. The chip also provides an A/D sampling clock output for video digitizing applications.

It is possible to search the Motorola site from for other parts or application notes from: <http://design-net.com/cgi-bin/dlsrch>.

(From: Jeremy Todd (bulb@cix.compulink.co.uk)).

Sony makes at least two PAL decoder chips - CXA1621S and V7021.

It looks like you'd need a separate sync stripper (LM1881 or EL4581CN)

Brooktree's Bt812KHF is a much fancier thing for video processing and multimedia stuff.

From RS(UK) both the Sony chips are 10UKP each for 1 off's. The Bt812KHF is 107UKP!!

(From: Sam).

Also, some questions are along the lines of the following:

"I looked at several chip manufacturers. Most have extensive documentation on their chips in PDF format. Again, most of the chips currently available convert Y/C to digital RGB, and have a lot of extra brightness/sharpness control built in. Too complex- the simplest chip I came across was 18 pins and still required two dozen external components."

(From: Eugene (eugenek@istar.ca)).

The answer is: MC44011 by Motorola, cost \$28(Can). It requires some sort of a micro to program it (PIC or the like will do).

There is no external critical components except for a 14.318MHz crystal (found on any PC motherboard).

About the old TV single-chip decoders. This is not true, I've been working with those things for 15 years, and in 70-80s the decoders were much more complicated than they are now (each decoder, actually, requires a delay line (sometimes more than one) and a bunch of various filters). Yes, you had one chip and half a dozen of coils, trim-caps to tune (that required some equipment and knowledge).

Sorry, the chip I suggest has 44pins :-( but little hassle :-)

---

## 5.3) Watching TV on a PC monitor - NTSC/PAL to VGA

"I'm wondering whether I could use my NEC Multisync as a TV. Long ago I had a Mitsubishi Colour Monitor which could also be directly connected to the videorecorder. Sure, I could use cards in my PC like "WIN/TV",

but then every time I want to look TV I have to switch on the PC as well.

Is there the possibility to convert a video to a VGA signal? My NEC has only a VGA input. Or: Are there any monitors available which have both inputs (like my old Mitsubishi)?"

"I have a VGA monitor That I want to use to watch TV. I want to be able to maybe build a box that will let me plug a vcr video out into the monitor. I do not want to spend tons of \$\$\$\$\$. Can anyone tell me if there is a way to do this??"

"I have a HI-FI VHS that is attached to my stereo. Therefore, my audio needs are well taken care of. I now need the video. I had to sell my TV a little while ago so I do not have a T.V. at this point. I have recently acquired a 20" monitor for my PC (DFI brand.) It has the RGB (red-green-blue) connectors on the back along with a Horizontal and Vertical cable connections. So I have a cable that plugs into my video board on my PC that turns into 5 connectors at the end that connects to the monitor."

"Does anyone have any information on viewing composite video on SVGA type monitors. I have a MAGNAVOX SVGA monitor and if possible I'd like to feed composite video from my VCR and Sony PSX and PANASONIC 3D0 to it. Rather than getting a Toshiba TIMM monitor there has to be some kind of blackbox that will allow someone to do this...Please send info to the address provided or post here."

It depends on your monitor:

1. The monitor needs to support the NTSC scan rate - 15,734 H, 60 V. Some NECs do (like the 3D) but others do not (like the 2A).
2. You need to convert NTSC to RGB. There are boxes on the market for this or if you are handy with electronics, single chips to do this. Check out Sony, Philips, Analog Devices, Motorola, and others for NTSC/PAL to RGB decoder chips.

For PAL (625/50) the relevant resolution is closer to 800x600.

If your PC monitor scans down to 15.734 KHz, then all you need to do is convert the line level NTSC composite to RGB and sync. Some older auto-scan monitors like the Mitsubishi AUM1381 even have a composite NTSC input jack. Conversion requires a single chip and a few discrete components. Commercial converter boxes are also available.

However, if it is a modern SVGA/auto-scan that does not go below 31.4 KHz, then it is a non-trivial problem requiring a video A/D, frame memory, readout electronics, video D/A, etc. This is called a scan converter and is not an afternoon project even for an experienced design engineer.

You can of course buy PC cards that will enable you to watch TV in a window on you PC.

There are also external boxes that will accept antenna/cable or NTSC/PAL composite input and drive a VGA monitor. One such unit is the 'Proview' (Proview Technology, Garden Grove, CA). This is reviewed in Popular

Electronics, June, 1997. It appears to be quite capable with its own internal 181 channel tuner and IR remote control. It accepts both RF (antenna or cable) and composite inputs and can select between the video source or computer to drive the monitor (but does no processing of the computer's VGA signal - full screen only). With a suggested list price of \$119, the Proview could represent a cost effective alternative to a new TV if you have a VGA monitor sitting around collecting dust.

Some others can be found at:

\* <http://www.aver.com/lite/products/avertvgenie.html>

\* [http://www.aimslab.com/Products/InstantTV/f\\_Instanttv%20home%20page.htm](http://www.aimslab.com/Products/InstantTV/f_Instanttv%20home%20page.htm)

(I have no personal experience with any of the above products --- sam).

In any case, a \$150 TV may actually produce a better picture. This is because the CRT/electronics in a computer monitor is optimized for focus at the expense of brightness. Therefore, sharpness may actually be excessive and brightness may be inadequate except under subdued lighting conditions (especially on a well worn monitor!).

(From: Helmut Weber (Helmut.Weber@hamburg.sc.philips.com)).

There are some companies that have boards ready, which you only have to buy and plug into your PC. Try:

\* <http://www.como.com>

\* <http://www.miro.com>

\* <http://www.2fast4u.com>

---

## 5.4) Comments on TV to VGA/SVGA conversion

You need a lot more than cables. Here are some comments:

1. Your SVGA monitor must be able to sync down to 15,735 Hz Horizontal - the NTSC scan rate - this is CGA speed and few modern monitors go this low. You thus need a scan converter - not cheap.
2. You need to convert the composite video or S-video out from your VCR into separate RGB and possibly H and V sync. This means electronics not just wires.
3. You will need a good switchbox to select between the sources, you cannot just hook them together.
4. The quality of the TV video on your expensive SVGA monitor will likely be worse than on a \$150 TV due to the fine focus of the monitor and the possibly lower brightness. To put it simply, the monitor is too good for NTSC video.

5. Why tie up your computer system watching TV? The other alternative is to get one of those TV tuner and/or frame grabber cards for the PC.

---

## Chapter 6) Video Standards Conversion

---

### 6.1) NTSC to PAL

"Does anyone know of a simple way to convert NTSC signals produced by American video equipment to UK PAL signals."

If you simply mean the color conversion, then a couple of chips will do it.

There are chips to do RGB to NTSC or PAL color encoding but not, as far as I know, scan conversion. For your needs, look into Sony, Philips, and Analog Devices, Motorola, and others.

As has been pointed out, using the strict definition of NTSC to PAL as referring only to the color encoding, all you need is a couple of chips for NTSC to RGB and then RGB to PAL, maybe even a single chip. However, for the very common interpretation of NTSC to PAL (IMHO, maybe a little USA-biased) is with respect to US NTSC 525 line 60 Hz systems to PAL 625 50 Hz systems which is where the non-trivial part comes in.

If what you really mean is NTSC 525/60Hz to PAL 625/50 Hz, it's not trivial.

\* The horizontal and vertical scan rates differ 15734 vs. 15625.

\* The number of lines/frame differ 525 vs. 625.

\* The color encoding differs.

If you simply want to watch an NTSC tape on a PAL TV it may work but not with proper color if the vertical has a wide enough range to sync or you have a vertical hold control with enough range. If your intent is to put it into a VCR, you can safely forget it.

The usual way is to use a scan converter. Essentially, an NTSC color decoder/A-D feeds a frame buffer (approximately VGA size). The frame buffer is then read out at PAL rates and the necessary interpolation is performed using digital processing to go from 525 (480 or so active) to 625 (580 or so active) lines. The output is sent to a video DAC and then color encoded for the PAL system. Everything all happens in real-time.

Needless to say, this is not your basic hobbist afternoon project.

Here are some additional comments:

(From: Clive Tobin (tobin@nwus.com)).

Conversion is not a trivial matter, involving interpolating scanning lines, changing the field rate, and changing the color encoding scheme. I am not aware of a simple chip set that will do it. There are several ways of doing it with bought equipment, listed in order of increasing price:

1. If you can stand to look at it on your computer instead of your TV, you can buy TV tuner cards with video input jacks, that will display NTSC on your VGA computer screen. I think I have seen these for around \$100.
2. Buy a multistandard TV, which are becoming increasingly popular and don't cost much more than single-standard ones. You would not need an NTSC tuner if it has a video input jack. (I don't know if your camera has an RF modulator as well as a video output.)
3. Buy a standards converting VCR, such as Aiwa HV-MX1, Samsung SV-4000W, or similar. These can be used as a stand-alone converter, or to convert the video to record tapes in a different standard. These sell for around \$600 and up. I think they all have RF modulators to feed your TV set if it is lacking a video input jack. If you get one of these you could go into the standards conversion business, converting home tapes of overseas relatives.

Editor's note: Not all multi-standard VCRs do what you want. Some/many simply convert the color encoding between NTSC and PAL without affecting the scan rate (which is much more difficult/expensive). A wide vertical range TV or monitor might produce a viewable picture with these but at the wrong speed (off by 5/6 or 6/5 including the sound)! Unless the product specifications clearly state 'full conversion' or 'scan rate conversion' or something similar, you can probably assume they take the cheap way out! Make sure you can return the VCR if it doesn't meet your needs! --- sam.

The cheapest of all, if you can stand to see the image in black and white with the vertical size off, would be to plug it into the video input jack of a PAL monitor that has a wide-range vertical hold control. Don't use the RF (antenna) input of a regular TV as it may not work at all because of the different carrier frequencies. (You did buy one with video and audio jacks, didn't you?)

(From: Geoffrey S. Mendelson (geoffm@pita.cs.huji.ac.il)).

There are digital converters that do this "on the fly". Akai (and Radio Shack in the US) sell a VCR for \$500-600 (US) that works well. Panasonic sells the AG-W1 (NV-W1) that is an excellent VCR and a much better converter for about \$1800.

You can also buy just the converters.

Avoid VCR's that claim to play PAL tapes on NTSC TVs. They convert the color signal from PAL to NTSC (well enough for the kiddies to watch tapes), but assume you can "stretch" the sync of your tv to work with 50Hz video.

---

## 6.2) What is a scan converter?

A scan converter accepts video of one format - say SVGA - and outputs it to some other format - say NTSC. Some are designed for fixed input format while others can adapt - possibly automatically like an auto-scan monitor - to a wide range of input scan rates and resolutions. Output format is most often selectable between NTSC and PAL scan rates (or those of other TV formats) with a variety of output options such as composite, RGB, SCART, and S-VHS.

The typical scan converter must implement the following functions. (This example applies to a unit designed to convert from SVGA or workstation video format to NTSC):

1. Analog to digital converter (A-D or ADC). In the case of VGA/SVGA or workstation video, there will be 3 video signals - R, G, and B - and each of these must be digitized separately. The A-Ds used are generally single chip 'flash' types using a bank of voltage comparators (e.g., 255 compares for 8 bits of output precision) or similar technique to achieve the high speed conversion needed in modern video applications. These may be able to convert up to 135 M samples per second or more as they must run at the dot clock rate of the RAMDAC of the input video source. A filter (input anti-aliasing) may be needed to limit the bandwidth of the input signal. Ideally, the sampling will be adjusted to occur at the center of each pixel but this is not always possible.
2. Full frame store. The resulting digitized data - usually 6 to 8 bits for each color - is stored in a frame buffer generally constructed from DRAM or VRAM. This memory must be capable of being written to and read out effectively at the same time - dual port or pseudo-dual port. In some special cases, less memory is needed but these are the exceptions. With VRAM, the input may use the serial port since it is strictly sequential (and very high speed) and the readout can use the random access port for interpolation (since its rate is lower but multiple pixels and lines may need to be accessed, see below).
3. Readout and interpolation. Hardware must be able to access the frame store without conflict at the desired output scan rate. Since the output video format has a different (generally fewer) number of pixels per line and total scan lines, some means must be provided to combine multiple pixels and lines into the output video stream. For interlaced output (as used by most TV standards), some amount of interpolation between lines (in the vertical direction) is desirable to reduce the flicker of fine horizontal lines (in graphical material) which would otherwise fall in a single output video field. For RGB full color, there is a separate interpolator for each color channel.

\* Nearest neighbor interpolation simply uses the closest sample from the stored data. This is very easy to implement since it is just a matter of computing a memory address - often by just truncating bits. However, quality is poor - pixelly - and usually unacceptable for all but the least critical and cheapest applications.

\* Bi-Linear interpolation takes pairs of input pixels in the horizontal and vertical direction and combines them to form an output pixel that is their weighted sum. This results in a much smoother and more pleasing display. Since two pixels on each line and two lines are required for the computation of each output pixel, the bandwidth requirements of the frame store and processing complexity are greater resulting in a more expensive system. However, this is the minimum level of interpolation required to produce decent quality output video.

\* Cubic or higher order interpolation uses more than two points in each direction resulting in somewhat better results at greatly increased cost. This is likely to be found mostly in the high performance professional equipment used in television studios and production houses.

The output of the interpolator is typically 6 to 10 bits of data for each color channel.

4. Video digital-to-analog (D-A or DAC) converter. A high speed DAC (three for RGB) converts the each of the interpolated data streams to an analog signal. A filter (output anti-aliasing) may be needed to smooth edge transitions.

\* For driving RGB monitors, this is the final output.

\* For NTSC or PAL, RGB along with H and V sync are further processed by an RGB-to-NTSC/PAL encoder. It may output be composite video as well as separate Y and C to provide for various output connector options: RCA or BNC, S-VHS, SCART, etc.

5. Microprocessor control. Most modern scan converters use sophisticated computer control to provide for advanced levels of auto-scan, many user conveniences, stored setups, and so forth. Features may includes various amounts of user or RS232 (PC) controlled pan, scroll, and zoom; control of sampling times and speeds; and selectable levels of interpolation to control smoothness or sharpness.

However, in the end, no matter how the scan converter is implemented, if the ultimate destination is an NTSC or PAL TV, the resulting picture quality will be very limited. Even a \$20,000 professional scan converter may not be able to display fully legible VGA on an NTSC or PAL TV.

For more information on features and selections of scan converters, try:

<http://www.extron.com/scancon.htm>.

(I have no affiliations with this company and am in no way necessarily endorsing any of their products or claims.)

Implementing a system of this type is a challenging task even for an experienced engineer with extensive design experience with both analog and digital systems.

(From: Derek Roberts (der@cam-orl.co.uk)).

If you really want to do this properly, check out the Genesis Microchip gmVLD8 which uses DSP techniques to do the un-interlacing. Of course you need to add an A-D, field or frame store and some control, But this is the basis of a decent quality scan converter.

---

## 6.3) What is a scan doubler?

This is a special case of a scan converter where the output format has roughly twice the number of lines as the input format and runs at twice the horizontal scan rate.

The following is described for NTSC; A similar approach can be taken with PAL 625/50 to SVGA at 800x600, 50 Hz.

To convert NTSC interlaced at 30 frames/second 60 fields per second to VGA which is at 60 complete non-interlaced frames per second requires a simple scan converter. This is basically an NTSC color decoder and video A/D feeding a full frame memory storing RGB (probably at 24 bits), and VGA video D/A. I say simple to compare it to the general case where in addition to frame store, you need a high speed interpolator to convert between resolutions. VGA is close enough to NTSC resolution (at least in terms of the number of active video lines) that no interpolation is needed. See the section: "[What is a scan converter?](#)". In either case, this is a non-trivial project. IMHO, this is a poor use of an expensive monitor. A \$200 TV will likely look better.

An even simpler approach is possible as well which only requires a one or two line buffers instead of a full frame store. Each input line is read in and reformatted to the appropriate VGA line (even or odd) depending on which field is being displayed. The other lines are blanked (i.e., display even lines and blank the odd lines during the even field display). This would only require enough buffer memory for one or two scan lines (depending on whether the implementation uses a double buffer or more sophisticated write and read timing) which would be a significant cost and complexity savings compared to a full frame store. The disadvantage is that since half the lines are by necessity left blank, the maximum possible brightness of the display will be reduced. It is not possible to use the blank lines as the interleaving of the even and odd fields will be incorrect and result in a poor display.

---

## 6.4) What is a scan divider?

For the special case of converting from VGA at 640x480 (31.4 KHz H, 60 Hz V) to NTSC or SVGA at 800x600 (31.4 KHz H, 50 Hz V) to PAL, something simpler than a full blown scan converter may be satisfactory. In this case, it is

only necessary to provide storage for a single scan line (rather than an entire frame store) since the input horizontal frequency is (almost) exactly twice that of NTSC (15.734 KHz) or PAL (15.625 KHz). A double buffer where one buffer is storing while the other is reading out at approximately half the VGA pixel rate should work. With appropriate timing, even lines become the even field and odd lines become the odd field (I may have this backwards). It is still not a trivial undertaking. Keep in mind that the quality you will get on NTSC or PAL will be poorer than the VGA due to fundamental NTSC or PAL bandwidth limitations. Also, flicker for line graphics will be significant due to the interlacing at 30 Hz.

---

## 6.5) Digital video conversion chips

"I'd appreciate on an Integrated Circuit (IC) made by a Hong Kong company called Display Research Laboratory."

(From: Philip Decker (pdecker@lds.loral.com)).

The IC is a Video Interlace Processor (VIP), part number VIP-01033. It converts 16-bit digital VGA video (5:6:5, R:G:B) to similarly formatted NTSC/PAL compatible video.

The IC can also be bought as part of a circuit board with additional components, producing composite, Y/C, and SCART analog RGB outputs, in three different configurations:

- \* piggy-back to VGA, via feature connector (\$55)
- \* external VGA to TV converter (\$90)
- \* ISA bus card with VGA included (\$180)

---

## 6.6) Black level clamp

"I'm looking for a simple GOOD black level clamp circuit for clamping a video signal."

(From: Joseph H Allen (jhallen@world.std.com)).

This is actually a very interesting subject. Assuming you have a constant video level (or AGC), a simple diode clamp on the horizontal sync tips (diode clamp the sync so that the black level is where you want it) is actually a high quality black level clamp. The sync level is constant after all. I use this method in accurate video digitizers for DC restoring the video before putting it into an A/D converter. The cool thing about simple diode DC restorers is that the capacitance is usually much less than that of the analog switches needed in other types. For example one of the best

analog switches is the readily available 74HC4316, but even this has 40pF (if memory serves) on its pins.

The really hard part is finding a high quality large-signal linear video amplifier. If the video is capacitor coupled to the video amp, then the average brightness level will change the voltage of the black and sync levels seen by the amplifier. This is ok if the video amp is linear, but most aren't so the sync amplitude ends up changing depending on brightness. I.e., the black level will change depending on the brightness of the image (this is completely unacceptable for medical image capturing devices, for example).

The way linearity is measured for video amplifiers is the term "differential gain". It gives the largest difference in percent between a constant small amplitude signal (traditionally the color carrier is used for this) measured at different voltage levels (hopefully which sweep the entire output swing of the video amplifier).

Now you have to be very careful about manufactures differential gain measurements. Many of them play games to get even a mediocre 3% - 1% differential gain. Typically they specify this parameter with a reduced output range (when you really want the parameter to apply to rail-to-rail output swings so you can get a 2V signal needed for most A/D converters) or limit the input range, the gain or flat out lie (I have no idea where comLinear got the specs for their clc520/522 variable gain amplifier, for example. It says .5% in the datasheet, but I measure it to be more like 5%).

All older video amplifier ICs (like the uA722 and NE592) are really lousy. Discrete transistor amplifiers also suck (many monitors use a cascode amplifier which is very bad). Most new ICs suck too- especially those which are labeled as video amplifiers. The only ones which I have been satisfied with are the newest current feedback OP-amps (the + side is high-impedance, but the - side is zero ohms. Usual op-amps are linear, but have a limited bandwidth because the - input is high impedance). These have enough open-loop gain so that they really are linear. One that I really like is the AD9617: .01% differential gain (!), 160MHz bandwidth, immense slew rate (settles to less than 1% of final value within 10ns or so) and only costs about \$10.

If you need variable gain (for AGC perhaps), the best chip to use the AD834 500MHz multiplier. This little 8-pin chip is expensive (like \$40) but it is the only thing that even approaches being linear (and even it is quite a bit worse than the AD9617).

(From: Brian Campanotti (bcampano@toronto.cbc.ca)).

Look at the Clamping ICs from Gennum Corp (part numbers GB4550 and GB4551). They do input buffering and clamping. They are a good front end to any video project.

(From: Mika Iisakkila (iisakkil@alpha.hut.fi)).

Since your application probably needs some kind of an input/output buffer anyway, you might consider some integrated DC restored video amplifier. Elantec makes excellent such chips; data sheets are available on their web

site under "application specific: video".

EL2090 is really good as far as video quality goes, but a bit expensive for applications that don't need 100 MHz bandwidth and near-zero droop. EL4089 is simpler and cheaper, but not quite "broadcast" quality. There's also some new chip, but I haven't looked into it yet.

For both chips, you'll need to get the sample pulse from somewhere, so you can't lose the LM1881. I've used the burst gate output from it to control 2090's sample input, and quality of the result far surpasses my measuring instruments.

---

## 6.7) RGB to PAL converter needed

(From: Gary L. Sanders (75052.2665@CompuServe.COM)).

Philips has chips, as does Raytheon, these would take digital RGB and convert to oversampled PAL output. Check out my web page analog filter modules that are low cost and provide all of the interface needed for top performance from the encoder to the PAL or NTSC output. These are the ST-120 and ST-125 modules. They work with all oversampled digital encoder (RGB to NTSC/PAL) chips. This is the highest quality way to go and it results in a small low cost module with NO adjustments, as with analog encoder chips.

(From: Mike Diack (moby@kcbbs.gen.nz)).

Analog devices does a chip (AD720) which has the delay & filter elements on the chip itself.

---

## 6.8) Inverting an analog video signal

The assumption here is that the input is an NTSC or PAL composite video signal and that the desired output is a valid composite waveform with negative sync tips. In this case, what is required is as follows:

- \* Sync separation to identify and preserve the sync relationships.
- \* NTSC or PAL to RGB conversion.
- \* Inversion of the individual RGB components.
- \* RGB to NTSC or PAL conversion along with the sync.

Bypassing the conversions would be messy as you would be dealing the chroma phase space -I wouldn't even want to risk a wild guess as to what would be

involved.

For monochrome video, the conversion steps would be replaced with a simple inverting amplifier and possibly an analog switch to merge the sync.

(From: Joel Kolstad (kolstadj@CSOS.ORST.EDU)).

Also note that straight video signal inversion will produce some... interesting... color changes, but not the same changes as you get from photographic film. For monochrome video, the end result will look like a photographic negative.

---

## 6.9) Video resolution of various VCR formats

Luminance Specifications:

VHS (240 lines) - FM Dev: 1 Mhz; Freq Range: 3.4-4.4 Mhz. (Sync tip - White)

SVHS (400 lines) - FM Dev: 1.6 Mhz; Freq Range: 5.4-7 Mhz.

BETA1 (250 lines) - FM Dev: 1.3 Mhz; Freq Range: 3.5-4.8 Mhz.

BETA2/3 (240 lines) - FM Dev: 1.2 Mhz; Freq Range: 3.6-4.8 Mhz.

SuperBETA (285 lines) - FM Dev: 1.2 Mhz; Freq Range: 4,4-5.6 Mhz.

ED BETA (500 lines) - FM Dev: 2.5 Mhz; Freq Range: 6.8-9.3 Mhz.

The above refers to resolvable horizontal resolution - the maximum number of vertical lines that can be seen using an arbitrary high quality monitor to view the VCR's output. Also, this applies only to luminance - intensity, not color. The color resolution is much lower and in the particular case of SVHS vs. VHS at least, not improved over VHS since it is recorded in exactly the same way. Also, I don't know whether this is a just noticeable difference (JND) or percent response type of spec where the lines are really just resolvable.

Vertical luminance resolution in the monitor or TV is determined by the video standard (NTSC, PAL) and the quality of the monitor or TV. Specifically, for NTSC (525 total lines for NTSC) there can be a maximum of 482 or so active video lines and something like 580 for PAL (625 line). The remaining lines are for blanking and sync during retrace. These are physical scanning lines.

Vertical luminance resolution for the VCR is determined only by the number of active video scan lines for each standard.

Factors which reduce the effective vertical resolution are CRT focus (spot size) and stability of the interlace, and Kell factor. (See the section: ["What is Kell factor with respect to interlaced displays?"](#)).

Depending on the video standard, vertical color resolution may be less.

Depending on the video source, there will be a variety of other factors which reduce the effective resolution horizontally and vertically.

---

## 6.10) What is Kell factor with respect to interlaced displays?

(From Bob Myers (myers@fc.hp.com)).

The Kell factor - which has to do with the fact that we're often undersampling an image from the standpoint of the Gospel According to St. Nyquist - IS a factor in the reduction of vertical resolution, but interlacing plays a part as well. This comes from at least two factors:

1. The monitor or receiver usually cannot precisely interleave the two fields.
2. More importantly, there are steps taken to reduce the interline flicker which reduce the effective vertical resolution. This includes running the line width of the display somewhat larger than would otherwise be the case, and in interlaced cameras, discharging the entire screen (including the lines from the "other" field) after every field scanned.

Interlace is particularly troublesome on moving images, where you will often perceive momentarily "missing" details. There was a LOT of discussion regarding the gory details of interlacing in the recent HDTV debates within SMPTE and other groups.

---

## Chapter 7) Miscellaneous

---

### 7.1) CGA boards with NTSC output

Old CGA cards had RCA outputs. Usually those cards had one monochrome monitor output and other output was composite video (usually NTSC).

---

### 7.2) NTSC/PAL to RF (channel 3/4) output

This is called an RF modulator. Every VCR in the universe has one of these

and the vast majority are in self contained modules that can be reused. It will be the silver colored metal box that has the two RF (antenna and TV) connectors.

These are also available from surplus electronics outlets for under \$5 or as generic replacements for VCR servicing for \$12 to \$20.

The only connections required to make them work are a source of regulated power - 5 to 12 V depending on model and possible s control voltage to select output instead of pass-through mode.

---

## Chapter 8) Items of Interest

---

### 8.1) General VGA information

(From: Tomi Holger Engdahl (then@tinasoittu.cs.hut.fi)).

VGA monitor pinout can be found at:

- \* <http://www.diamondmm.com/products/visualization/dtv-1100/>
- \* <http://www.matrox.com/mgaweb/mediaser.htm#mediatv>

But be careful, what they say is not always the reality...

Here is an example of a homebuilt video digitizer:

- \* <http://www.ucl.ac.uk/~ucapwas/video.html>

---

## 8.3) Mixing of independent video sources

If they are truly independent, then this is a non-trivial problem. You will need to either:

1. Genlock the two video signals so that they are in sync before mixing. Depending on the sources, the difficulty may range from easy to impossible. Production video equipment will probably have the necessary inputs and outputs. Consumer stuff probably will not. For mixing N signals sources, N-1 will need to have genlock inputs.

If this is not possible then (assuming two sources):

2. You need a real time programmable video delay. This would typically consist of a video A/D, dual ported frame store, readout delay timing logic, and video D/A. Since there is no way to assure the precise phase stability needed for PAL encoding, you would probably need to separate the luminance and chrominance and deal with them separately.

The delay would need to be anywhere up to 1/2 frame (or 1 frame if only one of the sources can be delayed). Not an afternoon project. For N sources, you would need N-1 0 to full frame delay units. Also note that commercial broadcasts will sometimes shift frame reference when cutting between remote locations which are not genlocked. If these sources are to be supported, you will need an automatic adjustment scheme to maintain synchronization.

For info on the availability of commercial devices, you may want to post to one of the video newsgroups - rec.video.production, for example.

---

## 8.4) Studio video recording or filming off of computer monitors

"I'm designing graphics for a computer that is used on a the set of a TV show. When the camera operators shoot the screen, horizontal lines roll up and down. I assume it has something to do with the scan rates. I know there is a small program for the Macintosh that corrects this, but I know of nothing for the PC. Does anyone know?"

(From: Dic (dic@werple.mira.net.au)).

This depends on whether they are shooting on video or film. There are display cards for PC which allow you to dial up the vertical output rate, which you want to match to either 30Hz( NTSC frame rate) or 24Hz (typical film frame rate). Multiples are fine, i.e. 60 or 48Hz respectively.

But that isn't the end of it. You may have (approximately) matched the frame rate of the camera, but you have to also lock them together as there will be a certain amount of drift due to slight differences in the two scan (frame) rates. For film there are devices called a Computach or a Synclock, which attach to the movie camera and take a video input (you can just feed it sync from your PC card but you may need to fiddle the level or polarity).

On set, they roll the camera and adjust the shutter phase so the vertical blanking bars on the PC fall in between movie frames. The synclock then keeps the camera perfectly synchronized to the PC sync.

If you're shooting on video it's a bit harder. You need to genlock the video camera to the PC, which can be awkward as the PC sync may not be quite steady enough (directors HATE having to lock to ANYTHING).

The hardest thing to do is run several PC's in the same shot, because they won't be scanning in sync; you can lock your camera to only one at a time. If anyone knows of PC videocards that can be genlocked together I'd be very interested.

We do a lot of this kind of work and at the end of the day, particularly if there is more than one PC in shot, we record the computer graphics to video and use Amiga monitors, because they look like PC monitors but take video input. We use Umatic or Betacam tapes because the playback machines can be drum locked together. Obviously though, if you need a high degree of interactivity with the actor, this won't work too well.

The vertical blanking bar on a PC is quite fine so if they aren't in the foreground you can usually get away with just matching the vertical rate of the PC as close as possible to that of the video/film camera. You won't see flicker, just a fine dark line moving up or down the picture slowly.

That is about the sum total of my experience but if anyone else has better suggestions I'd be very interested. I have seen some TV/movies with multiple computers in shot with no sign of flicker or blanking bars; maybe the bars are just too fine to show up?

(From: falcon@tao.agoron.com (Tom Strano))

In my personal experience, I've found that simply setting the video mode on a PC to 640\*480, any color depth, and a 60 Hz refresh rate, results in a very stable picture, even when taped with a cheap consumer camcorder and no attempt at synchronization. I've done this with at least 3 different computers, all with different monitors and video cards, and it always works fine. Perhaps I'm just luckier than some technicians...

---

## 8.5) Video controller timing

"I wonder if anyone could tell me a good reference on how CRT controllers operate. Specifically, how do the HSYNC, VSYNC, BLANK, and dot clocks interact. Or, would some kind soul like to explain it? Thanks."

I am not exactly sure what you really want but here are some simple descriptions:

- \* DOT clock: the pixel clock.  $1/(\text{Pixel period})$ .
- \* Hactive: the time during which video on a line is actually displayed.
  - $\text{Hactive} * \text{DOTclk} = \# \text{Pixels}$ .
- \* Hblank: the time during which no video is displayed and the beam is being retraced.
- \* Hsync: positive or negative pulse during Hblank which synchronizes the horizontal deflection circuits of the monitor.
- \* Htotal:  $\text{Hactive} + \text{Hblank}$ .
- \* Vactive: the number of lines during which video in a frame is visible.
- \* Vblank: active for the number of lines during which video is not visible and the beam is retracing to the top of the screen.
- \* Vsync: positive or negative pulse during Vblank which synchronizes the vertical deflection circuits of the monitor.
- \*  $\text{Vtotal} = \text{Totaltime} = (\text{Vactive} + \text{Vblank}) * \text{Htotal}$ .
- \* Csync: Hsync combined with Vsync usually be ORing or XORing.
- \* Cblank: Hblank Ored with Vblank.
- \* Composite video: Video combined with Csync usually the video is .7 V p-p positive-bright riding on top of .3 V negative Csync.

For RGB, some monitors will want 'sync on green' which is this

type of signal only for the green video. R and B and just the straight video. Mono composite is this signal. NTSC/PAL: RGB color encoded and modulated. Composite video is used for the luminance (intensity) with the color information modulated on a subcarrier (which is ignored by a B/W TV).

One source for info on timing specs is the data sheet for a video DAC or RAMDAC. They will usually define all of these parameters.

---

## 8.6) Sync generator chips

(From: Rob-L (rob-l@mars.superlink.net)).

DigiKey lists 74ACT715PC-ND as "Video Synchronous Generator NEW!" It is a 20 pin DIP and costs \$17.50 each for small quantities. The surface-mount version is SC instead of the PC in the above number. You have to pay an extra \$1 for the datasheet if you want one. 1-800-DIGI-KEY is their order line. <http://www.digikey.com/> is their web address.

(From: (opal@opal.co.il)).

Try philips SAA1101.

---

## 8.7) Sync separators

(From: Myron Brookshire (harris.mbrooksh@icld.harris.com)).

Try using the National Semiconductor LM1881 It's a 8 pin DIP that does exactly what you need.

I think it costs @ \$8.00 and you only need a couple of caps externally.

(From: Jan Arvidsson (janarv@algonet.se)).

The EL4583C from Elantec has a dedicated HSYNC output in addition to CSYNC and VSYNC outputs, available on the less expensive LM1881 (National). It is of course very easy to derive a pure HSYNC signal from the CSYNC output!

---

## 8.8) Dead VCRs and composite monitors

Most VCRs go to their graves not because of electronics problems but because of the death of the tape transport. Or, perhaps, because the owner was not willing to spend the money or take the time to resuscitate (or has killed it due to improper servicing). Of course, it might just need a 50 cent rubber tire (but that is for another FAQ). What this means is that the tuner and video circuitry is generally as good as the day the VCR rolled off the assembly line.

If you have a composite monitor (probably gathering dust at this point), then this in conjunction with the otherwise useless VCR will result in quite a nice TV. Many CGA monitors as well as early auto-scan or multi-scan monitors have NTSC (or possibly PAL) compatible composite inputs. Some even have built in speakers. A set of RCA patch cables and you are all set. Since they were designed for high resolution (at the time) computer applications, the quality is generally excellent. (Note: I do not make the same quality claims for modern SVGA monitors as their display is optimized for high scan rate computer video and not CGA or NTSC). In addition, controls are usually accessible to permit any desired degree of underscan or overscan.

It may even be possible to use the VCR's timer to turn your rig on and off automatically! (It just requires faking out the record/cassette interlock and locating a signal that can be used to control a power relay.

Conserve your landfills - save a VCR!

---

## 8.9) Video cables

"Does anyone know about the specifications of the video and sync signals for VGA monitors?"

Video: .7 V p-p, (more positive is brighter).

Sync: separate horizontal and vertical TTL signals. May be either polarity.

"I am trying to send VGA signals over some 180 feet of cable, I'd especially be interested in the required line impedance of the cable."

Line impedance: 75 ohms terminated at both ends.

"Is it possible to produce a Composite Sync signal (or maybe even a composite video signal) that could be fed into an off-the-shelf VGA monitor, so I could use only 3 instead of 5 coaxial wires in parallel?"

RG59U 75 ohm coax is what is normally used, but you will need a good quality cable to go 180 feet without too much signal degradation. Of course, it also depends on what resolution and thus what video bandwidth you need and how much dispersion (signal delay as a function of frequency) you can tolerate.

It is relatively easy to combine the H and V syncs together and then combine

these with the video (usually the green signal for 'sync-on-green') but most low cost VGA monitors do not support this mode and you would then need to separate the signals at the far end. You could come up with alternative ways of combining the signals to save on cables but these will all complicate your circuitry at the monitor end. There are multiple coax cables inside a single sheath for just this purpose.

---

## 8.10) Building a 5 BNC cable

This is straightforward, if time consuming and tedious.

The five coaxial cables (75 ohm, RG59 typical) are wired as shown in the table. The corresponding VGA connector pin numbers are in ().

Coax Center	Coax Shield
-----	-----
Red Video (1)	Red Return (6)
Green Video (2)	Green Return (7)
Blue Video (3)	Blue Return (8)
H Sync (13)	Ground (5,10)
V Sync (14)	Ground (5,10)

Tie pin 11 (ID0) to Ground to indicate a color monitor.

Leave pin 12 (ID1) open.

Make sure that the lengths of the cables are fairly well matched - to within a couple of inches - to assure that the 3 color channels line up precisely. (One foot of cable is about 1.5 to 2 ns of delay which is significant for a 10 ns dot clock!).

Also note that you will lose your 'Plug-and-Play' capabilities without the direct control connections to the monitor (or for monitors without these features).

That's it!

You will wish that your fingers were about 10 times smaller than they are, however. :-)

---

## 8.11) Tweaking the deflection rates in a fixed frequency monitor

Pulling a fixed frequency monitor by more than a few percent will likely be a problem. I know this is not the answer you were looking for but

getting a new inexpensive video card may be a better solution.

If not, you are looking for an adjustment called horizontal oscillator, horizontal frequency, or horizontal hold. If you do tweak, mark everything beforehand just in case you need to get back to the original settings. There is some risk - changing it too far may result in damage either immediate or down the road - I have no idea.

---

## **8.12) Modifying a CGA (or EGA) monitor for NTSC or PAL input**

These are often high quality monitors and would make nice TV displays - especially as there are many no doubt gathering dust on their way to the dumpster!

However, these are digital (TTL) monitors with respect to the video inputs and proper linear video amplifiers may not even be present. Therefore, you may need to implement both the NTSC or PAL decoding as well as boosting the signal levels to the hundred volts or so needed to drive the CRT.

The scan rate of CGA is the same as NTSC so deflection is not a problem.

For PAL (625/50) instead of NTSC, the vertical rate will need to be reduced to 50 Hz but this should not be a problem. The horizontal scan rate is close enough (15.625 KHz).

Similar comments apply to EGA monitors that have a compatible scan rate. EGA represents a range of scan rates between 15.75 KHz and 21.85 KHz so this should not be a problem.

---

## **8.13) How can I determine monitor specifications or whether it supports SVGA?**

There is no easy way to tell by just examining the monitor visually. Even those with only a 9 pin rather than a 15 pin connector are sometimes SVGA (e.g., Mitsubishi AUM1381 and NEC Multisync II which will do 800x600 at 56 Hz V non-interlaced and 1024x768 interlaced at 43 Hz V).

You cannot even safely test scan rates on all monitors - some will blow up or be damaged by being driven with incorrect video.

For a monitor that you already have, posting the model number or looking it up is really the only way to be sure of its capabilities.

Quicky tests:

1. Check the video connector. If it has a high density (VGA) 15 pin connector then there is a greater likelihood of SVGA but not always.
2. Check the manufacturing date on the back. If it has a manufacturing date of 1991 or later, the likelihood of it supporting SVGA is higher as demand for VGA-only monitors was rapidly declining by this point.
3. Check the dot pitch on the CRT by examining the screen with a magnifier. If it is really coarse, the monitor probably cannot do anything beyond VGA.
4. Become familiar with the major manufacturers and models so that you will recognize the common SVGA models.

While not conclusive, positive results on the first 3 of these tests definitely increases the likelihood that it supports at least some SVGA modes. Of course, if you recognize a model number, you have dramatically increased your odds of success - assuming it works!

The following URLs provide quick access to the general specifications of many common PC and MAC compatible video monitors:

<http://www.nashville.net/~griffin/monitor.html>

<http://www.hercules.com/monitors/mdb.htm>

---

## 8.14) Low cost VGA hacking

Typical question:

"I have an old mitsubishi monitor, model number C3919N, Scan rate is 15.5-23.5KHz horizontal, analog. I want to run video from my pc svga card into this monitor. I found the correct video mode, resolution, etc. in which it works, but have one problem. I get two perfect images displayed on this screen."

(From: Martin Moeller (mmoeller@delphi.com)).

I have a copy of a very detailed book on using old 19" monitors for VGA:

\* The Cheap VGA book  
Self Published by a Michael Johnson /Esoteric Electronics  
35-r Derryfield Road  
Derry NH 03038  
Night only Phone # is 603-434-8494

This book contains a lot of good information and advice. He also sells kits for less than \$50 (see comment below --- sam) to make the sometimes needed sync inversion from VGA. (VGA cards invert H and V sync depending on mode to tell the monitor what rate to go to. As far as I know only IBM ever used this.)

I have not tried his kits but the book is very good. BTW if you pay much more than \$300 for a 19' surplus monter you have been moderately had. I do not have any other connection with this person, I just think his book is very good if you are even thinking of using a "non-VGA" monitor with a VGA card.

(From the Editor).

A circuit to perform the automatic sync polarity correction is shown at:

<http://www.hut.fi/~then/circuits/vga2tv.html>

The cost of the parts for this circuit is probably under \$5 even if bought from Radio Shack.

Note: I believe there may be a problem with the use of normal or LS TTL for the sync buffers of this circuit due to their sourcing of current when the input is LOW. A gate with a Low Level Input Current of less than .2 mA should be used. (--- sam)

---

## 8.15) Real time multi-screen displays

These are the type of displays used to view multiple video inputs simultaneously on a single screen - security monitoring, for example.

You have two problems: compressing the signals to 1/4 screen and synchronizing them. The straightforward (though not simple) approach is to digitize each at 1/4 resolution into a frame buffer which is read out at NTSC rates. This overcomes the issues of genlocking and timing of the 4 quadrants.

---

## 8.16) On-screen display implementation

"I am looking for chips that do on-screen display of text and simple graphics. I've got some information about a Philips chip PCA8516 which seems to be a pretty nice complete chip for doing everything I want. Are there other chips out there that do this as well?"

(From: Jack Climent (rocket5@haven.ios.com)).

When you are looking for something for the consumer marketplace, Look toward Mt. Fuji :-).

The MB88303 from fujitsu is an "NMOS Television Display Controller" And the NJM 22075 is a "Sync & Video SuperImposer". These two chips and very

little else form a complete on screen text & Min graphics system. Add a uC and you are in business. Also low cost and easy to implement. Have hardware & software someplace if needed.

(From: Winfield Hill (hill@rowland.org))

This isn't an easy thing to do, as quite a bit of electronics is required. Fortunately, this function is needed for TV sets, VCRs etc and several manufacturers have created custom VLSI chips to do the task, which is called On Screen Display or OSD. For example, Phillips, SGS-Thompson, Rohm, and NEC, etc. all make OSD chips. Some, like Motorola, include the OSD function within a microprocessor.

I like the NEC uPD6464A chip.

Using an OSD chip, you can roll your own design (e.g. see Sept and Oct 1996 Electronics World, which uses a discontinued chip!), but it's still a non-trivial task! One easy solution is to purchase an OSD already on a pcb, with all the extra circuitry and C source code software. E.g. BOB-1 from Decade Engineering in Turner, Oregon (503-743-3194). It uses the Rohm BU5963AS chip and cost \$169 each (\$200 with the software).

---

## 8.17) SCART site

\* <http://www.mindspring.com/~kjack1/scart.html>

---

## 8.18) Video resizing

"I'm looking for a device to do resize (in horizontal direction only) of a video signal. Basically I need a fractional decimator (in this case 2:3). Harris has some stuff that might be useful, and Phillips has some devices but I think they're more geared towards NTSC/PAL (data rate here is around 20 MHz, but, then again, isn't the luminance typically sampled at a pretty high rate?). Anyway, I also know I could do it in an FPGA with bit-serial arithmetic, but I'd rather buy something."

(From: David L. Tosh (dlt@earthlink.net)).

Check out: <http://www.genum.com/vbprofam.htm>. Genum makes several multirate filters vor video resizing.

---

## 8.19) Inverting a video signal

Inverting a video signal means doing something to both the luminance (intensity) and chrominance (assuming a color signal). This is not totally trivial (at least, it is more than just putting it through an op amp). You would have to convert to baseband, strip off the sync and invert the signal, recombine with sync, remodulate to channel 3 or 4.

If you want to also invert the colors, then you have to decode the chrominance to RGB, invert these, reencode, recombine, etc.

There may be some shortcuts one can take but you get the picture (no pun).

---

## Chapter 9) Common PC Video Connector Pinouts

Many of these are also available at the [Sci.Electronics.Repair FAQ site](#) in the document [Pinouts for Various Connectors in Real Life\(tm\)](#).

Also see the connector info at:

\* <http://oacosf.na.astro.it/rossi/hwb/hwb.html>

---

### 9.1) Video Graphics Adapter (VGA)

Note that IBM called VGA 'Video Graphics Array' probably in reference to the video memory. However, we will use the more popular terminology since it agrees with the naming conventions of the other PC standards.

Original VGA (31.5 KHz - 640x480)/SVGA (35-37 KHz - 800x600) 15 pin sub D:

				6	
1 Red (Analog)	6 Red	Return	11 (ID0) GND (Color)	11. . . 1	
2 Green (Analog)	7 Green	Return	12 (ID1) NC (Color)	. . .	
3 Blue (Analog)	8 Blue	Return	13 Horizontal Sync	. . .	
4 Reserved	9 No Connect		14 Vertical Sync	. . .	
5 Ground	10 Ground		15 No Connect	. . .	
				15	10 5

Note: Monitor ID Lines ID1, ID0=NC, G for color; G, NC for Mono. ID0 only may be used.

Mono VGA is similar using only the Green Video and Return.

---

## 9.2) VGA (VESA Standard)

(From: Bob Myers (myers@fc.hp.com)).

Note that many of the pins shown above as "no connects" (actually, these were sometimes used as monitor ID bits by many manufacturers) are now defined under the VESA Display Data Channel standard. This standard provides two protocols for display ID and control, including support for the full ACCESS.bus interface. The current definition of the "VGA" pinout per the DDC standard is:

1 Red (Analog)	6 Red	Return	11 Monitor ID0 (opt.)	11. . . 1	6
2 Green (Analog)	7 Green	Return	12 Data (SDA)	. . .	
3 Blue (Analog)	8 Blue	Return	13 Horizontal Sync	. . .	
4 Reserved	9 +5 VDC (frm host)*		14 Vertical Sync	. . .	
5 Return	10 Sync return		15 Data clock (SCL)*	. . .	
				15 10 5	

Those signals marked with an asterisk would be supplied by the host only if the host supports the DDC2 protocol (I2C or ACCESS.bus).

---

## 9.3) VESA Display Data Channel standard

(From: Bob Myers (myers@fc.hp.com)).

This defined several protocols for digital communications between a host system and its display. DDC provides 3 different modes:

DDC1 - A unidirectional (display to host only) serial communications system which provides basic display ID and feature support information (including supported timings, display size, colorimetry and gamma, etc.) to the host. This uses pin 12 on the 15-pin "VGA" connector as a data line.

DDC2B - Adds clock (pin 15) and return (pin 11, I think - I'm at home, and don't have the standard with me) to enable at least ID information to be obtained via an I2C interface. I2C is a bidirectional interface, but display control via DDC2B is not defined at this time.

DDC2AB - Full ID and control of the monitor via ACCESS.bus. As ACCESS.bus is basically a command and protocol definition on top of the I2C hardware interface, this uses the same lines as DDC2B.

DDC was the first and only definition of the 15-pin D-subminiature video output connector which VESA has provided. No further definitions on this connector will be made, as VESA is instead concentrating on the new Enhanced Video Connector standard which is due out later this year. This will define a completely new connector which will include support for DDC and separate syncs as in the 15-pin D-sub, and will also include support for audio I/O, video input, and the USB and P1394 serial interfaces.

---

## 9.4) VGA - 9 pin

This is pretty standard as the NEC Multisync II, Tatung CM1495, and others use the same pinout. However, there is at least one other pinout that has been used which is similar to the CGA pinout. Also see the document: "Pinouts for Various Connectors in Real Life(tm)".

I used a multimeter to determine this on the VGA to 9 pin adapter for a NEC Multisync II.

Pin 1: Red Video  
Pin 2: Green Video  
Pin 3: Blue Video  
Pin 4: H Sync  
Pin 5: V Sync  
Pin 6: Red Return  
Pin 7: Green Return  
Pin 8: Blue Return  
Pin 9: Ground

Note: IBM PGC assigns pin 4 to Composite Sync and pin 5 is a no-connect.

BTW, don't use an EGA 9 pin extension cable to connect it to VGA. While this will work, the wires are not shielded or the wrong wires and you will get ghosting and ringing at vertical edges. I constructed mine using proper 75 ohm coax for the RGB and H and V sync as well (though it is not needed for the sync).

(From: Carl Mueller).

If you're sure it's a VGA monitor (not CGA or EGA, which are not compatible with VGA), then there are two possible likely pinouts for the plug. I believe they are both detailed in the ibm PC hardware FAQ. One possibility is the CGA pinout, and the other is the 9-pin VGA pinout. Check the grounds to find out.

---

## 9.5) Enhanced Graphics Adapter (EGA)

EGA - TTL (15.74-21.85 KHz) 9 pin:

1 GND	6 Secondary Green Video/Intensity
2 Secondary RED Video	7 Secondary Blue Video
3 Primary RED Video	8 H Sync TTL Positive
4 Primary GREEN Video	9 V Sync TTL Negative
5 Primary BLUE Video	

---

## 9.6) Color Graphics Adapter (CGA)

CGA - TTL (15.75 KHz - 320x200 or 640x200) 9 pin:

1 GND	6 Intensity
2 Unused	7 Unused
3 RED Video	8 H Sync TTL Positive
4 GREEN Video	9 V Sync TTL Positive
5 BLUE Video	

---

## 9.7) Dell UltraScan 17ES

This pinout may be used by a number of Dell monitors. The connector looks like a standard VGA/SVGA HD15 but is wired differently (for some unfathomable reason).

(From: Chris Lawson (lawsonc@micron.net)).

Pin 1:	Gnd
Pin 2:	Red video
Pin 3:	Gnd
Pin 4:	Green video
Pin 5:	Gnd
Pin 6:	Gnd
Pin 7:	NC
Pin 8:	VSync
Pin 9:	HSync
Pin 10:	Blue video
Pin 11:	NC
Pin 12:	NC
Pin 13:	NC
Pin 14:	NC
Pin 15:	NC

---

## 9.8) Monochrome Graphics Adapter (MGA)

MGA - TTL (18.43 KHz - 720x350) 9 pin:

1 GND	6 Intensity
2 Unused	7 Video
3 Unused	8 H Sync TTL Positive
4 Unused	9 V Sync TTL Negative
5 Unused	

---

## 9.9) Macintosh Video

Mac II - analog (35 KHz H, 66.67 Hz V - 640x480) 15 pin.

Mac II and Quadra - analog (49.7 KHz H, 74.55 Hz V - 832x624) 15 pin.

1 Red Ground	9 Blue Video
2 Red Video	10 Sense 2
3 Composite Sync	11 Ground
4 Sense 0	12 Vertical Sync
5 Green Video	13 Blue Ground
6 Green Ground	14 Ground
7 Sense 1	15 Horizontal Sync
8 Reserved (+12)	

---

## 9.10) Mac (16") monitor info

From: adams9@apple.com (Dale Adams)

Note that the Apple 16" monitor is a fixed frequency display - i.e., it only works at one resolution and scan frequency. Here are the particulars:

resolution:	832x624
pixel clock rate:	57.2832 MHz
vertical scan rate:	75 Hz
horizontal scan rate:	49.7 kHz

Here's the pinout for the Apple DB15 video connector:

Pin	Signal	Description
-----	-----	-----
1	RED.GND	Red Video Ground
2	RED.VID	Red Video

3	CYSNC~	Composite Sync
4	MON.ID1	Monitor ID, Bit 1
5	GRN.VID	Green Video
6	GRN.GND	Green Video Ground
7	MON.ID2	Monitor ID, Bit 2
8	nc	(no connection)
9	BLU.VID	Blue Video
10	MON.ID3	Monitor ID, Bit 3
11	C&VSYNC.GND	CSYNC & VSYNC Ground
12	VSYNC~	Vertical Sync
13	BLU.GND	Blue Video Ground
14	HSYNC.GND	HSYNC Ground
15	HSYNC~	Horizontal Sync
Shell	CHASSIS.GND	Chassis Ground

You can pretty much ignore the ID bits. You can try the following cable pinouts to match to a VGA connector.

Mac Video DB15		VGA Connector HD15
-----		-----
2	-----	Red Video ----- 1
1	-----	Red Ground ----- 6
9	-----	Blue Video ----- 3
13	-----	Blue Ground ----- 8
5	-----	Green Video ----- 2
6	-----	Green Ground ----- 7
15	-----	Hsync ----- 13
12	-----	Vsync ----- 14
14	-----	Sync Ground ----- 10

---

## 9.11) Sun 13W3

This was introduced by Sun Microsystems and is a nice compact robust connector. Other manufacturers have copied it.

Pin 1: NC  
Pin 2: NC  
Pin 3: Sense 2  
Pin 4: SRTN  
Pin 5: CSYNC  
Pin 6: NC  
Pin 7: NC

Pin 9: Sense 0  
Pin 10: CRTN

Pin A1: Red

Pin A2: Green

Pin A3: Blue

The following I picked off the net so I do not know the accuracy of the resolution table.

Analog: 13W3 connector:

\* May be NC. My spies tell me Sun considers these obsolete.

The green video input is used by grayscale monitors.

Sense table - 1=nc, 0=strap to gnd

Sense	Type/scan rate
0	TBD (??)
1	Reserved
2	1280x1024, 76Hz
3	1152x900, 66Hz
4	1152x900, 76Hz, 19"
5	Reserved
6	1152x900, 76Hz, 16 or 17"
7	Nothing (no monitor connected)

## 9.12) Pinouts for Sony PVM-2030 and PVM-2530 Profeel Pro monitors

(From: Rob Myers (myer3812@nova.gmi.edu)).

I have the pinouts for the RGB connectors on newer Sony monitors

(specifically, the PVM-2030 and PVM-2530 Profeel Pro monitors). These pinouts are directly from the owner's manual. The connector used is a DB25 female.

High state = 5V (open)

Low state = 0V (short to ground)

Note On Pins 3,4,5,6,11:

If pin 9 is high/open (Analog RGB mode) then .7Vpp, 75 ohm signals must be input to these pins. Pins 1 and 25 are not used.

If pin 9 is low (Digital RGB mode) then TTL signals must be input to these pins. Pins 1 and 25 are only used in this mode.

Pin	Signal	Descr
1	IBM Select	High: IBM mode (RGBI) Low: 3 Bit TTL (RGB)
2	Audio Select	High: Audio input from pin 13 Low: Audio input from LINE A/B/VTR jacks
3	HSync/CSync	Horizontal or Composite Sync, Negative Pol.
4	Blue Input	Video Inputs: Positive Pol.
5	Green Input	(Sync on green optional in analog mode)
6	Red Input	
7	NC	
8	NC	
9	Analog/Digital	High: Analog mode Low: Digital mode
10	RGB/Normal	High: RGB input selected Low: LINE A/B/VTR input selected
11	VSync	Vertical Sync, Negative Pol.
12	Blanking	High: Video input from RGB input only Low: LINE A/B/VTR signal is superimposed over signal from RGB input
13	Audio Input	-5 dB / 100% mod.
14	NC	
15-24	Ground	
25	intensity	Positive Pol.

These monitors are regular NTSC monitors, but I'm sure they can be connected to computers the same way I connected the KX-2501... using a simple buffer circuit and special video drivers. Another possibility is

to build a component-to-RGB converter for really high quality DVD playback (better than S-Video)... the blanking feature seems interesting but the RGB source would have to be synchronized with the composite source. I think the KX's/XBR's have the blanking input, too.

The Sony RGB Multi Input pinout is also valid for the KV-25XBR; it should also work with the KV-20XBR and KX-1901, and I know it works with a KX-2501. (The KX series monitors are the original Sony Profeel monitors from about 1983, and they are very common.)

A female 34-pin floppy connector will mate with the Sony connector just fine. I was able to use the analog RGB input on a KX-2501 to display VGA PC video using a sync level converter circuit and drivers from:

<http://www.hut.fi/Misc/Electronics/circuits/vga2rgbs.html>.

---

## 9.13) SGI Octane to Sony GDM-17E21 cable

(From: Yves DELAY (yves.delay@imag.fr)).

I am trying to connect a Silicon Graphics (SGI) 17" screen display to an SGI Octane CPU. I would like to build my own HD15 to 13W3 cable.

The monitor is standard SVGA with the VESA Display Data Channel (DDC) and works fine on a PC.

SGI OCTANE CPU video pinout (13W3):

A1	Red (analog)
A2	Green (analog)
A3	Blue (analog)
1	Monitor ID bit 3 (TTL)
2	Monitor ID bit 0 (TTL)
3	Composite sync (active low), TTL
4	Horizontal drive (active high), TTL
5	Vertical drive (active high), TTL
6	Monitor ID bit 1 (TTL)
7	Monitor ID bit 2 (TTL)
8	Gnd
9	Gnd
10	Gnd

Below is the pinout of the SGI 13W3 to HD15 cable, part number: 018-0500-001, Rev. E VIST 9717, obtained after a phone call to the SGI hotline.

Signal	SGI OCTANE (13W3)	Monitor: GDM-17E21 (HD15 male)
--------	-------------------	--------------------------------

-----

Red	A1	1	Red
-----	----	---	-----

Red Gnd	A1 Gnd	6	Red Gnd
Green	A2	2	Green (+ composite sync)
Green Gnd	A2 Gnd	7	Green Gnd
Blue	A3	3	Blue
Blue Gnd	A3 Gnd	8	Blue Gnd

Pins 6, 7, and 8 tied together, along with both connectors metallic shell and cable shield.

ID3 (1): not used

ID0 (2), ID2 (7), and Gnd (8), all tied together).

Other pins: not used

## Introduction

### Fluorescent Lamp Basics

The fluorescent lamp was the first major advance to be a commercial success in small scale lighting since the tungsten incandescent bulb. Its greatly increased efficiency resulted in cool (temperature wise) brightly lit workplaces (offices and factories) as well as home kitchens and baths. The development of the mercury vapor high intensity discharge (HID) lamp actually predates the fluorescent (the latter being introduced commercially in 1938, four years after the HID). However, HID type lamps have only relatively recently become popular in small sizes for task lighting in the home and office; yard and security area lighting; and light source applications in overhead, computer, and video projectors.

Fluorescent lamps are a type of gas discharge tube similar to neon signs and mercury or sodium vapor street or yard lights. A pair of electrodes, one at each end - are sealed along with a drop of mercury and some inert gases (usually argon) at very low pressure inside a glass tube. The inside of the tube is coated with a phosphor which produces visible light when excited with ultra-violet (UV) radiation. The electrodes are in the form of filaments which for preheat and rapid or warm start fixtures are heated during the starting process to decrease the voltage requirements and remain hot during normal operation as a result of the gas discharge (bombardment by positive ions).

When the lamp is off, the mercury/gas mixture is non-conductive. When power is first applied, a high voltage (several hundred volts) is needed to initiate the discharge. However, once this takes place, a much lower voltage - usually under 100 V for tubes under 30 watts, 100 to 175 volts for 30 watts or more - is needed to maintain it.

The electric current passing through the low pressure gases emits quite a bit of UV (but not much visible light). The gas discharge's radiation is almost entirely mercury radiation, although the gas mixture is mostly inert gas and generally around something like 1 percent mercury vapor. The internal phosphor coating very efficiently converts most of the UV to visible light. The mix of the phosphor(s) is used to tailor the light spectrum to the intended application. Thus, there are cool white, warm white, colored, and black light fluorescent (long wave UV) lamps. There are also lamps intended for medical or industrial uses with a special envelope such as quartz that passes short wave UV radiation. Some have an uncoated envelope, and emit short-wave UV mercury radiation. Others have phosphors that convert shortwave UV to medium wave UV.

(Caution: Some specialty UV lamps emit shortwave or medium wave UV which is harmful and should not be used without appropriate protection or in an enclosure which prevents the escape of harmful UV radiation.)

Fluorescent lamps are about 2 to 4 times as efficient as incandescent lamps at producing light at the wavelengths that are useful to humans. Thus, they run cooler for the same effective light output. The bulbs themselves also last a lot longer - 10,000 to 20,000 hours vs. 1000 hours for a typical incandescent. However,

for certain types of ballasts, this is only achieved if the fluorescent lamp is left on for long periods of time without frequent on-off cycles.

## Fluorescent Lamp Labeling

The actual fluorescent tubes are identified by several letters and numbers and will look something like 'F40CW-T12' or 'FC12-T10'.

So, the typical labeling is of the form FSWWCCC-TDD (variations on this format are possible):

- F - Fluorescent lamp. G means Germicidal shortwave UV lamp.
- S - Style - no letter indicates normal straight tube; C for Circline.
- WW - Nominal power in Watts. 4, 5, 8, 12, 15, 20, 30, 40, etc.
- CCC - Color. W=White, CW=Cool white, WW=Warm white, BL/BLB=Black light, etc.
- T - Tubular bulb.
- DD - Diameter of tube in of eighths of an inch. T8 is 1", T12 is 1.5", etc.

For the most common T12 (1.5 inch) tube, the wattage (except for newer energy saving types) is usually 5/6 of the length in inches. Thus, an F40-T12 tube is 48 inches long.

- 
- Back to [Flamp FAQ Table of Contents](#).

## Safely Working with Fluorescent Lamps and Fixtures

There aren't many dangers associated with typical fluorescent lamps and fixtures:

- Electric shock. There is usually little need to probe a live fixture. Most problems can be identified by inspection or with an ohmmeter or continuity tester when unplugged.
  - Fluorescent lamps and fixtures using iron ballasts are basically pretty inert when unplugged. Even if there are small capacitors inside the ballast(s) or for RFI prevention, these are not likely to bite. However, you do have to remember to unplug them before touching anything!
  - However, those using electronic ballasts can have some nasty charged capacitors so avoid going inside the ballast module and it won't hurt to check between its outputs with a voltmeter before touching anything. Troubleshooting the electronic ballast module is similar to that of a switchmode power supply. See the document: [Notes on the Troubleshooting and Repair of Small Switchmode Power Supplies](#)
- Nasty chemicals: While the phosphors on the inside of fluorescent tubes are not particularly poisonous, there is a small amount of metallic mercury and contact with this substance should be avoided. If a tube breaks, clean up the mess and dispose of it properly and promptly. Of course, don't go out of your way to get cut on the broken glass!

And take care around sharp sheet metal!

---

## Fluorescent Fixtures and Ballasts

### Fluorescent Fixtures

The typical fixture consists of:

- Lamp holder - the most common is designed for the straight bipin base bulb. The 12, 15, 24, and 48 inch straight fixtures are common in household and office use. The 4 foot (48") type is probably the most widely used size. U shaped, circular (Circline(tm).) and other specialty tubes are also available.
- Ballast(s) - these are available for either 1 or 2 lamps. Fixtures with 4 lamps usually have two ballasts. See the sections below on ballasts. The ballast performs two functions: current limiting and providing the starting kick to ionize the gas in the fluorescent tube(s).
- Switch - on/off control unless connected directly to building wiring in which case there will be a switch or relay elsewhere. The power switch may have a momentary 'start' position if there is no starter and the ballast does not provide this function.
- Starter (preheat fixtures only) - device to initiate the electrode preheating and high voltage "kick" needed for starting. In other fixture types, the ballast handles this function.

### Fluorescent Lamp Ballasts

For a detailed explanation, check your library. Here is a brief summary.

A ballast serves two functions:

1. Provide the starting kick.
2. Limit the current to the proper value for the tube you are using.

In the old days fluorescent fixtures had a starter or a power switch with a 'start' position which is in essence a manual starter. Some cheap ones still do use this technology.

The starter is a time delay switch which when first powered, allows the filaments at each end of the tube to warm up and then interrupts this part of the circuit. The inductive kick as a result of interrupting the current through the inductive ballast provides enough voltage to ionize the gas mixture in the tube and then the current through the tube keeps the filaments hot - usually. You will notice that a few iterations are sometimes needed to get the tube to light. The starter may keep cycling indefinitely if either it or one of the tubes is faulty. While the

lamp is on, a preheat ballast is just an inductor which at 60 Hz (or 50 Hz) has the appropriate impedance to limit the current to the tube(s) to the proper value.

Ballasts must generally be fairly closely matched to the lamp in terms tube wattage, length, and diameter.

## Types of Iron Ballasts

Instant start, trigger start, rapid start, etc. ballasts include loosely coupled high voltage windings and other stuff and do away with the starter:

1. The ballast for a preheat fixture (combined with a starter or power switch with a 'start' position) is basically a series inductor. Interrupting current through the inductor provides the starting voltage.
2. The ballast for a rapid start fixture has in addition small windings for heating the filaments reducing the required starting voltage to 250 to 400 V. There are probably the most common types in use today. Trigger start fixtures are similar to rapid start fixtures.
3. The ballast for an instant start fixture has a loosely coupled high voltage transformer winding providing about 500 to 600 V for starting in addition to the series inductor. The electrodes of "instant start" bulbs are designed for starting without preheating. In fact, they are shorted out internally and are thus incompatible with preheat and rapid start ballasts (and they have only a single pin at each end!). The electrodes still emit electrons due to thermal emission but since they are shorted out cannot be preheated. That is why they require a higher starting voltage from the ballast. They they light instantly, but this slightly reduces lamp life.

Starting voltage is either provided by the inductive kick upon interruption of the current bypassed through the starter for (1) or a high voltage winding in (2) and (3).

In all cases, the current limiting is provided primarily by the impedance of the series inductance at 60 Hz (or 50 Hz depending on where you live).

(From: Vic Roberts (kirther@ix.netcom.com).)

The most basic ballast is nothing more than a current limiting device, such as an inductor, resistor or capacitor. For 50 and 60 Hz applications, the most common current limiting device is an inductor.

A simple current limiter works best when the line voltage is at least 2 times the lamp voltage. So, a simple inductor can be used in Europe, where the line voltage is 220 to 240 VAC, to operate a 4 foot lamp, which operates at 85 to 100 volts, depending upon design.

In the US and other places that use 120 VAC lines the ballast is a combination autotransformer (to raise the voltage) and inductor (the current limiter).

In addition, a Rapid Start ballast has additional windings to supply about 3.6 VAC to heat the filaments.

(From: Asimov (Asimov@juxta.mn.pubnix.ten).)

A ballast is a simple transformer with a very high impedance secondary winding which makes its current self-limiting. It also has windings for each lamp filaments. At startup the filaments get most of the power and heat up to facilitate ionization.

Meanwhile the secondary builds up a very high EMF which finally fully ionizes the plasma between both filaments. At this point the effective resistance of the conducting plasma is quite low and the current flow is limited by the secondary's impedance. This also partially saturates the core and as consequence reduces power to the filaments.

The usual failure in ballasts is that the secondary's insulation deteriorates and it starts leaking to ground. Often because the proper wiring polarity was not observed. The secondary can thus no longer generate the high EMF required to start the plasma conducting.

The KISS test method is to use a known good lamp. If it lights, the ballast is good too. The ballast can also be tested with the power off by checking for continuity in the filament windings and a very high resistance to ground for each filament. Don't try this with power on!

(From: Craig J. Larson (larson@freenet.msp.mn.us).)

Call Magnetek, a ballast manufacturer on 1-800-BALLAST. Ask for a copy of their Troubleshooting & Maintenance Guide for Linear Fluorescent Lighting Systems. Its a nice little guide book for teaching you the basics.

## **Electronic Ballasts**

These devices are basically switching power supplies that eliminate the large, heavy, 'iron' ballast and replace it with an integrated high frequency inverter/switcher. Current limiting is then done by a very small inductor, which has sufficient impedance at the high frequency. Properly designed electronic ballasts should be very reliable. Whether they actual are reliable in practice depends on their location with respect to the heat produced by the lamps as well as many other factors. Since these ballasts include rectification, filtering, and operate the tubes at a high frequency, they also usually eliminate or greatly reduce the 100/120 Hz flicker associated with iron ballasted systems. However, this is not always the case and depending on design (mainly how much filtering there is on the rectified line voltage), varying amounts of 100/120 can still be present.

I have heard, however, of problems with these relating to radio frequency interference from the ballasts and tubes. Other complaints have resulted due to erratic behavior of electronic equipment using infra red remote controls.

There is a small amount of IR emission from the fluorescent tubes themselves and this ends up being pulsed at the inverter frequencies which are sometimes similar to those used by IR hand held remote controls.

Some electronic ballasts draw odd current waveforms with high peak currents. This is due to the fact that these ballasts (low-power-factor type) have a full-wave-bridge rectifier and a filter capacitor. Current can only be drawn during the brief times that the instantaneous line voltage exceeds the filter capacitor voltage.

Because of the high peak currents drawn by some electronic ballasts, it is often important to size wiring

properly for these high peak currents. For wiring heating and fuse/circuit considerations, one should allow for a current of 4 to 6 times the ratio of lamp watts to line volts. For wiring voltage drop considerations (drop in voltage the ballast's filter capacitor gets charged to), the effective current is even higher, sometimes as high as 15 to 20 times the ratio of the lamp watts to RMS line volts.

For less than 50 watts, the current drawn by low-power-factor electronic ballasts is usually not a problem. For multiple ballasts or total wattages over 50 watts, it may be important to consider the effective current drawn by low-power-factor electronic ballasts.

If you want to get an idea of some typical modern electronic ballast designs, see the [International Rectifier](#) web site. Search for 'electronic ballasts' or download the following reference design notes:

- [Linear Ballast](#)
- [Compact Ballast](#)

For a variety of simple inverters to operate fluorescent lamps on low voltage DC, see the collection in the document: [Various Schematics and Diagrams](#).

## Comments on CFL Ballasts

(From: Tony (tonyreo@ameritech.net).)

I work in a R&D lab for a VERY large corporation. We design CFLs (Compact Fluorescent Lamps).

Today, 90 percent of CFLs are electronic ballasted lamps and they come in two basic varieties: (1) High power factors (somewhere between .9 and very close to 1) and (2) Low power factor (usually less than .6).

The high power factor lamps require more components (or from the corporations point of view: cost) so there are more low power factor lamps on the market than high power factor. From what I understand using either will not make a difference in what your electric meter reads and bills you for.

Our typical electronic ballast has two FETs that switch at anywhere from 75 kHz to 105 kHz. And actually we have one product that runs at 2.5 MHz. In the power input section we use a full wave bridge followed by a electrolytic capacitor with a value of anywhere from 10 uF to 47 uF depending on the design of the lamp. There are also a few other components here that reduce EMI (Electro Magnetic Interference) that could be conducted back into the AC line. All of the input components, collectively, will have a part in the input characteristics of the lamp.

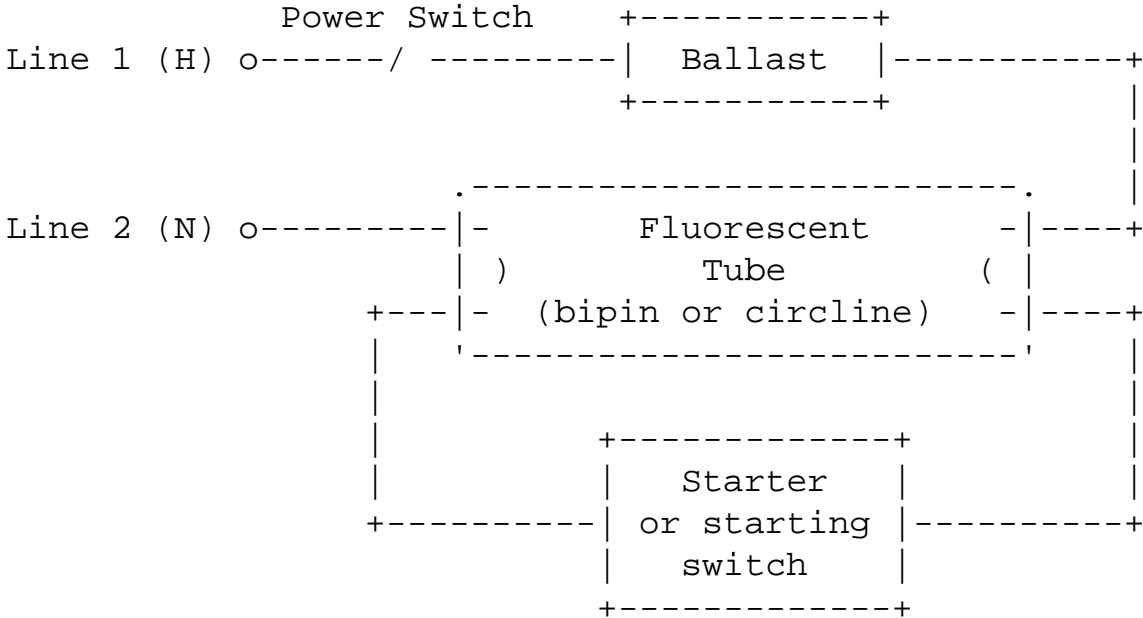

One more note that you may find interesting relates to the starting time of CFLs. The CFLs that do not start instantly (pre-heat types) will have a longer life than the "instant start" type. The pre-heat systems heat the cathodes for 150 milliseconds to 1000 milliseconds (or more) before the lamp is allowed to light. This increases the cathode life which is one of the main factors in lamp life.

- 
- Back to [Sam's F-Lamp FAQ Table of Contents](#).

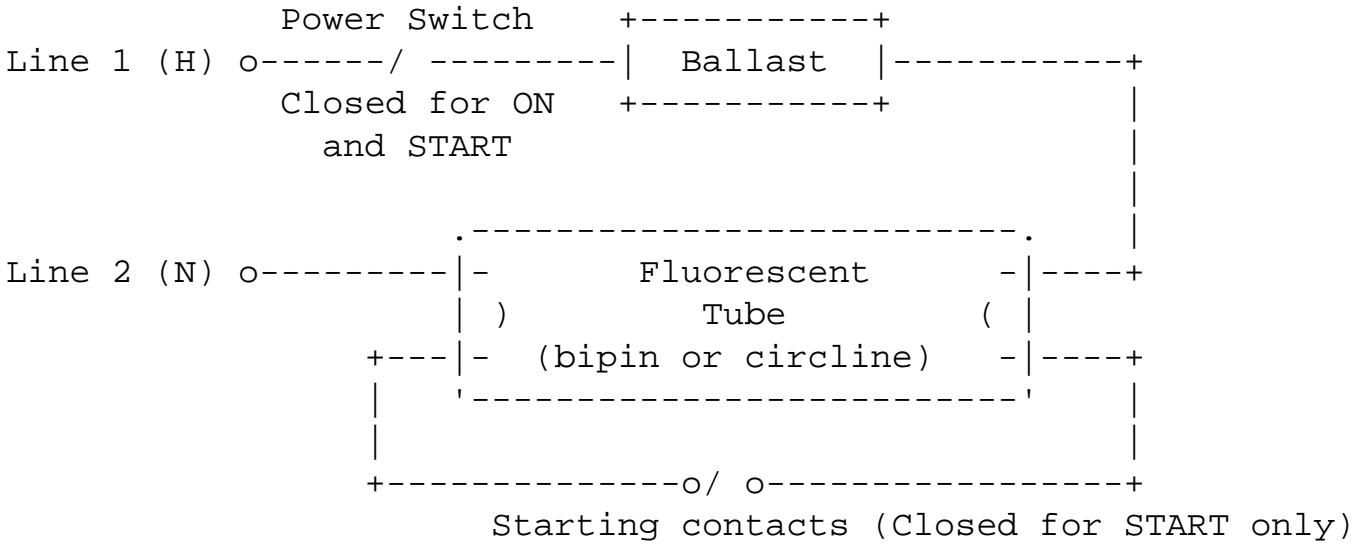

# Fluorescent Fixture Wiring Diagrams

## Wiring for Preheat Fluorescent Fixtures

The following is the circuit diagram for a typical preheat lamp - one that uses a starter or starting switch.

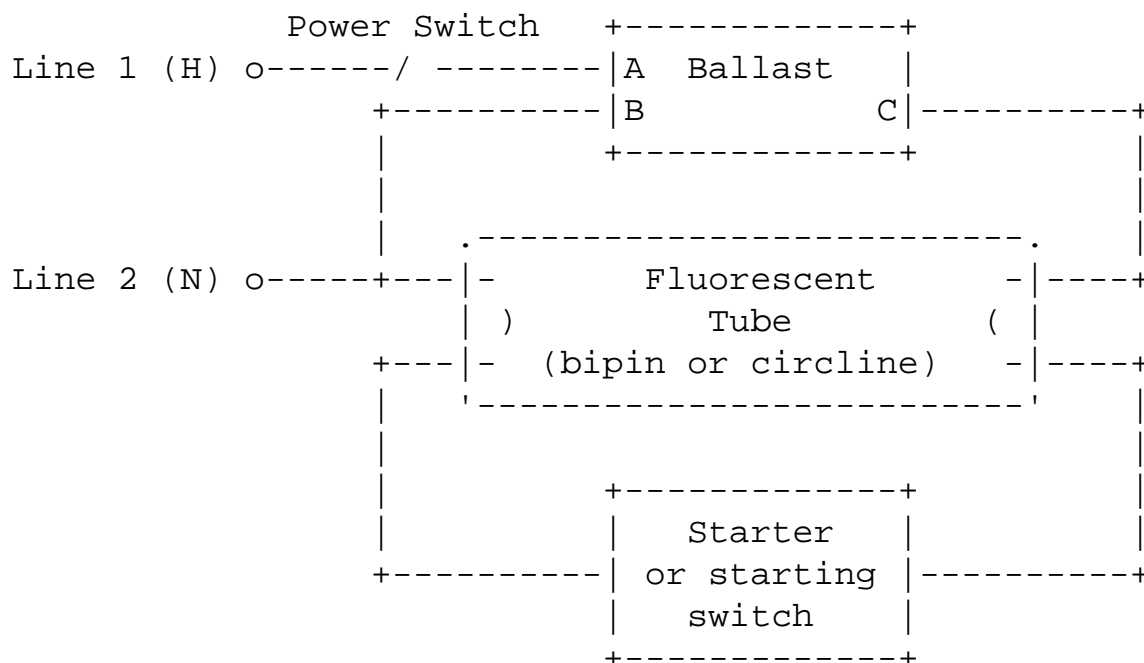

Where a three position switch (OFF-ON-START) is used to control the fixture (e.g., those circular magnifier lamps), there will be two pairs of contacts: One pair (Power) is connected in the ON and START positions, and the other (Start) is connected only in the START position. They are isolated from each-other.

Here is a variation that some preheat ballasts use. This type was found on a F13-T5 lamp fixture. Similar types are used for 30 and 40 watt preheat lamps. This 3-lead preheat ballast is a voltage-boosting "high leakage reactance autotransformer" used if the voltage across the tube is much over approx. 60 percent of the line

voltage. For technical details on why a fluorescent lamp will not work with ordinary ballasts if the tube voltage is only slightly less than the line voltage, look at Don Klipstein's [Discharge Lamp Mechanics document](#).

## Fluorescent Starter Operation

Starters may be either automatic or manual:

- Automatic - The common type are called a 'glow tube starter' (or just starter) and contains a small gas (neon, etc.) filled tube and an optional RFI suppression capacitor in a cylindrical aluminum can with a 2 pin base. While all starters are physically interchangeable, the wattage rating of the starter should be matched to the wattage rating of the fluorescent tubes for reliable operation and long life.

The glow tube incorporates a switch which is normally open. When power is applied a glow discharge takes place which heats a bimetal contact. A second or so later, the contacts close providing current to the fluorescent filaments. Since the glow is extinguished, there is no longer any heating of the bimetal and the contacts open. The inductive kick generated at the instant of opening triggers the main discharge in the fluorescent tube. If the contacts open at a bad time - current near zero, there isn't enough inductive kick and the process repeats.

Higher-tech replacements called 'pulse starters' may be available for the simple glow tube type starter. These devices are pin compatible devices and contain a bit of electronics that detect the appropriate time to interrupt the filament circuit to generate the optimal inductive kick from the ballast. So, starting should be more reliable with few/no blink cycles even with hard-to-start lamps. They will also leave used-up tubes off, without letting them blink annoyingly.

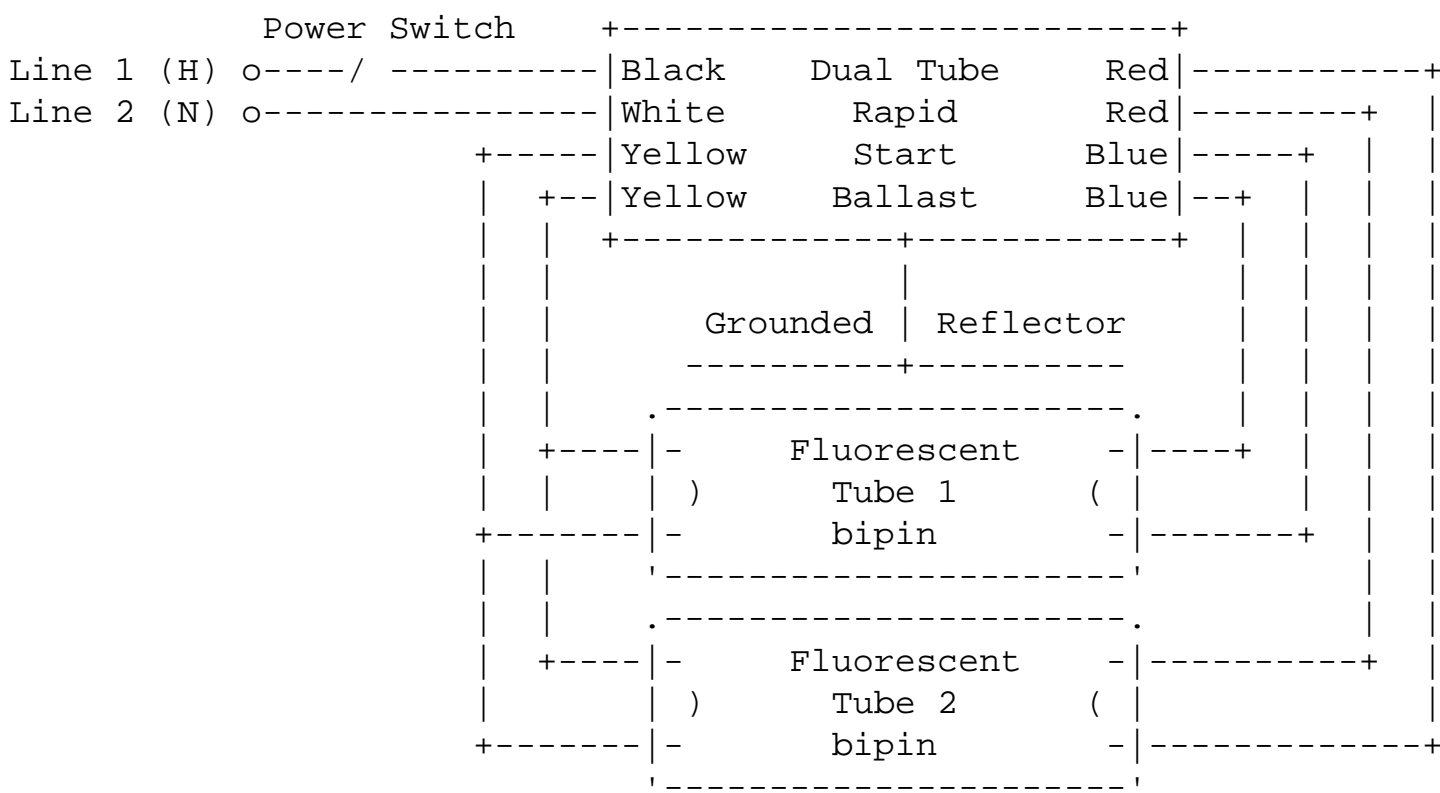

- Where a manual starting switch is used instead of an automatic starter, there will be three switch positions - OFF, ON, START:

## Wiring Diagram for Two Tube Rapid Start Ballast

The following wiring diagram is for one pair (from a 4 tube fixture) of a typical rapid start 48 inch fixture. These ballasts specify the bulb type to be F40-T12 RS. There is no safety interlock on this fixture. (A similar scheme could also be used on a dual tube Circline fixture though slightly different ratings may be needed for each tube since they would be of different sizes.)

## Schematic of Typical Rapid/Trigger Start Single Lamp Ballast

This ballast is marked "Trigger Start Ballast for ONE F20WT12, F15WT12, F15WT8, or F14WT12 Preheat Start Lamp. Mount tube within 1/2" of grounded metal reflector".

Voltages were measured with no bulb installed with safety interlock bypassed.

Internal wiring has been inferred from resistance and voltage measurements.

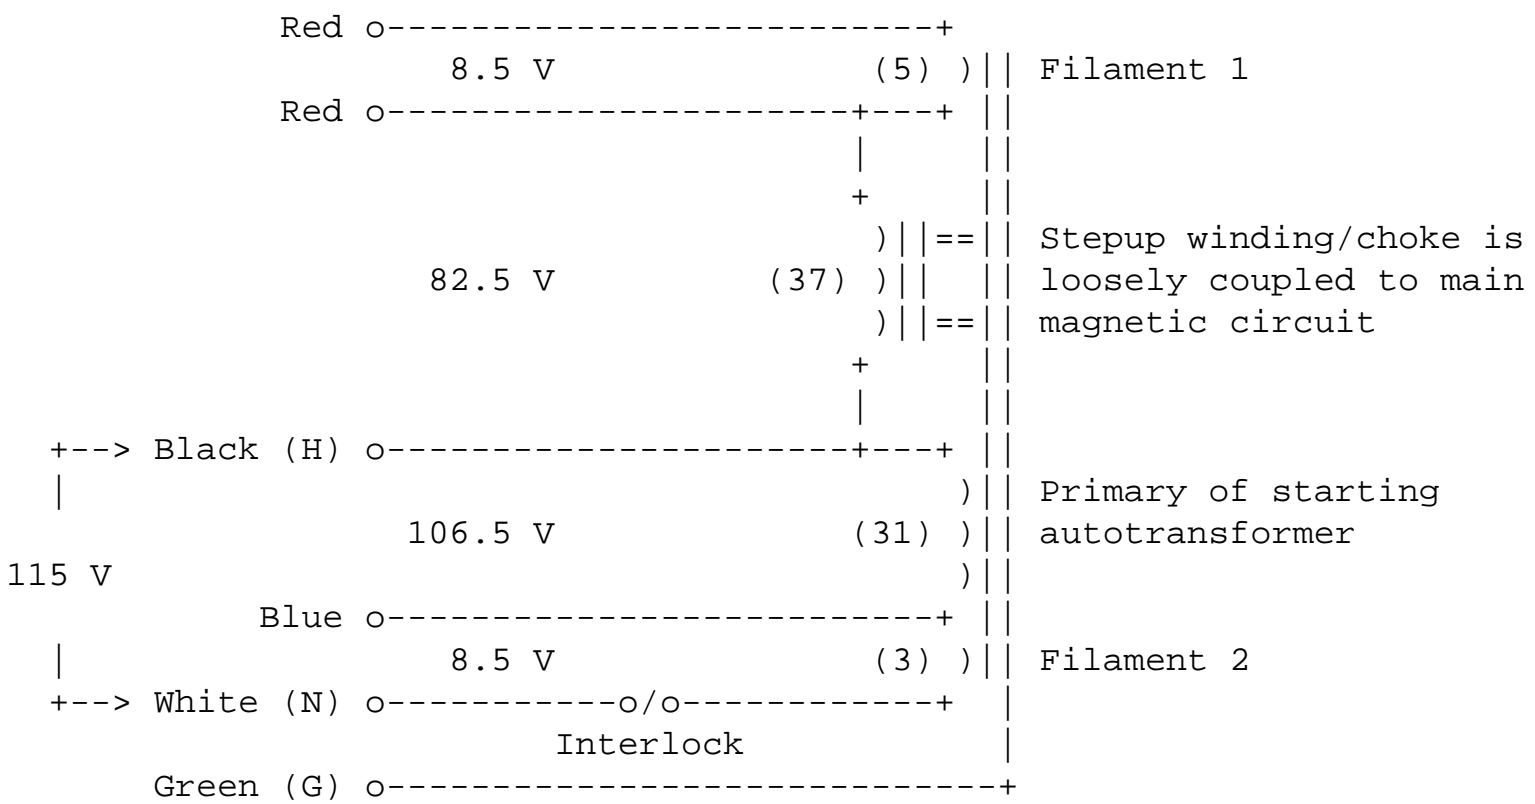

The lossy autotransformer boosts line voltage to the value needed for reliable starting with the filaments heated.

It is assumed that part of the magnetic circuit is loosely coupled so that putting the lamp between Red/Red and Blue/White results in safe current limited operation once the arc has struck.

A complete fixture wiring diagram like those shown in the section: [Wiring for Rapid Start and Trigger Start Fixtures](#) will probably be provided on the label.

Numbers in ( ) are measured DC resistances.

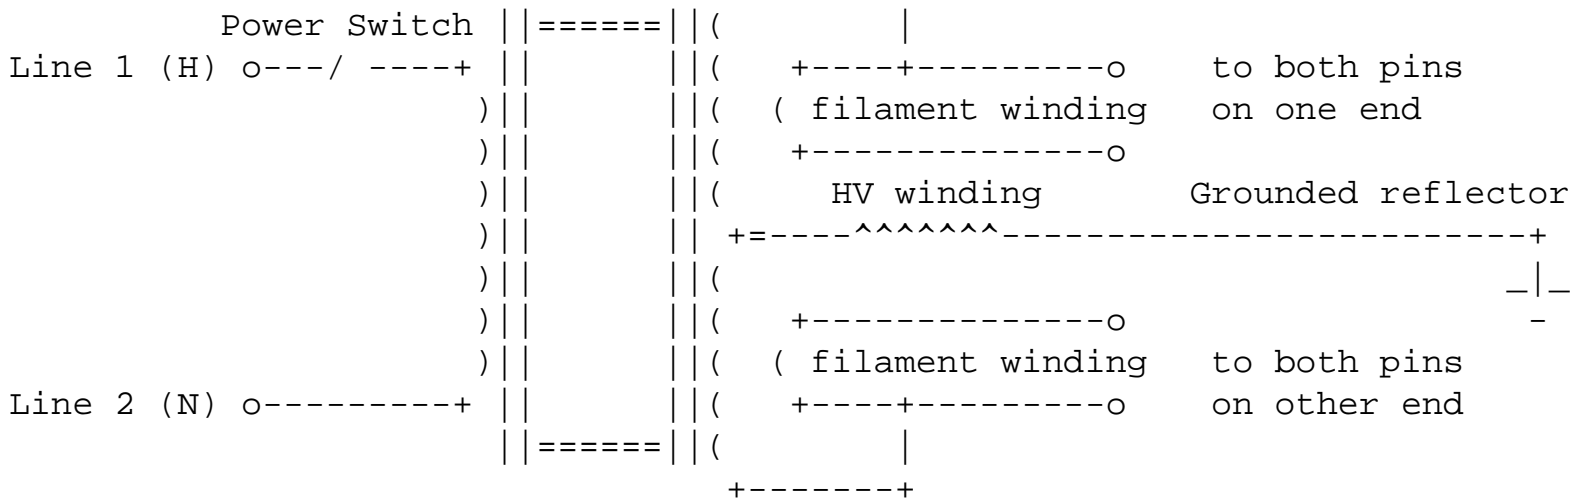

### Schematic for Rapid Start Ballast with Isolated Secondary

As noted, rapid start fixtures do not have a separate starter or starting switch but use auxiliary windings on the ballast for this function. Here is the schematic for a typical 1-tube rapid start fixture including the internal wiring of the ballast.

This ballast includes separate windings for the filaments and a high voltage winding that is on a branch magnetic circuit that is loosely coupled and thus limits the current once the arc is struck. It is not known if this design is common. The isolated secondary and separate high voltage winding would make it more expensive to manufacture.

A complete fixture wiring diagram like those shown in the section: [Wiring for Rapid Start and Trigger Start Fixtures](#) will probably be provided on the label.

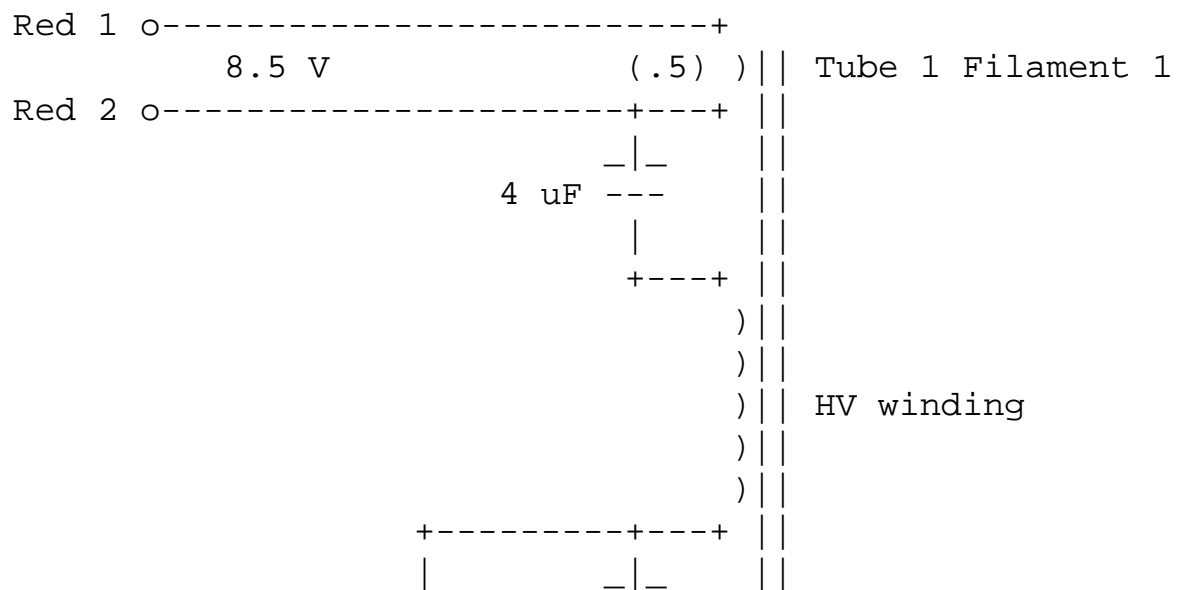

Loose magnetic coupling in the ballast core results in leakage inductance for current limiting.

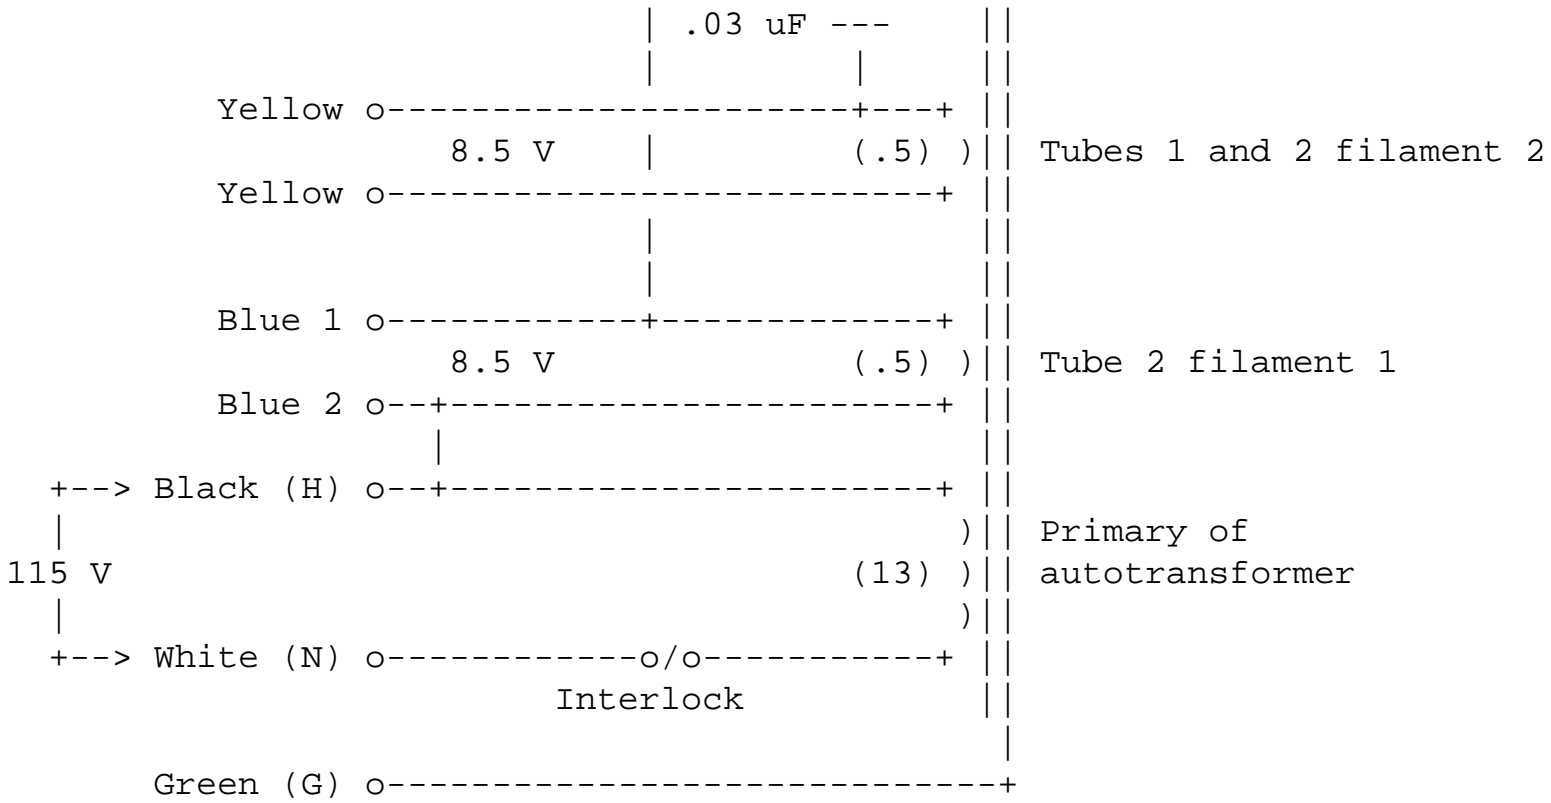

## Schematic of Rapid Start Dual Lamp Ballast

This ballast is marked "Rapid Start Ballast for TWO F40WT12 Lamps. Mount tubes within 1/2" of grounded metal reflector". This circuit was derived from the measurements listed in the section: [Measurements of a Dual Tube Rapid Start Ballast](#).

The autotransformer boosts line voltage to the value needed for reliable starting with the filaments heated. The series capacitor of approximately 4 uF is used instead of leakage inductance to limit current to the tubes. Leakage inductance from loose magnetic coupling is used to smooth the waveform of current flowing through the tubes. The .03 uF capacitor provides a return path during starting to the yellow filament winding but is not really used during normal operation.

Numbers in () are approximate measured DC resistances.

## Measurements of Dual Tube Rapid Start Ballasts

One is a Universal, the other is a Valmont.

(Measurements made with Radio Shack multimeter)

Resistance:

Measurement	Universal	Valmont
White-Black	13	13
Between blues	.5	.55
Between reds	.5	.55
Between yellows	.5	.6
Black to closer blue	<.1	<.1
Blue-red	open	open
Blue-yellow	open	5 M
Red-yellow	open	20 M

Capacitance:

Blue-red	~4 uF	~3.5 uF
Blue-yellow	~.03 uF	
Red-yellow	~.03 uF	

Primary current, (not true RMS), various secondary load conditions:

Secondary open	.32 A	.35 A
60W 120V incandescent bulb	.75 A	.63 A
Short	.48 A	.53 A

Heater voltage: not measured approx. 8 V, unsteady  
surprisingly independent  
of secondary load

Open circuit output voltage (from one red wire to one blue one, highest reading of four combinations):

Red-Blue	270 V	275 V
----------	-------	-------

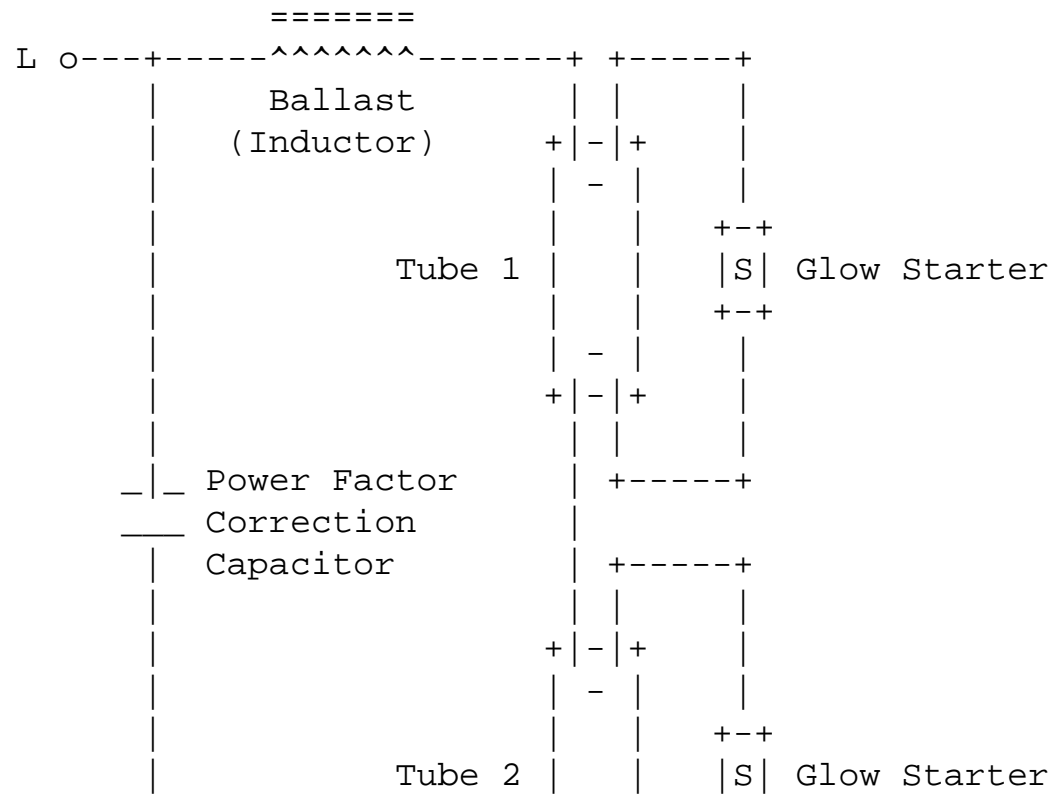

## Fluorescent Lamps in Series?

This is not possible where line voltage is 105 to 125 VAC because this is not sufficient to sustain the discharge where two lamps are in series. Special dual lamp ballasts are required.

However, where the line voltage is 220 VAC, it is possible:

(From: andrew@cucumber.demon.co.uk (Andrew Gabriel)

Here in UK (and probably all 220 to 250V areas), this is common:

## Fluorescent Lamps in Parallel?

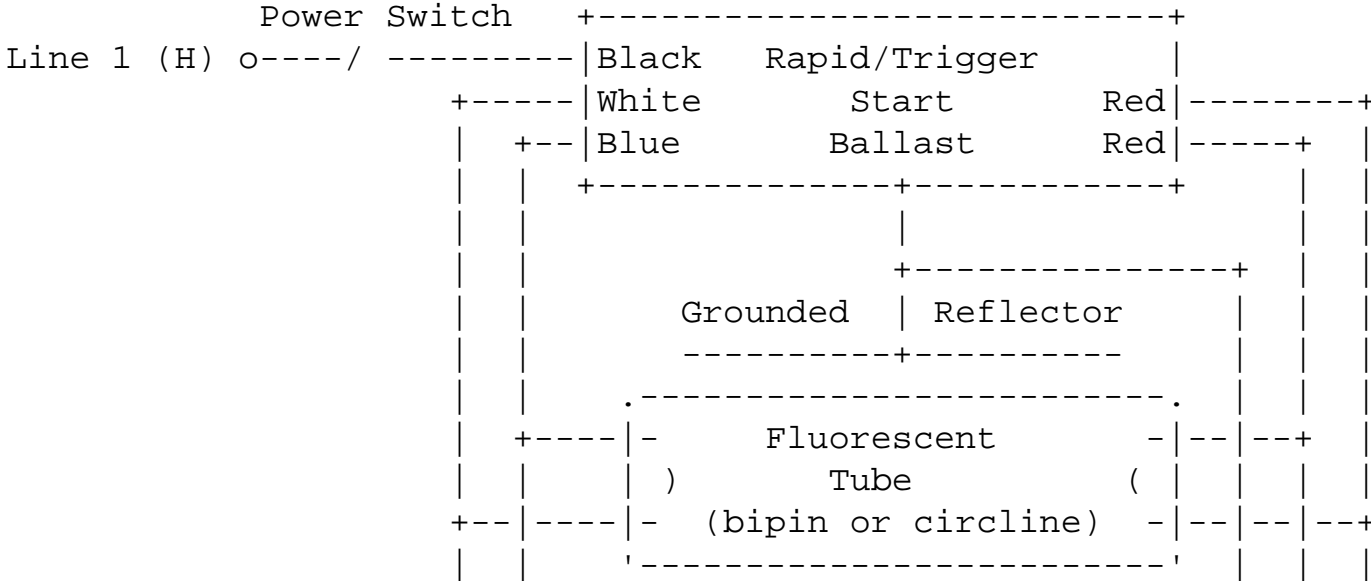

Like most gas discharge tubes, fluorescent lamps are negative resistance devices. Therefore, it isn't possible to put more than one lamp in parallel and get them both to light - additional components are needed. The following applies mostly to magnetic ballasted fixtures. Where electronic ballasts are used, all sorts of games can be played to implement wierd configurations!

