- Focus to high voltage (F-HV). High voltage will be pulled down - probably arcing at the focus spark gaps/other protective devices. Line fuse and/or HOT may blow. A high impedance short may only result in increased focus voltage but this is probably unusual.

- Other locations between electron gun elements as feed wires.

Except for the high voltage to other places, the short may actually be located in the CRT *socket* or even on the CRT neck board, probably in the spark gap(s) for the problem pins. Remove the socket and test between the suspect pins on the CRT itself. If the CRT itself is fine, the spark gaps should be inspected and cleaned/repaired and/or components replaced. At this point, the cause may still be present - a short inside the flyback for example resulting in excessive voltage on one or more pins.

Assuming this is not the case, replacing the CRT may be the best solution but there are a variety of 'techniques' that can often be used to salvage a monitor that would otherwise end up in the dump since replacing a CRT is rarely cost effective:

1. Isolation - this will usually work for H-K shorts as long as only one gun is involved. However, with high video bandwidth monitors, there may be some smearing of the affected color due to the added capacitance of the transformer and filaments now connected to its video signal.

2. Blowing out the short with a capacitor - depending on what is causing the short, this may be successful but will require some experimentation.

3. Placing the CRT (TV or monitor) face down on a soft blanket and *gently* tapping the neck to dislodge the contamination. Depending on the location of the short, one side or the other might be better as well. Sometimes, this can be done in-place while watching the picture.

A combination of (2) and (3) may be required for intermittent shorts which don't appear until under power. See the sections below for additional details. However, for shorts involving the focus and high voltage elements, even a sharp edge can result in arcing even if there is no actual short. There is no remedy for these types of faults.

Providing isolation for a CRT H-K short

This procedure will substitute a winding of your own for the one that is built in to the flyback to isolate the shorted filament from the ground or voltage reference. Note that if you have a schematic and can determine where to disconnect the ground or voltage reference connection to the filament winding, try that instead.

The flyback is the thing with the fat red wire coming out of it (and perhaps a couple of others going to the CRT board or it is near this component if your set has a separate tripler) and may have a couple of controls for focus and screen. It should have some exposed parts with a ferrite core about 1/2-3/4" diameter.

The filament of the CRT is the internal heater for each gun - it is what glows orange when the set is on. What has happened is that a part of the fine wire of the bad color's filament (assuming this is indeed your problem) has shorted to the cathode - the part that actually emits the electrons. Normally, the heater circuit is grounded or tied to a reference voltage so when it shorts to the cathode, the cathode voltage level is pulled to ground or this reference.

You will need some well insulated wire, fairly thick (say #18-22). Find a spot on the flyback where you can stick this around the core. Wrap two turns around the core and solder to the CRT filament pins after cutting the connections to the original filament source (scribe the traces on the board to break them). Make sure you do not accidentally disconnect anything else.

This winding should cause the filaments to glow at about the same brightness as before but now isolated from ground. If they are too dim, put another turn on the flyback to boost the voltage as low filament temperature will result in reduced emission, blooming, and possible damage to the cathodes after awhile. (Don't go overboard as you may blow the filament totally if you put too many turns on the core - you then toss the monitor.)

Route the wires so that there is no chance of them getting near the high voltage or any sharp metal edges etc. Your picture quality may be a tad lower than it was before because of the added stray capacitance of the filament wiring being attached to the the (formerly bad) video signal, but hey, something is better than nothing.

Rescuing a shorted CRT

If the short is filament-cathode (H-K), you don't want to use the following approach since you may blow out the filament in the process. If this is the case, you may be able to float the filament and live with the short (see the section on: "Red, green, or blue full on - fog over picture".

Shorts in the CRT that are between directly accessible electrodes can be dealt with in a more direct way than for H-K shorts. At this point you have nothing to loose. A shorted CRT is not terribly useful.

If the short is between two directly accessible electrodes like cathode-grid, then as a last resort, you might try zapping it with a charged capacitor.

Unplug the CRT socket!

Start with a relatively small capacitor - say a few uF at a couple hundred volts. Check to see if the short is blown after each zap - few may be needed. Increase the capacitance if you feel lucky but have had little success with the small capacitor.

If the fault is intermittent, you will, of course, need to catch the CRT with the socket disconnected and the short still present. Try some gentle tapping if necessary. If you do this with the charged capacitor across the suspect electrode, you **will** know when the short occurs!

Also see the section: High voltage to focus short.

High voltage to focus short

Symptoms would be (with the unit powered and high voltage present):

- With the CRT neck board plugged into the CRT, the focus spark gap is likely arcing.

- With the socket unplugged, putting anything connected to ground (or any other circuitry) near the focus pin would result in a juicy spark or arc. WARNING: Removing the CRT socket and powering the unit may destroy the CRT on some models. See the section: Warning about disconnecting CRT neck board.

If the CRT is gassy or up to air, forget it - it might make a decent fish tank :-). In this case, there would be visible arcing INSIDE the CRT probably not confined to a single location.

However, if there is just a metal whisker between the F and HV, that might be able to be cleared by careful tapping or a charged capacitor. You may even be able to see it if you were to remove the yoke - the gap is pretty large, about 1-2 mm - the last gap between electrodes before the start of the internal (Dag) coating.

See the section: Rescuing a shorted CRT.

Note that other damage may have been done as

Other components including the flyback, HOT, and parts on the CRT neck board and beyond, may have been damaged as a result of the short. Zapping the CRT may be just the beginning of what is required to repair it all.

Dark picture

A monitor with a picture that is too dark may have a fault or the CRT may just be near the end of its useful life.

First, confirm that your video source - computer, camera, etc. - is producing a proper signal.

Is the brightness at all erratic? Does whacking the monitor have any effect? If so, then you may have bad connections on the CRT driver card or elsewhere. If the brightness tends to fade in and out over a 10 to 20 second period, a bad filament connection is likely. Check for the normal orange glow of the filaments in the neck of the CRT. There should be 3 orange glows. If they are excessively reddish, very dim, or fade in and out, you have located a problem. See the section: Picture fades in and out.

Common causes of brightness problems:

1. Dirty CRT faceplate or safety glass. Don't laugh. It sounds obvious, but have you tried cleaning the screen with suitable screen cleaner? It is amazing how dirty screens can get after a few years - especially around smokers!

   (From: A. R. Duell (ard12@eng.cam.ac.uk).)

"I once spent a morning battling with a DEC VT105 terminal with a very dim and washed out picture, and only after checking everything on the video board did I wipe over the screen. That cured it. It's amazing how dirty screens can get after a few years use."

Wipe gently with a slightly dampened cloth - not soaking or you may end up with real problems when the water drips down inside and hits the electronics!

2. Old CRT. The brightness of the CRT deteriorates with filament on-time. It doesn't matter much what you are doing or if you use a screen saver.

   An indication of a weak CRT would be that turning up the SCREEN (G2) or master brightness control only results in a not terribly bright gray raster before the retrace lines show up. There may be indications of poor focus and silvery highlights as well. A CRT brightener may help. See the sections: Brightening a old CRT and Monitor life, energy conservation, and laziness.

3. Bad component in filament circuit or bad connection reducing filament voltage. This should be easy to check - there are only a few parts involved. If it is erratic, bad connections are likely.

4. Brightness control faulty - bad pot, bad connections, or problem with its power supply. Depending on specific problem, control may or may not have any effect. If digitally adjusted, there could be a problem with the logic or control chip. If the button or menu item has no effect at all, then a logic or control problem is likely.

5. Improperly set SCREEN (G2) voltage (usually on flyback) or faulty divider network. See the section: Brightness and color balance adjustment.

6. Improperly set video bias (background) levels or fault in video drive circuitry. See the sections starting with: "Optimal procedure for setting brightness/background and screen adjustments".

7. Fault in video amplifiers. With all three color affected equally, this would most likely be a power supply problem. A video amplifier problem is likely if turning up the SCREEN (G2) or master brightness control results in a very bright raster before the retrace lines appear. Cheack signals out of the video/chroma IC.

8. Fault in beam or brightness limiter. Many TVs and monitors measure the beam current (possibly indirectly) and limit the maximum to a safe value. The purpose of this may be to protect the CRT phosphors, and/or to assure that the power supply does not go out of regulation, and/or to limit X-ray emission. If this circuit screws up, a dark picture may result. Checking the signals and voltages at the CRT socket should determine if this is the problem.

9. High voltage is low. However, this would likely result in other symptoms as well with focus, size, and geometry.

Brightening an old CRT

If performing adjustments of the internal background and/or screen controls still results in a dark picture even after a long warmup period (and the controls are having an effect - they are not faulty), the CRT may simply be near the end of its useful life. In the old days of TVs with short lived CRTs, the CRT brightener was a common item (sold in every corner drugstore, it seemed!).

First confirm that the filaments are running at the correct voltage - there could be a marginal connection or bad resistor or capacitor in the filament power supply. Since this is usually derived from the flyback, it may not be possible to measure the (pulsed high frequency) voltage with a DMM but a service manual will probably have a waveform or other test. A visual examination is not a bad way to determine if the filaments are hot enough. They should be a fairly bright orange to yellow color. A dim red or almost dark filament is probably not getting its quota of electrons. It is not be the CRT since all three filaments are wired in parallel and for all three to be defective is very unlikely.

If possible, confirm that the video output levels are correct. For cathode driven CRTs, too high a bias voltage will result in a darker than normal picture.

CRT brighteners are available from parts suppliers like MCM Electronics. Some of these are designed as isolation transformers as well to deal with heater-to-cathode shorts.

You can try a making a brightener. Caution: this may shorten the life of the CRT - possibly quite dramatically (like it will blow in a couple of seconds or minutes). However, if the monitor or TV is otherwise destined for the scrap heap, it is worth a try.

The approach is simple: you are going to increase the voltage to the filaments of the electron guns making them run hotter. Hopefully, just hotter enough to increase the brightness without blowing them out.

Voltage for the CRT filament is usually obtained from a couple of turns on the flyback transformer. Adding an extra turn will increase the voltage and thus the current making the filaments run hotter. This will also shorten the CRT life - perhaps rather drastically. However, if the monitor was headed for the dumpster anyhow, you have nothing to lose. You can just add a turn to an existing winding or make your own separate filament winding as outlined in the section: Providing isolation for a CRT H-K short.

In some monitors, there is a separate filament supply on the mainboard - this should be obvious once you trace the filament wires from the video driver board). In this case, it still may be possible to increase this output or substitute another supply but a schematic will be required.

There are also commercial CRT rejuvenators that supposedly zap the cathodes of the electron guns. A TV or monitor service center may be able to provide this service, though it is, at best, a short term fix.

Color balance changes across screen from left to right

The characteristics are that a solid white screen will tend to be blue tinted on one side and red tinted on the other. This is usually a subtle effect and may be unavoidable with some designs.

There are several possibilities:

1. Purity - this means the beams are landing on the wrong phosphor dots. This is what would be affected by moving from one location to another or even rotating the TV on its base without degaussing. If the problem just appeared, degaussing may be needed.

   What do you have near the TV or monitor? Loudspeakers or other devices which generate magnetic fields can easily cause all sorts of color purity problems. Relocate the offending device(s) or the TV or monitor and then degauss it.

   See the section: Degaussing (demagnetizing) a CRT.

   If the problem still persists, purity adjustment may be needed. However, this isn't likely to have changed so look for other causes before tackling these adjustments.

2. Unequal electron gun to shadowmask/screen distance - the electron beams for the red and blue video travel

slightly different distances on the left and right sides of the screen so their intensity (due to focus not being optimal and other factors) in each case may differ slightly affecting color balance.

3. Doming - This would only happen in very bright areas and causes the shadow mask to expand and distort. (Doming should not be a problem with Trinitron CRTs which use tensioned wires in their aperture grill.) This would also not really affect left-right color balance in particular.

I don't really know how much of a problem (2) is in practice or whether some manufacturers compensate for it.

Bleeding highlights

On very bright areas of the picture, one or more colors may bleed to the right resulting in a trail of those colors. The difference between this problem and the section: Trailing lines in one or more colors is that in this case, only highlights are affected.

One cause of this is that the color gain, contrast, or intensity controls (whatever they are called on your monitor) are set too high. See the section on: "Brightness and color balance adjustment". Check the settings of any brightness limiter controls as well.

Trailing lines in one or more colors

Assuming this is not a form of ghosting resulting from cabling and/or use of switchboxes, etc, then it could be any of the following:

- Poor decoupling in the power supplies for the video drive circuits - probably on the CRT neck board. Check for bad (low uF or high ESR) filter capacitors (electrolytic mostly) on this board or the power supplies feeding it.

- Insufficient CRT filament voltage. This could be a result of bad connections or a bad component in the filament power supply (probably from the flyback). Check to see if the filaments are glowing bright orange and check the voltage if possible (though this can be tricky since it is often fed from a winding on the flyback and is a pulse waveform, not DC or a sinusoid. The service manual will probably have info and waveforms.

- Bad CRT (more likely if only one color is affected). A weak electron gun can result in this behavior. Swap it with one that work properly. If the same color is still bad, that CRT gun is weak. The CRT will need rejuvenation or need to be replaced (more likely, the entire monitor will be tossed into the dumpster).

Purity problems with bright pictures

Setting the brightness excessively high may result in enough heating of the shadow mask to distort it. IF severe enough, the positions of the holes will shift enough to result in visible purity problems. This is less of a problem with tubes using an InVar shadow/slot mask. It should also be less of a problem for Trinitron aperture grille CRTs.

The only solution is to reduce the brightness.

Why does the intensity appear so non-uniform in bright areas?

Actually, the intensity variation is likely to be even worse than you might think - possibly as much as 2:1 from the center to the corners. In most cases you do not notice it. With large deflection angle tubes, fewer electrons make it to phosphor dots near the edge of the screen. It is simple geometry.

(From: Bob Myers (myers@fc.hp.com).)

It is extremely difficult for any CRT display to maintain perfect brightness and color uniformity across the entire image. Just the geometry of the thing - the change distance from the gun to the screen as the beam is scanned, the changing spot size and shape, etc. - makes this nearly impossible, and there can also be variations in the phosphor screen, the thickness of the faceplate, etc.. Typical brightness-uniformity specs are that the brightness won't drop to less than 70% or so of the center value (usually the brightest spot on the screen).

On color tubes, the lack of perfect brightness uniformity is aggravated by the lack of perfect COLOR uniformity and purity. What appear to be "dark spots" on a solid gray image may actually be beam mislanding (color purity) problems, which may to some degree be remedied by degaussing the monitor.

Again, *some* variation is normal; if you think you're seeing too much, you can try degaussing the thing and seeing if that helps. If it doesn't, then the question is whether or not the product meets its published specs, and that 's something you'll have to discuss with the manufacturer or distributor.

Brightness changes from left-to-right across screen

Slight variations in brightness across the face of the CRT are not unusual. In fact, if you used a photometer to actually measure the brightness, you might be amazed at the actual variance even with the best monitor or TV - you just don't notice it. However, a major variation - usually a decay from left to right but could be the other way indicate a component failure. Of course, make sure the face of the screen is clean!

- A fault in the power supplies to the video amplifier and/or video output circuits. Most likely, an electrolytic capacitor has dried up and is not adequately filtering the power derived from the flyback which then has ripple at the horizontal scan rate and thus locked to the screen. The voltage decays from left-to-right between horizontal flyback pulses.

  The most likely location for these capacitors is in the vicinity of the flyback transformer on the mainboard or on the CRT neck board. Check the capacitors with capacitor tester or ESR meter and/or take a look at the power right at the video amplifier and video output drivers.

- Horizontal linearity is bad - this may actually be a horizontal geometry problem and not a brightness problem.

  See if objects on left side of the screen are stretched compared to those on the right (or vice-versa). If they are, the problem is in the horizontal deflection circuits - possibly a bad (or in the case of a multiscan monitor, correctly selected) S correction capacitor or linearity coil.

- Inoperative degauss circuit, monitor moved or rotated without degaussing, or magnetic field from some other device (like a permanent magnet) is affecting CRT - slight amounts of magnetization may reduce brightness (by moving the beams into the black space between phosphor dots) before affecting color purity (where the beams land on the wrong phosphor dots).

  See if the degauss button, if present, does anything. Try deguassing manually. See the section: Degaussing (demagnetizing) a CRT.

Picture fades in and out

If the picture faded away on the order of 10-20 seconds (and if it comes back, also comes up to full brightness in same time frame - possibly with the persuasion of some careful whacking) AND with NO other significant changes such as size, focus, etc., then take a look in the back of the tube for the filaments to be lit - the orange glow near the CRT socket. If the glow is coming and going as well, then you probably have a bad solder connection on the circuit board on the neck of the CRT. Look for fine cracks around pins on that board. Try prodding it with an insulating stick to see if the picture comes back. Resolder if necessary. It is probably not a bad CRT as the filaments are usually wired in parallel and all would not go bad at the same time.

However, if only a single color fades in and out, then a bad connection inside the CRT is a distinct possibility - look for only one of the filament's glow to be coming and going. This is probably not worth fixing since it will require CRT replacement.

If the picture faded away with other symptoms, then there is probably a fault in the video amplifier/output one of its power supplies - still probably a loose connection if you are able to get it back by whacking.

Occasional brightness flashes

These may last only a fraction of a scan line or much much longer.

Make sure it is not the video source - try another one.

This could mean an intermittent fault in a variety of places including the video circuitry and SCREEN power supply:

- Brightness circuitry - SCREEN, master background or its power supply. Could be in or around flyback or focus/screen divider. Could perhaps be in the CRT, but probably less likely.

- Video amp before or at chroma demodulator (if composite input) - since after this point, you would most likely get colored flashes since only one of the RGB signals would likely be effected. However, a bad power connection to the video circuitry could cause all the colors to be affected.

If you still get flashes, it should be quite easy to monitor either the video outputs or SCREEN supply (with a HV divider on your scope) for noise. Then trace back to power or noise source.

Occasional static, lines, spots, or other unsightly blemishes

First, confirm that these are not video source - PC - related. Try the monitor on another computer. This may be a problem with the hardware or driver (software) for the video card, the O/S, or memory or bus speed.

If it is not computer related, then it could be arcing, corona, bad connections, or some electronic component breaking down. See the appropriate sections for these problems.

Note that problems in absolutely fixed locations or with an extent related to pixel sizes in the video card are nearly always computer/video card related and not due to a faulty monitor.

Flickering monitor

First, make sure your scan rate is set high enough (but not beyond the capabilities of the monitor). A scan rate less than 60 Hz is likely to result in annoying flicker especially at high brightness levels.

See if the flickering correlates with any processor or disk activity indicating a software driver or video card problem.

Assuming neither of these applies and you are not doing your work by candlelight, a flickering image is probably due to an intermittent arc or short, probably in the high voltage section near or at the flyback transformer. However, it is also possible that it is due to a simple bad connection elsewhere.

So the first thing to do will be to remove the cover and without touching anything, carefully examine for any obvious signs of bad connections, arcing, or burned areas. In particular look for:

- hairline cracks around the pins of large components like power transistors, power resistors, transformers, and connectors.

- any discoloration, cracking, other unusual signs on the flyback. The flyback also provides, via a high resistance divider network, the several kV for focus and several hundred V for the G2 (screen) CRT electrode. These are the voltages that may be intermittently changing and resulting in flicker.

Now, with the monitor powered in a darkened room with a normal picture (use the highest resolution at which your monitor will work as this should put the most stress on it, maybe).

- Look for any arcing or corona around the area of the flyback or the neck of the CRT first, then just anywhere.

- Use a well insulated stick (wood or plastic) to gently prod the circuits board, components, wires, etc. to see if you can induce the problem.

There will probably be a pair of adjustments on the flyback itself. One of these is FOCUS and the other is SCREEN - essentially a master brightness.

- Now, with one hand in your back pocket, try turning each of these a fraction of a turn in each direction. Don't worry, you cannot hurt anything by doing this. The FOCUS should only change the sharpness of the picture. The SCREEN should only change the brightness. In both cases, this should be a smooth effect. Sometimes, these controls will simply get dirty and cause the problems you have seen. In this case, just moving them back and forth may clean them. If one affects the other - if turning focus alters brightness or vice-versa, there is a short between the focus and screen voltages, probably inside the flyback but it could be elsewhere.

It is likely that all of the above tests will come out negative as you may have an intermittent short internal to the flyback which can only be fixed by replacement. However, eliminate the easy fixes first.

Excessive brightness and/or washed out picture

There are a number of possibilities including incorrect screen (G2) or bias (G1) voltages, or a problem in the video or blanking circuitry. Any of these could be the result of bad connections as well. A short in the CRT can also result in these symptoms.

- Excessive brightness/washed out picture is often an indication of a problem with the screen (G2) supply to the CRT. May be a bad capacitor or resistor divider often in the flyback transformer assembly or on the board on the neck of the CRT.

- If the excessive brightness just developed over time, then a simple adjustment of the screen or background brightness controls may keep it (and you) happy for a long time.

  When good, a typical value would be in the 200 to 600 VDC at the CRT. The screen (it may also be called master brightness, bias, or background) control should vary this voltage. However, it may be difficult to measure as the resistors in the voltage divider network may be quite large - hundreds of M ohms. If your unit has an external screen control (less likely these days) and it has no effect, trace out the circuitry in the immediate vicinity and check the resistors and potentiometer for opens, look for bad connections, etc. If it is built into the flyback transformer and is sealed, the entire flyback will need to be replaced unless the actual problem turns out to be a bad connection or bad component external to the flyback.

- Where the brightness control has no effect, suspect a missing bias supply to the G1 (control grid) electrodes of the CRT. This is usually derived from the flyback with a simple rectifier/filter capacitor power supply. Parts may have failed (though not likely the flyback itself). Adjusting the user brightness control should vary this voltage over a typical range of 0 to -50 V with respect to signal ground.

- It could also be a problem with biasing of the video output transistors. There may individual controls for background brightness on the little board on the neck of the CRT. However, we are looking for a common problem since all colors are wrong in the same way. This is likely to be a missing voltage from a secondary supply from the flyback.

- A short between electrodes inside the CRT can result in brightness problems. It may be possible to check this with an ohmmeter with the power off and the CRT socket removed. Test between G1, G2, and F where all colors are affected though a short between F and G2 will result in the focus control changing brightness and vice-versa - a classic symptom.

  However, in some cases, it only shows up when operating and one must deduce the presense and location of the short from its affect on voltages and bias levels.

  See the section: Rescuing a shorted CRT and other related topics.

First, check for bad connections/cold solder joints by gently prodding with an insulating stick. Check voltages and bias levels.

Focus problems

Slight deterioration in focus can be corrected by adjusting the focus control usually located on the flyback transformer. Sometimes, this is accessible externally but usually not. On monochrome monitors, the focus control, if any, may be located on the main board.

Don't expect to have perfect focus everywhere on the screen. Usually there will be some degradation in the corners. A compromise can generally be struck between perfect focus in the center and acceptable focus in the corners.

If the adjustments have no effect, then there is probably a fault in the focus power supply.

For most color TVs and monitors, the correct focus voltage will be in the 4 to 8 kVDC range so you will need a meter that can go that high or some big resistors to extend its range or a HV probe. You must use a high impedance meter as the current availability from the focus power supply is very low.

The pots in the flyback are sometimes accessible by removing their cover, which may snap on. However, a typical focus circuit will have a large value resistor potted inside the flyback (like 200 Megohms).

Try to measure the focus in-circuit. If the value you read is very low (assuming your meter has a high enough impedance not to load the circuit appreciably), then disconnect the wire (from the PCB on the neck of the CRT or wherever) and measure again and observe any change in picture.

- If still low, then almost certainly there is a problem with the pot or the flyback. See if you can open it enough to measure and/or disconnect the pot. If the problem is inside the potted part of the flyback, the only alternative is a new flyback or an external divider if you are so inclined. However, once the focus network goes bad inside the flyback, there is an increased chance other parts will fail at some point in the future.

- If the voltages check out with the CRT disconnected, there is a chance of a bad CRT or of a shorted component on the PCB on the neck of the CRT. Look for shorted capacitors or burnt or damaged traces.

Measure the voltage on the focus pin of the CRT. WARNING: If there is an internal short, you could have the full 25kV+ at this location! If you get a reading, this would be an indication of an internal short in the CRT. See the section "Shorts in a CRT".

Bad focus (fuzzy picture)

Focus voltage on the CRT is usually in the range of 2-8 kV DC and should be controllable over a fairly wide range by the focus pot - usually located on the flyback or a little panel in its vicinity:

- If adjusting the pot results in a position of acceptable focus, you may be done. It is not unusual for the focus setting to drift a over time.
- If the setting is already as good as possible but not really good enough, the CRT may be tired. Alternatively, the filament voltage may be too low. Check for bad connections in the filament circuit.
- If the optimal setting is out of range of the focus pot, the problem is likely leakage in the focus divider in the flyback or one of the components on the CRT neck board.

Also see the sections: Focus adjustment and Focus drifts with warmup.

The focus wire usually comes from the flyback or if the general area or from a terminal on a voltage multiplier module in some cases. It is usually a wire by itself going to the little board on the neck of the CRT.

If a sparkgap (a little 2 terminal device with a 1/8" gap in the middle) is arcing with power on, then the resistive divider has shorted inside the flyback, focus board, or HV multiplier - whatever you TV has - and the this unit will need to be replaced. Ditto if the SCREEN control affects focus and/or vice-versa.

Using a suitable high voltage meter (range at least 10 kVDC, 1000 M ohm or greater input impedance), you should be able to measure it connected and disconnected. The ground return will be the outside coating of the CRT which may or may not be the same as the metal chassis parts. If the voltage is very low (less than 2 kV) and the pot has little effect:

- When measured right off of the source disconnected from the CRT neck board, then the problem is probably in the focus network in the flyback (or wherever it originates). Sometimes these can be disassembled and cleaned or repaired but usually requires replacement of the entire flyback or voltage multiplier. Note: you may need to add a HV (10 kV) capacitor between the focus wire and DAG ground to provide filtering so you get a DC level for your meter.
- When measured with the focus wire attached to the CRT neck board with the CRT connected but reasonable with the CRT unplugged, there is probably a short between the focus and another electrode inside the CRT. See the section: Rescuing a shorted CRT.
- When measured with the focus wire attached to the CRT neck board with the CRT unplugged, there is likely a component on the CRT neck board that is leaky or breaking down. Also, check for decayed (tan or brown) glue which may turn leaky with age.

Focus drift with warmup

This could be due to a problem with the focus voltage power supply, components on the CRT neck board, or a tired worn CRT.

Focus is controlled by a voltage of 2-8 kV DC usually derived from the flyback transformer and includes some resistors and capacitors. One of these could be changing value as it warms up. (assuming nothing else changes significantly as the unit warms up - e.g., the brightness does not decrease.)

Focus voltage is derived from a subset of the high voltage winding on the flyback using a resistive voltage divider which includes the focus pot. These are extremely high value resistors - 200 M ohm is common - and so leakage of any kind can reduce or increase the focus voltage. All other things being OK - i.e., the picture is otherwise fine - I would suspect this type of failure rather than the CRT.

The connection to the CRT is usually a separate wire running from the flyback or its neighborhood to the CRT neck board. Look for components in this general area. Use cold spray or a heat gun to isolate the one that is drifting. If you have access to a high voltage meter, you should be able to see the voltage change as the TV or monitor warms up - and when you cool the faulty part. If it is in the flyback, then sometimes the part with the adjustments clips off and can be repaired or cleaned. Most often, you will need to replace the flyback as a unit.

- If the optimal adjustment point of the focus control doesn't change that much but the best focus is simply not as good as it should be, the CRT is probably the problem. However, if the optimal point produces acceptable focus but it changes (and possibly moves off of one end of the adjustment knob range) as the unit warms up, the flyback or one of the components on the CRT neck board are likely drifting.

- If you have a high voltage meter, you can measure the focus voltage to determine if it is being changed by the focus pot and if it is in the ball park (2-8 kV typical). Sometimes, the part of the flyback with the focus pot can be snapped off and cleaned or parts replaced but usually you need to replace the whole unit. There may a capacitor or two on the PCB on the neck of the CRT that could have increased leakage as well thus reducing the focus voltage.

- To determine if the CRT is the problem, for sharp focus after the unit has warmed up. Power-off for an hour or so and carefully pull the CRT neck board off of the CRT. Then, power up the unit. Let it run long enough such that there would have been a detectable focus drift. Now, power-down, plug the CRT neck board back in, and power-up. Watch the image as it appears on the screen:

    - If the focus starts out fuzzy and sharpens up as the image appears and gradually becomes sharper as the CRT warms up the CRT is likely tired.

      The only catch here is that plugging the CRT neck board into the CRT results in an additional load on the flyback due to the picture beam current which heats it more as well. Thus, if the problem takes a few minutes to appear, keep the brightness turned down except to check the appearance of the picture from time to time.

      You can set the focus control for optimum when warmed up and just turn the monitor on in advance of when you will be needing it or add a user focus adjustment by drilling a hole in the plastic case for an *insulated* screwdriver or flyback focus knob extender :-). The CRT may continue to function for quite a while so this is not impending doom.

    - If the focus is relatively stable as the image appears and increases in brightness *and* is about as sharp as it would be with the monitor warmed up, the problem is most likely in the flyback. However, also check for bad components or decayed (tan or brown) glue on the CRT neck board. A drifting flyback will need to be replaced as it will probably get worse and fail completely. Clean the surface of the circuit board and CRT socket in the vicinity of the focus and screen terminals and traces. Contamination or just dirt and grime can easily cause problems especially on humid days since the resistance of these circuits is extremely high (100s of M ohms).

    - If the focus is relatively stable as the image appears and increases in brightness *and* is similar to what it would be with the monitor cold, you have a very strange situation where some load on the high voltage power supply, perhaps, is causing a thermal problem. This would be rare.

About the quality of monitor focus

Question: I have 2 identical monitors. One is razor sharp from edge to edge. The other is blurred at the corners- not from convergence problems, but just plain out of focus. In this monitor, the focus adjustment on the flyback can improve the focus at the edges, but then the center of the screen becomes worse..My question is : Is this a problem in the electronics and presumably a fixable flaw or is it caused by variance in the picture tube itself and not correctable ? Or is it some other issue?

(From: Bob Myers (myers@fc.hp.com).)

The adjustment on the flyback sets the "static" focus voltage, which is a DC voltage applied to the focus electrode in the CRT. However, a single fixed focus voltage will not give you the best focus across the whole CRT screen, for the simple reason that the distance from the gun to the screen is different at the screen center than it is in the corners. (The beam SHAPE is basically different in the corners, too, since the beam strikes the screen at an angle there, but that's another story.) To compensate for this, most monitors include at least some form of "dynamic" focus, which varies the focus voltage as the image is scanned. The controls for the dynamic focus adjustment will be located elsewhere in the monitor, and will probably have at LEAST three adjustments which may to some degree interact with one another. Your best bet, short of having a service tech adjust it for you, would be to get the service manual for the unit in question.

It is also possible that the dynamic focus circuitry has failed, leaving only the static focus adjust.

As always, DO NOT attempt any servicing of a CRT display unless you are familiar with the correct procedures for SAFELY working on high-voltage equipment. The voltages in even the smallest CRT monitor can be lethal.

Bad focus and adjustment changes brightness

This is the classic symptom of a short between the focus and screen supplies - probably in focus/screen divider which is part of the flyback or tripler. However, it could also be in the CRT. If you have a high voltage meter, measuring the focus voltage will show that (1) it is low and (2) it is affected by the SCREEN control Similarly, the SCREEN voltage will be affected by the FOCUS control (which is what is changing the brightness.

To determine if the problem is in the CRT, measure the FOCUS and SCREEN voltage with a high voltage meter. If they are identical pull the plug on the CRT. If they are now their normal values, then a shorted CRT is a distinct possibility - see the section: Rescuing a shorted CRT.

Charlie's comments on focus problems

(From: Charles Godard (cgodard@iamerica.net).)

Most true focus problems that I have encountered (when the IHVT is ok) are related to leaks or resistance on the focus output. The diming of the screen when the focus pot is adjusted leads me to think in terms of a leaky socket. I'd remove the ground from the crt socket to the tube dag and see if it sparks. If so there may be a leak in the socket to ground. It could also be leaking to another pin, such as the screen grid. A rhetorical question: What happens to the screen voltage when the focus pot is adjusted?

I have seen sockets that had no arching or other telltale signs, leak through the plastic housing to ground out the focus voltage.

Look closely at the screen. If the blurring is in the form of small circles, then you have an open or hi-resistance focus electrode inside the tube. The circles may vary in visibility with brightness.

If you still haven't found the problem, try to confirm that this is truly a focus problem. Remove the crt socket and observe the hi-voltage. If it climbs more than about 1k, say all the way up to 25kv, then you may have a beam current problem rather than a focus problem. In that case re-check all crt board voltages. WARNING: Removing the CRT socket and powering the unit may destroy the CRT on some models. See the section: Warning about disconnecting CRT neck board.

If you have done all of the above and removing the socket makes no change in the hi-voltage, then try to determine why the hi-voltage is low.

Watch the screen as the brightness, contrast, or screen control are adjusted. See if you can observe any signs of blooming. When the IHVT doesn't provide enough current to satisfy the demands of the tube for current, the the picture tends to appear to expand like a balloon. i.e., bloom. This can be caused by not enough drive to the IHVT. Carefully monitor the b+ to the horizontal drive stages to see that is is stable and correct.

Purple blob - or worse

Have you tried demagnetizing it? Try powering it off for a half hour, then on. Repeat a couple of times. This should activate the internal degausser. See the section: Degaussing (demagnetizing) a CRT.

Is there any chance that someone waved a magnet hear the tube? Remove it and/or move any items like monster speakers away from the set.

Was your kid experimenting with nuclear explosives - an EMP would magnetize the CRT. Nearby lightning strikes may have a similar effect.

If demagnetizing does not help, then it is possible that something shifted on the CRT - there are a variety of little magnets that are stuck on at the time of manufacture to adjust purity. There are also service adjustments but it is unlikely (though not impossible) that these would have shifted suddenly. This may be a task for a service shop but you can try your hand at it if you get the service manual - don't attempt purity adjustments without one.

If the monitor was dropped, then it is even possible that the internal shadow mask of the CRT has become distorted and you now have a seventy-five pound boat anchor. See the "Sony1" and "Sony2" photos in James Sweet's Sony/Trinitron Directory for some screen shots showing the symptoms resulting from a monitor falling on its face. :(If the discoloration is slight, some carefully placed 'refrigerator' magnets around the periphery of the tube might help. See the section: Magnet fix for purity problems - if duct tape works, use it!

It is even possible that this is a 'feature' complements of the manufacturer. If certain components like transformers are of inferior design and/or are located too close to the CRT, they could have an effect on purity. Even if you did not notice the problem when the monitor was new, it might always have been marginal and now a discoloration is visible due to slight changes or movement of components over time.

Color rings - bullseye pattern

This probably means the degaussing circuitry is terminating suddenly instead of gradually as it should. The most likely cause is a bad solder connection to the degauss thermistor or posistor or something feeding it.

You can confirm this by manually degaussing the screen with the TV or monitor turned on. If the problem disappears, the above diagnosis is probably valid. Check for bad solder connections in the vicinity of the degauss components and

AC line input.

Magnet fix for purity problems - if duct tape works, use it!

The approach below will work for slight discoloration that cannot be eliminated through degaussing. However, performing the standard purity adjustments would be the preferred solution. On the other hand, the magnets may be quick and easy. And, where CRT has suffered internal distortion or dislocation of the shadowmask, adjustments may not be enough.

In any case, first, relocate those megablaster loudspeakers and that MRI scanner with the superconducting magnets.

The addition of some moderate strength magnets carefully placed to reduce or eliminate purity problems due to a distorted or dislocated shadowmask may be enough to make the monitor usable - though it will probably not be perfect. The type of magnets you want are sold as 'refrigerator magnets' and the like for sticking up notes on steel surfaces. These will be made of ferrite material (without any steel) and will be disks or rectangles. Experiment with placement using masking tape to hold them in place temporarily. Degauss periodically to evaluate the status of your efforts. Then, make the 'repair' permanent using duct tape or silicone sealer or other household adhesive.

Depending on the severity of the purity problem, you may need quite a few magnets! However, don't get carried away and use BIG speaker or magnetron magnets - you will make the problems worse.

Also note that unless the magnets are placed near the front of the CRT, very significant geometric distortion of the picture will occur - which may be a cure worse than the disease.

WARNING: Don't get carried away while positioning the magnets - you will be near some pretty nasty voltages!

(From: Mr. Caldwell (jcaldwel@iquest.net).)

I ended up with the old 'stuck on a desert island trick':

I duck taped 2 Radio Shack magnets on the case, in such a way as to pull the beam back.!!!!

A $2 solution to a $200 problem. My friend is happy as heck.

RCA sells magnets to correct corner convergence, they are shaped like chevrons and you stick them in the 'right' spot on the rear of the CRT.

(From: Tom Sedlemyer (wesvid@gte.net).)

First set purity as best you can.

Obtain some pieces of refrigerator door magnet strips from an appliance repair shop (they usually have some lying around).

Cut the strips into 1 inch pieces. Place a strip as on the bell of the picture tube as close to the yoke as possible and in line with the corner that has the purity error. Rotate the magnet until you correct the purity error and tape it in place. Multiple magnet strips can be used and you may experiment with the size of the strips for best effect. It is very important that the strips are positioned close to the yoke or the effect will not hold. The only drawback to this method is some very slight distortion of the geometry of the raster, but it beats hell out of paying for a new CRT.

Color monitor only displays one color

I assume that now you have no other colors at all - no picture and no raster. Let us say it is red - R.

It is probably not the CRT. Do you have a scope? Check for the R, G, and B video signals at the CRT. You will probably find no signals for the defective colors.

This is almost certainly a chroma circuit problem as any failure of the CRT or a video driver would cause it to lose a single color - the other two would be ok. Therefore, it is probably NOT the CRT or a driver on the little board on the neck of the CRT.

Try turning up the SCREEN control to see if you can get a G and B raster just to confirm that the CRT is ok.

Locate the video drive from the mainboard for the good and a bad color. Interchange them and see if the problem moves. If so, then there is a video signal problem. If not, it is on the little CRT board.

It could be a defective chroma IC or something else in the chroma decoder.

Disappearing Red (or other color)

Problem: I have been given an old colour TV. The reception is good, but very often, when the contrast and brightness of the TV image is low (e.g. when a night scene is shown), the red colour slowly disappears, leaving behind the green and blue image and many red lines.

The remaining red retrace are the giveaway that this is most likely not a CRT problem.

(If there were no red lines, it could be the filament for the red gun of the CRT going on and off due to a bad connection inside the CRT - bad news.)

How is a black and white picture? (Turn down the color control).

If B/W picture is good, then the problem is somewhere back in the chroma decoder circuitry.

Check the video input to the CRT video driver board and signals on that board. If B/W picture is also bad, then you can compare red and green signals to determine where they are becoming different. The red lines in your description sounds like the red video output circuit is drifting and messing up the background level, blanking, screen, or other setting. Could be a capacitor or other component.

Interference resulting in jiggling or wiggling

Note: similar symptoms can be the result of a monitor defect or running the monitor at scan rate beyonds its capabilities. However, magnetic interference from electrical wiring, other equipment is very common and sometimes overlooked when looking for a complex, expensive, and obscure explanation for a misbehaving monitor (or TV).

Also, if your outlet is not grounded, I have heard of similar symptoms under certain conditions. Grounding IS essential for safety should a short circuit fault develop in the PC as well as to get the most benefit from a surge suppressor so now is a good time to upgrade!

Interference from electrical wiring

If the wiring of normal outlets is done correctly even without a safety ground, the currents should be balanced and you will not experience a problem. However, many circuits, particularly those involving setups like 3-way switches or switched outlets and wiring in older buildings can have unbalanced currents when active. If your monitors are close enough to the wiring, there can be interference which will take the form of a flickering or pulsating display.

Other than recommending moving the monitors, there is no easy solution. They can be shielded with Mu Metal but that is expensive. Or you could run all displays at a 60 Hz vertical rate (or 50 Hz depending on where you live). However, this is inconvenient and will never be quite perfect.

If you have flexibility during construction or renovation, there are ways to minimize the chance of unexpected behavior later:

Think of it this way: If the sum of the currents in the cable are zero, there will be no magnetic field to worry about. This will be the case for normal 110 VAC branch circuits.

Some sources for magnetic interference:

- Three (or more) way circuits - lamps or fixtures controlled from more than one location which use a 'traveler'. In this case, a single energized wire runs between switches and/or the switches and the load.
- Circuits which do not have their return in the same cable. For example, ceiling fixtures controlled from a wall switch but where the Hot comes from another location. Or, a string of baseboard heaters fed from opposite ends.
- Circuits which share a Neutral but where one or more of the Hots are not in the same cable. This is more likely to be found in old construction using knob-and-tube wiring where circuits were just connected in the most convenient way.
- Loops in Neutral and Ground conductors. The way circuits are supposed to be wired (U.S.A. at least) is nearly always in a star sort of configuration where the Neutral and Ground conductors never connect at the ends of the 'star'. However, due to poor wiring practices, it is quite possible for Neutrals to be connected to other Neutrals or Grounds to be connected to other Grounds or for them to be cross connected at various locations - all without any other symptoms. This can even happen between buildings. See the section: Interference from cross-connected buildings. However, the likelihood of this sort of fault isn't that great.

First confirm that the problem is due to inside wiring - shut off all power to the building (if possible) or at least switch off each circuit in turn to see if the problem disappears (run the monitor from a UPS or a remote outlet).

- If the symptoms persist, check for external sources of interference (although there could still be a Ground-Neutral loop formed by the connection between G and N at the service panel or to other buildings. In this case, the effect would likely be strongest near the service panel.). See the section: Interference from power lines.
- If the symptoms are gone, try to narrow down the circuit or circuits that are responsible by switching each one on individually.

In all cases, running the Hots and Neutrals for the circuit in the same cable (or at least in close proximity) will avoid this problem as the total current will sum to zero.

Realistically, you would have to be very unlucky to have a noticeable problem in residential wiring except near the service panel or high power appliances like baseboard heaters, equipment with large motors or transformers, etc.

Interference from power lines

Power lines (any size from local distribution to large intercontinental transmission lines) nearby can result in noticeable effects to monitors as a result of the magnetic fields surrounding the individual wires - similar to that from unbalanced inside wiring (see the section: Interference from electrical wiring. TVs may not be affected, at least not as much, since they will be running at a vertical rate almost the same as the power line frequency).

The severity of the effects will vary depending on the load distribution on the three (probably) phases, distance, orientation with respect to the monitor, etc. Moving the monitor as far from the offending power lines as possible, experimenting with its orientation, and seeing if you can live with a vertical scan rate equal to the power line frequency, are the only realistic options other than constructing an expensive mu-metal box for it. Check out MuShield specifically under "Monitor Enclosures" if you're curious. Less EMF, Inc. sells Mu-metal foil by the foot but what they have listed is rather thin - I don't know how well it would work for monitor CRT shielding.

Interference from cross-connected buildings

Here is a rare case where the neighbor was really at fault (in a historical sort of way).

(From: Tuyen Tran (ttran@ziplink.net).)

Get this: my house and my neighbor's house were grounded together, so we connected to the power company's neutral in two places. The way I understand it, this caused a ground loop between our two panels. My neighbors used to own this place. When they built a small house next door, instead of digging a separate well, they just ran a 3/4 inch copper pipe between my water tank and their new place. (This place used to be a dairy farm, so it had plenty of water capacity.) When they installed their panel, the electrician of course bonded their water pipes to the panel, which then connected our two grounds together. When they sold the place, they put in their own well, but nobody bother to cut the original pipe linking the two houses together. It's been like this for at least 40 years; I'm the third owner!

So I took a pipe cutter to the thing, and no more interference.

Interference from other equipment

Any type of equipment which uses or generates strong magnetic fields can interfere with a monitor. Other computer monitors or TVs, equipment with power transformers, and electric motors will cause a pulsating or flickering display. Loudspeakers or other equipment with static magnetic fields will cause color purity and/or geometric distortion problems which degauss will not cure.

The easiest way to confirm that interference is your problem is to move the monitor or suspect equipment to a different location. The only real solution is to separate the monitor and interfering device.

Note that with scan rates that are not even near the power line frequency any more, a variety of symptoms are possible including shimmering, wiggling, undulating (how many more adjectives can you come up with?). The rate of the movement will be related to the difference between the monitor scan rate and the frequency of interference.

My monitor is possessed!

Problems are that all graphics applications fade to black, lose their color on parts of the screen, and there are strange pincushion problems on the right side of the monitor? This all came up suddenly, with no apparent changes your my part.

You tried changing video drivers, modes, cleaning connections on cables and video card, even pulled the card and cleaned the edge connector.

After cleaning up, things seemed to work (still had pincushion problem), but next time it was powered on, same weird problems.

Voodoo might be required but more down-to-earth causes are likely:

Are you sure nothing changed in the building (like you installed a medical MRI unit with a 2T magnet in the same room)?

All monitors have a built in degauss circuit which operates when power is turned on after being off for at least 15 minutes or so. This could have failed - it is switching off suddenly instead of ramping down as it should - and is making the problem worse or you could have a power supply failure inside the monitor.

Gradual variations in color or brightness on the screen or over time are almost always monitor problems, not video card, software, or cables.

It won't hurt to try manual degauss with the monitor powered, see below. If this clears it up - possibly until you turn the power off and on again, then it may be the internal degauss circuitry.

Shimmering image due to vibrations

If your monitor uses a Trinitron or clone CRT, then this may be normal. Even with the 1-3 unsightly stabilizing wires running across the screen, the vertical aperture grille wires in a Trinitron type CRT can wiggle as a result of mechanical shocks or vibration. Any movement results in momentary changes in color purity, color balance, brightness. Gently tap on the side of the monitor and you may see the same effect.

Wiring transmitted interference

The power that comes from the wall outlet is supposed to be a nice sinusoid at 60 Hz (in the U.S.) and it probably is coming out of the power plant. However, equipment using electric motors (e.g., vacuum cleaners), fluorescent lamps, lamp dimmers or motor speed controls (shop tools), and other high power devices, may result in a variety of effects.

While monitors normally include some line filtering, the noise immunity varies. Therefore, if the waveform is distorted enough, some effects may show up even on a high quality monitor.

Symptoms might include bars of noise or distortion moving slowly or rapidly up or down the screen or diagonally. This noise may be barely visible as a couple of jiggling scan lines or be broad bars of salt and pepper noise, snow, or distorted video.

The source is probably local - in your house and probably on the same branch circuit - but could also be several miles away.

- One way to determine if the problem is likely to be related to AC power is to switch your vertical scan rate to match the power line frequency: 60 Hz in the U.S., 50 Hz in most European countries, etc. If the pattern of noise or distortion is now stationary (or at most slowly drifting up or down the screen), the interference is likely power line related:

  - A single bar would indicate interference at the power line frequency.

  - A pair of bars would indicate interference at twice the power line frequency.

  Either of these are possible.

- Try to locate the problem device by turning off all suspect equipment to see if the problem disappears.

- The best solution is to replace or repair the offending device. In the case of a light dimmer, for example, models are available that do a better job of suppressing interference than the typical $3 home center special. Appliances are supposed to include adequate noise suppression but this is not always the case.

  If the source is in the next county, this option presents some significant difficulties :-).

- Plugging the monitor into another outlet may isolate it from the offending device enough to eliminate or greatly reduce the interference.

- The use of a line filter may help. A surge suppressor is NOT a line filter.

- Similar symptoms could also be produced by a defective power supply in the monitor or other fault. The surest way of eliminating this possibility is to try the monitor at another location.

Jittering or flickering due to problems with AC power

If you have eliminated other possibilities such as electromagnetic interference from nearby equipment or electric wiring or a faulty video card or cable - or software - then noisy or fluctuating AC power may be a possibility. However, modern monitors usually have well regulated power supplies so this is less common than it used to be. Then again, your monitor may just be overly sensitive. It is also possible that some fault in its power supply regulator has resulted in it becoming more sensitive to minor power line fluctuations that are unavoidable.

One way to determine if the problem is likely to be related to AC power is to run the monitor on clean power in the same location on the same computer. For example, running it on an Uninterruptible Power Source (UPS) with the line cord pulled from the wall socket would be an excellent test. The output of the UPS's inverter should be free of any power line noise. If the monitor's image has now settled down:

1. Large appliances like air conditioners, refrigerator, or washing machines on the same circuit might cause significant power dips and spikes as they cycle.

   Plugging a table lamp into the same outlet may permit you to see any obvious fluctuations in power. What else is on the same circuit? Depending on how your house or apartment is wired, the same feed from the service panel may be supplying power to widely separated areas.

2. For some unfathomable reason, your monitor may just be more sensitive to something about the power from the circuit in that room. There may be nothing actually wrong, just different. While unlikely, a light dimmer on the same circuit could be producing line-conducted interference.

   If you have a multimeter, you could at least compare the voltages between the location where it has problems and the one where it is happy. Perhaps, the monitor is sensitive to being on a slightly different voltage. This might only be a problem if some circuitry in the monitor is marginal in some respect to begin with, however.

3. There could be a bad connection somewhere on the circuit. If your house has Aluminum wiring, this is a definite possibility.

   Try a table lamp since its brightness should fluctuate as well. This should be checked out by a competent electrician as it represents a real fire hazard.

An electrician may be able to pinpoint the cause but many do not have the training or experience to deal with problems of this sort. Certainly, if you find any power line fluctuations not accounted for by major appliances, on the same circuit this should be checked by an electrician.

My monitor has the shakes

You turn on your monitor and 5-10 seconds later, the display is shaking or vibrating for a second or so. It used to only occur when first turned on, but now, the problem occurs 3 times in 30 seconds. Of course, many variations on this general theme are possible.

Some possibilities:

1. Defective degauss circuit - this would normally cause a shaking or vibration when you first turn it on but you normally do not notice it since the CRT is not warmed up. The degauss circuit may have developed a mind of its own.

2. Other defective circuitry in monitor - power supply regulation, deflection, or bad internal connections.

3. External interference - did you change anything or move your setup recently? See the sections on: "Interference from other equipment", "Interference from electrical wiring", and "Interference from power lines".

4. Defective video cable (unlikely). Wiggle the VGA cable to be see if you can induce the problem.

5. Loose trim magnets of other magnetic components on or near deflection yoke. This is somewhat rare but if the adhesive comes apart, the magnetic fields from the deflection current can cause the parts to vibrate which will result in a jitter or movement of the picture. There may even be audible crackling or snapping sounds associated with this vibration.

Fred's comments on monitor interference problems

(From: Fred Noble) Fred_Noble@msn.com).)

Monitors are very susceptible to electromagnetic fields. If any of the following is "yes" it may point to an 'electrical' cause of the Monitor problem.

- Do you have a ceiling fan in the same room turned on?
- Do you have a wireless telephone in the room?
- Do you get similar effects on your TV?
- Are you near a large transformer, substation, or high voltage overhead wires?
- Is your computer located close to the meter on the other side of the wall?
- Do you have speakers next to the monitor? Are they shielded?
- Do you have a phone or other device with a magnet in it near the monitor?
- Is the cabling routed too near a printer cable?
- Do you have a surge/power strip or UPS near your monitor?

Reposition the monitor or move it to a different location. Also make sure that you are turning the monitor on first and then the system to ensure that the video card is properly recognizing the monitor.

Check cable connections (make sure no other cables are crossing the monitor cable. If you have an extension on the monitor output cable then remove it as well.

Try swapping out the monitor to verify if it really is the monitor or take your monitor to another system and see how it responds there.

If you are plugging the monitor into a surge strip, remove it from there and plug the monitor directly in the wall outlet.

Discussion:

There might be an ambient RFI/EMI electrical or magnetic field present around your computer location. Some of the electrical field or the conducted RFI/EMI electrical "noise" causes are considered here.

Rough summary of excessive magnetic & electric fields:

- Cause: Electrical wiring errors.

  Electrical wiring errors such as inappropriate or non-NEC code neutral to ground bonds in the facility (not at the common bus in the mains), and other non-NEC Code wiring that results in the HOT wire fields not being OFFSET by the neutral wire fields.

  Incorrect wiring will be aggravated (and will be noticed first) on a circuit where there is an Air Conditioner, copier, laser printer.

  Correction: This is an electrical problem that has resulted in a *net current* flowing in the facility and is also a shock hazard.

  Don't use devices that dump current onto the neutral line, and have an electrician correct the wiring to NEC code.

- Cause: Magnetic flux linkages.

  It is normal for transformers to use magnetic flux linkages (to couple primary to the secondary).

  Correction: Keep transformer based equipment away from sensitive equipment.

  There are other corrective measures here that can be discussed on the design level and on the application level.

  If the transformer is used to power a "noisy" load (high harmonics) perhaps a good harmonic filter can be used between the transformer and the load (example a good UL 1283 noise filter or Surge suppressor with UL 1283 filter).

- Cause: Motors also use magnetic flux linkages in normal usage.

  Correction: Keep large, active, motors away from sensitive equipment (and try to keep them on a different circuit if possible).

  The use of a good harmonic filter on that circuit will help reduce the harmonics (for example, a good surge suppressor with a UL 1283 RFI/EMI filter, or a Line Conditioner).

- Cause: UPSs, especially when on inverter (during brownout or blackout) create magnetic & electric fields.

  Correction: Keep them away from sensitive loads, and advise manufacturer of problems encountered with the UPS.

  The UPS may have a faulty inverter circuit or part, or may be in need of a re-design.

Loss of color after warmup

If there is a general loss of picture but there is light on the screen if the brightness is turned all the way up, then this is a video input, video amplifier, RGB driver, or power supply problem.

If it recovers after being off for a while, then you need to try a cold spray in the video/controller to identify the component that is failing. Take appropriate safety precautions while working in there!

If it stays broken, then most likely some component in the video circuitry, controller, or its power supply as failed. There is a good chance that it is a bad colder connection - the trick is to locate it!

Miscellaneous Problems

Contour lines on high resolution monitors - Moire

These fall into the category of wavey lines, contour lines, or light and dark bands even in areas of constant brightness. (Some people may refer to this phenomenon as "focus or Newton's rings".) These may be almost as fine as the dot pitch on the CRT or 1 or 2 cm or larger and changing across the screen. If they are more or less fixed on the screen and stable, then they are not likely to be outside interference or internal power supply problems. (However, if the patterns are locked to the image, then there could be a problem with the video board.)

One cause of these lines is moire (interference or beat patterns) between the raster or pixels and the dot structure of the CRT. Ironically, the better the focus on the tube, the worse this is likely to be. If the individual pixels do not cover enough phosphor dots, then the actual color and brightness displayed won't match what the video card is generating and this will depend on the actual location of the pixel relative to the phosphor dots. Trinitrons, which do not have a vertical dot structure should be immune to interference of this sort from the raster lines (but not from the horizontal pixel structure). Slot mask CRTs (not that common on monitors) also have fewer problems with vertical moire.

You can test for moire by slowly adjusting the picture size. If it is moire, you should see the pattern change in location and spatial frequency as slight changes are made to size. Changes to position will move the patterns along with the picture without altering their character and structure significantly (though fine detail will change).

If they are due to the raster line structure - your focus is too good - the patterns will remain essentially fixed in position on the face of the CRT for horizontal size and position adjustments - the patterns will remain fixed under the changing image.

How to eliminate it? If moire is your problem, then there may be no easy answer. For a given resolution and size, it will either be a problem or not. You can try changing size and resolution - moire is a function of geometry. Ironically, I have a monitor which is nicer in this respect at 1024x768 interlaced than at 800x600 non-interlaced.

Some monitors have a 'Moire Reduction Mode' switch, control, or mode. This may or may not be of help. One way to do this is - you guessed it - is to reduce the sharpness of the beam spot and make the picture fuzzier! Another approach adds a high frequency dither to the beam spot position which may result in a headache! You might find these cures to be worse than the disease.

Another cause of similar problems is bad video cable termination creating reflections and ghosting which under certain conditions can be so severe as to mimic Moire effects. This is unlikely to occur in all colors with a VGA display since the termination is internal to the monitor and individual resistors are used for each color (RGB).

I think it is ironic that some people will end up returning otherwise superb monitors because of moire - when in many cases this is an indication of most excellent focus - something many people strive for! You can always get rid of it - the converse is not necessarily true!

Moire and shadow mask dot pitch

(From: Bob Myers (myers@fc.hp.com).)

The density of the holes in the shadow mask set an upper limit on the resolution supported by that monitor. Lower resolutions work just fine; there is no need to have the logical pixels in the image line up with the physical holes in the mask (nor is there any mechanism to make this happen), and so you can think of this as the "larger pixels" of the lower-res image simply covering more than one hole or slot in the mask.

As the effective size of the pixels in the image approach the spacing of the mask holes, individual pixels are no longer guaranteed to cover enough phosphor dots on the screen to ensure that they are constant color or constant luminance, but an image will still be displayed which ON AVERAGE (over a reasonably large area) looks OK. Actually, the specified "top end" format ("resolution") for most monitors usually is at or slightly beyond this point - the effective pixel size is somewhat UNDER the dot pitch.

Sources of external interference that can affect the monitor display

The following list is just some of the ways your picture can get screwed up through no fault of the monitor. It's sort of amazing they work as well as they do! Most of these are discussed in greater detail in subsequent sections.

Static/DC magnetic fields:

- Unshielded/inadequately shielded multimedia speakers
- Stereo loudspeakers
- MRI scanner next door.

Transient magnetic fields:

- Kid's (or adults) playing with magnets
- Electro-Magnetic Pulse (EMP) from nearby lightning strike or nuclear blast
- Changing monitor location or orientation without degaussing.
- Shift in Earth's magnetic field every 10-20K years. :)

AC magnetic fields (usually at power line frequency):

- AC or DC wall adapters/transformers
- Fluorescent lamps (magnetic ballast)
- Laser printer and other peripherals
- TV, VCR, DVD, or other A/V equipment
- Additional computer monitor(s) too close
- Large appliances including furnace, A/C, fridge, microwave

- Wiring in walls (unbalanced load/shared Neutral)
- Wiring in electrical service panel
- Outside wiring and power distribution equipment

Radio Frequency Interference:

- High power radio transmitter nearby (broadcast, military, amateur)

Power Line Transmitted Interference:

- Lighting on dimmers (incandescent/halogen lamps/fixtures)
- Motor speed controls (ceiling fans)
- Fluorescent lamps (all types)
- Vacuum cleaners/shop equipment/other brush type motors
- Equipment using switchmode power supplies
- Heavy industry down the street

Interference affecting video signal:

- Lack of earth/safety ground (line filter ineffective)
- Ground loop caused by PC and monitor plugged into different circuits
- Cross connected buildings resulting in ground loop

Interference between monitor and VCR or TV

> "I've got a desktop computer with a VGA monitor above it. To the left of it (a few inches away), I have a VCR with a Commodore composite monitor above it (1084 model). I don't have Cable TV or anything special, just a simple antenna connected to the VCR to pick up the two local TV stations.
>
> The reception is pretty good with the computer off, but the problem arises when I turn the computer on. The VCR is already plugged into a different outlet than the computer. Since I am into video production, I need this setup as it is laid out (close together).
>
> So, how can I shield the VCR from the interference from the computer? Can I do something with the antenna to make the signal stronger, or can I place some kind of material between the VCR and computer?"

Your PC is a serious RF emitter. Areas of leakage include the case as well as the possibly the monitor and cable. Turn off the monitor and/or unplug the video cable to see if it is the latter.

You PC's case may not have adequate shielding. Better cases have grounding fingers and proper RF shielding throughout - that is one reason they are more expensive. This may be an option.

The VCR may be picking up the interference internally or via its antenna.

There may be some options but you first need to determine where the interference is coming from and where it is being picked up.

Cable installed upside-down - now monitor does not sync correctly

> "I have an old vga monitor that I screwed up. I plugged it into the vga card upside down. Now I know that seems impossible, but believe me, it isn't.
>
> Now the vertical is fine, but the horizontal is all screwy. (is that a word? screwy?) It's about 8" wide and can't be adjusted to normal size.

> The result is a very, um, interesting image. Is it possible that I did some minor damage like blowing a cap, diode, or horizontal transistor?"

I'll give you 100:1 odds that you bent the H sync pin and it is now bent over and not inserted in its hole. Remove the connector, and examine the pins - if this is the case, take a pair of needlenose pliers and **very carefully** straighten it out. If it was pushed in, grab hold and pull it out to the same length of the other pins and if necessary, put a drop of adhesive at its base to prevent it from being pushed in again. If it breaks off or is unreachable, you will need to replace the connector (unless the shell comes apart which is usually impossible or at least not easy on newer monitors).

Isolated spots on display

These could be a problem with the video source - bad pixels in the video card's frame buffer or bad spots on a camcorder's CCD, for example. Or, they could be dirt or dead phosphor areas in the CRT. Except for problems with the on-screen character generator, it is unlikely that the monitor's circuitry would be generating isolated spots.

You can easily distinguish between video problems and CRT problems - missing pixels due to the video source will move on the screen as you change raster position. CRT defects will remain stationary relative to the screen and will generally be much more sharply delineated as well.

There is a specification for the number and size of acceptable CRT blemishes so you may have to whine a bit to convince the vendor to provide a replacement monitor under warranty.

Power saving problems

Modern monitors are usually designed to permit software to control various levels of power saving ('green') features from blanking the screen to totally shutting down. Problems can occur if the software to control these features is not compatible with the monitor or not set up correctly or is attempting to control a monitor that lacks power saving modes or is defective or incompatible.

A monitor that behaves normally under most conditions but emits a high pitched whine when the computer attempts to direct it into power saving mode is probably not understanding the commands or does not have the appropriate power saving features. It probably behaves about the same as if there is no video signal - which indeed may be the case as far as it is concerned.

Many monitors not receiving proper sync signals are perfectly happy driving everyone in the office insane with that high pitched whine. Others will blow up eventually.

Recommendation: Don't use power saving until you have the proper software and you know what your monitor supports. Of course, your monitor could be defective and your current software is actually fine. Check your user manuals to determine compatibility and setup parameters. Also see the sections: Monitor life, energy conservation, and laziness and Implications of power saving modes.

Monitor drift?

Problem: I have a 17" monitor that has an image that EVER SO SLIGHTLY drifts to the left (and stops) after a long day's work (heat, I suppose). Also, the vertical height shrinks a little bit. Is this at all normal/acceptable?

How much is 'ever so slightly'? There are a fair number of components whose values could alter the position/size of a monitor image. I do not find it at all surprising that there should be a small shift due to heat. It really depends on many factors including the basic design, quality of components, ventilation/cooling, etc. Of course, it is possible to have a monitor that has a component that is worse with respect to temperature. Could also be related to line voltage depending on the regulation of your monitor's power supplies.

In general, my feeling is that if it is not objectionable (a 1/2" shift would be objectionable) AND it's severity is not changing with time, you can ignore it.

Many monitors do this. TVs do this but you are not aware of it since they are already 5-10% overscanned for just this reason, as well as compensating for component aging and line voltage fluctuations.

A can of cold spray or a heat gun will be useful to track down the bad component but it could be a frustrating search.

Monitor shuts down or goes blank at certain scan rates

It could be the monitor's components have drifted and are now marginal at your one or more of your scan rates. However, first check with an oscilloscope if possible to confirm that your horizontal and vertical timing are indeed as expected.

Some video cards modify horizontal and vertical frequency as part of their software size adjustment in their Setup program. For example, with ATI cards, even though the general resolution option in the DOS Install program may be 800x600 at 75 Hz, adjusting the horizontal size can actually vary the horizontal frequency over a greater than 10% range. A similar variation is possible with the vertical rate.

Does just the picture go away or does power die to the monitor? If you can see the neck of the CRT, the filaments glow orange when it is operating. Does this glow disappear indicating that the deflection/HV is shutting down?

There could be a number of possibilities - no way of knowing if it will be easy or inexpensive to repair without testing. It could be power supply, HV supply, X-ray protection, etc.

Monitor flickers when disk accessed

This is almost certainly a software problem. First, try moving the monitor away from the PC as far as the cable will stretch. If it still occurs, then it is probably not the monitor. Could have to do with power saving (just a guess) or some other incompatibility. Nothing the PC does should affect the monitor in any way once the refresh rate is set.

Buzzing monitor

Do you actually mean buzz - low frequency as in 50 - 120 Hz? Or, do you really mean high pitched whine. If the latter, see the section: High pitched whine or squeal from monitor with no other symptoms.

- If it is from inside the monitor - make sure it is not your multimedia speakers or sound card picking up interference - it is in the deflection (probably vertical) or power supply. Either of these can vary in severity with picture content due to the differing current requirements based on brightness. It could be a power supply transformer, deflection yoke, or other magnetic component. Even ferrite beads have been caught buzzing when no one was looking. :-) Any of these parts could vibrate if not anchored securely or as they loosen up with age.

  Some hot-melt glue, RTV silicone, or even a strategically wedged toothpick may help. A new part may or may not quiet it down - the replacement could be worse! For yoke noise, see the section: Reducing/eliminating yoke noise.

- There is a slight possibility that the AC power in your home or office has some harmonic content - the waveform is not sinusoidal. This might be the case if you try to run on the same circuit as an active dimmer or something else with thyristor control. Proximity to heavy industry could also cause this.

Relocating the offending device to another branch circuit may help. You could also try a line conditioner (not just surge suppressor) which includes filtering. Else, petition to have that paper manufacturer move out of the neighborhood :-).

- Sometimes, it is simply a design or manufacturing defect and the only alternative is a replacement - possibly a different brand. It may be more difficult to quiet down a buzz than a high pitched whine.
- Some monitorss are simply poorly designed. You cannot infer the severity of this annoyance from any specifications available to the consumer. It is strictly a design (e.g. cost) issue. The size of the monitor is not a strong indicator of the severity of the problem but there will be some relationship as the power levels are higher for larger units. The best you can do is audition various monitors very carefully to find one that you are satisfied with.
- One those rare monitors that have a cooling fan, its bearings may be worn or in need of cleaning and lubrication, or a blade may be hitting something.

High pitched whine or squeal from monitor with no other symptoms

Sometimes this is continuous. In other cases, it comes and goes almost as though there is an intelligence at work attempting to drive you crazy. All the more so since a technician may not even be able to hear what you are complaining about if their hearing is not as sharp at high frequencies as yours. Even high resolution computer monitors running at high horizontal scan rates (beyond human hearing) can have these problems due to the switching power supplies as well as subharmonics of the horizontal scan rate exciting mechanical resonances in the magnetic components or even a portion of the sheetmetal used for shielding if in close proximity to a magnetic component.

If it is a new monitor and you think the sounds will drive you insane, returning it for a refund or replacement may be best alternative. However, you may get used to it in time.

Note: if the whine only occurs when the monitor is unplugged from the computer or the computer is turned off, this is probably normal. Without valid sync signals the monitor defaults to a horizontal rate which is within the audible range (less than 20 kHz). Any vibrating components will be readily heard. It is usually not a sign of impending failure.

In most cases, this sound, while annoying, does not indicate an impending failure (at least not to the monitor - perhaps to your mental health) or signify anything about the expected reliability of the unit though this is not always the case. Intermittent or poor connections in the deflection or power supply subsystems can also result in similar sounds. However, it is more likely that some part is just vibrating in response to a high frequency electric current.

There are several parts inside the monitor that can potentially make this noise - the horizontal flyback transformer and to a lesser extent, the deflection yoke and associated geometry correction coils would be my first candidates. In addition, transformers or chokes in the switching power supply if this is distinct from the horizontal deflection circuitry.

You have several options before resorting to a 12 pound hammer:

- Confirm that the horizontal scan rate being used by the video card is well within the range supported by the monitor. If it isn't, change it to be a one that is - in addition to possible whining, this is stressful on the deflection and power supply and may result in an expensive repair in a very short time. Even if the scan rate is supposed to be fine, changing it slightly (e.g., 5 percent) might help just because it shifts the deflection frequency away from a mechanical resonance. However, this may not be a long term solution.

- As much as you would like to dunk the monitor in sound deadening insulation, this should be avoided as it will interfere with with proper cooling. However, the interior of the computer desk/cabinet can be lined with a non-flammable sound absorbing material, perhaps acoustic ceiling tiles. Hopefully, not a lot of sound energy is coming from the front of the monitor.

- Move the monitor out of a corner if that is where it is located - the corner will focus sound energy into the room.

- Anything soft like carpeting, drapes, etc. will do a good job of absorbing sound energy in this band. Here is your justification for purchasing those antique Persian rugs you always wanted for your computer room :-).

If you are desperate and want to check the inside of the monitor:

- Using appropriate safety precautions, you can try prodding the various suspect parts (flyback, deflection yoke, other transformers, ferrite beads) with an insulated tool such as a dry wooden stick. Listen through a cardboard tube to try to localizing the source. If the sounds changes, you know what part to go after. Sometimes a replacement flyback will cure the problem unless it is a design flaw. You do not want to replace the yoke as convergence and other adjustments would need to be performed. Other transformers can be replaced.

- Sometimes, tightening some mounting screws or wedging a toothpick between the core and the mounting or coils will help. Coating the offending part with sealer suitable for electronic equipment may quiet it down but too much may lead to overheating. A dab of hot-melt glue or RTV silicone may help. Even replacement is no guarantee as the new part may be worse. For yoke noise, see the section: Reducing/eliminating yoke noise.

- A few monitors have internal cooling fans. The whine may be due to worn or dry bearings. If this is the case, the fan must be serviced as it is not likely doing it job and damage due to excessive temperatures may eventually be the result.

Note that the pitch of the whine - the frequency - may not even be audible to a technician assigned to address your complaint. The cutoff frequency for our hearing drops as we get older. Someone over 40 (men more so than women), you may not be able to hear the whine at all (at least you can look forward to silence in the future!). So, even sending the monitor back for repair may be hopeless if the technician cannot hear what you are complaining about and you are not there to insist they get a second opinion!

Monitor whines in power saving (standby) mode

(From: Bob Myers (myers@fc.hp.com).)

In standby, the monitor is not being supplied with horizontal sync, and so the horizontal deflection circuits are free-running. (If they're still powered up in a given monitor design when in standby mode, that is; there are no standards governing what actually gets shut down in the various power-saving states.) It's likely that in this case, the horizontal is free-running at a frequency which is audible, and you're hearing a whine from a vibrating transformer core (for example, the flyback). This will NOT have anything to do with the timing used when the monitor is on and running normally, so it's no surprise that changing the refresh rate didn't affect this.

You can either have a technician try to track down the offending component and try to keep it from making the noise (usually by adding some "goop" to prevent or at least reduce the audible effects of the vibration), or you might try (if your system permits it) using one of the other power-management states instead of standby. Removing BOTH the horizontal and vertical sync signals places the monitor in the "off" condition (I'm assuming compliance to the VESA DPMS standard throughout this discussion), in which just about everything should be shut down. However, since this will remove the heater supply from the CRT as well, it WILL take longer to recover from the off state.

Reducing/eliminating yoke noise

(From: Terry DeWick (dewickt@esper.com).)

Carefully look under vertical core next to plastic liner, on top and bottom is a plate called the astigmatism shunt, it has come loose. Work RTV, epoxy, or service cement onto it to glue it down and noise should quit.

(From: TVman (tvman@newwave.net).)

I have fixed a total of 27 of these sets with noisy yokes by removing the yokes and using motor armature spray sealant.

If you carefully mark the EXACT position of everything (yoke, purity magnets), and slide the yoke off the CRT, then once the yoke has been sealed with motor armature spray sealant and has dried thoroughly, put the yoke back EXACTLY where it was, there should be no problems.

The only thing I have had to do was set the purity on one set, but it was off a little to begin with.

Monitor was rained on

Was the monitor plugged in when the leak started? Any piece of equipment with remote power-on capability has some portions live at all times when plugged in and so there may have been damage due to short circuits etc. Substantial damage could have already been done.

Otherwise, you may just need to give it more time to dry out. I have had devices with keypads getting wet that required more than a week but then were fine. There are all kinds of places for water to be trapped and take a long time to evaporate.

If the monitor got wet while unplugged or it has a mechanical (hard) on/off switch, then give it a lot of time to dry out completely. Assuming all visible water is drained, a week represents a minimum safe time to wait. Don't rush it.

Generally, some moisture will not do any permanent damage unless the unit was on in which case you will simply have to troubleshoot it the old-fashioned way - one problem at a time.

Monitor was dropped

If your work area is maintained like that of Nedrie in the movie "Jurassic Park", you might not even notice if one of your monitors fell off the table! This is no way to treat a monitor.

However, mishaps do happen.

Assuming it survived mostly intact - the CRT didn't implode, you could still have a variety of problems. Immediately unplug the monitor!

If you take it in for service, the estimate you get may make the national debt look like pocket change in comparison. Attempting to repair anything that has been dropped is a very uncertain challenge - and since time is money for a professional, spending an unknown amount of time on a single repair is very risky. There is no harm is getting an estimate (though many shops charge for just agreeing that what you are holding was once a monitor, or was it a fish tank?)

This doesn't mean you should not tackle it yourself. There may be nothing wrong or very minor problems that can easily be remedied. The following are likely possibilities:

1. Cracked circuit boards. These can be repaired since monitors usually have fairly wide open single or two sided boards.

2. Broken circuit components. These will need to be replaced.

3. Broken solder connections particularly to large heavy components on single sided boards. Reflow the solder. If the trace is cracked or lifted, repair as in (1).

4. Broken mounting brackets. These are usually made of cheap plastic and often don't survive very well. Be creative. Obtaining an exact replacement is probably not worth the trouble and expense.

5. Components knocked out of line on the CRT envelope or neck - deflection yoke, purity magnets, convergence magnets and coils, geometry correction magnets. These will need to be reattached and/or realigned. Some CRTs use little magnets glued to the funnel portion of the CRT envelope. If any of these have come loose, it could be quite a treat to figure out where they went and in what orientation.

6. Internal damage to the CRT - popped or distorted shadow mask, misaligned electron guns. Unfortunately, you will probably have no way of identifying these since you cannot see inside the CRT. They will not be apparent until all other faults have been remedied and the TV set is completely realigned. At that point, extremely severe purity or convergence problems that do not respond to the normal adjustment procedure would be one indication of internal damage. Give the TV a nice funeral. See the "Sony1" and "Sony2" photos in James Sweet's Sony/Trinitron Directory for some screen shots showing the symptoms resulting from a monitor falling on its face. :(

If you still want to tackle a restoration:

As noted, unplug the monitor even if it looks fine. Until you do a thorough internal inspection, there is no telling what may have been knocked out of whack or broken. Electrical parts may be shorting due to a broken circuit board or one that has just popped free. Don't be tempted to apply power even if there are no obvious signs of damage - turning it on may blow something due to a shorting circuit board.

Then, inspect the exterior for cracking, chipping, or dents. In addition to identifying cosmetic problems, this will help to locate possible areas to check for internal damage once the covers are removed.

(At this point, most people will assume there is no interior damage and plug the set back in and turn it on. My recommendation is to resist this temptation since as noted, this could result in further damage making the repair more expensive if there are circuit problems. However, if the unit was on at the time of the "incident" or you are really determined to get to the conclusion and would just throw the thing in the trash if it doesn't work or blows up, go for it! But, if you're the more cautious type, continue with the systematic diagnosis and repair procedure that follows.)

Next, remove the cover. Confirm that the main filter capacitors are fully discharged before touching anything. Check for mechanical problems like a bent or deformed brackets, cracked plastic parts, and anything that may have shifted position or jumped from its mountings. Inspect for loose parts or pieces of parts - save them all as some critical magnets, for example, are just glued to the CRT and may have popped off.

Carefully straighten any bent metal parts. Replace parts that were knocked loose, glue and possibly reinforce cracked or broken plastic. Plastics, in particular, are troublesome because most glues - even plastic cement - do not work very well. Using a splint (medical term) or sistering (construction term) to reinforce a broken plastic part is often a good idea. Use multiple layers of Duco Cement or clear windshield sealer and screws (sheetmetal or machine screws may be best depending on the thickness and type of plastic). Wood glue and Epoxy do not work well on plastic. Some brands of superglue, PVC pipe cement, or plastic hobby cement may work depending on the type of plastic.

Inspect for any broken electronic components - these will need to be replaced. Check for blown fuses - the initial impact may have shorted something momentarily which then blew a fuse.

There is always a risk that the initial impact has already fried electronic parts as a result of a momentary short or from broken circuit traces and there will still be problems even after repairing the visible damage and/or replacing the broken components. This is most likely if the monitor was actually on but some modern monitors have circuitry that is energized at all times. (If power is controlled by a tiny tiny pushbutton this is the case.)

Examine the circuit boards for any visible breaks or cracks. These will be especially likely at the corners where the stress may have been greatest. If you find **any** cracks, no matter how small in the circuit board, you will need to carefully inspect to determine if any circuit traces run across these cracks. If they do, then there are certainly breaks in the circuitry which will need to be repaired. Circuit boards in consumer equipment are almost never more than two layers so repair is possible but if any substantial number of traces are broken, it will take time and patience. Do not just run over them with solder as this will not last. Use a fine tipped low wattage soldering iron and run #22-26 gauge insulated wires between convenient endpoints - these don't need to be directly on either side of the break. Double check each connection after soldering for correct wiring and that there are no shorts before proceeding to the next.

If the circuit board is beyond hope or you do not feel you would be able to repair it in finite time, replacements may be available but their cost is likely to be more than the equipment is worth. Locating a junk unit of the same model to cannibalize for parts may be a more realistic option.

Degauss the monitor as any impact may magnetize the CRT. Power cycling may work but a manual degaussing is best.

Once all visible damage has been repaired and broken parts have been replaced, power it up and see what happens. Be prepared to pull the plug if there are serious problems (billowing smoke or fireworks would qualify).

Perform any purity, convergence, or other realignment as needed.

Then proceed to address any remaining problems one at a time.

Really cleaning a monitor inside and out

(From: Dr. Ludwig Steininger (drsteininger@t-online.de).)

Often I get defective monitors, which are more than 5 years old, and have been run in offices for 8 to 10 hours/day. So, their case and pcbs usually are very dirty and dusty.

What do I do (it's no joke!): After removing the case I carefully put them in a bath (on a flexible layer) and let them have a intensive shower of pure cold water (for 1 to 2 minutes). Additionally, the case is cleaned with soap or a detergent containing liquid (being careful, not to spill to much of it onto the PCBs). After rinsing with fresh clear water, dust and other kinds of dirt are removed and the monitors look new again. Then I allow all drops of water to run off. This can effectively be supported by turning the monitor on another side from time to time (duration: approximately 1 hour). Before turning on AC again, I let the wet monitor dry in ambient air for about 2 days (in the sunshine this can be finished in 1 day only).

This procedure has been applied for many monitors. I've never had any bad experiences (it's very important to wait, until the pcbs are really dry!). Considering this experience, I just can't imagine, that it might not be possible, to "save" a TV set or computer monitor, which has been drowned or some liquid has been spilled, and AC has been plugged off ASAP (although I've never had such a case). I think, that in such a case, it's important to have a rapid shower in order to prevent corrosion and deposits.

By the way: I know a German company, which uses water from cleaning PCBs of computer hardware for cleaning them after being contaminated by smoke from a fire.

So, in case of spillage, one has nothing to loose. Just try to shower your monitor or TV set!

Setup menus will not go away or hieroglyphics on screen

Both these problems could be caused by a faulty microcontroller or its associated circuitry. However, bad connections in the vicinity of the controller logic could also be at fault.

Unless you see something obvious, you will need schematics.

Setup Adjustments Lost

Many modern monitors have RAM, somewhat like the CMOS SETUP memory in your PC, that store all factory adjustments. When power is lost, there is power surge, lightning strike nearby, nuclear detonation or EMP, it may have put bad information into the ram and thrown it out of adjustment. There is a way to get into the service mode (depress and hold a secret button down and turn set on, special combination of buttons on the remote, etc.) and then use the remote to reinitialize and adjust the problems out.

HOWEVER, IF YOU DON'T KNOW WHAT YOU DOING YOU COULD GIVE YOURSELF WORSE PROBLEMS. YOU COULD EVEN BLOW THINGS OUT WITH SOME MONITORS!

The service manual will be essential to have any chance of successfully reinitializing everything without causing damage due to incorrect settings.

If it's not an adjustment problem you probably have a bad part - somewhere.

If you do manage to get into the setup menu and are willing to take the risk without service information, try not to make any unnecessary changes and document every change you make!!! That way you can go back if you do anything wrong (hopefully).

Monitor doesn't work after being in storage

So the monitor you carefully stuffed in a corner of the garage is now totally dead. You swear it was working perfectly a year ago and just have to get that state-of-the-art Commodore 64 up and running!

Assuming there was absolutely no action when you turned it on, this has all the classic symptoms of a bad connection. These could be cold/cracked solder joints at large components like transformers, power resistors, or connectors and connectors that need to be cleaned or reseated. By 'no action' I mean not even a tweet, bleep, or crackle from anything.

To narrow it down further, if careful prodding of the circuit board(s) and various large components with a well insulated stick does not induce the set to come on, even momentarily, check the following:

1. Locate the horizontal output transistor. It will be in a TO3 metal (most likely on an older set) or TOP3 plastic package on a heat sink. With the set unplugged, confirm that there is no voltage across C to E and then measure between them with an ohmmeter. In at least one direction it should be fairly high - 1K or more. This confirms that the HOT is probably good.

(There is also a slight chance that there is a low voltage regulator in addition to the horizontal output, so don't get them confused. The horizontal output transistor will be near the flyback transformer and yoke connector.)

2. Trace back from the HOT collector to the flyback and through the flyback to the B+ feed from the power supply. Clip a voltmeter between this point and the HOT emitter. Make sure the leads are well insulated and can't accidentally short to anything. (This test can be performed across C to E of the HOT but if the horizontal deflection were to start up unexpectadly, the meter could be damaged by the high voltage pulses on the HOT collector. But if you can't find the B+ source, it may be worth the risk.) Plug it in and turn it on.

   - If the problem is in the low voltage (line) power supply, there will be no substantial voltage across C-E.

     You should be able to trace from the power line forward to find the bad part though a schematic will help greatly.

   - If the problem is in the startup circuit or horizontal oscillator/driver, then there will be something on the order of 100 to 160 V across C-E.

     In this case, a schematic may be essential.

Note: don't assume that the metal parts of the chassis are ground - they may be floating at some line or B+ potential. Also, the HOT emitter may not be connected directly to ground.

Cheap monitors with multiple intermittent problems

If the monitor is a non-name or the company has since gone belly up (no surprise, right?) you may have a monitor with one of those circuit boards best described as bad solder joints held together with a little copper. In this case, prodding with an insulated stick and the use of a few select 4 letter words may get it going. The circuit boards may be double sided with what were called 'rivlets' for vias. The rivlets were relatively massive - literally little copper rivets - and they were not adequately heated or tinned during assembly so there were bucketloads of cold solder joints that show up during middle age. I repaired one of these by literally resoldering top and bottom of every one of the darn things with a high wattage iron. Or, the soldering just may be plain, well, horrible. Carefully going over every connection is the only solution. Sometimes, removing the solder from suspect joints, cleaning both the component lead and trace, and then resoldering will be needed if corrosion has set in.

Monitor has burning smell

Assuming there are no other symptoms:

If this appears after extended operation - an hour or more - it may just be a build up of dust, dirt, and grime over the years. After understanding the safety info, some careful vacuuming inside may help. Just don't be tempted to turn any screws or adjustments!

Dust is attracted to the high voltage section in particular - even the front faceplate of the CRT collects a lot and should be wiped with a damp cloth from time to time.

If the symptoms develop quickly - in a few minutes or less, then there could still be a dust problem - a power resistor may be heating a wad of it but other possibilities need to be considered.