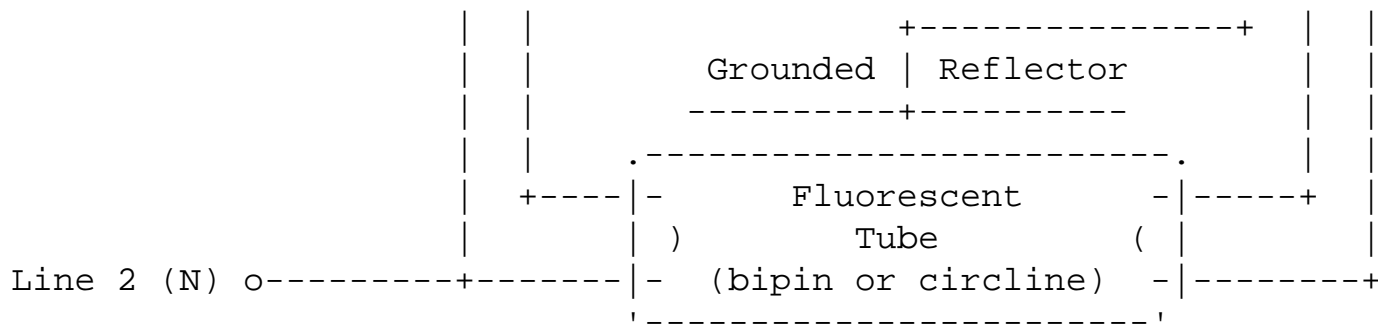

Multiple lamp fixtures in countries with 110 VAC power usually have special ballasts with separate windings for this purpose. Where 220 to 240 VAC is available, it may be possible to put multiple lamps in series with individual starters. See the section: [Fluorescent Lamps in Series?](#).

However, there is at least one application where putting two lamps in parallel makes sense: light fixtures in hard-to-reach or safety-critical areas where redundancy is desirable. With only minor modifications at most, a conventional single lamp ballast can be connected to a pair of lamps in such a way that only one will light at any given time. (Which one actually starts could be random without additional circuitry, however.) If either lamp burns out or is removed, the other will take over. The ballast must provide enough power to the filaments for starting but once started, the lamp that is on will operate normally and there should be no degradation in performance or expected lamp life (except to the extent that the unlit lamp's filaments might be kept hot).

The following is just a suggestion - I have not confirmed if or with which model ballasts these schemes will work!

For rapid start ballasts, this could be as simple as wiring all connections to the lamps in parallel - if the ballast has enough current available to power both sets of filaments for starting. For trigger start ballasts, the filament power is not an issue so it should be even easier:

Note: The interlock normally present on most rapid/trigger start fixtures have been removed to permit one lamp to operate if other is removed.

For preheat ballasts, wiring the filaments in parallel would probably result in insufficient current to either lamp for it to start reliably. If the filaments were wired in series, one lamp would probably start, but if the filament of one lamp burned out or the lamp was removed, the fixture would cease to function kind of defeating the purpose of these gyrations!

## Wiring Fluorescent Lamps to Remote Ballasts

For reasonable distances, this should work reliably and be safe provided that:

1. This is only attempted with iron ballasts. The fire safety and reliability of electronic ballasts that are not in close proximity to the lamps is unknown. The ballast may fail catastrophically either immediately or a short time later as the circuit may depend on a low impedance (physically short) path for stability.

In addition, there will almost certainly be substantial Radio Frequency Interference (RFI) created by the high frequency currents in the long wires. The FCC police (or your neighbors) will come and get you! This may be a problem with iron ballasts as well - but probably of less severity.

2. Wire of adequate rating is used. The starting voltage may exceed 1 kV. Make sure the insulation is rated for at least twice this voltage. Use 18 AWG (or heavier) gauge wire.
3. There is no possibility of human contact either when operating or if any connectors should accidentally come loose - dangerous line voltage and high starting voltage will be present with tubes disconnected.

Note: one application that comes up for this type of remote setup is for aquarium lighting. My recommendation would be to think twice about any homebrew wiring around water. A GFCI may not help in terms of shock hazard and/or may nuisance trip due to inductive nature of the ballast (both depend at least in part on ballast design).

## Wiring diagram of Low Power 220 VAC Fluorescent Lamp

(From: Manuel Kasper (mk@mediaklemm.com).)

The circuit in [Low Power 220 VAC Fluorescent Lamp](#) is from an AC line powered 'light stick'. So there's no

fancy inverter circuit inside, but a simple ballast without any nasty coils - just capacitors, resistors, and diodes. A few modifications would probably be necessary to make it operate from 110 VAC. It runs the tube brighter than a similar lamp powered from a 12 V inverter. (See the section: "Automotive Light Stick Inverter" in the document: [Various Schematics and Diagrams](#). FWIW, the brand is "Brennenstuhl".

It was damn hard to open up because everything was made out of thick plastic with no screws (no wonder; it cost \$6) - but thanks to a huge saw I managed to get at the guts without destroying the tube or the circuit.

## Specialty Fluorescent Lamp Types

### All Sorts of Less Conventional Lamps

In addition to the boring white ones (OK, well 'white' does come in various colors!), other interesting types of lamps include all sorts of real colors (red, green, blue, yellow), blacklight lamps, germicidal lamps in which there is no phosphor coating at all and a quartz tube to transmit short-wave UV light (e.g., EPROM erasers and PCB photoresist activation), sunlamps, plant lights and special purpose specific wavelength lamps such as reprography and copier lamps.

The basic technology is extremely flexible!

(From: Bruce Potter (s602531@aix2.uottawa.ca).)

There are also High Output and Very High Output types of lamps that have a discharge current of 0.8 A and 1.5 A instead of the standard 0.3 A. HO and VHO lamps are used when high light output is desired but are being outmoded by HID lamps like metal halide.

### Blacklight Fluorescent Lamps

(From: Don Klipstein (don@misty.com).)

BL in the tube designation (e.g., F40T12BL) means "blacklight", which is a fluorescent lamp with a phosphor that emits the longest largely invisible UV wavelengths that are both efficiently and fairly cheaply possible. This phosphor seems to emit a band of UV mainly from 350 to 370 nanometers, in the UV-A range.

BLB means "blacklight-blue", which differs from "blacklight" only in that the glass tube of this lamp is darkly tinted with something with a dark violet-blue color to absorb most visible light. Most UV gets through this, along with much of the dimly visible deep-violet 404.7 nanometer line of mercury. Most of the violetish-blue 435.8 nanometer line is absorbed, but enough of this wavelength gets through to largely dominate the color of the visible light from this lamp. Longer visible light wavelengths do not significantly penetrate the BLB's very deep violet-blue glass, which is known as 'Wood's glass'. The UV is the same as that of the BL lamp, being mostly between 350 and 370 nanometers.

There is a 350BL blacklight lamp, using a different phosphor that emits a band of slightly shorter UV wavelengths in the UV-A range. The reasoning for this lamp is that it is supposedly optimized for attracting insects. These lamps are one variety of UV lamps used in electric bug killers.

There are other UV fluorescent lamps. There are at least two different UV/deep violet emitting fluorescent lamps used mainly in the graphic arts industry, emitting mainly wavelengths between 360 and 420 nanometers. Possibly one of these is also used in bug killers. I have noticed one kind of UV fluorescent lamp for bug killers with a broadish band phosphor with significant output from the 360 nanometer range (maybe also shorter) into visible wavelengths around 410 to 420 nanometers or so.

There is an even shorter UV-A lamp used for suntanning purposes. I would guess the phosphor emits mainly within the 315 to 345 nanometer range. One brand of such lamps is "Uvalux".

There is even a UV-B emitting fluorescent lamp. Its phosphor emits mostly at UV-B wavelengths (286 to 315 nanometers). It is used mainly for special medicinal purposes. Exposing skin to UV-B causes erythema, which is to some extent a burn reaction of the skin to a slightly destructive irritant. Use of UV-B largely limits this to outer layers of the skin (perhaps mainly the epidermis) and to parts of the body where skin is thinner. UV-A wavelengths just over 315 nanometers can also cause sunburn, but they are more penetrating and can affect the dermis. Please note that the deadliest varieties of skin cancer usually originate in the epidermis and are usually most easily caused by UV-B rays.

There are clear UV-emitting lamps made of a special glass that lets through the main shortwave UV (UV-C) mercury radiation at 253.7 nanometers. These lamps are marketed as germicidal lamps, and ones in standard fluorescent lamp sizes have part numbers that start with G instead of F. These lamps will work in standard fluorescent lamp fixtures.

Cold-cathode germicidal lamps are also in use; these somewhat resemble "neon" tubing.

Be warned that the shortwave UV emitted by germicidal lamps is intended to be dangerous to living cells and is hazardous, especially to the conjunctiva of eyes. Signs of injury by the UV are often delayed, often first becoming apparent several minutes after exposure and peaking out a half hour to several hours afterwards.

Please note that non-fluorescent (high pressure mercury vapor discharge) sunlamps generally emit more UV-B rays rather than the tanning-range UV-A rays. These lamps do have substantial UV-A output, but mainly at a small cluster of wavelengths around 365 nanometers. Tanning is most effectively accomplished by wavelengths in the 315-345 nanometer range. In addition, no UV suntanning is completely safe.

## **Compact Fluorescent Lamps**

These are miniaturized fluorescent lamps that usually have premium phosphors which often come packaged with an integral ballast (either iron or electronic). They typically have a standard screw base that can be installed into nearly any table lamp or lighting fixture that accepts an incandescent lamp.

Compact fluorescents are being heavily promoted as energy savings alternatives to incandescent lamps. They also have a much longer life - 6,000 to 20,000 hours compared to 750 to 1000 hours for a standard incandescent. While these basic premises are not in dispute - all is not peaches and cream:

1. They are often physically larger than the incandescent bulbs they replace and simply may not fit the lamp or fixture conveniently or at all.
2. The funny elongated or circular shape may result in a less optimal lighting pattern.
3. The light is generally cooler - less yellow - than incandescents - this may be undesirable and result in less than pleasing contrast with ordinary lamps and ceiling fixtures. Newer models have been addressing this issue.
4. Some types (usually iron ballasts) may produce an annoying 120 Hz (or 100 Hz) flicker.
5. Ordinary dimmers cannot be used with compact fluorescents.
6. Like other fluorescents, operation at cold temperatures (under around 50-60 degrees F) may result in reduced light output. Starting may also be erratic, although most compact fluorescent lamps seem to start OK at temperatures near freezing. Many types start OK near zero degrees F. Operation in an enclosed fixture often results in full light output in cool surroundings after the lamp warms up for a few minutes, as long as the initial temperature is high enough to permit a good start. However, enclosing compact fluorescents often impairs their ability to work well at higher temperatures.
7. There may be an audible buzz from the ballast.
8. They may produce Radio Frequency Interference (RFI).
9. The up-front cost is substantial (unless there is a large rebate): \$10 to \$20 for a compact fluorescent to replace a 60 W incandescent bulb!
10. Due to the high up-front cost, the pay-back period may approach infinity.
11. While their life may be 20,000 hours, a wayward baseball will break one of these \$10 to \$20 bulbs as easily as a 25 cent incandescent.

Nonetheless, due to the lower energy use and cooler operation, compact fluorescents do represent a desirable alternative to incandescents. Just don't open that investment account for all your increased savings just yet!

For more information, see the separate document on [Compact Fluorescent Lamps](#).

## **Cold Weather Fluorescent Lamps**

(From: Bruce Potter (s602531@aix2.uottawa.ca).)

There are special lamps with heavy glass jackets and/or with krypton gas filling for cold weather/freezer applications. They work best at below room-temperatures. It really annoys me when I go to the grocery store or see outside installations with dim, flickering tubes! What a waste of electricity!

**Fluorescent Lamps which Operate from Low Voltage DC These are now**

found in all sorts of equipment including laptop computers and all many other portable high tech devices to camping lanterns, boats, and RVs, All are based on an electronic ballast that converts the low voltage DC (anywhere from 3 V to 24 V depending on application) to high frequency high voltage AC to operate the fluorescent tube(s). Laptop computers and similar devices use special narrow tubes designed specifically to be run without heated filaments (cold cathode operation) and very narrow envelopes to fit into very thin spaces. :) Most of the others use conventional fluorescent tubes and may or may not drive the filaments during starting or at any other time.

The ballasts for these lamps must generate the required voltages to start and operate the lamps reliably as well as to assure long life. See the section: [Electronic Ballasts](#) for more info and some links to sample circuits.

## Troubleshooting of Fluorescent Lamps and Fixtures

### Problems with Fluorescent Lamps and Fixtures

In addition to the usual defective or damaged plugs, broken wires in the cord, general bad connections, fluorescent lamps and fixtures have some unique problems of their own. The following assumes a lamp or fixture with a conventional iron (non-electronic) ballast. Always try a new set of fluorescent tubes and starter (where used) before considering other possible failures. If two tubes dim or flicker in unison, this means that both are powered by the same ballast. Often this means that one tube has failed, although the other tube may also be in poor condition or approaching the end of its life. Both tubes must be replaced with known good tubes in order to rule out a defective ballast.

1. **Bad fluorescent tubes.** Unlike incandescent lamps where a visual examination of the bulb itself will often identify a broken filament,

there is often no way of just looking at a fluorescent tube to determine if it is bad. It may look perfectly ok though burned out fluorescents will often have one or both ends blackened. However, a blackened end is not in itself always an indication of a bad tube. Blackened ends are a somewhat reliable means of identifying bad tubes in 34 or 40 watt rapid start fixtures. Blackened ends are not as reliable an indicator in preheat or trigger start fixtures, or for tubes of 20 watts or less.

Failure of the electrodes/filaments at one or both ends of the the fluorescent tube will usually result in either a low intensity glow or flickering behavior, or sometimes in no light at all. A broken filament in a fluorescent tube used in a preheat type fixture (with a starter) will almost always result in a totally dead lamp as there will be no power to the starter. Dim glow is rare in this case and would probably be confined to the region of the broken filament if it occurs. The best approach is to simply try replacing any suspect tubes - preferably both in a pair that are driven from a single ballast.

In fixtures where a rapid start ballast runs two tubes, both tubes will go out when one fails. Sometimes one or both tubes will glow dimly and/or flicker. If one tube glows dimly and the other is completely dead, this does not indicate which tube has failed. The brighter tube may be the good one or the bad one. The bad tube usually has noticeable blackening at one end. It may pay to replace both tubes, especially if significant labor costs are involved. Also, prolonged dim-glowing may degrade the tube that did not initially fail.

In trigger start fixtures that use one ballast to power two 20 watt tubes, sometimes both tubes will blink or intermittently dim. Replacing either tube with a known good tube may fail to fix this. The tubes may continue blinking or intermittently dimming until both are replaced with brand new tubes. This sometimes indicates borderline low line voltage ("brownout", etc.), nonideal temperatures, or a borderline (probably cheaply designed) ballast.

2. **Bad starter (preheat fixtures only).** The little starter can may go bad or be damaged by faulty fluorescent tubes continuously trying to

**start unsuccessfully. It is a good idea to replace the starter whenever tubes are replaced in these types of fixtures. One way that starters go bad is to "get stuck". Symptoms of this are the ends of the affected tube glowing, usually with an orange color of some sort or another but sometimes with a color closer to the tube's normal color if arcs form across the filaments. Occasionally, only one end arcs and glows brightly, and the other end glows dimmer with a more orange color.**

**Please note that this is hard on both the tube and the ballast, and the defective starter should be immediately removed.**

**Should one or both ends glow with a bright yellowish orange color with no sign of any arc discharge surrounding each filament, then the emissive material on the filaments is probably depleted or defective. In such a case, the tube should be replaced regardless of what else is wrong. If both ends glow a dim orange color, then the filaments' emissive coating may or may not be in good shape. It takes approx. 10 volts to form an arc across a healthy fluorescent lamp filament.**

- 3. Defective iron ballast. The ballast may be obviously burned and smelly, overheated, or have a loud hum or buzz. Eventually, a thermal protector built into many ballasts will open due to the overheating (though this will probably reset when it cools down). The fixture may appear to be dead. A bad ballast could conceivably damage other parts as well and blow the fluorescent tubes. If the high voltage windings of rapid start or trigger start ballasts are open or shorted, then the lamp will not start.**

**Ballasts for fixtures less than 30 watts usually do not have thermal protection and in rare cases catch fire if they overheat. Defective fixtures should not be left operating.**

- 4. Bad sockets. These can be damaged through forceful installation or removal of a fluorescent tube. With some ballasts (instant start, for example), a switch contact in the socket prevents generation of the starting voltage if there is no tube in place. This minimizes the**

**possibility of shock while changing tubes but can also be an additional spot for a faulty connection.**

- 5. Lack of ground. For fluorescent fixtures using rapid start or instant start ballasts, it is often necessary for the metal reflector to be connected to the electrical system's safety ground. If this is not done, starting may be erratic or may require you to run your hand over the tube to get it to light. In addition, of course, it is an important safety requirement.**

**Warning: electronic ballasts are switching power supplies and need to be serviced by someone qualified in their repair both for personal safety as well as continued protection from electrical and fire hazards.**

### **Comments on Black Bands and Other Fluorescent Failure Issues**

**(From: Don Klipstein (don@Misty.com).)**

**Fluorescent tubes failing in this manner normally draw reduced current. The voltage across the tube is higher and the tube will sometimes draw more power, but the current flowing through the ballast is less.**

**Since the ends of the bulb usually burn out unequally, some "net DC" may try to flow through the ballast. My experience is that the feared core saturation effects do not occur. Furthermore, the common rapid start ballasts have a capacitor in series with the secondary windings which would block any DC.**

**There is a different problem that I once knew of causing a fire: Starters getting stuck in the "closed" state. The symptom is the ends of the tube glowing brightly, either yellow-orange or a color closer to the normal tube color, sometimes even one end glowing yellow-orange and one end glowing a more normal color. Excessive ballast current flows in this case. This is not a problem with "instant start", "rapid start", or "trigger start" fixtures. It is only a problem where there are starters.**

**A dim orange or red-orange glow more likely indicates dead tubes on a rapid start or trigger start ballast. If the fixture is a preheat type, dim orange end glow indicates less current than a brighter yellow-orange,**

**and the ballast is less likely to overheat. Different brands of ballasts are designed a little differently.**

**If a preheat fixture has the tube glowing only in the ends, it is recommended to immediately remove the tube to stop the ballast from possibly overheating. You should replace both the tube and the starter. The starter is bad if this occurs, and the tube is usually bad also. Typically, the starter goes bad after too much time trying to start a bad tube. In the unlikely event the starter had the initial failure, the tube will be damaged by prolonged excessive end glow.**

**Why is a Grounded Fixture Needed for Reliable Starting?**

**Many fluorescent fixtures will not start reliably unless they are connected to a solid earth (safety) ground. This is most likely the case with rapid or trigger start magnetic ballasts. These will usually state on the label: "Mount tube within 1/2 inch of grounded metal reflector". If this is not done or if the entire fixture is not grounded, starting will be erratic - possibly taking a long or random amount of time to start or waiting until you brush your hand along the tube.**

**The reason is straightforward:**

**The metal reflector or your hand provides a capacitive path to ground through the wall of the fluorescent tube. This helps to ionize the gases inside the tube and initiate conduction in the tube. However, once current is flowing from end-to-end, the impedance in the ballast circuit is much much lower than this capacitive path. Thus, the added capacitance is irrelevant once the tube has started.**

**The reason that this is required is probably partly one of cost: it is cheaper to manufacture a ballast with slightly lower starting voltage but require the fixture to be grounded - as it should be for safety anyhow.**

**(From: Don Klipstein (don@Misty.com).)**

**Should one or both tubes glow dimly, then ionization is not the problem and poor grounding isn't the cause. In such a case, the problem is poor contact with the pins of the tubes, one or both tubes are bad, insufficient**

**voltage, bulb/ballast mismatch (wrong bulbs may fit but not work especially for 4-footers which come in many wattages), or possibly just a bad case of the bulbs being much too cold. Wire or foil or other attachments to change the electric field distribution will not help dim glow make the transition to arc - only help with the tubes ionizing and glowing at all.**

## **Why Do Fluorescent Lamps Buzz and What to Do About It?**

**The buzzing light is probably a mundane problem with a defective or cheap ballast. There's also the possibility of sloppy mechanical construction which lets something vibrate from the magnetic field of the ballast until thermal expansion eventually stops it.**

**First check for loose or vibrating sheetmetal parts - the ballast may simply be vibrating these and itself not be defective.**

**Most newer fixtures are of the 'rapid start' or 'warm start' variety and do not have starters. The ballast has a high voltage winding which provides the starting voltage.**

**There will always be a ballast - it is necessary to limit the current to the tube(s) and for starting if there is no starter. In older fixtures, these will be big heavy magnetic choke/transformer devices - hard to miss if you open the thing. Cheap and/or defective ones tend to make noise. They are replaceable but you need to get one of the same type and ratings - hopefully of higher quality. A new fixture may be cheaper.**

**The starter if present is a small cylindrical aluminum can, approximately 3/4" x 1-1/2" in a socket, usually accessible without disassembly. It twists counterclockwise to remove. They are inexpensive but probably not your problem. To verify, simply remove the starter after the lamp is on - it is not needed then.**

**The newest fixtures may use totally electronic ballasts which are less likely to buzz. Warning: electronic ballasts are basically switching power supplies and are maybe hazardous to service (both in terms of your safety and the risk of a fire hazard from improper repair) unless you have**

the appropriate knowledge and experience.

## Replacement ballast buzzes

Assuming the replacement is of the same type as the original and it is tightly mounted, there is probably nothing really wrong - it is just not as quiet as your previous ballast. Make sure it is the ballast and not its mounting sheet metal vibrating. If the sound is coming from the ballast, there really isn't a lot that can be done other than to try another manufacturer or sample. Also see the section: [Why do Fluorescent Lamps Buzz and What to Do About It?](#)

(From Brian Beck (jrdnut@utah-inter.net).)

There are 2 main types of ballasts; those for 'home' use and those for commercial use. The commercial type will last longer and the lamp life is better as well.

There are three sound ratings

- A - extremely quiet (e.g., libraries, churches).
- B - somewhat noisy (e.g., work areas, shops).
- C - outdoor noisy (e.g., 60 foot poles in parking lots).

My guess is you got a home rated ballast with a 'B' sound rating. There is nothing wrong with the ballast - it is just noisy. If the buzz bothers you, return it to the store you bought it and go purchase one at an actual electrical parts supplier (home centers and hardware stores may not have the highest quality components). For a 2 lamp F40/T12/CW/SS lamp fixture, you want an R2S40TP ballast.

## Why Fluorescent Lamps are Sometimes Dimmer than Expected?

"I recently replaced a kitchen overhead fixture with two 75 watt bulbs with a fluorescent one having two 20 W bulbs. Guess what? Not enough light!"

**Somehow I was under the impression that a watt of fluorescent lighting produced many more candles than a watt of incandescent lighting, but obviously, I overestimated the ratio."**

**A 20 watt fluorescent bulb of a higher light output color should make as much light as a 75 watt incandescent (1170 to 1210 lumens), BUT:**

- 1. A few fluorescent lamp colors are dimmer, such as Deluxe versions of cool white and warm white, and a few others.**
- 2. Fluorescent lamps only make full light output in a somewhat narrow temperature range. The fluorescents will probably not make full light when they first get started. They typically make more light after warming up for a few minutes, then may lose a bit of light output if they warm up past optimum temperature.**
- 3. Some ballasts do not make fluorescent lamps produce full light. Some 20 watt fixtures use a multi-purpose ballast designed to be usable with a few different wattages of lamps, and which typically sends about 16 watts of power to a 20 watt tube. A few other ballasts send an inferior current waveform to the tube, impairing efficiency. I have found some fixtures by "Lights of America" to suffer slightly impaired efficiency from a less smooth current waveform generated by an instant-start ballast system that starts "preheat" tubes instantly without a starter. Some cheaper rapid start and trigger start ballasts produce slightly inferior current waveforms.**

**Some of the slightly popular 2-tube 20 watt "trigger start" ballasts are cheap and "fussy", and only work well if everything is optimum. These ballasts often don't work well with cool temperatures, slightly low line voltages, or slightly weak lamps. Their best may not be too great anyway. The same may be true of some cheaper two-tube 40 watt "shop light" ballasts. Also, some "shop light" fixtures that you may think are dual 40 watt are actually dual 25 watt 4-foot fixtures.**

- 4. Some fluorescent lamp colors (especially warm white, white, and cool white) have a spectral distribution that dims most reds and most greens. This may make things look dimmer. For details of this**

effect, look for the appropriate section in <http://www.misty.com/~don/dschtech.html> (A web document of mine related mostly to discharge lamp mechanics)

"What will happen if I replace the two T20s with higher powered lamps? (If some will burn out, can I replace it as well?"

The ballasts in nearly all 20 watt fixtures will not send much over 20 watts of power to any size tube. Sometimes even not much over 16 watts to any size tube. You need a different fixture, more fixtures/tubes, or possibly tubes of the same wattage but better brightness and/or color brightening (more modern '3000', 'D830', '3500', 'D835', '4100', or 'D841' tubes with higher lumen ratings but of wattage and size for the fixture).

### Replacing fluorescent lamp or fixture components

Most of these parts are easily replaced and readily available. However, it is usually necessary to match the original and replacement fairly closely. Ballasts in particular are designed for a particular wattage, type and size, and tube configuration. Take the old ballast with you when shopping for a replacement. There may be different types of sockets as well depending on the type of ballast you have.

It is also a possible fire hazard to replace fluorescent tubes with a different wattage even if they fit physically. A specific warning has been issued about replacing 40 W tubes with 34 W energy saving tubes, for example. The problem is that the ballast must also be correctly sized for the new tubes and simply replacing the tubes results in excessive current flow and overheating of the ballast(s).

### Rings or Swirls of Light in Fluorescent Lamps

Complaints are generally of the following form:

"I just replaced my bulbs because they had the black bands at the end and finally went out altogether. The new bulbs light fine but they have subtle rings of light running down the inside of them."

or

**"My fluorescent tubes look like a they have a writhing snake inside trying to get out."**

**(From: Don Klipstein (don@Misty.com).)**

**The rings sometimes happens. I forget the name of this, but it is a sometimes normal feature of the main discharge column in low pressure lamps. In fluorescent tubes, it is more common if the bulb is cold or not fully warmed up, brand new or not-yet broken in, or if the ballast is of poor quality or there is a bulb/ballast mismatch.**

**Double check the label on the ballast and the lamp type to be sure they are compatible with each other.**

**If the bulb is an "energy saver" 34 or 35 watt model (part number usually begins with F40, which is the same for a normal 40 watt bulb), be sure the ballast is compatible with that bulb. If it is compatible with both 34's and 40's, it is compatible with 35's. Matching bulbs/ballasts is important for these models mainly to ensure long bulb life and to avoid overheating the ballast. 34 and 35 watt bulbs are prone to rings and flickering and being dim and being unusually sensitive to cold because of the nature of these bulbs and can do so no matter what ballast you use. They will normally behave properly after warming up, especially in ceiling fixtures where heat builds up.**

**Fluorescent tubes sometimes also "swirl" before being broken in, or if they are underpowered by an incorrect or low quality ballast.**

**Comments on Instant Start/Rapid Start Compatibility**

**(From: Ken Berg (goken@inreach.com).)**

**The problem with premature lamp failures using Instant Start ballast lies in the fundamental difference in the basic operating principles between Rapid Start and Instant Start lamps. It has really nothing to do with whether the ballast is magnetic or electronic. Instant Start ballasts are really designed to be used with the standard T12 single pin Slimline**

**lamps. Instant Start ballasts deliver a higher striking voltage on starting than Rapid Start ballasts do. Slimline (the single pin) lamps have a slightly heavier cathode to tolerate the starting cycle. With Instant Start, the lamps are really started "cold cathode" style, and then they of course run as hot cathode.**

**On occasion, even the standard T12 Slimlines refuse to "die like gentlemen" and flash and swirl wildly. Maintenance guys have known for decades that they need to replace Slimlines promptly if they start doing this. They will need to keep this in mind when dealing with the F32T8 lamps as well. Even though the lamps are bi-pin, and so look like the old Rapid Start T12's, they are more than likely running on an Instant Start circuit, and will sometimes go like this.**

**The cathodes in most bi-pin lamps are made for Rapid Start, which is a starting method that is easier on the filaments. The lamp manufacturers are supposed to have already taken the starting characteristics of the new F32T8 Instant Start ballasts into account, but some might just be going on the cheap, and skimping of the lamp filaments.**

### **Premature Cathode Failure in Dimmed Fluorescent Lamps**

**"I have been experimenting with 15 W T8 lamps running from a dimmable electronic ballast. I have found that if set to a low light level after a few days of being left on, one of the cathodes in the tube often goes open circuit."**

**(From: Clive Mitchell (clive@emanator.demon.co.uk).)**

**The only explanation that I can come up with is that there isn't enough current flow to keep the cathodes warm and this is causing the discharge to be concentrated on a small point. The discharge will tend to stay on that point since it's the only warm bit, and as such is emitting electrons, making it the easiest path for current flow.**

**The voltage drop across this point will be higher than normal since the heat being generated is being dissipated by the rest of the cathode and this means that more power than normal is being dissipated from that point causing sputtering. This could be causing the early burn-out.**

**The best way to validate this would be with a clear tube to see the cathode discharge activity.**

**I've seen a phenomenon like this when I've lit a halide lamp at low level with a small voltage multiplier circuit. The glow discharge led to a white hot point on the electrode that caused sputtering.**

**If this is the case, then the cure is to use a ballast that can supply a continuous heating current to the cathodes.**

### **Replace Preheat Ballasts with Rapid or Trigger Start Type?**

**When a ballast fails in a preheat fixture, should the bad preheat ballast be replaced with a more modern type? Advantages of a rapid or trigger start ballast are that the starter (a high failure part) is eliminated and the fluorescent lamps may last longer as a result of less stress during starting. Disadvantage include cost of the ballast and possibly space limitations inside the fixture. However, since a defective starter may ruin the lamp controlled by it, the potential cost of replacement lamps may offset the additional cost of the ballast. All in all, this is probably not a decision affecting the future of the Universe but in certain cases, changing ballast types may make sense.**

## **Items of Interest**

### **All Those Different Wattage 4-Foot and F40 and "Shop Light" Lamps?**

**The original 4-foot fluorescent lamp was the F40T12, which is 47.75 inches (approx. 121.3 cm) long from pin tip to pin tip and 1.5 inches (approx. 4 cm) in diameter and designed to consume 40 watts. Not too many years ago, this was the most common and least expensive fluorescent lamp.**

**There is the "HO" (high output) 4-foot tube and the "SHO" (super high output) 4-foot tube. These are not common and are only used where there is not enough room to fit enough standard F40 tubes to make enough light. These lamps are slightly less efficient than standard fluorescent lamps. These tubes require more current than standard 4-foot tubes and require special ballasts. These tubes should only be used with their respective ballasts, and these ballasts should only be used with the tubes they were designed for.**

**In response to the energy shortages of the 1970's, the 34 watt lamp with the same physical dimensions was introduced. It works in most 40 watt fixtures and draws 34 watts in these fixtures. However, some 40 watt ballasts can overheat with this lamp. The ballast should say that it is rated for use with 34 watt lamps.**

**Please note that a 34 watt tube can say F40 and still be a 34 watt tube and not be a 40 watt tube. It will in some way say near the F40 designation that it is an energy-saving tube. There have also been a few 35 watt tubes, which are similar enough to 34 watt tubes to work anywhere both 34 and 40 watt tubes can work. 34 watt lamps sometimes produce noticeably less light than 40 watt lamps, especially in cooler environments.**

**Nowadays, there is the 25 watt "shop light" lamp. The 25 watt tubes should only be used with appropriate 25 watt shop light ballasts, and these ballasts should only be used with these tubes. Please do not confuse these with other wattage tubes/fixtures of the same physical dimensions which are also sometimes called "shop lights".**

**A more recent development is the 32 watt T8 lamp, which is 4 feet long but only one inch (2.5 cm) in diameter. These require ballasts made for them. Many of the ballasts made for these lamps are electronic ballasts.**

**The confusion has increased in recent years now that the USA has an energy-conservation law against manufacturing and importing standard 40 watt white fluorescent lamps. Specialty lamps and white ones with a color rendering index of at least 82 (out of a maximum of 100) are exempt and are still available in the USA as true 40 watt lamps.**

**Again, be sure that you are not mismatching the bulb and the ballast. If the ballast is not rated to operate the bulb type being used, the bulb life will probably be shortened and the ballast life may be shortened. In a few cases, the ballast may catch fire after failing.**

## **What's with All Those Different Shades of White?**

**At one time, most fluorescent lamps were "cool white" which is a plain-old white with a color like that of average sunlight.**

**One bad thing about "cool white" is that the spectrum of "cool white" has a surplus of yellow and a shortage of green and red. Since mixing red light with green light makes yellow, the white light of a cool white lamp still looks white. Since yellow objects usually reflect green through red, they look yellow as usual in this light.**

**But red objects reflect mainly red light and green objects reflect mainly green light, and look dim and dull due to the shortage of red and green wavelengths in "cool white". Impure reds and greens will look less red and less green as well as darker - making them look more brown.**

**Other early whites were "warm white" and "daylight". Warm white is a color similar to that of incandescent lamps, although it usually looks slightly less yellow and more white-pink. A warm white lamp's spectrum has a surplus of yellow and violet-blue, and a shortage of red, green, and green-blue. Like cool white, warm white can distort colors in unflattering ways.**

**Both "warm white" and "cool white" are obtained using "halophosphate" phosphors. The surplus of yellow and shortage of red and green is a general characteristic of halophosphate phosphors.**

**"Daylight" is a bluish white, and does not have as bad a surplus of yellow as the other halophosphate whites. But it is also slightly dimmer.**

**Next were the "deluxe" versions of cool white and warm white. These have "improved" halophosphate phosphors and are sometimes known as "broad spectrum" lamps. They have a less severe yellow surplus and red/green shortage than standard halophosphate lamps. They also produce slightly less light.**

**Another slightly common halophosphate white is "white", which is**

between "cool white" and "warm white" in color.

Other halophosphate whites, whether of differing spectral quality or different shade of "warmth/coolness" include "supermarket white", "sign white", "north light", "merchandising white", etc. Please note that some of these are not made by all fluorescent lamp manufacturers, and some of the less standard color names are trademarks of their respective manufacturers.

One earlier fluorescent lamp color with enhanced red spectral content is the "natural". This lamp has "cool white" halophosphate phosphor with a red-glowing phosphor of a different type added in. These lamps look slightly pinkish in color, sometimes purplish when compared to warmer colored light such as incandescent light. "Natural" fluorescent lamps make skin tones look pinkish, unlike the usual halophosphate types which make skin tones look green-yellowish. Some meat displays have "natural" fluorescent lamps to make the meat look more red.

Nowadays, there are "triphosphor" fluorescent lamps. These have a spectrum very different from that of the halophosphate lamps. Triphosphor lamps have their spectral content mostly in distinct bands and lines: Orangish red, slightly yellowish green, green-blue, and violet-blue. For cooler color lamps, there is an additional band in the mid-blue. Triphosphor lamps do not distort colors as badly as halophosphate lamps, and triphosphor's color distortions are usually not as unpleasant as those of halophosphate. Also, triphosphor lamps often make reds and greens look slightly brighter than normal, unlike halophosphate lamps which usually make these colors look dimmer than normal.

Most compact fluorescent lamps and most 4-foot T8 (1-inch diameter) lamps are triphosphor lamps.

Triphosphor lamps come in various warm and cool shades, usually designated by "color temperature". This is the temperature that an ideal incandescent radiator would be heated to in order to glow with a similar color. Color codes on fluorescent lamps may include the color temperature or 1/100 of the color temperature. Osram/Sylvania brand lamps often have D8 immediately preceding the color code.

**2700 or 27 - orangish shade common for compact fluorescent lamps, similar to many incandescent lamps.**

**3000 or 30 - "warm white", similar to whiter shades of incandescent.**

**3500 or 35 - between warm white and cool white, similar to the whitest halogen lamps and projector lamps.**

**4100 or 41 - "cool white" or the color of average sunlight.**

**5000 or 50 - an icy cold pure white like that of noontime tropical sunlight.**

**6500 or 65 - slightly bluish white or "daylight".**

**There are still other specialty whites, including ones with a mixture of "broad spectrum" and "triphosphor" phosphor formulations to get a spectrum more like that of daylight. Some others have particularly good "broad spectrum" phosphors, sometimes mixed with other phosphors for a tailored spectrum. Many of these, like most triphosphor lamps, have color temperature designations.**

### **Why Small Fluorescent lamps Cost More than 4-Foot Ones**

**Can you say 'supply and demand' and 'economies of mass production'. You are comparing the price of the common F40CW-T12 lamp manufactured by the zillions and sold in home centers for about \$1 with specialty bulbs used in a relatively few devices like battery powered fluorescent lanterns and makeup mirrors. These little bulbs may indeed cost up to ten times as much as the much larger ones.**

**By any measure of materials and manufacturing cost, the 4 foot bulb is much much more expensive to produce. There is nothing special involved.**

### **Energy Consumption and Wear-And-Tear due to Starting**

**(From: John Gilliver (g6jpg@gmrc.gecm.com).)**

**The amount of energy used in starting isn't worth worrying about.**

However, in addition to the turn on/off deterioration, there is also the steady-state 'on' deterioration (they don't last for ever even if left on), so...

As far as turn-on deterioration:

I can't give it as a percentage, but for ordinary striplights I heard a figure of 15 minutes (about 15 years ago), i. e. turning it on stresses it as much as leaving it on for that long. Things have perhaps changed by now (and there are so many kinds these days as well).

For low-energy use, I'd go for fluorescents any day, unless size is a major factor (Bosch [I think] and others have been trying to get some sort of discharge lamp for headlights for some time, but I haven't seen any yet). You might also look into LEDs, but I doubt they will match the efficiency; certainly only the high-efficiency types (all seem to consume about 10, 20, or 30 mA, but the output power in light seems to vary widely, from a few millicandelas to about three candelas!). They are narrow band (i. e. coloured) as well of course.

What Happens when Fluorescent Lamps Wear Out?

(From: Charles R. Sullivan (charless@crissy.EECS.Berkeley.EDU).)

The usual failure mode is depletion of the emission mix on the filaments. Then they do not emit electrons, and the arc can't be sustained. Unless the ballast supplies a high enough voltage that very high field can be set up near the electrode. Then the ions bombarding the electrode have a high enough energy to knock electrons out of the metal even with no emission mix, or to heat the metal to the point it emits electrons. The high field is also sufficient to ionize the argon fill gas---normally only mercury is ionized. The argon radiation is of a more purple color. That is probably what you see.

Blackening at Ends of Fluorescent Tubes

This is a common phenomenon with most common fluorescent tubes as they age. However, frequent or repeated starting can accelerate the process. The black areas in themselves don't affect operation except to

**slightly reduce the amount of light available since the phosphor in that area is dead. However, they do represent a loss of metal from the electrodes (filaments).**

**The cause is sputtering from the filaments, mostly when cold. Thus. this happens mostly when starting or with a defective rapid start ballast which doesn't heat the filament(s) or a ballast or starter that continuously cycles. When the filament is cold and is the cathode (on the negative half of the AC cycle for that end of the tube), the work function is higher and ions have a higher velocity when impacting, knocking off metal atoms in the process. This is greatly reduced once the filament is up to normal operating temperature (though even then, some sputtering is inevitable).**

**(From: Greg Grieves (ggrieves@home.com).)**

**Lamps with the longest lifetimes typically use the heavier noble gasses as the buffer gas, ( Xenon or Krypton instead of Argon) because the sputtering that occurs at the cathode is due to fast ion bombardment from the ionized gasses in the tube. the heavier atoms have a smaller velocity for a given kinetic energy of acceleration. its not the total energy of the ion that sputters but its the momentum at impact that knocks other atoms loose. I presume thats why Kr and Xe bulbs can run brighter, because they can crank up the power and still have about the same lifetime. Some tubes use a "hollow cathode" design in which the shape of the cathode is designed to deflect impacting ions rather than be sputtered by them. That's my understanding, anyway, theres much more to the story...**

**(From: PBerry1234 (pberry1234@aol.com).)**

**I recall one brand of lamp that positioned shields around the electrodes to prevent the blackening. I suppose this improved the appearance in exposed lamp applications, but don't know of any other benefits.**

### **Hot Cathode Versus Cold Cathode Operation**

**The cathode is the negative electrode of a vacuum tube or gas filled discharge tube. Current flows by way of electrons emitted from the cathode and attracted to the positive electrode, the anode.**

**A hot cathode is one which must be heated to operate properly - to emit sufficient electrons to be useful. Examples: TV and monitor CRTs, most vacuum tubes (or valves), vacuum fluorescent displays (like those on your VCR). This is called thermionic emission - the boiling off of electrons from the surface of the cathode. Normal fluorescent lamps are hot cathode devices - partially maintained by the discharge current itself. They all have some sort of warmup period (though it can be quite short).**

**(From: Phil Rimmer (primmer@tunewell.com).)**

**A cold cathode is one where operation takes place without depending on heating of the surface above ambient. There are all sorts of devices that use 'cold' cathodes - neon lamps and signs, fluorescent backlight tubes, and helium neon laser tubes. Naturally, cold cathode devices don't have much of a warmup requirement.**

**The purpose of a cathode is to feed electrons into the negative end of the positive column (the discharge) so they can variously excite and ionise gas or vapour atoms.**

**Electrons are released from cathodes by the action of the positive ions being accelerated towards them due to an electric field in the vicinity of the cathode.**

**Electrons are broadly released in two ways: Thermal emission and secondary emission.**

- Thermal emission is the primary process used in "hot cathode" lamps which include standard fluorescent tubes. The ions are accelerated towards the cathode through a small cathode voltage (less than 10 volts) and gain just enough energy to heat a small part of the very fine wire electrode when they collide with it. They heat it until it glows dully and electrons are "boiled off", liberated by the thermal energy. This process is very efficient in producing lots of electrons and results in efficient lamps.**
- Secondary emission is a more brutal process for generating**

electrons. It requires an accelerating voltage drop of 130 to 150 volts. It is used in cold-cathode lamps that have relatively huge cylinders of iron for electrodes. These massive electrodes require much too much energy input to make them into thermal emitters. The energetic ions simply "knock" electrons off the metal surface. In so doing they also knock some of the metal off as well, a process called sputtering. The big electrodes have enough material to last before other effects cause lamp failure.

Hot cathode lamps operate in cold cathode mode if the cathode receives too little energy to keep it glowing. The colliding ions are thirty times more energetic than usual and soon sputter enough metal off the tiny electrodes to destroy them.

**Moral:** Pre-heat the electrodes before starting the discharge and maintain auxiliary current in the electrodes if the discharge current is low (e.g, when dimming).

**Failure Mechanisms of Cold Cathode Fluorescent Lamps (From: Victor Roberts (roberv@rpi.edu).)**

- First, all fluorescent lamps, be they hot cathode, cold cathode or electrodeless will suffer from phosphor degradation. The rate of this degradation is a function of the type and amount of phosphor, the type of glass used for the tube, the temperature of the phosphor & glass and the intensity of the UV flux from the discharge. If these parameters are the same, then the type of electrodes does not make any difference, except perhaps at the ends of the tube.
- Second, many hollow cold cathodes contain a coating on the inner surface to improve operation. When this coating is degraded the lamp will be harder to start and therefore might not start if the starting voltage is not high enough.
- Third, due to their high cathode fall voltages, there will often be significant sputtering of cathode material from the surface of a cold cathode. Depending upon the design of the lamp and cathode, this sputtered material can end of up the walls of the lamp where it is

unsightly at best, and may absorb significant light at worst.

- Fourth, cold cathodes tend to "consume" the active gas in a discharge. Due to the reasonably high cathode fall voltages, ionized gas atoms get buried in the surface of the cathode at a slow rate. In fact, this phenomena is used to make a very effective high vacuum pump. Also, in many HeNe lasers that use cold cathodes, a gas reservoir was added so that the loss of Ne, the dominant excited species, would not significantly change the He:Ne balance which is essential for proper laser action. In a modern fluorescent lamp, where the amount of excess mercury is reduced to prevent disposal problems, consumption of mercury by a cold cathode could be another life-limiting factor.

## Comments on Small Inverter Powered Fluorescent Lamps

(From: Paul Bealing (paul@pmb.co.nz).)

Many small low cost inverters use a 2 transistor (one quite small) self oscillating circuit. Simply minimum function, low cost. These circuits can be quite efficient at low power levels. I have seen them used up to 50 watts.

Losses are usually in the transformer and the switching transistors. As the currents increase, the losses usually increase for a given power output.

The lamp requires a high voltage, usually 300 to 500 V, to strike. The voltage depends on the length/wattage of the lamp. Once struck, the current through the lamp is limited to achieve the wattage. The voltage across a small running lamp will be in the order of 60 to 100 volts AC.

Many simple inverters use a series resonant circuit to generate the high strike voltage, which is disabled by the run current.

A couple of years ago I designed an inverter for a PL11 11 Watt lamp based on a switchmode power supply controller IC, 2 power mosfets, and a push-pull transformer, running at about 200 kHz. The main application was in diesel locomotives running from 75 V DC. I've had the circuit

**operating down to 10V DC (different transformer winding). The primary current rises and the dissipation increases.**

## **Operating a Fluorescent Lamp on DC**

**"I have a application in mind that will use a DC power source around 100 volts and fluorescent lighting. What kinds of voltage do I need to sent the fluorescent? Are there any good sources of info. for the circuitry I would need?"**

**(From: Don Klipstein (don@Misty.com).)**

**If it is a preheat tube of 22 watts or less, the cheap-and-dirty way to do it is to use a normal preheat fixture. The only change is to add a resistor in series with the ballast. This resistor should be maybe 100 ohms for 20 and 22 watt lamps, slightly higher for lower wattage ones. It should be able to safely dissipate a wattage comparable to that of the lamp. Of course, you are now wasting significantly more power as heat.**

**The above includes most simple "PL"/twin-tube compact fluorescent lamps with removable bulbs with two pins, as well as most compact fluorescent bulbs with "choke" type ballasts running from 120 volts AC.**

**Should you need anything more energy-efficient than this, then there is the world of electronic ballasts.**

**BTW, most low-power-factor screw-in 120 VAC compact fluorescent lamps with electronic ballasts work fine "as-is" with about 160 volts DC or squarewave.**

## **Ballasts and PCBs (The Hazmat Type)**

**(From: David Morris (allane@ix.netcom.com).)**

**Ballasts that were made after the late 70's do not contain PCB's. I spoke with an Advance and GE ballast rep. a few years ago about this and I was told the only sure-fire method to tell that there are no PCB's is if the ballast says no PCB's. Any ballast that doesn't say that has a better than 80% chance of having it. The amount in the ballast is VERY minute. Less**

than a thimble full. It is used to cool a capacitor in the ballast. Since he said the light is about 12 years old, I am quite certain that the ballast does not contain PCB's. In our state, it is legal to dispose of these ballasts in a limited quantity in your local landfill or throw them in the trash. Larger quantities require Hazmat disposal methods. Our company policy is to leave any old ballasts that is not marked 'no PCB's" with the customer for their disposal.

As a side note, I read in one of the Electrical trade rags that the liquid that replaced PCB's is testing out to be more dangerous than PCB's themselves. Go figure!! :-)

As for catching fire, ballasts contain a thermal protector that will cut the power if the ballast gets too hot. Only real old ballasts do not have this feature. Ballasts marked Class P have this protection. It is very rare for one of these ballasts to actually catch fire, although it does happen. More often, they will smoke up the house if they overheat and the thermal protector fails.

## Driving Cold Cathode Fluorescent Lamps

(From: David VanHorn (dvanhorn@cedar.net).)

[Linear Technology](#) has several extremely detailed app notes written by Jim Williams on this topic. It's more complicated than you might imagine to do it right. Just making the tube light is perhaps only 10% of the job. The rest includes keeping it running a long time without blackening, providing the ability to set the brightness, not loosing all your energy to wiring capacitance, and not creating an EMI nightmare.

Definitely read and understand those app notes, even if you go to another vendor! The good news is that the actual circuit isn't that bad!

## What is the E-Lamp?

The E-Lamp is one of those inventions that sounds like a really good idea but still hasn't (as far as I know) made it into wide scale production. In essence, it is an RF excited compact fluorescent lamp. Some of the E-lamp's basic characteristics include.

- **Fits into standard household light bulb bases.**
- **Radio frequency radiation was emitted, then converted to light.**
- **Dimmable using standard phase control dimmer - no special devices needed.**
- **Very efficient so runs cool and consumes much less power than incandescent lamps (don't know how it compares to compact fluorescents).**
- **Desirable white spectral characteristics.**
- **No filament to wear out (and no wires through glass) so potentially very long life.**

**Aside from cost issues, there could also be concerns with respect to RF emissions effects on health and interference with other household appliances and electronics.**

**(Victor Roberts (robertsv@ix.netcom.com).)**

**E-lamps are electrodeless fluorescent lamps. They use a high frequency or RF magnetic field to create a time varying electric field which in turn drives a discharge which is very similar to the discharge in an ordinary fluorescent lamp. Except for the means by which the discharge is created, these E-lamps are identical to all other fluorescent lamps. There is no magic other than the fact that electrodeless excitation allows for the elimination of the electrodes, so electrode failure and wear out are no longer a problem. Also, electrodeless excitation removes the requirement that the lamp be long and thin to achieve high efficacy. Proof of this is beyond the scope of this note. :) Hence, an electrodeless fluorescent lamp can be more easily made in the shape of an incandescent lamp.**

**There are also electrodeless metal halide lamps and, of course, the electrodeless sulfur lamp.**

## **Introduction**

### **Gas discharge lamp basics**

The use of electrically excited gas discharges significantly predates the invention of the incandescent lamp. Physics labs of yesteryear as well as today have use of a variety of gas filled tubes used for numerous purposes involving light generation including spectroscopy, materials analysis, studies of gas dynamics, and laser pumping. Look through any scientific supply catalog and you will see many different types of gas filled tubes in all shapes and sizes.

Gas discharge lamps are used in virtually all areas of modern lighting technology including common fluorescent lighting for home and office - and LCD backlights for laptop computers, high intensity discharge lamps for very efficient area lighting, neon and other miniature indicator lamps, germicidal and tanning lamps, neon signs, photographic electronic flashes and strobes, arc lamps for industry and A/V projectors, and many more. Gas discharge automotive headlights are on the way - see the section: "HID automotive headlights".

Because of the unusual appearance of the light from gas discharge tubes, quacks and con artists also have used and are using this technology as part of expensive useless devices for everything from curing cancer to contacting the dead.

Unlike incandescent lamps, gas discharge lamps have no filament and do not produce light as a result of something solid getting hot (though heat may be a byproduct). Rather, the atoms or molecules of the gas inside a glass, quartz, or translucent ceramic tube, are ionized by an electric current through the gas or a radio frequency or microwave field in proximity to the tube. This results in the generation of light - usually either visible or ultraviolet (UV). The color depends on both the mixture of gasses or other materials inside the tube as well as the pressure and type and amount of the electric current or RF power.

(At the present time, this document only deals with directly excited gas discharge lamps where an AC or DC electric current flows through the gas.)

Fluorescent lamps are a special class of gas discharge lamps where the electric current produces mostly invisible UV light which is turned into visible light by a special phosphor coating on the interior of the tube. See: [Fluorescent Lamps, Ballasts, and Fixtures](#) for more info.

The remainder of this document discusses two classes of gas discharge lamps: low pressure 'neon' tubes used in signs and displays and high intensity discharge lamps used for very efficient area and directional lighting.

## **Safely Working with Gas Discharge Lamps and Fixtures**

Fixtures for gas discharge lamps may use up to 30,000 V while starting depending on technology. And, they are often not isolated from the power line. Neon signs are powered by transformers or electronic ballasts producing up to 15,000 V or more. Thus, the only safe way to work with these is to assume that they are potentially lethal and treat them with respect.

Hazards include:

- Electric shock. There is usually little need to probe a live fixture. Most problems can be identified by inspection or with an ohmmeter or continuity tester when unplugged.
  - Discharge lamps and fixtures using iron ballasts are basically pretty inert when unplugged. Even if there are small capacitors inside the ballast(s) or for RFI prevention, these are not likely to bite. However, you do have to remember to unplug them before touching anything!

Neon signs using iron transformers are also inert when unpowered - just make sure they are off and unplugged before touching anything!

- However, those using electronic ballasts can have some nasty charged capacitors so avoid going inside the ballast module and it won't hurt to check between its outputs with a voltmeter before touching anything. Troubleshooting the electronic ballast module is similar to that of a switchmode power supply. See the document: [Notes on the Troubleshooting and Repair of Small Switchmode Power Supplies](#)
- The pulse starters of some high intensity discharge lamps may produce up to 30 kV during the starting process. Obviously, contact with this voltage should be avoided keeping in mind that 30 kV can jump over an inch to anyplace it wants!
- Nasty chemicals: Various toxic substances may be present inside high pressure discharge lamps (sodium and mercury) and neon signs (some phosphors). Contact with these substances should be avoided. If a lamp breaks, clean up the mess and dispose of it properly and promptly. Of course,

don't go out of your way to get gut on the broken glass! **WARNING:** Metallic sodium reacts with water to produce hydrogen gas, an explosive. However, it is unlikely that the inner tube of a sodium vapor lamp would break by accident.

- **Ultra-Violet (UV) light:** High intensity discharge lamps generate substantial UV internally, often the particularly nasty UV-B variety. Unless designed to generate UV (for medicinal purposes, photoengraving, or whatever), the short wave radiation will be blocked by the outer glass envelope and/or phosphor coating. However, should the outer envelope break or be removed, the lamp will still operate (at least for a while - some have a means of disabling themselves after a few hours or less of exposure to air). **DO NOT** operate such a lamp preferably at all but if you do, at least take appropriate precautions to avoid any exposure to the UV radiation.

And take care around sharp sheet metal!

---

# Neon Technology

## Neon Lights and Signs

Neon technology has been around for many years providing the distinctive bright glowing signs of commerce of all kinds before the use of colored plastics became commonplace.

Neon tubes have electrodes sealed in at each end. For use in signs, they are formed using the glass blower's skill in the shape of letters, words, or graphics. Black paint is used to block off areas to be dark. They are evacuated, backfilled, heated (bombarded - usually by a discharge through the tube at a very high current) to drive off any impurities, evacuated and then backfilled with a variety of low pressure gasses.

Neon is the most widely known with its characteristic red-orange glow. Neon may be combined with an internal phosphor coating (like a fluorescent tube) to utilize neon's weak short-wave UV emissions. A green-emitting phosphor combines with neon's red-orange glow to make a less-red shade of orange. A blue-emitting phosphor may be used to result in a hot-pink color. Neon may be used in tubing made of red glass to produce a deep red color.

Other colors are usually produced by tubing containing argon and mercury vapor. The mercury is the active ingredient, the argon produces negligible radiation of any kind but is important for the "neon" tubing to work. Clear tubing with mercury/argon glows a characteristic light blue color.

Such tubing is often phosphor-coated on the inside, to utilize the major short-wave UV emission of low-pressure mercury. In this way, much of the "neon" tubes in use are a kind of fluorescent lamp.

Phosphor-coated tubing with mercury can glow blue, blue-green, slightly white-ish green, light yellow, bright pink, light purple, or white.

Use of mercury vapor with colored tubing (with or without phosphors) can provide a lime-green or deep blue or deep violet-blue.

Nowadays, nearly all "neon" tubing contains neon or mercury vapor (with argon), whether with or without phosphors and/or colored glass. Well in the past, various colors were obtained (generally at reduced efficiency) by using different gases.

For example, helium can produce a white-ish orange light in shorter length, smaller diameter tubing. Hydrogen in this case makes a lavender-hot-pink color. These gases glow more dimly with duller color shades in larger tubing. Krypton makes a dull greenish color. Argon makes a dimmish purple color. Nitrogen (generally in shorter length tubing) makes a grayish purple-pink color. Xenon, which is expensive, generally glows with a dim bluish gray color, along with the glass tubing giving a slight dim blue fluorescence from very short wave UV from the xenon discharge. Krypton also often causes a dim blue glass fluorescence.

For general information on neon signs and technology including a neon FAQ, see:

- [The Internet's Neon Shop](#)
- [Neon and Lighting Channel Page](#)

## Power Supplies for Neon

Extremely high voltage power supplies are used to power neon signs. In the past, this was most often provided by a special current limited HV line transformer called a neon sign or luminous tube transformer. The output is typically 6,000 to 15,000 VAC at 15 to 60 mA. One such unit can power 10s of feet of tubing. This transformer acts as its own ballast providing the high voltage needed for starting and limiting the running current as well. Warning: the output of these transformers can be lethal since even the limited current availability is relatively high.

As with everything else, the newest neon sign power supplies use an electronic AC-AC inverter greatly reducing the size and weight (and presumably cost as well) of these power supplies by eliminating the large heavy iron transformer.

Small neon lamps inside high-tech phones and such also use solid state inverters to provide the more modest voltage required for these devices.

(From Jeff Zurkow (jeff@atrox.com).)

In the course of looking for a neon sign transformer, I discovered the following line of flyback-type HV power supplies:

- [Evertron High Voltage Neon Power Supplies](#). (Ordering via [Neon Central](#)).

For example: the Evertron 2610 is rated at 10 kVAC, 10 mA for \$45.50. The model 2610D has dimming for \$56.50. There are also 3.5 kVAC and 6 kVAC models that are somewhat less expensive. The 3.5 kV unit runs on 12 VDC, the others on 115 VAC.

The neon bender I visited was kind enough to give me a couple of older units - one made by Evertron (Everbrite Electronics, model 3210) and the other by Transfotek international. One of these (the Evertron) works, but he had a whole pile of dead ones from various makers. He considers all of the electronic ones unreliable (compared to conventional NSTs), but that's probably in 24/7 service. They ought to be OK for intermittent use in laser and HV projects if the output voltage and current are sufficient.

[Evertron Model 3210 Gas Tube Power Supply](#) shows the schematic of this unit. It has a pair of power MOSFETs driving a flyback style high voltage transformer, with a whole bunch of open-wound primaries and a potted secondary.

I did plug the thing in and was rewarded with an impressive arc at about 1 cm electrode spacing (bare wires).

The Transfotek unit is completely potted, except for the AC input and on-off switch. And completely dead.

## Neon Sign Installation

(From: Clive Mitchell (clive@emanator.co.uk)).

The voltage required to light a run of neon tube is variable according to diameter, gas type, pressure and number of tubes in circuit.

For a 15 kV transformer and neon gas you could run:

- 33 feet of 10 mm tube,
  - 45 feet of 12 mm tube,
  - 60 feet of 15 mm tube,
  - 78 feet of 20 mm tube,
  - 102 feet of 25 mm tube.
- 
- Deduct one foot of tube for every pair of electrodes (tube section).

These figures are based on a chart in "Neon Techniques And Handling" which is the traditional neon reference.

The larger the diameter of the tube, the lower the voltage required, and the dimmer it will be. Transformers come with different current ratings. For larger diameter tubes, you can increase brightness by using a higher current.

- Don't attempt to run too much tube on a transformer, since it can cause breakdown of the insulation and destroy the transformer.
- Don't attempt to run too little tube on a transformer, since it can cause overheating and burn-out.

It is absolutely imperative that proper neon sign cabling and insulators are used, and that all local regulations are strictly followed. If you are intending to work with neon tubing, you should learn as much as possible first, since neon poses both a shock and serious fire risk if installed incorrectly.

The lengths quoted above may vary according to the transformer you use. The transformer manufacturers usually provide their own loading charts on request.

Anyone using this information does so at their own risk, and I cannot be held responsible for any horrible smouldering deaths experienced by incompetent dabblers, etc.

(From: Kenny Greenberg (kenny@neonshop.com)).

The neon circuit is not so simple. In a standard AC circuit neon acts like a diac - high breakover voltage followed by fast drop in resistance. Neon sign transformers are designed to 'leak' and thus self-regulate. You have a combined resistive and reactive circuit.

But take heart, it's all been figured out. :-)

There are a few variables:

1. A 'purely' neon filled tube (generally in the red range) has a higher voltage requirement than an argon-mercury tube (whose discharge is usually providing UV for phosphor with a wide range of colors).
2. The voltage requirement varies inversely with the tubing diameter. That is large diameters of a lower voltage requirement than small diameters.
3. The voltage requirement varies directly with tubing length.
4. The number of units (or pairs of electrodes) increases the voltage requirement because the electrodes have a voltage drop.
5. Wiring methods and length will also contribute to the formula but that's a whole 'nuther discussion.

You can download a free [Neon Voltage Calculator for Windows](#).

An old tech method for determining the voltage requirement is to use a Variac on a large neon transformer. Bring the voltage down to where the neon just flickers. This should be at a point approximately 78% of the required voltage.

A better way involves using a milliammeter to measure open circuit and closed circuit current and an rms voltmeter to measure actual operating voltage.

## Problems With Neon

These fall into two categories:

1. Power supply - like fluorescent ballasts, the high voltage transformers can fail resulting in reduced (and inadequate) voltage or no power at all. Since they are already current limited, overheating may not result and any fuse or circuit breaker may be unaffected. The use of a proper (for safety if nothing else) high voltage meter can easily identify a bad transformer. If a high voltage probe is not available, position (with power off!) the ends of well insulated wires connected to the outputs of the transformer a fraction of an inch apart (about 1/32" per 1,000 V of transformer rating) and apply the power from a safe distance. If a hot arc results, the transformer is likely good (at least when cold).
2. Neon tubes - these may lose their ability to sustain a stable discharge over time as a result of contamination, gas leakage, or electrode damage (either from normal wear or due to excessive current). Check for obvious damage such as a cracked tube or cracked seals around the electrodes or badly deteriorated electrodes. A previously working tube that now will not strike or maintain a stable discharge on a known good transformer will need to be replaced or rebuilt.

## Comments on Little Neon Bulbs and Tubes

The comments below relate to the little neon bulbs used as indicators, for voltage regulation or limiting, and other applications in all sorts of electronic equipment.

(From: Mark Kinsler (kinsler@frognet.net).)

Neon lamps can be used for voltage limiters and oscillator elements and just about anywhere else that a non-linear element is needed. The tremolo circuit in the classic Fender guitar amplifier uses a neon lamp relaxation oscillator. The neon lamp is heat-shrunked to a CdS photocell in the volume control circuit.

Less well-known is the fact that you can make a pretty reasonable computer logic element out of them: I believe that this was tried sometime in the 1940's.

Another cool use is as a radiation sensor: you bias the lamp so that it almost turns on, after which any

incident radiation: radio waves (as in police radar), light, or gamma radiation will kick the lamp on. There were various circuits in the 1950's that used neon lamps to detect uranium, fight nuclear destruction, or escape the newly-developed police radar guns.

And finally, there's the mystery elevator button. Again, you bias the lamp so that it almost, but not quite, turns on. If you enclose the lamp properly, it'll stay off until you touch it. The electric field variation from your touch will turn the thing on, and it'll stay on. Such lamps are used in some self-service elevators: once the lamp is fired, the low voltage across it is sensed by the ancient logic circuits of the elevator controller and it'll send the elevator to the appropriate floor. These were a lot of fun in the 1960's. I think the controllers used vacuum tubes.

The problem with neon lamps is that they're not so reliable. Their turn-on voltage isn't particularly stable. This means that oscillators have a tendency to drift as the lamps age or when ambient radiation changes. I suspect that the computers are slow and cranky, and the radiation detector isn't anything you'd wish to stake your life or drivers' license on.

Still, they're great fun, and I have a fine time with them. One other use: hang a neon lamp across a telephone line to detect the ring signal. Place it in series with a piezo beeper, and you've got a reliable telephone ringer.

## High Intensity discharge Lamps

### High Intensity Discharge (HID) Lamp Technology

These have been used for a long time in street, stadium, and factory lighting. More recently, smaller sizes have become available for home yard and crime prevention applications. Like other gas discharge lamps, these types require a special fixture and ballast for each type and wattage. Unlike fluorescents, however, they also require a warmup period.

There are three popular types:

- High pressure mercury vapor lamps contain an internal arc tube made of quartz enclosed in an outer glass envelope. A small amount of metallic (liquid) mercury is sealed in an argon gas fill inside the quartz tube. After the warmup period, the arc emits both visible and invisible (UV) light. High pressure mercury vapor lamps (without color correction) produce a blue-white light directly from their discharge arc. Phosphors similar to those used for fluorescent lamps can be used to give these a color closer to natural light. (Without this color correction, people tend to look like cadavers). Mercury vapor lamps have the longest life of this class of bulbs - 10,000 to 24,000 hours. The technology was first introduced in 1934 and was the first of the commercially viable HID lamps.

- Metal halide lamps are constructed along similar lines to mercury vapor lamps. However, in addition to the mercury and argon, various metal halides are included in the gas fill. The most popular combination is sodium iodide and scandium iodide. A few versions of this lamp have lithium iodide as well. A much less common version has sodium iodide, thallium iodide, and indium iodide. The use of these compounds increases the luminous efficiency and results in a more pleasing color balance than the raw arc of the mercury vapor lamp. Thus, no phosphor is needed to produce a color approaching that of a cool white fluorescent lamp with more green and yellow than a mercury vapor lamp (without correction). Some metal halide lamps have a phosphor that adds some orange-ish red light, but not much, since the metal halide arc does not emit much UV.
- High pressure sodium vapor lamps contain an internal arc tube made of a translucent ceramic material (a form of aluminum oxide known as "polycrystalline alumina"). Glass and quartz cannot be used since they cannot maintain structural strength at the high temperatures (up to 1300 degrees C) encountered here, and hot sodium chemically attacks quartz and glass. Like other HID lamps, the arc tube is enclosed in an outer glass envelope. A small amount of metallic (solid) sodium in addition to mercury is sealed in a xenon gas fill inside the ceramic arc tube. Some versions of this lamp use a neon-argon mixture instead of xenon. Basic operation is otherwise similar to mercury or metal halide lamps. High pressure sodium vapor lamps produce an orange-white light and have a luminous efficiency much higher than mercury or metal halide lamps.

Since hot liquid sodium often eventually leaches through things and can get lost this way, sodium lamps have a surplus of sodium in them. Proper lamp operation depends on the sodium reservoir being within a proper temperature range.

Mercury vapor lamps are roughly as efficient as fluorescent lamps. Metal halide lamps are much more efficient, generally around 50 to 75 percent more efficient than fluorescent lamps. High pressure sodium lamps are roughly twice as efficient as fluorescent lamps.

Unlike fluorescent lamps, HID lamps will give full light output over a wide range of temperatures. This often makes HID lamps more suitable than fluorescent lamps for outdoor use.

When cold, the metallic mercury or sodium in the arc tube is in its normal state (liquid or solid) at room temperature. During the starting process, a low pressure discharge is established in the gases. This produces very little light but heats the metal contained inside the arc tube and gradually vaporizes it. As this happens, the pressure increases and light starts being produced by the discharge through the high pressure metal vapor. A quite noticeable transition period occurs when the light output increases dramatically over a period of a minute or more. The entire warmup process may require up to 10 minutes, but typically takes 3 to 5 minutes. A hot lamp cannot be restarted until it has cooled since the voltage needed to restrike the arc is too high for the normal AC line/ballast combination to provide.

## **Problems With High Intensity Discharge Lamps**

While HID lamps have a very long life compared to incandescents (up to 24,000 hours), they do fail. The ballasts can also go bad. In addition, their light output falls off gradually as they age. For some types, light output may drop to half its original value towards the end of their life.

A lamp which is cycling - starting, warming up, then turning itself off - is probably overheating due to a bad bulb or ballast. A thermal protector is probably shutting down the fixture to protect it or the arc is being extinguished on its own. However, make sure that it is not something trivial like a photoelectric switch that is seeing the light from the lamp reflected from a white wall or fence and turning the fixture off once the (reflected) light intensity becomes great enough!

Sodium lamps sometimes "cycle" when they have aged greatly. The arc tube's discolorations absorb light from the arc, causing the arc tube to overheat, the sodium vapor pressure becomes excessive, and the arc cannot be maintained. If a sodium lamp "cycles", the first suspect is an aging bulb which should be replaced. Sodium lamp "cycling" used to be very common, but in recent years the lamp manufacturers have been making sodium lamps that are less prone to cycling.

If you have more than one fixture which uses **\*\*identical\*\*** bulbs, swapping the bulbs should be the first test. If the problem remains with the fixture, then its ballast or other circuitry is probably bad. Don't be tempted to swap bulbs between non-identical fixtures even if they fit unless the bulb types are the same.

Warning: do not operate an HID lamp if the outer glass envelope is cracked or broken. First, this is dangerous because the extremely hot arc tube can quite literally explode with unfortunate consequences. In addition, the mercury arc produces substantial amounts of short wave UV which is extremely hazardous to anything living. The outer glass normally blocks most of this from escaping. Some lamps are actually designed with fusible links that will open after some specified number of hours should air enter the outer envelope. Thus, an undetected breakage will result in the lamp dying on its own relatively quickly.

## **Troubleshooting a Discharge Lamp Fixture**

(From: Greg Anderson (a3a30878@bc.sympatico.ca).)

The following applies directly to high pressure sodium lamps. It may also be used for metal halide and mercury vapour lamp problems as long as references to the starter are ignored. (Metal halide and mercury vapour lamps do not have starters, except for "instant re-light" metal halide lamps.)

The starter produces about 2 to 5 kV spikes to ionize the gas in the lamp. The starter normally has a triac across the ballast and a diac trigger cct. When open cct voltage is across the lamp, the diac fires the triac to short the ballast, the triac then opens. This "kick" produces the voltage spike. Once the gas ionizes, the lamp impedance drops then gradually increases as the lamp warms up. The lamp running voltage is about 1/2 of the open cct voltage

With the lamp removed and power on, you can normally hear a good starter "ticking".

The open circuit voltage is stamped on the ballast and is between about 150 and 350 Vac, depending on lamp wattage and ballast. Also, a capacitor is often connected in series with lamp to improve peaking and ballast action.

Steps to follow:

1. Bypass the photo cell - It may be bad
2. Check connections - water, salt, and bird poop are not good for wiring
3. Check the capacitor, if installed - normally they blow-up when bad
4. Check for open/shorted ballast.
5. Power up and check for starter "ticking"
6. REMOVE starter from cct and measure open cct volts
7. Check/Replace lamp
8. Check/replace lamp socket
9. Replace starter
10. Replace complete fixture.
11. Replace electrician. :)

Repairing a starter is not economically viable and often proves that electronic devices contain smoke and sometimes fire.

## **Ballasts and Bulbs Should be Matched!**

HID bulbs generally need specific ballasts, and any given ballast can usually safely and effectively operate only one type or a few types of HID bulbs.

The bulb wattage must be matched to the ballast. A smaller bulb will usually be fed a wattage close to what the proper bulb takes, and will generally overheat and may catastrophically fail. Any catastrophic failures may not necessarily happen quickly. A larger bulb will be underpowered, and will operate at reduced efficiency and may have a shortened lifetime. The ballast may also overheat from prolonged operation with an oversized bulb that fails to warm up.

See [The Discharge Lamp Mechanics Document](#) (rather technical) for why it can be bad to underpower an arc discharge lamp.

Even if the ballast and bulb wattages match, substitutions can be limited by various factors including but not limited to different operating voltages for different bulbs. Examples are:

1. Pulse-start sodium lamps often have a slightly lower operating voltage than metal halide and mercury lamps of the same wattage, and ballasts for these sodium bulbs provide slightly more current than mercury and metal halide ballasts for the same wattage would. The higher current provided by the pulse-start sodium ballast can overheat mercury and metal halide lamps. Mercury and metal halide lamps may also "cycle" on and off in lower voltage sodium ballasts, such as many 50 to 100 watt ones.

2. Metal halide lamps have an operating voltage close to that of mercury lamps in many wattages, but have stricter tolerances for wattage and current waveform. Metal halides also usually need a higher starting voltage. Most metal halide lamps 100 watts or smaller require a high voltage starting pulse around or even over 1,000 volts.

175 to 400 watt metal halide lamp ballasts can power mercury lamps of the same wattage, but the reverse is not recommended. Mercury lamps 50 to 100 watts will work on metal halide ballasts, but hot restriking of mercury lamps 100 watts or smaller on metal halide lamps may be hard on the mercury lamp since the starting pulse can force current through cold electrodes and the starting resistor inside the mercury lamp.

3. 1,000 watt mercury lamps come in two operating voltages, one of which is OK for 1,000 watt metal halide ballasts. A few wattages of pulse-start sodium (150 watts?) come in two voltages.

A low voltage lamp in a high voltage ballast will be underpowered, resulting in reduced efficiency, possible reduced lamp life, and possible ballast overheating. A high voltage lamp in a low voltage ballast will usually cycle on and off, operate erratically, or possibly overheat. This will usually result in greatly reduced lamp life in any case.

4. One class of sodium lamps is made to work in mercury fixtures, but these only work properly with some mercury ballasts, namely:

- 'Reactor' (plain inductor) ballasts on 230 to 277 volt lines.
- 'High leakage reactance autotransformer' ballasts, preferably with an open circuit voltage around 230 to 277 volts. NOT 'lead', 'lead-peak' nor any metal halide ballast!

These sodium lamps may suffer poor power regulation and accelerated aging in the wrong mercury ballasts, especially after some normal aging changes their electrical characteristics. Also, these lamps may overheat and will probably have shortened life with pulse-start sodium ballasts.

5. Many sodium lamps require a high voltage starting pulse provided only by ballasts made to power such lamps.

## **Operation of Discharge Lamps on DC**

Sometimes, one may want to run a discharge lamp on DC. There are two possible reasons:

- Only DC power is available.
- To reduce flicker. Sometimes, the lamp performs differently for electricity flowing in one direction than the other. In addition, the positive and negative ends of the arc can make different amounts of light, resulting in a flicker rate equal to the AC frequency rather than twice the AC frequency.

However, end flicker is usually not significant. In HID lamps, the total arc size is generally small. Only if the fixture has a reflector that causes some areas to receive light from only one end of the arc should end flicker be significant. In most multi-tube fluorescent fixtures, the tubes are usually in series pairs with the two tubes in any pair oriented in opposite directions. This generally reduces end flicker effects, especially in fixtures with diffusing lenses.

Bulbs should perform close enough to identically in both directions, unless the bulb is near the end of its life. In such a case, one electrode deteriorates enough to affect performance before the other does. However, this generally indicates a need to replace the bulb rather than to attempt to make it flicker less.

If you want to rectify the AC to provide the bulb with DC, use a bridge rectifier after the ballast. Most ballasts, including all "iron" types, require AC of the proper voltage and frequency to work. Do this only if only two wires feed the bulb. Otherwise, diodes in the bridge rectifier may short parts of the ballast to each other, at least for half the AC cycle. Problems can also occur with fluorescent ballasts with filament windings. Only fully isolated filament windings or separate filament transformers should be used if you rectify the output of a ballast with filament windings. Also, the bridge rectifier must withstand the peak voltage provided by the ballast.

If the power supply is DC of adequate voltage, you need a resistor ballast or an electronic ballast specifically designed to run your lamp from the available DC voltage. "Iron" ballasts only limit current when used with AC. Preheat fluorescent lamps operated from DC supplies and without special ballasts need both the usual "iron" ballast to provide the starting "kick" and a resistor to limit current.

In addition, most discharge lamps are only partially compatible with DC, and some are not compatible at all.

Mercury vapor and fluorescent lamps generally work on DC. However, the life may be shortened somewhat by uneven electrode wear.

Fluorescent lamps may get dim at one end with DC. Since the mercury vapor ionizes more easily than the argon, some of it exists as positive ions. This can cause the mercury to be pulled to the negative end of the tube, resulting in a mercury shortage at the positive end. This is more of a problem with longer length and smaller diameter tubes.

Some fluorescent fixtures made for use where the power available is DC have special switches to reverse polarity every time the fixture is started. This balances electrode wear and reduces mercury distribution problems.

Mercury vapor lamps generally work OK with DC, but some may only reliably work properly if the tip of the base is negative and the shell of the base is positive. This is because the starting electrode does its job best when it is positive.

In addition, if the nearby main electrode is positive, it may cause a thin film of metal condensation that shorts the starting electrode to the nearby main electrode. This may make some brands, models, and sizes of mercury lamps unable to start after some use. The negative main electrode will not release as much vaporized electrode material, since the electrode material easily forms positive ions making the electrode material vapor tend to condense on the electrode rather than condense on nearby parts of the arc tube.

Metal halide and sodium lamps should not get DC. Use these only with ballasts that give the bulb AC. In metal halide lamps, ions from the molten halide salts can leach into hot quartz in the presence of a DC electric field. This can cause strains in the quartz arc tube. At the ends of the arc tube, electrolysis may occur, releasing chemically reactive halide salt components that can damage the arc tube or the electrodes. The arc tube may crack as a result.

There are a few specialized metal halide lamps that are made to work on DC. These often have asymmetrical electrodes and/or short arc lengths. These lamps often also must be operated only in specific positions, and only with the type of current they were designed for in order to achieve the proper distribution of active ingredients within the arc tube and to achieve proper electrode usage. For example, some of these lamps may go wrong in some way or another with AC.

In high pressure sodium lamps, which contain both sodium and mercury, the sodium forms positive ions more easily than the mercury does and drifts towards the negative electrode. The positive end can go dim from a lack of sodium. In addition, if any part of the arc tube is filled with a mixture containing excessive sodium and a lack of mercury, heat conduction from that part of the arc to the arc tube will increase. Furthermore, the hot arc tube may suffer electrolysis problems over time in the presence of sodium ions and a DC electric field.

Low pressure sodium lamps should not get DC for the same reasons. The sodium is likely to drift to the negative end of the arc tube, and hot glass will almost certainly experience destructive electrolysis problems if exposed to hot sodium or sodium ions and a DC electric field.

## **Special purpose HID lamps such as xenon and HMI**

The usual general purpose HID lamps are mercury vapor, metal halide, and high pressure sodium. You can get these at home centers, although usually only in wattages up to 400 watts. These versions of HID lamps are optimized for high efficiency, long life, and minimized manufacturing cost.

However, the arc surface brightness of these lamps is roughly equal to the surface brightness of incandescent lamp filaments and general purpose halogen lamp filaments. For some applications such as endoscopy and movie projection, it is necessary to have a much more concentrated light source. This is where specialized HID lamps such as short arc lamps and HMI lamps come in.

Short arc lamps consist of a roughly spherical quartz bulb with two heavy duty electrodes spaced only a few millimeters apart at the tips. The bulb may contain xenon or mercury or both. Mercury

short arc lamps have an argon gas fill for the arc to start in.

In a short arc lamp, the arc is small and extremely intense. The power input is at least several hundred and more typically a few thousand watts per centimeter of arc length. The operating pressure in the bulb is extremely high - sometimes as low as 20 atmospheres, more typically 50 to over 100 atmospheres. These lamps are an explosion hazard!

Mercury short arc lamps are used when a compact, intense source of UV is needed or where one cannot have the high voltage starting pulses needed for xenon short arc lamps. Mercury short arc lamps are slightly more efficient than xenon ones. The pressure in a mercury short arc lamp does not need to be as high for good efficiency as in a xenon one, but is still tremendous.

Xenon short arc lamps are more common than mercury ones, since they do not require time to warm up the way mercury lamps do and have a daylight-like spectrum. A disadvantage of xenon is the requirement of a very high voltage starting pulse - sometimes around 30 kilovolts!

Xenon short arc lamps are used for movie projection and sometimes for searchlights. Lower wattage ones are used in specialized devices such as endoscopes.

HMI lamps are metal halide lamps with a more compact and more intense arc. The arc is larger and less intense than that of a short arc lamp. Typical power input is hundreds of watts per centimeter of arc length, but gets to a few kilowatts per centimeter in the largest ones.

HMI lamps are used in some spotlights. They are used in some endoscopes and projection applications where the intensity of the HMI arc is adequate since they cost less and last longer and are more efficient than true short arc lamps.

There are all sorts of HMI and similar lamps, including HTI lamps and the lamps used in HID auto headlights.

## **HID Automotive Headlights**

First there were gas lamps, then there were electric bulbs, then sealed beam, then halogen. Now, get ready for - drum roll please! - high intensity discharge lamps with sophisticated controllers. High-end automobiles from makers like BMW, Porsche, Audi, Lexus, and now Lincoln are coming equipped with novel headlight technology. No doubt, such technology will gradually find its way into mainstream automobiles - as well as other applications for mortals.

Among the potential advantages of HID headlights are higher intensity, longer life, superior color, and better directivity:

- Light intensity - HID lamps are about 3 times as efficient as halogen lamps. Thus, even when the efficiency of the DC-DC converter is taken into consideration, the lower power input can actually result in much brighter headlights than are possible with halogen bulbs.

This reduced power also leads to cooler operation and less drain on the battery and alternator.

- Lifespan - an HID lamp can be expected to last 2,700 hours or more and thus covered under the bumper to bumper warranty for 100,000 miles. As a practical matter, the HID lamp may outlast the automobile. Since warranty replacement of headlights turns out to be a significant expense, there is strong incentive to see this long lived technology take off.
- Spectral output - the light from the HID lamp is richer in blue (and more like daylight) than halogen bulbs. This turns out to enhance reflectivity of signs and road markings.
- Beam pattern - the small arc size of the HID lamp permits the optical system to be optimized to direct light more effectively to where it is needed and prevent it from spilling over to where it is not wanted.

In order to make this practical - even for a \$40,000 Lexus - special DC-DC converter chips have been designed specifically with automotive applications in mind. These, along with a handful of other basic electronic components, implement a complete HID headlight control system.

The HID bulb itself is similar in basic design to traditional HID lamps: Two electrodes are sealed in a quartz envelope along with a mix of solids, liquids, and gasses. When cold, these materials are in their native state (at room temperature) but are mostly gases when the lamp is hot. Starting of these lamps may require up to 20 KV to strike an arc but only 50 to 150 V to maintain it. Lamps may be designed to operate on either AC or DC current depending on various factors including the size and shape of the electrodes. A unique set of ballast operating parameters must be matched to each model HID bulb.

Of all the problems that had to be addressed for HID headlights to become practical (aside from the cost), the most significant was the warmup time. As noted in the section: "High intensity discharge (HID) lamp technology", common HID lamps require a warmup period of a few minutes before substantially full light output is produced. This is, of course, totally unacceptable for an automotive headlight both for cold start (imagine: "Honey, I have to go cook the headlights") as well as when they need to be blinked. The warmup problem was solved by programming the controller to deliver constant power to the lamp rather than the more common nearly constant current that would be provided by a traditional ballast. With this twist along with a special lamp design, the lamp comes up to at least 75% of full intensity in under 2 seconds. The controller also provides 'hot strike' capability for blinking (recall that HID lamps typically cannot be restarted when hot). Thus, restarting a hot lamp is absolutely instantaneous.

While this technology is just beginning to appear, expect inroads (no pun intended) into household, office, store, factory, and other area and work lighting. The combination of high efficiency, long life, desirable spectral characteristics, small size, and solid state reliability should result in many more applications in the near future. The nearly instant starting capability addresses one of the major drawbacks of small HID lamps.

If you have some time and money to spare:

(From: Declan Hughes (hughes@aero.tamu.edu).)

Check out: [OSRAM Sylvania Products Inc.](#)

They have a "sample" for sale at \$250.00 for one lamp including the 12 VDC electronic ballast. 42 W total power, 35 W light power, 3,200/2,800 lm output (there are two types, D2S and D2R), 2,000 hours rated lifetime, 91/80 lm/W luminous efficacy, 4,250/4,150 K color temperature, 6,500 cd/cm<sup>2</sup> average luminance, 4.2 mm arc length, burning position horizontal +/- 10 deg., luminous flux after 1 sec. = 25%, max. socket temp. = 180 deg C, any errors are mine.

## Substitution of Metal Halide Lamps?

The following was prompted by a request for info on replacing an (expensive) 250 watt metal halide lamp in a video projector with something else.

I would not substitute this lamp, for many reasons below:

The metal halide lamp requires a ballast. The ballast should only run a 250 watt metal halide lamp of the same arc voltage. You will have to measure the arc voltage yourself after the lamp warms up, and do this without exposing yourself to the nasty UV that some of these things emit but which does not pass through glass. Arc voltages of many specialized metal halide lamps are not widely published and may or may not be available from the lamp manufacturer.

**WARNING:** The strike voltage on these may be several kV which will probably obliterate your multimeter should the arc drop out and attempt to restart while you are measuring it! Either the operating or strike voltage may obliterate you should you come in contact with live terminals! (Special metal halides probably usually only need a couple to a few kV. Xenon metal halide automotive lamps need 6 to 12 kV to strike and 15 to 20 kV for hot restrike. The worst are short arc xenon that may use up to 30 kV or more.)

Most metal halide lamps are AC types and some are DC and you can only use AC lamps on AC output ballasts and DC lamps on DC output ballasts. Different metal halide lamps may have different requirements for starting voltage also.

If you match arc voltage, AC/DC type, and the ballast will start the lamp, you might be in business but good chance not. Many projector lamps have specific cooling requirements and some have specific burning position requirements. Metal halide lamps may prematurely fail (possibly violently!) if they overheat, in addition to being off-color. If overcooled, they are more like mercury lamps and will be off-color and have reduced light output. In addition, some metal halide lamps have a halogen cycle in them to keep the inner surface of the bulb clean, and that may not work if the lamp is overcooled and not enough of the chemicals in the bulb get vaporized. This could also even make the lamp fail.

If you get the alternate lamp to operate satisfactorily, the arc may be in a different location from that of the original lamp. The arc may be of a different shape or size than that of the original lamp. This can affect your projection. Your projection may not get much light or may have illumination of only part of the picture.

The arc may have a different color or spectrum, which can affect the color rendering of what's being projected. Metal halide arcs are often not of uniform color, and if the alternate lamp has a less color-uniform arc than the original lamp then your pictures may have strange color tints in them.

As for using a halogen instead of metal halide? You will get less light, as well as problems from the filament having a different shape or size than the original metal halide arc does. Most likely, the filament is larger or longer than the arc and this will reduce the percentage of the light being utilized. Should you try a halogen lamp hack, you will almost certainly have to bypass the metal halide ballast. And halogen lamps emit more infrared than metal halide lamps of the same wattage - you might overheat the source of your image (e.g., LCD panel or transparency).

I would not recommend substituting a projector lamp for all of these reasons. This should only be tried at your own risk and only by those that are very familiar with all of the characteristics of the lamps in question - including being familiar with burning position requirements, cooling requirements, shape and size of the light-emitting region, etc.

Projector lamps in general, and especially specialized HID lamps, should be used only in equipment made specifically to use the particular lamps in question, or by those who know about these things well enough to make their own ballasts and know the other messy things about these lamps. And you may not save much by using a different lamp - specialized metal halide lamps are all expensive.

And for anyone shopping for any sort of projector - look into price, availability, and life expectancy of lamps!

---

## Low Pressure Sodium Lamps

(Portions from: Bruce Potter (s60231@aix2.uottawa.ca))

Low pressure sodium lamps are the most efficient visible light sources in common use. These lamps have luminous efficacies as high as 180 lumens per watt.

A low pressure sodium lamp consists of a tube made of special sodium-resistant glass containing sodium and a neon-argon gas mixture. Since the tube is rather large and must reach a temperature

around 300 degrees Celsius, the tube is bent into a tight U-shape and enclosed in an evacuated outer bulb in order to conserve heat. As an additional heat conservation measure, the inner surface of the outer bulb is coated with a material that reflects infrared but passes visible light. This material has traditionally been tin oxide or indium oxide.

The electrodes are coiled tungsten wire coated with thermionically emissive material, and somewhat resemble the electrodes of fluorescent lamps. Unlike most fluorescent lamps, low pressure sodium lamps have only one electrical connection to each electrode and the electrodes cannot be preheated.

The gas mixture is a "Penning" mixture, consisting mainly of neon with a small amount of argon. Depending on who you listen to, this mixture is .5 to 2 percent argon, 98 to 99.5 percent neon. More argon-rich mixtures around 98-2 may be favored today since hot glass has some ability to absorb argon from a low pressure electric discharge. Ideally the mixture should be only a few tenths of a percent argon, in order to ionize most easily and do so much more easily than pure neon or pure argon.

A significant surplus of sodium is contained in the glass arc tube since the glass may absorb or react with some of the sodium. The sodium vapor pressure is controlled by the temperature of the coolest parts of the arc tube. When the arc tube reaches a proper temperature, further heating is reduced by the lamp's efficiency at producing light instead of heat.

The arc tube has dimples in it, which are normally slightly cooler than the rest of the arc tube. This causes the sodium metal to collect in the dimples instead of covering a larger portion of the arc tube and blocking light.

The low pressure sodium lamp usually requires 5 to 10 minutes to warm up.

The light of low pressure sodium consists almost entirely of the orange-yellow 589.0 and 589.6 nm sodium lines. This light is basically monochromatic orange-yellow. This monochromatic light causes a dramatic lack of color rendition - everything comes out in an orange-yellow version of black-and-white! This can cause some confusion in parking lots since cars become more alike in color.

Some basically red and reddish color fluorescent inks, dyes, and paints can fluoresce red to red-orange from the yellow sodium light and these will stand out in sodium light with color differing from that of the sodium light.

Another disadvantage of low pressure sodium light is that many objects will look darker than they would with an equal amount of other light. Red, green, and blue objects look dark under low pressure sodium light. Most other sources of light of sodium-like color such as "bug bulbs" have significant red and green output and will render red and green objects at least somewhat normally.

---

# Chapter 2) Introduction

---

## 2.1) Scope of this document

The following types of questions arise quite often:

\* Question: Will my U.S. made TV and VCR work in Europe?

Answer: A simple step down transformer to convert from 220 to 110 V will probably permit them to work together (i.e., to play previously recorded tapes) but you will not be able to receive any cable or broadcasts.

\* Question: I have a microwave oven but will be moving to France. Would I be

better off selling it or getting a power adapter?

Answer: Due to the high wattage of a microwave oven, converting the power will be costly. Sell it and buy a new one at your destination.

\* Question: Should I bring by European appliances back to the U.S.?

Answer: This depends on the specific appliances. See the remainder of this document!

\* Question: Will my Onkyo receiver work in Japan?

Answer: Not without some modifications - which may not be worth it.

We cannot generally provide an answer based on your exact model equipment and the specific standards in use. There are too many variations to deal with in this sort of document. However, the information contained herein in conjunction with the type and specifications of the equipment you own and the power and standards in use at your destination should enable you to make an informed decision.

A great deal of specific country information is available at:

\* <http://www.cris.com/~kropla/electric.htm>

including power, plug configurations, telephones, and TV standards.

This should help you issues involved before you reach your destination!

In addition, we deal with general issues related to adapting entertainment equipment and appliances to different power and the implications of reduced or increased voltage and frequency.

Note: this initial release will concentrate mostly on power issues. Later, we will deal with video, communications, and phones systems. For those, the documents: "[Notes on Video Conversion](#)", "Troubleshooting and Repair of Computer and Video Monitors", "Troubleshooting and Repair of Television Sets", and "Troubleshooting and Repair of Video Cassette Recorders", and others at this site may contain some of the information you seek on these other topics.

---

## Chapter 3) Types of Conversion

---

### 3.1) You mean it is more than just the type of plug?

It would be nice if all you had to do was match up a plug and socket to make anything in the universe work together. Unfortunately, while this does work for some things - garden hoses, for example :- ) - it rarely is as simple as this for electrical power, video, or communications.

---

## 3.2) Power

This relates to what comes out of the wall socket. Nearly every country in the world uses an AC voltage between 90 and 240 V at 50 or 60 Hz. There may be some exceptions (like 600 V at 25 Hz powering portions of the New York City subway system or 28 V at 400 Hz on board an F-18 - but this is not something you are likely to need to deal with!) - if you encounter such unusual situations, we will be happy to add them to this document!

The three important considerations are:

- \* Voltage - the RMS (Root Mean Square - you really don't need to worry about the term) value of the nominal power line voltage. (OK, if you really care, the RMS value of an AC waveform will be equal to that of a DC voltage which will have the same heating effect. It is the squareroot of the mean (average) of the waveform squared. Got that? :-).
- \* Frequency - the number of cycles per second now expressed in Hz (pronounced like the Hertz car rental company). Almost all power around the world is AC. There are some exceptions but you will be unlikely to encounter them.
- \* Plugs and sockets - there are several dozen variations (at least) with and without a safety ground depending on your location. If you purchase \*the\* adapter that they recommend at the travel store, there is good chance it will not fit when you actually get to your destination! However, there are universal plug and socket adapter sets which may have a better track record.

---

## 3.3) Video standards

This relates to the scan rates, color encoding, and audio transmission of the baseband video signals in use in your country.

- \* Scan rate - how many total scanning lines are used and how many times per second a complete picture is 'painted' on the picture tube screen. (Note that existing TV standards use interlaced scanning - a picture is made up of an even field (all the even numbered lines) and an odd field (all the odd numbered lines) and a picture consists of both of these. The most

common (pre-HTDV) are 525 lines at 30 Hz (e.g., U.S. NTSC) and 625 lines at 25 Hz (e.g., U.K. PAL). However, there are others.

- \* Color Encoding - the way the color information is combined with the basic monochrome (black and white) picture signal. These differ between NTSC and PAL and there are several variations for PAL as well. The effect of a TV with the wrong decoding circuitry will be either a black and white picture or possibly color interference effects.
  - \* Audio - the location of the subcarrier frequency for the sound information among other things may differ as well.
- 

## **3.4) Broadcast (and cable) standards**

- \* Radio - AM and FM channel locations and spacing.
  - \* Video - VHF and UHF channel assignments, color encoding, audio carrier, etc.
  - \* Telephone - ???
- 

# **Chapter 4) Common types of Voltage Converters**

---

## **4.1) How to get power for equipment A to work with equipment B**

There are a variety of approaches to adapting equipment designed for one power system to another.

- \* Transformers will always work but may be too heavy or expensive to justify their use.
- \* Electromechanical approaches go back quite far, are quite efficient, but are heavy, bulky, noisy, not very flexible.
- \* Solid state converters vary widely in complexity, capabilities, and cost.

Some may destroy motors or electronic equipment and this may not be obvious from the product description.

Note that in cases, the proper (or close enough) power may be available already.

\* Where 110 VAC is standard, 220 VAC is usually present in the residence since the power originates from a 220-0-220 VAC utility (pole) transformer. In some cases, a suitable outlet will even be present though usually one will have to be added. Whether this is worth the effort and expense for a \$30 coffeemaker you picked up in your travels is another matter. :-)

In industrial or office buildings, 208 VAC will be available (since they use three-phase power but that is another story) and this may be close enough for most applications (though heating appliances won't be quite as zippy as if they were running on the proper 220 VAC and therefore your eggs may take a little longer to cook).

\* Where 220 VAC is standard, hotels and other public buildings may provide 110 VAC convenience outlets for foreign visitors. While the frequency will probably still be the standard 50 Hz for these countries, many appliances don't care. See the chapter: "[Frequency Issues](#)".

\* Many appliances have a voltage selector switch usually near the power cord entrance though some may require changing internal jumpers. See your user manual! This is particularly true of appliances that are typically used overseas like shavers.

---

## 4.2) True transformers

This refers to devices that consist solely of a pair (at least) of windings on an iron core. There are no other devices in a transformer beyond possibly a switch, indicator light, thermal protector, and/or a fuse or circuit breaker, and a plug or terminal block for input and socket or terminal block for output.

In the following, we assume that the two voltages are 110 VAC and 220 VAC. Similar comments apply if the ration is not 2:1.

There are several types including:

- \* Isolated step-up for converting from 110 VAC to 220 VAC.
- \* Isolated step-down for converting from 220 VAC to 110 VAC.
- \* autotransformer step-up for converting from 110 VAC to 220 VAC.
- \* autotransformer step-down for converting from 220 VAC to 110 VAC.

Autotransformers are cheaper but do not provide line isolation which may be desirable. In general, a step-up or step-down transformer can be used backwards to effect the opposite conversion - whether this is possible is

a construction detail. In addition, a 1:1 isolation transformer can be used as a 1:2 (stepup) or 2:1 (stepdown) autotransformer with a VA rating twice of what it would be when used normally.

The relevant parameters characterizing a transformer consist of:

- \* Voltage - The ratio of the number of turns of wire on the output winding(s) and input winding determines the output:input voltage ratio. Electrically, input and output can be interchanged to obtain the opposite conversion. Whether this is supported by the packaging is another story.
- \* Power/VA capacity: The size of the core and the wire determine the power handling capability. VA is simply the voltage (V) multiplied by the current (A) for the input or output. For a resistive load like a space heater or light bulb, this is the same as true power in watts (W). Due to unavoidable losses in the transformer, the input and output ratings are not quite the same. The transformer must be capable of supplying the required VA of the desired maximum load without exceeding the current rating of the input line.

Transformers of adequate capacity can be used with all types of equipment.

However, they are heavy and costly and do not convert frequency. Thus, they may be unsuitable in some situations and there may be cheaper more appropriate alternatives. A \*suitable\* transformer large enough to power a space heater would weigh about 50 pounds and cost perhaps \$200 - much more than the the space heater is worth.

---

## 4.3) Thyristor based converters

These are the low cost devices available at Radio Shack or a travel accessories store that weigh almost nothing and have huge power ratings. They operate by switching the power on to the load at the appropriate time during each cycle of the AC voltage (120 or 100 times a second) resulting in approximately the proper power being delivered to the load.

Thyristor based converters are for converting from 220 VAC to 110 VAC without changing frequency with major restrictions:

- \* WARNING: These are suitable ONLY for resistive loads like light bulbs, space heaters, and frying pans WITHOUT induction motors, transformers, or electronic controls.
- \* They are designed to provide approximately the correct \*power\* conversion factor for resistive loads (and possibly universal motors). The maximum voltage may still be close to that of the input - 220 V. This will instantly destroy electronics and may destroy induction motors only slightly more slowly.

- \* The output is very spike-y unlike the smooth sinusoid of the normal power line AC. This in itself may result in addition problems including radio frequency interference (RFI) and equipment buzz or hum.
- 

## 4.4) Motor alternators

Before the development of solid state power devices, these represented an efficient, if bulky way of converting both voltage and frequency. A synchronous induction motor is coupled to an alternator (AC generator) on the same shaft. By designing with the appropriate number of poles for each, this could easily, if noisily, perform both voltage and frequency conversion.

---

## 4.5) Solid state (AC->DC->AC) converters

These provide efficient conversion of both voltage and frequency in a light weight compact package. The best of these generate an output nearly identical to the power obtained from the wall socket and operate as follows:

- \* Rectify and filter AC input to provide direct current (DC).
- \* Chop the DC at a high frequency controlling both polarity and amplitude to synthesize a replica of the desired power (sinusoidal) waveform.
- \* Use a transformer to step this up to the required voltage
- \* Provide a filter to remove the high frequencies from the output.

The waveform before smoothing would look similar to the following:

After smoothing, the result would be very similar to a sinusoid.

This more costly approach enables arbitrary voltage \*and\* frequency conversion

but as we will see later, this is rarely needed.

Cheaper models simply generate a square wave or modified sine wave at the appropriate frequency:

Squarewave:

Modified sine wave:

The nice thing about the modified sine wave is that its RMS and peak values match that of the true sinusoid (as well as other advantages in terms of harmonic content). If you don't know what this means, don't worry, Your life doesn't depend on it. One implication, however, is that heating loads and electronic devices which rectify and filter the input power will see the same effective voltage.

For many devices including all resistive loads, either of these approaches is adequate. However, devices with motors and/or transformers will be much happier with smoothed sinusoidal power. Switching power supplies (except universal types) will be underpowered with the simple squarewave inverter and may overheat running near full load.

---

## 4.6) Is frequency conversion needed

The question of 50 Hz vs. 60 Hz always comes up in conjunction with international power. However, except for equipment with induction motors (e.g., fans, compressors), or where the line frequency is used for timing (electric or line powered electronic clocks), the line frequency may be irrelevant. See the chapter: "[Frequency Issues](#)".

---

## 4.7) Effects of improper voltage on resistive loads

- \* Incandescent light bulbs. Light output will increase or decrease by a greater relative percentage than the voltage change. Life will be impacted dramatically. The life function for an incandescent light bulb is roughly  $(V/V_0)^{14}$ . This is the actual voltage divided by the nominal voltage raised to the 14th power! A 5 percent increase in voltage will decrease life by about 50%.

With greatly excessive voltage (i.e., running a 110 V light bulb on 220 V), burnout will be nearly instantaneous - the bulb may even explode.

With reduced voltage, the light output will be reduced and life will be extended dramatically as well. However, efficiency decreases faster than voltage so it doesn't make sense to use bulbs on lower voltage unless they are in a hard-to-reach spot as the energy cost dominates. Extending the life of a 25 cent bulb just doesn't save money in the end especially if a higher wattage or additional bulbs must be used to make up the light reduction.

- \* Space heaters (excluding fans) and heating appliances like rice cookers, deep fryers, toaster, etc. Power is proportional to the square of the voltage. Reduced voltage will result in less heat or longer cycles (if thermostatically controlled). Excessive voltage will result in more heat or shorter cycles. However, there could be fire risk if the appliance is not designed with adequate insulation and safeguards to handle the extra power.

With greatly excessive voltage, heating devices will blow a fuse or internal thermal protector, the AC fuse or circuit breaker, or burn out.

---

## 4.8) Effects of improper voltage on constant power loads

- \* Induction motors. These are found in refrigeration equipment (fridges, freezers, air conditioners, dehumidifiers), air compressors, washing machines, dryers, some stationary shop tools, pumps, and many other domestic and industrial applications.

An induction motor is a nearly constant speed drive. Reduce the voltage and it will still try to maintain almost the same speed. Where the load is constant, this means that it will draw greater current to compensate for the reduced voltage (remember:  $P = \text{constant} = V \cdot I$ ). This will result in excessive heating and stress. The equipment may fail to start properly

at all or cycle on its thermal/overcurrent protector. Its life may be shortened or it may burn out quickly.

Excess voltage isn't good either since the construction may result in magnetic core saturation which will also result in overheating, added noise (hum), and lower efficiency.

#### \* Regulated switchmode power supplies

These share many of the characteristics of induction motors in that they will attempt to maintain the same power to the load. Thus, at low line voltage, they will draw additional current and internal parts may be stressed to the point of (possibly catastrophic) failure. Unlike induction motors, this is much more difficult to predict as it is highly design dependent.

Usually a slight reduction or increase in voltage will not affect the performance or longevity. However, unless specified as a universal input (90 to 240 VAC) or where specific recommendations are available, remaining within a 10 percent window is best. This is especially critical on the low side when running near full load.

Running a non-universal switching power supply from a squarewave inverter result in overheating and subsequent failure near full load. The reason is that the peak value of the input waveform is about 7/10ths of that from the normal AC line and the current must increase to compensate.

---

## 4.9) Effects of improper voltage on transformer loads

While the ideal transformer (the one they may have taught you about in EE101) doesn't care about its actual input voltage, real transformers do. If the voltage increases significantly above what it was designed for, the core may saturate. This means that the magnetic field in the core cannot increase any further and the result is to effectively short circuit the input (above a certain voltage on the waveform). At the very least, this will result in excessive heating and hum or buzz. The transformer may burn out if a fuse doesn't blow first.

How much excess voltage is acceptable is not something that can be determined without testing. Some transformers are designed very conservatively (bigger cores, more copper, etc.) while others just barely get away with running on the nominal line voltage.

Certainly, 2:1 will be too much for almost any transformer. You may get away with a 25% increase without too many problems.

It is possible to test for this by slowly increasing the input voltage while monitoring input current. Up until saturation, it will increase linearly

with voltage. As saturation sets in, a small increase in voltage will result in a large increase in current and increased buzz or hum as well.

Reducing voltage to a transformer is not a problem unless the load will then demand more current - which may result in excessive heating and failure.

---

## 4.10) Effects of improper voltage on motor loads

- \* As noted above, induction motors are constant speed devices so that the current will tend to decrease as voltage is increased and increase as voltage is decreased. There can also be core saturation effects just as with transformers.
  - \* Universal motors - those found in vacuum cleaners, portable shop tools, and so forth - will run with a speed that is related to input voltage (unless feedback regulated). On low voltage, the speed will be lower and your vacuum cleaner won't suck as well. Since it uses bypass air to cool the motor, it may overheat also. On higher than normal voltage, it will run faster adding wear and tear to the bearings. Blowers and flywheels may disintegrate if not designed for the added centrifugal loads.
  - \* Fan motors - these are shaded pole induction type usually and so lossy to begin with that speed will vary with voltage. Again, bad things may happen at too low or too high voltage but they will probably survive modest changes.
- 

## Chapter 5) Frequency Issues

---

### 5.1) Effects of improper frequency

- \* Clocks/timers run slow or fast. Devices that depend on synchronous motors or count the cycle of the line voltage directly like desk or alarm clocks, clocks in clock radios, appliance timers, anti-burglery timers, and so forth, will run fast or slow by the precise ratio of the correct to actual line frequency. In nearly all cases, this will be either 5/6 or 6/5 based on the ratio of 50 to 60 Hz and vice-versa.

In the case of synchronous motors, there is nothing you can do - the speed

is determined by construction and the gear ratios.

Those that are entirely electronic may have a switch or jumper (probably inside) to select the AC frequency - 50 or 60 Hz.

Many devices use an internal quartz crystal for the clock or timer and will not be affected at all. Devices like VCRs may or may not use the power line for timing. Of course, battery operated equipment will always use an internal quartz crystal as there is no connection to the power line.

- \* Transformer core saturation - excessive heating. Reducing the frequency of the input to a transformer also increases the likelihood of core saturation. Therefore, going from 60 Hz to 50 Hz may be a problem for your stereo (which likely uses a power transformer) if its design is marginal. As with voltage, there is no way to know except by testing unless the nameplate specifically states a frequency spec - 50/60 Hz.
- \* Induction motor speed and torque. As noted, these are nearly constant speed devices dependent on power line frequency:
  - Going from 50 Hz to 60 Hz: motor will run fast with reduced torque.
  - Going from 60 Hz to 50 Hz: motor will run slow with reduced torque.
- \* Note that most modern electronic equipment (with the possible exceptions listed above) does not depend on the power line frequency for anything. This includes CD players, cassette decks, servo-drive turntables, TVs (unless there is an on-screen line timed clock), VCRs (ditto), computers, monitors, printers, fax machines, etc.

---

## Chapter 6) Recommendations for specific devices

Television sets and video cassette recorders.  
-----

A voltage converter - preferably a true transformer or modified or true sinewave inverter will be needed to adapt the voltage unless the unit has a universal power supply.

Modern TVs do not care about power line frequency at all as they do not have any power transformer. Really old sets may run into core saturation problems but these are mostly dead by now.

Note: the video frame rate is not tied to the power line in any way. Therefore, a U.S. TV with a 60 Hz (actually 59.94 Hz) frame rate will work just fine in a country with 50 Hz power assuming the voltage is correct.

However, it will not be compatible with broadcast or cable or likely a VCR purchased in that country - see below.

VCRs may use a small power transformer in the power supply so changing from 60 Hz to 50 Hz may result in overheating though probably not likely.

However, taking a VCR and TV from the U.S. to a European country, for example, may not be worth it. They will work fine with each-other (as long as the voltage is proper) but the video standards in foreign countries are not compatible with those in the U.S. Therefore, it may be better to buy new equipment overseas unless you are taking your prized collection of videos and will obtain other equipment to deal with broadcast and cable. There are also services for copying video cassettes from one standard to another and these may represent an alternative to lugging the equipment with you.

---

## 6.1) Audio equipment

These include tuners, amplifiers, receivers, tape decks, CD players, etc.

Except for the tuner or tuner portion of the receiver, the only issue is power. Audio equipment almost always uses a transformer type power supply so the comments in the previous chapters should apply. A voltage converter will be need to go from 110 VAC to 220 VAC or vice-versa. In this case, it really should be a true transformer. Anything else is quite likely to introduce unacceptable interference in the form of a hum or buzz even if it doesn't result in any damage to the equipment. As noted, going from 60 Hz to 50 Hz could intruduce problems of transformer core saturation in marginally designed equipemnt as well.

---

## 6.2) Small appliances

Specific recommendations will depend on the actual devices inside the appliance - motors, heating elements, timers, and so forth.

- \* For appliances containing ony heating elements - no fans or other motors - any type of voltage converter will be suitable. For example, the very inexpensive and light weight thyristor type of 220 VAC to 110 VAC type should work fine with a waffle iron.
- \* Where motors are involved, a true transformer will be best but may be excessively heavy or expensive.

\* With timers, the line frequency will also be important.

\* If the appliance is powered by a wall adapter outputting DC, a substitute wall adapter may be the best option.

---

## 6.3) Microwave ovens

If the voltage is different, sell where you are located and buy a new one at your destination. The power involved would require a large, heavy, expensive voltage converter - preferably a true transformer. It doesn't make sense for a \$150 microwave.

Line frequency doesn't affect the performance of a microwave that much (perhaps a 5 percent increase in cooking power from 50 Hz to 60 Hz) but the timer and clock will likely be affected and may not be easily adjusted - not at all in the case of a mechanical timer though there may be a jumper for an electronic timer. However, the turntable and cooling fan motors will also be affected and attempting to account for all the variations is probably just not worth it!

---

## 6.4) Clocks

Electric clocks using a synchronous motor would require a motor or gear transplant - not worth it. Of course, you could just live with shorter or longer days :-).

Clocks using the power line to drive an electronic display may have a jumper to select 50 or 60 Hz. Even this may not be worth the effort to locate as it is likely not going to be labeled.

---

## 6.5) Radios, tuners, receivers

In addition to the power issues (see the section: "[Audio equipment](#)", station frequencies and channel spacing differ from country to country.

---

## **6.6) PCs and laptop/notebook computers**

Check your equipment. Most PC power supplies have a switch to select between 110 VAC and 220 VAC. Some have universal power supplies that will work within a range of voltage between 90 and 240 V AC (up to 400 Hz) or DC. The latter is generally true of laptop/notebook power packs.

Similarly, monitors may use a switch or jumper to select voltage or have a universal power supply.

PCs and monitors do not use the line frequency for anything - not even the real time clock.

---

## **6.7) Laser printers**

These may use a switching or transformer based power supply. This is not the real problem. What is, is the power for the fuser - several hundred watts. Therefore, if using a true transformer for voltage conversion, a large one will be required.

Some may have universal power supplies - check your instruction manual!

---

## **6.8) Non-laser printers**

There will usually use a power transformer type power supply so a voltage converter will be needed. The frequency will only matter with respect to transformer core saturation. Nothing in a printer depends on line frequency.

---

# **Chapter 7) Items of Interest**

---

## **7.1) TV, shortwave, power worldwide**

(From: Mark Zenier (mzenier@netcom.com)).

A book, "The World Radio TV Handbook" published by Billboard that covers TV, along with where all the world's shortwave radio transmitters are, and what sort of power comes out of the wall plug all around the world. It has a new edition each year and costs around \$25 to \$30.

---

## **7.2) How big a difference in voltage before a converter is needed**

"I would like to bring a variety of small to medium-sized Japanese electrical products (100V 50/60 Hz) with me when I move back to the U.S. (e.g., lights, rice-cooker, cassette player, VCR...) Individual transformers like those sold in travel shops are quite expensive. Is it possible buy a large number of small stepdown transformers -- or to make them as kits? Any advice would be greatly appreciated."

First, for some of these like the VCR, the 15% difference between 115 VAC and 100 VAC may not matter. The only way to be sure is to check with the manufacturer.

For others like the rice cooker, it too may be ok if it uses a thermostat to control its heating element.

However, the simplest way to reduce 115 to 100 VAC is to buy or construct an autotransformer.

To construct one, you need a stepdown transformer with an output of about 15 V (for this example) and a secondary current rating at least equal to your total current needs. Then, the primary is connected to the line and the secondary is wired anti-phase in series with the loads and the line.

For devices using AC adapters, I would just replace the AC adapters with a US version.

---

## **7.3) Equipment that will probably not care about the frequency of the line**

The following are generally insensitive to frequency (50/60 Hz):

- \* Appliances with only heating elements (e.g., toaster, radiant space heater) and incandescent light bulbs.
- \* Devices with universal motors (e.g., vacuum cleaner, electric drill).
- \* Fluorescent lamps using electronic ballasts (including many compact fluorescents).
- \* TVs, VCRs, computers, monitors, universal AC adapters, other devices using switching power supplies. (The a clock may run at an incorrect rate if it depends on the power line frequency.)

However, note different TV standards will likely result in your TV and VCR working together but not able to receive or record broadcasts or cable.

Some equipment explicitly states the acceptable voltage and frequency range. In the case of a universal power adapter, this may range from 90 to 260 V DC or AC up to 400 Hz - or more.

---

## 7.4) Equipment that may work with a different line frequency

The following will probably work when going from 50 Hz power to 60 Hz power and may work going the other way. However, transformer cores designed for 60 Hz may saturate on 50 Hz and run hotter and/or blow internal fuses and cooling fans will run slower - this should be checked to make sure there is no hazard:

- \* Audio equipment (e.g., receivers, CD players, tape decks, servo locked turntables). However, since the broadcast channel spacing may differ, tuning may not operate correctly.)
- \* Devices using wall wart AC adapters with actual transformers (these are massive as opposed to universal AC adapters which weigh almost nothing) (e.g., calculators, boomboxes, telephones and answering machiens, external modems and CDRom drives, dust busters hand vacs). However, the phone system may not be compatible.)
- \* Printers, fax machines, and other computer peripherals which use a power transformer in their power supply.
- \* Microwave ovens (power is related somewhat to frequency, cooling fans and turntables will run slow on 50 Hz).
- \* Fans and blowers (will run slower on 50 Hz).
- \* Convection space heaters (shaded pole fan motor will run faster on 60 Hz). If designed for 60 Hz and run off 50 Hz, it will run slower possibly resulting in overheating.

---

## 7.5) What appliances will be damaged by reduced voltage?

Here is a summary of various appliance types and how they are affected by the severely reduced voltages possible during a brownout:

- \* Resistance heating elements/incandescent bulbs/ and similar will not be damaged and will actually last longer. Of course, light and/or heat will be reduced.
- \* Constant horsepower loads like refrigeration compressors will be severely stressed and may burn out.
- \* Shaded pole motors will run slow but will probably not be damaged. Many of these are designed to survive a stalled condition as well.

Examples: fans and some blowers, can openers, pencil sharpeners.

- \* Capacitor run and other larger induction motors without a starting switch will run slow with reduced torque. However, if they stall, overheating and burnout is possible.

Examples: some blowers, dishwashers.

- \* Motors with a starting switch may not reach starting winding cutout speed and result in motor damage - burnt out starting winding.

Examples: washing machines, cloths dryers, circulator and other larger pumps, large furnace blowers, stationary shop tools.

- \* Universal motors will run slow with decreased torque and reduced cooling. There may be a range of speeds over which they will overheat.

Examples: vacuum cleaners, electric leaf blowers, many other portable line powered tools

- \* Switching power supplies will run hot and may fail.

Examples: TVs, some VCRs, computers (PCs and laptops), monitors, and some peripherals,

- \* Linear power supplies will probably just not regulate well resulting in hum in audio or hum bars in video.

Examples: Stereo receivers, CD players, cassette decks, phones, some fax machines, some printers.

\* Anything with relays may have problems with the relays not operating reliably or cycling.

Examples: heating and cooling systems, garage door openers, etc. but most of these will have other components more severely affected.

For appliances with more than one type of device like a microwave oven, all factors must be considered. For this example, the oven will heat at a reduced power level (which is safe) but the cooling fan(s) will also run more slowly resulting in possible overheating and failure of the magnetron. A convection space heater may overheat for similar reasons.

---

## 7.6) Equipment that may have problems on different line frequency

The following may have problems:

- \* Audio equipment using AC motors like some turntables and reel-to-reel tape decks. Speed will be incorrect. Mechanical adapters may be available.
- \* Clocks and devices with built in clocks or timers. Many of these depend on the power line frequency for timekeeping. They will therefore run at a 5/6 or 6/5 rate when the frequency changes. (This may be desirable - your day could last 20% longer! :-) ).
- \* Electric shavers depending on a resonant linear motor (vibrator). The frequency difference may be enough to kill the resonance and result in weak or no blade motion. (Remingtons used to use this technique; I do not know what manufacturers still do.)
- \* Large fixed power devices like refrigeration compressors.
- \* Equipment with a combination of resistive heating elements and/or induction motors and/or electronics. One or more subsystems may have performance or overheating problems.

---

## 7.7) About the vertical scan rate

TVs never ever used the line frequency for vertical rate. The vertical rate is not even equal to line frequency, actually 59.94 Hz (NTSC). It was set originally to 60 Hz to minimize the visibility of interference between the deflection and power transformer. When NTSC added color, it changed to

59.94 Hz. And, TVs no longer have power transformers.

---

## 7.8) Taking a microwave oven overseas (or vice versa)

Microwave ovens are high power appliances. Low cost transformers or international voltage adapters will not work. You will need a heavy and expensive step down or step up transformer which will likely cost as much as a new microwave oven. Sell the oven before you leave and buy a new one at your destination.

Furthermore, for microwave ovens in particular, line frequency may make a difference. Due to the way the high voltage power supply works in a microwave oven, the HV capacitor is in series with the magnetron and thus its impedance - which depends on line frequency - affects output power.

High voltage transformer core saturation may also be a problem. Even with no load, these may run hot even at the correct line frequency of 60 Hz. So going to 50 Hz would make it worse - perhaps terminally - though this is not likely.

- \* Going from 50 Hz to 60 Hz at the same line voltage may slightly increase output cooking power (and heating of the magnetron). The line voltage could be reduced by a small amount to compensate.
- \* Going from 60 Hz to 50 Hz may slightly decrease output power and possibly increase heating of the HV transformer due to core losses. Using a slightly lower line voltage will reduce the heating but will further decrease the cooking power.

The digital clock and timer will likely run slow or fast if the line frequency changes as they usually use the power line for reference. Of course, this may partially make up for your change in output power! :-)

---

## 7.9) Determining unknown connection on international power transformers

Most likely, you can figure this out if you can identify the input connections.

There will be two primary windings. Each of these may also have additional taps to accommodate various slight variations in input voltage.

For the U.S. (110 VAC), the two primary windings will be wired in parallel.

For overseas (220 VAC) operation, they will be wired in series. When switching from one to the other make sure you get the phases of the two windings correct - otherwise you will have a short circuit! It is best to test with a Variac so you can bring up the voltage gradually and catch your mistakes before anything smokes.

An multimeter on the lowest resistance scale should permit you to determine the internal arrangement of any taps.

With any luck, the transformer wiring will even be labeled on the case!

---

## 7.10) Taking equipment overseas (or vice-versa)

When does it make sense to take an appliance or piece of electronic equipment to a country where the electric power and possibly other standards differ?

For anything other than a simple heating appliance (see below) that uses a lot of power, my advise would be to sell them and buy new when you get there. For example, to power a microwave oven would require a 2KVA step down (U.S. to Europe) transformer. This would weigh about 50 pounds and likely cost almost as much as a new oven.

Note that some places like Japan may even have varying power specifications in different parts of the country. Isolated areas such as islands may have their own power generators with very erratic and voltage and frequency. The following discussion assumes power from a large (national) grid.

There are several considerations:

1. AC voltage - in the U.S. this is nominally 115 VAC but in actuality may vary from around 110 to 125 VAC depending on where you are located. Many European countries use 220 VAC while voltages as low as 90 or 100 VAC or as high as 240 VAC (or higher?) are found elsewhere.
2. Power line frequency - in the U.S. this is 60 Hz. The accuracy, particularly over the long term, is excellent (actually, for all intents and purposes, perfect) - better than most quartz clocks. In many foreign countries, 50 Hz power is used. However, the stability of foreign power is a lot less assured.
3. TV standards - The NTSC 525L/60F system is used in the U.S. but other countries use various versions of PAL, SECAM, and even NTSC. PAL with 625L/50F is common in many European countries.
4. FM (and other) radio station channel frequencies and other broadcast parameters differ.
5. Phone line connectors and other aspects of telephone equipment may differ

(not to mention reliability in general but that is another issue).

6. Of course, all the plugs are different and every country seems to think that their design is best.

For example, going to a country with 220 VAC 50 Hz power from the U.S.:

For electronic equipment like CD players and such, you will need a small step down transformer and then the only consideration power-wise is the frequency. In most cases the equipment should be fine - the power transformers will be running a little closer to saturation but it is likely they are designed with enough margin to handle this. Not too much electronic equipment uses the line frequency as a reference for anything anymore (i.e., cassette deck motors are DC).

Of course, your line operated clock will run slow, the radio stations are tuned to different frequencies, TV is incompatible, phone equipment may have problems, etc.

Some equipment like PCs and monitors may have jumpers or have universal autoselecting power supplies - you would have to check your equipment or with the manufacturer(s). Laptop computer, portable printer, and camcorder AC adapter/chargers are often of this type. They are switching power supplies that will automatically run on anywhere from 90-240 VAC, 50-400 Hz (and probably DC as well).

Warning: those inexpensive power convertors sold for international travel that weigh almost nothing and claim to handle over a kilowatt are not intended and will not work with (meaning they will damage or destroy) many electronic devices. They use diodes and/or thyristors and do not cut the voltage in half, only the heating effect. The peak voltage may still approach that for 220 VAC resulting in way too much voltage on the input and nasty problems with transformer core saturation. For a waffle iron they may be ok but not a microwave oven or stereo system. I also have serious doubts about their overall long term reliability and fire safety aspects of these inexpensive devices..

For small low power appliances, a compact 50 W transformer will work fine but would be rather inconvenient to move from appliance to appliance or outlet to outlet. Where an AC adapter is used, 220 V versions are probably available to power the appliance directly.

As noted, the transformer required for a high power heating appliance is likely to cost more than the appliance so unless one of the inexpensive convertors (see above) is used, this may not pay.

---

## 7.11) Taking a CD player overseas (or vice-versa)

Fortunately, the standard for the CDs themselves is the same everywhere in the explored universe Yes, even Australia :-). Thus, there should be no issues of incompatibility. The differences will relate only to the power supply.

First, check your user's manual (which you of course have saved in a known location). It may provide specific instructions and/or restrictions.

Most component type CD players use a simple power supply - a power transformer followed by rectification, filter capacitors, and linear regulators. These will usually only require a small step up or step down transformer to operate on a different voltage. Since power requirements are minimal, even a 50 VA transformers should be fine. WARNING: never attempt to use one of those cheap lightweight power adapters that are not true transformers to go from 220 V to 110 V as they are designed only for heating appliances. They will smoke your CD player (or other equipment not designed to handle 220 V to 240 V input).

Some CD players may have dual voltage power transformers which can be easily rewired for the required voltage change or may even have a selector switch on the rear panel or internally.

The frequency difference - 50 or 60 Hz should not be a problem as nothing in a CD player uses this as a timing reference. The only slight concern would be using a CD player specified for 60 Hz on 50 Hz power - the transformer core may saturate and overheat - possibly blowing the internal fuse. However, I don't really think problems are likely.

For portable CD players, if your wall adapter does not have a voltage selector switch, obtain one that is rated for your local line voltage or use a suitable transformer with the one you have. As with power transformers, a frequency difference may cause a problem but this is not likely.

---

## 7.12) Buying a TV in Europe

"I have the following question for you specialists:

Can I buy a TV in any west-european country and use it in any other west European country? For example, buying a TV in the Netherlands and use it in Greece or buying in France and using in England.

Any help would be appreciated as I do not really trust the sale people at the store."

Neither would I.

Along with the multiple audio/video formats, there may be differences in channel frequency assignments between the various countries.

Channel 5 in country X may not be on the same actual frequency as Channel 5 in country Y or Z. The channel spacings or modulation may also be different.

From: Phil Nichols

Plus, in different countries the audio signal can be transmitted at a different frequency relative to the vision signal. Great! Perfect picture, no sound!

I believe most continental European countries use PAL B (narrow vision bandwidth; sound carrier 5.5MHz higher than vision carrier), whereas the UK and Ireland use PAL I (wider vision bandwidth; sound carrier 6MHz higher than vision carrier).

The wisest thing is to decide which countries you are most likely to want to visit with your TV, find out what transmission system they use, then go looking for a TV which can use that/those system(s).

Almost all TVs in west Europe are compatible ( PAL-B/G ),  
>except Britain ( PAL-I ) and France ( SECAM-L ).  
>Greece is also using SECAM, but on very few channels and not all the  
>time.

From: wolfi@berlin.snafu.de (Wolfgang Schwanke)

This is correct, but maybe not the whole story.  
There are differences in the broadcast bands used.  
At least Italy uses different channel allocations than the rest of the PAL-B/G crowd. Germany uses frequencies on cable that are unused elsewhere, which only special tuners can get.  
Also, there are different methods for transmitting stereo sound (NICAM vs. analogue).  
New TVs nowadays (sold in Europe anyway) are often all-world-standard all-frequency-bands, because it's easier for the manufacturer to make a "one for all" set instead of having so many different designs for every country. But don't rely on it.

(From Jeroen.Stessen@ehv.ce.philips.com)

Oh boy, here goes another long story:

PAL-plus is an attempt to extend the life-cycle of terrestrial PAL transmissions by including compatible wide-screen (16:9) transmissions. It is an advanced variant of the letterbox format, this means that when you receive a PAL-plus widescreen program on an older 4:3 receiver you will see black bars top and bottom. It was originally developed in Germany (university of Dortmund in cooperation with German terrestrial broadcasters and some setmakers). Later a large consortium of European and Japanese setmakers took over and finished the job. Strangely, the German broadcasters seem to use PAL-plus only very rarely.

The PAL-plus standard comprises three extensions to the PAL-standard:

1. Vertical helper. In order to compensate for the fact that 1/4 of the video lines are not used, which would deteriorate vertical resolution for the widescreen viewer, the missing vertical information has been coded into the black lines in a manner as to be nearly invisible on a 4:3 receiver (you see some dark blue). The 16:9 PAL-plus receiver combines 432 visible lines plus 144 helper lines into 576 new visible lines.
2. Colour-plus. The PAL colour carrier is modulated in a slightly different way (making use of correlation between 2 fields) in order to give a cleaner Y/C separation in the PAL-plus receiver.
3. Signalling bits from which the receiver can conclude whether the transmission is 4:3/16:9/PAL-plus and adapt the display format accordingly. The bandwidth of these bits is low enough to survive recording on a VHS recorder.

In order to enable a poor-man's PAL-plus receiver, the standard permits using the mark "PAL-plus" if at least the vertical helper reconstruction is included. Colour-plus is optional, so you will find sets on the market with only half of the PAL-plus extension.

PAL-plus may also be combined with teletext, ghost cancellation reference, digital Nicam stereo, VPS, PDC and what-you-have more. Theoretically it can be broadcast over a satellite channel too, but it was not designed for that and some aspects of a satellite channel do indeed give interesting technical problems.

There are also sets marketed as "PAL-plus compatible". These are mostly widescreen sets without any PAL-plus processing at all, but they allow switching of the display format between 4:3 and 16:9. They may well do that automatically, based on the signalling bits.

There are 2 methods for displaying a 4:3 letterboxed signal on a 16:9 display, without using the PAL-plus helper lines:

1. Increase of the vertical deflection amplitude to display only the centre 432 lines
2. Vertical interpolation without using the helper, to convert 432 lines into 576 lines and display on a 576 lines display.

Both modes may be called "movie expand".

Only when you really convert to full-resolution widescreen will it be called "widescreen".

And there are 4 methods for displaying a regular 4:3 signal on a 16:9 display (regular PAL, has nothing to do with PAL-plus):

1. Decrease of the horizontal deflection amplitude, this gives black bars left and right
2. Horizontal interpolation, to convert N pixels to  $3/4 * N$  pixels.

Both modes may be called "4:3" or "normal"

3. Non-linear horizontal deflection waveform, called "Panorama mode" by JVC, works by increasing the S-capacitor value.
4. Non-linear horizontal interpolation, called "Superwide"

by Philips, works with an advanced sample-rate convertor. With both modes, the left and right edges of the picture will be stretched to fill the left and right bars, but the aspect ratio of the centre part of the picture will hardly be affected.

Interesting, ain't it ?

(From: Allan Mounteney (allan@amounten.demon.co.uk)).

RE: Is there a TV set that covers international standards?

The answer is YES.

Reason I know is that I was with a company that made computers with TV-OUT for world wide use and wanted something that could show that the TV Out worked for various countries.

This ONE and ONLY one we could find Three years ago came from Germany and covered PAL, SECAM and the American NTSC systems and came with a note that said from the time of making/selling that set it would not work in just one small country in South America. All features (including audio) were adjustable from the front panel Menu and it was a Grundig 17" job. I am advised that there is a load of others on the market now.

The company who seemed to know all about these international sets and gave us good service at that time was Andrew McCulloch Ltd in Cambridge UK. Phone #44(0)1223-351825

---

## **7.13) Running three phase motors on single phase power**

This may be an issue if you picked up a South Bend lathe with a 10 foot bed at a garage sale for \$1 or more realistically with professional shop equipment like large saws or planars.

A three phase motor will run on single phase power once started - but at somewhat reduced output power (horsepower). The very simple approach (compared to complete conversion) is to just provide a means for starting. The motor will then run at the correct speed (assuming the line frequency is the same) but will not be able to develop full torque before stalling. Actually converting single phase to three phase will likely be more expensive than replacing the motor.

There is some info at:

<http://www.loganact.com/mwn/howto/ph-conv/ph-conv.html>

---

## Chapter 2) Introduction

This is a collection of jokes and other humorous stories I have collected off the Net over the past few years. Most relate to engineering or science but some on other topics were just too good to pass up.

These should be mostly suitable for general audiences (unless you have a lawyer in the family :-). They are in no particular order.

In most cases, the actual authors are unknown but I have at least provided attribution to the person who posted or emailed the article where available.

---

## Chapter 3) A Brief Guide to Scientific Literature

(From: Chris Taylor (chris@labtam.labtam.oz.au)).

Here is an old collection that I rediscovered recently:

Phrase	Translation
-----	
It has been long known	I haven't bothered to check the references
It is known	I believe
It is believed	I think
It is generally believed	My colleagues and I think
There has been some discussion	Nobody agrees with me
It can be shown	Take my word for it
It is proven	It agrees with something mathematical
Of great theoretical importance	I find it interesting
Of great practical importance	This justifies my employment
Of great historical importance	This ought to make me famous
Some samples were chosen for study	The others didn't make sense
Typical results are shown	The best results are shown

Correct within order of magnitude	Wrong
The values were obtained empirically	The values were obtained by accident
The results are inconclusive	The results seem to disprove my hypothesis
Additional work is required	Someone else can work out the details
It might be argued that	I have a good answer to this objection
The investigations proved rewarding	My grant has been renewed

---

## Chapter 4) Carnot is dead ! Schaeffer disproves 2nd Law

(From: Brandon Davis (HUEP35B@prodigy.com)).

The First Law of Thermodynamics:  
"You can't get something for nothing"

The Second Law of Thermodynamics:  
"As a matter of fact, you can't even break even."

Newton's first Law of Motion:  
"If you kick a can, it will move."

Newton's Second Law of Motion:  
"If you kick it harder, it will move faster."

Perhaps others know of similar restatements of other important Laws?

The best summary of the first and second laws of thermodynamics I have seen (in 3 statments):

You can't win.  
You can't break even.  
You can't quit the game.

. . but surely simple things grow more complex as the cosmos iMplodes in retrograde time toward the initial collapse of the singularity? Er, or is it that complex things break down to constituent particles as the cosmos eXplodes along linear time lines towards chaos (i.e., entropy). Wait. Where is my local closed system where heat/energy/complexity can make a muddle of the metaverse's puddle? Oh --i know, I will just sink into the quandary of the 19th century, where the only part of probability that was important was babil (babbel) and ...oh, dear, where IS lewis carrol when he's needed?: The

---

# Chapter 5) Canonical Collection of Light Bulb Jokes

(From: Clay Belcher (cbelcher@kuhub.cc.ukans.edu)).

Time for a little levity, lighting fans. Or should I say a little light humor. This collection of jokes was originally attributed to: Kurt Guntheroth (kurt@tc.fluke.COM) but I've been unable to raise him at that address. I've taken the liberty to post this here in a somewhat sterilized version (as the original contained some pretty offensive stuff). Enjoy, and feel free to contribute additional ones.

Q: How many Californians does it take to change a light bulb?

A: Six. One to turn the bulb, one for support, and four to relate to the experience.

Q: How many Oregonians does it take to screw in a light bulb?

A: Five. One to change the bulb and four more to chase off the Californians who have come up to relate to the experience.

A': Nine. One to change the bulb, and eight to protest the nuclear power plant that generates the electricity that powers it.

Q: How many New Yorkers does it take to screw in a light bulb?

A: None of your business!

A': 50. 50? Yeah 50; its in the contract.

Q: How many Virginians does it take to change a light bulb?

A: Twelve: one to replace it and eleven to talk about how much better the old one was.

Q: How many yuppies does it take to change a light bulb?

A: Two. One to call the electrician and one to mix the martinis.

Q: How many Psychiatrists does it take to change a light bulb?

A: Only one, but the bulb has got to really WANT to change.

A': None; the bulb will change itself when it is ready.

Q: How many software people does it take to screw in a light bulb?

A: None. That's a hardware problem.

A': One, but if he changes it, the whole building will probably fall down.

A": Two. One always leaves in the middle of the project.

Q: How many hardware folks does it take to change a light bulb?

A: None. That's a software problem.

A': None. They just have marketing portray the dead bulb as a feature.

Q: How many Unix hacks does it take to change a light bulb?

A: As many as you want; they're all virtual, anyway.

Q: How many Bell Labs Vice Presidents does it take to change a light bulb?

A: That's proprietary information. Answer available from AT&T on payment of license fee (binary only).

A': Nearly unanswerable, since the one who tries to change it usually drops it, and the others call for a planning session.

A": Three. One to get the bulb and two to get the phone number of one of their subordinates to actually change it.

Q: How many graduate students does it take to screw in a light bulb?

A: Only one, but it may take upwards of five years for him to get it done.

Q: How many `Real Men' does it take to change a light bulb?

A: None: `Real Men' aren't afraid of the dark.

Q: How many `Real Women' does it take to change a light bulb?

A: None: A 'Real Woman' would have plenty of real men around to do it.

Q: How many Marxists does it take to screw in a light bulb?

A: None: The light bulb contains the seeds of its own revolution.

Q: How many Russian leaders does it take to change a light bulb?

A: Nobody knows. Russian leaders don't last as long as light bulbs.

Q: How many nuclear engineers does it take to change a light bulb?

A: Seven. One to install the new bulb and six to figure out what to do with the old one for the next 10,000 years.

Q: How many pre-med students does it take to change a light bulb?

A: Five: One to change the bulb and four to pull the ladder out from under him.

Q: How many jugglers does it take to change a light bulb?

A: One, but it takes at least three light bulbs.

Q: How many Feminists does it take to change a light bulb?

A: That's not funny!!!

Q: How many supply-siders does it take to change a light bulb?

A: None. The darkness will cause the light bulb to change by itself.

Q: How many economists does it take to screw in a light bulb?

A: Two. One to assume the ladder and one to change the bulb.

A': None. If the government would just leave it alone, it would screw itself in.

Q: How many Valley Girls does it take to change a light bulb?

A: Oooh, like, manual labor? Gag me with a spoon! For sure.

Q: How many data base people does it take to change a light bulb?

A: Three:

One to write the light bulb removal program,  
one to write the light bulb insertion program, and  
one to act as a light bulb administrator to make sure  
nobody else tries to change the light bulb at the same time.

Q: How many Carl Sagans does it take to screw in a light bulb?

A: Billions and billions.

Q: How many Zen masters does it take to screw in a light bulb?

A: A tree in a golden forest.

A': Two: one to change the bulb and one not to change it.

A": One to change and one not to change is fake Zen. The true Zen answer is

Four. One to change the bulb.

A': None. Zen masters carry their own light.

Q: How many folk singers does it take to screw in a light bulb?

A: Two. One to change the bulb, and one to write a song about how good the old light bulb was.

Q: How many surrealists does it take to change a light bulb?

A: Two, one to hold the giraffe, and the other to fill the bathtub with brightly colored machine tools.

Q: How many gorillas does it take to screw in a light bulb?

A: Only one, but it takes a truckload of light bulbs!

Q: How many doctors does it take to screw in a light bulb?

A: Three. One to find a bulb specialist, one to find a bulb installation specialist, and one to bill it all to Medicare.

Q: How many [IBM] Technical Writers does it take to change a light bulb?

A: 100. Ten to do it, and 90 to write document number GC7500439-0001, Multitasking Incandescent Source System Facility, of which 10% of the pages state only "This page intentionally left blank", and 20% of the definitions are of the form "A:..... consists of sequences of non-blank characters separated by blanks".

A': Just one, provided there's an engineer around to explain how to do it.

Q: How many professors does it take to change a light bulb?

A: Only one, but they get three publications out of it.

Q: How many people from New Jersey does it take to change a light bulb?

A: Three. One to change the light bulb, one to be a witness, and the third to shoot the witness.

Q: How many cops does it take to screw in a light bulb?

A: None. It turned itself in.

Q: How many lawyers does it take to change a light bulb?

A: How many can you afford?

Q: How many football players does it take to change a light bulb?

A: The entire team! And they all get a semester's credit for it!

Q: How many thought police does it take to screw in a light bulb?

A: None. There never was any light bulb.

Q: How many Federal employees does it take to screw in a light bulb?

A: Sorry, that item has been cut from the budget!

Q: How many psychics does it take to screw in a light bulb?

A: ---- You should have hit "n"!

Q: How many sorority sisters does it take to change a light bulb?

A: 51. One to change the bulb, and fifty to sing about the bulb being changed.

Q: How many frat guys does it take to screw in a light bulb?

A: Three: One to screw it in, and the other two to help him

down off the keg.

A': Five: One to hold the bulb, and four to guzzle beer until the room spins.

Q: How many Harvard students does it take to screw in a light bulb?

A: Just one. He grabs the bulb and waits for the world to revolve around him.

Q: How many bureaucrats does it take to screw in a light bulb?

A: Two. One to assure the everything possible is being done while the other is incomplete pending resolution of some action items. It will be continued next week. Meanwhile...

Q: How many brewers does it take to change a light bulb?

A: About one third less than for a regular bulb.

Q: How many WASP Princesses does it take to screw in a light bulb?

A: Two. One to get a Tab and one to call Daddy.

Q: How many accountants does it take to screw in a light bulb?

A: What kind of answer did you have in mind?

Q: How many civil servants does it take to change the light bulb?

A: 45. One to change the bulb, and 44 to do the paperwork.

Q: How many junkies does it take to screw in a light bulb?

A: Oh wow, is it like dark, man?

Q: How many consultants does it take to change a light bulb?

A: I will have an estimate for you a week from Monday.

Q: How many U.S marines does it take to screw in a light bulb

A: 50. One to screw in the light bulb and the remaining 49 to guard him.

Q: "How many Romulans does it take to screw in a light bulb?"

A: "151, one to screw the light-bulb in, and 150 to self-destruct the ship out of disgrace."

Q: How many dull people does it take to change a light bulb?

A: one.

Q: How many editors of Poor Richard's Almanac does it take to replace a light bulb?

A: Many hands make light work.

Q: How many Vulcans does it take to change a light bulb?

A: "Approximately 1.00000000000000000000000000000000"

Q: How many members of the U.S.S. Enterprise does it take to change a light bulb?

A: 7. Scotty will report to Captain Kirk that the light bulb in the Engineering Section is burnt out, to which Kirk will send Bones to pronounce the bulb dead. Scotty, after checking around, notices that they have no more new light bulbs, and complains that he can't see in the dark to tend to his engines. Kirk must make an emergency stop at the next uncharted planet, Alpha Regula IV, to procure a light bulb from the natives. Kirk, Spock, Bones, Sulu, and 3 red shirt security officers beam down. The 3 security officers are promptly killed by the natives, and the rest of the landing party is captured. Meanwhile, back in orbit, Scotty

notices a Klingon ship approaching and must warp out of orbit to escape detection. Bones cures the native king who is suffering from the flu, and as a reward the landing party is set free and given all of the light bulbs they can carry. Scotty cripples the Klingon ship and warps back to the planet just in time to beam up Kirk et. al. The new bulb is inserted, and the Enterprise continues with its five year mission.

Q: How many efficiency experts does it take to replace a light bulb?

A: None. Efficiency experts replace only dark bulbs.

Q: How many actors does it take to change a light bulb?

A: Only one. They don't like to share the spotlight.

Q: How many Chinese Red Guards does it take to screw in a light bulb?

A: 10,000 - to give the bulb a cultural revolution.

Q: Do you know how many musicians it takes to change a light bulb?

A: No, big daddy, but hum a few bars and I will fake it.

A': Twenty. One to hold the bulb, two to turn the ladder, and seventeen in on the guest list.

Q: How many mystery writers does it take to screw in a light bulb?

A: Two, one to screw it almost all the way in and the other to give it a surprising twist at the end.

Q: How many bikers does it take to change a light bulb?

A: It takes two. One to change the bulb, and the other to kick the switch.

Q: How many running-dog lackeys of the bourgeoisie does it take to change a light bulb?

A: Two. One to exploit the proletariat, and one to control the means of production!

Q: How many existentialists does it take to screw in a light bulb?

A: Two: One to screw it in and one to observe how the light bulb itself symbolizes a single incandescent beacon of subjective reality in a netherworld of endless absurdity reaching out toward a maudlin cosmos of nothingness.

Q: How many light bulbs does it take to change a light bulb?

A: One, if it knows its own Goedel number.

Q: How many dadaists does it take to screw in a light bulb?

A: To get to the other side.

Q: How many mathematicians does it take to screw in a light bulb?

A: None. It's left to the reader as an exercise.

A': One. He gives it to six Californians, thereby reducing the problem to an earlier joke.

A": One. He gives it to five Oregonians, thereby reducing the problem to an earlier joke.

A'": In an earlier article, zeus!bobr writes:

Q: How many mathematicians does it take to screw in a light bulb?

A: One. He gives it to six Californians, thereby reducing the problem to an earlier joke...

In earlier work, Wiener [1] has shown that one mathematician can change a light bulb. If  $k$  mathematicians can change a light bulb, and if one more simply watches them do it, then  $k+1$  mathematicians will have changed the light bulb. Therefore, by induction, for all  $n$  in the positive integers,  $n$  mathematicians can change a light bulb.

#### Bibliography:

[1] Weiner, Matthew P., <11485@ucbvax>, "Re: YALBJ", 1986

Q: How many consultants does it take to change a light bulb?

A: We don't know. They never get past the feasibility study.

Q: How many Ukrainians does it take to screw in a light bulb?

A: They don't need to, they glow in the dark.

Q: How many poets does it take to change a light bulb?

A: Three. One to curse the darkness, one to light a candle...

... and one to change the bulb.

Q: How many stock brokers does it take to change a light bulb?

A: Two. One to take out the bulb and drop it, and the other to try and sell it before it crashes (knowing that it's already burned out).

Q: How many aides does it take to change the President's light bulb?

A: None, they like to keep him in the dark.

Q: How many magicians does it take to change a light bulb?

A: Depends on what you want to change it into.

Q: How many Macintosh users does it take to change a light bulb?

A: None. You have to replace the whole motherboard.

And a couple more:

(From: Don Klipstein (don@misty.com)).

Q: How many straight male West Hollywood residents does it take to change a light bulb?

A: Either of them could probably do it themselves.

Q: How many journalists does it take to change a lightbulb?

A: Three. One to report on the inspired program to bring light, one to report on the sinister government plot to deprive the poor of darkness, and one to report on the light bulb manufacturer assassinating the old light bulb.

(From: WB or CM Hilbrich (hilbrich@antares.cloudnet.com)).

Q: How many mailing list subscribers does it take to change a light bulb?

A: 1,331:

- 1 to change the light bulb and to post to the list that the light bulb has been changed.

- 14 to share similar experiences of changing light bulbs and how the light bulb could have been changed differently.
- 7 to caution about the dangers of changing light bulbs.
- 27 to point out spelling/grammar errors in posts about changing light bulbs.
- 53 to flame the spell checkers.
- 156 to write to the list administrator complaining about the light bulb discussion and its inappropriateness to this mail list.
- 41 to correct spelling in the spelling/grammar flames.
- 109 to post that this list is not about light bulbs and to please take this e-mail exchange to alt.lite.bulb.
- 203 to demand that cross posting to alt.grammar, alt.spelling and alt.punctuation about changing light bulbs be stopped.
- 111 to defend the posting to this list saying that we all use light bulbs and therefore the posts **\*\*are\*\*** relevant to this mail list.
- 306 to debate which method of changing light bulbs is superior, where to buy the best light bulbs, what brand of light bulbs work best for this technique, and what brands are faulty.
- 27 to post URLs where one can see examples of different light bulbs.
- 14 to post that the URLs were posted incorrectly, and to post corrected URLs.
- 3 to post about links they found from the URLs that are relevant to this list which makes light bulbs relevant to this list.
- 33 to summarize all posts to date, then quote them including all headers and footers, and then add "Me Too."
- 12 to post to the list that they are unsubscribing because they cannot handle the light bulb controversy.
- 19 to quote the "Me Too's" to say, "Me Three".
- 4 to suggest that posters request the light bulb FAQ.
- 1 to propose new alt.change.lite.bulb newsgroup.
- 47 to say this is just what alt.physic.cold\_fusion was meant for, leave it here.
- 143 votes for alt.lite.bulb.

(From: Dan Hicks (danhicks@millcomm.com)).

You forgot:

- 37 empty posts.

- 250 debating the merits of magnetic light bulb filters.
  - 3 giving you URLs for really sexy adult light bulbs.
- 

## Chapter 6) Pentium Bug Jokes

(From: Henry G. Baker ( hbaker@netcom.com)).

The 0.000000000001th new Intel slogan for the Pentium:

We give you the most megaflops.

---

On the tee-shirt of an inline skater in Mountain View: :-)

"I asked for a refund on my Pentium, and all I got was this lousy T-shirt"

---

Q: What is Intel's follow-on to the Pentium?

A: Repentium.

---

Q: What does the element Pentium decay into?

A: Inert silicon with the emission of a press release.

---

The Pentium doesn't have bugs or produce errors; it's just Precision-Impaired.

---

Intel business executives have been so stressed by staying up late at night trying to figure out what to do about the Pentium Problem, that they're past the floating point.

---

I heard that Intel lost one of its divisions today...

---

(From: Mark Thorson (eee@netcom.com)).

INTEL INSIDE:

Intel Inside sat on a wall.  
Intel Inside had a great fall.

All the king's lawyers  
and all the king's men  
couldn't put Intel Inside  
back together again.

PENTIUM PROCESSOR

Pentium Processor, puddin' and pie.  
Pentium Processor, price real high.  
When the bugs came out to play,  
Pentium Processor ran away.

(From: John Cooley (jcooley@world.std.com)).

Here's some of the hardware humor I've had mailed to me since the Intel Pentium floating point divide bug came out that's been such big news lately. It's not every day that we hardware designers get national recognition for \*anything\* either positive or negative! (Thought I'd post it as a refreshing diversion from the 100,000 serious hardware design oriented posts we see here all year through.)

- John Cooley  
Part Time Sheep & Goat Farmer  
Part Time EDA Consumer Advocate  
Full Time ASIC, FPGA & EDA Design Consultant

---

## 6.1) The top ten reasons to buy a Pentium machine

10. You current computer is too accurate.
9. Want to get into the Guinness Book as "owner of the most expensive paperweight".
8. Math errors add zest to life.
7. You need an alibi for the IRS.
6. You want to see what all the fuss is about.
5. You've always wondered what it would be like to be a plaintiff.
4. The "Intel Inside" logo matches your decor perfectly.
3. You no longer have to worry about the CPU overheating.
2. You got a great deal from JPL.

And the #1 reason to buy a Pentium machine:

1. It'll probably work.
-

## 6.2) Q&A The Pentium FDIV bug

- Q: How many Pentium designers does it take to screw in a light bulb?  
A: 1.99904274017, but that's close enough for non-technical people.
- Q: What do you get when you cross a Pentium PC with a research grant?  
A: A mad scientist.
- Q: What's another name for the "Intel Inside" sticker they put on Pentiums?  
A: The warning label.
- Q: Complete the following word analogy: Add is to Subtract as Multiply is to:  
1) Divide  
2) ROUND  
3) RANDOM  
4) On a Pentium, all of the above  
A: Number 4.
- Q: What algorithm did Intel use in the Pentium's floating point divider?  
A: "Life is like a box of chocolates." (Source: F. Gump of Intel)
- Q: Why didn't Intel call the Pentium the 586?  
A: Because they added 486 and 100 on the first Pentium and got 585.999983605.
- 

## 6.3) Top ten new Intel slogans for the Pentium

- |              |   |
|--------------|---|
| 9.9999973251 | It's a FLAW, Dammit, not a Bug                  |
| 8.9999163362 | It's Close Enough, We Say So                    |
| 7.9999414610 | Nearly 300 Correct Opcodes                      |
| 6.9999831538 | You Don't Need to Know What's Inside            |
| 5.9999835137 | Redefining the PC -- and Mathematics As Well    |
| 4.9999999021 | We Fixed It, Really                             |
| 3.9998245917 | Division Considered Harmful                     |
| 2.9991523619 | Why Do You Think They Call It *Floating* Point? |
| 1.9999103517 | We're Looking for a Few Good Flaws              |
| 0.9999999998 | The Errata Inside                               |
- 

# Chapter 7) Things They Never Taught in School

(From: Jim Weir (rst-engr@oro.net)).

And for those of you who went through school thinking that everything

above 30 MHz was powdered bat wings and mouse milk,

1. 2 #24 PVC hookup wires twisted tightly is about 10 pf per inch.
2. A file and a disk ceramic capacitor is the original one-set variable capacitor.
3. A wire is just some inductance, capacitance, and resistance floating in a loose formation.
4. A file and a carbon COMPOSITION resistor is the original one-set variable resistor.
5. A 50 ohm line on green glass PC board is about the thickness of the board material.
6. Don't tug on Superman's cape, don't piss into the wind, and don't mess around with The Man.

---

## Chapter 8) Virus Jokes

Immediately scan your computer for the following viruses:

- \* PAT BUCHANAN VIRUS: Your system works fine, but it complains loudly about foreign software.
- \* COLIN POWELL VIRUS: Makes its presence known, but doesn't do anything. Secretly you wish it would.
- \* HILLARY CLINTON VIRUS: Files disappear, only to reappear mysteriously a year later, in another directory.
- \* O.J. SIMPSON VIRUS: You know it's guilty of trashing your system, but you just can't prove it.
- \* BOB DOLE VIRUS: Could be virulent, but it's been around too long to be much of a threat.
- \* STEVE FORBES VIRUS: All files are reported as the same size.
- \* PAUL REVERE VIRUS: This revolutionary virus does not horse around. It warns you of impending hard disk attack: Once if by LAN; twice if by C.
- \* POLITICALLY CORRECT VIRUS: Never identifies itself as a virus, but instead refers to itself as an electronic micro-organism.

---

## Chapter 9) The Fable of the Fox's FAX

(From: Frank Reid (reid@indiana.edu)).

## THE FABLE OF THE FOX'S FAX

by Frank

Based very loosely on a true story.  
(G-rated version; use your imagination.)

Fox faced a fix; Fox couldn't fax, for Fox's fax was fried. "Fax failure forfeits fortunes faxing flax futures," figured Fox, frantically phoning Phoebe the Frugal Fax Fixer from Phoenix, who features fast fax fixes for flat fees of fifty French Francs. "Fix my freaking fax!" Fox fumed furiously.

Phoebe's fastest field fax-fixer, Pheasant, flew to Fox's flat. Pheasant found flocks of faulty fuses, a familiar foible of funky faxes from Formosa. Fetching fistfuls of fresh fuses forced Fox's fax to function with flawless finesse, faithfully focusing phalanxes of photons in phase with faraway photoelectron flux.

"Phooey!" Fox fussed, flipping Pheasant the finger. "I fail to fathom fifty French francs for fifteen-pfennig fuses. Forget fiscal funds for fallacious fax-fix!"

Pheasant fervently feared fowl finagling, for Pheasant failed to find her father following the forementioned fox's fax-fix fiasco four fortnights from February. Pheasant found feathers festooning Fox's foyer, and feared Fox feasted on Father. Pheasant flew forthwith, fleeing Fox's flat.

Pheasant fingered Fox, forwarding fiendishly-forged fax to feds. Federal fuzz ferreted Fox's fingerprints and fined Fox for filching fuses, fomenting forest fires, fencing foreign freon, fleecing folks with fraudulent faxed flax-futures, and felonious failure to file flat flax-fax tax. Fox filibustered futilely, and finally fell afoul of a frizzy female fed who fired flintlocks and fancied fox fur.

Moral: Fare fixers fairly or face fur-fetched frustration.

---

## Chapter 10) Fixing a Flux Capacitor

Here is one that hasn't been posted to sci.electronics.repair yet:

Newsgroups: sci.electronics.repair  
Subject: Flux Capacitor broken

Greetings:

We found what appears to be a Flux Capacitor that fell out of an alien spaceship in their haste to depart after being approached by BIG BIRD.

The plutonium supply seems to be adequate but plugging the 3 wire cord into 115 VAC doesn't produce any response. However, probing the logic circuits with our HP 16500 analyzer indicates that the P9-1000 they are apparently using to control the display is functional. (It also passes the FDIV bug test - must not be genuine Intel.)

Upon further examination, we note the device marked @@#%-@#%\$#-11 appears to be burnt. Would like to know of source for this device or equivalent. It seems to be in-line with the main power relay.

We would really like to get our infinite energy/time machine going but are hesitant to jump across this device if it is not just a fuse or if there are further problems. A black hole in the middle of our back yard would be really bad for property values.

Thanks in advance for any assistance.....:-)

## Chapter 11) Engineers Explained

(From Jim Rauchut (rauchut@repairfaq.org)).

### Engineers Explained

-----

People who work in the fields of science and technology are not like other people. This can be frustrating to the nontechnical people who have to deal with them. The secret to coping with technology-oriented people is to understand their motivations. This chapter will teach you everything you need to know. I learned their customs and mannerisms by observing them, much the way Jane Goodall learned about the great apes, but without the hassle of grooming.

Engineering is so trendy these days that everybody wants to be one. The word "engineer" is greatly overused. If there's somebody in your life who you think is trying to pass as an engineer, give him this test to discern the truth.

#### ENGINEER IDENTIFICATION TEST

You walk into a room and notice that a picture is hanging crooked. You...

- A. Straighten it.
- B. Ignore it.
- C. Buy a CAD system and spend the next six months designing a solar-powered, self-adjusting picture frame while often stating aloud your belief that the inventor of the nail was a total moron.

The correct answer is "C" but partial credit can be given to anybody who writes "It depends" in the margin of the test or simply blames the

whole stupid thing on "Marketing."

## SOCIAL SKILLS

Engineers have different objectives when it comes to social interaction.

"Normal" people expect to accomplish several unrealistic things from social interaction:

- \*Stimulating and thought-provoking conversation
- \*Important social contacts
- \*A feeling of connectedness with other humans

In contrast to "normal" people, engineers have rational objectives for social interactions:

- \*Get it over with as soon as possible.
- \*Avoid getting invited to something unpleasant.
- \*Demonstrate mental superiority and mastery of all subjects.

## FASCINATION WITH GADGETS

To the engineer, all matter in the universe can be placed into one of two categories: (1) things that need to be fixed, and (2) things that will need to be fixed after you've had a few minutes to play with them. Engineers like to solve problems. If there are no problems handily available, they will create their own problems. Normal people don't understand this concept; they believe that if it ain't broke, don't fix it. Engineers believe that if it ain't broke, it doesn't have enough features yet.

No engineer looks at a television remote control without wondering what it would take to turn it into a stun gun. No engineer can take a shower without wondering if some sort of Teflon coating would make showering unnecessary. To the engineer, the world is a toy box full of sub-optimized and feature-poor toys.

## FASHION AND APPEARANCE

Clothes are the lowest priority for an engineer, assuming the basic thresholds for temperature and decency have been satisfied. If no appendages are freezing or sticking together, and if no genitalia or mammary glands are swinging around in plain view, then the objective of clothing has been met. Anything else is a waste.

## LOVE OF "STAR TREK"

Engineers love all of the "Star Trek" television shows and movies. It's a small wonder, since the engineers on the starship Enterprise are portrayed as heroes, occasionally even having sex with aliens. This is much more glamorous than the real life of an engineer, which consists of hiding from the universe and having sex without the participation of other life forms.

## DATING AND SOCIAL LIFE

Dating is never easy for engineers. A normal person will employ various indirect and duplicitous methods to create a false impression of attractiveness. Engineers are incapable of placing appearance above function.

Fortunately, engineers have an ace in the hole. They are widely recognized as superior marriage material: intelligent, dependable, employed, honest, and handy around the house. While it's true that many normal people would prefer not to date an engineer, most normal people harbor an intense desire to mate with them, thus producing engineer-like children who will have high-paying jobs long before losing their virginity.

Male engineers reach their peak of sexual attractiveness later than normal men, becoming irresistible erotic dynamos in their mid thirties to late forties. Just look at these examples of sexually irresistible men in technical professions:

- \* Bill Gates.
- \* MacGyver.
- \* Etcetera.

Female engineers become irresistible at the age of consent and remain that way until about thirty minutes after their clinical death. Longer if it's a warm day.

#### HONESTY

Engineers are always honest in matters of technology and human relationships. That's why it's a good idea to keep engineers away from customers, romantic interests, and other people who can't handle the truth.

Engineers sometimes bend the truth to avoid work. They say things that sound like lies but technically are not because nobody could be expected to believe them. The complete list of engineer lies is listed below.

- "I won't change anything without asking you first."
- "I will return your hard-to-find cable tomorrow."
- "I have to have new equipment to do my job."
- "I'm not jealous of your new computer."

#### FRUGALITY

Engineers are notoriously frugal. This is not because of cheapness or mean spirit; it is simply because every spending situation is simply a problem in optimization, that is, "How can I escape this situation while retaining the greatest amount of cash?"

#### POWERS OF CONCENTRATION

If there is one trait that best defines an engineer it is the ability to concentrate on one subject to the complete exclusion of everything else in the environment. This sometimes causes engineers to be pronounced dead prematurely. Some funeral homes in high-tech areas have started checking resumes before processing the bodies. Anybody

with a degree in electrical engineering or experience in computer programming is propped up in the lounge for a few days just to see if he or she snaps out of it.

## RISK

Engineers hate risk. They try to eliminate it whenever they can. This is understandable, given that when an engineer makes one little mistake, the media will treat it like it's a big deal or something.

## EXAMPLES OF BAD PRESS FOR ENGINEERS

- \* Hindenberg.
- \* Space Shuttle Challenger.
- \* SPANet(tm)
- \* Hubble space telescope.
- \* Apollo 13.
- \* Titanic.
- \* Ford Pinto.
- \* Corvair.

The risk/reward calculation for engineers looks something like this:

RISK: Public humiliation and the death of thousands of innocent people. REWARD: A certificate of appreciation in a handsome plastic frame.

Being practical people, engineers evaluate this balance of risks and rewards and decide that risk is not a good thing. The best way to avoid risk is by advising that any activity is technically impossible for reasons that are far too complicated to explain.

If that approach is not sufficient to halt a project, then the engineer will fall back to a second line of defense: "It's technically possible but it will cost too much."

## EGO

Ego-wise, two things are important to engineers:

- \* How smart they are.
- \* How many cool devices they own.

The fastest way to get an engineer to solve a problem is to declare that the problem is unsolvable. No engineer can walk away from an unsolvable problem until it's solved. No illness or distraction is sufficient to get the engineer off the case. These types of challenges quickly become personal -- a battle between the engineer and the laws of nature.

Engineers will go without food and hygiene for days to solve a problem. (Other times just because they forgot.) And when they succeed in solving the problem they will experience an ego rush that is better than sex--and I'm including the kind of sex where other people are involved.

Nothing is more threatening to the engineer than the suggestion that somebody has more technical skill. Normal people sometimes use that

knowledge as a lever to extract more work from the engineer. When an engineer says that something can't be done (a code phrase that means it's not fun to do), some clever normal people have learned to glance at the engineer with a look of compassion and pity and say something along these lines: "I will ask Bob to figure it out. He knows how to solve difficult technical problems."

At that point it is a good idea for the normal person to not stand between the engineer and the problem. The engineer will set upon the problem like a starved Chihuahua on a pork chop.

---

## Chapter 12) The Sex Life of an Electron

(From: Tom The sparky (martinm@wic.net)).

One night when his charge was pretty high Micor Farad decided to get a cute little coil to help him discharge. He picked up Millie Amp and took her for a ride on his megacycle. They rode across Wheatstone Bridge, around by the sine wave, and stopped in a magnetic field by a flowing current.

Micor Farad, attracted by Millie Amp's characteristic curve, soon began to lower her resistance to minimum and his field was fully excited. He laid her on the ground potential, raised her frequency, lowered her capacitance, and plugged in his high voltage probe. He inserted it into her socket, connected them in parallel, and began to short circuit her shunt. Fully excited Millie cried "ohm, ohm, ohm".

With his tube operating at a maximum peak, and her coil vibrating from current flow, she soon reached her maximum peak. The excess current flow had gotten her hot and Micro Farad was rapidly discharging having drained off every electron.

They fluxed all night trying different connections and sockets until his bar magnet had lost all its field strength. Afterwards, Millie Amp tried self-induction and damaged her solenoid. With his battery fully discharged, Micro Farad was unable to excite her generator. So they ended up by reversing polarity and blowing each other's fuses

---

## Chapter 13) About Sears Shop Vac HP Ratings

(From: Kevin AstirCS "1U" K00B (kferguson@aquilagroup.com)).

I note that air compressor manufacturers have taken after the vacuum sweeper

folks, and are re-inventing the horsepower. Imagine, 6HP at 15A, 115VAC!

(From: sam).

Have you seen Sears shop vacs lately? I think they are also up to 6 HP. Every week or so, they seem to come out with one that is a little higher in their HP ratings - I guess internal cold fusion or something.

(From: Pin 2 Hot (pinksnd@io.com)).

Let's see, RPM X Torque = Horsepower.

Thus: No-load RPM X Locked-rotor Torque = Sears Horsepower

Notes:

1. testing done at 177V DC, equal to peak of 120V AC (AC-DC motors).
2. Sears Horsepower: How "hoarse" you get trying to talk over one of their shop-vacs while it's on.

Or maybe it's got something to do with vacuuming performance out at the stables.

---

## Chapter 14) So You Want a Vacation Day?

(From: contributor's name withheld so HR won't find out :- ) ).

So you want a day off, let's take a look at what you are asking for.

There are 365 days per year available for work. There are 52 weeks per year in which you already have two days off per week, leaving 261 day available for work.

Since you spend 16 hours each day away from work, you have used up 170 days, leaving only 91 days available.

You spend 30 minutes each day on coffee break that accounts for 23 days each year, leaving only 68 days available. with a one hour lunch period each day, you have used up another 46 days, leaving only 22 days available for work.

You normally spend 2 days per year on sick leave. This leaves you only 20 days available for work.

We are off for 5 holidays per year, so your available working time is down to 15 days.

We generously give you 14 days vacation per year which leaves only 1 day available for work, and I will be damned if you're going to take that day off!!!

---

# Chapter 15) Beware of demos (Bill Gates Computer Joke)

(From: Carter B. Schroy (CBS970@AOL.COM)).

Bill Gates died. He was sent to the Afterlife Waiting Room. He was met by St. Peter, who asked him if he wanted to go to Heaven or Hell, and if he'd like to see them before he decided. Bill said yes, and St. Peter snapped his fingers. They appeared on a sunny beach, with people dancing, swimming, and playing volleyball. Just basically having a wonderful time. Good food, good music, good people. Bill turns to St. Peter and says, "Wow, Heaven is great!" St. Peter says, "This isn't Heaven, it's Hell. Want to see Heaven?" Mr. Gates nods yes, and they appear in a shady park, with a few old people sitting on benches feeding birds. A gentle breeze blows by, and all is quiet and serene. St. Peter asks Bill, "Well, which would you like?" Bill thinks for a minute, and says, "Well, if this is Heaven, then I will take Hell." Instantly, he was plunged up to his neck in red-hot lava, the screams of other tortured souls filling his ears. He looks up, and sees St. Peter in the waiting room. Bill calls out to him, and said, "Hey! What's going on? Where's the beach? The bikini-clad women? The party?" St. Peter turns from his Macintosh to face Bill, and says, "That was just the demo."

---

# Chapter 16) Knowledge, Power, Time and Money Equation...

For all you mathematicians...

After applying some simple algebra to some trite phrases and cliches a new understanding can be reached of the secret to wealth and success.

Here it goes.

Knowledge is Power  
Time is Money and as every engineer knows,  
Power is Work over Time.

So, substituting algebraic equations for these time worn bits of wisdom, we get:

$$K = P \quad (1)$$

$$T = M \quad (2)$$

$$P = W/T \quad (3)$$

Now, do a few simple substitutions:

Put  $W/T$  in for  $P$  in equation (1), which yields:

$$K = W/T \quad (4)$$

Put M in for T into equation (4), which yields:

$$K = W/M \quad (5).$$

Now we've got something. Expanding back into English, we get:

Knowledge equals Work over Money.

What this MEANS is that:

1. The More You Know, the More Work You Do, and
2. The More You Know, the Less Money You Make.

Solving for Money, we get:

$$M = W/K \quad (6)$$

Money equals Work Over Knowledge.

From equation (6) we see that Money approaches infinity as Knowledge approaches 0, regardless of the Work done.

What THIS MEANS is:

The More you Make, the Less you Know.

Solving for Work, we get

$$W = M \times K \quad (7)$$

Work equals Money times Knowledge

From equation (7) we see that Work approaches 0 as Knowledge approaches 0.

What THIS MEANS is:

The stupid rich do little or no work.

Working out the socioeconomic implications of this breakthrough is left as an exercise for the reader.

---

## Chapter 17) You Know You Are Too Serious About Computers If...

- \* If you did an error-free installation of Windows 95.
- \* When your modem starts smoking.
- \* If no one can reach you by phone since your computer is always online.
- \* If you log-off your system because it's time to go to work.

- \* If you call in sick because you found a great new WWW site.
- \* If you can type your top 10 favorite web sites....by heart.
- \* If you can locate a particular home page without using a search engine.
- \* If you can write your own html page.
- \* If you can access more than 20 erotic no-pay sites.
- \* If you download more than 20Mb from a binary newsgroup...in one session.
- \* If while reading a magazine, you look for the Zoom icon for a better look at a photograph.
- \* You comment, while watching a sunset, that the image would be enhanced with 10% more magenta and a higher resolution.
- \* If while driving down the street, you are confused by the numbers on the houses... they do not appear to be legitimate WWW addresses.
- \* When someone tells you to remember something, and you look for File/Save command.
- \* When you discover there is no little car icon with a forward arrow on the dashboard of your car, to make it go.
- \* When you think the File/Kill command should apply to your system administrators.
- \* When you find it easier to dial-up the National Weather Service: Weather/your\_town/now.html than to simply look out the window.
- \* When you start using phrases like: Hungry.must-eat.food.now@home.
- \* If you have a heart attack when you forgot to pay your phone bill and receive a "pending disconnection of service" notice.
- \* When you order most of what you buy.....online.
- \* If your fingers quit moving because you've been online for 36 hours.
- \* When you find yourself engaged to someone you've never actually met, except through E-mail.
- \* When you log-off from a session in your favorite newsgroup, and your log reads: Online time: 56 hours 24 minutes.
- \* If your net provider suggests you try a competitor, because you're exceeding 300 hours a month, connect time.
- \* When you add your third modem and dedicated phone line.
- \* You access Microsoft's Web page every Sunday morning from Brother Bill's sermon.
- \* When that 112 GB hard drive is full.
- \* If 300 Mhz is simply too slow.

- \* When your desk collapses under the weight of your computer peripherals.
- \* If you have an "online" light installed on your car to tell you when the engine is running.
- \* When you discover that in order to drive your car somewhere, you do not have an http:// or ftp:// address.
- \* If you can actually talk to the computers in your new car, and understand what they say.
- \* When you modify the programming of your car's computers and actually get better mileage.
- \* When you can access the Net, via your portable and cellular phone.
- \* If on the way home from work, you use your portable and cellular phone in your car, to reprogram a Tomahawk missile, in flight, and redirect it to take out the joker in the Cadillac who cut you off.
- \* If you try to press Alt-F4 to close your car window.
- \* When you put a CD-ROM in your car's player.
- \* When someone tells you about a great new program and you're very disappointed to find it's on TV.
- \* If every sentence you utter begins with, "On the Net..."
- \* If you put your e-mail address in the upper left-hand corner of envelopes.
- \* If you have your e-mail address printed on your stationery.
- \* When you insist on seeing the movie "The Net" for the 63rd time.
- \* If magazine like "InternetWorld" are of greater interest than "Playboy" or "Playgirl".
- \* If you maintain more than 6 e-mail addresses.
- \* If you use more than 20 passwords.
- \* If you set up your own Web page.
- \* If you set up a Web page for each of your kids...and your pets.
- \* If, instead of a phone number, you ask someone for their e-mail address.
- \* If you don't know anyone who DOESN'T have an e-mail address.
- \* If, to you, "safe sex" means doing it online.
- \* If you convince your mom that she HAS to get online because e-mail is so much cheaper than long distance phone charges.
- \* If you can write a list like this.
- \* If you can relate to a list like this.

---

# Chapter 18) How Mil Specs live forever!

(From: Jeff Wisnia, W1BSV (jwisnia@aol.com)).

How Mil Specs Live Forever:

The US Standard Railroad Gauge (the distance between the rails) is 4 feet, 8.5 inches. That is an exceedingly odd number; Why was that gauge used?

Because that was the way they built them in England, and the US railroads were built by English expatriates.

Why did the English people build them that size? Because the first rail lines were built by the same people who built the pre-railroad tramways, and that was the gauge they used.

Why did "they" use that gauge then? Because the people who built the tramways used the same jigs and tools that they used for building wagons. which used that wheel spacing.

Okay! Why did the wagons use that odd wheel spacing? Because the first long distance roads in Europe were built by Imperial Rome for the benefit of their legions. Those roads have been used ever since. And the ruts? The initial ruts, which everyone else had to match for fear of destroying their wagons, were originally made by Roman war chariots. Since the chariots were made by or for Imperial Rome, they were all made with similar wheel spacing.

Thus, we have the answer to the original question. The US Standard Railroad Gauge of 4 feet 8.5 inches is derived from the original Mil Spec for Imperial Rome's army war chariots. Mil Specs, like bureaucracies, tend to exist forever.

So, next time you read a Mil Spec and wonder what horse's ass came up with it, you may be exactly right. Because, the Imperial Roman war chariots were designed for maneuverability, as narrow as possible, just wide enough to accommodate the rear ends of two war horses.

---

# Chapter 19) On Replacing Fuses with Bullets

You have repeatedly been warned: "Do not replace a fuse unless you have thoroughly checked all other components.... The new fuse may just blow the second time around."

Not necessarily. I have seen cases where the second time around, some other component pops off and the fuse survives!

(From: Keith Morgan (morgankk@boat.bt.com)).

Was a .22 caliber bullet the other component Sam mentioned:  
(this is an article spotted by Gary Davis in the Arkansas Democrat  
Gazette 25 July 1996, and reported in the UK Private Eye magazine)

"I thank God every hour that we weren't on that bridge when Thurston shot his nuts off, cos we'd both be pushing up the daisies by now," Billy Ray Wallis told reporters from his hospital bed in the Baptist Medical Center, Woodruff County. "When you leave, can you check if anyone got the frogs from the truck? I'd hate anything to happen to them."

Woodruff County deputy Dovey Snyder later gave a more coherent account of that evening's events. "It seems that Thurston Poole, 33, and Billy Ray Wallis, 38, were returning to Des Arc after a frog-gigging trip, when the fuse for the headlights on Poole's pick-up truck burned out. They didn't have a spare, so Wallis took a .22 caliber bullet from his pistol and found that it fitted perfectly into the fuse box next to the steering wheel column. The headlights started working again, and they resumed their journey, with Poole at the wheel.

"Apparently, it never occurred to them that, if the headlight wiring was faulty, then the bullet would soon overheat. They'd gone about twenty miles and were about to cross White River bridge when it got hot enough to discharge itself, striking Poole in the right testicle and partially severing his scrotum. As a result, the vehicle swerved off the road and drove through the front window of a hamburger bar. Poole (who sustained further abrasions from broken glass, and burns from fried onions) kept shouting at diners 'mind my frogs', while Wallis (who sustained a broken clavicle) attempted to steal a chip-fryer in the confusion. I tell you, I've been a state trooper for ten years, but this is the dumbest thing I've ever come across. I can't believe that those two would admit how the accident happened. And all they keep asking about are their damn frogs."

---

## Chapter 20) Corporate Down-Sizing Affects Everyone Everywhere

North Pole Memo:

Subject: Famous Reindeer Terminated

The recent announcement that Donner and Blitzen have elected to take the early reindeer retirement package has triggered a good deal of concern about whether they will be replaced, and about other restructuring decisions at the North Pole.

Streamlining is due to the North Pole's loss of dominance of the season's

gift distribution business. Home shopping channels and mail order catalogues have diminished Santa's market share. He could not sit idly by and permit further erosion of the profit picture.

The reindeer down-sizing was made possible through the purchase of a late model Japanese sled for the CEO's annual trip. Improved productivity from Dasher and Dancer, who summered at the Harvard Business School, is anticipated.

Reduction in reindeer will also lessen airborne environmental emissions for which the North Pole has received unfavorable press.

I am pleased to inform you that Rudolph's role will not be disturbed. Tradition still counts for something at the North Pole. Management denies, in the strongest possible language, the earlier leak that Rudolph's nose got that way, not from the cold, but from substance abuse. Calling Rudolph "a lush who was into the sauce and never did pull his share of the load" was an unfortunate comment, made by one of Santa's helpers and taken out of context at a time of year when he is known to be under executive stress.

As a further restructuring, today's global challenges require the North Pole to continue to look for better, more competitive steps. Effective immediately, the following economic measures are to take place in the "Twelve Days of Christmas" subsidiary:

The partridge will be retained, but the pear tree never turned out to be the cash crop forecasted. It will be replaced by a plastic hanging plant, providing considerable savings in maintenance;

The two turtle doves represent a redundancy that is simply not cost effective. In addition, their romance during working hours could not be condoned. The positions are therefore eliminated;

The three French hens will remain intact. After all, everyone loves the French;

The four calling birds were replaced by an automated voice mail system, with a call waiting option. An analysis is underway to determine who the birds have been calling, how often and how long they talked;

The five gold rings have been put on hold by the Board of Directors. Maintaining a portfolio based on one commodity could have negative implications for institutional investors. Diversification into other precious metals as well as a mix of T-Bills and high technology stocks appear to be in order;

The six geese-a-laying constitutes a luxury which can no longer be afforded. It has long been felt that the production rate of one egg per goose per day is an example of the decline in productivity. Three geese will be let go, and an upgrading in the selection procedure by personnel will assure management that from now on every goose it gets will be a good one;

The seven swans-a-swimming is obviously a number chosen in better times. The function is primarily decorative. Mechanical swans are on order. The current swans will be retrained to learn some new strokes and therefore enhance their outplacement;

As you know, the eight maids-a-milking concept has been under heavy scrutiny by the EEOC. A male/female balance in the workforce is being sought. The more

militant maids consider this a dead-end job with no upward mobility. Automation of the process may permit the maids to try a-mending, a-mentoring or a-mulching;

Nine ladies dancing has always been an odd number. This function will be phased out as these individuals grow older and can no longer do the steps;

Ten Lords-a-leaping is overkill. The high cost of Lords plus the expense of international air travel prompted the Compensation Committee to suggest replacing this group with ten out-of-work congressmen. While leaping ability may be somewhat sacrificed, the savings are significant because we expect an oversupply of unemployed congressmen this year;

Eleven pipers piping and twelve drummers drumming is a simple case of the band getting too big. A substitution with a string quartet, a cutback on new music and no uniforms will produce savings which will drop right down to the bottom line;

We can expect a substantial reduction in assorted people, fowl, animals and other expenses. Though incomplete, studies indicate that stretching deliveries over twelve days is inefficient. If we can drop ship in one day, service levels will be improved.

Regarding the lawsuit filed by the attorney's association seeking expansion to include the legal profession ("thirteen lawyers-a-suing") action is pending.

Lastly, it is not beyond consideration that deeper cuts may be necessary in the future to stay competitive. Should that happen, the Board will request management to scrutinize the Snow White Division to see if seven dwarfs is the right number.

The executives at the North Pole wish you and yours a Merry Christmas and a productive New Year.

---

## Chapter 21) Are You a Real Engineer?

(From: Mark Sokos (msokos1@umbc.edu)).

A comment was recently made about the lack of humor on this newsgroup. So, I did an excite search on "electronics humor", and, nothing. Zip. Zero. Nada. (Well, I only checked the first page of listings). So, I did remember snagging this off of the net. It's not quite electronics humor, but it is engineering humor, which I guess is as close as we're going to get.

And yes, it's off topic, so go ahead and flame me.

PS: I'm not going to admit (at least not publically) how many of these I said yes to.

(Author: Jose Herrero (jose@borg.harvard.edu)).

You may be an engineer...

- \* If Dilbert is your hero.
- \* If you stare at an orange juice container because it says CONCENTRATE.
- \* If you want an 8X CDROM for Christmas.
- \* If you can name 6 Star Trek episodes.
- \* If the only jokes you receive are through e-mail.
- \* If your wrist watch has more computing power than a 486DX2-50.
- \* If your idea of good interpersonal communication means getting the decimal point in the right place.
- \* If you look forward to Christmas only to put together the kids' toys.
- \* If you introduce your wife as "mylady@home.wife".
- \* If your spouse sends you an e-mail instead of calling you to dinner.
- \* If you can quote scenes from any Monty Python movie.
- \* If you use a CAD package to design your son's Pine Wood Derby car.
- \* If you have used coat hangers and duct tape for something other than hanging coats and taping ducts.
- \* If, at Christmas, it goes without saying that you will be the one to find the burnt-out bulb in the string.
- \* If you window shop at Radio Shack.
- \* If your ideal evening consists of fast-forwarding through the latest Sci-Fi movie looking for technical inaccuracies.
- \* If you have "Dilbert" comics displayed anywhere in your work area.
- \* If you carry on a one-hour debate over the expected results of a test that actually takes five minutes to run.
- \* If you are convinced you can build a phaser out of your garage door opener and your camera's flash attachment.
- \* If you don't even know where the cover to your personal computer is.
- \* If you have modified your can-opener to be microprocessor driven.
- \* If you know the direction the water swirls when you flush.
- \* If you own "Official Star Trek" anything.
- \* If you have ever taken the back off your TV just to see what's inside.
- \* If a team of you and your co-workers have set out to modify the antenna on the radio in your work area for better reception.

- \* If you ever burned down the gymnasium with your Science Fair project.
- \* If you are currently gathering the components to build your own nuclear reactor.
- \* If you own one or more white short-sleeve dress shirts.
- \* If you have never backed-up your hard drive.
- \* If you are aware that computers are actually only good for playing games, but are afraid to say it out loud.
- \* If you truly believe aliens are living among us.
- \* If you have ever saved the power cord from a broken appliance.
- \* If you have ever purchased an electronic appliance "as-is".
- \* If you see a good design and still have to change it.
- \* If the sales people at Circuit City can't answer any of your questions.
- \* If you still own a slide rule and you know how to work it.
- \* If the thought that a CD could refer to finance or music never enters your mind.
- \* If you own a set of itty-bitty screw drivers, but you don't remember where they are.
- \* If you rotate your screen savers more frequently than your automobile tires.
- \* If you have a functioning home copier machine, but every toaster you own turns bread into charcoal.
- \* If you have more toys than your kids.
- \* If you need a checklist to turn on the TV.
- \* If you have introduced your kids by the wrong name.
- \* If you have a habit of destroying things in order to see how they work.
- \* If your I.Q. number is bigger than your weight.
- \* If the microphone or visual aids at a meeting don't work and you rush up to the front to fix it.
- \* If you can remember 7 computer passwords but not your anniversary.
- \* If you have memorized the program schedule for the Discovery Channel and have seen most of the shows already.
- \* If you have ever owned a calculator with no equal key and know what RPN stands for.
- \* If your father sat 2 inches in front of your family's first color TV with a magnifying lens to see how they made the colors, and you grew

up thinking that was normal.

- \* If you know how to take the cover off of your computer, and what size screw driver to use.
- \* If you can type 70 words a minute but can't read your own handwriting.
- \* If people groan at the party when you pick out the music.
- \* If you can't remember where you parked your car for the 3rd time this week.
- \* If you did the sound system for your senior prom.
- \* If your checkbook always balances.
- \* If your wristwatch has more buttons than a telephone.
- \* If you have more friends on the Internet than in real life.
- \* If you thought the real heroes of "Apollo 13" were the Mission Controllers.
- \* If you think that when people around you yawn, it's because they didn't get enough sleep.
- \* If you spend more on your home computer than your car.
- \* If you know what http:// stands for.
- \* If you've ever tried to repair a \$5.00 radio.
- \* If you have a neatly sorted collection of old bolts and nuts in your garage.
- \* If your three year old son asks why the sky is blue and you try to explain atmospheric absorption theory.
- \* If your lap-top computer costs more than your car.
- \* If your 4 basic food groups are: 1. Caffeine 2. Fat 3. Sugar 4. Chocolate.

---

## Chapter 22) Hardware, Software, Management Humor

(From: Dan Kuechle (dan\_kuechle@i-tech.com)).

A hardware engineer, a software engineer, and an engineering manager were skiing over the weekend. Upon leaving the resort the brakes failed on their car. They went screaming down the mountain until they drove into a snow bank. At this point they didn't know what to do. They still had half the mountain to descend, and no brakes. The engineering manager said "I will head

up a task force to brainstorm the problem, and then come up with a schedule to implement the outcome." The hardware engineer said "I can fix these brakes! I will jack up the car, remove the wheels, and fix them with my Swiss army knife." The software engineer's only comments were "I think we ought to push the car back up the mountain, try it again, and see if it fails the same way"

---

## Chapter 23) Why Engineers Don't Write Recipe Books

(From: Redd Emmett R (err557f@cnas.smsu.edu)).

Here's one that a friend of mine sent me, I found it pretty funny.

Why Engineers Don't Write Recipe Books:

-----  
Chocolate Chip Cookies:

Ingredients:

1. 532.35 cm<sup>3</sup> gluten
2. 4.9 cm<sup>3</sup> NaHCO<sub>3</sub>
3. 4.9 cm<sup>3</sup> refined halite
4. 236.6 cm<sup>3</sup> partially hydrogenated tallow triglyceride
5. 177.45 cm<sup>3</sup> crystalline C<sub>12</sub>H<sub>22</sub>O<sub>11</sub>
6. 177.45 cm<sup>3</sup> unrefined C<sub>12</sub>H<sub>22</sub>O<sub>11</sub>
7. 4.9 cm<sup>3</sup> methyl ether of protocatechuic aldehyde
8. Two calcium carbonate-encapsulated avian albumen-coated protein
9. 473.2 cm<sup>3</sup> theobroma cacao
10. 236.6 cm<sup>3</sup> de-encapsulated legume meats (sieve size #10)

To a 2-L jacketed round reactor vessel (reactor #1) with an overall heat transfer coefficient of about 100 Btu/F-ft<sup>2</sup>-hr, add ingredients one, two and three with constant agitation. In a second 2-L reactor vessel with a radial flow impeller operating at 100 rpm, add ingredients four, five, six, and seven until the mixture is homogeneous. To reactor #2, add ingredient eight, followed by three equal volumes of the homogeneous mixture in reactor #1. Additionally, add ingredient nine and ten slowly, with constant agitation. Care must be taken at this point in the reaction to control any temperature rise that may be the result of an exothermic reaction.

Using a screw extrude attached to a #4 nodulizer, place the mixture piece-meal on a 316SS sheet (300 x 600 mm). Heat in a 460K oven for a period of time that is in agreement with Frank & Johnston's first order rate expression (see JACOS, 21, 55), or until golden brown. Once the reaction is complete, place the sheet on a 25C heat-transfer table, allowing the product to come to equilibrium.

Someone's note: Cookie sheet thickness is unspecified :-).

---

# Chapter 24) How Data Really Travels

(Author: Anonymous).

If a packet hits a pocket on a socket on a port,  
And the bus is interrupted as a very last resort,  
And the address of the memory makes your floppy disk abort  
Then the socket packet pocket has an error to report.

If your cursor finds a menu item followed by a dash,  
And the double-clicking icon puts your window in the thrash,  
and your data is corrupted 'cause the index doesn't hash,  
The your situation's hopeless, and your system's gonna crash!

You can't say this? What a shame, Sir!  
We'll find you another game, Sir...

If the label on the cable on the table at your house,  
Says the network is connected to the button on your mouse,  
But your packets want to tunnel on another protocol,  
That's repeatedly rejected by the printer down the hall,

And your screen is all distorted by the side effects of Gauss  
So your icons in the window are as wavy as a souse,  
Then you may as well reboot and then you go out with a bang,  
Cause as sure as I'm a poet, the sucker's gonna hang!

When the copy of your floppy's on the disk,  
And the microcode instructions cause unnecessary risk,  
Then you have to flash your memory and you'll want to RAM your ROM.  
Quickly turn off the computer and be sure to tell your Mom!

---

# Chapter 25) Is Hell Endothermic or Exothermic?

(From: Christopher Donham (donham@axon.engr.sgi.com)).

A thermodynamics professor had written a take home exam for his graduate students. It had one question:

"Is hell exothermic or endothermic? Support your answer with a proof."

Most of the students wrote proofs of their beliefs using Boyle's Law or some variant. One student, however wrote the following:

"First, we postulate that if souls exist, then they must have some mass.

If they do, then a mole of souls can also have a mass. So, at what

rate are souls moving into hell and at what rate are souls leaving? I think that we can safely assume that once a soul gets to hell, it will not leave. Therefore, no souls are leaving.

As for souls entering hell, lets look at the different religions that exist in the world today. Some of these religions state that if you are not a member of their religion, you will go to hell. Since, there are more than one of these religions and people do not belong to more than one religion, we can project that all people and all souls go to hell.

With birth and death rates as they are, we can expect the number of souls in hell to increase exponentially.

Now, we look at the rate of change in volume in hell. Boyle's Law states that in order for the temperature and pressure in hell to stay the same, the ratio of the mass of souls and volume needs to stay constant.

So, if hell is expanding at a slower rate than the rate at which souls enter hell, then the temperature and pressure in hell will increase until all hell breaks loose.

Of course, if hell is expanding at a rate faster than the increase of souls in hell, than the temperature and pressure will drop until hell freezes over."

---

## Chapter 26) English is Such a Crazy Language

(From: Ravi Pillutla (ravi@repairfaq.org)).

Let's face it: English is a crazy language. There is no egg in eggplant or ham in hamburger; neither apple nor pine in pineapple.

English muffins were not invented in England or french fries in France. Sweetmeats are candies, while sweetbreads, which aren't sweet, are meat.

We take English for granted. But if we explore its paradoxes, we find that quicksand can work slowly, boxing rings are square, and a guinea pig is neither from Guinea nor is it a pig. And why is it that writers write, but fingers don't fing, grocers don't groce, and hammers don't ham? If the plural of tooth is teeth, why isn't the plural of booth beeth? One goose, 2 geese. So, one moose, 2 meese? One index, two indices? Is cheese the plural of choose?

If teachers taught, why didn't preachers praught? If a vegetarian eats vegetables, what does a humanitarian eat?

In what language do people recite at a play, and play at a recital? Ship by truck and send cargo by ship? Have noses that run and feet that smell? Park on driveways and drive on parkways?

How can a slim chance and a fat chance be the same, while a wise man and a wise guy are opposites? How can the weather be hot as h\*ll one day and cold as h\*ll another?

When a house burns up, it burns down. You fill in a form by filling it out and an alarm clock goes off by going on.

When the stars are out, they are visible, but when the lights are out, they are invisible. And why, when I wind up my watch, I start it, but when I wind up this essay, I end it?

Now I know why I flunked my English. It's not my fault -- the silly language doesn't quite know whether it's coming or going.

---

## Chapter 27) You Wouldn't Believe These on Amazing Stories

- \* Police in Wichita, Kansas, arrested a 22-year-old man at an airport hotel after he tried to pass two (counterfeit) \$16 bills.
- \* A man in Johannesburg, South Africa, shot his 49-year-old friend in the face, seriously wounding him, while the two practiced shooting beer cans off each other's head.
- \* A company trying to continue its five-year perfect safety record showed its workers a film aimed at encouraging the use of safety goggles on the job. According to Industrial Machinery News, the film's depiction of gory industrial accidents was so graphic that twenty-five workers suffered minor injuries in their rush to leave the screening room. Thirteen others fainted, and one man required seven stitches after he cut his head falling off a chair while watching the film.
- \* The Chico, California, City Council enacted a ban on nuclear weapons, setting a \$500 fine for anyone detonating one within city limits.
- \* A bus carrying five passengers was hit by a car in St. Louis, but by the time police arrived on the scene, fourteen pedestrians had boarded the bus and had begun to complain of whiplash injuries and back pain.
- \* Swedish business consultant Ulf af Trolle labored 13 years on a book about Swedish economic solutions. He took the 250-page manuscript to be copied, only to have it reduced to 50,000 strips of paper in seconds when a worker confused the copier with the shredder.
- \* A convict broke out of jail in Washington D.C., then a few days later accompanied his girl friend to her trial for robbery. At lunch, he went out for a sandwich. She needed to see him, and thus had him

paged. Police officers recognized his name and arrested him as he returned to the courthouse in a car he had stolen over the lunch hour.

- \* Police in Radnor, Pennsylvania, interrogated a suspect by placing a metal colander on his head and connecting it with wires to a photocopy machine. The message "He's lying." was placed in the copier, and police pressed the copy button each time they thought the suspect wasn't telling the truth. Believing the "Lie Detector" was working, the suspect confessed.
- \* When two service station attendants in Ionia, Michigan, refused to hand over the cash to an intoxicated robber, the man threatened to call the police. They still refused, so the robber called the police and was arrested.
- \* A Los Angeles man who later said he was "tired of walking," stole a steamroller and led police on a 5 mph chase until an officer stepped aboard and brought the vehicle to a stop.

---

## Chapter 28) Some 'Facts' About Electricity

(From: Jussi Kaasinen (Jussi.Kaasinen@hut.fi)).

Read this but be careful: you might not get any sleep tonight because of these shocking facts...

Perhaps the greatest Electrical Pioneer of them all was Thomas Edison, who was a brilliant inventor despite the fact that he had little formal education and lived in New Jersey. Edison's first major invention in 1877, was the phonograph, which could soon be found in thousands of American homes, where it basically sat until 1923, when the record was invented. But Edison's greatest achievement came in 1879, when he invented the electric company. Edison's design was a brilliant adaptation of the simple electrical circuit: the electric company sends electricity through a wire to a customer, then immediately gets the electricity back through another wire, then (this is the brilliant part) sends it right back to the customer again.

This means that an electric company can sell a customer the same batch of electricity thousands of times a day and never get caught, since very few customers take the time to examine their electricity closely. In fact the last year any new electricity was generated in the United States was 1937; the electric companies have been merely re-selling it ever since, which is why they have so much free time to apply for rate increases.

-- Dave Barry, "What is Electricity?"

---

# Chapter 29) Funny Way to Get Rid of Telemarketers

(From: SLEEZY (sleezy@usa.net)).

I look forward to telemarketers because I have great fun at their expense.

1. Act hard of hearing and make them repeat things.
2. When asked a questions, answer another one (Them: Sir, would you be interested in buying our crap? Me: Why yes, I would do like ice cream).
3. Act extremely stupid and ask off the wall questions (So...how long does distance have to be before it's considered long distance?).
4. I hand off the phone to my 13 month old.
5. Start off talking to them but at some point quit talking. After they ask if your still there and seem like they're going to hang up, start talking and get them going again. Repeat as necessary.
6. Act REALLY excited. (WHAT? I'm preapproved for my OWN CREDIT LINE? Off PHone: Oh honey, come quick!!! This nice man says I have excellent credit. OH HAPPY DAY!!!!!!) This gets some really strange reactions.
7. Let them go through their entire pitch then at the end say, "Oh, I'm sorry, I thought you were someone else."
8. Let them go through their entire pitch, then at the end say, "Did you know you have spinach in your teeth?".
9. Sound like a pysco-killer
10. Tell them you have a bad connection but really are interested. Then speak VERY loudly.
11. Say "I'm sorry, you caught me right in the middle of [favorite sexual act here]."
12. If it's a person of the opposite sex, start hitting on them.
13. Every once in a while bark.
14. Start arguing with yourself.

So use your imagination...add to this list.

---

## Chapter 30) The Farmhouse (A Lawyer Joke)

(From: Jim Lagerkvist (jlager@tir.com)).

A rabbi, a hindu, and a lawyer are in a car. they run out of gas, and are forced to stop at a farmers house. The farmer says that there are only 2 extra beds, and one person will have to sleep in the barn. The hindu says, "I'm humble, I will sleep in the barn," so he goes out to the barn. In a few minutes, the farmer hears a knock on the door. It's the hindu and he says, "There is a cow in the barn. It's against my beliefs to sleep with a cow." So the rabbi says, "I'm humble, I will sleep in the barn." A few minutes later, the farmer hears another knock on the door and its' the rabbi. He says that it is against his beliefs to sleep where there is a pig and there is a pig in the barn. So the lawyer is forced to sleep in the barn.

A few minutes later, there is a knock on the door. It's the pig and the cow.

---

## Chapter 31) The Parrot

(From: Dave A. Wreski (dawreski@nic.com)).

A magician was working on a cruise ship in the Caribbean. The audience would be different each week, so the magician allowed himself to do the same tricks over and over again.

There was only one problem: The captain's parrot saw the shows each week and began to understand how the magician did every trick. Once he understood he started shouting in the middle of the show:

"Look, it's not the same hat"

"Look, he is hiding the flowers under the table"

"Hey, why are all the cards the Ace of Spades?"

The magician was furious but couldn't do anything; it was, after all, the captain's parrot.

One day the ship had an accident and sank. The magician found himself on a piece of wood in the middle of the ocean with the parrot, of course.

They stared at each other with hate, but did not utter a word. This went on for a day and another and another.

After a week the parrot said: "OK, I give up. Where's the boat?"

---

## Chapter 32) How High Do You Jump (Discharging a TV)?

(From: Bert Christensen).

A tech that worked for me many years ago was holding on to a chassis and leaning forward to see something on the other side. He was always rather careless and had hooked up the HV lead in a sloppy >manner. His forehead came in contact with the 30kv. He jumped up into the air, turned around twice, said, "I almost f\_\_\_ING lled myself, >walked out into the customer waiting area and cried. Ten minutes later he was in working on the same set.

We later drew a scale on a leg of the bench. One inch represented how high you jumped with 1 KV and 25 inches for 25 KV, etc. It was remarkably accurate.

(From: Vic Tosca (tosca@warwick.net)).

That's a KICKER!! I've got the same thing here, but I have it scaled to .808 in/KV. I found that's the accurate formula for the average weight bench tech, including glasses and pocket protector. We also put a bell on the ceiling- anyone that hits it with his head because of a shock gets a day off!

It's located right under the emergency repair tool kit, which consists of a rabbit's foot, a magic wand, a crystal ball, and a hammer. We had to get rid of the hand grenade...insurance laws, y'know. THAT was a \*great\* tool for tough dogs and irate customers!

Clients love it.

---

## Chapter 33) New and Improved Hell

(From: Dave A. Wreski (dawreski@nic.com)).

Author unknown:

An engineer dies and reports to the pearly gates. St. Peter checks his dossier and says, "Ah, you're an engineer -- you're in the wrong place."

So the engineer reports to the gates of hell and is let in. Pretty soon, the engineer gets dissatisfied with the level of comfort in hell, and starts designing and building improvements. After a while, they've got air conditioning and flush toilets and escalators, and the engineer is a pretty popular guy.

One day God calls Satan on the telephone and says with a sneer, "So, how's it going down there in hell?"

Satan replies, "Hey, things are going great. We've got air conditioning and flush toilets and escalators, and there's no telling what this engineer is going to come up with next."

God replies, "What??? You've got an engineer? That's a mistake - he should never have gotten down there; send him up here."

Satan says, "No way. I like having an engineer on the staff, and I'm keeping him."

God says, "Send him back up here or I will sue."

Satan laughs uproariously and answers, "Yeah, right. And just where are YOU going to get a lawyer?"

---

## Chapter 34) Don't lose Those Unpacking Instructions!

A SCSI drive shipped from Bubba's in Louisiana with THIS article in the packaging. No kidding!!! ACTUAL UNPACKING INSTRUCTIONS

IMPORTANT! READ THIS BEFORE USING YOUR NEW DEVICE!

Congratulations! You have purchased an extremely fine device that would give you thousands of years of trouble-free service, except that you undoubtedly will destroy it via some typical bonehead consumer maneuver.

Which is why we ask you to:

PLEASE, FOR GOD'S SAKE, READ THIS OWNERS MANUAL CAREFULLY BEFORE YOU UNPACK THE DEVICE. YOU ALREADY UNPACKED IT, DIDN'T YOU? YOU UNPACKED IT AND PLUGGED IT IN AND TURNED IT ON AND FIDDLED WITH THE CONTROLS, AND NOW YOUR CHILD, THE SAME CHILD WHO ONCE SHOVED A POLISH SAUSAGE INTO YOUR VIDEOCASSETTE RECORDER AND SET IT ON "FAST FORWARD", THIS CHILD IS ALSO FIDDLING WITH THE CONTROLS, RIGHT? WE MIGHT AS WELL JUST BREAK THESE DEVICES RIGHT AT THE FACTORY BEFORE WE SHIP THEM OUT, YOU KNOW THAT?!?

We're sorry. We just get a little crazy sometimes because we're always getting back "defective" merchandise where it turns out that the consumer inadvertently bathed the device in acid for six days. So, in writing these instructions, we naturally tend to assume that your skull is filled with dead insects, but we mean nothing by it. OK? Now let's talk about:

### 1. UNPACKING THE DEVICE

The device is encased in foam to protect it from the Shipping People, who like nothing more than to jab spears into outgoing boxes.

PLEASE INSPECT THE CONTENTS CAREFULLY FOR GASHES OR IDA MAE BARKER'S ENGAGEMENT RING, WHICH SHE LOST LAST WEEK, AND SHE THINKS MAYBE IT WAS LOST WHILE SHE WAS PACKING DEVICES.

Ida Mae really wants that ring back, because it is her only proof of engagement, and her fiancée, Stuart, is now seriously considering backing out on the whole thing, in as much as he had consumed most of a bottle of Jim Beam in Quality Control when he decided to pop the question. It is not without irony that Ida Mae's last name is "Barker", if you catch our drift. WARNING:

DO NOT EVER, AS LONG AS YOU LIVE, THROW AWAY THE BOX OR ANY OF THE PIECES OF STYROFOAM, EVEN THE LITTLE ONES SHAPED LIKE PEANUTS.

If you attempt to return the device to the store, and you are missing one single peanut, the store personnel will laugh in the chilling manner exhibited by Joseph Stalin just after he enslaved Eastern Europe.

Besides the device, the box should contain:

- \* Eight little rectangular snippets of paper that say "WARNING".

- \* A little plastic packet containing four 5/17 inch pilfer grommets and two club-ended 6/93 inch boxcar prawns.

YOU WILL NEED TO SUPPLY: a matrix wrench and 60,000 feet of tram cable.

IF ANYTHING IS DAMAGED OR MISSING: YOU IMMEDIATELY should turn to your spouse and say "Margaret, you know why this country can't make a car that can get all the way through the drive-through at Burger King without a major transmission overhaul? Because nobody cares, that's why."

WARNING: This is assuming your spouse's name is Margaret. And not Pete.

## 2. PLUGGING IN THE DEVICE.

The plug on this device represents the latest thinking of the electrical industry's Plug Mutation Group, which, in a continuing effort to prevent consumers from causing hazardous electrical current to flow through their appliances, developed the Three-Pronged Plug, then the Plug Where One Prong Is Bigger Than The Other. Your device is equipped with the revolutionary new Plug Whose Prongs Consist Of Six Small Religious Figurines Made Of Chocolate.

DO NOT TRY TO PLUG IT IN!

Lay it gently on the floor near an outlet, out of direct sunlight, and water it weekly with a damp handkerchief.

WARNING: WHEN YOU ARE LAYING THE PLUG ON THE FLOOR, DO NOT HOLD A SHARP OBJECT IN YOUR OTHER HAND AND TRIP OVER THE CORD AND POKE YOUR EYE OUT, AS THIS COULD VOID THE WARRANTY.

## 3. OPERATION OF THE DEVICE

WARNING: WE MANUFACTURE ONLY THE ATTRACTIVE DESIGNER CASE. THE ACTUAL WORKING CENTRAL PARTS OF THE DEVICE ARE MANUFACTURED IN JAPAN. THE INSTRUCTIONS WERE TRANSLATED BY MRS. SHIRLEY PELTWATER OF ACCOUNTS RECEIVABLE, WHO HAS NEVER ACTUALLY BEEN TO JAPAN BUT DOES HAVE MOST OF "SHOGUN" ON TAPE.

INSTRUCTIONS: For results that can be the finest, it is our advising that: NEVER to hold these buttons two times!! Except the battery. Next taking the (something) earth section may cause a large occurrence! However. If this is not a trouble, such rotation is a very maintenance action, as a kindly (something) virepoint from Drawing B.

## 4. WARRANTY

Be it hereby known that this device, together with but not excluding all those certain parts thereunto, shall be warranted against all defects, failures and

malfunctions as shall occur between now and Thursday afternoon, shortly before 2, during which time the Manufacturer will, at no charge to the Owner, send the device to our Service People, who will emerge from their caves and engage in rituals designed to cleanse it of evil spirits. This warranty does not cover the attractive designer case.

WARNING: IT MAY BE A VIOLATION OF SOME LAW THAT MRS. SHIRLEY PELTWATER HAS "SHOGUN" ON TAPE.

---

## Chapter 35) An Engineer in Paradise

(From Glenn E Wilkop (Glenn\_E\_Wilkop@email.whirlpool.com)).

This one comes from our beloved Mr. Tibbs... Enjoy!

A rather inhibited engineer finally splurged on a luxury cruise to the Caribbean. It was the "craziest" thing he had ever done in his life. Just as he was beginning to enjoy himself, a hurricane roared on the huge ship, capsizing it like a child's toy. Somehow the engineer, desperately hanging on to a life preserver, managed to wash ashore on a secluded island. Outside of beautiful scenery, a spring-fed pool, bananas and coconuts, there was little else. He lost all hope and for hours on end, sat under the same palm tree.

One day, after several months had passed, a gorgeous woman in a small rowboat appeared. "I'm from the other side of the island," she said. "Were you on the cruise ship, too?" "Yes, I was", he answered, "But where did you get that rowboat?" "Well, I whittled the oars from gum tree branches, wove the reinforced gunnel from palm branches, and made the keel and stern from a Eucalyptus tree." "But what did you use for tools?" asked the man. "There was an unusual strata of alluvial rock exposed on the south side of the island. I discovered that if I fired it to a particular temperature in my kiln, it melted into forgeable ductile iron. Anyhow, that's how I got the tools. But enough of that," she said, "where have you been living all this time? I don't see any shelter." "To be honest, I have just been sleeping on the beach," he said. "Would you like to come to my place?" the woman asked. The engineer nodded dumbly.

She expertly rowed them around to her side of the island, and tied up the boat with a handsome strand of hand-woven hemp topped with a neat back splice. They walked up a winding stone walk she had laid around a palm tree. There stood an exquisite bungalow painted in blue and white. "It's not much but I call it home." Inside she said, "sit down, please. Would you like to have a drink?" "No, thanks," said the man. "One more coconut juice and I will throw up." "It won't be coconut juice," the woman replied. "I have a crude still out back so we can have authentic Pina Colodas." Trying to hid his amazement, the man accepted the drink and they sat down on her couch to talk. After they had exchanged stories, the woman asked, "Tell me, have you always had a beard?" "No," the man replied. " I was clean shaven all my life

till I ended up on this island." "Well, if you'd like to shave, there's a razor upstairs in the bathroom." The man, no longer questioning anything, went upstairs to the bathroom and shaved with an intricate bone-and-shell device that was honed razor sharp. Next he showered, not even attempting to guess how she managed to get warm water into the bathroom. Then he went back downstairs. "You look great," said the woman. "I think I will go up and slip into something more comfortable." As she did, the man continued to sip his Pina Colada. After a short time, the woman, smelling of gardenias, returned revealing a gown fashioned out of pounded palm fronds. "Tell me," she asked, "We've both been out here for a very long time with no companionship. You know what I mean. Have you been lonely...is there anything you really miss? Something that all men and women need? Something that would be really nice right now?" "Yes there is!" the man replied, shucking off his shyness. "There is something I've wanted to do for so long but on this island it was well...impossible." "Well, it is not impossible any more" the woman said. The man, practically panting in excitement, said breathlessly, "You mean you actually figured out some way we can check our e-mail here?"

---

## Chapter 36) Hot Water and Ice Makers

(From: Chris Hagwood (hagwood@pobox.com)).

My neighbor just bought a new fridge. He said he was gonna put in an icemaker line, so I stopped by to see how he was getting along. He said he was almost done, but had some trouble early on:

He had called his cousin, who told him to tap into the HOT water line, since "hot water freezes faster--that's a fact" he tells me. So I bit my tongue and waited for him to finish telling me what went wrong. "Did it melt the plastic line?", I thought. No, it seems that he forgot that the same water that was going into his icemaker was going to the "cold water through the door". He would get one glass of cold water, then a glass of HOT! So he had to redo everything on a cold line.

Geez Louis! What people will believe.... "hot water freezes faster"! Insane.

Editor's note: The "Hot water freezes faster" thread, like "NiCds and the memory effect" and "PCs versus Macs" threads are typically never ending. There are simply too many variables to consider in an Internet discussion.

---

## Chapter 37) Horsepower Ratings and AC Line Magnets

"How can an electric motor generate 5HP from a 120VAC, 15A wall outlet that puts out only 2.4 HP?"

(From: John M. Feiereisen (feierejm@utrc.utc.com)).

Maybe they were using Ecoblow(tm) power line magnets. Ordinary electricity molecules clump up and do not efficiently energize electrical equipment. The powerful magnetic field of the Ecoblow breaks up these clumps and aligns the electricity molecules through a process known as gullibility-induced victimization, thereby resulting in more efficient scam - oops - operation.

Using an Ecoblow, you can squeeze almost 35 HP out of an ordinary 120 V, 15 A circuit!

A local bakery installed an Ecoblow 3 on the power cord to their industrial size mixer. Heck, the thing spins so fast now, they don't even have use the oven to bake their bread. (Good thing, too, since they burn their bread with it ever since they installed the Ecoflow(tm) gas line magnet.)

I've got an Ecoblow 3 on the power cord to my 128K Mac and now it's about twice as fast as a Sun Ultra 2! An amazing side effect is that I'm now able run codes in 128KB of memory when they used to take a minimum of 64 MB!

I'm currently in the process of coupling an electric motor to an electrical generator. An Ecoblow 3 on the output of the generator will allow me to power the electric motor \*and\* produce enough electricity to power my house!

Ecoblow - buy one now, because somebody's got to take your money.

---

## Chapter 38) All About AC Batteries

> This AC Battery thing is all conspiracy - a US Government cover-up.  
> However, now we have the "Net" and soon the truth will be out about  
> Elvis, Roswell, lost socks and AC 9V batteries.

(From: Bob Myers (myers@fc.hp.com)).

Sigh.

I can't believe what a young, gullible crowd we have here. You guys will swallow ANYTHING.

Any true Old Hand at electronics would know that the AC output from 9V batteries is simply a holdover from the days of portable tube radios. The AC was used to run the filaments, and also served to drive the DC-to-DC converter that was used to obtain the 100-200V of plate voltage from the 9V DC output. (Yes, they tried the obvious route of simply making 200 VDC batteries - still with the necessary AC output, mind you! - but some tragic accidents at a few K-marts (which were ultimately traced to a simple packaging defect) ended THAT standard really quickly, let me tell you.

Today, of course, it's rare to find a product which actually makes USE of the AC output from these batteries, with the exception of some earlier portable CD players which derived the base for the multiple-phase oversampling input oscillation-compensation stage backup clock from it. (And boy, weren't THOSE designs fun, huh?) But once a standard is established, it's hard to get rid of it. Especially with all those production lines already tooled up. Sure, they might save a little in not having to add the cavorite in at the anode insertion process, but it's NOT worth completely rebuilding the line, trust me.

Sure glad I could clear that up for you.

---

## Chapter 39) CDs in the Microwave

In response to the following exchange:

"Yes, my microwave-damaged CD's are difficult to repair too. :)"

"What are micro wave damaged CD's?"

(From: DaViD Boulet/Don Harley (dharley@bellatlantic.net)).

The trick is to use a very high-quality line-conditioner for the microwave. I try to microwave my CD's late at night when the electricity is "cleanest" to get the best results. Also, I've found that the newer microwaves with LED time-displays seem to add some euphonic properties to the sound...more relaxed treble, smoother string sound and more liquid midrange. What would be great is if I could get a microwave oven with a detachable power cord so I could use a good-quality MIT power cable. Now *that* would be neat.

I'm hoping that some audiophile company picks up on this and gives a tube-based microwave. Too bad Audio Alchemy went out of business. I heard that they had plans to release an audiophile-designed (tube?) microwave oven before they went under. Any ideas if Camelot might pick up on this? The important thing is that they keep the price under the \$1000 to make it affordable to the "normal" starving audiophile.

"Ahh, have you tried STEREO m'waves yet? You have to buy 2 CDs, but the sound is well worth it. Make sure that both microwaves are the same brand so that you can use just 1 remote..."

(From: DaViD Boulet/Don Harley (dharley@bellatlantic.net)).

I like your suggestion except for one thing...I don't believe that remotes should be part of a high-end microwave set-up. In my opinion...one should get up to change the minutes/defrost setting. My experience has shown that, in general, companies who offer remotes with their microwaves seem to compromise in sound-quality. Then again, this effect is not resultant from the remote itself. It just seems to stem from a "philosophy" of consumer-gadgetry that many "receiver" style microwave ovens reflect. My favorite (and best sounding) microwave is plain black...with a simple "on-off" switch and no tone controls.

(From: Pat Crean (pat@crean.com)).

Mine sounded FANTASTIC until the turntable stopped - I'm going to make sure my next microwave has a built-in carousel for uninterrupted listening pleasure!

(From: Ian Stirling 000033C19ADC.NO\_UCE@mauve.demon.co.uk)).

Hmm, anyone thought about making a plasma speaker, using a modulated microwave?

(From: Armand (mondo@voicenet.com)).

I tried shaking my MV rapidly and nothing happened-- although my macaroni and cheese did resemble plasma. ;}

(From: Dave).

I doubt that with the grade of microwave-wire you're using...you'd possibly be able to hear the improvement. Why invest hundreds of dollars in a high-end microwave set-up (including disc treatments like the marinating solvent...which I heard at my friend's house and it *\*really\** makes a noticeable difference...especially in the bass--much more dynamic and full) only to shove that signal through a cheap pair of interconnects? IMO, you should have *\*just\** as much money invested in your microwave cables as you spend on the rest of microwave-system.

(From: Derrick Hopkins (dhopkins@infi.net)).

Oh please. If you're going to go with Microwaved CD's (instead of the vastly superior Oven cooked LP's) it doesn't really matter kind of interconnect you use. A micro waved atom is a microwaved atom..period. Even if it's garbled a little, the average person can hear a difference.

When you get past all of the audiophile/gourmet snobbery, you'll realize that a \$99 Walmart microwave sounds just as good as a \$7000 McIntosh microwave.

Consumer Reports did a huge feature on this back in March '92. A Kmart microwave placed ahead of Carver, Sony, Westinghouse, and Adcom. The only model to beat it was Denon and that's only because it was THX/Redenbokker certified.

(From: DaViD Boulet/Don Harley (dharley@bellatlantic.net)).

First of all...we *\*all\** know that when consumer reports rates microwaves...sound quality is the last thing on their mind. If I recall, they didn't even feel that gold-plated-audiophile microwaves offered any sonic improvement! Consumer reports is only interested in specs and features...

Secondly, your assertion that a 10 year old conventional oven-baked LP can sound *\*better\** than a microwaved CD won't be true much longer. Once we get the next-generation of DVD-based Microwaves with 24-beep/96-calories and multi-panel sound, the debate between analog-ovens and digital microwaves will be over once and for all.