If not dust, then probably in the power supply but realize that TVs don't have a nice metal case labeled 'power supply'. It is just a bunch of stuff scattered around the main board. Without identifying the part that is heating, a diagnosis is tough especially if the set really does work fine otherwise. However, if a series regulator were faulty and putting out too much voltage, the set could appear to work properly but in fact have excessive power dissipation in certain components. If cleaning the dust does not solve the problem, you will probably need a schematic to identify the correct voltages.

Static discharge noise and picture tube quality

This question came up with respect to a large screen TV but may apply to large screen monitors as well.

> "I bought a 29" TV a couple of weeks ago and I have noticed that after being switched on for > about 15/20 minutes, whenever the picture changes from a "light" scene to a darker scene, the set makes a crackling noise. It sounds as though there has been a build-up of static and it is being discharged. I have never noticed this in a TV before and I was wondering if this is normal and acceptable behaviour for a large-screen TV?"

It probably is normal. Whether it is acceptable is a personal matter. In some geographic areas no countermeasures are taken at all...

When the scene changes from bright to dark, the beam current is reduced to practically zero. As a result, the high voltage rises. (The high voltage supply has a relatively high internal impedance.) The high voltage is connected to the inside layer of the picture tube. A voltage change on the inside will also cause a voltage change on uncovered parts of the outside, especially on the part of the picture tube that is hidden under the deflection coils. This causes little sparks between the picture tube surface and the inside of the deflection coils and this is accompanied by a crackling sound.

On the better picture tubes, a dark "anti-crackle coating" is painted on the picture tube near the deflection coil. This is a very high impedance coating, dark black, much darker than the usual aquadag coating over the rest of the picture tube. You should be able to see the difference.

If, on the other hand, the outside of the picture tube near the deflection coil is not coated then you have a problem. Then you will hear strong crackling also at switch-on and switch-off. Normally you shouldn't see such a 'cheap' picture tube on the European market...

The area of the picture tube around the anode connector is also not coated, for obvious reasons. Normally that should not cause any significant sound. Same goes for the front of the screen and neither should the anode cable crackle.

In a dark room you should be able to see from the tiny blue flashes where the sound comes from. This is perhaps best observed at switch-on and switch-off (with a black picture on the screen). Try and keep the back cover mounted !

Loudspeakers and monitors

Loudspeakers incorporate powerful magnets - the larger the speaker, the larger the magnet. However, anyone who goes ballistic when the mention is made of a loudspeaker near a TV or monitor, should take their Valium.

The fringe fields outside the speaker box will not be that great. They may affect the picture perhaps to the point of requiring degauss. The normal degauss activated at power-on will usually clear up any color purity problems (assuming the loudspeakers have been moved away). At worst, manual degauss will be needed. The CRT will not be damaged. The maximum field - inaccessible at the voice coil - is quite strong. However, even for non-shielded loudspeakers, the magnetic field decays rapidly with distance especially since the core structure is designed to concentrate as much of the field as possible in the gap where the voice coil travels.

Speakers specifically designed for use with multimedia computers have (or should have) specially shielded magnet structures or an additional magnet with its field set up to cancel the main magnet's fringe field which will minimize these effects. Nonetheless, if you see any indication of discoloration, move them to a greater distance.

However, keeping unshielded (e.g., megawatt stereo) speakers away from CRTs is a good idea.

Now, you really should keep your superconducting magnetic resonance imager magnet at least in the next room.....

Should I replace all the electrolytic capacitors if I find a bad one?

When a bad capacitor is found in a monitor, the question of course arises as to the likelihood of other capacitors going bad in short order. It might be worth checking (other) caps in the power supply or hot (temperature) areas but you could spend you whole life replacing **all** the electrolytics in your older equipment!

Black powder being generated inside monitor?

You have just noticed a black powder spontaneously appearing from inside your computer monitor. What is it? The monitor seems happy as a clam.

Well, it is probably just air-born dust that is collecting there due to the air flow in your area and high voltage static fields. The monitor is acting like an electrostatic dust precipitator. If there were really black powder being generated inside, I would expect you would smell something really really bad and the monitor would not continue to be happy.

Sweet little old ladies and TVs from attic

The following story is specifically for a TV but the same applies to any electronic servicing. Always confirm the customer's complaints first!!

Then verify that everything else works or you will never know if your efforts have affected something unrelated.

(Original request from rogerj@apex.com):

> "A sweet little old lady has duped me into repairing her old G.E. 13" color TV. Wanted me fix bad volume pot..... "oh it has such a good picture"... she says.
>
> Stupidly w/o even turning it on, (big mistake) I begin to open the set. After 15-20 min. of travail, I discover that a previous "repairman" has glued the case shut!
>
> Now w/ set open, I turn it on and this picture is LOUSY. Bad color, and very poor convergence. But I don't know if I'm to blame for banging it around trying to open it up. Also, no hor. or vert. hold. (fixed that w/a few caps) This things probably been sitting around for a few years."

Well, you certainly did not kill the caps. Anything that sits for a few years - probably in a damp unheated attic - is suspect.

Did you find the adjustments on the yoke assembly tight? If so, you probably did not move anything very much either. She may remember the good picture it produced before being stuffed away in the attic.

> "Anyway after going through all the adjustments, the convergence at the sides is still bad and the horizontal size is a tad insufficient (w/no adjustment available)"

Could be that the convergence (including pincushion) circuits are still faulty - not just misadjusted.

Other things that can effect horizontal size while still giving you a complete picture:

1. Voltage to horizontal output transistor low. Is there a voltage regulator in your set? The one I have has none. I assume your line voltage is ok.

2. Increased resistance or inductance of the yoke windings. For all you know, the yoke may have been replaced with the wrong part.

3. Yoke improperly positioned on tube neck.

4. Excessive high Voltage. This is usually not adjustable.

I bet the thing hasn't worked properly in 10 years.

Disposing of dead monitors (CRTs and charged HV capacitors)

I don't know what the law says, but for safety, here is my recommendation:

Treat the CRT with respect - the implosion hazard should not be minimized. A large CRT will have over 10 tons of air pressure attempting to crush it. Wear eye protection whenever dealing with the CRT. Handle the CRT by the front - not the neck or thin funnel shaped envelope. Don't just toss it in the garbage - it is a significant hazard. The vacuum can be safely released (Let out? Sucked in? What does one do with an unwanted vacuum?) without spectacular effects by breaking the glass seal in the center of the CRT socket (may be hidden by the indexing plastic of the socket). Cover the entire CRT with a heavy blanket when doing this for additional protection. Once the vacuum is gone, it is just a big glass bottle though there may be some moderately hazardous materials in the phosphor coatings and of course, the glass and shadow mask will have many sharp edges if it is broken.

In addition, there could be a nice surprise awaiting anyone disconnecting the high voltage wire - that CRT capacitance can hold a charge for quite a while. Since it is being scrapped, a screwdriver under the suction cap HV connector should suffice.

The main power supply filter caps should have discharged on their own after any reasonable length of time (measured in terms of minutes, not days or years).

Of course around here, TVs and monitors (well, wishful thinking as I have yet to see a decent monitor on the curb) are just tossed intact which is fortunate for scavengers like me who would not be happy at all with pre-safed equipment of this type!

Apple/Sony monitor dies after variable length of time

The following discussion relates to failures of the X-ray protection tap on a Sony part affectionately known as the 'big red cap' or the HSTAT block in some Sony manufactured monitors.

> "This is a (Apple) Sony 13" monitor, 4 years old. After being turned on for 30 minutes, the display goes completely blank and the front LED goes off. If the power is shut off for 10 minutes or so, it will come back on for another 15 minutes or so, then go blank again, etc. The +120v and +65v from the power module is still present when it blanks out, but no other voltages (+12, +960, etc) are present on the main circuit board. I've been told it might be the HV capacitor is bad; would like to hear a 2nd or 3rd opinion before buying a new capacitor."

That is the same diagnosis a friend of mine got for her monitor with that identical problem. Replacing the capacitor did fix the problem.

That 'big red capacitor' is a Sony part which includes some kind of low voltage sense connection as well. It is used to shut the monitor or TV down should the HV increase resulting in increased risk of X-ray generation. Unfortunately, the resistors inside often go bad causing the unit to shut off erroneously. The guy at the place where she got it repaired said that the capacitor is one of the most common problems with those monitors. $70 for the part + $50 for labor, ouch!

These used to be only available from Sony. Why can't Sony design monitors like everyone else? Sure, I know, theirs are better (well, except for the unsightly stabilizing wires on Trinitrons!). Now, however, less expensive replacements can be had at places like Computer Component Source.

For testing, it may be possible to disconnect the sense output. With shutdown disabled, the monitor should continue to run BUT WITH NO X-RAY PROTECTION. Therefore, this should only be used for testing - a replacement will be required.

Note: On some models, the sense wires need to be connected during startup or else it will never come on.

CAUTION: On some models (like the Sony CPD1302), the sense signal may be used for actual HV regulation. Thus, if the sense wire is disconnected, (or the divider inside the Hstat block fails open) there is no feedback and it is possible for the high voltage (and probably B+) to increase until the HOT (and possible other components) blow.

(From: Duke Beattie (beattie@wsu.edu).)

The low voltage connection of the 'big red cap' is part of the "X-ray protection" circuit. If the high voltage to the crt goes to high it is supposed to shut down the whole thing. Unfortunately the sensor inside goes bad and puts out the wrong voltage and that shuts down the world. The part is available at "Computer Component Source" for about $30, it is a "M041" (Sony/Apple part number" These things go out with great regularity. So if your Apple monitor shuts down this is probably the culprit.

(From: A.R. Duell (ard12@eng.cam.ac.uk).)

On some of the older Trinitrons (certainly on the 13" Trinitron monitor I have), the HSTAT pot is connected as a potential divider on the EHT supply. The slider of the pot is connected to the static convergence electrode, but a tap on the lower end of the pot goes to the protection circuit. Something like this:

```
            Static Conv Electrode
                  o
                  |
                  V
    EHT---------/\/\/\-------\/\/\---+---\/\/\-----+
                                     |             |
                                     o            _|_
                                 Protection      ///
```

If the EHT rises too high, then the voltage at the protection point also rises, and a shutdown signal is sent to the scan processor.

All those resistors are encapsulated in the HSTAT block which has an EHT input from the flyback, a Coaxial EHT output (EHT and Hstat electrode) to the CRT, an earth wire, and a 2 core cable (earth and Protection) that goes to the scan board.

Unfortunately, if those resistors change in value, then the protection circuit may operate even at the normal EHT voltage. And as they're all potted in one block, you have to change the complete unit.

(From: Neil brown (nbrown@whispa.co.nz).)

When your monitor works do you see faint diagonal white line on it?

If so the cutoff need adjusting and it will cause the symptoms you describe exactly, If it doesn't come on after a "rest" then yes it may be a bad cap but I have realigned a lot more than I have replaced HV caps!

Also on the adjustment board there is a resister that goes and pushes the cutoff up high, from memory it is a 1 M resister and it drifts up high.

More on the Apple/Sony 'big red capacitor thing'

(From Terry L. Wright (terryl@wolfenet.com).)

The big red thing has been called a capacitor, a voltage tripler and a diode assembly not to mention other less polite names. It is in fact at the root of the failure in this monitor but does not necessarily need to be replaced. You will find a low voltage shielded wire comes from the red block. It goes to a four lead jack and plug which connects to the main board. The two pins that the shielded cable goes to are marked ground and Href, short for high voltage reference. If these two pins are shorted together the unit will no longer shut off by itself.

Why does this work? Because the red block contains a voltage divider, the output of which tells the main board if the 25 Kilovolt supply to the crt goes too high. When the red block ages the relative values of the internal resistors changes and the block output increases. The main board interprets this as excessive high voltage and shuts the horizontal output down to protect the circuit and ostensibly to protect from Xrays. By shorting the output you can force the main board to assume that the voltage is not too high. Note that you have also disabled any protection that the circuit may have provided from Xrays or high voltages. Personally I do not care about this as I have never seen this monitor fail in any way to cause excessive second anode voltage.

Editor's note: failure (open) of a snubber capacitor across the HOT is one failure that can result in excess high voltage. Thus, I would consider this a temporary 'for testing' solution unless you add some other mechanism for detecting excess high voltage. First confirm with a high voltage probe that the monitor isn't shutting down properly - due to excess high voltage! In addition, the original problem may get worse and eventually affect the convergence and other functions of the Hstat unit. --- sam

(From: David J. Pittella (ddc_pitt@ix.netcom.com).)

I spent 8 years working for a very large Apple authorized service provider.

The original 13" Model MO-401 (not the MO401LL/B) actually had a bad run of these high voltage capacitors. Apple did have a warranty extension on specific date ranges of these parts, I would doubt this is still in effect ... but you could check.

The 'big red' high voltage capacitor is Apple P/N 910-0058, it is mounted to the bottom of the chassis on this display. This part connects between the flyback and the anode connector on the CRT, there is also small grey cable from this device to the "D" (main) board.

The "C" board (on the neck of the crt) is notorious for cold solder joints on the CRT connector. I would always resolder these whenever I worked on this display.

CTX monitor intermittent or blows fuse

Initial symptoms are erratic startup or shutdown sensitive to temperature or vibration. Eventually, the monitor will go totally dead if the original problems are not dealt with.

Look for a vertically mounted daughterboard. This board contains an IC UT3842 which is the pulse width modulator IC for the switcher supply. ECG makes a replacement although I don't have the number handy. Make sure you check associated parts on this card for damage, as this circuit usually fries pretty well.

The entire cause of these problems is generally bad solder joints on the back side of that daughter board. Unsolder it from the main board, and fix those first. Where a connector is used (P104) resolder this as well. Then replace Q101, the 18 V zener next to it (ZD101), and the .39 ohm resistor if necessary. Note: The zener is for protection only. Therefore its exact voltage rating is not critical - anything over about 6 V will work.

(From: Keith Scott (kscott@news.HiWAAY.net).)

Exactly! Every 14 or 15" CTX I've worked on had the MOSFET, zener and the low ohm resistor toasted. BTW, they use the low ohm resistor as a fuse to keep them catching on fire when the other stuff shorts out.

(From the editor).

Once the fuse blows, several parts have gone belly-up and will need to be replaced in addition to the soldering of the daughter board.

(From: Bill Rothanburg (william.rothanburg@worldnet.att.net).)

Replacing the fuse will not fix the monitor. The odds are rather overwhelming that you have been bit by the infamous CTX 'daughter board with bad solder joint' flaw. If you have the ability to handle a soldering iron, order the repair kit from CCS (1-800-356-1227). This will contain all of the parts and instructions on fixing this problem. IMPORTANT!!! Remove the daughter board, resolder all of the joints on the connector, and reinstall the daughter board.

CCS sells a kit for $13.99, includes 2SK955, 1N5248 18V zener, .39 R, and fuse. #07-1512 800 356-1227 They also warn of solder breaks on plug of daughter board. The service manual is available from CTX for $15, 800 888-2120 (compared to $50 from CCS!!).

Gateway Crystalscan and MAG monitor problems

The following applies to several Gateway monitors including the CS1572FS (very common) and CS1776LE, as well as similar models from MAG (who is the actual manufacturer of these Gateway monitors).

> "I have a Gateway CS1572 FS monitor. Recently, a high pitched whine accompanied by faint dark lines scrolling from top to bottom appeared. Initially the problem disappeared after a warm-up period, but now it is constant. Can anyone give me info on: solving similar problem, or a source for schematics on this type of monitor. Gateway wants me to send it to MAG, but that sounds like big $$$."

Other related symptoms: Wiggling raster, possibly only at higher scan rates.

R331 is a common failure in the power supplies of Gateway CS1572 monitors. Apparently, a number of other models also use this design, and got the same batch of bad resistors :-).

It is supposed to be 91K. 1 W but gradually increases in value until regulation is compromised. While it is marked 1%, hand selecting a 5% metal film resistor that is within tolerance will work fine and even this may not be needed as the voltage adjustment pot is in series with R331. Therefore, if you have the adjustment procedure, a 1% resistor is unnecessary in any case. Then, adjust the B+ to the value marked.

Note: It is probably a good idea to replace R331 for these symptoms even if it tests good. In some cases, it would appear that these resistors fail at full voltage but not when tested with a multimeter.

If symptoms persist, check ZD302 (12.2 V?).

While you are in there, check for bad solder connections or damage to R302 and Q105 (swivel base hits these).

Allergies from monitors?

Aside from eye, back, or finger strain, there may be two possible sources of actual chemical/gaseous emissions:

1. The materials used in some of the electronic components as well as the plastics of the case can outgas - possibly for quite some time after manufacture. This is made worse due to the heat inside.

2. Ozone production. This is caused by electrical discharges - corona - from various high voltage terminals. Ozone really shouldn't be a problem with a monitor in good condition but it is possible. And, as a monitor ages and collects all sorts of dirt and dust, it is more likely.

Items of Interest

Web sites with monitor specifications

Of the half dozen or so Web sites that I used to have for extensive monitor information, only Monitorworld has survived as far as I can tell: They still have the important specifications for a wide variety of monitors indexed by manuracturer and model:

- Monitor World

I am only recommending this site for the information on monitor specifications, not necessarilly for other products or services since I haven't evaulated them. Note that since this data comes from undetermined sources, it isn't always to be accurate. Sorry for the lack of additions Web sites but believe it or not, I am not usually informed when any particular company goes belly-up or their Marketing department decides that fluff is more important than substance and they pull the plug on the pages with useful information. :(

How do multiscan monitors determine and store the scan parameters?

With modern SVGA multiscan monitors, once a particular resolution and scan rate is set up, there is rarely a need to readjust size, position, and other parameters. How is this accomplished?

(From: Bob Myers (myers@fc.hp.com).)

It's different for different designs, of course, but in general today's 'digitally controlled' monitors recognize various timing modes by counting the horizontal and vertical sync pulses to determine the line scan and vertical refresh rates.

Any input within a certain tolerance of a recognized pair of frequencies here is assumed to be that timing, and a set of stored numbers corresponding to that timing are then read from a memory and used to set up the adjustments. In most of these monitors, the various adjustable parameters - size, centering, etc., - are controlled by voltages coming from a set of D/A converters, so the stored information is basically just a table of numbers that get sent to the D/As when that timing is recognized.

The number of both factory and user presets available varies from product to product, of course, but there's usually somewhere between 8-15 of each. The exact number is going to depend on how much memory is available, and how many different parameters need to be controlled for each recognized timing.

Unless the output of the graphics controller is an exact match for the timing used at the factory when the preset information was generated, there may still be slight errors, for obvious reasons. Fortunately, the widespread acceptance of timing standards (such as those produced by VESA) are reducing the severity of this problem.

Monitor reliability with SVGA

There are parts in the monitor which may get hotter with SVGA but if it is designed for SVGA resolution, there should be no problem (assuming you are not running in an excessively hot room or with the ventilation holes covered).

A good quality auto-scan monitor should not mind switching screen resolutions frequently (though doing it every few seconds continuously may stretch this a bit).

Newer auto-scan monitors should also be smart enough not to blow up if you feed then a scan rate which exceeds their capabilities. However, there are a lot of poorly designed monitors out there.

If it is supposed to run SVGA, use it at SVGA. If it blows up, switch to a different brand. There are a lot of crappy monitors being sold on their own and bundled with PCs.

How high a refresh rate should I use?

It is the vertical refresh rate that impacts display appearance. The visual effect of too low a vertical scan rate is excessive flicker.

Up to a point, higher is better. Everyone agrees that appearance improves up to at least 70-75 Hz (vertical) non-interlaced but beyond this point is a hotly debated issue (and a topic for a never ending discussion on your favorite Internet newsgroup). The use of interlaced scanning can reduce apparent flicker for a given scan rate for typical gray scale or color images but may result in annoying flickering or jumping of fine horizontal lines in graphics and text displays.

In any case, you must not exceed the maximum scan rate specs of your monitor. See the section: Web sites with monitor specifications if in doubt. Also, very high refresh rates may result in decreased graphics performance particularly with DRAM based video cards due to bus contention between the PC memory accesses and the video readout to the RAMDAC.

And, a horizontal scan rate below the specified limits may blow the HOT instantly.

For the discussion below, the key words are "well designed". There are a lot of mediocre monitors out there!

(From: Jeroen H. Stessen (Jeroen.Stessen@philips.com).)

The dissipation in the deflection coils rises sharply with the horizontal scan frequency. The horizontal scan frequency is of course higher at higher resolution and higher vertical refresh rates. But the monitor will have been designed to handle that, unless you don't permit adequate ventilation. Component failure occurs often during mode-switching, not due to keeping the monitor in one mode or another.

It is a popular myth that a (well-designed) monitor could be damaged by connecting it to a signal source with frequencies that are out of range. These will be (should be) automatically blocked by the sync circuitry and you will simply not get a stable picture. There will be no damage, and if there would be (most likely from a too LOW line frequency) then it would be done immediately. No need to rush setting things right.

So my advice would be to go ahead, use whatever resolution you like. The acceleration of the wear will be insignificant, you'll probably want a better monitor long before it is technically worn out. If you want to be kind to your monitor, then keep the contrast below maximum, use a black-screen screen saver and keep the dust and smoke and moisture and grease away.

Number of colors and monitor type

> "I have a CTX CVP-5468 that will not do more than 16 colors in windows. It is being driven by an Orchid Kelvin 64 VLB board, but had the same problem with an ATI card. When using it in linux under x-windows the same thing and more than vga and it goes blurry and very pixelated."

It is really not possible for this to be a monitor problem as the signals are analog - continuous - the monitor displays whatever it is given and does not even know the color depth except to the extent that cards are often set up via software to use different scan rates for different color depths (bits/pixel) often due to hardware memory/bandwidth limitations.

For the ATI in particular, I know that you can use ATI's DOS Install program to set it up for each resolution and mode - try this. I bet your monitor is fine.

Various video standards

Here is a link:

- Standards for analog component video

Monitors, humans, and flicker

(From: Bob Myers (myers@fc.hp.com).)

The flicker-fusion frequency for emissive displays such as CRTs cannot be given as a single number applicable to all people, all displays, and all ambient conditions. It is dependent on the particular individual, the size and brightness of the display (and the characteristics of the phosphor, if a CRT), the viewing distance, and the ambient lighting conditions.

For a typical color CRT computer monitor, at typical brightness levels and viewing distances, the image will appear "flicker free" to 90% of the population by the time the refresh rate has reached the upper 70 Hz range; into the low 80 Hz range, and you cover 95% of the population. Given the statistics, there are probably a few people who could still see flicker by the time you got above 90 Hz, but there sure aren't many of 'em.

The effects of the screen refresh rate on perceived motion have more to do with the relationship between that rate and the ORIGINAL sampling rate (i.e., ~60 Hz for standard video), and higher refresh rates are definitely NOT always better in this regard. Depends on the artifact in question.

Is fluorescent lighting a significant source of flicker?

(From: Bob Myers (myers@fc.hp.com).)

Actually, this is a myth. Ambient light flicker is at best a second-order effect in determining perceived flicker levels, and then only through modulating the display's contrast ratio. (Ambient light flicker isn't even considered in the flicker calculations of the various ergonomic standards, although the ambient light *level* is a concern.)

The notion that fluorescent lamps flicker and that this somehow produces a "beat" with the screen refresh is simple to disprove. First, if this were so, 75 Hz screen refresh would appear WORSE than 60 Hz, since it's farther removed from the line rate. In reality, the reverse is true - and if you REALLY want to maximize perceived flicker, turn OFF all the lights. The display will then appear to flicker MUCH worse, as one determining factor in flicker is the APPARENT brightness of the screen (how bright the screen is in relation to its surroundings). Lastly, people don't realize that fluorescents DON'T flicker at the line rate; being essentially plasma displays wherein the plasma emissions exicte a phosphor, these tubes flicker at TWICE the line rate - too high to be perceived. Fluorescents show a flickering appearance when they're failing, but that's a different kettle of fish altogether.

(Also note that a large percentage of fluorescent lighting these days uses electronic rather than magnetic ballasts. Most of these do not suffer from significant power line flicker (100/120 Hz) flicker as they are driven at 10s of kHz by what are essentially switching power supplies. Any variation in intensity is at too high a frequency to matter. This is true of most compact fluorescent lamps, many cheap fixtures, as well as large (newer) office installations or retrofits. --- sam)

Interlaced vs. non-interlaced monitors

The difference between interlaced and non-interlaced displays is in the video timing. Nearly all monitors can handle either. Monitors are specified as non-interlaced because for a given screen resolution and vertical refresh rate, this is the tougher (higher) horizontal (H) scan rate and it is desirable to minimize flicker in a graphical display (Fine horizontal lines will tend to flicker on an interlaced display). The H scan rate is double the interlaced H scan rate since all scan lines rather than just the even or odd lines are being displayed for every vertical scan.

Digital versus analog controls on monitors and picture quality

> "Could someone tell me if there's a noticeable difference in picture quality between analog and digital monitors? Is digital worth the extra money?"

There is no inherent reason for a digital monitor to have a better picture but as a practical matter, I would expect this to be the case in the vast majority of monitors - especially models from the same manufacturer. The digital monitors will be the ones that the designers concentrate on. Digital controls (both those you can access and those used only during setup at the time of manufacturing or servicing) permit more flexibility in setting parameters and automated more consistent adjustments on the assembly line (at least this is possible in principle).

For the average not terribly fussy PC user, the major difference is in the convenience of not having to adjust size and position whenever the scan rate changes. In my opinion, while the price difference between monitors having analog or digital controls but with the same screen size, resolution, and scan range specifications may seem excessive, the added convenience of digital controls and scan rate parameter memory makes the added cost well worthwhile.

Should I be concerned about very frequent scan rate switching

This question arises in a PC software development environment where the programmer needs to go back and forth between a Windows display and a DOS debugger, for example.

Obviously, without knowing the precise design of your monitor, there can be no definitive answer. It is true that some older monitors blew up if you looked at them the wrong way. Newer monitors from well known manufacturers like Nokia, NEC, and many others are designed with a moderate amount of scan switching in mind. However this is stressful for the monitor's power supply and deflection circuitry. I would suggest that you use a dedicated mono monitor for debugging if you really are switching multiple times per minute. If you cannot afford the space, you can probably assume that if the first few days of this kind of treatment have not induced a failure, the monitor is robust enough to withstand it indefinitely. If you really are switching many times per minute 8 hours or more a day, then what may wear out are the internal relays (the clicks you hear are from these). You are still talking about years, however. They are rated in 100s of thousands or millions of operations when used within their ratings.

Or, just go for the peace of mind of an extended warranty or service contract.

What is monitor video bandwidth and why is it important?

(From: Bob Myers (myers@fc.hp.com).)

Video bandwidth is an indication of the frequency range over which the monitor's video amplifiers are capable of doing their job, which is to translate the video signal at the monitor inputs (about 0.7 volt, peak-to- peak) to something like 35-40V peak-to-peak at the CRT cathodes. Higher bandwidths ARE better, UP TO A POINT.

The bandwidth required is NOT given by multiplying the numbers in the format (what most call the "resolution") by the refresh rate; even allowing for the required blanking time, what THAT gives you is the pixel rate or "pixel clock". As the fastest thing that happens in a video signal is one dot on followed by one dot off, the fastest FUNDAMENTAL frequency in the video signal is half the pixel clock. Normally, you might think you'd want to cover some of the harmonis to "sharpen up" the pixel edge, but that's actually less important than you might think (in part due to the fact that the CRT screen itself, being made up of discrete dots of color, already has the effect of "sharpening up" the image AND limiting how sharp it's going to get, anyway).

There's also the problem of "bandwidth" not being measured or speced consistently by all manufacturers, making it difficult to compare one product to another. Some simply give a "max. video rate supported" number, which is about as useless a spec as one can imagine. (It's just telling you the pixel rate of the fastest timing supported - but says nothing about the image quality at that timing!) Still, a claimed bandwidth of about 2/3 to 3/4 of the fastest pixel rate to be used should indicate adequate performance - beyond that, you need to compare products with the good ol' Mark I eyeball. Using this rule of thumb, a monitor intended for use at 1280 x 1024, 75 Hz (a 135 MHz pixel rate) needs a speced amp bandwidth of around 100 MHz. (But just to show how far you can trust this particular number, I know of a product which does a very nice job of displaying 1600 x 1200 at 75 Hz - slightly more than a 200 MHz pixel rate - but which has a video amp bandwidth of only about 100 MHz, if measured per certain definitions!)

I find the rise and fall time of a full-scale (white to black or black to white) video signal, as measured at the cathode, to be a much better spec, and here would look for something not slower than 2/3 of the pixel period for the timing of interest. But these numbers are rarely quoted in consumer-oriented spec sheets, and even these take some care in applying.

Why a good monitor may produce a fuzzy picture

The ultimate sharpness of the picture on your monitor depends on many factors including but not limited to:

1. Focus of the electron beam spot(s) at the face of the CRT.

Affected by: quality of the CRT and its supporting circuitry and adjustment of focus control(s).

2. Convergence of the RGB electron beams at each point on the face of the CRT.

   Affected by: quality of the CRT, deflection components, and how carefully the convergence adjustments were done during manufacture (or repair). In many cases, it is this last item that is most critical. Bad quality control during final setup can ruin a monitor manufacturer's reputation - and has.

3. Moire reduction (if any or if enabled) reduces the effective sharpness of the electron beam either through actual defocusing or a high frequency dither. IMO, the net effect is almost always bad.

   Affected by: enabling and magnitude of moire reduction.

Items (1) through (3) are somewhat independent (though not entirely) of scan rate. The newest high-end monitors have a fairly comprehensive set of digital (on-screen) adjustments for these but may still not produce acceptable results for every monitor.

4. Bandwidth of the video amplifiers in the monitor - essentially how quickly the intensity can be altered by the video signal.

   Affected by: design of video amplifier circuitry and circuit board layout. This used to be much more of an art than it is today. Integrated circuits have replaced many of the discrete components used in the past resulting in simple designs with clean circuit board layouts.

5. Bandwidth of the digital to analog converter (D/A, DAC, or RAMDAC) of the video card.

   Affected by: DAC or RAMDAC chip used, supporting circuitry, and video card board layout. As with (3), these are largely cookbook designs these days.

6. Dispersion in the video cable - how smeared out the video signal becomes traveling through the cable.

   Affected by: quality and length of video cable. Since cables often come attached to the monitor nowadays, you don't have much control of this. Just don't add problems such as switchboxes.

7. Reflections from any impedance discontinuities in the cable - video card DAC, video card connector, monitor connector, monitor video amplifier input, monitor termination. All of these will introduce just a bit of mismatch - or perhaps much more - which will add up to either barely detectable fuzziness or totally unacceptable ghosting or ringing at vertical edges.

   Affected by: connectors and circuit board layouts of both video card and monitor input as well as any additional connectors or a switchbox.

Items (4) through (7) are heavily dependent on scan rate since higher scan rates translate into higher video bandwidth. Any degradation of the edges of the video signal - transitions from black to white, for example - will be much more visible at the higher scan rates - they will be spread out resulting in pronounced blurring, ghosting, or ringing.

Thus, it is critical to use the highest quality components wherever possible. While you don't have control over what is on your video card and inside your monitor, selecting a high quality video card and monitor should help. If you have the option to use a BNC cable (at least your monitor has BNC jacks on the back), try out a high quality BNC cable - you may be pleasantly surprised at the improvement in edge definition and overall sharpness.

Ghosts - card or monitor?

(From: Bob Myers (myers@fc.hp.com).)

This isn't as simple as it may appear. 'Ghosts' are caused by reflections of the video signal edges, caused by impedance mismatches between the driver (graphics card), the video cable, and the monitor video inputs. Add in the problems caused by the video connectors, and you wind up having to say that this is really (most often) a system problem, and all the parts get some of the blame.

With that said, the practical answer is that you should avoid using anything other than a single, reasonably-good-quality video cable, with decent connectors, between your PC and monitor, this being the part that you have the most control over. The more breaks in the cable - adding extension cables, switchboxes, etc. - the more chances you have for a mismatch in the line. BNC connectors (or the new VESA EVC connector) are MUCH better in this regard than the 15-pin D "VGA" connector (although if you're getting good results with the D connector, don't worry about it). Also, do NOT make the mistake of using anything other than 75 ohm coax for your video cables. Just to mention one common mistake, LAN cable is *50* ohms, so it's NOT going to work here!

If you've done all you can with the cable, the next place to go is the monitor itself; there's probably something wrong with the video input termination. By the way, a simple way to confirm that what you're seeing IS a ghosting (reflections) sort of problem is to use a DIFFERENT LENGTH of the video cable. Since the ghost is the result of a reflection going from the monitor back to the PC and then back up the line, the length of the cable affects where the ghost appears relative the edge which caused it. Inserting a longer cable moves the ghost out (to the right), while a shorter one will move it closer in (to the left). If you change cable lengths and the ghost doesn't move, you most likely have a problem within the monitor itself, past the video inputs.

BTW, longer cables may also make the ghost less distinct, due to the increased attenuation of the signal by the cable. Unfortunately, the longer cable also means more attenuation of the video signals that you WANT, in addition

Extension cables and monitor ghosting

(From: Bob Myers (myers@fc.hp.com).)

With an extension cable, there is the chance that this ghost is being caused by an impedance mismatch AT THE CONNECTOR OF THE EXTENSION; unless the cable is completely the wrong impedance, it is unlikely that the cable itself (meaning the actual "wire") is the culprit. But any break in the cable (connectors, switchboxes, etc.) is a chance for a mismatch.

But before blaming the cable, there's another possibility to check out. One commone source of ghosting is a poor termination of the line at the monitor itself and at the graphics card driving it. It can look worse with an extension simply due to the extra cable length moving the "ghost" farther away from the image causing it. (The ghost is, after all, just a reflected signal that went back DOWN the cable, got reflected again at the controller, and sent back up to the monitor. Added cable length makes this round trip longer, and moves the ghost farther to the right of the original edge in the displayed image.) If this is the case, the you will also see the ghost without the extension - it'll simply be much closer to the original edge that it's "ghosting". In that case, a better extension cable can actually make the appearance of the ghost worse - a lower-loss cable means that more of the reflection will get through back to the monitor!

If it is being caused by the extension cable, you may get better results by using BNC connections instead of the D-sub at the point where the cables mate. The D-sub is a pretty poor connector in terms of providing the proper impedance. Using a pair of 15D-to-5-BNCs back to back may give better results.

Driving multiple monitors from a single PC

Where BNC monitors are involved and daisychaining is acceptable, additional circuitry is generally not required for reasonable distances. BNC cables for R, G, B, and possibly H and V sync, are run from the source to each monitor in turn with only the last one being terminated in 75 ohms (the others MUST be Hi-Z).

Some newer BNC monitors do not have a Hi-Z option for termination so daisychaining is not even an option with these.

Attempting to drive multiple monitors in a star configuration without buffering the signals will generally result in poor results - reduced brightness and contrast (by 1/n where n is the number of monitors) and ghosting and other signal degradation. However, nothing will blow up so for 2 monitors it may be worth trying.

In either of these cases, what is needed is a distribution buffer amplifier. One such circuit is shown at:

8. http://www.anatekcorp.com/driving.htm

This includes simple emitter follower circuits for each high speed signal.

Using a PC as a monitor test pattern generator

Almost any PC with at least a medium performance SVGA video card can be programmed for a wide range of resolution options, dot clocks, horizontal and vertical sync timing, and sync polarity. Some can be programmed to generate composite sync and sync-on-green as well.

DOS/Windows/Win95 will suffice for most PC applications using drivers supplied by the video card manufacturer but for complete flexibility, run under Linux - take a look at the Xfree86 documentation for more details.

Test patterns can be created with any graphics applications and then saved for rapid recall.

Of course, for different output levels and impedances you will need some extra electronics. A normal SVGA card only produces R,G,B video and H and V sync signals compatible with doubly terminated 75 ohm cables. As noted, some will generate composite sync and/or sync-on-green. See the "Sync-on-Green FAQ" for more information on how to do this if your card is not capable of it. For NTSC/PAL video generation, additional hardware will be needed. See the section: Displaying computer video on a TV.

Monitor testing programs

There are a variety of PC compatible software programs for testing of SVGA computer monitors. These display various test patterns and color charts which are appropriate for the procedures discussed in this document.

Here are a few pointers:

- The monitor test program "NTest" is very often recommended on the comp.sys.ibm.pc.hardware.video Newsgroup. This was originally available from Nokia but since Nokia sold their monitor division to Viewsonic, it has disappeared so here is a copy. I'll be happy to link to the Viewsonic site if they replace it.

  - Nokia Ntest Monitor Test.

- ComputerCraft provides a shareware program for testing monitors and video cards. I have not tested it but as they say: "If you are aware of the dangers, Monitors 1.01 is a powerful tool." See the document: Performance Testing of Computer and Video Monitors, specifically the section: "WARNING and DISCLAIMER" for some of these. This shareware program can also test video cards for characteristics and graphic modes.

- Monitors 1.01.

(From: Mark E. Nikl (markn3@infoave.net).)

In the download section of the Web site, there is a file called monitors. It will give you all the test patterns and setups for gray scales, HV regulation, tell you about you video card and much more. I just ran across it the other day. You can even set up the pincushion and lots more.

- SONERA Technologies markets a set of programs called "DisplayMate" available for DOS and Windows/Win95. This is supposed to guide you through the monitor testing and setup process with a series of test pattern 'slides'. I have not tried it so I cannot comment on its utility.

  A demo version with a few test patterns, more information on their products, and some video tech tips, and some test patterns are available at:

  - Display Mate Home Page and Demo.
  - Test Patterns.

  A subset of these test patterns is available courtesy of PC Magazine at: http://www8.zdnet.com/pcmag/features/monitors/test/. I don't know how long this will be available but for now, it is really easy to use and doesn't require that you even exit Windows. You may use it on 640 x 480, 800 x 600, 1024 x 768 screen resolution or windows of these size. Test patterns are provided for color rendition, horizontal resolution, dot/cross hatch, and more. The images files may be downloaded and saved as well.

- PassMark has a product that appears to have a fairly comprehensive set of features including 25 test patterns, display of monitor and video adapter information, and support for multiple resolutions, color depths, and display types. It can be downloaded for free with a 15 day evaluation, then costs $15:

  - PassMark MonitorTest.

Using a TV tuner card in a PC

These ISA, EISA, or PCI cards put TV programs or other NTSC/PAL source material into a window on your PC's monitor screen. The question has come up as to whether this will damage the monitor in the long term.

I would not think that there should be any problems unless you tend to turn the brightness up much higher than normally used for computer activities. If anything, the constantly changing picture will be better than a stationary window. However, moving it to different locations every so often will not hurt.

Similar comments apply to other types of image and video captures as well.

IMHO, I still think it is silly to use an expensive PC and monitor to watch TV.

What is color temperature and what does it affect?

Some monitors have the capability of selecting or adjusting for the 'color temperature' of the display. NEC AcuColor on the 4/5/6FG series of monitors is one example.

The terminology refers to the spectral output of an ideal black body source at that actual physical temperature. It essentially sets the appearance of a white screen. For example, a color temperature of 9300K will appear blue-white while 6300K will appear yellow-white.

It only affects the relative balance of R,G,B and has nothing to do with refresh rates or anything performance related. Unless you are doing work where the exact colors matter or are using multiple monitors where the colors need to match, use whichever setting ismore pleasing

What is this goop around some electrolytic capacitors and other components?

That goop is probably glue and generally harmless - it is there to hold down the components aganst vibration. I have heard of it sometimes decomposing and shorting stuff out but I doubt you have that problem.

Therefore, unless you find a bad cap in the focus or related circuit, we are still looking at a flyback problem.

What does the flyback (LOPT) transformer do?

The typical flyback or Line OutPut Transformer (LOPT) consists of two parts:

1. A special transformer which in conjunction with the horizontal output transistor/deflection circuits boosts the B+ (120 V typical for a TV) of the low voltage power supply to the 20 to 30 kV for the CRT as well as provide various secondary lower voltages for other circuits.

   A HV rectifier turns the high voltage pulses into DC and the CRT capacitance smooths it. The HV may be developed from a single winding with many many turns of wire or a lower voltage winding and a diode-capacitor voltage multiplier.

   The various secondary voltages power the logic, tuner, video signal, vertical deflection circuits, and CRT filaments. In fact, with many TV designs, the only power not derived from the flyback is for the keep-alive circuitry needed to maintain channel memory and provide startup drive to the horizontal deflection/high voltage system.

2. A voltage divider that provides the focus and screen supplies. The pots are in this divider network - and these things fail resulting poor focus, uncontrolled brightness, or fluctuating focus and/or brightness. A total short could also result in failure of other components like the horizontal output transistor. In some monitors, the focus and screen divider and/or controls are external to the flyback and susceptible to dust and problems particularly on humid days. The resistance of these circuits is so high that dirt or other contamination can easily provide a bypass path to ground especially when slightly damp.

Tony's notes on setting convergence on older delta gun CRTs

(From: ard12@eng.cam.ac.uk (A.R. Duell))

The older delta-gun tubes (3 guns in a triangle, not in a line) can give **excellent** pictures, with very good convergence, provided:

1. You've set those 20-or-so presets correctly - a right pain as they interact to some extent.

2. The CRT is set up in the final position - this type of tube is more sensitive to external fields than the PIL type.

Both my delta-gun sets (a B&O 3200 chassis and a Barco CDCT2/51) have very clearly set out and labeled convergence panels, and you don't need a service manual to do them. The instructions in the Barco manual are something like:

"Apply crosshatch, and adjust the controls on the convergence board in the numbered order to converge the picture. The diagrams by each control show the effect".

Here's a very quick guide to delta gun convergence where the settings are done using various adjustments on the neck of the CRT (if you don't have a service manual but do know what each control does, and where they all are - otherwise, follow the instructions in the service manual --- sam):

1. Apply a white crosshatch or dot pattern to the set. Don't try and converge on anything else - you'll go insane. It's useful to be able to switch between those 2 patterns.

2. Before you start, set the height, width, linearity, pincushion, etc. They will interact with the convergence. Also check PSU voltages, and the EHT voltage if it's adjustable. That's where you do need a service manual, I guess.

3. Turn off the blue gun using the A1 switch, and use the red and green static radial controls to get a yellow croshatch in the middle of the screen. These controls may be electrical presets, or may be movable magnets on the radial convergence yoke (the Y-shaped think behind the deflection yoke).

4. Turn on the blue gun and use the 2 blue static controls (radial and lateral) to align the blue and yellow crosshatches at the center of the screen. Some manufacturers recommend turning off the green gun when doing this, and aligning red with blue (using *only* the blue controls, of course), but I prefer to align blue with yellow, as it gives a check on the overall convergence of the tube.

5. Turn off the blue gun again. Now the fun starts - dynamic convergence. The first adjustments align the red and green crosshatches near the edges - I normally do the top and bottom first. There will be 2 controls for this, either a top and a bottom, or a shift and a linearity. The second type is a *pain* to do, as it's not uncommon for it to affect the static convergence.

6. Getting the red and green verticals aligned near the edges is a smilar process.

7. You now have (hopefully) a yellow crosshatch over the entire screen.

8. Now to align the blue. This is a lot worse, although the principle is the same. Turn on the blue gun again, and check the static (center) convergence

9. To align the blue lines with the yellow ones, you'll find not only shift controls, but also slope controls. Use the shift controls to align the centers of the lines and the slope controls to get the endpoints right. These interact to some extent. You'll need to fiddle with the controls for a bit to work out what they do, even if you have the manual.

The convergence over the entire screen should now be good....

A word of warning here... The purity is set by ring magnets on almost all colour CRTs, but on PIL tubes, there are other ring magnets as well - like static convergence. Make sure you know what you are adjusting.

Jerry's comments on convergence and other advanced CRT adjustments

(From: Jerry G. (jerryg@total.net).)

Convergence alignment is not something you can do yourself unless you have the proper calibration instruments and skills. It takes lots of experience and time. There are published specs for most of the good monitors. Most of the time they are as follows:

There is the 'A area', 'B area', and 'C area'. On a 15 inch monitor the A area would be a diameter of about 4 inches. The B area would be about 7.5 inches. The C area would be the outside areas including the corners. These numbers are approximate. There are actually standard specs for these areas. They are expressed in percentage of screen viewing area. Therefore the inches would vary with the CRT size.

The higher the price (quality) of the monitor CRT, yoke, and scanning control circuits, the tighter the convergence can be aligned by the technician. For the A area on a good monitor, the maximum error should not exceed 0.1 mm. For the B area it should not exceed more than about 0.25 mm. And for the C area, it can be allowed up to about 0.3 mm. Most of the monitors that I have repaired, seen, and used did not meet these specs unless they were rather expensive. With these specs there would not be any real visible misconvergence unless you put your nose very close to the screen... A lot of the ones in the medium price range they were about 0.15 mm error in the A area, about 0.4 in the B and greater than in the C area. This also annoys me because I am very critical.

If one has the skills and test gear he or she can do a better job on most monitors. It is a question of the time involved. To see the convergence errors a grating or crosshatch pattern is used. A full raster color generator is required for the purity adjustments as well. This is necessary to align the landing points of the CRT guns. The exact center reference and purity adjustments are done with the ring magnets on the CRT neck. The yoke position angle adjustments are also done for the side and top-bottom skewing as well. Everything interacts!

The corners are done with various sorts of slip or edge magnets. As for corner convergence skewing, button magnets are used. The color purity will be effected as you go, and must be also corrected. These adjustments interact on one another, and the processes continues until the convergence and purity are good at the same time...!

I don't recommend the amateur or hobbiest, or even the do-it-yourselfer to attempt this alignment procedure. The test gear would exceed the cost of a really good monitor anyways...!!! And without the proper skills required, he or she would only make it worse anyways...

As for purity specs, the color change from any corner to any corner must not exceed an error of more than 200 degrees Kelvin. The error in the B area should not exceed 300 degrees kelvin. This applies to a white raster. Most of the monitors I see don't get better than about 300 degrees Kelvin. And some are even 1000 out! The purity errors are best checked with a full Red raster using 100 % saturation. Then the other color vector angles are checked with cyan, and then magenta. The color temperature stability should be the same in all aspects.

A color spectrometer should be used to judge this error factor. As far as the eye is concerned, it will see a purity error of more than about 500 degrees Kelvin if the person knows what to look for...

When changing the CRT, this alignment must be done completely. Most shops do not even employ people who are skilled to a proper alignment, or don't even own the instruments to do it right, and the poor customer get back a monitor that is not in specs...!

Use of surge suppressors and line filters

Should you always use a surge suppressor outlet strip or line circuit? Sure, it shouldn't hurt. Just don't depend on these to provide protection under all circumstances. Some are better than others and the marketing blurb is at best of little help in making an informed selection. Product literature - unless it is backed up by testing from a reputable lab - is usually pretty useless and often confusing.

Line filters can also be useful if power in you area is noisy or prone to spikes or dips.

However, keep in mind that most well designed electronic equipment already includes both surge suppressors like MOVs as well as L-C line filters. More is not necessarily better but may move the point of failure to a readily accessible outlet strip rather than the innards of your equipment if damage occurs.

Very effective protection is possible through the use of a UPS (Uninterruptible Power Supply) which always runs the equipment off its battery from the internal inverter (not all do). This provides very effective isolation power line problems as the battery acts as a huge capacitor. If something is damaged, it will likely be the UPS and not your expensive equipment. Another option is to use a constant voltage transformer (SOLA) which provides voltage regulation, line conditioning, and isolation from power spikes and surges.

It is still best to unplug everything if the air raid sirens go off or you see an elephant wearing thick glasses running through the neighborhood (or an impending lightning storm).

GFCI tripping with monitor (or other high tech equipment)

Ground Fault Circuit Interrupters (GFCIs) are very important for minimizing shock hazards in kitchens, bathrooms, outdoors and other potentially wet areas. They are now generally required by the NEC Code in these locations. However, what the GFCI detects to protect people - an imbalance in the currents in the Hot and Neutral wires caused possibly by someone touching a live conductor - may exist safely by design in 3 wire grounded electronic equipment and result in false tripping of the GFCI. The reason is that there are usually small capacitors between all three wire - Hot, Neutral, and Ground in the RFI line filters of computer monitors, PCs, and printers. At power-on and even while operating, there may be enough leakage current through the capacitors between Hot and Ground in particular to trip the GFCI. Even for ungrounded 2 wire devices, the power-on surge into inductive or capacitive loads like switching power supplies may falsely trip the GFCI. This is more likely to happen with multiple devices plugged into the same GFCI protected outlet especially if they are controlled by a common power switch.

Therefore, I do not recommend the use of a GFCI for computer equipment as long as all 3 wire devices are connected to properly grounded circuits. The safety ground provides all the protection that is needed.

Monitors on foreign power

Using a monitor on a different voltage or frequency is usually not a serious problem.

Your PC and monitor should be fine requiring at most a transformer (not just an adapter for heating appliances, however) to convert the voltage. They both use switching power supplies which don't care about the line frequency.

Some power supplies are universal - they automatically adapt to the voltage they are fed without requiring even a transformer but don't assume this - check you user manual or contact the manufacturer(s) to determine if jumpers or switches need to be changed. You could blow up the PC or monitor by attempting to run it on 220 VAC when set of 115 VAC. If you are lucky, only a fuse will blow but don't count on it.

For non-switching power supply devices like printers and wall adapters that use line power transformers, in addition to matching the voltage (or setting jumpers or switches), running on a lower line frequency may be a problem. There is a slight chance that the power transformer will overheat on 50 Hz if designed for 60 Hz. (The other way around should be fine.) It is best to check the nameplate - it should tell you. If it does not, then best to contact the manufacturer.

Lifespans of Monitors

(From: Bob Myers (myers@fc.hp.com).)

Most manufacturers will quote an MTBF (Mean Time Before Failure) of somewhere in the 30,000 to 60,000 hour range, EXCLUSIVE OF the CRT. The typical CRT, without an extended-life cathode, is usually good for 10,000 to 15,000 hours before it reaches half of its initial brightness. Note that, if you leave your monitor on all the time, a year is just about 8,000 hours.

The only "tuneup" that a monitor should need, exclusive of adjustments needed following replacement of a failed component, would be video amplifier and/or CRT biasing adjustments to compensate for the aging of the tube. These are usually done only if you're using the thing in an application where exact color/brightness matching is important. Regular degaussing of the unit may be needed, of course, but I'm not considering that a "tuneup" or adjustment.

How do monitors know when to enter power saving modes?

(Portions from Bob Myers (myers@fc.hp.com).)

If the monitor complies with the VESA DPMS (Display Power Management Signalling) standard, it will go into power saving modes when either horizontal or vertical sync is disabled. Different combinations of the sync signals indicate different levels of power management, distinguished by how much the power is reduced and the expected recovery time. The greater the power savings, the greater the recovery time is expected to be. For instance, one thing that may distinguish the greater power savings states is turning off the CRT filament, something that you don't recover from in just a second or two.

You can tell which power saving mode is active by how long the monitor takes to come back to life:

1. Video blanking - image will appear instantly when any key is pressed since this is just a logic level inhibiting the video drivers.

2. Full shutdown - a warmup period of around 15 seconds will be needed for the image to reappear since the filaments of the CRT need to warmup.

Monitor life, energy conservation, and laziness

A common misconception about the care and feeding of computer monitors is that they should be left on all the time. While there are some advantages to this, there are many more disadvantages:

1. CRT Life: The life of a monitor is determined by the life of the CRT. The CRT is by far the most expensive single part and it is usually not worth repairing a monitor in which the CRT requires replacement. The brightness half-life of a CRT is usually about 10-15K hours of on time independent of what is being displayed on the screen. 10K hours is only a little more than a year. By not turning the monitor off at night, you are reducing the life of the monitor by a factor of 2-3. Screen savers do not make any substantial difference especially with modern displays using X-Windows or MS Windows where the screen layout is not fixed. With video display terminals, the text always came up in the same position and eventually burned impressions into the screen phosphor. With modern CRTs, the filaments can be left to minimize the time needed for a picture to appear since this doesn't affect CRT life very much.

2. Component life: The heat generated inside a monitor tends to dry out parts like electrolytic capacitors thus shortening their life. These effects are particularly severe at night during the summer when the air conditioning may be off but it is still a consideration year around.

3. Safety: While electronic equipment designed and manufactured in accordance with the National Electrical Codes is very safe, there is always a small risk of catastrophic failure resulting in a fire. With no one around, even with sprinklers and smoke alarms, such an failure could be much more disasterous.

4. Energy use: While modern monitors use a lot less energy than their older cousins, the aggregate energy usage

is not something to be ignored. A typical monitor uses between 60 and 200 Watts. Thus at a $.10 per kWH electric rate such a monitor will cost between $48 and $160 a year for electricity. During the night, 1/2 to 2/3 of this is wasted for every monitor that is left on. If air conditioning is on during the night, then there is the additional energy usage needed to remove this heat as well - probably about half the cost of the electricity to run the monitor.

The popular rationalization for what is most often just laziness is that power-on is a stressful time for any electronic device and reducing the number of power cycles will prolong the life of the monitor. With a properly designed monitor, this is rarely an issue. Can you recall the last time a monitor blew up when it was turned on? The other argument, which has more basis in reality is that the thermal cycling resulting from turning a monitor on and off will shorten its life. It is true that such thermal stress can contribute to various kinds of failures due to bad solder connections. However, these can be easily repaired and do not effect the monitor's heart - the CRT. You wouldn't leave your TV on 24 hours a day, would you? Full power saving where virtually everything including the CRT filaments is turned off is really best but the delay before a picture appears may be 20 seconds or more.

Also see the section: Thermal cycling and component life.

Most of the newest ('green') monitors have energy conserving capabilities but it is necessary for the software to trigger these power reduction or power down modes. However, many monitor still in use lack these features. And not all workstations or PCs are set up to support them. If you have such a monitor and computer to support it, by all means set up the necessary power off/power down timers.

However, using the power saving modes of a 'green' PC with an older monitor can potentially cause damage since some of the modes disable the sync signals. A 'green' monitor which can detect a blank screen and and use this as a trigger can easily be used with a screen saver which can be set to display a blank screen - on any PC or workstation.

Even if the monitor does not support power saving modes, a blank screen or dark picture will reduce stress on the CRT and power supply. Electronic components will run cooler and last longer.

Please make it a habit to turn your monitors off at night. This will extend the life of the monitor (and your investment) and is good for the environment as well. For workstations, there are good reasons to leave the system unit on all the time. However, the monitor should be turned off using its power switch. For PCs, my recommendation is that the entire unit be turned off at night since the boot process is very quick and PCs are generally not required to be accessible over a network 24 hours a day.

Thernal cycling and component life

(From: Bob Myers (myers@fc.hp.com).)

In a CRT monitor, the shortest-lived component BY FAR is the CRT itself, and it ages (more properly, the cathode is aging) as long as the heater is on and the tube is under bias. Most monitors don't get around to turning the heater down or off until they enter the DPMS "suspend" or "off" modes. (And no, screen-savers do NOT help here - the tube is still on and the cathode is aging.)

Other factors - simply having the circuits hot and powered up in general means that they're aging. Clearly, they're NOT aging when they're off. This needs to be balanced against the thermal-cycling sort of stresses that you mention which happen during power cycling, and this is why I recommend shutting off only when you're going to be away for an extended period, such as overnight. This is, of course, most important for those components which have clear heat-related aging, but most do to some extent. Esp. vulnerable are things like electrolytic caps, for obvious reasons.

The bottom line is that nothing is ever going to last forever, and trying to maximize the life of the product is an exercise in making tradeoffs between various aging/failure mechanisms.

Minimum and maximum lifespan of monitors

(From: Bob Myers (myers@fc.hp.com).)

There's no way to set a "minimum" or "maximum" life, as there's quite a variation from unit to unit. Some small percentage will fail right out of the box ("infant mortality") while others will run happily for years. We normally speak of a mean, or average, life expectancy, as in "MTBF" ("mean time before failure"). In a CRT display, the CRT itself is usually the limiting factor in this, and in THAT specific case we usually speak of "mean time to half-bright" instead, since it's rare for a CRT to simply die once it's past its early operating life. (Excluding such things as mechanical damage and so forth, of course.) Mean-time-to-half-bright is just what it says: how long, on average, can you operate the tube before the brightness drops to half its initial level for a given set of operating conditions. (Brightness is ALWAYS slowing decreasing throughout the tube's life, due to the aging of the cathode and the phosphor.) For most tubes with standard cathodes, this will be in the neighborhood of 10K-15K hours (a little over a year to not quite two years of continuous operation).

Implications of power saving modes

(From: Bob Myers (myers@fc.hp.com).)

Energy Star and similar power-saving certifications generally don't specify what is done inside the monitor to achieve the power reduction, just the maximum power dissipation in the "reduced power" state(s). Still, most designs WILL either reduce the voltage to the filament, or shut it off completely, depending on the degree of power reduction needed for a given state.

Thermal stresses would be damaging to the heater and cathode if they happened significantly more often than the daily power-down (you DO turn you monitor off for the night, don't you?). The way to use these features properly is to NOT set up the system to enter the more reduced states ("suspend" and "off") until a reasonably long period has passed with no action. Use the "standby" state for the first level, the one you enter after a few minutes (10?) of inactivity, and don't go beyond that unless the system is inactive long enough to suggest thay you're going to be away for a while. But make sure that the system WILL get to the deepest level of power reduction supported - with the monitor as close to full off as you can get - when you're going to be away for a really long while, like overnight. Turning the monitor off overnight is the best thing you can do for it.

And no, I don't think these monitors will be that much more difficult to service, just because they've got power management. This is usually a fairly simple addition to the power supply, and doesn't really affect the complexity of the rest of the unit. But modern monitors DO tend to be more complicated anyway - what with digital controls, on-screen displays, etc. - and so are somewhat more difficult to repair. It just doesn't really have much to do with the power-saving bits.

Methods to prevent screen burn-in on fixed format monitors

When TVs or monitors are used to display the same pattern day in and day out, screen burn is likely to result. This may happen with TVs used extensively for video games and text display terminals - both situations where the format of the screen is relatively fixed. It is not likely with TVs under normal usage or monitors used with windowing systems (e.g., Win95, X-windows) where the display changes from time-to-time.

With TVs, your only options are to reduce the brightness or get the kids (you?) to participate in less mind numbing activities.

For monitors, here are three approaches (they can obviously be used together).

9. Blank or dim the screen or use a screen saver when not in use (won't prolong CRT life but will reduce possibility of burn-in).

10. Only set the brightness and contrast as high as needed for comfortable viewing. Subdued ambient illumination will allow these to be greatly reduced (and save energy as well!).

11. Randomize the display. On a text entry terminal, for example, the system could be set up to vary the position of the text on the screen by a small amount - a random number of pixels horizontally and scan lines vertically less than the character size. This could be done every time it is switched on or periodically. Of course, unless you are the designer or programmer, this option probably isn't very viable!

    There will always be some degradation of the phosphor even during normal use. With changing scenes, it will simply result in a long term darkening of the screen and reduction in maximum brightness (independent of the reduced mission from the electron guns). This effect is likely very slight but my advice is to keep contrast (peak whites) only as high as you need and turn the brightness down when not using the monitor for a few minutes. Also see the section: Monitor life, energy conservation, and laziness.

Monitors, heat, and cooling fans

Electronic equipment in general most often really likes to be kept cool. Up to a point, cooler is better. However, to save a few cents and to avoid complaints about noise, few monitors come equipped with internal cooling fans even though these could substantially reduce the internal temperature and may prolong a trouble free life.

Without a fan, there are still (possibly) simple steps that can be taken to keep the monitor happy:

- Keep the ambient temperature low. There is no need for the humans to freeze, but if you are uncomfortably warm, so is your monitor.

- Run the monitor at the minimum brightness for your needs. It is better for the monitor and energy conservation use lower ambient illumination and lower brightness. Stress on both the CRT and power supply components is reduced and the monitor will run cooler.

- When idle, use a screen blanker (or screen saver that displays a dark picture) or take advantage of any power saving modes that may be supported. As above, this will reduce stresses on the monitor's components and save energy as well. Of course, turn all the monitors off at night. See the section: Monitor life, energy conservation, and laziness.

- Make sure the monitor's ventilation holes are not covered or blocked in any way. There should be several inches of clearance on all sides, top, and bottom. Make sure dust doesn't collect - suck it out with a portable vacuum cleaner.

However, even if you follow these recommendations (or have no control over some aspects of your monitor's environment and operation), some monitors run excessively hot.

While I don't know of any controlled studies on this topic, anecdotal evidence suggests a substantial benefit to forced air cooling for some monitors.

It doesn't take much - even a CPU style 1.5 inch fan will make a noticeable difference in nearly total silence.

The best place to mount such a fan is probably on the plastic case in the vicinity of the high power components - power supply or horizontal deflection. Provide a hole and grill to match the fan. Orienting it to blow outward may be better for general cooling. However, it will be easier to cool specific parts if the fan blows in and with a filter, this will also reduce dust infiltration.

Power can be tapped from any convenient source which provides a voltage that is compatible with the fan. For example, a 12 VDC fan can run on anything from 8 V (or somewhat less) to 15 V or so with a corresponding variation in speed. The current used by such a fan is generally negligible so it shouldn't be a problem to find a source with enough excess capacity.

If you really want to be slick, add a circuit to adjust fan speed based on scan mode (higher scan modes->higher air flow) and/or temperature.

Why are prices of video monitors so high compared to similarly sized TVs?

> "How come I can buy a 32" Sony Trinitron TV set for $800, but when it comes to buying a monitor for my PC, $1400 only gets me a no-name 20" tube?
>
> Why can't a giant like Sony produce a PC monitor anywhere close in cost to an equivalently sized TV set?"

Well, the bottom line is that there isn't much in common between a TV and computer monitor when one gets down to the details. The basic principles of raster scan display apply to both and that is about it! Monitors would already be much more expensive if it weren't for the additional fact that many more TVs are manufactured and sold than monitors - which drives down their prices still further:

(Some of this from: Mike Stewart (mstewart@whale.st.usm.edu).)

There are several significant factors being overlooked here:

1. Economy of scale. There are still *many* more TV sets being sold than computer monitors. Manufacturers order TV chipsets in much larger quantities. This drives down the price.

2. Resolution. NTSC TV signals aren't even VGA resolution. Try getting that 32" Sony Trinitron XBR to give you 1280x1024. A computer monitor has a CRT with a resolution about 2 to 3 times that of a TV of similar size in both horizontal and vertical directions. The beam is also more sharply focused.

3. Refresh rates. NTSC TV signals come at one refresh rate, period. You either watch broadcast NTSC at 59.94Hz (interlaced), or you don't watch it at all. No nice, clean 72Hz NI display on there. (NOTE: This only refers to the 99+% of TV playback equipment that contains no line- doubling circuitry. That's fair, as you'll pay a good bit more for a non-interlaced, line-doubled NTSC picture than the previous poster was complaining about, anyway.)

   Therefore, a auto-scan monitor needs more sophisticated deflection and power supply circuitry. It must run at much higher scan rates and this complicates the circuitry as well.

4. Geometry. The precision of a good computer monitor is much greater then any TV. The sides will be parallel and square. Adjustments are provided to eliminate pincushion, keystone, and trapazoid distortions.

5. Stability. The image on a high quality computer monitor is rock solid and does not shift position or change size as components warm up, or the power line voltage fluctuates, etc.

(From: Bob Myers (myers@fc.hp.com).)

The basic reason for the cost difference between CRTs for computer and TV is that they are NOT the same product

AT ALL.

They do not share ANY major component. The glass is different (for one thing, computer tubes are still almost ALL 90 deg. deflection; TV glass is for 110-114 deg. deflection). The electron guns are different (different spot size vs. brightness tradeoff). The shadow masks are different (computer displays use a much finer dot pitch than the same size TV tube). Even the phosphors used are sometimes different. They are aimed at different markets, with different requirements, and so are completely separate designs. They most often are not even produced on the same production line.

Beyond the CRT, every other major part of the display design is different, mostly owing to the difference in horizontal rates required (~15.7 kHz for TV, vs. 30-85 kHz and often MUCH higher for computer displays) and the need for multifrequency operation in the computer market, combined with the need to hold to much tighter geometry, convergence, etc. specs at these higher rates.

In short, the only thing that's the same between a TV set and a computer monitor is that they're both boxes which make pictures on a glass screen. Sort of like the Queen Elizabeth II and the Exxon Valdez - yes, they're both big metal things that float in the ocean, but there's not really all THAT much in common between the two designs.

Why is the resolution of a computer monitor so much better than a TV

Of course, computer displays may run at resolutions of 1280 x 1024 or more. These are not limited by minor considerations such as channel bandwidth, and to a lesser extent, cost. These are separate issues from why a computer monitor display is so much better even when the number of scan lines is the same - as with NTSC versus basic VGA (640 x 480).

1. NTSC (525/30) is fundamentally limited by the bandwidth and color encoding of the composite video signal. This is the most significant factor limiting any possible display on a TV via the RF/cable/antenna, or composite or NTSC (direct A/V) inputs to perhaps half of VGA resolution horizontally.

   PAL (625/25) more closely matches an 800x600 SVGA format but still suffers from similar limitations in horizontal resolution.

2. Monitors are designed to provide sharp focus at the expense of brightness. TVs don't have great focus but produce brighter display. This limits both horizontal and vertical resolution.

3. Monitor CRTs are designed with much finer dot/line pitch in the shadow/slot mask or aperture grill - often better than 2:1 smaller than similar size TVs.

4. TVs use interlaced scanning. Jitter in the vertical also affects perceived display quality.

Where a TV/monitor has direct RGB inputs, the limitation is primarily due to (2) to (4) though they may not have the same high bandwidth circuitry as a more costly computer monitor.

There are other factors but these are the most important.

Combined TV and computer monitor

> "This is a 27" VGA monitor which should also be able to be used as an NTSC television monitor. Can anybody comment on it?"

IMO, I think the entire idea of a combined TV/computer monitor is silly especially when the likely cost premium is taken into account. Watching the boob tube will tie up your entire PC. The optimal size for TV and computer use is not the same nor are the requirements in terms of scan rate, resolution, brightness, and sharpness. Thus, the design will be inherently more expensive and include more compromises.

So, I will probably be proved wrong by record sales of these things...

Problems with designing a combination TV and computer monitor

(From: Bob Myers (myers@fc.hp.com).)

It's possible, and has been done (for instance, Toshiba has one product and offerings from other companies are available or are on the way). But such designs ARE compromises, and won't give the best performance possible in either application.

There is a fundamental difference between CRTs designed for TV use, and those used in computer monitors. It's a brightness/resolution tradeoff - TV tubes are run about 3X or so the brightness of a typical computer monitor, but sacrifice the ability to use small spot sizes and fine dot pitches to do this. You don't see very many color tubes running at 100 - 150 fL brightness and still using an 0.28 mm pitch!

So, what about truly digital monitors?

The following issue is distinct from that of flat-panel technology which of course is rapidly replacing the CRT in computer monitors.

> "I am really interested in this Digital Revolution (DVD, HD-TV) but what about PC monitors? Wouldn't it be great to have a monitor that was also compatible with HD-TV? I want to buy a new 17" or 19" but I don't want to invest in CRT (analog technology), when will Digital PC Monitors be coming out?"

(From: Bob Myers (myers@fc.hp.com).)

Being compatible with HDTV just means having the right front end to interpret the signals, just as using NTSC video on a current computer monitor requires a decoder. I seriously doubt that we'll see computer displays which are DIRECTLY capable of handling the HDTV data stream.

Having said that, there is ALREADY a standard for a digital display interface, which was approved by VESA last year. The new "Plug & Display" interface standard supports BOTH digital and analog video outputs on a single standard connector, enabling monitors with either sort of interface to be easily supported. (The host uses ID information from the monitor - already a standard feature of most CRT displays - to decide which interface to use and how to configure it for a given monitor.) There are already products on the market (a few) or in development using the new interface.

Having said THAT, don't count the CRT monitor out just yet; it'll probably be with us for some time yet, and there's little reason to use a digital interface for a CRT-based display (since, under the new standard, you're going to have BOTH flavors of interface available anyway). Actually, there is very little inherent advantage for MOST display technologies in the interface itself being "digital" (even LCDs are "analog" at the pixel level); the problems most non-CRT displays have today with "analog" video have to do with getting a good TIMING reference with which to sample the video, NOT with whether that video is encoded in digital or analog form.

About sync polarity options

Many video cards provide polarity options for each scan mode. Why?

Probably to be compatible with older monitors. Most modern monitors are auto polarity detecting so the settings should not matter.

(Note that some of the digital PC video standard did have specific sync polarity specifications.)

Some software programs that directly access the video card may even be changing sync polarity - for apparently no reason - without you being aware of it.

Your video card determines the maximum video rate you can generate. The monitor has to be able to lock to it. So, if you cannot setup higher than some specified rate (i.e., the options do not exist in your menu), it is a function of the video card and drivers. If you can set it but the monitor displays garbage or nothing at all, it is a limitation of the monitor. The sync polarity rarely makes any difference and if it does, the effects will be obvious - picture shifted left/right/up/down on screen - or just won't sync at all.

If you experience problems of this type, experimenting with the sync polarity may be instructive.

If you do not know what your monitor wants and you have the option, set both horizontal and vertical sync polarities to be negative as this is nearly always acceptable (for studio video and VGA/SVGA monitors).

(From: Bob Myers (myers@fc.hp.com).)

This was used in older systems to identify certain display modes, but in general modern monitors accept either polarity equally well. Recent display timing standards have all been written specifying positive-polarity sync (the sync pulse is at logical "1" rather than "0"), but the use of negative polarity usually won't do anything except possibly cause the image to be off-center by the width of the sync pulse.

VESA Display Data Channel standard

(From: Bob Myers (myers@fc.hp.com).)

This defined several protocols for digital communications between a host system and its display. DDC provides 3 different modes:

```
DDC1 - A unidirectional (display to host only) serial communications system
         which provides basic display ID and feature support information
         (including supported timings, display size, colorimetry and gamma,
         etc.) to the host.  This uses pin 12 on the 15-pin "VGA" connector as
         a data line.

DDC2B - Adds clock (pin 15) and return (pin 11, I think - I'm at home, and
         don't have the standard with me) to enable at least ID information to
         be obtained via an I2C interface.  I2C is a bidirectional interface,
         but display control via DDC2B is not defined at this time.

DDC2AB - Full ID and control of the monitor via ACCESS.bus.  As ACCESS.bus is
         basically a command and protocol definition on top of the I2C
         hardware interface, this uses the same lines as DDC2B.
```

DDC was the first and only definition of the 15-pin D-subminiature video output connector which VESA has provided. No further definitions on this connector will be made, as VESA is instead concentrating on the new

Enhanced Video Connector standard which is due out later this year. This will define a completely new connector which will include support for DDC and separate syncs as in the 15-pin D-sub, and will also include support for audio I/O, video input, and the USB and P1394 serial interfaces.

Identifying connections on unknown or cut monitor cables

Obviously, this is best done with a schematic. However, since such a luxury may not be possible, how can you go about figuring out where all the wires go? Easy answer - very carefully.

For the following, I assume a VGA/SVGA monitor. You need to identify the grounds, video signals, H and V sync, and monitor sense lines. The procedure is described with respec to a cut cable but if you are trying to identify an unknown connector type on the monitor, the same comments apply to the wiring **inside** the monitor.

First identify the grounds. Use an ohmmeter between each wire and the shell of the video connector on the monitor. Resistance will be less than an ohm for the ground wires. These will often be colored black. The shields of the RGB coaxes will also be connected to ground.

The high bandwidth video signals will always use individual coaxial cables. These may even be color coded red, green, and blue. If not, you can determine which is which later on. If there are only three such coaxes, they are the video signals. If there are four, the extra one may be the H sync. If there are five, the extra two may be the H and V syncs. Testing between these wires and ground with an ohmmeter should measure 75 ohms for the video terminations.

Display a lively screen on your PC at a resolution you know the monitor should support (remember, trying to drive a monitor of unknown scan rate specifications beyond its ratings is like playing Russian Roulette.) When in doubt, VGA (640x480, 31.4 kHz H, 60 Hz V) should be safe.

Turn up the brightness and contrast on the monitor. If you are lucky, even without any sync, there will be a visible raster. Set it to be just visible. If there is none, then it should appear once there is valid sync.

You will need to bring out wires from the video connector on your PC.

Connect the ground of your video card to the ground wires you already identified on the monitor cable.

Attach a wire in series with a 200-500 ohm resistor to H sync (pin 13) on the VGA connector.

Momentarily touch the end of this wire to each of the remaining unidentified wires (including the coaxes if you have 4 or 5 of these and it is not obvious which are the video signals) on the monitor. When you find the H sync input, the raster should lock in and probably brighten up. If the monitor was originally whining due to lack of sync, it should quiet down.

Once you have located H sync, you can remove the resistor and connect the wire up directly.

Now, attach the video signals. It is likely that you will now have a picture but it will be rolling on the screen. Some monitors, however, will not unblank until they receive both valid H and V sync. Use your resistor with the V sync output of the video card (Pin 14) on the remaining unidentified wires. Once you find the V sync input, the display should lock in solid.

The only remaining unknowns are the monitor sense lines. For older monitors - those without the ACCESS.bus interface, you can just wire up the sense lines to the appropriate levels (Color: ID0 (Pin 11) to ground, ID1 (Pin 12) NC).

See the document "Pinouts for various connectors in Real Life(tm)" for detailed hookup information". Replacement

VGA connectors are readily available.

Also see the section: Replacing the cable on an HP D1182A monitor for some hints and helpful 'hassle savers(tm)'.

Replacing monitor cables or connectors

Many intermittent or erratic loss of color or loss of sync problems are due to a bad cable - more specifically, bad connections usually between the male pins and the wires. Or, perhaps, one or more pins were accidentally broken off as a result of the connector being forced in the wrong way around.

Unfortunately, it is all too likely - particularly with newer monitors - that the shell is molded on and impossible to non-destructively remove to access the connector for wire repair or pin replacement.

You have several options:

- For name brand monitors, entire replacement cables may be available. These will be pricey ($25 to $50 typical) but are by far the easiest solution.
- The connector itself can be replaced. Places like MCM Electronics stock VGA (HD15) male connectors and pins. These may be either solder or crimp type (both can actually be soldered if you work at it). It takes a steady hand, bright light, and patience to solder the fine wires to the tiny pins. A crimp tool is probably not worth the investment for a single repair.
- If you can locate a dead monitor with a good VGA cable still attached, it is possible to cut and splice the wires away from the connector. Use an ohmmeter to identify which signal pin connects to which color coded wire on each cable and then solder and tape the individual wires. It won't be pretty but should work reasonable well.

Replacing the cable on an HP D1182A monitor

(From: Marion D. Kitchens (jkitchen@erols.com).)

By following the procedure in the section: Identifying connections on unknown or cut monitor cables, I was able to get a D-15 correctly connected on the ends of an HP D1182A monitor's video cable. This was a monitor that came to me with the D-15 missing. The only remaining unknown is the brown wire but the monitor seems to work fine without it (however, see below).

Cable Wire	Internal Pin #	Function	Resistance	D-15 Pin	Notes
White Coax	5,4	Red Video	75	1,6	shield is 6
Black Coax	3,1	Green Video	75	2,7	shield is 7
Red Coax	7,6	Blue Video	75	3,8	shield is 8
Red	8	Gnd	0	10	red & blue are
Blue	9	V. sync	1K	14	twisted pair
Yellow	10	Gnd	0	10	yellow & clear are
Clear	11	H. Sync	500	13	twisted pair
Brown	12	ID0??	Infinite	11??	Works OK w/o

Internal pin numbers refer to a 12 pin, in-line connector inside the monitor. It is mounted on a circuit board (model XC-1429U printed on board) that is mounted on the neck of the CTR. There are 12 pins, but one is blank -- nothing connected. I have called that one pin # 2 for reference, and the pin furthermost away I called pin #12. Double numbers mean the first is connected to the coax center conductor, and the second is the coax shield.

The double numbered pins under D-15 above mean connect the center conductor of the coax to the first pin number, and the coax shield to the second pin number. All the coax shields should measure zero Ohms to ground, and all the center conductors should measure about 75 Ohms to ground. Ground is the outer shield of the video cable, which is connected to the D-15 connector shell when doing the wiring job.

Pins 5 & 10 are also listed as ground connections on the D-15 connector. I suspect these are for the H. sync & V. sync, but do not know that for a fact. I connected what I believe to be both ground returns (per the twisted pairs show above) to pin 10.

The currently unconnected brown wire does have a signal of some sort on it. At least when trying to find the H. sync and V. sync wires, I got screen reactions if I connected it to some pins on the D-15 connector. Since it was the only "left over" wire when I got H. sync & V. sync correct, I suspect it to be the ID0 wire. Yes? No? Maybe? Nothing seems to happen when I connect it to D-15 pin #11. The monitor SEEMS to be OK without the brown wire connected to anything (but the color balance is a bit off, green and blue OK, but red is a pale pink). An Ohmmeter connected between ground and the brown wire "acts like" it is charging a capacitor -- resistance starts low and increases with time to several 10's of Meg. Is that a clue?

As an aid in finding the correct wiring connections I make a special floppy. It is a bootable floppy for use in the A: drive. Boot the computer from that floppy. First format a system floppy for the A: drive. Then copy the ANSI.SYS file from your C:\DOS\ files to the floppy. Next write a CONGIF.SYS file to the floppy, containing one line --- DEVICE=A:\ANSI.SYS Now write three batch files to the floppy, one for each color.

```
RED.BAT file
  PROMPT  $p$g$e[41m
  CLS

GREEN.BAT
  PROMPT  $p$g$e[42m
  CLS

BLUE.BAT
  PROMPT  $p$g$e[44m
  CLS
```

In trying to find the H. sync and V. sync, I found it most helpful to use the following procedure.

1. Connect all of the ground wires, and one of the coax center conductors (any one at random) to D-15 pin #1.

2. Boot the computer from the above floppy. Watch the drive light to determine when the boot process is completed. Hit RETURN twice to get past the new time and date that it asks for.

3. Turn on the monitor, and type RED to run the red batch file.

4. Now follow the procedure in the section: Identifying connections on unknown or cut monitor cables to find the H & V sync wires. When you have them correct you should see a colored screen (it might be red, green, or blue) and two "A:>" prompts on screen. Make sure the brightness control is set for maximum brightness, and that contrast is high.

5. Once you have a readable screen, find the correct coax to produce a red screen when connected to D-15 pin #1. Then type GREEN to run the green batch file, and find the correct coax to produce a green screen. The remaining coax is, of course, the blue video. But verify that anyway by typing BLUE to run the blue batch file.

6. Now you should be able to get red, green, and blue screens buy running the respective batch files.

To aid in the trial and error process of finding all the correct wiring, I made a small (3 by 4 inch) PCB with 15 connection points and a large grounding point, and mounted a D-15 connector on one edge. The 15 copper traces were wired to the D-15 connector so that pin numbers 1 through 15 followed a simple series across one edge of the PCB. The 15 traces were about 1/4 by 1 inch to make life easy. I even soldered 220 Ohm resistors to pin numbers 13 & 14 on the board to make that easy too. With this "aid" I used a video extension cable to bring my working point to the front of the test bench, and had plenty of working room for all those trial and error connections. Yes, I do like 'hassle savers(tm)'!

How can I determine monitor specifications or whether it supports SVGA?

There is no easy way to tell by just examining the monitor visually. Even those with only a 9 pin rather than a 15 pin connector are sometimes SVGA (e.g., Mitsubishi AUM1381 and NEC Multisync II which will do 800x600 at 56 Hz V non-interlaced and 1024x768 interlaced at 43 Hz V).

You cannot even safety test scan rates on all monitors - some (mostly older ones) will blow up or be damaged by being driven with incorrect video.

For a monitor that you already have, looking it up in a monitor database is really the only way to be sure of its capabilities (well, pretty sure - these listings are not always correct!). See the section: Web sites with monitor specifications for on-line resources. If this doesn't help, you try posting the information you have (model number, FCC code, etc.) to the newsgroups: comp.sys.ibm.pc.hardware.video and sci.electronics.repair. Where none of this is production, here are some quickie tests:

1. Check the video connector. If it has a high density (VGA) 15 pin connector then there is a greater likelihood of SVGA but not always.

2. Check the manufacturing date on the back. If it has a manufacturing date of 1991 or later, the likelihood of it supporting SVGA is higher as demand for VGA-only monitors was rapidly declining by this point.

3. Check the dot pitch on the CRT by examining the screen with a magnifier. If it is really coarse, the monitor probably cannot do anything beyond VGA.

4. Become familier with the major manufacturers and models so that you will recognize the common SVGA models.

5. Check the databases listed in the section: Web sites with monitor specifications.

While not conclusive, positive results on the first 3 of these tests definitely increases the likelihood that it supports at least some SVGA modes. Of course, if you recognize a model number, you have dramatically increased your odds of success - assuming it works!

From: Adrian Kwong (a.kwong@ieee.ca).)

Most new monitors employ frequency protection. The symptom that you will typically see is, a complete lack of video. Most monitors with multicolored power LED's, usually change color to indicate an error. Some monitors like Nokia's, will flash the screen on and off (black and white) to indicate that the over-frequency protection circuits have been activated.

I have blown a few monitors by setting the video resolutions either too high, or setting the vertical refresh to something that puts the horizontal frequency waaay above the rated specifications.

I actually have no idea how some of these monitors actually received a UL or CSA approval stamp, as I have seen some of these monitors catch on fire. Most of the 'blow outs', were just capacitors that exploded and about a room full of smoke fills the vicinity.

All of the monitors that I blew up, were really old monitors with no frequency protection.

Is CRT replacement worth it?

The sad fact is that even if you can obtain a new CRT you won't have the proper set up for getting proper alignment and convergence. They generally use various permanent magnet glued to the perimeter of the yoke to set the geometry of the raster. It takes a special factory jig to do this step or really great persistence and patience. However, if you have the time and will resist punching a hole in the new CRT before you finish, by all means.

Also, consider the cost of a new CRT may be more than half the cost of the monitor when it was new.

Replacing a monochrome CRT is a snap in comparison.

A better (or at least less stressful) approach is to locate a monitor that died due to a circuit problem and salvage the CRT including the yoke and all the other magical magnets and coils.

(From: Andy Cuffe (baltimora@psu.edu).)

I have found that most 15" monitors use compatible CRTs. I just put the CRT from an old Gateway2000 with analog controls into a nice 2 year old monitor. As long as the yokes and CRT sockets are similar it should work fine. Don't try to swap the yokes or you will never get it converged.

An informal history of X-ray protection

(The following is from: Marty).

Most of the old tube type color TV sets used a shunt HV regulator tube, usually a 6BK4. If it failed, or some component in the HV circuit failed, the high voltage, normally 25 kV, could go up to 35kV or more, causing some X-Ray leakage from the CRT. In the early 70s when news of this radiation scare was first announced, there was a public outcry to immediately fix the problem. The Feds hastily imposed a requirement on manufacturers of TV sets to somehow render a TV set "unwatchable" if the HV exceeded rated limits.

The manufacturers first response was to follow the letter of the law and the first "HEW" circuit simply blanked the video when the HV exceeded a setpoint to make the set "unwatchable".

It was quickly noticed that the HV was not turned off with this circuit and the CRT still could emit some radiation. Many TV sets with this feature were left on so the consumer could listen to the sound, so the feds tightened the requirement.

By this time new TV sets were all solid state and some manufacturers experimented with HV shutdown circuits, but most of these circuits were poorly designed and not reliable.

Zenith thought they had the answer by regulating the HV with a bank of 5 capacitors across the horizontal output transistor to "hold down" the HV to 25kV. If one capacitor opened, the HV would only rise about 2kV, not a dangerous situation. This wasn't good enough for the feds.

The "fix" that Zenith finally came out with, was a "4 legged capacitor. Two legs were the emitter return for the horizontal output transistor, & two legs were the HV holddown capacitor (the equivalent value of the bank of 5 caps). This "fix" was accepted by HEW and millions of TVs were produced. It worked so well, that other manufacturers soon followed the lead (Magnavox, GE, etc.).

Then the worst happened! The 4 legged monsters started failing in a large numbers. Not opening completely & not shorting out. They sometimes allowed the HV to skyrocket to over 50kV. Some of them even cut the necks off of the CRTs.

Zenith issued a recall on those models with the problem (more than one entire model year). After several "improved" versions of the capacitor, the problem was fixed but that recall almost bankrupted the company. Other companies had failures too, but usually not as dramatic as Zenith's.

Magnavox used the HV holddown capacitor, both single & 4 leg version in several 70s era TV sets and is a good candidate for fireworks as well.

Turning a TV (or monitor) into an oscilloscope?

This question comes up so often and it does sound like a neat project to give a defunct TV a second life. Don't expect to end up with a Tek 465 on the cheap when you are done. However, it could be a fun learning experience.

CAUTION: See the safety recommendations below.

You will be severely limited in the performance of such a scope. TVs and monitors are designed to operate at a very narrow range of horizontal scan rates and the high voltage is usually derived from the horizontal deflection. So, you would need to retain the original deflection system for this purpose at least.

1. You will need to disconnect the defection yoke from the horizontal and vertical deflection circuits of the TV or monitor without killing the HV. (also, doing all this without killing yourself as well). Depending on the design, this may be as simple as unplugging the yoke connector. More than likely, you will need to substitute a load for the horizontal deflection coil. A coil from another sacrificial similar TV or monitor would probably suffice.

Warning: at this point you have a really bright spot in the middle of the screen which will turn to a really black spot if the brightness is not turned way down really really quickly.

2. For the horizontal, you need a ramped current source. You are driving a non-ideal inductor (the deflection coil) so it has both inductance and resistance. Thus the waveform is a trapezoid - a voltage ramp (for the resistive part) superimposed on a voltage step (for the inductive part). This should not be too difficult. Don't expect to be able to achieve really fast sweep. Even running at normal TV rates is non-trivial.

3. Similarly, for the vertical you need to drive with a voltage (your signal) controlled current source. However, if you just screwing around, then the linearity etc. for the vertical may not be that important. In this case, one way is to put a current sensing resistor in series with the deflection coil and use this in a power op amp type of feedback arrangement. (You could do this for (2) as well.

4. There is a good chance that the original brightness control will work as an intensity adjustment. However, with some TVs and monitors, this depends on receiving a valid video signal. You may need to improvise. If you do want to control the intensity from a signal source, you should be able to tap into the drive signals going to the little board on the neck of the CRT.

5. Don't expect high bandwidth, uniform response, or any of the other things you take for granted with a decent scope. That takes work. However, as a fun project, this certainly qualifies. Interchanging the functions of the

horizontal and vertical deflection yoke (and rotating it 90 degrees) may provide a better match of horizontal and vertical bandwidth to your intended applications or experiments.

6. With a color TV or monitor, these experiments could be quite interesting and educational but there may be color fringing effects since you are not compensating for certain aspects of dynamic convergence at all.

7. SAFETY: Once you disconnect the deflection yoke from the TV or monitor's circuits, move the original circuits out of the way and put a barrier between between you and the rest of the TV or monitor. All you will need are connections to the deflection yoke on the CRT (unless you want to do intensity modulation in which case you will need to drive the video output(s) to the CRT cathodes. I would recommend against doing this if your unit is one of those with a totally 'live' chassis as there would be additional safety hazards and circuit complications).

(From: Lance Edmonds (lanceedmonds@xtra.co.nz).

Some years ago ELEKTOR and Electronics Australia magazines published articles on a design for this. Dick Smith Electronics in both NZ & Australia used to sell the kit.

Max Bandwidth was a startling 10 or 15Khz. Enough for elementary audio servicing.

Those magazines also published designs for delayed sweep & trigger modules as additions to any basic 'scope. Plus, a storage scope design, logic analyzer design, and a Dual trace emulator design.

Enough to keep the average hobbist/experimenter happy for quite a while (g).

(From: Dale H. Cook (dhcook@rev.net).)

Every few months someone will pop up with this question. A TV would not make a very good scope. Bandwidth would be limited and the amount of work needed to build the horizontal and vertical amplifiers, sweep and triggering circuits and so on wouldn't be worth the effort. You'd need even more work to add modern features such as delayed triggering and variable hold-off. Don't even think about multiple channels and the advantages they offer. In a time when I see used Tek 465s offered for $200 it certainly doesn't pay to try to convert a TV. If you are just looking for a challenging electronic project I can think of several that have a far better chance of yielding something useful. Now, if you were starting with an antique set that used an electrostatic CRT you might do a bit better, but a 1937 Dumont will set you back about $3,000.00 or so - a little too much of an investment.

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

I've worked on the vector monitors that were used on some of the 1970's minicomputers. These are essentially X-Y displays (not raster scanned), and would make audio-bandwidth 'scopes if given a timebase. I would guess at a bandwidth of the order of 100kHz.

Some of them (DEC, certainly, maybe Tektronix) were electromagnetically deflected like a TV. However, there are a couple of things to be aware of. Firstly, the output amplifier, which drives the yoke at constant current, is pretty complex. Secondly, the yoke is specially made - the 2 sets of coils are pretty similar (unlike those in a TV), and the inductance is critical.

So, while I'll keep these monitors running, I'd not want to have to covert a TV into one :-).

(From: David Katz (DAVEkATZ@prodigy.net).)

If by chance what you want is an X-Y display for audio, not a (more typical) X-T, it's easy. Just put a resistor in series with each yoke (about 100 ohms, 5 W) and drive them with a stereo amp.

(From: Steve Roberts (osteven@akrobiz.com).)

Your best hope might be to get a older generation heart monitor from a hospital, these have a professional X-Y display module to begin with, and are surprisingly easy to hack, mine was $10 at the local surplus shop. The ultra long persistence phosphor is a pain/blessing depending on what you are doing.

For a description of what one person did, see: Dan's Home-Built O-Scope Page.

(From: Alan (revidyks@rocketmail.com).)

Apparently it's pretty hard to produce a decent scope.

It is, however, pretty easy to use the CRT as something like a scope, which I did recently with the built-in green screen monitor of a thing called a Kapro 2X. It was being thrown away, so I said I'd take it and have a look inside before throwing it away.

I wondered what if it was possible to drive the CRT from a source other than the computer video circuitry, so I did some tests, worked out how and by what voltage the deflectors were driven, (about 1v, 0.3A measured as an AC voltage).

Once I'd worked out that this was about the same as the output from a small stereo amp, I removed the horizontal signal from the CRT and hooked one channel of my stereo across the horizontal deflector , left the vertical deflector hooked up to it's (60Hz?, 30Hz?) signal, and switched it on. The results look pretty good, I get a full-screen moving trace of the sound wave. One other thing that I did was make the beam intensity constant by turning a knob marked 'B-SUB' a bit, this would have flooded the screen with 'white' ordinarily, but was perfect for me as I could now remove the computer motherboard all together.

I also tried connecting the left and right channels across the horizontal and vertical deflectors respectively (first disconnecting them from their normal inputs), which produced some really cool looking lissijous (sp?) figure type things, that change and throb with the music- each CD seemed to have distinctive characteristics. Maybe I'll try two different pieces of music across the axes, could be interesting...

I'd love to try throwing some different signals of different frequencies and shapes across the axes too, especially in combination a with musical one. The 'best' results so far, have been from music with a strong bass, simple beat (cymbals with a bass drum look great), and not too many layers of guitars, vocals, etc. (too many sounds and it's an uninteresting mess...)

If you want more information or have any advice on or experience with this sort of thing, mail me...

If you're thinking of trying any of this, remember (in case you don't know) that TVs/Monitors can be REALLY dangerous even when switched off and unplugged. See the section: SAFETY.

Displaying a video signal as a picture on an oscilloscope

I am not sure why anyone would really want to do this other than as an experiment - it would be interesting one.

If a composite video signal is the input, you will need a sync separator. For VGA, the sync signals are already available.

You will have to construct a vertical deflection voltage ramp generator which can be locked to your vertical sync signal.

The horizontal timebase of the scope will be fine for the horizontal deflection and should easily lock to your horizontal sync pulse or (if the scope has a TV trigger mode) directly to the video signal.

A video amplifier will be needed if your Z axis does not have an internal amplifier (you need .7 V p-p to be full brightness range.) Unless you provide automatic gain control, this will need to include offset (brightness) and gain (contrast) adjustments. Even if there is an internal amplifier, it may not have the required bandwidth for the video signal.

However, the overall brightness may be disappointing - a scope is not designed for overall high brightness. The beam focus will not be as good as that on a little TV either.

Could a monitor be modified for 3D (stereo) display?

The whole idea of stereo 3-D vision to put the left and right views to the appropriate eyeball. There are two common ways of doing this:

1. Use different colors for the two views with color filters in from of each eye to separate the views. This is what were often used for the really bad (content wise) sci-fi movies of the '50s.

2. Display alternate views on the same monitor screen but use LCD shutter glasses to allow each eye to only see the appropriate view. This requires increasing the refresh rate to avoid unacceptable flicker.

The first approach can be used with any TV and a pair of monochrome video cameras. Of course, true color cannot be used since pure colored images are needed to separate the stereo views.

Alternating views with synchronized LCD glasses is a possibility but and has been used commercially but requires special hardware to synchronize to the computer's video card. Best results are obtained with refresh rates of at least 120 Hz permitting 60 full left-right frames per second. If you try to this with a regular TV or CGA monitor, the resulting refresh rate would be 30 Hz with a 50% duty cycle which is likely to be useful only as a short experiment - else your viewers will likely develop splitting headaches.

Should I use a VGA to BNC cable if my monitor has BNC connectors?

(The following assumes a normal video card with a mini-DB15 VGA/SVGA connector - if yours has BNC connectors, the improvement may be even greater.)

The answer is an unqualified maybe. In principle, the BNC cable should have higher bandwidth and better transmission line characteristics (impedance, termination) and result in sharper crisper images with less ghosting, ringing, and other artifacts. However, this will only likely be significant at higher refresh rates (1024x768 at 75 Hz and beyond) and depending on your monitor and video card, you may see no change - or it may even get worse. It is best to purchase a good quality VGA to 5-BNC cable with a return privilage and try it. I suggest a 5-BNC cable even if you only need 3 or 4 connectors so that it will be compatible with any monitor or video card you might have in the future. Cost should be in the $25 to $70 range.

Potential advantages of using the BNC connector inputs on your monitor with a good quality cable are:

- higher video bandwidth -> sharper display.
- proper connectors (at one end, at least) and correct termination implies less ghosting and ringing.

For a good monitor with a high quality video card, the difference can be dramatic - as is the case with my ATI GPT and NEC 5FG.

(From Bob Myers (myers@fc.hp.com).)

However, one should also note that connecting via BNCs generally disables monitor "plug 'n' play" features, since these are based on ID information conveyed on dedicated pins (using the VESA DDC & EDID standards) on the 15-pin "VGA" connector.

As of last year, a new connector standard - the VESA Enhanced Video Connector, or EVC - has been released, which will provide both greatly improved video signal performance AND support for DDC and a number of other features.

Most current monitors comply with the VESA Display Data Channel (DDC) standard which provides a path and protocol for getting some basic ID information (model, manufacturer, supported timings, chromaticites, etc.) back from the monitor. Under that standard, the following new signals have been added to the DB-15 connector:

```
        Pin 9:  +5 VDC from host
        Pin 12: Serial data
        Pin 15: Data clock
```

Pin 10 (the old sync return pin) now does double duty as the return/reference for DDC. The DDC system uses the I2C spec for one level of implementation, although a base level is also provided in which the data is clocked back from the display by the vertical sync pulse.

The old 4-line ID scheme using pins 4, 11, 12, & 15 is obsolete. I can't think of too many hosts, or ANY monitors, still using it.

Additional information on the EVC standard is available from the VESA web site, http://www.vesa.org.

And one manufacturer's way around the preceeding:

(From: Russ Smith (smith@ur-guh.com).)

The Nanao F2-21 I'm using is connected via 5 split-out BNCs on its end; on the OTHER end is the standard VGA connector - that connector plugs into not the video card, but a little "black box" which performs the plug-n-play identification. That little widget plugs into the PnP-compatible video card (Matrox Millenium).

Thus, even though BNCs are used at the monitor end and the monitor itself can't communicate anything useful, the information is none-the-less communicated.

A hack that works.

Building a 5 BNC cable

This is straightforward, if time consuming and tedious.

The five coaxial cables (75 ohm, RG59 typical) are wired as shown in the table. The corresponding VGA connector pin numbers are in ().

```
     Coax Center         Coax Shield
  --------------------------------------
    Red Video  (1)      Red Return (6)
    Green Video  (2)    Green Return (7)
```

```
Blue Video  (3)     Blue Return (8)
H Sync (13)         Ground (5,10)
V Sync (14)         Ground (5,10)
```

Tie pin 11 (ID0) to Ground to indicate a color monitor. Leave pin 12 (ID1) open.

Make sure that the lengths of the cables are fairly well matched - to within a couple of inches - to assure that the 3 color channels line up precisely. (One foot of cable is about 1.5 to 2 ns of delay which is significant for a 10 ns dot clock!).

Also note (see the other sections on BNC cables) that you will lose your Plug and Play capabilities without the direct control connections to the monitor (or for monitors without these featuers).

That's it!

You will wish that your fingers were about 10 times smaller than they are, however. :-)

Using a workstation monitor on a PC

These are nearly always fixed frequency monitors with a scan rate that is not compatible with typical SVGA cards.

They may have a special connector like a 13W3 or 3, 4, or 5 BNC connectors. Some have a non-standard connector.

While these normally use standard analog video signal levels, you have a couple of problems out of the starting gate:

1. The fixed scanning frequencies of most of these monitors are not directly compatible with typical SVGA standards. Many high end boards like the ATI ProTurbo can scan at 1280x1024 probably at an appropriate refresh (horizontal is going to be the critical one) rate. Also, boards that allow software adjustment of size (like the ATI) are in effect changing scan rates as well so that gives another degree or two of freedom.

   However, many typical video cards do not provide this degree of flexibility.

2. The monitor needs sync-on-green (3 BNC connectors), composite H and V sync (4 BNC connectors and 13W3) or at least a VGA to BNC adapter cable (5 BNC connectors). Your VGA card normally puts out separate syncs.

   Many video cards have a software mode (probably accessible in the setup program) to enable composite sync output so for these at least there is no problem with a 4 BNC monitor.

   You can build a circuit to generate the required video for a 3 BNC monitor if you are so inclined. See the "Sync on Green FAQ" for detailed information and schematics.

3. What you do for booting since the default will be VGA (at least for DOS/Windows. If you only use your PC at one fixed high resolution, than this may not be that much of a problem..

There are specialized boards that will emulate standard VGA/SVGA modes using a fixed frequency monitor. For more information, see the document: Notes on Approaches to using Fixed Frequency or Non-Standard Monitors on PCs.

Tweaking the deflection rate of a fixed frequency or non-standard monitor

Pulling a fixed frequency monitor by more than a few percent will likely be a problem. I know this is not the answer you were looking for but getting a new inexpensive video card may be a better solution.

Other types of monitors - XGA for example - may be variable or multiple frequency but incompatible with VGA/SVGA. Some adjustment may be possible but how far you can go will depend on many factors.

If not, you are looking for an adjustment called horizontal oscillator, horizontal frequency, or horizontal hold. If you do tweak, mark everything beforehand just in case you need to get back to the original settings.

There is a slight risk of damage, particularly when lowering the horizontal rate as this increases peak current to the horizontal output transistor. This may result in immediate failure or more stress on components resulting in failure down the road. I have no idea with your monitor.

An alternative that may be possible is to use the setup or install program that came with your video card to decrease horizontal size and then adjust vertical size if needed. This would best be done while monitoring with a scope or multiscan monitor. A byproduct of software adjustments to size will often be a change in the scan rate of a few percent which may completely cover what you need. The reason this may work is that these adjustments vary the length of the H and V video back-porch which affect the total scan time.

I know I can do this with my ATI cards.

Also see the document: Approaches to Using Fixed Frequency or Non-Standard Monitors on PCs which includes a specific modification to permit an IBM9517 XGA monitor to be used at VGA/SVGA scan rates.

Displaying TV on a computer monitor

My general recommendation is that if you have the space, buy an inexpensive TV - the quality in the end may in fact be better. And, it will be usable without tying up your expensive monitor and (maybe) PC.

Some older monitors like the Mitsubishi AUM1381 and Emerson CGA (which also has a speaker) include a composite NTSC input jack requiring only a baseband video source like a VCR. These do produce a very nice picture. However, most newer auto-scan VGA/SVGA monitors do not go to low enough horizontal scan rates. To display NTSC or PAL on these requires a scan convertor (likely to be very expensive) or at least a scan doubler (less expensive but not as good).

For the case of older monitors with digital (TTL) inputs, see the section: Modifying a CGA (or EGA) monitor for NTSC or PAL input.

You can also buy video input cards complete with tuners ('PCTV') which will put TV into a window and allow you to idle away the time you are supposed to be working while watching 'Mork and Mindy'.

While various convertors are advertized to use a computer monitor with video from a VCR or other source, keep in mind that if it sounds too good to be true, it probably is like the claim of a $200 box for this:

OK, let me get this straight - this card/box will enable a 31.4 kHz horizontal scan rate monitor (VGA) be used as a TV - yes or no? It thus includes a video A/D, full screen frame buffer, D/A, and all the other tuner stuff for under $200? I don't think so. A scan doubler - which is a subset of the above - will not result in a high quality picture since it will display pairs of lines interleaved or leave alternate lines blanked reducing brightness. Or does the impressive advertisement leave out the key requirement that the monitor sync at the NTSC horizontal scan rate of 15.734 kHz (most newer monitor do not)? Or is it a board that plugs into a PC and indeed does use the resources of the PC including the VGA card and bus?

In any case, get a written money back satisfaction guarantee.

Modifying a CGA (or EGA) monitor for NTSC or PAL input

These are often high quality monitors and would make nice TV displays - especially as there are many no doubt gathering dust on their way to the dumpster!

However, these are digital (TTL) monitors with respect to the video inputs and proper linear video amplifiers may not even be present. Therefore, you may need to implement both the NTSC or PAL decoding as well as boosting the signal levels to the hundred volts or so needed to drive the CRT.

The scan rate of CGA is the same as NTSC so deflection is not a problem.

For PAL (625/50) instead of NTSC, the vertical rate will need to be reduced to 50 Hz but this should not be a problem. The horizontal scan rate is close enough (15.625 kHz).

Similar comments apply to EGA monitors that have a compatible scan rate. EGA represents a range of scan rates between 15.75 kHz and 21.85 kHz so this should not be a problem.

Picture instability of computer monitor used to watch videos

Assuming you have one of those older computer monitors that syncs to TV scan rates (NTSC/PAL/SECAM/whatever) or have found some other way to adapt your monitor to TV signals, you may find that when attempting to use it with a VCR, there is a bending or jittering at the top of the picture.

(From: Jeroen H. Stessen (Jeroen.Stessen@philips.com).)

The problem is with the timebase instability of modern VCRs. At the end of each frame there is a phase jump of up to +/- 20 microseconds in the H-sync. The line PLL in a computer monitor is way too slow to follow this jump. The line PLL in a television is switched to a fast mode to follow it just fast enough. This has never been a requirement for computer monitors. You may need a timebase corrector. You may be unable to afford it. Some VCRs have one built in. All Laserdisc players have built-in TBC. Video-CD and DVD don't need it.

Driving multiple non-daisy-chained monitors from one video source

It is not possible to just connect monitors in parallel. The terminating resistors (75 ohms) of each monitor will also be in parallel reducing signal strength and resulting in various problems with cable termination including ghosting, ringing, etc.

A simple circuit to implement a video splitter is shown at:

- Anatekcorp Articles Page.

This is just a set of emitter following buffer amplifiers and should suffice for many applications. Various companies including Elantec, Analog Devices, Maxim, and others have video amplifier chips as well but the basic approach may be adequate for your needs.

Displaying computer video on a TV

Assuming this means NTSC:

1. You need to convert RGB to NTSC - there are single chips for this. Try Sony, Philips, Motorola, and others. These will combine the R, G, B, H sync, and V sync into a single composite video signal using a minimum of additional components.

2. You need to match the scan rate to NTSC - 15.734 kHz horizontal. Even basic VGA is twice this - 31.4 kHz. If your video card can be programmed to put out interlaced NTSC rate video then this is easy. If not, it is more difficult. If you want to use anything higher res than VGA, it is a very non-trivial problem requiring the construction of a scan convertor which includes a video A/D, full frame store, interpolator/readout timing, video D/A. Unless you are an experienced digital/analog designer, you really do not want to tackle any of this.

For the special case of VGA->NTSC, you may be able to get away with just storing a single scan line since the horizontal frequency is (almost) exactly twice the NTSC horizontal of 15.734 kHz. A double buffer where one buffer is storing while the other is reading out at approximately half the VGA pixel rate should work. With appropriate timing, even lines become the even field for NTSC and odd lines become the odd field (I may have this backwards). It is still not a trivial undertaking. Also, keep in mind that the quality you will get on NTSC will be poorer than the VGA due to fundamental NTSC bandwidth limitations. Also, flicker for line graphics will be significant due to the interlacing at 30 Hz. Even this is a non-trivial undertaking.

The requirements for PAL are very similar. For 625 lines systems, the 800x600 is the format that most closely matches the TV resolution.

You can also buy little boxes to do this. Quality is general not great as you are seriously limited by NTSC/PAL and the VCR. Except for presentations on existing TV rate equipment, it is probably not worth the effort. This is totally useless for any serious computer applications.

For professional presentations, modern video projectors are available that use high resolution LCD panels and real-time scan conversion. However, they are still relatively expensive).

HDTV as computer monitor - Can it be worth it?

(From: Jeroen H. Stessen (Jeroen.Stessen@philips.com).)

Some info:

12. HDTV at 1080 lines interlaced uses a line frequency of 33.75 kHz.
13. Line-doubled PAL runs at 31.25 kHz, line-doubled NTSC at 31.47 kHz.
14. Philips has made VGA televisions capable of 31, 35 and/or 38 kHz.

Now what sort of computer performance does that buy you?

- 31 kHz: 640x480 NI @ 60 Hz
- 35 kHz: 800x600 NI @ 56 Hz
- 38 kHz: 800x600 NI @ 60 Hz

In other words: nothing to write home about compared to today's computer monitors. My 17A goes up to 95 kHz. TVs are good enough to be used as presentation displays - to be watched from a distance. They will also make excellent game displays. But you don't want to use them for word processing. Just because it is sold as an HDTV display does not mean that the sharpness will be that much better. Certainly not as good as that of a computer monitor.

HDTV monitors will never have only composite inputs, because composite=CVBS is used only for PAL/Secam/NTSC. Most likely it will have YPbPr inputs (Y,B-Y,R-Y), which is inconvenient with a computer that delivers only RGB. If you are lucky it will have a VGA input or a Golden Scart (a Thomson standard for RGB HDTV signals).

Hold on to your 17" computer monitor...

What is Kell factor with respect to interlaced displays?

(From Bob Myers (myers@fc.hp.com).)

The Kell factor - which has to do with the fact that we're often undersampling an image from the standpoint of the Gospel According to St. Nyquist - IS a factor in the reduction of vertical resolution, but interlacing plays a part as well. This comes from at least two factors:

1. The monitor or receiver usually cannot precisely interleave the two fields.

2. More importantly, there are steps taken to reduce the interline flicker which reduce the effective vertical resolution. This includes running the line width of the display somewhat larger than would otherwise be the case, and in interlaced cameras, discharging the entire screen (including the lines from the "other" field) after every field scanned.

Interlace is particularly troublesome on moving images, where you will often perceive momentarily "missing" details. There was a LOT of discussion regarding the gory details of interlacing in the recent HDTV debates within SMPTE and other groups.

Weird phenomenon of the month

Talk about unusual. This was posted to sci.electronics:

> "Something VERY strange is happening, and I cant explain it.
>
> There is a "ghost" on my TV screen of the text appearing on my computer screen. They are NOT hooked together in any manner. They are about 4-5 feet apart. Although, the antenna cable runs within a foot of my computer. I am wondering what causes this to happen. I have experienced interference, but this is more like a wireless second monitor. I can turn off my monitor, and look over at the TV. The text on the TV is scrolling up every 9 seconds. (like when the v-hold isn't adjusted.) Any Ideas?"

This is probably caused by RFI - radio frequency interference - from a CGA or PC TV card being picked up on the TV's cable or antenna. Only CGA has a scan rate that is nearly the same as NTSC. Any other PC video scan rate would result in a torn up or rolling picture.

(From: Bobby Richardson (boreal@vance.net).)

That is indeed RFI, and during the heyday of CGA was called 'Really Free Intelligence' in military intelligence circles because, with a highly directional, well-tuned antenna, intel ops could read the target's monitor just like looking over their shoulder.

Big Al's rules of thumb on monitor repair

1. Use an isolation transformer. A variac can be helpful too. A cheap isolation transformer can be constructed by wiring two identical transformers of adequate power capability back-to-back. (Here is a use for those old boat anchors you can't bear to part with).

2. If it's just the power supply or flyback switching transistors that have failed, then the repair is probably easy enough and quick enough to be worthwhile. Blown power transistors are trivial to locate in the circuit and quite easy to find replacements for. In many cases I've found that the monitor would have lived a much longer life if only the transistor mounting screws had been tightened properly by the manufacturer. Make sure you use appropriate replacements and the proper heat sink parts and heat sink compound.

3. If it's the flyback transformer, then judgement should be made based on the cost and availability of the replacement part. Also, on the risk of there being additional problems beyond that of the bad flyback. Who get's to eat the cost of the part in the event you don't succeed and give up? However, determining that the flyback is indeed at fault may prove challenging without a flyback tester. Sometimes there will be obvious damage such as burnt marks, cracked plastic, or other signs of overheating. If you have the correct resistance measurements, then for the primary you may be able to detect shorted windings. You can also construct the brute force flyback tester at the end of the document.

4. If it's the CRT then make the project "someone else's problem" and give the monitor to someone else to use as a parts carcass. My life is much happier since I learned there is no disgrace in making this choice.

5. There is another common failure category which is a result of people who are too lazy to turn off the power switch at night. The constant heat causes the electrolytic capacitors to dry out and become intermittent. I often replace all of the smallest electrolytics in the power supply section especially when I know the switching transistor is good. If after a couple of hours of labor and a dozen caps I still don't have it running, I give up on these too.

6. Be realistic with yourself about the value of a used working monitor. CGA's EGA's and monochrome Hercules monitors rarely fetch more than $25 at a swap meet.

7. Don't sell a used monitor to a friend unless you want to continue repairing the thing until you're old and grey.

8. Don't put a scope on the collector of the supply or flyback transistors, unless you have a special X100 high voltage / high frequency scope probe.

Tic-Toc Tips

(From: Andy Laberge (tic-toc@wolfenet.com))

1. When you go to discharge the anode of a picture tube make sure you hook up your ground first or you may get an unexpected surprise. I have.

2. Picture tubes will hold their charge for a long time. In fact I have been bitten from a tube that was removed from a TV, discharged and allowed to sit for six months. Treat all picture tubes as though they were fully charged.

3. There is a practical reason for using an isolation transformer for troubleshooting monitors besides the safety issue. The primary side of the power supply is isolated from ground and if you start probing it with a grounded scope you will short out components that were perfectly good until then. It will cost you more time in trouble shooting and more money.

4. When looking for real small cracks in a monitor board try to use a strong indirect light to keep the glare and reflections to a minimum. You can loose a crack in the glare. Cracks also hide underneath the solder mask (the green stuff). I have scrapped away the solder mask and there pretty as you please is that little beggar. Next you want to fix it; scrap more solder mask off the trace about 1/2" on both sides of the crack. Brighten the copper using an ink eraser (it has abrasive grit in it). Tin the exposed copper very well and then solder on a piece of

bare tinned buss wire. This is sort of an acquired art. Cut the bus wire about 6" long. Next bend the wire at 90 degrees at the 5" mark you now have an L that is 1" on the bottom and 5" on the stem. Hold the stem and solder the bottom to the PCB on top of your excessively soldered crack. Now just clip the stem off. You should now have a crack that is bridged by a soldered on wire which will give your cracked board the added strength that it needs. If there are near-by traces you should also check these for possible hairline cracks or the starts of some. On boards with high trace density this method may not be possible; in that case use small gauge (#30) Kynar covered wirewrap wire and solder it to the associated trace pads on opposite sides of the crack.

5. Some connections won't take the solder very easily. In that case remove all the old solder with either wick or a solder sucker. Pre-tin the connector until it excepts the solder readily and then solder the connector and it's pad. If you don't do this you will end up with a cold solder joint underneath your new solder.

6. If you are a person that is for some reason or other always moving or unplugging your monitor; go out and buy yourself an extension for your monitor signal plug. Hook the monitor signal plug to the extender and then use the male end of the extension plug as your signal plug. If you bend one of these pins it will be a lot cheaper then having to buy a signal plug for your monitor if you can find one.

7. In some VGA monitors you may have video smearing with dark letters on a light background. This maybe caused from some low value electrolytics (usually around 1 uf) that have gone bad in the video driver circuits. Usually you can check these in circuit with an oscilloscope or out of circuit with a capacitance checker.

8. Other filament problems might be low voltage caused from a leaky filter capacitor in the filament circuit. The capacitor will dropped the filament voltage down. A resistor can increase in value causing the filament current to drop off. Both of these problems can give you a faded picture look. A filter capacitor that has opened up will give you a bright picture full of noise and that is hard to trace especially if you are looking for it in the video.

9. Homemade degaussing coils can be made using three degaussing coils (out of junked monitors) in series that way you do not need a ballast load and it acts more like the heavy duty degaussering coils. They still get warm though.

10. When checking a focus control the main thing to look for here is that the best focus is not on one end of the control. If it is then your focus control block is bad or falling out of tolerance.

11. High voltage regulation circuits can give you some weird problems. One particular monitor would shut down when it went from high white screen to a black screen. High voltage will elevate when the screen is darker and sometimes exceed the high voltage safety limit activating the shut down circuit.

12. Changing CRT's is more of an art that gets better with practice. Some color CRT's line right up with a new tube and some take over four hours experimenting with results that still do not fall within specs.

13. Capacitors in the primary of the SMPS may go bad and cause the shape of the switching pulse to be distorted; the SMPS becomes inefficient and causing over heating and lower voltage. Change the capacitors if they look bad; shrinking of the vinyl casing or leakage underneath (looks like a leaky battery in a radio). Capacitors with 105 degree temperature ratings are recommended in power supplies instead of 85 degree types because of the self generated heat. Everything in the power supply is a suspect of failure. SMPS transformers can even fail although it is rare. Some produce a high audio frequency whine at times due to material oscillations and load conditions.

14. Metal film resistors can cause weird shut down and start up problems. These are usually found in the power supply over current sense circuits. These resistors check good cold but fail after applying heat to them. When cool they would seem to run all day but if heat is applied they fail faster. The value of these resistors would fall between 100k and 500k usually.

15. A good flyback source: Component Technology 1-800-878-0540

Monitor service and how to get some

A typical monitor warranty is something like: 2 years parts, 1 year parts and labor (i.e. you have to pay for labor the last year of your warranty). What should you do when you are totally unsatisfied with warranty service or when your monitor blows up 1 day after the warranty expires.

(From material provided by a former head service guy for a major computer sales/service company.)

The behind the scenes secrets to get what you want are to do one or a multiple of the following:

1. Call the "Service" (it appears they really aren't) Department of the company you procured the monitor from, and kindly ask to speak with the Service Manager. If they ask for your name, they will most likely pass it on, as well as your service history... The manager will be "not at his desk". They will ask to take a message... say something like "I would like to discuss a service contract" (free money) or "I would like to speak to him about your firm's good service" (appeal to his ego). These are positive things they like. They person on the phone will get your # and you will hear back within maybe an hour or so. Reason: Service people like myself live in a very, VERY negative world... in the back of our minds we like to hear good and hide from the every day bad. He will call back thinking good and when you get him, you can either beat him up, or butter him up... depending on your personality or style. The later is best. The nicer you are to someone, the more they will do for you... treat him like you've known him for years... talk to him on a one on one type style... tell him what has happened in a very calm, relaxed mood... sit back and relax... imagine yourself as Jack Nicolson.(?) Talk as long as you can... joke, talk about golf, whatever... The longer you are on the phone with him, the more likely he is to do something.

2. Hardball! Tell'em you are going to call the Attorney General and get this monitor covered under the Lemon law in your state if they don't get it fixed NOW! They will have to give you a new monitor if the machine has to be fixed under warranty more than 3-times in a 1-year period.

3. Call the manufacturer. Tell them your monitor is bad and that the company that sold you the monitor has sent it to for service multiple times and that you must have it fixed because it monitors a dialysis machine for a 5-month old baby with liver cancer and a broken leg or something like that... Pull their strings. Kindly let them know you aren't pleased with the monitor and you would like to send it in personally... (yes! you can do this!) The key acronyms are RMA# or RA# or MRA#.... they all refer to Return Merchandise Authorization number in some form.

4. (This one is from sam) Threaten to plaster their miserable product name all over the Internet. Note that I do not believe one should actually do this - posting whiney messages to a bunch of newsgroups is largely non-productive and may leave you open to legal repercussions. But, the threat will need to be taken increasing seriously as the importance of Internet as an international medium expands exponentially.

When you send it the monitor, the RMA# has to be on the box. Call the manufacturer at their 800 number. Ask for Customer Service. Tell them the story (kindly) and say that you would like to get an RMA#. This is a type of laundry ticket # they give you to track the monitor's progress... and they report directly to you when you call the RMA department to check on it's status. If they won't do this for an individual person, ask for an address of an Authorized Repair Depot. You will have to call the repair depot and get an RMA#.

Let them know you would like to deal with them directly. I would use tip (3) as a last resort, (just before I call the Attorney General).

I would also be careful of the game they may be playing: let the warranty on labor run over so we can get some money.

Shipping damage 1: why monitors are like basketballs

(From: Stephen Swann (swann@panix.com).)

Monitors are more prone to shipping damage than most other computer components, and it doesn't help that they typically pass through several people's hands (several stages of shipping) before they get to you: factory -> distribution center -> vendor -> you.

And from what I've seen first hand of shipping practices (I put in a couple of months working in a distribution warehouse during college), you can safely assume that each stage of shipping is roughly the equivalent of your monitor being dropped down a flight of stairs.

You wouldn't *believe* the abuse that UPS and FedEx can subject packages to. In fact, putting a *FRAGILE* sign on the side of the box is about the equivalent of writing "KICK ME" on it. I remember receiving packages marked "FRAGILE" where the (originally cubical) cardboard boxes had been smashed into shapeless cardboard "bags", and it took us 20 minutes to figure out what the contents of the box had originally been. ("What are all these shards?" "I think it was some kind of vase" "No, it was some kind of lamp." "Where's the bulb socket, then?" "How about this squashed piece of aluminum?" "Yeah, you're right, but where's the cord then?" etc). :-) Shipping guys would think nothing of dropping "fragile" boxes from waist-high onto a concrete floor - safe in the knowledge that the package had passed through so many hands that the damage could never possibly be traced back to them. "Blameless is Guiltless" should be the motto of these folks.

Basically, what I'm saying is that if 1 monitor in 3 arrives arrives in workable condition, you should be surprised that even that one monitor survived.

Shipping damage 2: why monitors are like hammers (as in throw)

(From: Steve Cunningham (swc@tamu.edu).)

Yes folks! As a training exercise for the 2002 Summer games, Bill Baxter (not his real name), a union thug from United Parcel will attempt to beat the steroid enhanced monitor-throw record of 55 1/4 feet set by Udo Schrank of the former East Germany.

But seriously folks--UPS and I just "go round 'n' round!" Over the past two years, they have broken about one third of the monitors shipped to us, even those packed in the original polystyrene foam. One monitor had the case shattered, and the tube neck sheared off--even though the monitor was packed securely in the original box and foam. The stock response from UPS is that "it probably wasn't packed securely," or some such drivel, while ignoring the obvious--they are careless with fragile merchandise.

The latest outrage was when I was taking a short nap in my house (I work out of my house), and a very loud crashing sound startled me awake. My wife said that it sounded as if someone was crashing through the front door. Turns out that the UPS dude dropped a $2000.00 70 pound 20" Ikegami monitor from waist level to the ground, hitting the front door in the process. After cooling off, I carefully inspected the monitor, and, amazingly, it wasn't destroyed (I have witnessed monitor boxes dropped from the airplane to the ground).

To add to the outrage, when I was ready to return the repaired monitor, the local UPS manager made me purchase a new box, and have foam injected into it, at a cost to the customer of about 50 bucks, before they would consider shipping it (the old box was dented, but no worse for wear). In a remarkable bit of restraint (if I don't say so myself), I calmly walked out of the UPS office (after waiting in line 30 minutes), and used a remailing company in the area to ship it via UPS at an additional fee. The customer received the monitor a few days later, and yes, it was broken. All of this despite being packed with several inches of hard foam, and in a new, sturdy, 27" Uhaul TV box. The package arrived at the customer's place of business upside down, despite up arrows.

I realize that they are a discount shipper, but, they are not paid to merely ship packages. They are paid to ship them in one piece. If they can't do that, I think that they should get out of the business and quit running an insurance scam. I can't return repaired monitors to people with the screws missing, saying, "it's because I'm a discount servicer." There is a minimum level of quality that is acceptable. Sometimes the lowest price is not the best value. As in all things human, let the buyer beware! Hopefully someone will find this useful to that end. We won't be using UPS anymore.

Shipping damage 3: why small monitors are like footballs

(From: Captain Mocha (CaptainMocha@Electra.com).)

I used to work for UPS, I loaded the trucks.

It's amazing you get anything in one piece when shipping with UPS. There are so so so so many packages that need to be loaded in those trucks in just three hours per work shift. The floor managers would encourage us to get the trucks loaded in 'any way possible'.

We used to treat the small packages as 'footballs' and try to throw them through box "goals" from the other end of the truck. We also did 'punt kicking' etc.

So get your facts straight!! It's not 'Hammer Throwing', it's football! =)

(From: Michael Schuster (schuster@panix.com).)

A friend used to work in Manhattan, NYC and during lunch hour he often passed the large camera/electronics retailer, 47th Street Photo, just as the UPS truck was unloading.

It was common for this to be accomplished by having the driver stand in the truck, and KICK the boxes to the ground one by one. So you see, it isn't a hammer throw... It's football (or soccer) that they're modeled after.

Shipping damage 4: so maybe if monitors were packed and shipped like eggs

> "After receiving my third crunched monitor this week, I've about had it with these "Brown Shirted Box Stompers-in-the-mist!" You would think that a well packed 14" clone monitor would survive a 30 mile journey while in their very incapable hands. Actually, I should apologize to Jane Goodall, or whoever that Gorilla babe was--her objects of study would probably be much more care with monitor boxes than the knuckle-walkers at UPS. I have been thinking of doing my own study as to what deceleration it takes to do the damage to a monitor that they have done. My guess is that they must have to drop the thing on concrete from 5 to 7 feet high! I've seen high impact cases shattered, tube necks sheared off, board cracked in half--sheesh, where do they get these guys? From a zoo? Sure, they reimburse the owner, but I lose the repair fee. Does anyone know if can make a loss claim also?"

(From: David Rouse (david.rouse@engineers.com).)

Actually they are probably only being normally clumsy. It probably is the packaging of the monitor that is causing the failures. A monitor is a fragile thing. It only takes about 50 g's of acceleration to kill one. This translates into about a 3-4 inch drop onto a hard surface. The packaging is supposed to protect it by spreading the shock pulse out over a longer time period. Alas, though, all styrofoam (or whatever is being used for cushioning) is not created equal. The maker was most likely trying to save a couple of pennies and use something a little too rigid. The wrong material can provide too little cushioning and in some cases even amplify the shock transmitted to the product under the right(or wrong) circumstances. FYI Trinitron tubes have really bad shock characteristics.

Cleaning plastic monitor cases

For surface contamination like grease or tobacco smoke, a variety of household cleaners will work including Fantastik, Windex, 409, etc. - some better than others depending on the type of coating. Verify that whatever you use is safe for the plastic by trying it out on an inconspicuous location first.

For ozone or heat damage which penetrates deeply into the plastic, painting may be the only a solution. Test on a non-visible section to see how deeply the discoloration has penetrated. For modest discoloration, I have had some success with water and scouring powder containing bleach.

Secret menus

> "I've seen some tantalizing references to the SECRET menu for adjusting VisionMaster Pro 17 monitor secret menu.
>
> Could someone kindly point me to some details so that I can access and properly use this covert functionality?"

(From: Scot Miller (scot@cts.com).)

Shut the power off, then switch it back on while simultaneously holding down the 'menu', '-', and '+' buttons. Then the 'menu' button works normally but will bring up the secret menu.

Reliability and performance of refurbished or remanufactured monitors

> "Considering a 21-inch monitor and have seen a number of resellers beginning to carry refurbished monitors. Under most circumstances I would walk right past anything refurbished for the shiny new model, but at the price of new 21 inchers, well... Monitor would be used primarily in Windows and for playing Quake. Locally I'm seeing prices of $1100.00 to $1300.00 with a 2 year warranty for 1st & 2nd tier products. Feedback, anyone?"

Assuming you can fully test drive it and/or get a money back no questions asked warranty, then they are worth considering. The most critical issue is the condition of the CRT make sure it is bright, sharp, and has no screen burn. If the CRT is in good condition, then there is no reason to think that the rest of the monitor will fall apart or go up in smoke. Note: Test from a power off for at least an hour condition. Once an old CRT warms up, it may appear to be better than it actually is. See the document: Performance Testing of Computer and Video Monitors for additional evaluation criteria but be warned that no monitor is perfect - some 'defects' you find may be inherent in the design or simply due to normal variations in manufacturing quality control.

The two terms 'refurbished' and 'remanufactured' may be mean the same thing. However, it would probably be worth trying to get a clarification in writing of exactly what was done to the monitor. Depending on the integrity of the reseller, these terms could mean anything from 'well, we turned it on and it didn't blow up' to 'unit was completely overhauled and restored to new specifications replacing parts where necessary'.

Ron's notes on video signal quality problems

From: pinecone@pacbell.net (Ron)

Here are some possible causes for ghosting, smearing, etc.:

1. A poor quality video cable.

2. A video extension cable (making the cable longer always makes things worse).

3. Running the video card and/or monitor too close to their maximum bandwidths.

4. Impedance mismatch between the video card and the monitor. Most cards, monitors, and cables are 75 ohms, but 50 ohm parts exist.

5. Bad video card. I've seen many video cards with this problem, and a manufacturer recently admitted to me that one revision of their board has a grounding defect that causes...ghosting.

6. Bad monitor. I think this is unlikely. Usually poor monitors produce muddy images that hide ghosting, if indeed there is any.

Monitor quality control

(From: Bob Myers (myers@fc.hp.com).)

The bottom line is that I've been involved with the design, manufacture, specification, and purchase of CRT displays for longer than I care to admit, and I can tell you one thing with absolute certainty: it is IMPOSSIBLE to maintain visibly perfect geometry, linearity, etc., on the things over a production run. You can spend hours and hours getting a given unit to look pretty darn good, but even that is iffy - it depends to much on the limitations built into that particular CRT and yoke. And even if you CAN get that unit 'perfect', this ISN'T something that you can do in normal production - not unless you find customers willing to pay SIGNIFICANTLY higher costs for the products. Despite claims to the contrary here, that has NOT been the desire expressed by the market.

(From: Gary Flynn (gary@habanero.jmu.edu).)

Many years ago I did TV repair and there were LOTS of adjustments available. I haven't cracked open a TV or monitor lately but your statement about CRT and yoke limitations jogged my memory. Are most monitors today "rack and stack" or are there internal factory adjustments? Having just ordered a 17" Trinitron based monitor and having confidence in my old TV abilities makes me want to explore :-)

(From: Sam.)

No, you will not find many of these sorts of twiddles in modern monitors. Most purity, convergence, and geometry adjustments are via strategically placed magnets glued to the CRT, the orientation of multiple magnetized rings, the position and tilt of the deflection yoke, etc. You really do not want to mess with these unless you have no choice and lots of time.

Many modern monitors control the picture adjustments via hidden menus and digital controls.

The 'good old days' are gone forever... :-) :-(.

Is Big Brother watching over your shoulder?

> "Does anyone out there know how the Timex/Microsoft watch is programmed by holding the watch in front of a VGA monitor. There must me some sort of sensor on the watch that picks up some sort of pattern on the screen retrace of the monitor...."

(From: Len Turnbow (quartlow@netcom.com).)

I know nothing about the Timex/Microsoft VGA optical communications protocol. But, sometime when you have nothing better to do, you might connect a phototransistor to a biasing source and thence to your oscilloscope. Aim phototransistor at your computer monitor and check out all the weird patterns produced as a result of various screen displays.

Before long, you will note that the leftmost edge of your scope display represents information present near the top of your screen. If you have your trigger properly set, you will also note that the whole contents of the screen are presented (top to bottom) on your scope (left to right).

With a blank white raster, you will be able to move your hand in front of the screen and see the result on your scope a la flying spot scanner. But I digress.

Armed with a borrowed copy of the Microsoft interface software and your phototransistor, you could probably reverse engineer the protocol.

Or ask someone at Microsoft.com :-). What would be the fun in that, though?

(From: David Fries (dfries@mail.win.org).)

I don't know why it would be referred to as 'the Timex/Microsoft watch', when it just includes windows software. It really should be referred to as the Timex Datalink watch. Microsoft wouldn't know anything about the protocol as it is a Timex product (and patent I believe).

I maintain the Linux software to interface with the Timex Datalink watches, model 70, 150, 150s, and Ironman. See: Datalink Library for the Ironman Watch. I can say something of the physical layer communication and that in the past I have decoded the ironman protocol by using a photocell (as opposed to a phototransistor) connected to the sound card input of another computer. A photocell varies resistance with the amount of light it receives, perfect for plugging into a sound card mic in without any other components.

There are two variations, the 150, 150s, and Ironman both send two bytes per screen refresh. There are up to nine lines lit at the top of the screen and 9 lines at the bottom. Each line is a solid white or off. The first line of each set is always on, and used as a start bit, the rest are data bits. The protocol partitions the data into packets with check bytes at the end of each packet followed by a few completely black screens before the next packet. That is why it looks like it flickers, stops, flickers, stops, etc. The screen is set to 60Hz, two bytes per refresh or 120 bytes a second, not exactly speedy by any means and that doesn't include the built in pauses.

The model 70 is similar, but only fills the top nine lines giving it an even slower transfer rate of one byte per refresh or 60 bytes per second.

The protocol makes the monitor into a serial output device because the watch doesn't pay any attention to where the lines are, only the overall brightness of the screen.

Lament of the lack of adjustment pots on the newest monitors

In 'the good old days' before digital controls and service menus, one could spend a substantial fraction of one's life tweaking monitor adjustments. The newest monitors (and TVs) are nearly totally controlled by settings stored in EEPROM. The service adjustments may only be accessible via a port connection to a PC running a special manufacturer specific setup program.

This is the wave of the future and we are stuck with it for better or worse. In all fairness, digital adjustments are less costly to manufacture and permit much more automation in the factory setup of screen geometry, color, and so forth. However, not making the setup software available for a reasonable licensing fee is a serious problem which will result in lost opportunities for smaller independent repair shops.

(From: CiaraTom (ciaratom@aol.com).)

The point is that each manufacturer has written a program for his monitor to tweak things that we used to do with a screwdriver. It is model specific, not generic, and often requires an interface (special cable, with or without circuitry in between) sometimes connecting to your parallel port, sometimes to the serial.

Goldstar does this with a special proprietary software and special cable; Viewsonic has (that cost me $220 - try to recoup that from a repair) and it is so user unfriendly that you don't even know what to do with it.

Analog versus digital LCD flat screen monitors

(From: Bob Myers (myers@fc.hp.com).)

This refers to the interface to the monitor, with "analog" generally meaning that it can plug directly into the same video connector as your typical CRT monitor. Digital-input monitors have in the past required special interface cards, but there are new standards for digital video outputs (such as the VESA "Plug & Display" connector family). The displays themselves (the inner workings aren't REALLY "inherently digital" either - although the interface to the panel itself usually is - but they ARE fixed-format devices, which brings along its own set of problems.

Digital interfaces, assuming you DON'T need a special interface card in the PC, will be less expensive than analog interfaces and will offer better performance. The performance increase doesn't come so much from having the information provided in "digital" form, but rather from having accurate timing information available. The biggest headache in designing an analog interface for these monitors is trying to generate the correct clock for sampling the incoming video. It's usually been done by multiplying the horizontal sync rate up to the proper frequency, but that is hard to do with REALLY good stability, and the phase relationship between the H. sync signal and the video isn't all that reliable. This makes for an unstable display, with what looks like considerable noise (especially when you have lots of single-pixel details).

Why is there a growth on my monitor cable?

(From: David Kessner (davidk@peakaudio.com).)

Well, it is a ferrite sleeve or bead. There's a thing called a ferrite bead which is a simple doughnut, sleeve, or bead that a wire goes through. Electrically this is similar to an inductor. There are other, larger, types that are made to clamp on to cables.

The practical effect of a ferrite bead (FB) is that it causes a resistance at high frequencies, but almost no resistance at low frequencies. Most FB's are rated at XXX ohms at YYY MHz. Small ones are typically about 25 ohms at 100 MHz, with the resistance increasing with frequency.

Usually, FB's are used to filter out high frequency noise. In a cable, if you provide a high frequency resistance then you will have less high frequency current as well. This means less high frequency signals or noise on the line. This makes the FCC happy, since you won't be emitting as much EMI/RFI.

When you see FB's on cables, it is usually put there as a quick fix. Someone will design a device and it'll fail FCC testing. Through trial and error, they will find that putting a FB on the cable will make it pass. So they put one on and ship it that way. Well designed cards either have FB's on the PCB, or they do something else to reduce the EMI/RFI emitted.

There are other uses for FB's, but this is the general use of them when cables are concerned.

(From: Douglas W. Jones (jones@pyrite.cs.uiowa.edu).)

The thing is a ferrite core. It is used to control EMI/RFI interference. They're sometimes called filter blocks, because they're a block of ferrite used as a filter, but sometimes people just call the thing "a ferrite".

You can buy after-market filter blocks from ParaCon; these just clip onto the outside of a cable. They're listed in the DigiKey catalog under the name "ferrites" on the catalog page, but they're indexed under "filter blocks".

What do they do? Two things. First, if you've got a wire coming out of your electronic whatsit, that wire can act as a transmitting antenna for any RF oscillator within the whatsit. So, the cable between your computer and your video monitor might end up transmitting not only a base-band video signal at somewhere near 10 Mhz, but it could also transmit your CPU clock signal and other annoying signals generated within your computer's box.

To keep the cable from transmitting a video signal, we use coaxial cable with a decent shield. To keep the cable as a whole from transmitting the CPU clock and other higher frequency signals, we put a ferrite core around the cable. This acts as a low-pass filter preventing common-mode signals from getting through while allowing balanced signals (properly sent over the coaxial cable) to get to the video monitor.

The second possibility to worry about is the cable acting as a receiver. This is particularly troublesome when there is a ground loop. For example, my computer and video monitor both have grounded line cords that are plugged into the wall. The computer cable to the video monitor also has a ground path, through the shield, so there's a loop, from wall outlet to computer to video monitor to wall outlet. This loop acts as a loop antenna, and it can pick up signals from around 100 Khz to 1 Mhz quite well, depending on the geometry of the loop. These could cause real problems if they were confused with logic signals inside the computer.

The standard advice to electrical engineers is: Avoid ground loops. When this advice fails, the fallback position is, break the loop with a filter. That's what the filter block does!

---

15. Back to Monitor Repair FAQ Table of Contents.

Service Information

Advanced monitor troubleshooting

If the solutions to your problems have not been covered in this document, you still have some options other than surrendering your monitor to the local service center or the dumpster.

Also see the related document: Troubleshooting of Consumer Electronic Equipment.

Manufacturer's service literature: Service manuals may be available for for your monitor. Once you have exhausted other obvious possibilities, the cost may be well worth it. Depending on the type of equipment, these can range in price from $10-150 or more. Some are more useful than others. However, not all include the schematics so if you are hoping to repair an electronic problem try to check before buying.

Inside cover of the equipment: TVs often have some kind of circuit diagram pasted inside the back cover. In the old days, this was a complete schematic. Now, if one exists at all for a monitor, it just shows part numbers and location for key components - still very useful.

SAMs Photofacts: These have been published for over 45 years but have never been common for monitors. There are a few for some early PC monitors but for anything modern, forget it.

Whatever the ultimate outcome, you will have learned a great deal. Have fun - don't think of this as a chore. Electronic troubleshooting represents a detective's challenge of the type hat Sherlock Holmes could not have resisted. You at least have the advantage that the electronics do not lie or attempt to deceive you (though you may beg to differ at times). So, what are you waiting for?

Additional information

For general information on PC video cards and monitors, see the FAQ of the USENET newsgroup: comp.sys.ibm.pc.hardware.video. This document has a wealth of data on nearly everything you could possibly want to know about video for the PC world.

The FAQ is available via ftp and the WWW:

To ftp a text-only version of this FAQ, and/or the chipset list:

- Compressed Video FAQ
- Compressed Video Chipset List

The FAQ has received news.answers approval, so it should be archived at rtfm.mit.edu and all mirrors, as well as in news.answers and comp.answers.

Contributions, questions and corrections always welcome and appreciated.

The USENET newsgroup: sci.electronics.repair

Where you have a specific question on a particular monitor (or other equipment), posting the make and model and a concise description of the problem and what you have already attempted, may result in suggestions from both professionals and others like yourself who have had experience with your monitor.

See the document: Troubleshooting of Consumer Electronic Equipment for many additional on-line resources to aid in monitor servicing.

Suggested references

There don't seem to be that many readily available books on monitor repair. Here are a couple:

- Troubleshooting and Repairing Computer Monitors
  Stephen Bigelow
  McGraw Hill, 1995
  Hardcover, 304 pages
  ISDN 0-07-005408-8

  Some of the topics are

  - CRT alignment and degaussing
  - State-of-the-art plasma displays
  - Specifications and architectures of monochromw, CGA, EGA, VGA, and SVGA

- Linear, switching, and high voltage powersupplies
- Logic and drivers supporting both CRT and LCD monitors
- Graphics standards
- Sample schematics

However, a couple of people have commented that the document you are reading is more useful and better organized than this book :-). I cannot comment as I have not seen it. So, try to check it out before purchasing or make sure you can return it if not satisfied.

- Computer Monitor Troubleshooting and Repair
  Joe Desposito and Kevin Garabedian
  Howard W Sams and Co, 1997
  ISBN: 0-7906-1100-7

  Lots of diagrams and photos, schematics, and examples of problems and how they are solved. This is a good basic book.

Also, since monitors share much in common with color TVs, books on their repair would also be applicable for many problems - and may be more readily available from your local public library.

There don't seem to be nearly as many TV repair books for modern solid state TVs as I recall for old tube sets. Here are is one suggestion which you may find (or its predecessor) at your local public library (621.384 if you library is numbered that way) or a technical book store. MCM Electronics has this as well.

- Troubleshooting and Repairing Solid State TVs
  Homer L. Davidson
  2nd Edition, 1992
  TAB Books, Inc.
  Blue Ridge Summit, PA 17214

(From: Skip (skipperm@mtc2.mid.tec.sc.us))

I recently attended a monitor repair course put on by Philips electronics. They have a technical training manual which can probably be ordered without signing up for the course:

- Hi-Res Computer Display Systems
  Part # ST1496-1093LE/KGPGC
  Philips Service Co.
  P.O. Box 555, Jefferson City, TN 37760
  Phone: 423-475-0044

  This book does an excellent job of explaining how these monitors work. Most is about Philips monitors but the material is applicable to most manufacturers. This course and reading this text has help me a lot with my monitor repair efforts.

The following doesn't specifically deal with monitors but may be of interest as well:

- Video Demystified: A Handbook for the Digital Engineer
  Keith Jack
  Brooktree Corporation, 1993
  ISBN 1-8787-0709-4

FCC ID Numbers of monitors

Only a few manufacturers actually produce the vast majority of computer and video monitors. For example, Radio Shack, Magnavox, and Emerson do not make their own monitors (I can tell you are not really surprised!). All those house-brand monitors that come bundled with mail order or 'Mike and Joe's Computerama' PCs are not actually put together in someone's garage! Well, not that many, at least :-).

How do you determine the actual manufacturer? For most types of consumer electronic equipment, there is something called an 'FCC ID' or 'FCC number'. Any type of equipment that may produce RF interference or be affected by this is required to be registered with the FCC. This number can be used to identify the actual manufacturer of the equipment.

A cross reference and other links can be found at:

- S.E.R. FAQ FCC ID Links

Parts information

I have found one of the most useful single sources for general information on semiconductors to be the ECG Semiconductors Master Replacement Guide, about $6 from your local Philips distributor. STK, NTE, and others have similar manuals. The ECG manual will enable you to look up U.S., foreign, and manufacturer 'house' numbers and identify device type, pinout, and other information. Note that I am not necessarily recommending using ECG (or other generic) replacements if the original replacements are (1) readily available and (2) reasonably priced. However, the cross reference can save countless hours searching through databooks or contacting the manufacturers. Even if you have a wall of databooks, this source is invaluable. A couple of caveats: (1) ECG crosses have been known to be incorrect - the specifications of the ECG replacement part were inferior to the original. (2) Don't assume that the specifications provided for the ECG part are identical to the original - they may be better in some ways. Thus, using the ECG to determine the specifications of the parts in your junk bin can be risky.

Other cross reference guides are available from the parts source listed below.

Monitor schematics and manuals

In some cases, these may be available from the manufacturer and even reasonably priced (much less than other sources). For example, a manual for a typical CTX monitor is only $15 from CTX but around $50 elsewhere. However, more often than not, this will not be the case.

The following three companies have an extensive inventory of computer monitor service manuals and schematics. Typical prices are between $25 and $100.

- Anatekcorp (http://www.anatekcorp.com) has a set of nine CD ROM's that contain the full technical manuals (in most cases) produced by the original manufacturer. Go to: http://www.anatekcorp.com/schematic/monsch.htm. However, this would probably be extravagant for a single repair!

- Electronix (http://www.electronix.com/schematics/)

The following may only be for IBM monitors (I don't know) and doesn't appear to have a web site:

- Eagan Technical Services, Inc, 1380 Corporate Center Curve, Suite 115, Eagan, MN 55121, 612-688-0098.

  Eagan has several schematics for IBM monitors. I believe it includes the 8503, 8512, 8513, 8514, 8518 and

8511. Most are $50. The 9517 schematic is an unbelievable $165. You can order them directly from Eagan or through Sams' Photofacts, same price.

And another:

- Chuntex, 1-800-888-2120.

Also see the manuals list in the document: Troubleshooting of Consumer Electronic Equipment.

Information sources on the Internet

Many manufacturers are now providing extensive information via the World Wide Web. The answer to you question may be a mouse click away. Perform a net search or just try to guess the manufacturer's home page address. The most obvious is often correct. It will usually be of the form "http://www.xxx.com" where xxx is the manufacturers' name, abbreviation, or acronym. For example, Hewlett Packard is hp, Sun Microsystems is sun, Western Digital Corp. is wdc. NEC is, you guessed it, nec. It is amazing what is appearing freely accessible via the WWW. For example, monitor manufacturers often have complete information including detailed specifications for all current and older products. Electronic parts manufacturers often have detailed datasheets for their product offerings.

For Apple monitors (and other Apple peripherals) in particular, the E-MAC Web site (http://e-mac.com/) has a variety of information including some (mostly user) manuals, specifications, and technical forums.

Don't expect to find complete schematics (at least none of the models I checked went into this depth) but there will be specifications, setup and adjustment instructions, and, depending on model, some troubleshooting information, disassembly instructions and exploded views, etc.

Interchangeability of components

The question often arises: If I cannot obtain an exact replacement or if I have a monitor, TV, or other equipment carcass gathering dust, can I substitute a part that is not a precise match? Sometimes, this is simply desired to confirm a diagnosis and avoid the risk of ordering an expensive replacement and/or having to wait until it arrives.

For safety related items, the answer is generally NO - an exact replacement part is needed to maintain the specifications within acceptable limits with respect to line isolation, X-ray protection and to minimize fire hazards. Typical parts of this type include flameproof resistors, some types of capacitors, and specific parts dealing with CRT high voltage regulation. However, during testing, it is usually acceptable to substitute electrically equivalent parts on a temporary basis. For example, an ordinary 1 ohm resistor can be substituted for an open 1 ohm flameproof resistor to determine if there are other problems in the horizontal deflection circuits before placing an order - as long as you don't get lazy and neglect to install the proper type before buttoning up the monitor or TV.

For other components, whether a not quite identical substitute will work reliably or at all depends on many factors. Some deflection circuits are so carefully matched to a specific horizontal output transistor that no substitute will be reliable.

Here are some guidelines:

1. Fuses - exact same current rating and at least equal voltage rating. I have often soldered a normal 3AG size fuse onto a smaller blown 20 mm long fuse as a substitute.

2. Resistors, capacitors, inductors, diodes, switches, potentiometers, LEDs, and other common parts - except for those specifically marked as safety-critical - substitution as long as the replacement part fits and specifications should be fine. It is best to use the same type - metal film resistor, for example. But for testing, even this is not

a hard and fast rule and a carbon resistor should work just fine.

3. Rectifiers - many are of these are high efficiency and/or fast recovery types. Replacements should have at equal or better PRV, Imax, and Tr specifications.

4. Posistors - many of these are similar. Unfortunately, the markings on the devices are generally pretty useless in determining their ratings. Note, however, that the prices for replacement posistors may be quite reasonable from the original manufacturer so it may not make sense to take the risk of using an unknown part.

   (From: Stefan Huebner (Stefan.Huebner@rookie.antar.com).)

   In most cases you can use a standard 3-terminal-device, the resistance of the temperature dependent resistors in it are nearly identical. Here is a list of possible replacement devices:

   380000-01, 24340521, 2199-603-1201, 163-024A, 163-035A, CO2200-N66, C8ROH, QX265P05503, 32112026, 4822-A1-11240148, 02199-003-120, 15-08-001A, 5391560067, F400001.

5. Transistors and thyristors (except HOTs and SMPS choppers) - substitutes will generally work as long as their specifications meet or exceed those of the original. For testing, it is usually OK to use types that do not quite meet all of these as long as the breakdown voltage and maximum current specifications are not exceeded. However, performance may not be quite as good. For power types, make sure to use a heatsink.

6. Horizontal output (or SMPS) transistors - exact replacement is generally best but except for very high performance monitors, generic HOTs that have specifications that are at least as good will work in many cases. Make sure the replacement transistor has an internal damper diode if the original had one. For testing with a series light bulb, even a transistor that doesn't quite meet specifications should work well enough (and not blow up) to enable you to determine what else may be faulty. The most critical parameters are Vceo/Vcbo, Ic, and Hfe which should all be at least equal to the original transistor. I have often used by favorite BU208D as a temporary substitute for other HOTs in TVs and SMPS (chopper) transistors. However, for high performance monitors, a BU2508D type is a better choice. Make sure you use a heatsink (with insulating washer if applicable) and thermal grease in any case - even if you have to hang the assembly with a cable-tie to make it fit.

   However, using an HOT with much better specs may actually result in early failure due to excessive heating from insufficient and/or suboptimal base drive. See the document: TV and Monitor Deflection Systems for more info.

   Also see the section: Replacement power transistors while testing.

7. Deflection yokes - in the old days, particularly for TVs, all of these were quite similar. It was common to just swap with one that fit physically and at most need to adjust or change a width coil. With high performance auto-scan monitors, this is no longer the case. Sometimes it will work but other times the power supply won't even be able to come up as a result of the impedance mismatch due different coils and pole piece configurations. In addition, there may be other geometry correction coils associated with the yoke that could differ substantially.

   However, if you are really determined, see the section: Swapping of deflection yokes.

8. CRTs - aside from the issues of physical size and mounting, many factors need to be considered. These include deflection angle, neck diameter, base pinout, focus and screen voltage requirements, purity and convergence magnets, etc. Color CRT replacement from scratch (not using a CRT and yoke/convergence/purity assembly from another monitor) is rarely worth the effort in any case. But, trying to substitute a different CRT is really

asking for frustration.

For monochrome CRTs, there is less variation and this may be worth a try.

The following are usually custom parts and substitution of something from your junk box is unlikely to be successful even for testing: flyback (LOPT) and SMPS transformers, interstage coils or transformers, microcontrollers, and other custom programmed chips.

Substituting mainboards and other modules from identical models is, of course, possible but some realignment may be needed. Even a monitor from the same manufacturer that is not quite identical may use the same subsystems, perhaps depopulated or jumpered differently.

Horizontal output transistor pinouts

You will nearly always find one of two types of horizontal output transistors in TVs and monitors:

- Metal can - TO3 package:

```
          _
        / O \          View from bottom (pin side)
      / o   o \
     (  B   E  )       B = Base, E = Emitter, C = Collector
      \       /
        \ O / C        The metal case is the Collector.
```

- Plastic tab - TO3Pn (n = several suffixes) package:

```
        _____
       /     \
      |   O   |       View from front (label side)
      |       |
      |       |       B = Base, E = Emitter, C = Collector
      |_______|
        | | |         If there is an exposed metal tab, this is the
        | | |          Collector as well.
        B C E
```

Some other transistor types use the same pinout (TO66 for metal can, TO218 and TO220 for plastic tab) but not all. However, for horizontal output transistors, these pinouts should be valid.

Note that those with a built in damper diode may read around 50 ohms between B and E (near 0 on the diode test range) - this is normal as long as the resistance is not really low like under 10 ohms.

How do you locate the HOT

Well, it is usually the LARGEST transistor in the set near the LARGEST transformer in the set (flyback - the thing with the FAT red wire connecting to the picture tube) on the LARGEST heat sink in the set.

Got that? :-)

Or, in the good old days - oops - but that was before computer monitors...

(From: Don Wall (d.wall@nunet.neu.edu).)

Sure, it's usually the largest tube in the set, has a top cap, runs very hot, and is often a 6BQ6G or some such. (tongue firmly in cheek) Actually, back in the days of yore, the Horizontal Output Tube was frequently referred to as the HOT; guess some things don't change!

Replacement power transistors while testing

During testing of horizontal deflection circuits or switchmode power supplies, particularly where the original failure resulted in the death of the HOT or chopper, overstress on replacement transistors is always a possibility if all defective components have not be identified.

Therefore, using a part with better specifications may save you in the long run by reducing the number of expensive blown parts. Once all other problems have been located and repaired, the proper part can be installed.

However, this is not always going to work. In a TV and especially a high performance monitor, the HOT may be closely matched to the drive and output components of the deflection circuits. Putting in one with higher Vce, I, or P specifications may result in overheating and failure due to lower Hfe.

Where possible, a series load like a light bulb can be used limit the maximum current to the device and will allow you to power the equipment while checking for other faults. Some designs, unfortunately, will not start up under these conditions. In such cases, substituting a 'better' device may be the best choice for testing.

(From: Glenn Allen (glenn@manawatu.gen.nz).)

I been repairing SMPS of all types but when I started on those using MOSFETs I was blowning a few of them when replaced because something else was faulty.

Ever since I have been using a BUZ355 on a heat sink I haven't blown it. It is rated at 800 V, 6 A, and 220 W. it is a TO218 case bigger than a T0220. It seems the higher ratings allows you to do repair where as a something like a 2SK1117 or MTP6N60 will just blow.

Testing of replacement HOTs

The following is useful both to confirm that a substitute replacement HOT is suitable and that no other circuit problems are still present. However, single scan line anomalies (particularly when changing channels and/or where reception is poor with a TV or when switching scan rates and/or when no or incorrect sync is present with a monitor) resulting in excessive voltage across the HOT and instant failure are still possible and will not result in an HOT running excessively hot.

(From: Raymond Carlsen (rrcc@u.washington.edu).)

After installing a replacement HOT in a TV set or monitor, I like to check the temperature for awhile to make sure the substitute is a good match and that there are no other problems such as a weak H drive signal. The input current is just not a good enough indicator. I have been using a WCF (well calibrated finger) for years. For me, the rule of thumb, quite literally, is: if you can not hold your finger on it, it's running too hot, and will probably fail prematurely. Touching the case of the transistor or heat sink is tricky....

Metal case transistors will be connected to the collector and have a healthy pulse (>1,200 V peak!) and even with plastic case tab transistors, the tab will be at this potential. It is best to do this only after the power is off and the B+ has discharged. In addition, the HOT may be hot enough to burn you.

A better method is the use of an indoor/outdoor thermometer. I bought one recently from Radio Shack for about $15 (63-1009). It has a plastic 'probe' on the end of a 10' cable as the outdoor sensor. With a large alligator clip, I just clamp the sensor to the heat sink near the transistor and set up the digital display near the TV set to monitor the temperature. The last TV I used it on was a 27" Sanyo that had a shorted H. output and an open B+ resistor. Replacement parts brought the set back to life and the flyback pulse looked OK, but the transistor was getting hot within 5 minutes... up to 130 degrees before I shut it down and started looking for the cause. I found a 1 uF 160 volt cap in the driver circuit that was open. After replacing the cap, I fired up the set again and monitored the heat sink as before. This time, the temperature slowly rose to about 115 degrees and stayed there. I ran the set all day and noticed little variation in the measurement. Test equipment doesn't have to cost a fortune.

Removing and replacing the deflection yoke

Should you need to remove the deflection yoke on a color CRT, some basic considerations are advised both to minimize the needed purity and convergence adjustments after replacement as well as to prevent an unfortunate accident.

The position and orientation of the yoke (including pitch and yaw) and magnet assembly (purity and static convergence rings, if used) are critical. Use paint or White-Out(tm) to put a stripe across all of the magnet rings so you will know their exact positions should they accidentally shift later. If there are rubber wedges between the yoke and the funnel of the tube, assure that they are secure. Tape them to be doubly sure as adhesive on old tape dries up with age and heat and becomes useless. This will avoid the need for unecessary dynamic convergence adjustments after reassembly.

The neck is the most fragile part of the CRT so do not apply any serious side-ways force and take care not to bend any of the pins when removing and replacing the CRT socket.

The yoke and purity/static convergence assemblies will be clamped and possibly glued as well. However, the adhesive will probably be easily accessible - big globs of stuff like hot melt glue and/or RTV silicone. Carefully free the adhesive from the glass neck of the CRT. Loosen the clamps and gently wiggle the magnets and yoke off the neck. They may appear stuck from age and heat but should yield with gently persuasion.

Once the yoke is replaced, some fine adjustments of the picture rotation, purity, and static and dynamic convergence may be needed but hopefully with your most excellent diagrams, these will be minimal.

Similar comments apply for monochrome CRTs but there are far fewer issues as the yoke is positioned firmly against the funnel of the CRT and rotation and centering are usually the only adjustments. However, there may be magnets located on swivels or glued to strategic locations on the CRT envelope to correct for geometric distortion.

Swapping of deflection yokes

This should work with identical TVs or monitors. Your mileage will vary if you are attempting a swap between monitors with similar specifications. Chances of success for monitors with widely different screen sizes or scan rate specifications is close to zero.

One indication of compatibility problems would be major differences in resistance readings for the corresponding yoke windings, CRT HV and other bias levels, etc.

Before you do the transplant, see the section: Removing and replacing the deflection yoke for procedures and precautions to minimize problems in realignment.

Make a precise diagram of everything you do.

Keep the purity/static convergence magnet assembly with the original CRT if possible and install it in the same or as nearly the same position as possible when you replace it.

Once you are sure of the connections, power it up carefully - there is no assurance that your yokes are compatible. A yoke with a much lower resistance or inductance than the original may overstress components in the power supply.

You will then need to go through all the adjustments starting with purity and convergence.

Swapping of non-identical CRTs

Given the problems of just replacing a CRT with an identical new one, it isn't surprising that attempting to substitute a CRT which is not the same type will result in difficulties - to say the least. Obviously, the closer in size, scan rate (for monitors), and deflection angle, the more likely the chances of success. Where the alternative is to junk the TV or monitor, it may be worth a shot - and you may get lucky!

It may be best to transfer as much as possible with the CRT - yoke and purity and convergence magnets. The connectors to the yoke may need to be changed but this may be the least of your problems. Difference in yoke impedance and other characteristics may result in anything from incorrect size to a truly spectacular melt-down! The latter is much more likely with SVGA monitors compared to similar size/deflection angle TVs.

Where the neck size is the same, the yoke can be moved from one CRT to the other but you will have to do a complete purity and convergence set up and even then you may have uncorrectable convergence errors. See the section: Swapping of deflection yokes.

(From: J. G. Simpson (ccjgs@cse.bris.ac.uk).)

Monitors are generally designed by choosing a CRT, then the EHT, then designing a yoke to scan the CRT, then designing a driver circuit to drive the yoke.

In a CRT test lab it's common to have variable supplies for EHT and other voltages, a small selection of yokes, and variable amplitude drive circuits.

EHT affects scan sensitivity, brightness, spot size. You can't get high brightness and small spot size on a large monitor with 3 kV of EHT. Virtually every variable has some effect on convergence. Spot size is important, in as much as you want most of it on the phosphor and not the shadow mask.

Provided the neck size is the same you can swap tubes in yokes but don't expect it to work very well. Different tube manufacturers may use radically different gun structures. A given yoke and its driver may give underscan or overscan and it's pretty well certain that convergence will be way off.

The military spends a small fortune on trying to get the drop into the yoke and it flies with no adjustment or convergence CRT. For the rest of us swapping a CRT is a pain in the butt.

Decayed glue in electronic equipment

Larger components like electrolytic capacitors are often secured to the circuit board with some sort of adhesive. Originally, it is white and inert. However, with heat and age, some types decay to a brown, conductive and/or corrosive material which can cause all sorts of problems including the creation of high leakage paths or dead shorts and eating away at nearby wiring traces.

The bottom line: Most of the time, this stuff serves no essential purpose anyhow and should be removed. A non-corrosive RTV or hot-melt glue can be used in its place if structural support is needed.

Repair parts sources

For general electronic components like resistors and capacitors, most electronics distributors will have a sufficient variety at reasonable cost. Even Radio Shack can be considered in a pinch.

However, for modern electronic equipment repairs, places like Digikey, Allied, and Newark do not have the a variety of Japanese semiconductors like ICs and transistors or any components like flyback transformers or degauss Posistors.

See the document: Major Service Parts Suppliers for some companies that I have used in the past and others that have been recommended. Also see the documents: Troubleshooting of Consumer Electronic Equipment and Electronics Mail Order List (this one is quite dated though) for additional parts sources.

Sources for adapters and cables

Office and computer supply companies like Inmac and Global may have some very common types like VGA switch boxes and extension cables - of unknown quality.

However, there are companies specializing in cables for computers, video, and communications. For example:

- Black Box Corporation. Check out their on-line catalog and other information.

Monitor replacement cables

Here is a company that will supply replacement cables for a wide variety of computer monitors.

- Interface 2 Ltd (UK) (formerlay A+G Computerware Limited)

2.There is no charge except to cover the costs of copying.

WARNING and DISCLAIMER

Attaching an incompatible video source to a monitor (i.e. the signals do not have the proper voltages as with digital or analog levels) or using the wrong scan rate are both potentially risky to the monitor.

- Incorrect signal levels or connections can damage the monitor's input circuitry and/or the output drivers of the video (or other interface card if you happen to accidentally plug it into an Ethernet or serial card by mistake!).

  Don't arbitrarily attach the monitor cable to a socket just because they physically mate or have the same number of pins!

- Setting the scan rate of a monitor outside its specified range may overstress components and can result in expensive damage to power supply and deflection components. Whether or not this happens with a given model depends on its design and there is no way to know beforehand which monitors are susceptible. Some monitors will be perfectly happy working beyond their published specs; others will politely shut down with a warning; but all too many will go up in smoke!

  It can be very risky to experiment with scan rate settings either because you have no idea of what is valid or to 'explore the envelope'. Either of these could result in expensive repairs. The only hint you may get just before the smoke comes out are unusually poor geometry or instability but it would be foolish to depend on these possible warnings.

We will not be responsible for any damage to your monitor or ego that may result from such experiments!

- Back to Monitor Testing Table of Contents.

Introduction

Scope and Purpose of This Document

This document provides a guide to the testing of computer and video monitors for functional characteristics like color purity, convergence, geometry, focus, resolution, Moire, switching between scan rates (where applicable), and acoustic noise. A subset of these tests apply to television sets as well.

Although flat panel monitors based on LCD and other discrete technology are increasing in popularity, their higher cost and spotty performance, especially when not used at their native resolution, means that CRT monitors will continue to be important for several years to come. And many of these tests apply to flat panel displays as well.

WARNING: No monitor is perfect. Running these tests on your monitor or one you are considering may make you aware of deficiencies you never realized were even possible. You may never be happy with any monitor for the rest of your life!

Note: the intent of these tests is **not** to evaluate or calibrate a monitor for photometric accuracy. Rather they are for functional testing of the monitor's performance.

Obviously, the ideal situation is to be able to perform these sorts of tests before purchase. With a small customer oriented store, this may be possible. However, the best that can be done when ordering by mail is to examine a similar model in a store for gross characteristics and then do a thorough test when your monitor arrives.

Comments on Monitor Performance and Sample-to-Sample Variations

(From: Will Nott (bnott@barngate.compaq.com).)

As with every piece of machinery built in mass production, monitors have performance specifications which define tolerances on performance, as well as operational limits. This has always been the case for monitors, and, in fact, front of screen performance specifications have not changed appreciably over the last ten years. Other items, such as for video & scan rate capabilities have changed, but those items do not appreciably affect the front of screen issues which most users find disappointing.

Most users never see the detailed specifications which the manufacturer works to, but may see a sub-set intended to "feature" the product's strong and/or competitive points. There are some variables which may be compensated for with more sophisticated circuits, but that usually results in higher product cost (*not* necessarily sales price; see below). There are other variables which are subject to normal state of the art production tolerances, and because of this, some units will actually come off the line looking better than others, even though they all meet spec.

For an example, misconvergence is a variable subject to production tolerances, and practically all monitors have similar spec's, even though most people would not like to settle for a unit which is at the limit of the spec. The typical spec. is 0.3 mm in the area within a circle equal to the height of the image, and 0.4 mm outside that area. That is actually more than the theoretical pixel size on a 14" monitor, and hardly anyone will want to use a display with that performance. However, the spec. allows such variations to exist.

An example of a feature which can be affected by additional circuit sophistication is Geometry, or line straightness - each manufacturer has specifications to meet, but here some units may allow as much as 6 mm of non-straightness, where other units may have the ability of being adjusted to a straightness of less than 1mm.

So, what the user runs into are variations of two kinds:

1. Normal manufacturing tolerances explain differences that may be expected among various examples of the same brand & model monitor.

2. Differences in design (circuits) which provide the possibility of adjusting out other kinds of distortion explain differences between different brands and models.

Of course, this probably has very little correlation with the price at which the product is being offered, because of other competing factors in the marketing game, so it's not really fair (although we all are likely to do it) to expect a more expensive product to perform better - maybe that company is doing better at "charging what the traffic will bear". That's why it's always advisable (within practical limits) to try and understand the spec's, and to try and examine the actual unit which you will be taking home, not a showroom example.

What About the New Flat Panel Displays?

The information in this document applies directly to the vast majority of CRT (picture tube) based equipment. However, what may be surprising, is that much of it also applies to the new generation of flat screen SVGA monitors based on LCD, plasma, or other discrete pixel based technology. Why? While these devices cannot suffer from some of the problems inherent with CRTs (like imperfect geometry, convergence, or non-linearity), many characteristics can still be quite variable from one design or even one sample to another. These include brightness, brightness uniformity, range of viewing angle), color rendition, flicker, and ghosting (if analog interface).

Furthermore, digital scan converters need to be built into autoscan (SVGA type) flat screen monitors since they are basically fixed format devices. These are needed to accommodate the multiple scan rates and resolutions produced by PC based video cards when used with DOS/Windows or any situation where the resolution does not match the native resolution (number of pixels and lines) of the physical display device. Problems can arise from less than optimal resampling or inadequate conversion speed where motion is involved. These include: reduced sharpness, Moire, flicker or limited frame rate of changing/moving images, stability, and more.

Therefore, much of the testing information provided below can still be used to at least provide guidelines as to what to look out for when selecting a flat screen display, and evaluating and comparing sample units side-by-side.

Comments on Selecting an LCD Monitor

As with virtually everything else, there is a lot of hype and specsmanship with respect to flat panel monitors. After screen size, native resolution, maximum refresh rate, the specification that many people consider most important is contrast ratio, loosely defined as the ratio of the brightest white to blackest black. Or, perhaps contrast ratio is the #1 consideration. All else being equal, a higher contrast ratio should result in better rendition of continuous tone (i.e., photographic) images. Photos without black blacks tend to look washed out or muddy. However, for much of what one does on a computer, this may not really matter.

So, don't base your decision only on the contrast specifications. Check out the monitors personally if possible and determine which you like best under a variety of viewing conditions and screen material (e.g., text, photos, graphics).

There are additional issues like maximum brightness and viewing angle which may be equally or more important.

A monitor with high brightness may also end up with a bright "black screen". Those with best contrast specs may have a mediocre viewing angle. The contrast ratio spec may only apply at maximum brightness.

One of the things I dislike about all LCDs is that remaining illumination even for a totally black display. Compared to a properly adjusted CRT, displays like the "Flowerbox" screen saver really look bad, especially in a dark room.

- Back to Monitor Testing Table of Contents.

Basic Monitor Performance Criteria

The following are among those characteristics of a monitor that should be evaluated:

- Screen size and general appearance.
- Brightness and uniformity, purity and color saturation.
- Stability.
- Convergence.
- Edge geometry.
- Linearity.
- Tilt.
- Size and position control range.
- Ghosting or trailing streaks.
- Sharpness.
- Moire.
- Scan rate switching.
- Acoustic noise - buzzing and whining.

For monochrome monitors, use the appropriate subset of these tests. The descriptions below usually assume an auto-scan SVGA type of monitor. Modify accordingly for fixed scan computer monitors and studio video monitors.

Note: we use the term 'auto-scan' to describe a monitor which accepts a wide (and possibly continuous) range of scan rates. Usually, this refers mostly to the horizontal frequency as the vertical refresh rate is quite flexible on many monitors of all types. Fixed scan or fixed frequency monitors are designed to work with a single scan rate (though a 5% or so variation may actually be accepted). Multi-scan monitors sync at two or more distinct scan rates. While not very common anymore, multi-scan monitors may still be found in some specific applications.

CAUTION: since there is no risk-free way of evaluating the actual scan rate limits of a monitor, this is not an objective of these tests. It is assumed that the specifications of both the video source/card and the monitor are known and that supported scan rates are not exceeded. Some monitors will operate perfectly happily at well beyond the specified range or will shut down without damage. Others will simply blow up instantly and require expensive repairs.

Note: throughout this document, the term 'raster' is used to refer to the entire extent of the scanned portion of the screen and the terms 'picture', 'image'. or 'display', to refer to the actual presentation content.

Test Patterns

Three kinds of test patterns will be needed:

1. Solid, saturated primary colors (R,G,B) and combinations of these (Y,C,M,W). These will be used for brightness and color purity tests. Total black will also be required to set background level and evaluate black level retention.

2. White cross hatch, fine dot, alternating vertical and horizontal line patterns and bounding box outline. These will be used for convergence, geometry, size, and position, focus, and Moire tests.

3. High quality graphic or photographic image for general color appearance and overall aesthetic tests. If no suitable material is available, a Windows desktop with a vibrant color scheme (computer monitors) or an outdoor scene on a sunny day (studio video monitors) may be used.