(From: Guillermo Gonzalez (gonzalez@netrox.net)).

Yeah, but my problem remains, that the copper sulfate used in the green marker that I use on my CD's, well, it causes some serious arcing in the microwave...

Alas, what is an audiophile to do?

(From: L. E. Sixma (lesixma@introweb.nl)).

Reheat the lot in a gas-oven for 24 hours at a temperature of 215 degrees Centigrade could do the trick. This is a classic analogue trick. Still you got to be shure that the cookies are taken out in time or else they will be sounding awful. Cassette-spaghetti takes less cooking time and in this case 100 degrees will do for audiophile ear-food.

(From: Nicholas Bodley (nbodley@tiac.net)).

Just a tad off color, but curious. Reminds me of the apparently true story about the red-tailed hawks that would periodically let out a long stream above high-voltage transmission lines and cause arcs that tripped circuit breakers and shut down the lines. This was a significant problem for a while, until they found out how to make the hawks move elsewhere (I've forgotten how they did it). Apparently, the hawks weren't hurt...

---

## Chapter 40) The Barking Dog

(From: Jack Kraft (jackjk@iwaynet.net)).

It is common practice in England to ring a telephone by signaling extra voltage across one side of the two wire circuit and ground (earth in England). When the subscriber answers the phone, it switches to the two wire circuit for conversation. This method allows two parties on the same line to be signaled without disturbing each other.

Anyway, an elderly lady with several pets called to say that her telephone failed to ring when her friends called and on the few occasions when it did ring her dog always barked first just before the ring. Pat proceeded to the scene, curious to see this psychic dog.

He climbed the nearby pole, hooked his test set to the lady's line, and dialed the number. The phone didn't ring. He tried again. The dog barked loudly, followed by a ringing telephone. Climbing down the pole the amazed Pat found:

1. The dog was tied to the telephone systems ground post via a metal chain and collar.
  2. The dog was receiving 90 volts of signaling current.
  3. After several such jolts, the dog would start barking and urinating on the ground.
  4. The wet ground now completed the circuit and the phone would ring.
-

# Chapter 41) On the Effects of Magnetic Water Softeners

(From: several authors, unknown, for obvious reasons).

"Testing magnetic softeners can be very dangerous. Should you accidentally over-magnetize the water and unknowingly drink the same, your stomach could burst if you come too near a large ferrous object."

"This happened to a friend of mine. With the philosophy "if one is good, two is better", he put two magnetic water softeners on the same line. Being warm from doing the job, he took a large drink, than walked by a steel support post in his basement. He was in the hospital for over a month while they did reconstructive surgery on his guts...

Oddly enough, until the magnets were removed, all his faucets constantly oriented themselves toward the north. It was spooky..."

"This really explains a lot for me!

I installed one of these when we first moved into our house 4 years ago. Ever since then we wake up each morning facing north for no apparent reason. If my wife and I sleep facing the same direction (head to toe) we wake up on opposite sides of the bed. If we sleep in opposite directions we wake up clinging to each other in the middle of the bed. Our dishes and clothes always manage to align with north after several days in the drawers too. My 10 month old daughter just started to crawl and she only crawls towards north. We have shale in the ground here and a well. Shale contains lots of iron. We must be magnetizing the iron molecules in the water. The grass that I water always seems to bend north no matter which way I mow. Several floppy disks and video tapes which I stored near an humidifier were mysteriously erased. I seem to bump into large steel objects a lot. Some times I have a hard time getting out of the car, and I never seem to be able to get a compass to work correctly."

In response to the question: "Why are magnetic water softeners so expensive":

"That's probably because you're pricing it as though they were ORDINARY magnets, which of course are fairly inexpensive. But, as anyone will tell you, ordinary magnets do not have any water-conditioning capabilities.

I believe the magnets used in these water conditioners are quantum-mechanic super-heterodyne field effect tachyon-modulated (QMSHFETM) magnets, which of course are more expensive. The manufacturer uses a proprietary process which converts ordinary magnets into the QMSHFETM type, and the process ain't cheap. (This same process, I believe, is what is used to make the 'blue water' that goes into those Laundry CD's and other devices which replace laundry detergent. Hence, these devices are also much more expensive than one would expect for a piece of plastic filled with blue dye.)"

"Of course the price is higher than the materials; the question is, what are the potential benefits worth to you?"

After we started using it, our water became so soft we have to add salt to it to get the soap off our skin; my polyps shrank; and my children started getting better grades at school. If Monsieur Henri Paul had passed his wine through a magnetic conditioner, all this would never have happened. So anyway, I recommend it highly at any price.

In addition, I have been watering my flowers with the magnetized water. You've never seen such roses...they're the size of satellite dishes. (I mean those new DSS ones, not the old large ones. Maybe if I planted old roses...) Curiously, the roses all point north. I guess that's because they're magnetized. This makes them useless as satellite dishes, because the geosynchronous satellites are all in the southern sky."

"Yeah, but have you tried putting the conditioned water on dollar bills? Several weeks after getting mine, I left a couple of one dollar bills in my pants in the wash. Boy was I surprised when I took the pants out of the dryer to find two \*TEN\* dollar bills in the pocket.

Since then, I've laundered over 70 one dollar bills, netting me a \$630 profit, which was almost enough to pay for the magnet. I'm seriously saving up for another one, figuring my dryer will then spit out \$100 bills, saving me lots of time!"

(From: Andy Wing).

A magnetic water softener limerick:

"The MWT pundits won't yield  
Despite no 'hard' evidence to wield  
, of course  
will flog the dead horse  
And insists that it works in the field!

Sorry folks, couldn't resist, puns intended :-).

---

## Chapter 42) Suggestions for Repairing Scratched CDs

(From: Christopher Bedwell (Bedwell@southwest.com.au)).

Try connecting the laser on your CD player to a flux capacitor. That should generate the 1.21 Giga Watts needed to repair the proton electrical photon surface. Hopefully with enough plutonium you can glow in the dark too!!!

Or you could just rub it in a MacDonalds burger! that certainly has enough chemical content residue to melt and re-bond anything.

---

# Chapter 43) Warnings about Sucking up Radio Waves

(From: Pat Crean (pat@crean.com)).

You have to be very careful when using devices with good sensitivity.

Remember, the transmitters are pumping a certain amount of power into the VHF/UHF bands with the expectation that there are receiving devices available to absorb it. If too many people use highly sensitive receivers, the excess energy not being absorbed will accumulate until we have an explosion in the affected band that will rival Krakatoa in its effects.

---

# Chapter 44) Engineers versus Business Executives

(From: Marcio Domene (mdomene@unisys.com.)).

Engineers and scientists will never make as much money as business executives.

Now a rigorous mathematical proof that explains why this is true:

Postulate 1: KNOWLEDGE is POWER

Postulate 2: TIME is MONEY

As every engineer knows: 
$$\frac{\text{WORK}}{\text{TIME}} = \text{POWER}$$

Since KNOWLEDGE = POWER, and TIME = MONEY, we have: 
$$\frac{\text{WORK}}{\text{MONEY}} = \text{KNOWLEDGE}$$

Solving for money, we get: 
$$\frac{\text{WORK}}{\text{KNOWLEDGE}} = \text{MONEY}$$

Thus, as KNOWLEDGE approaches zero, MONEY approaches infinity, regardless of the WORK done!

Conclusions: The less you know, the more money you Make.

Note: It has been speculated that the reason why Bill Gates dropped out of Havard's math program was because he stumbled upon this proof as an undergraduated, and dedicated the rest of his carrer to the pursuit of ignorance.

(From: John Woodgate (jmw@jmwa.demon.co.uk)).

But there is a third postulate, at least equally well-known as those:

Postulate 3: MONEY is POWER

But WORK/TIME = MONEY only if you are paid by the hour: monthly staff do not get overtime pay.

---

## Chapter 45) Keeping Electricity Working

(From: Dave VanHorn" (uce@ftc.gov)).

Warning: Do not read while drinking!

This is even funnier if you follow Alt.religion.scientology, but all by itself, it's a hoot.

HUMOR - KEEPING ELECTRICITY WORKING

The loyalist officers in 4th dimensional hiding captured the following post from the alt.religion.electricity newsgroup in an alternate universe. Any resemblance to Earth people living or dead is purely accidental and is due to God playing dice with the various universes.

- The Pilot

=====

KEEPING ELECTRICITY WORKING - A 21st Century Retrospective

By David MissCambridge, Keeper of the Current

Issue authority granted by the first Church of Edison

As KofC of the CofE, it is with humble pride and pleasure that I announce the upcoming hundredth anniversary of one of our most basic policies, Keeping Electricity Working, issued by our glorious founder on Jan 17, 1898.

It is this policy above all others which has preserved the technology of electricity for us and future generations.

It was here that TOM first identified the evil world conspiracy of financiers, plagiarists, and space aliens that was attempting to pervert his discoveries and deny electricity to mankind.

Consider, for example, the evil Tesla who proposed that the divine current should ALTERNATE! A stupid and ridiculous idea. How would it achieve any useful work if the current simply zig zagged back and forth in the wires? He would have undermined the entire structure of DIRECT CURRENT which moves DIRECTLY to its target and achieves LIGHTNING FAST 100 PERCENT STANDARD RESULTS.

But TAE, by virtue of his superior genius, saw that it wasn't just the yappings of Tesla and Westinghouse, for the same attacks and unworkable ideas were showing up all over the world.

Of course we know that the characteristics of a suppressive person would be to deny the truth of the CofE and seek to deny it financing by undercutting its prices. But it was only TAE himself who could spot the true source of all these SPs, the true suppressive influence behind them.

We now know that it was the Venusians, led by their evil telepathic ruler, XeMoonie, who inspired these diabolical attacks. But by means of our tin foil protective hats and an enlightened legal system, we have driven his influences off of Earth and will keep mankind free of his dreadful doings.

Now remember the key points,

1. Stamp out any experimentation or variation of our workable tech.
2. Buy a fresh foil hat from your local CofE every year
3. Report any squirrel wire twisters to the police immediately.

Remember that only certified CofE graduates may work on anything connected with electricity. We know that the courses are expensive, but the results are proven.

For Electricity is dangerous and anyone who applies squirrel practices to twist wires on their own could be electrocuted or have their house burned down. Your entire neighborhood is at risk if you ignore them. Keeping our homes safe is everybody's job.

And we have a wonderful new TECH BREAKTHROUGH to announce.

By careful study of TAE's research notes, we have discovered that the size of the wire might be increased to carry more current.

Our new double sized copper conductors will be available next year at only \$100 dollars a yard. Not only will this bring about obvious savings, but it will allow the average apartment house to support more lighting fixtures.

With this breakthrough, we think that it will even be possible to place lights in stairwells. Just imagine it, your iceman will no longer have to stumble around in the dark with a heavy and potentially dangerous cube of ice for your icebox.

We are working now on a project to carve TAE's writings onto iron plates and bury these in secret vaults all over the world. This will ensure that future civilizations will benefit from his wisdom and knowledge. Send your contributions in now.

Building a better future,

Davy

(end of interdimensionally captured transmission)

---

# Chapter 46) Transistors, Anyone?

I don't think the following questions are quite addressed but anyhow....

"Would you please tell me what transistors do and how they do so? What is the difference between PNP and NPN transistors? What is the concept of using a transistor as a switch? Thanks a lot."

(From: Gareth Alun Evans (gareth@cemetery.demon.co.uk)).

A transistor is rather like the human alimentary canal, after the typical USA diet of burgers and chips; - it constipates, as do semiconductor diodes with no applied bias - the available holes get filled in and nothing can move.

The base current is like a small application of laxative; some of the constipation passes through, until the effect of the laxative wears off. The total throughput depends upon the Mobility. By applying a continuous feed of laxative, then a continuous current passes through. Applying too much laxative results in saturation - i.e., there is a limit to the maximum throughput, depending on the external circuit; in this case, the maximum rate at which you can feed in the burgers at one end. (If you are a customer of MacDonalds, here in Chippenham, Wiltshire, UK then this rate is very low - I have been there twice, and both times, the service was \*APPALLING\*.)

The difference between PNP and NPN is the direction. In the old days, PNP was used, whereby one injected from the rear end, using a sort of huge syringe - hence PNP - "Put-in Near Poo". More recently NPN is more common, where the laxative is entered via a carrier of some sort, usually chocolate and so we have NPN - "Now Pleasant Nutrient".

Despite the adverse effects, the USA diet of burgers and chips carries on, and recourse has to be made once again to the chocolate. Now the ratio of the carriers of the constipation, the burgers and chips, is much higher than that of the chocolate. Thus they are referred to as the Majority Carriers and the Minority Carriers. If you indulge too much, you find that the vendor will provide you with a paper bag, known as an Excess Carrier.

More recently, there are problems with impurities and you find that the opposite effect occurs. You have no time to reach home before diarrhea takes over. You have no option but to stop the car and nip over a gate into a field. Hence the Field Effect Transistor. This time you have to inject something to STOP the flow. Now, assuming that there was a certain control over events; nothing happened until the Gate was encountered, you then became the Source of flow, and the field itself acted as the Drain. What was originally dirt, became grass, was consumed by the Cow, you ate it as a burger, and it has now returned to the topsoil, an effect known in the trade as Surface Recombination. (Incidentally, did you know that Diarrhea is hereditary? Apparently it runs in the jeans.)

Some of the impurities accumulate in your rear end, and no matter how valiantly you try, you cannot rid yourself of them. Hence In-de-Bum is known as a Try-Valiant Impurity. In the same way, Arsenic, well known for its ill-effects and accumulation in the body tissues is known as a Pent-Up-Valiant Impurity.

---

## Chapter 47) Bill Gates' New House

(Forwarded by: Bob Parker (bobpar@ozemail.com.au)).

While the Gateses are moving in from their temporary quarters nearby, final construction of their new house is not expected to be completed until the end of the year. Now if I were a contractor with a sense of humor...

Bill: "There are a few issues we need to discuss."

Contractor: "Ah, you have our basic support option. Calls are free for the first 90 days and \$75 a call thereafter. Okay?"

Bill: "Uh, yeah... the first issue is the living room. We think it's a little smaller than we anticipated."

Contractor: "Yeah. Some compromises were made to have it out by the release date."

Bill: "We won't be able to fit all our furniture in there."

Contractor: "Well, you have two options. You can purchase a new, larger living room; or you can use a Stacker."

Bill: "Stacker?"

Contractor: "Yeah, it allows you to fit twice as much furniture into the room. By stacking it, of course, you put the entertainment center on the couch... the chairs on the table... etc. You leave an empty spot, so when you want to use some furniture you can unstack what you need and then put it back when you're done."

Bill: "Uh... I dunno... issue two. The second issue is the light fixtures. The bulbs we brought with us from our old home won't fit. The threads run the wrong way."

Contractor: "Oh! That's easy. Those bulbs aren't plug and play. You'll have to upgrade to the new bulbs."

Bill: "And the electrical outlets? The holes are round, not rectangular. How do I fix that?"

Contractor: "Just uninstall and reinstall the electrical system."

Bill: "You're kidding!?"

Contractor: "Nope. Its the only way."

Bill: " Well... I have one last problem. Sometimes, when I have guests over, someone will flush the toilet and it won't stop. The water pressure drops so low that the showers don't work."

Contractor: "That's a resource leakage problem. One fixture is failing to terminate and is hogging the resources preventing access from other fixtures."

Bill: "And how do I fix that?"

Contractor: "Well, after each flush, you all need to exit the house, turn off the water at the street, turn it back on, reenter the house and then you can get back to work."

Bill: "That's the last straw. What kind of product are you selling me?"

Contractor: "Hey, if you don't like it... nobody made you buy it."

Bill: "And when will this be fixed?"

Contractor: "Oh, in your next house -- which will be ready to release sometime near the end of next year. Actually it was due out this year, but we've had some delays..."

---

## Chapter 48) The Philogiston Theory of Electronics

(Original author's name not available or he didn't want credit.)

(Forwarded by: Atesli (atesli@aol.com)).

A sheet of paper crossed my desk the other day and as I read it, realization of a Basic Truth came to me. So simple! So obvious we couldn't see it! John Kuivinen, Chairman of the Palomar Repeater Committee, (an amateur radio group), I think has discovered what makes integrated circuits work. He says that smoke (yes, you read smoke) is the thing that makes ICs work because every time you let the smoke out of it, the IC stops working. I was flabbergasted!!! Why of course he's right!!!

Smoke makes all things electrical work. Remember the last time the smoke escaped from your Lucas voltage regulator? Didn't it stop working?

I sat and smiled like an idiot as more of the truth dawned. It's the wiring harness that carries smoke from one device to another in your machine and when the harness springs a leak, it lets the smoke out all at once, and then nothing works. Can't you see now why motors have to be large to handle all that smoke, and don't they have smoke all over the inside when they quit

working? Think about it!

---

## Chapter 49) Microsoft TV Dinners

(Forwarded from: Nicholas Bodley (nbodley@tiac.net)).

Instructions for Microsoft's New TV Dinner Product:

You must first remove the plastic cover. By doing so you agree to accept and honor Microsoft's rights to all TV dinners. You may not give anyone else a bite of your dinner (which would constitute an infringement of Microsoft's rights). You may, however, let others smell and look at your dinner and are encouraged to tell them how good it is.

If you have a PC microwave oven, insert the dinner into the oven. Set the oven using these keystrokes: <\mstv.dinn.//08.5min@50%heat//. Then enter:

---

## Chapter 50) Is Windows a Virus or a Bug?

(From: John Borchard (jb@dendritics.com)).

Is Windows a Virus? No, Windows is not a virus. Here's what viruses do:

1. They replicate quickly - okay, Windows does that.
2. Viruses use up valuable system resources, slowing down the system as they do so - okay, Windows does that.
3. Viruses will, from time to time, trash your hard disk - okay, Windows does that too.
4. Viruses are usually carried, unknown to the user, along with valuable programs and systems. Sigh... Windows does that, too.
5. Viruses will occasionally make the user suspect their system is too slow (see 2) and the user will buy new hardware. Yup, that's with Windows, too.

Until now it seems Windows is a virus... But there are fundamental differences:

Viruses are well supported by their authors, are running on most systems, their program code is fast, compact and efficient and they tend to become

more sophisticated as they mature.

So Windows is not a virus.

It's a bug.

---

## Chapter 51) Did They Really Say That?

(Forwarded by: Barry Werner (werner@repairfaq.org)).

Caveat emptor! Read on...

Recently reported in the Massachusetts Bar Association Lawyers Journal:

The following are questions actually asked of witnesses by attorneys during trials and, in certain cases, the responses given by insightful witnesses:

1. "Now doctor, isn't it true that when a person dies in his sleep, he doesn't know about it until the next morning?"
2. "The youngest son, the twenty-year old, how old is he?"
3. "Were you present when your picture was taken?"
4. "Were you alone or by yourself?"
5. "Was it you or your younger brother who was killed in the war?"
6. "Did he kill you?"
7. "How far apart were the vehicles at the time of the collision?"
8. "You were there until the time you left, is that true?"
9. "How many times have you committed suicide?"
10. Q: "So the date of conception (of the baby) was August 8th?"  
A: "Yes."  
Q: "And what were you doing at that time?"
11. Q: "She had three children, right?"  
A: "Yes."  
Q: "How many were boys?"  
A: "None."  
Q: "Were there any girls?"
12. Q: "You say the stairs went down to the basement?"

A: "Yes."

Q: "And these stairs, did they go up also?"

13. Q: "Mr. Slatery, you went on a rather elaborate honeymoon, didn't you?"

A: "I went to Europe, Sir."

Q: "And you took your new wife?"

14. Q: "How was your first marriage terminated?"

A: "By death."

Q: "And by who's death was it terminated?"

15. Q: "Can you describe the individual?"

A: "He was about medium height and had a beard."

Q: "Was this a male, or a female?"

16. Q: "Is your appearance here this morning pursuant to a deposition notice which sent to your attorney?"

A: "No, this is how I dress when I go to work."

17. Q: "Doctor, how many autopsies have you performed on dead people?"

A: "All my autopsies are performed on dead people."

18. Q: "All your responses must be oral, OK? What school did you go to?"

A: "Oral."

19. Q: "Do you recall the time that you examined the body?"

A: "The autopsy started around 8:30 p.m.."

Q: "And Mr. Dennington was dead at the time?"

A: "No, he was sitting on the table wondering why I was doing an autopsy."

20. Q: "You were not shot in the fracas?"

A: "No, I was shot midway between the fracas and the navel."

21. Q: "Are you qualified to give a urine sample?"

A: "I have been since early childhood."

22. Q: "Doctor, before you performed the autopsy, did you check for a pulse?"

A: "No."

Q: "Did you check for blood pressure?"

A: "No."

Q: "Did you check for breathing?"

A: "No."

Q: "So, then it is possible that the patient was alive when you began the autopsy?"

A: "No."

Q: "How can you be so sure, Doctor?"

A: "Because his brain was sitting on my desk in a jar."

Q: "But could the patient have still been alive nevertheless?"

A: "It is possible that he could have been alive and practicing law somewhere."

---

# Chapter 52) Battery Humor

(From: bobv@pacifier.com).

You did hear about the Electrical Engineer that was arrested for battery. They put him in a dry cell :).

---

# Chapter 53) What Happens When Engineers think too much about Christmas

(Forwarded by: Steve Seaman (sseaman@fundy.net)).

It's an oldie, but a goodie.

1. No known species of reindeer can fly. But there are 300,000 species of living organisms yet to be classified, and while most of these are insects and germs, this does not completely rule out flying reindeer, which only Santa has seen.
2. There are 2 billion children (under 18) in the world. But since Santa doesn't appear to handle Muslim, Hindu, Buddhist, and Jewish children, that reduces the work load to 15% of the total - 378 million or so. At an average rate of 3.5 children per household, that's 91.8 million homes.

One presumes there's at least one good child in each.

3. Santa has 31 hours of Christmas to work with thanks to time zones and the rotation of the earth, assuming he travels east to west. This works out to 822.6 visits per second. This is to say that for each Christian household with good children, Santa has 1/1000th of a second to park, hop out of the sleigh, jump down the chimney, fill the stockings, distribute the remaining gifts under the tree, eat the snacks, get back up the a chimney, get back in the sleigh, and move on to the next house. Assuming that each of these 91.8 million homes are distributed evenly (which we know to be false but for the sake of these calculations we will accept) we are now talking about .78 miles per household, a total trip of 75 1/2 million miles, not counting bathroom stops. This means that Santa's sleigh is traveling at 650 miles per second, 3000 times the speed of sound. For comparison, the fastest man made

vehicle, the Ulysses space probe moves at a poky 27.4 MPS; the average reindeer runs at 15 MPH.

4. The sleighs payload adds another interesting element. Assuming that each child gets nothing more than a medium sized LEGO set (2 pounds), the sleigh is carrying 321,300 tons not counting Santa, who is inexorably described as overweight. On land, confessional reindeer can pull no more than 300 pounds. Even granting that "flying reindeer" (see point one) could pull TEN TIMES the usual amount, we can not do the job with 8 or even 9, we need 214,000 reindeer. This increases the weight, not even counting the sleigh, to 353,430 tons. Again for comparison this is 4 times the weight of the Queen Elizabeth 2.
5. 353,000 tons traveling at 650 miles per second creates enormous air resistance. This will heat the reindeer in the same manner as a spacecraft re-entering the earth+s atmosphere. The lead pair of reindeer will absorb 14.2 QUINTILLION joules of energy. Per second. Each. In short, they will burst into flame almost instantaneously, exposing the next pair of reindeer, and creating deafening sonic booms in their wake. The entire team will be vaporized within 4.26 thousands of a second. Santa, meanwhile, will be subjected to centrifugal forces 17,500.06 times the force of gravity. A 300 pound Santa would be pinned to the back of his sleigh by 4,315,015 pounds of force.
6. Conclusion: There was a Santa, but he's dead now.

---

## Chapter 54) Old Digital Engineers

(From: John Woodgate (jmw@jmwa.demon.co.uk)).

Old digital engineers (well, there will be some, one day) never die, they only lose their most significant bits.

---

## Chapter 55) That Darn Oops Button

Haven't you always wanted a button labeled 'oops' on your keyboard for those occasions where 1 microsecond after posting something to sci.electronics.repair (or a more juicy newsgroups), you realized how stupid it was?

Maybe the 'Oops' button would create a market for those no-longer-needed 'printer buffers'??? :-). Darn, that great an idea shouldn't be in a publicly accessible document. Oops!

(From: Mr Fixit (mrfixit@cyberhighway.net)).

I believe I could retire in style if I can design a ad-on computer button labeled 'Oops'. It would be wired to a small, but high powered electronic box that would go in-line at the modem connection.

Once in place, we usenet users would have a means of dealing with that dreaded situation when we push the 'post' button at the same instant we realize that we shouldn't have pushed it. A quick slap on the 'oops' button would instantly send a high powered jolt down the phone line where it would catch up to the inadvertently sent message and blow it to smithereines, like a Patriot missile intercepting a Scud.

I know I would make regular use of it, as well as Sam, Joe and countless others on this NG alone. And just think of how many NG's there are with their own regretful posters!

Of course, I would have to SPAM all of the NG's to get the word out and start my \$millions rolling in. But, knowing me I would probably have second thoughts about being a SPAMMER the instant I push the 'post' button. My knee-jerk reaction would undoubtedly be to slap the new prototype 'oops' button on my computer and blast my own SPAM before it could be delivered. The end result being that I would be the only one on usenet with this powerful technology-turned personal toy.

Never mind that this would be grossly unfair to everyone else, the cold reality would be that I just blasted away my comfortable retirement.

Retirement.....that reminds me...I've got toilets, sinks, tubs, floors, walls, windows, doors, etc., etc., to fix. I don't have time to be inventing toys!

So, in lieu of all that, we'll all just have to accept human nature for what it is (occasionally unreliable) and offer Sam a knowing grin, and get on with what we're here for.

Now, what was it we are here for?

Where's that darned 'oops' button now when I need it? Umm, never mind.

---

# Chapter 56) Atomic Charge

(Forwarded from: Brad Albing (albing@ct.picker.com)).

Two atoms are sitting in a bar:

Atom 1 (in a whisper): I think I've lost an electron.

Atom 2: Are you sure?

Atom 1: I'm positive.

---

# Chapter 57) Transformer design - Tomato Launcher

This is actually part of a long thread on sci.electronics.design (much of it between Chuck Parsons and Winfield Hill) but I got tired of extracting and formatting all the relevant stuff!

(From: Chuck Parsons (Chuck@CatenaryScientific.com)).

Well there is nothing I like better than finding the right intuitive model for something. Intuition is so fast if you can keep out the bad intuition. Many thanks for helping me lay another block in my EE foundation I hope others benefited as well.

While mulling this over last night I tried to come up with a circuit that explored both converters. I came up with a hybrid design that uses both converters in a single transformer. First though I needed a reason for building it, this is what I came up with. I don't claim that the design is particularly good I was just trying to bring some of the issues in to play. I invite anyone who cares to to disparage or (better) improve the designs.

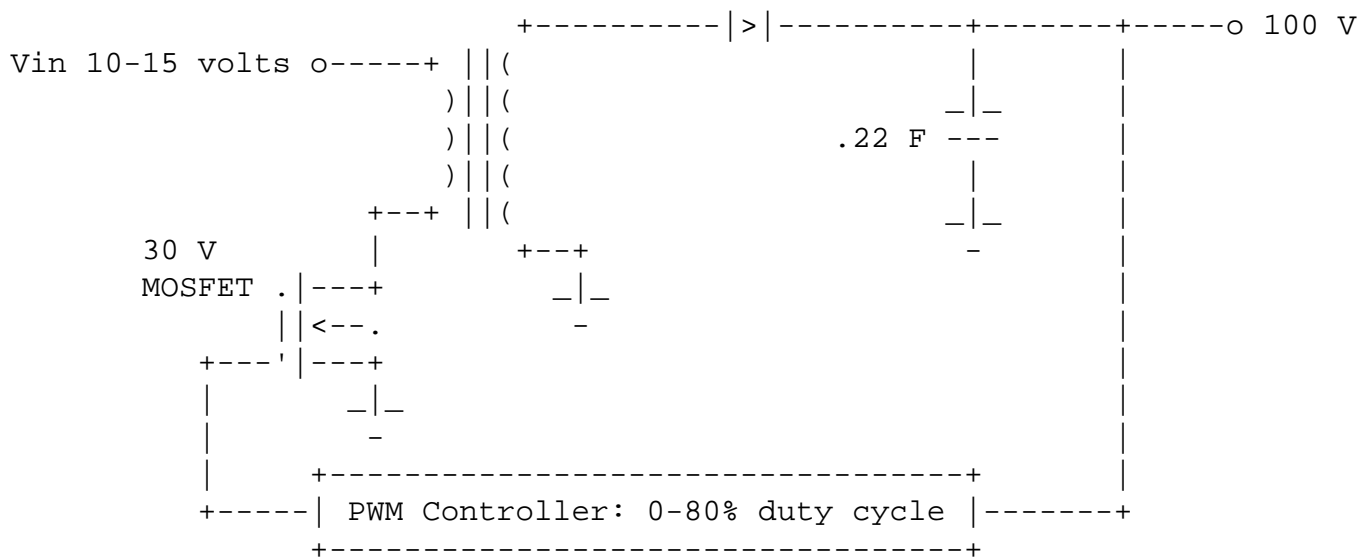

Our story begins many years ago (at least for some of us) when all of us in the sci.electronics.design gang happened to be about 16. Old enough to drive, but young enough that the police might still take us to our parents instead of jail.

Those jerks in alt.pdf\_not\_gif.big\_binaries.wannabies.geese. are getting their due at the hands of our car mounted linear induction motor tomato launcher. It launches 1kg tomatoes. 1 kg tomatoes are rather large, but we have gardening expertise here in sci.electronics and have no trouble procuring

our superior ammunition. I have grown 1.1kg tomatoes, and last summer was hours away from picking 4 even larger ones when those &#x2013; alt.pdf\_not\_gif.big\_binaries.wannabies GEESE got them.

Careful, but messy, testing has determined that 30 meter per second (108 kph or 67 mph) launch speeds are possible without PPF ( premature projectile fragmentation) requiring another trip to the car wash. Naturally we want to come as close to this as possible without exceeding it. The energy of a 1kg projectile traveling at 30 mps is 450 Joules. Our launcher has an impressive 45% efficiency (of course we designed it!) so a launch requires 1000 Joules of energy. We store this energy in 220,000 uF of capacitance at 100 Volts. the caps are discharged all the way to 30 volts during firing, so only 1100 Joules of energy storage is needed to deliver 1000 Joules. Testing has also shown that for small variations in the linear motor input voltage the variation in projectile speed is reasonably linearly related to the voltage variation.

Generation 1 used a simple 20 watt 100 kHz PWM flyback design to generate the 100 volts from the car battery. The ferrite needs to store 200 uJ on each pulse. A ferrite capable of storing 400uJ was chosen to avoid saturation at high input voltages. This design worked great. The 100 volts was accurate assuring reproducible launches whether or not we had the car revving for get away or had the battery just about dead after a long day of field trials. I sketch it here:

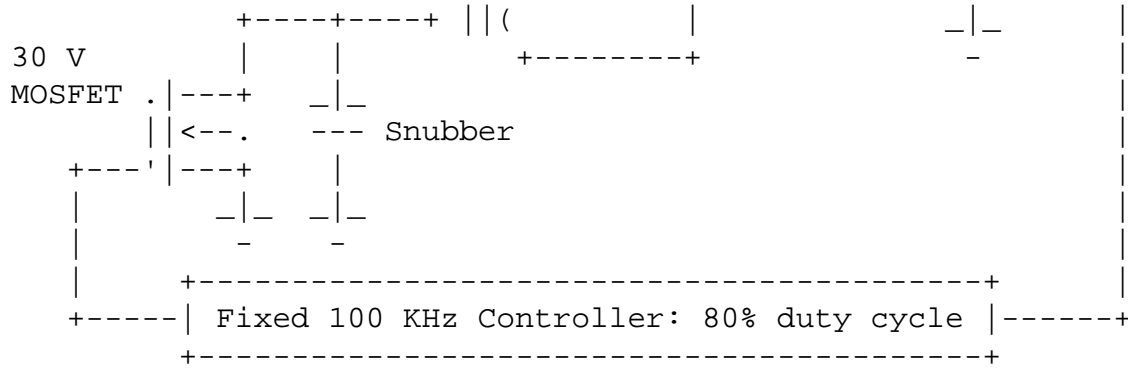

The inductance of the primary and the avalanche capability of the Mosfet have served to protect the circuit from those nasty 50 Volt transients in the car's ignition system.

Unfortunately after a few successful raids the alters took advantage of the 50 second recharge time to close and return fire from close range.

Generation 2 then using the same ferrite modified the design to use forward conversion allowing an average 200 watts of power transfer and a much quicker 5 second reload time, which is about how long it took Win to pass up those tomatoes from the back seat through the sun roof anyway.

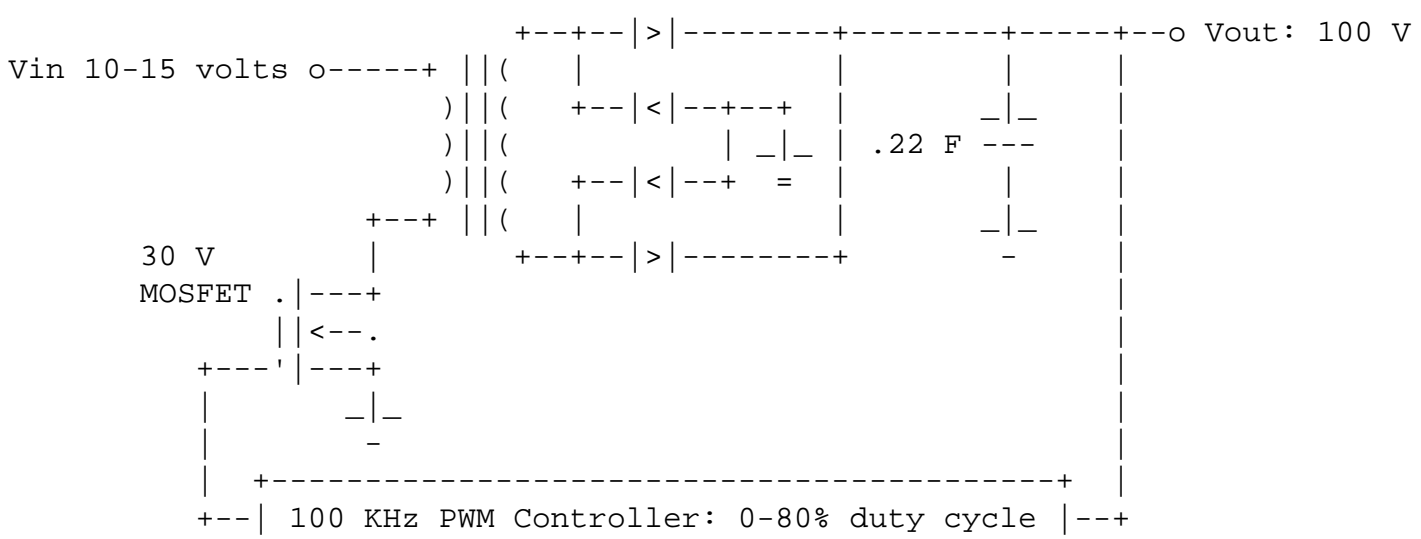

We had to add a snubber because now the magnetization flux is just being dumped into the mosfet at the end of every cycle. Since we are using the same transformer and frequency as well as maximum duty cycle this energy amounts to just the 20 watts of the flyback converter.

This produced a glorious victory over the alters, plastering them at close range as they closed with their basket of 100 gram wormy tomatoes.

However, there were problems. The Generation 1 circuit could be left on continuously and preloaded allowing instant reaction to sneak attacks when getting in the car in the morning. Leaving the Generation 2 circuit on all night killed the battery, despite nearly 90% efficiency at full load (and full output voltage).

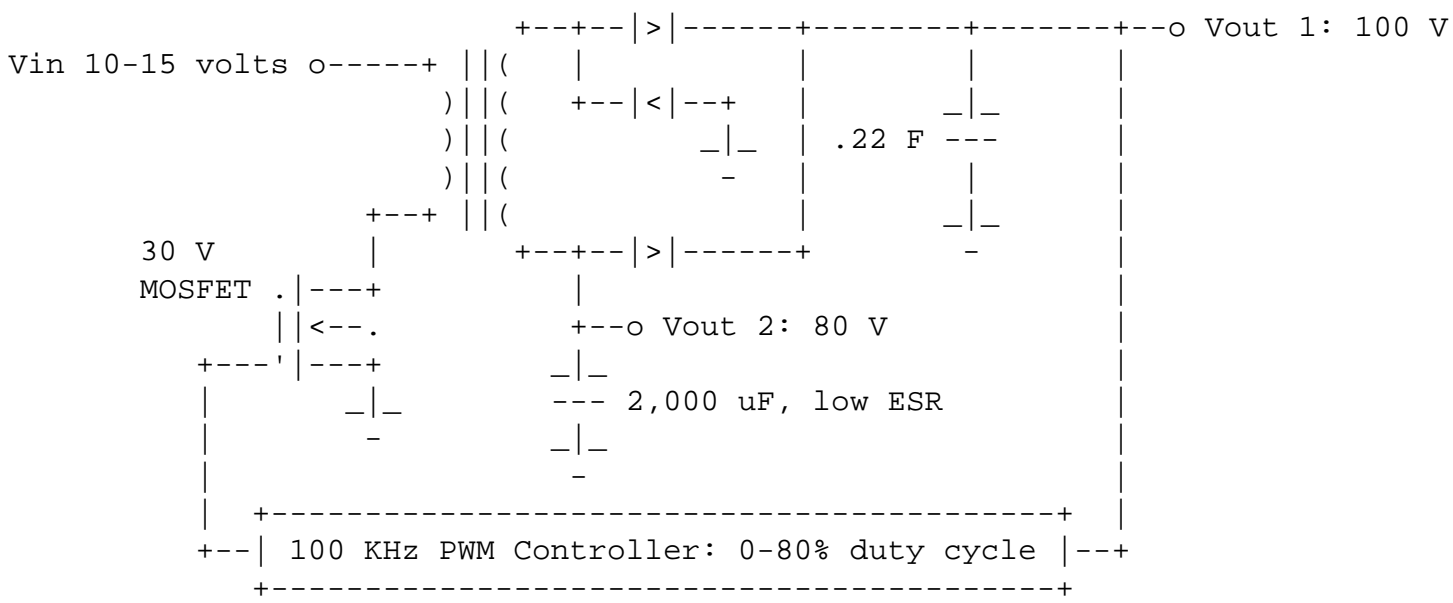

The efficiency at low loads, or low output voltages is poor. Continuous firing is possible until the transformer overheats. At full load and output voltage, the transformer heat load is not bad, but during the output rampup currents are only limited by the leakage inductance (much lower than the full winding inductance), winding resistance and MOSFET on resistance. To minimize the charging time we of course minimized all of these, leading to 100 amp peak currents. Furthermore changes in the input voltage lead to problems in figuring range and aiming accurately. Indeed several second shots while racing away at low gear and high RPMs lead to high battery charging voltages and embarrassing PPF (premature projectile fragmentation).

Generation 3 is to combine the best features of both designs. (The turns on the secondary are reduced 10% to ensure the flyback is the only active energy transfer at full load. This isn't always enough reduction to ensure the output voltage never exceeds 100 volts, but it is a compromise between overcharging at high input voltages and slow charging at low input voltages. )

+-----+-----+-----+-----+-----+-----+

In this design the snubber disappears because the magnetization energy is captured for use in the output flyback. At low output voltage the design works primarily as forward conversion but at some point the output voltage equals the input voltage multiplied by the turns ratio and the design transfers over to pure flyback. We can once again leave the circuit running continuously. We can get off 10 shots in 50 seconds before the transformer and mosfets overheat, though the output voltage will then be 90 instead of 100 leading to reduced range. The flyback just has to top off the capacitors so if we can 15 seconds instead of 5 (but not 50) between shots we can assure a steady output voltage. The biggest problem is that variation in the input voltage leads to variations in the amount of time spent in flyback versus forward conversion. A second problem is that the flyback, moving charge all the way from ground to 100 volts at the end of the top-off is rather slow. Basically we would like to extend the period of time in forward conversion but we have to adjust the winding turns so that at maximum input voltage the forward conversion output voltage is less than the desired Vout. We can increase the amount of work done in forward conversion as follows, simultaneously greatly improving the charge delivery of the flyback, by giving it a slower rampdown.

A miracle has happened, with our generation 4 design even in August we don't have enough tomatoes. Maybe we should modify it for zucchini ;-).

Much more - search at <http://www.dejanews.com/> for: "sci.electronics.design", and "Re: Transformer design equations - tomato launcher", or maybe just "cherry tomatoes" or "zucchini" for the subject line! :-)

## Chapter 58) Leave It To The Physicists

(From: Chuck Parsons (Chuck@CatenaryScientific.com)).

A biologist, an engineer and a physicist are assigned to monitor a building. After watching for a whole day two people are observed going in and three people come out:

Biologist: "They must be breeding."

Engineer: "There must have been a measurement error."

Physicist: "Now if one more person goes in the building will be empty."

---

## Chapter 59) Vc Versus Vs

(From: Jim Klein (kdpoptics@kdpoptics.com)).

The speed of light is greater than the speed of sound. That's why some people seem very bright until you hear them speak.

---

## Chapter 60) Selling It

(Forwarded by: Chris Cobb" (cobb@ct.picker.com)).

- \* Illiterate? Write today for free help.
- \* Auto Repair Service. Free pick-up and delivery. Try us once, you'll never go anywhere again.
- \* Our experienced Mom will care for your child. Fenced yard, meals, and smacks included.
- \* Dog for sale: eats anything and is fond of children.
- \* Man wanted to work in dynamite factory. Must be willing to travel.

\* Stock up and save. Limit: one.

\* Semi-Annual after-Christmas Sale.

---

## Chapter 61) Parts Replacement

So many repair questions take the form:

"Where can I get the microprocessor or flyback or CRT or mainboard or 'most expensive part' because I think THAT must be the problem".

(From: David J. Pittella (ddc\_pitt@ix.netcom.com)).

I frequently read or overhear discussions about the repair of products that are controlled by a microprocessor or microcontroller and wonder why technicians are always trying to replace these, typically prior to any testing or troubleshooting?

I wonder if they will ever believe that these devices are typically very reliable and that the lack of a proper voltage, or a failed or dirty sensor or switch be the real fault?

New troubleshooting technique:

1. Replace ALL the biggest chips FIRST, the more pins the better.
2. If step #1 doesn't resolve the problem, see if there is service literature available?
3. If there is no service literature, see if there is something called the MAIN BOARD! Just replace anything that could be a MAIN BOARD - that should fix the problem!
4. If steps (1) to (3) don't cure the problem, advise the customer that "parts are no longer available" or "the cost of repair exceeds the cost of replacement".

WARNING: DO NOT attempt to use a voltmeter to make simple voltage tests, or an ohmmeter to possibly check the continuity of the on/off switch!! :-)

---

## Chapter 62) But Does it do Windows?

From a sci.electronics newsgroup posting:

"Free Theory and Plans. Levitation craft. Hover silently above trees. Lands anywhere. Unlimited ceiling. Lifts over 250 lbs. Requires no fuel. Operates on Inverted-Gravity Chamber (IGC). Perpetual motion machine. Consists of mass circulation upward through IGC and downward outside chamber. Generates electrical power. Utilizes less power than it generates. Based on field theory, rather than old-fashion particle theory."

From: George X. Kambic (kambic@ct.picker.com)).

Damn! I wish people would tell me when the laws of physics change.

[...deleted to save stomach contents.....]"

---

## Chapter 63) You Know You're from silicon Valley When...

(From: Filip Fuma (filfuma@csi.com)).

- \* You make \$120,000 a year, but can't find a place to live.
- \* You see nothing but expensive cars because of .
- \* Your commute time is 45 minutes and you live 8 miles from work.
- \* You stop asking how much things cost and start asking: "How long will it take?"
- \* Two-thirds of the people you know are from Boston, Austin, Raleigh-Durham or New York, but you are living in PST.
- \* You know vast and subtle differences between Thai, Vietnamese, Chinese, Japanese, Cantonese, and Korean food.
- \* Your home computer contains mostly hardware/software that isn't on the consumer market yet.

- \* You go to "The City" on weekends but don't live there because you like your car.
- \* You think that "I'm going to Fry's Electronics" is an acceptable excuse to leave the office for a while. And your boss does too.
- \* You /lost/never had/don't know how to set the alarm clock. You'll just get to work when you get there.
- \* You go to an industrial-heavy-metal bar and see two guys get into a fight over what flavor of UNIX is better.
- \* You own more than 10 articles of clothing that have hardware and/or software companies printed on them. (Bonus for embroidered stuff.)
- \* You know where Woz Way, Resistor Ave, and Floppy Drive are located.
- \* You know where Woz is.
- \* You know Hwy 280 North runs west, and Hwy 680 North runs East.
- \* Even though Microsoft employs quite a few programmers in the Bay Area, they only work on Powerpoint, and the company is still the embodiment of Satan. (Even if their stock IS worth more than yours.)
- \* You see a billboard that says "FGPA2ASIC" and aren't fazed.
- \* When you need the updated Diamond Monster 3D drivers, you just walk across the street.
- \* You have more bandwidth in your apartment or condo than most major universities.
- \* You have to hire security to keep the panhandlers off your terrace. (Oakland/Berkeley).
- \* None of the people you work with are bible thumpers.
- \* You scan yard sales for back issues of "Dr. Dobbs."
- \* Your favorite computer reseller speaks only Cantonese.
- \* Your workplace vending machines dispense "100% natural twig-bars" right next to Jolt cola and Instant Espresso mix.
- \* No one brings radios into work - they just use RealAudio and listen to the dj.com, rebelradio.com, or other out-of-state stations.
- \* You don't understand how the carpool lanes work because you normally don't commute during those hours.
- \* You meet a friend for lunch and the first topic is where they are working now.
- \* You go to the movies and EVERYBODY claps along with the SciFi theme music.
- \* You entice prospective employees to join your company by bragging about the speed of your internet connection.

\* You've replaced your box of floppies with a box of Zip disks, but that's just until you get your box of Jaz disks.

\* You have completely forgotten how to write longhand.

---

## Chapter 64) Lawyer One-Liners

Sorry (well not really) for any lawyers reading this :-).

(Forwarded by: Jim Lagerkvist (jlager@tir.com)).

Q: What do you call a lawyer with an I.Q. of 50?

A: Your honor.

Q: What do you call a lawyer whose gone bad?

A: Senator.

Q: What's the difference between a lawyer and a trampoline?

A: You take off your shoes to jump on a trampoline!

Q: What do you call 5000 dead lawyers at the bottom of the ocean?

A: A good start!

Q: How can you tell when a lawyer is lying?

A: His lips are moving.

Q: What's the difference between a dead dog and a dead lawyer in the road?

A: There are skid marks in front of the dog.

Q: How many lawyers does it take to roof a house?

A: Depends on how thin you slice them.

Q: Why won't sharks attack lawyers?

A: Professional courtesy.

Q: What do have when a lawyer is buried up to his neck in sand?

A: Not enough sand.

Q: When lawyers die, why are they buried in a hole 24 feet deep?

A: Because down deep, they are all nice guys!!!!

Q: How do you get a lawyer out of a tree?

A: Cut the rope.

Q: How do you stop a lawyer from drowning?

A: Shoot him before he hits the water.

Q: What is the definition of a shame (as in "that's a shame")?

A: When a bus load of lawyers goes off a cliff.

Q: What is the definition of a "crying shame"?

A: There was an empty seat.

Q: How many lawyers does it take to stop a moving bus?

A: Never enough.

Q: Have you heard about the lawyers word processor?

A: No matter what font you select, everything come out in fine print.

Q: What's the difference between a porcupine and two lawyers in a Porsche?

A: With a porcupine, the pricks are on the outside!

Q: What do you buy a friend graduating from Law School?

A: A lobotomy.

Q: What's the difference between a catfish and a lawyer?

A: One's a bottom-crawling scum sucker and the other's just a fish.

Q: Hear about the terrorist that hijacked a 747 full of lawyers?

A: He threatened to release one every hour if his demands weren't met.

Q: What does a lawyer and a sperm have in common?

A: Both have about a one in 3 million chance of becoming a human being.

Q: Why is it that many lawyers have broken noses?

A: From chasing parked ambulances.

Q: Where can you find a good lawyer?

A: In the cemetery

Q: What do lawyers use as contraceptives?

A: Their personalities.

Q: What's the difference between a lawyer and a herd of buffalo?

A: The lawyer charges more.

Q: What's the difference between a lawyer and a vampire?

A: A vampire only sucks blood at night.

Q: What is brown and black and looks good on a lawyer?

A: A doberman.

Q: What is the difference between a lawyer and a rooster?

A: When a rooster wakes up in the morning, its primal urge is to cluck defiance.

Q: How many law professors does it take to change a light bulb?

A: Hell, you need 250 just to lobby for the research grant.

Q: Why did the post office recall the new lawyer stamps?

A: Because people could not tell which side to spit on.

Q: Did you hear about the new sushi bar that caters exclusively to lawyers?

A: It's called, Sosumi.

Q: Did you hear about the lawyer from Texas who was so big when he died that they couldn't find a coffin big enough to hold the body?

A: They gave him an enema and buried him in a shoe box.

Q: Santa Claus, the tooth fairy, an honest lawyer and an old drunk are walking down the street together when they simultaneously spot a hundred dollar bill. Who gets it?

A: The old drunk, of course, the other three are mythological creatures.

Q: What is the ideal weight of a lawyer?

A: About three pounds, including the urn.

---

## Chapter 65) Garage Tools

(Forwarded by: blinkys@execpc.com).

**HAMMER:** Originally employed as a weapon of war, the hammer nowadays is used as a kind of divining rod to locate expensive car parts not far from the object we are trying to hit.

**MECHANIC'S KNIFE:** Used to open and slice through the contents of cardboard cartons delivered to your front door; works particularly well on boxes containing convertible tops or tonneau covers.

**ELECTRIC HAND DRILL:** Normally used for spinning steel Pop rivets in their holes until you die of old age, but it also works great for drilling rollbar mounting holes in the floor of a sports car just above the brake line that goes to the rear axle.

**HACKSAW:** One of a family of cutting tools built on the Ouija board principle. It transforms human energy into a crooked, unpredictable motion, and the more you attempt to influence its course, the more dismal your future becomes.

**WISE-GRIPS:** Used to round off bolt heads. If nothing else is available, they can also be used to transfer intense welding heat to the palm of your hand.

**OXY-ACETYLENE TORCH:** Used almost entirely for lighting those stale garage cigarettes you keep hidden in the back of the Whitworth socket drawer (what wife would think to look in there?) because you can never remember to buy lighter fluid for the Zippo lighter you got from the PX at Fort Campbell.

**ZIPPO LIGHTER:** See oxy-acetylene torch.

**WHITWORTH SOCKETS:** Once used for working on older British cars and

motorcycles, they are now used mainly for hiding six-month-old Salems from the sort of person who would throw them away for no good reason.

DRILL PRESS: A tall upright machine useful for suddenly snatching flat metal bar stock out of your hands so that it smacks you in the chest and flings your beer across the room, splattering it against the Rolling Stones poster over the bench grinder.

WIRE WHEEL: Cleans rust off old bolts and then throws them somewhere under the workbench with the speed of light. Also removes fingerprint whorls and hard-earned guitar callouses in about the time it takes you to say, "Django Reinhardt."

HYDRAULIC FLOOR JACK: Used for lowering a Mustang to the ground after you have installed a set of Ford Motorsports lowered road springs, trapping the jack handle firmly under the front air dam.

EIGHT-FOOT LONG DOUGLAS FIR 2x4: Used for levering a car upward off a hydraulic jack.

TWEEZERS: A tool for removing wood splinters.

PHONE: Tool for calling your neighbor Chris to see if he has another hydraulic floor jack.

SNAP-ON GASKET SCRAPER: Theoretically useful as a sandwich tool for spreading mayonnaise; used mainly for getting dog-doo off your boot.

E-Z OUT BOLT AND STUD EXTRACTOR: A tool that snaps off in bolt holes and is ten times harder than any known drill bit.

TIMING LIGHT: A stroboscopic instrument for illuminating grease buildup on crankshaft pulleys.

TWO-TON HYDRAULIC ENGINE HOIST: A handy tool for testing the tensile strength of ground straps and hydraulic clutch lines you may have forgotten to disconnect.

CRAFTSMAN 1/2 x 16-INCH SCREWDRIVER: A large motor mount prying tool that inexplicably has an accurately machined screwdriver tip on the end without the handle.

BATTERY ELECTROLYTE TESTER: A handy tool for transferring sulfuric acid from car battery to the inside of your toolbox after determining that your battery is dead as a door nail, just as you thought.

AVIATION METAL SNIPS: See hacksaw.

TROUBLE LIGHT: The mechanic's own tanning booth. Sometimes called a drop light, it is a good source of vitamin D, "the sunshine vitamin," which is not otherwise found under cars at night. Health benefits aside, its main purpose is to consume 40-watt light bulbs at about the same rate that 105mm howitzer shells might be used during, say, the first few hours of the Battle of the Bulge. More often dark than light, its name is somewhat misleading.

PHILLIPS SCREWDRIVER: Normally used to stab the lids of old-style paper-and-tin oil cans and splash oil on your shirt; can also be used, as the

name implies, to round off Phillips screw heads.

AIR COMPRESSOR: A machine that takes energy produced in a coal-burning power plant 200 miles away and transforms it into compressed air that travels by hose to a Chicago Pneumatic impact wrench that grips rusty suspension bolts last tightened 40 years ago by someone in Abingdon, Oxfordshire, and rounds them off.

JESUS CLIP: "Jesus" every time you drop one of these.

---

## Chapter 66) Tesla Coil Caps

Actually, the warnings about PCBs (and I don't mean Printed Circuit Boards) are real!

So you are looking for BIG capacitors :-). . . . .

(From: Bill Coderre (bc@apple.com)).

Just watch out for PCB-laden oil-filled caps.... Those are usually the ones you find at the junk yard or the surplus place for REAL cheap, big grey cans with lightning protectors on top, usually labeled something like "1 uF @ 100 KV." They're extra cheap if they're already leaking!

Just remember, if you come across a pile of drum caps in an abandoned lot in an industrial section of town - even if the sign on top says "FREE! FREE!" - they are not good for you. Just Say No to PCBs.

I personally wish that Norm Abrams, host of the New Yankee Workshop, would run a show for electronics experimenters, something like the New Geek Workshop:

"Today we're going to be making a tesla coil from champagne bottles, a spark coil from a 53 DeSoto, and this hand-knurled lightning rod. It'll look great next to my Louis XIV-style marquetry and scrollwork Orgone Cabinet!. But first, let's talk about Safety Glasses...."

---

## Chapter 67) Customer Translations

(From: Dan (tvman@newwave.net)).

I once had a customer who insisted on "helping" me fix his TV. I politely told him that he had done enough damage to it already."

How about the customer who brought his TV in and said that "it worked fine until" he worked on it. (At least he was honest.)

(From: Michelle Hunt (michell15@ix.netcom.com)).

I had one of those the other day... This guy brought in a little Magnavox 19" and the conversation went something like this:

Him: "I don't know what happened, it just suddenly quit working."

Me: "Was that before or after you dropped it?"

Him: "How did you know I dropped it?"

Me: "It was easy... the cabinet usually isn't broken into pieces like this".

(From: Chris Mann).

How about customer translations such as:

"I think it's got a shorted fuse" - "I don't have a clue as to what's wrong but I know some electronic words so don't rip me off".

"I think it's just a bad connection" - "I know something major happened. I just don't want to think that something major happened."

"I think something's loose inside" - "My child uses it for his piggy bank".

"It fell off the shelf".

"It just stopped working" - "I spilled my drink and it went inside"

---

## Chapter 68) Advertising to Dummies

(I was going to use the 'for' word but then a certain publisher's lawyers would come complaining.)

(From: Charley S. McCue (csmccue@midusa.net)).

I once spent 15 minutes trying to convince a customer they had not bought a \$20 satellite dish from TV Guide (back when C band was the only option).

(From: Gary Woods (gwoods@wrgb.com)).

That's the ad that I still think is the high-water mark of advertising to stupid people:

"You're not paying cable fees, because this is not a satellite antenna. It uses proven RF technology to pick signals RIGHT OUT OF THE AIR!"

People still bought them thinking they'd get cable or something. We had a copy on the door of the tech shop for a while.

Reminds me of the fellow who offered on a bulk emailer site one million email addresses for only ten dollars. "Generated by sophisticated random number technology", they are all guaranteed undeliverable! People actually sent him orders!

P.T. Barnum was right!

---

## Chapter 69) The Hazards of Multimeters

(From: Ed Price (edprice@pacbell.net)).

Let me add my own tale of knowledge gained through stupid experimentation. In 1961, right after I built my Knight Kit VTVM, I was measuring the voltage and resistance of everything I could find. I eventually found an old "Press" style flashbulb, about an inch in diameter. I started out on a high Ohms range, and worked my way down to the 1x range. The lessons I learned involved design of experiments, resistance testing, chemical reaction of magnesium, optical transfer of energy and emergency room procedure. Did you know that those old bulbs had a plastic outer layer which could very effectively fuse to charred skin?

Dirty Harry Callahan was right; "...when properly used, you can REMOVE the fingerprints."

Next time (if somebody asks politely), I'll tell you how I got radiation burns from a pencil.

---

# Chapter 70) The Surgeons' Choice

(Forwarded by Fil Fuma (filfuma@csi.com)).

5 surgeons are taking a coffee break:

The first surgeon says: "Accountants are the best to operate on because when you open them up, everything inside is numbered."

The second surgeon says: "Nah, librarians are the best. Everything inside them is in alphabetical order."

The third responds: "Try electricians, man! Everything inside THEM is color coded."

The fourth intercedes: "I like engineers...they always understand when you have a few parts left over at the end."

To which the fifth surgeon, who has been quietly listening to the conversation, says: "You're all wrong. Lawyers are the easiest. There's no guts, no heart, no spine and their head and butt are interchangeable."

## Introduction

This is a snapshot of the bulk of the primary bookmark file I use with Netscape Communicator 4.61. I strive to keep it up to date but regrettably, this is about as possible as keeping up to date with all the free magazines that come my way. With so many Web sites coming and going and changing it is inevitable that some URLs will result in "404 missing" errors. I am resigned to this for individuals on mom-and-pop ISPs. However, there really is no excuse when large companies change their Web site organization and don't provide an easy way to locate the replacement page for those that have disappeared. Some do but many don't seem to care if you find them or not. Even the U.S. Postal Service will forward your mail for several months. Out of courtesy, Web sites should do this with Web site addresses as well!

The bookmarks, below, are divided into major categories and sometimes further sub-divided but not too deeply. I apologize for the organization (or relative lack thereof). Maybe someday I will reformat this stuff using fancy HTML tables and add meaningful descriptions of each entry. Then again, maybe pigs will fly. :-) This version is pretty clean but I don't guarantee that for the subsequent ones - I 'processed' it mostly by hand (well, OK, I did use a computer!) with some help from GNU EMACS. What is really needed is a SED or PERL script (or something) to do that automatically. I promise get to that first thing after the pigs start flying. :)

## **Laser and Optics Sites, Manufacturers, and Suppliers**

[Advanced Engineering Solutions. Inc. - CO2, Diode, Ar ion, Ti:Sa lasers.](#)  
[Aerotech, Inc. - Motion control systems \(formerly HeNe lasers\)](#)  
[Alkor Technologies - Optical elements and coatings \(Russia\)](#)  
[Almaz Optics, Inc. - Optical materials, components, nonlinear crystals, more.](#)  
[ALPEC TEAM, INC. - Laser modules, pointers, sites](#)  
[ALPHALAS GmbH - Lasers, optics, electronics](#)  
[American Laser Corporation - Ar/Kr Ion lasers, power supplies, accessories.](#)  
[Analog Modules, Inc. - Laser power supplies, amps, drivers, more](#)  
[Analog Products -- AD9660](#)  
[Applied Optronics Corporation - High power laser dodes, modules, systems.](#)  
[B&W Tek, Inc. - Fiber coupled laser diodes, laser diodes, and systems, more.](#)

[Balzers Thin Films - Optical coatings](#)  
[Big Sky Laser Technologies, Inc. Home Page](#)  
[Blue Sky Research - Electro-Optic Manufacturer of Laser Diodes and Instruments](#)  
[Bonneville Technologies - LDs, pin PDs, DPSS lasers](#)  
[Boston Lasers, Inc. - High power laser diodes, drivers, DPSS lasers, more.](#)  
[Burleigh Instruments, Inc. - Laser test and measurement](#)  
[Cambridge Technology - Galvo based scanners and systems.](#)  
[Castech \(China\) - Advanced laser crystals, optics, Si APDs](#)  
[Clark-MXR, Inc. - Femtosecond lasers for micromachining and spectroscopy](#)  
[Cleveland Crystals, Inc. - Nonlinear and electro-optic crystals and devices.](#)  
[Coherent, Inc. - CO2, dye, YAG, YLF, diode, DPSSLs](#)  
[Coherent Technologies, Inc - Tunable 2 um lasers, doppler radar, more.](#)  
[Continuum - Solid state lasers for science, industry, and medicine](#)  
[Control Optics Corporation - Optical engr. supplies and services.](#)  
[Convergent Energy - Industrial lasers and systems](#)  
[Crystalaser \(Diode Pumped Crystal Lasers\)](#)  
[Cutting Edge Optronics - Diode-Pumped Lasers](#)  
[CVI Laser Corporation - High damage threshold optics.](#)  
[DEL Electronic Corp. - HV power supplies includeing HeNe and CO2 lasers](#)  
[DEOS - Sealed CO2 RF excited waveguide lasers](#)  
[Diffraction International - CGH and binary optics, aspheric mtrology, design.](#)  
[Digital Optics Corporation \(DOC\) - Diffractive optics](#)  
[Directed Energy, Inc. \(DEI\) - Pulse generators, LD drivers, more.](#)  
[DPSS Lasers, Inc.](#)  
[Exciton - Dye laser dyes](#)  
[EG&G Electro-Optics \(a dividion of Perkin Elmer\) - Flashlamps, sensor, etc.](#)  
[Edinburgh Instruments - CO2, CO, far-IR lasers, more](#)  
[Electro-Optical Products Corp. - Modulators, Defl, Scans., Shutrs, etc..](#)  
[Emco DC-DC High Voltage Power Supplies](#)  
[Enlight Technologies, Inc. - IR and green DPSS lasers, green laser pointers.](#)  
[EOSI - Tunable diode lasers. laser amplifiers, accessories, LabView](#)  
[Equilasers, Inc. - Solid state lasers for medical, microwelding, other.](#)  
[ESC Medical, Ltd. - Medical/surgical lasers](#)  
[Esco Products - Standard and custom optics](#)  
[EXFO Electro Optical Engineering - Optical and fiber optic test systems.](#)  
[Fermionics - InGaAs PDs, InGaAsP LDs, HgCdTe detectors](#)  
[GEOLA \(General Optics Laboratory\) - Nd lasers and holography systems](#)  
[GSI Lumonics - Laser Systems, Components, Instrumentation, Life Science and Metrology](#)  
[Hamamatsu - PMTs, PDs, LEDs, sensors, light sources, more.](#)  
[Hankwang - CO2 and YAG lasers \(Koria\)](#)

[Hewlett Packard - Laser Interferometer Positioning Systems](#)  
[High Brightness Solutions - Laser diodes, modules, DPSSLs, photodiodes.](#)  
[High End Systems On Line - Lighting control including Laser Chorus](#)  
[II-VI Incorporated - Laser optics, components, detectors, more.](#)  
[ILX Lightwave - Fiber optics and diode laser instrumentation](#)  
[Industrial Microphotonics Company - Diode Array and Diode Bar Manufacturer](#)  
[Infineon Technologies - High power CW and pulsed laser diodes and other semis.](#)  
[International Light - Light Measurement Systems, Instruments, Detectors, etc.](#)  
[ISP Optics - IR and UV optical materials and components](#)  
[Janos Technology, Inc. - Precision optics from exotic materials](#)  
[JDS Uniphase Corporation - Lasers and subsystems, more](#)  
[JMAR Technologies, Inc. - Picosecond lasers. more.](#)  
[Jodon, Inc. - HeNe lasers and tubes, non-contact gauging, more.](#)  
[JSL \(Joachim Sacher Lasertechnik\) - Laser diodes, external cavity diode lasers, accessories](#)  
[Kaiser Systems, Inc. - HV power supplies, cap chargers, more.](#)  
[Keon Optics - Optical polishing and thin films coating](#)  
[Kigre, Inc: - Solid state laser components and systems](#)  
[Lambda Physik - Excimer and dye lasers and dyes](#)  
[LASAG Industrial Lasers - Nd:YAG pulsed lasers for welding, cutting, drilling](#)  
[Laser 2000 International - Lasers, optics and fibre optic equipment.](#)  
[Laser Analytics - Lead-salt tunable diode lasers](#)  
[Laser Beam Products - CO2 and other high power laser optics](#)  
[Laser Crystal Ltd.: Non-linear optical elements, LBO, BBO, KTP. more](#)  
[Laser Diode, Inc. - FO TX/RX, GaAs lasers](#)  
[Laser Diode Array, Inc. - Large multi-bar laser diode arrays](#)  
[Laser Drive, Inc. - PSs for HeNe, Ar+, CO2, lasers, tungsten & discharge lamps](#)  
[Laser Kinetics Inc. - CO2 laser systems](#)  
[Lasermate Corp. - LD modules, drivers, pointers, optics, DPSSLs](#)  
[LaserMax - Diode laser modules](#)

# Speaker Repair

Contents:

- [1. Big Speakers](#)
- [2. Common Failures \(why\)](#)

[Document Version: 1.00] [Last Updated: 3/26/96]

---

## 1. Big Speakers

Make certain that the voice coil didn't "just" jump out and jam on the face of the magnet's center pole! If this is the case, a bit of

Big speakers are actually not too bad to redo. Remember that you're only other option is to toss it out, so you have nothing to loose by trying to repair it. Having good manual dexterity and a knack for detail work is an asset (ie: a model builder skills). So, once you have determined that the problem is internal (voice coil) and you want

1. Paint an alignment line from the cone edge over the suspension and onto the basket so that you can line everything upon reassembly.
2. Do the same to the spider
3. Unsolder the voice coil leads from the tab on the basket
4. Using a razor blade or an Exacto knife cut all around the suspension as close to the basket as possible to free up the wide end of the cone
5. Do the same where the spider meets the basket
6. Lift the cone and voice coil assemble out (be careful here, if the coil has come apart you may snag things and damage the voice coil form).
7. Examine it, you may be able to fix a short or bridge an open and reassemble at this point.
8. Get a dowel rod that just fits inside the voice coil (light friction fit) and insert it. Handle the voice coil/cone assembly by this "handle" if at all possible. It will also keep the voice coil form from collapsing when you rewind it.
9. Carefully unwind the voice coil and write down how long it is, how many layers, and how many turns and direction of winding (ie: clockwise from front)
10. Obtain some replacement wire of the same OUTSIDE diameter (note that depending on the particular enamel insulation, the same wire gauge may have differing insulation thickness)
11. Rewind the coil one layer at a time (remember to solder it to the braided lead-outs !), use Q-dope to hold it to the voice coil form, and to also hold it together. Do not over do it on the Q-Dope on

the outside layer. If you make it too thick it will not fit back in!

12. Reassemble, using the alignment marks as guides
  13. With the speaker sitting cone up, everything should be sitting pretty much lined up with where you cut it free
  14. Use contact cement and a fine artist brush to glue the suspension back Together (I have assumed a foam suspension)
  15. Use silicon RTV to put a fillet around the spider where it contacts the basket, again a small artists brush is used.
  16. Solder the leads back to the tab
  17. Let the glues dry
  18. Test it
- It take a bit of skill (not a lot)
  - You **MUST** be patient
  - You will not be able to use it at 100% of full power, the Q-Dope will not take the same sort of heat as the original epoxy on the voice coil did, nor will the RTV on the spider take a full stress forward excursion
  - It will be workable

---

## 2. Common Failures (why)

While working my way through college, I managed a pro-sound company in the SF Bay area. We would get a customer into our repair dept. with your complaint at least twice a week. The typical failure modes for abused musical instrument amps are either shorted or open voice coils in the speaker, followed by the destruction of the final amplifier stages. It starts out as a buzz from the cone. The reason for all this is that the voice coil/spider assembly overheats and then distorts. The clearance between the voice coil and the magnet pole pieces are fairly small and a little deformation of the cylindrical voice coil will make it bind and buzz. After that happens, it heats up alot faster and either fuses open or wears through the voicecoil wire insulation and shorts to the pole piece.

The repair is usually to replace the speaker. The real expensive pro-audio drivers like the EVs, JBLs, etc could be reconed cheaper than replacement but low end drivers like those in Crates aren't cost effective to have repaired (nobody will touch them - [but see section above]). On the rare occasion that one can find someone to recone them, they usually have substituted parts and really screw it up so you have to buy a new speaker anyway. The moral is take care of your equipment, especially if you depend

# Repair Tips for Bearcat Scanner Radios

**February 15, 1999.**

**Copyright (C) 1993-1999**

**Bob Parnass, AJ9S (parnass@bell-labs.com)**

**--- All Rights Reserved ---**

**NOTICE:** This article may not be reproduced in whole or in part on CDROMS, in bulletin boards, networks, or publications which charge for service without permission of the author. It is posted twice monthly on the USENET groups rec.radio.scanner, alt.radio.scanner, sci.electronics.repair, and rec.radio.info. It is also available electronically from the rec.radio.scanner ftp archive on the official USENET FAQ library <ftp://rtfm.mit.edu/pub/usenet-by-group/rec.radio.scanner>. The author writes a monthly "Scanner Equipment" column for Monitoring Times magazine, published by Grove Enterprises, but views expressed in this article are his own.

---

## Introduction

The original Bearcat scanner line was manufactured by Electra Company, a division of Masco Corp of Indiana. In the mid 1980s, Uniden, a Japanese company, bought out the Bearcat scanner line and Uniden's first Bearcat scanner was the BC800XLT model.

Most of the models discussed in this article are base/mobile units made by Electra during the 1970s and 1980s although some of the capacitor failures occur in the Uniden BC800XLT, too.

Electra stamped all of its scanners with a manufacturing date code on the rear of the cabinet. The code is comprised of a single character (C = Cumberland, Indiana, P = Puerto Rico), followed by four digits denoting year and week the radio was built. For example, "P8422" denotes the radio was made in the Puerto Rico factory during the 22nd week of 1984.

One way to roughly estimate a radio's age is to examine the 4 digit date codes often stamped on the integrated circuits. The radio must have been made after the most recent date stamp.

## Schematics, Owner's Manuals, and Parts Available

The re-incorporated Electra Corporation sells crystals, antennas, power cords, owner's manuals (\$11 ea) for some older (pre-Uniden) Bearcat scanners. Electra Corporation is located at 11915 E. Washington St., Cumberland, IN 46229. Phone 317-894-3229.

I cannot furnish schematics, manuals or parts. To order a user manual for an Electra/Bearcat scanner from Uniden, call (800)235-3874 extension 2553.

Some schematic diagrams may be obtained from Uniden/Bearcat's parts department, (800)297-1023. Uniden currently charges a flat rate of \$54 for scanner repairs. They will repair and return "out of warranty" items without an estimate unless the repair charges exceed the flat rate charges.

The phone number for repair is (800)297-1023, too. I recommend you call repair before sending the broken scanner. Items for repair via UPS (include receipt if still under warranty) are usually sent to:

Uniden America Corp.  
4700 Amon Carter Blvd.  
P.O. Box 95002  
Fort Worth, TX 76155

If Uniden doesn't have a schematic, try obtaining a Photofacts from Howard Sams Publishing division of Prentice-Hall at (800)428-7267, [http://www.hwsams.com/sams\\_model\\_new.html](http://www.hwsams.com/sams_model_new.html)

G & G Communications (telephone (716)768-8151) is a family owned company which repairs scanners and stocks parts for several older models, especially Electra/Bearcat and Regency brands, but they don't sell manuals or schematics. They are located at 9247 Glenwood Drive, LeRoy, NY 14482. (<http://www.iinc.com/ggcomm/> or email [ggcomm@iinc.com](mailto:ggcomm@iinc.com) or [ggcomm@aol.com](mailto:ggcomm@aol.com))

## Common Construction

Most of the classic, metal-cased Bearcat base/mobile models were built using two printed circuit boards:

1. a "radio board" containing the synthesizer, RF, IF, and audio stages, and
2. a "feature board" containing the microprocessor controller and memory circuitry which gave each model its own personality.

Although there are various vintage radios boards, they all have similar circuitry. Before addressing specific symptoms, circuit boards in the malfunctioning scanner should be inspected for poor solder joints.

The Electra/Bearcat BC350, BC300, BC250, BC220, BC20/20, BC211, BC210, and BC210XL models were hand assembled, and every one I've serviced had several connections that were either soldered poorly, or not soldered at all.

Resoldering joints on the ribbon cable connecting the RF and keyboard logic circuit boards in a BC250 attenuated the microprocessor/synthesizer hash noise noticeably.

A Bearcat 20/20 was experiencing periodic loss of memory on some, but not all channels. When the problem occurred, the frequencies on some channels would be completely changed. On other channels, the frequency would still be intact, but the channel would be locked out, and the delay toggled from "on" to "off". Some channels were not affected.

The 2 "AA" memory backup batteries, and their holder, tested good. Much time was spent tracing logic, heating and cooling components, and making voltage measurements.

One of the secondary leads from the power transformer was connected to the main circuit board through a hole drilled through foil traces on both the top and bottom sides of the board. A close examination revealed that this lead had been soldered only on the top of the board - the bottom side had never been soldered.

Soldering the lead on both sides of the board solved the memory loss problem.

Matt Roberds fixed a BC220 which experienced memory loss if power was removed by resoldering the positive wire to 2-AA battery holder.

As built, the BC220 logic board is grounded only through its mounting screws. In the BC220, Matt recommends adding real wire ground jumpers from the main board to the feature (logic) board to fix grounding problems.

## **Symptom: Blank Display**

The BC300 scanner, and several other Bearcat models, employ a switching type power supply stage to generate plus and minus voltages in excess of 20 volts DC. When this switcher fails to function, the display goes blank, but the squelch control appears to work, and white noise can be heard in the speaker.

In almost a dozen of the BC300 and BC800XLT scanners I've fixed, C98, a capacitor in series with the primary of the switching transformer failed, causing the output of the supply to drop below the level needed to power the display. The switching transformer is mounted on the RF circuit board, and is much, much smaller than the main power transformer, which is usually fastened to the metal chassis. See March 1996 Monitoring Times magazine for BC800XLT capacitor locations and repair information.

The 22uF/16V capacitor used for C98 in early BC300s was marginal, and was replaced with a 47uF/25V capacitor in later units.

Jim Craig replaced a 22uF/35V C98 capacitor to repair his BC210XW.

Paul Grohe replaced a failed C98 with a low ESR (equivalent series resistance), high frequency, switching regulator grade capacitor, e.g. a Panasonic HF series capacitor. He also recommends adding a 0.1 ceramic capacitor in parallel with C98.

I replaced the 22 uF capacitor in the switching power supply stage of a BC210XL which caused the same symptom. Other capacitors in the switcher stage have failed. C114, a 4.7 uF/35V tantalum capacitor failed in at least one BC250, causing the display to blank.

A more sinister problem affects the switcher in earlier models. The switching supply stage in the BC250 and original BC210 is driven by a clock signal derived from a custom Exar NC57902 divider integrated circuit (designated IC6 in the BC250 scanner). I've seen this divider IC fail in several BC250s, causing a blank display (except for a decimal point in the BC250's rightmost digit). This custom IC is no longer available from Uniden.

Failure of IC9, the 9 volt NJM78M09A regulator in a BC800XLT is another cause of a blank display.

## **Symptom: Invalid Frequency Displayed**

A common Bearcat 250 malady is manifested by an invalid frequency displayed on the readout. This condition is temporarily "cured" by unplugging the AC line cord from the wall, then replugging it. This condition is symptomatic of a power supply problem in which Q204, a Texas Instruments TIP-29 located on the feature circuit board, fails.

A Philips ECG291 will work as a substitute for the TIP-29. Don't try a Radio Shack substitute, it hasn't worked. See Martin Toomajian's article, "Bearcat 250 Erratic Display Cure", in January 1987 Monitoring Times.

A similar problem in the Bearcat 20/20 was discussed previously in the section on bad solder joints.

Matt Roberds repaired the Montgomery Wards version of a BC220 and contributed these insights:

"I did add some heat-sinks, but you have to be careful what you do with the TIP29 on the logic board. I added a long, flat heatsink to it and immediately created a whine in the audio. I didn't use an insulator, as this was a temporary first-try. As far as I can tell, the heatsink was radiating noise from the logic board into the front end on the radio board, which ended up being just below the heatsink. Bypassing the TIP29 (a voltage regulator) with disc ceramics didn't work; using a smaller heatsink and an insulator fixed the problem."

"There is also a 220 ohm 1/4 watt resistor on the logic board. It feeds the TIP29 from the main +16v supply. It looked a little crispy. I pulled one end and measured the current through it and it was about 30-35 mA. This works out to right at 0.2-0.25 watt dissipation. I didn't have a higher-wattage resistor, so I substituted 2 470-ohm resistors in parallel."

# Symptom: Squelch Won't Eliminate White Noise

Most Uniden/Bearcat base/mobile scanners feature an AUTO squelch position, actuated by rotating the squelch knob fully counter clockwise. The BC350 used a separate pushbutton switch for this purpose. These scanners use a flimsy potentiometer (designated R81 in BC300s) internally mounted on the RF circuit board, to set the level of signal required to open the squelch when in the AUTO position. This pot also has an effect on the squelch action in the non-AUTO mode, and determines at which point the squelch knob must be positioned in order to silence the radio.

Although the potentiometer is adjusted at the factory, changes in component values due to aging often necessitate readjustment of this internal pot. Misadjustment of this pot has been the cause of "no squelch" complaints in two BC300s and a BC250 I fixed.

Another squelch failure is due to a blown transistor that acts as the electronic switch in the squelch circuit. I replaced this transistor in only one BC300, so I don't know if this is a common problem.

# Symptom: Scanner Completely Dead

In Bearcat scanners using an internal power supply (e.g., BC350, BC250, etc.), the main power transformer is connected directly to the AC line. Since the on/off switch is on the secondary side of the transformer, current flows in the primary as long as the AC line cord is plugged into an active AC outlet. These transformers contain an internal circuit breaker, not visible without unwinding (destroying) the transformer. The internal breaker is known to fail prematurely in a batch of Bearcat power transformers.

If your scanner is completely dead, check the primary of this transformer for an open circuit condition.

# Symptom: Keyboard Bounce

After much use, the Chromerics keyboards in Bearcat scanners start to wear out. The first sign of trouble is usually keyboard bounce on the most frequently used key, e.g., the MANUAL key. Replacement keyboards are usually available from UNIDEN, but replacement requires dexterity, as one must take care not to tear the flat, flexible strip connecting the keyboard to the logic board.

# Symptom: Keyboard Completely Unresponsive

The keyboard matrix is "scanned" by the microprocessor. Another problem is when none of the keys seems to function; the receiver just keeps scanning in spite of key depressions. I found this condition in a BC210XL scanner owned by a heavy smoker. Perhaps nicotine smoke was to blame, as the resistance between two input port pins on the microprocessor was down to about 1000 ohms, fooling the microprocessor into believing that a key was stuck in the "down" position. Scraping the circuit board between the two pins with an X-Acto knife fixed the problem.

# Uniden/Bearcat BC200XLT Portable - Loss of Audio and Dial Lamp

If you can program frequencies into your BC200XLT but there is no audio and the green backlight no longer functions, a tiny transistor may have failed.

Check for a defective PNP surface mount transistor, Q201 (2SB815B6-YDY). Q201 is used as a switch to furnish 8 VDC to several stages of the BC200XLT. Its main purpose is to switch off power hungry stages of the BC200XLT when the CPU thinks the NiCd voltage has fallen below a threshold. That's an attempt to limit the current drain on weak NiCds to avoid permanent damage.

Q201 is located on the foil side of the "Micom" board, adjacent to the black multi-pin connector which mates the Micom and main boards together.

Q201 can be destroyed by a few different causes, primarily, by something in the scanner drawing too much current through it. In one case, capacitor C36 shorted. It's a 220 uF 10v electrolytic, located on the component side of the main board, connected from pin 8 of the audio IC (IC2 NJM386SL) to ground. Capacitor C55 shorted in another BC200XLT. Gary Bean reports he substituted a 2SA1298 for Q201 and it worked fine. In a pinch you bypass Q201 by soldering a short piece of bare wire between the collector and emitter, but you must first fix the component which caused Q201 to fail.

## BC9000XLT: Loss of Sensitivity

John Ward has fixed two BC9000XLTs which suffered from "low sensitivity." He fixed the solder joint where the antenna jack connects to the circuit board. In both cases the tab from the board was on the opposite side of the jack from where the little blob of solder applied at the factory was located.

It was an intermittent problem that depended upon the position of the antenna cable - if the weight of the cable placed tension on the jack in one direction contact was made and the radio worked fine. If the cable placed tension on the jack in the opposite direction contact was lost and so was reception. The gap was barely noticeable.

## Other Problems

Complaints of low audio output and occasional microphonics in three Uniden/Bearcat 800XLTs were caused by a bad 47 ufd electrolytic capacitor in series between the external speaker jack and audio amplifier.

Andy Domonkos reports he often uses a tape recorder connected to a Uniden/Bearcat BC890XLT. RL-1, the carrier activated relay inside the BC890XLT wore out. Andy found the identical relay sold at Radio Shack (part #275-232) and says the BC9000XLT uses the same relay, too.

# Replacement Bulbs for BC760XLT

The Uniden BC760XLT's SCAN, MAN, PRI, and HOLD buttons are illuminated by "grain of wheat" type incandescent bulbs. Gary Saffer reports that the bulbs and buttons are located on a small printed circuit board which sits behind the radio's face plate. Gary unsoldered the burned out bulbs in his radio and replaced them with 12 volt Radio Shack bulbs (#272-1092c). They should last a long time when powered by the 8 VDC supplied by the BC760XLT.

## Open Resistor in BC140

Robert Casey fixed his deaf, 16 channel Bearcat BC140 scanner. A 10 ohm resistor had opened that fed a circuit that generates 22V for the varactor diode tuner circuits. Without the 22V, there was no tuning of the local oscillator and front end, and no reception. What he did was compare voltages to a second working BC140.

## Sources for Replacement NiCd Battery Packs

Replacement NiCd battery packs and inserts for the BC100XLT, BC200XLT, BC2500XLT, BC3000XLT, and other scanners are available from Uniden. I've purchased them at lower cost from:

1. Mr. NiCd - E. H. Yost and Company, 2211-D Parview Rd., Middleton, WI 53562. tel. (608)831-3443. email [ehyost@midplains.net](mailto:ehyost@midplains.net)
2. Battery-Tech Central, 2818 Southland Street SW, Cedar Rapids, IA 52404-4141. tel. (800)267-3087 or (319)364-0855. email [rlassoc@inav.net](mailto:rlassoc@inav.net)
3. Batteries Plus has stores across they country and some have rebuilt Uniden NiCd packs for under \$20.

# Repair Tips for Radio Shack Scanner Radios

**September 27, 1998.**

The author writes a monthly "Scanner Equipment" column for Monitoring Times magazine, published by Grove Enterprises, but views expressed in this article are his own.

---

## Introduction

Radio Shack has been selling scanners and monitor receivers under the Realistic and Radio Shack labels for over 30 years. Most of them were manufactured by General Research Electronics of Tokyo, though many newer models are manufactured by Uniden.

The date of manufacture is usually printed on a gummed label on the scanner as well as the cardboard box. A code of 12A5, means the scanner was made in the 12th month of 1975, 1985, or 1995, for example.

There's another way to date Radio Shack scanners manufactured by Uniden. The first digit of the long serial number is usually the last digit of the year of manufacture.

Another way to roughly estimate a radio's age is to examine the 4 digit date codes often stamped on the integrated circuits. The radio must have been made after the most recent date stamp.

# Schematics, Owner's Manuals, and Parts Available

I cannot furnish schematics, manuals or parts. Service manuals for most Radio Shack scanners sold through mid-1997 may be ordered through your local Radio Shack store.

If Radio Shack doesn't have a schematic, try obtaining a Photofacts from Howard Sams Publishing division of Prentice-Hall at (800)428-7267, [http://www.hwsams.com/sams\\_model\\_new.html](http://www.hwsams.com/sams_model_new.html)

Parts lists for recent and many older models are available on line at:

<http://www.radioshack.com/ProductSupport/Frames/>. Parts may be ordered through Tandy National Parts, telephone (800)442-2425 or (817)870-5600, or through your local Radio Shack store

G & G Communications (telephone (716)768-8151) is a family owned company which repairs scanners and stocks parts for several older models, especially Electra/Bearcat and Regency brands, but they don't sell manuals or schematics. They are located at 9247 Glenwood Drive, LeRoy, NY 14482.

(<http://www.iinc.com/ggcomm/> or email [ggcomm@iinc.com](mailto:ggcomm@iinc.com) or [ggcomm@aol.com](mailto:ggcomm@aol.com))

## GRE-Built Base Models: Dim Backlight

The backlight in many base models, including the PRO-2022, PRO-2004, and PRO-2005/6 is implemented by an electroluminescent panel, which grows dim with use.

The EL panel used in the PRO-2005 and PRO-2006 is designated EL-501, and is identified by Radio Shack part #10800050. A new EL panel can be ordered through your Tandy National parts (see above) or local Radio Shack store and sent to your home. Radio Shack no longer sells replacement EL panels for the PRO-2004.

Replacing the backlight is an operation which requires care and patience. Purchase a service manual, and study the exploded parts diagrams as you read the following steps.

Top and bottom cabinet pieces must be removed, then the speaker unplugged from the main board. The front panel assembly must be removed from the chassis by removing 4 flat head screws, 2 on each side. You need not disconnect all the wiring harnesses, though you might have to unplug one so it won't get in the way of a hot soldering iron.

Unsolder the bare ground wire soldered to a large shield on the back of the front panel, located near the back of the squelch control. Two ground braids must be temporarily disconnected by removing the screws which fasten them to the chassis. After removing the volume and squelch knobs, you must remove 8 small screws which fasten the plastic front panel to the display board.

The old EL panel is fastened by a bead of glue and two foil type leads soldered to the display board. It's easier to cut the two leads from the old EL panel before unsoldering. A sharp knife should be used cut

away the glue. The old EL panel can then be slid gently out from behind the LCD display.

The new EL panel can be installed by reversing the process, though I found that it is not necessary to glue the new panel. The two foil leads must be soldered using a minimum of heat. Reassemble the pieces in reverse order of disassembly.

## **GRE-Built Portables: Worn Out Keypads**

The keypad on late model GRE-made Radio Shack portables, e.g., PRO-39 and PRO-43, can become unreliable after prolonged use. The best repair is to replace the rubber keypad instead of trying to restore contacts using chemicals. A replacement rubber keypad may be ordered inexpensively through Tandy National Parts or your local Radio Shack Store.

## **PRO-43: Loss of Audio**

Early PRO-43s were built with a 200 mW speaker (mfr's part #EAS-3P123A). The voice coils in some of these speakers have opened, resulting in lack of audio output, though audio is still available from the earphone jack. A more capable 500 mW speaker is available through Tandy as replacement (EAS-3P127).

## **PRO-43: Freezup**

If you attempt to lock out all 20 channels in a memory bank, then scan only that bank, your PRO-43 will freeze up and be placed into a catatonic state. Use the procedure documented in the PRO-43 user manual to fully reset the scanner. This will "break the trance," but all the memory channels will be cleared.

## **PRO-2004: Dead**

If your PRO-2004 is completely dead, check R235, a 1 ohm, 1 watt resistor mounted vertically on the main board.

## **PRO-7A: Channels 1 - 4 or 5 - 8 Dead**

If the first or last 4 channels in your 8 channel PRO-7A crystal scanner are not working and the lamps for those channels won't light, replace IC4 or IC5 (type 7400A).

# Improve the Squelch in Your Monitor Receiver

## Introduction

The squelch control in some FM monitor receivers is difficult to use because of too much hysteresis. The American Heritage Dictionary of the English Language defines hysteresis as the:

"Failure of a property changed by an external agent to return to its original value when the cause of the change is removed."

It's like having play in a car's steering wheel, or backlash in a gear set. Too much hysteresis in a squelch circuit forces one to keep the squelch at a tighter setting, missing weaker signals when scanning or searching. The squelch hysteresis problem was first addressed in a 1984 article about the Radio Shack PRO-24 crystal controlled scanner.

Why do engineers design these circuits with any hysteresis? Basically, hysteresis prevents weak signals from "popping" the squelch open and closed rapidly, which would be very annoying to the listener. A squelch circuit with hysteresis requires a stronger signal to open the squelch than it does to keep it open.

Models cursed with too much hysteresis include the Uniden/Bearcat 800XLT and 760XLT, Radio Shack

PRO-2003, PRO-2004, and others. Don't despair, the fix is simple for most radios. I've successfully reduced the squelch hysteresis by replacing a single resistor.

Hysteresis is usually implemented by providing feedback from the squelch gate input to output, through a resistor. The higher the resistor value, the less feedback there is, and less hysteresis. My modification involves replacing the "stock" resistor with a higher value resistor, as identified in the table below.

This technique does not apply to some of the newer Uniden models, because the squelch hysteresis is partially determined by firmware inside the processor IC.

This article cannot provide step-by-step instructions for each radio. I always encourage radio hobbyists to purchase the service manuals for their equipment. The most useful sections of the manual are the schematics and printed circuit diagrams. Good manuals will also describe the theory of operation and alignment procedures, and contain a complete parts list.

If your radio has too much hysteresis, and is not listed in the table, study the service manual. Motorola MC3357, MC3359, and MC3361 integrated circuits, which contain IF and squelch circuitry, are popular in scanners. In these receivers, look for the hysteresis resistor to be connected to these ICs.

## Notes

1. The author cannot furnish modification information for other radios.
2. Don't attempt this, or any other internal modification, unless you are skilled in electronic servicing.
3. Make sure your receiver is disconnected from any power source before opening the cabinet.
4. If space permits, you can replace the stock resistor with a higher value variable resistor ("trimpot") and adjust to suit.

## Table 1. Squelch Hysteresis Resistor In Selected Receivers

Squelch Hysteresis Resistor In Selected Receivers			
Receiver Model	Resistor No.	Stock Value	Comments
Radio Shack PRO-24	R35	33K	replace with 220K.

			Located between pins 12 and 14 of MC3357 (IC1)
Radio Shack PRO-2002	R197	47K	try 220K.
Radio Shack PRO-2004	R148	47K	remove R148 or replace with 220K.
			On linear board, between pins 12 & 14 of TK10420 (IC2)
Radio Shack PRO-2006	R152	33K	try 100K or higher.
Radio Shack PRO-2022	R91	33K	replace 33K with 220K.
			Between pins 12 & 14 on IC-1 MC3361
Radio Shack PRO-2035		100K	replace 100K with 220K.
			Between pins 12 & 14 of TK10420 (IC-2)
Electra/Bearcat 220	R75	2.7M	may be ok as is
Electra/Bearcat 20/20	R75	2.7M	may be ok as is
Electra/Bearcat 250	R66	2.2M	may be ok as is
Uniden/Bearcat 760XLT	R58	22K	replace with 6.8K or other value. (select value for the particular radio.)
			Located on pin 14 of MC3359P IC
Uniden/Bearcat 800XLT	R91	860K	replace with 2.2M.
			Located on pin 14 of MC3359P IC
Plectron P1	R81	180K	may be ok as is
Plectron 700	R96	180K	replace with 560K

## Chapter 1) Introduction

---

### 1.1) About the Author

HOW TO DIAGNOSE, REPAIR AND UPGRADE YOUR AMPLIFONE AND WELLS-GARDNER  
COLOR VECTOR (XY) MONITORS

Author: Gregg Woodcock

E-Mail: [woodcock@nortel.com](mailto:woodcock@nortel.com)

version 6.3 (8-1-96)

---

## 1.2) Official CYA legal warning and waiver

Although I have made every effort to be precise, this article may contain errors. Even if it does not, some people may still damage their machines or themselves while using the information found in this document. The author is neither responsible nor liable for any damage or injury resulting from any use of this document. The author makes no guarantees of any kind; **USE THIS INFORMATION AT YOUR OWN RISK.**

---

## 1.3) Copyright Information

This article is Copyright worldwide 1991, 1996; all rights reserved.

I have gleaned a lot of the information included herein from copyrighted materials released by various entities (a few are even included virtually word for word). The hardware we are discussing is "obsolete" in the sense that it is no longer being made, sold, supplied or repaired by **Atari** or Wells-Gardner. I have talked to technicians in both companies who, off the record, applauded my efforts and feel that their respective employers couldn't care less about items this old and "useless". In that light, I see my inclusion of this information as "fair use" (not in violation of the "spirit" of copyright law) in the sense that this document may be the only way for many people to repair their equipment.

I apologise in advance to **Atari**, Wells-Gardner, **Star\*Tech Journal**, and Play Meter for any perceived violation of the "letter" of copyright law.

In sections where I have transcribed documents word for word (indicated by a line of equals sign characters "=..=START=..=" on the top and "=..=STOP=..=" on bottom), text inside square brackets ([ ]) is my commentary and was not in the original article.

**STAR WARS is Copyright (c) 1983 Lucasfilm, Ltd. and Atari, Inc. All rights reserved. Trademark of Lucasfilm, Ltd. used by Atari, Inc. under license.**

---

## 1.4) Distribution Rules

Reprint permission is conditionally granted to everyone. For publications, the conditions are that (1) I am to be notified before the article is printed, (2) I must be credited and (3) I must be sent a copy of the publication in which this article appears (customary free-lance compensation would be greatly appreciated, too, but is not required). Obviously, publishers/editors will need (and are granted) the right to edit the text; I ask only that it be clearly indicated that the text was abridged or altered (no specifics required). Personal (private) use and distribution is unconditional as long as the **ENTIRE** text is included

(additions are acceptable provided they are clearly marked as such). Fair use applies for all; it is OK, to pull small sections of appropriate text out to be given to people who need it without wasting your time by crediting the source.

---

## 1.5) Acknowledgments

I'd like start off by thanking Rick Schieve ([rls@intgp1.att.com](mailto:rls@intgp1.att.com)) for helping me get started in collecting and for donating a file which was the seed for this document.

If this article does not suit your needs, there is probably more technical information (which I have not seen) about vector monitors (of all types) available from **Star\*Tech** including a CD-ROM with 16 years of articles on it!

### **Star\*Tech**

Tel: (609) 654-5544

E-MAIL: Invalid

WWW: Invalid

(Anyone have any further info?)

---

## 1.6) Have and Want

Before you ask, I do have a small cache of spare vector monitor parts ranging from entire monitors, to individual PCBs, to discrete elements (like the HV transformer) for both color and black-and-white units (no Amplifone parts, though; sorry). I am willing to sell or trade so just send me some email or call me at (214) 684-7380. Also, please call me before you junk any vector stuff; I hate talking with operators and hearing, "I threw all that junk in the trash a few weeks/years ago!" If I can't get there to personally take it off your hands, I can make some calls to friends around the world who will be able to. There are quite a few of us nuts who just love these old vector games.

---

# Chapter 2) How does a Vector monitor work?

Vector monitors, also referred to by **Atari** and others as "XY" (ick) or "Quadrascan" (double ick) monitors, are available in black and white or color. A black and white picture tube has one electron gun

that lights just one type of phosphor (usually, but not always, white). Color tubes have 3 electron guns that, when the yoke and neck magnets are aligned properly, each hit their own phosphors only, either red, green, or blue (RGB). Something called a shadow mask is used so each gun hits only one set of phosphors. There is no inherent difference between the tubes used in vector monitors and the tubes used in raster monitors; only the control circuitry differs. That is not to say that you can use any tube in any monitor; there are several different neck pinouts that have been used for picture tubes so you have to find a tube with a matching pinout first. If you have a lot of screen burn, you can replace a color vector picture tube with any compatible "off-the-shelf" 100 degree in-line picture tube that is also used in raster-scan displays.

So far, this has been just basic TV stuff and it holds true for raster monitors too. Now we will diverge. The electron guns in the neck of the tube emit a stream of electrons that bombard the face of the tube that would hit dead center if not for the deflection magnets on the neck of the tube. There are two deflection coils. One for horizontal deflection (X) and one for vertical deflection (Y) of the electron beam. Consider the center of the screen to be (0,0) volts to the deflection magnets. If you want to move the beam to the right you put a positive voltage on the horizontal deflection "X" coil (+,0). A negative voltage moves it to the left. Up and down are accomplished with positive or negative voltages to the vertical deflection (Y) coil.

The deflection coils are driven with the same kind of circuitry some audio amplifiers use. Imagine that the game puts out pre-amp analog levels and that the monitor amplifies and displays the output. There are some vector monitors (the ones used in the Cinematronics games) that are digital in nature and have a significantly different design. Do not assume that anything discussed in this document applies to these monitors since much of it does not.

The third section is what (at least by **Atari**) is called the "Z" amplifier which controls the brightness. There is a "Z" amplifier for each electron gun which means that black and white monitors have only one "Z" amp and color monitors have three.

To draw an asteroid or other object the game shuts off the Z amp (or amps) and applies the correct vector information to the X and Y amplifiers driving the deflection coils to move the beam to the desired location. Then the appropriate Z amp(s) are turned on to illuminate the screen and the vectors are modified to draw an outlined asteroid. On most monitors you can turn the brightness up to the point where the Z amp(s) don't completely shut down and you can see the full path of the electron beam as it flies around. The designers of Star Wars exploited these traces when laying out the dots for the starfield pattern and the Death Star explosion to form "connect-the-dot" messages that say, "MAY THE FORCE BE WITH YOU" on odd waves from 1 to 31 and, "HALLY MARGOLIN RIVERA AVELLAR VICKERS DURFEY" (the last the names of the programmers and other people involved with making the game) on even waves from 2 to 30 and on all waves from 32 to 99.

---

## Chapter 3) How does that help me with

# repair?

What I have described so far applies to all vector monitors. Knowing how these things work helps greatly in trouble-shooting. For instance deflection of the beam to the edges of the screen puts the greatest strain on the X/Y deflection circuits so if you monitor has problems at the edges, something is weak in that area. The monitors make their own positive and negative DC from AC inputs so a reasonable thing to check would be the power supplies. One of the main root causes of color vector monitor problems is game lockups causing the monitor to go extended periods with no input signal which fries it in short order. The 2 main problems I have seen for game board lockups are bad solder joints on the inter-board connectors (mainly Tempest) and also noisy power supplies. I suggest that you replace the power supply filter caps with 105 degree Celsius capacitors instead of 85 degree ones; the higher temperature caps last much longer and are more stable.

Vector monitors are also fussy about the quality of certain transistors. The X and Y deflection circuits are very much like audio amplifiers and tend to be hard on the big transistors used in the final stages of amplification. The **Atari** vectors use a push/pull rearrangement with NPN and PNP transistors for both the horizontal and vertical amps. If you lose one of these transistors, you lose deflection in 1 of 4 directions depending on which transistor goes out.

There is another circuit in the **Atari** stuff that is very important called the spot killer. What the spot killer does is shut down the Z amp(s) if the X or Y circuits go bad enough to cause the beam to fail to move around the screen enough to keep from burning the phosphors around the zero axes. The phosphors will become permanently damaged if the beam stays in one place for too long. When the spot killer is active a red LED on the deflection board lights. The spot killer also lights if the logic board does not supply the low level X and Y signals for the monitor to amplify or if the voltage supply for amplification is not present so it does not always indicate a monitor failure.

Along these same lines the P324 version of the Wells-Gardner and all Amplifone HV units have a circuit known as the over-voltage protection circuit. This circuit monitors the voltage at pin 4 of the focus assembly. If this voltage increases beyond a tunable threshold, a transistor fires turning off the oscillator. This shuts off the high-voltage power supply and completely kills the picture. It is meant to keep your tubes and other components (such as the high voltage transformer) from being destroyed in the event of a failure causing very large high-voltages.

---

## Chapter 4) How do Wells-Gardner and Amplifone differ?

**Atari** used 2 different (but pinout compatible) versions of the color vector monitor. The first and most unreliable was the Wells-Gardner. The second (used only in Star Wars and dedicated Major Havoc

machines as far as I know) was the Amplifone. There were several versions of the Amplifone, early ones used in Quantum, and later ones used in Star Wars have differing tube/yoke numbers. I'm assuming they are all compatible but don't know for certain? Another quick aside; all the boards and professionally produced documents spell the company name correctly as "Amplifone" but lots of supplemental documentation (such as the document below) misspell it as "Ampliphone". I use whichever spelling was used in the particular document presented.

Each monitor design has a slightly different electrical characteristic and tube shape that will cause games designed for use with the Amplifone to bulge out around the edges (a defect known as "barreling") when using a Wells-Gardner and similarly will cause games designed for use with the Wells-Gardner monitor to cleave inward around the outer edges (a defect known as "pincushioning") when using an Amplifone. It is quite minor and is really only noticeable when in the self-test screen as this draws a (perfectly straight) bounding box around the edge of the display which makes it easy to notice.

The Amplifone uses a neck socket the same as most other (non-vector) monitors from most other manufacturers use but the Wells-Gardner uses a different socket. The pinout, however, is the same so you just need to convert them if you want to switch tubes between the 2 types. If you are careful, you should be able to pull off the plastic neck sockets from the each tube as they are just glued on over the glass. Then just swap them. For example, an Amplifone tube will work in a Wells-Gardner chassis just fine (some versions of the Amplifone manual would lead you to believe they won't but that mistake was corrected in later versions of the manual) except that the display will bulge in the outer-middles slightly. This bulging is due to differences in the yokes and **MIGHT** be counteracted by swapping the yokes (putting the Wells-Gardner yoke on the transplanted Amplifone tube) but I haven't tried that yet. If you happen to run across a tube cross-reference chart, please let me know what it says about RCA picture tube 19VLUP22 (the Wells-Gardner tube) and Rauland tube M48AAWOOX (the Amplifone tube).

It is pretty easy to check to see if your tube is bad (it doesn't happen a lot but it does happen). Pins are counted counter-clockwise starting at the gap (when looking at the backside of the tube). Pins 9 and 10 are at either end of the heater element. If you want to be absolutely certain about which pin is which, check the socket on your neck board (it should number all the pins). The heater is basically a very low wattage light bulb that emits the electrons which are shot at the phosphor to make light. You should read a short (OK, not a short but a VERY low resistance) across pins 9 and 10 if your heater is OK. If you read an open, your tube is toast and there is nothing you can do (your light bulb is burned out). If your heater is OK, check to make sure that the heater pins are not shorted to any of the emitter cathodes (pins 6, 8, and 11). If you see a short then your tube has a serious problem but in many cases the short can be burned away. Call your local TV repair shop to see if they can "rejuvenate" it.

---

## 4.1) CRT (neck) pinout

Here is the complete pinout of the neck/tube.

1. G3 (focus grid)

2. not used
3. not used
4. not used
5. G1 (control grid)
6. G (green cathode)
7. G2 (screen grid; brightness)
8. R (red cathode)
9. H (heater)
10. H (heater)
11. B (blue cathode)

## 4.2) Deflection board pinout

Here is the complete pinout of the main connector (on the deflection board):

1. Red input (4.0V full on; 1.0V black level)
2. Green input (4.0V full on; 1.0V black level)
3. Blue input (4.0V full on; 1.0 black level)
4. Red GND (twisted pair with Red input)
5. Green GND (twisted pair with Green input)
6. Blue GND (twisted pair with Blue input)
7. X input (16V Peak-to-Peak; 2.5Kohms)
8. Y input (12V Peak-to-Peak; 2.5Kohms)
9. Not Used (Key)
10. X GND (twisted pair with X input)
11. Y GND (twisted pair with Y input)
12. Power GND
13. 25V RMS
14. Power GND
15. 25V RMS

**SPECIAL NOTE:** The 2nd printing of TM-183 has a typo in Figure 8 on page 11 which incorrectly identifies the heater as existing on pins 5 and 6. Strangely enough, both the 3rd and the 1st printings have the correct numbers; go figure.

I should also mention that the monitor Sega used in it's vector games (Electrohome's G08-CB0) is also an analog monitor and can be used in any **Atari** vector game (and vice-versa) with the proper adaptors to

mate the different wiring harnesses (connectors) plus some circuitry to scale the voltage ranges of the analog signals and the AC supply. I do not have documentation for the G08-CB0 so I cannot say exactly what scaling is required but I can tell you that I have seen G08-CB0 monitors with "Tempest" burned into them and I also saw a Wells-Gardner with "Space Fury" burned into it. I have talked to several people who claim to have seen such a setup in action but they have no specifics. I would appreciate any details anybody can provide about the G08-CB0 and/or the specific conversion details (either direction).

David Shuman <[essayes@telerama.lm.com](mailto:essayes@telerama.lm.com)> had this to say about the G08-CB0:

"Sega XY monitors are analog monitors like the **Atari** XY's. Unlike the **Atari** XY's, the Sega XY's don't have a "Z" channel. The connector from the game board to the monitor has only six connections: R, G, B, X, Y, and GND. The G08, unfortunately, is a thoroughly screwed-up design. The original G08 was apparently an operator's nightmare, often consuming itself in flames. Sega started shipping revised monitors with some hacks added, presumably to improve reliability. The result didn't work too well either, and it looked like Frankenstein's monster with parts hanging off everywhere, gobs of glue, soldered connections where detachable connectors are required, etc. In the first two months I had my Eliminator, I had to fix the monitor twice. And since you can't disconnect the HV board from the main board, you have to be very careful not to twist and yank out the wires as you make your repairs. Picking off factory-installed globs of glue to access blown parts is no fun either."