For computer monitors, software programs are available to conveniently generate the required test patterns. However, an application like Windows MSPAINT in conjunction with a picture with vibrant colors can be used to create anything that is needed. It just will not be quite as easy to switch between patterns. Video cards like those from ATI come with a software Install program which provides a bounding box pattern and at all (PC DOS/Windows) resolutions and scan rates.

Test pattern generators for TV monitors are readily available and relatively inexpensive. However, a camcorder viewing appropriate printed material or a prerecorded tape can be used in a pinch.

- Back to Monitor Testing Table of Contents.

Testing a New or Used Monitor

Before starting the series of tests, allow the monitor to warm up for at least 1/2 hour and make sure it is completely degaussed (see the document: Notes on the Troubleshooting and Repair of Computer and Video Monitors for details on degaussing techniques. Power the monitor up in the physical orientation you will be using it (front-back facing North-South if you do not know how your setup will be arranged) and don't rotate it on its tilt swivel base after degaussing and for the duration of these tests. Make sure the monitor is not near any sources of electromagnetic interference (i.e., other powered monitors, loudspeakers, motors, transformers, etc.). Subdued lighting is best.

Use only the original video cable that came with the monitor or high quality BNC cables as appropriate. If you have a choice, opt for a BNC cable - the quality at higher scan rates will be noticeably better. Do not use any extension cables, any video switch boxes, or excessively long BNC cables.

Obviously, if you can do any of this in a store at all, then you may not quite have the luxury to fully control your environment!

Note that for an auto-scan monitor, all tests should ideally be performed at several points including the extremes upper and lower limits of each scan range. Most aspects of a auto-scan monitor's performance are affected by scan rate.

Unless otherwise noted, all controls are those available to the user.

For each test, adjust the size and position controls so that the raster fills as much of the screen as possible or as appropriate for the particular test.

Screen Size and General Appearance

Screen dimensions are normally measured diagonally - corner to corner.

So you thought you were buying a 17 inch monitor, right? Wrong. A monitor that is advertised as 17" (or 15" or 21") will rarely give you anything near that viewable size. The specification is of the CRT - including what is covered up by the front bezel and not considering the actual maximum size picture that may be possible in all scan modes.

Easily, 1.5 to 2 inches of your valuable diagonal screen real estate may be lost to marketing hype. As a result, you might find as much as a 20% difference in usable screen area between monitors which claim to be the same size. This is like buying a 17" monitor and getting one that is only 15"!

At certain scan rates, it may not be possible to get a picture corner to corner so even more usable area will be lost. Check out the section: Size and Position Control Range.

Some advertisements now include actual viewable screen size. Hopefully, this will become a universal practice but I will not hold my breath.

Other aspects of the monitor to check out:

- Screen curvature - some are curved, others are nearly flat, Trinitrons are cylindrical. For the most part, this is strictly a matter of preference. However, if you intend to photograph (still or video) off the screen, a flatter screen (all other factors being equal like geometric accuracy) will result in less distortion.

- Screen surface finish - this may be highly polished resulting in annoying reflections or dull (flat) which if excessively graining will decrease the crispness of the display. A highly polished surface with an anti- reflective coating (see below) is probably best.

- Antireflective and/or black (smoked) glass - usually, a CRT with a dark appearance will produce a higher contrast picture but possibly at the expense of overall brightness. Antireflective coatings like on camera lenses help also but are easily smudged and may be damaged by excessive cleaning.

- Convenience of the user controls. Digital controls are nice in that the settings for each resolution and scan rate are stored in memory. However, knobs are much easier to adjust in many cases. I prefer knobs for at least brightness and contrast.

- The aesthetics of the case. While this is usually unimportant from a performance point of view, it could be of great significance to your happiness. However, I know of some incredibly ugly monitors with great performance!

Brightness and Screen Uniformity, Purity and Color Saturation

Display a black - totally blank screen (but don't just pull the video cable as the monitor will be running with the normal voltages and signals) so that the raster is just barely visible. This adjustment should be possible but as noted below, not all monitors have totally independent brightness and contrast controls - you may need to bring up contrast a bit also.

The raster should be of uniform intensity and neutral gray. If it is not of uniform intensity or has hum bars - full width areas of varying brightness - or full height vertical rippled areas, the monitor's power supplies may be defective or of poor design. The only way to be sure is to compare several samples of the same model.

If the raster is not a neutral gray but has a tint, the color balance may need to be adjusted. See the section: Brightness and Screen Uniformity, Purity and Color Saturation.

Make sure you can actually set the brightness for total black (turn out the lights and check). If not, you will never have truly dark shadow areas in your display. Blacks will never be black and the display will always look a washed out. This may be adjustable internally.

However, inability or difficulty in adjusting for a totally or nearly black raster and vibrant bright display - or if the background brightness shifts as the picture content changes - may indicate a deficiency or defect in the black level retention circuitry. Since video signals are usually AC coupled, a clamping circuit is needed to set the black reference. If this does not work correctly or is poorly designed, the black level may shift depending on the picture content. Modern monitors should be nearly perfect in this regard. This problem is still seen in some cheap TVs, however.

Now set brightness to make the raster just disappear. Set the contrast control all the way up. Display a pure red (R) full intensity raster. The entire screen should be a pure, fairly uniform fully saturated red. There should not be any areas that are not pure red. Repeat with the other two primaries - green (G) and blue (B). Follow this up with tests of pairs of primaries resulting in yellow (R+G), cyan (G+B). and magenta (R+B). Again, these should result in pure vibrant colors.

Finally, display a pure white full intensity screen. The raster should be pure white. There should be no patches of discoloration. It may be a warm white (somewhat redish) or a cool white (somewhat bluish) but not objectionably so. Some monitors permit this color 'temperature' to be adjusted by the user (e.g., NEC AccuColor models like the 4FG or 5FG). If the screen is noticeably colored and there are no user adjustments, then the internal video gain controls need attention - see the section: Brightness and Screen Uniformity, Purity and Color Saturation.

Note that the term 'vibrant' here is a subjective term but relates to the boldness, saturation, and, well, zappiness! However, this is affected both by the choice of spectral output of the primary color phosphors and to your perception. For a given CRT, the phosphors set the spectral characteristics of the display. Expensive studio monitors can be ordered with a specific CRT to suit the needs of the video standard. This is rarely an option with computer monitors. You probably do not have control over your visual perception (but do take off those autocompensating sun glasses!) In other words, your mileage may vary.

If any of these tests detect a problem, the color purity may need to be adjusted. (By you or by a professional as appropriate). A brand new monitor should not have purity problems unless it is near a source of magnetic fields like a loudspeaker or MRI scanner.

The pure white screen can also be used to evaluate the brightness uniformity of the CRT. Don't expect perfection. The actual quantitative measured brightness may vary quite a bit even with a high quality monitor. The corners and edges may be noticeably darker than the center even on the low deflection angle CRTs used in high performance monitors. With the high deflection angle CRTs in TVs and cheap monitors, this may be even worse.

However, local significantly darker or brighter areas could indicate defects in the CRT dot/slot mask or aperture grille or phosphor screen which should not be tolerated.

Should you see color or uniformity problems at full intensity, try turning down the contrast control. If the uniformity improves after a few seconds, the shadowmask in the CRT may be heating and deforming. This is not unusual with color monitors. One of the advantages of an InVar shadowmask is that it is less prone to these problems, however.

Also note if there is a brightness limiter circuit that is kicking in with the full white screen. As you turn up the contrast, is there a point where further increase has no effect on the intensity of the display or where the intensity actually decreases? These brightness limiters are designed to maintain the beam current at supposedly safe levels to minimize X-ray generation and/or to mimize the shadowmask heating effects. Is the maximum brightness adequate for you needs and viewing enjoyment?

Using the full white screen, adjust the contrast and brightness controls through their full range. The size of the raster should not change noticeably. A significant change in size - more than 1 or 2 percent - would indicate poor power supply regulation.

Examine the entire screen closely for blemishes both in the surface finish and for dead spots.

If you see any dead or darker spots, confirm that these are not due to the video source: if they are CRT defects, they will not move as you adjust the position controls.

There is a specification for the number and size of acceptable CRT blemishes so you may have to whine a bit to convince the vendor to provide a replacement monitor under warranty. Defects in the corners will likely only be noticed if if you are looking for them. However, dead spots in the central area of the screen will always be a distraction. Before the purchase is the time to find these.

(From: Jamie Carter (jacarter3@onebox.com).)

The specification for display brightness has always been subject to specsmanship. For example, a CRT or CRT based display will quote lux or lumens/m^2 based on a 10% white field which is a small square in the display set at maximum output. A CRT display cannot achieve the same current density on the phosphor with the whole screen being white and thus the full white screen will give a significantly smaller value not to mention that the resolution suffers significantly with the high electron beam density.

These effects are obviated for the most part with LCD or DMD displays because the brightness engine is decoupled from the resolution engine. But even in these cases, the color temperature of the white field, the color purity (saturation) of the color channels and gain of the screen (distribution of the luminous flux) all factor into the perception of display quality and image "goodness" (a very subjective quality at best). Your best bet is to compare the actual display units under your specific viewing conditions and intended display content. Note that the "Compu-Hut" will line up a whole bunch of displays for your comparison but only display photographic images with rather limited spatial bandwidth. This gives no indication of display quality when viewing 1 pixel wide strokes for desktop and application fonts. Make the sales ape show some of the GUI windows and a text file before you buy.

Then there's an industry term: "Market Comparable Lumens". I am sure that the real basis for this is to create a metric that cannot be disputed or independently tested by the buyer. :)

Stability

Display a picture having a complete range of colors and intensities.

At refresh rates beyond 70-75 Hz, even a very bright display should appear rock solid. Turn off any fluorescent lights (whose possible flicker at twice the power line frequency can confuse the test) and examine the screen closely. There should be no shimmering, wiggling, jittering, or dark or light flashes. Any of these would indicate either (1) external electromagnetic interference or (2) a poorly designed or defective power supply in the monitor. It is also possible, though less likely, that the incoming AC power is noisy but modern monitors generally do a decent job of filtering the power lines to eliminate most of this.

Convergence

Ideally, all three electron beams in a color CRT should be precisely coincident at every point on the screen. While this is never quite achieved, the degree of convergence even at the corners is generally quite impressive - less than .5 mm for many moderately priced monitors.

Display a white crosshatch pattern with boxes about 1/2 inch square. IF you do not have this, use a white-on-black graphics or text screen with a lot of fine detail - small fonts or intricate patterns.

The lines should appear white without excessive color fringing. The individual primary colors should not be visible at a normal viewing distance. First, examine the center. This should be nearly perfect. If your monitor has any user adjustable convergence controls, set these for best center convergence. Convergence will be worst in the corners but even there, it should not be objectionable.

A serious convergence problem in the center of the screen is definitely an indication of a defective monitor or one that needs internal adjustments. Slightly poorer convergence at the corners may be within specifications. A new monitor with significant convergence problems should be rejected.

Edge Geometry

Display a bounding box image - one that extends to the very edge of the raster on all sides.

Adjust any user pincushion controls (amplitude and phase) for minimum distortion along the vertical edges. Amplitude moves the sides in and out. Phase sets where, vertically, this effect takes place. If there are any other user controls that affect raster shape, optimize these for a perfectly rectangular display.

Now, examine all edges for curves, wiggles, dips, keystoning, or trapezoidal deviations from a perfect rectangle. These are all considered defects in the geometry of the raster. These will likely be more pronounced at high scan rates - near the limits of the specifications for the monitor. In particular, you may see a wiggle or wave on the left and right edges near the top of the screen which will be come more pronounced as you approach the highest scan rate (this is a deflection problem, however, not strictly a CRT geometry problem).

During manufacture, various magnets are strategically glued around the CRT or carefully positioned on rotating swivels on the deflection yoke frame or elsewhere. You need to decide if any remaining errors in geometry are acceptable or not because improving upon these settings is not something that is easy or fun to do - by you or a professional! As noted, if the geometry becomes noticeably inferior at high scan rates, this indicates a problem in the deflection circuitry - adjustments will probably not help. Consider another monitor if you intend to run at these rates.

Linearity

Display a crosshatch pattern of roughly 1/2" spaced lines. Take a tape measure and compare the exact spacing of vertical lines in the left, middle, and right areas of the screen. Do the same for the horizontal lines in the top, middle, and bottom of the screen. Modern monitors should have very little variation - probably undetectable using a tape measure.

Linearity may or may not be adjustable.

Tilt

Inspect the bounding box for tilt - is it perfectly aligned with the cosmetic bezel of the CRT? If the monitor has a tilt control, see if it will compensate. Few do. The only way to correct tilt on monitors without a tilt adjustment is to rotate the deflection yoke or entire CRT - not recommended. If the degree of tilt bothers you in the slightest and you are a perfectionist, reject the monitor or insist that the tilt be corrected - and be present if possible to make sure that the adjustment is done to your satisfaction.

Size and Position Control Range

Determine if the size and position controls have enough of an range to fill the screen totally (for computer monitors) or (possibly in conjunction with an underscan switch) allow for a suitable reduced raster size (studio video monitors).

For computer monitors, these tests may need to be done in conjunction with the video card you will be using and the software setup program for that video card. Ideally, all size and position adjustments can be done in software with the monitor's controls left at their center (default) setting. However, this is not always the case.

Some people want their computer monitors to extend to or past the edges of the CRT. Many monitors may leave a large border around the picture particularly at higher scan rates. Test at the resolutions and scan rates you expect to use. Obviously, a monitor that will not fill the screen is shortchanging you in terms of how much screen size you purchased!

Often, slightly reducing the scan rate at a given resolution will allow for a larger picture. This is one alternative if the flicker is not objectionable.

Ghosting or Trailing Streaks

Display a picture with a large number of high contrast vertical edges - a Windows desktop with many open folders, for example.

Vertical edges should be crisp and clear. Examine these for smearing, ghosting, or trailing darker or lighter lines. Any deficiencies will be most evident at high scan rates since these require the most bandwidth from the video card, cables, and monitor. Also, any ringing, undershoot, or overshoot, will extend for a longer space following the edge.

Without substituting video cards, cables, and monitors, it is not usually possible to determine which is the limiting factor.

The most common cause of these types of problems are inferior, defective, or excessively long cables; use of cable extensions or video switch boxes; or improper termination if there are termination options on the monitor.

Full brightness vertical edges should not smear or bloom to the right - possibly with a color change. This is due to the internal video gain controls being set too high and may be correctable but possibly with a reduction in maximum brightness.

There should also be no trailing lines to the right of long bright or dark horizontal areas. Similarly, the edges of the raster should not bulge out where the picture is very bright. These types of problems would indicate problems with the power supplies or just poor design.

Sharpness

Display a white screen at the highest resolution and scan rate your system is capable of (or the highest you ever anticipate using). See if you are able to make out the individual scan lines. Turn down the brightness - this will decrease the effective spot size and make the scan lines more visible.

Display a fine dot pattern. The individual dots should be tiny, crisp, and fairly symmetric. If the spot size changes drastically with brightness, focus may need to be adjusted or the monitor's power supplies or CRT may be mediocre or defective.

Note that it is not always best to have super sharp focus as long as the spot size is small enough. A slightly defocused spot will result in a smoother display and less likelihood of Moire effects.

Moire

Moire is caused by interference - beating - between the picture or raster and the phosphor dots or lines that make up the display. Technically, it is an aliasing artifact due to the relative sampling rates of these two structures.

There are several causes of Moire. The following will address two of these: scan line Moire and pixel Moire.

Try these tests with any 'Moire reducing modes' both off and on. However, the use of such 'features' may reduce the quality of the display in other ways like reducing sharpness or stability.

Display a solid white screen at mid brightness. Look for patterns that look similar to contour lines on topographic maps. Adjust the vertical size and position controls to see if these move around or change their severity and spacing. Repeat with a display of alternating black and white horizontal lines.

Now, display a pattern consisting of alternating black and white vertical lines at the maximum possibly frequency (alternating dark and light pixels for a computer display - make sure your software is not doing any dithering). Look for serious contour lines in this display. Adjust the horizontal size and position controls to see how these affect any Moire.

Try these tests at multiple resolutions including the highest you will ever use. However, the highest may not necessarily be the worst with respect to Moire.

Other than using any 'Moire reducing mode' provided by the monitor, there may not be anything you can do to reduce the severity of Moire other than running at resolutions which do not exhibit a serious problem.

Nonetheless, I think it is ironic that some people will end up returning otherwise superb monitors because of moire - when in many cases this is an indication of most excellent focus - something many people strive for! You can always get rid of it - the converse is not necessarily true!

Scan Rate Switching

When running Windows or DOS with a auto-scan monitor, switching scan rates may be done quite frequently. Some monitors take longer than others to perform this switchover. There may be clicks (due to relays) and other sounds. Better monitors will blank the video until the new scan rate has stabilized. On cheaper monitors, you may see the image as it locks in. Some monitors are very quick. Others can take several seconds - an eternity if you are doing this frequently. Try switching between scan rates at the limits of each scan range as this will be the toughest situation. While it is hard to pin down what makes for a suitable outcome of this test (unless there is an actual failure to properly sync), a monitor that appears to be struggling or which doesn't always make it may be trying to tell you something.

Note: there have been some monitors that blow up - fail completely and require expensive repairs - simply as a result of the video card initialization at boot time due to its power on self test when the video signal may be unspecificed and driving the monitor at an invalid scan rate. However, this is not likely to be a problem with any modern auto-scan monitor.

Acoustic Noise

Ideally, a monitor is seen and not heard. However, there are a variety of components inside that can vibrate and this may be quite annoying in a quiet room or late at night. A buzz may originate from the switching power supply or vertical deflection components. A high pitched whine, squeal, or twittering may originate from the switching power supply, flyback (LOPT) transformer, or horizontal deflection components. Some people aren't bothered by these sounds at all or cannot hear them. Others will be driven stark raving bonkers.

Listen carefully through the grille in the cover for any indication - even momentary - of annoying sounds. Try all scan rates - very often various resonances will only occur at particular horizontal or vertical scan frequencies. Even with high quality monitors, these problems sometimes occur erratically and no quick test will identify such faults. Obviously, doing this in a quiet location is best.

Note that any decreasing hum or buzz that may be heard at power-on is due to the internal degaussing coil and is usually normal and unavoidable.

Checking the Age of the CRT

This doesn't (or shouldn't) apply to a new monitor, but suppose you found this great deal on a used TV or monitor. How can you tell if the picture tube is about to die on you?

(From: Andy Cuffe (baltimora@psu.edu).)

The best way to tell is to look at the picture quality. There is no way to tell the exact number of hours. Also, the life of CRTs varies quite a bit. some will go down hill much faster than others.

- It should be sharply focused over the entire screen and all 3 colors should be equally sharp.
- Set the picture brightness and color to maximum. If you see any bleeding or smearing to the right of bright objects don't buy it.
- When you first turn it on the picture should look normal in well under a minute. If it is dim, tinted, or blurry for more than a minute or two the CRT is getting weak.
- A B/W picture should not be tinted.
- The picture should have decent brightness with the picture at about mid range.

Apart form that, if the overall picture is good the CRT is fine. CRTs usually fail very slowly. Even if it's starting to show it's age it probably has several years left.

(Portions from: Jerry G. (jerryg50@hotmail.com).)

You cannot tell the hours used by just looking or even measuring a tube. A tube can go at any time. There are no hour counters!

Turn on the unit and see if there is any unusual bleeding of the image in the picture at high contrast levels. When turning the brightness up and down, the color temperature should not change, only the brightness. When turning the contrast up and down, the focus at the center should also be very stable. It may change only a little bit. When turning on the set, the color temperature should be stable within about 3 to 5 minutes.

Look at the colors in the corners to see if the purity is good. Bad purity can be attributed to a miss-adjusted yoke assembly, to a bad shadow mask.

To know the manufacture date of the unit, it us usually on the back with the model and serial number. Most TV sets are on about 5 to 8 hours a day if it is a family TV. If it is a bedroom TV the hours may be 1/2 that amount. Monitors may be on 24 hours a day - or much less.

A good way to know if the emission of the CRT is up to specs is to get a CRT analyzer and measure the gun emission. Some service centers own one.

Specifically for Used Monitor Purchases

In addition to the previous tests, general condition may be a good indication of the future holds for the monitor. Aside from obvious damage from being dropped off a 10 story building, there can be scuffing, dings, and dents which may not affect performance but look bad. Equipment operated in dirty or dusty locations, among heavy smokers, or in or near greasy kitchens, may become coated and this can be difficult or impossible to clean up completely. The inside may be clogged as well which may ultimately affect reliability. Such monitors may also always smell bad.

When buying a used monitors, particularly sight unseen (as on eBay), asking the proper questions will be most important. Age alone isn't necessarily a reliable indication of performance or future reliability. I'm typing this on a 10 year old NEC 5FG which I still consider to be as good as any monitor sold today. However, a 2 year monitor run 24 hours a day could be ready for the dumpster. It's probably best to stay with a major brand name. If possible, ask about most of the items listed above, but particularly the brightness, focus, convergence, geometry, and overall picture quality.

- Back to Monitor Testing Table of Contents.

Final Evaluation

If after these tests, you determine that your monitor or the one you are considering is perfect - let me know as this is extremely unlikely. More likely is that you found a number of deficiencies. If this is a monitor you are considering purchasing, you need to decide if the benefits outweight the defects. For certain problems like color balance, the vendor may work with you to tweak the needed internal controls. Alternatively, using the information contained in the document: Notes on the Troubleshooting and Repair of Computer and Video Monitors, you may decide that you will be able to take care of the problem yourself. However, for problems like severe misconvergence, uncorrectable pincushioning, serious Moire, or audible buzz, there may be no easy solution and searching for another monitor may be the only option. If you inherited the monitor or are getting a really good deal, then many of these problems can prboably be dealt with but with some risk that significant improvement may not be possible.

- Back to Monitor Testing Table of Contents.

Monitor Testing Programs

There are a variety of PC compatible software programs for testing of SVGA computer monitors. These display various test patterns and color charts which are appropriate for the procedures discussed in this document.

Here are a few pointers:

- The monitor test program "NTest" is very often recommended on the comp.sys.ibm.pc.hardware.video Newsgroup. This was originally available from Nokia but since Nokia sold their monitor division to Viewsonic, it has disappeared so here is a copy. I'll be happy to link to the Viewsonic site if they replace it.

    - Nokia Ntest Monitor Test.

- ComputerCraft provides a shareware program for testing monitors and video cards. I have not tested it but as they say: "If you are aware of the dangers, Monitors 1.01 is a powerful tool." See the section: WARNING and DISCLAIMER for some of these. This shareware program can also test video cards for characteristics and graphic modes

    - Monitors 1.01.

  (From: Mark E. Nikl (markn3@infoave.net).)

  In the download section of the Web site, there is a file called monitors. It will give you all the test patterns and setups for gray scales, HV regulation, tell you about you video card and much more. I just ran across it the other day. You can even set up the pincushion and lots more.

- SONERA Technologies markets a set of programs called "DisplayMate" available for DOS and Windows/Win95. This is supposed to guide you through the monitor testing and setup process with a series of test pattern 'slides'. I have not tried it so I cannot comment on its utility.

  A demo version with a few test patterns, more information on their products, and some video tech tips, and some test patters are available at:

  - Display Mate Home Page and Demo.
  - Test Patterns.

- The following link provides some simple test patterns for color, focus, convergence, and black level, using just HTML pages which can be downloaded.

  - Various Display Tests.

- PassMark has a product that appears to have a fairly comprehensive set of features including 25 test patterns, display of monitor and video adapter information, and support for multiple resolutions, color depths, and display types. It can be downloaded for free with a 15 day evaluation, then costs $15:

  - PassMark MonitorTest.

- Here are a variety of common geometry and color test patterns for monitor adjustment.

  - Eric Richards' Web Site (Run on-line)
  - patterns.zip (Download Java applet)

Important Notice

The author of this document has absolutely no affiliation of any kind with any hardware, software, or service company which has a vested interest in advocating one solution over another.

The purpose of the FF Mon FAQ is to provide unbiased information to aid in making an informed decision when considering the acquisition of a fixed frequency monitor for use on a PC.

Contributions of a non-commercial nature to enhance this document are welcome.

WARNING and DISCLAIMER

Attaching an incompatible video source to a monitor (i.e. the signals do not have the proper voltages as with digital or analog levels) or using the wrong scan rate are both potentially risky to the monitor.

- Incorrect signal levels or connections can damage the monitor's input circuitry and/or the output drivers of the video (or other interface card if you happen to accidentally plug it into an Ethernet or serial card by mistake!).

  Don't arbitrarily attach the monitor cable to a socket just because they physically mate or have the same number of pins!

- Setting the scan rate of a monitor outside its specified range may overstress components and can result in expensive damage to power supply and deflection components. Whether or not this happens with a given model depends on its design and there is no way to know beforehand which monitors are susceptible. Some monitors will be perfectly happy working beyond their pusblished specs; others will politely shut down with a warning; but all too many will go up in smoke!

  The designers of fixed frequency monitors originally designed for specific workstation applications may very likely have taken even less care in dealing with unexpected scan rates as their environment is closed and such treatment isn't expected. Spectacular and expensive failure is quite possible.

  It can be very risky to experiment with scan rate settings either because you have no idea of what is valid or to 'explore the envelope'. Either of these could result in expensive repairs. The only hint you may get just before the smoke comes out are unusually poor geometry or instability but it would be foolish to depend on these possible warnings.

Some of the procedures described in this document may require going inside the monitor to make adjustments or add circuitry. There are both high voltages (25 kV OR MORE for the typical 19 inch workstation monitor) and AC line voltage all too easily accessible once the case is removed. Don't even think about doing anything inside a monitor unlil you have read and understood everything in the document: Safety Guidelines for High Voltage and/or Line

Powered Equipment. Something that looks innocent can really ruin your whole day!

We will not be responsible for any damage to your monitor or ego that may result from such experiments!

Introduction

That Bargain Monitor

So, you have got the deal of a lifetime - a brand spanking new (or at least low mileage) high resolution 21" computer monitor that came from a DEC Alpha Workstation - or a Sun or HP - or Macintosh. Or, perhaps an IBM 9517 which you were told has a super sharp bright picture. The cost to you: $1 or you haul it away. Is this really and truly a good deal if you use a PC?

Questions like this come up all the time on comp.sys.ibm.pc.hardware.video.

These are either fixed frequency monitors or are incompatible with the common VGA/SVGA 'standards' in some other ways.

This document provides unbiased information on the problems and possible solutions to dealing with these monitors on PCs (where the term 'PC' mostly refers to DOS/Windows based x86 and Pentium boxes but may include Macs and Linux based systems as well).

Note that some/many/most newer workstation monitors may indeed NOT be fixed Therefore, before spending a lot of time, effort, and money to adapt a fixed frequency monitor that isn't, attempt to determine its specifications from the manufacturer - all you may need is a cable! That workstation monitor may be identical internally to a one sold for PCs but with a different model number and video caonnector. Why is this now the case? Simple: Because it is cheaper for a monitor manufacturer to produce a single standard model rather than a one for the large PC market and another for the much smaller workstation market - even if it is somewhat simpler with a lower parts cost.

Fixed Frequency Monitor Basics

A fixed frequency monitor is designed to operate at a single scan rate which usually means a single resolution such as 1280x1024. (Strictly speaking, the horizontal resolution is determined by the number of pixels sent on each scan line by the video card but this is a detail.) PCs running DOS, Windows 3.1, WFWG3.11, and Win95 generally require the monitor to run at multiple scan rates - one for each corresponding resolution. For example, boot at 640x400, VGA at 640x480, Windows at 1024x768 - and each one may have a correspondingly different horizontal and vertical scan rate. (Some workstation monitors are actually dual frequency but this does not really help since neither of the supported scan rates are what a PC wants.)

Monitors like the IBM 9517 are not fixed frequency but are XGA compatible. This was an IBM abortion and not compatible with VGA/SVGA even for booting your PC.

These types of monitors are generally manufactured by the best names in the industry such as Hitachi, Mitsubishi, Philips, Sony, etc. - and are thus often of very high quality. The specifications of these monitors may exceed those of any but the very top-of-the-line monitors used on PCs. The origianl cost of these monitors was probably much higher than an equivalently sized PC monitor as well. They become available as high performance workstations (whose technology advances nearly as quickly as that of PCs) are decommissioned or upgraded. The cost to you now is usually very low since they just take up space and you know how bean counters at big companies like to have all their beans lined up in a nice neat row :-)

Some fixed freqeuncy monitors may be from Apple Macintosh computers as well.

It would be nice if all you needed was a cable to use one of these beauties on a PC. Unfortunately, there is often much more involved in making these freebie monitors conveniently usable on a PC under DOS, Windows, or Win95.

Some of these comments - a la scan rates - may not apply to PCs running oprating systems like Linux where scan rate switching isn't required (at least after boot).

And, just because a monitor has BNC connectors (or does not have a VGA/SVGA connector or cable) does not necessarily mean that is is a fixed frequency monitor and therefore a problem. Many top quality monitors only have BNC connectors and might be fully compatible with most video cards running PC/DOS/Winddows. The only way to be sure is to obtain the detailed video, sync, and scan rate specifications.

Are you totally confused yet? :-) The purpose of the FF Monitor FAQ is to try to sort through all the confusing compatibility issues and alternative solutions to enable you to use that fabulous monitor.

- Back to FF Mon FAQ Table of Contents.

Problems with Fixed Frequency Monitors on PCs

While workstation monitors look like PC monitors - they have a CRT and a power cord, after all - there are generally significant differences that prevent these from being a 'drop in' solution.

The following are the principle difficulties in using a fixed frequency monitor on a PC:

- Scan rates. PCs particularly with DOS/Windows/Win95 may require a number of different resolutions and scan rates during any work or play session. Workstations use one scan rate and resolution at all times including during boot. That is why the monitors are called fixed frequency. The video source must match the parameters of the monitor withing a few percent, not enough variance for typical PC applications.

- Sync. PC VGA and SVGA video cards generate separate horizontal and vertical sync signals. Some may be programmable to generate what is known as composite sync. Workstation monitors may require composite sync or sync-on-green (this will be explained later). They rarely use separate H and V sync like a PC. Many PC video cards can only provide separate syncs. Some workstation monitors are already set up for various sync schemes but not all.

- Video connectors. PCs nearly always have a miniature DB15 VGA/SVGA type connector. Workstation monitors may use separate BNC connectors (3, 4, or 5 depending on sync options), a 13W3 Sun style connector, or something totally non-standard.

- Plug-and-play. The newest PCs and video cards expect to determine the capabilities of your monitor (to a greater or lesser extent) by either reading the monitor sense lines on the VGA connector or interrogating the ACCESS.bus. Neither of these will be present by default with a workstation monitor. The PC may come up in glorious black and white or refuse to operate in all modes.

Scan Rate Issues

A workstation runs at a fixed resolution and scan rate. All software is written to interface to the screen via a windowing system like X-Windows. PCs, on the other hand, must be able to drive a monitor at several quite different resolutions and scan rates:

- DOS - 640 x 400 default boot screen.

- DOS programs - 640 x 400 (EGA compatible), 640 x 480 (basic VGA), etc. (Note: CGA resolutions like 320x200 are emulated by modern video cards by running at 640x400 (for this example) and replicating pixels and lines.)

- Windows/Win95 - 640x480, 800x600, 1024x768, 1280x1024, 00x1200 etc. depending on your hardware and software. Normally, the highest resolution that the video card/monitor combination supports with good quality will be used most often. Some options like a larger desktop than the physical display with dynamic resolution switching require multiple scan rates, however.

Therefore, a fixed frequency monitor driven from a typical video card (e.g., ATI GPT) running under DOS/Windows has a problem. For a typical workstation monitor with a resolution of 1280x1024 operating at 78 kHz horizontal scan rate and 72 Hz vertical scan rate (fixed frequency), you only have one option - and that precludes the display of the DOS boot messages or running DOS applications or games.

Note: for the remainder of this document, I use the term 'Windows' to refer to MS Windows 3.1, WFWG 3.11, and Win95/98 interchangeably.

If all you run is Windows - never any DOS games or other applications that require you to suspend to a full screen DOS shell or run in native DOS mode - then you can always use a second VGA monitor for booting and then just switch over to the high resolution monitor once Windows comes up. Or, just assume your system **will** come up and forgo a display until the Windows desktop appears.

Unfortunately, there are a lot of DOS applications still used so this not a solution for everyone.

However, if you mostly use your PC for Autocad or Lotus, then this is a perfectly reasonable option if you have a suitable video card. (However, read on).

Sync Options - Separate, Composite, Sync-On-Green, Sync Polarity

In order for the monitor to display a picture, it must know where the lines and frames begin. The synchronization signals - sync for short - are pulses sent for each line (horizontal sync) and each frame (vertical sync). There are 3 common schemes for doing this:

- Separate horizontal and vertical sync signals. Individual wires are used for the H and V sync. This is the scheme that has been used for most PC video cards including MGA, EGA, VGA, and SVGA. It makes for easier hardware - particularly in the monitor.

- Composite sync signal. The H and V syncs are logically combined (usually either OR or XOR) and sent on a single wire. This is used by Macintosh computers and Sun workstations, for example. Basically, it saves a wire.

- Sync-on-green. The composite sync signal from (2) is combined with the green video signal (it actually goes on the bottom, from 0 to .3 V or so). The Red and Blue video signals usually do not have sync added to them but this is not always the case. Note that theoretically, (1) or (2) are best as there is no interaction between the digital sync signals and analog video signals but in practice, the difference is usually undetectable.

The users manual for your monitor will identify which options the monitor supports. OK, so you don't have a users manual:

For monitors with BNC connectors, it may be possible to determine capabilities by counting them:

- 3 BNCs - Sync-on-green only (Red, Green+Sync, Blue).

- 4 BNCs - Composite sync (R,G,B,CS) and possibly sync-on-green.

- 5 BNCs - Separate syncs (R,G,B,HS,VS) and possibly composite or sync-on-green as well.

Where: HS=Horizontal Sync, VS=Vertical Sync, and CS=Composite Sync.

Monitors with a 13W3 connector will generally accept composite sync though the other options may be possibilities as well.

Some video cards (like the ATI GUP, GPT, and others) can be programmed in their SETUP or INSTALL program (or possibly from a command line option) to generate composite sync on the H or V sync wire. These will then work (at least with respect to sync) with a monitor requiring either separate or composite syncs. A few high-end cards can generate sync-on-green as well.

Sync polarity (whether the pulses are negative or positive going) may be an issue depending on the design of the monitor. However, most suitable video cards can be programmed for either polarity.

Therefore, depending on your video card, the sync issue may be a non-issue.

Otherwise, an adapter will be needed. Unfortunately, this is not just a cable as circuitry is required to combine the signals. If you are electronically handy, it is a simple matter to construct a suitable circuit but if you are not, this may be a show-stopper unless you can locate a commercial product. Note that the term 'electronically handy' means a bit more than knowing how to read the resistor color code. The circuits are very simple. However, for the adapter to work well at the very high video bandwidths of the typical (1280x1024) display, you must use the proper 75 ohm coax and connectors, and assemble the circuitry itself in a shielded metal box, if possible. Otherwise, there could be degredation of the displayed video - ghosting, ringing, and less than optimal image sharpness. If you will be making a cable from scratch, there will be some precision (very tiny pins) crimping or soldering needed to construct the VGA and/or 13W3 (typically) connectors as well.

Video Connectors

Most common are BNCs - individual coax connectors for each signal - and 13W3 which combines 3 coax and 10 normal signal pins in a single shell. Except for some really strange custom connectors, adapters are available:

- VGA to 3, 4, or 5 BNC (might as well get the 5 BNC as the increased cost may not be that great and it is the most flexible should you come across another 'bargain'.

- VGA to 13W3. (e.g., Sun monitor).

- VGA to MAC (regular DB15). (e.g., Macinstosh monitor).

Plug-and-Play

When your PC boots, it may interrogate the monitor to determine what its capabilities are. With BNC or 13W3 connectors, the needed signals are generally not present. Some manufacturers are addressing this by providing little widget boxes that plug in as part of an adapter cable to provide these signals but these are not common at the present time. Therefore, you may need to take steps in hardware or software to get around this deficiency.

- Back to FF Mon FAQ Table of Contents.

Alternatives to the Dumpster

Perhaps that deal-of-the-century doesn't sound so great at this point. Don't give up yet. There are several possibilities.

- High-end video cards with compatible scan rates. As noted above, for use with applications that run entirely in windows and/or at a single resolution and scan rate. A separate monitor (or no monitor in case you trust your setup) is used for booting.

- Special fixed frequency monitor video cards. These emulate VGA and SVGA video cards as far as the PC's software is concerned but drive the monitor at a fixed (high) resolution and scan rate even when booting (in most cases).

And who knows? Sometimes you can get lucky with your $20 bargain basement video card!

High-End Video Cards

If you already have an investment in a good video card (not a $29 K-Mart special), then this may be a possibility.

- Advantages: you may already have one and it will be good for a PC compatible multiscan monitor in the future.

- Disadvantages: Not usable for booting and DOS applications. It may not be capable of generating composite sync or sync-on-green (if needed) without an adapter.

(From: Royce Liao (liaor@uci.edu).)

ALL modern video adapters (PCI/AGP) incorporate programmable dot clock generators. So *any* decent video card should be able to output the necessary scan-rate video signal. Unfortunately, unless you have access to a special refresh-rate utility, and you *know* the precise frequency, this info still won't help your situation.

Scitech Display Doctor has a Windows based display utility which works with majority of contemporary video cards. The control center lets you tweak video refresh rates down to 0.1Hz, and adjust H/V sync polarity.

Special Video Cards for Fixed Frequency Monitors

These are special video cards. You remove and mothball your current video card (if you already have one) and replace it with one of these. You then install the special video drivers (where required) supplied with the card.

Some models appear to be quite competitive in terms of graphics performance (Windows accelerated, etc.) so these may represent an attractive alternative even for high performance applications like Autocad.

After specifying the monitor type and/or scan rate parameters for your monitor, the behavior of the card should be essentially transparent to your software. That is, programs think they are talking to a VGA/SVGA card but the output of the card drives your fixed frequency workstation monitor properly at all times - including booting, DOS games, Windows, etc.

- Advantages: full DOS/Windows, possibly high performance (some models claim Windows accelerated video performance), drop-in solution (no adapters, circuits, cables, etc.).

- Disadvantages: cost if you already have an expensive video card, possible lack of wide or long term support (these are not exactly Fortune-500 companies).

Mirage and Photon appear to be the most well known of the companies providing fixed frequency video cards. However, there are others. The listing below is in alphabetical order and may change without prior notice :-). In other words, the position of any given company doesn't represent any sort of recommendation.

1. MaxVision
   Phone: 1-800-533-5805 ext. 202

Then Again, Maybe it Will Work

Having been told by all the experts that his monitor was fixed frequency and a pain to use:

(From: Malik (psxpic@malik.eng.net).)

Against all odds i thought what the hell and tried it anyway... And hey, presto! it works perfectly, no problems.

I had to feed a vertical sync into the monitor which would not have been possible because the feed for this was not present on the plug. However it was possible to remove one of the unwanted wires in the RGB lead and reconnect it to the unused Vsync input.

It appears Sony just fit the appropriate lead/connectors to the monitor depending on its purpose then badge it for Sun, etc.

The model number is GDM-17E20 its absolutely a superb monitor... If you can get one I suggest you do.

I know there is a 17E10 and 17E11 that are older.... the situation maybe the same with these.

Web Information

General Video Card and Monitor Information

Here are some on-line sources of information relating to monitors, video cards, and fixed frequecy monitors issues:

- The Fixed frequency monitor FAQ and Sync-on-green FAQ are available at:
  - The Sci.Electronics.Repair FAQ
- Some other sites with information and links relating to fixed frequency monitors (in no particular order):
  - http://saturn.tlug.org/sunstuff/ffmonitor.html (Using a Fixed-Frequency Monitor on a PC)
  - http://www.devo.com/video/ (Fixed Frequency Video FAQ).
  - http://www.sunhelp.org/ (SunHELP)
  - http://cvs.anu.edu.au/monitorconversion (Use your old Workstation Monitors with Linux/XFree86)
  - http://sdss.ucsd.edu/~jesus/ibm.htm (Fixed frequency Monitor Info)
  - http://www.geocities.com/SiliconValley/Foothills/4467/fixedsync.html (Connecting the SONY GDM-1960/GDM-1961 to a PC)
  - http://wmad95.mathematik.uni-wuerzburg.de/~buckel/projects/schalt.html (How to Connect a Fixed Frequency Monitor to a PC Running Linux)
  - http://www.llamacom.com/~joebuck/c2746a.htm (Using a Hewlett Packard C2746A workstation monitor with a PC)
  - http://grafi.ii.pw.edu.pl/gbm/matrox/nonvgamon.html (Using Matrox cards with non-VGA monitors)
- The Comp.sys.ibm.pc.hardware.video FAQ includes a lot of general information as well as some directly related to fixed frequency monitors:

  The FAQ has received news.answers approval, so it should be archived at rtfm.mit.edu and all mirrors, as well as in news.answers and comp.answers. There used to be a Web site with the FAQ but it appears to have vanished.
- The following company sells various inexpensive fixed frequency monitors and video cards. I have not dealt with them so I have no idea of their quality or customer service.
  - Machias Computer Systems
    Phone: 1-207-546-3030
    Web: http://www.nemaine.com/~jims
- Ian's Fixed Frequency Monitor Conversion Page for the Sony GDM 1660 fixed frequency monitor. However, I wonder about the operation of this circuit and part values, particularly for the R and C on the V-Sync input.

Web Sites with Monitor Specifications

Check out the following when you have an SVGA, MAC, or workstation (possible fixed frequency) monitor and need to know its specifications (sites listed in alphabetical order):

- Computer Shopper (1994-1996)
- Griffin Technology
- Monitor World
- Rasterstone
- Table of monitor specs
- Linux/XFree86 Monitor Database
- Links (mostly the same as those above)

Some of these are companies that sell various video products that may be useful. However, I am only recommending these sites for the information on monitor specifications. Note that since this data comes from undetermined sources, it isn't always to be accurate - check with more than one site to see if they agree. And, these Web sites come and go - I apologize for the likely broken links but believe it or not, I am not usually informed when any particular company goes belly-up or their Marketing department decides that fluff is more important than substance and they pull the plug on the pages with useful information. :(

Additional Fixed Frequency Monitor Information Links

(Some of these may be listed elsewhere in this document as well.)

Miscellaneous Monitor Information

Tweaking the Deflection Rates of a Fixed Frequency Monitor

Pulling a fixed frequency monitor by more than a few percent will likely be a problem. I know this is not the answer you were looking for but getting a new inexpensive video card, video card designed for fixed frequency monitors, or new monitor, may be a better solution.

If you insist, the adjustment would be called something like horizontal oscillator, horizontal frequency, or horizontal hold. If you do tweak, mark everything beforehand just in case you need to get back to the original settings.

WARNING: Make sure you understand the issues involved in working inside a monitor! See the document: [Safety Guidelines for High Voltage and/or Line Powered Equipment](). Something that looks innocent can really ruin your whole day!

There is also some risk to the monitor - changing it too far may result in damage either immediately (the horizontal output transistor or power supply may blow) or increase component stress reducing reliability and shortening its life. There is no way to know without looking at the design.

IBM 6091 Monitor Information

(From: Richard Shima (RShima@att.net).)

The IBM (Sony?) display 6091-19 is a 5-BNC type, and is, indeed, a fixed frequency type. Therefore, you'll need certain special modes available in a display adapter to accommodate it, beside the correct cable, of course.

I'm pretty certain that IBM 6091 was actually made by Sony, and, in their better displays, they still use the 5-BNC (separate signal) video cable, i.e., on their current SE series, etc. I'm certain you could buy a Sony (or other) replacement cable that would do the job, tying your display to a PC-type 15-pin VGA/SVGA "D" video connector, once you know you have a video card that will support it.

(From: Justin Thiessen (thiessen@physics.arizona.edu).)

I *know* the officially sanctioned video modes for my version (the 6091-19 (_not_ the 6091-19i)) limit the refresh rate to 67 Hz, but the one I have happily syncs to quite a few non-standard modes:

```
#
# Following modelines are for linux and work under XFree86 3.3.6
#
# H - 69.84 kHz; V - 61.37 Hz; Pixel Clock 138 Mhz
# Generated by Colas XFree Modeline Generator
Modeline "1464x1098" 138 1464 1524 1844 1976 1098 1100 1112 1138 -hsync -vsync

# H - 71.15 kHz; V - 79.58 Hz; Pixel Clock 108 Mhz
# Borrowed from somewhere
Modeline "1152x864" 108.00 1152 1156 1300 1518 864 865 868 894 -hsync
-vsync

# H - 72.76 kHz; V - 59.84 Hz; Pixel Clock 78 Mhz
# Thrashed out on my own - small black space at sides of screen
Modeline "768x576" 78.00 768 792 888 1072 576 579 585 608 -hsync -vsync
DoubleScan

# H - 66.67 kHz; V - 66.14 Hz; Pixel Clock 64 Mhz
# Thrashed out on my own - almost fills screen
Modeline "640x480" 64.00 640 728 856 960 480 482 484 504 -hsync -vsync
DoubleScan
```

Note the use of the DoubleScan parameter on the last couple of modes, which just (as I understand) draws each scan line twice, allowing the use of (much) lower apparent modes than the 6091-19 is technically capable of displaying.

Also, if I'm clear on what's happening here, then the "real" pixel clocks for the last two modes are twice the number listed in the modeline. (Each line is drawn twice, therefore there are twice as many pixels actually being plotted as the modeline indicates, yielding double the clock.) Please correct me if I'm wrong on this. This indicates, however that the monitor is capable of handling signals with bandwidth up to 156 Mhz, quite a bit higher than its official rating.

And, truthfully, as much as I relish the real estate of the higher resolution modes, the actual dpi of the monitor combines with the relatively low refresh rates to make them a bit harder on the eyes than I'd prefer. The 1152x864 mode is (by my guess) probably the one best-suited to the actual physical limits of the monitor. If I manage to get 2nd monitor hooked up and running under X I'll probably drop both of them down to this relatively eye-friendly mode.

I still don't get a boot-up screen, nor do I ever expect to without some hardware hacking. The low-end modes are just fun for trying out games. Since my video card (ATI Xpert98) has an apparent text-mode dot clock limit of 60 Mhz (according to the SVGATextMode documentation), I haven't been able to get a text screen yet, although exploring the DoubleScan parameter in that context may eventually yield results.

Now I take no responsibility for just how strangely I have all the pots inside the monitor tweaked. I never use anything that doesn't function in "Mode 3", and if I do happen to flip the switch to Mode 1/Mode 2, any signal that actually resolves is, at best, displaced and suffers severe fish-eye effects, but in mode 3, my monitor looks pretty good for being 10 years old. I also have no idea how much I'm shortening the life of the monitor by running it at these scan rates, nor do I have any clue as to just how far over actual spec I'm pushing it. (Who knows what the internal Sony/IBM engineering specs were for this beast?) I'd give a lot for a manual, but such seem to be scarce for most of the old workstation monitors available.

As a side note, a great deal of info is available on the 6091-19 on a few web sites:

- Jonas Svensson's IBM 6091-019 FAQ or Info Page
- Joakim Wallman's IBM 6091 19" Color Monitor Page
- Sven Koelsch's IBM 6091/19 Fixed-Frequency Monitor Page

I also found the Colas Modeline Generator useful, although I created most of the modes I use by hand with the Xfree video timings HOWTO.

- Colas Modeline Generator

Well, I can't stop tinkering.

I still have a IBM 6091-19, though now it's the 2nd head of a dual-head setup, and in an effort to match up the capabilities of my two monitors, (gdm20e20 rebadged by sun + the 6091-19) I've scraped out a few more modelines to fit the VESA-standard resolutions.

Here are some more:

```
# V - 64 Hz
ModeLine "ibm1400x1050" 133.38 1400 1480 1800 1912 1050 1052 1064 1090
 -hsync -vsync

# V - 71.21 Hz
ModeLine "ibm1280x960" 122 1280 1324 1716 1720 960 963 974 996 -hsync -vsync

# V - 79.58 Hz
```

```
ModeLine "ibm1152x864" 108.00 1152 1172 1316 1518 864 865 868 894 -hsync -vsync

# V - 86.26 Hz
ModeLine "ibm1024x768" 103 1024 1124 1364 1500 768 770 782 796 -hsync -vsync

# V - 59.90 Hz
ModeLine "ibm800x600" 81 800 804 908 1080 600 604 622 626 -hsync -vsync
 DoubleScan
```

Including the modeline above for 640x480, these cover the VESA standard resolutions (though not at the suggested refresh rates) from 640x480 to 1152x864. Also included are a nice 1280x960 mode (with a desirable 4:3 pixel ratio) and a large but very readable 1400x1050 mode.

Note that all these modes fill the screen, with the exception of 1024x768, which has some (quite small) black space on the left and right, and 800x600, which has a slight bit more black space on the left and right, but is still quite usable.

I am now using a Matrox Millenium II to drive the monitor, if it is of any concern.

Using the IBM 6091 with Standard Video Cards

Using the IBM 6091 with the Cornerstone ImageAccel

(From: Helmut P. Einfalt (hp.einfalt@t-online.de).)

The IBM 6091-xx series can be driven by Cornerstone ImageAccel cards, at least by various ImageAccel 1 cards, including the MCA version MC1608C/11. And, above all, there are drivers for DOS, WfW, Win9x, NT3.51, *and* NT 4.0. A detailed account on how to install the MC1608C/11 and a 6091-19 (the procedure being the same for all other 6091s) can be found at

- Helmut's Cornerstone ImageAccel MC1608C/11 and the IBM 6091-19 Monitor Page.

Cirrus BIOS Modifications to use the IBM 6091-19i Monitor

(From: u1061771156@csi.com)

I've gone through the more interesting task of adjusting the BIOS ROM on my video card so the boot screen and DOS work nicely as well. (It's a Cirrus 5429 based card). I still have the Vesa modes to fix, next weekend maybe. ;-)

The IBM 6091-19i has 4 modes of operation (1-4). The first three are based around 1024 lines of vertical resolution and are good for "desktop" use (I'm using the 1024x1024 mode under X as you can't get much more that 1024 Pels across with a 5429 since it's limited to 85MHz clock. As I currently only have 1M ram that fits neatly with 8bpp too.)

Mode 4 (the mode that was introduced new with the 6091-19i and was not supported in the old 6091-19) is more interesting for VGA use. It runs 63 kHz horizontal rate, and 120 Hz vertical rate, with a vertical total of 528. This is a similar geometry to the VGA modes, except about twice the rates. In practice I find the monitor will sync quite happily with vertical frequencies of 120 to 140 Hz and a bit beyond. (Incidentally this mode was originally intended for 3-D viewing with LCD shutter glasses synced to the vertical, and left/right images displayed on alternate frames by software.)

So the first step was to double the Pel clock (and hence all timings). After some serious disassembly, I found the first three PLL multiplier/divisor values for the Pel clocks are in a little table. The table contains the six values: 4A 2B 5B 2F 42 1F. For the particular BIOS version I have (CL-GD5429 Bios Version 1.00a) this is at BIOS address 0812, on an older BIOS, I found the same table with the same values at a slightly different address. If you do a search in any Cirrus 542X rom it's probably there somewhere. Paraphrasing a little (see the .pdf on the Cirrus Website) the Pel clock is generated by taking a 14.318 MHz crystal, and multiplying it by the first value and dividing by the second (ignoring the bottom bit) e.g. the first is 14.318*74/42 = 25.22 MHz and the second is 14.318*91/46=28.32 MHz. The bottom bit of the denominator byte is a "divide by 2" bit, if cleared the frequency is doubled. That's so convenient!! Hence step one is to clear these bottom bits, making the table into 4A 2A 5B 2E 42 1E and magically the monitor syncs up in all VGA modes!

(There are a few peculiarities to note when actually editing the EPROM. Firstly, like all Bios extension ROMs, there is a checksum at the end so the sum of all bytes in the rom is zero. Hence you have to add 3 to this to make the checksum correct. Secondly, the EPROM is a 27C512-150 which is 64Kx8 when the Bios is only 32K. There are two identical copies in it, only the later one is used as the A15 pin is wired high on the adapter card. Thirdly, and most annoyingly, the PC address line A0 is connected to eprom pin A14, and all the others shift down one. So Bios location 0812 (hex) is in the eprom at address 8409 when it's on the programmer. Why on earth did they do that?!)

If all you want is to be able to see your boot messages, this could be enough. However the image is a few columns too wide for the screen so you can't see both sides at the same time (the front panel control lets you move it side to side a bit.) So I've increased the frequencies a little more to make the Pels closer together. The table I'm currently running with contains 51 2A 62 2E 47 1E To maintain the correct scan rates and centering one has to increase the vertical total (CRTC register 0) as well as these frequency tweaks. This meant finding the VGA CRTC mode tables, a search for 2D 27 28 90 2B A0 finds the first one (mode 0 40x25 text). Each mode table (there are 1D of them) follows in steps of 40 hex bytes. Some experimentation showed that there are 3 different timings to change:

```
Modes starting 2D xx xx xx xx A0   I changed to 31 xx xx xx xx B1
Modes starting 2D xx xx xx xx 80   I changed to 32 xx xx xx xx B1
Modes starting 5F                  I changed to 66
```

With these changes, all VGA modes produce a nicely centered image that is close to filling the screen (about 1cm black top and bottom).

There are a few mode tables that didn't start 2D or 5F which I have left alone for now, and affect Vesa modes, and there are other vesa tables elsewhere in the eprom that ought to be changed one day.

Note: I've been working on a Cirrus 5429 chip. Doing the same with a 5428 gave somewhat erratic results (shimmering characters) sometimes. I think this is due to the Sequencer(0x1F) register which sets the memory clock rate being initialized slower on the 5428 (1E versus 22 hex) so it's failing to get enough bytes out of ram in time to display. 22 is out of spec range for the 5428 but putting it up to that as an experiment seemed to fix it. ;-) I didn't find where that register is loaded in the EPROM though, but that fix is fine for a little DOS program to fiddle the modes. As I intend using the 5429 I haven't pursued it any further.

The only obvious side effect I'm left with is that the cursor flashes too fast. I can live with that! ;-) Maybe there's a register somewhere to fix that too?

Of course any noxious game that meddle with the registers direct may well screw up (but note that the Pel divisor registers are not part of regular VGA so may survive.)

I note that sync polarity doesn't affect the monitor at all. I guess its circuits accept either polarity and invert if necessary. Also, sync rates out of range don't appear to damage the monitor, it just loses sync quietly and the picture goes haywire. ;-)

I have the original "User Guide" and "Maintenance Guide" books which makes life a lot easier.

P.S. I see that the IBM 9517 can do 1024x768 if you can get to 85Hz vertical interlaced, maybe starting with a 1240x768 interlaced mode and fiddling the frequency up in a similar way that I did would work for the original question? Of course interlaced modes are yucky unless you're viewing images...

Comments on IBM 9515 Monitor

(From: Peter Duck (pduck@zetnet.co.uk).)

This monitor is not VGA/SVGA but XGA2, as used in IBM PCs with the short-lived MCA bus.

There are said to be ISA (PCI?) cards that drive them, but a friend (ironically, ex-IBM, but not the 'toy computer' end) who bought a stack of the monitors cheap never found any.

It is near-enough to impossible to convert 'properly' and can't be made to run at the 31.5 start-up scan-rate without the HOT (Horizontal Output Transistor) dropping dead.

Complete Plans for Sync-on-Green Adapter

Sync-on-Green Adapter Description

Here, courtesy of Berg Hawkins, are complete plans for a cable adapter to convert separate H and V sync to the requirements of many common fixed frequency monitors. This approach uses a programmable logic device (GAL) to implement the function. For an alternative using discrete logic, see the document: Notes on Video Conversion in the section "Notes on VGA to RGB Conversion".

Note that he also sells both the cable as well as just the required GAL (CMOS programmable logic device) already programmed so providing this information is truly in the spirit of these FAQs and the "open source movement". Thanks. However, purchasing the completed unit may indeed be the best use of your resources.

(From: Berg Hawkins.)

I sell a sync-on-green cable for single frequency monitors. It is $75 and will run any of a half dozen monitors from most standard video cards on the PC and Macintosh G3/G4. The cable contains a chip, a CMOS GAL programmed with the appropriate equations. It fits in a plastic housing that goes over/around a 15 pin VGA connector which plugs into the video card. A source of +5 VDC from a Molex connector tied to one of the power supply outputs on the PC drive it.

I have been selling it for about 7 years and have done hundreds of monitors. The equations are free, so is the schematic. I will even mail the programmed chips to anyone who does not have a GAL programmer for a small fee.

The best is to buy the whole cable since it takes me about 45 minutes to make one and involves some close-in soldering work.

I have done Sony GDM1950s, Hitachi 4119s and CM2086s, IBM 6091s and other monitors.

Important note: This setup WILL NOT allow DOS full screen or most video games or DVDs to be played, all other Windows applications will work with most any video card.

The equations are included in the .PDS file, they go right into the AMD PALASM compiler and have been tested. The output of the compiler is in the .JED file, this is what is fed to the PAL programmer. It has also been tested. Note that ONLY CMOS GALs such as 16V8s are to be used since the circuit needs to SOURCE a few milliamps into the GREEN color output. This is done by means of an approximately 330-360 Ohm resistor (1/4 Watt) connected between pin 12 of the GAL and the GREEN video signal. One weakness of this circuit is that power from a 4 pin Molex connector on the PC's power supply output needs to be applied to pin 20 of the GAL. Also note that power to the chip MUST be applied BEFORE a signal is input, otherwise the chip can latchup and be damaged. This is accomplished by connecting the power Molex connector while the PC is powered off, then plugging in the VGA connector at any time.

Any speed 16V8 can be used, down to -25 parts, speed is not critical.

A crude diagram showing the chip, the VGA connector and the BNCs is included in the file diagram.txt.

It is best if all unused GAL inputs are connected to ground. I can program and mail the 16V8 chip and the 330 Ohm resistor for $5. I sell the complete cable for $75 (recommended since it takes me about 45 minutes to make one - I have been making these for 7 years and have some experience in this. It involves some close-in soldering work.

I also sell 20" single-frequency monitors, refurbished and tested for $200 to $250 with 6 month warranty.

The chip can be used without the resistor if composite sync is needed (a small minority of monitors will not sync-on-green, in this case connect pin 12 directly to the horizontal sync input of the monitor. Some monitors need POSITIVE composite sync, in this case pin 13 can be output to the composite sync of the monitor. In either of the 2 above cases, 4 BNCs will be needed instead of 3.

I have also successfully used this circuit to connect to monitors under Linux. Macintosh PCs also work, including PowerMacs, G3s and G4s. Over 8 types of 17" and 20" single-frequency monitors have been successfully driven by this circuit.

Send me email if you have problems syncing up a monitor. My phone number is 1-310-839-6430 in Los Angeles.

Case Studies - Using, Modifying, Adapting Fixed Frequency Monitors

Steve's Experience With a Special Video Card

As noted below, this is an experience with one particular video card - I don't even know which one or how old it was. Thus, these comments should only be used as an indication of what kinds of questions to ask when selecting a card and the possible problems you may encounter.

(From: Steven Leinwand (steve_leinwand@hp.com).)

It is true that the most expensive solution (a special video card) is usually the best solution. I bought one a while back, and in the interest of 'truth in advertising' let me describe some of the drawbacks you will experience. In all fairness, I will mention that I haven't tried all the video boards out there, and am basing my comments entirely on my experience. Your mileage may vary.

Fixed frequency monitors like those commonly supplied with Sun workstations cannot change video modes like multiscan monitors. In order to get them to work in DOS modes, video card vendors like Mirage and Photon modify the VGA bios on their cards to 'emulate' *some* DOS modes at a fixed scan frequency. This works well in *some* modes, works poorly in others, and doesn't work at all in some.

These BIOS mods interfered with motherboard timing on two VLB motherboards. I tested it with four video cards, the problem was the VGA BIOS). Video wouldn't sync after warm-booting. I had to shut the machine off, and wait about 10 minutes. In all fairness, I have not heard of similar problems on ISA and/or PCI cards, so that problem may be on that vendor's VLB boards only.

It usually works best in Windows, where the display is always in the same graphics mode, and mode switching isn't an issue. It works for *some* DOS programs, depending on what video mode they try to put the display in. It works poorest on games, which seem to insist on using weird and/or undocumented VGA video modes. At least half my games either wouldn't work, or their image was so small, as to negate any benefit of having a large monitor.

** Modes less than the monitor resolution will usually be displayed at 1/2 the screen size of the monitor **

This was a surprise to me, and was never mentioned in any of the ads for video boards. I've been told this is a fact of physics, and cannot be overcome in fixed frequency monitors. (Editor's note: it can be overcome using a scan converter but this is much more complex than a BIOS change! See the "Notes on Video Conversion" document for further information on scan converters.)

I finally sold both monitor and video card, bit the bullet, and bought a 17" SVGA monitor and card. If I didn't have the VGA BIOS timing problems with the VLB version, I might have been able to re-use the video card, but was tired of the hassle. Since I got the monitor for free (obsolete product destined for the dumpster), it wasn't that bad. My advice is ask detailed questions before you buy, get a money-back guarantee, and test with all your applications. If you can't live with the results, exercise your guarantee.

Also check out support capabilities. One of those vendors I mentioned was very responsive and helpful. The other one started out awful, but made some progress in responsiveness over time.

Check and Dirty Way to Display Lower Resolutions on Fixed Frequency Monitor

(From: Karl Ivar Dahl (karl_ivar.dahl@capgemini.no).)

I have a SONY GDM-1961 (a.k.a. VRT 19-HA) fixed frequency (sync-on-green) monitor. This monitor displays 1280x1024, but I have recently been able to tweak it to display 1024x768, 800x600, and 640x480!

So now I can play Quake full screen under NT and Linux :-)

The clue is to reduce the visible resolution and add the missing pixels to the front and back porch. The image of course doesn't fill the entire screen, but it's a *lot* better than having none at all.

I have made a page with my experiences with making a fixed-sync monitor work on linux, NT and win95 to help others with access to these extraordinarily cheap and large workstation monitors:

- Connecting the SONY GDM-1961 to a PC

Using IBM 6091 Monitor on PC

(From: Wayne Rothermich (wayne@utilicom.com))

I had to learn what signals my IBM 6091 monitor wanted versus what signals my video card provided by experimenting with a scope and a pulse generator for a day or so. In my case, the monitor wanted inverted polarity on the horizontal sync line. I found that I could provide this by triggering a lab pulse generator from the video card's horizontal sync output, and using the resulting (inverted) pulse to sync the monitor. Fortunately, the timing jitter in the pulse generator was low enough that no horizontal jitter was noticeable on the display.

I used the monitor this (rather nerdy) way for a while, and then I noticed a small ad in Nuts and Volts magazine for a moderate cost ($200) translating video card made by a company called Ming. I ordered one, and it turned out to be a modified (new video BIOS chip, a few wire jumpers) Jaton 58P card, which uses the Tseng Labs ET6000 chip.

This has proven to be a good solution to my fixed frequency monitor problem. I ran comparative benchmarks using the Landmark PCPRO test program, and the speed of this card - when writing to video RAM - is similar to other high performance (Matrox Millenium 2, Diamond Stealth 3D 2000), cards I have tested recently. Ming makes cards for several different fixed frequency monitors, so they could be a viable choice for many of your readers. You can check their web page at http://www.riverside.quik.com/ming for more details. (From: Fabio Quenel (info@tesitalia.it).) I've managed to get this monitor to work in Windows98 at 1152x864, 76 Hz, in true color (24 bit) with a 4 MB Matrox Mistique card (170 Mhz RAMDAC). I had tried with the 1280X1024 resolution but the refresh was 67 Hz and it really was straining for my eyes (also the definition lacked a bit). In DOS mode the monitor doesn't work and I don't know if thare is a way (if you know please tell me).

(From: Sam).

> Since the 6091's lowest horizontal scan rate is 63 kHz, you would need over a 120 Hz vertical scan rate for the 640x400 boot screen. Even if you could set up your video card for 120 Hz or more refresh, the 6091 almost certainly won't work at too much beyond its 67 Hz vertical scan rate specification.

Here is what my mga.mon file of the Matrox seems like:

```

Modifying an IBM 9517 XGA Monitor for SVGA Operation

(From Arnoud van der Wel (a.p.vanderwel@student.utwente.nl).)

Well, I did this to two of them about a year ago. Of course I wrote down what I did, so I'll try to reconstruct for you what I did.

There are two modifications, one is the H-FREQ control, the other is the H SHIFT VGA control.

To boot, you need it to display the standard 31.5 kHz VGA text mode.

Turning the H FREQ pot (on the rear edge of the PCB) will eventually give you a display, but it is off-screen to the right. You then adjust the H SHIFT VGA pot (on the right of the PCB) and find that this pot has insufficient range to center the display. The H FREQ pot is 4.7K from the factory. It is in series with an 18K SMD resistor on the solder side of the PCB. I found that I had to turn the 4.7K pot to max resistance to move the display to the left, so I removed the 18K resistor and the 4.7K pot, and replaced them with a 22K resistor and a 10K pot.

I was then able to center the display for text mode. The only problem is that the horizontal linearity in text mode is now off. The letters near the right of the screen are narrower than elsewhere. The problem is not serious (a casual observer does not see it) so I can live with that. Moreover, I never use text mode anyway (except during booting and for BIOS setup, etc.) The 320*200 mode (games) also works correctly after this modification.

Now, we want it to sync to highter refresh rates, specifically, 1024*768. That is the mode I adjusted it for. All the 1024*768 parameters are separately adjustable from the ones for the other modes, except the H FREQ. The pots that govern this mode are all labeled "4,5", meaning, I presume, that they govern the operation of what the monitor manufacturer calls mode 4 and mode 5. I found these to coincide with H frequencies of over approximately 50 kHz.

I found that by tweaking the H freq, I could get the text mode to be all right, *or* the 1024 mode, but not both at the same time. (BTW, I run 1024 with a pixel clock of 77 MHz, H freq. of 57.63, and V freq. of 68.13 Hz. I don't know what the specs for this monitor are, so I thought it was prudent to stay on the low side.)

So I needed two instead of one H FREQ pots. I also found that there is a relay click if you throw something over 50 kHz at this monitor. Hence, I tapped the relay coil to give me the 0/12 volt signal to tell me what mode the monitor is displaying. This signal I take to a little PCB that holds my two H FREQ pots, an inverter, and two NPN transistors that switch in one or the other pot instead of the original one.

The schematic is shown in ASCII below. Or, see the Gif version provided by: Puiu Chiselita (puiu@microinfo.logicnet.ro).

```
                                           TO H-FREQ

```

```
|                              +------+------+-----+-----+                |
|                                           _|_ Gnd                         |
|                                            -                              |
+---------------------------------------------------------------------------+
```

Transistors can be any general purpose type:

- Typical NPN: 2N2222, 2N3904, BC547.
- Typical PNP: 2N2907, 2N3906, BC557.

I added the diodes to make sure we have a real OR circuit here, not a bit of AND left in it, since that would (albeit momentarily) drive the H FREQ up way too high and send the monitor into its OV protection.

Now I can tweak the H FREQ pot for both modes separately. To sum up, my 9517 now displays VGA text modes, 320*200, and 1024*768 in approx 70 Hz. When it is warm, I can also get it to display 640*480. I could probably do a fix for that too, but haven't bothered since I don't need that mode. Moreover, I don'thave schematics, so I'm a bit hesitant to continue modifying it, when it already works adequately for my use right now. The H linearity in the 320 and 1024 modes, by the way, exhibits no problems.

This solved monitor number one, and oddly enough, when I did monitor number two. I was able to get it working after installing only mod number one. A little help from the VGA card (Diamond Speedstar if I remember correctly) did the rest. So maybe you are in luck and need only one mod. A flexible VGA card definitely helps. (Or good setup-software for the VGA card.)

When you are turning all the little presets, be careful not to short the wipers to the chassis... use a plastic tool! The wipers are not insulated from the screwdriver slots. You can easily destroy some of the SMD transistors by doing that. That's what I did, and I had some VERY lucky guesswork in unsoldering them and replacing them by normal transistors (that is what I tend to do when I find a dead SMD transistor...)

These are beautiful monitors and well worth modifying. Fortunately, not a lot of people are able to do this, and this means that they are available rather cheaply. :)

SVGA to Sun Fixed frequency Monitor - Complete Solution

Here is a success story for the Sun 21" fixed frequency color monitor. The only active part in the circuit is a 74HCT86 quad XOR chip. Only one XOR gate is used - to combine H and V sync. All the other signals are wired through to the monitor (using RG59, 75 ohm coax for each of the RGB videos.)

(From: Ken Jones (k.jones@coastlight.com).)

Disclaimer: I will not be responsible for any damage to your monitor or ego that might be caused by the use of this circuit.

I don't know if this works with all VGA Cards. I've tested this with my Matrox Millenium and Mystique VGA Card, and it worked well. But there is a tricky part!!! For all those, who are trying this circuit with their Matrox Card, be sure to accomplish the following steps:

1. Buy all the needed hardware parts - 74HCT86 (TTL-XOR), 0.1uF Capacitor, Print, HF-Box - and assemble it. I use a small HF-Box, to eliminate interference problems. Be sure to make all wires as short as possible!

2. In Win95, go to the Display Properties:

    - Select MGA-Monitor Panel.
    - Choose a Monitor which can Display 1152x864. (Hitachi CM2111 for example)
    - Select this Monitor, and press 'Properties'.
    - Now select 1152x864x256 or 1152x864x65535 (as you like) and press 'Apply'.
    - Select the MGA-Settings Panel and increase the Display-Area to 1152x864 too. Press 'Apply' and reboot Win95.

    Now, your Monitor could work. If not, (as it happened to me...) do the following:

3. Go to the Display-Properties again:

    - Select MGA-Monitor Panel.
    - There is a Button named 'TEST!'. (First it was grayed out). Press it. (What for?.. Well, read on)
    - A Monitor Test-Pattern should appear, nothing special, but there is a small Button, called 'DETAILS'. This is the key for all...
    - Press 'DETAILS' and a new form appears. Now you can choose Sync-Negotiation, Vertical, and Horizontal, Refresh-Rates, etc., etc... (AHA!)
    - Set all you need to get your Monitor running. (In my case I changed the horizontal refresh rate to 71 kHz)

Using a Sony GDM-1950 Monitor on a PC

(From: Ross (rross@hotkey.net.au).)

I've had one of these working on a PC. From memory, the refresh rate is 1280x1024 at 60 Hz (therefore pretty crappy). You can either use a fixed frequency video card (expensive) or as I did, a Matrox Millenium which allows custom refresh rates in 1 Hz increments. Simply set up the computer on another monitor, and plug in the GDM-1950. The cable should not be a problem, easy to get here in Australia, so no problems in the states.

(From: Bill (bill_h@azstarnet.com).)

I have one - seems to me it was around 72 kHz/75 Hz refresh, but I'd have to check to be sure. I use a Quantum128 (costs around $150) but comes with a $30 adapter (Griffin Technologies) that makes the sync_on_green (this would be for 3 BNC type monitors) AND Composite sync (for the 4 BNC type monitors). You don't need this adapter if you're planning to use only the GDM-1950. If you buy the board, I'd be sure to get this adapter anyway. It comes in handy for checking the 'other' types of fixed frequency monitors.

The cable you need is pretty simple - just 'normal' VGA to the 5 BNC's.

This same cable is/was used on some sort of MAC's, and I found one in the close-out pile of a retailer dropping MAC's (for ten bucks).

(From: Joe McCarthy (mccarthy@si87.com).)

The GDM-1950 was sold by Sony to many different OEMs. The standard GDM-1950 is a 64 kHz, 60 Hz monitor designed to run 1280x1024 resolution. Radius bought a lot of these monitors and tweaked them to the MAC frequency of 63 kHz, 75 Hz, at 1024x768.

SVGA to Sun/Sony GDM-1960

(From: Flupke ut Warns (P.O.Langemeijer@student.utwente.nl).)

The most important thing is to get the sync pin(s) connected and the horizontal scan rate as close to the required value.

There is much more info and links at:

- http://www.geocities.com/SiliconValley/Foothills/4467/fixedsync.html

(From Paul Langemeijer).

If you have a GDM-1960, you can make an even easier modification to the monitor. A thing I might add to the problem of the sync-on-green, is the 'modifying' of your monitor. Well actually it isn't that hard. If you remove some of the panels (the one near the connectors with the monitor turned off!), I found holes for two more BNC connectors. You can put them in, attach a bridge and put in two resistors (the holes for these are obvious, the numbers are above them). And you've got a 5-BNC monitor (and it works). You should use 75 Ohm resistors and the monitor syncs perfectly at 1024*768 at 85 Hz (Standard VESA videomode).

(From: Pascal Specht (specht@roguewave.fr).)

I'm now running the GDM-1960 from my DECstation 5000 on my PC.

I found an even easier way (if you can live without the three VIDEO OUT BNC's). Simply reuse two of them for H and V-sync - No resistors, no holes to bore. This applies to my Digital GDM-1960 D3. Simply follow up the cables going from these 'video out' BNC's and take them off at the other end. Put these ends now into the obvious holes for the two predesigned places intended to take in the missing BNC connectors. Add the bridge to make the HSync connected. That's it. It perfectly works on my nVidia RIVA 128 with 1024x768 at 85 Hz, but also 1280x1024 at 60 Hz.

Sun 365-1335 or Sony GDM-20E20 monitor on PC

(From: Anders Stenkvist (Anders.Stenkvist@uab.ericsson.se).)

I just wanted to share some info about a Sun monitor I recently acquired. It's one of the new 20" multisync monitors you get together with Ultras with part number 365-1335 or GDM-20E20 made by Sony. Searching the net told me it should be possible to connect it to my PC but gave no info on how. So, armed with a screwdriver, an soldering iron and a lot of curiosity a started to investigate my new monitor, and after some iterations I got the following "new" pinout of the 13W3 connector.

```
    Analog:  13W3 connector:

          +-----------------
          |   +-------------
          |   |   +---------
          |   |   |   +-----
          |   |   |   |   +-   horizontal sync (new multisync only)
          |   |   |   |   |
          |   |   |   |   |  grey
    red   |   |   |   |   |  green blue
     |   1o  2o  3o  4o  5o    |     |
    (O)                       (O)   (O)
       6o  7o  8o  9o 10o
       |   |   |   |   |
       |   |   |   |   +---   sync common (gnd)
       |   |   |   +-------
       |   |   +-----------
       |   +---------------   vertical sync (new multisync only)
       +-------------------
```

The monitor works with a PC driver from Sony named "SONY Multiscan 20SE" and is able to do at least 1280x1024 @ 75Hz, that's at least what my video card is capable of.

Looking inside it I also found markings for one of the PC-monitor buses used for autoconfig but I have not bothered to get that to work. Any info on that would be appreciated but it does work nicely without it. Converting Sun Workstation Monitors for use on MACs (From: Phil Lee (plee@orbis.net).)

Here is a cheap, less than $300 total, solution for converting legacy Sun 20" workstation monitors for Macintosh use. Over the summer, there were large batches of Sun OEM Sony monitors, model GDM-20D10 being auctioned by ubid.com for about $225. They were being bundled with a Mirage Diablo 3D AGP, mirage-mmc.com, board and the package was advertised as compatible with PCs only.

The Sony 20D10 is a "limited multi-sync" monitor which is still satisfactory for the standard Mac two page display resolution 1152 x 870 @ 75 Hz (horiz=68.7KHz) for desktop publishing. Two cable related add-ons was required to convert it for Mac use.

1. DB13W3 female coupler, PI Manufacturing P/N 000-530, $14. 1-909-598-3718.
2. DB13W3 to DB15 cable with Mac sense switches, PI P/N 530-BNC-Mac, $28.

The 4 sense switches was set to all on, similar to using a Griffin MacSync griffintechnology.com , for legacy monitors. Was attached to a Mac IIfx using a SuperMac Thunder 24bit large screen Nubus card. Using the monitor controls, was able to center the image nicely. The Trinitron display was nice, sharp, and bright for light DTP and CAD use.

Not bad for repurposing legacy equipment.

There were other Sun (Sony OEM GDM-1962b) monitors also being auctioned. Other WS mfgrs such as HP, DEC, and IBM have similar monitors. They may work as well. I chose the 20D10 as they seemed to be newer.

Also see the section: Sun 365-1335 or Sony GDM-20E20 monitor on PC and the following for more technical info:

Mitsubishi HL7965 Workstation Monitor on PC

(From: Wong Sy Ming (simingx@yahoo.com).)

The SGI (Mitsubishi) HL7965KW-SG monitor is widely advertised as a Fixed-Sync, Sync on Green monitor in the workstation world. Well, most people know that this is actually a multisync monitor but not many people may know that it actually has inputs as well!

I don't know if they appear on the video input board, but if you remove the board where the 13W3 connectors are on you can actually see, beautifully silk-screened on the main PCB, near the connectors that once went to the input board, pins labeled: R G B and HSYNC, VSYNC!

So this is actually NOT a sync-on-green monitor as everyone says. It's a separate sync monitor! (Yes I have this and it works beautifully in Windows up to 1600x1200x60hz. At 1280x1024 it does 75Hz.

However, the pincushioning will need adjustment (I don't know how) but if you are willing to live with a little distortion at the sides it's perfectly OK. You'll also need to solder in some 75 ohm resistors where the RGB goes in (conveniently, there are SMT pads there!) otherwise you'll get extremely severe ghosting. You might also want to replace a new 13W3 plug to cover up the rather unsightly holes left from removing the input board, although these can get *very* expensive and *almost impossible* to get.

And this is a monster of a monitor, weighing more than a 21" Sony CPD-G500! There's actually a warning label at the back saying "Caution: 23kg" with a picture of those "10 ton weights" that you see so much in cartoons :) All that said, the video amps look like miniature tanks, they're fully encased in shiny aluminum blocks and there are a ton of ferrite blocks and shielding screens inside.

Although mine was manufactured in 1993, it still gives a better picture than a slightly-less-than-new Philips monitor.

DISCLAIMER

Interconnecting a video source and display device that are not compatible can potentially result in expensive damage to either or both pieces of equipment. While this isn't that likely with just a bit of care, it cannot be ruled out.

We will not be responsible for damage to equipment, your ego, blown parts, county wide power outages, spontaneously generated mini (or larger) black holes, planetary disruptions, or personal injury that may result from the use of this material.

Introduction

Scope and Purpose of This Document

Questions relating to various aspects of converting one video format (like PC SVGA) to another (like NTSC) are very common.

Most of the articles in this document have been compiled over the last two years based on replies from myself and others to postings on the USENET newsgroups comp.sys.ibm.pc.hardware.video and those of the sci.electronics hierarchy. I apologize if your response is not here - it could have been that I missed the posting and will welcome contributions.

As always, comments, suggestions, and corrections are welcome.

Note: in this document, the terms 'VGA' and 'SVGA' are used somewhat interchangeably. However, strictly speaking:

- VGA refers to the basic original IBM VGA standard of 640 x 480 at 60 Hz.
- SVGA refers to scan rates greater than and including the basic VGA rate.

Commercial Solutions

A number of companies offer adapters to handle many of the problems discussed below. They may advertise in the backs of electronics/hobbyist magazines (many are not exactly large companies!) or turn up with a Web search. One example is Magenta Research. Look under: "Video Adapters, Cables, Accessories". (I have absolutely no affiliation with this company nor do I have any first hand knowledge of their products.)

TV (NTSC/PAL) to RGB

Watching TV on a VGA/SVGA Monitor

Depending on the monitor, you may need a lot of electronics. VGA uses a 31.47 kHz horizontal scanning frequency - twice NTSC.

1. If it is auto-scan and goes down to 15 kHz horizontal, then you need an NTSC to RGB converter. There are chips from companies like Sony, Signetics, and others that will do this without too much pain.

2. If it will not sync at 15.734 kHz, you will need a real time digital scan converter consisting of a video digitizer and a full frame buffer with suitably fast I/O, For the special case of basic VGA, a subset of this called a line doubler or scan doubler will also work but there are some problems with this approach. See the section: What is a Scan Doubler?.

For PAL (625/50) the relevant resolution is closer to 800x600.

There are boards for your PC that will take NTSC/PAL and put it into a window.

There are also stand-alone boxes that will allow you to view NTSC/PAL on a VGA computer monitors. One example is the Z64 V-Box. I have no idea how well it performs. However, from the specs, it would appear to have a limited color resolution (only Y:U:V 4:2:2) so while adequate for some games, it may display annoying contours for continuous tone images. And since it only generates a resolution of 640x460, there may be serious artifacts when driving a higher resolution flat panel display.

What you may find in the end is that your $150 TV gives you a better picture.

(The following from: Stan Rohrer)

For cards as well that take NTSC and put it into a window on your PO:

Check in the PC mail-order catalogs and your local PC parts outlets. There are a number of TV boards and frame grabber boards that do what you want. Prices start (I think) around $150. Professional level conversion boxes soar above there somewhere.

I've just started investigating such devices. PC Zone (800-258-2088 for orders/catalog) and MicroWarehouse (800-367-7080) carry Computer Eyes and TelevEyes by Digital Vision. Prices here range from $300 to $600 with the highest reported to include genlock and overlay capability.

PC Zone has an AITech TV board for $150. I don't know if it will take NTSC video input or not. One of the guys I work with just bought an (unknown brand) TV board that takes NTSC but he doesn't have it installed yet.

SCART to VGA

This will only be possible without a lot of work if the VGA compatible monitor or video projector can sync at the PAL (or whatever) scan rate. If so, this may be possible with just a special cable. If available, use an oscilloscope to confirm that your equipment produces the relevant signals (not all SCART connectors have all the signals). See the document: Pinouts for Various Connectors in Real Life(tm) for the SCART pinouts.

While VGA usually expects separate H and V sync - it looks like SCART has them only in combined (composite) form but many monitors and video projectors will accept either.

(From: Someone who wishes to remain anonymous.)

I just bought a box that lets me view PAL/NTSC output from a VCR or DVD player on an old (but big) VGA monitor I had spare.

It's called the Gamars V-box. (Gamars and Gamars Europe) Inside it has a Philips SAA7111 and an Averlogic AL250 IC. Inputs are composite video and S-video, autodetecting PAL or NTSC. Output is VGA.

The quality is great. The only problem is that playing an NTSC disc in my PAL DVD player causes the DVD player to output PAL at 60 Hz. This fools the V-box into engaging NTSC mode, which results in a black and white picture.

The box was inexpensive, about $40 or so. Cheap importer: Golden Shop VGA Box Page.

(From: Mike Deane.)

I have played with the V-Box unit, and it's pretty good considering it = wasn't really meant for converting monitors into TVs. However, it only = produces 640 x 480 resolution, which is not so great if you were = planning to use a 1024x768 TFT display with it. The screen syncs up OK, = but cannot do a decent job of multiplying up the resolution, so the = result is fairly nasty.

TV to Fixed Frequency Monitor

The hardware needed to watch TV on a typical high resolution fixed frequency monitor would cost more than a nice large TV. In two words, forget it! In addition to decoding the NTSC/PAL to RGB, the scan rates are SO different that the only hope would be to build a full blown scan converter.

TV to MGA

> "How hard would it be to make my amber Hercules monitor display the output from my VCR? the VCR has a RCA video output and a coaxial RF output and I want to use the monitor as an orange TV."

This is almost certainly not worth the effort as the monitor accepts TTL (2 bits) and can display at most 4 gray (well, amber) levels without extensive modifications. In addition, the scan rates differ substantially between NTSC or PAL and the Hercules standard. As noted below and elsewhere in this document, a CGA monitor with a composite video input would be a better choice.

(From: Jerry Penner (jpenner@sentex.net).)

You want to connect a Herc Mono TTL monitor to a composite video signal? Can you say 'Big Waste of Time and Effort'? If you want a black and orange or black and green TV screen, connect your RCA video output on your VCR to the input of a composite CGA monitor. These monitors were used on Sanyo MBC computers, and early Apple clones as well as some XT's. Colour composite CGA monitors used to be used on C-64 and Vic-20 computers. Their usefulless as TV/game monitors is legendary, and you'll be lucky to find a used one for under CDN$80.

TV to CGA

> "I have a RGB CGA monitor and would like to use it to display a composite or S-video signal from a VCR. I was wondering if anyone knows how to accomplish this or knows of any economical products that will be able to do this. Any info on S-video pinouts would also be greatly appreciated."

Is it strictly CGA? If so, that is TTL and you can forget about displaying VCR S-video without extensive and not worth-it modifications. Some CGA monitors have composite inputs or analog RGB inputs. With analog RGB inputs, you need an NTSC to RGB converter. These can be built with a single chip and some discrete components. There are probably converter boxes available as well. If it accepts composite, then just use the normal video out from your VCR. S-video won't gain you anything unless the monitor has separate Y and C inputs as well. If all it has is S-video in, then you can combine the Y and C signals with a resistor and capacitor. See the section: S-Video to Composite.

I have a Magnavox CM8762-074T RGB Color Monitor which accepts both CGA TTL and NTSC color composite video inputs. Locating monitors of this type may be an alternative to video format conversion. These may be available for next to nothing as the owners have upgraded and are often not interested in (or aware of) their present utility. They are often of relatively high quality and display a very nice picture since their original intended resolution is similar to that of NTSC. I use the Magnavox CM8762-074T for testing of VCRs and other baseband video sources.

PC VGA/SVGA to/from TTL

VGA to TTL (MGA, CGA, EGA)

Both the signal format and scan rates are incompatible. Therefore, simple conversion between analog VGA/SVGA and any of the TTL formats - Mono, CGA, and EGA - is generally not realistically possible.

Some (mostly older high-end) monitors will accept multiple input types like VGA, EGA, and composite. Some examples are: Mitsubishi AUM1371/81, Tatung CM1495, Princeton Ultra-14, and NEC MultiSync. These can select between VGA and EGA input (either a switch or cable) and the Mitsubishi (at least) will also accept composite (NTSC) video.

VGA to CGA1

The following applies with minor changes (scan rates, number of bits) to MGA, CGA, EGA, and most other TTL video signal formats as well.

> "I am trying to use an old Sony monitor, (PVM-1342Q), which only accepts a CGA video signal through a 9 pin connector. My output is SVGA via a HD15 pin connector. Any suggestions on pin assignments or existing converters to do the job?"

Assuming the monitor is actually CGA, it is probably not worth it. CGA is TTL and SVGA is analog - you would need a converter and then only end up with CGA's 8 colors or whatever.

The scan rates differ by a significant factor. If you can program your VGA card for the monitor's horizontal scan rate (around 15.734 Hz - similar to NTSC in the case of CGA), then the remaining problem is converting from analog to TTL. This will require some high speed comparators and logic.

VGA to CGA 2

For the general case of desiring to drive a true CGA-TTL monitor from a VGA card, there are three options:

1. Replace the monitor with a VGA monitor.

2. Replace the video card with a CGA card if you can find one.

3. Completely redesign the CGA monitor to accept the VGA scan rate and analog video input. Neither of these is easy or necessarily even possible and the resolution of the CRT may be inadequate in any case.

If the monitor accepts analog RGB, it may be possible to program you VGA card to put out the CGA (15.734 kHz) horizontal scan rate to be compatible with a CGA monitor of this type. Your hardware and software may or may not support this easily or at all.

If it's a true CGA monitor, there simply is no practical way to use it with a VGA card. Period. If it's one of the original multisyncs that happens to work with CGA, then there's some hope. However, these weren't so common: Sony 1302, Mitsubishi AUM1381 or Diamond Scan, plus a few others). In this case, you just need the proper cable and the appropriate switch settings for the monitor.

VGA to CGA 3

> "We are trying to upgrade our print servers and have a lot of CGA monitors and a lot of PS2 computers with VGA cards. We don't need more than 2 colors (mono) but when we make an adapter to connect the R to R, G to G, B to B, H to H, V to V, Ground to Ground and the rest NC we don't really get what is wanted.
>
> Well, what happens is that the display is quite acceptable other than the fact that there are two of everything on the screen indicating timing problems. Covering the right side of the screen with a sheet of paper works to cure the problem but a more acceptable solution is needed.
>
> Adjustments to the monitor frequency, width, phase, H-hold, etc. don't help."

This is not surprising as the horizontal scan rates for VGA and CGA differ by about a factor of two. This is much too large change for the monitor to accommodate.

Note that CGA outputs TTL level signals (0 to 3-5V) and VGA outputs analog levels (.7 V p-p). Therefore, what you have done may not work in any case if the monitor expects strictly a TTL input. However, your monitor must be compatible with the VGA levels.

The monitor would have to sync at double its normal scan rate for the picture to properly fill the screen. First, it would be difficult to modify the monitor for such a substantial change in horizontal scan rate. Second, and more importantly, any such change could compromise the safety - stressing the monitor's circuitry - increasing the risk of failure and the possible fire hazard. Therefore, I would not recommend even making the attempt unless you are quite knowledgeable in the design of monitor deflection circuits and power supplies.

One other option other than replacing the video card or the monitor would be to determine if your PC is capable of putting out CGA scan rate video. Many video cards do have this capability not so much for CGA as for NTSC/PAL compatibility. However, some programming or use of special video drivers (software) may be required.

Alternatively, you may be able to find an inexpensive card that would be able to provide the correct timing or even some old CGA cards that no one wants anymore. Also, monochrome video rates are 18.43 kHz. If you can find some MGA cards, you may be able to tweek the monitor that far.

Actually, for your intended application, painting over one half of the screen isn't such a bad idea. :-)

TTL to VGA/Analog

This requires matching the scan rates and implementing a suitable digital to analog converter to take the TTL data and produce analog signals.

A scan converter can be used on the analog signals once they are generated to adapt the video to your monitor. However, I don't know if scan converters with suitable input and/or output capabilities exist.

The digital to analog conversion can be done with a few resistors if you are not terribly fussy about the quality. For example, the following circuit should be able to generate a reasonable VGA signal from a 2 bit input (e.g., MGA or one of the EGA color channels):

```
                     450 ohms
  Bit 1 (MSB) o--------/\/\/------------+
                                        |
                     900 ohms           |
  Bit 0 (LSB) o--------/\/\/------------+-------+----o Analog video signal
                                                |
                                                /
                                                \ 75 ohms (termination, may
                                                /           be inside monitor).
                                                \
                                                |
  Ground o--------------------------------------+----o Monitor Ground
```

This assumes the H and V sync are separate signals. If this is not the case, these will need to be combined into this signal (at least one of the channels) as well.

I have not tested this circuit. Using low value pullups on the TTL signals (say 220 ohms) should help improve the high level consistency.

CGA to VGA

There are two problems:

- CGA is TTL; VGA is analog. Relatively simple circuitry can deal convert the TTL levels into the .7 or so V signal.
- CGA scan rate is approximately 15.75 kHz; VGA is 31.4 kHz. Therefore, unless the VGA monitor can scan at the lower rate (some early multiscan monitors like the Mitsubishi AUM1371/81/91 can do this), a scan doubler will be needed. See the section: What is a Scan Doubler?.

In general, where only 1 (or a few) of these are needed, locating true CGA monitors at used computer stores or thrift shops is definitely the easier way to go!

- Back to Video Conversion FAQ Table of Contents.

VGA to Analog RGB

Note that in some cases, no actual hardware is needed - the video adapter may be programmed to do what you want either using existing or special driver software or at a low level by directing controlling the video chipset:

(From: Jack Schidt (jack@wintel.net).)

Most questions regarding changing or using VGA signals in non-standard (PC) methods, is answerable only by consulting either:

1. Graphics adapter manufacturer (if known) of the VGA adapter, or integrated motherboard. They may have the information you need.
2. Graphics chip manufacturer. They will have programming information or books you can read to change the device programming. NTSC mode set commands are sometimes on the graphics chip mfg's Website or BBS.

   However, this is not always simple!

If you are lucky, you can reach an apps engineer in either case who has knowledge of your requirements, and has the means to supply you a solution. Otherwise, you need to write a short assembly language program to stuff the VGA controller registers with the correct parameters for what you are trying to do.

VGA to Fixed Frequency Monitor (3, 4, or 5 BNC Connectors)

Questions about this specific problem are among the most common as low cost fixed frequency monitors become available when their workstation hosts are decommissioned due to the march of progress.

You will have to obtain the specs to have any idea of whether what you want to do is possible. These are very often high resolution with a typical horizontal scan rate of 64 kHz.

There are several issues:

- Video compatibility - here is the one area where you are likely fine - your monitor is probably compatible with VGA analog video levels - .7 V p-p.

- Scan rate - your horizontal and vertical refresh rate. I would expect that the monitor is not auto-scan and probably not compatible with VGA or SVGA. Please check the specs if you have them or post a message so that someone else can identify it. You need to know its horizontal and vertical scan frequency range.

  If it is fixed frequency, you will be able to use it only in your high resolution (probably) applications. Booting the PC will require a normal VGA monitor for the messages to be seen.

Assuming you are willing to use something else to boot and only run at a single resolution, then the last hurdle is sync:

- Sync. You have 5, 4, or 3 BNC (coax) connectors on the back of the monitor.

  - 5 BNC connectors - this means that your likely have separate horizontal and vertical (H and V) sync inputs - just what your VGA card wants. In this case, as far as sync is concerned at least, all you need is a VGA-to-5 BNC cable.

  - 4 BNC connectors - this means that your monitor requires composite sync. The H and V sync signals must be combined into one TTL level signal. Some cards like those from ATI will probably drive it with just a VGA to 4 BNC cable since they can be programmed to generate composite sync with no additional hardware. (Actually, get a VGA to 5 BNC - you just won't use one of the syncs and this may come in handy at a later time).

    You need to determine what its expected H and V rates are to see if they fall within the range of the video card. Some internal twiddling may be possible depending on the monitor. Also, the software size adjustment in the ATI Install program also affect rates so that adds another couple of degrees of freedom.

    If you need to combine the H and V sync, a TTL gate, single transistor circuit, or sometimes just a couple of resistors will do it.

    For example, if you are able to program your video card for negative sync polarity, then an AND gate (which will act as an OR for negative logic) should do it. For positive sync polarity, a NOR gate or NPN transistor will work. It is also possible to build an auto-polarity switching circuit to accommodate any combination of positive and negative sync polarities. In some cases, just using a resistor in series with each sync line will be enough.

  - 3 BNC Connectors - these monitors need what is known as 'sync-on-green'. This will require some circuitry to combine the H+V+video into one signal. The circuitry is quite simple if you are electronically handy. Commercial boxes to do this are also available.

    (From: Exar (exar@aol.com).)

    For any type of video converters call ALTINEX,INC. in California 714-524-5400 they make a device that will combine sync, separate sync, put it on Green, shift image left or right. Product name is

DA1910SX. I have several of them for my PC, MAC SGI and SUN.

See the documents: "Fixed Frequency Monitor FAQ" and "Sync-On-Green PC Video FAQ" for details.

Some monitors have the required circuitry to accept separate sync internally that is not brought out for a particular model. In this case, some careful exploration may reveal hidden treasures.

So, check your scan rate. If that is not compatible, then you will need a new display board anyway. If it is compatible, then you will just need the sync combiner. Then there is the problem of booting DOS or Windows - these usually want 640x400 at boot.

There are video cards designed for just this purpose. Whether the investment is worth it compared with a new PC compatible monitor is questionable IMO.

See the document: Notes on Approaches to Using Fixed Frequency Monitors on PCs for additional information and names of companies who manufacture the special video adapters.

VGA to Apple RGB

> "Is there any way to modify an Apple 12-inch RGB color monitor so that it can display 640x480 (instead of 512x384)?
>
> Has anyone ever managed to do this? Any opinions on whether or not it is possible?"

I assume you want VGA resolution - 31.4 kHz horizontal.

This would require changing the horizontal scan rate by a large amount and is unlikely to be easily accomplished without extensive modifications to the monitor's circuitry. This should not even be attempted unless you are knowledgeable in the design of monitor deflection circuits and power supplies.

For other Apple (MacIntosh) monitors, see the section: VGA to Fixed Frequency Monitor (3, 4, or 5 BNC Connectors) as most of these run at a fixed frequency. For example, the Mac II rate is 35.0 kHz H and 66.67 Hz V.

VGA to Mac (Monitor) Conversion

I have no idea of what this gadget actually does but it may be worth checking out:

(From: James Willcox (jwillcox@spitfire.net).)

Boca makes an adapter. I have one and it works fine. It has little switches on it to select resolution and refresh rate.

VGA to Sun/Sony GDM1960

(From: Flupke ut Warns (P.O.Langemeijer@student.utwente.nl).)

The most important thing is to get the sync pin(s) connected and the horizontal scan rate as close to the required value.

There is much more info and links at:

- http://www.ifi.uio.no/~karld/fixedsync.html

VGA to Amiga 1024

From: jcaldwel@iquest.net (Mr. Caldwell)

It is a CGA frequency only monitor. It has an 8 pin analog jack on the back and may have a 5 pin ttl jack and ttl to analog converter inside for standard CGA, you can use a cable for the analog plug to a 9 pin d plug for MCGA and get 320 x 200 by 16 Million colors. Some IBM cards will put out the correct frequency and analog signal, most won't. I used an ATI Wonder VGA card that would work correctly *if* manually configured.

Otherwise you need a VGA to NTSC converter. See the section: VGA to TV - NTSC or PAL for more information.

VGA to SCART

SCART is basically an analog RGB + composite sync interface found mostly on PAL (and maybe other European standard) TVs but rarely on TVs in the U.S.

Signal conversion from VGA to SCART is straightforward - just a matter of generating composite sync and making the proper cable. However, it has the same problems as the others with respect scan rates unless you are running an O/S like Linux or an X-server - for the latter case, see: X on TV.

Notes on VGA to RGB Conversion

See the document: Approaches to Using Fixed Frequency Monitors on PCs for an adapter using a programmable logic device to implement conversion from separate H and V sync to sync-on-green. Or, here is a solution using discrete logic:

(From: Jon Jenkins (jenkinsj@ozy.dec.com).)

I use standard 74HC DIP gates available from any electronics store. I use a 14 pin DIP socket originally so that I could change gate types (OR/XOR/AND) easily. 74HC86 (XOR) works just great with the VR320 (I am using it now can also use OR, don't understand why ??).

The VN10KM is a small signal N channel enhancement mode MOSFET also available from most electronics store.

If the video card you are using is a standard VGA output (I'm using a diamond stealth 64 VRAM):

Pin 1: Red video
Pin 2: Green video
Pin 3: Blue video
Pin 4: Monitor ID bit 2
Pin 5: Ground
Pin 6: Red return
Pin 7: Green return
Pin 8: Blue return
Pin 9: NC
Pin 10: Sync return

Pin 11: Monitor ID bit 0
Pin 12: Monitor Id bit 1
Pin 13: H sync
Pin 14: V sync
Pin 15: NC

I join all the "returns" together with the ground on the small PCB and use that as a common ground for the RGB cable to the monitor. You can use separate if you want to but you should join the green return and sync returns together. I did find some small shadowing if I didn't group them all together.

Just a note, when you set up your video card in Windows (or Win95) set it to 1280x1024x72|66 or whatever is closest. I use a VR260 (1024x864) at 1027x768@66Hz (check with your manual DA or D4 are 72Hz) your VGA will not like this frequency so either disconnect it quickly or before you actually set the video card to this mode (i.e. put the OK as the active control in Windows and then connect the VR320 and hit return) My diamond setup gives me 10 seconds to do this adjustment When you exit you will probably have to select the 1280x1024 mode with your old VGA connected again and from then on every time you start Windows you will be able to view it in "big" colour mode. Note the vr320 will not work in DOS mode as it is not an auto-scan monitor so all you see when you boot up is garbage until Windows starts, I put "win" in my autoexec.bat file.

Note there is a danger here: I had set up the monitor and for some reason it did not work so I couldn't see what was going on: my old VGA wouldn't work and the VR wouldn't work either so I had to find the cards .ini files and edit by hand to get back to usable video!!

For FreeBSD/XF86 the lines are:

```
#VR260 monitor is 70MHz 1024x864
#VR320/319 monitor is 130MHz 1280x1024
Modeline "1280x1024" 130.81 1280 1312 1472 1696 1024 1027 1030 1063 +hsync +vsync
Modeline "1024x864" 69.2 1024 1040 1168 1272 864 864 867 904 +hsync +vsync
```

The circuit to do this is as follows:

Notes:

1. You may be dealing with 135MHz square waves so there are lots of high frequency stuff around; use good RF practices.
2. The coupling capacitors are a safeguard to start with. I don't use them because they caused shadowing around sharp colour changes (the old RC effect).
3. Use the XOR gate first as a test but you may need other gates to actually get it working.
4. An oscilloscope will be handy for final adjustment.
5. Make the device is as close as possible to the video outlet on the VGA card.
6. Take the 5V from the PC power supply inside the box. I just hooked one of the spare connectors which I also use for an external fan (Pentiums being the heaters they are!). Make sure (check it again!!) (and again!!!) you don't get the 12V one!!

7. You must use a VN10KM or other small signal N-channel enhancement mode MOSFET. Others will not work!!

```
                         +5 V
                           o
                           |
                           /
                           \ VR1 (1k carbon mini pot)
                           / (Warning: don't let this go near zero!)
                           \
           33uF tantalum   |   ~0.3V DC in porch area
    GREEN o----+----||-----+----------------------+---o GREEN to monitor
               +----||-----+                      |
           .1-.01uF ceramic                       |
                                                  |
           Gnd                                    |
            o                                     |
            |                                     |
            /                                     |
            \ 47k                                 |
            |                                    _|
    HSYNC o-+----|-------\                      |
                 | GATE   |------CSYNC----+----||   VN10KM or similar small
    VSYNC o-+----|-------/                |     |_  N channel enhancement MOSFET
            |                             \       |
            \                             / 47K   o
            /                             \      Gnd
            \ 47K                         /
            /                             |
            |                             o
           gnd                           gnd
```

HSYNC, VSYNC and CSYNC are grounded with 47k carbon resistors

Gate type=LS or HC types, HC preferred:

- OR: for -ve logic sync and no hsync during vsync.
- NAND: for +ve logic sync and no hsync during vsync.
- XOR: for -ve or +ve logic sync and hsync during vsync.

Capacitors are optional, I don't use them.

Use XOR gate with DEC monitors and as a first shot with others, then OR gate then NAND gate.

Get an oscilloscope and adjust porch levels to 0.3V and 0 level (sync level) to 0.0V

- Back to [Video Conversion FAQ Table of Contents](#).

VGA to TV - NTSC or PAL

> "I am interested in converting a signal from my video card to a signal that can be taken into the video in on my vcr. I realize that it is not going to be easy. Still I would appreciate how to do it."

You are correct - this is not easy.

1. You need to convert RGB to NTSC or PAL - there are single chips for this. Try Sony, Philips, Motorola, and others. These will combine the R, G, B, Hsync, and Vsync into a single composite video signal using a minimum of additional components. The same part can usually do either NTSC or PAL by changing a jumper and possibly some of the external components.

   For example:

   (From: Brian B

   > "In the July 1996 issue of Electronics Now, a MC1377P (Motorola) is used to convert RGB to NTSC/PAL. The chip can be purchased through the Newark catalog. This chip is very easy to use and should make your circuit simple." (See the wiring instructions, below. --- sam.)
   >
   > Some other possibilities may be: ADV7175/ADV7176, UPC1352 (ECG/NTE1416).

   (From: Quick Fix (iradg@guru.nu).)

   > "The MC1377 is a 20 pin all-in-one chip. Connect the following: +12 VDC to pin 14 and ground to pin 15, composite sync to pin 2, RGB to pins 3, 4, and 5, respectively. Put a 3.58 MHz xtal between pins 17 and 18. Optional Y delay pin 6 to 8. Video output at pin 9. I have made and sold many of these. If you have any more questions, you can visit the Motorol Website and search for: "MC1377".

2. You need to match the horizontal scan rate to NTSC (15.734 kHz) or PAL (15.625 kHz). Even basic VGA is roughly twice this - 31.4 kHz. If your video card can be programmed to put out interlaced NTSC or PAL rate video then this is easy. If not, it is more difficult. If you want to use any higher resolution than basic VGA (640x480) for a 60 Hz system or 800x600 for a 50 Hz system, it is a very non-trivial problem requiring a scan converter which includes a video A-D, full frame store, interpolator, readout timing, and video D-A. Unless you are an experienced digital and analog designer, you really really do not want to tackle this.

For the special case of VGA to NTSC or PAL, you may be able to get away with something less than a full blown scan converter. See the section: What is a Scan Divider?".

You can also buy little boxes to do this. Quality is general not great as you are seriously limited by the NTSC/PAL standards. Even with S-video inputs to a TV or and S-VHS VCR played on a high-end TV, don't expect to be able to throw away your computer monitor!

Here's one link to check:

- RAM Electronics Industries, Inc. SVGA to Video Adapter

I have no idea of whether this devices works as advertised.

(From: Tomi Holger Engdahl (then@neppari.cs.hut.fi).)

There is all sorts of information relevant to video at:

- http://www.hut.fi/~then/electronics/video.html

There is collection of links to RGB to NTSC/PAL converter and other video chips at:

- http://www.hut.fi/~then/electronics/video.html#chips

or

- http://www.hut.fi/Misc/Electronics/videochips.html

For more detail on this, check my circuit and related software at

- http://www.hut.fi/~then/circuits/vga2tv/

Probably the most complete VGA to TV conversion pages in the web can be found at:

- http://www.hut.fi/Misc/Electronics/circuits/vga2tv/

There you can find schematics, drivers, tips, ideas, documents, links to commercial products and much more. It does not have everything you need but it is a good start. Going to composite video or RF is more complicated as there are three composite video standard NTSC, PAL and SECAM in use in the world and there are also some small differences in modifications of those used in different countries) which is the reason why there are not much of this kind of project. VGA to TV conversion is not simple technology either (the circuit can be simple but there are quite many things to consider when designing such circuit).

Homebuilt circuit persons should take a look at:

- http://www.hut.fi/Misc/Electronics/circuits/vga2tv/

There you can find my design of VGA to TV converter which outputs RGBS signals suitable for TV SCART RGB input (I have also designed one with composite video output, but that's for a commercial application). At the same page you can find a PAL composite video output version of the circuit designed by Paulo Coelho.

For introduction to scan conversion, check

- http://www.extron.com/

Specifically:

- http://www.extron.com/product/scanconv.html

Flickering is a problems always when yu do graphics to TV systems. The graphics material must be designed so that flicker is not noticeable or the scan converter box must include some kind of filtering to do the job.

NTSC/PAL system limit the bandwidth which makes picture to loose some details. The picture is usually even worse than that, because of the cheap video encoding chips used in many converters.

(From: Bill Sloman (sloman@sci.kun.nl).)

Try the Analog Devices AD721 and AD722. When I used the AD720, I had to add a National Semiconductor LM1881 sync separator, and black-level clamps on the red, green and blue inputs to get the right DC levels.

Check them out at Analog Devices.

(From: Leon Heller (leon@lfheller.demon.co.uk).)

Raytheon has a chip which produces broadcast quality PAL/NTSC from VGA. I think that Harris does one, as well.

VGA to TV Converter Boxes, Adapters, and Boards

(From: Kevin Centanni (kpc@panix.com).)

There are a couple of VGA-to-TV converter boxes that also output an NTSC RGB signal. I own one from UMAX - I think it's called the TV-Mini. I bought it from Global Computer Supplies for about $175. I also think that MicroWarehouse sells this product. There's a model sold by AVer also that has RGB out... but it's over $300.

The UMAX TV-Mini is a small box that plugs into your VGA card... it also has a female VGA connector on it so you can display images on your computer monitor and television monitor at the same time. The TV-Mini is powered by the PC's keyboard connector. It has an RCA jack for composite NTSC, an S-Video jack for S-video output and a Mini-8-DIN for RGB output... if you go to UMAX's web page, they'll talk about how the TV-Mini comes with an RGB SCART cable (SCART is a strange looking connector that's used on many European televisions) - but it doesn't come with this cable.

I was able to build a small adapter cable with some parts from Digi-Key. The TV-Mini manual provides the Mini-9-DIN pinouts.

(From: Jerry G. (jerryg@total.net).)

I have played around with a few. The ones in the upper $300 to $400 are not too bad. You will get a reasonable picture. I found the cheap ones are extremely poor.

The best way to do it is with a video display card that has it built in. These cards are expensive because the scan rate must be changed. There is a lot of high speed ram and processing involved to do it right.

It is not a question of movement involved. It is a question of scan rate conversion that makes things complex. With this conversion there is the requirement of some complex quantizing to also convert the characters to match as well. In a lower priced card that I have seen good results is the ATI card with the NTSC output. I don't know the price of the card, but it is not cheap...! There is a Targa card that is excellent, but the price is too high unless you are in the business... But like I said, the higher the price, I found the pictures get better.

Also, the bandwidth for the fonts, and data comming through the conversion is extremely wide. It is wider than off of a conventional TV broadcast, or what comes out of a VCR. The TV set that you use must have a Video Component input, and be able to handle at least 600 lines resolution or better. If not, you will be cutting the performance of the signal right at the end! If your TV has S-Video capability, get the card with that option. It is better than using encoded NTSC or PAL. The S-Video mode keeps the color information separate for processing. This allows for a better signal to noise in the luminance signal, thus rendering cleaner pictures.

Please note, that you will never get the same picture out of a TV video monitor as your computer monitor. They are based on very different processing and CRT design. There are VGA Monitor projectors on the market, and I would consider renting one for the casual use. It will certainly do a much better job. This is what I recommend and do for my clients. Don't even think about buying such a projector unless you have a lot of use for it. They are extremely expensive, and require periodic maintenance.

(From: E. Abel (EugeneA1@worldnet.att.net).)

I've used an ATI 3D Expression+ PC2TV. The S-Video output is not bad, although text is really not very crisp.

Surprisingly, the TV output from the Canopus Pure 3D card is much better. Text is actually readable. (this is on a 27" Sony trinitron TV.) The Canopus card uses a Chrontel chip to do the conversion.

Of course, at $190 the card is a little pricy.

VGA to NTSC/PAL Chips

> "I am trying to build a circuit to convert the RGB output of a video game to my large screen TV."

(From: Leon Heller (Leon@lfheller.demon.co.uk).)

If the game outputs VGA, Raytheon has a chip, the TMC2360, which converts it to broadcast quality PAL/NTSC video.

Another IC that does most of the required functions is the Analog Devices AD725 "RGB to NTSC/PAL Encoder".

(From: a-freak@freenet.de.)

A very nice IC is the TDA8501 which converts RGB or YUV to Y/C and FBAS signals, needs very few external parts ana can be switched between NTSC and PAL with a single jumper. See TDA8501 Datasheet for more details.

Together with a sync processor like the TDA2579 and a colour decoder like the TDA4650 it gives a very simple color standard converter. Also the fast input switch allows one to build a very simple video genlock for home computers.

Questions and Answers on VGA to NTSC Considerations

This dialog resulted from the desire to construct a VGA to NTSC converter to output PC video to a TV or VCR.

"I managed to construct a VGA to RGB converter so far, so I'm almost halfway there, all I believe I need now is an RGB to NTSC converter circuit, although i was trying to avoid the cost of buying one they sell in the PC catalogs."

Can you program your video card to output 15,734 Hz H interlaced scan? If so, you will have a lot less hassle.

> "I figure the odds are in my favor by creating one myself, and as far as I know, no harm could come to my computer by attempting it since the VGA/RGB is and output only and not and I/O. Now since I

> already manged to convert my VGA to RGB, hopefully you might be able to answer some specific questions for me?"
>
> "Is there a minimum & maximum resolution for a TV , or does that depend on the size of the TV?"

If you mean resolvable spots on the TV screen, realistically, it is about half VGA horizontally and perhaps a little more than half vertically or about 320x300 give or take.

If you mean scan lines, that is pretty much fixed at 525 total interlaced 2:1 at 60/30 Hz (625 at 50/25 Hz for PAL 50 Hz systems) with about 420 (540) actually visible on a typical TV. TV's are not auto-scan - they are designed to run at a single scan rate.

Therefore, even displaying easily viewable VGA resolution will be tough. A TV with an S-video input may do somewhat better.

(Remember when you had at most 40 characters across on a Commodore?)

> "Assuming the construction of this circuit would only allow a maximum output from my VGA card, what resolution would that be? 640x480 or 800x600? (I have no expectations of anything higher)"

As noted, for a regular TV, you can send it 640x480 but it will be somewhat fussy. 800x600 is really out of the question. A high quality TV-monitor might do VGA ok. The actual number of lines on a TV is, of course, only about 480 active with perhaps only 420 visible due to the CRT bezel. Unlike an auto-scan monitor, you don't get easy control of this and no control of the number of lines.

> "Finally, taking into consideration the limitations of such a device, I only intend for this to be used for full motion video playback, as my current video capture card, as well as all other cards currently on the market, lack the ability to output the video back to the original source (i.e. a VCR or camcorder)."

Unfortunately, even expensive solutions are still limited by NTSC. However, since your playback is often at reduced resolution (e.g., MPEG) to begin with, this may be acceptable.

(From: FoulDragon (fouldragon@aol.com).)

I'll warn you: You can get a box that will make your PC display on a TV, but it will not be worth your while. We use them at our school, they cost from US $100 and up, and the picture, even on a good TV is very poor. If you can afford one of those boxes, buy a used VGA [even monochrome] and use that as you will be much happier.

(From: Terry Lin (tlin@servtech.com).)

I find that with the ATI PC2TV, on a S-Video hookup on a Sony XBR, the image quality is pretty decent. The flicker removal makes even a full white screen easy to look at (provided you have the contrast turned down, which should be done on every set). I have seen what poor external boxes can do, they give me adaches with the flicker and blurriness. Just make sure your setup is right before evaluating the entire PC to TV monitor thing.

- Back to Video Conversion FAQ Table of Contents.

VGA to Composite Video

Realize that no matter what you do, the quality you get on the TV/VCR is not going to be anywhere near what you see on the computer screen. You must keep this in mind when designing layouts, selecting text fonts and font sizes, etc. The new video cards with on-board NTSC/PAL output should be better than your average cheap converter but don't expect miracles.

> "I need a bit of advice on converting VGA or SVGA to output suitable for a color composite monitor and/or a regular NTSC standard television. I have seen add on cards or outboard boxes that will convert VGA to standard TV but I am not sure if this will have the same effect on a Color Composite Monitor. You see I am wondering if it would be more cost effective to keep my old Apple Color Composite Monitor and buy the necessary hardware to convert VGA output from my IBM clone or to just go ahead and buy a bottom end 14" VGA monitor? Can I even get true 24 bit 800 x 600 color performance out of a TV or a color composite monitor?"

A color composite monitor may be somewhat better than a good TV but it is still limited by the NTSC standard - mainly horizontal resolution but color rendition as well. There is no way to get even basic VGA performance (640 x 480) from a TV or composite monitor.

You are much better off getting a bottom-end SVGA monitor for your PC. As noted, the resolution of a TV or composite monitor is not even good enough to do justice to VGA (640x480) when using the composite video input. Direct RGB can be better but the pitch of the CRT relatively coarse dot or slot mask or aperture grill is then likely to be the limiting factor. A composite monitor or TV will give you approximately 480-490 lines vertically but 10 to 15 percent of these may be hidden by the CRT bezel due to overscan. However, horizontal resolution is much worse. You will be lucky to get half the VGA resolution (300 to 350 lines). For SVGA, there is simply no way to display 800 x 600 without expensive scan conversion on such a tube and you will not be able to read text or display clear graphics. In addition, since the composite monitor or TV is interlaced, there will be annoying flicker of graphics with thin horizontal lines.

Save your pennies - prices for basic monitors are dropping. Your Apple monitor may work fine on your VCR, however.

(From: Jerry Roush (roush_jerry@htc.honeywell.com).)

There is an "inexpensive" device available from JDR Microdevices that works fairly well, called the AVerKey (JDR part no. VGA-NTSC) They are about $100. It also has S-video output.

VGA to Grayscale Composite Monitor

This will only work if you can program the video card to produce a compatible resolution and scan rate.

If you would like to experiment, here is a really simple circuit that may work well enough for combining Hsync, Vsync, and one of the VGA color signals, say green, into a composite video.

If the monitor sense lines on the VGA connector are tied MS1 (pin 12) = GND, MS0 (pin 11) = no connect, then some programs will default to monochrome and use a reasonable color map. I don't know how you will get a reasonable mapping to monochrome for the others.

All you will need are 4 resistors.

I am calling your connector on the monitor 'Composite Video In'.

- Hsync through 500-1K ohm (R1) to Composite Video In.
- Vsync through 500-1K ohm (R2) to Composite Video In.
- Green Video through 200 ohm (R3 - variable) to Composite Video In.
- Green Video side of R3 to Ground through an 82 ohm (R4) resistor.
- Tie this ground to the BNC or RCA connector ground.

```
                         R1
        Hsync o--------/\/\/------------+
                                        |
                         R2             |
        Vsync o--------/\/\/------------+
                                        |
                         R3             |
  Green Video o----+---/\/\/--+---------+--------o Composite Video In
                   |     ^    |                    (Termination = Hi Z)
                   \     +----+
                   /                    +--------o GND of monitor
                   \ R4                 |
                   /                    |
                   |                    |
 GND (shield) o----+--------------------+
```

It is essential that all this be built as close to the monitor as possible for best signal quality.

Set monitor video termination for Hi-Z. R4 provides the cable termination to minimize reflections and ghosting of the green video signal.

Set your video card for negative sync polarity.

You may need to tweak these values for best results. This will depend on your actual signals. The variable R3 may provide enough range for this.

- Back to Video Conversion FAQ Table of Contents.

TV or Composite Video to RGB (Analog or Digital)

NTSC to CGA

> "Does anyone know how to convert a video out signal into a signal usable by a CGA monitor (RGB + H and V sync)?"

If your CGA monitor is TTL, then it may not be possible, at least not without modifications to the monitor. You need to convert from NTSC to RGB. There are single chips (with a few external components) solutions to this. Try Sony, Philips/Signetics, and Analog Devices (I think) as well as others. These take NTSC (or PAL) and output RGB and sync. CGA is not analog (continuous range of video values). It is TTL with Red, Green, and Blue signals as well as a separate Intensity signal. Unless your CGA monitor can take analog video (.7 V p-p) inputs, you will still only be able to get 8 or 16 colors - not a normal TV picture. (And even for that, you will need external circuitry to convert the analog output of the decoder chip to TTL.)

However, some CGA monitors have internal NTSC composite inputs and in that case, it is simply a matter of flipping the appropriate switch.

Composite Video (NTSC/PAL) to RGB

Several companies provide single ship solutions requiring only the addition of a few discrete components to convert NTSC or PAL to RGB and H+V or C sync. Some have options for YIQ, S-Video, and other formats at the input or output in as well.

See: Tomi Engdahl's (then@neppari.cs.hut.fi) Video chips and circuits page:

- http://www.hut.fi/Misc/Electronics/videochips.html

for an extensive list of video encoder, decoder, sync, and other chips with links to their datasheets. Also, check out the web sites or databooks of Sony, Philips, Brooktree, Motorola, Linear Technology, etc.

One example is the Motorola MC44011. (However, it would appear to not be a currently available part as of Summer, 2001, as I could not find it on either the Motorola or On-Semi Web sites).

This part can be used without an external delay line (for PAL to RGB) but a delay is recommended. The chip also provides an A/D sampling clock output for video digitizing applications.

(From: Julie Porter (Julie.Porter@efi.com).)

I was able to get my Sony PVM Monitor to successfully take a YC input on the RGB port. I used the MC44011 and it worked! However be advised. The MC44011 has just been announced for last buy this month! March of 1999. There are no other non digital solutions. The TDA3330 has been unavailable for some time. There is some additional information on my Video Animation Web site. I urge people to call Motorola and ask that this component, not be discontinued as there are many web references designs that use it. There are no substitutes. It should also be noted that if people are considering these designs then they should get the parts soon. The part will go out of production this fall (1999).

(From: Jeremy Todd (bulb@cix.compulink.co.uk).)

Sony makes at least two PAL decoder chips - CXA1621S and V7021.

It looks like you'd need a separate sync stripper (LM1881 or EL4581CN)

Brooktree's Bt812KHF is a much fancier thing for video processing and multimedia stuff.

From RS(UK) both the Sony chips are 10UKP each for 1 off's. The Bt812KHF is 107UKP!!

(From: Sam).

Also, some questions are along the lines of the following:

> "I looked at several chip manufacturers. Most have extensive documentation on their chips in PDF format. Again, most of the chips currently available convert Y/C to digital RGB, and have a lot of extra brightness/sharpness control built in. Too complex- the simplest chip I came across was 18 pins and still required two dozen external components."

(From: Eugene (eugenek@istar.ca).)

The answer is: MC44011 by Motorola, cost $28(Can). It requires some sort of a micro to program it (PIC or the like will do).

There is no external critical components except for a 14.318MHz crystal (found on any PC motherboard).

About the old TV single-chip decoders. This is not true, I've been working with those things for 15 years, and in 70-80s the decoders were much more complicated than they are now (each decoder, actually, requires a delay line (sometimes more than one) and a bunch of various filters). Yes, you had one chip and half a dozen of coils, trim-caps to tune (that required some equipment and knowledge).

Sorry, the chip I suggest has 44pins :-(but little hassle :-)

Watching TV on a PC Monitor - NTSC/PAL to VGA

Questions are along the lines of the following:

> "I'm wondering whether I could use my NEC Multisync as a TV. Long ago I had a Mitsubishi Colour Monitor which could also be directly connected to the videorecorder. Sure, I could use cards in my PC like "WIN/TV", but then every time I want to look TV I have to switch on the PC as well.
>
> Is there the possibility to convert a video to a VGA signal? My NEC has only a VGA input. Or: Are there any monitors available which have both inputs (like my old Mitsubishi)?"
>
> "I have a VGA monitor That I want to use to watch TV. I want to be able to maybe build a box that will let me plug a vcr video out into the monitor. I do not want to spend tons of $$$$$. Can anyone tell me if there is a way to do this??"
>
> "I have a HI-FI VHS that is attached to my stereo. Therefore, my audio needs are well taken care of. I now need the video. I had to sell my TV a little while ago so I do not have a T.V. at this point. I have recently acquired a 20" monitor for my PC (DFI brand.) It has the RGB (red-green-blue) connectors on the back along with a Horizontal and Vertical cable connections. So I have a cable that plugs into my video board on my PC that turns into 5 connectors at the end that connects to the monitor."
>
> "Does anyone have any information on viewing composite video on SVGA type monitors. I have a MAGNAVOX SVGA monitor and if possible I'd like to feed composite video from my VCR and Sony PSX and PANASONIC 3D0 to it. Rather than getting a Toshiba TIMM monitor there has to be some kind of blackbox that will allow someone to do this...Please send info to the address provided or post here."

It depends on your monitor:

1. The monitor needs to support the NTSC scan rate - 15,734 H, 60 V. Some NECs do (like the 3D) but others do not (like the 2A).

2. You need to convert NTSC to RGB. There are boxes on the market for this or if you are handy with electronics, single chips to do this. Check out Sony, Philips, Analog Devices, Motorola, and others for NTSC/PAL to RGB decoder chips.

For PAL (625/50) the relevant resolution is closer to 800x600.

If your PC monitor scans down to 15.734 kHz, then all you need to do is convert the line level NTSC composite to RGB and sync. Some older auto-scan monitors like the Mitsubishi AUM1381 even have a composite NTSC input jack. Conversion requires a single chip and a few discrete components. Commercial converter boxes are also available.

However, if it is a modern SVGA/auto-scan that does not go below 31.4 kHz, then it is a non-trivial problem requiring a video A/D, frame memory, readout electronics, video D/A, etc. This is called a scan converter and is not an afternoon project even for an experienced design engineer.

You can of course buy PC cards that will enable you to watch TV in a window on you PC.

There are also external boxes that will accept antenna/cable or NTSC/PAL composite input and drive a VGA monitor. One such unit is the 'Proview' (Proview Technology, Garden Grove, CA). This is reviewed in Popular Electronics, June, 1997. It appears to be quite capable with its own internal 181 channel tuner and IR remote control. It accepts both RF (antenna or cable) and composite inputs and can select between the video source or computer to drive the monitor (but does no processing of the computer's VGA signal - full screen only). With a suggested list price of $119, the Proview could represent a cost effective alternative to a new TV if you have a VGA monitor sitting around collecting dust.

Some others can be found at:

- http://www.aver.com/lite/products/avertvgenie.html
- http://www.aimslab.com/home.htm

(I have no personal experience with any of the above products --- sam).

In any case, a $150 TV may actually produce a better picture. This is because the CRT/electronics in a computer monitor is optimized for focus at the expense of brightness. Therefore, sharpness may actually be excessive and brightness may be inadequate except under subdued lighting conditions (especially on a well worn monitor!).

(From: Helmut Weber (Helmut.Weber@hamburg.sc.philips.com).)

There are some companies that have boards ready, which you only have to buy and plug into your PC. Try:

- http://www.como.com
- http://www.miro.com
- http://www.2fast4u.com

(From someone else. --- sam).

> "I want to display output of VCR on my computer monitor. Is there a video card that has Video In (such

as RCA in)? Would you tell me which video cards they are? Or does anyone know any other way to display VCR out on a computer monitor? Or Is there a PC monitor exist that has RCA input jacks?"

(From: Todd McCormick (todd@galstar.com).)

There are lots of video cards that have video capture and real time display from RCA phono and S-Video inputs, Matrox Rainbow Runner (which requires a Matrox Millenium/Mystique 220/G200) or the upcoming Marvel, the ATI All-In-Wonder and it's decendents.....

There are several other cards that fill this bill. There are external devices that attach to your parallel ports, or USB port, or Firewire port which can also do this. Some of the older Diamond monitors also had video input as well as a computer input but they were quite expensive.

Comments on TV to VGA/SVGA Conversion

You need a lot more than cables. Here are some comments:

1. Your SVGA monitor must be able to sync down to 15,735 Hz Horizontal - the NTSC scan rate - this is CGA speed and few modern monitors go this low. You thus need a scan converter - not cheap.

2. You need to convert the composite video or S-video out from your VCR into separate RGB and possibly H and V sync. This means electronics not just wires.

3. You will need a good switchbox to select between the sources, you cannot just hook them together.

4. The quality of the TV video on your expensive SVGA monitor will likely be worse than on a $150 TV due to the fine focus of the monitor and the possibly lower brightness. To put it simply, the monitor is too good for NTSC video.

5. Why tie up your computer system watching TV? The other alternative is to get one of those TV tuner and/or frame grabber cards for the PC.

Video Standards Conversion

NTSC to PAL

"Does anyone know of a simple way to convert NTSC signals produced by American video equipment to UK PAL signals."

If you simply mean the color conversion, then a couple of chips will do it.

There are chips to do RGB to NTSC or PAL color encoding but not, as far as I know, scan conversion. For your needs, look into Sony, Philips, and Analog Devices, Motorola, and others.

See: Tomi Engdahl's (then@neppari.cs.hut.fi) Video chips and circuits page:

- http://www.hut.fi/Misc/Electronics/videochips.html

for an extensive list of video encoder, decoder, sync, and other chips with links to their datasheets.

As has been pointed out, using the strict definition of NTSC to PAL as referring only to the color encoding, all you need is a couple of chips for NTSC to RGB and then RGB to PAL, maybe even a single chip. However, for the very common interpretation of NTSC to PAL (IMHO, maybe a little USA-biased) is with respect to US NTSC 525 line 60 Hz systems to PAL 625 50 Hz systems which is where the non-trivial part comes in.

If what you really mean is NTSC 525/60 Hz to PAL 625/50 Hz, it's not trivial.

- The horizontal and vertical scan rates differ 15734 vs. 15625.
- The number of lines/frame differ 525 vs. 625.
- The color encoding differs.

If you simply want to watch an NTSC tape on a PAL TV it may work but not with proper color if the vertical has a wide enough range to sync or you have a vertical hold control with enough range. If your intent is to put it into a VCR, you can safely forget it.

The usual way is to use a scan converter. Essentially, an NTSC color decoder/A-D feeds a frame buffer (approximately VGA size). The frame buffer is then read out at PAL rates and the necessary interpolation is performed using digital processing to go from 525 (480 or so active) to 625 (580 or so active) lines. The output is sent to a video DAC and then color encoded for the PAL system. Everything all happens in real-time.

Needless to say, this is not your basic hobbiest afternoon project.

Here are some additional comments:

(From: Clive Tobin (tobin@nwus.com).)

Conversion is not a trivial matter, involving interpolating scanning lines, changing the field rate, and changing the color encoding scheme. I am not aware of a simple chip set that will do it. There are several ways of doing it with bought equipment, listed in order of increasing price:

1. If you can stand to look at it on your computer instead of your TV, you can buy TV tuner cards with video input jacks, that will display NTSC on your VGA computer screen. I think I have seen these for around $100.

2. Buy a multistandard TV, which are becoming increasingly popular and don't cost much more than single-standard ones. You would not need an NTSC tuner if it has a video input jack. (I don't know if your camera has an RF modulator as well as a video output.)

3. Buy a standards converting VCR, such as Aiwa HV-MX1, Samsung SV-4000W, or similar. These can be used as a stand-alone converter, or to convert the video to record tapes in a different standard. These sell for around $600 and up. I think they all have RF modulators to feed your TV set if it is lacking a video input jack. If you get one of these you could go into the standards conversion business, converting home tapes of overseas relatives.

   Editor's note: Not all multi-standard VCRs do what you want. Some/many simply convert the color encoding between NTSC and PAL without affecting the scan rate (which is much more difficult/expensive). A wide vertical range TV or monitor might produce a viewable picture with these but at the wrong speed (off by 5/6 or 6/5 including the sound)! Unless the product specifications clearly state 'full conversion' or 'scan rate conversion' or something similar, you can probably assume they take the cheap way out! Make sure you can return the VCR if it doesn't meet your needs! --- sam.

The cheapest of all, if you can stand to see the image in black and white with the vertical size off, would be to plug it into the video input jack of a PAL monitor that has a wide-range vertical hold control. Don't use the RF (antenna) input of a regular TV as it may not work at all because of the different carrier frequencies. (You did buy one with video and audio jacks, didn't you?)

(From: Geoffrey S. Mendelson (geoffm@pita.cs.huji.ac.il).)

There are digital converters that do this "on the fly". Akai (and Radio Shack in the US) sell a VCR for $500-600 (US) that works well. Panasonic sells the AG-W1 (NV-W1) that is an excellent VCR and a much better converter for about $1800.

You can also buy just the converters.

Avoid VCR's that claim to play PAL tapes on NTSC TVs. They convert the color signal from PAL to NTSC (well enough for the kiddies to watch tapes), but assume you can "stretch" the sync of your tv to work with 50Hz video.

(From: Tim Jacobs (timothy.jacobs@gecm.com).)

The output from these PAL VCRs won't always record properly, because they take advantage of the fact that the TV can put up with some signal variations that a low-bandwidth VCR (such as an ordinary VHS machine) can't.

The other big problem is the higher frame rate of NTSC as opposed to PAL. In NTSC you have 30 frames per second against PAL's 25. PAL frames have 100 more lines than NTSC frames. So to convert, you have to drop 5 frames each second, add 100 lines every frame, and then you have to worry about the Colour!

This is very complicated if you want good quality.

Here in the UK, there is a VCR available from, IIRC, Panasonic, that will convert between PAL, NTSC, and SECAM (French system). You chose your input system which is either from socket inputs or the tape play-back, and your output system which is to socket outputs or tape record. The machine then does the conversion for you.

The only problems I see with this VCR are, no TV Tuner, and they cost around 1000 UKPounds.

(From: Chris Hall christopher.hall@bbc.co.uk).)

At a broadcast level, probably the best known TV standards converters are made by Snell and Wilcox. I have also used a Barco unit. At a PC level, Vine Micros made a number of boxes for much less money than broadcast kit which do the conversions between PC (and Mac) video standards and broadcast ones. (From: Steve Darsey, N5PMB (sdarsey@yahoo.com).) We use a Sony DSC1024G everyday, does what you ask. Up to 1024x768 to NTSC or PAL video in composite, component (RGB or Y,RY,BY) and S. It will also go the other way. NTSC or PAL to a computer monitor. Also does NTSC to/from PAL. It will also do aspect ratio conversion. Did a letter box from a 16x9 source, no sweat. I have also seen it used to down-convert HD to SD TV.

The Hyperconverter is very comparable, at the time of our purchase, it did not do much more than pure scan conversion from the PC to video. I have no knowledge of their current model.

If price is no object, look for the Fulsom 9000 series boxes. Those machines can deal with much larger (over 1600x1200) pixel rates and will probably walk your dog and water the plants. :)

Find an AV rental or convention show production facility and see if they rent one. We use Alford Media, they have a few locations around the country.

What is a Scan Converter?

A scan converter accepts video of one format - say SVGA - and outputs it to some other format - say NTSC. Some are designed for fixed input format while others can adapt - possibly automatically like an auto-scan monitor - to a wide range of input scan rates and resolutions. Output format is most often selectable between NTSC and PAL scan rates (or those of other TV formats) with a variety of output options such as composite, RGB, SCART, and S-Video.

The typical scan converter must implement the following functions. (This example applies to a unit designed to convert from SVGA or workstation video format to NTSC):

1. Analog to digital converter (A-D or ADC). In the case of VGA/SVGA or workstation video, there will be 3 video signals - R, G, and B - and each of these must be digitized separately. The A-Ds used are generally single chip 'flash' types using a bank of voltage comparators (e.g., 255 compares for 8 bits of output precision) or similar technique to achieve the high speed conversion needed in modern video applications. These may be able to convert up to 135 M samples per second or more as they must run at the dot clock rate of the RAMDAC of the input video source. A filter (input anti-aliasing) may be needed to limit the bandwidth of the input signal. Ideally, the sampling will be adjusted to occur at the center of each pixel but this is not always possible.

2. Full frame store. The resulting digitized data - usually 6 to 8 bits for each color - is stored in a frame buffer generally constructed from DRAM or VRAM. This memory must be capable of being written to and read out effectively at the same time - dual port or pseudo-dual port. In some special cases, less memory is needed but these are the exceptions. With VRAM, the input may use the serial port since it is strictly sequential (and very high speed) and the readout can use the random access port for interpolation (since its rate is lower but multiple pixels and lines may need to be accessed, see below).

3. Readout and interpolation. Hardware must be able to access the frame store without conflict at the desired output scan rate. Since the output video format has a different (generally fewer) number of pixels per line and total scan lines, some means must be provided to combine multiple pixels and lines into the output video stream. For interlaced output (as used by most TV standards), some amount of interpolation between lines (in the vertical direction) is desirable to reduce the flicker of fine horizontal lines (in graphical material) which would otherwise fall in a single output video field. For RGB full color, there is a separate interpolator for each color channel.

    - Nearest neighbor interpolation simply uses the closest sample from the stored data. This is very easy to implement since it is just a matter of computing a memory address - often by just truncating bits. However, quality is poor - pixelly - and usually unacceptable for all but the least critical and cheapest applications.

    - Bi-Linear interpolation takes pairs of input pixels in the horizontal and vertical direction and combines them to form an output pixel that is their weighted sum. This results in a much smoother and more pleasing display. Since two pixels on each line and and two lines are required for the computation of each output pixel, the bandwidth requirements of the frame store and processing complexity are greater resulting in a more expensive system. However, this is the minimum level of interpolation required to produce decent quality output video.

  - Cubic or higher order interpolation uses more than two points in each direction resulting in somewhat better results at greatly increased cost. This is likely to be found mostly in the high performance professional equipment used in television studios and production houses.

   The output of the interpolator is typically 6 to 10 bits of data for each color channel.

4. Video digital-to-analog (D-A or DAC) converter. A high speed DAC (three for RGB) converts the each of the interpolated data streams to an analog signal. A filter (output anti-aliasing) may be needed to smooth edge transitions.

   - For driving RGB monitors, this is the final output.

   - For NTSC or PAL, RGB along with H and V sync are further processed by an RGB-to-NTSC/PAL encoder. It may output be composite video as well as separate Y and C to provide for various output connector options: RCA or BNC, S-Video, SCART, etc.

5. Microprocessor control. Most modern scan converters use sophisticated computer control to provide for advanced levels of auto-scan, many user conveniences, stored setups, and so forth. Features may includes various amounts of user or RS232 (PC) controlled pan, scroll, and zoom; control of sampling times and speeds; and selectable levels of interpolation to control smoothness or sharpness.

However, in the end, no matter how the scan converter is implemented, if the ultimate destination is an NTSC or PAL TV, the resulting picture quality will be very limited. Even a $20,000 professional scan converter may not be able to display fully legible VGA on an NTSC or PAL TV.

For more information on features and selections of scan converters, try:

- http://www.extron.com/scancon.htm

(I have no affiliations with this company and am in no way necessarily endorsing any of their products or claims.)

Implementing a system of this type is a challenging task even for an experienced engineer with extensive design experience with both analog and digital systems.

(From: Derek Roberts (der@cam-orl.co.uk).)

If you really want to do this properly, check out the Genesis Microchip gmVLD8 which uses DSP techniques to do the un-interlacing. Of course you need to add an A-D, field or frame store and some control, But this is the basis of a decent quality scan converter.

What is a Scan Doubler?

This is a special case of a scan converter where the output format has roughly twice the number of lines as the input format and runs at twice the horizontal scan rate. Various scan doubler boxes are available commercially. For example, check out the offerings from Harmonic Reseach. (I have no idea of whether they are any good - just an example.)

The following is described for NTSC; A similar approach can be taken with PAL 625/50 to SVGA at 800x600, 50 Hz.

To convert NTSC interlaced at 30 frames/second 60 fields per second to VGA which is at 60 complete non-interlaced frames per second requires a simple scan converter. This is basically an NTSC color decoder and video A/D feeding a full frame memory storing RGB (probably at 24 bits), and VGA video D/A. I say simple to compare it to the general case where in addition to frame store, you need a high speed interpolator to convert between resolutions. VGA is close enough to NTSC resolution (at least in terms of the number of active video lines) that no interpolation is needed. See the section: What is a Scan Converter?. In either case, this is a non-trivial project. IMHO, this is a poor use of an expensive monitor. A $200 TV will likely look better.

An even simpler approach is possible as well which only requires a one or two line buffers instead of a full frame store. Each input line is read in and reformatted to the appropriate VGA line (even or odd) depending on which field is being displayed. The other lines are blanked (i.e., display even lines and blank the odd lines during the even field display). This would only require enough buffer memory for one or two scan lines (depending on whether the implementation uses a double buffer or more sophisticated write and read timing) which would be a significant cost and complexity savings compared to a full frame store. The disadvantage is that since half the lines are by necessity left blank, the maximum possible brightness of the display will be reduced. It is not possible to use the blank lines as the interleaving of the even and odd fields will be incorrect and result in a poor display.

Inexpensive scan doublers do exist. For example:

(From: Jeffrey Kessler (kessler@fas.harvard.edu).)

I picked up a device called the "Video Cheese Box" from a company called TVOne. This is a $70 box that acts as a rudimentary line doubler. It takes a composite or S-Video input and outputs a 640 X 480 60 Hz VGA signal.

The picture is dramatically better than on a regular TV.

I'm in no way affiliated with this company except for having purchased one of their products.

Scan Doubler Chips

Several companies now provide single chip (or minimal chip) solutions to a major part or all of this problem. For example, Siemans has just announced the SDA9400 Scan Rate Converter which appears to includes nearly everything required - even the buffer memory - to convert from interlaced to progressive (i.e., non-interlaced) scan in Y-U/V format.

(From: Richard Birchall (birchallr@aecl.ca).)

AverLogic has a chip that makes the task of implementing a scan doubler almost trivial. From their product description: "The AL250 is a 64 pin single chip scan doubler/de-interlacer. It converts interlaced TV signals (e.g., NTSC or PAL) into non-interlaced RGB format for output to a PC monitor or LCD panel. The single device also corrects color accuracy on different types of CRT and removes jagged edge artifacts from motion pictures. To allow a regular PC monitor to display television or video input you just need to add a de-coder and the AL250."

What is a Scan Divider?

For the special case of converting from VGA at 640x480 (31.4 kHz H, 60 Hz V) to NTSC or SVGA at 800x600 (31.4 kHz H, 50 Hz V) to PAL, something simpler than a full blown scan converter may be satisfactory. In this case, it is only necessary to provide storage for a single scan line (rather than an entire frame store) since the input horizontal frequency is (almost) exactly twice that of NTSC (15.734 kHz) or PAL (15.625 kHz). A double buffer where one buffer is storing while the other is reading out at approximately half the VGA pixel rate should work. With appropriate timing, even lines become the even field and odd lines become the odd field (I may have this backwards). It is still not a trivial undertaking. Keep in mind that the quality you will get on NTSC or PAL will be poorer than the VGA due to fundamental NTSC or PAL bandwidth limitations. Also, flicker for line graphics will be significant due to the interlacing at 30 Hz.

RGB to PAL Converter Chips

(From: Gary L. Sanders (75052.2665@CompuServe.COM).)

Philips has chips, as does Raytheon, these would take digital RGB and convert to oversampled PAL output.

(From: Mike Diack (moby@kcbbs.gen.nz).)

Analog devices does a chip (AD720) which has the delay & filter elements on the chip itself.

Digital Video Conversion Chips

> "I'd appreciate on an Integrated Circuit (IC) made by a Hong Kong company called Display Research Laboratory."

(From: Philip Decker (pdecker@lds.loral.com).)

The IC is a Video Interlace Processor (VIP), part number VIP-01033. It converts 16-bit digital VGA video (5:6:5, R:G:B) to similarly formatted NTSC/PAL compatible video.

The IC can also be bought as part of a circuit board with additional components, producing composite, Y/C, and SCART analog RGB outputs, in three different configurations:

- piggy-back to VGA, via feature connector ($55)
- external VGA to TV converter ($90)
- ISA bus card with VGA included ($180)

Black Level Clamp

> "I'm looking for a simple GOOD black level clamp circuit for clamping a video signal."

(From: Joseph H Allen (jhallen@world.std.com).)

This is actually a very interesting subject. Assuming you have a constant video level (or AGC), a simple diode clamp on the horizontal sync tips (diode clamp the sync so that the black level is where you want it) is actually a high quality black level clamp. The sync level is constant after all. I use this method in accurate video digitizers for DC restoring the video before putting it into an A/D converter. The cool thing about simple diode DC restorers is that the capacitance is usually much less than that of the analog switches needed in other types. For example one of the best analog switches is the readily available 74HC4316, but even this has 40pF (if memory serves) on its pins.

The really hard part is finding a high quality large-signal linear video amplifier. If the video is capacitor coupled to the video amp, then the average brightness level will change the voltage of the black and sync levels seen by the amplifier. This is ok if the video amp is linear, but most aren't so the sync amplitude ends up changing depending on brightness. I.e., the black level will change depending on the brightness of the image (this is completely unacceptable for medical image capturing devices, for example).

The way linearity is measured for video amplifiers is the term "differential gain". It gives the largest difference in percent between a constant small amplitude signal (traditionally the color carrier is used for this) measured at different voltage levels (hopefully which sweep the entire output swing of the video amplifier).

Now you have to be very careful about manufactures differential gain measurements. Many of them play games to get even a mediocre 3% - 1% differential gain. Typically they specify this parameter with a reduced output range (when you really want the parameter to apply to rail-to-rail output swings so you can get a 2V signal needed for most A/D converters) or limit the input range, the gain or flat out lie (I have no idea where comLinear got the specs for their clc520/522 variable gain amplifier, for example. It says .5% in the datasheet, but I measure it to be more like 5%).

All older video amplifier ICs (like the uA722 and NE592) are really lousy. Discrete transistor amplifiers also suck (many monitors use a cascode amplifier which is very bad). Most new ICs suck too- especially those which are labeled as video amplifiers. The only ones which I have been satisfied with are the newest current feedback OP-amps (the + side is high-impedance, but the - side is zero ohms. Usual op-amps are linear, but have a limited bandwidth because the - input is high impedance). These have enough open-loop gain so that they really are linear. One that I really like is the AD9617: .01% differential gain (!), 160MHz bandwidth, immense slew rate (settles to less than 1% of final value within 10ns or so) and only costs about $10.

If you need variable gain (for AGC perhaps), the best chip to use the AD834 500MHz multiplier. This little 8-pin chip is expensive (like $40) but it is the only thing that even approaches being linear (and even it is quite a bit worse than the AD9617).

(From: Brian Campanotti (bcampano@toronto.cbc.ca).)

Look at the Clamping ICs from Gennum Corp (part numbers GB4550 and GB4551). They do input buffering and clamping. They are a good front end to any video project.

(From: Mika Iisakkila (iisakkil@alpha.hut.fi).)

Since your application probably needs some kind of an input/output buffer anyway, you might consider some integrated DC restored video amplifier. Elantec makes excellent such chips; data sheets are available on their web site under "application specific: video".

EL2090 is really good as far as video quality goes, but a bit expensive for applications that don't need 100 MHz bandwidth and near-zero droop. EL4089 is simpler and cheaper, but not quite "broadcast" quality. There's also some new chip, but I haven't looked into it yet.

For both chips, you'll need to get the sample pulse from somewhere, so you can't lose the LM1881. I've used the burst gate output from it to control 2090's sample input, and quality of the result far surpasses my measuring instruments.

Inverting an Analog Video Signal

Inverting a video signal means doing something to both the luminance (intensity) and chrominance (assuming a color signal). This is not totally trivial (at least, it is more than just putting it through an op amp). You would have to convert to baseband, strip off the sync and invert the signal, recombine with sync, remodulate to channel 3 or 4.

If you want to also invert the colors, then you have to decode the chrominance to RGB, invert these, reencode, recombine, etc.

The assumption here is that the input is an NTSC or PAL composite video signal and that the desired output is a valid composite waveform with negative sync tips. In this case, what is required is as follows:

- Sync separation to identify and preserve the sync relationships.
- NTSC or PAL to RGB conversion.
- Inversion of the individual RGB components.
- RGB to NTSC or PAL conversion along with the sync.

Bypassing the conversions would be messy as you would be dealing the chroma phase space - I wouldn't even want to risk a wild guess as to what would be involved.

For monochrome video, the conversion steps would be replaced with a simple inverting amplifier and possibly an analog switch to merge the sync.

There may be some shortcuts one can take but you get the picture (no pun).

(From: Joel Kolstad (kolstadj@CSOS.ORST.EDU).)

Also note that straight video signal inversion will produce some... interesting... color changes, but not the same changes as you get from photographic film. For monochrome video, the end result will look like a photographic negative.

- Back to Video Conversion FAQ Table of Contents.

Miscellaneous Video Conversion Topics

CGA Boards with NTSC Output

Old CGA cards had RCA outputs. Usually those cards had one monochrome monitor output and other output was composite video (usually NTSC).

CGA to VGA

This requires both converting the signal levels from TTL to analog as well as doubling the scan rate since modern VGA monitors will not go down below 31 kHz H. CGA is around 15.7 kHz. If you aren't fussy about how the colors map, the signal level conversion may be just some resistors. However, the scan rate conversion requires capturing the data on each line and spitting it out twice in one line time, and providing the proper H sync to match. This would consist of a double buffer digital line memory (for the CGA TTL bits) and timing logic to store line n while reading out line n-1 twice at double the rate. It's all doable but not a project for a digital novice.

NTSC/PAL to RF (Channel 3/4) Output

This is called an RF modulator. Every VCR in the universe has one of these and the vast majority are in self contained modules that can be reused. It will be the silver colored metal box that has the two RF (antenna and TV) connectors.

These are also available from surplus electronics outlets for under $5 or as generic replacements for VCR servicing for $12 to $20.

The only connections required to make them work are a source of regulated power - 5 to 12 V depending on model and possible s control voltage to select output instead of pass-through mode.

SVGA Monitor on Sun Sparc

This question comes up somewhat less frequently than the opposite (Sun fixed or dual frequency monitor on PC SVGA):

- It needs to accept the single or dual fixed frequencies put out by the Sun frame buffers. This shouldn't be a problem for most modern higher-end SVGA monitors but it should be confirmed. These specs should be in the Sun user manual.
- It needs to accept composite sync. Sometimes, this is listed as a feature in the monitor specifications. Or, it may work but not be advertised where the monitor is to be connected to a PC (i.e., why manufacture more than one version of the monitor circuitry if you don't have to?). Else, you will need an adapter to separate the H and V sync.
- You will need a 13W3 to HD15 cable. Unless the adapter cable provides them, the monitor sense lines will not be present (at least not automatically), so you may have to tell the Sparc the resolution explicitly.

(From: jmz@southwind.net).

Most any multisync "VGA" style monitor will work with the GX, TX or CG3/CG6 frame buffers on a Sun Sparc. Commercial 13W3 cables and adapters are available or you could get the instructions from a couple of places on the net.

I use my ViewSonic 17s on both Macs and Suns.

You should have a copy of Birdsall's Sun FAQ and you may wish to join the Suns-at-Home mail list, for all Sun self-maintainers. Use a search engine for these and they should vector you to the cable pinouts as well.

S-Video to Composite

(From: David Kuhajda (dkuhajda@locl.net).)

Usually the chroma line (C) is passed through a capacitor and tied to the luma line (Y) after it is passed through a resistor. Usually 470 pF and 100 ohms.

Composite to S-Video

Basically, all that is needed is to separate the Y and C signals. It would probably be best if the C were put through a high pass filter to remove the Y and Y were put through a low pass filter to remove the C but the following appears to work with just a cable and a small capacitor.

- Tomi Engdahl's S-Video to Composite Video Page.

Comparison of Composite, S-Video, Component Video, and RGB

(From: Dave Martindale (davem@cs.ubc.ca).)

Composite is better than using an RF modulator and feeding the signal into the TV tuner but is otherwise the worst of them all.

S-video uses two signal paths, luma and chroma. It's better than composite video, which mix both together into a single signal.

But component video is better than S-video. With component, you have three separate signals - usually Y, R-Y, and B-

Y. This bypasses the subcarrier encode/decode process entirely, and gives better quality.

There's also RGB, which is potentially just a bit better than Y/R-Y/B-Y, but can also be considered a different type of "component".

TV Capture Cards for PCs

Here are some Web sites of companies who market various video products for PCs.

- http://www.hauppauge.com/hcw/index.htm
- http://www.aimslab.com/f_products.htm
- http://www.fast-multimedia.com/fast/html/products/products.html

But be careful, what they say is not always the reality...

Here is an example of a homebuilt video digitizer:

- http://www.ucl.ac.uk/~ucapwas/video.html

Mixing of Independent Video Sources

If they are truly independent, then this is a non-trivial problem. You will need to either:

1. Genlock the two video signals so that they are in sync before mixing. Depending on the sources, the difficulty may range from easy to impossible. Production video equipment will probably have the necessary inputs and outputs. Consumer stuff probably will not. For mixing N signals sources, N-1 will need to have genlock inputs.

   If this is not possible then (assuming two sources):

2. You need a real time programmable video delay. This would typically consist of a video A/D, dual ported frame store, readout delay timing logic, and video D/A. Since there is no way to assure the precise phase stability needed for PAL encoding, you would probably need to separate the luminance and chrominance and deal with them separately.

   The delay would need to be anywhere up to 1/2 frame (or 1 frame if only one of the sources can be delayed). Not an afternoon project. For N sources, you would need N-1 0 to full frame delay units. Also note that commercial broadcasts will sometimes shift frame reference when cutting between remote locations which are not genlocked. If these sources are to be supported, you will need an automatic adjustment scheme to maintain synchronization.

For info on the availability of commercial devices, you may want to post to one of the video newsgroups - rec.video.production, for example.

Studio Video Recording or Filming Directly from Monitors

> "I'm designing graphics for a computer that is used on a the set of a TV show. When the camera operators shoot the screen, horizontal lines roll up and down. I assume it has something to do with the scan rates. I know there is a small program for the Macintosh that corrects this, but I know of nothing for the PC. Does anyone know?"

(From: Dic (dic@werple.mira.net.au).)

This depends on whether they are shooting on video or film. There are display cards for PC which allow you to dial up the vertical output rate, which you want to match to either 30Hz(NTSC frame rate) or 24Hz (typical film frame rate). Multiples are fine, i.e. 60 or 48Hz respectively.

But that isn't the end of it. You may have (approximately) matched the frame rate of the camera, but you have to also lock them together as there will be a certain amount of drift due to slight differences in the two scan (frame) rates. For film there are devices called a Computach or a Synclock, which attach to the movie camera and take a video input (you can just feed it sync from your PC card but you may need to fiddle the level or polarity).

On set, they roll the camera and adjust the shutter phase so the vertical blanking bars on the PC fall in between movie frames. The synclock then keeps the camera perfectly synchronized to the PC sync.

If you're shooting on video it's a bit harder. You need to genlock the video camera to the PC, which can be awkward as the PC sync may not be quite steady enough (directors HATE having to lock to ANYTHING).

The hardest thing to do is run several PC's in the same shot, because they won't be scanning in sync; you can lock your camera to only one at a time. If anyone knows of PC videocards that can be genlocked together I'd be very interested.

We do a lot of this kind of work and at the end of the day, particularly if there is more than one PC in shot, we record the computer graphics to video and use Amiga monitors, because they look like PC monitors but take video input. We use Umatic or Betacam tapes because the playback machines can be drum locked together. Obviously though, if you need a high degree of interactivity with the actor, this won't work too well.

The vertical blanking bar on a PC is quite fine so if they aren't in the foreground you can usually get away with just matching the vertical rate of the PC as close as possible to that of the video/film camera. You won't see flicker, just a fine dark line moving up or down the picture slowly.

That is about the sum total of my experience but if anyone else has better suggestions I'd be very interested. I have seen some TV/movies with multiple computers in shot with no sign of flicker or blanking bars; maybe the bars are just too fine to show up?

(From: falcon@tao.agoron.com (Tom Strano)

In my personal experience, I've found that simply setting the video mode on a PC to 640*480, any color depth, and a 60 Hz refresh rate, results in a very stable picture, even when taped with a cheap consumer camcorder and no attempt at synchronization. I've done this with at least 3 different computers, all with different monitors and video cards, and it always works fine. Perhaps I'm just luckier than some technicians...

Video Controller Timing

> "I wonder if anyone could tell me a good reference on how CRT controllers operate. Specifically, how do the HSYNC, VSYNC, BLANK, and dot clocks interact. Or, would some kind soul like to explain it?

Thanks."

I am not exactly sure what you really want but here are some simple descriptions:

- DOT Clock: the pixel clock. 1/(Pixel period).
- Hactive: the time during which video on a line is actually displayed.
    - Hactive*DOTclk=#Pixels.
- Hblank: the time during which no video is displayed and the beam is being retraced.
- Hsync: positive or negative pulse during Hblank which synchronizes the horizontal deflection circuits of the monitor.
- Htotal: Hactive+Hblank.
- Vactive: the number of lines during which video in a frame is visible.
- Vblank: active for the number of lines during which video is not visible and the beam is retracing to the top of the screen.
- Vsync: positive or negative pulse during Vblank which synchronizes the vertical deflection circuits of the monitor.
- Vtotal=Totaltime=(Vactive+Vblank)*Htotal.
- Csync: Hsync combined with Vsync usually be ORing or XORing.
- Cblank: Hblank Ored with Vblank.
- Composite video: Video combined with Csync usually the video is .7 V p-p positive-bright riding on top of .3 V negative Csync.

For RGB, some monitors will want 'sync on green' which is this type of signal only for the green video. R and B and just the straight video. Mono composite is this signal. NTSC/PAL: RGB color encoded and modulated. Composite video is used for the luminance (intensity) with the color information modulated on a subcarrier (which is ignored by a B/W TV).

One source for info on timing specs is the data sheet for a video DAC or RAMDAC. They will usually define all of these parameters.

Sync Generator Chips

(From: Rob-L (rob-l@mars.superlink.net).)

DigiKey lists 74ACT715PC-ND as "Video Synchronous Generator NEW!" It is a 20 pin DIP and costs $17.50 each for small quantities. The surface-mount version is SC instead of the PC in the above number. You have to pay an extra $1 for the datasheet if you want one. 1-800-DIGI-KEY is their order line. http://www.digikey.com/ is their web address.

(From: (opal@opal.co.il).)

Try philips SAA1101.

Sync Separators

(From: Myron Brookshire (harris.mbrooksh@ic1d.harrris.com).)

Try using the National Semiconductor LM1881 It's a 8 pin DIP that does exactly what you need.

I think it costs @ $8.00 and you only need a couple of caps externally.

(From: Jan Arvidsson (janarv@algonet.se).)

The EL4583C from Elantec has a dedicated HSYNC output in addition to CSYNC and VSYNC outputs, available on the less expensive LM1881 (National). It is of course very easy to derive a pure HSYNC signal from the CSYNC output!

Dead VCRs and Composite Monitors

Most VCRs go to their graves not because of electronics problems but because of the death of the tape transport. Or, perhaps, because the owner was not willing to spend the money or take the time to resuscitate (or has killed it due to improper servicing). Of course, it might just need a 50 cent rubber tire (but that is for another FAQ). What this means is that the tuner and video circuitry is generally as good as the day the VCR rolled off the assembly line.

If you have a composite monitor (probably gathering dust at this point), then this in conjunction with the otherwise useless VCR will result in quite a nice TV. Many CGA monitors as well as early auto-scan or multi-scan monitors have NTSC (or possibly PAL) compatible composite inputs. Some even have built in speakers. A set of RCA patch cables and you are all set. Since they were designed for high resolution (at the time) computer applications, the quality is generally excellent. (Note: I do not make the same quality claims for modern SVGA monitors as their display is optimized for high scan rate computer video and not CGA or NTSC). In addition, controls are usually accessible to permit any desired degree of underscan or overscan.

It may even be possible to use the VCR's timer to turn your rig on and off automatically! (It just requires faking out the record/cassette interlock and locating a signal that can be used to control a power relay.

Conserve your landfills - save a VCR!

Video Cables

> "Does anyone know about the specifications of the video and sync signals for VGA monitors?"

Video: .7 V p-p, (more positive is brighter).

Sync: separate horizontal and vertical TTL signals. May be either polarity.

> "I am trying to send VGA signals over some 180 feet of cable, I'd especially be interested in the required line impedance of the cable."

Line impedance: 75 ohms terminated at both ends.

> "Is it possible to produce a Composite Sync signal (or maybe even a composite video signal) that could be fed into an off-the-shelf VGA monitor, so I could use only 3 instead of 5 coaxial wires in parallel?"

RG59U 75 ohm coax is what is normally used, but you will need a good quality cable to go 180 feet without too much signal degradation. Of course, it also depends on what resolution and thus what video bandwidth you need and how much dispersion (signal delay as a function of frequency) you can tolerate.

It is relatively easy to combine the H and V syncs together and then combine these with the video (usually the green signal for 'sync-on-green') but most low cost VGA monitors do not support this mode and you would then need to separate the signals at the far end. You could come up with alternative ways of combining the signals to save on cables but these will all complicate your circuitry at the monitor end. There are multiple coax cables inside a single sheath for just this purpose.

Building a 5 BNC Cable

This is straightforward, if time consuming and tedious.

The five coaxial cables (75 ohm, RG59 typical) are wired as shown in the table. The corresponding VGA connector pin numbers are in ().