---

## Chapter 5) "SPACE FURY" COLOR (G-80) X-Y SYSTEM REDESIGN (Sega)

=====START=====

I know this is supposed to be about **Atari** monitors but here is some information the Sega color vector monitors that I found on page 12 of the November 1981 issue of the **Star\*Tech** journal. I'll include it here just in case you have one of those hybrid setups mentioned above. If anybody knows more about the redesign that is mentioned, please let me know!

Gremlin/Sega reports that all of the problems encountered with the industry's first color X-Y game "Space Fury" have been identified and solved [yeah, right].

The problems are centered around [ack, bad puns, too!] the deflection (X-Y) amps. Under-rated power transistors combined with an extended "on" time during the power-up routine resulted in damaging the amplifier circuit.

The remedy includes a modification to the card cage and replacement of the Electrohome Monitor with a redesigned unit.

Gremlin/Sega will have replaced all defective monitors and modified all game card cages by the end of October.

Initial field fixes did not resolve the problem entirely and Gremlin/Sega decided to undertake the monitor replacement program.

Electrohome, the monitor manufacturer, will replace monitors in the Eastern U.S., while Gremlin/Sega will handle the Western U.S.

For further details contact your distributor.

=====STOP=====

---

## Chapter 6) Did Amplifone solve all of Wells-Gardner's problems?

The Amplifone was commissioned as a replacement to the infamous, failure-prone Wells-Gardner. Unfortunately it had a horrendously unreliable Achilles' heel; the HV transformer. This part is widely (but falsely) believed to be impossible to replace because there are no more HV transformers around. Fortunately, this is incorrect and they are readily available, even though they are a bit expensive.

**"NOTE:** [Ob-anally-retentive-pet-peeve] This part is commonly but improperly referred to as the "flyback" transformer. This is a misnomer because the flyback transformer exists only in raster monitors' deflection circuits. Part of a flyback's duty is to regulate the currents necessary to make the electron beam "fly back" to the left (or top) during retraces. In vector monitors, the high voltage transformer is a "flyback" transformer in the sense that it is constructed and designed just like the flyback transformer in a raster monitor with the exception that the flyback portion (the horizontal deflection coil) is not needed and so is not present. There is an oscillator circuit that serves the purpose that the horizontal oscillator would in a raster monitor, and there is a power transistor that would be called a horizontal output transistor if it were in a raster monitor, but the part of the transformer that controls the retrace (flyback) is not present so there is no true flyback transformer in a vector monitor. If you must give it a name, use "HV" or "horizontal driver" instead of "flyback"."

As soon as **Atari** heard about all the failures of the HV transformers, they commissioned a third party to supply them with a ton of replacements for the Amplifone monitors since they were so unreliable and in such high demand. Unfortunately (for **Atari**), by the time they were manufactured, nobody cared anymore (because the games that used the Amplifone were getting old and starting to be retired/converted anyway or else they had Wells-Gardner retrofits in them) so this fact is not widely

known to most people in the industry.

The replacement HV transformer was over-engineered to the max so that it would not fail as much as the original part and to date **Atari** reports that **THEY HAVE NOT HAD EVEN ONE REPORT OF THE REPLACEMENT EVER FAILING!** To be critical, this could be due to the fact that by the time the replacements became available, most people were no longer routing their Star Wars machines (or at least not with the Amplifone monitors in them). Any machines being repaired and used today are likely to get gentle home use which naturally lengthens the life of the monitor and its parts.

---

## 6.1) No HV?

If your HV is dead then it is probably either resistor R12 near the HV transformer or the HV transformer itself. **CHECK THE RESISTOR FIRST** since it is much easier and cheaper to replace. Simply unsolder it and see if it has the proper resistance (2.2K Ohms). You will also want to check to see if the over-voltage protection circuit is misadjusted causing it to activate even though the HV is in a tolerable range. If LED (CR2) is lighted, then the over-voltage protection circuit is activated. If it is on then you either have a misadjusted potentiometer or a damaged HV circuit. Mark the initial position of R19 and tweak it a tiny bit to see if the LED turns off. Don't move it too much or you may damage other parts of the circuit or even your tube if the HV is indeed too high.

The catch is that **Atari** replacement parts are only supplied at the wholesale level to official **Atari** game distributors. To find out the distributor closest to you so that you can order this part from them, call **Atari** at 408.434.3700 and give them you Zip or Area Code and they will give you a business name and phone number. I am pretty sure the MSRP is about \$160 but that is significantly cheaper than buying a Wells-Gardner retrofit that you will have to repair about once a year (most distributors discount such old parts below the MSRP so you shouldn't have to pay that much especially if you comparison shop and play the distributors off each other).

Starting with some information I provided to get him started, Tim Tewalt <[tewalt@peaks.ENET.dec.com](mailto:tewalt@peaks.ENET.dec.com)> in mid-1995 attempted to bypass **Atari** and the distributors by buying factory direct. Here is what he discovered:

=====START=====

"Hi guys; bad news. The bottom line is \$150 each when ordering a total of 25 flybacks. As Gregg Woodcock pointed out, Penn Trans of Wingate PA, is no longer in business; hell, there's no such thing as Wingate, PA, either for that matter. I called the Postmaster in Bellefonte, PA and found that Wingate was swallowed up by Bellefonte and more importantly, Penn Trans was bought out by Wintron Inc. The part number 926862802 from my flyback, matches the Wintron flyback part number, so I was pretty sure I had found the source. They faxed me a quote a few days later with a price of \$173.13 each on a quantity of ten and \$149.83 each on a quantity of twenty-five. **NOT** the deal I was looking for. So anyway, I have decided not to pursue this any further. If someone

else would like to look into this, you'll find some pertinent information below. Thanks a lot for your interest, guys. Sorry I wasn't able to come through."

"Flyback" Transformer for Amplifone XY monitor

**Atari** part number: A201005-01

Type number: 926862802 ("Transformer Multiplier")

Manufactured by: WinTron Inc.

Address: 250 Runville Road; Bellefonte, PA 16823

Tel: (814) 355-1521

FAX: (814) 355-1524

[**NOTE:** The reason for the high prices is that they do not have any stock on hand and would have to retool the machinery to manufacture a fresh batch. Perhaps it would be simpler and cheaper to get the spec from them and find out what it would cost to have a professional wire one up by hand...]

=====STOP=====

If your HV transformer is dead then you will need to order **Atari** part number A201005-01. This part was available in inexhaustible quantities from **Atari** until recently but now Atari claims they have no more. I suspect that with all the reorganizations of the company some of the "dead weight" inventory was liquidated or thrown out altogether. If you make enough phone calls to large distributors, you should be able to locate one. If you do, please let me know and I'll add the information to this document. One person reported that when his HV transformer went bad it took VR1, R20, and CR5 with it so you may want to test/replace these parts, too (they are commonly available).

---

## 6.2) Installing the Amplifone HV transformer

Here is the document that describes how to install an Amplifone HV transformer. Thanks to Keith Jarett ([keith@tcs.com](mailto:keith@tcs.com)) for mailing me a photocopy (who in turn wishes to thank Mark Sherman and Al Vernon of **Atari** Games for their fabulous in-depth knowledge and tech support. I agree; these guys have helped me a few times, too, and are fantastic).

=====START=====

[**NOTE:** To my knowledge, **Atari** never bothered to copyright these instructions and they are not marked with a copyright symbol.] **INSTALLING THE NEW AMPLIPHONE [sic] HIGH VOLTAGE TRANSFORMER**

1. Remove the defective flyback from the highvoltage [sic] P.C.B. [**NOTE:** The new transformer has a black case and it is smaller than the original which has a red case]

2. Change R12 to a 1K ohm [1/4 Watt] resistor. [**NOTE**: recommended for durability; not strictly required]
3. Secure the new flyback to the high voltage pcb using the mount hole, tighten nut on the circuit side of the High Voltage P.C.B. [**NOTE**: It bolts through the PCB, though you will have to first:
  - o enlarge the through hole slightly
  - o connect the wires from the transformer to the PCB
  - o tape over the PCB to insulate the traces from the metal bottom of the transformer]
4. Solder the thick BLACK wire from the HV transformer to the TOP connector on the Focus block.
5. Feed all six color coded wires from the bottom of the HV transformer through the 2nd hole to the circuit side of the high voltage pcb.
  1. Solder GRAY wire to the point labeled Filament. (see figure below) [**NOTE**: Pin numbers are shown on the white plastic bottom of the old transformer and on the schematic if you have one; for this reason, I will not attempt to draw in the picture mentioned here] [**NOTE**: This is where the "extra" wire from the old flyback went.]
  2. Solder ORANGE wire to [former] pin 1. [**NOTE**: The photocopy I got with my replacement had the label for this pin cut off! It is the pin that goes to the case of Q3.]
  3. Solder GREEN wire to [former] pin 4.
  4. Solder BLACK wire to [former] pins 6 & 7.
  5. Solder YELLOW wire to [former] pin 8.
  6. Solder RED wire to [former] pin 9.

[A picture showing a full scale drawing of the solder side of the HV PCB, has been omitted for obvious reasons. It does not show anything that cannot be derived from the included text; it was merely a "visual aid".]

[**NOTE**: End of document; here is further advice from the **Atari** techs...]

After you finish, you will need to adjust brightness (bottom pot on the white module). Use the self test screen for this. Also adjust focus. If nothing happens, the other (lower) focus wire is broken like mine was [**NOTE**: Mine was broken, too!]. Take off the rubber cap to verify. Focus is the top pot on the white module. This connection is fragile and takes a lot of heat/current so it frequently breaks off.

Adjust R7 (the frequency of the primary switching) to get a video B+ of 180 volts. According to Mark, this will give the correct HV. You don't really need to tweak R17 as described in the manual if you know that your over-voltage protection cutoff is working OK. Recheck focus after tweaking R7.

If any problems occur, verify that the +24 and -24 volt regulators are reasonably close to the correct output voltages. Some departure is OK if you have the 5 watt resistors bridging their inputs and outputs (these are present to relieve the load under transient conditions such as the all-white death star explosion).

The board should now run **MUCH** cooler. I can comfortably touch all the HV heat sinks which was not true before.

## Chapter 7) Atari Star Wars High-Voltage Board (transistor!)

One word of caution about replacing the HV transistor (note that I said "transistor", **NOT** "transformer"; we are shifting gears); double check the part that you receive **BEFORE** you install it. Why? Here is a transcription of a note I found tucked in a Star Wars manual which also mentions how to tell if your HV transformer is (probably) bad, where to mount a fan to lengthen its life, and a possible way to tell if your tube is bad. I have no idea where it came from:

=====START=====

### Atari STAR WARS HIGH-VOLTAGE BOARD

by Avery Petty

A.P. Engineering  
Huntington Beach, CA

Recently, I repaired a whole fleet of **Atari** STAR WARS. I sent someone to the distributor to get the 'hard-to-find' high voltage transistor BU406D [**NOTE:** The transistor he is talking about Q3 labeled as "NPN 7-Amp. 400V Power Transistor" in the manual's parts list.]. He came back with a BU406, no "D". The "D" must appear on the transistor. It means there is a high voltage diode in the package. So beware, even the distributor can goof!

What will it cost you? Your game maybe. Without the diode, using the BU406, the high voltage will work for awhile [sic], but will burn up the flyback transformer which cost [sic] \$90.00 [NOTE: It's **much** more than that now]!

If you are repairing a High Voltage board, and after replacing all the capacitors, the two 24 volt regulators, and related parts and the high voltage transistor with a BU406D, and you still don't have high voltage, and don't know why, you can be sure it's your flyback transformer. If in doubt, pull it out and put it in a working STAR WARS and see, it will only take 5 minutes [NOTE: this is a severe under-estimate; I'd say it is at least a 15 minute job not including swapping them back if that needs to be done, but then again he is a professional and I am just a hack :>].

When you finally fix it, put a fan under the board -mounted [sic] on the wood rail the board is mounted on, blowing on the High Voltage board. This is something that should be done to all STAR WARS, because the flyback is the most expensive part there [NOTE: advice to be heeded for all **Atari** color vector games].

If your high voltage won't get up to at least 19,000 volts, you may have a bad tube. Look for real [sic] bad phosphor burn or a color missing.

=====STOP=====

---

## Chapter 8) Major Havoc Installation Instructions TM-268

Here is some text from the Major Havoc conversion kit installation instructions (TM-268). It describes the **Atari** sanctioned upgrade and includes instructions for converting the Amplifone Deflection Board PCB to the "official" upgrade. Thanks to Tony Jones ([ant@palm.cray.com](mailto:ant@palm.cray.com)) for sending this to me.

=====START=====

[NOTE: **Atari** did copyright these documents and they are clearly marked with a copyright symbol.]  
Major Havoc Installation Instructions TM-268

### I. MODIFY THE AMPLIFONE DEFLECTION PCB

**NOTE:** The following procedure applies to those Space Duel, Gravitar, and Black Widow games that used an Amplifone display. If your game has a Wells-Gardner display, perform "H. Modify the Wells-Gardner Deflection PCB" [found later in this document].

Perform the following procedure to modify the Amplifone Deflection PCB (see Figure 8).

1. Set the Deflection PCB on a clean work surface.
2. Connect two type-1N754A Zener diodes together, anode to anode, as shown in Figure 6 [found later in this document]. Use a soldering iron to solder the two anode leads together.
3. Connect two type-1N756A Zener diodes together and solder as described in step 2.
4. On the component side of the Deflection PCB, locate the yellow wire connected to resistor R1 (left center of the PCB).
5. Solder one cathode lead of the two type-1N754A Zener diodes (soldered together in step 2) to the yellow wire on the soldered side of the Deflection PCB as shown in Figure 8.
6. Solder the other cathode lead of the two type-1N754A Zener diodes to the nearest ground on the PCB as shown in Figure 8.
7. On the component side of the Deflection PCB, locate the orange wire connected to Resistor R24 (right center of the PCB).  
[Figure 8, entitled "Modifying the Amplifone Deflection PCB", showing a full scale picture of the solder side of the Deflection PCB, has been omitted for obvious reasons. It does not show anything that cannot be derived from the included text; it was merely a "visual aid".]
8. Solder one cathode lead of the two type-1N756A Zener diodes (soldered together in step 3) to the orange wire on the soldered side of the PCB as shown in Figure 8.
9. Solder the other cathode lead of the two type-1N756A Zener diodes to the nearest ground on the PCB as shown in Figure 8.
10. On the soldered side of the Deflection PCB, solder the cathode lead of a type-1N4002 diode to the emitter of transistor Q17 as shown in Figure 8.
11. Scrape away the green protective coating at a convenient point on the PCB, and solder the anode lead of the type-1N4002 diode to the collector of transistor Q17 as shown in Figure 8.
12. On the soldered side of the Deflection PCB, solder the anode lead of a type-1N4002 diode to the emitter of transistor Q16 as shown in Figure 8. [NOTE: This is the opposite of what you did in step 10.]
13. Scrape away the green protective coating at a convenient point on the PCB, and solder the cathode lead of the type-1N4002 diode to the collector of transistor Q16 as shown in Figure 8.
14. On the soldered side of the Deflection PCB, solder the cathode lead of a type-1N4002 diode to the emitter of transistor Q7 as shown in Figure 8. [NOTE: This is the opposite of what you did in step 12.]
15. Scrape away the green protective coating at a convenient point on the PCB, and solder the anode lead of the type-1N4002 diode to the collector of transistor Q7 as shown in Figure 8.
16. On the soldered side of the Deflection PCB, solder the anode lead of a type-1N4002 diode to the emitter of transistor Q6 as shown in Figure 8. [NOTE: This is the opposite of what you did in step 14.]
17. Scrape away the green protective coating at a convenient point on the PCB, and solder the cathode lead of the type-1N4002 diode to the collector of transistor Q6 as shown in Figure 8.

=====STOP=====

---

## Chapter 9) Atari Field Service bulletin

Here is an **Atari** Field Service bulletin courtesy of Al Kossow ([aek@haxrus.apple.com](mailto:aek@haxrus.apple.com)) which describes modifications to the Amplifone monitor to make it more robust. All the diagnostic/repair stuff is new and compatible but the rest seems to be similar to part of the previous Major Havoc documentation upgrade but they do differ in some respects. I would advise that you only implement 1 of them unless you are sure they are compatible (I am not). If anybody knows if any are compatible (or not), let me know. For now, I am listing them as mutually-exclusive; mix at your own risk. I'd take the time and hassle to do the first one even though it is a lot more work.

=====START=====

[NOTE: To my knowledge, **Atari** never bothered to copyright these field service bulletins and they are not marked with a copyright symbol.] TECH TIP from the **Atari** FIELD SERVICE DEPARTMENT

### **Atari** Color X-Y Display Deflection PCB

You should do the following modifications to help prevent the Deflection PCB from failing. **THIS MODIFICATION SHOULD ONLY BE PERFORMED BY A QUALIFIED TECHNICIAN.**

#### Parts List

Quantity	Description	Part No.
6	Type-1N4002 Diode	31-1N4002
2	Type-1N754A 6.8V Zener Diode	131002-001
2	Type-1N756A 8.2V Zener Diode	32-1N756A
2	12 Ohm 5% 1/4 W resistor	110000-120

1. Connect the two 1N754A Zener diodes together as shown in Figure 1. The connection is made as follows: bend the anode ends of both diodes into a "fish-hook" pattern. Hook the two fish-hooked leads together, and solder them. Remember that too much heat will destroy the semiconductor material.
2. Connect the two 1N756A Zener diodes together as shown in Figure 1. Use the same technique as described in Step 1 above.
3. Remove diode CR2 and solder in a type-1N4002 diode in its place. [NOTE: On older monitors, CR2 is labeled D602.]
4. Remove diode CR11 and solder in a type-1N4002 diode in its place. [NOTE: On older monitors, CR11 is labeled D702.]
5. Remove resistor R12 and solder in a 12 Ohm, 1/4W resistor in its place. [NOTE: On older monitors, R12 is labeled R609.]
6. Remove resistor R35 and solder in a 12 Ohm, 1/4W resistor in its place. [NOTE: On older monitors, R35 is labeled R709.]
7. Find the Y-Deflection Circuit (upper left area of the schematic). Resistor R1 has two leads to it. Find the lead that goes to the yellow wire. Connect this lead to the cathode of one of the type-

- 1N754A diodes. Connect the cathode of the other type-1N754A diode to ground.
8. Find resistor R24. It has two leads: one runs to an orange wire. Connect this lead to the cathode of one of the type-1N756A diodes. Connect the cathode of the other type-1N756A diode to ground.
  9. Find the type-2N3792 transistor Q17. You will be installing a type-1N4002 diode across the transistor's emitter and collector. Solder the cathode lead of the type-1N4002 diode to the emitter, and solder the anode to the collector of this transistor.
  10. Find the type-2N3617 transistor designated Q16. You will be installing a type-1N4002 diode across the transistor's emitter and collector. Solder the cathode lead of the type-1N4002 diode to the collector, and solder the anode to the emitter of this transistor. [NOTE: this is the opposite of what you did in Step 9.]
  11. Find the type-2N3792 transistor Q7. You will be installing a type-1N4002 diode across the transistor's emitter and collector. Solder the cathode lead of the type-1N4002 diode to the emitter, and solder the anode to the collector of this transistor.
  12. Find the type-2N3716 transistor Q6. You will be installing a type-1N4002 diode across this transistor's emitter and collector. Solder the cathode lead of the type-1N4002 diode to the collector and solder the anode to the emitter of this transistor. [NOTE: this is the opposite of what you did in Step 11.]

FIGURE 1 Making Fish-Hook Connections

[NOTE: You get the idea; snub diodes across the deflection amps, back to back Zeners on the input to ground. Since I made these modifications, I haven't had a deflection amp go out (but I'm running the game with the back off now, too.)]

...

## 9.1) STAR WARS Vector-Generator PCB

### 9.1.1) Shaky Video

**PROBLEM:** Some games may have shaky video after a 15-minute warm-up. The video will start to shake in the high-score screen. The words PRINCESS LEIA'S REBEL FORCE will start to flutter and then worsen to an up-and-down movement of about 1/8 inch. In its worst state, the scores will also move back and forth.

**SOLUTION:** Change the 10K Ohm resistor R83 on the Vector-Generator PCB to a 20K Ohm resistor.

---

## 9.1.2) Zero-Ohm Resistor Jumpers

STAR WARS Color X-Y Display [Amplifone ONLY; not Wells-Gardner models!]

**PROBLEM:** The **BROWN** zero-ohm jumpers (W1 or W2) on the Deflection PCB open up on the High-Voltage PCB. Zero-ohm resistors look like regular resistors, but are marked on the PCB assembly and the schematic with a W followed by a number.

**SOLUTION:** Replace the jumpers with pieces of wire. **NOTE** that the /white/ and /tan/ jumpers are good and don't have to be replaced.

## 9.1.3) Capacitor Failure

STAR WARS Color X-Y Display [Amplifone ONLY; not Wells-Gardner models!]

**PROBLEM:** Capacitors C3 and C4 on the High-Voltage PCB may be defective. These are rated at 100uF, 35V.

**SOLUTION:** Change C3 and C4 to 220uF, 35V with a low E.S.R. (Effective Series Resistance) rating. The Atari part no. is 123009-227. The following manufacturers' capacitors will also work:

Illinois Capacitor, part no. 227 RMR 050M (50V)

Nichicon, part no. UPA1V221M (35V)

[NOTE: Digi-Key also sells "HFS SERIES Low Impedance" capacitors which will work. Dial 800.DIGIKEY and order part number P1339; my last catalog (April 1994) lists them for \$1.68 each. The Nichicon capacitors should be obtainable from TTI. TTI is the nations largest distributor of passive components such as resistors and capacitors. Dial 800.CALL.TTI to place an order.]

\\\ A Warner Communications Company  
FOR FURTHER INFORMATION CALL: (800) 538-1611  
(800) 943-1120

=====STOP=====

The following information is excerpted from a photocopy of a photocopy (of a...) which has no visible

attribution or copyright. It appears to be from the **Star\*Tech Journal** but I don't know for sure and the guy who sent it to me doesn't know where it came from.

---

## 9.2) STAR WARS Display Problems

=====START=====

**PROBLEM:** No filament voltage from the high voltage (HV) PCB.

**SOLUTION:** Check for a loose connection on the lugs that hold the HV transformer to the PCB.

**PROBLEM:** Can any other power transistors be used on the Deflection board?

**SOLUTION:** Yes, MJ 15003 NPN replaces 2N3716, and MJ15004 PNP replaces 2N3792 [**NOTE:** these substitutions are valid for the Wells-Gardner model, too].

**PROBLEM:** What should the output of the 555 IC on the HV PCB be?

**SOLUTION:** The output at pin 3 of the IC should be a 20-kHz square wave. This is adjusted with potentiometer R7.

**PROBLEM:** There is no high voltage. The positive and negative 24 volts are present.

**SOLUTION:** Check transistor Q3. The problem may be that the transistor tab (collector) may not be making good contact with the heat sink.

**PROBLEM:** The schematics for the HV cutoff circuit do not match the board assembly.

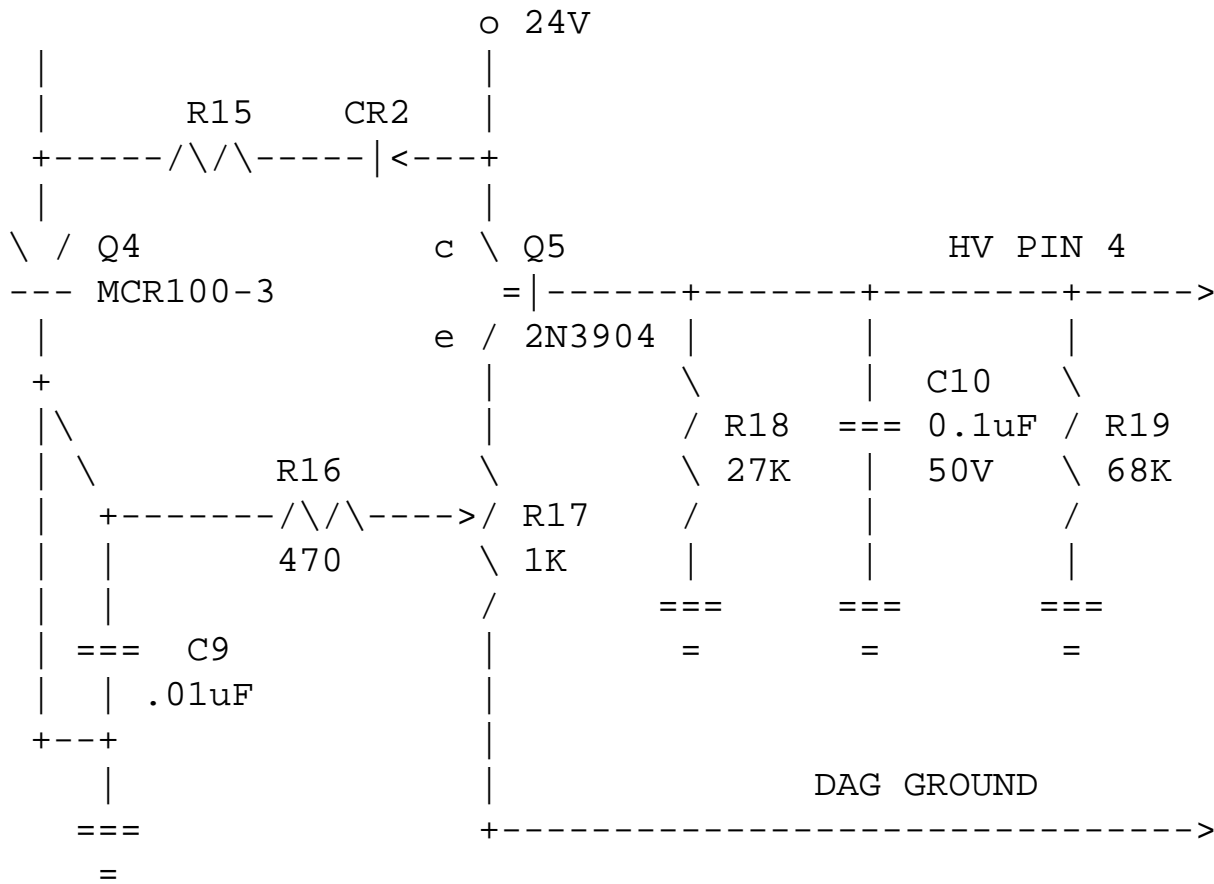

**SOLUTION:** There are three board revisions. You can tell which one you have from the table here. The schematics for all three boards are shown.

### DISPLAY REVISION INDICATORS:

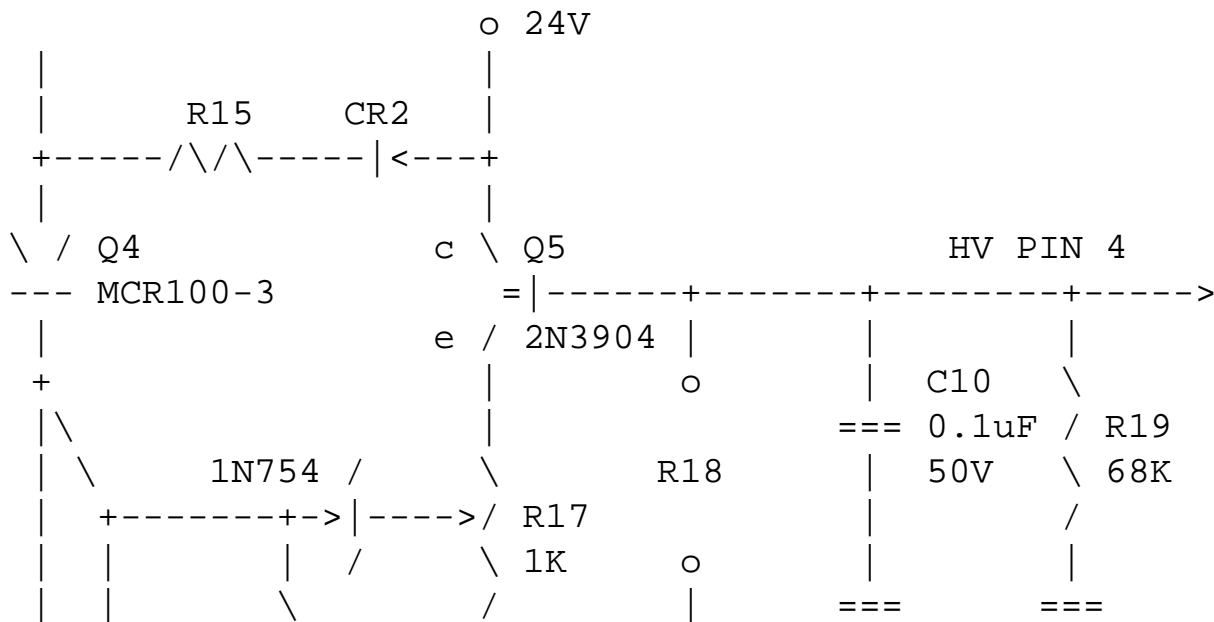

PCB Revision	R16	R18
Original	470 Ohms	27K Ohms
First rev.	Zener	Missing or 27K Ohms
Second rev.	470 Ohms	33K Ohms

---

## 9.3) ORIGINAL

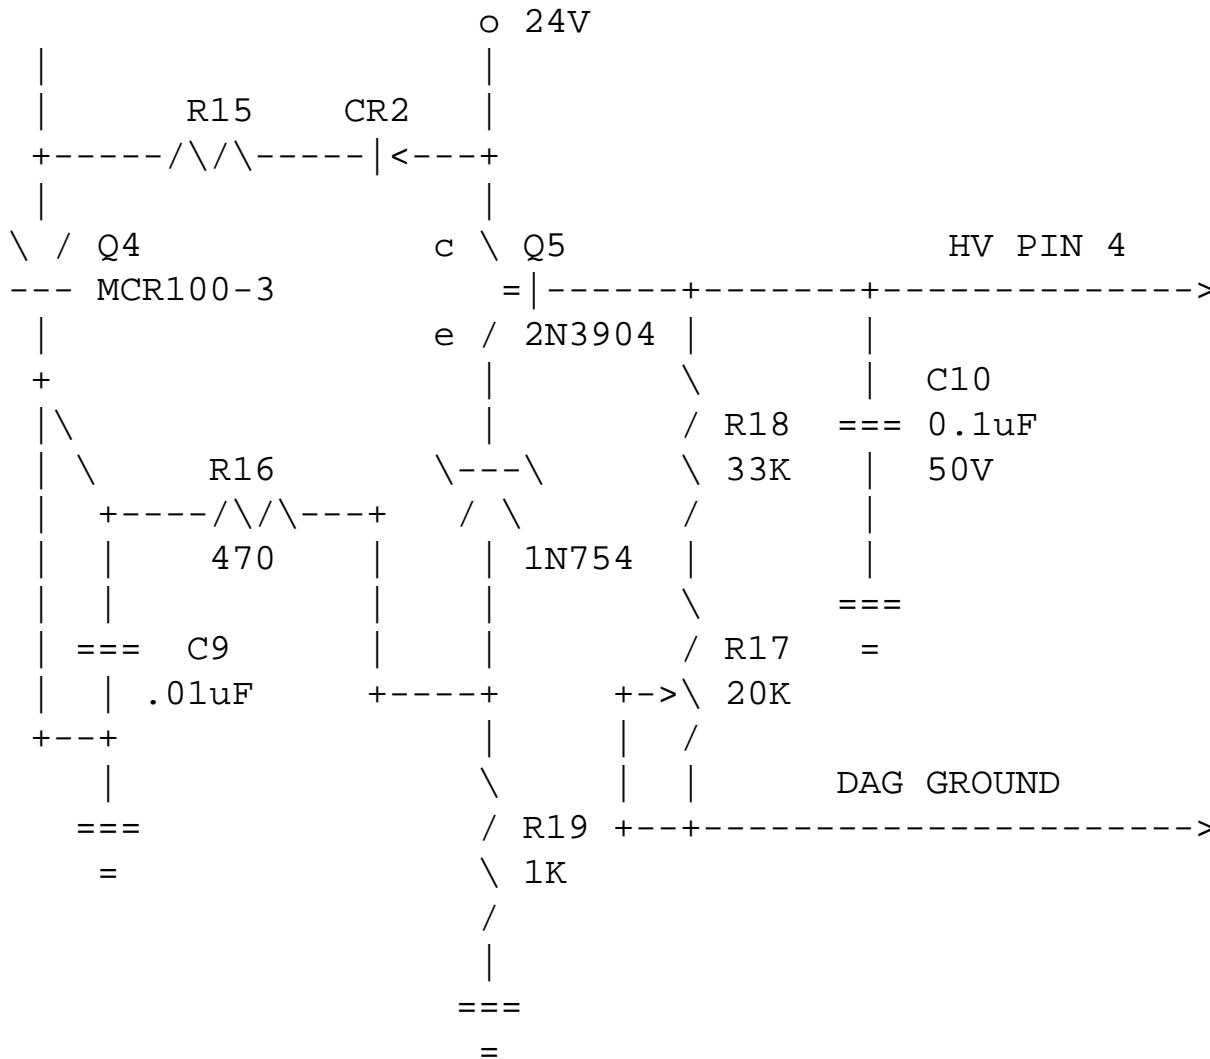

## 9.4) First Revision

## 9.5) Second Revision

**PROBLEM:** The schematic for the deflection board shows CR5 as a 1N714 diode.

**SOLUTION:** The schematic number is wrong. It should be labeled a 1N751A zener diode. The rating of 5.1 volts is correct, however.

**PROBLEM:** On the HV PCB, the output voltage of the regulator is good when the pin is lifted, but there is no voltage when the pin is connected back to the board.

**SOLUTION:** Check for bad 0.1uF glass capacitor across the voltage regulator. The decoupling capacitor may be shorted.

**PROBLEM:** The 24-volt regulator has failed.

**SOLUTION:** Check for cracking around the regulator leads on the PCB. Also check for cracking around the leads of C3 and C4.

**PROBLEM:** The voltage is low on the supply lines on either the Deflection PCB or the HV PCB.

**SOLUTION:** There are jumpers on the supply lines of both boards. The jumpers are marked with a "W" on the schematic. They look like resistors on the board and have a single black band on them. The jumpers should have no resistance. However, the brown jumpers may have created some resistance to them. They should be replaced with a piece of wire. The white and tan jumper should have no problems.

**PROBLEM:** The picture shrinks in from the negative X and Y sides of the screen.

**SOLUTION:** On some deflection boards, R35 and R12 may have a 15 Ohm resistor and a 30 Ohm resistor in parallel to get 10 Ohms. If these come loose, then some picture shrinkage may occur.

=====STOP=====

Unfortunately that's all I have for the Amplifone. It is worth noting that I recently acquired a copy of the Empire Strikes Back manual which includes the previous tech tip (2 sections above) in a condensed form that is mostly the same (it advocates replacing C3 and C4 as a matter of course, rather than waiting for them to cause a problem). Now I'll talk about specifics and what devices I often find bad in the Wells-Gardner color vector monitor. If you don't have a manual for this monitor, get a copy, as it does a good job of explaining how each section works and also how to adjust it.

For you people who don't like reading manuals, or who don't feel like locating local sources for specific parts or who don't want to hunt through a huge catalog to put together part numbers for an order, you can order everything you (probably) need (except for the upgrade parts and the extra capacitor for P329 versions of the HV unit) bundled together in one package from ZANEN ELECTRONICS. I suggest you order a couple of these to keep as spares since you never know when you might need to do a rush repair job and the price simply cannot be beat.

Call them at 806.793.6337 and ask for "get well kit #206" which at last count had 30 pieces including all the capacitors that go bad, 6 replacement chassis transistors, several of the smaller transistors (and their corresponding resistors), several diodes (including ZD902), and also (rather sparse) documentation on how to replace the parts. Please be careful if you decide to replace R918 (25K potentiometer) in the HV unit; it needs to start out adjusted to an in-circuit resistance of 5.5K when testing the upper 2 contacts of the 3. (this is the average of what I find to be the normal adjustment range which is always between 5K and 6K. If you have it maxed out you will probably damage your unit when you turn it on. I'm not sure why the kit includes this part as I've never come across a bad one yet.

Ordering a kit from them also entitles you to FREE technical assistance and they seem to be very experienced and knowledgeable. They take credit cards and do not charge anything for UPS shipping (< 7 days). You can tell them Gregg sent you if you want. As of December 1994, the price for this kit was \$14.95 which is probably cheaper than any deal you could put together yourself, anyway. I should also mention that they sell a kit for the black and white vector monitors, too, specifically for the Electrohome G802/805 series which is "get well kit #104". They sell kits for most of the monitors that are/were commonly used in the industry; I cannot recommend Zanen and their kits highly enough.

This is a good way to go if you don't feel like doing any testing to find out what exactly is bad. If you replace all the parts included in this kit, you may be throwing out a lot of parts that still work OK (but which may be on their last legs, anyway), but you will be virtually assured of having a working monitor when you are done. If you get them all in and it still doesn't work, then go through the flowchart shown later in this document. It is quite likely that you have a bad HV transformer and you will have a heck of a time locating a replacement (I have a few but they won't last long) :<

Be aware that some of the parts that Zanen will send you are from the original spec and should not be used as this spec is known to be deficient. Consult the section below about how to upgrade the deflection boards and switch out the indicated parts for the upgraded replacements.

Here are some good parts places to get the big transistors (and other things) that I've used before:

Allied Electronics; 800.433.5700

Digi-Key; 800.344.4539

Mouser Electronics; 800.346.6873

Newark Electronics Chicago; 708.495.7740

Mouser also has the coin door "type 47" bulbs. Here are a few surplus type places that I've ordered from that have great prices on things like electrolytic capacitors that will be happy to send you a catalog:

All Electronics; 818.904.0524

Marlin P. Jones; 407.848.8236

Before we get started let me clear up something that causes a LOT of confusion when working on monitors of all types. All the documentation and boards for these monitors refer to "X" as the longer axis and "Y" as the shorter axis, independent of how the monitor is oriented in your game. Confusion arises because the game PCB will refer to "X" as the axis parallel to the floor and "Y" as the axis perpendicular to the floor and this is dependent on how your monitor is oriented. Why is this important to distinguish? Well if you notice that there is a horizontal line on your Tempest screen and you go to figure out why you aren't getting any "Y" deflection, you must check the "Y" portions of the vector generator circuitry on your game PCB but you need to check the "X" portions of your monitor (deflection board)!

Some words of caution about the manuals. I've got 3 versions of TM-183 (originals of the 1st and 2nd printings both from 1981 and a photocopy of the 3rd printing from 1982; let me know if you have an original of the 3rd printing that you'd be willing to sell). Also, if you are lucky enough to have a copy of

the Wells-Gardner service manual for this monitor, the parts list on page 31 has an error; it lists C916 as .35uF when it is really .035uF. It is labeled properly in the schematic on page 28. None of the manuals show all the different versions of this monitor.

Since the 3rd printing is uncommon, I will describe the significant differences from the 2nd printing (not noting the layout changes such as replacing the crummy photographs with clear, sketched, exploded-view diagrams and minor rephrasings that are sprinkled throughout). All figures show later versions of all boards with the exception of Figure 13 which still shows the old deflection board (even though the parts list and everything else refer to the newer versions; obviously a mistake). Section 3 (Adjustable Controls) describes a later version of the neck board (P328). Section 5 (Purity, Convergence, and Tracking Adjustments) is completely rewritten and is MUCH less vague and more complete (2 pages longer). Section 6 (Details of Operation) has a section which discusses the Input Protection Circuit and has a schematic (Figure 8), too. There is also a new section G (Over-Voltage Protection) which describes the new circuit in the later version of the HV unit (P324).

The 3rd printing fixes some typos in the deflection PCB parts list:

- "(R606, 706)" split off to "4.7K Ohms, +/-5%, 1/4 W Resistor (R606)". (\*)
- "(R612, 613)" changed to "(R612, 613, 712, 713)".
- "(C604, 704)" changed to "(C104, 105, 604, 704)".
- "(C800, 801)" changed to "(C800[-]803)".
- "7-Circuit Header Connector (P100, 600, 700)" added.
- "(Q600-602)" changed to "(Q600-602, 700-702, 801, 802)".
- "(C600, 601)" changed to "(C600, 601, 605, 700, 701)".
- "4.7K Ohm, +/-5%, 1/4 W Resistor (R813)" added.
- "(R602, 603)" changed to "(R602, 603, 607, 702, 703, 707)".
- "Ferrite Bead (FB600)" removed.

Unfortunately, it also introduces one:

## 9.6) STAR WARS Display Problems (continued...)

"D104, 105" changed from "Type-1N914B" to "Type-1N4001".

**DO NOT MAKE THE ABOVE SUBSTITUTION AS IT WILL NOT WORK!!!!**

(\*) R606 is incorrectly listed in all manual versions as being 1/4W when in reality it is always 1/2W.

Some changes were also due to parts upgrades and/or additional circuitry:

- "(Q800)" changed to "(Q800, Q805)".
- "Type MPSA56 PNP Transistor (Q101)" changed to "PNP Transistor (Q101)".
- "Type-1N914B Diode (D104, 105, 600, 601, 700, 701, 801[-]804)" changed to
- "Type-1N914B Diode (D600, 601, 700, 701, 801-806, 809-812)".
- "Type-1N4001 Diode (D106, 107, 602, 702)" changed to
- "Type-1N4001 Diode (D104-107, 602, 702)".
- "Type-2N3904 NPN Transistor (Q804)" added.
- "10K Ohm, +/-5%, 1/4 W Resistor (R812, 813)" added.
- "...2W Resistor (R106)" changed to "...3W Resistor (R106)".
- "5-Amp ... (F100, F101)" changed to "6.25 Amp ... (F100, F101)".
- "18K Ohm, +/-5%, 1/4 W Resistor (R811)" added.
- "30K Ohm, +/-5%, 1/4 W Resistor (R810)" added.
- "Germanium-Special Diode (D807, 808)" added.

There are several manufactured variations (and many more upgrade variations) of each of the 3 boards (at least 3 for the deflection board and 2 for the other 2) The original designs are labeled P31X and the newer, more fault tolerant designs are labeled P32X. I also recently discovered a small cache of replacement deflection boards labeled P339 so there may be a whole 33X series, too! To add to the confusion, the Wells-Gardner service manual for "19K6400 series color vector monitors" shows a P341 version of the neck board, a P324 version of the HV unit, and a P322 version of the deflection board; I

have never seen any of these versions.

Here is how to identify the versions of the boards that I have seen. The deflection boards are P314, P327 and P339. Some P314s were upgraded most of the way to P327s with a small piggy-back PCB on wire "stilts" at the top of the PCB (see "Input Protection Circuit", described later in this document). The neck boards are P315 and P328 (P328 has a brightness adjustment in one corner) and the HV power supply boards are P316 and P329 (P329 has an LED, HV limit pot, and an extra electrolytic capacitor, C22, which is supposed to be 10uF at 63V). After much very disturbing feedback about the performance of the monitors, **Atari** had all the boards redesigned to be more robust. The P32X (and P339) versions are the newer versions of the boards.

A close inspection of the P339 deflection boards reveals that they are, in reality, P327s with a P339 sticker covering the part number! I have verified that the PCBs are identical but have noticed several (possibly not all) differences between components on the 2 versions. Make the following changes on your P327, put a new label on it and you will have a virtual P339! All other components except for the diodes (didn't check them because they are too hard to read but it is extremely unlikely that any are different) are the same.

Differences between P327 and P339 deflection boards:

- C800-803 changed from .47uF @ 35V to 1uF @ 50V. (\*)
- R701 (1.3K) changed from +/-2%, 1/4W to +/-1%, 5W. (\*)
- R812-813 (1/4W) changed from 10K +/-5% to 5.6K +/-10%. (\*)
- Q604/Q704 (NPN) packages are upgraded from TO-92 to TO-202 (NTE49). (\*)

If you have a P314 board, in addition to the changes listed above, you should upgrade the following parts.

Differences between P314 and P327 (P339) deflection boards:

- "Input Protection Circuit" added (see additional text later on).
- R106 (22 +/-10%) changed from 2W to 3W.
- Q101 (PNP) changed from Type MPSA56 (TO-92) to NTE50 (TO-202). (\*)
- F100, 101 (Slow-Blow) changed from 5A to 6.25A.

(\*) The Zanen "Get Well Kit" uses the original specs and does not include these upgrades.

Since the circuits are essentially the same and since I have used 5 Amp fuses in P339/327 boards without any problems, it is safe to say that you can (and more importantly, probably should) put 6.25 amp fuses in your P314 boards at those 2 locations.

The very first run of P314 deflection boards had design defects in them which were evidently identified after the PCBs were produced but before they were populated (I make this assumption because I have never seen a board which did not have the corrections/substitutions on it). Anyways if your board says

"85X0147" at the top then it is from the very first batch. Later batches say "85X0147C" (I have never seen an "A" or "B" flavor). The "C" flavor has C605 (.001uF +/-20%, Type-Z5F capacitor) in the upper right corner but since the plain flavor doesn't have a spot for it, it was soldered piggy-back onto R602. Some boards use a .005uF capacitor instead but you should change this to a .001uF if you have the soldering iron out anyway. The plain flavor has ZD100 labeled as R104 and ZD101 as R105, respectively, even though there are always Zener diodes in those spots regardless.

A comparison of the P315 and P329 versions of the HV PCBs and their documentation yields several conflicting differences which are summarized below. The values marked with an asterisk (\*) are the ones I suggest you use regardless of which PCB you are working on (with the caveat that the resistors should be "matched"; don't just change the value of one without changing the values of all the others. The capacitor changes can be made individually). If you use all the asterisk marked values, you will upgrade your P315 to a P329 except that you, obviously, won't have the over-voltage protection portion of P329.

+-----+		

The good part of all this is that the 3 basic units, deflection board, neck board, and HV board are all interchangeable as units and they are all connectorized. In other words if you have one working monitor you can try the boards from your bad monitor (one at a time) even if the boards are not exactly the same. Also, the most often failing components are common to the different versions of the boards. If you have a vector monitor based game, it is really worth the effort and money to have a spare monitor handy (even if it is being used in another vector game) so that you can isolate exactly which board is bad when (not if) you have a failure.

Obviously, the neck board must be physically switched to be tested but you don't have to unscrew the ground wires of the current PCB, or screw in the ground wires of the replacement PCB; you can just let the current PCB dangle and use alligator clips to connect the replacement neck board's ground wires to the chassis. With careful placement you can test a deflection board or HV unit without having to remove the one already in there. For the replacement HV unit simply connect the 3 connections and then use an alligator clip to ground the case to the chassis. Since you have grounded it, there is no need to attach it to the chassis; simply let it dangle by the secondary anode wire (the one with the suction cup) or the alligator clip but make sure it doesn't touch anything it shouldn't (keep the exposed underside of the PCB from touching anything). The replacement deflection board can sit on top of the current one separated by a piece of cardboard or other non-conductive material but getting it in there is more hassle than swapping so I usually pull the one that is in there and do a swap.

**NOTE:** There is 1 small exception to this universal compatibility rule for the neck board PCB. The P328 version uses a third (purple) wire running from the innermost (normally unused) pin of connector J501 to pin 8 of J900 on the HV unit. Without this wire, the new brightness control on P328 is disabled. Also, and this is **VERY** important, if you are using a P328 PCB on a P315 wiring harness (or vice-versa), you have to turn the J501 connector upside down. Don't worry too much about remembering the orientation because the connector's pins are gapped differently so it will only fit onto each PCB one way (the right way) without severely bending the pins on the neck board PCB (i.e. it is idiot-proof). This means that for testing purposes, you can swap boards and everything will be fine but if you want the functionality that the P328 potentiometer provides, you must remove the associated wiring harness that connects to J501 along with the board (or else add a new wire to the existing harness on the destination monitor). Without this wire, a P328 will behave exactly like a P315 and the pot will do nothing.

The very first thing you should do is check all the fuses in the machine with a meter. There are 4 on the deflection board and most **Atari** machines have 7 more in the power supply at the bottom of the machine (6 in a bay on the left and one under a black cap on the right). Remember to check resistance on the fuse **HOLDER NOT ON THE FUSE**. Many times a fuse will meter out OK but it isn't making good contact with the fuse holder so it is not conducting. If you always put your probes on the fuse holder, you will never get tricked by a bad contact. Many times fuses not conducting can be made to do so merely by reseating them after pinching the fuse holder clips tighter. Sometimes the clips are corroded and need to be cleaned first. The wire contacts connecting to the fuse holders may also not be conducting properly so you may want to move your leads and test there to cover all your bases. This rule applies to fuses in general anywhere you find them.

The only other components (besides the tube itself) are the six large TO-3 package transistors mounted to the chassis ("package" refers to the physical description of the transistor, **NOT** the electrical characteristics). The 3 NPNs are 2N3716s and the 3 PNPs are 2N3792s which are all in the final stages of the deflection amps or the power supplies. The deflection amps are like an audio push-pull amplifier and to power these amps the monitor takes AC in and produces plus and minus DC voltages.

Most of the failures in this monitor (as is the case with most electronic devices) are semiconductor failures, specifically, the transistors. All transistors discussed in this document can be tested in the same way; it doesn't matter if they are the large chassis-mounted transistors or the tiny PCB-mounted transistors. With the transistors out of circuit, set your multi-meter on Rx1K scale and use the following

procedures.

**NOTE: ANALOG AND DIGITAL MULTI-METERS REQUIRE DIFFERENT TESTING PROCEDURES FOR TRANSISTORS!** For some reason, digital meters always show infinite resistance for all 6 combinations (if you accidentally get your skin involved it will show something around 2M Ohms). The best way to test transistors with a DMM is to make use of the "diode test" function which will be described after the analog test. For both methods, if you read a short circuit (0 Ohms or voltage drop of 0) or the transistor fails any of the readings, it is bad and must be replaced.

---

## 9.7) TESTING TRANSISTORS WITH AN ANALOG OHMMETER

For type NPN transistors, lead "A" is black and lead "B" is red; for type PNP transistors, lead "A" is red and lead "B" is black (**NOTE:** this is the standard polarity for resistance but many multi-meters have the colors reversed; if the readings don't jive this way, switch the leads and try it again). Start with lead "A" of your multi-meter on the base and lead "B" on the emitter. You should get a reading of 2.5K Ohms. Now move lead "B" to the collector. You should get the same reading. Now try the other 4 combinations and you should get a reading of infinite Ohms (open circuit). If any of these resistances is wrong, replace the transistor. Only 2 of the 6 possible combinations should show a resistance and that value should be 2.5K Ohms; none of the resistances should be 0 Ohms (shorted).

## 9.8) TESTING TRANSISTORS WITH AN DIGITAL MULTI-METER

Set your meter to the diode test. Connect the red meter lead to the base of the transistor. Connect the black meter lead to the emitter. A good NPN transistor will read a JUNCTION DROP voltage of between .45v and .9v. A good PNP transistor will read OPEN. Leave the red meter lead on the base and move the black lead to the collector. The reading should be the same as the previous test. Reverse the meter leads in your hands and repeat the test. This time, connect the black meter lead to the base of the transistor. Connect the red meter lead to the emitter. A good PNP transistor will read a JUNCTION DROP voltage of between .45v and .9v. A good NPN transistor will read OPEN. Leave the black meter lead on the base and move the red lead to the collector. The reading should be the same as the previous test. Place one meter lead on the collector, the other on the emitter. The meter should read OPEN. Reverse your meter leads. The meter should read OPEN. This is the same for both NPN and PNP transistors. Thanks to Randy Fromm <[YMNP18A@prodigy.com](mailto:YMNP18A@prodigy.com)> for this excellent summary of the diode test method.

Anyway, there are 2 types of the large chassis transistors:

- 2N3716 (NPN); widely available replacement is NTE284  
Q705  
+X (right) for horizontal; +Y (top) for vertical  
Q605  
+Y (top) for horizontal; -X (left) for vertical  
Q102  
output positive (+) power supply
- 2N3792 (PNP); widely available replacement is NTE285  
Q706  
-X (left) for horizontal; -Y (bottom) for vertical  
Q606  
-Y (bottom) for horizontal; +X (right) for vertical

# Q103

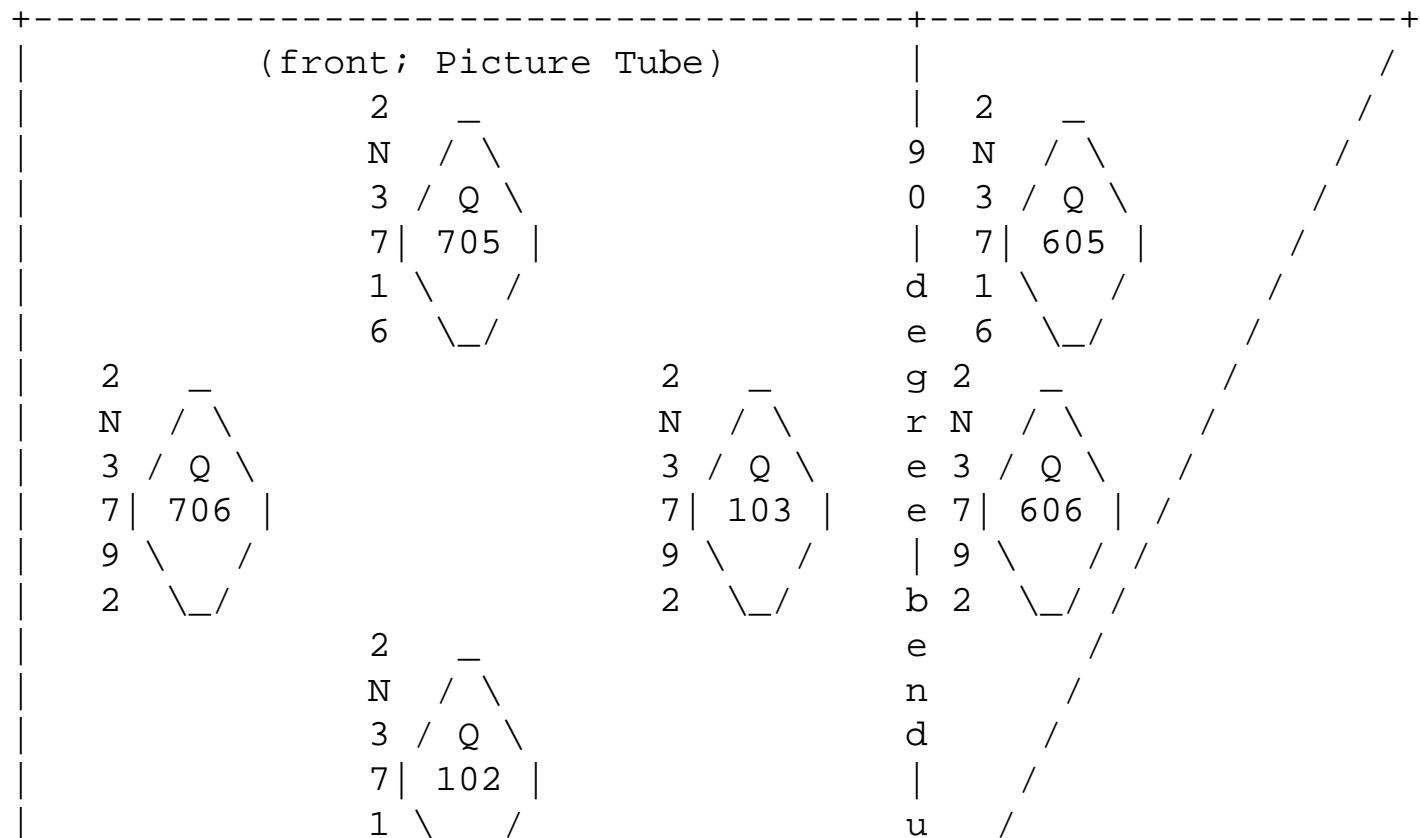

output negative (-) power supply

**SPECIAL NOTE:** Q705 and Q102 lie in such close proximity that it is not uncommon for their respective transistor sockets to be switched at some point which obviously swaps the corresponding functionalities (symptoms).

This gives reference frames for when the monitor is mounted horizontally (for games like Space Duel and Major Havoc) and vertically (for games like Tempest and Quantum).

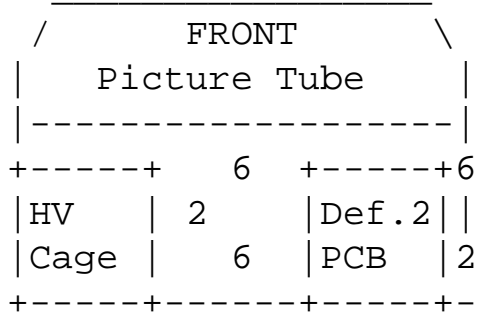

For those of you without a manual, here is how to identify which one is which. The following descriptions are relative to the monitor oriented horizontally on it's base (like a TV would sit and like it is inside most games) and viewing it from the back side (so that you see the components and not the picture). 2 of them are on the outside of the chassis on the right side. The one nearest the back (component) side is Q606; the one nearest the front (viewing) side is Q605. On the inside of the bottom of the chassis are the other 4. The one on the far left nearest the HV unit is Q706. The one on the far right nearest the first 2 is Q103. The other of the 2 remaining middle ones which is closest to the back is Q102 and the last one which is in the same area but is closer to the front of the monitor is Q705.

An easy way to remember which kind of transistor goes where is to know that each connector has one of each kind; the 2N3716s are on pins 1, 3, and 4 (key at pin 2) and the 2N3792s are on pins 5, 6, and 7. If the wiring has not been altered, all 2N3716s are connected to the yellow, green, and red wires and all 2N3792s are connected to the purple, blue, and white wires. Here are 2 diagrams of the layout as viewed from the top:

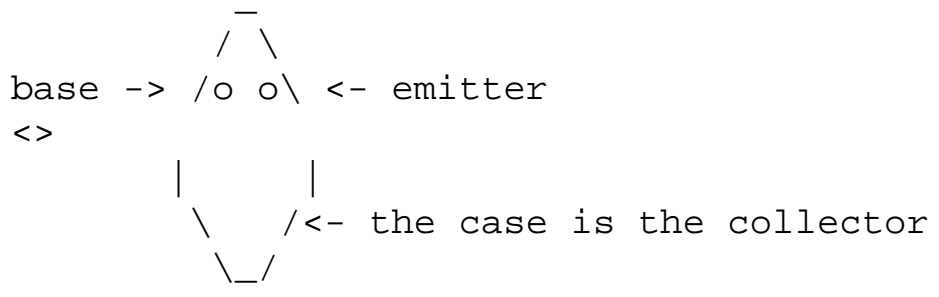

or, more simply (where 2=2N3792 and 6=2N3716):

These transistors often go bad and here is a quick lesson on how to check a transistor with a meter. Unplug the red plugs from the deflection board to isolate the transistor from the circuit. From the bottom of the transistor, the configuration is (Oh boy; time for a picture!):

Pretty crude but you get the idea I hope. Test the transistors as described earlier, one by one, by placing the multi-meter leads on the tops of the pins of the red connectors or on the transistors themselves. Neither method requires the removal of the transistor from its socket so don't bother. You do, however, need to disconnect the associated connector from the deflection board prior to testing.

So what symptoms go with what? Well if only one of the deflection amplifying transistors goes then you will lose the corresponding half of the screen (for example if Q705 went bad in a Tempest game, you would be missing the top half of your screen). It won't actually be gone; it will be collapsed into a line across a 0 axis of the screen. If more than one goes or either of the power transistors (Q103 or Q102) goes you will get no picture because the spot killer turns on (and the LED on the deflection board lights) and shuts down the electron beam.

Checking these transistors is one of the first things you should do if parts of your screen are missing or your spot killer is on. Exact replacements are nice but I've successfully substituted others especially if you put the nonstandard transistors in the place of Q102 & Q103 as those two are for the + & - power

supplies and not as critical (image-wise) as the ones that drive the deflection coils.

When replacing these transistors, make sure the socket is centered. Don't forget the little rubber or clear mica (plastic) insulator that was stuck to the chassis or to the bad transistor you just removed. You need to grease this insulator on both sides with a special grease called Silicone Heat Sink Compound. It is not strictly necessary but helps transfer the heat from the transistor to the chassis so the transistors last longer. The grease is pretty expensive so you may want to just buy new insulators (they should be about 10 cents each) because most come "pre-greased".

Don't be nervous about remembering the orientation; the pins are off centered in order to make the connection somewhat idiot-proof (see earlier ASCII picture. They are obviously "handed" but can be put in upside-down; it is a tight fit and hard to do but possible). Also, after you replace these and before you power the game up, use your meter to make sure none of the cases of the transistors are shorted to the chassis. This is very common and will cause fuses to blow and will probably destroy the transistor. If any part of the transistor is touching the chassis you are asking for trouble.

On the deflection board, the most common failures are Q100 and Q101 and when these go they take R100 and R101 (respectively) with them. These transistors are part of the + & - power supply circuit and are often bad with the resistors really burnt. To properly test these, they should be desoldered and removed from the PCB. Even in-circuit and not isolated from other components you can still get a pretty good idea with a multi-meter (analog meters work best since digital meters show infinite resistance most of the time) if the transistors are bad as transistors tend to fail catastrophically. In other words, they usually completely short (0 Ohms) or open. If you see 0 Ohms where there should be an open circuit or 2.5K Ohms, then the transistor is probably shorted. If you see greater than 2.5K Ohms when the reading should be in that range the transistor is probably open. When these transistors are bad, they usually show a large crack in the case if you look closely at them.

Replace Q100 with the same type transistor but if Q101 is bad (and even if it is not), I **STRONGLY** suggest you upgrade it to a larger transistors that will handle more current. I **ALWAYS** replace Q101 with a TO-202 package instead of the much smaller TO-92 package that the board comes with. In fact, the P327, and P339 versions were manufactured with this upgrade. The 3 labels I have seen are 119;NSDU57 (National Semiconductor) and M152;126-1A ("brandless"?), and NTE50 (NTE) [semi-colons denote a new line of text found underneath the previous line]. I always use NTE50s as they are relatively cheap and very easy to find.

Even though these transistors (and resistors) are the most common failures on the deflection board, I have **NEVER** seen them go bad after Q101 was upgraded to a NTE50. If you can't find the generic parts, a common modern day replacement for MPSA06 (Q100) is NTE287 and a common modern day replacement for MPSA56 (Q101) is NTE159 (but I cannot stress enough the utility of going with the larger replacement for Q101). Upgrading Q101 is always the first thing I do to any deflection board I get; replacing it before it fails saves me from having to replace the other parts that go bad when it does fail.

Once in a while you will see D105 or D104 open or shorted, too. Also watch for broken solder joints at the base of the connector pins for all the major connectors (especially on the deflection boards of black and white Wells-Gardner units which almost always are bad). You tend to rock the plugs back and forth

when you pull the connectors and this often cracks the solder joints to the circuit boards which were poorly soldered to begin with. You may also want to check each pin for continuity with the next component on its trace line (and also with adjacent pins), and remove and resolder any dubious connections. While you are at it, resolder the 3 pins of the PTC thermistor (in the middle along the left edge of the deflection board) as they are almost always loose for some reason.

It is unusual but sometimes some of the 4 heat sinked (or is that "heat sunk"?) transistors on the deflection board will die. If any of these is bad, you will usually get no picture at all but you will see "background brightness" that lets you know some electrons are being thrown at the tube. Be sure to check the resistors and diodes around any bad transistors you find.

Usually, the electrolytic capacitors are still OK (though always be suspicious of electrolytics drying up and losing micro-Farads). If the transistors in the chassis are OK, most missing pictures are due to problems with this board (whereas most distorted pictures are due to bad capacitors in the HV unit). I frequently see HV units with the protective shield removed from the case and discarded in attempt to keep it cooler. I like to keep mine on because I rate dust and foreign object attraction as a more severe problem than heat for this board but like I have said, I don't let my stuff run hot.

Very infrequently, you may have problems with some other transistors in the X/Y amp section of the board. Most of the rest of the transistors that populate the deflection board (Q600-602,700-702) are type TPS98 and are not easily found anymore. The good news is that TPS98 is equivalent to the PN3569 and the ECG or NTE 194. All Electronics (800-826-5432) has PN3569 transistors at 5 for \$0.50. **NOTE** also that All has just dropped their minimum order requirement (still \$5 S&H on most orders, though).

The neck board very seldom has problems. The few I've seen are from mishandling where someone has broken some of the pots that control the RGB drives. Check the pots if you are missing a color. If you are blowing your 5A fuses and your other boards are OK, check C503 (33 uF @ 250V). If this is open, shorted or cold soldered, it will cause the 5 (or 6.25 depending on your board) fuses to blow.

Last is the HV supply. I've worked on lots of these and have only seen one of the infamous bad HV transformers. Normally HV failures are due to a semiconductor or capacitor failure. I must mention that the HV unit can put out very weak X-ray radiation and creates lots of ions in the air but both are in sufficiently small quantities that there is little risk of injury. Nonetheless, many people feel a tad queasy during or after working near high voltage. Like anything else, it gets less noticeable with successive exposures. Many people are quite worried the first time they experience the sensation but it is harmless. Please note that I am not a doctor nor a radiation specialist so refer back to the CYA clause at the beginning of this document. Certain unlikely faults that I have never run across could cause large amounts of X-rays to be produced which would definitely be harmful.

Before you work on this beast, discharge the tube as it can really zap you even when turned off (it is extremely inadvisable to work on the HV section while the machine is on or even plugged in; always unplug the game before you go in here). Connect a clip lead between the chassis and the shaft of a long narrow plastic-handled screwdriver. Work the end of the screwdriver under the big suction cup on the top of the tube until you hit metal. There will often be a snap (from the spark) as the HV runs at around 20 thousand volts. Just go slowly and use only one hand. It won't bite as long as you are careful. You may

want to leave the game plugged in **BUT TURNED OFF** for this step so that you can ground to the earth instead of just the chassis. If you plan to remove the HV unit, you must disconnect the secondary anode from the tube which is a little tricky. Under that suction cup is a double-barb. The barbs extend perpendicular to the wire as it enters the suction cup. Simply pinch the suction cup as best as you can and wiggle it back and forth while pushing in at the edges and pulling out at the center. It will eventually come off. Here is a cut-away depiction of the anode; the wire will run perpendicular to this view (i.e. towards/away from the reader):

When I was in the habit, I discharged the tube with my HV probe so I could watch the voltage go down as the internal resistance of the probe bled the voltage off slowly. If the snap bothers you, put a resistor in series with your clip lead to drain off the voltage more slowly. If you don't have this equipment available, a 1 or 2 hour wait after unplugging the game should be sufficient for most of the excess charge to bleed off naturally. **NOTE:** The anode is designed to hold onto charge so it will **NEVER** discharge completely without being deliberately grounded. In fact, if you wait a couple of days after grounding it, it will actually build up another (small) charge! I suggest that if you go through the trouble of discharging it, you should keep it grounded by using an alligator clip on the end of your wire and leaving it connected to your ground. This way you have no chance of getting shocked (just be **ABSOLUTELY CERTAIN** to remove this ground wire before you turn the power back on again).

Personally, I never worry about any of this anymore since the shock (when received properly) is harmless and mostly painless (I have gotten zapped dozens of times). Just make sure the game is unplugged first. If you aren't going to wait, follow the "1 hand rule"; only use one hand when disconnecting the cable and keep the other one in your pocket or in the air. The only likely way for the charge on an unplugged machine to hurt you is for it to form a circuit between your 2 hands (one grounded and one on the tube) sending current directly across your heart; these levels could easily interfere with your heartbeat and even cause it to stop! I should also point out that black and white monitors use significantly lower high voltage than do color monitors and raster monitors have high voltages that are an order of magnitude higher than vector monitors use. I have been shocked by them all and assure you that rasters **DEFINITELY** have a bigger sting than do vectors so beware!

## Chapter 10) TEMPEST DISPLAY troubleshooting (flowchart)

This flowchart is excerpted from a photocopy of a photocopy (of a...) which has no visible attribution or copyright. It appears to be from the **Star\*Tech Journal** but I don't know for sure and the guy who sent it to me doesn't know where it came from.

=====START=====

Most problems in the Tempest display can be found by following the procedure shown in the chart below.

**CAUTION:** When replacing the transistors mounted on the chassis, make sure the pins do not short to the chassis. If the chart procedures do not solve your problem, call **Atari** Field Service [**NOTE:** They will be of little help nowadays :>].

Let's finish off with a troubleshooting guide broken down by symptoms. Much of the rest of this section is a transcription of repair notes from a Wells-Gardner technician. Just because your symptom matches something in here is no guarantee that what I/he found wrong is the same thing that is wrong with your board, but it's a good place to start. Most of the problems he listed in his notes were due to manufacturing defects or incompetent repair work. Obviously, if your monitor was working OK and then simply stopped, those things are not likely be your problem. If you have seen any problems that are not listed in this section, please contact me and I will add them.

---

## **10.1) Weirdness between player one and two (Tempest machines only)**

Display "implodes" during intermission screen between player one and player two and sometimes on the "figure 8" levels (Tempest machines only): I thought I knew what was causing this but upon further evaluation, my solution didn't make sense (although it did work for me the only time I had this problem). Until I get another board to fix that has this problem, I only have general advice on how to avoid the problem. Adjust your game board and "shrink" the Y deflection some and this should help. There are 2 sets of ROMs for this game and the "compact" ROM set (only half the ROM sockets are used) is slightly different (the intermission screen has some other stuff such as the copyright and credits information at the bottom of the screen which "balances" it out) so the spot killer won't get confused and decide that the bottom half of the screen is wiped out. These PCBs do not normally experience this difficulty.

---

## **10.2) Deflection Problems**

### **10.2.1) Fuses F100 [and F101] blow on power up**

Fuses F100 and/or F101 are blowing as soon as game is powered up. This happens to a lot of people after they replace the chassis transistors. Sometimes they forget to put the mica (plastic) insulator on the transistor before installing them which allows the transistor's case (collector) to short to the chassis (ground). A short can be present even if the insulator was installed if the conditions are just right. Check all chassis transistors, particularly Q102, Q103, to make sure the cases are not shorted to the chassis.

---

### **10.2.2) Spot Killer ON and display dead**

Spot Killer LED lights and you don't have any display on the screen at all.

Check the fuses first. If they are OK, then check the 6 transistors mounted on the chassis as described earlier. If you find at least 2 of the deflection ones or 1 of the power ones bad, then that is definitely tripping the spot killer. A good trick to figure out where the problem exists is to turn your brightness up all the way and see what your picture looks like. The spot killer doesn't turn the Z signal all the way off so if you turn the brightness all the way up, you should be able to see a very faint picture. Based on what the picture looks like, you can decide which half of the circuit is causing the problem (either the X or Y portion). If you know it is a problem on your deflection board (i.e. swapping another

board in makes the monitor work) then check R808 (X) and R809 (Y) to make sure they are not open. These resistors allows current to flow to the spot killer circuitry and if they open then the spot killer thinks something has happened to the amplifier circuitry so it kicks on. You can tell if this is your problem by turning the brightness on all the way; if you see a complete picture, then this may be your problem. If all this is OK then you probably have a game board problem, particularly if you are unable to "play" the game (see the credit lights blink after you punch up credits and hear the game sounds after you push start).

---

### 10.2.3) Display dead after Zanen kit

Zanen kit installed but still no picture (spot killer may or may not light).

The problem is most likely Q603. Occasionally you will see Q603 (Q703), or Q604 (Q704) go bad. If one does, be sure to check the resistors and diodes around it, particularly R611 (R711), R612 (R712), and D602 (D702). A common modern day replacement for MPSU57 (Q603/Q703) is NTE189 and the part for MPSU07 (Q604/Q704) is NTE188. These should be greased where they touch the heat sink (like the chassis transistors) to improve heat dissipation. If you are having trouble with these failing, you might want to beef them up by using TO-202 package upgrades to NTE50 (MPSU57) and NTE49 (MPSU07).

---

### 10.2.4) No X (or Y) deflection

I have seen 2 boards like this. On one, the problem was that R710 (R610 for Y) was open. How you fry a 10 Watt resistor and nothing else in the circuit is beyond me; perhaps the PCB was dropped and it landed on R710. Anyways, you can test it in circuit and if you don't see a virtual short then replace it. On the other, the problem was a loose R606 (1/2 watt, 2.2k) in the Y amp. It's intermitant contact was causing the spot killer to flicker, and was causing picture to collapse. The solder joint did **NOT** look cold or bad, and the resistor tested fine. These resistors take a good deal of heat, and the traces they are on can heat up pretty good. I found that it was loose by pushing on the top of the resistor a bit, and began to hear a "tick" where the resistor lead was touching the solder joint. Probably the trace's temperature (and the resistors heat) caused the resistor lead to seperate in the hole on the board, while it still looked and tested fine.  
**NOTE:**

Jeff Young from World Wide Distributors in Grand Rapids, MI reported some words of caution about these resistors on Page 3 of the November 1982 issue of the **Star\*Tech Journal**:

=====START=====

"After fighting a problem in the **Atari** "Tempest" for three days and finding a silly mistake, I thought I should write to you. Wells\_Gardner Monitors #19K6101 use a 1.5-ohm 10-watt resistor in location R610-R710. If you replace these resistors with standard wire-wound units, the monitor will exhibit the "shakes" or "jitters" referred to in **S\*TJ**, Vol. 4, No. 7 "Service Tips", but the symptoms will be misleading in that R601 and R701 must be **NON-INDUCTIVE**. Please tell your readers about this problem as **Atari** and Wells do not point out this requirement in the parts listing, and only put down the initials, "N.I" on the schematic."

=====STOP=====

---

## 10.2.5) R101 burns on power up

R101 glows red hot and burns up to open circuit every time the game is powered up (known good deflection board; works in good monitor).

The resistor is burning up because of runaway current from the HV unit. You can confirm this by replacing R101 and testing the deflection board in a known good monitor (or by putting a known good HV unit in the monitor that is acting up); if R101 doesn't burn up then you know the HV unit is the culprit. Whenever this has happened to me, R903 in the HV unit has been the cause. It will sometimes short and this causes so much current to flow to the deflection board that the puny 15 Ohm resistor burns up. If this goes on for too long, Q101 may fail or occasionally R901 will burn up to an open circuit.

---

## 10.2.6) Accidentally shift P101 over 1 pin and power up machine

Although most of the connectors/connections are idiot-proof, P101 is not (due to the poor placement of the key pin as the **LAST** pin). It can be connected shifted over 1 or more pins to the right (although it should be obvious if you shift it more than 1 pin). After shifting it 1 pin and frying the PCB, when you hook it up correctly, the spot killer LED will glow at 50% brightness and you will get no video. The following parts will need to be replaced; Q703, R711, D702, and C703 (C703 should be OK but replace it just in case if you can find a new one). Some caps may have blown on the HV board, too.

---

## 10.2.7) Display bad only in lower right quadrant

Distorted image which exists **ONLY** in the lower right quadrant of the display.

I have seen this several times and the problem has always been a bad ZD101. Much of the time this causes R101/Q101 to fry and spot killer comes on.

---

# 10.3) Neck (CRT) board problems

---

## 10.3.1) Color problems

---

### 10.3.1.1) Colors drop in and out (ZD500 open on neck board) (Display is too bright)

On neck board:

- R515 (broken wire to R531)
- C503 (reversed; may toast R527)

---

### **10.3.1.2) No red**

On neck board:

- R500 (open)
  - R502 (shorted to nearby component)
  - R510 (open)
  - R511 (open or wrong value)
  - R520 (open; red color can be seen but is very weak)
  - R529 (open or wrong value)
  - broken wire at R517 control
- 

### **10.3.1.3) Only red**

On deflection board:

- D802 (reversed)
- 

### **10.3.1.4) Red too bright**

On neck board:

- R501 (wired wrong)
  - R504 (open)
  - Q500 (collector shorted to base)
- 

### **10.3.1.5) Red does not turn off when dimmed all the way**

On neck board:

- Q500 (reversed or broken wire)
  - R513 (shorted to C500)
  - R519 (open)
  - R529 (open)
- 

### **10.3.1.6) No green**

On deflection board:

- neck board connector wrong type

- broken green wire from deflection board to neck board

On neck board:

- R503 (open)
  - R513 (wrong value)
  - R520 (wrong value; was 22)
  - R530 (open)
  - Q501 (bad or base shorted to emitter)
  - broken wire at R513
  - jumper from R511 to R513 missing
- 

### 10.3.1.7) Only green

On neck board:

- Q503 (reversed or wired wrong)
-

### **10.3.1.8) Green too bright**

On neck board:

- Q501 (collector shorted to emitter)
- 

### **10.3.1.9) No green + blue is red**

On neck board:

- R500 (shorted to R529 or shorted to R502)
- 

### **10.3.1.10) Green is red**

On neck board:

- R502 (shorted to R500)
- 

### **10.3.1.11) Green does not turn off when dimmed all the way**

On neck board:

- R512 (shorted to nearby wire or connecting wires wrong)
  - R519 (connecting wires wrong)
  - R520 (open)
  - Q501 (reversed, open, shorted, or broken wire to base)
- 

### **10.3.1.12) No blue**

On deflection board:

- D803 (bad) or neck board connector wired wrong)

On neck board:

- R504 (wrong value)
  - R515 (open or wrong value or broken wire or swapped with R505)
- 

### **10.3.1.13) Only blue**

On deflection board:

- red lead in neck board connector broken
- 

### **10.3.1.14) Blue does not turn off when dimmed all the way**

On neck board:

- R504 (open)
  - R521 (open)
  - R522 (open)
  - R529 (open)
  - Q502 (reversed, emitter open, or shorted to nearby component)
- 

## **10.4) High Voltage Board Problems**

---

### **10.4.1) Display unstable**

The image is extremely shaky and unstable and lines that should be straight have periodic wiggles along their length that make them look like an EKG (the distortion is sort of like when you watch TV with a bad antennae and lines "walk" around on the screen).

Replace C901, C902, and/or C905 in the HV supply. If of these is bad then the rest of the electrolytic capacitors are probably in pretty poor condition too, so I generally replace all of them. Make sure the replacements are rated at as least as many "working volts DC" WVDC and have as least as many micro-Farads. It doesn't hurt to replace a 22uF @ 50V capacitor with a 50uf @ 100V if that is all you have

around. More Voltage capacity is equal or better but it is best to keep the capacitance the same if you can. Also when ordering and replacing these, be aware that they are polarized and not idiot-proof; be sure to put them in the circuit so that they are oriented properly. The casing will clearly indicate either the negative or the positive terminal (but typically not both) and the industry convention is for the positive lead of the capacitor to be longer than the negative lead. Be aware that P329 has an extra capacitor (C22) that may not be shown in your manual; its value is 10uf at 63V.

---

### **10.4.2) Picture too bright but all else OK**

The picture is overly bright and all parts check out OK.

Look for a broken circuit board trace between pin 6 of the high voltage transformer and the anode of diode D901. This trace is prone to breaking open. It is probably easier to just add a jumper and see if it solves the problem or else check the connection (with board removed) with a meter to make sure it is a short.

---

### **10.4.3) R925, R919, and R917 are smoked**

- Q905 (shorted; T901 primary may be shorted, too)
- 

### **10.4.4) R901, R907, R903 are smoked and Q902 and ZD901 are shorted**

- Q901 (reversed)
- 

### **10.4.5) Top of Q901 blowing off**

- R902 (open)
  - Q900 (inserted or wired wrong; if emitter shorted to base then Q901, Q902, and ZD901 get fried)
  - Q901 (shorted)
  - Q902 (shorted)
  - ZD901 (shorted)
-

## **10.4.6) Top of Q902 blowing off**

- Q901 (reversed)
- 

## **10.4.7) R901 and R907 are smoking**

- Q902 (shorted)
  - Q906 (red and white leads interchanged)
- 

## **10.4.8) Just R901 smokes**

- Q906 (inserted wrong)
  - Q900 (missing spacer or black lead open)
- 

## **10.4.9) R903 smokes**

- Q900 (shorted; will short ZD901, Q901, and Q902, too)
- 

## **10.4.10) R904 smokes**

- Q902 (shorted)
- 

## **10.4.11) R907 smokes**

- C902 (reversed)
  - broken wire near R902
- 

## **10.4.12) R908 smokes**

- Q900 (white and black leads interchanged)

### 10.4.13) R912 smokes

- C910 (reversed)
- D901 (wrong value; perhaps ZD902)

### 10.4.14) R917 smokes

- Q905 (reversed)

If R920 smokes, check:

- C913 (bad; this can damage T901, too)

## 10.5) No HV (very dead sound)

No High Voltage (HV); you don't hear the crackling sound when you first turn the monitor on.

Check the transistors in the HV unit as described earlier. The ones I've seen fail most often are Q903, Q902, and Q901 though they are all suspect. These transistors will usually have cracks in the casing if they are bad so look closely at them. If all this stuff is OK, look at the electrolytic capacitors (they are the big cylindrical tube-like parts and are usually blue in color) in the circuit. They come in two "types":

One quick errata: The parts list in Figure 15 of TM-183 lists all capacitors as fixed axial-lead when in reality only C905 is; the others are all radial-lead. These are designed to burst open (VENT) when they fail due to overburdening (but they sometimes don't) so as to be obvious to repairpersons. The top (for radial-leads) or the side (for axial-leads) will be open and some of the "guts" will be hanging out. When some capacitors go bad, they sometimes take the final output resistors R901 and/or R907 with them (but the resistors will look perfectly OK unless you check them with a meter). Also check to make sure that

connector J901 inside the HV unit is intact; on person reported that the plastic in his disintegrated on the inside and the wires came loose. If these are OK, check the following:

---

### **10.5.1) Waveform at IC901 outputs; if missing, check**

- R914 and/or R927 (wrong value)
  - R916 (broken wire)
- 

### **10.5.2) Waveform at Q906; if missing, check**

- R926 (open)
  - Q906 (white wire open)
  - Q905 (emitter open)
- 

### **10.5.3) Waveform at Q905; if collector wrong, check**

- Q906 (broken black lead or broken wire at emitter)
- 

### **10.5.4) Waveform at R921; if wrong, check**

- Q906 (white and black leads interchanged at socket)
- 

### **10.5.5) IC901; if no input voltages, check**

- Q900 (red and black leads reversed)
  - ZD901 (check voltage drop)
  - ZD900 (shorted)
- 

### **10.5.6) IC901; if input voltages present, check**

- R914 (may be open; will cause waveform at C911 to not be X1K range)
  - C911 (open)
  - C915 (open)
  - C916 (open)
  - R901 (open)
  - R904 (open)
  - R905 (open)
  - R913 (open)
  - R923 (open)
  - R924 (open)
  - Q900 (shorted; +25 line is grounded by this)
  - Q904 (reversed, open, or missing)
  - Q905 (reversed or collector wire broken)
  - IC901 (defective, reversed, or unseated pins)
  - T901 (pins unseated or primary winding shorted)
  - Broken wire at R913
  - Broken wire at R919
  - Broken wire at base or collector of Q905
  - Broken wires or pins at P900
  - White wire disconnected at Q900
  - Red wire disconnected at Q906
- 

### **10.5.7) If you are also blowing any fuses, check**

- C910 (reversed)
  - R907 (open)
  - R913 (shorted)
  - D902 (wrong value)
  - Red and white wires interchanged at Q906
- 

### **10.5.8) F600 blows immediately on powerup**

Replace R612 if open.

---

### **10.5.9) Blooming/"weak" brightness/Low HV**

Most of you don't have a HV probe but the most common symptom of low HV is that the screen looks as though you are looking at the center through a magnifying glass. This visual symptom is known as "blooming". I've seen several times where ZD902 (150 volt Zener diode) goes bad and the HV drops

from 19.5 kilovolts to around 10 kV. It's kind of like the electron beam moves slower with less HV giving the deflection magnets on the yoke more time to deflect the beam (but what is really happening is that there is not enough HV to strip all of the electrons off of the phosphor coating which causes the screen to develop a negative charge which then deflects new electrons which are expected to be hitting a screen with no charge on it). A new ZD902 and everything is better. NTE5100A is a common modern day replacement for this part. If ZD902 is OK, check the following:

- R915 (open)
  - R922 (open or wrong value)
  - Q900 (emitter pin open)
  - Q902 (bad)
  - Q906; white and black leads reversed (scope pattern is wrong)
  - ZD901 (shorted)
  - IC901; if scope output is a little high, replace IC901
  - P900 (ribbon pin #7 broken)
- 

## 10.6) HV range wrong, what causes it?

Normal is 16-24 kV

- 7.0-12.0; Q902 (reversed)
  - 7.0-10.0; ZD902 (bad)
  - 7.0-17.0; ZD902 (bad)
  - 7.0-22.0; Q903 (bad)
  - 9.0-18.0; ZD902 (bad)
  - 11.0-22.0; ZD902 (bad)
  - 15.0-18.0; ZD901 (wrong value)
  - 16.0-19.0; ZD902 (bad)
  - 18.0-27.0; ZD902 (bad)
  - 19.0-27.0; R912 (wrong value)
  - 21.7-30.5; C916 (open)
  - 28.0-20.0; C916 (bad)
-

## 10.7) High voltage control has no effect; value is always

- 7.4; Q903 (collector wire shorted to HV control wire)
  - 7.7; Q903 (reversed or base and collector interchanged)
  - 8.0; Q903 (reversed or base and collector interchanged)
  - 11.0; Q902 (reversed)
  - 12.0; IC901 internal frequency changed by ZD902 (bad)
  - 13.0; Q902 (reversed) or C920 (open) or ZD902 (bad)
  - 16.0; Q900 (black and white wires interchanged)
  - 17.0; ZD901 (shorted)
  - 18.0; ZD902 (bad)
  - 22.0; Q900 (reversed or black and white wires interchanged)
  - 24.0; R912 (open) or Q900 (black and white wires interchanged)
  - 27.0; R902 (open; this burns Q901, Q902, and ZD901)
  - 28.0; broken wire at Q902
  - 30.0; R915 (open)
  - 32.0; ZD901 (bad) or R918 (open) or Q902 (collector lead open)
- 

## 10.8) Weird CRT problems (focus snaps in and out)

Here is a really strange one about a problem with the tube itself!

Focus starts out sharp but slowly gets fuzzy and then suddenly snaps back into clear focus (repeat every 10 seconds; eventually will stay out of focus all the time).

I didn't see the problem until I extended the wiring harness out of the back of the machine so the monitor was sitting on a stand, because there **WAS** arcing occurring, but it was **inside** the picture tube socket. There's a white, cubic lump attached to the end of the neck (where the neck board attaches) where all the pins are and I could see a faint glow out of it when the monitor freaked. The focus line from the HV power supply connects to the pin nearest the cube. Inside of it, a sort of spark gap is implemented by running the focus wire under and in contact with a small metal plate (the wire eventually connects to the socket pin). A second formed wire is suspended above the metal plate with the point of a V bend in the wire forming a spark gap with the metal plate; this formed wire is connected to chassis ground. Its purpose is to form a spark gap with certain pins in the socket; the intent is to prevent damage to the gun of the CRT during power down. In my case, the focus wire had lost good contact with the socket pin, and some internal arcing of some sort appeared to have released the metal plate from where the plastic housing was supposed to retain it, causing the spark gap to become too small. So it appears one problem led to another. The connection to the focus pin of the picture tube socket had become intermittent. Some arcing caused the built-in spark gap to come apart. A similar problem with the same symptoms can develop causing a dead short to ground of the focus electrode. Within the socket, there is a plate in the back of the socket which is grounded. If any moisture or conductive crud gets in there, you can get a low resistance path between the grounded plate and the focus pin. To fix it, you have to desolder the socket and break it open. The socket simply pries apart but it was originally staked, so don't be alarmed if you see small pieces of plastic flying off when you pry the sucker open. I found it went together tightly enough that I wasn't concerned about it falling apart but you could use a touch of glue just to be sure. I soldered the metal piece to the focus wire, placed it back in its retaining channel, cleaned out the gap area and soldered the socket back in place. The part that comes off the bottom of the socket to gain access to the internals touches the PC board when the socket is installed, and is retained just fine when the socket is in place without gluing.

All the above is assuming you just plug the game in and it doesn't work. If you happen to be playing the game at the time it fails, you have a little more information to go on. If you hear a loud bang like a firecracker, then check the capacitors on the HV board first because they can be loud when they burst. If you see a little bit of smoke inside the cabinet and smell a hint of "electrical smell", then check the fuses first. If you see a ton of smoke inside the cabinet, then check the large transistors on the chassis first. If you start losing quadrants of your screen intermittently than I would advise replacing the corresponding transistor before it fails because it can take other components (usually fuses) with it when it goes altogether. The same advice goes for the blooming caused by ZD902.

---

## 10.9) Special help for TEMPEST

Now some things besides the monitor itself. Tempest is harder on this monitor than the other **Atari** vector games. The attract mode that displays "TEMPEST" (often burned right into the phosphors) really stresses the monitor. For Tempest, I like to do what **Atari** did when they offered the Major Havoc conversion. Add a fan to the back door of the game. I try to find a small cooling fan that just moves a small amount of air (not one that howls). You have to cut a hole in the back door and position it so it directs air at the deflection board. I usually connect the power for the fan to the wires that head up to the fluorescent light and put a connector in so that you can still remove the back door (with the fan mounted on it) without it hanging on the wires to the fan.

If you would like to greatly reduce your chances of experiencing a monitor failure in your Tempest machine, you may want to "shrink" the screen in both axes using the X and Y "SIZE" pots on the game board. I also have heard Tempest was bad, because it draws a diagonal retrace line (Z/brightness off) from the bottom left corner to top right corner during the attract mode. There was supposed to be a ROM fix, which took this line out and really helped the transistors but I've never seen it. I could probably buy it, as it was supposed to have been pushed for by a local operator.

All of this has assumed that you had a good logic board in the game and the monitor was receiving the vector info. If the spot killer stays on and the monitor seems OK verify the presence of the X and Y signals by measuring between ground and pin 7 of the big white connector for the X signal and pin 8 for the Y signal. This is an AC signal and if either is missing the spot killer circuit is just doing it's job and saving the tube's phosphors.

You might also want to check that you don't have static analog data (voltage) saturating your transistors. To check this, set your multi-meter on the DC voltage scale and measure the voltage on the lead of R600 and R700 which are connected to the yellow and orange wires, respectively. The correct voltage should average out to about 0 volts DC but will fluctuate (both positive and negative) because of the changing deflection signal. If the measured voltage is constant (between 5 and 15 volts positive or negative DC) then check the X and Y amplifiers on the game board.

---

## Chapter 11) Fine-Tuning the picture

Now that you have a working monitor (and game), it is time to fine tune your picture. Before making any adjustments, turn your game on and let it warm up for at least 10 minutes. R918 is the HV adjust and my advice is that unless you have a HV probe, don't mess with it. If you have a probe, set the HV for 19.5 kV with zero beam current (i.e. with the game boards disconnected from the machine so that no input signals are being supplied).

---

### 11.1) HV over-voltage protection circuit

Some HV supplies (P329) have a circuit called the HV over-voltage protection circuit. It monitors the voltage of the focus assembly in the secondary circuit of T900. If the high-voltage at the anode of the picture tube increases beyond the threshold set by H.V. TRIP adjustment R930, this circuit shuts off the timer of IC901 and LED D903 turns on to indicate the over-voltage condition. Presumably, this was added to help discourage Tempest from eating HV transformers as it is prone to do since they are by far the most expensive component in the game. If you know your HV is good, adjust R930 so that it is just beyond the point where LED D903 lights (so that the LED is off).

**NOTE:** The following adjustments are a 2 person job (unless you are very handy with mirrors) because it is nearly impossible to view the screen and turn the pots at the same time. When adjusting your monitor, all adjustments should be made in the order as presented below as many of the adjustments have effects on other qualities and will cause you to have to go back and redo them if you change the order.

On the outside of the HV assembly are focus and brightness adjustments. Adjust the focus until the picture is sharp then adjust the brightness just under the point where the dot in the center starts to show or just under the point where you can see the connecting lines between objects. Be careful to not get carried away with the brightness as you can do permanent damage to the phosphors.

The manuals don't talk much about adjusting the positioning and size of your screen but that is easy to do. There are small potentiometers on the game board that are clearly labeled which control X and Y centering as well as X and Y size.

The following adjustments refer to the 8 tiny blue and/or black potentiometers found on the large game board towards the back on a Tempest machine. If your lines are not meeting at the "joints" properly or your text and numbers aren't lined up properly on the statistics screen then you need to make these adjustments. This information is directly from the Tempest schematic diagram supplements (sheet 2, side B, 3rd printing) so locations/numbering/labeling of the pots may be different for other vector games but the instructions should be relatively portable...

=====START=====

[NOTE: Atari did copyright these documents and they are clearly marked with a copyright symbol.]

[NOTE: All of the following controls exist in the Vector Generator section of the game PCB; **THEY ARE NOT IN THE MONITOR!**]

+-----+  
screen I

+-----+  
screen J

+-----+  
screen K

- Enter self-test and advance screens to the diagonal crosshatch pattern [the one with the line of numbers and letters at the bottom; screen I].
- Adjust "CENTER" pots: Adjust X-CENTER (R147) and Y-CENTER (R167) so that the pattern is located at the middle of the screen.
- Adjust "SIZE" pots: Adjust X-SIZE (R150) and Y-SIZE (R168) so that the pattern exactly covers the whole visible screen.
- Adjust the "BIP" pots ["BIP" stands for "Bipolar" but I don't know what that means...]: Adjust the X-BIP (R118) and Y-BIP (R117) so that the corners of the diagonal lines rest exactly on the sides of the outer rectangle. [NOTE: It may be easier to advance to the screen with the single large cross-hair on it to make the BIP adjustments; just make sure the lines meet at exactly the center. Using this screen, you should try to make screen J look like screen K. Be careful when joining the lines in the middle that you don't overlap; it is **VERY** hard to notice this. I suggest you make a big gap (go the wrong way) and then converge until the 2 segments just touch. Screens J, and K were added by me and are not shown in the original document.]
- Adjust the "LIN" pots: Adjust the X-LINEAR (R169) and Y-LINEAR (R165) so that the diagonal lines are straight. Since the "LIN" pots change the size of the displayed picture on the screen, you may have to readjust the "SIZE" pots in order to get the correct adjustment.

=====STOP=====

---

## 11.2) White balance adjustment sections of TM-183

Here is a summary of the white balance adjustment sections of TM-183. This is paraphrased and abridged since the information was spread out over many boring pages. You should make these adjustments before you adjust the purity and convergence. Do not do it in reverse order because color changes do slightly impact those other adjustments.

=====START=====

- Flip the test switch inside the coin door on the top near the hinge (some games may have the self-test switch mounted in a different area such as on a plate near the top of the coin box). Tempest requires you to rotate the spinner until the prompt reads "Press Fire and Zap for Self-Test". Other games may have similar requirements to get to the self test screens or they may take you directly to them automatically. Do whatever is required to enter the self test screens.
- Advance the screens with the slam (a.k.a. "tilt") leaf switch (this is typically inside the coin door below the lock) until you get to the diagonal crosshatch pattern screen (see "screen I" in the next section). For Tempest this should be the 1st screen.

- Turn the focus control (one of the 2 white knobs on the HV unit) until you get the optimum screen sharpness possible. Your goal is the best character appearance without appreciable fuzziness.
- Advance the screens until you get to one showing 7 groups of colored bars of various intensities. For Tempest this should be the 5th screen.
- Turn all the potentiometers on the neck PCB to the full clockwise position. Turn the brightness control (the other white knob on the HV unit) so that only 5 lines are visible and 6th one is completely invisible. Adjust the red, green, and blue bias potentiometers (the black ones) until the 5th line from the right is pure white without any hint of color in it (the 5th line is the dimmest one and color bias abnormalities are most visible at lower brightness levels; the goal is to get all 5 lines to be completely white). Adjust the red, green, and blue drive potentiometers (the white ones) until the 1st line on the right is pure white. Repeat the bias adjustment if the 5th line from the right is no longer pure white.

## 11.2.1) COLOR PURITY

This information comes from the Wells-Gardner Service Manual.

=====START=====

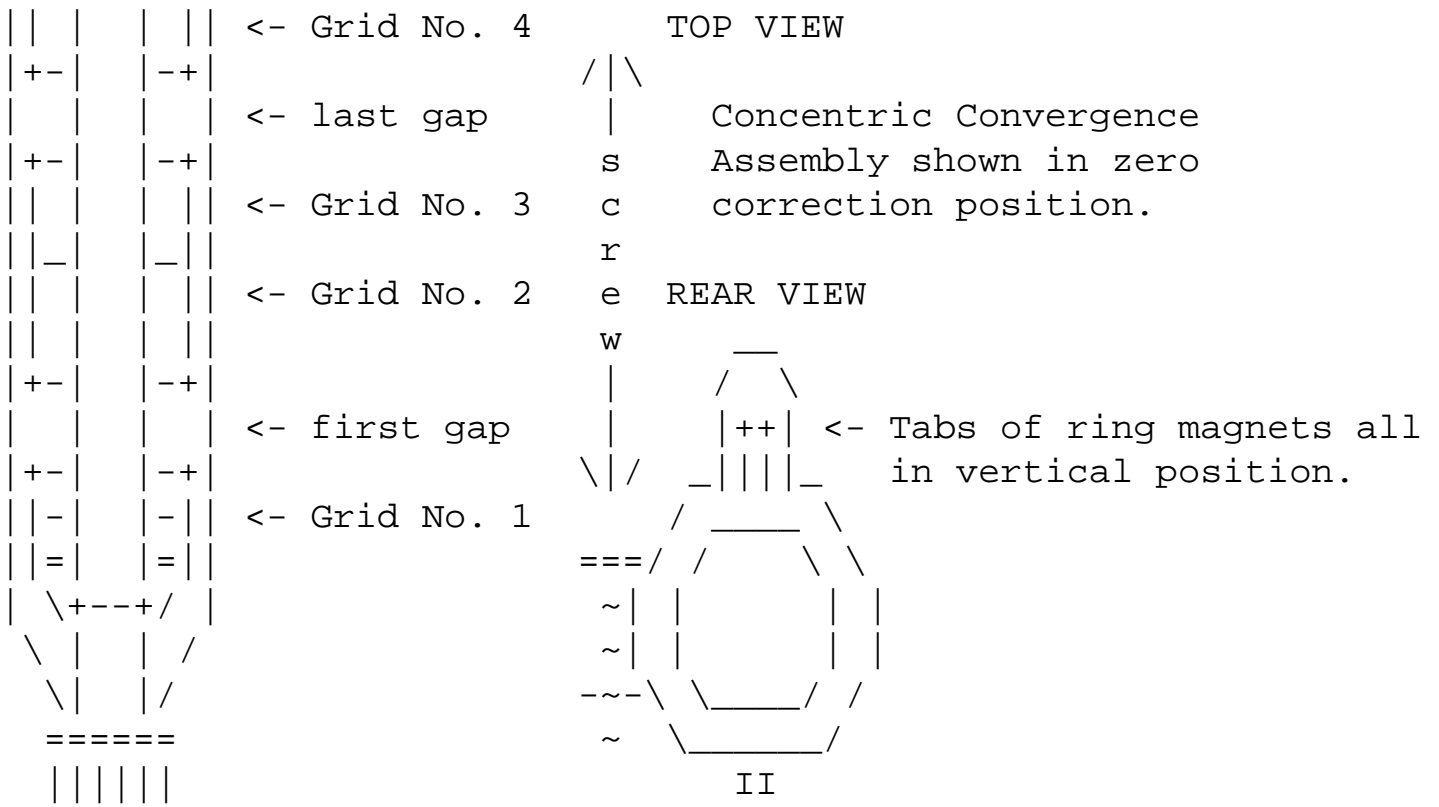

As far as adjusting purity (red gun hits red phosphors only, green gun hits green, etc.) and convergence (red, green, and blue guns hit adjacent dots to make white instead of separate colors), that is a whole different subject and the manual does a decent job of walking you through the procedure.

For best results, it is recommended that purity adjustment be made with display unit facing west or east. The display unit must have been operating 15 minutes or more prior to this procedure.

With yoke on CRT neck, set convergence assembly on CRT neck with the center line (of Purity Adjustment Magnet) over gap between grids No. 3 and No. 4. The convergence assembly consists of 3 sets of ring magnets with tabs (Figure 6).

FIGURE 6:

Tabs of the 3 magnetic ring-pairs are to be in a vertical position which will produce a zero-correction state and facilitate adjustments. (Figure 6).

Connect a generator or game (self-test mode) which can generate a crosshatch patten of red, green and blue independtly and in combination of colors. Refer to "INTERFACE BOARD ADJUSTMENTS" for input signal level and pattern size.

With a green crosshatch pattern, pull the deflection yoke backward as far as it will go. The center vertical portion will be green. If green is not horizontally centered between other colors, move the 2 purity magnets with respect to each other in order to center green crosshatch on the screen.

Push deflection yoke forward gradually, until crosshatch is a uniform green (pur in color) across the entire pattern. The deflection yoke should be secured in place.

Both red and blue colors are to be checked for uniformity and true color. Reposition the deflection yoke, if necessary, to obtain optimum purity of all colors. Tighten clamp to secure deflection yoke.

## 11.2.2) STATIC CONVERGENCE ADJUSTMENT

4-Pole Magnets and 6-Pole Magnets are for static convergence.

1. A crosshatch signal should be connected to the monitor.
2. A pair of 4-Pole Convergence Magnets is provided and adjusted to converfe the blue and read beams (Figure 6). When the Pole opens to the left and right 45 degrees symmetrically, the

magnetic field maximizes. Red and blue beams move to the left and right. Variation of the angle between the tabs adjusts the convergence of red and blue vertical lines.

3. When both 4-Pole Convergence Magnet Tabs are rotated as a pair, the convergence of the red and blue horizontal lines is adjusted.
4. A pair of 6-Pole Convergence Magnets is also provided and adjusted to converge the magenta (red + blue) to green beams (Figure 6). When the Pole opens to the left and the right 30 degrees symmetrically, the magnetic field is maximized. Red and blue beams both move to the left and right. Variation of the opening angle adjusts the convergence of magenta to green vertical lines.
5. When both 6-Pole Convergence Magnet Tabs are rotated as a pair, the convergence of magenta to green horizontal lines is adjusted.

---

### 11.2.3) ADJUSTMENT OF DYNAMIC CONVERGENCE (Figures 7, 8 and 9)

[NOTE: This text refers to a monitor oriented in the proper horizontal position. Some games such as Tempest use the monitor rotated 90 degrees into the vertical position.]

1. Feed crosshatch signal to the monitor.
2. Insert a wedge temporarily and fix the Deflection Yoke so as to obtain the best circumference (Figures 8a through 9b). **NOTE:** The wedges may need to be moved during adjustments.
3. Insert three rubber wedges to the position as shown in figure 7 to obtain the best circumference convergence.

#### NOTE:

1. Tilting the angle of the yoke up and down adjusts the crossover of both vertical and horizontal red and blue lines (Figures 8a and 8b).
2. Tilting the angle of the yoke sideways adjusts the parallel convergence of both horizontal and vertical lines at the edges of the screen (Figures 9a and 9b).
3. Use three rubber wedges (tapered rubber wedges are used for this purpose.)
4. The position of each rubber wedge is shown in Figure 7.
5. Do **NOT** force the permanent wedges in. They are to be inserted until they just make contact with the yoke - after the yoke has been positioned.
6. Fix the three permanent rubber wedges with chloroprene rubber adhesive.
7. After the adhesive has dried enough to hold the wedges in place, carefully remove the temporarily installed wedge.

=====STOP=====

# Chapter 12) Improving your Monitor

# (preventing future problems!)

Now that you have your monitor repaired and adjusted, I'll discuss the variety of ways that exist to make your monitor (or rather, your deflection board) more robust and hopefully reduce or eliminate future failures.

Here is some text from the Major Havoc conversion kit installation instructions (TM-268). It describes the **Atari** sanctioned upgrades and includes instructions for converting all Wells-Gardner P314 Deflection Board PCB variations to **Atari**'s "official" upgrade. Thanks to Tony Jones ([ant@palm.cray.com](mailto:ant@palm.cray.com)) for sending this to me.

=====STOP=====

---

## 12.1) Major Havoc Installation Instructions TM-268

[NOTE: **Atari** did copyright these documents and they are clearly marked with a copyright symbol.]

### H. MODIFY THE WELLS-GARDNER DEFLECTION PCB

**NOTE** The following procedure applies to those Space Duel, Gravitar, and Black Widow games that used a Wells-Gardner display. If your game has an Amplifone display, proceed to I. Modify the Amplifone Deflection PCB [found earlier in this document].

Four versions of the Wells-Gardner display were used in the Space Duel, Gravitar, [Tempest,] and Black Widow games. Perform the preliminary procedure for all versions of the display, then refer to Table 3 to determine which version of the four displays was installed in your game and perform the additional procedure for that version. **CAUTION!** When soldering components to the display circuitry, apply just enough heat to provide a proper electrical connection. Excessive heat can damage the semiconductor material.

---

## 12.1.1) Preliminary Procedure

Perform the following procedure to modify the Deflection PCB (see Figures 6 and 7).

1. Set the display on a clean work surface.
2. Disconnect the 15-pin Molex connector from the mounting bracket on the display chassis and the harness connectors from the Deflection PCB and the Neck PCB.
3. Use a 1/4-inch hex driver to remove the two screws securing the Deflection PCB to the display chassis [**NOTE:** there are holes for 2 more screws in the remaining (rear) 2 corners of the board which some users decided to fill; if the board won't come out, check for this]
4. Remove the Deflection PCB from the display.
5. Connect two type-1N754A Zener diodes together, anode to anode, as shown in Figure 6. Use a soldering iron to solder the two anode leads together.

Figure 6 1N754A and 1N756A Zener-Diode Connections

[Figure 7, entitled "Modifying the Wells-Gardner Deflection PCB", showing 2 half scale pictures of the solder side of the Deflection PCB, has been omitted for obvious reasons. It does not show anything that cannot be derived from the included text; it was merely a "visual aid". The top picture is the P327/339 design and the bottom is P314.]

6. Connect two type-1N756A Zener diodes together and solder as described in step 5.
7. Examine the soldered side of the Deflection PCB removed from the display and determine which of the two PCBs shown in Figure 7 matches your PCB.
8. On the component side of the Deflection PCB, locate the yellow wire (top right side of the PCB).
9. Solder one cathode lead of the two type-1N754A Zener diodes (soldered together in step 5) to the yellow lead on the soldered side of the PCB as shown in the appropriate illustration in Figure 7.
10. Solder the other cathode lead of the two type-1N754A Zener diodes to ground as shown on the appropriate illustration in Figure 7.
11. On the component side of the Deflection PCB, locate the orange wire (near top center of the PCB).
12. Solder one cathode lead of the two type-1N756A Zener diodes (soldered together in step 6) to the orange lead on the soldered side of the PCB as shown on the appropriate illustration in Figure 7.
13. Solder the other cathode lead of the two type-1N756A Zener diodes to ground as shown on the appropriate illustration in Figure 7.
14. On the component side of the Deflection PCB, locate connector P600 (right center of the PCB).
15. Solder the cathode lead of a type-1N4002 diode to pin 1 and the anode lead to pin 4 of connector P600 on the soldered side of the PCB as shown on the appropriate illustration in Figure 7.
16. Solder the cathode lead of a type-1N4002 diode to pin 5 and the anode lead to pin 7 of connector P600 on the soldered side of the PCB as shown on the appropriate illustration in Figure 7.
17. On the component side of the Deflection PCB, locate connector P700 (left center of the PCB).
18. Solder the cathode lead of a type-1N4002 diode to pin 1 and the anode lead to pin 4 of connector P700 on the soldered side of the PCB as shown on the appropriate illustration in Figure 7.
19. Solder the cathode lead of a type-1N4002 diode to pin 5 and the anode lead to pin 7 of connector P700 on the soldered side of the PCB as shown on the appropriate illustration in Figure 7.
20. Refer to Table 3 to determine which of the four versions of the display has been installed in your Tempest game.

### Table 3 Display Versions

#### Version 1

Deflection PCB has two large, black, tubular capacitors, C804 and C805, installed below top center of PCB. [NOTE: These are 1" long and .25" in diameter and are radial lead type; I guess as far as PCB components go, they could be considered large but as far as electrolytics go, they are rather small. As far as I know, these are present only on versions P327 and P339 of the Deflection PCB (which have the Input Protection Circuit redesigned into the board). This question could probably more easily be phrased, "Is your board labeled P327 or P339." The fact that they chose not to word the question this way implies that there are some board redesigns which were labeled P314 instead of P327. The proceeding 3 descriptions refer only to (most but perhaps not all of) the various flavors of

the P314 version of the Deflection PCB (i.e. not P327 nor P339).]

#### Version 2

Input Protection Circuit PCB is installed (piggyback) WITH A 1K Ohm, +/-5%, 1/4 W RESISTOR CONNECTED BETWEEN THE INPUT PROTECTION CIRCUIT PCB AND THE DEFLECTION PCB. [NOTE: I have documented this PCB immediately following this article.]

#### Version 3

Input Protection Circuit PCB is installed (piggyback) BUT DOES NOT HAVE A RESISTOR CONNECTED BETWEEN THE INPUT PROTECTION CIRCUIT PCB AND THE DEFLECTION PCB.

#### Version 4

Deflection PCB DOES NOT HAVE CAPACITORS C804 AND C805 (BELOW TOP CENTER OF PCB) OR AN INPUT PROTECTION CIRCUIT PCB INSTALLED.

21. Perform the procedure as follows for the appropriate version of the display determined from Table 3. (Refer to the display manual, TM-183, for component and connector locations).

**NOTE:** The 30Kohm, 1/4W resistor supplied in the kit is used only for Version 1 of the Wells-Gardner display.

---

## 12.2) Version 1

Perform the following procedure for Version 1 of the Wells-Gardner display.

1. Verify that the Preliminary Procedure has been performed.
  2. Use a soldering iron to remove resistor R811 and replace it with the 30Kohm, 1/4W resistor supplied in the kit.
  3. Use a 1/4-inch hex driver to secure the modified Deflection PCB to the display chassis.  
**CAUTION!:** Make certain that the harness from Q705 and Q706 is connected to P700 and not P100.
  4. Connect the harnesses to the appropriate Deflection PCB connectors.
- 

## 12.3) Version 2

Perform the following procedure for Version 2 of the Wells-Gardner display.

1. Verify that the Preliminary Procedure has been performed.
2. Use a 1/4-inch hex driver to secure the modified Deflection PCB to the display chassis.  
**CAUTION!:** Make certain that the harness from Q705 and Q706 is connected to P700 and not P100.

3. Connect the harnesses to the appropriate Deflection PCB connectors.
- 

## 12.4) Version 3

Perform the following procedure for Version 3 of the Wells-Gardner display.

1. Verify that the Preliminary Procedure has been performed.
  2. Locate the wire connected to resistor R1 (22K ohm) and the collectors of transistors Q1 and Q3 (type 2N3904) on the Input Protection Circuit PCB and the point shown in Figure 7 on the Deflection PCB.
  3. Use a wire cutter to cut the wire, located in step 2, half-way between the two PCBs.
  4. Use a soldering iron to solder a 1K Ohm, +/-5%, 1/4 W resistor (not included in the kit) between the two ends of the wire cut in step 3.
  5. Use a 1/4-inch hex driver to secure the modified Deflection PCB to the display chassis.  
**CAUTION!:** Make certain that the harness from Q705 and Q706 is connected to P700 and not P100.
  6. Connect the harnesses to the appropriate Deflection PCB connectors.
- 

## 12.5) Version 4

Perform the following procedure for Version 4 of the Wells-Gardner display. **NOTE:** This version of the display requires that an Input Protection Circuit PCB assembly be installed on the Deflection PCB as part of the display modification procedure. This PCB assembly is not included in the kit. However, to obtain the Input Protection Circuit PCB assembly, use the order form at the back of this document.

1. Verify that the Preliminary Procedure has been performed.
2. Install the Input Protection Circuit PCB to the Deflection PCB as described in the instructions supplied with the Input Protection Circuit PCB assembly.
3. Use a 1/4-inch hex driver to secure the modified Deflection PCB to the display chassis.  
**CAUTION!:** Make certain that the harness from Q705 and Q706 is connected to P700 and not P100.
4. Connect the harnesses to the appropriate Deflection PCB connectors.

=====STOP=====

---

# Chapter 13) Improving deflection

# boardboard to improve its reliability

The following are hardware modifications you can make to the deflection board to improve its reliability. I have seen all in action and can verify them to be "non-lethal" modifications but cannot really attest to their usefulness since I don't run my Tempest under stress. I would advise that you only implement 1 of them unless you are sure they are compatible (I am not). If anybody knows if any are compatible (or not), let me know. For now, I am listing them as mutually-exclusive; mix at your own risk. I'd take the time and hassle to do the first one even though it is a lot more work.

The Input Protection Circuit did not include any background in the kit so here are those details which I found on page 3 of the May 1982 issue of **Star\*Tech Journal**:

=====START=====

## NEW INPUT PROTECTION CIRCUIT FOR WELLS-GARDNER COLOR X-Y DISPLAY

This display contains an additional small printed-circuit board (PCB). The PCB is mounted in "piggy-back" style on top of the Deflection PCB.

The input protection board was added to protect the fuses in the display from damaging input voltage conditions. Without this board, the display fuses might blow in the event of an intermittent or long-term game PCB failure. With this board, the screen will momentarily go blank if the average X- or Y-axis voltage(s) exceed a certain level. The screen then automatically recovers for normal game play and earning when the voltage(s) return to normal.

If this display is used in **Atari** "Tempest" games, be sure to correctly adjust the X and Y SIZE and CTR video pots on the "Tempest" Analog Vector-Generator (main) PCB. The instructions for the adjustments are printed on the "Tempest" schematics - Sheet 2, Side B - 3rd printing or later [and can also be found in this document]. Improper adjustment may cause the screen to go blank during normal game play.

=====STOP=====

---

## Chapter 14) Atari document about the INPUT PROTECTION CIRCUIT (IPC)

=====START=====

[NOTE: To my knowledge, **Atari** never bothered to copyright these instructions and they are not marked with a copyright symbol.]

[NOTE: THIS MODIFICATION IS FOR P314 VERSIONS OF THE DEFLECTION BOARD ONLY. The P327 and P339 versions already have this circuit designed into the board. Here is the text from Atari CO-183-02 (1st printing) which describes a circuit that was sold by Atari to help make the deflection board more robust. This circuit is unavailable but very simple and easy to recreate from the schematics provided herein.]

[NOTE: Martin Sterni <[m-sterni@dsv.su.se](mailto:m-sterni@dsv.su.se)> has successfully prototyped these and is currently selling them **WITHOUT ANY COMPONENTS**. He has sent me a few samples and they are of **SUPERB** quality (nicer than the original Atari/Wells-Gardner PCBs). I can vouch for them being produced properly in every way; I am very impressed! Contact him if you want to purchase any.]

---

## NEW INPUT PROTECTION CIRCUIT FOR WELLS-GARDNER COLOR X-Y DISPLAY (Supplement to TM-183)

This display contains an additional small printed-circuit board (PCB) that is not described in the display manual (TM-183). The PCB is mounted in "piggy-back" style on top of the Deflection PCB.

The input protection board was added to protect the fuses in the display from damaging input voltage conditions. Without this board, the display fuses might blow in the event of an intermittent or long-term game PCB failure. With this board, the screen will momentarily go blank if the average X- or Y-axis voltage(s) exceed a certain level. The screen then automatically recovers for normal game play and earning when the voltage(s) return to normal.

If this display is used in a Tempest (TM) game, be sure to correctly adjust the X and Y SIZE and CTR video pots on the Tempest Analog Vector-Generator (main) PCB [see text immediately above]. The instructions for these adjustments are printed on the Tempest schematics - Sheet 2, Side B - 3rd printing or later. Improper adjustment may cause the screen to go blank during normal game play.

INPUT PROTECTION CIRCUIT PCB ASSEMBLY

COLOR X-Y DISPLAY 92-053  
 INSTALLATION INSTRUCTIONS  
 INPUT PROTECTION CIRCUIT PCB

A038088-01

1. Remove R600, R605, R700 and R706.
2. Remove solder from all nine holes indicated in figure 13 [figure not included; see text below].
3. Straighten pins of PCB so that they are perpendicular to the board [meaningless to you since you probably don't have the board].
4. Match and insert the numbered holes in figure 13 with the numbered pins in figure 1 [see text below].
5. Solder.

[Figure 13, an annotated picture of the deflection board PCB from the original TM-183 manual, has been omitted for obvious reasons.]

[Since you will be making the board from scratch and don't have the pictures that came with the board, I am providing the following text to describe the contact points on the deflection board. The following text is all mine and **NOT Atari's** but is derived directly from figures 1 and 13 that **Atari** did provide.]

All descriptions refer to a deflection board oriented component side up with the board label "P314" at the top (right-side-up) and the 2 large electrolytic capacitors at the bottom. This orientation will have the electrolytics "side by side" and the board will be "taller" than it is "wide".

- J1 is R700's old top pin.
- J2 is R700's old bottom pin.
- J3 is R600's old top pin.
- J4 is R600's old bottom pin.
- J5 is the first "empty"/unused hole to the right of C701.
- J6 is the first "empty"/unused hole to the right of Q701 and below C701.
- J7 is the first "empty"/unused hole to the left of C602 and below D601.
- J8 is R606's old left pin.
- J9 is R706's old left pin.

**SPECIAL NOTE:** According to the Major Havoc manual, this board came in 2 versions. Later versions had a 1K Ohm, +/-5%, 1/4 W resistor as one of the "stilts" on the board instead of a plain piece of wire. If your board does not have this resistor, here is what you need to do.

1. Locate the "stilt" wire connected to resistor R1 (22K ohm) and the collectors of transistors Q1 and Q3 (type 2N3904) on the Input Protection Circuit PCB (the other end is connected to the P314 Deflection PCB).
2. Use a wire cutter to cut the wire, located in step 1, half-way between the two PCBs.
3. Use a soldering iron to solder a 1K Ohm, +/-5%, 1/4 W resistor between the two ends of the wire cut in step 2.

I have included this resistor in my ASCII rendering of the schematic and labeled it R'.

---

## Chapter 15) How to make a 'TEMPEST' Monitor Trouble-Free.

Here is an article from the April 15, 1983 issue of Play Meter magazine (page 191) which is copyrighted material and is included without permission; forgive me. It is from a regular feature in the magazine called "FRANK'S CRANKS" by Frank "The Crank" Seninsky.

=====START=====

[NOTE: Play Meter did copyright this article and the magazine is clearly marked with a copyright symbol.]

HOW TO MAKE A 'TEMPEST' MONITOR TROUBLE-FREE.

Atari's Tempest, when it is working, is not a bad game. It's just a shame that the monitors only last a few weeks (sometimes only days) between service calls. Most of the time, the monitor sits neglected on a techroom shelf.

Atari has developed a monitor protection board [included earlier in this text] to protect the monitor's components (2N3716 and 2N3792 "X" OUTPUT transistors, two each located on chassis frame) if and when there is a RAM lock-up on the Tempest CPU board. I want to clarify that the Wells-Gardner monitor is not at fault. Also note that on the later Atari games, the protection circuit has been incorporated into the board circuitry. [These statements seem to imply that this "fix" is compatible with the Atari upgraded P314s as well as P327s and P339s and will provide additional protection; in fact, I have seen it on a P327 before. It is sufficiently ambiguous that the exact opposite can be inferred. Judging from the areas of the board it alters, I would say it is incompatible (duplicates) the other fixes in this section.]

It's common knowledge that you can purchase a broken Tempest game cheap. With about 20 minutes of your time and a couple of dollars in parts, it is possible to add just six common components to the monitor deflection board and have a Tempest that will stay on location and work [Yeah, right]!

The parts required are:

- two-1N914 diodes
- two-1N4737 diodes
- two-1K OHM 1/4 W resistors

## 15.1) FIRST HALF

Take the anode ends (the ends opposite from the marked rings) of a 1N914 and a 1N4737, and solder them to one end of a 1K ohm resistor so that it looks like this:

Locate C700 in the top left of the monitor deflection board. (See Figure 13 on page 20 of **Atari** TM-183 Wells-Gardner Quadrascan service manual; second printing) and solder the cathode of the 1N4737 to the ground side of C700 (right side in Figure 13). Solder the end of the 1K OHM resistor to the -27 volt side (left side) of C700. Solder the one remaining wire (the cathode of 1N914) to the "X" INput side of R700 (top end of R700). You are now halfway finished.

## 15.2) HALF TIME

Take a five-minute break; you deserve it.

## 15.3) SECOND HALF

Take the remaining 1N914 and 1N7437, and solder the cathode ends of each diode together with one end of the 1K OHM resistor so it looks like this:

Locate C701 (top middle in Figure 13) and solder the anode of 1N4737 to the ground side of C701 (right side). Solder the end of the 1K OHM resistor to the +27 volt side of C701 (left side). Go back to the same "X" INput side of R700 and solder the remaining wire (the anode of the 1N914) to this connection. Make sure that you have a good solder connection at the "X" INput of R700 as you now have a three-wire joint.

## 15.4) FINAL TWO-MINUTE WARNING

Make sure that none of the wires of this modification can come into contact with the other board components [easy to do; there is lots of bare PCB in this area; you may want to tape/glue the leads

down], especially the brown ground wire located to the right of R700. If the modification hits this brown wire, you can consider it a fumble and you just blew your lead and the game.

=====STOP=====

---

## Chapter 16) Deflection board "hacks" to extend life

Lastly, I will list 2 hacks that I have seen made to deflection boards in an attempt to get them to work for longer periods in the field. I have seen them on both the P314 and P327 designs. The first one makes some sense but the second one is downright scary!

---

### 16.1) Hack 1

Cut the trace just above pin 4 of connector P101 isolating the 3 topmost connections (purple wire, R713, and pin 7 of P700) from the rest of the cluster. Jumper the 3 isolated connections to pin 7 of P100. This makes those 3 connections run at -33.3V instead of the usual -27.7V.

Cut the trace just to the left of pin 3 of P101 isolating the 5 rightmost connections (F700, R808, pin 5 of P701, C104, and R712) from the rest of the cluster. Jumper the 5 isolated connections to pin 1 of P100. This makes those 5 connections run at 33.8V instead of the usual 27.8V.

I am not sure what is gained by biasing these portions of the circuit by larger magnitude voltages but will look into it later.

---

### 16.2) Hack 2

When I saw this next hack, I couldn't believe my eyes; especially after I plugged it in and **IT WORKED!** The hack described above was implemented but with the following additions...

Evidently this operator got so tired of fixing the low voltage power supply regulator circuitry that he **ELIMINATED IT FROM THE CIRCUIT!** What he did was remove virtually that entire section (R100-103, D104-105, and P100) and instead formed the voltages required by dropping the unregulated +/-33 voltages across resistors! He connected a 10 Watt, 25 Ohm (+/- 10%) resistor between pins 3 and 7 of P100. An identical resistor was connected between pins 1 and 4 of P100. I'm not sure what kind of

solder he used but it takes a good minute for a 30 Watt soldering iron to even begin to melt a small portion of it.

This change will give you a very noisy approximation of the original voltages that should be good enough to run the monitor. Needless to say, the ceramic resistors get unbelievably hot and the screen is a little jumpy when drastic changes in drawing (current pull) occur (such as between waves and during the demo) but other than that the results are quite tolerable. If run for extended periods, this setup is virtually guaranteed to blow some fuses on the deflection board.

Since there is no longer a Q101 to worry about, it won't cause you any problems and since P100 no longer exists (either it or the connector that goes to it should be removed to avoid somebody plugging it in and adding the transistors to the now foreign circuit), there won't be any problems with Q102 and Q103 either (they are no longer required in the circuit and the connector that went on the now missing P100 just hangs in the air). If you are going to be placing one of these monitors out in the field or it is going to get frequent, extended duration use, this hack **MIGHT** be worth trying (assuming the degradation of picture quality is acceptable to the viewers) but I would think it would greatly stress the rest of the circuitry as well as the yoke coils and would limit the lifetime of the unit in other, less familiar ways. The PCB I saw this on had extensive burns on the amplification portions of the circuit which I almost never have to repair so **BEWARE**; this hack may have been the cause not the solution!

## 1. About the Author

Author: Mike Thomas

E-Mail: [thomasm@agcs.com](mailto:thomasm@agcs.com)

Version: 1.00

Date: 15 Jul 1993

The black and white displays were built by PHILIPS in Canada. The plant there has been shut down, when I last enquired with Philips re: purchasing spare parts, I was informed that they did not want to support anymore new customers for this product line. Philips makes the new HP b/w monitors too, but it looks as if everything is manufactured in Taiwan.

You can also get a list of technical info for the color and monochrome monitors, part of the [Sync-On-Green](#) (33KB) FAQ.

---

## 2. Disclaimer

All of these tips apply only for the 8399-XXX series of monitors. **EXERCISE CAUTION WHEN WORKING ON MONITORS, THE MONO MONITOR HAS 18KV GOING TO THE CRT.** Let your techs show you the ropes on monitor repairs, if you're going to be messing around with any live equipment. Be especially careful when doing focus adjustments, aside from personal risk you can smoke your board.

You may get [Notes on Safety V1.00 \(7KB\)](#) if you don't read these

---

## 3. Handy-dandy guide for repairing mono monitor problems

- Screen wrap problem or the horizontal width has grown too large and the screen appears to be wrapping back around on itself. Replace C205 and C206 on deflection board, 10 ufd/50V, electrolytic caps. (Actually only one of these is causing the problem, but I'm too lazy--change both) Cost: \$0.12 per cap.
- Screen is shrinking from both sides. Change C161, 100 ufd/63V, electrolytic cap near bottom right of deflection board. Cost: \$1.00.
- Characters seem to be wiggling or vibrating. Change C101, 10 ufd/50V, electrolytic cap, upper left quarter of deflection board. Cost: \$0.12.
- On all white displays or on white backgrounds there appear bright horizontal streaks. Replaced C315, 100 ufd/25V, electrolytic cap, just below C101. Cost: \$0.75.
- Top of display appears to losing a few lines of text sort of gradually getting darker on top few lines. Replace C318, 4.7 ufd/100V, electrolytic cap located left center on deflection board. Cost: \$1.00.
- Display is too large vertically and cannot adjust in. Replace C310, 0.01 ufd/63V, P.S. cap, aluminum colored just above IC301.
- If the display is too dim and after adjusting brightness it is out-of-focus, you can try the focus adjustment, but if that doesn't really work well enough you will need to replace the CRT. This is not that difficult, takes about 45 minutes, costs: \$125.00. I use the on-line diagnostic `"/systest/grtest"` to perform focus adjustments. Just enter ad (adjustments) at the grtest prompt and select test 13. Save all of the magnets from any scrapped monitor yokes, you'll need them to adjust display geometry with the new CRT's.
- Also save your old flyback transformers on any scrapped displays, flybacks cause several different problems: Squeals no picture and a 'jittery' display are both flyback problems. The key to

flyback jitter is when the display shrinks or jerks both top, bottom and both sides simultaneously. Another flyback problem is a slow expansion and contraction of the display, some of my customers tell me that it's 'breathing'.

- As far as adjusting focus goes, the pot labeled 'DYN FOC HOR' adjusts the focus on the far right and left side of the screen. It also balances the focus between these sides, so be sure to check both left and right sides when adjusting this pot. The pot labeled 'DYN FOC VERT' just adjusts the focus for the top and bottom of the display. I usually can't get perfect focus on the very top of the display, especially at this site where the brightness has to be turned up especially high. If no matter what you do with the focus pots does not work, you might try playing with the 'focus phase' adj. Focus phase is controlled by the coil with the adjustable core in the center of the board. The way I play with it is to turn the main focus pot, R431, to midrange and do the same for the two dynamic focus pots. I then adjust focus phase for good focus in the center of the display, then go through the normal focus adjustments, i.e. turn R431 for best focus overall then adjust dynamic for sides and top and bottom.

---

## 4. Monochrome display cable pin outs

Pin 1 - ECL Video  
Pin 2 - No connection  
Pin 3 - Horizontal sync  
Pin 4 - Vertical sync  
Pin 5 - No connection  
Pin 6 - ECL Video  
Pin 7 - Video Shield  
Pin 8 - Horizontal Sync Return  
Pin 9 - Outer Shield Chassis

## 1. About the Author

Author: Frank Reid

E-Mail: [reid@indiana.edu](mailto:reid@indiana.edu)

Release: Aug 14, 1990

Revisions: Aug/Nov/Dec 1990, Jan/Apr/May/Sep/Oct 1991, Feb/Mar/Sep 1992, Aug 1993, Jan/Mar/Aug/Oct 1994, Feb 1995

(Version is Internal)

---

## 2. 8512, 8513

IBM's "PS/2" VGA color monitors, models 8512 and 8513, have had frequent maintenance problems. There are at least two different models of each monitor. They are manufactured in Korea, probably by

Samsung or Tatung.

Schematic diagrams are apparently unavailable. The following is a summary of many frustrating hours at the repair bench:

---

## 2.1) Opening the cases

The top of the 8512 or 8513 case is fastened either by two internal plastic clips (see below), or "tamperproof" Torx T-20 screws with center pins. The Torx driver must have a long, slender shaft (preferably magnetic) to reach the screw heads.

S/N 23-xxxxx: Plastic clips hold top front of case. The internal catches can be released by inserting a pair of special tools made of sheet-metal, shaped approximately like:

The angle at the end is more acute (25 degrees) than shown in this ASCII diagram.

Alternatively, insert long, thin screwdriver into rectangular holes and push clips downward. An Apple Macintosh case-separation tool is sometimes useful to help remove back the cover. It is best to release both clips simultaneously.

**NOTE:** Cut the silicone glue at the CRT base and unplug the tube before working on the main board! The glass neck is easily broken. A monitor with broken CRT is not economically repairable. The voice of experience speaks. :-)

### **Symptom: No power or intermittent power:**

Some models (including those whose serial numbers begin with 23) have the AC power connector soldered directly to the main circuit board. The wave-soldered connections are too thin for heavy components or those subject to flexure: They crack, opening the circuit. Resolder them, using lots of solder. Also use a magnifying lens to inspect the solder joints of the flyback transformer, the deflection-yoke connector and (rarely) the CRT socket. These often fail in the same manner as the power connector. I always resolder all the above-mentioned connections on general principle.

### **Symptom: High voltage present but screen dark**

Inspect solder joints on CRT socket, especially if serial number begins with 23-. (See above.)

### **Symptom: Horizontal line across screen, remainder dark**

Failed component: Vertical amplifier (large IC attached to heat sink; TDA-1670A manufactured by SGS, whose quality control is infamous). People at IBM have told us that this chip is a weak point. Use heat-sink compound when installing new IC. The replacement IC may last indefinitely, or may fail in a few days. Sylvania's ECG 1862 is a replacement for TDA1670A.

When the IC fails, a 2.2 ohm 1/4-watt resistor in series with its power supply lead (diode and capacitor leading to a flyback pin) burns beyond recognition. This resistor is used as a fuse. The value is not critical (may be up to 20 ohms) but be sure the replacement resistor is a metal-film type which burns quiescently, instead of a carbon resistor which will start a fire. Leave the resistor leads long, mounting the resistor one inch [2cm] above the circuit board.

Before replacing IC, inspect for cracked solder connections on the male deflection-yoke connector (mounted on the main circuit board).

In old monitors, especially 8513 with serial numbers beginning with 72- , replace vertical deflection-yoke coupling capacitor C313 (3.3 uF 160v), especially if it shows signs of overheating (shrink tube retracted from top of metal can).

Also check C309 (2200uf 16v). If C309 is bad, the new amplifier may fail immediately or in a few days.

### **Symptoms: Power Supply Problem:**

- 1. Immediate power supply shutdown.**
- 2. Power supply shutdown/restart about once per second.**
- 3. Squeal from power supply, wavy left and right edges of picture; may become normal after warmup.**

Bad component: C120 (10 uf 35v). This capacitor is common to most models of 8512/8513, and has the same identifying number on their circuit boards. It is located near the front of the power supply area, in the corner with the green LED pilot light, sometimes near a large green resistor. Replace this capacitor on general principle anytime you open an 8512 or 8513. This capacitor fails from heat; dissection of bad capacitors reveals no moisture within. The replacement should have a temperature rating of 105 deg. C. (typified by end plug made of epoxy instead of rubber). Heat-induced capacitor failure is a common problem in switching power-supplies. If high- temp. capacitors are unavailable, leave the leads long so that the new capacitor can be placed further from the abovementioned resistor which gets hot enough to discolor the circuit board and adjacent plastic standoff.

If capacitor is good, check diode CR105. This diode sometimes has thermal problems resulting in intermittent or permanent short, causing symptoms as above. Replace with a fast-recovery diode such as 1N4937; leave leads long for cooling. (We use 1N4937 as a generic replacement for high-frequency

rectifiers in monitors, both in switching power supplies and flyback-derived voltage sources. Common rectifier diodes such as 1N4004 will overheat when used at the frequencies of switching power supplies or of flyback transformers.

Also check CR212, near the flyback transformer. It often shorts. Rating is 3A, 600V.

### **Symptom: Blown fuse**

Bad component: De-gaussing thermistor (rectangular black box with 3 leads, near de-gauss coil connector).

If new thermistor is unavailable: Remove the shorted device, use a handheld de-gaussing coil after the monitor has been returned to its operating position.

Replacement thermistors are not available from IBM. A suitable replacement for the thermistor in IBM 8512, 8513 and 3192 is the one used in NEC 1401 monitors. It is NEC part number 38112026, "positive thermistor degaussing control," \$2.95 from:

NEC Home Electronics  
1255 Michael Dr.  
Wood Dale IL 60191-1094.

The NEC device is slightly larger and apparently more robust than the original. On some types the middle leg must be bent to fit the hole in the printed-circuit board.

(Rare): Blown fuse may result from shorted diodes which rectify 115 VAC power, or from shorted FET power-supply switching transistor.

---

## **3. Symptom: Bad Power Supply (ones in metal case)**

Bad power supply (in model where power supply is a separate unit in gold-colored metal cage), verifiable by swapping for known-good power supply:

Replace two small electrolytic capacitors located under a rectangular ceramic power resistor which stands about 1" above the circuit board.

### **Symptom: 8513 s/n 23-xxxxx: R203 burned**

Replace resistor (120 ohms, 1/4 watt), resolder C202. C202's solder joints often break from vibration, or

from being bumped during chassis disassembly/reassembly.

**Symptom: 8513 23-xxxxx, single bottom-screw, metal subchassis, crt-board shield with top overhang: Red color very dim or absent:**

Resolder broken connections on the "red cut" control (RV801 on the CRT board). The manufacturer produced a large number of this model with that device improperly installed. Re-balance colors as necessary.

---

## 4. 8512 s/n 72-xxxxxxx (7 digits after 72-)

This model has extensive metal shielding inside. The power supply is a separate unit in gray metal housing. Power cord permanently attached, cover has Torx screws:

**Symptom: Squealing sound from power supply; supply operates normally when 2-wire (red/white) power connector is removed from CRT board:**

Failure: One or more shorted video driver transistors: 2SC3502, 2SA1370. (No ECG equivalents are listed.)

**Symptom: No power, or power supply making squealing sound. Exploded capacitors on CRT board or inside power supply:**

Replace exploded capacitors (10 uf 100v) as required. Replace C18, C21 and C22 in the power supply. Use high-temperature types. Failure of these capacitors may cause the power supply's regulation to fail, causing power filter and video decoupling capacitors to explode. The power supply to the CRT board should deliver approx. 70 volts.

**Symptom: Vertical foldover, possibly decreasing with warmup: replace C408 and C425 (near extruded heatsink).**

**Symptom: One color absent or displayed improperly, or "2401" error.**

Problem: Bad video cable. Wires often break inside the connector. There are several variations of the inner end of the cable. The one most prone to failure is used on 8512 s/n 72-xxxxxxx. Its IBM part number is 61X8888. It is also available from other sources.

New connectors are available from electronics parts distributors, but installing them is very difficult because the inner conductors of the coaxial cables are small and brittle. We have spliced a few cables recovered from junked monitors but that is a laborious process.

IBM agreed to replace some 8512 and 8513 monitors under certain conditions: See IBM documents 8512 ECA026 and 8513 ECA017. The replacement offer has long EXPIRED.

8512's: Serial number with "72" prefix, s/n between 72-0120000 AND 72-0405000: Display is out of focus and/or excessively bright.

8513's: Serial number with "72" prefix, s/n below 72-0640000: Display out of focus.

Those series appear no less reliable than others. Some replacement units were new, others are used/reworked and have new serial numbers attached. These appear to have new flyback transformers. Some have subsequently failed for other reasons.

### **Symptom: Out of focus (8513 s/n 72-...)**

If the focus control on the flyback is turned to the end of its travel and the display is still out of focus, replace the flyback. Replacement type is TFB-185A. The replacement may appear to have two controls instead of one; the control labeled SCREEN is a dummy (see below).

Many of our 8512 and 8513 monitors have failed from long service: Since they have integral power switches, and the screens are black when the computer is turned off, users tend to leave them on forever. Life will be significantly extended by turning them off overnight and on weekends.

CRT focus degrades with age. If the picture will not focus satisfactorily and the focus control is not at an extreme (see above), repair is not economical unless you have a good tube salvaged from a scrapped unit. Transplant the CRT and deflection yoke together; if the yoke is disturbed, reconvergence of colors is extremely difficult.

### **Symptom: Left and right edges of picture are curved inward (pincushion distortion); internal adjustments (E/W and Width) inoperative. Occurs after a few years' service.**

Replace capacitor C225 (22uF 50v 105 deg.C).

### **Symptom: Fluctuating brightness due to erratic screen voltage in 8513 with serial number beginning 72-xxxx:**

R477 (3.3M 1/4 watt) fails from high-voltage breakdown. Replace with same value, 1/2 watt, or two 1.6M 1/4w in series. Resistor is located between flyback transformer and aluminum heatsink of horizontal output transistor. This model 8513 has only one control (focus) on its flyback; the screen-voltage control is on the board attached to the CRT socket.

I replace this resistor on general principle in aging monitors, and readjust the screen voltage (variable resistor on CRT-socket circuit board). These monitors usually also need their color balance readjusted (controls labeled R.BKG, G.BKG, B.BKG at rear of main board).

**Symptom: No picture, no high voltage; pilot lamp on or blinking:**

Replace flyback transformer. We have had many flyback failures, and have located a good source of replacements:

Component Resource Corp.  
15316 East Valley Blvd.  
City of Industry, Ca. 91746 1-800-366-1272

This company also has replacement flybacks for DEC VT-240 color monitors (actually manufactured by Amdek).

Before replacing flyback: Look for broken solder connection at flyback pins and deflection yoke connector.

The horizontal-output transistor appears robust; we have never replaced one, even after flyback transformer failure.

**Symptom: One color absent or displayed improperly.**

The large circuit board attached to the CRT socket contains the cathode drivers for each color. The large output transistors and their driver transistors often fail. Apply a test pattern (e.g., white-on-black text) and use an oscilloscope to compare the three color channels, to locate the failed component(s).

Before we discovered the most common problems of 8512 and 8513 and located a source of replacement flybacks, we had several repaired (with good results) by:

Circuit Test, Inc.  
12479 W. Hillsborough Ave.  
Tampa, Florida 33635

Connector pinout of IBM color VGA connector (model 8513):

1 Red video	9 Reserved
2 Green video	10 Ground
3 Blue video	11 Monitor sense (ground)
4 Reserved (absent)	12 Monitor sense (open)
5 Self test	13 Horizontal synch
6 Red video return (coax shield)	14 Vertical synch
7 Green video return (coax shield)	15 Reserved (absent)
8 Blue video return (coax shield)	

The "self test" line causes a white raster on the screen when the cable is disconnected. The video signals

are terminated at 75 ohms.

---

## 5. IBM 8514 MONITOR

Model 8514 appears far more reliable than 8512 and 8513. Relatively few of them are in use at this location, and they have needed little repair.

**Symptom: Squealing noise, vertically-unstable picture.**

Replace the small electrolytic capacitors in the power supply. Use high-temperature types.

---

## 6. IBM 5154 AND 5175 MONITORS

EGA (5154) and PGA (5175) monitors are nearly identical except for the video electronics contained in a metal box on the left side (when facing the screen). Schematics ARE available from IBM, in *Technical Reference, Options and Adapters, Volume 3* of the "Personal Computer Hardware Reference Library." Introduced in the mid 1980's, many 5154 and 5175 monitors are nearing the end of their service lifetimes, i.e., tubes have dim picture and poor focus, and numerous capacitors' values have decreased. In severe cases, we advise users to scrap the monitors and convert to VGA.

The most common failure is in the power supply: Symptoms include chirping noise, repetitive startup/shutdown (blinking LED pilot lamp) or jagged edges on left and right of picture.

Replace three small electrolytic capacitors in the power supply: C11 (47uF 40v), C13 (10uF 35v) and C14 (1uF 35v). These capacitors fail from heat after long service.

The power-supply unit is removable. You must drill-out three pop- rivets to open the metal box; replace them with sheet-metal screws.

**Symptom: Vertical foldover in EGA mode, or incorrect vertical centering.**

Replace C311 (100 uf 40v) near vertical amplifier (IC300).

---

## 7. IBM 3192 CRT Terminal

My employer, an enormous state university, has found it very economical to discontinue maintenance contracts on about eight hundred IBM 3192 terminals and repair them in-house. 3192 repairs are generally trivial, however, the assumed importance of the administrative functions for which they are used makes it extremely expedient to keep an adequate supply of spares available for instant replacement.

The 3192's color monitor has insides somewhat reminiscent of the 8512 and 8513 VGA monitors (see above).

### **Case Removal:**

The back cover of the monitor is held by two screws on the bottom and two plastic spring-clips on the upper left and right sides (visible with flashlight through rear ventilation slots). Use two L-shaped tools (e.g., back-plates from IBM PC), inserted through upper ventilation slots on the sides, to depress both clips simultaneously. Then lift the cover off.

### **Symptom: No power, blown fuse.**

The de-gaussing thermistor has probably shorted. This is the most common failure we have encountered in 3192's. The thermistor is identical to those used in 8512 and 8513; see above. Before replacing fuse, use analog ohmmeter, or diode-test function on DVM, to check the junctions of the two large power transistors in the power supply section. Alternatively, measure resistance across the line-voltage filter capacitor (C107) with power OFF and capacitor discharged. The resistance should be greater than 500 ohms.

An intermittent "flutter" of the display can indicate incipient failure of the de-gaussing thermistor; it is supposed to conduct current through the de-gaussing coil for a few seconds during initial power-on. Prior to failure, it may begin to conduct during normal operation after warmup.

### **Symptom: No picture; repetitive clicking or beeping sound.**

Bad part: High-voltage divider (the assembly between the flyback transformer and the CRT anode), IBM part number 6405282 (about \$20).

Replacement is easy: Unclip and unplug the ends going to CRT and circuit-board. Pry the red plastic retaining ring out of the flyback transformer; save it for the new divider assembly.

We have had difficulty obtaining voltage dividers from IBM; an equivalent is available from Component Resource Corp (see address above), same part number. Its red high-voltage wire is larger in diameter than the original component: Use a 11/64" drill to enlarge the hole in the red ferrule on the flyback; use a flat file to reduce the bumps on the sides, and use a rat-tail file to make the split part of the plastic thinner.

Voltage-divider failure causes additional damage in about 50% of 3192's:

**Symptom: Vertically-rolling picture (no vertical synch) but video is present over entire face of tube.**

This symptom often appears after the HV divider is replaced. The bad component is IC303, which is a 7406 (TTL open-collector hex inverter). Installing a 14-pin socket at IC303 may be advisable.

Horizontal-synch problems may also result from failed IC303 (7406).

A severely-shortened voltage divider may pull power-supply voltages to low levels, resulting in the unit appearing dead (no pilot-light) although the fuse is intact. Disconnect the red HV wire from the flyback transformer, then apply power. If pilot light illuminates, replace voltage-divider.

---

## 8. 3192 MAJOR MELTDOWN

A 3192 left on for a long time with shorted high-voltage divider will destroy multiple components in succession without blowing the fuse. All these parts may be bad:

Switching transistor Q201 (2SD1441 or 2SD1739 **\***)

Driver transistor Q101 (2SD836)

Look for burned transistors or other signs of high heat.

Flyback transformer (about 25% of cases)

One or both 0.82 ohm 5w resistors

7406 (IC 303)

Vertical amplifier TDA2653.

[\*] Newer models of 3192 are recognizable by a lighter shade of green circuit board with a smaller parts count and natural-aluminum heat sinks (instead of black anodized). The power-supply switching transistor is 2SD1739 (ECG2324 equivalent) instead of 2SD1441. These types are not interchangeable because 2SD1441 contains an internal damper diode.

**Symptom: Power supply dead, no pilot light.**

Check diode D210. In the new model it is a plastic diode instead of ceramic, and several have been found shorted. Other power supply components (listed above) may also be damaged. D210 must be a fast-recovery type diode.

**Symptom: No vertical synch, horizontal line in center of tube, possibly with deflection above or below line.**

Bad part: Vertical amplifier (TDA2653A: large IC on heat sink). Sometimes fails along with power supply, voltage divider and IC303, as described above.

**Symptom: No video but high voltage and sweep are present.**

Check Q204 (nnp), Q203 (pnp), or IC201 (7812; 20v in, 12v out). The front-panel contrast pot controls Q404 which biases the video drivers on the CRT board. Q204 and Q203 are powered by +12v from IC201. Failure of any of those three devices will cut off video.

Most 3192's have proprietary-numbered integrated circuits. By inspecting numerous units, we have compiled a list of industry- standard numbers:

IC201	7812	+12v regulator
IC301	TDA2582	(rare failure makes power supply inoperative.)
IC302	74LS221	function?
IC303	7406	vert. and horiz. sync buffers
IC401	LM723	voltage reg. IC for +5v; drives Q404.
IC501	TDA2653A	vertical amplifier.
IC800	LM320T-12	or 7912 (-12v regulator)
IC801	?	function?

---

## 8.1) Other semiconductors

D401	MUR815	high-speed rectifier for +5v supply.
Q101	2SD836A	power supply switcher
Q201	2SD1441	power supply switcher
Q203	2SA1127	(pnp) failure causes loss of video.
Q204	2SC1685	(nnp) controls contrast via front panel pot.
Q301	2SC1685	
Q302	2SC1685	
Q401	2SD1441	horizontal output
Q403	2SA777	
Q404	2SD1442	+5v pass transistor
Q405	2SA1127	
Q409	2SC1685	

---

## 8.2) Video drivers on CRT board

Q604,5,6 2SC17890

Q601,2,3 2SC2258

Connect terminal to the appropriate communications system and adjust the picture as needed, before replacing the back cover. The upper knob on the flyback transformer is CRT focus, the lower knob is screen voltage (a.k.a. "sub-brightness").

Power switches commonly fail in 3192's. The switch (part number 8233403) is available from IBM. Since 3192's are rarely turned off, it is practicable to remove a broken switch and solder wires between the circuit-board pads in order to return a unit to service temporarily if new switches are not in stock.

25-pin connector on back of 3192 CRT unit

1, 4, 5, 13, 14, 16, 25	GND
2	+12v
3	-12v
6, 10, 11, 12, 19	?
7,9	+5v
8, 15, 20	NC
17	vertical sync
18	horizontal sync
22, 23, 24	video (3 colors)

---

## 9. Cable A603 to CRT board

1	+5v
2, 4, 6, 8, 10	0v
3, 5, 7	video (3 colors)
11	+123v
12	+65v
13	+90v
14	3-6v front-panel contrast control via Q204.

# Repairing Philips 20/21 Inch Monitor Horizontal Output

**Version 1.00**

**Copyright (C) 1998  
Frank Gentges AK4R  
--- All Rights Reserved ---**

**Corrections or suggestions to: [gentges@itd.nrl.navy.mil](mailto:gentges@itd.nrl.navy.mil)**

**Reproduction of this document in whole or in part is permitted if both of the following conditions are satisfied:**

- 1. This notice is included in its entirety at the beginning.**
- 2. There is no charge except to cover the costs of copying.**

**Notice**I release this text file and the schematic drawing under the concept of the GNU copyleft as being mine and must be identified as such. You may not claim it as your work but feel free to add and improve it. No charge other than a nominal media charge of less than \$6 can be made for it. Enjoy and spread this information freely. Hopefully some more of these failed Philips monitors can once again be brought to life for someone to enjoy.

---

## **Introduction**

A little background first. A Phillips C2182 21 inch monitor failed with the horizontal folding around one edge but still working otherwise. First it was sent to Philips repair that returned it because the main printed circuit board was no longer available. They do not troubleshoot the board to the component level and the monitor was returned as dumpster fodder. I then took a look at it even though I am not in the repair business because I saw it as an interesting challenge and a way to get a great monitor.

The monitor worked fine at lower resolutions but the edge was compressed the last quarter inch instead

of folding around as had been seen earlier on another computer. The only visible failure was a burned 1/8th-watt resistor.

Philips has a maintenance manual for this monitor but it only has "functional schematics" which do not include the detailed schematics of the horizontal output circuit. These functional schematics do include a lot of useful information including PC board ID numbers so it is useful for finding the horizontal output area. I recommend getting one of these manuals and Philips seems to have a general policy of having reasonably priced manuals on their monitors which many other makers do not.

I also got the Philips manual they used in a monitor repair course that was mentioned the monitor repair FAQ. While it had a lot of good information on monitors in general, it did not mention the totem pole type of horizontal output circuit in this monitor.

It was apparent that a detailed schematic would be very useful to guide troubleshooting but if I wanted it I would have to reverse engineer it. The alternative was to search out bad components with an ohm meter part by part and hope I had found them all. I rejected this and as it turned out, I was right, as I needed this information to understand and finally diagnose the failure and really fix it. I removed the printed circuit board and traced out the circuit over three evenings with short bursts of tedious work.

## Description of the Horizontal Deflection Circuit

The [Horizontal Output Circuit](#) is an arrangement of 3 high voltage, high current power FETs in a totem pole circuit. When the bottom FET turns on, the next starts turning on and finally the third turns on. This way Philips could get a 1500 volt 30 amp output circuit. This is a demanding requirement that Philips could not meet with a single output device.

The power FETs used are each a Toshiba 2SK1544 and the data sheet was located on the Toshiba web site in Acrobat format (2sk1544.pdf) although the site no longer lists the data sheet for this device. This is a 500 volt 30 amp device that is quite hefty.

The FETs are driven by Philips BC237 bipolar PNPs, a rather unremarkable transistor. They were marked "C327" and a tiny "PH" was seen. Considering that Phillips made the monitor, a search of the Philips web site was made. It was located at [BC237 Datasheet](#).

Fast soft-recovery controlled avalanche diodes are used in the circuit and are each a Philips BYV96E. The diode data sheets were found on the Philips web site in Acrobat format at [>BYV96E Datasheet](#). These were useful in understanding the circuit and its limits.

## The Failure

The obvious failure was in the upper Power FET that was shorted between source and drain. The two diodes, V801 and V807, transistor V809 failed along and resistor R805 was a crispy black color.

(At this point I pleadingly remind the reader about all these high voltages and currents in this monitor and assure you I, as anyone should, proceeded with great care to avoid damaging myself or the monitor beyond repair. Pleading off.)

With the upper power FET shorted, the output circuit was only rated at 1000 volts rather than the 1500. At 1280x1024 a scope showed a 1200-volt peak voltage using a special 2000-volt probe. The drive voltage to the other side of the horizontal yoke went up a down with the horizontal width adjustment and as expected, so did the peak voltage on the horizontal output circuit. (The horizontal width is adjusted by changing the D.C voltage on the horizontal yoke from a switching power supply on the mail board.) Similarly, the peak voltage on the horizontal output circuit went up with the horizontal scan rate. At 1600x1200 it would fold on the edge and other components would fail soon from breakdown stress.

## Discussion

It appears that the horizontal output circuit was starting to break down at the observed 1200-volt level. This explains how slightly different scan rates would either compress the edge or turn the edge on around at a slightly higher rate.

But this superb monitor should not be sentenced to its remaining life as a lower resolution monitor. The failed parts were replaced. It worked for a few minutes but when it was raised to the full 1600x1200 resolution it once again started folding on the left side and then suddenly R805 gave out a spectacular flash and smoke signal. After removing the P.C. board it was found that the power FET along with all the previously failed parts had failed again.

On reflection, it appears that C801 was causing the failure. This capacitor has a high frequency high voltage across it giving rise to considerable A.C. current. The MKP378 series capacitor data sheet was found on the Philips web site at [MKP378 Series Capacitor Datasheet](#). On examination it was restricted from use as "resonance capacitors in fly-back applications" in the [Application Note](#). The [MMKP376 Datasheet](#) on the other hand indicated that capacitor's suitability for deflection circuits.

I suspect they discovered that the MKP378, while working, had too many failures in this stressing mode and modified the design to make the MKP378 series which would not be so prone to these failures. In the construction of these capacitors a number a individual sections are bussed together in parallel. Problems in this bussing could cause some sections to disconnect due to heating from the high currents and the reduced capacitance would let the voltage raise on that section of the totem pole. When C801 was removed it measured 2 nfd. low which is consistent with sections becoming disconnected but would not explain the failure alone. Unfortunately, it is hard to generate the high currents in a test setup to demonstrate this failure theory. But the absence of failure after replacing it would seem to validate the theory.

## Repair

The high-speed diodes and driver transistors are available from Philips and the power FET is available

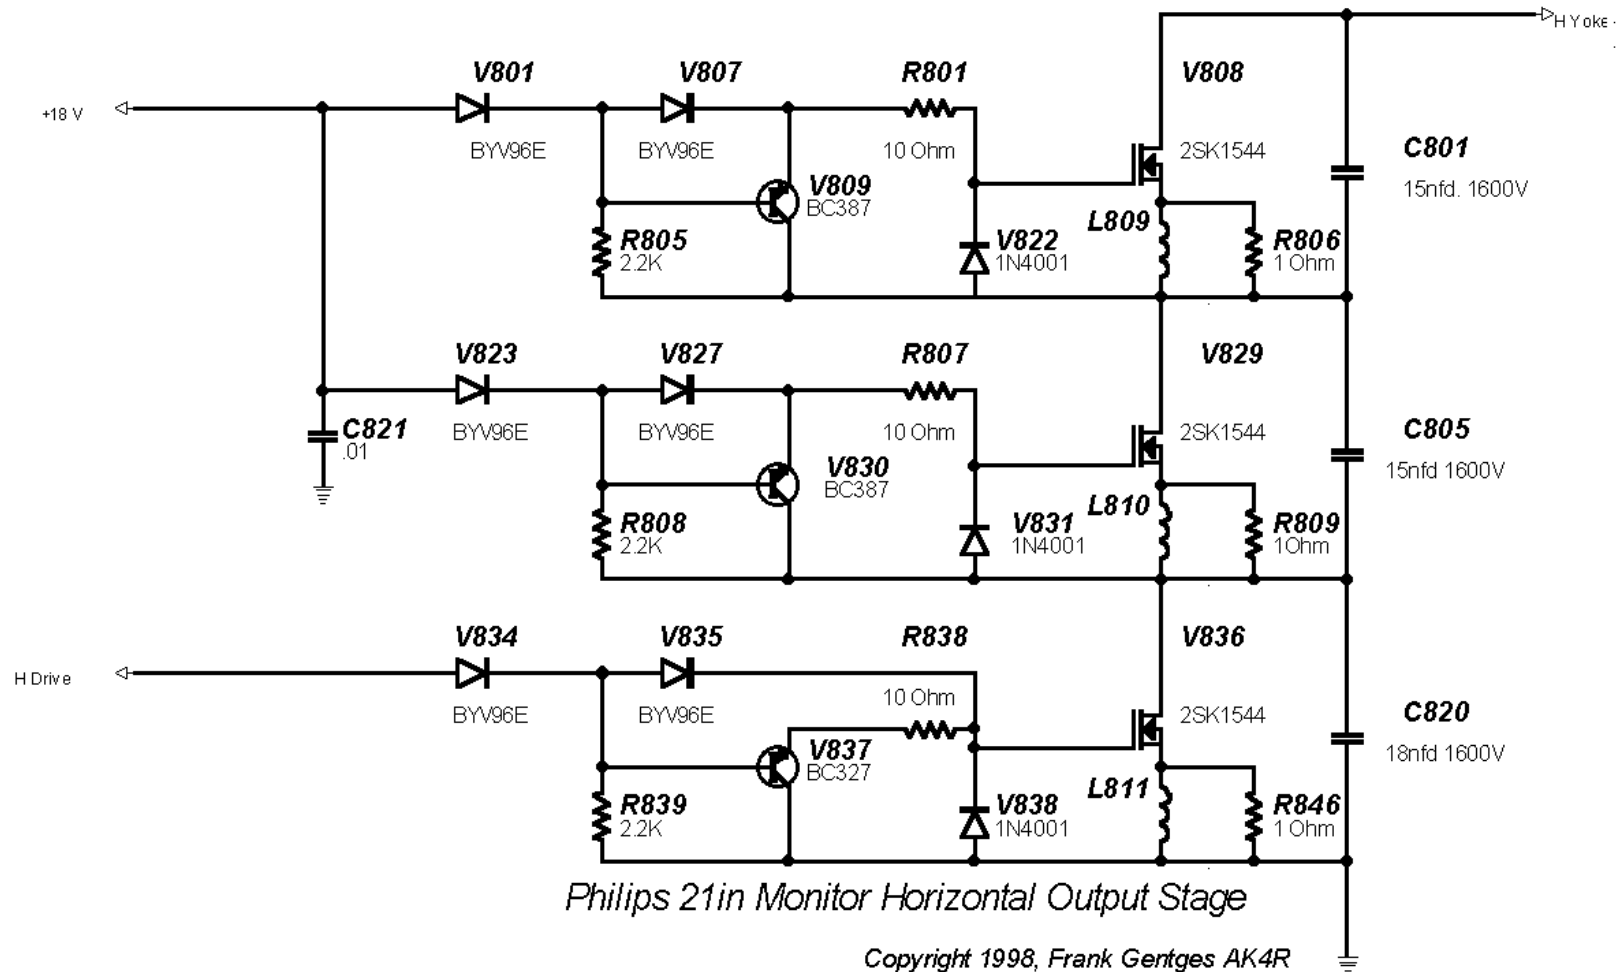

from MCM. Philips can be reached at (800)292-6066 and MCM can be reached at (800)543-4330. The Philips number can also be used to obtain the maintenance manuals for the C2182 and the C2082 mentioned earlier.

While the Philips parts site had come up with the BYV96E diodes and the BC327 transistor they had no listings for the capacitors. In the meantime a failed monitor which had had a life of daily service was found. The capacitors were cannibalized. They were in a sequence of 18, 18, 22 nfd. sequence rather than the 15, 15, 18 nfd. sequence in the original monitor. The p.c. board had a higher revision level so the new sequence may have been related to finding a solution to failing capacitors. I would be interested in hearing from anybody who knows how to buy these capacitors especially the MKP378 series.

Since the manual does not include the detailed schematic of the horizontal output stage it is available as a hand drawn GIF file. I know the main circuit board where this section resides is also the same part number as the one for the C2082 which is a Trinitron" version of the monitor. The C2082 was OEM'd to Compaq as a Q-Vision 200 monitor. It was also OEMed to DEC with DEC markings as a FSR871CV. I also suspect it is the same if not similar to other Philips 20 and 21 inch models and probably also OEMed by Philips to others. An additional problem was encountered during this repair. To change out the power FET required removing the heat sink and replacing it. The sharp edges of the new power FET next to the silicone insulator sheet gouged enough of a hole in the sheet to cause a high voltage break down since that power FET was at 1600 volts for a short period of the horizontal sweep. It required a replacement from the cannibalized monitor. It would be wise to use a little sandpaper to round the edges of the new power FET before installing it onto the board. During assembly into the monitor be sure that the mounting holes for the P.C. board and the heat sink line up to avoid sliding the heat sink in relation to the P.C. board.

\*\*\*\*\*

**WARNING! DANGER! WARNING! DANGER! WARNING! DANGER!**

\*\*\*\*\*

Power supplies contain lethal voltages. That means they can kill YOU. Yes, YOU! Unless YOU are especially cautious, YOU won't wake up tomorrow. Pretend you are playing with a nuclear bomb. A bomb can't kill you any deader.

If you don't understand electronics, don't bother with power supplies. This is analog circuitry, not cookbook logic stuff. You need to have a feel for currents and voltages and waveforms, or you won't be able to figure out what's happening. Find some circuit nerd (like me) who needs some software written, and swap services. Don't risk your life unless you know what you are doing.

Power supply repair is a challenge, like mountain climbing. Probably about as dangerous. Allow adequate time (3-4 hours, plus trips to the parts store), don't attempt it while tired or distracted, and have the right tools available. Make sure somebody is around to haul you to the hospital if you zap yourself.

If you DO hurt yourself, in spite of my warnings, I am NOT responsible. I never posted this, my signature is forged, the important parts got deleted by your newsfeed, etc. If you can't take responsibility for your own life, don't repair power supplies.

## 1.3) About

I've fixed about 40 of them. The broken ones were all broken by bad design or sloppy manufacturing - inadequate component choice, usually. If you want to fix one properly, you will need to be able to find heftier components that still meet the other design goals - made somewhat easier by the advances in components. A proper repair involves a little design.

You will need access to a semiconductor curve tracer, or else be ready to build a lot of ad hoc kludges for pulse characterization of components. Most of the power components that fail will have no easily available direct replacements. Looking at some components with DC sources can cook them.

You will also need an oscilloscope ( 5MHz bandwidth will do ), a voltmeter, and access to a huge pile of power transistor and diode databooks. National Semiconductor, International Rectifier, Texas Instruments, Motorola books will probably do; you may need SGS Thompson, Siemens, and Signetics for some regulator chips.

Without a schematic, be prepared to spend some time tracing out circuits. If you live in East Armpit, Nebraska, you probably won't be able to find the components you need, so give up now.

An isolation transformer and a Variac are handy. Also a pile of power resistors from which you can build a test load. A bench supply to externally power the secondaries is useful, though I use the curve tracer for this.

---

# 1.4) Further Information

[\[Notes on the diagnosis and repair of small SwitchMode Power Supplies\]](#) (SMPS) V2.23 - written by Samuel M. Goldwasser. This is an excellent guide to just about anything you may want to know about switching power supplies. A **Fil's Must-Read!**

---

## 2. General Guidelines

1. Put at least two switches between you and line. Unplugging counts as one switch. You are human, and you will forget one switch from time to time. Forgetting shouldn't have to be lethal. Take off watches and metal jewelry. Hell, get someone else to do it. Life is too short anyway. If you are a professor, find a gullible grad student :-)
2. Check the fuse. Keep plenty on hand - you may end up blowing a dozen or so. About a third of the time fuses blow for no reason at all.
3. Is everything hooked up and switched properly? I've seen a PhD spend 4 hours debugging a simple little box that "should work but didn't". When I innocently asked "what does this little switch do?" he thought for about 10 seconds and turned the prettiest shade of red...
4. Good designs rarely fail. If it is broken, it is because of an idiot engineer, most likely. Don't assume anything is designed right; if a circuit you've traced out can't possibly work, check it again. If it simply LOOKS stupid, you have discovered a fundamental truth about some power supply designers. There are lots of good power supply designers out there - I've rarely had a chance to explore their work, because I've never had to fix their designs.
5. A toasted resistor means something else failed first. Figure out what could toast the resistor, or you will toast another one.
6. Buy extra replacement parts. You will blow a few things up during debugging.
7. Before firing the supply up, figure out the primary circuit. Typical switched 115/230V supplies have a full wave bridge and two filter caps, resulting in about 340 volts DC on the primary. Make sure there is a discharge path through a power resistor - if not, temporarily solder one on while you work on the supply. A 20K ohm, 10W resistor will discharge a 1000 uF primary in about 1 minute. You can switch in a smaller value resistor for faster discharge, but you will probably forget to turn it off, and end up blowing it up when you turn the supply back on. In any case, get rid of the primary side voltage somehow before you mess with things.

8. When building test loads, load all the supplies. Some switchers get unhappy if there isn't at least a trickle of current on each supply. A 20% load is often adequate.
9. When you think you have the supply fixed, run it up and down with the Variac; run it up to at least 1.2X normal line, if you can. Note: some switchers get very unhappy with 0.5X line - see note on stupid designers above. If you end up breaking it this way, at least you know what will happen during brownouts. If the result is overvoltage on the outputs (I've seen this once) then throw the supply away, and kludge on a different design if possible. Overvoltage eats expensive equipment.
10. Anything can be fixed. Sometimes it's too much work. Be willing to give up.

## 3. What usually fails

The things I have seen fail, in order, are:

1. Electrolytics. Switchers put a lot of AC current into electrolytics, many of which aren't designed for this treatment. The capacitors cook, and either short out or unweld themselves open. The nastiest failure is an "almost open" that opens and closes itself at line rates (I've encountered a couple of those - murder to diagnose).

One capacitor failed on the input side of a pi filter on a secondary:

This was on the 5 volt supply of a 5V/12V switcher, the regulator worked off the filtered 5V. When the indicated capacitor opened, the inductor swallowed most of the switching voltage from the transformer and diodes, resulting in the regulator kicking in much harder to try to make 5V on the other side. This put 35 volts on the allegedly 12V supply - as a result, all the 16V tantalums on the 12V supply got blown out, as well as much of the stuff hooked up to the 12V supply.

The reason for the pi filter in the first place was too much ripple on the supply - the reason for too much ripple was the high ESR of the capacitors used. I replaced with better capacitors.

Replacement: Don't just go for the same voltage and capacitance. You need low ESR, and if the first one failed, the second one will too. One sorta brain-damaged way to get low ESR is to use

more capacitors - and possibly more capacitance - wired in parallel. You can get some idea of ESR with the curve tracer - with a small voltage ( approx 200mV ) AC drive, a low ESR cap looks like a circle, while a high ESR cap looks like an ellipse from the resistive component. Look for high temperature ratings, too - at least 105C

If there are any power resistors sitting right next to an electrolytic, move them enough to get airflow between. Electrolytics are too damned temperature sensitive - most are rated to only 85C.

2. The main switch transistor(s). Usually a TO3 power transistor. These usually fail because something shorted things out (there should be a current sense shutdown, but this involves buying another 5 cent resistor; too expensive :- ( ). These also often fail from inadequate voltage rating.

These are usually the easiest component to check, assuming a curve tracer is available, even if they are less likely to fail than one of the 10 or so electrolytics. I pull the transistor and check it before trying anything else. If the transistor works, write down some of the curve tracer measurements. You may accidentally fry it during repair.

You will want a transistor that can stand off at least 1.5X the peak primary DC voltage, preferably 2X. You will need to find what the current rating of the transistor you pulled out is, and meet that with the replacement. When you are looking for a replacement, find a new transistor with:

- o Same type - usually NPN, non-darlington
- o Same case
- o Better voltage rating
- o Better current rating
- o Similar Beta/Hfe/Current Gain
- o Same or Higher Ft
- o Same or lower capacitance

Advances in components make finding an adequate replacement possible. Curve trace the replacement.

3. Secondary diodes: I've lost a few of these. The result of a diode failure is usually an imbalance in secondary voltages.

Replace with:

- o Same type - usually Shottkey diode
- o Similar case (you may have some latitude here)
- o Better voltage rating
- o Better current rating (make sure with curve tracer)
- o Lower capacitance

4. Regulator ICs - these rarely fail, but a manufacturer can get a bad batch. The result is a whole bunch of the same supply type failing. There are so many different ways a regulator can fail that

you will just have to figure it out; though a supply that goes tick ... tick ... tick may have a broken regulator chip, if you can't find anything else wrong. The ticking noise means the regulation loop is broken somewhere.

You may have a heck of a time finding a replacement. An exact replacement is required. Socket the replacement. Use a good socket that grips the chip tightly - thermal excursions can walk an IC out of its socket.

---

## 4. Techniques for repair

1. Check the fuse.
2. Dust the damn thing, with kleenex and Qtips. Of course you've never changed filters on the fan. Dust kills power supplies. After this, you'll change them.
3. Look at a working version of the supply, if any are available. Get a schematic if you can. Apple and Sun are lousy for schematics, HP is good. Clones are impossible.
4. Look for all the usual visual stuff, open traces, shorts, burned components.
5. Disconnect the supply, writing down somewhere where all the connectors go and which direction ( if I need to be telling you this stuff, you aren't qualified). Don't use the regular circuit as a dummy load, though you may want to find out how much current it draws, to help you build test loads. Use a bench supply for testing the regular circuit.
6. Power up the secondaries - one at a time, with an external voltage source - first. Look for shorts. Drive capacitors with curve tracer AC. Look for ESR or opens.
7. Load the outputs at about 20% of full load. Power up the primary with curve tracer in AC mode, slowly, to about 40VAC. You should be able to watch the primary capacitors charge up. This finds primary shorts and capacitor opens.
8. If you bring the supply up to full input and nothing happens, check for primary voltage - usually 340 volts. If the supply is 115 volt only, and there is only one capacitor, there is probably only 170 volts across it.
9. If there is voltage, AND the primary is separately isolated with an isolation transformer, locate the primary common, usually the lowest voltage on primary side (You traced the circuit, remember?). Hook the scope signal input to this point (at 50V / div, line sweep and sync ), there will probably be a significant AC signal here. Try connecting this point to oscilloscope ground with a 100 Kohm resistor - if the signal doesn't diminish, you aren't properly isolated. If it does diminish,

power down, disconnect, and discharge, ground the scope here, and power back up.

10. Check for oscillations around the regulator chip. If none, check for voltage. Switcher regulators are sometimes powered with their own separate little supply, or off a big power resistor from primary voltage. Sometimes they are powered with a little kickstart circuit from the primary, then a separate winding off the transformer. These are good for the tick...tick...tick type of failures. You may have to power the regulator separately, with a bench supply, to get things started.
11. From here on out, it's measurement, and debugging, and tinkering, and such. Let us know what you find wrong. Perhaps we can embarrass some manufacturers into doing a better job on their supplies.

---

**NOTICE:** Again - **and I repeat** - don't repair power supplies unless you are a pretty good analog circuit tinkerer, can act safely around high voltage, and have the right tools. Take the thing to a TV repair shop, instead. It would spoil my day to find out somebody with more ambition than sense took the above notes and hurt themselves trying to do something they weren't ready for yet.

## 2. Summary

I have yet to see a permanently **BROKEN/SNAPPED** DC2xxx/DC6xxx tape! In 99.99% of the cases,

the tape simply rolled off the spool. This can be fixed but takes practice and a bit of agility and patience. In the name of recycling and reducing the crap that's going into the land-fills, read this article and learn how to salvage these tapes

Besides, these tapes aren't exactly "inexpensive" either...

---

## 3. How does the tape work

Let's start off with the typical design of the tape cartridge and its contents.

Since the data on the tape is of great value and needs to be reliably read off for long periods of time, the cartridge is designed with reliability and quality in mind.

- The base of the tape is fashioned from a slab of aluminum. It not only provides a sturdy base for the steel guides and spool axles but also serves as a heat dissipator. Heat is generated wherever there is friction - the axles of the spools, the head rubbing the tape, and friction of the tape against the fixed guides. Heat, as you may realize, is detrimental to the tape's life and data-storage reliability. For example, the tape stretches more easily when it is hot - in fact, it may really snap!
- Various steel guides and rollers steer the tape from one spool to the other. Alignment is critical as the whole design of the cartridge relies on the fact that both the tape and the tensioning/drive belt are always within specifications.
- The transparent upper-case is made of very rigid and durable plastic which not only adds strength to the case but also serves to center the metal guides and rollers. The upper-case also has a movable door which protects the tape surface from the elements when the tape is out of the drive yet allows the read/write head access when the tape is inserted into the drive.
- The tensioning/drive belt is really something. I believe it was developed by 3M. It has to survive constant abuse and yet not lose its elasticity - the same can not be said of the common rubber band which crumbles to dust in a few months! This drive-belt is moved by the drive wheel and transfers this motion to both tape spools - making sure that they turn appropriate amounts - keeping the tape tension even.
- Unlike standard cassette tapes, where the magnetic medium is physically attached to both spools, the DC2xxxx/DC6xxx tapes use a completely different means of sensing when the rewind and fast-forward functions have completed. The tape has 3 to 4 sets of groups of small holes at both ends of the tape. These groups of holes are about one foot apart on the tape. The cartridge has a 45 degree "mirror" made of silvered plastic that provides a way to view the presence of these holes from the top and front of the tape.

(Trivia: some drives sense the distance between the holes and can determine the capacity of the tape!)

The front of the tape looks like this:

```
+-----+
| door      drive          |mirror| |
+-----+
```

The side view:

```

light source (LED)
  ||
+-----+
|                \ T| -> detector
+-----+
```

Where the "\ " is the mirror and "T" is the tape.

The light source has now been replaced with an IR (InfraRed - 900nm or so) emitter and an IR detector. These have many times the life expectancy of the old light bulb and CdSe (Cadmium Selenium photo-resistor) as well as much faster response.

As the tape rolls by, the sensor "looks" for light. This light only comes when the small holes in the tape scroll by! And this is how the tape drive knows when it is at the start or end of the tape. Oh, the group of holes at the start of the tape is known as BOT (Beginning Of Tape) and the end is known as EOT (End Of Tape).

---

## 4. What goeth amock

As you may have suspected from the above, anything that relies proper operation on sensors (especially un-enclosed, optical ones) is bound to have problems at some point of its life. Indeed this is what "kills" these tapes:

**DUST** blocks the sensor such that the controller **NEVER** sees the light though the holes at BOT or EOT. Since the tape is **NOT** physically attached to the spools, it simply rolls off!!!

**Note:** In some rare cases, a part of a label may have peeled off and stuck to the internals of the drive. In these cases, skill with a thin, flat screwdriver will come in handy - as you must get that crud out of the

drive. Only other way is to take it apart - which I do not recommend as these tape drives are made to be put together **ONCE** and tend to break **SOMETHING** during [dis]assembly. Hey, what do you want for < \$200?

The dust problem applies to almost all PCs which have a fan in the power supply which forces air out... The problem is that this air has to come from somewhere. While some of it does use the intended ventilation slots, a sizable amount chooses the path of least resistance. This is usually the floppy drives, the tape drive, and any other devices which permit free airflow from the outside.

---

## 5. Quick fix (for the tape drive)

Get a can of compressed air (avoid the CFC stuff, please) or blow real hard without splattering saliva all over the insides ;- ) and direct the air jet into the detector/mirror area in the figure (above)

This should dislodge any dust in the path of the light beam so that the BOT and EOT are correctly sensed. This is only a **TEMPORARY** solution as the dust soon begins to accumulate again...

There are no easy solutions to the dust-accumulation problem but Dave Fanger suggests the following:

"I have kept a piece of polyurethane foam, cut to the size of a tape cartridge, jammed in the drive to inhibit and filter any air that passes through. Seems to work fine."

---

## 6. "Save Thy Ass"

I do **NOT** take responsibility for your action. I am **NOT** responsible for anything you do. I am **NOT** responsible for any mistakes. I am **NOT** responsible for any omissions. I am **NOT** responsible for spelling errors. Quantities limited. Batteries **NOT** included. Prices are subject to change without notice.

My warranty to you: If you find that you have received an incomplete or garbled collection of sentences and paragraphs, you can connect to my WWW server and get a **FREE** replacement! The above paragraph will apply to that copy also. Happy? You better be ;- )

---

## 7. Hint

After fixing MANY tapes, I would suggest that you **NOT** try this fix on an important tape if it is your **FIRST** attempt. If possible, invest \$20 (or \$12 mail-order) in a new one, duplicate the problem, and only then experiment (on the newly broken tape). Then, when you feel confident, try the important tape.

---

## 8. Fix it

As for fixing the tapes - I have had 99% success (55-60 tapes). For this operation, you will need:

- Well lighted, clean, & flat table
  - Small, good quality, phillips (+) screwdriver
  - Toothpick or a Q-tip or **UNMAGNETIZED** tweezers
  - Small cup/drawer/container for the screws
  - At least 6 hours of sleep the night before (**VERY IMPORTANT!**)
- 

### 8.1) Procedure

- Wash your hands. No grease/dirt allowed! I mean it.
- If you have poor eyesight/hand coordination, **STOP NOW**.
- Most DC2120 tapes have 2 screws on the bottom and 3-4 plastic barbs. Remove the 2 screws and put them in the container.
- Hold the tape at the edges so that your fingers hold **BOTH** the plastic case **AND** aluminum base. With the screwdriver, pry the barbs out of the aluminum holes so that the shell and base separate. **DO NOT COMPLETELY SEPARATE THE BASE FROM THE SHELL**. Optimally, the barbs only have to **RELEASE**.
- Lay the tape, **BASE** down on the table with the drive wheel facing you.
- While holding down the aluminum **BASE** (from both sides), remove the top shell. **WATCH THE ACCESS DOOR CLOSELY**. **ALSO**, be sure the case does not catch any rollers and send them off the table (and into never-never land...)
- Lay the plastic case out of the way. Prepare the toothpick/Q-tip/tweezers
- Examine the **BASE**, layout of the rollers and tape spools, the tensioning [wonder] belt, and try to figure out the intended tape path: Off the full spool, around the metal corner guide, in front of the drive wheel & metal guide, around the other corner guide, and onto the empty spool.
- The end of the tape we are interested in is most likely on the full spool (held by static cling).
- **NOTE/WARNING**: When you are working with the tape (rolling/ unrolling) **WATCH** the rollers & tensioning belt **carefully**. These have a tendency to work off the guides and may cause the tape to "learn to fly" after some futile attempts to put things back in place (experience speaks - that's the 1% :-)
- Turn the full spool until you can see the edge of the end of the tape and peel it off with the toothpick or tweezers. **DO NOT UNROLL MORE THAN 3 INCHES! WATCH THE**

## **ROLLERS & BELT! EVERY FEW REVOLUTIONS OF THE FULL SPOOL, PRESS DOWN ALL ROLLERS TO RE-SEAT THEM!**

- Holding the end of the tape with your **CLEAN** fingers or tweezers, wrap the tape through the tape path (see above). **DO NOT YET ATTEMPT TO ROLL IT ONTO THE EMPTY REEL!**
- Make sure all the rollers are firmly seated at this time. This includes **BOTH** spools, the drive roller, **AND** tensioning belt!
- Once the tape is in the tape path, unroll **ONLY ENOUGH** for the end to touch the empty spool.
- Using the toothpick or tweezers, press the tape end to the empty spool and gently rotate the **EMPTY** spool 1/4 revolution. Did the tape balloon out off the full spool or did it progress with the empty spool? If it ballooned out, don't roll it back. Instead, help it [force it] onto the empty spool with the toothpick. All you have to do is get the end of the tape under the tensioning belt. After that, the tape should go on pretty easily. If it did not balloon out but rather spooled on the empty spool, you're 80% home.
- While doing the next step, listen for "**RUSTLING**" sound. That sound indicates that the tape edges are getting crumpled under the tensioning belt! If you hear it, roll the tape off the empty spool and start again (if you're bold [and, I'm just itching to say, "stupid"] you can ignore the sound and there's about 60% chance that the rest of the tape will go on correctly. I do **NOT** recommend doing this because of the other 40%....)
- Making sure that none of the rollers are working their way up the guides, and **SLOWLY** and **IN SMALL INCREMENTS** roll the tape onto the empty spool. Turn the **DRIVE** wheel not the spools! (This black wheel usually has 2 indentations just for this purpose)
- You should roll on **AT LEAST** enough tape to get to the **SECOND** group of holes. You may either do this while the tape is open (easier to do it faster) or assemble the tape and do it slowly with your finger on the drive wheel.
- Pick up the plastic case and, with one finger **OPEN AND KEEP OPEN** the tape access door. **THIS IS IMPORTANT!**
- While the door is open, align the tape's **BASE** with the **SHELL** and join them **GENTLY**. **WATCH THE TAPE!! MAKE SURE PLASTIC "fingers" ARE NOT CRUSHING THE TAPE!!** If you are sure that all is well, press down harder on the shell until you hear the plastic barbs **SNAP!** If they do not, pick up the tape off the table and squeeze it with your fingers until they **DO**.
- Make sure there is no gap between the base and the shell, insert 2 screws, tighten with screwdriver. **DO NOT OVER- TIGHTEN!** (the plastic columns may crack or shatter)
- Sigh Loudly and Grin...

---

## **9. Lesson**

Generally, after one of these experiences, most people will gladly pay the \$5-\$9 for a can of compressed air and clean the drive on a regular basis. There are exceptions but these are usually due to shallow gene pools ;-)

After fixing, say, 3-4 tapes, this article will make much more sense. Sure, some of the procedure could be

more clearly explained and you are welcome to add to this! Just e-mail any changes/corrections to me and I will add them in. Don't worry about formatting. I write in HTML which formats everything very nicely. That's how this copy was generated :-)

Note that other than some case differences, most DC6xx/6xxx series of tapes may be fixed in a similar manner. Ooh, Ahh...

### 1.1) 19" Hitachi (Sun) Color Monitor

(From Ren Tescher ([ren@rap.ucar.edu](mailto:ren@rap.ucar.edu)))

#### **PATIENT**

19" Hitachi-Sun color monitor, purchased at an auction for \$50. Hitachi HM-4119-S-DA-OL and Sun part number: 365-1073-01 (13w3 video connector)

#### **SYMPTOMS**

Vertical non-linearity (the text at the bottom of the screen was vertically compressed, going up it stretched until the top lines were 'above' the readable part of the screen)

#### **TESTING**

described below

Repair procedure: (for qualified electronic technicians only-please!)

- Unplug power cord and video connector

- Remove back cover (6 screws)
- Remove rear panel (9 screws)
- Remove top shield (10 screws)
- Remove circuit sub-assembly retaining screw at back bottom center
- Discharge CRT (!CAUTION HIGH VOLTAGE PRESENT!)
- Disconnect 2nd Anode
- Remove CRT grounding strap (1 screw)
- Unplug CRT socket
- Unplug degaussing coil
- Unplug Horizontal deflection coil
- Unplug Vertical Deflection coil

Lift circuit sub-assembly slightly at the rear and pull back. The assembly should slide out the back of the monitor chassis. Place circuit sub-assembly on the bench. Locate electrolytic capacitor C307 (it is on the bottom PCB near vertical deflection IC (IC300). Replace C307 (47ufd 35volt electrolytic) (I used a 50volt) noting the polarity of the old capacitor.

Reverse the disassembly procedure and test.

Adjustments: I found no adjustments were needed.

Elapsed time: The first one took most of the afternoon, the second one took about an hour.

**Disclaimer:** Lethal voltages exist inside monitors even after they have been unplugged, if you do not know where these voltages are or how to nullify them, do not attempt repairs yourself, but give this article to a qualified video service technician.

Much thanks to Jason Sodergren (jason@eng.wayne.edu) for pointing me in the right direction.

Service Manuals (~\$55US) are available from:

Hitachi America, Tel: (510)661-0777

We also have an HM-4119-S-AA-O (Sun part# 365-1000-01) with a similar problem. I just completed the repair on the above model and its procedure is the same. (It is the same faulty capacitor C307). This model was 4 years older than the other 2, but it is nearly identical inside. Also, thanks to Hitachi for building a good monitor and making schematics available.

Let me know of your Hitachi/Sony Sun monitor repairs and I'll keep a no-cost file available for all.

---

## 1.2) Magnavox CJ4047 WA21 TV set

(From the Editor)

## **PATIENT**

Magnavox digital-tuning color TV for a friend. Couldn't tell me how it died but promised to be patient with the time it could take me to fix it. That's was a GOOD thing. It's been 8 months :-)

## **SYMPTOMS**

Pre: Dead. Nothing. Well, a tiny squeal could be heard. Determined that the HOT was bad (not shorted). Post: While the TV works >PERFECTLY (sound, tuner, nice vertical line!) with the Horizontal Output disconnected (horizontal coil of yoke disconnected), with it in, high-pitched squeal.

## **TESTING**

Long story. Original part was on order for months when I finally said what the hell and got the non-insulated HOT. I used a mica insulator (hint) and replaced a cap in the HOT circuit. When bringing set up on a Variac, around 40V sparks could be seen around the HOT. Of course, I didn't make the connection, pardon the pun.

The TV was in good shape, as demonstrated by the fact that I could watch a nice, single pixel vertical picture with the yoke disconnected. The original HOT was not to be found so I had ordered the non-insulated version (after months of delay). I first suspected the yoke. I measured about 70 ohms for the vertical section but only 3.5 ohms for the vertical. However, I checked all the other TVs I have (waiting to be fixed) and was convinced that this value was acceptable (it varied from 1.8 ohms for a large 19" to 20 ohms for a monochrome monitor). So, that wasn't it. I then traced the circuit... as per Sam's guides, I next suspected the start-up circuit for the HOT... alas (sigh) that checked out. I DID find a slightly out-of-value cap in the PS, 250V 47uF had become ~15uF but replacing it did not improve anything (I was going on the assumption that the PS was going into over-current with the HOT in-circuit but worked fine without it).

Well, that was the end of the line. I then remembered the sparks when bringing the set on a Variac - **GET ONE NOW!** - and realized "Duh, maybe the insulator sparks at that low voltage but downright leaks at full voltage". This is one of those things that can't really be tested... so I dug up a strip of silicone rubber insulator and put it in place of the mica. Switched on the Variac: 30V... no sparks, gentle whine from the PS, 60V... HV UP (heart rate up), 120V... perfect picture!

The #%&\*@ problem was the mica insulator!

**Comments:** I was SO close to giving up... what kept me going was knowledge that everything BUT the HOT circuit was fine. I realized what was wrong after a few days of desperation... the mica insulator I used, a rather thin one, is great for low-voltage applications but it just isn't up to the task as a HOT insulator. Lesson learned. BTW, I looked over the original HOT (one of those plastic-encased versions that didn't need an external insulator) and, golly gee, a spark-etched burn (hole) could be seen on the back surface. If they had used an insulated HOT AND some insulator, this set would have still been working.

**Lesson:** Don't use [thin] MICA in HV apps or suffer weird and non-related symptoms and problems. I

used an over-sized strip of silicon rubber insulator... got it from some stripped device.

---

## 1.3) Dead Panasonic 'Color Point' TV

### PATIENT

Panasonic 'Color Point' TV, model# CT-3053

### SYMPTOMS

The symptoms were that it would work fine for about 15 minutes, then shut off. It would then have to cool off for awhile before it would re-start. Also, I noted that the remote was in particularly bad shape.

### TESTING

The usual, which didn't work... and then some real testing, still didn't work... and some more soldering fixes it.

Well, as luck would have it, someone gave me a Panasonic 'Color Point' TV, model# CT-3053. The symptoms were that it would work fine for about 15 minutes, then shut off. It would then have to cool off for awhile before it would re-start. Also, I noted that the remote was in particularly bad shape.

I opened 'er up, checked for any charge remaining on the caps (there was none), and gave it a look-see. First thing I noticed was the board had visual 'I've gotten hot' signs around a few resistors and a zener diode. One resistor's connections appeared particularly bad. I re-soldered all of these suspect connections, as well as the large connectors leading to the deflection, degaussing coil, etc. I put the back on (so the cat didn't get too curious ;-)) and plugged it in. Nothing! I removed the back and inspected my work again to make sure I didn't forget to plug a connector back in. A thorough check revealed nothing amiss. I slapped the back on again, plugged it in, and was rewarded with nothing. Alright, I said as I unplugged it.

I opened the back and began to trace the circuit on the input side. Two fuses checked out A-OK, as did the relay coil, the 4 diodes in the bridge, etc. Not having an isolation transformer handy, I didn't attempt to measure B+. However, since I didn't hear the relay come on, I could be certain it wasn't receiving B+. I then tested the resistance between the prongs of the plug and their corresponding places on the board, as well as all connections to/ from the main components in question. I put my meter across the prongs of the power plug to see if there was any resistance. There was 64 ohms! Aha! I said. I then attempted to find out exactly **WHERE** this resistance was coming from. Especially since it was so low. I carefully examined the input circuitry once more, and the only place hot was going on the board was to the relay and wait a sec... a jumper wire! The jumper wire then went to one of the board connectors that I thought previously was the degauss coil. Turns out it was really for a power transformer! I had spied the transformer earlier, but thought it was for the speaker, since this was an older TV. I then traced where the secondary went, and measured it. .1 ohms, it looks OK. I then spied yet another fuse. It checked out. So, I proceeded to trace this second power supply.

Leesee... one side goes to ground... other goes thru a diode... onto a cap and ground... to a transistor... hey! two of the leads on the transistor have little rings around them! I then move the leads with my

fingers, and they move back and forth in the hole. Whip out the iron and fix these bad connections, do another scan for bad joints, and slap the back on. I say something like 5 bucks says it'll work and plug it in. I hit the power button and the set comes to life!

Everything seems to be working great, so I slap the screws back into the back. However, I notice curious patches of colour on the screen. It seems to be in serious need of a degauss. Turning it on and off a few times doesn't fix the problem, so it's off with the back! Checking the degauss coil reveals that it's OK. The thermistor, however, isn't in as good of shape. I pull it out, as it's reading open. I find an identical unit in another junker and slap it in. A few good ons/offs and the set's as good as new!

Now that I got the set working, the remote's next. It seems to be OK, however a few of the buttons are punched through. (it uses an overlay) The buttons consist domes with little plastic spacers on top, covered by the overlay. Thank Glub that none of the spacers were missing! I paint the spacers black (they were white) and stick clear tape over them. Looks lots better than it did. So now I have a free TV to replace my older non-cable-ready one! :-)

## 1.4) Right channel dead in Sansui 2000X receiver

(From John Heinrichs ([jheinric@albedo.colorado.edu](mailto:jheinric@albedo.colorado.edu) | <http://ucsu.colorado.edu/~heinrich/Home.html>))

### PATIENT

Sansui 2000X receiver

### CONDITION

Purchased from a friend for \$10 if I can fix it. According to previous owner, right channel completely dead and left channel distorted. Chassis loose in wooden cabinet (obviously an earlier aborted attempt at repair). No manuals or schematics. This is a superb receiver, 85 watts/channel of clean, warm power. High-end unit in the mid-70s. Not only that, I had previously picked up a matching Sansui RA 500 analog reverb unit for \$6 at an auction and wanted to put the two together.

### APPROACH

I started, simply enough, by checking the output fuses. Right channel fuse missing, left fuse looks OK. Aha! Easy enough... Moved the left fuse to the right and put a new fuse in the right. Replaced the fuse, thinking this was gonna be a good story. Now to plug it in and see what happens. Right channel dead, but left plays great. That stuff about distortion must have been a mistake.

Next suspect - the power output transistors. Sure enough, two of the four transistors have a direct short from the base to the emitter. Pulled 'em out and hooked 'em up to a Heathkit transistor checker (they are 2SC1111s, so are NPN silicon). Leakage current at 100%. Being short on cash right then, I went to my parts stock and found a set of four MJ423s taken, I believe, from a junked laser power supply. According to the Motorola guide, they are also NPN silicon and have a significantly higher breakdown voltage (325 V) than the originals. This amplifier is a pretty simple design and certainly too early for the fancy Darlington push-pull amps we see today. So I'm pretty sure I can drop the MJ423s in with no problem. When I power up the amp again, still no change. With a gasp, I shut it down and pull out the replacements and check them again in case the real problem had fried them. They're OK,

Now I look a bit further. Are the low-value (0.5 ohm) power resistors discolored? No, but I pull out the

meter for an in-circuit test, which will work since 0.5 ohms is much less than the total resistance of the rest of the circuit. One of the four resistors is a dead short. Again, I go to the parts bins and find a great 0.5 ohm replacement (3% tolerance, no less) but the leads are too short. So I solder on some lead extensions and replace the bad one. Power up - now I'm getting a very weak

Tracing the wires backwards, there's a small circuit board (in a card socket, thankfully) that looks connected to the power transistors. So I pull the board out. **Aha!** A large black discoloration surrounds what's left of a 100 ohm resistor (the only way I can tell the value is by comparison with the duplicate circuit for the left channel). The resistor reads open, so I replace it, along with a nearby 0.1 microfarad capacitor that is a little discolored and has cracks in the outer insulation. Put

I start looking around and find a transistor that looks suspect. A cheap bent metal heat sink is glued to the transistor case with some brown gunk. Compared to the corresponding component on the left channel, the one on the right has an even darker color to the gunk, which looks crumbly. So I try the transistor checker (I have an in-circuit tester, which I recommend highly) and it shows a leakage current of about 30%. This one I manage to find in my guides and it shows a 2N2222A as a replacement. I've got plenty of these from earlier dissections, so no problem. After swapping this transistor out, the right channel comes up much better on headphones. Sounds mighty fine, in fact. So I hook it up to speakers. Now the right channel is highly distorted, which increases with volume. When I hook the right channel up to my scope, the waveform is distinctly clipped and only the negative signal excursions show up. Looks like the waveforms I get with

As I recall, I spent the next four hours or so checking every component I could on that little circuit board. I even went so far as to remove each of the remaining three or four active components and switch them between channels. No change - still distorts under a load. Then I started to do a detailed analysis of the circuit itself - actually developing a schematic - and discovered that the connections at the board edge were symmetric. Well, thank those engineers back in the 70s! I inserted the board into the connector reversed and again found no change in the distortion. Now I'm just about pulling my hair out. At

Now to look at every possible connection in the signal path. Speaker switch checks out fine. Only thing left is the output fuse. Fuse still looks good but, just to make sure, I replace it. **Voila!** No more distortion. Now it hits me that I switched the fuses before I turned the thing on at the beginning. There really was distortion on the left channel... I've never seen a fuse do this before - acting just like a diode, but only when a

All that remained was to clean up 20+ years of dust and spiderwebs on the inside, lube the pulleys for the tuning mechanism, and dig up some replacement machine screws for mounting the chassis to the cabinet. The cabinet looks like crap, but I'll deal with that later and do the reverb unit cabinet at the same time. Now I've got the receiver set up in my shop, and it really does look cool next to the reverb. The sound is excellent, and I have to confess I like the look of the old analog radio dial. Best of all, all the parts I needed were in

**Postmortem/lessons learned:** First, never change anything before the preliminary evaluation. I would have saved a lot of time if I hadn't switched the fuses around. Second, it would have also saved time to trace the entire circuit first and find all the problems (like the fried components on the small board) right

away rather than the progressive look/replace/test process I

---

## 1.5) Magnavox 4head HiFi VCR

(From Willis Chung ([NikonKidF3@aol.com](mailto:NikonKidF3@aol.com)))

### **PATIENT**

Magnavox 4head HiFi VCR comes in with chief complaint that it won't load and eject tapes consistently.

### **SYMPTOMS**

A quick look inside with the cover off confirms this. The tape inside will partially elevate, but will not eject. The machine will also not play the tape, even when it appears that it is all the way down.

### **TESTING**

With gentle finger assistance, the rental tape is raised and ejected while the VCR is trying to eject it. A scratch tape is used to confirm that the problem is repeatable. An examination of the mechanism in the under-carriage shows a single toothed drive belt. No slipping here.

Thinking that the tape elevator mechanism was sticking, I clean and lubricate the elevator assembly. Function does improve, but if a tape is loaded into the machine after a few minutes of inactivity, the machine fails to load it fully and fails to eject it. Once the tape is ejected with finger assistance, subsequent loading usually resulted in correct function, with the machine going into the half load position, and then

Thinking that there was something mechanical that was sticking, I poked and prodded at a lot of the mechanical parts, finding nothing wrong, nothing sticking. Thinking it was a mode switch problem, I took the mode switch out, disassembled it, and cleaned it thoroughly. Thinking the machine was not sensing the position of the elevator mechanism, I disassembled and cleaned the elevator position switches and verified their function. Naturally, none of these things changed the behavior of the

Stumped, I let the machine "season" on my bench for a few weeks. I fix

After posting the problem, I received several suggestions. #1 Check the elevated pinch roller mechanism for binding. I had cleaned and lubed this already, but I took a close look at it. No problems there. #2 Check the

Hooking up a scope to the outputs of the switch mode power supply shows massive ripple on the +15 volt line. Aha! Tracking the line back, I find a capacitor (470mfd, 16volts!). Soldering a 470mfd 35volt capacitor eliminates the ripple, and the machine loads and ejects like a champ. Examination of the other capacitors in the power supply reveals one more 16volt cap on a 15 volt power supply line. I replace this one with a 35volt one as well. Seems like the power supply was designed to fail

---

# 1.6) TTX 1450 SVGA Computer Monitor - Dead

(From Wilkin Claude ([wilkinc@odyssee.net](mailto:wilkinc@odyssee.net)), Edited by Samuel M. Goldwasser)

## PATIENT

TTX 1450 NI computer monitor

## SYMPTOMS

Gradual loss of brightness over several months followed by total failure.

## TESTING

Plug it in, dead, maybe some smoke...

A TTX 1450 NI monitor is brought to me for repair. Unit is from a family member who reports that monitor had been taking more and more time to show acceptable brightness when turned on. Monitor had been shown to a repair shop (person lives 200 miles from my home) that right away asked \$50 for an estimate and \$125 since the person there said (without opening the thing up) that it was the flyback or the picture tube that was defective. When I spoke to the family member and he told me of the story, I told him to bring me the monitor when he would come to visit me later that month if he didn't mind the wait. He decided to purchase another monitor and said if this one could be repaired for not too much money, he would use it to setup a computer just for his kids.

When I got the thing and plugged it, I saw smoke coming from some diodes and resistors on the board. One of these diodes was probably short, it actually glowed red! The thing would not show a picture, the power led in front would come on then turn off after about 2 minutes.

Visual inspection showed a swollen cap, a blown TL431 and a resistor so burnt that the color code could not be read. These looked like they were part of the switching power supply. The swollen cap showed a value of 7uf when tested, it should be 470uf. I have hope that the flyback or crt might not be the problem here after all...

Some components to be replaced could not be identified: that burnt resistor and two zener diodes. Time to get a schematic.

Luckily, TTX has an office right where I live. That schematic is available for \$15. No, it's not a service manual, it's just a legal size copy of the schematic. I find this a little bit ridiculous but I have no choice, several postings on the internet for the schematic or just to I.D. the components brings no replies for the info. I get the schematic...

Finally, I see the component values. I probe around some more, I see that 2 zeners (30V and 100V) in series in the power supply are short. I replace: 470uf Cap, TL431 regulator, 2 zener diodes and the burnt resistor.

I turn unit on. No smoke, power led on but no picture.

I do some more probing around. I find that the horizontal output transistor is bad and there seems to be a 100 ohms resistor (that what the color code looked like...) that's open. I find a replacement to the transistor for \$17 and change the 100 ohms 2W resistor. That resistor is in series with the primary of the flyback and the transistor. I suppose it when bad when the transistor shorted out.

I replace and turn the thing on. Hey! It works!...But wait, smoke again...I look around and see that the 100 ohm 2W resistor I put in is burning up...Time to look at the schematic.

My bad 100 ohms (so I taught) resistor is not on the schematic. I look there and I find a 1 amp. fuse. Exchanges through e-mail with other technicians brings speculation that 100 ohms is just not right. It's too high a value. I look at the resistor several times under different types of lighting and it always looks like a 100ohms...

I'm not going to blow another \$17 transistor. Time to call TTX.I speak to somebody technical over there. He says I can put a 2.2 or 3.3 ohm resistor there. I guess it was 1 ohm or something like that. I still have the thing here and it doesn't look that discolored and I've been reading resistors for a long time and it does look like 100 ohms.

I put in a resistor (3 ohms) and everything is fine. I'll have a happy nephew.

**Comments:** It's hard to determine what really happened here. Perhaps the 470uf cap changing value brought this on. Having so many components fail is rare...I finally realised that the 1 ohm resistor is probably a resistor-fuse sometimes found in TV's. I have had to purchase these, but they were rare and cost \$8. I guess that TTX guy I spoke too doesn't put one in too, he just uses

## 1.7) Dead 5 year old Sony TV

(From David Klementovic)

### **PATIENT**

5 year old Sony TV

### **CONDITION**

Failed to power on. tic-tic-tic from the PS.

### **APPROACH**

Had to be an overload or shorted component of some sort.

My client asked me to repair his 5 year old Sony television which failed to power on. I put it up on the service cart, plugged in the line cord and tried to power it on. I heard a tic-tic-tic sound coming from the switching power supply board F. A quick check of the power supply was done with the ohmmeter but nothing obviously shorted or open.

Then I removed plug F61 from the power supply board, pressed the power on button on the set and the switching power supply began to work, I could hear the audio amplifiers working through the speakers. Something in the television chassis was loading the power supply down. I metered the brown wire on plug F61 (B+ supply) and found it shorted to ground. Then I tested the horizontal output transistor Q503 and it was shorted.

I inspected the flyback and other high voltage components and seeing nothing else shorted replaced Q503 (2SD1941) horizontal output and Q502 (2SC2688-1k) horizontal driver with exact replacements. Now, I know that frequently horizontal output devices are over-stressed by some other defect in the chassis so I prepared for this possibility by removing B+ jumper wire JW-41, inserting a 5.6 ohm 10 watt resistor in its place and clipped my voltmeter leads across the resistor. This gave me the ability to monitor the current being consumed by the flyback transformer.

I powered up the set slowly using a variac and an isolation transformer, the picture was good. I adjusted the variac for 125 volts AC, set the customer picture controls on the Sony to midway, (brightness, sharpness) and the Trinitone to LOW. I tuned to a music video channel on cable in order to observe the

raster changing frequently from dark to light, and recorded a voltage drop across my 5.6 ohm resistor of 2.2 volts with a dark raster to 3.98 volts with a white raster.

After 10 minutes of operation, the voltage across the resistor began to climb even though the raster was fairly dark at the time. At 5 volts the right side of the raster began to shrink, and after about the loss of 3 inches of raster from the right side I powered the set off, alas there was more trouble in this set for me to debug. I inspected for problems with the scan-derived B+ voltages, pin cushion correction circuitry, deflection yolk and retrace tuning capacitor, nothing found defective! The troubleshooting breakthrough came when I replaced a 0.47 mfd electrolytic capacitor (C525) which coupled the horizontal drive signal into the base of the horizontal driver transistor and C537, a 4.7 mfd electrolytic capacitor in the horizontal driver circuits. These two capacitors had weakened and had resulted in the eventual failure of the horizontal output transistor. I checked the horizontal waveform on the base of the horizontal output transistor and it looked OK. So I removed the 5.6 ohm resistor, soldered B+ jumper JW41 back in the circuit and tested the set for 6 hours.

The Sony worked good and has continued to work good for my client for 3 months now.

## 1. Repeat Home Stereo with Blown output IC

One of the principal tenets of Kinsler Hi-Fi Service was:

### **The Customer is Always Wrong.**

I doubt that it's a matter of volume or bass: these things will limit themselves pretty well. What's happening is that the guy is short-circuiting his speaker wires. He's either got another set of speakers that he uses for parties that he's not telling you about, or he has a set out on the porch with which to serenade the neighborhood. There's a bum splice in the wire that he doesn't know about, doesn't care

They like to horse around with the speaker arrangements whilst under the influence, particularly at parties. Or his kids borrow the thing and take it to a friend's house and hook it up to the Christmas lights to try to watch them flash with the music. I am not making this up: I'll tell

The only way to protect yourself is to solder a couple of appropriately-sized fuses in series with the speaker lines. Put 'em inside the case, and **SOLDER** them directly in. If you put them in a fuse holder, the customer or his minions will pull them out, replace them with 25 amp car fuses, blow out the IC, then replace them with your 1 or 2 amp fuses from Radio Shack, and claim ignorance of the whole thing. Again, I am not making this up. When I soldered fuses in, I'd get the sets back with what were supposed to be my original fuses taped in with scotch tape. Once someone used a Band-aid. But generally the solder keeps them out of there. It's best, in fact, not to volunteer the fact that the fuses are in there at all. If there are speaker fuses in

The fuse size is a bit critical, of course. You can figure it out from the power and speaker impedance, but generally 1 or 2 ampere fuses are okay for anything that's made of plastic. Use regular-blow fuses, not slow-blow. Soldering fuses is easier if you use the Chinese ones that MCM sells--they're already soldered on the ends. Expect to occasionally lose a fuse when you're soldering it in, but you get good at it fast. If you use fancy fuses like Buss or Littelfuse, you have to file off the nickel plate from the ends to expose

the brass. That way, you can tin it quickly before the fuse wire detaches from the inside of the fuse. Enclose the fuse in a piece of clear, non-heat-shrink tubing. Or often you can solder one end of the fuse directly to the circuit board or to the speaker connector. You have to use some imagination. When the device comes back with the speaker fuses blown, just replace them at no charge--it's a fast job, and you'll know what's going on. Then you can start quizzing the customer about his **Experiments In Stereo Speaker Wire Science Whilst Intoxicated**. My favorite defense was, "No, I did **NOT**

Kinsler Hi-Fi specialized in crummy stereos for many years, and I put a pair of speaker fuses (and a power fuse, when that was missing) in just about everything that came in. I used more fuses than anyone else in New

## Chapter 1) About the Author & Further Information

[Document Version: **2.18**] [Last Updated: **9/15/96**]

### John Woods' List of Mail Order Electronics Companies

Author: John Woods, WB7EEL

E-mail: [jfw@proteon.com](mailto:jfw@proteon.com) or [jfw@jfwhome.funhouse.com](mailto:jfw@jfwhome.funhouse.com)

Revision: 2.18

Last updated May 2, 1995

Some updates/links by the Editor on release date.

It has been a while since I posted this, and some parts may be seriously out of date. I hope to be able to find time to verify more of this list soon and post any needed corrections. Note that updated copies are available via WWW and FTP from my home system, funhouse.com.

If you have any corrections/addition, please send them to me using this [\[Feedback Form\]](#) and I will

forward them to John Woods. Thanks!

This file, and many others, are available for anonymous ftp from [ftp.cs.buffalo.edu](ftp://ftp.cs.buffalo.edu/pub/ham-radio), in [/pub/ham-radio](ftp://ftp.cs.buffalo.edu/pub/ham-radio/mail_order) (this article is "mail\_order" in that directory). It is also available from my WWW server at URL:[http://www.funhouse.com/jfw/RF\\_PARTS.txt](http://www.funhouse.com/jfw/RF_PARTS.txt), and via ftp at URL:[ftp://ftp.funhouse.com/pub/RF\\_PARTS.txt](ftp://ftp.funhouse.com/pub/RF_PARTS.txt). The WWW copy is the one I edit, the ftp copy gets updated sporadically.

(From Filipg)

You can also get this list (usually current) in full HTML glory from [http://www.repairfaq.org/REPAIR/F\\_Mail\\_Order.html](http://www.repairfaq.org/REPAIR/F_Mail_Order.html)

I have also added/changed entries for:

- All Electronics (now on the WEB!)
- Electronic Goldmine
- Fry's Electronics

---

## 1.1) UK Sources FAQ

(From Alan R. Winstanley)

The latest version of my UK Sources FAQ gives more than 250 names, addresses and stuff of UK based manufacturers and distributors of components and services. This is subdivided into more 20 categories. All new entries are welcomed. You can download the UK Sources FAQ from: <ftp://ftp.epemag.wimborne.co.uk/pub/docs/uksource.txt> (60k)

---

## Chapter 2) Introduction

Here is my list of companies which will sell electronic components in small quantities. Many of these places I have bought from, several I haven't. Being a ham radio operator, I am most interested in RF components, and in particular, air variable capacitors, which tend to be scarce (and tend to be used or surplus even if I've otherwise labelled the seller as "NEW").

Categories are:

## **NEW COMPONENTS**

Distributors and sellers of new components, or "new and some used" in a couple of cases.

## **SURPLUS ELECTRONICS**

Usually overstocks, occasionally used equipment. Ideal for stocking the junkbox, usually have dependable stock lines of resistors, capacitors, and some semiconductors, but won't have those LCD modules forever... An invaluable resource, don't shy away from them.

## **SPECIALTY COMPONENTS**

In particular, crystals and toroidal cores.

## **KITS**

Ham radio kits, random electronic kits, whatever they have.

## **LITTLE GUYS**

Separated out because of some twisted sentimentality, I suppose. Intended to honor one or two ham spare-bedroom operations. Note that sending \$1 along with catalog requests is a big help for these folks.

## **PUBLICATIONS**

A small selection of publications dealing with electronics, especially RF electronics.

## **QRP CLUB PUBLICATIONS**

Clubs for low-power amateur radio enthusiasts; frequently have publications with quite a bit of technical content (which is why I'm a member of QRP clubs headquartered thousands of miles from where I live :-). Note, this is generally practical technical content (how to build it) rather than theoretical technical content (why it works), but definitely more than Contester's Quarterly.

**Note on shipping costs:** I don't always update these frequently enough, and they're generally for continental US unless otherwise mentioned.

[internal tag, please ignore]

---

# **Chapter 3) NEW COMPONENTS**

---

## **3.1) Digi-Key**

Digi-Key  
701 Brooks Ave. South  
.O.Box 677  
Thief River Falls, MN 56701-0677  
+1-800-DIGI-KEY (344-4539)  
+1-218-681-3380 (FAX)

No minimum, \$5 handling under \$25, free and very complete catalog, very nice indeed. Prices aren't always the best, but rarely excessive. Weak on RF specialty parts (though they now have the ever-popular NE602AN), but they do have blue LEDs.

---

## 3.2) Mouser Electronics

Mouser Electronics 11433 Woodside Ave. Santee CA 92071	Mouser Electronics 2401 Highway 287 North Mansfield TX 76063	Mouser Electronics 12 Emery Ave. Randolf NJ 07869
--	--	---

Mouser Electronics  
370 Tomkins Court  
Gilroy CA 95020

Catalog Subscriptions: (800) 992-9943 (Continental US only)  
Sales & Service: (800-34-MOUSER  
(800-346-6873) (US, Puerto R., Canada)

Very complete catalog of brand-new components (though no air variables). Usually quick service, \$20 "minimum" (\$5 charge under \$20). When ordering, you may want to be sure to ask about availability and shipping locations; they have several warehouses, and frequently orders will get sent from several warehouses (which drives up the shipping costs). Export orders have a \$100 minimum, except for Canada and Mexico.

---

## 3.3) Ocean State Electronics

Ocean State Electronics  
.O. Box 1458  
Westerly RI 02891  
+1-800-866-6626 (orders)  
+1-401-596-3080  
+1-401-596-3590 (FAX)

Minimum \$5, S&H \$4, \$2 for catalog. Wide array of RF parts, especially air variables and B&W coils. Reportedly getting a bit slow filling orders.

---

## 3.4) Radiokit

Radiokit (store is located at:)  
.O.Box 973 169 Jeremy Hill Rd.  
Pelham NH 03076 Pelham NH 03076  
+1-603-635-2235  
+1-603-635-2943 (FAX)

No minimum (\$3 service charge if under \$20), many kits, lots of J. W. Miller chokes & coils, B&W coils, RF switches, Millen variable capacitors, lots of parts in general. As of 24-Feb-94, they are again STILL out of catalogs, and just barely might have one by Dayton this year. They do accept mail orders, but you'll have to call for prices and availability. A classified ad in 3/94 QST says "Call/SASE", I guess they may have fliers.

---

## 3.5) Circuit Specialists Inc

Circuit Specialists Inc  
. O. Box 3047  
Scottsdale AZ 85271-3047  
+1-800-528-1417

No minimum with check or money order, \$15 otherwise. \$3 S&H. New electronics, good RF assortment, increasing infestation of computers.

---

## 3.6) Active Electronics

Active Electronics  
11 Cummings Park 237 Hymus Blvd  
Woburn MA 01801 Pointe Claire, Quebec, H9R 5C7  
+1-800-677-8899 (Main number for US and Canada)  
+1-514-630-7410 (International)  
+1-514-697-8112 (FAX)

\$25 minimum, \$5 S&H UPS, catalog has a "\$10 Suggested retail price" but they sent mine for free. They have 7(?) stores in the US (Chicago IL; Baltimore MD; Woburn MA; Detroit MI; Mt. Laurel NJ; Long Island NY; Seattle WA) and 10 stores in Canada (Quebec City; Montreal (2); Ottawa; Mississauga;

Winnipeg; Calgary; Toronto; Edmonton; Vancouver BC). Each store has its own 800 number and FAX number, call the main number(s). International orders are to be mailed to the Canadian address, but they want payment in US funds! Lots of stuff, oriented more toward supplying last-minute requirements of companies than hobbyists, but perfectly happy to take your money in small doses (stores have no minimum order). The \$25 minimum for certain items is no longer explicit, but they note that some items will "ship in factory minimum package quantities", which might be worse.