```
   Coax Center         Coax Shield
---------------------------------------
  Red Video  (1)      Red Return (6)
  Green Video  (2)    Green Return (7)
  Blue Video  (3)     Blue Return (8)
  H Sync (13)         Ground (5,10)
  V Sync (14)         Ground (5,10)
```

Tie pin 11 (ID0) to Ground to indicate a color monitor. Leave pin 12 (ID1) open.

Make sure that the lengths of the cables are fairly well matched - to within a couple of inches - to assure that the 3 color channels line up precisely. (One foot of cable is about 1.5 to 2 ns of delay which is significant for a 10 ns dot clock!).

Also note that you will lose your 'Plug-and-Play' capabilities without the direct control connections to the monitor (or for monitors without these features).

That's it!

You will wish that your fingers were about 10 times smaller than they are, however. :-)

Tweaking the Deflection Rates of a Fixed Frequency Monitor

Pulling a fixed frequency monitor by more than a few percent will likely be a problem. I know this is not the answer you were looking for but getting a new inexpensive video card, video card designed for fixed frequency monitors, or new monitor, may be a better solution.

If you insist, the adjustment would be called something like horizontal oscillator, horizontal frequency, or horizontal hold. If you do tweak, mark everything beforehand just in case you need to get back to the original settings.

WARNING: Make sure you understand the issues involved in working inside a monitor! See the document: Safety Guidelines for High Voltage and/or Line Powered Equipment. Something that looks innocent can really ruin your whole day!

There is also some risk to the monitor - changing it too far may result in damage either immediately (the horizontal output transistor or power supply may blow) or increase component stress reducing reliability and shortening its life. There is no way to know without looking at the design.

Modifying a CGA (or EGA) Monitor for NTSC or PAL Input

These are often high quality monitors and would make nice TV displays - especially as there are many no doubt gathering dust on their way to the dumpster!

However, these are digital (TTL) monitors with respect to the video inputs and proper linear video amplifiers may not even be present. Therefore, you may need to implement both the NTSC or PAL decoding as well as boosting the signal levels to the hundred volts or so needed to drive the CRT.

The scan rate of CGA is the same as NTSC so deflection is not a problem.

For PAL (625/50) instead of NTSC, the vertical rate will need to be reduced to 50 Hz but this should not be a problem. The horizontal scan rate is close enough (15.625 kHz).

Similar comments apply to EGA monitors that have a compatible scan rate. EGA represents a range of scan rates between 15.75 kHz and 21.85 kHz so this should not be a problem.

How Can I Determine Monitor Specifications or Whether It Supports SVGA?

There is no easy way to tell by just examining the monitor visually. Even those with only a 9 pin rather than a 15 pin connector are sometimes SVGA (e.g., Mitsubishi AUM1381 and NEC Multisync II which will do 800x600 at 56 Hz V non-interlaced and 1024x768 interlaced at 43 Hz V).

You cannot even safety test scan rates on all monitors - some will blow up or be damaged by being driven with incorrect video.

For a monitor that you already have, posting the model number or looking it up is really the only way to be sure of its capabilities.

Quicky tests:

1. Check the video connector. If it has a high density (VGA) 15 pin connector then there is a greater likelihood of SVGA but not always.

2. Check the manufacturing date on the back. If it has a manufacturing date of 1991 or later, the likelihood of it supporting SVGA is higher as demand for VGA-only monitors was rapidly declining by this point.

3. Check the dot pitch on the CRT by examining the screen with a magnifier. If it is really coarse, the monitor

probably cannot do anything beyond VGA.

4. Become familiar with the major manufacturers and models so that you will recognize the common SVGA models.

While not conclusive, positive results on the first 3 of these tests definitely increases the likelihood that it supports at least some SVGA modes. Of course, if you recognize a model number, you have dramatically increased your odds of success - assuming it works!

The following URLs provide quick access to the general specifications of many common PC and MAC compatible video monitors:

- Griffin Technology
- Hercules
- Monitor World
- Rasterstone
- Table of monitor specs

Low Cost VGA Hacking

Typical question:

> "I have an old mitsubishi monitor, model number C3919N, Scan rate is 15.5-23.5kHz horizontal, analog. I want to run video from my pc svga card into this monitor. I found the correct video mode, resolution, etc. in which it works, but have one problem. I get two perfect images displayed on this screen."

(From: Martin Moeller (mmoeller@delphi.com).)

I have a copy of a very detailed book on using old 19" monitors for VGA:

- The Cheap VGA book
  Self Published by a Michael Johnson, Esoteric Electronics
  35-R Derryfield Road
  Derry, NH 03038
  Night only Phone: 1-603-434-8494

This book contains a lot of good information and advice. He also sells kits for less than $50 (see comment below --- sam) to make the sometimes needed sync inversion from VGA. (VGA cards invert H and V sync depending on mode to tell the monitor what rate to go to. As far as I know only IBM ever used this.)

I have not tried his kits but the book is very good. BTW if you pay much more than $300 for a 19' surplus monter you have been moderately had. I do not have any other connection with this person, I just think his book is very good if you are even thinking of using a "non-VGA" monitor with a VGA card.

(From the Editor).

A circuit to perform the automatic sync polarity correction is shown at:

- http://www.hut.fi/~then/circuits/vga2tv.html

The cost of the parts for this circuit is probably under $5 even if bought from Radio Shack.

Note: I believe there may be a problem with the use of normal or LS TTL for the sync buffers of this circuit due to their sourcing of current when the input is LOW. A gate with a Low Level Input Current of less than .2 mA should be used. (--- sam)

Real Time Multi-Screen Displays

These are the type of displays used to view multiple video inputs simultaneously on a single screen - security monitoring, for example.

You have two problems: compressing the signals to 1/4 screen and synchronizing them. The straightforward (though not simple) approach is to digitize each at 1/4 resolution into a frame buffer which is read out at NTSC rates. This overcomes the issues of genlocking and timing of the 4 quadrants.

On-Screen Display Implementation

> "I am looking for chips that do on-screen display of text and simple graphics. I've got some information about a Philips chip PCA8516 which seems to be a pretty nice complete chip for doing everything I want. Are there other chips out there that do this as well?"

(From: Jack Climent (rocket5@haven.ios.com).)

When you are looking for something for the consumer marketplace, Look toward Mt. Fuji :-).

The MB88303 from fujitsu is an "NMOS Television Display Controller" And the NJM 22075 is a "Sync & Video SuperImposer". These two chips and very little else form a complete on screen text & Min graphics system. Add a uC and you are in business. Also low cost and easy to implement. Have hardware & software someplace if needed.

(From: Winfield Hill (hill@rowland.org))

This isn't an easy thing to do, as quite a bit of electronics is required. Fortunately, this function is needed for TV sets, VCRs etc and several manufacturers have created custom VLSI chips to do the task, which is called On Screen Display or OSD. For example, Phillips, SGS-Thompson, Rohm, and NEC, etc. all make OSD chips. Some, like Motorola, include the OSD function within a microprocessor.

I like the NEC uPD6464A chip.

Using an OSD chip, you can roll your own design (e.g. see Sept and Oct 1996 Electronics World, which uses a discontinued chip!), but it's still a non-trivial task! One easy solution is to purchase an OSD already on a pcb, with all the extra circuitry and C source code software. E.g. BOB-1 from Decade Engineering in Turner, Oregon (503-743-3194). It uses the Rohm BU5963AS chip and cost $169 each ($200 with the software).

SCART Site

- http://www.mindspring.com/~kjack1/scart.html

Video Resizing

> "I'm looking for a device to do resize (in horizontal direction only) of a video signal. Basically I need a fractional decimator (in this case 2:3). Harris has some stuff that might be useful, and Phillips has some devices but I think they're more geared towards NTSC/PAL (data rate here is around 20 MHz, but, then again, isn't the luminance typically sampled at a pretty high rate?). Anyway, I also know I could do it in an FPGA with bit-serial arithmetic, but I'd rather buy something."

(From: David L. Tosh (dlt@earthlink.net).)

Check out:

- http://www.gennum.com/vbprofam.htm

Gennum makes several multirate filters vor video resizing.

Video Resolution of Various VCR Formats

Luminance Specifications:

- VHS (240 lines) - FM Dev: 1 Mhz; Freq Range: 3.4-4.4 Mhz. (Sync tip - White)
- SVHS (400 lines) - FM Dev: 1.6 Mhz; Freq Range: 5.4-7 Mhz.
- BETA1 (250 lines) - FM Dev: 1.3 Mhz; Freq Range: 3.5-4.8 Mhz.
- BETA2/3 (240 lines) - FM Dev: 1.2 Mhz; Freq Range: 3.6-4.8 Mhz.
- SuperBETA (285 lines) - FM Dev: 1.2 Mhz; Freq Range: 4,4-5.6 Mhz.
- ED BETA (500 lines) - FM Dev: 2.5 Mhz; Freq Range: 6.8-9.3 Mhz.

The above refers to resolvable horizontal resolution - the maximum number of vertical lines that can be seen using an arbitrary high quality monitor to view the VCR's output. Also, this applies only to luminance - intensity, not color. The color resolution is much lower and in the particular case of SVHS vs. VHS at least, not improved over VHS since it is recorded in exactly the same way. Also, I don't know whether this is a just noticeable difference (JND) or percent response type of spec where the lines are really just resolvable.

Vertical luminance resolution in the monitor or TV is determined by the video standard (NTSC, PAL) and the quality of the monitor or TV. Specifically, for NTSC (525 total lines for NTSC) there can be a maximum of 482 or so active video lines and something like 580 for PAL (625 line). The remaining lines are for blanking and sync during retrace. These are physical scanning lines.

Vertical luminance resolution for the VCR is determined only by the number of active video scan lines for each standard.

Factors which reduce the effective vertical resolution are CRT focus (spot size) and stability of the interlace, and Kell factor. (See the section: What is Kell Factor with Respect to Interlaced Displays?.

Depending on the video standard, vertical color resolution may be less.

Depending on the video source, there will be a variety of other factors which reduce the effective resolution horizontally and vertically.

What is Kell Factor with Respect to Interlaced Displays?

(From Bob Myers (myers@fc.hp.com).)

The Kell factor - which has to do with the fact that we're often undersampling an image from the standpoint of the Gospel According to St. Nyquist - IS a factor in the reduction of vertical resolution, but interlacing plays a part as well. This comes from at least two factors:

1. The monitor or receiver usually cannot precisely interleave the two fields.

2. More importantly, there are steps taken to reduce the interline flicker which reduce the effective vertical resolution. This includes running the line width of the display somewhat larger than would otherwise be the case, and in interlaced cameras, discharging the entire screen (including the lines from the "other" field) after every field scanned.

Interlace is particularly troublesome on moving images, where you will often perceive momentarily "missing" details. There was a LOT of discussion regarding the gory details of interlacing in the recent HDTV debates within SMPTE and other groups.

Common PC Video Connector Pinouts and Assorted Monitor Info

Many of these are also available at the Sci.Electronics.Repair FAQ site (and its mirror sites) in the document: Pinouts for Various Connectors in Real Life(tm).

Also see the connector info at:

- http://oacosf.na.astro.it/rossi/hwb/hwb.html
- Gamesx.com - A/V and Miscellaneous Pinouts

Video Graphics Adapter (VGA)

Note that IBM called VGA 'Video Graphics Array' probably in reference to the video memory. However, we will use the more popular terminology since it agrees with the naming conventions of the other PC standards.

Original VGA (31.5 kHz - 640x480)/SVGA (35-37 kHz - 800x600) 15 pin sub D:

```
                                                                6
 1 Red (Analog)   6 Red   Return    11 (ID0) GND (Color)    11. . . 1
 2 Green (Analog) 7 Green Return    12 (ID1) NC (Color)       . . .
 3 Blue (Analog)  8 Blue  Return    13 Horizontal Sync        . . .
 4 Reserved       9 No Connect      14 Vertical  Sync         . . .
 5 Ground        10 Ground          15 No Connect             . . .
                                                            15  10  5
```

Note: Monitor ID Lines ID1,ID0=NC,G for color; G,NC for Mono. ID0 only may be used.

Mono VGA is similar using only the Green Video and Return.

VGA (VESA Standard)

(From: Bob Myers (myers@fc.hp.com).)

Note that many of the pins shown above as "no connects" (actually, these were sometimes used as monitor ID bits by many manufacturers) are now defined under the VESA Display Data Channel standard. This standard provides two protocols for display ID and control, including support for the full ACCESS.bus interface. The current definition of the "VGA" pinout per the DDC standard is:

```
                                                                      6
 1 Red (Analog)   6 Red   Return       11 Monitor ID0 (opt.)    11. . . 1
 2 Green (Analog) 7 Green Return       12 Data (SDA)              . . .
 3 Blue (Analog)  8 Blue  Return       13 Horizontal Sync         . . .
 4 Reserved       9 +5 VDC (frm host)* 14 Vertical  Sync          . . .
 5 Return        10 Sync return        15 Data clock (SCL)*       . . .
                                                                15  10  5
```

Those signals marked with an asterisk would be supplied by the host only if the host supports the DDC2 protocol (I2C or ACCESS.bus).

VESA Display Data Channel Standard

(From: Bob Myers (myers@fc.hp.com).)

This defined several protocols for digital communications between a host system and its display. DDC provides 3 different modes:

- DDC1 - A unidirectional (display to host only) serial communications system which provides basic display ID and feature support information (including supported timings, display size, colorimetry and gamma, etc.) to the host. This uses pin 12 on the 15-pin "VGA" connector as a data line.
- DDC2B - Adds clock (pin 15) and return (pin 11, I think - I'm at home, and don't have the standard with me) to enable at least ID information to be obtained via an I2C interface. I2C is a bidirectional interface, but display control via DDC2B is not defined at this time.
- DDC2AB - Full ID and control of the monitor via ACCESS.bus. As ACCESS.bus is basically a command and protocol definition on top of the I2C hardware interface, this uses the same lines as DDC2B.

DDC was the first and only definition of the 15-pin D-subminiature video output connector which VESA has provided. No further definitions on this connector will be made, as VESA is instead concentrating on the new Enhanced Video Connector standard which is due out later this year. This will define a completely new connector which will include support for DDC and separate syncs as in the 15-pin D-sub, and will also include support for audio I/O, video input, and the USB and P1394 serial interfaces.

VGA - 9 Pin

This is pretty standard as the NEC Multisync II, Tatung CM1495, and others use the same pinout. However, there is at least one other pinout that has been used which is similar to the CGA pinout. Also see the document: Pinouts for Various Connectors in Real Life(tm).

I used a multimeter to determine this on the VGA to 9 pin adapter for a NEC Multisync II.

> Pin 1: Red Video Pin 2: Green Video Pin 3: Blue Video Pin 4: H Sync Pin 5: V Sync Pin 6: Red Return Pin 7: Green Return Pin 8: Blue Return Pin 9: Ground

Note: IBM PGC assigns pin 4 to Composite Sync and pin 5 is a no-connect.

BTW, don't use an EGA 9 pin extension cable to connect it to VGA. While this will work, the wires are not shielded or the wrong wires and you will get ghosting and ringing at vertical edges. I constructed mine using proper 75 ohm coax for the RGB and H and V sync as well (though it is not needed for the sync).

(From: Carl Mueller).

If you're sure it's a VGA monitor (not CGA or EGA, which are not compatible with VGA), then there are two possible likely pinouts for the plug. I believe they are both detailed in the ibm PC hardware FAQ. One possibility is the CGA pinout, and the other is the 9-pin VGA pinout. Check the grounds to find out.

Enhanced Graphics Adapter (EGA)

p> EGA - TTL (15.74-21.85 kHz) 9 pin:

```
 1 GND                       6 Secondary Green Video/Intensity
 2 Secondary RED Video       7 Secondary Blue Video
 3 Primary RED Video         8 H Sync TTL Positive
 4 Primary GREEN Video       9 V Sync TTL Negative
 5 Primary BLUE Video
```

Color Graphics Adapter (CGA)

CGA - TTL (15.75 kHz - 320x200 or 640x200) 9 pin:

```
 1 GND                       6 Intensity
 2 Unused                    7 Unused
 3 RED Video                 8 H Sync TTL Positive
 4 GREEN Video               9 V Sync TTL Positive
 5 BLUE Video
```

Dell UltraScan 17ES

This pinout may be used by a number of Dell monitors. The connector looks like a standard VGA/SVGA HD15 but is wired differently (for some unfathomable reason).

(From: Chris Lawson (lawsonc@micron.net).)

> Pin 1: Gnd Pin 2: Red video Pin 3: Gnd Pin 4: Green video Pin 5: Gnd Pin 6: Gnd Pin 7: NC Pin 8: VSync Pin 9: HSync Pin 10: Blue video Pin 11: NC Pin 12: NC Pin 13: NC Pin 14: NC Pin 15: NC

Monochrome Graphics Adapter (MGA)

MGA - TTL (18.43 kHz - 720x350) 9 pin:

```
 1 GND                         6 Intensity
 2 Unused                      7 Video
 3 Unused                      8 H Sync TTL Positive
 4 Unused                      9 V Sync TTL Negative
 5 Unused
```

MacIntosh Video

Mac II - analog (35 kHz H, 66.67 Hz V - 640x480) 15 pin. Mac II and Quadra - analog (49.7 kHz H, 74.55 Hz V - 832x624) 15 pin.

```
 1  Red Ground              9 Blue Video
 2  Red Video              10 Sense 2

 4  Sense 0                12 Vertical Sync
 5  Green Video            13 Blue Ground
 6  Green Ground           14 Ground
 7  Sense 1                15 Horizontal Sync
 8  Reserved (+12)
```

Mac (16") Monitor Info

(From: Dale Adams (adams9@apple.com).)

Note that the Apple 16" monitor is a fixed frequency display - i.e., it only works at one resolution and scan frequency. Here are the partculars:

- Resolution: 832x624
- Pixel clock rate: 57.2832 MHz
- Vertical scan rate: 75 Hz
- Horizontal scan rate: 49.7 kHz

Here's the pinout for the Apple DB15 video connector:

```
Pin    Signal          Description
-----  -----------     ----------------------------------------
1      RED.GND         Red Video Ground
2      RED.VID         Red Video
3      CYSNC~          Composite Sync
4      MON.ID1         Monitor ID, Bit 1
```

```
5      GRN.VID         Green Video
6      GRN.GND         Green Video Ground
7      MON.ID2         Monitor ID, Bit 2
8      nc              (no connection)
9      BLU.VID         Blue Video
10     MON.ID3         Monitor ID, Bit 3
11     C&VSYNC.GND     CSYNC & VSYNC Ground
12     VSYNC~          Vertical Sync
13     BLU.GND         Blue Video Ground
14     HSYNC.GND       HSYNC Ground
15     HSYNC~          Horizontal Sync
Shell  CHASSIS.GND     Chassis Ground
```

You can pretty much ignore the ID bits. You can try the following cable pinouts to match to a VGA connector.

```
 Mac Video DB15                        VGA Connector HD15
----------------                      --------------------

 2  ------------------- Red Video ------------ 1
 1  ------------------- Red Ground ----------- 6
 9  ------------------- Blue Video ----------- 3
 13 ------------------- Blue Ground ---------- 8
 5  ------------------- Green Video ---------- 2
 6  ------------------- Green Ground --------- 7
 15 ------------------- Hsync ---------------- 13
 12 ------------------- Vsync ---------------- 14
 14 ------------------- Sync Ground ---------- 10
```

Mitsubishi Diamond Scan Monitors

These monitors accept PC video (at least standard VGA - 640x480 at 60 Hz - but have non-standard connectors. Here are two types - there may be others.

(From: Tony Matt (tonym@world.std.com).)

Cable for Mitsubishi Diamond Scan 20M (Model HC3925ETK)

```
 Pin Function        PC Connector    Monitor Connector

 Red (Analog)              1                  2
 Green (Analog)            2                  4
 Blue (Analog)             3                 10
 Reserved                  4                  6
 Return                    5                  6
 Red Return                6                  1
 Green Return              7                  3

Green (Analog)            2                  4
Blue (Analog)             3                 14
Red Return                6                  3
Green Return              7                  5
Blue Return               8                 15
Sync Return              10                  1
Monitor ID0              11                  1
Horzontal Sync           13                 16
Vertical Sync            14                 17
```

1. Cable is marked "Mitusbishi CAT. NO. 246C057-8".
2. Cable material is E41447 (AWM Style 2560).
3. Color signals are carried on coax with their respective returns.
4. Pins 10 and 11 use separate wires in the cable, which are connected together at Pin 1 of the DB-25.

Sun 13W3

This was introduced by Sun Microsystems and is a nice compact robust connector. Other manufacturers have copied it but there are several variations. See: MonitorWorld Video Standards Page. Towards the bottom they have several different 13W3 pinouts. Some only accept composite sync, some have the sync pins reversed, etc.

Pin 1: NC
Pin 2: NC
Pin 3: Sense 2
Pin 4: SRTN
Pin 5: CSYNC
Pin 6: NC
Pin 7: NC
Pin 8: Sense 1
Pin 9: Sense 0
Pin 10: CRTN

Pin A1: Red

Pin A2: Green
Pin A3: Blue

The following I picked off the net so I do not know the accuracy of the resolution table.

Analog: 13W3 connector:

```
         +------------------ * gnd
         |   +-------------- * vertical sync
         |   |   +----------   sense 2
         |   |   |   +------   sense common (gnd)
         |   |   |   |   +-    composite sync
         |   |   |   |   |
         |   |   |   |   |   grey
    red  |   |   |   |   |   green blue
     |   1o  2o  3o  4o  5o    |     |
    (O)                       (O)   (O)
       6o  7o  8o  9o 10o
       |   |   |   |   |
       |   |   |   |   +---    composite common (gnd)
       |   |   |   +-------    sense 0
       |   |   +-----------    sense 1
       |   +---------------- * gnd
       +-------------------- * horizontal sync

    * May be NC. My spies tell me Sun considers these obsolete.
```

The green video input is used by grayscale monitors.

Sense table - 1=nc, 0=strap to gnd

```
  Sense      Type/scan rate
 -------------------------------------------
    0      TBD (?))
    1      Reserved
    2      1280x1024, 76Hz
    3      1152x900, 66Hz
    4      1152x900, 76Hz, 19"
    5      Reserved
    6      1152x900, 76Hz, 16 or 17"
    7      Nothing (no monitor connected)
```

Sun/Sony GDM17E10

(From: Andy Cuffe (baltimora@psu.edu).)

This is a good SVGA monitor (same as Sony Multiscan GDM-17SE). The Sun version doesn't connect the H and V sync lines to the video connector. If you open it, on the the video board there will be a 3 pin connector labeled H sync, V sync, and ground. All you have to do is connect these to some unused wires in the video cable. There will be several wires going to a small board which I think is used for monitor detection, or other functions only used by a sun station. You can just cut any two of these and use them for sync. Cut off the 13W3 and attach a HD15 connector, remembering which pins are used for sync.

If you're not into soldering, I'm fairly sure there is an adapter fit this that just converts the separate sync to sync on green. If I remember correctly, the web site that was selling it incorrectly identified it as a fixed frequency monitor and said you needed one of their special video cards. It is NOT fixed frequency.

Sony PVM-2030 and PVM-2530 Profeel Pro Monitors

(From: Rob Myers (myer3812@nova.gmi.edu).)

I have the pinouts for the RGB connectors on newer Sony monitors (specifically, the PVM-2030 and PVM-2530 Profeel Pro monitors). These pinouts are directly from the owner's manual. The connector used is a DB25 female.

- High state = 5V (open)
- Low state = 0V (short to ground)

Note On Pins 3,4,5,6,11:

- If pin 9 is high/open (Analog RGB mode) then .7Vpp, 75 ohm signals must be input to these pins. Pins 1 and 25 are not used.

- If pin 9 is low (Digital RGB mode) then TTL signals must be input to these pins. Pins 1 and 25 are only used in this mode.

```
Pin   Signal         Descr
---------------------------------------------------------------
1     IBM Select     High: IBM mode (RGBI)
                     Low:  3 Bit TTL (RGB)

2     Audio Select   High: Audio input from pin 13
                     Low:  Audio input from LINE A/B/VTR jacks

3     HSync/CSync    Horizontal or Composite Sync, Negative Pol.

4     Blue Input     Video Inputs: Positive Pol.

5     Green Input    (Sync on green optional in analog mode)

6     Red Input

7     NC

8     NC

9     Analog/Digital High: Analog mode
                     Low:  Digital mode

10    RGB/Normal     High: RGB input selected
                     Low:  LINE A/B/VTR input selected

11    VSync          Vertical Sync, Negative Pol.
```

```
12    Blanking        High: Video input from RGB input only
                      Low:  LINE A/B/VTR signal is superimposed over
                            signal from RGB input

13    Audio Input     -5 dB / 100% mod.

14    NC

15-24 Ground

25    intensity       Positive Pol.
```

These monitors are regular NTSC monitors, but I'm sure they can be connected to computers the same way I connected the KX-2501... using a simple buffer circuit and special video drivers. Another possibility is to build a component-to-RGB converter for really high quality DVD playback (better than S-Video)... the blanking feature seems interesting but the RGB source would have to be synchronized with the composite source. I think the KX's/XBR's have the blanking input, too.

The Sony RGB Multi Input pinout is also valid for the kV-25XBR; it should also work with the kV-20XBR and KX-1901, and I know it works with a KX-2501. (The KX series monitors are the original Sony Profeel monitors from about 1983, and they are very common.)

A female 34-pin floppy connector will mate with the Sony connector just fine. I was able to use the analog RGB input on a KX-2501 to display VGA PC video using a sync level converter circuit and drivers from:

- http://www.hut.fi/Misc/Electronics/circuits/vga2rgbs.html

SGI Octane to Sony GDM-17E21 Cable

(From: Yves DELAY (yves.delay@imag.fr).)

I am trying to connect a Silicon Graphics (SGI) 17" screen display to an SGI Octane CPU. I would like to build my own HD15 to 13W3 cable.

The monitor is standard SVGA with the VESA Display Data Channel (DDC) and works fine on a PC.

SGI OCTANE CPU video pinout (13W3):

> A1 Red (analog)
> A2 Green (analog)
> A3 Blue (analog)
>
> 1 Monitor ID bit 3 (TTL)
> 2 Monitor ID bit 0 (TTL)
> 3 Composite sync (active low), TTL
> 4 Horizontal drive (active high), TTL
> 5 Vertical drive (active high), TTL
> 6 Monitor ID bit 1 (TTL)
> 7 Monitor ID bit 2 (TTL)
> 8 Gnd
> 9 Gnd

10 Gnd

Below is the pinout of the SGI 13W3 to HD15 cable, part number: 018-0500-001, Rev. E VIST 9717, obtained after a phone call to the SGI hotline.

```
 Signal     SGI OCTANE (13W3)                Monitor: GDM-17E21 (HD15 male)
----------------------------------------------------------------------------

 Red              A1                        1      Red
 Red Gnd          A1 Gnd                    6      Red Gnd
 Green            A2                        2      Green (+ composite sync)
 Green Gnd        A2 Gnd                    7      Green Gnd
 Blue             A3                        3      Blue
 Blue Gnd         A3 Gnd                    8      Blue Gnd

                                     Pins 6, 7, and 8 tied together, along
                                       with both connectors metallic shell
                                       and cable shield.
```

Notes:

1. ID3 (1): not used
2. ID0 (2), ID2 (7), and Gnd (8): all tied together.

3. Other pins: not used.

S-Video Note that this is often called S-VHS. I don't know whether this is correct. I assume that S-Video refers to the use of separate luminance (intensity) and chrominance (color) signals and that S-VHS refers to a modified recording standard for the VHS tape format to achieve higher resolution on special S-VHS tape. S-VHS may or may not use S-Video signals and vice-versa.

In any case, S-Video uses a 4 pin mini-DIN connector. Viewing from the female-end with the key at the bottom:

Pin 1 (lower right): Y Ground
Pin 2 (lower left): C Ground
Pin 3 (upper right): Y (Intensity/Luminance)

DISCLAIMER

The procedures described in this document require access to potentially dangerous voltages, proximity to the CRT and its implosion risk, and other possible dangers lurking inside a television set. Furthermore, while your symptoms may fit those described below, there is no guarantee that resoldering the tuner module WILL fix your problem. The actual cause could be elsewhere.

We will not be responsible for personal injury resulting from attempting these repairs nor damage to the equipment that may result from lack of soldering experience or inadequate desoldering or soldering equipment.

- Back to RCA Solder FAQ Table of Contents.

Introduction

IMPORTANT NOTICE: If you find that your TV has symptoms matching those caused by bad solder connections as described in this document, or have had an RCA/GE/Proscan TV repaired for similar symptoms, or are just curious, there is a class action suit pending against Thomson Consumer Electronics which if approved, may entitle you to a cash rebate. Go to the TOB Settlement Information Website for more info and a claim form. The deadline is May 20, 2001.

Scope of This Document

Problems with bad solder connections, mostly in and around the tuner are very common with several series of late model (e.g., CTC175-187 and higher chassis) RCA/GE/Proscan TVs. Ignoring these erratic and intermittent problems can lead to serious damage including failure of the EEPROM and possibly other expensive ICs. Therefore, it is essential to deal with the solder connections as soon as these symptoms appear. The repairs are straightforward though perhaps tedious. Thomson may reimburse for reasonable cost of repairs.

Also, some LXI TVs may actually be of RCA/GE manufacture: LXI is sold by Sears. If the model number starts with 274.something it is an RCA CTC176/7 or 187 chassis. (pwhite4@aol.com (PWhite4).)

Sometimes, similar symptoms are the result of bad solder connections elsewhere on these chassis. Check around the pins of large components like power transistors, power resistors, transformers, etc. However, since problems with the tuner soldering are so common, this is usually the place to start.

Note that many other RCA chassis as well as other manufacturer's TVs are also susceptible to similar symptoms with similar causes.

Some of the common symptoms include:

- Random power cycling. It may come on in the middle of the night!
- Picture shifts or changes size vertically or horizontally.
- Picture turns to snow or shows other reception problems.
- Picture turns to random display of time or other data.
- Noisy or muted sound, volume buttons have no effect.
- Remote has no or unexpected effect.

The articles in this document have been compiled over the last few months from postings on the USENET newsgroup sci.electronics.repair.

Contributions are welcome to increase the coverage of this set of notes as well as those for the very similar set of problems and solutions for late model Sony TVs: "Sony TV Tuner and IF Solder Connection Problems". (Symptoms are very similar and repair requires removing and resoldering connections inside the tuner and IF boxes. Unfortunately, at least on some models, removing these modules is a real treat!)

Proper attributions will be made for all providers of solutions. I apologize if I have incorrectly referenced you or left your name off. I will be happy to make any necessary corrections in the next revision. Please email me with any additional sections. I would very much like to improve the details of the repair procedure if possible.

Corrections and additions to any specific symptom or solution are also welcome.

I have no connection with Thomson Electronics or any other manufacturer of consumer electronics. These articles have been included unedited except for some spelling, grammar, and format cleanup.

Problems with CTC195 and More Recent Chassis

(From: David Kuhajda (dkuhajda@locl.net).)

The CTC195/197/203 series with the onboard tuner has a batch of other problems, not the same type of failures that the CTC177 line was notorious. Most of which are addressed with service bulletins given the units serial number. However they are suffering from a conductive glue syndrome the Thomson engineers are still in denial about. It seems the glue they are using to attach the surface mount components is sometimes becoming conductive from the manufacturing process and will cause all kinds of really odd intermittent problems, most of which cannot be fixed unless you get lucky enough to see it several times while working on the set. Specifically c17503 and c17504 inside the tuner, and some down by the microcontroller are the most common culprits.

The latest Thomson sets we have been seeing have a stand up tuner that runs off the I2C bus, but those are failing at an alarming rate. Seems they are using the same I2C prescaler IC by Philips that Zenith and Sony are using and also having high failure problems. If you generate too much static by sneezing near the cable line you can blow one of these ICs. For a cheap TV set if you can live with the poor focus, contrast, and poor convergence on most of the Thomson sets, they are comparable with everything else that is selling that cheaply.

Safety

Before removing the case on any TV or monitor, make sure you understand AND follow the safety guidelines provided in the document: Safety Guidelines for High Voltage and/or Line Powered Equipment.

- Back to RCA Solder FAQ Table of Contents.

Solder Connection Problems and Solutions

Symptoms of Cracked Solder Connections

Here are some typical sets of symptoms resulting from bad solder connections in and around the tuner of these late model TVs:

> "I have a 26" RCA television with a "squeezed" vertical and "snowy" picture, at its worst times it also shuts off and on again. This problem is occurring 50% of the time, I noticed that tapping the panel where the 75ohm and rca connectors are attached will realign it temporarily. Is this a symptom of the "solder cracking I read about in RCA's or a bad EEPROM and if it is a bad EEPROM why does a smack offer a quick fix and why is it shutting off and on?"
>
> "This picture is short vertical about 1/2 inch at top and two inches at the bottom. Anyone seen this problem on this chassis. Is it possibly related to all the bad solder joints in the tuner area?"
>
> "I have an RCA TV with the following symptoms:
>
> - The audio will suddenly switch to maximum volume.
> - The volume buttons on the TV and the remote control have no effect on the volume during this time.
> - If the blaring condition occurs and I attempt to adjust the volume very low, then when the condition returns to normal, the volume comes back at this very low volume. So the signal to adjust the volume must be received by the controller while the speaker is blaring.
> - If I use the remote to mute the volume a slight diminishing in the volume can be noticed, but the mute is not accomplished.

- If I cycle power, the problem persists, unless I leave the unit off for a while (sometimes 30 seconds, sometimes a few minutes) before turning it back on.

- If I adjust the volume to minimum and turn on the muting, just using my stereo for sound from the VCR, the TV will still begin to blare in short burst and then eventually come on and remain at full volume."

"My parents' RCA TV has lost some volume, and is now barely audible when on full volume. The controls are all electronic and on screen. Is this a known problem with RCAs, and could there perhaps be a pot I could adjust inside to 'boost' the volume?"

"I have a GE 31" (about 3 years old) where the picture moves down the tube, like a DC offset is present. The top of the picture is down about 1/3 from the top of the screen and the bottom of the picture compresses. Occasionally, the picture turns to snow. If I turn off the power and back on, it temporarily cures the problem. Could these symptoms also be caused by poor tuner connections?"

"I have the SAME TV, and mine is about 1/5 off. Some channels also have lots of Snow etc."

"I tried using a VCR as a tuner & running the signal in through the RCA plugs in the back. Same difference. I still experience the same problems. Does this rule out the turner?"

"I am having the following problem with the TV:

- The screen will go black and display: 1:5P A-- (the "P" is sometimes an "8" or possibly a "B")

- The screen will suddenly go from showing a picture to show nothing but "snow". There is no sound, the remote control won't shut it off, the power button on the set won't shut it off, it has to be shut down by unplugging it.

- When it is plugged back in it will sometimes come back on without pushing the power button or using the remote, screen shows nothing but snow, no sound.

- Sometimes when it is plugged back in it works normally (won't come on until you push the power button or use the remote), it then acts normally except there is no sound until you use the remote or the buttons on the set to adjust the sound."

"My RCA XL-100 TV has begun to develop a life of its own -- it intermittently goes crazy."

"My two and a half year old GE 25" set started having troubles with the picture shrinking from top to bottom, losing signal strength (snow) and now shifting of the picture off the bottom of the screen. This would occur usually right after turning it on, and sometimes could be cured by turning off the set and turning it back on again. Lately it has been getting worse so I took it in for repair. Lo and behold, there were several GE and RCA sets there that had similar complaints. All ended up needing an "S-kit" from GE, an item apparently supplied to the repair center for free from GE. I needed a crystal as well. This sounds like some kind of widespread problem that maybe should be looked at as if it is an unwritten warranty? Anyone care to comment?"

"I have a 27" GE Model 27GT610. About a year ago a problem started to develop. It would take turning it on 2-3 times before the picture came up. Initially all I would get was a black screen and static on the speakers as if it wasn't on a broadcast channel. Over the last year it has progressed to taking me 20-30 minutes to get the picture to come on. I suspect it might be a corroding startup relay but am unsure. Does anyone have a part# and component# that could point me in the right direction? Any other suggestions would also be appreciated. Thanks, btw I already have the FAQ.

"I have a 2 year old RCA XL100 television. It has worked just fine up until the last 2 or 3 weeks. I now have severe problems with it and am hoping that someone who reads this posting will recognize the symptoms and help steer me in the right direction to fix the damned thing! I know of another person who had the exact same model and 2 years after he bought it, it started acting up in the same way, so I assume this is a well documented problem that I'm seeing...

When the set is turned on, the "reception" on some cable channels is terrible, but others are fine. Turning off and on again fixes those channels, but within a few seconds, the reception goes bad again. There is a time display function and a mute function on the TV. When I press a button, the channel displays in the upper right corner. Likewise in the lower left corner with mute. When the TV is misbehaving, these words "walk" down on the set. The MUTE word goes so far that it's unreadable since only the tops of the letters show. Turning off and then back on temporarily solves the problem. Whenever this phenomenon occurs, the top of the picture gets "squashed" down and a black band appears at the top of the screen. When I look at CNN, the sportsticker at the bottom is almost unreadable and it appears that the lower part of the picture is forced into the non-viewable area of the screen. If I struggle through these problems for an hour or so, then everything is almost back to normal, but the problems do appear intermittently. When I switch over to the VCR tuner, my reception problems are solved, but I still get the screen "walking" behavior, so it looks to be more that the tuner chip (unless that also controls these extra functions). Does anybody know about this problem??? Is it just a bad chip or component that I can replace? What should I do about it? (I'm a EE and am quite capable of fixing simple soldering problems and such myself). Before I take it to a repair shop or buy a new one, I'd like to see if I can fix this one... in a word... HELP!"

"I have an RCA FMR70ER TV that only works when the room temperature is warm. If the temperature is cool the TV will never turn on .

"The problem tends to show up after the TV has been on for a few minutes. The picture will appear to have signal problems (i.e. a snowy picture), and then the top line of the picture will begin to dip down, until it is approximately 25% of the way down the tube. There is just black above it. When its really bad, the picture will be just snow, the top will drop down almost half, and there will be a very bright band at the bottom of the screen. Now, one way to remedy this problem is to shut the TV off, and then back on again. Sometimes this will 'reboot' the TV and the picture is fine. Sometimes it doesn't work.

The problem is beginning to become more persistent and annoying!"

"I have a General Electric 21" (or 23"...can't remember) colour remote control television. It's about two and a half years old.

The problem we're having is that the picture is 'dropping' off the bottom of the screen. This sometimes happens shortly after turning the TV on, or sometimes not for some time after turning the TV on. What happens is that the whole picture seems to move down a bit on the screen, then it moves a little further, then before you know it, there's about a couple of inches of black at the top of the screen, above the picture. You can't see the bottom of the picture because it is now below the bottom of the screen (i.e. the picture doesn't just shrink). Sometimes a bright white line will appear at the very bottom of the screen, and after a snapping sound the picture will jump back up (sometimes back to the top, sometimes just part of the way up). Then it happens all over again, kind of random. If you turn the TV off, wait a few seconds, then turn it back on, most of the time (not always) the picture will start out back at the top of the screen as it should."

"2 year old GE has tuner problem. Some channels part snowy others very snowy. Sometimes don't work at all. But, only on some channels.(Vertical is not shrinking). Any case histories?"

"I have a CTC177 that instead of the two relay clicks of the degaussing circuit will click 6-8 times when it is first turned on. Signal was coming from U3101 - changed IC, no change in problem. Works fine once it's warmed up, anyone else have this problem?"

"I have a weird problem, or at least I have never seen it before. I have a GE colour television that when it is initially turned on the lower channels are not existent (snowy) and the upper channels are crystal clear. When the TV has been on for about half an hour, all the channels are crystal clear."

"I had/have the same problem w/ an RCA CTC175. Picture shrunk down to letterbox size. When i was going to check the joints, I turned it on (hasn't been used in a couple weeks), to see if the picture came in full size, but to my surprise i had no picture. When i say no picture i> mean it's like my cable has been disconnected. After a little fiddling here and there i came up with the following:

- Cable box hooked - no picture on any channel.
- Straight cable to TV - only cable channels 54, 55, 64, & 76 (nice and clear).

Should i go ahead and resolder the tuner connections and see what happens or does it sound like the microprocessor may be out?"

"I have a GE TV 25GT543, CTC187AA chassis with a vertical intermittent where a whack on the side fixes it. Is this 'the resolder under and around the tuner' fix? Is there anyway to tell exactly which connection is really the bad one rather than randomly resoldering everything within sight? I like the feeling I get when I know that I have really found the source of the problem rather hope I got it....."

"Volume and channel OSD shifted off to the right so that channels are not visible. Closed captioning and customer menus shifted to the left. Tuner shield was done about a year ago and is ok. Problem occurred after a power surge that caused C7 the main filter capacitor to fail. Otherwise the set seems to work fine. Horizontal and vertical sync pulses are present on pins 26 and 27 of the micro."

General Repair Considerations

Caution: See the document: Troubleshooting and Repair of Consumer Electronic Equipment before attempting to repair or replace the tuner module. You *must* have proper soldering equipment and desoldering tools. Attempting to remove, solder, or replace the modules(s) without these *will* result in a mess and a very expensive bill when you finally take your TV to a professional.

Someone brought me a TV to look at. After a little prodding, it was learned that he had lent it to a friend and it died after six months or so. The 'friend' then attempted to replace the tuner module based on the description on a refused estimate from a TV service shop. He did not have proper soldering equipment - perhaps only a Weller 100 W soldering gun. Needless to say, the TV did not work - nearly every pad on the PC board under the tuner had been destroyed. I had to run wires from the pins on the tuner to the their destinations on the mainboard. It was not fun. Luckly, no permanent damage was done but it could have easily been a lot worse.

I've also heard of at least one case where rather than resolding all the ground connections as described below, a much simpler repair was made by just adding a thick short jumper wire from the metal shield to a ground on the PCB or existing ground wire soldered to the PCB. This probably isn't quite as effective as the proper repair may be a reasonable alternative to try if your soldering skills aren't very well polished. However, I don't know whether this will work on all chassis versions. The specific example was for a CTC187.

About that Special RCA Solder and Soldering of the Tuner in General

Also see the section: That Special RCA Solder - Various Opinions There seems to be some disagreement on whether to use the 'special RCA soler' or not:

(From: Charles Godard (cgodard@iamerica.net).)

The solder RCA recommends doesn't flow properly. The only returns I've had after doing this repair have been because of using their solder. The best way to do the job is to use regular 60-40 lead tin and apply the right amount of heat with a controlled heat solder gun. Too much heat and you peal the board, not enough and it won't stick or will crack again.

I first flux the joint's with rosin solder paste. I clean my tip before starting, and a couple of times during the job. Again, I use a controlled heat solder gun.

This seems like a simple job because it is 'simply' soldering. Don't be fooled. I've been at this business for twenty years and am an expert at soldering. Of the first dozen or so of these sets that I worked on, I had a couple of solder spills that cost me a couple of extra hours to locate because I didn't realize I had made a spill and assumed another problem. Another hazard is that if you are not skilled and attentive, you may loose one of the small resistors or capacitors from the board. If you find it, then you've got to figure out where to put it back. :> If you flex this board you may cause a crack on a resistor or capacitor lead that could be very difficult to find.

In addition to all that, there are some hidden joint's that won't be apparent to even a skilled technician the first time he does the job. (The stuff in the middle :)

If you are a trained technician and do soldering regularly and have a controlled heat gun, and are used to working with these flimsy consumer type circuit boards, then you can probably do it with no problem. There are some jobs that are suited for do-it-yourselfers and I don't hesitate to tell a guy if I think he can do it and save a few bucks. This is not a job I would recommend for the average guy to tackle. I can think of very few solder job's I've ever done that require more skill and attention than this one.

Sorry, I'm sure that's not what you wanted to hear. However, next time you have a problem, just ask. I may have an easy fix for you, and will be glad to give it if I do.

Descriptions of the Solutions

Here are some of the responses - many from experienced techs who fix (too) many of these sets:

(From: J. Caldwell).

Following the instructions packed with the service bulletin will allow a proper job to be performed. Overheating the board substrate and surrounding components will cause future and horrible failures.

The connection will NOT look shiny but shouldn't look bubbly or crinked, the solder will only flow if you use the special solder paste, rosin core solder will cause it to corrode oddly so clean all rosin core off the board.

A standard Weller station does the job quite well and experience has shown me that the full repair with jumpers and the special solder (as the bulletin states) is the best thing to do for reliability and customer satisfaction. I was mistaken in earlier ramblings.

(From: (JohnSon) johntrum@netonecom.net).)

This sounds like the typical shield/pcb solder joint problems that RCA has had made famous with their CTC175/177 chassis. It's a common problem. We have fixed literally "tons" of them. I'm guessing it would be this series of chassis because you also mentioned the EEPROM.

The symptoms you mentioned are all associated with these bad solder connections and there are even more symptoms that can appear from this same problem. No video, color drop, etc. are other common symptoms. Just get your solder iron hot and do a good job soldering ALL bad connections related to the shield areas and you'll be in business again. You'll still just have a "new model" RCA, but, the symptoms you describe should go away. If you catch it while it is in the "smack" condition, you shouldn't need any parts. If you wait until it dies completely, you could be looking at an IC or EEPROM replacement. You DON'T want to replace the EEPROM, trust me!

(From: Jaclyn (lambert@sos.net).)

Possibly.. :) Once you think you've got all the solder connections done - you've only just begun. Also check for cracks on the pads surrounding the tuner grounds. Oh, you might want to order an extra pound of solder before you begin....

(From: Louis A. Iannotta (bouncer@nauticom.net))

The problem is bad solder connections under the tuner shield. The bad connections cause false signals to the EEPROM which cause the reduced vertical height. RCA just recently has issued a bulletin and a kit to repair the connections with a special "elastic" solder which isn't supposed to crack under temperature fluctuations.

(From: Chuck (Nordic@osuunx.ucc.okstate.edu).)

I would open the tuner control module and solder all the posts that are around the periphery of the board. Also on rare occasions, the solder connections break on the main board jack that the plug from the tuner control module attaches to. Resolder them also. Good luck.

(From: JohnSon (johntrum@netonecom.net).)

I am sure you are probably talking about the "infamous" Thomson (the RCA/GE owners) bad solder joint chassis'. They started with the CTC175/176/177 and from what I see they have continued on up through the CTC187 at least and maybe further. You can confirm your chassis number by checking inside the back of the set or on the back of the set sometimes. These sets have a variety of symptoms accompanying the bad solder joints. The two you listed are only a couple. When repairing these sets, all of the trouble areas should be repaired at that time. You will be just asking for more problems if you don't. If you are very technically minded, you may be able to repair this yourself. If not, you could try a local repair shop. I have heard repair prices for this range from $50.00 to $140.00. I don't have any idea what the shops are doing to repair them for $50.00, but, I suspect they may be just going in and soldering the obvious bad joint, at the time. As I mentioned, this would only be a temporary repair at best. The majority of the problems are under the shield of the "built into the board tuner", but, there are others also. I know our charge to repair them, complete, runs about $100.00. (lots of soldering to do the job right.) If you decide you need further info, post what model and chassis number you are working on. If it is the problem that I think it is, I can tell you, from our complete repairs, we have never had a recall on these chassis for this same trouble and we have literally repaired tons of these things.

(From: Kevin (giddy@ac.dal.ca).)

In RCA/GE chassis CTC-175,176,177, There is a common problem with bad solder on the tuner shields and around the microprocessor shield.

The symptom is usually intermittant snowy picture and reduced vertical height. Please do not be misled into trying to troubleshoot the vertical section as you may be wasting your time. Often you can confirm if this is your problem by grabbing the RF input connector firmly and wiggling it while observing the picture.

Thomson seemed to have solved the problem around the end of 1993.

I have done lots of these.

(From: BELJAN E (lvpy67c@ix.netcom.com).)

It is the CTC series chassis and the tuner solder joints break. You should take the set in as soon as the problem develops to avoid permanantly damaging the set. The S-kit is most likely the repair kit for the GE series (S stands for solder) it has special flexible solder that will keep the tuner from going again.

(From: Marlin (mister-m@ix.netcom.com).)

Yea! These RCA/GE all are having the problem of loose grounds. They are mostly around the Micro and Tuner grounds. If your having problems with the picture becoming snowy you may have to remove the tuner shield and do those also.

The intermitten power on and off may also be around T4401 Flyback Transformer. Check or resolder this area also.

(From: Mark Paladino (paladino@frontiernet.net).)

I'm not familiar with this model in particular but the symptoms you describe my be similar to another well documented RCA tuner problem. That problem involves tv's of about the same vintage and after a year or so develop symptoms similar to what you describe. The solution to those maladies is resoldering all of the tuner shield connections where the shield connects to the pc board. I have accomplished the "fix" on several RCA TVs of that vintage with similar tuner symptoms and in each instance was able to completely correct the problems and restore the tv to workable condition.

(From: Mr. Caldwell (jcaldwel@iquest.net).)

It is not a picture tube. Why is it that some people think that the picture tube is bad when the set has a snowy picture?

It's solder connection in the tuner, the tuner is not replaceable it is part of the mother board. Call RCA and ask them if they will foot the bill. If not call an authorized repair center and get an estimate.

(From: Lawrence E. Manion (MANION.L.E@worldnet.att.net).)

Get the problem fixed now or the connections will cause enough noise on the microprocessor that it will eventually 'deprogram' the EEPROM and you'll need that replaced and it's quite expensive as this part holds *all* adjustments.

There are only 2 or 3 controls that are manually aligned.

I have fixed many, many TV's with this problem. It is common to all RCA, GE, LXI model. The problem is easy to fix, but its hard to get the area ready for repair. To those that are brave remove the back, pull out the chassis, (some plugs must be removed so mark as needed) turn the mother board over. Now find the metal can near the cable connection. Their will be 4 solder connections, remove (its harder than it look) then remove shield to expose inner tuner area. You will need to solder all ground inside and around the shield mound you removed, and the connection that was unsoldered from the shield. Now solder any connections that looks bad including surface mounded components i.e.: transistors, IC, and the cable input connections. reassemble in reverse order then your problem will be gone. Be careful not to bridge any connections that is NOT connected a good mag light is a must! I normally charge $70 labor for this job takes about an hour of work and 8 hours of playing time to confirm the problem is fixed. Only one out of 20-30 TV's required parts.

(From: John F. Reeves (jreeves@uwf.edu).)

On the CTC175 family of chassis, the tuner shield soldering job must be performed before any other troubleshooting can be done as this procedure will correct many such symptoms. the tuner shield on the bottom of the board must be removed and resoldering around the shield structure should be done. There are four posts that need to be resoldered, and check for any other suspicious looking connections. There are other circuits to check also. Give the entire board a good look. When that is done, see if there is any change in your symptom. These chassis also have a service menu that can accessed by pressing and holding the menu button then momentarily pressing the power and volume up buttons. CAUTION!!! If you are not familiar with these procedure DO NOT MESS WITH IT!!! You can really foul up your set. This procedure is included in the service manual.

(From: Paul White (pwhite4@aol.com).)

I advise resoldering the chassis, all ground and shield lugs that feed through the board, especially around and under the tuner shield. If you can't do this take it to a shop and tell them the symptom and that it needs resoldering, if they don't know what you are talking about take it somewhere else. If you wait to long the problem will get worse and will damage IC U3201, the EEPROM IC, which means a complete alignment of this IC. Most techs will fudge these settings and may be ok but don't wait till that occurs for your own benefit.

(From: Bill A. (Lucy27@ix.netcom.com).)

Yup!! Actually, the whole tuner shield/microprocessor shield grounds all are poorly soldered. You can sometimes with the naked eye or magnifier see some of the loose connections, but if you solder just a few now you will be back in there in a month or less guaranteed. So just do the whole solder job. It is actually a much better repair and you can rest easier at night knowing that you resolved the problem rather than patching it.

The 'classic' problem is prone to the CTC175 through CTC187 chassis. I'm also seeing the same problem on the newer generation CTC178 through CTC189 chassis. Instead of RCA redesigning their 'On-Board' tuners, they would rather re-design the solder thats been around for hundred years give or take. Good Luck!!!

(From: Edwin Calmes (uscalmes@yahoo.com).)

After thousands of on-board tuner repairs. I have started to get recalls (couple of years old) and finding that sets suffered from grounding problems around the tuner, Again!! After re-doing the grounds once more, recalls within weeks, sometimes DAYS. Apparently, the foil is breaking loose from the board around the tuner. Solution: Scrape all the points mentioned in the RCA tuner modification (except the goofy solder), and then re-solder once more. But do not overladen the the joint with too much solder. Then it lasts a couple years at least.

Detailed Solder/Shield Repair Procedure

(From: Gilbert (osmyn@together.net).)

RCA CTC175A Tuner Solder Locations shows the problem areas for this chassis. I have highlighted in red the ground points that were actually broken on that set, and in yellow the ones that were either suspicious or appeared OK. The section of the panel which is connected to the power supply's ground, (labeled "main ground") seems to be the most likely to break of them all, and wreaks the greatest havoc. I keep a print of this on my bench (stapled to a few pages from the Sci.Electronics.Repair FAQ Web site!) and refer to it whenever I do a complete resolder of one of these shields.

Photos of another CTC175 showing parts location can be seen at CTC175 Mainboard - Top View and CTC175 Mainboard - Bottom View.

(From: Sam.)

I don't know how similar other chassis are but the photos may be helpful in any case. I have oriented RCA CTC175A Tuner Solder Locations photo to be the same as the diagram below. I assume the inconsistency in aspect ratio is just due to the ASCII art!

(From: Mr. Paul (jcaldwel@iquest.net).)

RCA now offers a 'kit' to repair these, the only thing in the kit that is of any use is the paper template that shows exactly where to solder. But I'll give it a shot:

First under a bright light, after removing the bottom shield look for solder splashes or components that may have been desoldered by heat.

Kind of short....view from bottom with RF connector toward top:

```

```

Two X's will cause a snowy pix, they are posts from the shield that are supposed to poke through the bottom but don't quite make it. A small round pad that may look like a test pad or that has a component lead poking through the board are good points to solder.

Also when you remove the board in some sets the leads on a filter to the left of the deflection/color/etc. IC can be bent and short, usually resulting in a snowy pix or just snow. (View from bottom, IC is below tuner, filter is to left, has three in-line pins.

(From: Glen Sapilewski (glen@step.Stanford.edu).)

I made up this CTC175 Tuner Solder Locations diagram to help understand what was under the tuner cover and where to solder.

(From: Ken Bouchard (bouchard@ime.net).)

On all of these RCA chassis, with the 'sandwich' type tuners, the shield must be removed, and then carefully solder everything you can see on the top and bottom of the tuner. Then re-install shields and solder them in as many places as you can as well.

A special solder (very very expensive) is sold to the repair centers, that has an elasticity to it to allow a correct fix for this problem. However, you can get away with just normal soldering in most cases, to cure the problems.

I cured our set of all of this, by soldering and soldering.... Most of it has to do with grounds that pass through the tuner, as well as 0 ohm jumpers and such that have bad soldering....

The connections that are bad, are feed-through holes as well as all connections around the perimeter of the tuner can. Each feed-through can be spotted and rca supplies you with a mask. There are about 15-20 connections in all. RCA has a fix for this, which uses a very special ($700 a pound) solder which has elasticity to it. That and the solder mask helps to make a fast repair. Also look about for ends of any chip components that were poorly soldered. Got to have a fine point tip, or your likely to short something out in your effort to repair.

Be advised that there are many surface mount transistors, chip caps, and resistors that are in the tuner, so you will need a fine point low wattage or temperature controlled soldering iron for these.

(From: Tech 7 (gscivi@aol.com).)

You don't really need a template! Just solder the shield all the way around, and at each point where it comes through the chassis. (this is easily observed by removing the top shield cover as well). and instead of adding jumpers, I simply solder each corner of the bottom shield to the pc board. Jumpers work just as well, so if you want to follow the instructions of the people who didn't make it right in the first place, be my guest. A close inspection will also reveal the locations to solder. And resolder the upc shield too!

Tuner Repair Instructions for Typical 3 Year Old CTC Chassis

(From: Henry Poland (hep@gte.net).)

Disconnect the power, remove the back of the set. You'll see the circuit board in held in a smaller plastic sub chassis/tray. flip the set so that the picture tube is face down on the table. Remove the 2 screws that hold the tray. You can now flip it back up but be careful after removing the tray that the set doesn't fall backwards and break the picture tube neck. the circuit board slid into the tray from the front. Take off the hex nut on the antenna input, look at the video and audio input RCA connectors next to the antenna you'll see a bracket held in place with a removed plastic rivet. push it out from the rear and remove it. Look at the power cord where it connects to the tray, you'll see a plastic tie strap cut that. There may or may not be one screw towards the front of the tray that holds the circuit board in the tray, if so remove it also. The circuit board should now be free to slide out of the tray.

Now that the board is free turn it over and you'll see the bottom of the tuner. It's a metal cover about 2.5" by 3" You'll have to unsolder 4 solder points on the tunner cover. Do this with care, you may need an 80Watt or better iron to do this. Once done you can Very, Very Carefully pry the tunner cover off. Take Care not to damage any Components/ Circuit Traces on the board. Now you can solder all the grounds to the tuner shield and the four pin that the cover is soldered to. Use care, don't overheat the small SMT capacitor, resistor and diodes.

It's not a hard repair if your careful.

Still Doesn't Help?

> "I need some help with this GE tv. Its a 1993 vintage model 27GT613 with a chassis number of CTC177BH."
>
> I resoldered the tuner shield and connections. However, when I powered it to check to see if I had resolved the intermittent tuner situation I found that I receive stations 2-13 with much snow in the picture."

(From: Nice address (jbc@blkbox.com).)

If you are sure that you did not make a mistake in soldering, check the RF coils. The coils are small wires through the PC board in the tuner section. I have seen a few cases where the wire was probably not clean when soldered. You may have to scrape each wire and solder it again. A bad MIXER coil may cause snow on some channels and be ok on others. EEPROM alignment will not solve the problem.

- Back to RCA Solder FAQ Table of Contents.

EEPROM Information, Problems, and Solutions

Bad EEPROM

Almost any problem can be due to a bad EEPROM since it contains the 'boot' information needed to set up all the TV's subsystems. These include reception, raster, picture, menu, closed captioning, color, sound, and other symptoms The most common cause are the bad tuner solder connections discussed elsewhere in this document. However, EEPROMs can and do fail on their own.

Where the TV has died totally - particularly after having had prior problems caused by bad solder connections - the EEPROM may be corrupted so totally that the set cannot even 'boot':

I, however, the TV comes on well enough to access the user adjustments:

(From: John Del (ohger1@aol.com).)

> "Try running the color adjustment *down* all the way and keep holding the button down until pointer stops moving. If the EEPROM has damaged data, running ALL the adjustments up and down at their extremes may restore them. If this solves it, have the tuner serviced by a Thomson service center to keep the data from being scrambled again (or perform the soldering as described elsewhere in this document --- Sam). A carry in job for just the tuner service w\update kit should be approx $100 depending on

market."

If you have an oscilloscope, monitor the DATA line from the EEPROM when you turn the set on. Normally data should appear for a short time and then disappear. If there is a continuous stream of data on the DATA line, the EEPROM is probably corrupted. (For the CTC177, it is U3201, pin 6 if you don't have a schematic.)

> "I have a GE model 25GT505 that suddenly developed a problem. Here's what happened:
>
> For 2 years the set has worked fine. Went on vacation for two weeks - house at 63 degrees. Used TV for 3 hours one night with no problems. Next morning, picture is bad as follows:
>
> Picture is as wide as the screen but the vertical height is compressed. Picture starts about 1/3 of the way down the tube and extends to about 1/3 of the way up from the bottom. Furthermore, the bottom traces seem to be overlayed resulting in brighter than normal lines."

(From: DCAVS (dcavs@aol.com).)

This is a common problem for all GE, RCA, ProScan televisions of a variety of chassis. It is due to a design and manufacturing flaw. You should call RCA Customer Relations at 317-587-4151 and take it to a Thomson Authorized Service Center. (Thomson Electronics of France owns the names, RCA, GE, and ProScan for Televisions.) Thomson has been sending their customers $75.00 for carry in service and $95.00 for in-home service. This amount should cover the bill as any technician who knows what they are doing should be able to complete the repairs quickly. There is a small chance that the data in the EEPROM IC that stores all the setup data has become corrupted. In this case the set needs to be reprogrammed to operate correctly. This is a time consuming process and can have a great affect on the quality of reception.

Verifying that the EEPROM is Bad

> "I have a dead RCA CTC175 chassis in my shop that I have traced down to a bad EEPROM. The tuner shield solder connections were repaired, but how do I read the EEPROM contents when the set can't be fired up? We have done a number of these EEPROM change outs, but never with a dead set."

The following applies specifically to the GE model 31GT657 but the general approach (with appropriate changes in chip IDs and pins) applies to many other models:

(From: seabulls@unlimited.net).

If you do have troubleshooting experience, scope pins 5 and 6 of U3201 when the set is first plugged in to see if data is being exchanged momentarily. if the data continues on and on, then the eeprom is bad. If data occurs for just a moment then settles into a steady 4.8V, then troubleshoot the horizontal drive circuitry, and if there is no data and no 5V on pin 8, then troubleshoot U4101 and the 1.5meg resistor off pin 4 (I think) for open. As Hank pointed out, you could have a blown fuse and shorted flyback although they are unlikely on this chassis. If you do have a blown fuse, U4101 is most likely shorted and the 140V rectifier is probably shorted too (CR4106 I think is the location). The flyback, while possible, is the last thing I would try.

(From: Videotek (dmcdonal@Direct.CA).)

You are right, it is probably the EEPROM. When you install the new one, the set should fire up, but the horizontal sync will likely be out. Just enter the service menu, and reprogram the eeprom. There are about 80 parameters that need to be set. To verify that it IS the EEPROM, scope the data line on the EEPROM, and plug the set in. If you see a burst of data, and then nothing then the EEPROM is OK. If you see continual data, then the EEPROM is bad, as the CPU is trying to find it, and the eeprom is not responding. If no burst of data, then check your power supply.

Everything from soup to nuts can be blamed on that blasted EEPROM. No audio, no vertical, no color. All bad eeprom. I have changed hundreds, and have 3 sets in my shop now waiting for their turn to my bench.

(From: Charles Godard (cgodard@iamerica.net).)

I keep one known good EEPROM to use as a test. It just takes a few minutes to sub it. It doesn't matter what chassis the EEPROM is from when you are using it for test purposes. You can remove it and order the correct one if the set starts with the sub or if your symptom disappears with the sub.

About the only thing you might have to do with it is to set the horizontal frequency for various models but you can get a pretty good idea whether or not the original is the problem.

More on Diagnosing EEPROM Problems

(From: Darren (fatal@net.bluemoon.net).)

For the RCA series CTC chassis that have been produced in say the past 6 or 7 years, there is a 4 pin IC near the front of the chassis..... that is the EEPROM. Every chassis has letters such as CTC175 A or K or E2 etc. When you call for this part you need to know the exact letters of the chassis, because the programming in the eeprom differs for every chassis. I have a complete list ng of all eeproms to chassis part numbers. The info on the ic is useless. The majority of the EEPROMs run about $4 to 6 which is not all that much. We stock all RCA EEPROMs.

How do you know when your RCA needs a new EEPROM? The two most common reasons are: no power (TV will not turn on) or no audio.

Yes, sometimes the TA audio chip goes bad, or the fat flameproof resistor that feeds the main voltage to that IC burns up, or solder loosens from the board.

When you determine you need a new EEPROM, and you put it in, audio should come back. But if it does not and you know the audio IC is good, chances are you may have zapped the IC or the new one is defective. These EEPROMs are extremely sensitive. To determine if it is the EEPROM, you need to desolder a pin on the main IC and apply a 4.6 volt source to it to see if it will bring audio back. I don't have the schematic handy so I cannot tell you which pin that it is but that is a definite way to determine a bad ic due to an EEPROM.

Once you replace the EEPROM, you need to reprogram the set. off of the main menu you have to put the TV into service mode. If you were smart (and the TV was not in shutdown) you copied all the codes from the old EEPROM, so you know the settings for the new one. Knowing these codes is extremely important! There are something like 50 main options 100 more just for the tuner set-up. Get the service manual!

Replacement EEPROMS

Replacement EEPROMs are now available from:

- Dalbani (1-800-325-2264) for over 150 different RCA/GE chassis between CTC175 and CTC187. About $3 in singles.

- MAT Electronics. Go to "Catalog", then "EEPROMs". Listed by chassis number.

- TV Man has all Thomson, RCA, and GE EEPROMs in stock.

EEPROM Organization

The Technician's Desk provides a listing of RCA CTC175-177 family EPROM Reference Data. This tech-tips site is currently free but I don't know how long that will last!

(From: Mr. Caldwell (jcaldwel@iquest.net).)

There are three sections to the EEPROM:

- The factory identification section is where the generic microprocessor gets the data on what chassis it is in. If this get's scrambled the set might think it's a PTV or other size set or has a different type of audio system, etc. This is only alterable by a device that can directly write to the EEPROM and cannot be modified by the TV (except when something goes wrong) or the technician without knowing the data and having and I2C EEPROM programmer.

- The factory adjustment section is that part that stores technician alterable settings such as horizontal hold, stereo alignments, etc. and can be adjusted by entering a code and then using the remote or chipper checker from Thomson.

- The Customer adjustment section holds all customer controls and is adjustable in normal use of the set.

Since this chip is an I2C bus memory chip it should be quit easy to buy one of each chip from RCA and pull out the chassis coding for each chip then buy the IC in bulk at 1.00 a pop. It's an interesting chip anyway and worth experimenting on.

I think Phillips has such a programmer available since I2C is there baby.

BTW, you should get the FULL 'service' model number and FULL chassis number when ordering parts. Having the service model number makes it easy to look up the full chassis number, you only need the full chassis number to actually get the EEPROM but some parts require the 'service' model number.

The service model number is the model number in smaller print on the back that has 3 or more extra digits on the end.

CTC175 CTC176 CTC177 EEPROM Addresses and Comments

(From: J. Dow).

The contents of address 0x00 of a CTC175/176/177 chassis V-line EEPROM is:

```
bit 0: 1=speakers enabled 0=disabled
bit 1: 1=tone high 0=normal
bit 2: 1=air 0=cable
bit 3: 1=autocolor enabled 0=disabled
bit 4: 1=closed captioning enabled 0=disabled
bit 5: unused
```

```
bit 6: unused
bit 7: unused
```

The contents of address 0x00 of a CTC175/176/177 chassis W-line (with ST-9 micro) EEPROM is:

```
bit 0: 1=speakers enabled 0=disabled
bit 1: 1=tone high 0=normal
bit 2: 1=air 0=cable
bit 3: 1=autocolor enabled 0=disabled
bit 4: 1=closed captioning enabled 0=disabled
bit 5: 1=alarm enabled (4K EEPROM only)
bit 6: unused
bit 7: 1=adjust/setup menus disabled (commercial sets only)
```

Now it's pretty clear, if the very first bit of your EEPROM gets cleared, the sound is gone. So, before you touch anything else, try writing 0x0F to address 0x00.

If you're familiar with I2C, you know, address zero (and subsequent addresses if you're really unlucky) can be cleared easily by accident if one keeps the data (SDA) low and bangs the clock (SCL) long enough.

On early sets, crazy things like that happen when the micro loses ground due to an intermittent tuner shield contact. Newer sets have the micro grounded thru other paths; nevertheless, EEPROM corruption is not completely eliminated.

The EEPROM has a bunch of chassis dependent setup as well. Losing the channel list and labels is only an inconvenience, but losing the tuner setup can make the TV worthless if you can't realign the tuner. Losing some other values, such as hor. freq., B+ voltage, etc. can make the set blow the fuse....

The EEPROM map varies, even for the same chassis due to revisions. EEPROMs are *not* interchangeable! A factory new EEPROM does *not* have any correct alignment values: it's only good enough to start up!

No TV made by Thomson(GE/RCA/ProScan) has ever had a non-volatile memory built into the microcontroller. Some sets have more than one EEPROM. Some ancient AccuScan boat anchors have the channel list in the *remote* and not the *TV* set.

Once I had the pleasure of aligning a couple of hundred chassis in a couple of days; The defaults were grossly incorrect for tuner settings; failing minimum gain, tilt and out-of-band rejection specs. Some channels wouldn't come in at all, and a few sets wouldn't sync up.

If you don't understand how the micro works and what's in the EEPROM, it's all black magic and you'll be cussing and replacing chips at random. If you know the game, you can fix a number of things without ever having to solder or buy a component!

Difference in EEPROM Contents Depending on Model

Videotech has settings for several sets with the CTC175 and CTC177 chassis. However, these at best get you started.

(From: Matthew L. Kruckeberg (MKRUCKEBERG@pol.org).)

Various configurations require various EEPROMs. Stereo/Mono, AV jacks/no AV jacks, PIP/no PIP, linear power supply/switch mode power supply, pincushion circuitry/no pincushion circuitry, hotel set/consumer set, and the screen size are all variables stored in the section of the EEPROM not accessible from the on screen menu. There also at least 2 different microprocessors. The early sets were produced without closed captioning and require a different micro. I agree that there is a lot of confusion caused by the variety of EEPROMS and the lack of properly trained techs to service these sets. I have seen quite a few butcher jobs to the tuner shields, wrong EEPROMs installed, and incorrect or no realignment of the EEPROM values. Unfortunately there are many people who think they are qualified to service these units just because they claim to know how to solder. When in doubt about the correct EEPROM check with the local RCA parts distributor with a chassis number or better yet buy a manual.

Comments on EEPROMs

(From: Raymond Carlsen (rrcc@u.washington.edu).)

There are dozens of different models, each with different functions supported by "instructions" in that EEPROM. You could buy one of each (chip) and clone them with a burner, but unless you have hundreds of sets to repair, it wouldn't make sense to go to all that trouble. There are now quite a few after-market sources for those EEPROMS. The specific one for the chassis you're working on must be installed or the set will not work properly.

Some of the 'programming' of the chip must done *after* it is installed, by the tech, such as the tuner setup adjustments. Each tuner is of course different and so requires tuning. Other factory-programmed EEPROM data cannot be changed by the tech during setup... that's the basic reason the EEPROM must be replaced when the tuner grounds corrupt the data.

Rather than start from scratch each time the chip must be changed, the tuner settings can be 'copied' from the old chip (Note: not always possible), i.e. readings written down on paper and then entered into the new chip during the setup adjustments. After you've done the tuner resoldering, install a socket for the EEPROM. Unplug the TV, install the replacement chip and power up the set. With the set still plugged in (but turned off, of course), remove the chip and install the "bad" one and copy the "parameters". Put the replacement back in and enter the values you copied down. The set should now work properly. I've been able to do that on all but one set I've worked on. You will not find that information in the RCA service literature. It's essentially a workaround, dreamed up by a tech to save time. Bless that one!

Lastly, don't get me started on why Thomson treats it's servicers like [censored]. Chipper Check... Nipper Net... all paid for by techs who can barely afford the coffee they're drinking. Who needs it? You *must* buy RCA's test fixtures and software to service and do even simple adjustments on the new sets! I pass. If that's leading edge.....

EEPROM Part Numbers

> "I have a GE 27 inch stereo TV (model 27GT613, chassis CTC177BH) on which I just repaired the tuner shield cracked solder connections."

(From: Michael D. Long (longm@tusmp004.allied.com).)

A friend of mine who repairs machines said it was the EEPROM before he even scrolled done to see that you had had a repair tech look at it. He also has told me that to replace the eeprom you need to get the correct eeprom from RCA and prior to removal all of the factory settings need to be recorded from service menu(he doesn't remember exactly how to get to it without a tv in front of him--check a sam's photofact for details--you can also get the correct part number from that too.

(From: "Nice address" (jbc@blkbox.com).)

Do not trust Sam's photofact for the correct part number. There are about 14 different part numbers for CTC177. They may all use the 24C02 but the default values are different.

Hey, NAP uses a 24C01 and they charge about $25 for it. Has anyone built the I2C programmer yet?

(From: YonyMar (yonymar@aol.com).)

Your problem could be caused by a bad EEPROM. First you need to get the correct replacement EEPROM. The letters at the chassis will get you the correct part number, i.e. CTC177XX. Before you remove the old EEPROM enter the software service mode and copy down all the settings so you can write them into the new EEPROM. I would suggest using a socket also.

Article on EEPROM Problems and Servicing

The July 1997 issue of "Electronic Servicing & Technology" magazine has an article "Servicing EEPROM problems in RCA televisions", by Bob Rose. (Editor: Nils Conrad Persson (CPersedit@aol.com), Sales: Electronic Servicing & Technology, 76 N. Broadway, Hicksville, NY 11801, 1-516-681-2922. Editorial office: PO BOX 12487, Overland Park, KS 66212 1-913-492-4857.

ES&T has also had articles on CTC17x servicing and of course all sorts of other repair of consumer electronics in general. While not something you will find on the newsstand, you might be able to get a peak at one if you snuggle up to your local electronics repair shop :-).

(From: Ted Gondert (vcrepair@bbs.industrynet.net).)

The article is good with some useful information. There is a chart with average values to use for setup/alignment of the new EEPROM. Compared the printed numbers to what I wrote down from RCA CTC175A that was repaired by replacing the EEPROM using a socket and switching the old for new EEPROM after turning on the set to read the old parameters. Then setting the new ic to match. His numbers are close, so maybe TV would work about the same, just set new EEPROM to the average values in the chart.

The article also explained cure for the no sound problem caused by the speakers being muted by pin 29 on microprocessor high. That can be fixed by removing resistor R1915 in the muting transistor circuit, etc., as mentioned on the sci.electronics.repair newsgroup many times. But, he said RCA doesn't approve of it and recommends this technique:

1. Disconnect AC from chassis by unplugging the set.
2. Unsolder pin 8 of EEPROM (and isolate from pad).
3. Use a pick to short pin 8 to the pad, temporarily restoring B+.
4. Plug in set and turn it on.
5. Remove the pick and therefore the short circuit (to the pad).
6. Use the menu function to select speaker on-off.
7. Reinsert pick to restore B+.
8. Turn speaker back on.
9. Unplug set and resolder pin 8.

I haven't tried it but sounds interesting. Wonder if some other EEPROM problems can be cured that way? ;-).

Restoring EEPROM Defaults on CTC177

Restore defaults I assume.

From: jcaldwel@iquest.net (Mr. Caldwell)

Trick # 722

1. Press and hold menu then press power and then press volume +
2. Release menu
3. Press menu (vertical will collapse don't panic)
4. Press menu
5. Press power

You may have restored the EEPROM, it's worked for me with some very weird problems with the eeprom where I'd normally have replaced the eeprom.

Note: You need the FULL chassis number and failing that the FULL model number to get the correct eeprom.

The full chassis number may be on the back if the set but it is always inside and, it begins with CTC get all the digits after it. I.e CTC177AE CTC177BA CTC177BA2 etc etc

The generic number on the eeprom will only get you an un-factory programmed eeprom that will not work or work *very* strange.

The full model is the 'Service Model' in small print near the large print model number. There are several digits after it that point to the correct chassis number and thus the correct eeprom number.

In-Circuit EEPROM Reprogramming

In many cases, while the contents of the EEPROM have been corrupted by write errors caused by bad solder connections, the actual chip is undamaged and really does not need to be replaced.

The following isn't something you could likely justify for one repair but if you have a motel full of RCAs, it could easily pay for itself and then some in saved time and money! Note: I have not tested this software/device so I do not have any first hand knowledge of its performance.

The hardware interface schematic is free from the Web site or you can buy it preassembled.

(From: Jim Lawnichak (tvdr@mail.emeraldnet.net).)

If you get the chance, stop by http://www.emeraldnet.net/~tvdr and take a look at Quick Clip. The program eliminates most tuner alignments and repairs the EEPROM while its still in the set.

(From: David (dakuhajda@aol.com).)

Thomson's proper repair per their tech-tips is to reinitialize the EEPROM using the chipper check interface and software via computer.

It only takes 5 minutes to reinitialize the EEPROM. It also gives the option of storing both the main EEPROM and the pip tuner EEPROM data values to disk for future writing to a new eeprom on the set being worked on.

EEPROM and Audio Problems

First, make sure the audio hasn't been shut off in the menu (either due to EEPROM corruption or by a human). (From: Paul R Gendreau Jr. (tvman@biddeford.com).)

The 175/6/7 (and more) chassis has a SPEAKER MUTE feature for those chassis that sport speaker output jacks, and the speaker mute is also used during the POWER ON or POWER OFF functions. Even if your model doesn't have the jacks - the software and hardware to mute the speakers exists! When the EEPROM data is being corrupted by the poor solder connections - one piece of data that can become corrupted is the bit that is set to turn the SPEAKER MUTE circuit on. Since the on screen display for that model has no menu feature to allow the customer (or technician) to turn the speakers back on - you cannot correct the data in the EEPROM without an EEPROM programmer. There are some servicers that are using EEPROM programmers to access the data.

A easy and cost effective work around is to disable the speaker mute circuit in hardware. This involves the removal of a diode or a surface mounted device (SMD) transistor - what part to remove depends of the chassis involved. If Q903 is present on the foil side of the board - remove it. If Q903 is not there, then CR1953, a diode, will be present on the component side of the board and it should be removed. Only one component, not both, will be in a given TV. Removal of whichever of these 2 is present will disable the speaker mute circuit. If the rest of the EEPROM data is OK or can be corrected by the on screen menu then this procedure will save the replacement cost of the EEPROM (less than $5.00 wholesale) and the tedious job of performing about 100 alignments to the tuning system which is *REQUIRED* after EEPROM replacement.

On the negative side: The customer will find a difference in the way the TV operates! The software in the TV mutes the speakers during POWER ON or POWER OFF functions. This make both of those functions very quite. With the speaker mute circuit disabled there will be a small burst of noise during both of those functions. The level of the noise is not objectionable - but it will be a cause of concern for customers that are not forwarned. I would guess that over 80% of our customers choose the modification and subsequent cost savings rather than have the EEPROM replaced.

(From: Woodie Morris (bwmorris@bellatlantic.net).)

Here's what I do:

- If it's a stereo model, short Q903 emitter to base. (surface mounted)

- If mono, cut or remove CR1953. (From: Sam). However, see below. There could be potential problems down the road with these half baked solutions: (From: David (dakuhajda@aol.com).) We have replaced many blown speakers in these sets that someone else had removed or shorted that same transistor. The mute at turn on and turn off is critical to the long life of the speaker.

EEPROM Replacement Tricks

(From: Raymond Carlsen (rrcc@u.washington.edu).)

Hopefully you saved the old chip. If so, you can use it to put the original values back for the tuner (assuming a snowy picture was not one of the original problems). There are no "ball park" values. Install a socket for the EEPROM. Fire up the set with the new chip, then power it down. Without unplugging it from the AC outlet, remove the new chip and put the old one back in. Turn on the set and run the menu and copy down *all* the parameters for the tuner. Turn the set off again and install the new chip. Put in the values you copied down and exit. Power down and unplug the set for a few minutes. Now, fire it up again and see if it works. You may have to reset some of the operational parameters like height and RGB values, but the tuner should be OK. I've used this technique several times with very good results. It saves having to start from scratch. The trick is that some of the values in the EEPROM are sent to the micro when the set is plugged in, and others when the set is turned on. That's the reason you don't unplug it to swap chips. It's a bit of a gamble with the new chip, but worth it for the time it saves. Good luck.

(From: n3evg@aol.com)

Next time you're faced with a RCA/GE dead set due to shot EEPROM from bad tuner grounds and connections...and worried that you can't dump the contents of the bad EEPROM to reset the tuning alignment and other parameters, do this:

Remove the "bad" chip and solder an 8 pin dip socket in its place. Now take the new chip, plug it in the socket, plug in the set and turn it on. If all goes well and the set comes on (make sure you have already had all the solder connections repaired in the tuner before this of course) turn the set off and Without unplugging the set! Remove the new EEPROM and replace the original in its place. Turn the set on and enter the programming menu and proceed to copy down the contents of each of the memory registers. Do all of the tuning channels regardless of how many stations you are receiving. After you have completed, you can now replace the bad eeprom with the new one and program each of the registers. When finished, I then turn the TV off, unplug it wait a few seconds, plug it back in and make sure everything held. Sometimes I have to redo the horizontal hold and RGB registers.

(From: jcaldwel@iquest.net (Mr. Caldwell).)

- Pull plug!
- Get an 8 pin socket and remove the new IC and reinstall the old IC in the socket (I'm hoping it's not zapped).
- Plug set in and turn on.
- Enter the access code to get the numbers out of the old EEPROM and copy them down (all entries - even channels you aren't using --- sam).
- Pull Plug.
- Put new IC in socket and copy in the numbers you wrote down.

Now enter all the numbers from the old IC into the new IC and see if problem is solved. If not, I've forgotten which numbers are for the sound but since you copied the new IC's numbers you should have no problem when you read the service literature or someone here tells you what they are .

Also pull the shield from the bottom of the tuner and resolder the grounds or expect to keep doing this.

If you zapped the old IC then use the TV for target practice with a high powered rifle, I suggest .308 with a soft-point :-). Just kidding, you should probably get it professionally aligned.

Unless you are willing to purchase the equipment needed to perform the tuner alignment and preserve your sanity or some kind repair shop owner who lurks here will accept the chassis you send them for repair.

Steps to Troubleshoot Dead Set on CTC177

This may also apply with minor changes (e.g., part numbers) to other CTC chassis.

(From: David Kuhajda (dkuhajda@locl.net).)

1. With the back off, plug the TV in. Do you hear a chirp as the power supply comes up?

   - If yes, check for +5 V at pin 8 of EEPROM U3201, if it is there, the power supply is working at least in standby.

   - If not, remove the small 1.5 Mohm 1/4 watt resistor (I think it is R4104) and measure it. It is very common to be open, and you won't hear the power supply chirp.

2. If power supply passes #1, remove the top shield off the tuner and run a jumper clip from the tuner ground shield and the vertical output heatsink, at the front of the circuit board. Plug the TV in and press power button. If the TV turns on, you will have to rebuild all the ground connections inside the tuner and run a couple of extra jumpers. Be very careful when removing the bottom tuner shield as there are many small surface mount components that are easily damaged. DO NOT place a screwdriver under the shield and pry up on it. Use a good soldering iron with a small high temp tip and resolder the inner ground posts preferably with the solder Thomson supplies, or use a good quality Silver Solder. Resolder all the outside grounds and add an extra jumper from the top tuner ground to E116 jumper at the bottom tuner ground.

3. TV fails #2 test. Place a scope on pin 5 or pin 6 of the EEPROM U3201 and plug the TV in. You should see data for an instant then it will go away. If data is there all the time, the EEPROM is corrupted and the TV will need to go in for service as you will need several signal generators to realign the TV's chassis values and a calibrated cable signal generator to realign the tuner stored values. Should be around $90 for the repair.

   (However, see the section: Getting into Programming Mode on dead set and others dealing with tuner alignment. --- sam).

4. Where the TV seems to turn on, you hear the degauss relay click when you push power and you feel the high voltage come up on the face of the picture tube but no picture appears, the possibilities are:

   - TV is going into shutdown due to corrupted EEPROM data. See above.

   - HV stays up but no video. Turn the screen drive on the back of the flyback up (bottom control). What do you see?

     - Retrace lines and a blank raster? Bad eeprom from #1 cause, above. - White line across the screen? Shorted CR4704 and 2 open resistors.

   Proper resetting of screen control on flyback Once the TV is fixed: Turn TV on to a video input with no signal. Turn the control up until you see the retrace lines, turn it back until the lines go away and you just see the raster scan lines.

   ## Getting Into Programming Mode on Dead Set

   Where the set does not come on at all or shuts down immediately, the following MAY get you going.

WARNING: If the shutdown is actually being caused by excessive HV, this could result in a dangerous and/or destructive situation!

(From: Wes Black (wesmike@aol.com).)

On the "T" Chip solder a temporary jumper from terminal 26 to ground this will bypass the HV shutdown circuitry. You should be able to fire the set up and enter into the program mode. When finished be sure to remove the jumper. This procedure has worked many times for me. Oh Ya!! don't forget to resolder the tuner section first.

(From: J. Caldwell (jcaldwel@iquest.net).)

Setting the horizontal frequency to low (by accident or from corrupted EEPROM) may cause the TV to shutdown or give the with the appearance of being dead.

To fix this is you need to check the value of the main 'critical safety capacitor' a.k.a 'redundant capacitor' a.k.a 'tuning capacitor' This is a larger blue capacitor that is connected from the collector of the horizontal output, it can be connected to ground in smaller sets or is run through the pincushion circuit to ground.

Once you have the RCA part number order one, solder this in parallel to the existing capacitor and the set will fire up and not activate the high voltage shutdown circuit. You can enter the factory setup, reset the horizontal frequency for a stable picture, turn the set off and remove this added capacitor.

I've used this sporadically only to be able to copy down all the other values in an EEPROM since if this happens on it's own it's a good idea to replace the EEPROM. This is not needed if you have the RCA signal generator for these newer chassis.

(From: Tech 7 (gscivi@aol.com).)

Don't let the set run too long with the shunt capacitor either! This does work however, and is even the suggested method by RCA itself! After a number of these badly machined chassis, I have learned to count the service menu items in the event this very symptom crosses my bench. (once the resoldering has been accomplished, there is no need to replace the eeprom!) ; Clip shunt cap to horizontal output, turn set on (full AC), enter service mode, press Volume Up 76 times, Channel Up once, you are now in the horiz oscillator adjustment parameter. Volume up/down will adjust the oscillator to near sync. As soon as you see two or three slanted sync bars shut the set down, remove the shunt capacitor and try the set again. Isn't this fun?!

(From: Vern (vgdeuel@ticnet.com).)

Before you change the EEPROM, try using a Variac starting at about 40V AC. You may be able to get the set to come on enough to reset the register. If you change the EEPROM, your tuner setup may not be right anymore.

---

Tuner Alignment and Related Problems

Tuner Alignment Problems

> "This RCA CTC175 came in with dead set diagnosis, as usual the problems was the EEPROM. I installed a new one and the set came on, but the new EEPROM came with the parameters set at default, and in some channels I had poor reception. When I get into the service mode I can adjust this parameters (100 and further) of the electronic tuner and I achieved a good reception changing this parameters. The problem is that, as far as I know, the way to save these parameters is pressing power, but when I restarted the set, got poor reception again. When I checked the parameters, the new data was there, at least in the display, but it has no effect in the reception. I think the procedure to save this parameters is not the correct."

(From: Dogcatcher (Dogcatch@ix.netcom.com).)

The correct procedure for aligning the tuner parameters is with a special piece of gear that you can purchase from RCA called a 'TAG001' generator. According to the manual once you adjust any of the tuning parameters you must align all. It is true, I've tried to "tweak" them in myself and you think it looks clear but when you turn the unit off or change the channel it is snowy again. I really suggest you check with RCA or a distributor and do it right.

(From: PWhite4 (pwhite4@aol.com).)

Pressing the power button is how you write your settings to memory. You are saving the parameters correctly. I have noticed on the CTC175 chassis that the settings for several of the parameters above 100 can affect the reception of the different bands in the tuner. 2 through 6 or 7 through 13 etc. can become snowy and clear as you adjust. If you don't have the RCA Tuner Alignment Generator (TAG) you just have to fudge until you get all the tuning bands acceptable. This is very time consuming and frustrating.

GE/RCA CTC177AF Tuner Alignment

(From: J. Dow).

Tuning voltages for channels: 2,6,14,17,18,13,34,37,48,50,51,57,63,76,83,93, 110,117, and 125 are stored in the EEPROM. Primary, secondary and single tuned. Three values per channel. Every chassis is different because of individual variations in manufacture, coil knifing, etc. So the factory default middle values are no good for any particular set.

You may try to copy the data from the old EEPROM from 0x54 through 0x8C into the new one. If that doesn't help, you really have to realign the set.

If you have the factory ATE rig it's less than 4 minutes.

If you have the service rig (TAG001 or similar), it can be half an hour or more.

The procedure is described in the service manual.

You need a VHF/UHF signal generator at least; a spectrum analyzer is also very handy but not essential. You also need a lot of patience if you're doing it by hand and not software.

Comments on Alignment after EEPROM Replacement

(From: Author Unknown) The EEPROM data is different for the CTC175, CTC176, CTC177 and up chassis. For correct EEPROM alignments, access to the service data is required! You can install an EEPROM IC and only adjust the fist dozen settings, which deal with picture color and size, and this might result in a pretty good picture. But the TV will be far from correct in operation! Keep in mind that the tuner alignments are all set to mid-range when you install the new EEPROM. The tuner is therefore far out of alignment and requires full alignment! Proper alignment requires 3 things:

1. The correct service information for the chassis involved.

2. A signal generator capable of generating a signal on all cable channels.

3. A digital volt meter.

While items 1 and 3 are either inexpensive or common, the signal generator is neither!

For any problems you might have, I recommend that you find a factory authorized service center for the brand you want repaired. There are several reasons for this suggestion. The primary reason is that only a factory authorized service center has the service manual, technical support and access to original specification parts that should make the service of your product effective. In addition, only a factory authorized service center will have knowledge of common problems which may occur in your model and may have suggestions from the manufacturer as to the best solution for those problems.

Call the manufacturer to locate your nearest FACTORY AUTHORIZED SERVICE CENTER, or check your local Yellow Pages. Then call ahead to confirm that the service center is authorized not only for the brand of product you need serviced but for the specific type of product (for example, a Sharp FACTORY AUTHORIZED SERVICE CENTER may not repair Sharp CD players).

If your product is less than 2 years old and you have concerns regarding early product failure, product quality, or repair problems, then you should direct those concerns to the manufacturer. Many manufacturers are eager to assist you if you take the time to call or write. If you do contact the manufacturer, it is important to have ready the model number, serial number and purchase date of your product. Many times they cannot assist you without that information.

If you need to have a product repaired within the terms of the manufacturers warranty and you do not have your bill of sale (proof of purchase) then all is not lost! Most companies are prepared to send you a PROOF OF PURCHASE DOCUMENT if you call them with the model number, serial number and what you feel is the purchase date. This can take some time to obtain. If the FACTORY AUTHORIZED SERVICE CENTER you'll use has a fax number - ask the manufacturer to fax the letter to the service center. This will speed the repair along.

(From: Matthew L. Kruckeberg(MKRUCKEBERG@pol.org).)

Alignment is a must for proper operation. You will need a service manual for the instructions which should be available from your RCA distributor. You will also need a RF signal generator capable of generating the entire tuning range on the set (up through cable channels 120+). RCA sells one under the part number TAG-001 for about $200. There are about 150 parameter that will need to be aligned. With a lot of practice I have gotten the time down to about 45 minutes but the first ones became afternoon projects. Unless you plan on doing a lot of them you may be better off cutting your losses and referring the job to a shop with the needed equipment and experience.

The problem with just copying data from the old EEPROM is that you run the risk of copying corrupted data. By the time a set fails to turn on due to EEPROM corruption the problem has existed for quite some time and corruption is usually widespread and a complete realignment should be done for peak performance.

(From: David Kuhajda (dkuhajda@locl.net).)

You are definitely not completing the repair properly unless you perform the eeprom chassis alignment per Thomson's specifications. Thomson sells a relatively inexpensive TAG generator that can generate all cable channels up to 125 and IF output. They calibrate it before they send them out. It also is crystal controlled, so it does not drift much over time, at least ours hasn't in five years of use. You cannot use cable as : 1. most cable systems don't send out 125 channels and 2. Cable systems are never 100% on correct frequency. Since we do over 2000 Thomson sets a year, it takes generally less than 45 minutes to troubleshoot, repair, and realign the CTC177 series of sets, all done to Thomson's specifications. It is extremely important to use the special solder and add the jumpers where appropriate per Thomson's solder kit.

Back in 1995 a local hotel was having continual failures of the CTC176 chassis sets in over 200 rooms. Thomson paid us to go in and resolder all of the tuner grounds, spring of 1995, the sets were approximately 1.5 years old. We are now in 1998 and these same sets are starting to fail again. Thomson says it is due to the difference in expansion and contraction due to temperature of the metal shield and the solder. The special solder takes quite a high level of good soldering technique and a precisely controlled soldering iron. Once it sets up it stays slightly flexible, and the jumpers bypass the external grounds that cause the most problems should they fail again.

One special note: the short internal jumper changes the tuners parameters and causes the set to need an eeprom tuner alignment for proper operation.

Except for the fact the we only have UHF over the air broadcasts here, we would have not had anyone complain but channel 15 looks really bad unless the tuner is properly aligned.

The newest Thomson sets do require the use of a computer interface to perform many adjustment operations. As well as turning the speakers back on after the set detects mare than 3 dc shorts at the rear speaker terminals.

Some Channels Still Fuzzy After Soldering Tuner

(From: Steve Helling).

I don't suppose you have a Thomson manual for the set, but they have a tuner troubleshooting flowchart and voltage chart in the manual. If the tuner checks out OK, it may simply need a tuner alignment. That requires a Tuner Alignment Generator (TAG) and DMM. It's done through the service menu. Don't move the coils or anything like that.

If the EEPROM was corrupted due to the tuner ground problem, it could have messed up the parameter 100-156 tuner alignments. More likely you have a component failure or solder bridge in the tuner section.

If you're serious about fixing the set or expect to see more Thomson sets, you'd be smart to buy their service manual, as well as the CTC175/176/177 Training Manual and CTC177/187 troubleshooting Guide.

Setup Information

Setup Menus for the Uninitiated

> "There are some secret codes on this GE TV. I had a Circuit City guy here before, and he held down the power-key or something & fiddled with the other keys during startup. Its almost like a computer's BIOS... Wild! Is this list available to mere mortals?"

Setup for CTC175/176/177

(From: yonymar@aol.com).

The following is the setup procedure for the Thomson CTC 175/176/177 chassis.

Software setup procedure:

1. Press and hold Menu button, press Power, then Vol+.
2. Two displays appear at the right and left of center. Use the Vol+ button to step the right display to # V76 (Group 1 setup V76).
3. Press Ch+ or CH- button to access parameter.
4. Press Vol+ or Vol- buttons to change software value.

Group 1: V76 Service Adjustment Parameters

```
Parameter   Parameter Value          Range
(Ch+/-)     (Vol+/- to change)

00         Security pass # for Service Adjustment.  Must set to 76.  May not
           advance until value set.

01         Horz freerun freq          00-31
02         Horz phase                 00-15
03         Width (27/31 )             00-15
04         Pin amp (27/31 )           00-07
05         Vert center                00-15
06         Vert height                00-31
07         Red bias                   00-127
08         Green bias                 00-127
09         Blue bias                  00-127
10         Red drive                  00-63
11         Green drive                00-63
12         Blue drive                 00-63

13         Security pass # for Chassis Adjustment.  Must set to 77.  May not
           advance to higher param. until value set
```

Group 2: V77 Chassis Alignment Parameters

```
Parameter (Ch+/-), Value (Vol+/-).