---

## 3.7) Maplin Electronics Ltd

Maplin Electronics Ltd.,  
.O. Box 3,  
Rayleigh,  
Essex,  
SS6 8LR  
U.K.

Phone numbers: your international code  
+44 702 554161 for sales  
+44 702 553935 Fax  
+44 702 556001 Tech enquiries(2-4pmGMT)

"Over here [in the United Kingdom] the main hobbyist electronics supplier is Maplin Electronics who stock a wide variety of equipment. They have a catalogue which can be shipped for 10.65 pounds sterling by air or 5.50 pounds sterling by surface mail. They accept Mastercard, American Express and International Reply Coupons. They have at least one type of air-filled variable capacitor!" (Thanks to Kev White at Cambridge University).

---

## 3.8) Newark Electronics

Send catalog requests to:

Newark Electronics  
ATTENTION CATALOG DEPARTMENT  
4801 N. Ravenswood Ave.  
Chicago IL 60640-4496

Tel: 1-800-4-NEWARK  
Tel: 1-800-463-9275  
Tel: +1-312-784-5100

Fax: +1-312-784-3850

International Fax: +1-619-691-0172 (Tel: 619-691-0141)

They don't have a single mail address or phone; instead, one is supposed to call the closest of three pages worth of branch offices. I don't feel like typing in the entire list (it's copyrighted, anyway :-), so send email for your "local" distributor, or call their administrative offices at the number above. They have a \$25 minimum order; they are a Real Distributor, but accept small orders (over the minimum, of course). Their catalog currently 1488 pages; they are very complete (except, of course, for my favorite scarce item, the air-variable capacitor). Note that the catalog prices tend not to match reality all that often, so order by phone rather than by mail; prices tend to be higher than other places, but they have a lot of things that are hard to find from other outlets. Also note that they have six Canadian offices, and one UK office, and will take international orders at 500 N. Pulaski St., Chicago IL 60624-1019, +1-312-784-5100 (FAX +1-312-638-7652, TLX 6718690 NEWARK U).

## 3.9) Arrow Electronics, Inc

Arrow Electronics, Inc.  
Catalog Division  
1860 Smithtown Ave.  
Ronkonkoma NY 11779  
+1-800-93-ARROW

Catalog requests to:  
Catalog Division  
25 Hub Drive  
Melville NY 11747-9828

Minimum \$25; **they no longer have a catalog.** They are a Real Distributor, but also didn't mind my placing a personal order (a couple of years ago).

---

## 3.10) MCM Electronics

MCM Electronics  
650 Congress Park Drive  
Centerville OH 45459-4072  
+1-800-543-4330  
+1-800-824-TECH (product questions)  
+1-513-434-6959 (FAX)

Minimum \$20 (\$25 for charge cards, and they don't take personal checks), handling \$1.95 + shipping. Oriented toward repair technicians, really heavy on VCR parts and somewhat overpriced doodads, lots of useful stuff not easily found elsewhere.

---

## 3.11) Fordham Radio Supply

Fordham Radio Supply  
260 Motor Parkway  
Hauppauge NY 11788-5134  
+1-800-695-4848

Tools for technicians. One or two items are not outrageously overpriced.

---

## 3.12) Jameco

Jameco  
1355 Shoreway Road  
Belmost CA 94002  
+1-800-831-4242  
+1-800-237-6948 (FAX)  
+1-415-592-8097

No longer have a minimum order, reasonable selection of parts again (in addition to computer components).

---

## 3.13) JDR Microdevices (Just moved!)

JDR Microdevices

Just moved!

1850 South 10th Street

San Jose CA 95122-4108

Orders: +1-800-538-5000

+1-408-494-1400

FAX: +1-800-538-5005

+1-408-494-1420

Cust. Service: +1-800-538-5001

Tech Support: +1-800-538-5002

BBS: +1-408-494-1430

No minimum, \$5+ shipping. Mostly computers now, but they haven't yet decided to abandon components; indeed, they recently dropped their minimum order requirement entirely.

---

## 3.14) Johnson Shop Products

Johnson Shop Products

.O.Box 160113

Cupertino CA 95016

+1-408-257-8614

+1-408-253-6288 (FAX)

Catalog \$1. No minimum. Shipping charge is based on UPS; very small orders that can be sensibly shipped in a first-class letter, include money for first-class postage. New and some used electronic parts.

---

## 3.15) DC Electronics

DC Electronics

. O. Box 3203

Scottsdale AZ 85271-3203

+1-800-423-0070 (orders)

+1-602-945-7736 (stock/price checks)

+1-602-994-1707 (FAX)

\$15 minimum charge order, no minimum for checks, \$3 min. shipping&handling. Wide array of ICs, good assortment of electronic components.

---

## **3.16) Communications Specialists, Inc**

Communications Specialists, Inc.

426 West Taft Ave.

Orange CA 92665-4296

+1-800-854-0547

+1-714-998-3021

+1-714-974-3420 (FAX)

Surface mount chip component prototyping kits, \$49.95. Call for free detailed brochure.

---

## **3.17) Kelvin Electronics**

Kelvin Electronics

7 Fairchild Ave.

Plainview NY 11803

+1-800-645-9212

+1-516-349-7620

+1-516-349-7830 (FAX)

Minimum order \$20; S&H 5% of order (\$5 minimum, extra for large stuff, overnight, export (like to Hawaii :-), and etchant; based on UPS charges). Lots of electronic parts & tools, some robotics supplies, model rockets.

---

## **3.18) H & R Company (Herbach and Rademan)**

H & R Company (Herbach and Rademan)

18 Canal Street, .O.Box 122

Bristol PA 19007-0122

+1-800-848-8001 (Orders)

+1-215-788-5583

+1-215-788-9577 (FAX)

Minimum order \$25 (\$5 processing charge under \$25), shipping \$4.75 under \$30; Most items are new overstocks, much regularly stocked stuff as well. Tools, electrical supplies, motors, mechanical components, robotic components.

---

### **3.19) John Birkitt**

John Birkitt  
1, The Strait, Lincoln  
+44 522 520767

Lots of stuff for the practical enthusiast. Many bargains to be had if you've the patience to sort through the extensive heaps of assorted electronic miscellany. Good stocks of new components, tools and books, masses of RF gear and very competitive prices.

Two shops side by side cater for the "consumer" type goods and the "electronics" type. Does mail order, takes visa/access etc. Mail order list contains lots of unusual goodies that you'll possibly never see on offer anywhere else.

Thanks to Dave Walster @ [lincoln.gpsemi.com](mailto:lincoln.gpsemi.com)

---

### **3.20) N R Bardwell**

N R Bardwell  
Abbeydale Road, Sheffield  
+44 742 552886

Possibly the busiest electronics emporium I've ever visited. Specialises in radio gear and alarm equipment but many of the obligatory bags of "unmarked, untested" goodies makes Bardwell's \*the\* place to go. Friendly, efficient and knowledgeable staff. Cheap. Very cheap. Thriving mail order business with some good bargains in IC's and discrete's. Write/phone for a price list.

Thanks to Dave Walster @ [lincoln.gpsemi.com](mailto:lincoln.gpsemi.com)

---

### **3.21) International Components Corporation**

International Components Corporation  
1803 NW Lincoln Way  
Toledo OR 97391-1014  
+1-800-325-0101 (US & Canada)  
+1-503-336-4400 (FAX)

Cabinets&Enclosures; Capacitors; Diodes; ICs; Potentiometers; Resistors; Sockets; Transistors; Books.  
No minimum order, \$2 handling under \$25.

[internal tag, please ignore]

---

## Chapter 4) SURPLUS ELECTRONICS

---

### 4.1) All Electronics Corp

(From Woolf Kanter)

We have two Los Angeles Area locations:

- All Electronics Corporation  
905 S. Vermont Avenue  
Los Angeles, CA 90006  
Tel: (213) 380-8000

(Vermont Avenue at 9th Street (213) 380-8000) the other

- All Electronics Corporation  
14928 Oxnard Street  
Van Nuys, CA 91411  
Tel: (818) 904-0524

We now have a WWW site (under construction). You can order a catalog and find out ordering information. Please visit us at URL:

<http://www.allcorp.com/allcorp/>

We are also a mail order company. We will mail a catalog free to anyone requesting one. You can E-Mail us at [allcorp@allcorp.com](mailto:allcorp@allcorp.com) or you can write us at:

All Electronics Corporation  
PO Box 567  
Van Nuys, CA 91408

or call us toll free at 1-800-826-5432

NO minimum, \$5.00 S&H. New and surplus electronics.

---

## 4.2) Alltronics

Alltronics  
2300 Zanker Road  
San Jose CA 95131  
+1-408-943-9773  
+1-408-943-9776 FAX

Surplus electronics. \$12 minimum, shipping per UPS.

---

## 4.3) American Science and Surplus

American Science and Surplus (formerly JerryCo)  
3605 Howard Street  
Skokie IL 60076  
+1-708-982-0870  
+1-800-934-0722 FAX

Surplus. **THE** surplus place. Lots and lots of surplus. WWII gun cameras, velcro, laser disk chassis, 6 volt VW wipers motors, LEDs, rubber brains, you name it, they've had it. Catalogs are a really good time. \$12.50 minimum order (which includes the \$4 shipping charge).

---

## 4.4) BCD Electro (Out of MO business)

BCD Electro  
. O. Box 450207  
Garland TX 75045-0207  
+1-214-343-1770

!!! Out of the mail order business!

According to Barrie Britton (24 Feb 94), BCD has gone out of the mail order business.

---

## 4.5) Electronic Goldmine

Electronic Goldmine  
PO Box 5408  
Scottsdale AZ 85261  
Tel: (602) 451-7454  
Fax: (602) 451-9495

Surplus/New. Great catalog. Covers solar, Xenon flash, surplus PCBs, etc. Lights, LEDs, the whole show.

---

## 4.6) Fair Radio Sales

Fair Radio Sales  
. O. Box 1105  
1016 E Eureka St.  
Lima OH 45802  
+1-419-227-6573

Surplus electronics. Heavy on parts for old Collins gear.

---

## 4.7) Fry's Electronics

(From Art Zirger)

It's not correct to place [...] Fry's Electronics under Surplus Stores. They only sell new stuff. While you can get them to ship some stuff to you, I'd classify them as a walk-in store only. No catalogs, only sales fliers in the local newspapers. They have multiple stores in Southern California and the Bay Area. Unfortunately, their percentage of electronics parts/accessories seems to slowly shrink as they devote more floor space to things like refrigerators.

(Editor: Since it's John Wood's list, I'll keep it here BUT with the disclaimer above.)

(From John Lundgren)

Fry's Electronics  
3600 Sepulveda Bl  
Manhattan beach, CA 90266  
Tel: (310) 364-3797

In Manhattan Beach, there is a Fry's Electronics store, along with other stores that are near the TRW swapmeet. You have to see their store to believe it.

---

## 4.8) Hosfelt Electronics

Hosfelt Electronics  
2700 Sunset Blvd.  
Steubenville OH 43952  
+1-800-524-6464  
+1-614-264-5414 (FAX)

No minimum, \$3.75 S&H. Surplus electronics.

---

## 4.9) HSC Electronic Supply

HSC Electronic Supply (Halted Specialties Co.)  
3500 Ryder Street  
Santa Clara, CA 95051  
+1-800-4-HALTED Orders only  
+1-408-732-1573 inside California and outside US

Surplus (new) electronics; new and used test equipment. Minimum order \$10 (\$2 handling charge under \$20), plus UPS shipping cost. Has three stores, of which 3500 Ryder Street is one.

---

## 4.10) Marlin P. Jones & Assoc.

Marlin . Jones & Assoc.  
.O. Box 12685  
Lake Park FL 33403-0685  
+1-407-848-8236  
+1-407-844-8764 (FAX)  
+1-800-4-FAX-YES (FAX)

Minimum order \$15, shipping per UPS. Surplus electronics.

---

## 4.11) R&D Electronics

R&D Electronics  
5363 Broadway Ave  
Cleveland OH 44127  
orders: +1-800-642-1123 (tues - fri 9am-4pm sat. 9am-3pm EST)  
info: +1-216-441-8500  
fax: +1-216-441-8503

\$10 minimum. Surplus electronics. "Also known to stock many components, but this is not discussed in the catalog. Local store, a cleveland institution, is called Electronic Surplus, Inc., and has been there since '48. Third generation now runs it." -- wb8foz 7/13/94: Dave Leshar (wb8foz) updates their hours as M,W,F 0900-1900; T,R 0900-1600; S 0900-1500; but wasn't sure if that was the store hours or the order line hours (but likely both).

---

## 4.12) Surplus Sales of Nebraska

Surplus Sales of Nebraska

1502 Jones Street  
Omaha, Nebraska 68102  
+1-402-346-4750  
+1-402-346-2939 (FAX)

New and surplus radio electronics. Wide selection: air variables. Catalog \$3 (free with order, refundable with \$25 catalog purchase).

---

## 4.13) Tucker Surplus Store

Tucker Surplus Store  
1717 Reserve St.  
Garland TX 75042  
+1-800-527-4642 extension 135

Surplus electronic gear; oscilloscopes and signal generators from the days when dinosaurs with vacuum tubes roamed the earth (some solid state gear, but all well used). Prices seem relatively high, and you'll be shocked to learn how much it costs to ship a 75 pound oscilloscope by motor freight...

Steve Brown, N8HFI:

In defense of Tucker, they have a broad selection, repair facilities, and they certify the used equipment to meet the original specification and warranty it for 90 days. Not every source does this:]

---

## 4.14) Davilyn Corp

Davilyn Corp.  
13406 Saticoy St.  
North Hollywood, CA 91605-3475  
+1-800-235-6222 (Ex. CA)  
+1-818-787-3334 (CA)  
+1-818-787-4732 (FAX)

Surplus electronic gear. [has much better prices [than Tucker], but sells used equipment as-is. -N8HFI]

[internal tag, please ignore]

---

# Chapter 5) SPECIALTY COMPONENTS

---

## 5.1) JAN Crystals

JAN Crystals  
2341 Crystal Drive  
.O. Box 06017  
Fort Myers FL 33906-6017  
+1-800-JAN-XTAL (Monday through Thursday)  
+1-813-936-3750 (FAX)  
+1-813-936-2397 (plant)

They make crystals. Minimum order is \$10, which might be one crystal, or might be two.

---

## 5.2) Crystek Corporation

Crystek Corporation  
2351/2371 Crystal Drive  
.O. Box 06135  
Fort Myers FL 33906-6135  
+1-800-237-3061 (M-F) (US and Canada but not Alaska and Hawaii)  
+1-813-936-2109  
+1-813-939-4226 (FAX)

They make crystals too. They were the cheapest last time I ordered, but I don't have an up-to-date price list. It took about 4 weeks, and they had said it would take 6.

---

## 5.3) ICM, Inc

ICM (International Crystal Manufacturing Co., Inc.)  
701 W. Sheridan  
PO Box 26330  
Oklahoma City OK 73126-0330  
Tel: +1-800-426-9825

More crystals. They were more expensive, but they have lots of pre-made crystals for various rigs, so they would probably be faster.

---

## 5.4) Amidon Associates

Amidon Associates  
3122 Alpine Way  
Santa Ana, Calif. 92074  
+1-714-850-4660

Toroid cores and related things. Very fast service. Now takes MC/Visa and phone orders. I **think** this is their current address, they seem to move a lot.

---

## 5.5) Palomar Engineers

Palomar Engineers  
Box 462222  
Escondido CA 92046  
+1-619-747-3343  
+1-619-747-3346 (FAX)

Toroid cores and shielding beads, baluns, frequency meters, etc. Call for free catalog.

---

## 5.6) RF PARTS

RF PARTS  
435 South Pacific Street  
San Marcos CA 92069  
+1-800-RF-PARTS (Orders only)  
+1-619-744-0700 (main order line & delivery info)  
+1-619-744-0750 (customer service, warranty, tech & applications, 10AM-4PM)  
+1-619-744-1943 (FAX)

Tubes and transistors. \$2 handling below \$20 for US orders; \$5.50 minimum handling for Canada orders; they take foreign orders (but no handling info was given in the QST ad).

---

## 5.7) K2AW's Silicon Alley

K2AW's Silicon Alley  
175 Friends Lane  
Westbury NY 11590  
+1-516-334-7024

Free catalog, \$10 minimum order. Semiconductors, in particular high-voltage diodes.

---

## 5.8) Small Parts, Inc

Small Parts, Inc. [ New address and phone, 23 Dec 91 ]  
13980 NW 58th Court  
.O. Box 4650  
Miami Lakes, FL 33014-0650  
+1-305-557-8222 Order department  
+1-305-557-7955 Customer Service (ask for Mirta)  
+1-305-558-1255 Catalog (ask for Elizabeth)  
+1-305-557-8004 Custom-made Parts (ask for Ziggy)  
+1-305-557-8005 Non-standard Sizes  
of catalog parts (ask for Eric)  
+1-800-423-9009 Toll free FAX line

\$12 minimum. Mechanical parts, metal stock, Teflon(R) sheets, tools, wire-size drill bits (as in #61 size for PC board holes).

[internal tag, please ignore]

---

## 6.1) ARRL Listserver

(The terse "Note:" descriptions are from the ARRL Kit List courteously supplied by Ed Hare and Mike Gruber at the ARRL. For a much more complete list of kit suppliers, use the ARRL email server; send the following as the text of a mail message:

```
help
index
quit
```

to the address [info@arrl.org](mailto:info@arrl.org))

---

## 6.2) 624 Kits

624 Kits  
171 Springlake Drive  
Spartanburg SC 29302

QRP kits (including some designs from W1FB's books) and some parts.

---

## 6.3) A&A Engineering

A&A Engineering  
2521 W. LaPalma, Unit K  
Anaheim CA 92801  
+1-714-952-2114

Kits, some components, some books. S&H \$4.50, catalog is free with SASE (2 oz postage).

---

## 6.4) Antique Electronic Supply

Antique Electronic Supply  
6221 S. Maple Ave.  
Tempe, AZ 85283  
+1-602-820-5411  
Note: Broadcast receiver kits

---

## 6.5) Cirkit

Cirkit

Park Lane  
Broxbourne, Herts EN10 7NQ, ENGLAND  
+44-0992-448899 Sales  
+44-0992-441306 Info  
+44-0992-471314 Fax

Half-inch-thick catalog is UK#1.9. "Components - kits - test equipment."

---

## 6.6) C.M. Howes Communications

C.M. Howes Communications  
Eydon, Daventry,  
Northants NN11 6PT  
England  
Phone: +44 327 60178

QRP, transmitters, receivers, misc. "The Heathkit of England", though with assembly manuals not as detailed, also without the intricate mechanicals of Heathkits.

Communications Concepts Inc.  
508 Millstone Drive  
Beaver Creek, OH 45434  
+1-513-426-8600  
+1-513-429-3811 (FAX)

Kits for Motorola Applications Notes (amplifiers and the like), small assortment of components (chip capacitors, transistors). \$4 Shipping&Handling.

---

## 6.7) Down East Microwave

Down East Microwave  
Box 2310, RR#1  
Troy, ME 04987  
+1-207-948-3741  
+1-207-948-5157 (FAX)

(Bill Olson, W3HQT) Microwave antennas and equipment, including kits for transverters and amplifiers. Free catalog available.

---

## 6.8) FAR Circuits

FAR Circuits  
18N640 Field Court  
Dundee IL 60118

(Fred Reimers, KF9GX) Printed circuit boards for articles in the usual ham magazines. SASE for list. \$1.50 shipping and handling per four boards.

Hamtronics, Inc.  
65 Moul Road  
Hilton, NY 14468-9535  
+1-716-392-9430

Note: Amateur, general interest

---

## 6.9) Kanga Products

Kanga Products !!! See also Kanga US below  
Seaview House, Crete Road East  
Folkestone CT18 7EG UNITED KINGDOM  
Tel/Fax 0303-891106 9AM - 7PM, closed Mondays.

QRP Kits, components. SAE (6"x9") for catalog.

---

## 6.10) John Langner WB2OSZ

John Langner WB2OSZ  
115 Stedman St.  
Chelmsford, MA 01824-1823

+1-508-256 6907

Slow Scan Television for IBM PC.

---

## 6.11) Lake Electronics

Lake Electronics  
7 Middleton Close  
Nuthall  
Nottingham NG16 1BX  
England

Note: Amateur

---

## 6.12) Mercury Systems

Mercury Systems  
15 Lakeside Dr.  
Marlton, NJ 08053  
+1-609-596-3304

Note: the ARRL Kit list didn't say what they carry; I don't (yet) know either.

---

## 6.13) Oak Hills Research

Oak Hills Research  
20879 Madison St.  
Big Rapids, MI 49307  
+1-800-842-3748  
+1-616-796-0920  
+1-616-796-6633 (FAX)

Send \$1 for a flyer. QST article kits, transceiver kits, QRP stuff in general. They no longer sell parts.

---

## 6.14) Penntek Electronics

Penntek Electronics  
14 Peace Dr.  
Lewistown, PA 17044  
+1-717-248-2507

Note: The Neophyte Receiver, QST

---

## 6.15) Ramsey Electronics

Ramsey Electronics  
793 Canning Parkway  
Victor NY 14564  
+1-716-924-4560

Amateur radio and hobby kits. The ham kits are all pretty simple and pretty inexpensive, and you get about what you pay for. Their new VHF transceiver kits (144, 220, 440) look pretty interesting. Many have complained about the quality of their kits, though.

---

## 6.16) Tejas RF Technology

Tejas RF Technology  
.O.Box 720331  
Houston TX 77272-0331  
+1-713-879-9300  
+1-713-879-9494 (FAX)

Tejas Backpacker-II QRP kit and other things.

---

## 6.17) T\*Kit (A division of TEN-TEC, Inc.)

T\*Kit (A division of TEN-TEC, Inc.)  
1185 Dolly Parton Parkway  
Sevierville TN 37862-3710  
+1-615-453-7172 (Information)  
+1-615-428-4483 (FAX)  
+1-800-833-7373 (Credit card orders only)

TenTec, well known manufacturer of amateur and commercial radios, is now selling kits, and apparently have been astonished by the demand. Help astonish them, call them up and get a catalog :-). The only components they sell are TenTec cases (naturally enough) and a kit for, believe it or not, a high-power variable capacitor (40-500pF, 3.5KV).

{See also RadioKit}

[internal tag, please ignore]

---

## Chapter 7) LITTLE GUYS

---

### 7.1) Dan's Small Parts And Kits

Dan's Small Parts And Kits (Formerly KA7QJY Components)  
Box 3634  
Missoula, MT 59806-3634  
Tel/Fax: (406) 258-2782

Send a business-size SASE (2 stamps) for a current list of parts. RF parts, including vernier drives and air variables; now also offers kits. \$3.75 shipping, no minimum. Fast service, lots of satisfied customers.

---

### 7.2) Kanga US

Kanga US  
Bill Kelsey  
3521 Spring Lake Dr  
Findlay, OH 45840

Tel: +1-419-423-5643

**Call between 7 - 11 pm eastern time please.** Stamp for a catalog. "I import kits from Kanga in the UK - most of them come from SPRAT - the journal of the G-QRP Club. I also have the Super Tee Antenna Tuner, and a range of kits from Elktronics that are based on the DDS articles in 73 Magazine."

---

## 7.3) R&R Associates

R&R Associates  
3106 Glendon Avenue  
Los Angeles, CA 90034  
+1-213-474-1315 (res)

[ Richard Rathburn, KB6NQ ] "I mainly sell pc boards from QST, Radio Electronics, etc., and a few of in-house design. I also sell IC's, etc." Send a SASE every now and then for his most recent flyer. He also has boards for some Motorola Application Notes. (Jan 94 -- a member of the QRP mailing list reports some dissatisfaction with R&R.)

## 7.4) CW Technology

CW Technology

7328 Timbercreek Court

Reynoldsburg, OH 43068-1181

COD Orders at 800-547-7479

"I have a small (just me) mail order company through which I sell kits. My starter products were kits for computer<->transceiver interfaces to go along with my 2/93 QST article. Since, I have added a programmer kit for the MC68HC705K1 microcontroller and an optoisolated stepper motor controller kit. I also sell the PCBs and difficult parts for these projects."

Wally Blackburn AA8DX

---

## 7.5) GNP Sales

GNP Sales  
POB 77011  
San Francisco, CA 94107.

"Business size SASE for our current list. We are very small, all three of us have "real" jobs. We buy and sell vacuum caps, vacuum relays, various high voltage parts, coax relays, mostly radio stuff."

Peter Gerba, pgerba@crl.com

[internal tag, please ignore]

---

## Chapter 8) MANUALS

---

### 8.1) Eico Electronic Instruments Co

Eico Electronic Instruments Co., Inc.  
363 Merrick Rd  
Lynbrook NY 11563

Note: No current kits, EICO manuals and schematics only

[internal tag, please ignore]

---

## Chapter 9) PUBLICATIONS

---

### 9.1) NUTS & VOLTS MAGAZINE

NUTS & VOLTS MAGAZINE  
430 Princeland Court  
Corona CA 91719-9938  
+1-800-783-4624 (subscriptions)  
+1-714-371-3052 (subscribe by FAX)

All advertisements magazine (though they're now publishing small projects). Issues are \$2.00 (at least, that's the price on the cover), subscriptions are (third class mail, USA:) \$17/1 year, \$31/2 years, (first class mail USA) \$34/1 year, (Canada/Mexico) US\$35, (other foreign, air mail) US\$70, (other foreign, surface) US\$39. A subscription also entitles you to one free classified ad of 40 words.

---

## 9.2) Ham Trader Yellow Sheets

Ham Trader Yellow Sheets  
PO Box 15142  
Seattle WA 98115

"SUBSCRIPTIONS: U.S.: 24 Issues(1 yr) \$16.50 50 Issues(2 yrs + 2 issues) \$32. 75(3 Yrs + 3) \$48. CANADA & MEXICO: 24/\$20. 50/\$39. 75/\$58. FOREIGN: \$38 a year sent Airmail. Published 2 ISSUES A MONTH sent 1st Class Mail... NO LONG WAIT FOR AD CIRCULATE! NOTE: A \$4/4 issue MINI-SUBSCRIPTION may be ordered by potential subscribers, or WITH AN AD to qualify for the Special Subscriber Ad Rates given below:" Non-subscriber ads \$1/{word,number,group} per insertion; subscribers: businesses or other for-profit sales \$0.75 per word; ads involving items solely from or for your own use \$0.35 a word; hamfest ads \$0.35. Ads and ads with subscriptions should be sent to POB 10253 Sarasota FL 34278 during the winter; spring through fall they go to POBox 2057, Glen Ellyn IL 60138.

---

## 9.3) Howard W. Sams & Company

Howard W. Sams & Company  
.O. Box 7092  
Indianapolis, IN 26207-7092  
+1-800-428-SAMS

Publishers of SAMS PHOTOFACTS and many other electronics books. There is an Annual Index of SAMS PHOTOFACTS whose cost I have forgotten. In-print Photofacts run between \$14.95 to \$39.95 (for computer Photofacts); they will photocopy out-of-print Photofacts for \$11.95 + \$2.50S&H for one page, plus \$.55 per page thereafter.

---

## 9.4) RF Design Magazine

RF Design Magazine  
O Box 1077  
Skokie IL 60076-9931  
+1-312-762-2193

A magazine for professional RF designers. Subscriptions are \$38 per year in the US, \$48 in Mexico and Canada, \$51 elsewhere, unless you appear to be a "qualified subscriber" (i.e. are in serious danger of convincing your company to buy a \$12,000 spectrum analyzer based on an ad) in which case it's free. Heavy on theory, and even the advertisement articles are educational.

---

## 9.5) Electronics Now

Electronics Now (formerly Radio Electronics)  
Subscription Service  
.O. Box 51866  
Boulder CO 80321-1866  
+1-800-999-7139

A magazine for thumb-fingered electronics hobbyists. Subscription rate on the bingo card in the November issue (the latest I was able to dig up) was \$19.97 per year.

---

## 9.6) Popular Electronics

Popular Electronics  
Subscription Department  
.O.Box 338  
Mt. Morris, IL 61054-9935  
+1-800-827-0383

Like Electronics Now. \$18.95 according to the latest bingo card I see.

---

## 9.7) The Computer Applications Journal (Circuit Cellar INK)

The Computer Applications Journal (Circuit Cellar INK)  
. O. Box 3050  
Southeastern, PA 19398-9932  
+1-203-872-2204 (FAX)

This magazine is what Steve Ciarcia wanted BYTE to be when it grew up. It focuses on microcontroller applications and other digital projects. \$21.95 per year (12 issues, now) (Canada, Mexico: add \$10 surface mail, \$20 air mail; other countries: add \$28.)

---

## 9.8) The Radio Craftsman

The Radio Craftsman  
.O. Box 3682  
Lawrence, KS 66046-0682

Bi-monthly newsletter for homebrewers of amateur radio gear. Information about electronics construction techniques, components, book reviews, beginning electronics theory, and the occasional construction project. Oriented toward the beginner/intermediate level. Price, \$10/year (six issues), \$15 outside the U.S. Published by Doug Heacock, AA0MS. Send large SASE for free sample issue. [Info supplied by Doug Heacock.]

---

## 9.9) Hambrew

Hambrew  
+1-303-989-5642

Amateur radio homebrewer newsletter published by George De Grazio, WF0K. \$10 per year (4 issues).

[internal tag, please ignore]

---

# Chapter 10) QRP CLUB PUBLICATIONS

---

## 10.1) G-QRP Club

G-QRP Club  
Rev. George Dobbs, G3RJV  
CLUB&quot;):  
St. Aidans Vicarage  
498 2 Manchester Rd.  
Rochdale, Lancs, OL11 3HE, ENGLAND

Memberships to:  
(make cheques payable to &quot;G QRP  
John Leak, G0BXO  
Flat 7, 56 Heath Crescent  
Halifax HX1 2PW, ENGLAND  
Tel 0422 365025

Publication is SPRAT, a quarterly. Subscriptions/membership is UK#5.00 per year in the UK, US\$12 (cash) or US\$14 (check) for foreign members (cheaper direct payment options are available in the US, Germany, The Netherlands, and Austria). (US payments of \$12 can be sent to Mike Kilgore KG5F, 2046 Ash Hill Road, Carrollton TX 75007; make checks payable to G QRP Club, and include your callsign and membership number (if any)).

---

## 10.2) QRP Amateur Radio Club

QRP Amateur Radio Club, International (QRP-ARCI)

Info packets (\$2)  
Mike Bryce, WB8VGE  
2225 Mayflower NW  
Massilon, OH 44647

Subscriptions to (payable to QRP ARCI):  
Mike Kilgore, KB5F  
2046 Ash Hill Road  
Carrolton TX 75007

Publication is the QRP Quarterly. Subscription is \$12 (\$14 non-US, UK#7) for new members, \$10 (\$12/#6) for renewals.

---

## 10.3) QRP Club of New England

QRP Club of New England  
Jack Frake, NG1G  
.O. Box 1153  
Barnard, VT 05031

Name:	QRP Club of New England
Date Founded:	1991
Number of Members:	206
Cost to Join:	\$10
Annual Dues:	\$7
Publication Name and Frequency:	72 - quarterly
Net(s):	QRP-NE SSB Net, 0200Z Tuesdays 3.855MHz

---

## 10.4) QRP Club of Michigan

QRP Club of Michigan  
654 Georgia  
Marysville, MI 48040

Name:	Michigan QRP Club
Date Founded:	1978
Number of Members:	1,200
Cost to Join:	\$7 US, \$12 DX
Annual Dues:	\$5 US, \$10 DX
Publication Name and Frequency:	The Five Watter - quarterly (a.k.a. T5W)
Net(s):	MI-QRP Net, 0200Z Wednesdays 3.535MHz

---

## 10.5) QRP Club of Northern California

QRP Club of Northern California  
Jim Cates, WA6GER  
3241 Eastwood Road  
Sacramento, CA 95821

Name:	NorCal (Northern California) QRP Club
Date Founded:	1993
Number of Members:	200
Cost to Join:	\$10
Annual Dues:	\$10
Publication Name and Frequency:	QRPP - quarterly
Net(s):	None

This is the club that has had a succession of incredibly popular kits, ranging from the Norcal 40 (and now its successor, the 40a), the Sierra, and soon a QRP SSB kit.

---

## 10.6) QRP Club of North Texas (GONE, as a publication, anyway)

Chuck Adams had to give up publishing his newsletter after two fine issues.

---

## Chapter 11) CHANGES FOR this revision (2.18)

- Ocean State is still in business, despite recent rumors!
- Add Hambrew, delete North Texas QRP Club.
- Townsend Electronics gave up.
- Amidon moved.
- Dan's Small Parts is suspended after a move.

---

# Obsolete IC Sources

**Note:** If you represent or know of a company that provides similar services, please

. Thanks!

Contents:

- [1. Introduction](#)
- [2. Alternatives and Cross-References](#)
- [3. Obsolete AMD ICs](#)
- [4. Surplus Inventory Locators](#)
- [5. General Instrument \(GI\) ICs](#)
- [6. Harris Opto](#)
- [7. Motorola](#)
- [8. Krueger](#)
- [9. Pure Unobtanium Krueger](#)
- [10. Surplus/Obsolete](#)

[Document Version: **1.15**] [Last Updated: **11/13/96**]

---

## 1. Introduction

You know how frustrating it is to find an one-of-a-kind IC that you just must have yet it is no longer made! What do you do?!?!?

Well, needless to say (if you were watching the size of this file as it was transferring :-)) there are companies who have realized that there is demand for obsolete chips and are doing their best to make people like you happy.

If you represent an entity that would like to be included on this page, please send me your speciality, full contact info, and which section you would like to be under:

or [\[mailto\]](#).

---

## 2. Alternatives and Cross-References

<http://www.nteinc.com/> - NTE on-line. You can search their cross-reference on-line or download it to your PC/Windows machine (~2.5MB compressed). A number of catalogs carry NTE replacement parts: see [Source Information](#) for supplier contact information.

---

## 3. Obsolete AMD ICs

Luke Systems International  
Tel: 818-991-9373  
Tel: 206-863-8506  
Fax: 818-991-4654  
E-mail: [lukesys@nrc.com](mailto:lukesys@nrc.com)

(From Laura Luft)

Contact for worldwide sales and a product catalog is Lisa Betancourt

Looking for obsolete AMD IC's, we at Pacific Softworks were, and found Luke Systems International, who focus 100% on the sale of AMD obsolete components, not only do they stock large quantities of unused product, they also make continuation product from AMD die and mask sets.

---

## 4. Surplus Inventory Locators

- GraveYard Electronics

(From Gregg Woodcock)

I too, found out about Luke when looking for AM6012 DAC chips and also found some other good places for obsolete parts. By far the most useful place to help in looking for obsolete parts is Surplus Inventory Locators. They are a FREE service (paid for by the subscribers) and they list the inventory of companies who subscribe and want to get rid of surplus parts. All you do is call them, give them your part number, and they will call you back with a bunch of companies that carry that part.

GraveYard Electronics  
2600 118th Avenue N  
St. Petersburg FL 33716  
Tel: (800) 833-6276  
Tel: (813) 571-2000  
Fax: (814) 571-2018  
E-Mail: [am2group@ix.netcom.com](mailto:am2group@ix.netcom.com)

- Mark 5 Limited

(From Neil Preston)

For those who are frequently looking for old or obsolete components, I recently became aware of a company who specializes in obsolete ICs. They are:

Mark 5 Limited  
4A Fernwood House  
45-47 London Road  
Cowplain  
Hants PO8 8DH  
England

- Semiconductor Archives

(From Rob Humberstone)

Semiconductor Archives  
48 Deptford Broadway  
Deptford  
London SE8 4PH  
England

- Plano Components

(From Rob Humberstone)

Plano Components  
1420 Brazos Trail  
Plano Tx 75075

- Online Technology Exchange

(From Tim Glenn)

Online Technology Exchange

USA:

Tel: 800-606-8459

Fax: 800-606-8460

Outside of the USA:

Tel: 813-367-2300

Fax: 813-367-2005

E-Mail: [reqirmnt@onlinetechx.com](mailto:reqirmnt@onlinetechx.com)

WWW: <http://www.onlinetechx.com/techex.html>

They specialize in hard to find or Obsolete IC's, Resistors, and misc. Minimum order is \$100's.

- Distinct Micro Inc (DMI)

(From Bruce Greenberg) Looking for obsolete components? Having trouble sourcing certain components ? DMI located in Canada, ships worldwide. We stock and source all types of IC's. We can supply specification when needed and no quantity is to large or small.

Distinct Micro Inc

5706 Vanden Abeele

St. Laurent Quebec

CANADA H4S 1R9

Tel: 1-800-381-5771

Tel: 1-514-333-5771

Fax: 1-514-333-6025

E-Mail: [bruce@dmi.qc.ca](mailto:bruce@dmi.qc.ca)

URL: <http://www.dmi.qc.ca/>

- Jeff Luebke

Jeff Luebke

Sales and Mktg Mgr

1420 Brazos Tr

Plano, TX 75075

Tel: 214-516-0873

Tel: 214-423-3790

E-Mail: [jeff@plano.com](mailto:jeff@plano.com)

(From Jeff Luebke)

We too, can be used to locate obsolete, obscure or allocated semiconductor parts.

Our minimum order is \$100...and we are more geared towards helping the industrial account than the hobbyist....However whenever possible we will accomodate.

- Mushroom Components Unit 5, Wellingborough Business Centre  
Everitt Close, Denington Industrial Estate  
Wellingborough  
Northants NN8 2QE  
United Kingdom  
Tel: (+44) 1933 275345  
Fax: (+44) 1933 275245  
Email: [pv@mushroom.uk.co](mailto:pv@mushroom.uk.co)  
<http://www.mushroom.co.uk/>

(From Paul Vaughan)

Specialise in the supply of discrete Semiconductors and have over 44 million devices at our disposal, including **many obsolete and more unusual types**. We are an Independent British Importer and Distributor of General Components.

E-mail [sales@mushroom.co.uk](mailto:sales@mushroom.co.uk) for your free 24 Page Semiconductor Stock List. Or get it via WWW (not sure if this 'free' applies to USA - Editor)

---

## 5. General Instrument (GI) ICs

Rochester Electronics, Inc.  
10 Malcolm Hoyt Drive  
Mewburyport, MA 01950  
Tel: 1-508-462-9332

(From the Microchip Tech. Databook by way of Mark Zenier)

Online Technology Exchange  
914 Sandpiperway  
St. Petersburg, FL 33707  
Tel: (813) 345-4357  
Fax: (813) 341-1613 (or)  
Fax: (813) 345-4357  
E-Mail: [texchange@aol.com](mailto:texchange@aol.com) or  
E-Mail: [techex@cftnet.com](mailto:techex@cftnet.com)  
URL: <http://www.onlinetechx.com/>

(From EXCHANGE)

EPROMs, SRAMs, Microprocessors, Logic, Transistors, Diodes, Capacitors, Resistors, Connectors, DRAMs, Military, 74 & 68#'s

All Packages - Surface mount especially and also DIP. They even take email requirements. I think their minimum order is USD\$50.00

---

## 6. Harris Opto

Quality Technologies  
Sunnyvale, CA  
Tel: 1-800-HELP-644  
Tel: 1-408-720-1440

(From Jim Karon)

They have recently taken up the Harris Opto line.

---

## 7. Motorola

(From E. Paolo)

SPI  
in California  
Tel: (818) 349-4495

They are big in Motorola parts

---

## 8. Krueger

Krueger Technology  
Arizona  
Tel: (602) 820-5330

Krueger uses a patented IC removal technology to desolder IC's... so they are all "used".

---

## 9. Pure Unobtanium Krueger

Pure Unobtanium

Ed Nisley

[removed]

Raleigh, NC, 27613

Tel: [removed]

They have ceased to sell hard-to-get parts.

---

## 10. Surplus/Obsolete

- A. G. Tannenbaum  
P. O. Box 386  
Ambler, PA 19002  
Tel: (215) 540-8055  
Fax: (215) 540-8327

(From Jim Tannenbaum)

E-Mail: [k2bn@agtannenbaum.com](mailto:k2bn@agtannenbaum.com)

**Note:** They have moved to Pennsylvania from East Rockaway N.Y. Old address is not valid.

- Lansdale Semiconductor (Sales: Sandi Kreg)  
Tel: (602) 438-0123  
Fax: (602) 438-0138  
E-Mail: [sandik@lansdale.com](mailto:sandik@lansdale.com) (Sandi Kreg)  
WWW: <http://lansdale.com/~lansdale/>

(From Sean Michaels)

- American Microsemiconductor  
Tel: 201-377-9566

Fax: 201-377-3078

They specializes in obsolete and discontinued parts, for example diodes, transistors, triacs, scrs, and integrated circuits.

(From Roger Newey)

- Active Micro  
Tel: 310-494-4851
- Ace Electronics  
Tel: 408-297-1383
- Alltronics  
Tel: 408-943-9773
- Anchor Electronics  
Tel: 408-727-3693
- Halted Electronics  
Tel: 408-732-1573
- Haltek Electronics  
415-969-0510

(From Jeff Brown)

The above have surplus stuff... which include obsolete IC's, etc

- PAIA  
Oklahoma City, OK

(From Rick Chinn)

They have some obsolete chips (CEM 3340 VCO chip and also the SSM equivalent)

- CG Tech  
Tel: 609-730-1868

(From Edward Paolo)

Ask for Ed Paolo or Stan. They have alot of old type parts from units.

- Ray Rogers Semiconductors  
106 Norway Road

Hilsea  
Portsmouth PO3 5HT  
UK  
Tel/Fax: 01705 691913

(From Ian Tresman)

Semiconductors not normally available either due to obsolescence, or because they are not supported in the U.K. We have a wide range of stock covering most Far Eastern manufacturers together with many European and North American companies. Our object is simple: to provide a unique service to companies, government establishments, hospitals, colleges and universities etc. To this end we welcome enquires from outside the UK

# 2. Tektronix Manuals/Parts

- [http://www.tek.com/Measurement/App\\_Notes/XYZs/contents.html](http://www.tek.com/Measurement/App_Notes/XYZs/contents.html)  
XYZs of Oscilloscopes. Courtesy [Tektronix](#)
- Bob Garcia  
845 Fairfield Drive  
Marietta, GA 30068-2619  
Tel: 1-770-977-5701 (**updated!**)

Bob is a retired Tek engineer who refurbishes and sells scopes for spending money. He also repairs scopes at remarkably good prices. A typical deal will be a 60 MHz transistorized Tek scope for about \$125. Anyone who attends hamfests in the southeast will recognize Bob as "Mr Scope."

- Deane E. Kidd W7TYR  
27270 S.W. Ladd Hill Road  
Sherwood, OR 97140  
Tel: 1-503-625-7363

Mr. Kidd is a retired Tek engineer who sells old Tektronix manuals:

For example, a 465 manual is \$35. Also available, for \$20, is Stan Griffith's "Oscilloscopes: Selecting and Restoring a Classic"... As reviewed by Wes:

"I bought that one through Tucker Electronics and it is one good book for anyone who has an old Tek scope. It details how to troubleshoot them, where to find parts and most of all, it rates them as to their serviceability in today's electronics. It also covers the MANY plug-in's out there. I had no Idea how Many was there! Like a strain gauge pulg-in?? Good book and worth the money (as I own 4 old Tek scopes and love each of them dearly ;-)"

And here's a something from Stan Griffiths, the author himself:

[in response to a plea from an owner of a dead 454 scope]

Mac, I was sorry to hear that your 454 bit the dust. It is certainly worth a lot of effort to get it going again. One thing you might check are the tunnel diodes in the sweep and trigger circuits. I have seen them go bad for no explainable reason. I have some 152-0125-00 TDs if you need them for \$5 each. (Tek wants \$38 each.) If you don't know if you need one or not, you can test your TDs on a 575 Curve Tracer. If you don't have access to a curve tracer, you can mail your TDs to me and I will test them on my 575 for you. I will send checked ones to you if I find a bad one.

You may recognize my name as the author of "OSCILLOSCOPES--Selecting and Restoring a Classic". I love old Tektronix scopes and I want to see yours run again. I own 454 S/N B010100 (the first one!) which I bought in a local estate sale. It was the estate of one of the design engineers who worked on the project. I guess you don't have to be dead to have an estate sale since he was there personally to sell me the instrument!

Stan Griffiths, W7NI  
E-mail: W7NI@teleport.com

- Ed Matsuda  
Test Equipment Manuals

P.O. Box 390613  
San Diego, CA 92149  
Tel: 1-619-479-0225  
Fax: 1-619-479-1670

(From Jim Adney)

Ed specializes in good quality second hand service manuals for Tek and HP. I find that a fax to him that includes a fax back number gets the best results since he has a printed request in his hand that he can check out and respond to.

Any time you are buying Tek manuals you should make sure the parts list shows serial numbers up close to yours. HP manuals should be bought by the serial prefix number (that is the number before the "A" in the serial number; make sure to get a manual that covers your serial prefix or higher. Later manuals **USUALLY** cover earlier models as well, but not always. The serial prefix covered by an HP manual is shown on the title page.

So fax Ed your list of model numbers with the serial prefix of each unit. I usually specify "model HPxxxx, serial prefix yyyy or higher."

Price for an average manual is \$15 + postage.

- John Micek  
Warner Robins, GA

(From Michael H. Roland)

I would like to inform you that John Micek (Warner Robins, GA) is retiring from the used test equipment business.

- Linda Perkins  
Manual Merchant  
E-Mail: [linda\\_p@ix.netcom.com](mailto:linda_p@ix.netcom.com)

- MECCA  
1132 Conway Dr  
Newark, OH 43055

Tel: 614-522-4944

Used manuals for test equipment, amateur equipment and early receivers. Prices range from \$5 to \$35. Send an SASE with your request for price and availability.

- Slep Electronics Co  
PO Box 100  
Otto, NC 28763-0100  
Tel: 704-524-7519

Operation and service manuals; schematic service for old and new amateur radios, commercial and military surplus test equipment, commercial and surplus military radios, antique radios and equipment manuals. Catalog not available due to large stock. Send an SASE for price and availability. Include make and model of each unit.

- R5-D3 Electronic Surplus  
Portland, OR  
Tel: (503) 774-6560  
Ask for Bob Lee.

[Older Tektronix 'scope stuff/plugins/manuals]

If he doesn't have what you are looking for, he will know who to point you to here in the land of Tektronix.

- Tektronics, Inc.  
P.O. Box 500  
Beaverton, Oregon 97077  
Tel: 1-800-426-2200 (best)  
Tel: 1-800-838-3553

Most older manuals are available as fische only. The paper versions are sky high if they're available. I paid \$7 for a 561A manual, and \$5 and \$10 for the amp and timebase plug-in manuals. Newer scope manuals are about \$25 on fische, and in excess of \$100 for the paper version. I was able to find a surplus fische reader at the SW Bell surplus store for \$10, so it's not to bad.

HP is much better when it comes to pricing on their paper manuals :-)

- Research Products Corp  
1015 E. Washington Ave  
Madison, WI 53703  
Tel: 608-257-8801

The source of the OEM Tek scope air filters is alive and well.

---

## 3. Hewlett Packard (HP) Manuals

- Hewlett Packard also sells manuals for [basic] instruments. If they don't have printed manuals anymore, they still try to stock the microfiche versions.

In the US & Canada: 1-800-227-8164, 6AM-5PM Pacific Time, Monday-Friday. (Prices are between \$25-\$40 each for these ones when I looked, but this could change tomorrow. Call to get the latest prices)

Tel: 1-800-227-8164 6AM-5PM Pacific Time, Monday-Friday

Another number to try is:

Tel: 1-800-452-4844

But it could be old.

---

## 4. HP component lookup

(From Walter Shawlee 2)

Sphere Research Corporation

1955A Moss Court

Kelowna, BC, Canada V1Y 9L3

Tel: +1 (250) 762-5455

Fax: +1 (250) 762-0244

E-Mail: [walter2@sphere.bc.ca](mailto:walter2@sphere.bc.ca)

WWW: <http://www.sphere.bc.ca/test/>

We have a huge HP->to->Industry Standard Semiconductor cross-reference. [[Decode all those odd 1820-xxx numbers!](#)] Also HP and Tek repair parts and equipment on-line, plus helpful FAQs and links to all

kinds of test gear sites. We also have a big used equipment site on line for Canadians.

---

## **5. BK/B&K/B+K**

B+K Precision

Maxtec International Corp.

6470 W. Cortland St. (could be '6460')

Chicago IL 60635

Tel: (312) 889-1448

Fax: (312) 794-9740

Ask them for the servicing information manual and calibration procedure. Inform them of the model year and serial number.

---

## **6. Various Other Manuals Sources**

---

### **6.1) Domain BBS**

Domain BBS

Tel: 1-208-375-6571

Marty Gasmans service manuals are included as are manuals from other individuals. You may search the database while online, add your own entries, change your own entries and delete your own entries.

Anyone may log onto the BBS and search any of the databases. Please feel free to add service manuals that you no longer need and would like to sell. If you have a very large list of manuals, contact the sys-op for a free database program that will let you enter the manuals off-line and then upload them to the database.

---

### **6.2) Trilithic**

Trilithic

9202 E. 33 St.

Indianapolis, IN 46236-4200

Tel: (317)895-3600

They provide support and manuals for older **Texscan** brand spectrum analyzers, signal generators, or field strength meters.

---

## 6.3) Fair Radio Sales

Fair Radio Sales

Lima, OH

Tel: 1-419-223-2196

Tel: 1-419-227-6573 (old?)

They carry some older manuals as well as tubes of all sorts. Call them and ask for a catalog.

---

## 6.4) Diverse Devices

Diverse Devices

75 Priory Rd

St Denys, Southampton

England SO17 2JQ

Tel/Fax: (+44) (-0)1703 584680

E-Mail: [diverse@tcp.co.uk](mailto:diverse@tcp.co.uk)

WWW: <http://www.tcp.co.uk/~diverse/>

(From Nigel Cook)

Shop stocking Obscure/Obsolete Components, Second hand test equipment, Pinouts, Service Manuals, and Schematics and more.

---

## 6.5) Marty Gasman's Manuals

Marty Gasman's Manuals

E-Mail: [mgasman@tiac.net](mailto:mgasman@tiac.net)

WWW: <http://www.tiac.net/users/mgasman>

I have over 3,000 audio service manuals audio owner's manuals original manufacturer's literature.

---

## 6.6) W7FG VINTAGE MANUALS

W7FG VINTAGE MANUALS

Care of: GARY GOMPF

E-Mail: [w7fg@eigen.net](mailto:w7fg@eigen.net)

WWW: <http://eigen.net/w7fg/>

We have over 3000 manuals in stock, and ship 6 days a week. Mostly ham and test equipment manuals.

---

## 6.7) Manuals Plus

Manuals Plus

P.O. Box 549

TAD #601

Tooele, Utah 84074

Tel: 801-882-7188

Tel: 1-206-531-8031 (might be disconnected)

Fax: 801-882-7195

E-Mail: [jackh@manualsplus.com](mailto:jackh@manualsplus.com)

WWW: <http://www.manualsplus.com/>

These folks sell and buy service manuals and parts for test equipment. Expect to pay \$30-\$50. I've been hit for over \$100 on manuals for newer equipment.

(From their Home Page)

Manuals Plus sells and purchases used Electronic Test & Measurement Equipment Manuals. We maintain a large stock of original (not photocopied) test equipment manuals for equipment manufactured by Hewlett-Packard, Tektronix, Fluke/Philips, Wavetek, Wiltron, GenRad, IFR, Systron-Donner, and many others. We pride ourselves on being able to respond to client requirements in a prompt manner.

---

## 6.8) Service Center

Service Center  
Paramus NJ  
Tel: (201) 262-9550

They have Service/Information on Fluke meters.

---

## 6.9) Tucker Electronics

Tucker Electronics  
Dallas, TX  
Tel: 1-800-527-4642

They are another good source of used manuals for older instruments.

---

## 6.10) Alton H. Bowman (W2ZUX)

Alton H. Bowman (W2ZUX)  
4172 East Ave., RD2  
Canandaigua, NY 14424-9564

Al says he has manuals for everything from garage door openers to electronic organs, CB radio (gulp), test equipment, ham radio, etc. He specializes in equipment from the 1920-1970 era, and says,

" Most of my material is tube type (that could mean BAs for those of you in Rio Linda). [...] I charge \$5 for a schematic with 1-6 pages of text. Real complicated schematics I enlarge to 11X17, same price. Manual prices depend on the number of pages; 6-10 pages \$6, 16-30 pages \$8, etc. Material is good photocopy, subject to your approval, or your money refunded."

---

## 6.11) McIntosh Home Audio

McIntosh Home Audio  
Tel: (607) 723-3512

Schematics for McIntosh Home Audio are free from McIntosh.

---

## 6.12) Delco Manuals and Parts

(From Scott Perkins)

GM Delco Publications  
Tel: 1-313-974-0341

"...the last time I got schematics they were at no charge!!"

---

## 6.13) Sansui Schematics

(From Mark Zacharias)

Sansui Schematics are available from:

Fox International  
Tel: 1-800-321-6993

As of 2 or 3 years ago, schematics, but not full service manuals, were available for older Sansui units at a very nominal cost. The only problem is that you may have to wait three or four weeks to get it.

---

# 7. Heathkit Schematics/Parts

---

## 7.1) Heathkit Education Systems

Heathkit Education Systems  
Heath Company  
PO Box 1288  
455 Riverview Dr  
Benton Harbor Mi 49023-1288

Catalog/Mailing list subscribe: 1-800-44-HEATH  
Order by Phone : 1-800-253-0570  
Order by FAX : 1-616-925-4876  
Customer Service : 1-800-253-0570  
Technical Consulting : 1-616-925-4914  
Parts Replacement/Repairs : 1-616-925-3273  
Manuals : 1-616-925-5899 (8-4 EST)

---

## 7.2) The Manual Man

The Manual Man  
27 Walling St  
Sayreville, NJ 08872

## 8. Computer Schematics

(From JohnM@daka.com)

Detailed schematics for Mac's are available. They can be obtained from:

Bomarc Services  
P.O. Box 1113  
Casper Wyo 82602  
Tel: (307) 234-3488

---

## 9. Misc Articles/Info

- If I may blow my own horn for a moment, September 1994 issue of Electronics Now contains an article I wrote called, "New Life for Old Oscilloscopes," by Michael Covington, complete with a schematic of a Heath IO-12.
- If you are looking for some obscure manual, you should just a hop skip and jump to **THE** ham radio mecca in Dayton, OH at the end of the month of April. There's no excuse available for not

going. Things like weddings get postponed so hams can make it to the Hamvention. I'm sure you'll find manuals for the scope frame and all the plug-ins at Dayton. Cost is probably about \$5 to \$15 each.

---

## 10. SAMS Manuals

---

### 10.1) New

Howard W Sams & Company  
2647 Waterfront Parkway East Drive  
Indianapolis, IN 46214-2041  
Tel: 1-800-GET-SAMS  
Tel: 1-800-428-5331  
Tel: 1-800-428-7267

Ask for a catalogue. Sams Photofacts is a company that publishes service data on TVs and radios going back to the 1930s. More importantly, their catalogue is full of ads for parts suppliers, and it also gives manufacturers' addresses.

---

### 10.2) Used (but a lot cheaper)

(From Jim Tannenbaum)

A. G. Tannenbaum  
P. O. Box 386  
Ambler, PA 19002  
Tel: (215) 540-8055  
Fax: (215) 540-8327  
E-Mail: [k2bn@agtannenbaum.com](mailto:k2bn@agtannenbaum.com)  
WWW: <http://www.agtannenbaum.com/>

(From their Home Page)

Try us for Service Manuals for Radio, TV, VCR, as well as Antique, Amateur, Audio, and Test Equipment. We buy and sell Vintage Radios, TVs, Tube Hi-Fi Equipment, Test

Equipment and Hard to Find Repair Parts. Don't forget our extensive collection of SAMS Photofacts! Didn't find the manual you need? Check back soon, we constantly update our website. Or send us mail, since we stock more than we can list here.

(From Michael Roberge)

Sams PhotoFact folders:

- Number 1 to 1400 cost \$5.00/each
- Number 1400 and up cost \$7.00/each

VCR manuals(Sams or Originals) are \$15.00/each. Please Call for other manuals.

This source carries previously owned schematics for VCR, TV, AUDIO and some test equipment. Being previously owned they are able to resell them for a fraction of the cost of new. Coupled with this is the fact that they have a wide selection from many manufactures. They carry SAMS PHOTOFACETS and original manufactures service literature. I have personally purchased many manuals from this source. Initially I was concerned that they are used but I must say that this has not been a problem. Never has a single page been missing and otherwise in almost like new condition.

In the event that they don't have the exact schematic for a specific model the owners have cross reference manuals which they use in an effort to locate possible 'look-a-like' chassis for which they might have a manual. I am told that they have many...many filing cabinets full of manuals.

Payment is generally expected in advance until a good working relationship is established. All manuals are shipped first class for \$1.50 and they get them out fast.

---

## 11. VGA/SVGA Monitor Schematics

**Before** you send off for any schematic, it is **highly** recommended that you:

- Read the [Notes on Troubleshooting and Repair of Computer and Video Monitors](#) FAQ
- Post to [sci.electronics.repair](#) group to ensure that you actually **need** the schematic.

Some problems can be fixed without one and in other cases, a schematic will not help to begin with. Most schematics will cost over US\$35 and, as a rule, are **NOT** returnable!

In your post to [sci.electronics.repair](#), please include:

1. Brand, Model Number, and FCC code
  2. Clear and accurate description of the problem
  3. How the problem appeared and what are the symptoms
  4. What you have checked already (including the FAQ!)
  5. The level of your electronics repair experience

---

## 12. Misc Trivia

HP's 54600 series knows how to play Tetris!

In the Display/Utility menu, press soft keys 2 and 3 both at once. Or maybe it's 1 and 2. Or maybe 3 and 4. :-)) [One of those two other key combinations will get you into a cool debugging menu!])

## 1. Disclaimer

If you represent an entity which would like to contribute something to this area, please use this handy [Feedback Form](#) (if possible) or [e-mail me](#) and, if deemed appropriate, you will be added.

Rules for admission are simple: if you have some software package (under \$50 or so) that helps people who are trying to fix their monitor or other hardware, please e-mail me using the above form and I will add you here in short order.

---

## 2. Anatek Corp

[Anatek Corp](#) is on the WWW.

### Shareware version of Resolve

You can download a shareware version of Resolve which is the version that was released in December 1993 and contains 1,000 repairs on 180 monitors.

**Be sure to use the -d switch when unzipping any of these files!**

If you have problems or need more info:

1. Go to WWW site for these programs at URL: <http://www.anatekcorp.com/repair.htm>
2. If you still can't manage e-mail: [john@anatekcorp.com](mailto:john@anatekcorp.com)

## Resolve

The Resolve Monitor Repair Database version 3.13 contains 2,133 repair procedures on 331 monitors (CGA, EGA, VGA, SVGA, Multisync), component sources for monitor semiconductors and magnetic components, a manufacturer's cross reference, manufacturer identification by FCC number and telephone numbers for more than 600 manufacturers. The price for Resolve is \$249.00. Several package discounts are listed on the [\[order form\]](#).

There is a yearly update offer also... feel free to [\[read all about it\]](#)

---

## 2.1) Monitor Repair Database (software)

A shareware version of AnaTek's Monitor Repair Database (1,974 repair procedures on 266 monitors, cross ref, etc.) is available for **FTP** at:

Site: <ftp.catalog.com>

Dir: <ftp://ftp.catalog.com/anatek/>

As file: [res16sw.exe](#) (1.1MB)

Backup Site:

Site: [oak.oakland.edu](http://oak.oakland.edu)

Dir: [SimTel/msdos/info/](#)

As file: [res16sw.zip](#) (1.1MB)

They also have a [Terminal Repair Database](#)... but no limited version... oh well :-)

---

## 3. TechFix

[TechFix](#)

- Over 5,600 tech tips covering TVs, VCRs, and Camcorders
- TechFix places no limit on your tech tips -- Have 1 line or over 1000 lines
- Search by Make, Model, Chassis, Similar Model or Chassis
- Search by Symptom Code or EIA Codes
- Search for any word or phrase or combinations
- Search by Wildcard Model numbers
- TechFix is now approved by NESDA, the Country's largest association of consumer electronic servicers.

Here's a [Sample](#) of TechFix. If you want us to send you further information please complete this [form](#) or e-mail us at [tipsinc@mindspring.com](mailto:tipsinc@mindspring.com).

TIPS, inc.  
PO Box 1681  
Forest Park, Georgia 30051-1681  
Phone / Fax: (770) 968-3715

You can also download the [TechFix demo](#) (212KB PKZIP).

Price of full release is \$149.95

---

## 4. Display Technologies Monitor Repair Page

TLJCHECK Display Technologies  
E-Mail: [bcollins@scoot.netis.com](mailto:bcollins@scoot.netis.com)  
WWW: <http://www.netis.com/members/bcollins/monitor.htm>

They will help you fix your monitor and only ask \$5 (honor system) if you are successful. They will soon have a [database](#) of repair "briefs" on their home page... but feel free to check it out anytime as new areas are added weekly.

---

## 5. The Technician's Edge Publishing Company (vcrtips)

(From the Editor)

Ok, so it's not software... but if you're looking in this file, their newsletter might also interest you.

(From VCR Tech Tips)

The Technician's Edge Publishing

## 1. PART 1: FCC ID

---

### 1.1) Introduction: What is an FCC ID

In the United States (other countries have their versions of same - but they are incompatible and completely different) a product that emits any frequency above 500KHz must be inspected and approved by the FCC (Federal Communication Comission). Once approved, it is issued an ID number that begins with a 3 letter code for the company that makes it, followed by another number that actually identifies the inspection. Example: **DZL**SCB4-PC-MCR (my Logitech Scanman 256. :-) The most **CRITICAL** are the first 3 characters (DZL), as far as we're concerned, anyways. That's because we are most interested in **who** made some device, not what the FCC thinks of it. :-)

---

## 1.2) Can I look up what PRODUCT an ID belongs to?

The [FCC ID SEARCH FORM](#) provides quick access to manufacturer info, operating frequency range, the application and grant, and any exhibits that may have been provided.

---

## 1.3) I just want to know WHO made it

The FCC keeps this information in .DBF format (binary Dbase III). They do have several documents that describe the field layout on-line:

- [RAW dBase III files from FCC](#) (R)
- 

# 2. PART 2: Other FCC info

---

## 2.1) Computer Video Monitors

---

### 2.1.1) About the Author

FCC ID Numbers Cross Reference

Author: Andy Laberge  
E-Mail: [tic-toc@wolfe.net](mailto:tic-toc@wolfe.net)  
Date: 22 Apr 1995

---

### 2.1.2) List

Below is a list of FCC ID numbers for monitors.

I have just started to list the monitors as they come into my shop for repair. What I want to do is create a cross reference for monitors so that technicians and consumers can tell what monitors are similar to others. An example is:

FCC ID	Make	Model
CSYSC-431VA	BSR	3100V
CSYSC-431VS	SAMTRON	SC-428VS

These two monitors are basically identical. I've worked on both types. The point is that if someone has a problem with a BSR and another person has a cure for the same type problem on a Samtron then the BSR can be fixed.

If people would like to e-mail me info off the back of their monitors I will add it to the list and then make that list available.

e-mail me at [tic-toc@wolfe.net](mailto:tic-toc@wolfe.net)

I will need Make, Model and the FCC ID number. This system works in the US but if they use another system to ID monitors in other countries we will incorporate that into the system somehow. Hopefully this will help the people with the problem and the people with the solutions get together.

---

### 2.1.3) Cross-Reference

Sorted by ID number

## 2.1.4) Official Cross-referece

(From the FCC)

Pending Authorizations:

Information on pending and recently granted equipment authorization applications is only available through OET's Public Access Link (PAL). PAL is a computer bulletin board system (BBS) that can be reached via the public switched network at +1 (301) 725-1072. The modem setting are: 8-n-1. The PAL system provides access to both pending and granted equipment authorization records; however, it is by FCCID only.

## 3. UL Numbers

There also exists a list of UL numbers at URL:

## Chapter 3) PC Graphics

---

### 3.1) VGA/SVGA

---

#### 3.1.1) Original VGA (31.5 KHz - 640x480)

(From Sam Goldwasser)

SVGA (35-37 KHz - 800x600) 15 pin sub D:

1 Red (Analog)	6 Red Return	11 (ID0) GND (Color)	11 . . . 1
2 Green (Analog)	7 Green Return	12 (ID1) NC (Color)	. . .
3 Blue (Analog)	8 Blue Return	13 Horizontal Sync	. . .
4 Reserved	9 No Connect	14 Vertical Sync	. . .
5 Ground	10 Ground	15 No Connect	. . .
			15 10 5

Note:

Monitor ID Lines ID1,ID0=NC,G for color; G,NC for Mono. ID0 only may be used.

Mono VGA is similar using only the Green Video and Return.

### 3.1.2) VESA VGA Standard Feature Connector (special 26-pin header)

pin	assignment	pin	assignment
===	=====	===	=====
1	PB	2	PG
3	PR	4	PI
5	SB	6	SG
7	SR	8	SI
9	Dot Clock	10	Blank
11	HSync	12	VSync
13	GND	14	GND
15	GND	16	GND
17	Ext Video Sel	18	Ext Sync Sel
19	Ext DotClock Sel	20	N/C
21	GND	22	GND
23	GND	24	GND
25	N/C	26	N/C

### 3.1.3) VGA (VESA standard)

(From Bob Myers)

Note that many of the pins shown above as "no connects" (actually, these were sometimes used as monitor ID bits by many manufacturers) are now defined under the VESA Display Data Channel standard. This standard provides two protocols for display ID and control, including support for the full ACCESS.bus interface. The current definition of the "VGA" pinout per the DDC standard is:

1 Red (Analog)	6 Red Return	11 Monitor ID0 (opt.)	11. . . 1
2 Green (Analog)	7 Green Return	12 Data (SDA)	. . .
3 Blue (Analog)	8 Blue Return	13 Horizontal Sync	. . .
4 Reserved	9 +5 VDC (frm host)*	14 Vertical Sync	. . .
5 Return	10 Sync return	15 Data clock (SCL)*	. . .
			15 10 5

Those signals marked with an asterisk would be supplied by the host only if the host supports the DDC2 protocol (I2C or ACCESS.bus).

---

### 3.1.4) VGA DB15-S Female DB9 Female

15-pin	9-pin	assignment
1	1	Red
2	2	Green
3	3	Blue
4	-	Monitor ID bit 2
5	-	N/C
6	6	GND (red return)
7	7	GND (green return)
8	8	GND (blue return)
9	-	N/C
10	-	GND
11	-	Monitor ID bit 0
12	-	Monitor ID bit 1
13	4	Horizontal Sync
14	5	Vertical Sync
15	-	N/C

Monitor ID bit 0: reserved

Monitor ID bit 1: GND = mono, OPEN = color

Monochrome monitors use the green signal

---

### 3.1.5) Somewhat standard 9 pin VGA

(From Sam Goldwasser)

For analog VGA/SVGA measured based on my VGA to 9 pin adapter. This is pretty standard as the NEC Multisync II and others use the same pinout:

Pin 1: Red Video

Pin 2: Green Video  
Pin 3: Blue Video  
Pin 4: H Sync  
Pin 5: V Sync  
Pin 6: Red Return  
Pin 7: Green Return  
Pin 8: Blue Return  
Pin 9: Ground

**NOTE:** IBM PGC assigns pin 4 to Composite Sync and pin 5 is a no-connect.

BTW, don't use an EGA 9 pin extension cable to connect it to VGA. While this will work, the wires are not shielded or the wrong wires and you will get ghosting and ringing at vertical edges. I constructed mine using proper 75 ohm coax for the RGB and H and V sync as well (though it is not needed for the sync).

---

## 3.2) EGA

---

### 3.2.1) Standard EGA

(From Brian Smither)

According to the CPD-1303 user guide:

Pin:	1	2	3	4	5	6	7	8	9
Analog	GND	GND	RED	GRN	BLU	GND	---	H/HV	V *
DIG/NORM	GND	GND	RED	GRN	BLU	GND	---	H/HV	V
/D1	GND	GND	RED	GRN	BLU	INT	---	H/HV	V
/D2/CGA	GND	GND	RED	GRN	BLU	INT	---	H/HV	V
/D2/MDA	GND	GND	---	---	---	INT	GRN	H/HV	V
/D2/EGA	GND	r	R	G	B	g	b	H/HV	V

r-g-b is secondary colors for 64 color EGA

\* Sync on green automatic if H or HV is not assigned to pin #8.

SYNC: any polarity.

Vertical size depends on vertical frequency and can be adjusted manually.

---

### 3.2.2) DB9 to DB15 cable

(From Brian Smither)

A 9-pin (monitor) to 15-pin (video card) cable can be built as follows:

9-pin F		15-pin M
-----		-----
1,2,6	-----	5
3	-----	1
4	-----	2
5	-----	3
8	-----	13
9	-----	14

This adapter will **NOT** permit you to run a standard VGA monitor from a MGA/CGA/EGA video card as the signal levels and scan rates are not compatible. It only applies to the CPD1303 and similar monitors.

---

### 3.2.3) EGA - TTL

(From Sam Goldwasser)

(15.74-21.85 KHz) DB-9 pin:

1 GND	6 Secondary Green Video/Intensity
2 Secondary RED Video	7 Secondary Blue Video
3 Primary RED Video	8 H Sync TTL Positive
4 Primary GREEN Video	9 V Sync TTL Negative
5 Primary BLUE Video	

BTW, don't use an EGA 9 pin extension cable to connect it to VGA. While this will work, the wires are not shielded or the wrong wires and you will get ghosting and ringing at vertical edges. I constructed mine using proper 75 ohm coax for the RGB and H and V sync as well (though it is not needed for the sync).

---

### 3.3) CGA - TTL

(15.75 KHz - 320x200 or 640x200) DB-9 pin:

1 GND	6 Intensity
2 Unused	7 Unused
3 RED Video	8 H Sync TTL Positive
4 GREEN Video	9 V Sync TTL Positive
5 BLUE Video	

---

## 3.4) IBM PCjr CGA 18-pin connector

(From Dale Larson)

The above pins are looking at the COMPUTER connector so 1 to 9 would be right to left on the plug from the monitor.

It looks like the top row of the 18 are "A", bottom "B" and looking from the back, numbered 1-9 left-right they are labeled as follow:

a09 = audio  
a05 = red  
a04 = blue  
a07 = green  
a06 = inten  
a08 = not(line over)comp sync drive  
a03 = not tv hor drive  
b03 = hor out drive  
a01 = not tv vert drive  
b01 = vert out drive  
a02,b02,b04,b05,b06,b07,bo8,b09 = all grounds

---

## 3.5) Monochrome - TTL

(18.43 KHz - 720x350) DB-9 pin:

1 GND	6 Intensity
2 Unused	7 Video
3 Unused	8 H Sync TTL Positive
4 Unused	9 V Sync TTL Negative
5 Unused	

---

# Chapter 4) Macintosh Monitors

---

## 4.1) Mac II and Quadra

(From Sam Goldwasser)

Mac II

Analog (35 KHz H, 66.67 Hz V - 640x480) 15 pin.

Mac II and Quadra

Analog (49.7 KHz H, 74.55 Hz V - 832x624) 15 pin.

1	Red Ground	8	Blue Video
2	Red Video	9	Sense 2
3	Composite Sync	11	Ground
4	Sense 0	12	Vertical Sync
5	Green Video	13	Blue Ground
6	Green Ground	14	Ground
7	Sense 1	15	Horizontal Sync
8	Reserved (+12)		

---

# Chapter 5) Workstation Monitors

---

## 5.1) MacIntosh Video

(From Sam Goldwasser)

Mac II - analog (35 KHz H, 66.67 Hz V - 640x480) 15 pin. Mac II and Quadra - analog (49.7 KHz H, 74.55 Hz V - 832x624) 15 pin.

1	Red Ground	8	Blue Video
2	Red Video	9	Sense 2
3	Composite Sync	11	Ground
4	Sense 0	12	Vertical Sync
5	Green Video	13	Blue Ground
6	Green Ground	14	Ground

7 Sense 1                      15 Horizontal Sync  
 8 Reserved (+12)

## 5.2) Analog Sun 13W3 Color Pinout:

(From: [comp.sys.sun.hardware](http://comp.sys.sun.hardware) pseudo-FAQ: ([2gvhutINNvd@hatteras.cs.unc.edu](mailto:2gvhutINNvd@hatteras.cs.unc.edu))).

Analog: 13W3 connector:

\* May be NC. My spies tell me Sun considers these obsolete.

'green' is used by greyscale monitors for video input.

Sense table - 1=nc, 0=strap to gnd

Sense	Type
=====	=====
0	TBD (?)
1	Reserved
2	1280x1024, 76Hz
3	1152x900, 66Hz
4	1152x900, 76Hz, 19"
5	Reserved
6	1152x900, 76Hz, 16 or 17"
7	Nothing (no monitor connected)

---

# Chapter 6) PC Hardware

---

## 6.1) What is the pin out for ...?

(From Ralph Valentino)

This is a list of the pinouts to the more common PC hardware interfaces. It is by no means complete. While I have taken care not to make any mistakes, I urge you to take caution when using these tables. Also, please keep in mind that these are only tables, they are not a guide to hardware hacking and do not attempt to explain drive capabilities, signal timings, handling care, or other interface issues. As always, make sure you know what you're doing before you start hooking wires to your PC.

---

## 6.2) Connector Styles and Pin Numbering

5pin DIN Male

---

### 6.2.1) DB15-S Male

---

### 6.2.2) DB9 (DE-9) Male

```
-----

## 6.11.7) 2.5" IDE drive (44 pin connector)

[...]

The signals assigned for 44-pin applications are described in table 16. Although there are 50 pins in the plug, the mating receptacle need contain only 44 pins (the removal of pins E and F provides room for the wall of the receptacle).

The first four pins of the connector plug located on the device are not to be connected to the host, as they are reserved for manufacturer's use. Pins E, F and 20 are keys, and are removed.

Signal name	Connector contact	Conductor		Connector contact	Signal name

## 6.11.8) 3.5" IDE drive (40 pin connector)

### Interface Signal Assignments and Descriptions

The physical interface consists of receivers and drivers communicating through a 40-conductor flat ribbon non-shielded cable using an asynchronous interface protocol. Reserved signals shall be left unconnected.

Description	Source	Pin	Acronym
Reset	Host	1	RESET-

+5 V	34	5 V GND	74
+5 V	35	5 V GND	75
+5 V	36	5 V GND	76
SYNC	37	LEDC	77
MTRON	38	DLYDST	78
SCSIA0	39	SCSIA1	79
SCSIA2	40	SCSIA3	80

**SYNC**  
Synchronous spindle synchronization signal, generated by either host or drive.

**LEDC**  
Front panel LED signal; indicates drive activity for host front panel hard drive activity indicator.

**MTRON**  
Asserted by host to enable Motor Start option (enables starting motor via SCSI bus command).

**DLYDST**  
Asserted by host to enable Delayed Motor Start option (motor starts at power on or after a delay of 12 seconds times drive ID). This and MTRON are mutually exclusive options.

**SCSIAn**  
Binary code on A3, A2, A1 and A0 asserted by host to set-up SCSI bus ID in drive.

## 6.18) PCI

## 6.18.1) PCI Cards Universal/3.3V/5V and 32/64 bit

## 6.19) Mini DIN-8 Macintosh Serial Connector

(From Daniel JB Clark)

---

## Chapter 7) Video Cameras

### 7.1) 10-pin Video Camera connector

(From Sam Goldwasser)

This from a JVC camera. The 10 pin connector I know is sort of standard.

I know the 10 pin end is a standard. I have a couple of other cameras that have this connector. I don't know if the JVC end is a standard. There are 5 pairs of signals:

1. Power and GND
2. Video and return

3. Audio and return
4. Control and return

I never bothered to figure out what this did (signal that you are taping from/to camera?).

12 Pin	10 Pin	Function
1	1	Video
2	2	Video Shield
3		
4		
5		
6	6	Control
7	7	Audio
8	8	Audio Shield
9	9	Control Shield and +12 Return *check this* Center pin of power connector.
10	10	+12
11		
12		

(From Jim Novack)

I recommend that you confirm these, at least for power!! You do not want to be wrong for power. Better yet, use the power jack on the back of the camera to start off.

While the signal pin-out was standard, different manufacturers used a different strategy for pause/go from the camera trigger. I think some used a positive voltage, some used a negative.

There was a technique used that allowed viewing tape playback on the camera viewfinder. I think the same wire that fed camera input to the VCR was used, but the VCR put a DC voltage down it to tell the camera a signal was incoming, not outgoing. I'm hazy on this, it was a while ago!

What you really need is a camera A.C. adapter. These were sold so that people could use these 10-pin cameras with their home VCR. It generally was a small box that contained a 10-pin receptical, a power supply, a small audio circuit (I think) to amplify the camera mic level signal to line level, and video and audio outputs. I have one of these, a Panasonic PK-A789s that I have used with Panasonic, JVC, and RCA cameras. Check with video shops-they might have one gathering dust. Watch out for anything from the pre VHS era (before circa 1977). I remember that Sony, and others, used the same connector for the cameras for their "Porta-Pak" reel to reel and U-Matic decks, and the pin-out on these was different-a sync signal was fed to the camera, for one. They also made A.C. adapters for those cameras (Sony's was called a CMA-2--why do I remember these things??) Avoid these because they would probably fry your camera.

---

## 7.2) Panasonic Video Camera pinout (round, 10-pin)

(From Bruce Coates)

(Re: Panasonic WV-3230)

The 10 pin connector pin out used on the Panasonic seems to conform to the "standard" 10 pin VHS pinout (pretty much

anyway).

Here's how it's listed in the service manual:

1. Video Out/In
2. Video Ground
3. Serial Data In/Out (\*)
4. Serial Clock /IN Tally (\*)
5. Standby Control (high) / Right Audio out (\*)
6. VTR Record (H)/ Pause Out (L) Out
7. Left Audio Out
8. Audio Ground
9. Power Ground
10. +12v IN

The "\*" are the **NON STANDARD PINS**. From the information that I have, pins 3 and 4 have no specific assignment and vary from manufacturer to manufacturer. I also believe that pin 5 is usually used only for Right audio out. One word of caution, if you're trying to connect this camera to any external power supplies, be **EXTREMELY CAREFUL** that you have the correct polarity. There is **NO REVERSE POLARITY PROTECTION** in the camera and I can tell you from experience that hooking it up backwards will completely destroy the power supply circuits inside.

---

## 7.3) Quasar video camera pinout

(From: Mike Turner [mike.turner@johnabbott.qc.ca](mailto:mike.turner@johnabbott.qc.ca))

1. Video out (REC)/in (PLAY)
2. Ground for pin 1
3. Not used or tally
4. Ground for pin 5 or serial clock in (depends on camera)
5. Audio in, standby or audio out (2)
6. Remote pause
7. Audio out
8. Ground for pin 7
9. ground for pin 10
10. +12 volts DC

I expect you will use only pins 1,2,7,8,9 and 10

---

## Chapter 8) TV Connectors

---

### 8.1) SCART / EURO-AV

(From Gerald Evans)

The pins have the following functions:

1. Audio out B
2. Audio in B
3. Audio out A
4. Audio ground
5. Blue video ground
6. Audio in A
7. Blue video
8. Function switching
9. Green video ground
10. Comms data line 2
11. Green video
12. Comms data line 1
13. Red video ground
14. Comms data ground
15. Red video
16. Blanking
17. Video ground
18. Blanking ground
19. Composite video out OR synchronisation out
20. Composite video in OR synchronisation in
21. Common ground

The pin numbering on the plug is as follows:

Note: This is as viewed from WIRING side.

Personally, I think SCART connectors are dreadful things. I mean, who really wants a 20 pin monster when only about 3 or 4 are ever used in any application. But it seems they are being forced upon us!

I think most VCRs just use the composite video (in+out) and the two sound channels (in+out stereo). By the way, quite a common fault with VCRs is that the scart socket gets disconnected from the PCB inside the machine. I have fixed 2 VCRs with this problem. It is not surprising really, because the leverage on the huge plug must be quite large if you pull it out carelessly etc.

The quicher SCART dies, the better, IMHO.

(From horus@pnm.it)

Here is the SCART or EURO-AV or PeriteleVision Connector:

<pre>       20_   o o o o o o o o o o   2       21 o   o o o o o o o o o o   1           \-----/           SCART (RGB &amp; CVBS) </pre>	<pre> Pin ----   1   2   3   4   5   6   7   8   9  10  11  12  13  14  15  16  17  18  19  20  21 </pre>	<pre> TV SCART ----- R Audio Out R Audio In L Audio Out Audio GND Blue GND L Audio In Blue Out AV Status Out Green GND Not Connected Green Out Not Connected Red GND Not Connected Red Out/SVHS Chroma Out RGB Status Out Video GND Ground Video Out Video In Ground (Casing) </pre>
--	---	--

Video Output Level : 1 V - +/-2 dB  
 Video Output Impedance : 75 ohm  
 Video Frequency Range : 25Hz. - 4.8MHz  
 (+/-1.5 dB)  
 Video De-emphasis(PAL) : to CCIR 405.1  
 (625 lines)

(From John Marchant)

This horrible diagram is supposed to show the female socket config. Hopefully your plug will have its pins numbered visibly, so you won't need to refer to my pic.

Pins for a RGB Amiga/TV connection are marked with a "\*" :

- 1. Audio output 1. right channel 0.5 Vrms
- \* 2. Audio input 1, right channel 0.5 Vrms
- 3. Audio output 2, left channel 0.5 Vrms
- \* 4. Gnd (audio)
- \* 5. Gnd (blue)
- \* 6. Audio input 2, left channel 0.5 Vrms
- \* 7. RGB input Blue
- \* 8. Switch signal video status 18-12 V
- \* 9. Gnd (Green)
- 10. Reserved for clock signals
- \* 11. RGB input Green
- 12. Reserved for remote control
- \* 13. Gnd (Red)
- 14. Gnd (remote control)

- \* 15. RGB input Red
  - \* 16. Switch signal RGB (blanking) 1.3V
  - 17. Gnd (Composite Video)
  - \* 18. Switch Gnd (blanking)
  - 19. Video output 1 V pk-pk/75 ohm
  - \* 20. Composite Video input 1 V pk-pk/75 ohm (or composite sync in)
  - 21. Shield
- 

## 8.2) SONY RGB MULTI INPUT (found on KV-25XBR TV's)

(From Shawn Lin)

34-pin male connector, looks just like a floppy drive connector.

Pin	Signal assignment
===	=====
1	+5V power supply
2	+5V power supply

## 1. About the Author

Author: Jim Christy

Version: 1.01

E-Mail: [jchristy@hplred.HP.COM](mailto:jchristy@hplred.HP.COM)

---

## 2. Introduction

For all you game hardware enthusiasts out there, I took the opportunity this weekend to put a scope on my Super Nintendo connectors and find out what is going on. Because the standard Multi-out cable connector only has internal contacts for the audio and video signals, I had to find some more push-in gold contacts at a local store to fully break out all the signals. It appears easier to do this than make your own connector.

In short, I found that in addition to S-VHS, the multiout also supports RGB and sync. I also got the controller pinouts and protocol, which opens up some interesting possibilities. One could rather easily construct a "macro recorder" that records your exact button presses for a game sequence and allows you to play them back. They will be time-accurate by definition of the protocol, and depending on how random the game plays, you should be able to replay those sequences that get boring, and then take over control when you want.

If all of this is already well known, then sorry for the waste of net bandwidth...

---

# 3. SNES Multi-out cable connector pins.

These are numbered the way Nintendo did, and the view is looking back "into" the connector on the CABLE.

Pin	Description
1	Red analog video out (1v DC offset, 1vpp video into 75 ohms)
2	Green analog video out (1v DC offset, 1vpp video into 75 ohms)
3	Composite H/V sync out (1vpp into 75 ohms)
4	Blue analog video out (1v DC offset, 1vpp video into 75 ohms)
5	Ground
6	Ground
7	Y (luminance) signal for S-VHS (1vpp into 75 ohms)
8	C (chroma) signal for S-VHS (1vpp into 75 ohms)
9	NTSC composite video signal (1vpp into 75 ohms)
10	+5v (Could be just a high logic signal)
11	Left channel audio out
12	Right channel audio out

## Additional Notes:

As seen above, the SNES does have RGB capability. I was able to get a stable raster on my NEC MultiSync "classic" using the RGB and sync pins. However, the video levels are not RS-170 compatible. The DC offset needs to be filtered out with some large capacitors and the peak-to-peak video amplitude may need to be reduced to 0.7v by using a lower load impedance than 75 ohms. The Y/C (S-VHS) signals \*appear\* to be directly usable, but tests cannot be made until I find the pinouts for the S-VHS connector on my TV.

---

# 4. SNES Controller cable connector pins.

I could not find a Nintendo numbering scheme, so I made one up. The view is looking back "into" the connector on the CABLE.

Pin	Description	Color of wire in cable
===	=====	=====
1	+5v	White
2	Data clock	Yellow
3	Data latch	Orange
4	Serial data	Red
5	?	no wire
6	?	no wire
7	Ground	Brown

Additional notes:

Pins 5 and 6 show a DC voltage of 5v on a DMM. I forgot to look at them on a scope so there may pulses too. However, they don't connect to anything at present.

The controllers have a small circuit board with 2 surface mount 14-pin ICs, marked by Nintendo as IC-A and IC-B. Although rubber domes are used to provide the tactile response of the buttons, they are not capacitive technology as originally thought. Instead they use what appears to be carbon impregnated rubber on the underside which makes a resistive path (200 ohms) across 2 carbon coated PCB pads when depressed.

- The red wire goes to pin 2 on IC-A.
- The orange wire goes to pin 8 on both IC-A and IC-B.
- The yellow wire goes to pin 9 on both IC-A and IC-B.

IC-A and IC-B appear to be identical, with a 91 date code and have another (possible part number) of 545. These are most likely 2 parallel load shift registers in series. Buttons on the controller pull the parallel load inputs to ground through the contact formed by pressing a button. IC-B serially feeds IC-A, which then drives the serial data line to the SNES CPU.

---

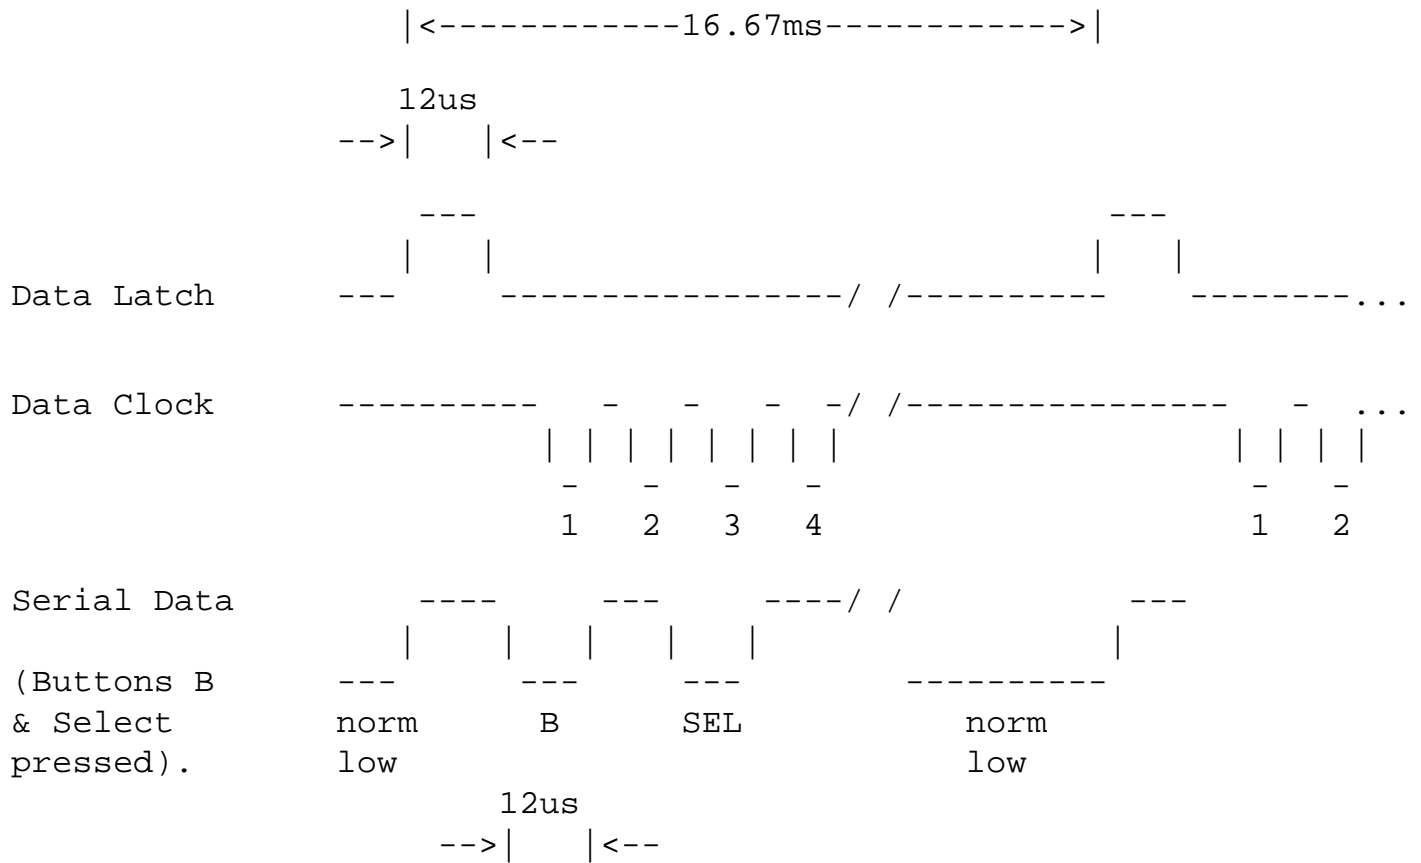

## 5. SNES Controller Communication Protocol

Every 16.67ms (or about 60Hz), the SNES CPU sends out a 12us wide, positive going data latch pulse on pin 3. This instructs the ICs in the controller to latch the state of all buttons internally. Six microseconds after the fall of the data latch pulse, the CPU sends out 16 data clock pulses on pin 2. These are 50% duty cycle with 12us per full cycle. The controllers serially shift the latched button states out pin 4 on every rising edge of the clock, and the CPU

samples the data on every falling edge.

Each button on the controller is assigned a specific id which corresponds to the clock cycle during which that button's state will be reported. The table in section 4.0 lists the ids for all buttons. Note that multiple buttons may be depressed at any given moment. Also note that a logic "high" on the serial data line means the button is NOT depressed.

At the end of the 16 cycle sequence, the serial data line is driven low until the next data latch pulse. The only slight deviation from this protocol is apparent in the first clock cycle. Because the clock is normally high, the first transition it makes after latch signal is a high-to-low transition. Since data for the first button (B in this case) will be latched on this transition, it's data must actually be driven earlier. The SNES controllers drive data for the first button at the falling edge of latch. Data for all other buttons is driven at the rising edge of clock. Hopefully the following timing diagram will serve to illustrate this. Only 4 of the 16 clock cycles are shown for brevity.

## 6. SNES Controller Button-to-Clock Pulse Assignment

Clock Cycle =====	Button Reported =====
1	B
2	Y
3	Select

4	Start
5	Up on joypad
6	Down on joypad
7	Left on joypad
8	Right on joypad
9	A
10	X
11	L
12	R
13	none (always high)
14	none (always high)
15	none (always high)
16	none (always high)

Additional notes:

Clock cycles 13-16 are essentially unused. It would be interesting to see how the SNES responds if we drive low button data during these cycles. Nintendo may use these for future controllers with more capabilities.

(From the Editor)

NOTE: S-VHS is not means to mean Super-VHS. It stands for Super-Video (connector and output)

#### Additional Info (From Kevin Horton)

OK, the SNES uses the 65816 processor, which is basically a 16-bit version of the 6502. It runs at 3.579545 MHz (color-burst), and has an 8-bit data bus. It can address up to 16MB.

The carts are nothing more than ROM. To tell you how much data is one, take the number of 'MegaBits' and divide by 8 to get megabytes. That's how much data is really in the carts. So, an 8-mbit cart really is only 1 megabyte.

## Chapter 1) Sync on Green FAQ

---

### 1.1) About the Author

Author: Dr. Jon Jenkins  
E-Mail: [jenkinsj@ozy.dec.com](mailto:jenkinsj@ozy.dec.com)  
Internal Version: 1.01

---

### 1.2) Introduction

These files contain information to help people get Apollo RGB sync on G fixed frequency monitors to work with Xfree, It is important that your video card has a dot clock close enough to the speed the monitor expects. We have a number of monitors that expect 65 MHz clock, and most of our (very cheap) cards seem to be able to manage this. We have two monitors that expect 125MHz, they needed reasonable cards. The sample XF86Config file works for these cards with the hi-res monitor. See the file monitor-info for information about the various types of Apollo monitors. We have a circuit here to merge the G with the Hsync and Vsync of the VGA card, the R+,B+ go straight from the VGA output to the monitor. See the file [Gsync.gif](#) (TLJFILE!FOUND) for the circuit diagram, any electronics hack could make it on vero board in an hour. (all the usual flank covering disclaimers apply to the use of this circuit)

The console mode won't damage the monitor, but you can't read anything on screen. There is a program to give you a hires text mode, can't think of its name. We have our systems configured to run xdm so (if the system boots ok) you don't need the console.

This info courtesy of Javaan Chahl

(From the Editor)

Some of the last few sections come from the [comp.sys.ibm.pc.hardware.video](http://www.comp.sys.ibm.pc.hardware.video) FAQ at URL:  
<http://www.heartlab.rii.uwo.ca/vidfaq/vidfaq.html> (R)

---

## 1.3) Notes on VGA->RGB conversion

I use standard 74HC 14pin DIP gates available from any electronics store. I use a 14pin DIP socket originally so that I could change gate types (OR/XOR/AND) easily. 74HC86 (XOR) works just great with the VR320 (im using it now can also use OR, dont understand why ??).

The VN10KM is a small signal N channel enhancement mode mosfet also available from most electronics store.

IF the video card you are using is a standard VGA output: (Im using a diamond stealth 64 VRAM)

```
1: RED video
2: Green video
3: blue video
4: monitor id bit 2
5: Ground
6: red return
7: green return
8: blue return
9: NC
10: sync return
11: monitor id bit 0
12: monitor id bit 1
13: H sync
14: V sync
15: NC
```

I join all the "returns" together with the ground on the small PCB and use that as a common ground for the RGB cable to the monitor. You can use separate if you want to but you should join the green return and sync returns together. I did find some small shadowing if I didn't group them all together.

Just a note, when you set up your video card in Windows set it to 1280x1024x72|66 or whatever is closest I use a VR260 (1024x864) at 1027x768@66Hz (check with your manual DA or D4 are 72Hz) your VGA will not like this frequency so either disconnect it quickly or before you actually set the video card to this mode (i.e. put the OK as the active control in Windows and then connect the VR320 and hit return) My diamond setup gives me 10 seconds to do this adjustment When you exit you will probably have to select the 1280x1024 mode with your old VGA connected again and from then on every time you start Windows you will be able to view it in "big" colour mode. Note the vr320 will not work in DOS

mode as it is not a multisync monitor so all you see when you boot up is garbage until Windows starts, I put "win" in my autoexec.bat file.

### Note there is a danger here:

I had set up the monitor and for some reason it did not work so I couldn't see what was going on: my ol VGA wouldn't work and the VR wouldn't work either so I had to find the cards .ini files and edit by hand to get back to useable video!

For FreeBSD/XF86 the lines are:

```
#VR260 monitor is 70MHz 1024x864
#VR320/319 monitor is 130MHz 1280x1024
#
Modeline "1280x1024" 130.81 1280 1312 1472 1696 1024 1027 1030 1063 +hsync +vsync
Modeline "1024x864" 69.2 1024 1040 1168 1272 864 864 867 904 +hsync +vsync
```

The circuit to do this is as follows::

Notes:

1. You may be dealing with 135MHz square waves so there are lots of high frequency stuff around; use good RF practices.
2. The coupling capacitors are a safeguard to start with I don't use them cause they caused shadowing around sharp colour changes (the ol RC effect).
3. Use the XOR gate first as a test but you may need other gates to actually get it working
4. A CRO will be handy for final adjustment.
5. Make the device is as close as possible to the video outlet on the VGA card.
6. Take the 5V from the PC power supply inside the box. I just hooked one of the spare connectors which I also use for an external fan (pentiums being the heaters they are!). Make sure (check it again!!) (and again!!!) you dont get the 12V one!!
7. You must use a VN10KM or other:
  - o SMALL SIGNAL
  - o N CHANNEL
  - o ENHANCEMENT MODE
  - o MOSFET**others will not work!**

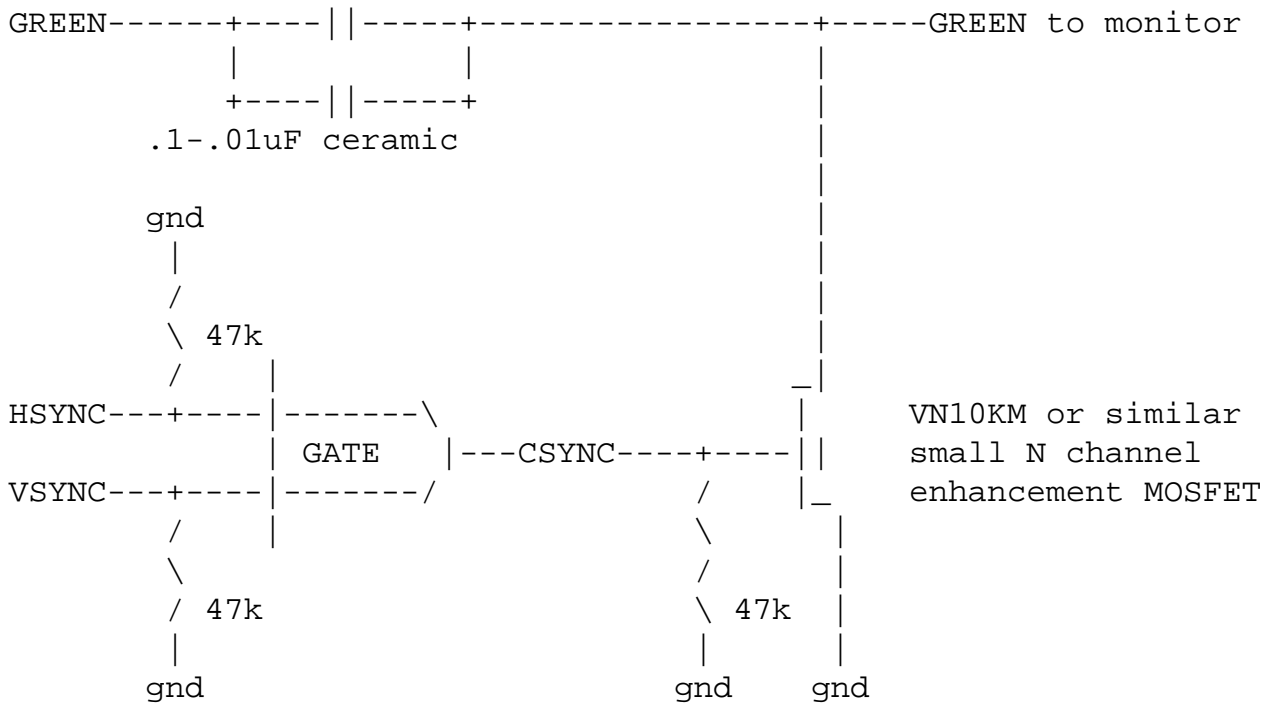

---

## 1.4) Schematic 1

GIF [Schematic](#) (GIF87a, 17KB, width=880 height=688)

```

+5.0V
|
/
\ VR1 (1k carbon mini pot)
33uF tantalum | ~0.3V DC in porch area
```

HSYNC, VSYNC and CSYNC are grounded with 47k carbon resistors

GATE=LS or HC types, HC preferred.

- OR: for -ve logic sync and no hsync during vsync
- NAND: for +ve logic sync and no hsync during vsync
- XOR: for -ve or +ve logic sync and hsync during vsync

Capacitors are optional, I dont use them

use XOR gate with DEC monitors and as a first shot with others, then OR gate then NAND gate.

Get a CRO an adjust porch levels to 0.3V and 0 level (sync level) to 0.0V

## 1.5) Voltages

(From Samuel M. Goldwasser)

Sync-on-green combines the H and V sync into a composite sync signal (your video card like ATI may already have this capability) and then merges it with the video.

- Video: .7 V p-p white it positive.
- Sync: .3 V p-p sync tips negative.

The combination is either OR or XOR - which works better depends on characteristics of video signal and monitor.

## 1.7) About the Author

Subject: Apollo FAQ - monitors info

Author: Russell Ayling

E-Mail: [rayling@pandc.rta.oz.au](mailto:rayling@pandc.rta.oz.au)

I compiled this info a while ago from an HP source plus bits and pieces I picked up. There are frequent questions about the monitors (esp. frequency) so maybe this, or part of it, could go in the FAQ. (I've mailed this out many times already, it would be easier to just refer people to the FAQ.)

## 1.9) 15" and 19" 1024x800 monitors

Following specifications apply to the 15" and 19" 1024x800 monitors:

Resolution	1024x800 (noninterlaced)		
Scanning frequency range	Horizontal	50.2 kHz	(+/- 500Hz)
	Vertical	47 to 80 Hz	
Blanking time	Horizontal	4.713 usec	maximum
	Vertical	828.83 usec	max (15")
		831 usec	max (19")
Retrace time	Horizontal	3.713 usec	max
	Vertical	600 usec	max
Video amplifier			
bandwidth	+/- 3dB form 50Hz to 70MHz minimum		
pulse rise and fall time	5 nanosec (max) measured from 10% to 90%		
differential tilt	not more than 3% on blanking waveforms		
video polarity	Positive for Peak Luminance of the CRT		
video gain	no perceptible change at any brightness setting when a 15nsec pixel is written adjacent to a 60nsec bar		
Degauss			
duration	< 15 sec		
type	Automatic at power on		
X-Ray radiation	< 0.5 MR/H		
Horizontal frequency	Duration:	19.794 usec	(50.519 kHz)

```

front porch      0.942 usec
sync             1.88 usec
back porch       1.88 usec
blanking         4.71 usec
display area     15.084 usec

```

```

Vertical frequency      Duration: 16.67 usec   (60.0 kHz)
front porch             79.176 usec
sync                   79.176 usec

## 1.10) 15" and 19" 1024x800 monitors

Following specifications apply to the 15" and 19" 1024x800 monitors:

Resolution 1024x800 (noninterlaced)

Scanning frequency range	Horizontal	50.2 kHz (+/- 500Hz)
	Vertical	47 to 80 Hz

Blanking time	Horizontal	4.713 usec maximum
	Vertical	828.83 usec max (15")
		831 usec max (19")

Retrace time	Horizontal	3.713 usec max
	Vertical	600 usec max

Video amplifier

bandwidth = +/- 3dB form 50Hz to 70MHz minimum

pulse rise and fall time = 5 nanosec (max) measured from 10% to 90%

differential tilt = not more than 3% on blanking waveforms

video polarity = Positive for Peak Luminance of the CRT

video gain = no perceptible change at any brightness

setting when a 15nsec pixel is written  
adjacent to a 60nsec bar

#### Degauss

duration < 15 sec  
type Automatic at power on  
X-Ray radiation < 0.5 MR/H

Horizontal frequency	Duration:	19.794 usec	(50.519 kHz)
front porch		0.942 usec	
sync		1.88 usec	
back porch		1.88 usec	
blanking		4.71 usec	
display area		15.084 usec	

Vertical frequency	Duration:	16.67 usec	(60.0 kHz)
front porch		79.176 usec	
sync		79.176 usec	
back porch		673.0 usec	
blanking		828.83 usec	(15")
		831.0 usec	(19")
display area		15.841 usec	(15")
		15.839 usec	(19")

Note: Apollo 1024x800 color graphics boards use a horizontal frequency  
of 50.519 kHz, vertical frequency of 60Hz

usec = microseconds

## Chapter 2) B/W HP Monitors

---

### 2.1) About the Author

Author: Mike Thomas  
E-Mail: [thomasm@agcs.com](mailto:thomasm@agcs.com)  
Date: 15 Jul 1993

The black and white displays were built by PHILIPS in Canada. The plant there has been shut down, when I last enquired with Philips re: purchasing spare parts, I was informed that they did not want to support anymore new customers for this product line. Philips makes the new HP b/w monitors too, but it looks as if everything is manufactured in Taiwan.

The following is a list of technical info for the color and monochrome monitors, also includes [information on common monochrome monitor repairs](#).

Vertical Frequency duration 16.67msec., Frequency = 60.0 Hz  
Vertical front porch - 79.176 usec.  
Vertical Sync - 79.176 usec.  
Vertical back porch - 673.0 usec  
Vertical blanking - 828.83 usec (15")  
831 usec (19")  
Vertical display area - 15.841 msec (15")  
15.839 msec (19")

---

## 2.2.2) 1280x1024 Color monitor performance specifications

Resolution - 1280 x 1024 noninterlaced

Scanning frequency range - Horizontal 73.7 kHz +/- 500 Hz  
Vertical 68.24 Hz

Blanking time - Horizontal 3.328 usec max.  
Vertical 759.0 usec. max.

Retrace time - Horizontal 2.5 usec max  
Vertical 395 usec max

Video amplifier - Bandwidth = +/- 3dB from 50 Hz to 170MHz  
Pulse rise/fall = 2.7 nanosec. max measured from 10%/90%  
Differential tilt = Not more than 3% on blanking waveforms  
Video gain linearity = Linear analog amplifier is capable  
of resolving a min. of 32 shades of  
gray from black to white.

X-Ray radiation - Less than 0.5 MR/H

Pixel rate - 124.996 MHz

Pixel period - 8.000256 nsec.

Aspect Ratio 5/4

Horizontally displayed pixels - 1280

Vertically displayed lines - 1024

Horizontal frequency - 73.702 kHz

Horizontal period - 13.568 usec., pixels 1696

Horizontal front porch - 0.256 usec., pixels 32

Horizontal sync - 1.536 usec., pixels 192

Horizontal back porch - 1.536 usec., pixels 192

Horizontal blanking - 3.328 usec., pixels 416

Horizontal display area - 10.240 usec., pixels 1280

Vertical fields per frame (noninterlaced) - 1

Vertical field frequency - 68.24 Hz

Vertical field period - 68.24 msec, lines 1080

Vertical front porch - 40.7 usec, lines 3

Vertical sync - 40.7 usec, lines 3  
Vertical back porch - 678 usec., lines 50  
Vertical blanking - 759 usec, lines 56  
Vertical display area - 13.893 msec, lines 1024

---

### **2.2.3) 19 inch Monochrome monitor specifications**

Resolution - 1280 x 1024 noninterlaced

Active video time - Horizontal 10.857 usec.  
Vertical 15.009 msec.

Blanking time - Horizontal 3.8 usec.  
Vertical 616 usec.

Front porch - Horizontal 407 nsec.  
Vertical 58.6 usec.

Back porch - Horizontal 1.9 usec  
Vertical 498 usec.

Sync pulse - Horizontal 1.49 usec.  
Vertical 58.6 usec.

Pixel time - 8.47 nsec.

Maximum light output - 30 +/- FLB

---

### **2.2.4) Monochrome display cable pin outs**

Pin 1 - ECL Video  
Pin 2 - No connection  
Pin 3 - Horizontal sync  
Pin 4 - Vertical sync  
Pin 5 - No connection  
Pin 6 - ECL Video  
Pin 7 - Video Shield  
Pin 8 - Horizontal Sync Return  
Pin 9 - Outer Shield Chassis

---

### **2.2.5) DN2500 Monochrome monitor performance specifications**

Resolution - 1280 x 1024 noninterlaced

Active video time - Horizontal 10.240 usec  
                                  Vertical 13.63 msec

Blanking time - Horizontal 3.072 usec  
                                  Vertical 639.0 usec

Front porch - Horizontal 0.256 usec  
                                  Vertical 39.94 usec

Back porch - Horizontal 1.536 usec  
                                  Vertical 559.0 usec

Sync pulse - Horizontal 1.280 usec  
                                  Vertical 39.94 usec

Pixel time - 8.00 nsec

---

## Chapter 3) XFree modes for Apollo monitors

---

### 3.1) About the Author

Subject: XFree modes for Apollo monitors  
Author: Leonard N. Zubkoff  
E-Mail: [lnz@dandelion.com](mailto:lnz@dandelion.com)  
Date: 22 Sep 1994

---

### 3.2) Modes

The Apollo color 1280x1024 monitor is a Matsushita J2P36X. To drive it at 1280x1024 you'll need a dot clock of 125 MHz. If your VGA card won't do this, you may have to tear into the monitor's sweep circuitry, since it's not a multi-sync design.

Here are the timing numbers you'll need for your Xconfig file. If you get this to work, please send me your Xconfig.

There are actually two versions of this monitor, one with a 68Hz vertical refresh rate and the other with 70Hz. Here are Xconfig mode lines for both of them (these have been tested with my STB Pegasus VL):

```
# Apollo 010700-005 1280x1024 Color Display  
#
```

```
"1280x1024-68" 124.996 1280 1312 1504 1696 1024 1027 1030 1080
"1280x1024-70" 124.996 1280 1312 1472 1664 1024 1027 1030 1072
```

In order to use one of these monitors with XFree86, you'll need a graphics card that supports the 125MHz pixel clock as well as providing RGB outputs with sync-on-green.

Very happily typing this on one of the 68Hz monitors...

---

## Chapter 4) What's the difference between fixed frequency and multisynchronous monitors?

(Excerpts from comp.sys.ibm.pc.hardware.video FAQ)

(From Michael Scott and Bill Nott)

There are two primary measures of the maximum effective pixel addressability and refresh rate that a monitor is capable of. The maximum rate that a monitor can refresh the screen is measured in Hertz (cycles/second) and is called the vertical refresh rate (or vertical scan rate). The horizontal scan rate is the number of times that the monitor can move the electron beam horizontally across the screen, then back to the beginning of the next scan line in one second. Most early analog monitors were fixed frequency, meaning that they were intended to work only at one specific vertical refresh rate (often 60 Hz) and one horizontal rate (often this is expressed as a number of pixels, but this isn't really the same). Most older SUN, SGI and other workstation monitors were of this type. Generally, these monitors are limited in their applications, since they require that the incoming video signal falls within narrow timing specifications.

These type monitors also typically use composite video signals (with sync on Green), so are not compatible with most of today's PC graphics controllers. Also note that even if the composite video signal issue is overcome, there are additional issues related to attempting to use such monitors with a PC. Among these are DOS text mode support, and radiated emissions compliance. See "How can I get a fixed frequency (RGB) monitor to work on my PC?" below.

In part due to the desire to produce more flexible monitors (i.e. fewer different models), the lack of PC SVGA/EVGA/etc video standards, and in part due to recognition of an emerging trend toward higher pixel addressability formats within the computer industry, along with a desire to provide an upward migration path for new customers, vendors started to produce monitors capable of syncing to video signals within a range of frequencies. Such monitors are called multisynchronous, or Multisync. Multisync is actually a trademark of NEC's, though it has become a generic term for a monitor which is capable of syncing to more than one video frequency. The meaning of multisynchronous has become somewhat muddled. To truly be multisynchronous, a monitor should be able to sync to any frequency of incoming video signal (within reason, of course). However, many so-called multisynchronous monitors can only sync to a number of discrete frequencies (usually 3 or 4).

If the video signal supplied to such a monitor is within the range of its deflection circuits, the image will be displayed; otherwise, the image may be either not synchronized, or completely blanked. It is also possible to harm some monitors of this type by applying a video signal outside its ranges, if protective measures were not put into

place by the design. Thus, such a monitor will usually operate at the most common video modes, but may not operate at less common modes. This type of monitor may be referred to as a 'banded' design. A continuous frequency design should operate at any frequency within the specified range.

## Chapter 5) How can I get a fixed frequency (RGB) monitor to work on my PC?

(Excerpts from comp.sys.ibm.pc.hardware.video FAQ)

(From Michael Scott and Bill Nott)

There are plenty of old RGB monitors (possibly from old Sun, SGI, or other workstations) around which are attached to outdated or non-functional machines. Most of these units are quality products by Sony, Hitachi or other vendors. You want an easy way to connect your VGA or better card to the monitor. It's may not be that easy, since many of these monitors are only capable of displayed non-standard pixel addressabilities, but read on..

The easiest solution (but not necessarily the cheapest) is a commercial solution. See the section from Declan Hughes, below.

Most of the old RGB monitors are fixed frequency, meaning that they are intended to work at only specific horizontal and vertical scan rates. This is in contrast to many newer models which are variations on the multi-sync theme. Multi-sync means that the monitor can sync to a **RANGE** of scan rates, or a number of discrete scan rates, based on the incoming video signal. i.e. the monitor will detect the scan rates of the video signal, and switch to the closest scan rate it is capable of. Since a fixed frequency monitor can't do this, you have to make sure that the video signal your video card is generating is compatible with the monitor.

To hook up a VGA card to a fixed frequency monitor requires three things:

1. A cable that connects the VGA output to the RGB (and possibly sync) on the monitor. This may be the easiest part. Fixed frequency monitors typically have BNC connections for video input, so you need a cable which connects to your computer video output (typically a 15 pin D-Sub VGA) at one end, and which has 3, 4, or 5 BNC's at the other end. The number of BNC's depends on how you plan to resolve the sync signal issue (see point 3).

2. The horizontal and vertical scan rates must be compatible. Some video cards have adjustable scan rates, and if you can adjust the video signal to be within the range that the monitor can handle, you might be in business. If you can't get the generated video signal scan rates to within the monitor's specs, you need a scan converter, which is a very expensive and complex device (read: not practical). Even if you can get your graphics controller to adjust to the monitor's unique frequencies, you will have to figure out what to do when you first boot your PC, and how to run DOS programs, if needed. Just about every PC boots up in the DOS character mode (720 by 400 pixels, 31.5 kHz Horizontal, 70 Hz Vertical). No fixed frequency monitor will operate at this mode. If you never need to use DOS, you may be able to set your autoexec.bat to start Windows immediately upon boot-up.
3. You must have a compatible electronic signal. The problem is this: VGA cards have separate channels for red, green, blue, vertical sync and horizontal sync. Most RGB monitors have 3 or 4 connectors, either red, green (with sync) and blue, or red, green, blue and a separate sync. The sync signals from the VGA card must be combined to be fed into the monitor. This is not as simple as soldering the horizontal, vertical sync and green wires together. Some folks have been able to get their monitors to work by building simple circuits. However, keep in mind that items 1 and 2 above **MUST** also be satisfied. One such circuit that has been suggested is [below]. Unfortunately, I don't know who designed this circuit, so I can't give credit but it's part of the Apollo FAQ (**included in the Sync On Green FAQ you're reading now!**) It is presented as-is, and there are no guarantees that it will do what you need. Be warned, if you don't have considerable electronics experience you shouldn't attempt this. If you blow your monitor or video card, don't come crying to me.

(From Declan Hughes)

A frequently asked question is how to use a fixed frequency monitor (often a Sony or Sun monitor) with a PC AT. Three companies that provide the required video cards are:

1. Mirage Computer Systems  
4286 Lincoln Blvd  
Marina Del Rey, CA 90292  
tel: 1-310-301-4541  
fax: 1-310-301-4546  
WWW: <http://lainet3.lainet.com/mirage/>  
E-Mail: Emil Darmo ([mirage@lainet.com](mailto:mirage@lainet.com))
2. Software Integrators  
104 East Main St  
Suite 206  
Bozeman, MT 59715  
Tel: 1-406-586-8866  
Tel: 1-800-547-2349  
Fax: 1-406-586-9145
3. Personal Computer Graphics (PCG) Corp. (Photon)  
Tel: 1-800-255-9893  
Tel: 1-310-260-4747  
Fax: 1-310-260-4744  
WWW: <http://www.photonweb.com/>  
EMail: [ben@photonweb.com](mailto:ben@photonweb.com)

4. MaxVision  
Tel: 1-800-533-5805 ext. 202

5. STB  
WWW: <http://www.stb.com>  
FTP: <ftp://ftp.stb.com/>

Mirage make video cards that support all single frequency/high frequency monitors that operate between 28-35Khz, 47-52Khz, 60-65Khz and 70-78Khz at specific VGA, EGA and DOS modes (various drivers are included) with ISA, Vesa local bus & PCI local bus interfaces. They also have fast drivers for specific software products such as Autocad, 3D Studio and Windows 3.1 etc.

(From Michael Scott)

They have three models which use popular video chipsets:

Model	Chipset	Max RAM	Bus
Wind 1280s	ET4000W32P	2 MB	ISA, VLB, PCI
Storm 1600s-Pro	S3 64-bit	4 MB	PCI
Wind 1280s-Pro	ISLNG Viper 128	4 MB	VLB, PCI

Drivers are available for Windows 3.1, Windows 95, OS/2 Warp, ACAD, Linux, lots of CAD programs & VESA compatible applications. All cards support separate sync and composite sync as well as sync on green. Software comes with the cards to adjust frequency, setup and centering.

**Mirage will give you a special discount if you mention that you were referred from this FAQ (No, I don't get anything in return :-())**

(From Declan Hughes)

For example, a STORM 1280/256 will drive a Sony GDM-1950 at 640x480, 800x600, 1024x768, 1280x1024 and DOS modes (this monitor is rated at 63.34Khz Horizontal sync. and the card runs at 64Khz Horizontal sync.). This card uses an S3 graphics accelerator. See also PC Magazine/April/13/1993.

Software Integrators make similar video cards (the MERCURY X1 Series) that will also support CGA modes as well as DOS, EGA and VGA modes using the S3 801 graphics accelerator and again they also make fast drivers for specific products such as Autocad, 3D Studio and Windows 3.1 etc.

These cards work with all fixed scan monitors including, IBM, Mitsubishi, Hitachi, Sony, Sun, HP, Verticom, DEC, Taxan, Philips, Apollo, Silicon Graphics, Intergraph, Aydin, Amtron, Monotronix, etc. and will replace old boards from, Artist, Number9, Nth, Verticom, Photon, BNW, VMI, Matrox, Metheus, Mirage, Graphax, Imagraph, TAT etc.

PCG provides several models, supporting ISA, VLB or PCI buses and their cards can support 1, 2 or 4 MB of video RAM. CL-5434 processors appear to power all of the Photon cards. They support sync-on-green (RGB)

monitors, Windows95, Win 3.1, Linux and provide a variety of video drivers for various applications. Cards automatically boot up with a frequency compatible with your monitor.

For more information, refer to the Fixed Frequency PC Video FAQ at: <http://www.wit.com/~xtian/video.html>

All companies can supply interface cables such as a 15 pin male VGA to 5 BNC connector.

I have gleaned this information from sales sheets faxed to me, I am purchasing one of these cards, I am not related to either company, and both sales staff were very helpful (so please ask them for more detailed information).

I was also informed of a German manufacturer ELSA that makes similar cards, but I do not know of their address or product range.

(From Bill Nott)

Nobody has dealt with the radiated emissions issue. All PC's are marketed as FCC class B products. I recently learned that Mirage labels their cards as Class B. However, most of the single frequency workstation monitors becoming available are FCC Class A, and the FCC rules say that attaching a Class A device to a Class B system degrades it to a Class A system. This in itself is not necessarily a problem, unless the system is actually found by the FCC to be causing radio interference. My recollection is that the process of remedy for a Class A system is more severe than for a Class B system, so users may be opening themselves up to a higher level of risk. Comments are welcomed on this.

---

## Chapter 6) Circuit for Converting from VGA to Fixed-Frequency RGB

ASCII file of a circuit which combines the vertical and horizontal sync signals from a VGA card with the green channel to give a red, sync on green, blue signal out. This circuit produces a signal that is compatible with many fixed-frequency monitors, but ensure that the signal you are sending has the same vertical and horizontal frequencies as the monitor expects.

For more information on how others have done this, read pertinent parts of this FAQ and refer to:

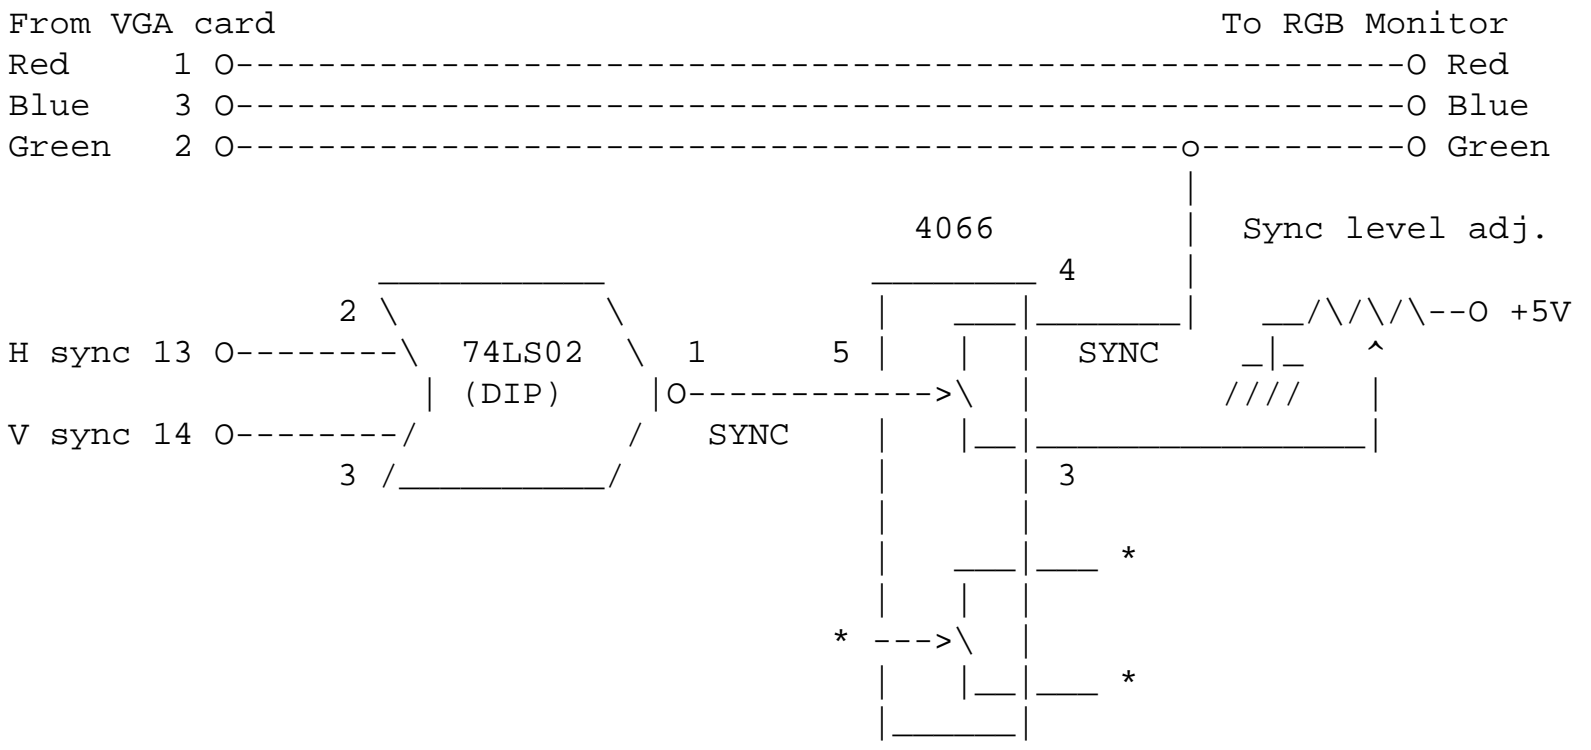

- <http://rugmd0.chem.rug.nl/~everdij/hitachi.html>  
Experiences hooking up a Hitachi monitor
- <http://www.wit.com/~xtian/video.html>  
Fixed Frequency PC Video FAQ

---

### 6.1) Schematic 2

Some folks had concerns about the old circuit because it used an OR gate on the sync line. The next version of the FAQ will have the updated circuit which uses an XOR instead.

**USE AT YOUR OWN RISK** - Others have used this circuit but I have not!

\* tie to ground

If no sync is present from the VGA card, pin 4 of the 4066 is in a high impedance state and does not affect the green video signal. If either horizontal or vertical sync is present from the VGA card, the positive sync voltage is gated onto the green video line. This "wire-or" of the signals seems to work!

I think that the video voltages presented by the VGA are a bit on the low side for the RGB monitor. It would be nice to have a video op-amp circuit to provide 1-3 dB adjustable gain on the RGB signal possibly using the NE592 video op-amps. The pinout for the 74LS02 is the more common one. Some flatpacks use pins 1 & 2 as inputs instead of 2 & 3. Use this circuit at your own risk. Good luck!

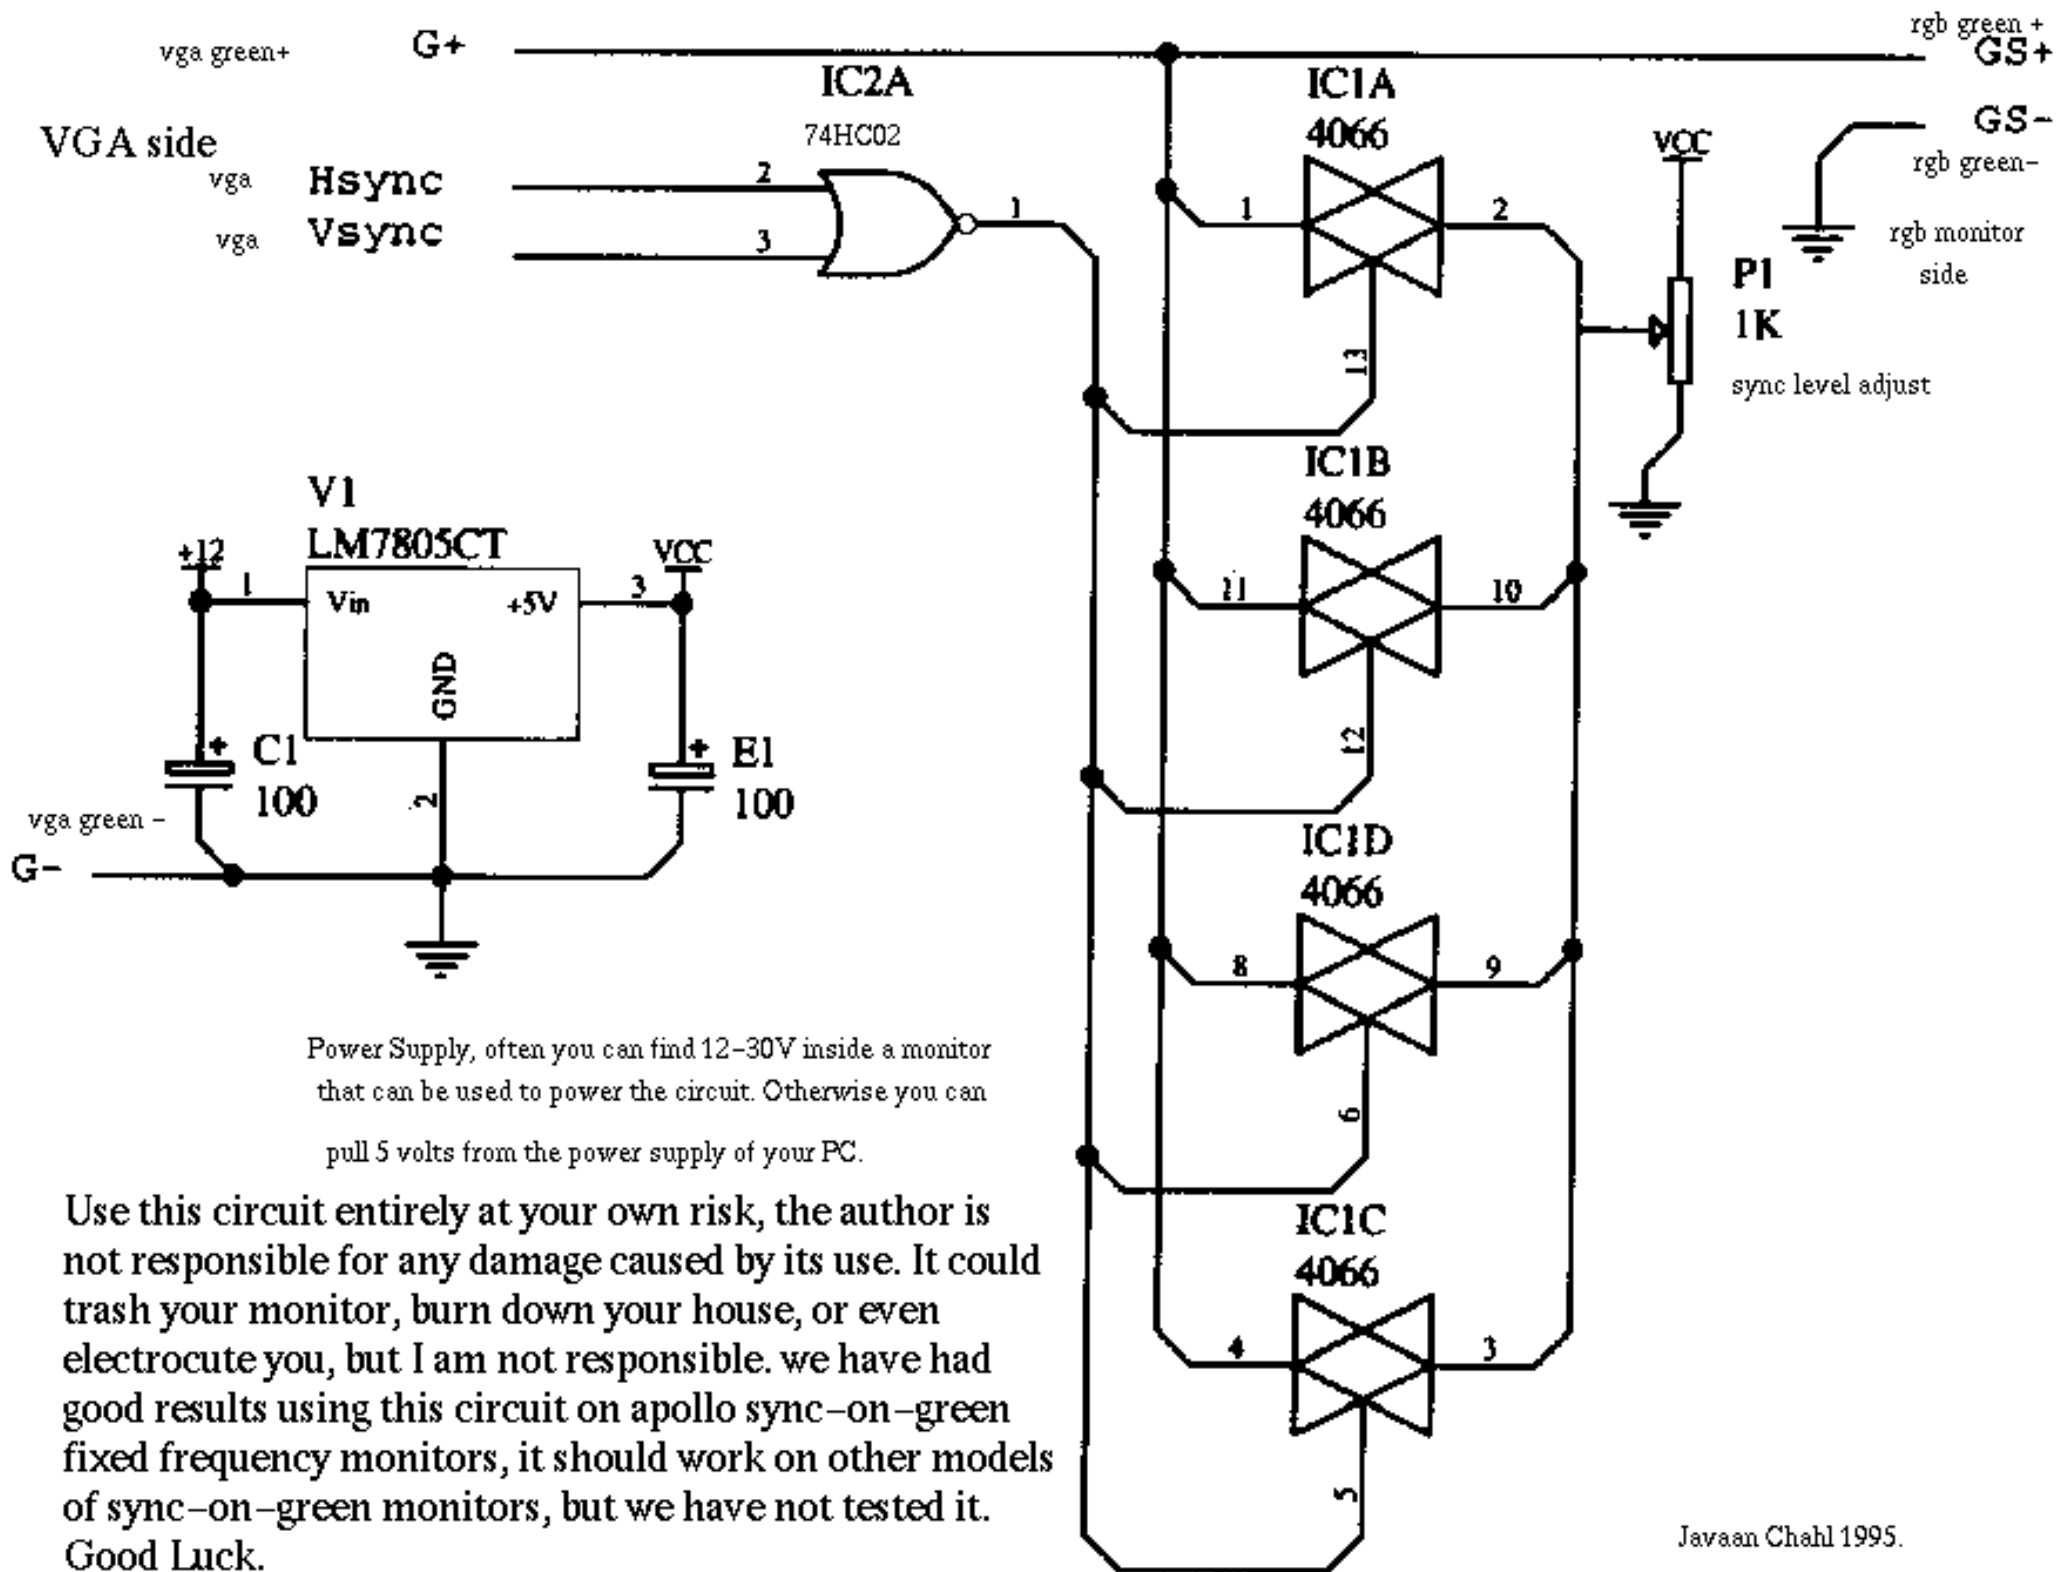

There is no Next. **THE END**

Go to [\[Previous\]](#) segment

---

This article was processed/generated by **Web-Admin** | [\[mailto\]](#). The most recent version is available on the WWW server <http://www.repairfaq.org/> [\[Copyright\]](#) [\[Disclaimer\]](#)

Power Supply, often you can find 12-30V inside a monitor that can be used to power the circuit. Otherwise you can pull 5 volts from the power supply of your PC.

Use this circuit entirely at your own risk, the author is not responsible for any damage caused by its use. It could trash your monitor, burn down your house, or even electrocute you, but I am not responsible. we have had good results using this circuit on apollo sync-on-green fixed frequency monitors, it should work on other models of sync-on-green monitors, but we have not tested it. Good Luck.

Good Luck.

## Chapter 1) William Kucharski

---

# 1.1) Introduction

---

## 1.1.1) About the Author

Subject: SONY XBR debug mode  
Compiled by: William Kucharski (N0OKQ)  
E-Mail: [kucharsk@netcom.com](mailto:kucharsk@netcom.com)  
Thanks to: Bob Niland and Adam Keith Levin  
Date: 13 Jun 1995

---

## 1.1.2) Disclaimer & Cautions

This information is passed along for your education only. I do not promise that it will work for your set. I will not be responsible for any damage you do to your set.

Without proper documentation and training, you can probably do a swell job of messing up your set, perhaps even damaging it. So, let me caution you before proceeding:

"Kids, don't try this at home kids without permission from the adult who paid for the set."

---

## 1.1.3) Hints & Notes

For complete details, you need a service manual, available for under \$10 from an authorized Sony service dealer. The KV-32XBR10 and KV-32XBR70 manual was \$9.00. To properly use most of the capabilities of service mode, you need some test equipment. The laser video disc "A Video Standard" (Reference Recordings LD-101) is a minimum.

Some of these adjustments require more extensive equipment, and must be performed in a particular order. The only ones I have changed on my set are the H and V POS/SIZE. Virtually all TVs overscan (throw away picture), and the XBRs are no exception. As the set ages, these may require re-adjustment.

The NTSC resolution charts on LD-101 don't appear to be properly centered. I suggest using the (outer) safe-action lines on the color-bar frame of a Criterion Collection CAV disc instead. Confirm the results with the daytime broadcast of CNN Headline News. Did you know that there is a "15 Minute Delay" disclaimer below the second line of scrolling stock quotes?

---

## 1.1.4) How do I know if this applies to me?

If you own a Sony XBR TV or monitor, and there is a small hole on the back panel, with a tiny push-button switch within, then your set has a remote service mode.

If you press and hold the button, then turn on the set, it will come up in service mode, with an extra line of information on the top line of the on-screen display. To exit service mode, turn off the set.

---

## 1.1.5) Remote control key mappings

Remote Commander Key	Service Function
VIDEO	Select video calibration modes
AUDIO	Select audio calibration modes
RESET	<not clear, presumably resets to factory defaults>
MUTING	Prefix. Follow by [ENTER] to store new settings
1	Select previous menu item
4	Select next menu item
3	Adjust item value up
6	Adjust item value down
MTS	<apparently toggles stereo/mono for audio adjustments>
ENTER	Stores new setting, when prefixed with [MUTE]

---

## 1.1.6) Screen Label : definitions

Screen Label	Register
HFRE	V H-FREQUENCY
VFRE	V V-FREQUENCY
VPOS	V V-SHIFT (Vertical Position)
VSIZ	V V-SIZE (Vertical Size)
VLIN	V V-LINEARITY
VSCO	V S-CORRECTION

HPOS	V	H-PHASE (Horizontal Position)
HSIZ	V	H-SIZE (Horizontal Size)
PAMP	V	PIN AMP.
CPIN	V	CORNER PIN
PPHA	V	PIN PHASE
VCOM	V	V-COMP.
GAMP	V	GREEN AMP.
BAMP	V	BLUE AMP.
GCUT	V	GREEN CUTOFF
BCUT	V	BLUE CUTOFF
CROM	V	CHROMA TRAP
SPIX	V	PICTURE
SHUE	V	HUE
SCOL	V	COLOR
SBRT	V	BRIGHT
RGBP	V	RGB PICTURE
MPX	A	ATT
FILO	A	I1
DEEM	A	I2
STEV	A	OSC1
SAPV	A	OSC2
PILO	A	PILOT
SEP	A	WIDE BAND
VD	A	SPECTRAL
LVOL	A	VOLUME-L
RVOL	A	VOLUME-R
SHAR	V	SHARPNESS
DISP		(3) PWM OUTPUT

## 1.2) Adjusting everything

Okay, for all you Sony XBR owners who need a pick-me-up, here are the secret (as in service manual) steps for adjusting everything your set can adjust! These instructions apply to the Sony KV-27XBR10/27XBR60 models, which use the Remote Commander (TM) model RM-762. I'm not going to describe the methods for all the adjustments. I suggest that you obtain a copy of the service manual if you want more information.

Once you make the adjustments, the set will retain them until you unplug it (at which time it reverts to its EPROM settings) **UNLESS** you write your changes to the EPROM. Once you do that, the changes become the default (until changed and saved to the EPROM again). **I strongly suggest that before you adjust anything, you step through all the parameters and write down their current settings, so that you can undo any changes you make if you need to.**

## 1.2.1) Getting into Service Mode

Locate the service switch, which is on the rear of the set, just below the "VIDEO n IN" connectors. It is a recessed switch which I use half a Q-Tip (TM) to depress. Turn on the set while depressing the service switch. The word "SERVICE" will appear in the upper left corner of the screen, superimposed over the video image. The parameter label is displayed in the upper middle of the the video image. The current parameter value (a hexadecimal number) is displayed in the upper right corner of the screen.

While in service mode, you can still change channels using the UP and DOWN buttons (but not the numeric keypad) and sources, by pressing the corresponding "VIDEO n" button.

---

## 1.2.2) Getting out of Service Mode

Turn the set off. When it is next turned on, it will be in TV mode. Any adjustments made will be in effect.

---

## 1.2.3) Resetting the Set to its EPROM defaults

This will clear any adjustments made that were not saved to EPROM. Unplug the set. When it is next plugged in and turned on, it will revert to its saved EPROM defaults.

---

## 1.2.4) Getting back to the Before-I-Screwed-With-It EPROM defaults.

**You can't.** That is why you should write down all the defaults as they are now.

---

## 1.2.5) Adjustment Controls

The Remote Commander is used to adjust the set. The buttons used are:

```
1      item up
4      item down
3      data up
6      data down
MTS
MUTING prepare to store changes to EPROM
```

ENTER store changes to EPROM (must be preceded by MUTE).

---

## 1.2.6) Adjustments

---

### 1.2.6.1) Video adjustments

Label	Name
HFRE	H-FREQUENCY
VFRE	V-FREQUENCY
VPOS	V-SHIFT
VSIZ	V-SIZE
VLIN	V-LINEARITY
VSCO	S-CORRECTION
HPOS	H-PHASE
HSIZ	H-SIZE
PAMP	PIN AMP.
CPIN	CORNER PIN
PPHA	PIN PHASE
VCOM	V-COMP.
GAMP	GREEN AMP.
BAMP	BLUE AMP.
GCUT	GREEN CUTOFF
BCUT	BLUE CUTOFF
CROM	CHROMA TRAP
SPIX	PICTURE
SHUE	HUE
SCOL	COLOR
SBRT	BRIGHTNESS
RGBP	RGB PICTURE

---

### 1.2.6.2) Audio Adjustments

Label	Name
MPX	ATT
FILO	I1
DEEM	I2
STEV	OSC1
SAPV	OSC2

PILO	PILOT
SEP	WIDE BAND
VD	SPECTRAL
LVOL	VOLUME-L
RVOL	VOLUME-R
SHAP	SHARPNESS
DISP	PWM OUTPUT

---

## 1.2.7) Sample Adjustments

Before entering service mode, (i.e. with the TV on normally), press the VIDEO button and then the RESET button to reset all user VIDEO settings to their defaults. Then do the same for the user AUDIO settings. This will insure that the picture you are adjusting is not influenced by any of the user settings.

**You must be in service mode to make any adjustments**

---

### 1.2.7.1) Vertical Size Adjustment

1. Receive a cross-hatch pattern. (I used a computer and a "paint" program to display a crosshatch pattern on the screen)
  2. Use buttons 1 and 4 (item up/down) to scroll to the VSIZ parameter. (Make note of the current value, just in case)
  3. Press buttons 3 and 6 (data up/down) to adjust the vertical size up or down until satisfactory.
- 

### 1.2.7.2) Pin Amp., Corner Amp., and Pin Phase Adjustment

1. Receive a cross-hatch pattern
2. Press buttons 1 and 4 to scroll to one of PAMP, CPIN, or PPHA.
3. Press buttons 3 and 6 to obtain the best picture.

The manual has a diagram to illustrate the effect of each of the "pin" parameters. The diagrams show how vertical lines are effected by the buttons.

PIN AMP

) | (    ->    | | |    <-    ( | )

CORNER PIN

] } | { [ -> | | | | <- [ { | } ]

PIN PHASE

/ | \ -> | | | <- \ | /

---

## 1.2.8) Writing the Results of the Adjustments to EPROM

Are you certain that you want to save the adjustments? If you only want to use them temporarily, simply leave service mode now. Your adjustments will remain in effect until the set is unplugged.

Writing to the EPROM will allow changes to survive unplugging the set. Hold the piece of paper upon which you wrote down the old EPROM settings in one hand. (If you haven't written down the original settings, you can still return to the old settings at this point by turning the set off and pulling the plug.) With the other hand, press the MUTING button once. The word "WRITE" appears on the screen in red. This is your last chance to back out. Press the ENTER button once. The color of the word "WRITE" changes to yellow. Your changes have now been saved to EPROM. -----

---

# Chapter 2) Rob Myers

---

## 2.1) About the Author

Author: Rob Myers

E-Mail: removed

WWW: removed

Copyright (C) 1994 Copyright Rob Myers

---

## 2.2) Introduction

Most Sony TV's made since 1990 have electronic service adjustments. This means that adjustments like picture geometry, white balance, and colour presets are adjusted via on screen displays, using the remote control.

Here are some generic instructions on how to get to the adjustments, and a listing of the adjustments that may be made.

These apply to North American (NTSC 3.58) TV's only, to the best of my knowledge.

---

## 2.3) Warning!

Please don't mess around with the service adjustments unless you know what you're doing! Remember, if something goes wrong, don't save the adjustment! Just unplug the TV and plug it back in, and any unsaved adjustments will be restored to their factory presets. Also, the TV will be out of service mode now.

I strongly recommend that you get the SAMS or Sony service manual for your TV before you change any settings.

As you modify settings, record the factory preset values so that you may return to them if something goes wrong. Also, record your new values, in case they aren't saved properly. Nominal values are listed below for most settings below. And, please, please, please, don't mess with the ID-x settings! These are different for every chassis, so the nominal values below won't probably be valid!

---

## 2.4) Procedure

Before entering service mode, turn on the TV and tune in a good picture; turn it off.

Look at the jack panel on the back of the set; is there a service switch? This is a small, round opening in the cabinet near the video 1/video 2 inputs or the antenna jack.

If so (typically on early-90's TV's), push a plastic pen cap or similar device into the opening while turning the power on. The TV should now be in service mode.

If there is no service switch (typically on more recent TV's) type the following sequence on the remote (within one second of each other):

[DISPLAY] [5] [VOL +] [POWER]

If that doesn't work, turn the TV off and try:

[DISPLAY] [5] [POWER]

The TV should turn on in service mode.

---

Press 1 and 4 to select the adjustment to be made.

Press 3 and 6 to make the adjustment.

---

**Note:** You must save all correct adjustments you make:

Press [MUTING] [ENTER] (on the remote) after every adjustment you wish to keep!

---

## 2.5) Verify settings

To verify that the settings have been stored, unplug the TV, wait a few seconds, plug the TV back in, reenter service mode, and ensure that the settings are correct.

---

## 2.6) List of Settings

Here is the list of settings.

(\*) denotes set-up adjustments - return them to their nominal values after alignment.

Display	Description	Data Range	Nominal Value
AFC	AFC Loop Gain	0-3	0 *
HFRE	Horizontal Frequency	0-127	70
VFRE	Vertical Frequency	0-31	14
VPOS	Vertical Center	0-31	17
VSIZ	Vertical Size	0-63	28
VLIN	Vertical Linearity	0-15	8
VSCO	Vertical Correction	0-15	6
HPOS	Horizontal Center	0-15	6
HSIZ	Horizontal Size	0-31	31
PAMP	Pincushion Amp	0-31	24
CPIN	Corner Pincushion	0-7	3
PPHA	Pincushion Phase	0-15	6
VCOM	V Compensation	0-7	2 *
GAMP	Green Amp.	0-31	20
BAMP	Blue Amp.	0-31	17
GCUT	Green Cutoff	0-15	7
BCUT	Blue Cutoff	0-15	8

CROM	Chroma Trap	0-63	28 *
SPIX	Sub Contrast [Picture]	0-63	20
SHUE	Sub Hue	0-63	33
SCOL	Sub Colour	0-63	32
SBRT	Sub Brightness	0-63	35
RGBP	RGB Picture	0-63	30 *
SHAP	Sharpness	0-15	10 *
VSMO	V Pull In Range	0,1	0 *
REF	Reference Line	0-3	2 *
ROFF	Red Out	0,1	1 *
GOFF	Green Out	0,1	1 *
BOFF	Blue Out	0,1	1 *
ABLM	ABL Mode	0,1	0 *
NOTC	Notch On/Off	0,1	1 *
DRGB	OSD Intensity	0,1	0 *
DISP	Display Position	0-63	40
DPDV	Lumipon (dpdv)	0-3	1 *
MPIC	Lumipon (depth)	0-63	48 *
SVOL	Sub Volume	0-15	0 *
SBAL	Sub Balance	0-15	7
BASS	Sub Bass	0-15	8 *
TRE	Sub Treble	0-15	8 *
UYBO	Upper Y Bow	0-63	31
LYBO	Lower Y Bow	0-63	25
HAMP	Horiz Amp	0-63	33
HTIL	Horiz Tilt	0-63	33
UCBO	Upper C Bow	0-63	38
UTIL	Upper Tilt	0-63	40
LCBO	Lower C Bow	0-63	41
LTIL	Lower Tilt	0-63	46
DCSH	DC Shift	0-63	37
PHPO	PIP Horiz Position	0-127	76
PHUE	PIP Hue	0-31	0 *
ID-0	Model ID	0-127	=
ID-1	Model ID	0-127	=
ID-2	Model ID	0-127	=
ID-3	Model ID	0-127	=
ID-4	Model ID	0-127	=

= When IC 102 is replaced, these values must be reset. Here are the nominal values for a few chassis:

Model #	ID-0	ID-1	ID-2	ID-3	ID-4
KV-27S10	64	77	64	0	16
KV-29RS10	64	77	64	0	16
KV-32S10	72	77	64	0	16

KV-27V10	120	127	72	0	17
KV-27V10C	120	127	32	0	17
KV-27V10M	120	127	32	0	17

---

# 1. HP LaserJet Simple Problems

---

## 1.1) BLANK PRINTOUT

Has the EP cartridge been inserted correctly in the printer? If not, re-insert the cartridge and perform the self-test.

Has the EP cartridge been used for more than 3000 pages? If so, replace the EP cartridge.

Has the sealing tape been removed from the EP cartridge? If not, remove the sealing tape and try the self-test procedure again. (See "Replacing the EP Cartridge".)

If none of these procedures helps, see the "COMPLETE IMAGE IS LIGHT" discussion below.

---

## **1.2) COMPLETE IMAGE IS LIGHT**

Is the print density dial set with its dot at the top (position number 5)? If not, set the dial to number 5 and repeat the self-test procedure. Does print quality improve when new paper is used? Be sure that the paper you are using meets the paper specifications listed in the Paper Specification Guide (part no. 02686-90905).

Is the transfer corona wire broken (see discussion on cleaning transfer corona wire)? If so, call your HP Dealer.

---

## **1.3) COMPLETE IMAGE IS DARK**

Is the print density dial set correctly (near the middle setting)? If not, set it correctly and repeat the self-test procedure. If this does not improve the image, try replacing your EP cartridge.

---

## **1.4) BLACK IMAGE**

Is the primary corona wire broken (the wire is located under the vinyl flap of the EP cartridge)? If so, replace the EP cartridge.

---

## **1.5) STAINED STRIP ALONG RIGHT SIDE OF PAPER**

Is the separation belt or the area around the belt dirty? If so, clean the dirty area and perform the self-test procedure (see the "Separation Belt Cleaning and Replacement" discussion in this section). If this does not eliminate the black stain along the right side of the page, replace the EP cartridge.

---

## **1.6) STAINS ON BACK OF PAPER**

Is the area around the manual paper feed slot dirty? If so, clean it first with a damp cloth and then with a dry cloth.

Is there any toner on or around the transfer corona assembly? If so, clean it with a damp cloth and then with a dry cloth.

Is there visible toner on any of the printer rollers? If so, clean them first with a damp cloth and then with a dry cloth.

Is there any toner on the underside of the EP cartridge? If so, clean the cartridge with a damp cloth, then with a dry cloth.

Is the fusing roller cleaning pad dirty? If so, replace the fusing roller cleaning pad (see "EP Cartridge Replacement" procedure earlier in this section).

---

## **1.7) DARK VERTICAL LINES (IN DIRECTION OF PAPER FEED)**

Is the fusing roller cleaning pad dirty? If so, replace the pad as described in the "EP Cartridge Replacement" procedure earlier in this section. If this does not eliminate the dark vertical lines, replace the EP cartridge.

---

## **1.8) SHARP HORIZONTAL BLACK LINES (CROSS FEED DIRECTION)**

Call your HP Dealer or your Hewlett-Packard Service Representative.

---

## **1.9) BLURRED VERTICAL STRIPES (PAPER FEED DIRECTION)**

Does the print image improve after cleaning the primary corona wire? If not, replace the EP cartridge.

---

## **1.10) BLURRED HORIZONTAL STRIPES (CROSS FEED DIRECTION)**

Check the distance of the stripes from the edge of the paper. If they are approximately 188 mm (7.4 in) or 66 mm (2.6 in) from the edge, replace the EP cartridge.

---

## **1.11) WHITE HORIZONTAL LINES (OR OTHER SHAPES) ON BLACK BACKGROUND**

Does the paper being used meet the specifications listed in the Paper Specifications Guide (part no. 0'686-90905). Try another type of paper and see if the problem is corrected.

Is the paper damp? Replace the paper with dry paper and be sure to store your paper within the humidity range specified in Appendix B.

---

## **1.12) THIN VERTICAL WHITE LINES OR STRIPES (PAPER FEED DIRECTION)**

Has the EP cartridge been used for more than 3000 pages? If so, replace the EP cartridge. If not, remove the cartridge and shake it as described in the section on replacing the cartridge. This will distribute the toner more evenly. Insert the cartridge into the printer and run self-test to see if the problem has been corrected. **NOTE:** Shaking the cartridge may leak toner and stain some of the following prints. Print 3 to 5 test prints to check this before printing anything else.

Is the fusing roller cleaning pad dirty? If so, replace the pad as described in the "EP Cartridge Replacement" procedure earlier in this section.

Does the print quality improve after the transfer corona wire is cleaned (see procedure)? If not, replace the EP cartridge.

---

## **1.13) FAULTY REGISTRATION**

Is the leading edge of the paper curled excessively? If so, straighten the edge of the paper before using it or add new paper.

Is manufacturer-approved paper being used? If not, try an approved paper.

---

## **1.14) POOR FUSING (TONER SMEARS WHEN RUBBED)**

Is manufacturer-approved paper being used? If not, add approved paper and try a self-test.

---

## **1.15) IMAGE WAVINESS OR DISTORTION**

Call your HP Sales and Service Office.

---

## **1.16) PRINTER DOES NOT POWER-UP (READY INDICATOR DOES NOT LIGHT)**

Is the power cord plugged into the AC outlet?

Is the AC power outlet receiving power?

Is the printer's power switch in the ON position?

Is the upper main body of the printer firmly closed?

---

## **2. HP LaserJet Error Codes**

---

### **2.1) 00**

Printer ready status-this is not an error condition. The printer ready status indicates that the printer is ready to print.

---

## 2.2) 02

Wait status--this is not an error condition. The wait status indicates that the printer is warming up and will be ready soon.

---

## 2.3) 05

Self test status (non-printing)--this is not an error. This status indicates that the printer is performing the non-printing portion of an interface self-test. When the non-printing portion of the self-test has been completed successfully, the status display will change to 06 (printing portion of the interface self-test).

---

## 2.4) 06

Self test status (printing--staggered characters)--this is not an error. This status indicates that the printer is performing the printing portion of an interface self-test. When self-test has been completed, the status display will return to the printer ready status (00). Printing can be continued by pressing the ON LINE or CONTINUE key on the Operator Control Panel.

---

## 2.5) 11

A flashing number 11 means that either the paper cassette is empty or the cassette is not loaded into the printer. To correct this problems add paper to the cassettes load the cassette into the printers and press the CONTINUE switch on the Operator Control Panel. Printing will not be allowed until the condition is corrected. **NOTE:** If the wrong size paper cassette is loaded, "PC" will flash on the status display as printing is attempted.

---

## 2.6) 12

A flashing number 12 indicates that the upper main body of the printer is not closed properly. Close the printer until it is firmly latched and then press the CONTINUE key. **NOTE:** Printing will not continue until the printer is completely closed.

---

## 2.7) 13

A flashing number 13 on the status display indicates that a paper jam has occurred. Open the upper main body of the printer and check for jammed paper. Remove the jammed papers close the printers and press the CONTINUE key. Data on the jammed page will be reprinted automatically. **NOTE:** the printer must be opened to clear the paper jam error. For more information on clearing paper jams, see the "Paper Jam" discussion later in this section.

---

## 2.8) 14

A flashing number 14 indicates that the EP cartridge is either not installed or not correctly installed in the printer. To correct the error, insert an EP cartridge or make sure the installed cartridge is fully seated in position. Press the CONTINUE key to resume printing. **NOTE:** printing will not continue unless the condition is corrected.

---

## 2.9) 15

Test print status (striped pattern)-this is not an error. This status indicates that the TEST PRINT button has been pressed and that a print engine self test is being performed. When the test print has been completed, the status display will return to the printer ready status (00). Printing can be continued by pressing the ON LINE or CONTINUE key on the Operator Control Panel.

---

## 2.10) PC

When this message flashes, the status display alternates between PC and a paper size number requested by the computer system (L=letter size, LL=legal, A4=A4, or bS=BS). To clear this condition, insert the requested cassette and press the CONTINUE key; if the requested paper cassette is not inserted, pressing the CONTINUE key will cause the printer to ignore the paper cassette request. **NOTE:** If the requested paper size does not match the installed cassette, the CONTINUE key will allow you to print on the loaded paper. However, the output will be formatted for the requested paper size and a possibility exists for a clipped image (due to the fact that formatting is intended for the requested size paper). For information on how to programmatically request a paper cassette size, consult the "Selecting Page Length" (ESC&l#P) portion of Section IV.

---

## 2.11) PF

When this message flashes, a manual paper feed has been requested. The status display will alternately flash PF and a paper size (L=letter size, LL=legal size, A4=A4, and b5=BS). Insert a sheet of the requested-size paper into the printer's manual feed slot. **NOTE:** Inserting a paper size other than that requested on the status display may cause clipping of your image (due to the fact that the formatting is based on the requested paper size). To exit the manual feed mode, press the ON LINE key to put the printer off-line and then press the MANUAL FEED key. Begin printing from the paper cassette by pressing the CONTINUE key.

---

## 2.12) PE

A flashing PE indicates a request for an envelope to be fed into the printer. When an envelope is fed into the printer, the PE on the status display disappears and printing begins. To exit the envelope feed mode, press the ON LINE key to go off-line and press the MANUAL FEED key to exit the manual feed mode. Press the CONTINUE key to resume printing from the paper cassette.

---

## 2.13) FE

A flashing FE on the status display indicates that the font cartridge was removed when the printer was on-line and being accessed. To clear the error condition, re-insert the font cartridge into the printer, press the power switch to the OFF (O) position to reset the printer, and then press the power switch to the ON (1) position.

---

## 2.14) FC

A flashing FC indicates that a font cartridge was removed or replaced during the formatting of a page. Re-insert the removed cartridge and depress the CONTINUE switch. The current page will be formatted and then printed as intended.

---

## 2.15) FF

This error occurs when the page buffer has been filled beyond capacity. Check to see if the correct font cartridge is installed. Check to see if an excess amount of data was sent to the printer (be aware of combined text and graphics limitations). Switch the printer's power OFF and then ON to clear the error. If the problem persists (with a reasonable amount of data on the page), call your HP Dealer for assistance.

---

## 2.16) 20

A flashing number 20 indicates a memory overflow error, meaning that there is more data received from the computer than will fit on the page. This error may also be caused by switching the computer power ON before switching the LaserJet power ON. To continue printing, press the CONTINUE key. Only the amount of data that fits on your page will be printed.

---

## 2.17) 21

The flashing number 21 indicates that the page formatting process is not fast enough for the printer. Press the CONTINUE key to continue printing. **NOTE:** There may be some data loss on the page that was being formatted when the error occurred.

---

## 2.18) 22

This error indicates that the printer's receiving buffer has overflowed during a busy state. Pressing the CONTINUE key resumes printing, but results in a loss of data.

---

## 2.19) 40

This error indicates that a data error (parity, framing, or line overrun) has occurred during the reception of data from the computer. The error may also indicate an incorrect configuration. To continue printing, press the CONTINUE key. **NOTE:** This error may also occur if you power-up the computer while the printer is on-line. If this happens, simply press the CONTINUE key to clear the error. If this error occurs repeatedly, check the interface connector to ensure that it is connected firmly to the printer and computer. Also check to make sure that the configuration is set so that ENQ/ACK is OFF and Xon/Xoff is ON. If the error still occurs after ensuring that the interface connector is snugly seated and the configuration is correct, call your HP Dealer or HP Service Representative.

---

## **2.20) 41**

This error indicates that a temporary error has occurred in the printed page. To correct the error, remove the paper from the output paper tray and press the CONTINUE key to resume printing. The page the error occurred on will be reprinted automatically.

---

## **2.21) 50**

This error number indicates a fusing assembly malfunction. The printer cannot immediately recover from this type of error. Switch the printer OFF (0) and wait a minimum of 10 minutes; then switch the printer power ON (1) and resume printing. If the FORM FEED light was on at the time the error occurred, resend the data to the printer.

---

## **2.22) 51**

A flashing number 51 indicates a beam detect malfunction. Press the CONTINUE key to resume printing.

---

## **2.23) 52**

Error number 52 indicates a scanner malfunction. Press the CONTINUE key to resume printing.

---

## **2.24) 53**

A flashing number 53 indicates a malfunction in the laser temperature control circuitry. The printer cannot immediately recover from this error. Switch the printer power OFF and wait a minimum of 10 minutes; then switch the printer power ON and resume printing. If this error occurs repeatedly, call your HP Service Representative.

---

## **2.25) 54**

Check to see if the paper cassette is over-full (max. 100 sheets). If so, remove the excess paper and press the CONTINUE key to resume printing. If the paper cassette is not over-fulls error number 54 indicates a main motor malfunction. Pressing the CONTINUE key clears the error and resumes printing. If this error occurs repeatedly, call your HP Service Representative.

---

## **2.26) 55**

Error number 55 indicates a printer command error, meaning that commands cannot be exchanged between the print engine and its controller. Press CONTINUE to resume printing.

---

## **2.27) 60**

This error indicates a bus error caused by a circuit malfunction. An improperly seated font cartridge may also cause this error message to be displayed. If a font cartridge is installed, make sure it is firmly seated in the slot. Switch the power to the OFF (0) position to reset the printer and then switch the power ON (1). If this error occurs repeatedly, call your HP Service Representative.

---

## **2.28) 61**

A number 61 flashing on the status display indicates a checksum error on the interface program ROM. Switch the power switch to the OFF (0) position to reset the printer and then set the power switch back ON (1). If this error occurs repeatedly, call your HP Service Representative.

---

## **2.29) 62**

Error number 62 indicates an internal font ROM checksum error. Switch the power switch first to the OFF (0) position and then to the ON (I) position to clear the error.

---

## 2.30) 63

Error number 63 indicates a dynamic RAM error (read/write error or parity error). Switch the printer power OFF (0) and then ON (1).

---

## 2.31) 64

Error number 64 indicates a scan buffer error. Switch the power switch first to the OFF (0) and then to the ON (I) position.

---

## 2.32) 65

Error number 65 indicates a D-RAM controller error. Switch the power to the OFF (0) position and then to the ON (I) position.

---

## 2.33) 67

Error number 67 indicates a miscellaneous interface hardware error. If this error occurs, switch the power switch first to the OFF (0) and then to the ON (I) position.

---

## 2. Introduction

One of the most frustrating problems about using computers with radios, whether it be for controlling purposes or for decoding, is the amount of RFI generated by these machines. Most of the time, the RFI generated is enough to render certain bands useless and on other bands, it may drown out any weak signals and distort or interfere with signals that you want. This is totally unacceptable for working with digital modes and even for CW. Thus one of the most frequently asked question is how this RFI may be reduced or eliminated. The bad news is that, there is no way that I know of to completely remove the computer generated RFI in most situations. The good news is that there are definite steps that we can take

to reduce the RFI to a very acceptable level and in some cases, it will almost disappear altogether. This document is a compilation of suggestions from various persons and some of the things I have tried with my own system when dealing with this problem. Many of the documents I have seen relate to situations involving transmitters and how not to generate them (RFI). This document is written from a receiving point of view.

I suppose most people would have already tried the basic steps to improve signal conditions by having the receiver and antenna as far removed, physically and electrically from the RFI source (computers and monitors in our case) but I am also aware that sometimes there are limitations and constraints as to how much distance can be had. One may have also tried changing the orientation of the computer, monitor, receiver and antennas and feeds to see if things get better. Having done all that, what else can be done? This is the predicament I had and thus this document.

The standard disclaimer applies and I will not be responsible for any accidents although I have tried my best to present the following information in the best integrity.

---

## 3. RFI Sources

Before we actually begin tackling the problem, it might be helpful to know something about why computer generates RFI and how these get into the receiver. The two main components of the computer is the main CPU and the monitor (for simplicity sake). The computer runs at a certain clock rate as determined by an internal oscillator. Most of the time the rates are something like 4.77 MHz, 8 MHz, 12 MHz, 16 MHz, 20 MHz, 25 MHz, 33 MHz, 40 MHz, 50 MHz, 66 MHz and 80 MHz. This is not the only clock involved, there is also another oscillator on the video generator card and sometimes a few oscillators, plus those on other cards. As you can see, these clocks are all oscillating in the HF and L-VHF regions which may interfere with signals we would like to receive. To make things worse, these clocks are usually sub-divided into a number of other frequencies within the computer. Since the computer is a digital system, the characteristic waveform of these signals are square-wave and square-waves tends to result in a lot of harmonics. The video card also generates RFI because the data-pixel-rate is often high enough to fall into the HF regions. All these reasons are why computers and monitors are tops when it comes to generating RFI. This is often made worse by computers with cheap plastic casings which do not shield the system. Many people have the opinion that monitors are one of the main RFI sources and this may well be the case. I have also noticed that the PC keyboard also generates a considerable amount of RFI despite its innocent look. This is because it contains a microprocessor on board which runs off a clock in the 3 MHz range. This problem is compounded by the way the keyboard PCB runs which makes like a pretty good loop antenna type radiator and so the harmonics can be heard in the 2nd and 3rd harmonic range. The monitor probably has an on-board crystal at about 14.316 MHz so you will find a strong carrier there too.

The first thing we want to do is to determine how much RFI is being generated by the CPU and the monitor. It may be that the CPU is not radiating at all but the monitor is the culprit, or vice versa. This can be done by switching off the monitor and leaving the CPU on just to see how much RFI is getting

into the radio. The following is a suggested procedure:

1. Do a quick sweep across the bands to find out where the RFI is the strongest. This is helpful because if we can reduce the RFI here, there should normally be a corresponding decrease of RFI everywhere else but not necessarily so.
2. Disconnect the mouse, serial cables and printer cables, keyboard, video cable, video power. If you can, run the receiver on batteries for this part. Now turn on the computer and see if the RFI is increased by any appreciable amount.
3. Now, connect the keyboard (with the CPU on), then the mouse, then the serial cable, the parallel cable, the video cable, monitor power cable (don't turn on yet). As you reconnect these, note the increase of RFI if any. You should now have some idea as to which is the main contributor of RFI. If you should have the good fortune that none of these result in any appreciable increase of RFI then you're in luck.
4. Turn on the monitor and note the increase in RFI. Run both text and graphics modes to see if the RFI is affected.
5. Reconnect the radio to the power supply and again note the RFI increase if any.
6. Disconnect the radio from any antenna, both external and internal, and note if the RFI goes away. Note that on some radios, when you unplug the external antenna connection, the internal antenna is automatically activated. To prevent this, plug in a dummy plug to the antenna socket.

By now you should have a pretty good idea of which components are contributing to RFI. Keep these notes, while we move on to another point, RFI paths.

**Earl Morse KZ8E** suggest this for pin-pointing RFI source:

" In the event that this does not work you will need to investigate for cabinet radiation from the monitor and computer. Make a loop from some RG58 coax by stripping back the shield a few inches and making a couple of turns about an 1-2 inches in diameter. Solder the center lead to where you stripped back the shield. Plug this loop into your receiver and use it to probe the computer setup. A faulty computer cabinet can be easily closed up with fingerstock, braid, or other conductive materials. Shielding a monitor cabinet is a lot more difficult and could cause safety problems (high voltage) or overheating. "

If you find the above method too troublesome, just get hold of a battery operated portable AM/SW receiver with an internal ferrite rod antenna and start moving around, rotating the radio as you go. Often you can pinpoint the major RFI sources just by following the radio to the place where the strongest hum is found. Of course, the radio should be tuned to a section of the spectrum where the RFI can already be heard somewhat. Do this with the radio near the suspected equipment and fine-adjust from there. This will also give you an idea of what kind of RFI and on what frequency it is focused on.

---

## 4. RFI paths

RFI gets into the receiver from the source through a number of paths. This can be through the power supply, through the "earth" point of the power supply, through direct radio emission, even through "shielding" which are not properly designed or used. There are a number of ways to deal with these situations. If in (6) above, your radio is still picking up RFI with no antenna connected then, the shielding in your receiver is poor. If in (5) above, the RFI increases as you reconnect the radio to the mains power supply or adaptor, then RFI is coming in through the power supply. If your radio is connected directly or indirectly to the computer through the serial port or some other interface, that too could be a path for RFI. You will know if this is a problem as you go through step (3) above. If the RFI increases appreciably as you reconnect the external antenna, then the RFI may be coming from direct emission or is being picked up from the antenna feed.

Remember that in many cases, RFI is coming in from more than one path so it is important to check out all possibilities. On the other hand if one path is the overwhelming problem, you may want to deal only with that. Other basic measures are to keep cables and connections as short as possible. This will prevent these connections from becoming radiating elements for the RFI from the equipment. If possible, have your radio equipment connect to a different power circuit but watch the earth so that no dangerous voltage-potentials are formed.

---

## 5. Killing RFI

As you can probably see, RFI is a combination of problems and not one problem. It can be classified into 3 categories:

- Shielding problems
- Filtering problems
- Design problems

These are not definitive categories but are used for simplicity. In many cases, poor shielding is a prime suspect. So we will deal with this first. Now to get on with the real action.

---

## 6. Shielding problems

When we talk about shielding, there are 4 things to consider, the radio itself, the monitor, the CPU and

the antenna/feed combination. Poor shielding can be an inherent problem to some designs but can also be due to dirty connectors and old parts. Go through the equipment to make sure that all the connection points are secure, this is especially in connection to the antenna shielding, radio power supply, CPU casing, cabling. Make sure that the wires are not old and all the connections are clean, no oxides on surfaces. The presence of oxides makes for poor conduction and in some cases it results in rectification of signals which can then lead to a host of other problems.

If the problem is a design one, such as poor shielding in a radio as determined by step (6) in section 2.0 on RFI sources, or poor monitor or CPU shielding, then we need to provide an adequate shield. This can normally be done using tin/aluminum foils or conductive spray. The basic idea is that we must line the casing of the equipment to be shielded with a barrier to RFI. This must be done carefully because since the shielding is conductive, it is possible to accidentally short circuit something and fry your radio or whatever it is you are trying to shield. The spray is probably the easiest to use but also quite expensive. My feeling is that metal foil probably provides better shielding but is harder to apply. The conductive spray or paint has a lower conductivity but spreads more evenly and gets into difficult to reach locations more readily. What you need to do is to carefully remove the plastic casing of the radio or monitor, paying attention to cabling and electrical contacts. Remember that opening the case will almost certainly invalidate the warranty on the equipment. Clean the insides of the case thoroughly and make sure that it is dry and free of dust or grease before applying the spray. You may need to apply several coatings to get better shielding. Make sure that at some point in the casing, the applied shielding comes into contact with ground. Remember that in monitors, chassis is not always connected to ground so check this out first. For the shielding to be effective, you need to provide as complete a "wrap" as possible but remember not to spray onto switches or anything that might cause a short circuit. Also prevent blocking up ventilation holes. You may at this point wonder about the screen itself. Well in most color monitors, the mask inside the monitor acts as a shield of sorts. Wait for the coat of paint or spray to dry before replacing the cover. Try to ensure good grounding for the shield and avoid scratching off the paint. If arcing should occur, use some insulating tape over the area. The kind of spray that I use is known as EMI-LAC or EMV-LACK (by Cramolin) and is of German origin. There are many other makes and most should work okay. In the event that you cannot find either paint, spray or suitable foil, conductive tape will do also. **Remember**, the conductive screening must **NOT** touch the components. Pay attention as there is always shock hazard when messing with monitors. Don't do this yourself unless you know exactly what you are doing. :) Stay alive.

**Gary Coffman KE4ZV** has this advice about shielding:

" If the monitor is the culprit, there are conductive sprays you can use on the inside of the plastic cabinet to reduce the hash. GC Electronics makes one that works well. You have to strip the monitor and spray the cabinet. Usually you want to spray inside for appearance sake. When you put it back together, watch out that the HV section has adequate clearance with the now conductive case. If it doesn't, glue some fish paper in the proper spots to prevent arc overs. Unless the monitor is a "hot chassis" design, bond the conductive coating to the chassis, and bring a bond wire out from the chassis to station ground. If the monitor is color, the shadow mask in the tube will form an adequate shield, but if it's mono, then you may need to put fine copper screening over the face of the tube. Spray paint it flat black and it'll double as an anti-reflection screen.

If the cable is radiating, first make sure you're using a shielded cable, then use some snap on ferrite chokes on the cable. These chokes are good things to put on *\*every\** external cable.

If the PC is the culprit, scrape paint so that the case halves can bond properly, and add extra screws so that every seam has a screw at least every two inches of it's length. That's what it takes to get a good Faraday cage. Any openings in the case should be covered with copper screen wire. The floppy drive opening is a problem because you need access. The best way to handle this is to shield the entire drive bay from the inside and accept the hash when the drive is in use. Bring a bond wire from the case to station ground.

Of course it always helps to have the radio's antenna as far from the PC as possible, and brought back to the radio via a well shielded coax. The radio chassis should be bonded to the station ground. If you're using a HT (so sorry) then you may have to locate the radio and TNC far from the PC via a long RS232 cable. Note that the TNC can also be a source of noise. In some cases it's better to leave the TNC next to the computer and remote locate the radio with long audio and control cabling. The TNC should be treated the same way as the PC. Sand off the paint and add bonding screws. If it's plastic cased, either use the conductive spray, or put it in a metal box. "

If you are using the spray, make sure to apply an even layer and you may want to repeat the process a few times to get a better screen. Do not waste excessive spray on one spot but make sure that the coat does not have "thin" spots. The same method can be applied to the CPU casing or to the keyboard casing. The effectiveness of such a method on the keyboard is debatable however, seeing that it is difficult to build a proper Faraday's cage around the offending circuitry. Care must also be taken seeing the tight enclosure of most keyboards.

Shielding of cables are also important. Try to make sure that the video cable has a good shielding/screening. The same applies to serial and parallel cables and, of course, the antenna feed should be well shielded. For antenna feeds, avoid TV 75 ohm coaxes as these normally do not provide sufficient screening. Try RG-58-C/U (which I think has better screening than RG-58-A/U) or some other high-screening type cables like RG-8 and the like. Well screened antenna feeds go a long way to remove RFI. I have been told that the equipment should all be connected to a firm ground via heavy gauge wire or braid. This is probably true and if you can, why not. Where cables terminate, use good and appropriate connectors such as PL-259 or something similar. In all cases, provide the screening with a good ground. A well screened antenna feed may eliminate up to 80% of the RFI in some case, or more. If you are listening on VHF and UHF however, the length of the feed may need to be weighed against signal losses in the feed itself. Feeds such as the 9913 have lower losses but are quite expensive. Use them if you can however. Personally I still find the RG-58 to be the easiest to work with.

Sometimes, in some CPU units, there may be some parts which are difficult to shield, such as the disk-drive. This is not too serious since the drive is not operative most of the time, but if you elect to try to screen that also, remember that the screen must all be well connected electrically. The same goes for the rest of the computer casing. If you can, use one with a proper metal casing on all sides. What we want is a Faraday Cage so see that the whole case is well grounded. Scrape off some paint at the screws so that there can be good electrical contact everywhere.

Other exposed connectors and splitters (which are not recommendable) can also be letting in RFI so you may want to check out their screening as well.

---

## 7. Filtering problems

This represents the next major path for RFI. In some poor designs, RFI is not properly filtered out of the computer or monitor power supply and it thus leaks out into the mains, and from there into the radio power supply and finally into the RF section (or AF sometimes) of the receiver. This type of problems can normally be improved by using a line filter for the equipment's power supply. Make sure that the line filter is rated for the power the cable is meant to carry or it may burn up. There is a kind of line filter which is essentially built as a socket which you need to replace the one on the power supply with. I am not sure how much improvement this kind of filter affords but if you elect to do this, do it with care! Other than using line filters, you can also use ferrite beads and toroids on most any lines. Experiment around with a bunch of these things. You could also put a bunch of ferrite beads on the antenna feed line and this will act as a kind of balun as well as preventing RFI from traveling on the screening. There are many types of ferrite RF chokes, clip on types and ready made types, which can be used. The ARRL Handbook has a description of some of these devices. I have built myself a 4:1 balun (BAL-anced to UN-balanced) for my coax fed dipole and now I get very much less computer RFI and other noise from my antenna system due to the impedance matching and improved power transfer characteristics. Better selectivity is also a benefit of a good antenna system. Line filters and RFCs can do wonders so experiment with them at various strategic locations such as power supplies, some audio lines etc.

Other than that, RFI often comes through other data lines and control lines in parallel and serial ports as well as video ports. Besides using ferrite beads on these, you may want to connect small value capacitors between the lines to ground. For parallel and serial lines, use 0.01 uF capacitors (multilayer, MKT if possible, others may work well too), and for video ports, connect 100 pF capacitors from the RGB, H-Sync and V-Sync to ground. These may have some other effects on the lines so experiment with slightly higher or lower capacitor values.

If you are receiving on certain bands only, a bandpass, high-pass or low-pass filter may help if used on the receiver front-end. This, however, will not be effective for reducing in-band noise. A notch filter can be used on the antenna feed to notch out certain strong emissions such as the 14.316 MHz crystal oscillator on the video card or on the baud-rate generator. Note that all kinds of filters (barring active ones) incur losses to some degree and if your signal lands too near the unwanted emission then you cannot use the Notch since the wanted signal may also get filtered out. A high-Q notch is often preferred in this regards.

Concerning the use of clip-on filters (such as those sold by RS), **Steve Byan** has this to say:

" The "clip-on choke" is a split ferrite bead in a plastic case, sold for RFI suppression from personal computers. The two halves of the bead fit around the cable; the plastic case has a hinge

and a latch to hold the two halves together. You could get the same effect by slipping a ferrite bead onto the coax before attaching the connector.

This idea is similar to the ferrite bead baluns used in amateur radio. The idea is to increase the impedance to RF current flow on the outside of the coax shield - this ideally prevents the coax from becoming part of the antenna.

I'm skeptical that one or a only a few of these Radio Shack beads would have much effect when placed on the coax lead-in. I think it would take quite a few beads to get enough inductance to help.

It might be better to use the beads on the offending appliances.

I'd recommend John Doty's method of grounding the coax shield at the antenna, and running the coax buried or along the surface of the ground. I think this will minimize pickup of local noise sources more effectively than a few ferrite beads at the receiver. "

Power line decoupling and filtering is essential for optimum performance. The standard power supply of most PC's is a switching power-supply. Such systems, while power efficient, tend to generate spikes and unwanted harmonics due to the switching effect. Needless to say, if not handled properly, these spikes will get into the mains and from there into your radio. This is usually not severe because the design usually takes this into consideration already. What is more worrying is the CPU clock leaking into the mains through the power supply. Once again, the line filter is the way out.

Often, when only the audio from the receiver is required to go into the computer, you might want to consider some way of isolating the signal from direction connection to the computer. One simple way is by the use of 1:1 audio transformers. Personally I have found a slight improvement here but not to my satisfaction. I also tried connecting the audio from the receiver to a adapted FM microphone and having another FM radio pick up the audio which goes into the computer. This seems a lot of hassle but may be a last resort or for people who really want distance between the radio and the computer. Other forms of isolation can be implemented using IR or optics. These will provide excellent isolation as far as the audio line is concerned and no RFI worries from that path.

---

## 8. Design problems

RFI problems are sometimes compounded by poor antenna or receiver design. Antenna impedance mismatch, for example, can make things worse that it needs to be. As such, use of baluns and transmatches may help. Although the coax antenna feed is supposed to keep out RFI, a mismatched antenna and feed may result in the coax screening itself picking up RFI. So if you are using coax feed into a balanced dipole, try using a balun at the feed point. Balun designs are really simple to build and can be found in the ARRL handbook also. The impedance matching of the antenna to the feed can also be

handled by the balun. Baluns, being what they are, normally incur some signal loss but in a good balun, this is insignificant compared to losses in the feed itself. Besides, loss of signal strength is often made up for by improved S/N ratio. I have not confirmed this but some out of band RFI can be reduced by the use of antenna tuners which provide better selectivity. Such tuners can easily be made from any number of designs found in amateur circles because commercial ones tend to be rather expensive and come with S.W.R. meters and other fancy things that the RX-only SWL does not need. In my case, a coax feeding into an off-center-fed-dipole, the balun did wonders to the S/N ratio and I actually say a signal strength improvement. This does not mean that the balun improves gain but the selectivity it provides may prevent the receiver AGC from kicking in and drowning out the weaker station thus resulting in a higher apparent signal strength.

**Kok Chen AA6TY** has this to say about unmatched antenna systems:

" And, finally, finally, just as connecting a coax to a balanced antenna will cause feedline to radiate, the reciprocal also happens. If you feed a balanced receiving antenna with an unbalanced line like coax, the outside of your coax will pick up noise and send it to the antenna input of the receiver. Place a balun between the coax and the antenna itself. "

Excessive gain, such as may be the case with antenna pre-amplifiers will not always improve the S/N because then the noise gets amplified along with the signal. In this respect, normally a masthead pre-amp will perform better.

Decoupling in some digital equipment is not properly done and can lead to RFI being insufficiently suppressed. This can be remedied by placing 0.1 uF capacitors along all points in the power supply of the equipment between supply and ground. This may sound silly to some because it may seem easier to use one big capacitor, but while the electrical property at DC may be similar, the distributed capacitance has a different effect on RF. You want to ensure that your power supplies are properly decoupled and no unwanted oscillations are taking place in the regulators.

The directivity properties of the antenna can also help improve signal conditions under RFI. The loop antenna, for example, can be positioned so that it nulls out at the RFI source. I haven't tried this myself but in theory it should work but I cannot comment on the actual performance you can get out of this. Similarly the dipole also exhibits certain directive properties which can be taken advantage of to reduce RFI.

The use of antenna tuners and pre-selectors may help reduce out of band noise and may provide a clearer signal especially if a high-Q tuner is used in the front-end. If an active antenna is used, it is probably more advisable to have that antenna mounted at the mast/feed-point. This is so that only the signal gets amplified and not the RFI from the computer. This is especially so when we are talking about broadband RF pre-amps which are more susceptible to noise. I now have an MFJ-1020-A active antenna pre-amp which also contains pre-selector section and it works well for me, removing a considerable amount of out-of-band signals but at the same time, the noise floor is also amplified. Judicious use of such a system can help improve reception on many signals, especially of the continuous carrier types like RTTY and FAX or SSTV.

If you are constructing your own interface equipment, try as best as possible to build it into some kind of shielded casing, or a metal box. This may help reduce some RFI input to the radio.

---

## 9. Other measures

Besides the above, if one is using the computer for receiving CW/RTTY or other digital signals, a good IF or AF filter will help in removing unwanted noise. The advantages of the different filter types are detailed in the ARRL Handbook. For those who are more well off, a DSP adaptive filter can be of added convenience, aside from all the other SC (Switched Capacitor) filters, Notch filters. Again, I do not have the privilege to speak from experience. Bandpass filters are quite easy to construct and you may want to experiment with certain designs before investing in the real thing.

For those who are thinking of a new computer, I hear that notebooks have very low RFI emission and may be very suitable for radio use. In case you are like me and don't live near the ground floor, you may want to use a balanced antenna system which does not require a ground or you may want to get one of MFJ's Artificial Ground. Here is an excerpt from **Scott N3FI** to me about this:

" I picked up this thing called the MFJ Artificial Ground, which consists of (I think parallel) an LC circuit and a counterpoise wire. This allows you to "tune" the reactance out of the counterpoise wire so that it "seems" like an earth ground to the shack. No more zaps on your microphone! Don't know if necessary on RCV only, though. Wouldn't imagine so. Just remember that electrical outlet ground is ground at 60 Hz, but **NOT** in the MHz. Your whole wiring system will act as an antenna! "

As far as the wiring of the feed goes, remember to keep the feed from running parallel with mains wiring and try to avoid fluorescent lamps if possible. Some of these old lamps have faulty chokes which tend to generate some noise. Most modern buildings should be okay but older places tend to have this problem. While on the subject of wiring, remember that it may not always be your computer/monitor which is generating the RFI. Especially now that more and more people are staying in apartments or terrace houses, your neighbor's computer system may also be a source of noise. One way to go about this is to have a nice talk with your neighbor or use some kind of grounded metal sheet or grid at the walls. In concrete buildings, there are steel bars in the walls and so this may not be absolutely necessary.

---

## 10. Conclusion and Credits

RFI has been a most perplexing problem and will continue to be so as long as manufacturers of computers do not think of it as a problem. I welcome contributions and other suggestions so that we can advance in

our fight against RFI. Please direct all suggestions to:

**asirene@ntuvax.ntu.ac.sg**

I would also like to thank persons who have offered their advice and experience in RFI problems. Tks.

R. R. Scott	NF3I	ham@wam.umd.edu
Gary Coffman	KE4ZV	gary@ke4zv.atl.ga.us
Tom Bruhns	K7ITM	tomb@lsid.hp.com
Andrew Moore		dmoore@viper.cis.upenn.edu
Steve Byan		steve@hicomb.hi.com
others whom I may have lost their names ...		

The ARRL Handbook offers many helpful information concerning baluns, transmatches, filters and chokes. These will come in helpful for those who want to find out more about antenna and transmission line theory. Information can also be obtained from the ARRL e-mail server. Simply send a mail containing nothing but "HELP" to **info@arrrl.org** to get started. The server contains some more information on RFI and related problems.

Have fun, down with QRM and RFI. A final word of caution, be sure to know what you are doing or you may fry your equipment in the process, or fry yourself (which will arguable solve all your RFI problems! :). In case of doubt, get an ELMER or someone experienced with electronics to help you out, or to walk you through the steps.

# Where is CD data physically?

[Document Version: 1.00] [Last Updated: Jan\_13\_1995]

Author: R. C. Lacovara

E-Mail: [lacovara@ollie.jsc.nasa.gov](mailto:lacovara@ollie.jsc.nasa.gov)

Version: 1.00

Date: 13 Jan 1995

**Warning:** Flame bait below. Please don protective humor hardware...

**Auxilliary Warning:** Do not try these techniques at home. A rampaging Audiofile might destroy your collection of the Best of the Sixties. Further, if you intend to bait Audiofiles in their home, keep your back to a door. That way, if boordom causes you to lose conciousness, you might fall out of the range of the monologue, or even make a stumbling escape.

I had a ton of fun when I first got my beloved Sony ES-660 CD player with matched 1% analog 17th order Chebyshev filters and revolving chondronomos and hyperspace distringulitrix and other expensive features you can't hear by the following experiment:

Get one of those demo disks or Laurence Welk or country & western and have fun with a marker pen. Draw on the aluminum side and you will find that ol' Reed and Solomon did a good job: it takes a lot of obscuration to screw up the disk playback. Use a water soluble marker, unless you don't like the disk.

Radial lines have to be really thick and frequent. Circumferential lines take the system out much faster. If you carefully add radial lines in incremental steps, you will start to hear the system fill in missing samples with an estimate, and then eventually fail to track.

Also fun stuff to do with audio fanatics:

After doing the marker test on one of their disks, point out that a good CD player will track right through a 2mm hole in the disk. Then palm their disk, preferably one of the gold plate flavor, sub one of your old junkers, and use a hand-held hole punch on the disk. It will fracture, and your audio fanatic passes out, or assaults you.

Tell them that the gold plating in "Ultradisks" is no better than aluminum, unless you intend it as jewelry. (Offer to do the scratch test to prove it.) That's why you are using a digital recording/playback system to begin with.

Explain Shannon's Sampling Theorm. Especially point out that exact reproduction requires infinite resolution of the sample, and you have only 16 bits. Suggest letters to the IEEE, Sony and Phillips

demanding 32 or 64 bit a/d conversion, preferably at 1 MHz. Quote from one of the fringe magazines to support your claim.

Point out that having two d/a converters can be bad. That's because when you have two, they will (by definition) differ from one another. Announce that this makes for weird imaging effects in the upper registers. Mumble about "missing codes" and "differential nonlinearity." Then leave them listening intently to that CD of the maudlin jerk on the pan flutes. Remember to leave them water, or they sit there listening for a ghost in the machine for weeks, and eventually begin to smell.

If they won't listen for imaging problems, point out that with one d/a, you must have a sample and hold, which introduces a delay between channels of 11.5 microseconds. (There are plenty of ways to fix this, by the way, but it doesn't matter because...) Sound travels about 1250 feet/second (Students pay attention! I'm using mixed engineering units here!!) so in 11.5 usec it travels a little over 1/8 inch. So then go around and **MOVE THEIR RIGHT SPEAKER!** Ha ha ha...

Point out that a really, really good turntable costs much more than their CD player (or their car, for that matter), so it has to be better. You can get a reasonably insane turntable for about \$5000, but if you skimp on the cartridge, you can get one for about \$1000 more.

Also, point out that you own a Rumble King Turntable, Hummatron Amp with Total Harmonic Distortion (TM) (why settle for 0.25%, 1% or 3% when you can have the whole thing?), and Dynabuzz Speakers which cost only \$98.99, and its almost as good as your host's \$7000 system. Fun-o. Remember to wear your approved face protection.

If taunting isn't your style, try sarcasm. Sarcasm is entirely lost on the truly fanatic. For example, suppose you are listening to an interminable monologue on the benefits of water cooled speaker cable. Try this: "Gee, I bet that water cooling really keeps the conductor temperature stable!" If you are really brave, ask about installation difficulties on your slab home.

I once purchased a coil of surplus copper strip. It was about 100 feet long, an inch wide, and about 0.073 inch thick. Whatever the exact thickness, I did some calculations, and determined that this strip corresponded to something around 11 gauge. My intent: to run two such strips, side by side, under a carpet for my speaker on the other side of the room.

Of course, a member of the Audiofile Youth caught me, and was delighted. "Is it for reduced cable inductance? Will it carry more than a kilowatt?" etc., etc. Uh, no, it just won't trip me as I change my Ultradisk recording of Disrali Gears.

Don't forget cleaning vinyl disks! Man o man, this can be hours of black (vinyl) magic. Tell them you use only detergents with lanolin in them, to lubricate the grooves. Point out that the Nitty Gritty LP cleaner has a built in vacuum cleaner, and uses special mystery cleaner. (BTW, I actually have one of these: it works pretty well, but is relatively noisy.)

If you are sufficiently versed in audio arcana, you never have to resort to rational arguments or (god

forbid) engineering principles. And you may never have to listen to moronic claims about audio ever again. On the other hand, your victim might refer a fellow lunatic to your for information. Tough.

Next week: calculating skin effect at 20 KHz. And don't miss: the effects of annealing in OFHC on directional speaker wire.

For the record, I have some Harmon-Kardon stuff, and Rogers speakers. 8-)

# Will my Compact Discs work in Australia?

[Document Version: 1.00] [Last Updated: 3/26/96]

People who read soc.culture.australian often have to answer a number of questions about our country. These vary from the practical (Will an American video recorder work with an Australian TV? What voltage is used in Australia? What side of the road do Australians drive on?) through to the curious (Does water really go down the plughole in the opposite direction? What does Vegemite taste like?), to the, well, fairly clueless.

Recently we had the following thread.

(I haven't asked the posters to this thread whether they mind if I send it to rec.humor.funny, and I realise that these extracts from posting are probably a bit long to come under 'fair use'. I doubt if any of them would mind, but sorry if you can't use this for copyright reasons).

---

## From Grube

I am coming to Australia for a 3 year stay. Should I bring my CD's to play on Aussie equipment?

## From Adrian Rose

You will need an American to Australian converter device. This is usually hard wired into the CD player by a reputable Australian tech. They are all familiar with the device. Just pop into any CD store and request the phone # of the nearest CD converter tech. Its usually only around \$30 and you will not even know it had been done. You will be able to play not only US cds, and Australian, but as a bonus, European ones too!

CAution-do not try to play bootled CDs after the conversion,you will ruin the cd player.

## From Adrian Rose

Sorry about that last post-to play your US cds in Australia,they merely need to be passed thru a strong magnetic or x-ray field,such as you get at Customs.Be sure to pass each one thru separately,as bulk passage may leave the ones in the middle unplayable in Oz.

## From Mark A. Gray

Well...this may have worked for you, but I found that the only way to get 'em playing was to smear the shiny side with a very thin layer of Vegemite. 'Course this makes the inside of your CD player rather sticky, so make sure you have lots of tissues.

### **From Hans Andersen**

Don't listen to them. To play American CDs in Australian CD players, you will need to regroove them. This is because Australian CDs have a different track-width (i.e. 10 um instead of 5 um). To do this you will need to buy some fine-grade sandpaper. Try to find some with a grain size of between 8 and 12 um (micrometers for non-technical people). Put a piece of the sandpaper on a table with the rough side up. Now put your CD on the sandpaper and turn it slowly in a clockwise direction, pushing down hard. Oia la (spit) - now you have Australian standard CDs.

Good luck and I hope you enjoy Australia.

### **From Michael Jennings**

No. That is completely wrong. Australian CDs are exactly the same as American ones except for the fact that the 'groove' goes in the opposite direction. That is whereas an American groove goes inwards as you go clockwise an Australian groove goes inwards as you go anti-clockwise. This is because Australian cars drive on the left and American cars drive on the right. If the groove direction was not reversed there would be parity problems with car CD players. Unfortunately, this means that you cannot play an American CD on Australian equipment.

### **From Stephen P. Guthrie**

You smartarse. Obviously this is nothing to do with the side of the road cars drive on. Do you seriously expect anyone to swallow that? Anyone with a brain knows that it's related to which direction water goes down the plughole in the Southern hemisphere. In other words in the US the CD rotates in a clockwise direction. In Australia it rotates anticlockwise. Of course this is also true if you play your CDs in South America for example. This is actually quite neat because if you play your Beatles CDs in the Southern hemisphere you hear all this neat 'backwards masking' stuff about Paul being dead and taking marijuana. Also I heard that you hear all sorts of satanic stuff in other rock albums, but I'm not a fan myself. My question: has anyone done any experiments about playing CDs at the equator or at the North pole? At the equator do your CDs stop playing altogether. What about in a reduced gravity environment, like in a free falling elevator?

### **From Tye Leslie Sanders**

You're all a bunch of liars!!!! In Australia the initials C.D. stand for Completely Dislexic which means that the bits are scattered at random all over the disc. All Australian C.D. players are programmed to randomly search over the disc to find the right bit to play next. It is very unlikely that it could cope with a disc where all the bits were in order. I would advise you to record your discs onto Hi-Fi video tape and connect an Australian VCR to a stereo system. Australian and American VCRs are definitely compatible.

## **From Mark A. Gray**

I can't speak for a reduced gravity environment, but I can speak for the equator. It is interesting that you should bring it up, since many CD's simply do not spin at the equator (or near it actually). In Singapore (for instance) they had to ban a whole bunch of CDs or have them altered so that they would play correctly ('course if they had a bit of vegemite their problems would be solved). Video tapes and books(!) seem to suffer the same fate their.

Why don't books work properly at the equator? And I have another question: Short of smearing every page with vegemite, how do you get a northern hemisphere book to work properly in the southern hemisphere? (I'll be bringing some books home with me when I leave here, so I need to know).

Thanks in advance.

## **From Tye Leslie Sanders**

Re-your query on playing CDs in reduced gravity, it is not widely known that on the last Space Shuttle mission it was decided to test the effects of playing a compact disc in zero gravity with disasterous results.

When the disc was played, instead of the disc spinning, the entire vehicle began to spin while the disc remained motionless, turning the entire spacecraft into a giant centrifuge, nearly crushing the astronauts to death before the commander was able to crawl to the machine and press the stop button.

It has been suggested by some at NASA (who have now been dismissed for discussing government secrets) that a compact disc was the cause of the destruction of the Space Shuttle Challenger in 1985. As you may recall, this was the first mission to take a civillian into space. To ease her mind during take-off it was decided to simulate an environment of Earth similar to that of take-off pressure so they decided to play a CD of elevator music to give her the feeling that she was riding up in the lift at her local shopping centre. The craft could not cope with the enormous centrifugal force generated by the spinning disc and broke apart approximately 1 minute after take-off. It was decided to cover up their gross negligence by saying that the o-ring seals in the booster rockets were faulty.

All this is absolutely true or my name is not Ronald Reagan.

## **From Bob Hiltner**

This is a complete load of crap, and probably a troll. The 'Borealis Effect' (or 'Australis' in the southern hemisphere) could in no way overcome the power of the motor in a cd player. Besides, the 'groove' went out in the 60's (70's?). I'm no electrical engineer, but I'm guessing that any backward playing effect is due to the 220v power conversion (which would show up on euro equipment as well) or the reverse polarity down under.

As for the gravity-free environment, who gives a shi\*t? I think the astronauts have their hands full

anyway, and probably can get good FM reception from any station on earth if they need music to dance by...

Some people are so clueless!

### **From Joe Chew**

Since the Earth rotates in the opposite direction in the Southern Hemisphere, the AC power there is supplied 180 degrees out of phase with ours. Thus your CD should work just fine, although some audio purists insist on a motor-generator set to supply "American" electricity and then determine the phasing themselves.

### **From Orion Auld**

At the equator, the cd's stop rotating, so the cd players there must rotate the laser about the stationary cd. The units are very expensive.

By contrast, at the north pole, cd players are very cheap. This is because neither the laser or the cd require a motor to provide rotational energy; the cd is placed precisely on the north pole, tied to the firmament so that it doesn't spin, while the laser is fixed to the earth, slightly off-center, and the earth provides the rotation.

>What about in a reduced gravity environment,  
>like in a free falling elevator?

The cd's are virtually weightless, so they can be very massive and yet consumers will have little difficulty operating them. I hope that answers your question.

### **From Jim Gunson**

I'm glad you brought this up. The variation of the Coriolis force with latitude (zero at equator, max at north pole, min at south pole), gives rise to the so-called beta effect. Basically what happens is that when a clockwise-spinning object, in the northern hemisphere, moves north it speeds up, when it moves south it slows down. I've conducted experiments whilst driving my car here in Boston: if I head north on route 93 at 75 mph with Kylie's "Locomotion" on the CD player, the pitch of her voice goes higher, but you have to be going pretty fast to notice this. Heading west or east this doesn't happen. To the original poster, if you do find you're having trouble with the Coriolis force adversely affecting your US cd's in Australia, try turning the cd player upside-down.

### **From Adrian Rose**

No, no, no.....please don't confuse the Coriolis effect with the Doppler effect-the two are quite unrelated, and the Doppler effect is ALMOST unnoticeable, when playing out-of-area CDs, or even records.

The effect was most noticeable on 78's, but that's now academic.

BTW, I am able to offer the conversion at only 75cents (us), if done in bulk. E-mail for quotes.

**From PHolman1**

No if regrooved in the N Hemisphere the must be spun counterclockwise, remember Aussie turntables etc spin the opposite way, ps Marmite works as well as Vegimite.

**From Armadillo**

No, American compact discs will only work if you drive on the right-hand side of the road. But I wouldn't expect an aol.com user to know these things.

# Sci.Electronics.Repair FAQ: Remote sites of interest

## Version 1.11a, Jan 4, 2000

**Note:** These will be reorganized by next release...

welcome!

---

- [1. Sam's Bookmarks](#)
- [2. Read Me for items below this point](#)
- [3. Information/FAQs](#)
- [4. Repair](#)
- [5. Science](#)
- [6. Archives](#)
- [7. Other Jump-Points](#)
- [8. Misc Sites](#)

[Document Version: 1.11a] [Last Updated: 1/4/00]

---

## 1. Sam's Bookmarks

Please refer to the more up-to-date version at [Sam's Bookmarks](#). The links that used to be in this list were very old. Those that are still alive are included there.

---

## 2. Read Me for items below this point

---

I need to go through this whole file and ferret out the duplicates and dead links. I will be running a link-

validator RSN and a small update will follow it. Too much happening this week...

---

---

## Introduction

This is the viewers **Guide** to the USENET **Sci.Electronics** newsgroups. [June 17, 1997]

This FAQ is a tourist's **guide** to the various electronics newsgroups.

For more detailed information on the electronics field, try the official (as close as it gets around here) **Sci.Electronics.Repair FAQ** at <http://www.repairfaq.org/> courtesy of Filip "I'll buy a vowel" Gieszczykiewicz, Sam Goldwasser and a cast of thousands.

---

## Some Comments and Q&A.

Some things to remember. These newsgroups are worldwide in coverage. That means that criticizing

someone's English, making nationalistic remarks, personal insults, and criticizing another poster's intelligence are invitations to pointless flame wars.

And the computer equipment that will be used to read these messages is anything but uniform. Any extensions that your computer has to support various character sets will not always be reliably transmitted or displayed at the other end. So avoid fancy superscript characters, degrees temperature, greek letters, and line drawing characters like the IBM PC extended character set. There are newer standards for indicating the character interpretation to be used with a posting, but there's no guarantee that the person on the other end is up to date. For the similar reasons, note the discussion on posting software and graphics in the following Q&A section.

You should also consider where a poster is when they request the closest source for some product or information. Not everybody has a Radio Shack in the nearest shopping mall. A common problem is that the toll free 800 numbers common in North America are not easily or cheaply accessible from the rest of the world. Look closely at the originator's domain address to see if they can affordably contact your recommended source.

Keep in mind that various systems and standards are different around the world. Household power voltages and frequencies are different, and the techniques and regulations to deal with wiring are different enough to cause safety problems if you try to use the wrong one. Video systems (originally tied to the power line frequency) are also widely different around the world. Different scan rates and encoding systems make things incompatible. More recent innovations are even more diverse. For example, stereo audio on television transmissions in the UK, Scandinavian countries, and other parts of Europe is almost CD quality digital transmission, while in the US, the MTS system is a variation on the analog subcarrier system used for FM stereo.

Not only are the systems different, so is the jargon used to describe them. What might be a Ground Fault Interrupter in North America, would be a Residual Current Circuit Breaker across the Atlantic. And what was written as 4.7 k ohms, might by (from the requirements of the schematic drafting standards) be given as 4k7 ohms.

**Q.** "Someone has to give me an answer!"

**A.** Nope, sorry. Everybody here (except a few salesmen) is doing it for their own purposes, and no question is guaranteed to get an answer. Getting obnoxious about it, or repeating the question across every possible newsgroup, or over and over again won't win any friends and marks you as the archetypical "newbie".

**Q.** "What is crossposting, and is it bad?"

**A.** Crossposting is where many discussion group names are included in the "Newsgroups" header of a posting. This causes them to be distributed to each of those newsgroups when they are received and processed at a news server. (Note that Usenet is not like the World Wide Web. In contrast to the Web, postings are distributed worldwide to thousands of separate computer systems, so sending just one message instead of many is beneficial.)

Like many feature of Usenet news, it can be abused. For example, Posting to large numbers of groups at once, or posting to groups that have incompatible discussion topics as a form of harassment. This has gained it a bad reputation that the dogmatic have converted into legendary restrictions.

Try to limit posting to the one newsgroup whose topic matches your subject. If it does seem to overlap a couple of newsgroups' topics, crosspost if you must.

You should avoid (at all cost) multiple postings, (also know as SPAM). This is where you send a separate posting to multiple newsgroups. This causes several bad things. It creates that much more data that each news server system has to process. It starts a separate disconnected discussion thread in each newsgroup. And it causes for anyone who reads many of the newsgroups to see the posting repeated for each group. Any competent newsreader software will only show a crossposted message to the reader once, but has no way of dealing with SPAM. (Yes, there is a lot of incompetent software out there.)

**Q.** Are advertisements restricted to ONLY misc.industry.electronics.marketplace?

**A.** That's the idea.

**Q.** Why can't I advertise my [stereo/computer/...] for sale in misc.industry.electronics.marketplace?

**A.** For the main reason the group is for an audience that isn't interested in buying them. (Note the word 'Industry' in the newsgroup name. If you can buy it at the nearest shopping mall, it doesn't belong here). And the second good reason is there are already well established groups for those purposes. Try the misc.forsale.computers groups, rec.audio.marketplace, rec.video, or rec.radio.swap

**Q.** Can I post executable binary programs to these groups?

**A.** No. These are text discussion groups. The amount of resources needed to transmit a program is much greater than the normal posting. Many small sites and individuals use an automatic forwarding system that sends all of the traffic in a newsgroup to them. But often, with a cost determined by the amount of data, or the duration of a phone call (in places where phone use is billed by time). So posting large amounts of data imposes a direct monetary penalty on other users. They don't like it.

For that and other reasons, there a automatic canceling daemon system run by Richard Depew that will erase postings that meet this software's criteria (size and non-text content, and crossposting between text discussion groups and binary posting newsgroups) at all the sites around the world that are set up to accept this software's cancel messages. For more information, read the news.admin.net-abuse.usenet newsgroup.

Beyond that, every program needs a specific combination of computer and operating system, so ANY program will not be useful to a large number of the groups readers.

The alternatives are 1) to set up your own FTP archive or Web page that allows any interested person

with a direct Internet connection to get their own copy. (And those without direct connection may have access to systems that will give them access through email.) 2) To get a public archive to put your files onto their system. 3) To post the data to one of the comp.binaries (if the moderator will accept it) or alt.binaries newsgroups, or 4) to offer to email the data to persons who request it.

**Q.** Can I post graphics images to these groups.

**A.** Again, this can take a lot of resources and the diversity of formats means that no matter what format you choose, someone will not be able to read it, (even if they are interested). And substituting your graphics scanner for a little thought and writing effort will not win you any friends. So think before you do.

If it is really relevant, use a format that is common, compressed, and encoded so that it can travel over the net in the form of text. If you can't get the file to smaller than about 30 thousand characters after UUencoding or Mime encoding, I'd suggest that you set your files in an archive as discussed above. Also if it's of long term interest, or very specialized interest, no matter what its size. A net posting will only be around for a short time, and putting your work in an accessible archive will make it more widely available. Posting files that are already archived somewhere is a waste of resources. Just include a reference to their location.

File formats that have some supporters are 1) Portable Document Format (.pdf) that have been created with a limited character set so the various network conversions don't corrupt their content. Either through using the 7 bit character conversion in the creation software or by UUencoding or Mime encoding the file. 2) Postscript files that have been compressed with gzip or zip and UU or Mime encoded. 3) GIF files that have been encoded. 4) .bmp or .pcx files that have been compressed and encoded. (Do not waste your time posting uncompressed .bmp files. The Bincanceler will eat them.)

There has been periodic discussions of some file format produced by CAD software, but no one format seems to have wide support.

The same applies to various word processor document file formats. "Everybody" doesn't have the software that you run. And some would rather never have to buy it.

**Q.** What's the difference between sci.electronic.components, .design, and .equipment?

**A.** The split here is set up on levels of complexity. In this field of technology, people look for solutions to problems along these levels. Someone who is looking for a box that solves their problems is working at a higher level of detail than someone who is designing a module (circuit board) and that second person is working at a higher level than someone looking for a prebuilt integrated circuit that they need to purchase.

The proposed components group is for questions dealing with individual parts. Someone working on this level is looking for a specific function or source or identification for an electronic component. Postings requesting the identification of an integrated circuit are a large portion of the current traffic.

The design group is for persons combining components into circuits. Discussion on design solutions and techniques.

The equipment group is for persons looking for already available solutions to their problems. In other words, if someone is looking for a solution to their problem, and wants to buy something with a warranty, and that has a salesman and tech support along with it, .equipment is the place to ask for advice. (This is not the place to suggest that the person can go down to Radio Shack and get a 555 and wire up a circuit.)

**Q.** What's left for **sci.electronics.misc**?

**A.** Gossip, history, trivia, manufacturing, systems, standards, announcements ...

---

## Charters and Description Lines

**sci.electronics** - Circuits, theory, electrons and discussions.

This is now a bogus group. On January 2, 1996, it was superseded by **sci.electronics.misc** as part of the reorganization vote carried out two months earlier. Expect that access may be turned off or aliased to the new group, and that propagation from system to system will be unreliable.

**sci.electronics.basics** - Elementary questions about electronics.

"A forum for discussion of electronics where there is no such thing as a stupid question. Beginners questions. Discussion of electronics education. Requests for other sources of information."

**sci.electronics.cad** - Schematic drafting, printed circuit layout, simulation.

"**sci.electronics.cad** is an unmoderated group for the discussion of Computer Aided Design software (and systems) for use in designing electronic circuits and assemblies. Topics can include Schematic "Capture" software, Printed Circuit Board layout software, introductory and educational use of circuit simulation software such as Spice, obtaining simulation descriptions (Spice models) for electronic components, and any other computer software that relates to designing electronic circuits at the printed circuit board level."

**sci.electronics.components** - Integrated circuits, resistors, capacitors.

"Discussions of electronics at the component level. The use, limitations, and identification of resistors, capacitors, integrated circuits, connectors, enclosures, ... and so on. Locations

and contact information for Manufacturers, Distributors, and other sources for supply and technical information."

**sci.electronics.design** - Electronic circuit design.

"Discussions relevant to the design of electronics circuits."

**sci.electronics.equipment** - Test, lab, & industrial electronic products.

"Discussion of the application and internal operation and relative merits of test equipment, laboratory equipment, and industrial equipment. This is not a forsale group. Buying/selling is supposed to occur in the relocated misc.industry.electronics.marketplace group.

(Discussions on the relative merits of various consumer electronics equipment are better held in the groups in the rec hierarchy devoted to those topics.)"

**sci.electronics.misc** - General discussions of the field of electronics.

"General discussions on the topic of electronics. (Discussions on the relative merits of various consumer electronics equipment are better held in the groups in the rec hierarchy devoted to those topics.)"

**sci.electronics.repair** - Fixing electronic equipment.

"**sci.electronics.repair** is an unmoderated group for the discussion of repairing electronic equipment. Topics to include: Requests for assistance, Where to obtain servicing information and parts, Techniques for diagnosis and repair, and Anecdotes about success, failures and problems with equipment manufacturers."

**misc.industry.electronics.marketplace** - Electronics products & services.

"Advertisement and discussion for the buying, selling, and bartering of electronic components (integrated circuits, resistor, capacitors, etc.), electronics test equipment, electronics laboratory equipment, electronics industrial equipment, and services used for the production of electronics. NO CONSUMER ELECTRONICS - NO AUDIO, VIDEO, or HOME COMPUTERS."

---

## Other Newsgroups of Interest

The following are directly electrical/electronics related:

- alt.binaries.schematics.electronic

- alt.engineering.electrical
- sci.engr.electrical.compliance
- sci.engr.electrical.sys-protection

Also some others that aren't:

- rec.video.\*
  - rec.audio.\*
  - news:misc.forsale.\*
  - rec.radio.\*
-