  14 to 24.
  25        Security pass # for Tuner Adjustment (Must set to 78)
```

Group 3, V78 Electronic Tuner Alignment Parameters

```
Parameter (Ch+/-), Value (Vol+/-)

100 to 156.
```

Or more specifically:

(From: Glenn Watkins (blueribb@comcat.com).)

To access the second level of the service menu, first press and hold MENU. Then tap the POWER and then the VOLUME UP buttons. You should see 4 zeros. Press VOLUME UP until the right zeros read '76'. You are now in the first level. Now press CHANNEL UP until you get to 13. Now press VOLUME UP again to '77' on the right zeros.

You are now in the second level.

Thomson has a CTC 175/176/177 Technical Training Manual which has all this information. Get a copy!

(From: P. White4 (pwhite4@aol.com).)

If this set has the RCA CTC195/197 chassis you will need a lap top computer and the RCA chipper check software to adjust the digital convergence beyond the 25 steps in the set up menu. RCA is forcing the software on us in this chassis and any beyond it.

---

7. Back to RCA Solder FAQ Table of Contents.

Miscellaneous Problems

Bad Buttons?

(From: Zapper (zap@mhv.net).)

I have run into at least 6 sets of the CTC177 family with bad channel up/down switches. One switch would get 'leaky'...stick on I guess. Everybody that I talk to has not seen this except fer me.

Lost Sound After Repairs?

(From: mandacat@ix.netcom.com).

I've had two RCA (Thomson) Chassis with intermittent vertical problems. The fix was to install jumpers to carry the ground through all points on the PCB.

The interesting thing in troubleshooting this intermittent (prior to learning the cause) was that you would typically resolder what you thought was suspicious solder connections (grounds and components to the PCB). Now to the point. One of the sets I worked on lost sound AFTER the repair. I found out that if the set didn't have an 'Internal speaker off' option, one connection on the sound module was not soldered at the factory. I soldered it when I was re-soldering connections and I lost sound! If you have the schematic, I think its Pin 3 on the TDA7263 Sound Module which is not connected at the factory on sets that do not have the internal speaker off feature. Very Interesting! Another way to re-enable the sound would be to lift R1915 (you can cut it on the top of the chassis) from the collector of Q1903 (Transistor is always turned on for the case mentioned above).

The Ultimate in Trapezoid Distortion on CTC177?

> "The raster is full height and is centered, but narrow at the top (less than half the width of the screen) and nearly full width at the bottom. The image is extremely distorted with gross convergence error at the sides.
>
> With the vertical drive connector removed from the yoke, the display consists of the red line sloped down from left to right, the green line roughly horizontal and the blue line sloped upward from left to right. The three lines cross approximately in the middle of the screen. The ends of the lines fit the shape that the raster has when the vertical yoke connector is in place. That is, the upper ends of the lines are closer together than the bottom ends. A rough diagram of this display may be viewed at
>
> All waveforms associated with the horizontal output, vertical output and high voltage transformer (T4401) appear as depicted on the service notes."

My first thought was mechanical - the yoke is grossly tilted on the neck of the tube - the TV was dropped or something. This would result in both trapezoidal distortion and convergence problems (probably purity as well).

Another possibility is that a portion of the horizontal yoke windings (the upper half, in this case) have opened due to bad connections or a break in the wire. This would mean that the R, G, B electron beams would see less deflection at the top than the bottom and could conceivably result in the severe convergence problems as well.

A short between H and V windings of the yoke is not a likely cause as this would result in much more severe (if that is possible) problems (including much smoke).

I do not know whether EEPROM problems could result in this but considering that so much is controlled digitally these days, I would not discount it as a possibility. Width and Height are digitally controlled so that some peculiar failure in an LSI chip or the EEPROM might be possible.

First, eliminate the more likely possibilities unless you have an EEPROM to swap and quickly confirm.

The November issue of Electronic Servicing reviews the 175 and the 177. It appears that the EEPROM in these sets can cause a great deal of weird problems. It goes into great detail and gives some circuit diagrams of these sets.

Service Information, Costs, Reliability, Reimbursement

Source for Thomson (RCA/GE/Proscan) TV Service Manuals

(From: Michael Caplan (cy173@freenet.carleton.ca).)

The following has always worked for me:

> TCE Publications
> 10003 Bunsen Way
> Louisville, KY 40299
> Phone: 502-491-8110

Solder and EEPROM Repair Costs

> "I live in New Haven, CT and my local RCA/GE repair center tells me that a repair for this problem will cost about 145$??? Everyone who has responded to this post says under $100. Am I being taken to the cleaners?????????? That would really piss me off."

(From: Paul R Gendreau Jr. (tvman@biddeford.com).)

We are an RCA/GE factory authorized service center. (You should have this work done by an authorized service center because we are the ONLY people who understand where all the problems are with this TV!) Our rate for this job is $77.00. Furthermore, if the TV is less than 2 years old it would be a good idea for you to call RCA/GE (same company). Call consumer affairs at 1-317-587-4151. Explain how you feel about the cost of repair and the set not being very old. The numbers of posts in this group referring to this problem confirms that there is a PROBLEM. Ask them to reimburse you for part of the cost.

RCA/GE/Thomson is a good company and has always been willing to address complaints from consumers.

That Special RCA Solder - Various Opinions

(From: Raymond Carlsen (rrcc@u.washington.edu).)

I understand it is a different Tin/Lead formulation with Gallium added to both lower the melting point and make it more flexible after it hardens. With regards the melting point, as people have pointed out here, you have to get it up to at least 800 degrees to make it flow properly. Well, yes and no. I get the best results With a Weller PTC station and a PTE8 (800 degree screwdriver tip), which I think is the biggest physical size tip made for that iron. That's the clue... use a big tip and solder quickly. Use the edge of the tip for the areas close to SMDs. The large mass heats the metal quickly so you don't have to cook the board.

(From: Charles Godard (cgodard@iamerica.net).)

I've done hundreds of these sets and since the first few when we didn't know about all the 43-46 (depending on how you count) joints, have NEVER had one come back and NEVER expect to see one back. If one ever does come back, I'll fix it for free! Guaranteed!

I've had a few from other shops and from refurbish shops that were not properly soldered. But, if done right with 60-40, they will not come back!

We have been soldering grounds containing various mixes of metals ever since the PC boards first came out. Soldering grounds is nothing new. The same requirements hold now as always did. Flux + Clean joint + proper heat will make a good joint! Every time!

Of the ones that I've seen lately that have come from the refurb shops, the same problem exist. They didn't heat the NEW solder to the flow temp and it still didn't make a good joint. Even with the NEW solder, they still can't get it right.

Is there anything wrong with using the new solder? NO

Is it a waste of resources? YES!

Why would it work? It is a gimmick to make the tech heat the ground connection to the proper temp to make the solder bond to the ground. It requires a higher temp to flow the NEW solder. In the process, the temp of the ground metal is heated enough to accept the bond.

Why would TCE recommend the new solder? It's called CYA (Cover Your A**). There's got to be an excuse for their continuing to sell so many of the units with a manufacturing defect. This is an excuse because they can't figure out how to fix the problem on the assembly line without spending mega bucks.

Do I care? No it makes me mega bucks.

What causes the problem in the manufacturing plant? The solder bath does not heat the grounds to the proper temp.

If the manufacturing process heated the grounds to the proper temp, would there be any problem with the finished product? NO

Is the original solder in the solder bath sufficient to make a good ground if proper heat is applied? YES

Then why would there be any need to change the specifications for the solder applied to the board on a refurb job instead of instructing the tech to heat the joint to the proper temp to flow the solder? CYA

If the original solder in the solder bath is not sufficiently flexible to make a good ground, then is there a defect in engineering or the manufacturing process? YES

Why don't they just put the new solder in the solder bath? Because the temp required to flow the new solder would peal the board.

Why don't they just heat the solder bath hot enough to make the grounds bond with the solder? Because a temp that high would peal the board.

Why do they do it this way? Because it is a cheap process.

Is there any need to use the new solder? NO, just heat the grounds until the solder flows.

Will the joint hold if 60-40 is used? YES, just as they have always held ever since we first started working with PC boards if solder is properly flowed, various metals notwithstanding.

(From: Brian Broderick (beab951@yahoo.com).)

You are incorrect about the lack of heating of the tuner caused the poor solder to the tuner grounds. The problem was that the board and tuner had a different expansion rate, this caused the solder to tear apart over time. Since TCE used wave flow and pre-heated the entire unit before the solder was applied, the stress started as soon as it cooled down. If you re-solder, it will last longer but the same problem will come back in time. TCE changed the tuner shield material several time before finding the right match. The solder was a by-product of the tuner shield material, the new shield had a melting point that was close to the solder melting point.

TCE was sued over this and is very tight lipped about this information. I was there, as a EE and a QA person. I watched the hole bloody mess develop.

(From: Dave Moore (penguin@datastar.net).)

Call TCE at: 1-317-415-4370 and request that they fax you an order form for S-kits.

The kits are free and if you do the rework the way that it is described, your customers will have a permanent fix.

The advice being given to you by those who would just use regular solder is a temporary fix that will probably last about 5 years if your customers are lucky. Of course some tech's will delight in this thinking of repeat business... Others may have actually convinced themselves of this to justify the "easy money". Some will pretend that they know better because they are old timers. I've been working in the electronics industry for over 25 years. I consider this long enough to know whereof I speak.

In any event I'm sure that if you use regular solder you won't have any comebacks for probably about three to five years. And if you do it the way TCE says you might have problems there too because they have not covered all the grounds that should be jumpered with their rework instructions.

Here are links to my computer enhanced rework instructions:

- Rework Diagram Using Normal Solder
- Rework Diagram Using TCE Special Solder
- Soldering Template
- Detailed Soldering Instructions - Page 1
- Detailed Soldering Instructions - Page 2

I have used the computer to show only the the ground traces so that it is easy to see the ground scheme around the tuner. I have a modified jumper scheme that grounds a couple of points that aren't covered in the TCE instructions.

I have not had any comebacks using my improved rework instructions, and have the satisfaction of knowing that my customers are getting the best service possible.

I'm tired of watching the mindless babblings of debate concerning this subject.

(From: Steve Helling).

Right On, Dave. Regular solder doesn't get it. I've been doing warranty work for Thomson since before the CTC17x & CTC18x chassis with the tuner problems came out. Have done several hundred tuner repairs on these sets.

The original technical bulletin issued by Thomson for this problem, TV 94-006 (5 August 94), instructed the tech to inspect and resolder tuner ground connections as necessary. Nothing more. Less than a month later, they issued an enhanced procedure for doing the same old resolder job. The resoldering wasn't holding up, so in February 96, they issued TV 96-005, giving the current procedure with special solder and jumpers.

I have seen about a dozen sets come in that had obviously been resoldered somewhere else, and the connections had cracked again. I had one of my own customer's sets come back in less than two years after I had resoldered the tuner grounds with plain solder per the first bulletins.

I know all of you who have been slapping tin/lead on the tuners don't want to hear that it doesn't hold up, but that's the facts, jack! If you haven't seen any of those sets you've soldered come back, it's probably because those particular customers don't trust you anymore and took their sets somewhere else. Maybe out to the dumpster.

(From: David (dakuhajda@aol.com).)

Use the special solder PERIOD.

We have properly resoldered thousands of these ground connections, over one thousand before Thomson came out with the solder kit. Many of those are now coming back with cracked solder connections 3 years later. Actually, looking at only the 3 motels that were resoldered in early 1995, approximately 15% of them have failed since the start of this year. Once we got use to having the soldering iron at the exact proper temperature, the repairs only take a few extra minutes.

The engineers when they first designed the sets overlooked the fact that they were working with 3 different kinds of metals with different heat-cold expansion rates, this is why even when soldered properly they can and do break again. The "special" solder is of a material that stays somewhat pliable after it sets up, allowing for sufficient expansion so the solder connections will then outlast the expected 5 years of the picture tube.

The new sets do not have nearly the failure of the old ones in the tuner grounds. Why? they have changed the solder formulation, the metals used in the shield and added traces to bypass the failure of the connections. They also greatly reduced the size of the holes the can gets inserted into.

Prior to Thomson bringing out the s-kit, we were adding 3 extra jumpers in the most critical failure points and using a silver based solder. This was our best attempt to provide the customer with the best possible repair.

Terry's Comments on Why Factory Solder Fails

Factories try to minimize:

1. Power consumed per manufactured item,
2. Fabrication time per manufactured item,
3. Materials used per manufactured item.

Frosting a beer mug and vapor soldering a circuit board are similar. Higher temperatures (more power consumed), longer deposition times (more time to fabricate) and more solder (more materials) produce solder more like hard ice on a mug rather than frost. "Frosty" solder is softer and will fail from thermal cycling or mechanical stress much more easily.

Factory quality control departments try to minimize in-warranty failures (mean time between failure) just to the point where it balances the (1), (2), and (3), minimums, above.

Thomson Consumer Electronics Saga

(From: Gregg Lansley (gregglns@ix.netcom.com).)

The good news is that Thomson Consumer Electronics has recently released a repair kit for the 175/177 chassis. The bad news is, as far as I've been able to determine, that this kit appears to be limited, as yet, to Thomson authorized service dealers, which I ain't. My supplier, Andrews Electronics in California, doesn't stock it and doesn't know when/if they will. The stock number is S-Kit-1. I've only seen a copy of the instruction sheet that comes with it, but it consists of solder and paste flux (enough for 10 repairs) and a template. The key seems to be the solder. To quote from the instruction sheet:

The special solder supplied in the kit is *not* a rosin-core solder. Paste flux must be used to get the solder to flow. The solder included in the kit remains elastic when cool to prevent joints from breaking due to thermal expansion.

There. Now, you know everything I know!

> "I guess that's good news for the RCA/GE group (Thomson), but, unfortunately it took them over 2 years to correct the problem. They should have had a factory recall on these tv's and made their customers happy or at least "happier" than they are now! Instead, I have found, they won't even honor their extended warranty in several cases. I just fixed one of these tvs for a lady that had exactly that problem. Her extended warranty is good to January 1988. She called Thomson when she started having problems with the tv. They gave her a list of about 3 or 4 "authorized service centers" for the RCA/GE tvs. She spent the better part of 2 hours on long distance calls and to her surprise, they would not honor the warranty as stated. The warranty states that they will provide IN HOME service for any tv that is 19" or larger. She has a 20" tv and when she called the closest warranty center, they told her they did not travel that far for repairs. The distance was approximately 75 miles for the closest "service center" that they referred her to. She got the same answer from the other places they offered . They said they would fix it if she brought it in, but, this lady is elderly and obviously her mother is older. She got this tv for her mother, with the extended warranty, so she could eliminate the problem of having to haul it somewhere if she had a problem."

Typically, these days, the customer is expected to bring in sets of that size. However, if in home service was a condition of the warranty, then it seems to me a service call should have been made. Look closely at the warranty, however, and see if there's some fine print that allowed them to get out of making such a distant service call. Remember, these documents are written by lawyers!

> "Her reasoning was that it was a GE and they are a "GOOD TV""

> "We bring good things to life"!

Fooled *her*! In my opinion, those sets are crap. For that matter, what about "RCA"? For years, they were a better color TV than GE. How many consumers really know that today, RCA = GE? Don't own one, don't want one. But how does the average would-be purchaser know this?

I noticed these things beginning to come in, with the same type of problems, about a year ago. Not till I began reading this group did I realize how common the RCA/GE failure is. I don't think a week goes by without somebody posting about the CTC175/177. In fact, I've saved several of the posts on the subject. Now, if a customer stops by with one, and expresses disgust at the set's needing repair at such an early date, I just bring them over to the computer and let them read a few of these posts. The one that sticks in my mind was made last spring. Somebody posted of an odd problem they'd been having with a late model RCA or GE, and whoever replied said something like, "Oh, you must have a CTC 175/177. Hehehehehe!"

> "And the company would back up any claim they gave in writing! Right?? WRONG!! She was so disgusted after she attempted to get them to repair it that she called me back and said to come and pick it up, fix it, and she would just pay for it. She was not messing around any more with them. So, on top of buying the tv and paying for the extended warranty, she now has an additional charge for my repair bill. I'm sure she won't be purchasing another Thomson product.. ever!! This tv was purchased brand new in January 1995."

Barely more than a year old. Unfortunately, that's fairly typical for the RCA/GE with that problem. In fact, I have to go look at one today, same problem description, about the same age; a 27" floor model.

> "I'm also sure she is not the only customer who has experienced these similar problems. Don't get me wrong, I don't think this mishap will put a company the size of Thomson out of business or anything close to that, but, I'm sure it hasn't helped their public image at all."

Oh, I don't think it's even registered with the public. You'd think that you'd read of this dismal repair record in a publication like Consumer Reports, but they are silent on the matter. Makes you wonder how much the magazine is worth....

> "I know they sold a ton of these sets that will still need repairs in the future too!"

Yeah, we'll have work for some time to come.

> "I just think their announcement is just too little, too late. I'm sorry for rambling on, but, some of these companies and their greed just get me a little pissed off."

Don't blame you. I think you're absolutely right. Although maybe there is just a bit of corporate honesty showing here; the RCA symbol is, after all, a *dog*! ;-)

In Defense of Thomson Consumer Electronics

At least here are a couple of people's experiences:

(From: Daryl Smith (darsmith@spk.hp.com).)

Thomson Consumer Electronics has been good about taking care of this problem, despite the TV's being out of the warranty period, in my case, anyway.

There is a 1-800 number to call Thomson Consumer Electronics about this problem. My 2 year old 31" GE TV had the same problem. I called, they sent an acknowledgement letter, I had the set repaired (~$90), I sent a copy of the repair bill along with the letter back to Thomson, and they reimbursed me the full cost of the repair. I don't have the number with me right now, but if you can't locate it elsewhere, I will dig it up at home. I had it repaired in late May and the reimbursement check came last week. You will also need to send them a copy of the original sales receipt for the TV. Good luck.

(BTW, they originally said they would pay up to $75 toward the repair labor + the full cost of any required parts, but the check came back for the full $90 it cost to have the set fixed, so I'm not complaining. Maybe it was for the extra effort to get a 31" set hauled down to and back from the shop [it must be a factory authorized shop].)

(From smaher@freyja.solano.cc.ca.us).

I like many others have faced the solder problem. I bought my 27" RCA, Model F273S1WN, television on January 9, 1995, and paid for a two year extended warranty. With the extended warranty, my labor was covered until April 9, 1997.

I first experienced video and sound problems in August 1996 while the television was still on warranty. I had almost the identical symptoms as stated in section 1.2 of you article.

I brought the set in for repair and was immediately informed that I needed a part to repair the problem. After three weeks, I got my television back, and it worked fine until April 17, 1997 (eight days after the warranty expired).

I again brought the set to the same repair company. This time I was told that all the solder connections had to be resoldered at a cost of $115.00. Since my television had the same symptoms as it had the first time it went bad, I asked if they just fixed the same problem again.

The repair company could not find any paperwork of the previous repair so I called the warranty company and they stated to me the the repair done in August 1996, and the problem was soldering not a part replacement.

I called RCA at (317) 415-4151 and stated that I felt I should not have to pay for repairs even though my warranty had expired. They agreed to reimburse me for $85.00 of the cost of the repair.

(From: Dave Fredricks (fred@rea-alp.com).)

If you have to, there is a 900 number supplied by Thomson. Yes it is $2.50 a minute, but if you can clear customer for the bill at least the set is fixed and you get the money. They have been pretty helpful when I have had to use them on a dog unit.

Reliability of Repaired Sets and New Models

Since these are manufacturing problems and not electronic design faults, the long term reliability of these RCA/GE chassis with properly repaired solder connections should be excellent.

However, not everyone shares this opinion:

> "How far to the landfill? I expect these TVs to be problems for years to come. Cut your losses now!"

(From: Bert Christensen (bert.christensen@rose.com).)

My experience with these sets has been that once the grounds are repaired they are quite trouble free. I would much rather have a set with one or two easily repaired faults than one with different faults everywhere like the Zenith System series.

(From: Mick DeMaria (bmvid@snet.net).)

For what its worth. We are an authorized TCE service center in the central CT area. TCE has been giving customers special authorization. Letters for tuner-skit repairs in the amount of $75.00 for carry in, and an extra $20 for in-home on 31" and larger sets. The customer is expected to pay the difference. So far if the s-kit instructions are followed, we have only had one or two repeat failures out of at least 500 repairs done to specs. in the TCE bulletin. Many authorized servicers in this area seem to think the jumpers and special are just BS. I can't say for sure but TCE's procedure seems to work.

(From: John Del (ohger1s@aol.com).)

If you scrap it, donate it to a repair shop. Despite this chassis' notoriety, once PROPERLY repaired and updated, it will outlast pretty much any other TV under $400. We sell these reconditioned with a two year parts and labor carry in warranty, and see less of these come back percent-wise than the new TVs we sell, regardless of brand. Tossing useful products in the landfill doesn't make a lot of sense.

Would You Buy One of These Sets?

(From: Mr. Caldwell (jcaldwel@iquest.net).)

I would buy an RCA/GE TV. The problems with the solder connections have been solved on the newer chassis. Once the connections have been fixed on the problem sets there is no other common problem. If you yell at RCA they have have been paying for the repair.

(From: Mr. Caldwell (jcaldwel@iquest.net).)

I would, the problem with the solder connections has been fixed in the newer chassis. Once the connections have been fixed on the problem sets there is no other common problem. If you yell at RCA they've have been paying for the repair.

(From: Bert Shristensen (bert.christensen@rose.com).)

My experience with these sets is that once the grounds are repaired they are quite trouble free. I would much rather have a set with one or two easily repaired faults than one with different faults everywhere like the Zenith System series.

(From: Leon Thomas (lthomas@bcn.net).)

I live in Mass. and have sold and repaired hundreds of the ctc175/6/7 chassis. If a technician is called when these problems are first noticed I would call it a minor repair. If the repair is done properly, it WON'T happen again. The most you should be charged for this repair (no parts changed) is around $70.00. I have never had to do a second repair on the same set. I do not recommend anyone without experience touch these chassis. You can mess up the tuner very badly if you touch the soldering iron to one of the many surface mounted components. Pay the $70 and have it done right. I even let people watch me fix this problem to show them what it was. What you have to realize is RCA has made a terrific set with a minor bug. These chassis, in my mind, are the best on the market once they have been repaired. The new chassis they produce now ctc189 is a great improvement. Basically the same design with no bugs. I have sold many of these sets and have had not one return!

Discontinuation of Out-of-Warranty Reimbursement?

I haven't confirmed this so I don't know if getting reimbursement will be possible after the close of 1998. I also understand there may be a class action lawsuit brought against TCE so we may not have heard the last of it in any case!

(From: Cedar On 1/1/99 TCE will discontinue issuing concessions to help cover the costs of the tuner jobs (S/B 96-005). Up to this point TCE would cover $65 of the labor and all of the parts for any of the chassis: CTC175, 176, 177, 185, 186, 187 - units that met the serial number group mentioned in the service bulletin.

Their feelings are that all of the units in that S/N range that are going to fail, have done so already. They will also discontinue the special commercial program design to assist motel and other institutional users with this modification as well.

Getting Service/Reimbursement 1

> "Just got off the phone with Thomson. I was "authorized" to receive $75 for the repair, plus $20 for travel to my house. My local repair shop quoted $110, if I brought it to them. So if I can't talk them down much, I may tackle the repair myself. I'm a EE, which isn't saying much, but I work with many talented techs who can help get the job done."

(From: Siva Subramaniam (SubraS@cat.com).)

The same thing happened to my GE 25" TV. I was told it is a problem with bad solder near the tuner. This problem is very prevalent and GE (Thomson Electronics rather) is aware of it. My TV was out of warranty too, but when I called GE at 317-415-4151 and complained about it, they offered to assist me in taking care of the problem. They paid $75 in labor and all parts charges. They even set me up with an authorized service center locally and paid them directly. I did not even have to get anything reimbursed. I had to pay $90.00 for labor ($15.00 out of my pocket), and the unit now works fine. Even though the quality of GE TV was bad (this solder problem), I laud their customer service. I hope you could get taken care of in a similar way.

(From: algba@ix.netcom.com).)

If you call that # and find that you get nowhere, call it back another day and talk to a different person and you will probably get satisfactory results. I've told this to many customers that didn't get results on the first call and they had success on the next call.

(From: Colin Fisher (gomark06@aol.com).)

Call them at the:

1. Beginning of a month and quarter (best)
2. Beginning of the month (least)
3. Beginning of the quarter (next best)

Why?....that's when many corps dole out budgets.....

(From: Dave (moonwolf@fundy.net).)

We just had our 3 year old GE TV serviced for a problem with the tuner shielding. The tech had to resolder the shield. Even though our warranty just ran out, it was honored. The tech said this was a common problem with GE & RCA - the board heating up and cracking the solder joints. He also touched up a couple of other areas in the vicinity as 'preventive maintenance', he said.

It's back to working fine now.

(From: Gary Ferris (grferris@voyager.net).)

Thomson Consumer Electronics' US headquarters is in Indianapolis, IN. I have found them relatively accommodating if a product is 1 or 2 years old. Any older an they tend to take a harder line (which is not unreasonable). Many other manufacturers have "silent recalls" for products that develop problems in a significant percentage of the same model. These will usually last for 6 months to a year and service centers are reimbursed for the repair as if under normal warranty. Two examples are Gold Star with the infamous reel sensor failure and Sharp with Hi-Fi audio crackling. Both of these were covered for one year.

Getting Service/Reimbursement 2

> "I am trying to decide if I should attempt to repair this myself or take it to the shop. While I have am a degreed EE (who actually has his own lab bench), this only serves to remind me of how much I actually don't know about TV repair. From reading the above information, it seems that there are no component leads that need resoldering, only the shield connections. Is my perception accurate? Are all of these spots easy to access? Is the template in the repair kit helpful/accurate? Can a do-it-yourselfer get the template? Is it really necessary to use the "elastic" solder? (Got to admit - I've never seen elastic solder - wonder if that's a marketing ploy to try and convince you that you'll never have to repair cracked joints three years from now.

(Responses from: Matt Kruckeberg (mkruckeberg@pol.org).)

If your are skilled in soldering you may be able to do it yourself. Be advised that the traces and components under the shield are fairly small and subject to damage and detuning. The template provided is accurate. As to the reliability of the repair only time will tell. I have had no reoccurrances on the units serviced with standard solder 3 years ago before the "elastic" solder kit and jumper wire instruction set was made available.

> "Because of the above uncertainties, I would prefer to have a professional do the repair. However, I want Thomson/GE to pay for it. It appears as though there is an obvious design/manufacturing flaw. My company would recall/repair its product if this happened. So I feel Thomson/GE should also. It's the principle of the situation. But, from this web page, it seems as only RCA is reimbursing their customers for the repair, not GE. Does anybody know a phone number where I can call and complain to Thomson/GE? Has anybody heard of any successes in getting GE to pay for it? Does it have to be a GE authorized repair center? Any help is appreciated."

Good luck. Thomson Consumer Electronics the parent company of RCA and GE televisions has been quite difficult to deal with regarding this problem. I have had them tell customers that I did not know what I was talking about and denying that a problem exists. This after sending out 3 service bulletins on the problem. I even received a letter and phone call from the field service manager stating that such information was not to be released to the general public. The phone number I have for TCE customer relations is 1-317-415-4151. Be prepared for busy signals and a wait on hold. Officially the work is to be done by an authorized service center but I have heard of cases of reimbursement for work done by non authorized servicers, generally in rural areas where an authorized servicer is not locally available. I would suggest having the work done by an authorized servicer since they should have the needed solder, training, and experience. The good news is that these sets have been very reliable otherwise.

Getting Service/Reimbursement 3

(From: Steve Backi (backis@rjrt.com).)

I have an RCA 27" TV with a CTC 177 chassis. This set was manufactured in June 93, and I purchased it in September of 93. A couple of months ago, I started experiencing problems with the set, i.e: snowy picture, picture compressed, picking up other channels. Typical problems associated with CTC175/176/177 chassis. I telephoned several repair shops. Each one of them was very familiar with the problem. I took it to one shop in the area. He charged $115 for the repair. $85 for the solder problem and $30 for additional EEPROM configurations. Based on estimates I seen, this seemed like a fair price.

My repair man gave me the telephone number of Thomson Consumer Electronics, and asked that I request partial reimbursement for the repairs. This is where the fun begins. I first spoke with a customer service rep(Patrice) who would not give me her last name. She stated that she was not aware of any problems. I asked for the supervisor's name. After a brief conference with the supervisor, (I suppose), she gave me the name Ryan Brown. She also said because the set was older than 3 years, I was not entitled to any refund. She hung up before I could get further explanation. I telephoned back, and asked for Ryan Brown. Mr. Kevin Johnson answered my call. He very rudely said he was unaware of any problems despite what every repair person I spoke with and the hundreds of responses on the internet.

While he did say he would not offer any type reimbursement, he was willing to offer a certificate towards the next RCA/GE/ProScan TV purchase. I told him, I will no longer be purchasing any brands manufactured by Thomson Consumer Electronics, because in my opinion, they do not stand behind their products. I will no longer purchase those brands, and I urge consumers not to purchase those products. I suspect that the reason towards my bitterness, is that I own two other Sony TV's, and a Mitsubishi, which are at least 12 years old, and they perform flawlessly.

Getting Service/Reimbursement 4

(From: Karen Justice (Karen.Justice@PSS.Boeing.Com).)

We had the misfortune of buying a 35" RCA TV in September 1995. We chose the RCA based on a Consumer Guide rating that indicated it to be a "best buy". We paid over $1200 for the television. Within 8 months, we were experiencing the "shrinking picture" problem. I believe the manufacturer's warranty was 90 days on labor and 1 year on parts. I called the authorized service dealers in our area as well as several others and learned that the estimate for the repair was typically more than $200. No repair shop was able to tell me that it was a known problem and that I should contact the manufacturer to see if they could offer any type of assistance. I went with a non-authorized dealer close to home who charged me $138 to fix the "vertical output system". Of that amount, $30 was for pick-up/delivery and the rest for labor. The TV worked fine after spending the $138.

Well, less than two years later, the same problem is occurring again. It just so happened that last month's Consumer Report magazine (my subscription hasn't expired) indicated that Thomson Electronics recognized a defect with the TV's and suggested that the Customer Service number be called. So, after numerous long distance phone calls (the first time I was told I needed the exact date of purchase, since I couldn't recall if I bought it on 9/5/95 or 9/6/95, and to call back). I can't imagine that the one day made any difference, but I verified the date, called back and eventually got through. They said they do NOT admit to the televisions having a problem. However, since the TV is relatively new and I have already had one out of pocket expense, they would give me a "special warranty". They said that I am "lucky" to get this, since I had a non- authorized repairman look at it originally. They agreed to pay for all parts and up to $80 for labor, if I went to an authorized service center. They recommended Martha Lake Electronics. I called Martha Lake and learned they have a "flat rate minimum" charge for large TVs and won't even begin to look at the TV for less than $225 and it could go up from there! Pickup/delivery is another $110 at Martha Lake (which is about two miles from my house). So, I contacted the other authorized repair service and he said he could probably do it for $150 plus $40 for pickup/delivery. I called Thomson back to let them know that the amount they are authorizing doesn't even come close to covering the cost of the repair. They were unwilling to negotiate a different amount. They gave me the names of other authorized service centers in other cities within a 30 mile radius that I could call for comparison. They said they had mailed out my authorization on April 29, but I told them I never received it. They checked and for some reason it didn't get sent. After another long distance call of probably 20 minutes they said they would send another authorization today.

Needless to say, I am thoroughly disgusted. I am mad at Consumer Reports for recommending a TV as a "best buy" which was built by a manufacturer that had a running history of a known defect. I am mad at the authorized service dealers who didn't mention the problem to me when I first called in June 1996 when I could have perhaps negotiated with Thomson Electronics to pay for at least part of the repair. I am mad at the repair service dealers who appear to be charging customers much more than they should for this repair (all other information in your article on the internet said that all the repair associated with this problem should easily be accomplished for $99 or less). They tell me it is a "major repair" to do the soldering. I am mad at Thomson Electronics for not authorizing full repair of my television, since it is a recognized problem (in your article, someone indicated they should even authorize a recall).

The one thing I did learn is that I will never buy another RCA (or GE) product again and I will no longer use the Consumer Guide recommendations upon which to base my buying decisions. So maybe I made a one time purchasing mistake, but they have lost my business forever, which in the end, could be even costlier for them.

(a week or so passed)

Since I wrote the note, other problems are occurring with the television (we can't turn it off - other than unplugging it, and the picture is nearly obliterated now with "snow"). By the way, I got a letter from Thomson Electronics on Friday, May 8 (dated April 29), authorizing the repairs/labor (up to $80). I have All Area Servicing coming this morning to fix it (they said they should be able to do the repairs at our house). The "house call" is $54.95 and the repair will be another $100 plus tax. They say that once a complete soldering job is done that the TV's seem to work fine. I certainly hope so. I don't look forward to facing another $150 bill in another two years. Thanks for listening!

DISCLAIMER

While it is hard to imagine any catastrophic consequences resulting from attempting to repair a remote control, we will not be responsible for such consequences or collateral damage should it occur! :)

- Back to IR Remote Repair FAQ Table of Contents.

Introduction

Remotes, Remotes, and More Remotes

Twenty years ago, a wireless remote control was a $50 or $100 option (in 1980 dollars) to a TV or VCR. Early remote controls used ultrasound or radio frequency analog transmission and could perform only limited functions - you were lucky to get anything beyond on/off, volume, and channel up/down. Today, a remote control is standard with even the lowest cost basic electronic equipment. Nearly all modern remote controls use Infra Red (IR) light for digital data transmission. Some have more buttons and functions than a personal computer! Unfortunately, many have row upon row of tiny identical size buttons with no logical layout of functions. Others are a masterpiece of ergonomic engineering almost operating by themselves.

There are two kinds of problems with remotes:

1. They seem to have legs of their own and disappear at the most inconvenient times.

2. They get abused by being dropped, dunked in Coke or beer, chewed on by the pet tiger, or left alone to develop dead leaky batteries.

While there are some remotes that will respond to a whistle and beep back to identify their location, most are the ordinary deaf, dumb, and blind variety. I cannot help you locate your missing remotes. If you have disappearing remote syndrome, a well designed universal remote - on a tether - may make a good investment. However, the following was too good to pass up:

(From: Bill Samuel (phantom@isoc.net).)

"In '89, a Customer brings in their VCR for me to fix. (Zenith VRE-200) It won't accept tapes, plus their kids misplaced their remote, so they wanted a price on a new one.

Well, after taking the unit apart, I called them and said, "Sir, I've found the problem with your VCR. BTW, you don't need a new remote.""

Most actual problems with remotes can be solved relatively easily. They are often of a physical nature. Since remotes operate on low voltages under non-stressful conditions, spontaneous electronic failure is relatively uncommon. The following are not good for remotes: Sitting or stepping on them, using them as drink stirrers, door stops, projectiles for target practice, substitutes for dog bones, or depositories for your old leaky batteries.

- Back to IR Remote Repair FAQ Table of Contents.

IR Remote Diagnosis and Repair

SAFETY

There isn't anything dangerous inside a remote hand unit. Even staring point blank into the IR emitter isn't likely to harm anything. The worst that will happen if you make a mistake is that the circuit will be damaged beyond beyond repair and a new remote control will be in your future! :)

However, if you go inside the TV, VCR, or other controlled device, see the respective repair guide for that equipment for essential SAFETY information.

Testing of Remotes

Unless your remote hand unit has been run over by a bulldozer and is flat as a pancake, don't immediately assume it is actually broken.

- First, confirm that your problem is not simply due to a selector switch in the wrong position or an accidental press of a key selecting 'VCR' instead of 'TV'.

- If your 'problem' unit is a universal type, make sure it has not simply forgotten its programming or codes - reinitialize it. A common cause of memory loss is the batteries falling out or losing contact for an instant due to a fall or bump. To be sure it is properly reset, remove the batteries for a minute or so and also press the power button for a few seconds (to discharge any internal capacitors) before doing the reprogramming. See the section: Forgot Your Universal Remote Setup?.

- Some older TVs in particular may have a 'vacation' or other switch to disable the set (or just the remote functions). For that matter, if you cannot get the equipment to turn on at all, make sure it is plugged into a live wall socket. :-)

- Some TVs may occasionally become confused due to a power surge or for no good reason at all. Unplug the TV for a few minutes to reset it. It is also possible (though I don't have any evidence of this) that a remote can become confused. See the note above on programmable remotes.

- Before doing anything else, check and/or replace the batteries with fresh ones. Who knows how long they have been in there.

- Don't ignore the possibility that your spouse (or the local poltergeist) accidentally dropped the remote spilling the batteries - and put some back in backwards! This could result in either a totally non-functional remote, weak (limited range), or erratic operation. Permanent damage is not that likely but possible with some designs if the resulting voltage to the circuit board actually had reverse polarity.

- Next, try to determine whether the problem is indeed in the remote itself and not the TV, VCR, CD, or other controlled equipment. The easiest way to do this is to temporarily program a universal remote to match your equipment. If this now operates successfully, then you can be pretty certain that the problem lies in the remote unit.

- If you are not able to get a universal remote to operate your equipment, then either you have not found the proper code setting or the remote itself is indeed faulty (or you don't have a universal remote!).

- Should you or a friend have an identical or nearly identical piece of equipment, try the (faulty) remote on that (and its remote on your equipment) as a further test.

- If you have multiple pieces of equipment, make sure you have not accidentally substituted an apparently identical remote for a slightly different model VCR, for example. Not all equipment - even of similar type - from the same manufacturer necessarily use the same signal transmission format.

Diagnosing the Problem

The following assumes that there is no response to the hand-unit even if up close to the TV, VCR, or other controlled equipment. Where the remote works but only over a shorter distance than when new, see the section: Reduced Operating Range.

To narrow down the problem, use an IR detector to determine if the remote is emitting an IR signal when each button is pressed. While this does not guarantee that the signal is correct, it eliminates most common problems from consideration. An IR detector card or an IR detector circuit like one of those described in the section: IR Detector and Related Circuits are very handy for testing remote controls and other IR emitters. Some camcorders (those that do not incorporate an IR blocking filter) are sensitive to IR as well and will show a bright spot of light if aimed at a working source of IR. And, PCs and PDAs with IR links and suitable software (e.g., OmniRemote for the Palm III) may be useful for remote testing. See the section: Some Alternative 'Quick and Dirty' Remote Testers for additional options.

MCM Electronics, Centerville, Ohio/1-800-543-4330, list 2 different shaped cards for $7.29 each (#72-005/3.5 x 2.5" card & 72-003 /4.75 x 0.75" probe. Radio Shack, Edmund Scientific, and others offer similar detectors.

The salvaged IR sensor module from a TV or VCR may also be used as an IR detector. These usually operate from a single supply (12 V typical) and output a clean demodulated signal - you will not see the carrier, only the 1s and 0s. This will be true of an IR detector circuit as well unless you are careful to position the remote and photodiode just so as the circuit acts as somewhat of a low pass filter due to the B-E capacitance of the transistor. Radio Shack and Digikey (among other) also sell inexpensive IR receiver modules (under $5) which would also provide a demodulated signal for your viewing pleasure. However, note that some may be tuned for a particular carrier frequency like 40 kHz and therefore may not respond to all remotes. (Note, I have heard of spurious pickup issues with some of the Radio Shack units - they are not the same as those sold a while ago.)

(From: Brett Walach (bwalach@dpg.devry.edu).)

For anyone needing a great IR receiver at a reasonable price, try Radio Shack's MOD1. It's an IR receiver that demodulates the data for 40Khz x-mitters. The output can then be viewed on a scope or used to drive a small transistor which would in turn drive a speaker! The output from the MOD1 is the inverse of the code sent. That is, the TTL logic level from the MOD1 is high when no IR is present. If by chance you need an IR receiver that operates on a different carrier, try DigiKey (1-800-DIGI-KEY). I know that they have the other two types for sure.

Reduced Operating Range

With proper design, there really shouldn't be anything in a remote control (or the receiver) that degrades with reasonable use (at least in terms of operating distance). However, not all remote controls are properly designed (or manufactured) and there can be other causes for a remote that used to operate reliably from the other end of the house or bounced off the far wall but now won't even respond directly from a few feet away:

- Weak batteries - replace them!
- Dirt, gunk, tobacco smoke or cooking grease residue, and other coatings on the windows of the hand-unit or receiver. Clean thoroughly (but gently) with detergent and water, and alcohol, as required. This may mean INSIDE as well as outside!
- Damaged window in hand-unit or receiver. If someone attempted to clean the window with sandpaper, there could be problems. Remove, replace, or polish the damaged area.
- Weak IR LEDs. Since these are driven hard, it is possible for them to degrade over time. Replace with high intensity IR LEDs from Radio Shack or a real electronics distributor and see if that helps.
- Dried out reservoir capacitor. To drive the IR LEDs requires large peak currents. Sometimes, this depends on the input capacitor fed from the battery and not the battery itself. If this capacitor goes bad, the peak output will be greatly reduced or will be erratic. Test and/or just replace all electrolytic capacitors in the hand-unit.

Remote Repair

Most problems can be remedied without any special skills. However, where bad connections or component replacement is involved, you will have to be able to do just a bit of fine soldering. In this case, a low power (e.g., 25 W) fine tip soldering iron and fine rosin core solder will be needed. Fortunately, the circuit boards in remotes are generally constructed using features sizes (pads and lines) that are state-of-the-art from the 1950s. Therefore, rework isn't nearly as challenging as, say, on your 500 MHz PC!

CAUTION: You can easily turn a simple repair (e.g., bad solder connections) into an expensive mess if you use inappropriate soldering equipment and/or lack the soldering skills to go along with it. If in doubt, find someone else to do the soldering or at least practice, practice, practice, soldering and desoldering on a junk circuit board first! See the document: "Troubleshooting and Repair of Consumer Electronic Equipment" for additional info on soldering and rework techniques.

Test equipment beyond a good eye and maybe a multimeter is rarely needed.

The most challenging part of repairing a remote hand unit may be just getting inside! Manufacturers seem to pride themselves on the extent to which this is becoming more nearly impossible without dynamite:

- Screws - Some well designed (from the point of view of repair) units have a screw or two in obvious places (back cover and/or inside the battery compartment). Once removed (generally with a proper fine tipped Philips blade screwdriver), the two halves of the case come apart, possibly after sliding one with respect to the other a fraction of an inch.

- Hidden snaps - If no screws are visible (and even after removing them in some cases), it will be necessary to carefully examine the seam and possibly inside the batter compartment to determine where the likely locations of plastic snaps. Running a butter knife or similar thin tool along the seam may persuade the unit to pop in half.

- Glue - I don't know if any remote controls use this more-or-less permanent approach but if so, careful use of a hacksaw may be necessary. :-(

Even if the case is slightly damaged after disassembly (e.g., a snap or two break off), the sparing use of a semi-permanent adhesive like windshield sealer will probably be able to fasten it all back together in such a way that little evidence remains of its traumatic experience.

Problems with Remotes

Most problems occur in the hand units due to the abuse inflicted on them by kids, pets, and even otherwise well behaved adults. However, the equipment or even outside interference can also be at fault. Therefore, also see the sections: Problems with the Equipment and Problems Due to Interference.

The following are the most common types of problems and suggested solutions. As noted, most are physical in nature: dead batteries, gunk, bad connections.

For all but the first two, disassembly will be required. Manufacturers seem to be using more and more creative (read: obscure and difficult to open) methods of fastening the two halves of the remote shell together. There may be a screw or two and/or the case may simply 'crack' in half by gently prying with a knife or small screwdriver along the seam or sliding the two halves a fraction of an inch to unlock some catches. Look for screws on the back (possibly under a not-so-easy to peel off label) and inside the battery compartment, as well as hidden snap fasteners.

Dead Batteries or Batteries Inserted Incorrectly

Solution obvious. If batteries tend to go dead quickly - the batteries in a remote typically last years - then you may have a stuck button, some conductive grime under one of the buttons, or a defective IC - or you may be using cheap batteries.

Make sure that all the batteries point in the correct direction as marked inside the battery compartment or under its cover. If it uses more than 2 batteries, getting one in backwards could also result in weak or erratic operation.

Corroded Battery Contacts

Clean off the chemical deposits - first dust out the dried material with a soft brush and then remove the remainder with a damp lint free cloth or paper towel. Polish the contacts with a Fiberglass brush and/or pencil eraser and/or very fine sandpaper or a nail file. If there is evidence that the battery juice made its way inside the case, you will need to open the remote and thoroughly clean the interior. Additional repairs may be needed if damage to wiring, components, or circuit board traces is evident.

Broken or Intermittent Contacts

There are most often between the battery connections and the circuit board. Carefully resolder and reinforce them if necessary. There could also be cracked solder joints on various component pins (particularly those that get abused like switches) as well. Reflow the solder on any suspect joints.

In addition, check selector, power, or enable) switches for proper operation. Remove the batteries and use an ohmmeter to test across the contacts with the switch(es) in all positions. These switches can be easily damaged as a result of dropping or squashing the remote. The contacts may become dirty, gunked up, corrode, or simply wear out as well. Locating a replacement may prove challenging. Disassembling the switch may allow you to clean or restore the contacts in some cases.

Broken Ceramic Resonator

These may fail from shock when remotes are dropped.

The frequency is often 455 kHz (I assume since they are widely used as filters in the IF section of AM radios and are thus inexpensive.)

If you have an oscilloscope, check for signals on the IC when buttons are pressed - if there is no action on any pin, then you may have a bad resonator (or bad IC, etc.). Monitoring on one lead of the ceramic resonator should produce a signal at its resonant frequency when a button is pressed. A typical waveform may have an amplitude of a few tenths of a volt.

If you do not have a scope, one possible indication of a bad resonator (aside from it being smashed) would be a steady output from the IR LED for all button presses - normally the output would be visibly pulsating. Of course, this could indicate a bad IC as well.

A ceramic resonator usually is a small blue or orange object that looks similar to a plastic (sharp edges) or dipped (smooth edges) capacitor.

The circuit board marking will be X1 or CR1 or something like that. Replacements may be available from places like MCM Electronics or other electronics distributors. Or, consider an organ donation from a remote for equipment that has long since gone to that entertainment center in the sky if the frequency of its resonator is the same.

However, the frequency may be fairly critical for proper operation (within 5 percent or better may be required for some) and while not a common failure, I've heard of the resonator frequency changing (probably from a trauma) by enough to cause problems.

(From: Lewin A.R.W. Edwards (sysadm@zws.com).)

If your resonator has 3 pins instead of 2, and you can't find a replacement, you can use a 2-pin resonator, but you'll need to add two small caps (perhaps 33 pF?) between the legs of your resonator and ground.

Dirt, Spills, Gunk, Oily Buildup Inside

This may cause circuit problems preventing keys from operating reliably or physical problems resulting in keys being just plain stuck or sticky. Unreliable or erratic operation from these causes is probably the most common remote control problem after dead batteries.

- If you have recently cleaned the outside with a wet or damp cloth (or in your dishwasher!), then this is quite likely as liquid can seep inside and result in all sorts of strange behavior immediately or delayed by some time.

- Disassemble completely and wash both sides of the rubber membrane keypad, circuit board, and plastic case with water (and mild detergent if necessary) to remove sugar based grime and then isopropyl alcohol. Dry thoroughly.

- For stubborn crud, a pencil eraser and/or Fiberglass brush may be used with care (on the circuit board only). However, the gold plating (if present) and/or copper trace itself is quite thin!

- Where you find a oily film between the rubber and the circuit board, unless you really do a SUPER job of cleaning, it will come back quickly. It may come back no matter what you do.

  Once you think you got it all, do it again - and with soap and water as well - both the rubber and circuit board.

> This goo may originate from a number of sources (no one seems to know for sure) including: body oils, spills, plasticizers from the flexible keypad, protective grease, etc. Unless you had dunked the remote in a vat of motor oil to create this problem there may be no sure way to prevent it from returning in the future. More below.

CAUTION: In some cases, the conductive black material may be soluble in alcohol - carefully test first on the pad of a key you don't care much about. If black material comes off on your cloth or swab, use only the water and detergent. Putting the black stuff back on is much more difficult than removing it. :-)

I have one (1) data point to suggest that cleaning the rubber pad with a soft pencil eraser may be better than washing. However, this may *also* remove the conductive material in some units.

(From: Steve Lenaghan (tamerica@prairie.ca).)

We do a ton of cordless phones and I have never had to repair a conductive pad in my career (35 years). We soak them in scalding water and dish soap for 30 minutes. I clean the PC boards with alcohol and a rough cloth. Works every time.

(From: Michael Shell (mikes1987@yahoo.com).)

People have noticed that the keys (and remotes) that are used more often, tend to have more oil problems. This is in agreement with my observations.

One thing I have to make clear is that I *KNOW* that whatever is going on is NOT due to spillage or other external contamination. If I had not seen it with my own eyes, I would not believe it either! Sometimes the keys that are used most often (and have the most oil) are in the center - this is a LONG way for an external contaminant to have to travel!

The oil behaves a bit differently from most normal household (and hand) oils.

1. It is not sticky in the least
2. It is VERY clear.
3. It is VERY hydrophobic and detergent action is noticeably less than with most petroleum based oils.

I would not have noticed these fine points except for the fact that I have worked with Silicone (DOT 5) brake fluid which, except for an added purple dye, behaves in the same way.

Check this out: Silicone Rubber Components Manual (down at the bottom, section 7.0, Quality).

So, it seems the silicone keypad manufacturers have been keeping a dirty little secret all these years!

I guess we all have to look forward to our 3 year cleaning ritual. I suppose a hardcore hardware hacker could do his own keypad baking and post some before and after weight measurements to tell us how many grams of oil these things hold! (WARNING: you may have to do the baking in an oxygen free atmosphere!)

Worn or Corroded Pads on Circuit Board

These may be interdigitated or semi-circular patterns and suffer from both wear and corrosion. Conductive Epoxy or other similar conductive paint (like that used for rear window defogger repair) or ink may be used for repair. A piece of thin copper foil can be glued to the circuit board and soldered to the appropriate circuit trace. (Gold foil would be better as it will not corrode but might be just a tad pricey for a $10 remote!)

If the plating has worn off and cleaning the contacts doesn't last for more than a few days or weeks, tinning them with a thin coating of solder should help.

Worn Conductive Material on Rubber Buttons

Compare the bottoms of frequently used keys with those that are rarely pushed. If you can see the rubber through the conductive material after cleaning, the pad is likely worn to the point of being non-functional. This may be repaired with conductive Epoxy or other similar conductive paint or ink. A sliver of aluminum foil can sometimes be glued to the rubber surface. 3M makes EMI/RFI foil shielding tape, type 1181, that should work very well for this. Another source for small quantities of metal tape would be a shop that makes stained glass or sells supplies for making it. Pencil lead (graphite) may also work though for how long is unknown (though some have reported good success with this readily available material).

MCM Electronics at 1-800-543-4330 lists a Rubber Keypad Repair Kit for $24.95. It is supposed to contain enough material to repair 400 contacts (2 containers each good for 200 contacts). Their part number is 20-2070. Not cheap but 400 contacts covers quite a few typical remotes. Note: I do not know whether it is easy to mix only enough material for just 1 or 2 contacts - it would be worth confirming that this is possible before ordering. Or else, invite a few dozen friends (and their flakey keypads) over for a remote repair party. :-)

For a similar price, Remote Control Keypad Repair also has a kit for coating the worn out rubber. It consists of a little bottle of some conductive paint which doesn't appear to need mixing.

There is also a material called 'resistive coating' or something like that that goes on like paint. It may be available from an electronics distributor. Or, if you are friendly with your local repair shop, they may be willing to spare a few drops.

Occasionally, the conductive material is not actually worn off entirely only on the surface and there may still be some beneath surface. Light sanding may help.

Unfortunately, there is no single best solution since the material used for the conductive rubber pads in remotes is not all the same.

(From: Paul Weber (webpa@aol.com).)

> "If you're looking for aluminum or copper foil tape with adhesive on it, visit your local hardware store, in the plumbing and/or roof rain gutter sections. Alternatively, try an auto parts store. I've found a variety of adhesive foils (including stainless steel) in these kinds of establishments.

As for as repairing conductive rubber keypads: I've not used the metal tape method, but will probably try it. I've had great success with a thorough cleaning and light buffing of the contact area with very find (1000 grit) wet/dry sandpaper."

(From: Rufus (Pink@Floyd.Edu).)

"If you can find similar pads on another remote's membrane, trim them off square and use them to replace the defective pads. You can use silicone glue to attach them. Be careful to trim off the same amount from each pad so the buttons throw will be the same, and don't trim too deep as to damage the rubber dome."

(From: Wes Hilterbrand (replayelectronics@usa.net).)

"About the best way I have found is to take an old remote (trash or have absolutely no need for) with the same type of conductive pads. Look for a little used pad (such as a record button), add some skillful maneuvering with an exacto knife, and some SuperGlue, and you can sometimes replace the bad pad(s) on your remote with better pads. The way I have done this is to cut the pad about halfway down from the sheet it's connected to (around the pad's circumference, a little ways under the conductive surface). This should probably be done only as a last resort, and WATCH YOUR FINGERS!

BTW, this is just my opinion. I CANNOT be held responsible for any damage incurred due to following this procedure. Try this AT YOUR OWN RISK! Remember, if you mess up your working remote, there is no recourse."

(From: Keith Craig (kcraig@mlode.com).)

"I use a can of 'TV TUBE COAT' (GC Electronics), a conductive paint used for picture-tube aquadag (black paint on outside of picture tube used for ground). Squirt a tiny amount on a piece of paper and use a Q-tip (cotton swab) to drop on the pad."

(From: Mark Saterfield (kc4tzn@webtv.net).)

"Pens are available that come preloaded with conductive ink at local electronics stores though apparently not Radio Shack."

(From: Mike Harrison (wwl@netcomuk.co.uk).)

"It isn't the same as the silver stuff used for car screen heaters, etc., which I'd guess probably dries too hard and cracks off. It's made by Circuit Works, who also do conductive epoxies. Their part number is CW2610 for a repair kit, UK supplier is Farnell, price is UKP 22.33."

(From Rodney A Schmidt (rschmidt@iastate.edu).)

"What I used to remedy it was to use the stainless steel tape that is sold to seal ducting insulation, use a paper hole punch, and super glue the punched stainless onto the pad. I have had

> extremely good luck using this, and since the stainless is adhesive anyway, it stays in place while the super glue is drying."

Cracked Circuit Board

These can be repaired easily as the circuit boards are usually very simple, single sided, and have wide traces. Use Epoxy or an adhesive like Duco Cement(tm) or windshield sealer to repair and reinforce the circuit board. Scrape off any insulating coating and jumper breaks with fine wire and solder. Do not just bridge the gaps with solder as cracks and future problems are a certainty.

Bad IR LED

Test the IR LED(s) with an external power supply (with current limiting resistor) and IR detector and/or monitor voltage across them while operating. Substitute a visible LED and see if it lights up when keys are pressed. Use a scope to monitor the drive to the LED. You should see the pulse code modulated carrier. If faulty, replace with a readily available high intensity IR LED.

Note that strictly speaking, these IR emitters should perhaps be called Infra Red Emitting Diodes or IREDs since they produce no visible light. However, we will use the term IR LED throughout this document since its meaning is understood by the vast majority of readers.

Bad IC

If the remote uses a custom chip, throw it away! However, a failed chip is usually quite unlikely unless struck by lightening (now how would that happen?). Even accidentally inserting the batteries backwards (though definitely not recommended!) - which tends to kill many devices - may not cause any harm to a remote. Check each pin on the IC with a scope to determine if it is at least alive.

(From: Duane P Mantick).

> "An awful lot of IR remotes use IC's from the same or similar series. A common series comes from NEC and is the uPD1986C which, incidentally is called out in the NTE replacements book as an NTE1758. A lot of these chips are cheap and not too difficult to find, and are made in easy-to-work-with 14 or 16 pin DIP packages. Unless you have no soldering or desoldering skills, replacement isn't difficult."

Alternatives to Repair

There are a large variety of preprogrammed universal remotes available starting at $10. These are set up by inputting a code number for each type of equipment you will be using - TV, VCR, Cable box, etc. Don't loose the instruction manual or you will not know what codes to use if the batteries go dead or the remote looses its memory for any reason! Record the codes in pen on a label on the back of the remote and inside the battery compartment. For general TV/VCR/cable use, the $10 variety are fine. However, many will not provide special functions like programming of a TV or VCR or access to other model specific menu functions.

However, some of the One-For-All (and probably others as well) remotes do have capabilities not listed on the package (or web site). Check with the manufacturer (in the case of Universal, this can be via email) to determine whether any of their products have what is needed for your model(s).

Universal 'learning' remotes are available at slightly higher cost (perhaps, $25-100). The better ones are capable of memorizing all of the actual signals sent by your original remotes by viewing the IR transmission directly. Of course, your existing remotes must be working properly for teaching purposes. Make sure you get a money back guarantee with these as some may not be compatible with all equipment. The advantage of a learning remote is that it can be taught to perform setup, adjustment, and programming functions as well as those for normal operation. However the teaching process is likely to be tedious and time consuming and you will have to keep track of which buttons do what - possibly not worth the effort in the end. If the backup batteries should ever go dead, the entire learning process will need to be repeated.

(From: Michael Schuster (schuster@panix.com).)

> "You can get most of the Zenith OEM remotes from MCM Electronics. These include some that were sold under the Gemini name as consumer items; their 4-device learning/preprogrammed remote was particularly nice).
>
> These definitely =behave= as though they have EEPROMS; i.e. learned functions are retained indefinitely without power.
>
> Also the upgradable one-for-all remotes from Universal Electronics (i.e. the ones with the 'magic' key) almost certainly have EEPROM since they can be customized by moving buttons around and assigning straight binary functions to keys not in the original pre programmed arrangement. Such customizations are also retained if power is lost."

(From: Dakuhajda (dakuhajda@aol.com).)

> "Unfortunately RCA remotes cannot be repaired on any made after 1986. The circuit board is molded to the plastic case, only way to get the darn thing apart and you break it beyond being able to put it back together. Rca sells a universal remote control system link 5 that even has the pip feature. Usually $25. If you really want an exact match look inside the battery cover you can get the part number for the remote control, six digits, usually 221000 or similar. You can call any RCA authorized servicer and they can order it for you, or you can contact MCM electronics, Excel electronics, or any other authorized Thomson parts distributor. "
>
> By the way the most expensive RCA universal remote that Wal-Mart sells I use in our shop for almost all but the very newest RCA TV sets. Last 2 years models.

(From: techman@niobiumfive.co.uk.)

Some universal remotes are better than others. I recently bought (here in the UK) one called "Wizard" made by Philex (a big manufacturer of replacement remotes). It has several levels of programming:

1. Manufacturer-based code numbers, which get you a basic level of functionality, similar to simple universal remotes

2. Key reconfiguration. Once (1) has been set, one can select a button and pressing it repeatedly causes it to issue sequentially all (?) codes with the same manufacturer part but varying the second part of the code. Once you hit the right one, you can save the code for that button (in flash). A bit tedious but good coverage.

3. It can learn the code from an existing remote, and save on any button.

All this can be setup for 8 different devices. Settings are saved in FLASH memory so you don't lose any programming when the batteries die. :-) It does has a few undocumented quirks, like setting a new manufacturer code seems to clear all existing "learned" codes. :-(

I bought it from Grandata (UK 0208-900-2329, international +44-208-900-2329) for GBP 16.50 + tax and postage.

I have also wired a phototransistor and an IR LED to the serial port on an old laptop, and experimented with turning that into a learning remote. I must say I was surprised at how many different coding schemes seem to be in use, just running through a) above and observing the waveforms I documented about 20 variations before I got bored. I got it working with my UK satellite "digibox" and with a JVC VCR, but haven't taken it much further. I was particularly interested that the VCR (HR-S4700EK) responds to two quite different coding schemes, presumably it was designed to be backward-compatible with some old code of theirs, but the newer code is required to get all the functions to work. A few codes do functions for which there is no button on the official remote (and are normally only accessible from buttons on the front panel!) One code wipes out all ones timer recording settings! :-(

Original Replacement Remotes

In some cases, the only realistic option is to obtain an original replacement remote control. This might be the case where special functions need to be easily accessible or you have fallen in love with the button layout, style, or decorator colors! If you need to access special functions on your equipment, a learning remote might be an alternative if you have access to a working remote control so you can teach it. However, learning remotes are rarely as convenient as the original. As for color, there is always spray paint!

- Consider the original manufacturer of the equipment only as a last resort as they will likely want to charge you an arm and a leg (or more) for a replacement.

  Panasonic has a web site you can enter your model number and get a parts list with list prices and part descriptions:

  - Panasonic Parts & Service Online

  This site includes support for Panasonic, Technics, and Quasar consumer electronics. However, my quick visit only showed accessory type items (e.g., replacement original remote controls, cables, etc.). Encrypted credit card protection presumably makes it possible to order parts directly.

- Electronics distributors like MCM Electronics do stock a variety of original remotes - prices range from $9 - $143 (Wow $143 for just a stupid fairly basic remote! It doesn't even have high definition sound or anything exotic. You can buy an entire VCR these days for less than $143 including its own remote!), The average price of these replacements is a still rather inflated $40.

- Remote and Manual Service offers factory original remote controls from a large number of companies. I do not know how their prices compare with the manufacturer direct or with places like MCM Electronics:

  - Remotes.com, Phone: 1-800-REMOTES (1-800-736-6837).

- Here is one that also appears to specialize in this area:

  - Replacement Remote Controls

  They also do will research on hard to find remotes.

- Back to IR Remote Repair FAQ Table of Contents.

Problems Not Due to a Defective Hand Unit

Problems with the Equipment

While circuit problems with the hand unit discussed in the section: Problems with Remotes are most likely, the following causes should not be overlooked if the remote does not work or has limited range:

- Dirty IR window - The plastic sheet which covers the IR detector may be coated with dust, grease, grime, or tobacco smoke, or other wise damaged. If sensitivity has decreased even with a new set of batteries, this is a distinct possibility. It is not always obvious whether a particular type of dirt or damage will affect response. Some condensation may be totally opaque to IR while appearing transparent to visible light. On the other hand, I have a TV where someone must have cleaned the sensor window with sandpaper or a strong solvent - it is totally clouded over but works just fine with my $10 universal remote.

  Test by removing the front panel if possible and direct the remote at the sensor directly. Inspect and clean the sensor window thoroughly with mild detergent and water.

- Defective IR sensor, receiver electronics, or microcontroller can result in the equipment simply ignoring you and/or doing whatever it pleases. The first two of these can generally be tested without service information. However, if they check out, advanced troubleshooting will be required.

  Borrow a replacement or universal remote to determine if the device responds with a known good unit. Check demodulated waveforms with an oscilloscope to confirm proper signal levels and reliable operation. See the section: Diagnosing the Problem as well.

Note that if this is a problem with new equipment (or if it has always been this way), don't neglect the obvious: Has the protective plastic film been removed? This is often present to prevent damage during manufacturing and shipping. It is amazing how many people neglect to remove this - I have gotten 10 year old TVs and VCRs at garage sales with this ugly film still in place!

And, there could be a design or manufacturing problem with your set....

While the IR-receiver module inside that TV may be a mature component and may function well on the test bench, it is entirely possible that the TV manufacturer has made a (design) fault in applying it. An IR-receiver is a very sensitive device, and a television is a very dirty environment. This may be a case of an EMC problem, not an optical problem. Under the right conditions, with this type of IR-transmitters and IR-receivers, distances of 100 feet or better may be crossed...

But, this should not be the customer's problem. The service organization of the TV manufacturer is the proper place to obtain a fix. The complaint is valid and it should be cured.

Problems Due to Interference

Symptoms for the following may range from no, intermittent, or incorrect response or greatly reduced range to the equipment being possessed - a TV changing channels, volume, or powering itself on and off as though being controlled by a poltergeist. (Where the problem is due to more than one piece of equipment interacting, see the next section.)

These are likely possibilities if you have just changed your room layout or added something to it:

- Interference from another remote in the same room which is defective (or is being squashed by a gorilla). Make sure there are no other IR transmitters including those like the a VCR+ or remote repeater that might be activated accidentally due to faulty programming or something pressing on the buttons. Do you know where all your remotes are hiding?

  A neighborhood kid (or adult with the maturity of a kid) may be playing tricks on you from outside your window or even across the street. It doesn't take much (a lens) to extend the effective distance over which a universal remote will operate reliably.

  Cover the sensor of the misbehaving equipment with a piece of black tape to see if the problem goes away. Then round up your other remotes (and/or other animate objects) and discipline them!

- Fluorescent lamps using electronic ballasts - These may be newer ceiling fixtures or the energy efficient compact fluorescents used as replacements for the regular light bulbs in table lamps. The electronic ballasts are switching power supplies and these may result in modulation of the light intensity at high frequencies confusing the remote control receiver.

  Turn off all fluorescent lamps to see if the problem goes away. A cardboard baffle can be taped to the sensor to block the interfering light. Try a different brand of compact fluorescent as not all cause interference.

- Bright lights in general - Enough ambient light, be it from the Sun or a 1000 W flood may overload the sensor. Ceiling fans can sometimes modulate the light with their fan blade rotation or vibration of the filaments of the bulbs which can confuse the remote control receiver and microprocessor.

  Turn off the lamps or move the Sun to see if the problem goes away. A cardboard baffle can be taped to the sensor to block the interfering light. Simply changing the orientation of a lamp shade or slightly moving one of components may be all that is needed.

- Electrical interference from nearby equipment. Inadequate shielding in the sensor electronics could result in susceptibility to RF emissions from other gear.

  Turn off suspect devices. If the problem goes away, they will need to be moved to another location. Shielding is probably not a viable option.

Where Multiple Pieces of Equipment Use the Same Codes

It sometimes happens: A second VCR or TV, even if from a different manufacturer, may use exactly the same remote coding. Where there is no unit select switch on the device and hand unit, only careful aiming (possibly with a set of blinders!) will allow control of one at a time.

There are three ways to solve this problem: changing the wavelength of the light, the modulation frequency, or coding used by the remote. Only the first of these is likely to be realistically possible without major effort and would involve replacing the IR LED(s) in the hand unit with visible ones (red, yellow, or green) and replacing the IR passing filter on the controlled equipment with one selective for the visible wavelength. The silicon sensor in the remote receiver probably will work just fine for visible light. A colored piece of cellophane or plastic may be adequate for the filter. Using a green LED may be best since its wavelength is furthest away from the IR wavelength making the filtering easier.

I have not actually tried this stunt but there is no fundamental reason why it shouldn't work. However, some experimentation may be required to find a suitable high brightness LED and to match it to driver in the hand unit since the LED's voltage drop will be different and may require changing a resistor. And yes, with care, it should be possible to extend this approach to 3, maybe even 4 devices. Multicolored remotes might be kind of cool. :)

Forgot Your Universal Remote Setup?

Hopefully, you saved the instruction manual. No? Some universal remotes like the Zenith Allegro have an 'auto search function' which will sequence through all possible codes. You then push a button to lock in the proper settings when the TV or VCR's channel or power status changes. Of course, since you don't have the instruction manual, you likely don't know how to use this feature either!

The manufacturer of the remote control is the next likely source (after the instruction manual) for the codes and other information. However, there is a good chance that one of the following web sites may be able to help you:

- Memorex has a web site at:

- Memorex.com

  But they suggest using the technical support line (800-636-8352) for remote control programming and other Memorex consumer electronics questions.

- The RCA Web site used to have complete user manuals for their universal remotes. Maybe they still do but navigating that site is so confusing with multiple 404 errors that I gave up. However, I was told that you should go to: "Shop RCA", then "Accesories", then "Universal Remote Controls", then the model in question. The PDF link to the owner's manual is at the bottom of the page listed as "Owner's Manual". Maybe. :)

  - RCA Electronics

- Remotes has extensive info on both Radio Shack and One-For-All brand remotes. This Web site may be more stable than the ones provided by the manufacturers.

- The Sony Web site has detailed programming codes and some troubleshooting info for some of their universal remotes:

  - Sony Consumer Electronics Guide - Remote Control Solutions

- Tandy (Radio Shack) has a nice web resource and fax-back service. This is mostly for their equipment but some of it applies to other brands as well and there are diagrams which may be useful for other manufacturers' VCRs, TVs, CD players, camcorders, remote controls, and other devices.

  - Radio Shack Product Support

  In particular, there is information on many many universal remotes including setup instructions. Since, it is likely that your model is actually one of these rebranded by Radio Shack, it is worth checking.

- Universal Electronics, makers of the One-For-All(tm) line of universal remote controls (and other products) has a web site:

  - Universal Homepage
  - Universal USA

  There is complete info on programming and special functions for many models. Since other universal remotes may be rebranded One-For-Alls, this information may be useful for those as well.

- US Electronics, makers of a variety of universal remotes (1-in-1 CATV, 2-in-1 Universal, 3-in-1 Universal, 4-in-1 Universal, ABC (Promote series), etc.) has a web site:

  - US Electronics Homepage

There are complete specifications and setup instructions for most of their products (with the rest coming soon).

- Zenith has an extensive web site with product specifications for many of their audio/video products. Gemini remotes (e.g., Easy-3) are made by Zenith. There is nothing there at the present time but indications are there may be remote information in the near future.
  - Zenith Homepage
- Metronics International Components has programming instructions for various univeral remotes including Curtis, Magnavox, Quik, RCA, and Sony:
  - Universal Remote Programming Instructions (Metronics)

  And here is another one:

  - xDiv's Universal Remote Control Codes

Next time, make copies of the instruction manual(s) and put them in obvious places like taped to the back of the TV or inside the entertainment cabinet.

Better yet, print the specific instructions and/or codes on a slip of paper and stuff it into the battery compartment of the remote. Or tape the info to the back and then cover with clear tape to protect it from wear.

One of the primary axioms of life is that you will lose those instruction manuals. :-)

Code search Programming of RCA SystemLINK Remote Controls

Perhaps this is your lucky day and this is the type of remote you have that is in search of an instruction manual.

I know this procedure works for models 3 and 4+ and assume it to be similar for the others.

(From: Larry Sabo (sabo@storm.ca).)

1. Make sure the device you are programming is turned off.
2. Press and hold CODE SEARCH.
3. Press and release TV, VCR, or CABLE corresponding to the device to be controlled. The indicator light will flash once to indicate the search is enabled.
4. Release CODESEARCH.
5. Press OFF/ON repeatedly until the device turns on.

6. Press CHANNEL V (channel down) for verification. DO NOT press any other buttons at this time.

    - If the channel changes on the device, the code is valid. Press ENTER to complete the search.

    - If the channel does not change, turn off the device (without attempting to use the remote). Then continue search by repeating steps 5-6. When all codes have been searched, the indicator light will flash twice and the remote will return to the normal mode.

(From: Aldrich TV, Inc. (aldrichtv@centuryinter.net).)

> "I find it works better if you have the unit on and watch for it to go off. It is easy to miss it coming on and then you have already passed the proper code and have to start over."

IR Items of Interest

Increasing the Range of a Remote Control or IR Data Link

For operation between rooms, a repeater is best - an IR receiver that sends the data over a cable to an IR transmitter in the other location. This would require an IR receiver module similar to the one found in a TV or VCR, buffer to drive the cable, and a IR transmitter modulated at the appropriate carrier frequency (around 40 kHz typically).

If extra distance or sensitivity is needed in the same room, it may not be too hard to replace the IR LEDs in the hand unit with more and/or higher power devices (though the IR LEDs used originally are generally quite powerful) but this would require some circuit hacking and possibly some reverse engineering of the design to determine what is possible. A small convex lens over the IR window on the receiver will help as well but will reduce the angle to the receiver over which response will be reliable. This would be suitable if you always use the equipment from a fixed location like a couch at the opposite end of the room.

Where the transmitter and receiver are both in restricted locations, a short focal length convex collimating lens can be added to the transmitter as well as the receiver. The angular coverage of both receiver and transmitter will be reduced but the range will increase. Reducing the beam divergence by a factor of 2 at the transmitter will increase the range by approximately a factor of 2. Doing this at the receiver as well will add another factor of 2. Several hundred feet should be possible with very inexpensive lenses. I would suggest a lens of around 1 inch diameter with a 1 inch focal length. This is not critical but an IR detector circuit or card should be used to help set up the proper distance to the transmitter IR LED and receiver photodiode.

Remote Remotes (Remote Extenders)

In some situations, it is desirable to be able to operate a remote controlled piece of equipment from another room - where a direct line-of-site path does not exist. One example of this would be to control a stereo receiver in the living room (which has speakers wired all over the house) from a bedroom.

There are a number of ways of implementing this:

1. RF - An IR receiver in the bedroom retransmits the codes over on a radio frequency carrier to an IR transmitter in the living room.

2. Hard-wired - An IR receiver in the bedroom converts the IR to TTL (or other electrical) pulses wired to an IR transmitter in the living room.

   Where at least one video cable exists between the two rooms, a variation on this theme uses a combination of the coax shield and earth ground to send the signal between the rooms.

3. House wiring - An IR receiver in the bedroom modulates a carrier injected into the AC wiring. An IR transmitter picks off the signal from the AC wiring.

In all cases, the IR receiver should be a module that includes automatic level control and generates a logic level output. If possible, it should NOT demodulate the IR signal so that the frequency of the carrier is maintained. The IR transmitter then only needs to convert this logic level to on-off IR pulses. Widgets based on all of these schemes are available commercially.

(From: Robert Scott (Robert.Scott@ncl.ac.uk).)

One of these circuits exists at:

- ftp://ftp.ee.ualberta.ca/pub/cookbook/optic/irrepeater.tar.Z

  (From: Francis VE2FGS (sonytech@videotron.ca).)

  I personally have small pyramids called "Powermid" made by X-10 which work fine.

  Those come by pair, one transmitter and one receptor. You plug them in 120 VAC wall outlet and it transmit signals between the two pyramids with FM signals. It work very fine and I think it's the most practical, cheap, and fast way to transmit IR signals from one room to another.

  I paid about $40 (Canadian) for the pair.

  ## Controlling TVs, VCRs, CDs, etc., From a PC

  (From: Donald Hoffman (dhoffman@epix.net).)

  I know of 2 links to such devices. Try:

  - The B.I.R.D. Computer Controllable Learning IR Remote

- The RedRat Infrared Remote Control for your PC

IR Signal Transmission and Coding

Modern remotes use a pulse code modulated carrier to send the command. Typical carrier frequencies vary between roughly 36 and 56 kHz (although rumor has it that Bang and Olefsun remotes may use 455 kHz for the actual IR carrier - I have not been able to confirm this). Each pulse or bit consists of multiple cycles (e.g., 32) of this carrier. Here are approximate measurements made of the general characteristics of some typical remotes:

Model	Carrier	Cycles/bit	Repeat rate
Emerson VCR	36 kHz	32	10 Hz
Mitsubishi VCR	38 kHz	10	20 Hz
Panasonic VCR	56 kHz	48	10 Hz
RCA TV	56 kHz	28	16 Hz
Sony CD	40 kHz	24/48	20 Hz
Sylvania TV	36 kHz	32	10 Hz
Technics CD	56 kHz	48	10 Hz
Toshiba VCR	38 kHz	20/320*	9 Hz
Yamaha receiver	38 kHz	20/320*	9 Hz

For buttons that repeat, typical rates are 10 to 20 Hz and the entire code may actually be sent only when the button is first pressed with only a 'repeat' code sent while it is held down. (* This extra length 'bit' was evident in the repeat code for the Toshiba VCR and Yamaha receiver - which both seemed to use very similar coding schemes. Repeat for all keys used a 320 cycle bit followed by an 80 cycle gap and a 20 cycle bit.) It would appear that various combinations of NRZ, RZ, PWM, and others are used depending on manufacturer and model. Think of the challenges involved in designing a universal remote!

The carrier frequency and coding schemes (these are even more varied than the table above would indicate) have apparently not been standardized. They may also vary quite a bit even different models of equipment from the same manufacturer. Therefore, it is beyond the scope of this document to enumerate them all. It is possible to see these types of waveforms with an oscilloscope by monitoring internal signals of the remote including certain pins on the controller IC as well as the IR LED or its driver or across the transistor of the IR detector circuit (see the section: IR Detector and Related Circuits).

Capturing Remote Control Codes

(From: Dez Ellis (dezellis@lineone.net).)

Check out ZipLabel.com Computerized Infrared Remote. They have a very cheap and cheerful method of obtaining IR codes. DOS software is provided for textual or binary capture of remote control codes. Windows software for the device is also linked to the site. The Windows software "Monster Clicker" allows you to create any number of virtual remote control functions. This software also has full Macro facilities. It is well worth a visit for the small amount of construction required this is an excellent option.

Links to IR Related Web Sites

The sites below have quite a bit of information on IR remote data transmission, coding schemes, various circuits. There are even tables of formats for the remotes from a number of manufacturers:

Finally, here is a site that appears to have a lot of more or less non-commercial info on medium to high end (they say) remote controls from various manufacturers including detailed coding and other technical details:

- Remote Central

- Back to IR Remote Repair FAQ Table of Contents.

IR Detector and Related Circuits

IR Detector Circuits

Two approaches are shown below.

1. The first uses a bare photodiode as the sensor. It is simpler, lower power, and shouldn't care what, if any, modulation is used by the IR source.

2. An IR detector module salvaged from a TV or VCR, or purchased from Radio Shack or elsewhere may be used instead of a photodiode. This will have a much greater dynamic range (response to both weak and powerful signals) than a simple photodiode. However, some of these assume a particular modulation frequency and will be blind to anything else. Power requirements may also be more restrictive - it may insist on regulated 12 V).

IR Detector Circuit Using Bare Photodiode

This IR Detector may be used for testing of IR remote controls, CD player laser diodes, and other low level near IR emitters. It will not have the sensitivity or dynamic range of the approach described in the section: IR Detector Circuit Using IR Receiver Module but will respond to all sources of IR falling within the wavelength range of the photodiode used since there is not demodulation or coupling circuitry to get in the way.

IR radiation falling on the photodiode causes current to flow through R1 to the base of Q1 switching it and LED1 on.

Component values are not critical. Purchase photodiode sensitive to near IR - 750-900 um or salvage from optocoupler or photosensor. Dead computer mice, not the furry kind, usually contain IR sensitive photodiodes. For convenience, use a 9V battery for power. Even a weak one will work fine. Construct the circuit so that the LED does not illuminate the photodiode!

The detected signal may be monitored across the transistor with an oscilloscope.

```
Vcc (+9 V) o-------+---------+
                   |         |
                   |         \
                   /         /  R3
                   \ R1      \  500
                   / 3.3K    /
                   \       __|__
                   |       _\_/_  LED1 Visible LED
                 __|__       |
       IR ---->  _/_\_ PD1   +--------o Scope monitor point
         Sensor    |         |            (low active)
       Photodiode  |     B |/ C
                   +-------|    Q1 2N3904
                   |       |\ E
                   \         |
                   / R2      |
                   \ 27K     |
                   /         |
                   |         |
      Gnd o--------+---------+--------o Gnd
                  _|_
                   -
```

IR Detector Circuit Using IR Receiver Module

This one uses an entire IR receiver module as the IR sensor. Its sensitivity and dynamic range will be much better than the circuit described in the section: IR Detector Circuit Using Bare Photodiode since these modules have automatic gain control circuitry built in. However, some modules are tuned to a particular modulation frequency and/or are AC coupled and will not respond to all remotes or other pulsed or continuous IR sources.

The IR receiver module from a TV, VCR, or purchased from Radio Shack or elsewhere, drives the base of Q1 through R1. It may even be possible to eliminate the transistor circuit entirely and connect the LED directly to the module's output (in series with a current limiting resistor to Vcc or Gnd) but that depends on the drive capabilities of the module. You can use whatever Vcc is required for the IR receiver module for the LED circuit as well but may need to change the value of R2 to limit the current to the LED to less than its maximum rating.

The specific case where Vcc is +5 V is shown.

```
                                R2
   Vcc (+5) o------+-----------/\/\--------+
                   |           220       __|__
                   |                     _\_/_  LED1 Visible LED
                   |                       |
                   |+                      +--------o Scope monitor point
```

```
         +----------+                |             (low active)

         +----------+                |
              |-                     |
   Gnd o------+----------------------+--------o Gnd
```

Steve's Instant IR Tester

(From: Steve Rice (punky@efortress.com).)

IR receiver diode (from scrap Penney's unit) attached to 18" single pair wires-passed through heavy-gauge straw (from some unknown latte drink in the early A.M.). RTV the tip to maintain rigidity. Positive end to plus end of 9 V battery. Negative end to 330 ohm 1/4 W resistor, and from there to display LED (I chose a pretty red one from the scrap box), and then back to negative of battery.

Time consumed: 2 hours. (1 hour to make sure the RTV was cured properly.)

Application to numerous remote control sources and to a couple of CD pickups provided nice glow from the indicator LED.

I just received a Fisher 25 disc unit for repair, and the above tester was instrumental in determining that over 12 IR emitters were functional. (Some of these were in locations otherwise very difficult to access.)

Some Alternative 'Quick and Dirty' Remote Testers

In addition to the IR detector circuits, IR detector card, and camcorder or video camera, here are a few other options:

(From: Raydon Berry (rayberry@pt.lu).)

Measure the current consumption from the batteries. Put the multimeter on a range of about 25 mA and when you press each button, the code being sent will show up as a wagging needle on a VOM or an average current for a DMM. If the ceramic filter or the IR diodes have failed, the current remains very low, but if OK, you should see pulses of 5 to 10 mA.

(From Malik (M.dad@mmu.ac.uk).)

> "If you have a IR remote TV in the workshop for testing VCRs and other video equipment, you can modify this so that audio can heard from the speaker which represents the IR signal.
>
> Simply couple the output of the IR receiver (in the TV) to the input of the audio output stage. Use a low value ceramic cap and a high value resistor, this should be possible on all remote TV's and will cost you next to nothing."

(From: ShyGuy4Yu (shyguy4yu@aol.com).)

> "Take a known good IR receiver from an old set. Supply proper DC to it. Feed the output into an audio amplifier. You can hear intermittent operation really well without squinting at test equipment. Put one on the counter for demo to customers.. Great!!"

(From: Sam).

What a nice idea! The only concern I would have is that not all IR transmitters use the same modulation frequency so I don't know how forgiving the demodulator in the IR receiver would be. Thus, you might think a remote control is bad when in fact it is just incompatible.

You could probably learn to recognize the codes by ear after a while as well! :-)

(From: Paul Grohe (grohe@galaxy.nsc.com).)

> "Here is a another "quick" and "very dirty" test of the IR emitter I have used:
>
> Clip a *glass* encased diode (1N34, 1N914, 1N4148, etc.) between your scope probe tip and ground clip. Crank the scope sensitivity up to about 20 tp 50mV/div. Hold the diode by the grounded lead (to reduce noise pickup).
>
> Point the "business" end of the remote directly at the clear part of the diode body. The IR packets will now be visible on the scope.
>
> You may have to move the remote around to find the "hot spot" in the window. The more of the diodes junction that is exposed, the better the response.
>
> A Sony remote generates about 50mVpp with a typical 1N4148/1N914 and more than 200mVpp with a "wide open" 1N34A point-contact Germanium (at 1 cm).
>
> BTW, the time constant of this setup may mask the actual 40kHz carrier pulses. Place a 100k resistor in parallel with the diode to see the individual pulses clearly (sensitivity *is* reduced).
>
> Or just simply hold the remote against an AM radio for a quick test."

(From: Sam)

And, Filip also suggested that last one so I will honor him as well. :-) Almost any sensitive amplifier may pick up some clicks from a working remote. A guitar or microphone amp may work for this. However, none of these indirect methods actually test the IR output but probably are accurate enough in most cases.

(From: Filip M Gieszczykiewicz (filipg@repairfaq.org).)

> "Simply hold a pocket AM radio or Walkman set on AM and push the buttons. This works for

> all the remotes I have.... except the ultrasonic one. :-)"

(From: Bob Quackenbush (quackenb@heidelberg-emh11.army.mil).)

> "Tune an AM radio to a quiet area of the band, hold the remote near the (normally internal) antenna, press and hold any key on the remote. The sound will be a quiet fluttering, so listen carefully. Be careful with your interpretation of the results. "No flutter" may NOT mean that the transmitter isn't working."

(From: David C. Brink (db@mcs.com).)

> "Just dissect the remote far enough to get access to the IR LED(s) leads (if the remote has been through the moving bits of the Lazy-Boy a few times, such disassembly might not even be necessary). Hold a LED in parallel with it and see if it lights when you press the remote buttons."

(From: Sam)

Note: Since the voltage drop across an IR LED is usually less than that across a visible LED, this may not work unless the remote uses two LEDs in series. In that case, substitution may be needed.

Introduction

Fluorescent Lamp Basics

The fluorescent lamp was the first major advance to be a commercial success in small scale lighting since the tungsten incandescent bulb. Its greatly increased efficiency resulted in cool (temperature wise) brightly lit workplaces (offices and factories) as well as home kitchens and baths. The development of the mercury vapor high intensity discharge (HID) lamp actually predates the fluorescent (the latter being introduced commercially in 1938, four years after the HID). However, HID type lamps have only relatively recently become popular in small sizes for task lighting in the home and office; yard and security area lighting; and light source applications in overhead, computer, and video projectors.

Fluorescent lamps are a type of gas discharge tube similar to neon signs and mercury or sodium vapor street or yard lights. A pair of electrodes, one at each end - are sealed along with a drop of mercury and some inert gases (usually argon) at very low pressure inside a glass tube. The inside of the tube is coated with a phosphor which produces visible light when excited with ultra-violet (UV) radiation. The electrodes are in the form of filaments which for preheat and rapid or warm start fixtures are heated during the starting process to decrease the voltage requirements and remain hot during normal operation as a result of the gas discharge (bombardment by positive ions).

When the lamp is off, the mercury/gas mixture is non-conductive. When power is first applied, a high voltage (several hundred volts) is needed to initiate the discharge. However, once this takes place, a much lower voltage - usually under 100 V for tubes under 30 watts, 100 to 175 volts for 30 watts or more - is needed to maintain it.

The electric current passing through the low pressure gases emits quite a bit of UV (but not much visible light). The gas discharge's radiation is almost entirely mercury radiation, although the gas mixture is mostly inert gas and generally around something like 1 percent mercury vapor. The internal phosphor coating very efficiently converts most of the UV to visible light. The mix of the phosphor(s) is used to tailor the light spectrum to the intended application. Thus, there are cool white, warm white, colored, and black light fluorescent (long wave UV) lamps. There are also lamps intended for medical or industrial uses with a special envelope such as quartz that passes short wave UV radiation. Some have an uncoated envelope, and emit short-wave UV mercury radiation. Others have phosphors that convert shortwave UV to medium wave UV.

(Caution: Some specialty UV lamps emit shortwave or medium wave UV which is harmful and should not be used without appropriate protection or in an enclosure which prevents the escape of harmful UV radiation.)

Fluorescent lamps are about 2 to 4 times as efficient as incandescent lamps at producing light at the wavelengths that are useful to humans. Thus, they run cooler for the same effective light output. The bulbs themselves also last a lot longer - 10,000 to 20,000 hours versus 750 to 1,000 hours for a typical incandescent. However, for certain types of ballasts, this is only achieved if the fluorescent lamp is left on for long periods of time without frequent on-off cycles.

Over the years, fluorescent lamps in approximately the shape of incandescent lamps with built-in ballasts have been evolving. These "compact fluorescent lamps" or CFLs have all of the advantages of ordinary fluorescent lamps but fit into most table lamps and incandescent fixtures. Phosphors have been improved to the point where the color is very similar to that of incandescent lamps. While the initial cost is high ($5 to $20), this is easily recovered several times over in the energy savings over the long life of the lamp due to the much higher efficiency (typically 4X) since most of the lifecycle cost of an incandescent is in the electricity used (typically $10 for power versus $0.50 for the lamp) and not the lamp itself.

Fluorescent Lamp Labeling

The actual fluorescent tubes are identified by several letters and numbers and will look something like 'F40CW-T12' or 'FC12-T10'.

So, the typical labeling is of the form FSWWCCC-TDD (variations on this format are possible):

- F - Fluorescent lamp. G means Germicidal shortwave UV lamp.
- S - Style - no letter indicates normal straight tube; C for Circline.
- WW - Nominal power in Watts. 4, 5, 8, 12, 15, 20, 30, 40, etc.
- CCC - Color. W=White, CW=Cool white, WW=Warm white, BL/BLB=Black light, etc.
- T - Tubular bulb.
- DD - Diameter of tube in of eighths of an inch. T8 is 1", T12 is 1.5", etc.

For the most common T12 (1.5 inch) tube, the wattage (except for newer energy saving types) is usually 5/6 of the length in inches. Thus, an F40-T12 tube is 48 inches long.

Safely Working with Fluorescent Lamps and Fixtures

There aren't many dangers associated with typical fluorescent lamps and fixtures:

- Electric shock. There is usually little need to probe a live fixture. Most problems can be identified by inspection or with an ohmmeter or continuity tester when unplugged.
  - Fluorescent lamps and fixtures using iron ballasts are basically pretty inert when unplugged. Even if there are small capacitors inside the ballast(s) or for RFI prevention, these are not likely to bite. However, you do have to remember to unplug the fixture before touching anything!

- However, those using electronic ballasts can have some nasty charged capacitors so avoid going inside the ballast module and it won't hurt to check between its outputs with a voltmeter before touching anything. Troubleshooting the electronic ballast module is similar to that of a switchmode power supply. See the document: Notes on the Troubleshooting and Repair of Small Switchmode Power Supplies

- Nasty chemicals: While the phosphors on the inside of fluorescent tubes are not particularly poisonous, there is a small amount of metallic mercury and contact with this substance should be avoided. If a tube breaks, clean up the mess and dispose of it properly and promptly. Of course, don't go out of your way to get cut on the broken glass!

And take care around sharp sheet metal!

Fluorescent Fixtures and Ballasts

Fluorescent Fixtures

The typical fixture consists of:

- Lamp holder - the most common is designed for the straight bipin base bulb. The 12, 15, 24, and 48 inch straight fixtures are common in household and office use. The 4 foot (48") type is probably the most widely used size. U shaped, circular (Circline(tm).) and other specialty tubes are also available.

- Ballast(s) - these are available for either 1 or 2 lamps. Fixtures with 4 lamps usually have two ballasts. See the sections below on ballasts. The ballast performs two functions: current limiting and providing the starting kick to ionize the gas in the fluorescent tube(s).

- Switch - on/off control unless connected directly to building wiring in which case there will be a switch or relay elsewhere. The power switch may have a momentary 'start' position if there is no starter and the ballast does not provide this function.

- Starter (preheat fixtures only) - device to initiate the electrode preheating and high voltage "kick" needed for starting. In other fixture types, the ballast handles this function.

Fluorescent Lamp Ballasts

For a detailed explanation, check your library. Here is a brief summary.

1. Provide the starting kick.

2. Limit the current to the proper value for the tube you are using.

In the old days fluorescent fixtures had a starter or a power switch with a 'start' position which is in essence a manual starter. Some cheap ones still do use this technology.

The starter is a time delay switch which when first powered, allows the filaments at each end of the tube to warm up and then interrupts this part of the circuit. The inductive kick as a result of interrupting the current through the inductive ballast provides enough voltage to ionize the gas mixture in the tube and then the current through the tube keeps the filaments hot - usually. You will notice that a few iterations are sometimes needed to get the tube to light. The starter may keep cycling indefinitely if either it or one of the tubes is faulty. While the lamp is on, a preheat ballast is just an inductor which at 60 Hz (or 50 Hz) has the appropriate impedance to limit the current to the tube(s) to the proper value.

Ballasts must generally be fairly closely matched to the lamp in terms tube wattage, length, and diameter.

There are two general types of ballast: Iron ballasts consist of a core, windings, and maybe a few other passive components like capacitors. Electronic ballasts are basically switching power supplies.

Types of Iron Ballasts

Preheat ballasts require starters or manual starting switches. Instant start, trigger start, rapid start, etc. ballasts include loosely coupled high voltage windings and other stuff which does away with the starter:

1. The ballast for a preheat fixture (combined with a starter or power switch with a 'start' position) is basically a series inductor. Interrupting current through the inductor provides the starting voltage.

2. The ballast for a rapid start fixture has in addition small windings for heating the filaments reducing the required starting voltage to 250 to 400 V. There are probably the most common types in use today. Trigger start fixtures are similar to rapid start fixtures.

3. The ballast for an instant start fixture has a loosely coupled high voltage transformer winding providing about 500 to 600 V for starting in addition to the series inductor. The electrodes of "instant start" bulbs are designed for starting without preheating. In fact, they are shorted out internally and are thus incompatible with preheat and rapid start ballasts (and they have only a single pin at each end!). The electrodes still emit electrons due to thermal emission but since they are shorted out cannot be pre-heated. That is why they require a higher starting voltage from the ballast. They they light instantly, but this slightly reduces lamp life.

Starting voltage is either provided by the inductive kick upon interruption of the current bypassed through the starter for (1) or a high voltage winding in (2) and (3).

In all cases, the current limiting is provided primarily by the impedance of the series inductance at 60 Hz (or 50 Hz depending on where you live).

(From: Vic Roberts (Vic@RobertsResearchInc.com).)

The most basic ballast is nothing more than a current limiting device, such as an inductor, resistor or capacitor. For 50 and 60 Hz applications, the most common current limiting device is an inductor.

A simple current limiter works best when the line voltage is at least 2 times the lamp voltage. So, a simple inductor can be used in Europe, where the line voltage is 220 to 240 VAC, to operate a 4 foot lamp, which operates at 85 to 100 volts, depending upon design.

In the US and other places that use 120 VAC lines the ballast is a combination autotransformer (to raise the voltage) and inductor (the current limiter).

In addition, a Rapid Start ballast has additional windings to supply about 3.6 VAC to heat the filaments.

(From: Asimov (Asimov@juxta.mn.pubnix.ten).)

A ballast is a simple transformer with a very high impedance secondary winding which makes its current self-limiting. It also has windings for each lamp filaments. At startup the filaments get most of the power and heat up to facilitate ionization.

Meanwhile the secondary builds up a very high EMF which finally fully ionizes the plasma between both filaments. At this point the effective resistance of the conducting plasma is quite low and the current flow is limited by the secondary's impedance. This also partially saturates the core and as consequence reduces power to the filaments.

The usual failure in ballasts is that the secondary's insulation deteriorates and it starts leaking to ground. Often because the proper wiring polarity was not observed. The secondary can thus no longer generate the high EMF required to start the plasma conducting.

The KISS test method is to use a known good lamp. If it lights, the ballast is good too. The ballast can also be tested with the power off by checking for continuity in the filament windings and a very high resistance to ground for each filament. Don't try this with power on!

(From: Craig J. Larson (larson@freenet.msp.mn.us).)

Call Magnetek, a ballast manufacturer on 1-800-BALLAST. Ask for a copy of their Troubleshooting & Maintenance Guide for Linear Fluorescent Lighting Systems. Its a nice little guide book for teaching you the basics.

Electronic Ballasts

These devices are basically switching power supplies that eliminate the large, heavy, 'iron' ballast and replace it with an integrated high frequency inverter/switcher. Current limiting is then done by a very small inductor, which has sufficient impedance at the high frequency. Properly designed electronic ballasts should be very reliable. Whether they actual are reliable in practice depends on their location with respect to the heat produced by the lamps as well as many other factors. Since these ballasts include rectification, filtering, and operate the tubes at a high frequency, they also usually eliminate or greatly reduce the 100/120 Hz flicker associated with iron ballasted systems. However, this is not always the case and depending on design (mainly how much filtering there is on the rectified line voltage), varying amounts of 100/120 can still be present.

I have heard, however, of problems with these relating to radio frequency interference from the ballasts and tubes. Other complaints have resulted due to erratic behavior of electronic equipment using infra red remote controls.

There is a small amount of IR emission from the fluorescent tubes themselves and this ends up being pulsed at the inverter frequencies which are sometimes similar to those used by IR hand held remote controls.

Some electronic ballasts draw odd current waveforms with high peak currents. This is due to the fact that these ballasts (low-power-factor type) have a full-wave-bridge rectifier and a filter capacitor. Current can only be drawn during the brief times that the instantaneous line voltage exceeds the filter capacitor voltage.

Because of the high peak currents drawn by some electronic ballasts, it is often important to size wiring properly for these high peak currents. For wiring heating and fuse/circuit considerations, one should allow for a current of 4 to 6 times the ratio of lamp watts to line volts. For wiring voltage drop considerations (drop in voltage the ballast's filter capacitor gets charged to), the effective current is even higher, sometimes as high as 15 to 20 times the ratio of the lamp watts to RMS line volts.

For less than 50 watts, the current drawn by low-power-factor electronic ballasts is usually not a problem. For multiple ballasts or total wattages over 50 watts, it may be important to consider the effective current drawn by low-power-factor electronic ballasts.

If you want to get an idea of some typical modern electronic ballast designs, see the International Rectifier web site. Search for 'electronic ballasts' or download the following reference design notes:

- Linear Ballast
- Compact Ballast

Two typical commercial electronic ballasts compact fluorescent lamps are shown in:

- CFL Electronic Ballast 1 (Techna-Bright EDXR-38-16).
- CFL Electronic Ballast 2 (General Electric FLE26HT3/2/SW).

For additional info on these as well as a variety of simple inverters to operate fluorescent lamps on low voltage DC, see the collection in the document: Various Schematics and Diagrams.

Comments on CFL Ballasts

(From: Tony (tonyreo@ameritech.net).)

I work in a R&D lab for a VERY large corporation. We design CFLs (Compact Fluorescent Lamps).

Today, 90 percent of CFLs are electronic ballasted lamps and they come in two basic varieties: (1) High power factors (somewhere between .9 and very close to 1) and (2) Low power factor (usually less than .6).

The high power factor lamps require more components (or from the corporations point of view, cost) so there are more low power factor lamps on the market than high power factor. From what I understand using either will not make a difference in what your electric meter reads and bills you for.

Our typical electronic ballast has two FETs that switch at anywhere from 75 kHz to 105 kHz. And actually we have one product that runs at 2.5 MHz. In the power input section we use a full wave bridge followed by a electrolytic capacitor with a value of anywhere from 10 uF to 47 uF depending on the design of the lamp. There are also a few other components here that reduce EMI (Electro Magnetic Interference) that could be conducted back into the AC line. All of the input components, collectively, will have a part in the input characteristics of the lamp.

One more note that you may find interesting relates to the starting time of CFLs. The CFLs that do not start instantly (pre-heat types) will have a longer life than the "instant start" type. The pre-heat systems heat the cathodes for 150 milliseconds to 1 second (or more) before the lamp is allowed to light. This increases the cathode life which is one of the main factors in lamp life.

Notes on Bllast Compatibility

Can a 30 W lamp be run on a 27 W ballast? What about a 22 W ballast?

The answer is an absolutely possibly qualified maybe. :)

Any fluorescent lamp is expected to run at some specific current to produce its rated light output and life. (There is also the issue of preheat, instant, and rapid start types but that's for another discussion!) At the rated current, there will be a certain voltage across the lamp. The voltage drop is related to tube diameter, length, filament type, and gas fill. It goes up with length but is not directly proportional to length. Being gas discharge devices, the impedance of a fluorescent lamp is negative - its voltage actually goes down with increasing current, thus the need for a ballast to limit the current. Some iron ballasts are rated to handle more than one size lamp maintaining a nearly constant current over a range of lamp voltages - 12, 15, and 20 W, for example. What this means is that the voltage drop across all these lamps is similar enough that the current will be nearly the same and/or the ballast has a magnetic shunt to provide a quasi-constant current characteristic over a range of voltages.

The typical ballast will list compatible lamp types and wattages on its label. Wattage, starting type, and lamp diameter are all critical. With all the variations in lamps, there's no hard and fast rule that will determine whether a non-listed combination will work or even be safe. A higher wattage lamp may run and even be easier on the ballast since with its higher voltage drop, it will draw less current. Of course, there will also be less than rated light output. However, if the incompatibility is great enough, it may flicker, cycle on and off, or not start at all. A lower wattage lamp may burn out quickly and/or cause either type of ballast to overheat and fail.

Where the rated lamp current is known or where the same lamp could be run on a compatible ballast, it might be possible to measure the current with the ballast combination being tested to determine if it is acceptable. However, this is clearly above and beyond what is normally required when changing a light bulb. :)

Fluorescent Fixture Wiring Diagrams

The following wiring diagrams are typical of fluorescent fixtures using iron ballasts. These do NOT generally apply directly to fixtures using electronic ballasts.

Wiring for Preheat Fluorescent Fixtures

The following is the circuit diagram for a typical preheat lamp - one that uses a starter or starting switch.

```
              Power Switch    +-----------+
 Line 1 (H) o------/ ---------|  Ballast  |-----------+
                              +-----------+           |
                                                      |
                      .---------------------------.   |
 Line 2 (N) o---------|-       Fluorescent      -|----+
                      | )         Tube         ( |
                  +---|-  (bipin or circline)   -|----+
                  |   '---------------------------'    |
                  |                                   |
                  |          +-------------+          |
                  |          |   Starter   |          |
                  +----------| or starting |----------+
                             |   switch    |
                             +-------------+
```

Where a three position switch (OFF-ON-START) is used to control the fixture (e.g., those circular magnifier lamps), there will be two pairs of contacts: One pair (Power) is connected in the ON and START positions, and the other (Start) is connected only in the START position. They are isolated from each-other.

```
              Power Switch    +-----------+
 Line 1 (H) o------/ ---------|  Ballast  |-----------+
              Closed for ON   +-----------+           |
                and START                             |
                                                      |
                      .---------------------------.   |
 Line 2 (N) o---------|-       Fluorescent      -|----+
                      | )         Tube         ( |
                  +---|-  (bipin or circline)   -|----+
                  |   '---------------------------'    |
                  |                                   |
                  +--------------o/ o-----------------+
                          Starting contacts (Closed for START only)
```

Here is a variation that some preheat ballasts use. This type was found on a F13-T5 lamp fixture. Similar types are used for 30 and 40 watt preheat lamps. This 3-lead preheat ballast is a voltage-boosting "high leakage reactance autotransformer" used if the voltage across the tube is much over approx. 60 percent of the line voltage. For technical details on why a fluorescent lamp will not work with ordinary ballasts if the tube voltage is only slightly less than the line voltage, look at Don Klipstein's Discharge Lamp Mechanics document.

```
              Power Switch   +-------------+
Line 1 (H) o------/ --------|A  Ballast   |
                 +----------|B          C|----------+
                 |          +-------------+          |
                 |                                   |
                 |   .---------------------------.   |
Line 2 (N) o-----+---|-       Fluorescent      -|----+
                     | )         Tube         ( |
                 +---|-  (bipin or circline)   -|----+
                 |   '---------------------------'   |
                 |                                   |
                 |          +-------------+          |
                 |          |   Starter   |          |
                 +----------| or starting |----------+
                            |   switch    |
                            +-------------+
```

Fluorescent Starter Operation

Starters may be either automatic or manual:

- Automatic - The common type are called a 'glow tube starter' (or just starter) and contains a small gas (neon, etc.) filled tube and an optional RFI suppression capacitor in a cylindrical aluminum can with a 2 pin base. While all starters are physically interchangeable, the wattage rating of the starter should be matched to the wattage rating of the fluorescent tubes for reliable operation and long life.

  The glow tube incorporates a switch which is normally open. When power is applied a glow discharge takes place which heats a bimetal contact. A second or so later, the contacts close providing current to the fluorescent filaments. Since the glow is extinguished, there is no longer any heating of the bimetal and the contacts open. The inductive kick generated at the instant of opening triggers the main discharge in the fluorescent tube. If the contacts open at a bad time - current near zero, there isn't enough inductive kick and the process repeats.

  Higher-tech replacements called 'pulse starters' may be available for the simple glow tube type starter. These devices are pin compatible devices and contain a bit of electronics that detect the appropriate time to interrupt the filament circuit to generate the optimal inductive kick from the ballast. So, starting should be more reliable with few/no blink cycles even with hard-to-start lamps. They will also leave used-up tubes off, without letting them blink annoyingly.

  A defective or incorrect starter is a common cause of erratic starting and possibly random restarts during operation.

- Where a manual starting switch is used instead of an automatic starter, there will be three switch positions - OFF, ON, START:

    - OFF: Both switches are open.
    - ON: Power switch is closed.
    - START (momentary): Power switch remains closed and starting switch is closed.

  When released from the start position, the breaking of the filament circuit results in an inductive kick as with the automatic starter which initiates the gas discharge.

Wiring for Rapid Start and Trigger Start Fixtures

Rapid start and trigger start fixtures do not have a separate starter or starting switch but use auxiliary windings on the ballast for this function.

The rapid start is now most common though you may find some labeled trigger start as well.

Trigger start ballasts seem to be used for 1 or 2 small (12-20 W) tubes. Basic operation is very similar to that of rapid start ballasts and the wiring is identical. "Trigger start" seems to refer to "rapid starting" of tubes that were designed for preheat starting.

The ballast includes separate windings for the filaments and a high voltage starting winding that is on a branch magnetic circuit that is loosely coupled to the main core and thus limits the current once the arc is struck.

A reflector grounded to the ballast (and power wiring) is often required for starting. The capacitance of the reflector aids in initial ionization of the gases. Lack of this connection may result in erratic starting or the need to touch or run your hand along the tube to start.

A complete wiring diagram is usually provided on the ballast's case.

Power is often enabled via a socket operated safety interlock (x-x) to minimize shock hazard. However, I have seen normal (straight) fixtures which lack this type of socket even where ballast labeling requires it. Circline fixtures do not need an interlock since the connectors are fully enclosed - it is not likely that there could be accidental contact with a pin while changing bulbs.

Wiring Diagram for Single Tube Rapid or Trigger Start Ballast

Below is the wiring diagram for a single lamp rapid or trigger start ballast. The color coding is fairly standard. The same ballast could be used for an F20-T12, F15-T12, F15-T8, or F14-T12 lamp. A similar ballast for a Circline fixture could be used with an FC16-T10 or lamp FC12-T10 (no interlock).

```
             Power Switch    +----------------------------+
 Line 1 (H) o----/ ----------|Black   Rapid/Trigger       |
                      +------|White       Start       Red|------+
                      |  +---|Blue       Ballast      Red|---+  |
```

```
                     |  |   +-------------+-------------+   |  |
                     |  |                 |                 |  |
                     |  |        Grounded | Reflector       |  |
                     |  |       ----------+----------       |  |
                     |  |    .-------------------------.    |  |
                     |  +----|-      Fluorescent      -|----+  |
                     +------x| )         Tube        ( |       |
Line 2 (N) o----------------x|-  (bipin or circline)  -|-------+
                             '-------------------------'
```

Wiring Diagram for Two Tube Rapid Start Ballast

The following wiring diagram is for one pair (from a 4 tube fixture) of a typical rapid start 48 inch fixture. These ballasts specify the bulb type to be F40-T12 RS. There is no safety interlock on this fixture. (A similar scheme could also be used on a dual tube Circline fixture though slightly different ratings may be needed for each tube since they would be of different sizes.)

```
            Power Switch    +--------------------------+
Line 1 (H) o----/ ----------|Black    Dual Tube     Red|-----------+
Line 2 (N) o----------------|White      Rapid       Red|--------+  |
                      +-----|Yellow     Start      Blue|-----+  |  |
                      |  +--|Yellow    Ballast     Blue|--+  |  |  |
                      |  |  +-------------+------------+  |  |  |  |
                      |  |                |               |  |  |  |
                      |  |       Grounded | Reflector     |  |  |  |
                      |  |      ----------+----------     |  |  |  |
                      |  |    .----------------------.    |  |  |  |

Schematic of Typical Rapid/Trigger Start Single Lamp Ballast

This ballast is marked "Trigger Start Ballast for ONE F20WT12, F15WT12, F15WT8, or F14WT12 Preheat Start Lamp. Mount tube within 1/2" of grounded metal reflector". (Note that while labelled "Trigger Start", it does heat the filaments so I assume it is similar or identical to a rapid start ballast.)

Voltages were measured with no bulb installed with safety interlock bypassed.

Internal wiring has been inferred from resistance and voltage measurements.

The lossy autotransformer boosts line voltage to the value needed for reliable starting with the filaments heated. It is assumed that part of the magnetic circuit is loosely coupled so that putting the lamp between Red/Red and Blue/White results in safe current limited operation once the arc has struck.

A complete fixture wiring diagram like those shown in the section: [Wiring for Rapid Start and Trigger Start Fixtures](#) will probably be provided on the label.

Numbers in () are measured DC resistances.

Schematic for Rapid Start Ballast with Isolated Secondary

As noted, rapid start fixtures do not have a separate starter or starting switch but use auxiliary windings on the ballast for this function. Here is the schematic for a typical 1-tube rapid start fixture including the internal wiring of the ballast.

This ballast includes separate windings for the filaments and a high voltage winding that is on a branch magnetic circuit that is loosely coupled and thus limits the current once the arc is struck. It is not known if this design is common. The isolated secondary and separate high voltage winding would make it more expensive to manufacture.

A complete fixture wiring diagram like those shown in the section: Wiring for Rapid Start and Trigger Start

Fixtures will probably be provided on the label.

         Loose magnetic coupling in the ballast core results
         in leakage inductance for current limiting.
```

Schematic of Rapid Start Dual Lamp Ballast

This ballast is marked "Rapid Start Ballast for TWO F40WT12 Lamps. Mount tubes within 1/2" of grounded metal reflector". This circuit was derived from the measurements listed in the section: Measurements of a Dual Tube Rapid Start Ballast.

The autotransformer boosts line voltage to the value needed for reliable starting with the filaments heated. The series capacitor of approximately 4 uF is used instead of leakage inductance to limit current to the tubes. Leakage inductance from loose magnetic coupling is used to smooth the waveform of current flowing through the tubes. The .03 uF capacitor provides a return path during starting to the yellow filament winding but is not really used during normal operation.

Numbers in () are approximate measured DC resistances.

Measurements of Dual Tube Rapid Start Ballasts

One is a Universal, the other is a Valmont.

(Measurements made with Radio Shack multimeter)

Resistance:

Measurement	Universal	Valmont
White-Black	13	13
Between blues	.5	.55
Between reds	.5	.55
Between yellows	.5	.6
Black to closer blue	<.1	<.1
Blue-red	open	open
Blue-yellow	open	5 M
Red-yellow	open	20 M

Capacitance:

```
  Blue-red                                ~4 uF               ~3.5 uF
  Blue-yellow                           ~.03 uF
  Red-yellow                            ~.03 uF

Primary current, (not true RMS), various secondary load conditions:

  Secondary open                         .32 A                 .35 A
  60W 120V incandescent bulb             .75 A                 .63 A
  Short                                  .48 A                 .53 A

Heater voltage:                   not measured    approx. 8 V, unsteady
                                                  surprisingly independent
                                                  of secondary load
```

Open circuit output voltage voltage (from one red wire to one blue one, highest reading of four combinations):

```
  Red-Blue                              270 V                  275 V
```

Fluorescent Lamps in Series?

This is not possible where line voltage is 105 to 125 VAC because this is not sufficient to sustain the discharge where two lamps are in series. Special dual lamp ballasts are required.

However, where the line voltage is 220 VAC, it is possible:

(From: andrew@cucumber.demon.co.uk (Andrew Gabriel))

Here in UK (and probably all 220 to 250 V areas), this is common:

```
                    =======
        L o---+-----^^^^^^^-------+ +-----+
              |     Ballast       | |     |

              |                  |   |   +-+
              |           Tube 1 |   |   |S| Glow Starter
              |                  |   |   +-+
              |                  | - |    |
              |                  +|-|+    |
              |                   | |     |
             _|_ Power Factor     | +-----+
             ___ Correction       |
              |  Capacitor        | +-----+
              |                   | |     |
```

```
            |                  +|-|+     |
            |                  | - |     |
            |                  |   |    +-+
            |           Tube 2 |   |    |S| Glow Starter
            |                  |   |    +-+
            |                  | - |     |
            |                  +|-|+     |
            |                   | |      |
      N o---+-------------------+ +------+
```

Note that starters for a 230 VAC two tube fixture may NOT be the same as those for a 230 VAC single tube fixture. Installing single tube starters in a two tube fixture may result in no action at all since their breakdown voltage may be too high. Doing the reverse may result in damage.

Fluorescent Lamps in Parallel?

Like most gas discharge tubes, fluorescent lamps are negative resistance devices. Therefore, it isn't possible to put more than one lamp in parallel and get them both to light - additional components are needed. The following applies mostly to magnetic ballasted fixtures. Where electronic ballasts are used, all sorts of games can be played to implement wierd configurations!

Multiple lamp fixtures in countries with 110 VAC power usually have special ballasts with separate windings for this purpose. Where 220 to 240 VAC is available, it may be possible to put multiple lamps in series with individual starters. See the section: Fluorescent Lamps in Series?.

However, there is at least one application where putting two lamps is parallel makes sense: light fixtures in hard-to-reach or safety-critical areas where redundancy is desirable. With only minor modifications at most, a conventional single lamp ballast can be connected to a pair of lamps in such a way that only one will light at any given time. (Which one actually starts could be random without additional circuitry, however.) If either lamp burns out or is removed, the other will take over. The ballast must provide enough power to the filaments for starting but once started, the lamp that is on will operate normally and there should be no degradation in performance or expected lamp life (except to the extent that the unlit lamp's filaments might be kept hot).

The following is just a suggestion - I have not confirmed if or with which model ballasts these schemes will work!

For rapid start ballasts, this could be as simple as wiring all connections to the lamps in parallel - if the ballast has enough current available to power both sets of filaments for starting. For trigger start ballasts, the filament power is not an issue so it should be even easier:

```
             Power Switch   +----------------------------+
 Line 1 (H) o----/ ---------|Black   Rapid/Trigger       |
                      +-----|White       Start        Red|--------+
                      |  +--|Blue       Ballast       Red|-----+  |
                      |  |  +--------------+-------------+     |  |
```

```
                      |  |                 |                  |  |
                      |  |                 +---------------+  |  |
                      |  |       Grounded  | Reflector     |  |  |
                      |  |       ----------+----------     |  |  |
                      |  |    .-------------------------.  |  |  |
                      |  +----|-     Fluorescent       -|--|--+  |
                      |  |    | )       Tube          ( |  |  |  |

                      |  +----|-      Fluorescent      -|-----+  |
                      |       | )        Tube         ( |        |
 Line 2 (N) o---------+-------|-  (bipin or circline)  -|--------+
                              '------------------------'
```

Note: The interlock normally present on most rapid/trigger start fixtures have been removed to permit one lamp to operate if other is removed.

For preheat ballasts, wiring the filaments in parallel would probably result in insufficient current to either lamp for it to start reliably. If the filaments were wired in series, one lamp would probably start, but if the filament of one lamp burned out or the lamp was removed, the fixture would cease to function kind of defeating the purpose of these gyrations!

Wiring Fluorescent Lamps to Remote Ballasts

For reasonable distances, this should work reliably and be safe provided that:

1. This is only attempted with iron ballasts. The fire safety and reliability of electronic ballasts that are not in close proximity to the lamps is unknown. The ballast may fail catastrophically either immediately or a short time later as the circuit may depend on a low impedance (physically short) path for stability.

   In addition, there will almost certainly be substantial Radio Frequency Interference (RFI) created by the high frequency currents in the long wires. The FCC police (or your neighbors) will come and get you! This may be a problem with iron ballasts as well - but probably of less severity.

2. Wire of adequate rating is used. The starting voltage may exceed 1 kV. Make sure the insulation is rated for at least twice this voltage. Use 18 AWG (or heavier) gauge wire.

3. There is no possibility of human contact either when operating or if any connectors should accidentally come loose - dangerous line voltage and high starting voltage will be present with tubes disconnected.

Note: one application that comes up for this type of remote setup is for aquarium lighting. My recommendation would be to think twice about any homebrew wiring around water. A GFCI may not help in terms of shock hazard and/or may nuisance trip due to inductive nature of the ballast (both depend at least in part on ballast design).

Wiring diagram of Low Power 220 VAC Fluorescent Lamp

(From: Manuel Kasper (mk@mediaklemm.com).)

The circuit in Low Power 220 VAC Fluorescent Lamp is from an AC line powered 'light stick'. So there's no fancy inverter circuit inside, but a simple ballast without any nasty coils - just capacitors, resistors, and diodes. A few modifications would probably be necessary to make it operate from 110 VAC. It runs the tube brighter than a similar lamp power from a 12 V inverter. (See the section: "Automotive Light Stick Inverter" in the document: Various Schematics and Diagrams. FWIW, the brand is "Brennenstuhl".

It was damn hard to open up because everything was made out of thick plastic with no screws (no wonder; it cost $6) - but thanks to a huge saw I managed to get at the guts without destroying the tube or the circuit.

Alternatives to Commercial Iron Ballasts?

While the circuit diagrams of iron ballasts may resemble those of common power transformers, I wouldn't recommend attempting to use these as ballasts unless you really know how to implement controlled impedance behavior in a non-current limited transformer. Ballasts are rather special and unless you are willing to blow a lot of fluorescent lamps, transformers, fuses, and circuit breakers, just go with commercial ballasts. :)

Even for small lamps using a glow starter or separate starting switche, while it's certainly possible to use an ordinary inductor rather than something labeled "ballast", it's still probably not a good idea from fire safety and liability considerations.

- Back to Sam's F-Lamp FAQ Table of Contents.

Specialty Fluorescent Lamp Types

All Sorts of Less Conventional Lamps

In addition to the boring white ones (OK, well 'white' does come in various colors!), other interesting types of lamps include all sorts of real colors (red, green, blue, yellow), blacklight lamps, germicidal lamps in which there is no phosphor coating at all and a quartz tube to transmit short-wave UV light (e.g., EPROM erasers and PCB photoresist activation), sunlamps, plant lights and special purpose specific wavelength lamps such as reprography and copier lamps.

The basic technology is extremely flexible!

(From: Bruce Potter (s602531@aix2.uottawa.ca).)

There are also High Output and Very High Output types of lamps that have a discharge current of 0.8 A and 1.5 A instead of the standard 0.3 A. HO and VHO lamps are used when high light output is desired but are being outmoded by HID lamps like metal halide.

Blacklight Fluorescent Lamps

(From: Don Klipstein (don@misty.com).)

BL in the tube designation (e.g., F40T12BL) means "blacklight", which is a fluorescent lamp with a phosphor that emits the longest largely invisible UV wavelengths that are both efficiently and fairly cheaply possible. This phosphor seems to emit a band of UV mainly from 350 to 370 nanometers, in the UV-A range.

BLB means "blacklight-blue", which differs from "blacklight" only in that the glass tube of this lamp is darkly tinted with something with a dark violet-blue color to absorb most visible light. Most UV gets through this, along with much of the dimly visible deep-violet 404.7 nanometer line of mercury. Most of the violetish-blue 435.8 nanometer line is absorbed, but enough of this wavelength gets through to largely dominate the color of the visible light from this lamp. Longer visible light wavelengths do not significantly penetrate the BLB's very deep violet-blue glass, which is known as 'Wood's glass'. The UV is the same as that of the BL lamp, being mostly between 350 and 370 nanometers.

There is a 350BL blacklight lamp, using a different phosphor that emits a band of slightly shorter UV wavelengths in the UV-A range. The reasoning for this lamp is that it is supposedly optimized for attracting insects. These lamps are one variety of UV lamps used in electric bug killers.

There are other UV fluorescent lamps. There are at least two different UV/deep violet emitting fluorescent lamps used mainly in the graphic arts industry, emitting mainly wavelengths between 360 and 420 nanometers. Possibly one of these is also used in bug killers. I have noticed one kind of UV fluorescent lamp for bug killers with a broadish band phosphor with significant output from the 360 nanometer range (maybe also shorter) into visible wavelengths around 410 to 420 nanometers or so.

There is an even shorter UV-A lamp used for suntanning purposes. I would guess the phosphor emits mainly within the 315 to 345 nanometer range. One brand of such lamps is "Uvalux".

There is even a UV-B emitting fluorescent lamp. Its phosphor emits mostly at UV-B wavelengths (286 to 315 nanometers). It is used mainly for special medicinal purposes. Exposing skin to UV-B causes erythema, which is to some extent a burn reaction of the skin to a slightly destructive irritant. Use of UV-B largely limits this to outer layers of the skin (perhaps mainly the epidermis) and to parts of the body where skin is thinner. UV-A wavelengths just over 315 nanometers can also cause sunburn, but they are more penetrating and can affect the dermis. Please note that the deadliest varieties of skin cancer usually originate in the epidermis and are usually most easily caused by UV-B rays.

There are clear UV-emitting lamps made of a special glass that lets through the main shortwave UV (UV-C) mercury radiation at 253.7 nanometers. These lamps are marketed as germicidal lamps, and ones in standard fluorescent lamp sizes have part numbers that start with G instead of F. These lamps will work in standard fluorescent lamp fixtures.

Cold-cathode germicidal lamps are also in use; these somewhat resemble "neon" tubing.

Be warned that the shortwave UV emitted by germicidal lamps is intended to be dangerous to living cells and is hazardous, especially to the conjunctiva of eyes. Signs of injury by the UV are often delayed, often first becoming apparent several minutes after exposure and peaking out a half hour to several hours afterwards.

Please note that non-fluorescent (high pressure mercury vapor discharge) sunlamps generally emit more UV-B rays rather than the tanning-range UV-A rays. These lamps do have substantial UV-A output, but mainly at a small cluster of wavelengths around 365 nanometers. Tanning is most effectively accomplished by wavelengths in the 315-345 nanometer range. In addition, no UV suntanning is completely safe.

Compact Fluorescent Lamps

These are miniaturized fluorescent lamps that usually have premium phosphors which often come packaged with an integral ballast (either iron or electronic). They typically have a standard screw base that can be installed into nearly any table lamp or lighting fixture that accepts an incandescent lamp.

Compact fluorescent Lamps (CFLs) are being heavily promoted as energy savings alternatives to incandescent lamps. They also have a much longer life - 6,000 to 20,000 hours compared to 750 to 1,000 hours for a standard incandescent. While these basic premises are not in dispute, before replacing all the incandescent lamps in your house with CFLs, that there are some disadvantages and quirks:

1. CFLs are often physically larger than the incandescent bulbs they replace and simply may not fit the lamp or fixture conveniently or at all. However, they are getting smaller as the technology matures.

2. The funny elongated or circular shape may result in a less optimal lighting pattern.

3. The light is generally cooler - less yellow - than incandescents - this may be undesirable and result in less than pleasing contrast with ordinary lamps and ceiling fixtures. Newer models have been addressing this issue and color temperature of some are now very close to incandescent lamps.

4. Some types (usually iron ballasts) may produce an annoying 120 Hz (or 100 Hz) flicker.

5. Ordinary dimmers cannot be used with compact fluorescents and may result in immediate destruction of the CFL.

   In addition, CFLs should not be used with illuminated switches, electronic timers, or any other means of control that results in a small current in series with the lamp when it is supposed to be off. With some electronic ballast designs, the small current will slowly charge a filter capacitor inside the CFL until it reaches a critical threshold, at which point the lamp will flash on momentarily - perhaps every 5 seconds. This may be kind of cool and may not damage the CFL (at least not immediately) but probably isn't the intended effect in your home. :) For illuminated switches, the switch won't be affected (though it may pulse synchronously with the cycle of the flashing CFL), but for timers and the like, the non constant current is likely to result in erratic behavior if not actual damage to the control device.

6. Light output may depend somewhat on mounting orientation.

7. Some CFLs come on instantly while others may have a delay of a up to a second or more where nothing

appears to happen. They generally go off instantly. There characteristics may be annoying to anyone used to normal incandescent desk lamp behavior where which has a small but noticeable (and expected) delay as the filament heats or cools.

8. There will usually be a warmup time of a few seconds to a minute or more before full light output is produced even in warm temperatures.

9. Light output will decline slightly over the course of the life of the CFL.

10. Like other fluorescents, operation at cold temperatures (under around 50 to 60 °F) may result in reduced light output. Starting may also be erratic, although most compact fluorescent lamps seem to start OK at temperatures near freezing. Many types start OK near zero °F. Operation in an enclosed fixture often results in full light output in cool surroundings after the lamp warms up for a few minutes, as long as the initial temperature is high enough to permit a good start. However, enclosing compact fluorescents often impairs their ability to work well at higher temperatures.

11. CFLs should not be use in an unenclosed fixture outdoors since the electronics are really not always well protected. There may be additional specific environmental limitations stated on the package.

12. There may be an audible buzz from the ballast, especially the iron type.

13. CFLs may produce Radio Frequency Interference (RFI).

14. While their rated life may be 6,000 to 20,000 hours, a wayward baseball will break one of these as easily as a 25 cent incandescent as I've found out - but that's how I was able to trace the ballast schematics!

The prices of CFLs are dropping and $5 or $6 for one that does a decent job of replacing a 100 W incandescent lamp (in terms of color, light output, and fit) is now common. Depending on the cost of electricity in your area, these should pay for themselves over the number of hours equivalent to the lifetime of 1 to 2 incandescent lamps.

As an example, in 750 hours, a typical 26 W (consumed) CFL with a light output of 1,700 lumens (similar to a 100 W soft white incandescent) will use 19.5 kWh, compared to 75.0 kWh for the incandescent. At 10 cents/kWh, this represents a saving of $5.55. Add in $0.50 for the cost of the incandescent lamp and it's already just about break-even for a $6 CFL. And, most of the life of the CFL and continued savings on electricity lies ahead. With special discounts and promotions, CFL prices may be even lower resulting in quicker pay-back periods.

Identify locations where lamps or fixtures are left on for a significant number of hours on average per day. Or equivalently, where it seems you are always replacing bulbs (but they are actually lasting for their rated life, not burning out due to vibration or bad connections). It doesn't make sense to put a CFL in a closet or attic which isn't used much. Even a bathroom is typically a marginal location. Go for CFLs that will fit physically and and where their color and appearance is acceptable. Home centers may have better prices than corner hardware stores but not always. Shop around before buying (or at least before buying a bushel).

For more information, see the separate document on Compact Fluorescent Lamps.

If you're into recycling electronics to other uses, see Andrew Gabriel's D.I.Y. Electronic Gear Page for taking the electronic ballasts from compact fluorescents that died due to lamp failure and using them to drive normal fluorescent lamps as well as remotely connected CF lamps.

(From: Victor Roberts (Vic@RobertsResearchInc.com).)

One big difference between the low cost electronic ballasts designed for integral CFLs and the higher cost ballasts designed to be used with plug-in CFLs or linear fluorescent lamps, is that the former are usually not designed to survive if the lamp does not light or is not present. After all, for an integral system, once the lamp dies there is no reason why the ballast cannot also burn out. One reason external electronic ballasts are more expensive than the electronic ballasts used in integral CFLs is that external ballasts are designed to survive if the lamp does not light or is not present.

If you "harvest" an electronic ballast from an integral CFL, in addition to making sure you know what you are doing so you don't kill yourself or someone else, make sure that you never operate the ballast without a operating lamp attached. If you do, the ballast will most likely burn out in less than a few seconds.

Cold Weather Fluorescent Lamps

(From: Bruce Potter (s602531@aix2.uottawa.ca).)

There are special lamps with heavy glass jackets and/or with krypton gas filling for cold weather/freezer applications. They work best at below room-temperatures. It really annoys me when I go to the grocery store or see outside installations with dim, flickering tubes! What a waste of electricity!

Fluorescent Lamps which Operate from Low Voltage DC

These are now found in all sorts of equipment including laptop computers and all many other portable high tech devices to camping lanterns, boats, and RVs, All are based on an electronic ballast that converts the low voltage DC (anywhere from 3 V to 24 V depending on application) to high frequency high voltage AC to operate the fluorescent tube(s). Laptop computers and similar devices use special narrow tubes designed specifically to be run without heated filaments (cold cathode operation) and very narrow envelops to fit into very thin spaces. :) Most of the others use conventional fluorescent tubes and may or may not drive the filaments during starting or at any other time.

The ballasts for these lamps must generate the required voltages to start and operate the lamps reliably as well as to assure long life. See the section: Electronic Ballasts for more info and some links to sample circuits.

Troubleshooting of Fluorescent Lamps and Fixtures

Problems with Fluorescent Lamps and Fixtures

In addition to the usual defective or damaged plugs, broken wires in the cord, general bad connections, fluorescent lamps and fixtures have some unique problems of their own. The following assumes a lamp or fixture with a conventional iron (non-electronic) ballast. Always try a new set of fluorescent tubes and starter (where used) before considering other possible failures.

If two tubes dim or flicker in unison, this means that both are powered by the same ballast. Often this means that one tube has failed, although the other tube may also be in poor condition or approaching the end of its life. Both tubes must be replaced with known good tubes in order to rule out a defective ballast.

1. Bad fluorescent tubes. Unlike incandescent lamps where a visual examination of the bulb itself will often identify a broken filament, there is often no way of just looking at a fluorescent tube to determine if it is bad. It may look perfectly ok though burned out fluorescents will often have one or both ends blackened. However, a blackened end is not in itself always an indication of a bad tube. Blackened ends are a somewhat reliable means of identifying bad tubes in 34 or 40 watt rapid start fixtures. Blackened ends are not as reliable an indicator in preheat or trigger start fixtures, or for tubes of 20 watts or less.

   Failure of the electrodes/filaments at one or both ends of the the fluorescent tube will usually result in either a low intensity glow or flickering behavior, or sometimes in no light at all. A broken filament in a fluorescent tube used in a preheat type fixture (with a starter) will almost always result in a totally dead lamp as there will be no power to the starter. A dim glow is rare in this case and would probably be confined to the region of the broken filament if it occurs. The best approach is to simply try replacing any suspect tubes - preferably both in a pair that are driven from a single ballast.

   One end glowing bright orange means the tube is dead - the filament has lost its electron-emitting coating. A working filament at that temperature will emit enough electrons to cause a discharge around it which will make the phosphor glow at that end (even without any voltage across the tube). The electron-emitting coating is normally to be found at this stage coating the inside of the glass, resulting in black tube ends.

   Before such complete failure, while the coating on one filament is much less effective that the other, this results in asymmetric current flow and 50/60 Hz flicker. This can have a bad psychological effect on people (even if they are not actually aware of the flicker), and is very bad news for anyone susceptible to epilepsy (50 Hz supplies are probably worse in this respect).

   In fixtures where a rapid start ballast runs two tubes, both tubes will go out when one fails. Sometimes one or both tubes will glow dimly and/or flicker. If one tube glows dimly and the other is completely dead, this does not indicate which tube has failed. The brighter tube may be the good one or the bad one. The bad tube usually has noticeable blackening at one end. It may pay to replace both tubes, especially if significant labor costs are involved. Also, prolonged dim-glowing may degrade the tube that did not initially fail.

   In trigger start fixtures that use one ballast to power two 20 watt tubes, sometimes both tubes will blink or intermittently dim. Replacing either tube with a known good tube may fail to fix this. The tubes may continue blinking or intermittently dimming until both are replaced with brand new tubes. This sometimes indicates borderline low line voltage ("brownout", etc.), nonideal temperatures, or a borderline (probably cheaply designed) ballast.

A simple test that will confirm that a tube is bad is to check the continuity between the pair of pins at each end. If either set are open, the tube is guaranteed bad if used in a preheat or rapid start fixture. It might still work in an instant or trigger start fixture. However, if there is continuity, the tube could still be bad as noted above.

2. Bad or incorrect starter (preheat fixtures only). The little starter can may go bad or be damaged by faulty fluorescent tubes continuously trying to start unsuccessfully. It is a good idea to replace the starter whenever tubes are replaced in these types of fixtures. One way that starters go bad is to "get stuck". Symptoms of this are the ends of the affected tube glowing, usually with an orange color of some sort or another but sometimes with a color closer to the tube's normal color if arcs form across the filaments. Occaisionally, only one end arcs and glows brightly, and the other end glows dimmer with a more orange color. This is hard on both the tube and the ballast. The defective starter should be immediately removed.

   A starter that is rated for a different wattage lamp can result not only in starting problems, but erratic behavior if the lamp does successfully start. For example, a starter rated for a lower wattage or shorter lamp (lower voltage drop) may be randomly activated resulting in flickering as it attempts (incorrectly) to restart.

   Should one or both ends glow with a bright yellowish orange color with no sign of any arc discharge surrounding each filament, then the emissive material on the filaments is probably depleted or defective. In such a case, the tube should be replaced regardless of what else is wrong. If both ends glow a dim orange color, then the filaments' emissive coating may or may not be in good shape. It takes approximately 10 volts to form an arc across a healthy fluorescent lamp filament.

3. Defective iron ballast. The ballast may be obviously burned and smelly, overheated, or have a loud hum or buzz. Eventually, a thermal protector built into many ballasts will open due to the overheating (though this will probably reset when it cools down). The fixture may appear to be dead. A bad ballast could conceivably damage other parts as well and blow the fluorescent tubes. If the high voltage windings of rapid start or trigger start ballasts are open or shorted, then the lamp will not start.

   Ballasts for fixtures less than 30 watts usually do not have thermal protection and in rare cases catch fire if they overheat. Defective fixtures should not be left operating.

4. Bad sockets. These can be damaged through forceful installation or removal of a fluorescent tube. With some ballasts (instant start, for example), a switch contact in the socket prevents generation of the starting voltage if there is no tube in place. This minimizes the possibility of shock while changing tubes but can also be an additional spot for a faulty connection.

5. Lack of ground. For fluorescent fixtures using rapid start or instant start ballasts, it is often necessary for the metal reflector to be connected to the electrical system's safety ground. If this is not done, starting may be erratic or may require you to run your hand over the tube to get it to light. In addition, of course, it is an important safety requirement.

WARNING: Electronic ballasts are switching power supplies and need to be serviced by someone qualified in their repair both for personal safety as well as continued protection from electrical and fire hazards.

Causes of Short Lamp Life

The following directly addresses issues with the common 4 foot 34 to 40 W fluorescent lamps and fixtures. However, most will apply to other wattages.

(From: Don Klipstein (don@Misty.com).)

There are two likely reasons for short lamp life:

1. **Bulb-ballast mismatch:** There are several different wattages of 4-foot fluorescent bulbs, two of which are called F40. The "energy saver" F40 is usually 34 watts but sometimes 35 watts but treatable as a 34. F40 with no mention of "energy saver" or "energy saving" is a true 40 watt.

2. **Subtle partial ballast failure:** Sometimes, usually in a 2-bulb magnetic rapid start ballast, a capacitor in series with the transformer's secondary winding fails. Excessive current flows through the lamp and the ballast can overheat. If you have or can borrow one of those "clamp-on" AC ammeters, clamp it around the black lead or the white lead (but not both, for a 120 VAC USA-usual ballast of this sort). A good ballast will draw approximately 0.8 A. A bad one will draw around 1.5 A.

Some less likely reasons:

3. **Excessive cycling:** You turn the lamps on and off a lot.

4. **The ballasts are cheap junk:** Replace them with "commercial grade" ballasts.

5. **Corroded contacts in the sockets:** Try twisting the bulbs around. Slight chance you need to clean the socket contacts with sandpaper (WITH POWER OFF - 280 volts is a popular output voltage of a 2-bulb F40 rapid start ballast.) Slight chance you need a new fixture - and then replace the cheapo-junko ballast with a proper "commercial grade" one, if the usually 2-inch-longer-length of the proper ballast is something the fixture will accept.

6. **Bulbs need to be cleaned:** More likely in humid coastal areas - a slightly conductive film of dust/salt/dirt on the bulbs can affect electric field distribution within bulbs that have not yet started and that can impair starting.

7. **The fixture may not be grounded:** It should be connected to the grounding conductor of the cable feeding it. This sometimes affects starting and sometimes unpredictably or in a manner varying with bulb age, temperature and humidity.

   But if the bulbs always start until some time when they act up and never start again, then grounding is probably not the problem.

Comments on Black Bands and Other Fluorescent Failure Issues

(From: Don Klipstein (don@Misty.com).)

Fluorescent tubes failing in this manner normally draw reduced current. The voltage across the tube is higher and the tube will sometimes draw more power, but the current flowing through the ballast is less.

Since the ends of the bulb usually burn out unequally, some "net DC" may try to flow through the ballast. My experience is that the feared core saturation effects do not occur. Furthermore, the common rapid start ballasts have a capacitor in series with the secondary windings which would block any DC.

There is a different problem that I once knew of causing a fire: Starters getting stuck in the "closed" state. The symptom is the ends of the tube glowing brightly, either yellow-orange or a color closer to the normal tube color, sometimes even one end glowing yellow-orange and one end glowing a more normal color. Excessive ballast current flows in this case. This is not a problem with "instant start", "rapid start", or "trigger start" fixtures. It is only a problem where there are starters.

A dim orange or red-orange glow more likely indicates dead tubes on a rapid start or trigger start ballast. If the fixture is a preheat type, dim orange end glow indicates less current than a brighter yellow-orange, and the ballast is less likely to overheat. Different brands of ballasts are designed a little differently.

If a preheat fixture has the tube glowing only in the ends, it is recommended to immediately remove the tube to stop the ballast from possibly overheating. You should replace both the tube and the starter. The starter is bad if this occurs, and the tube is usually bad also. Typically, the starter goes bad after too much time trying to start a bad tube. In the unlikely event the starter had the initial failure, the tube will be damaged by prolonged excessive end glow.

Why is a Grounded Fixture Needed for Reliable Starting?

Many fluorescent fixtures will not start reliably unless they are connected to a solid earth (safety) ground. This is most likely the case with rapid or trigger start magnetic ballasts. These will usually state on the label: "Mount tube within 1/2 inch of grounded metal reflector". If this is not done or if the entire fixture is not grounded, starting will be erratic - possibly taking a long or random amount of time to start or waiting until you brush your hand along the tube.

The reason is straightforward:

The metal reflector or your hand provides a capacitive path to ground through the wall of the fluorescent tube. This helps to ionize the gases inside the tube and initiate conduction in the tube. However, once current is flowing from end-to-end, the impedance in the ballast circuit is much much lower than this capacitive path. Thus, the added capacitance is irrelevant once the tube has started.

The reason that this is required is probably partly one of cost: it is cheaper to manufacture a ballast with slightly lower starting voltage but require the fixture to be grounded - as it should be for safety anyhow.

(From: Don Klipstein (don@Misty.com).)

Should one or both tubes glow dimly, then ionization is not the problem and poor grounding isn't the cause. In such a case, the problem is poor contact with the pins of the tubes, one or both tubes are bad, insufficient voltage, bulb/ballast mismatch (wrong bulbs may fit but not work especially for 4-footers which come in many wattages), or possibly just a bad case of the bulbs being much too cold. Wire or foil or other attachments to change the electric field distribution will not help dim glow make the transition to arc - only help with the tubes ionizing and glowing at all.

Why Do Fluorescent Lamps Buzz and What to Do About It?

The buzzing light is probably a mundane problem with a defective or cheap ballast. There's also the possibility of sloppy mechanical construction which lets something vibrate from the magnetic field of the ballast until thermal expansion eventually stops it.

First check for loose or vibrating sheetmetal parts - the ballast may simply be vibrating these and itself not be defective.

Most newer fixtures are of the 'rapid start' or 'warm start' variety and do not have starters. The ballast has a high voltage winding which provides the starting voltage.

There will always be a ballast - it is necessary to limit the current to the tube(s) and for starting if there is no starter. In older fixtures, these will be big heavy magnetic choke/transformer devices - hard to miss if you open the thing. Cheap and/or defective ones tend to make noise. They are replaceable but you need to get one of the same type and ratings - hopefully of higher quality. A new fixture may be cheaper.

The starter if present is a small cylindrical aluminum can, approximately 3/4" x 1-1/2" in a socket, usually accessible without disassembly. It twists counterclockwise to remove. They are inexpensive but probably not your problem. To verify, simply remove the starter after the lamp is on - it is not needed then.

The newest fixtures may use totally electronic ballasts which are less likely to buzz. Warning: electronic ballasts are basically switching power supplies and are maybe hazardous to service (both in terms of your safety and the risk of a fire hazard from improper repair) unless you have the appropriate knowledge and experience.

Where the buzzing started after replacing the ballast, assuming the replacement is of the same type as the original and it is tightly mounted, there is probably nothing really wrong - it is just not as quiet as your previous ballast. Make sure it is the ballast and not its mounting sheet metal vibrating. If the sound is coming from the ballast, there really isn't a lot that can be done other than to try another manufacturer or sample. Also see the section: Why do Fluorescent Lamps Buzz and What to Do About It?.

(From Brian Beck (jrdnut@utah-inter.net).)

There are 2 main types of ballasts; those for 'home' use and those for commercial use. The commercial type will last longer and the lamp life is better as well.

There are three sound ratings

- A - extremely quiet (e.g., libraries, churches).
- B - somewhat noisy (e.g., work areas, shops).
- C - outdoor noisy (e.g., 60 foot poles in parking lots).

My guess is you got a home rated ballast with a 'B' sound rating. There is nothing wrong with the ballast - it is just noisy. If the buzz bothers you, return it to the store you bought it and go purchase one at an actual electrical parts supplier (home centers and hardware stores may not have the highest quality components). For a 2 lamp F40/T12/CW/SS lamp fixture, you want an R2S40TP ballast.

Why Fluorescent Lamps are Sometimes Dimmer than Expected?

> "I recently replaced a kitchen overhead fixture with two 75 watt bulbs with a fluorescent one having two 20 W bulbs. Guess what? Not enough light!"
>
> Somehow I was under the impression that a watt of fluorescent lighting produced many more candles than a watt of incandescent lighting, but obviously, I overestimated the ratio."

A 20 watt fluorescent bulb of a higher light output color should make as much light as a 75 watt incandescent (1170 to 1210 lumens), BUT:

1. A few fluorescent lamp colors are dimmer, such as Deluxe versions of cool white and warm white, and a few others.

2. Fluorescent lamps only make full light output in a somewhat narrow temperature range. The fluorescents will probably not make full light when they first get started. They typically make more light after warming up for a few minutes, then may lose a bit of light output if they warm up past optimum temperature.

3. Some ballasts do not make fluorescent lamps produce full light. Some 20 watt fixtures use a multi-purpose ballast designed to be usable with a few different wattages of lamps, and which typically sends about 16 watts of power to a 20 watt tube. A few other ballasts send an inferior current waveform to the tube, impairing efficiency. I have found some fixtures by "Lights of America" to suffer slightly impaired efficiency from a less smooth current waveform generated by an instant-start ballast system that starts "preheat" tubes instantly without a starter. Some cheaper rapid start and trigger start ballasts produce slightly inferior current waveforms.

   Some of the slightly popular 2-tube 20 watt "trigger start" ballasts are cheap and "fussy", and only work well if everything is optimum. These ballasts often don't work well with cool temperatures, slightly low line voltages, or slightly weak lamps. Their best may not be too great anyway. The same may be true of some cheaper two-tube 40 watt "shop light" ballasts. Also, some "shop light" fixtures that you may think are dual 40 watt are actually dual 25 watt 4-foot fixtures.

4. Some fluorescent lamp colors (especially warm white, white, and cool white) have a spectral distribution that dims most reds and most greens. This may make things look dimmer. For details of this effect, look for the appropriate section in Some Bits of Discharge Lamp Theory andOther Technical Information!, (a web document related mostly to discharge lamp mechanics).

   > "What will happen if I replace the two T20s with higher powered lamps? (If some will burn out, can I replace it as well?"

The ballasts in nearly all 20 watt fixtures will not send much over 20 watts of power to any size tube. Sometimes even not much over 16 watts to any size tube. You need a different fixture, more fixtures/tubes, or possibly tubes of the same wattage but better brightness and/or color brightening (more modern '3000', 'D830', '3500', 'D835', '4100', or 'D841' tubes with higher lumen ratings but of wattage and size for the fixture).

Replacing fluorescent lamp or fixture components

Most of these parts are easily replaced and readily available. However, it is usually necessary to match the original and replacement fairly closely. Ballasts in particular are designed for a particular wattage, type and size, and tube configuration. Take the old ballast with you when shopping for a replacement. There may be different types of sockets as well depending on the type of ballast you have.

It is also a possible fire hazard to replace fluorescent tubes with a different wattage even if they fit physically. A specific warning has been issued about replacing 40 W tubes with 34 W energy saving tubes, for example. The problem is that the ballast must also be correctly sized for the new tubes and simply replacing the tubes results in excessive current flow and overheating of the ballast(s).

Rings or Swirls of Light in Fluorescent Lamps

Complaints are generally of the following form:

> "I just replaced my bulbs because they had the black bands at the end and finally went out altogether. The new bulbs light fine but they have subtle rings of light running down the inside of them."

or

> "My fluorescent tubes look like a they have a writhing snake inside trying to get out."

(From: Don Klipstein (don@Misty.com).)

The rings sometimes happens. I forget the name of this, but it is a sometimes normal feature of the main discharge column in low pressure lamps. In fluorescent tubes, it is more common if the bulb is cold or not fully warmed up, brand new or not-yet broken in, or if the ballast is of poor quality or there is a bulb/ballast mismatch.

Double check the label on the ballast and the lamp type to be sure they are compatible with each other.

If the bulb is an "energy saver" 34 or 35 watt model (part number usually begins with F40, which is the same for a normal 40 watt bulb), be sure the ballast is compatible with that bulb. If it is compatible with both 34's and 40's, it is compatible with 35's. Matching bulbs/ballasts is important for these models mainly to ensure long bulb life and to avoid overheating the ballast. 34 and 35 watt bulbs are prone to rings and flickering and being dim and being unusually sensitive to cold because of the nature of these bulbs and can do so no matter what ballast you use. They will normally behave properly after warming up, especially in ceiling fixtures where heat builds up.

Fluorescent tubes sometimes also "swirl" before being broken in, or if they are underpowered by an incorrect or low quality ballast.

Comments on Instant Start/Rapid Start Compatibility

(From: Ken Berg (goken@inreach.com).)

The problem with premature lamp failures using Instant Start ballast lies in the fundamental difference in the basic operating principles between Rapid Start and Instant Start lamps. It has really nothing to do with whether the ballast is magnetic or electronic. Instant Start ballasts are really designed to be used with the standard T12 single pin Slimline lamps. Instant Start ballasts deliver a higher striking voltage on starting than Rapid Start ballasts do. Slimline (the single pin) lamps have a slightly heavier cathode to tolerate the starting cycle. With Instant Start, the lamps are really started "cold cathode" style, and then they of course run as hot cathode.

On occasion, even the standard T12 Slimlines refuse to "die like gentlemen" and flash and swirl wildly. Maintenance guys have known for decades that they need to replace Slimlines promptly if they start doing this. They will need to keep this in mind when dealing with the F32T8 lamps as well. Even though the lamps are bi-pin, and so look like the old Rapid Start T12's, they are more than likely running on an Instant Start circuit, and will sometimes go like this.

The cathodes in most bi-pin lamps are made for Rapid Start, which is a starting method that is easier on the filaments. The lamp manufacturers are supposed to have already taken the starting characteristics of the new F32T8 Instant Start ballasts into account, but some might just be going on the cheap, and skimping of the lamp filaments.

Premature Cathode Failure in Dimmed Fluorescent Lamps

> "I have been experimenting with 15 W T8 lamps running from a dimmable electronic ballast. I have found that if set to a low light level after a few days of being left on, one of the cathodes in the tube often goes open circuit."

(From: Clive Mitchell (clive@emanator.demon.co.uk).)

The only explanation that I can come up with is that there isn't enough current flow to keep the cathodes warm and this is causing the discharge to be concentrated on a small point. The discharge will tend to stay on that point since it's the only warm bit, and as such is emitting electrons, making it the easiest path for current flow.

The voltage drop across this point will be higher than normal since the heat being generated is being dissipated by the rest of the cathode and this means that more power than normal is being dissipated from that point causing sputtering. This could be causing the early burn-out.

The best way to validate this would be with a clear tube to see the cathode discharge activity.

I've seen a phenomenon like this when I've lit a halide lamp at low level with a small voltage multiplier circuit. The glow discharge led to a white hot point on the electrode that caused sputtering.

If this is the case, then the cure is to use a ballast that can supply a continuous heating current to the cathodes.

Replace Preheat Ballasts with Rapid or Trigger Start Type?

When a ballast fails in a preheat fixture, should the bad preheat ballast be replaced with a more modern type? Advantages of a rapid or trigger start ballast are that the starter (a high failure part) is eliminated and the fluorescent lamps may last longer as a result of less stress during starting. Disadvantage include cost of the ballast and possibly space limitations inside the fixture. However, since a defective starter may ruin the lamp controlled by it, the potential cost of replacement lamps may offset the additional cost of the ballast. All in all, this is probably not a decision affecting the future of the Universe but in certain cases, changing ballast types may make sense.

Items of Interest

All Those Different Wattage 4-Foot and F40 and "Shop Light" Lamps?

The original 4-foot fluorescent lamp was the F40T12, which is 47.75 inches (approx. 121.3 cm) long from pin tip to pin tip and 1.5 inches (approx. 4 cm) in diameter and designed to consume 40 watts. Not too many years ago, this was the most common and least expensive fluorescent lamp.

There is the "HO" (high output) 4-foot tube and the "SHO" (super high output) 4-foot tube. These are not common and are only used where there is not enough room to fit enough standard F40 tubes to make enough light. These lamps are slightly less efficient than standard fluorescent lamps. These tubes require more current than standard 4-foot tubes and require special ballasts. These tubes should only be used with their respective ballasts, and these ballasts should only be used with the tubes they were designed for.

In response to the energy shortages of the 1970's, the 34 watt lamp with the same physical dimensions was introduced. It works in most 40 watt fixtures and draws 34 watts in these fixtures. However, some 40 watt ballasts can overheat with this lamp. The ballast should say that it is rated for use with 34 watt lamps. Please note that a 34 watt tube can say F40 and still be a 34 watt tube and not be a 40 watt tube. It will in some way say near the F40 designation that it is an energy-saving tube. There have also been a few 35 watt tubes, which are similar enough to 34 watt tubes to work anywhere both 34 and 40 watt tubes can work. 34 watt lamps sometimes produce noticeably less light than 40 watt lamps, especially in cooler environments.

Nowadays, there is the 25 watt "shop light" lamp. The 25 watt tubes should only be used with appropriate 25 watt shop light ballasts, and these ballasts should only be used with these tubes. Please do not confuse these with other wattage tubes/fixtures of the same physical dimensions which are also sometimes called "shop lights".

A more recent development is the 32 watt T8 lamp, which is 4 feet long but only one inch (2.5 cm) in diameter. These require ballasts made for them. Many of the ballasts made for these lamps are electronic ballasts.

The confusion has increased in recent years now that the USA has an energy-conservation law against manufacturing and importing standard 40 watt white fluorescent lamps. Specialty lamps and white ones with a color rendering index of at least 82 (out of a maximum of 100) are exempt and are still available in the USA as true 40 watt lamps.

Again, be sure that you are not mismatching the bulb and the ballast. If the ballast is not rated to operate the bulb type being used, the bulb life will probably be shortened and the ballast life may be shortened. In a few cases, the ballast may catch fire after failing.

What's with All Those Different Shades of White?

At one time, most fluorescent lamps were "cool white" which is a plain-old white with a color like that of of average sunlight.
One bad thing about "cool white" is that the spectrum of "cool white" has a surplus of yellow and a shortage of green and red. Since mixing red light with green light makes yellow, the white light of a cool white lamp still looks white. Since yellow objects usually reflect green through red, they look yellow as usual in this light.
But red objects reflect mainly red light and green objects reflect mainly green light, and look dim and dull due to the shortage of red and green wavelengths in "cool white". Impure reds and greens will look less red and less green as well as darker - making them look more brown.

Other early whites were "warm white" and "daylight". Warm white is a color similar to that of incandescent lamps, although it usually looks slightly less yellow and more white-pink. A warm white lamp's spectrum has a surplus of yellow and violet-blue, and a shortage of red, green, and green-blue. Like cool white, warm white can distort colors in unflattering ways.
Both "warm white" and "cool white" are obtained using "halophosphate" phosphors. The surplus of yellow and shortage of red and green is a general characteristic of halophosphate phosphors.
"Daylight" is a bluish white, and does not have as bad a surplus of yellow as the other halophosphate whites. But it is also slightly dimmer.

Next were the "deluxe" versions of cool white and warm white. These have "improved" halophosphate phosphors and are sometimes known as "broad spectrum" lamps. They have a less severe yellow surplus and red/green shortage than standard halophosphate lamps. They also produce slightly less light.

Another slightly common halophosphate white is "white", which is between "cool white" and "warm white" in color.

Other halophosphate whites, whether of differing spectral quality or different shade of "warmth/coolness" include "supermarket white", "sign white", "north light", "merchandising white", etc. Please note that some of these are not made by all fluorescent lamp manufacturers, and some of the less standard color names are trademarks of their respective manufacturers.

One earlier fluorescent lamp color with enhanced red spectral content is the "natural". This lamp has "cool white" halophosphate phosphor with a red-glowing phosphor of a different type added in. These lamps look slightly pinkish in color, sometimes purplish when compared to warmer colored light such as incandescent light. "Natural" fluorescent lamps make skin tones look pinkish, unlike the usual halophosphate types which make skin tones look green-yellowish. Some meat displays have "natural" fluorescent lamps to make the meat look more red.

Nowadays, there are "triphosphor" fluorescent lamps. These have a spectrum very different from that of the halophosphate lamps. Triphosphor lamps have their spectral content mostly in distint bands and lines: Orangish red, slightly yellowish green, green-blue, and violet-blue. For cooler color lamps, there is an additional band in the mid-blue. Triphosphor lamps do not distort colors as badly as halophosphate lamps, and triphosphor's color distortions are usually not as unpleasant as those of halophosphate. Also, triphosphor lamps often make reds and greens look slightly brighter than normal, unlike halophosphate lamps which usually make these colors look dimmer than normal.

Most compact fluorescent lamps and most 4-foot T8 (1-inch diameter) lamps are triphosphor lamps.

Triphosphor lamps come in various warm and cool shades, usually designated by "color temperature". This is the temperature that an ideal incandescent radiator would be heated to in order to glow with a similar color. Color codes on fluorescent lamps may include the color temperature or 1/100 of the color temperature. Osram/Sylvania brand lamps often have D8 immediately preceding the color code.

2700 or 27 - orangish shade common for compact fluorescent lamps, similar to many incandescent lamps.

3000 or 30 - "warm white", similar to whiter shades of incandescent.

3500 or 35 - between warm white and cool white, similar to the whitest halogen lamps and projector lamps.

4100 or 41 - "cool white" or the color of average sunlight.

5000 or 50 - an icy cold pure white like that of noontime tropical sunlight.

6500 or 65 - slightly bluish white or "daylight".

There are still other specialty whites, including ones with a mixture of "broad spectrum" and "triphosphor" phosphor formulations to get a spectrum more like that of daylight. Some others have particularly good "broad spectrum" phosphors, sometimes mixed with other phosphors for a tailored spectrum. Many of these, like most triphosphor lamps, have color temperature designations.

Why Small Fluorescent lamps Cost More than 4-Foot Ones

Can you say 'supply and demand' and 'economies of mass production'. You are comparing the price of the common F40CW-T12 lamp manufactured by the zillions and sold in home centers for about $1 with specialty bulbs used in a relatively few devices like battery powered fluorescent lanterns and makeup mirrors. These little bulbs may indeed cost up to ten times as much as the much larger ones.

By any measure of materials and manufacturing cost, the 4 foot bulb is much much more expensive to produce. There is nothing special involved.

Energy Consumption and Wear-And-Tear due to Starting

(From: John Gilliver (g6jpg@gmrc.gecm.com).)

The amount of energy used in starting isn't worth worrying about. However, in addition to the turn on/off deterioration, there is also the steady-state `on' deterioration (they don't last for ever even if left on), so...

As far as turn-on deterioration:

I can't give it as a percentage, but for ordinary striplights I heard a figure of 15 minutes (about 15 years ago), i. e. turning it on stresses it as much as leaving it on for that long. Things have perhaps changed by now (and there are so many kinds these days as well).

For low-energy use, I'd go for fluorescents any day, unless size is a major factor (Bosch [I think] and others have been trying to get some sort of discharge lamp for headlights for some time, but I haven't seen any yet). You might also look into LEDs, but I doubt they will match the efficiency; certainly only the high-effificiency types (all seem to consume about 10, 20, or 30 mA, but the output power in light seems to vary widely, from a few millicandelas to about three candelas!). They are narrow band (i. e. coloured) as well of course.

What Happens when Fluorescent Lamps Wear Out?

(From: Charles R. Sullivan (charless@crissy.EECS.Berkeley.EDU).)

The usual failure mode is depletion of the emission mix on the filaments. Then they do not emit electrons, and the arc can't be sustained. Unless the ballast supplies a high enough voltage that very high field can be set up near the electrode. Then the ions bombarding the electrode have a high enough energy to knock electrons out of the metal even with no emission mix, or to heat the metal to the point it emits electrons. The high field is also sufficient to ionize the argon fill gas---normally only mercury is ionized. The argon radiation is of a more purple color. That is probably what you see.

Blackening at Ends of Fluorescent Tubes

This is a common phenomenon with most common fluorescent tubes as they age. However, frequent or repeated starting can accelerate the process. The black areas in themselves don't affect operation except to slightly reduce the amount of light available since the phosphor in that area is dead. However, they do represent a loss of metal from the electrodes (filaments).

The cause is sputtering from the filaments, mostly when cold. Thus. this happens mostly when starting or with a defective rapid start ballast which doesn't heat the filament(s) or a ballast or starter that continuously cycles. When the filament is cold and is the cathode (on the negative half of the AC cycle for that end of the tube), the work function is higher and ions have a higher velocity when impacting, knocking off metal atoms in the process. This is greatly reduced once the filament is up to normal operating temperature (though even then, some sputtering is inevitable).

(From: Greg Grieves (ggrieves@home.com).)

Lamps with the longest lifetimes typically use the heavier noble gasses as the buffer gas, (Xenon or Krypton instead of Argon) because the sputtering that occurs at the cathode is due to fast ion bombardment from the ionized gasses in the tube. the heavier atoms have a smaller velocity for a given kinetic energy of acceleration. its not the total energy of the ion that sputters but its the momentum at impact that knocks other atoms loose. I presume thats why Kr and Xe bulbs can run brighter, because they can crank up the power and still have about the same lifetime. Some tubes use a "hollow cathode" design in which the shape of the cathode is designed to deflect impacting ions rather than be sputtered by them. That's my understanding, anyway, theres much more to the story...

(From: PBerry1234 (pberry1234@aol.com).)

I recall one brand of lamp that positioned shields around the electrodes to prevent the blackening. I suppose this improved the appearance in exposed lamp applications, but don't know of any other benefits.

Hot Cathode Versus Cold Cathode Operation

The cathode is the negative electrode of a vacuum tube or gas filled discharge tube. Current flows by way of electrons emitted from the cathode and attracted to the positive electrode, the anode.

A hot cathode is one which must be heated to operate properly - to emit sufficient electrons to be useful. Examples: TV and monitor CRTs, most vacuum tubes (or valves), vacuum fluorescent displays (like those on your VCR). This is called thermionic emission - the boiling off of electrons from the surface of the cathode. Normal fluorescent lamps are hot cathode devices - partially maintained by the discharge current itself. They all have some sort of warmup period (though it can be quite short).

(From: Phil Rimmer (primmer@tunewell.com).)

A cold cathode is one where operation takes place without depending on heating of the surface above ambient. There are all sorts of devices that use 'cold' cathodes - neon lamps and signs, fluorescent backlight tubes, and helium neon laser tubes. Naturally, cold cathode devices don't have much of a warmup requirement.

The purpose of a cathode is to feed electrons into the negative end of the positive column (the discharge) so they can variously excite and ionise gas or vapour atoms.

Electrons are released from cathodes by the action of the positive ions being accelerated towards them due to an electric field in the vicinity of the cathode.

Electrons are broadly released in two ways: Thermal emission and secondary emission.

- Thermal emission is the primary process used in "hot cathode" lamps which include standard fluorescent tubes. The ions are accelerated towards the cathode through a small cathode voltage (less than 10 volts) and gain just enough energy to heat a small part of the very fine wire electrode when they collide with it. They heat it until it glows dully and electrons are "boiled off", liberated by the thermal energy. This process is very efficient in producing lots of electrons and results in efficient lamps.

- Secondary emission is a more brutal process for generating electrons. It requires an accelerating voltage drop of 130 to 150 volts. It is used in cold-cathode lamps that have relatively huge cylinders of iron for electrodes. These massive electrodes require much too much energy input to make them into thermal emitters. The energetic ions simply "knock" electrons off the metal surface. In so doing they also knock some of the metal off as well, a process called sputtering. The big electrodes have enough material to last before other effects cause lamp failure.

Hot cathode lamps operate in cold cathode mode if the cathode receives too little energy to keep it glowing. The colliding ions are thirty times more energetic than usual and soon sputter enough metal off the tiny electrodes to destroy them.

Moral: Pre-heat the electrodes before starting the discharge and maintain auxiliary current in the electrodes if the discharge current is low (e.g, when dimming).

Failure Mechanisms of Cold Cathode Fluorescent Lamps

(Portions from: Victor Roberts (Vic@RobertsResearchInc.com).)

- All fluorescent lamps, be they hot cathode, cold cathode or electrodeless will suffer from phosphor degradation. The rate of this degradation is a function of the type and amount of phosphor, the type of glass used for the tube, the temperature of the phosphor & glass and the intensity of the UV flux from the discharge. If these parameters are the same, then the type of electrodes does not make any difference, except perhaps at the ends of the tube.

- For heated filament lamps (which means most of those in residential and commercial lighting), the usual failure mode is depletion of the emission mix on the filaments. Then they do not emit electrons, and the arc can't be sustained.

- Many hollow cold cathodes contain a coating on the inner surface to improve operation. When this coating is degraded the lamp will be harder to start and therefore might not start if the starting voltage is not high enough.

- Due to their high cathode fall voltages, there will often be significant sputtering of cathode material from the surface of a cold cathode. Depending upon the design of the lamp and cathode, this sputtered material can end of up the walls of the lamp where it is unsightly at best, and may absorb significant light at worst.

- Cold cathodes tend to "consume" the active gas in a discharge. Due to the reasonably high cathode fall voltages, ionized gas atoms get buried in the surface of the cathode at a slow rate. In fact, this phenomena is used to make a very effective high vacuum pump. Also, in many HeNe lasers that use cold cathodes, a gas reservoir was added so that the loss of Ne, the dominant excited species, would not significantly change the He:Ne balance which is essential for proper laser action. In a modern fluorescent lamp, where the amount of excess mercury is reduced to prevent disposal problems, consumption of mercury by a cold cathode could be another life-limiting factor.

Comments on Small Inverter Powered Fluorescent Lamps

(From: Paul Bealing (paul@pmb.co.nz).)

Many small low cost inverters use a 2 transistor (one quite small) self oscillating circuit. Simply minimum function, low cost. These circuits can be quite efficient at low power levels. I have seen them used up to 50 watts.

Losses are usually in the transformer and the switching transistors. As the currents increase, the losses usually increase for a given power output.

The lamp requires a high voltage, usually 300 to 500 V, to strike. The voltage depends on the length/wattage of the lamp. Once struck, the current through the lamp is limited to achieve the wattage. The voltage across a small running lamp will be in the order of 60 to 100 volts AC.

Many simple inverters use a series resonant circuit to generate the high strike voltage, which is disabled by the run current.

A couple of years ago I designed an inverter for a PL11 11 Watt lamp based on a switchmode power supply controller IC, 2 power mosfets, and a push-pull transformer, running at about 200 kHz. The main application was in diesel locomotives running from 75 V DC. I've had the circuit operating down to 10V DC (different transformer winding). The primary current rises and the dissipation increases.

Fluorescent Lamp Voltage and Frequency Considerations

For those using iron ballasts, both voltage and frequency will be significant. Though it may be possible to come up with a formula which incorporates both, the best thing to do is to only use the line voltage for which the unit was designed.

Where the frequency isn't the same, the current through the lamp may differ, most likely too high in going from 60 Hz to 50 Hz, too low the opposite way. If the current is too high, there could be shortened lamp life at the very least or even a serious fire hazard. If the current is too low, the lamp may not remain on in a stable manner, flickering, or constantly restarting. Initial starting could also be affected.

If they use electronic ballasts, the frequency probably won't matter. Some "universal" types, can accommodate an input voltage from 90 to 250 VAC up to 400 Hz or even DC.

In all cases, it is best to consult with the manufacturer if the product label doesn't explicitly indicate "50/60 Hz" operation. When in doubt, leave them behind since there is really no way to be sure of the safety issues.

Operating a Fluorescent Lamp on DC

> "I have a application in mind that will use a DC power source around 100 volts and fluorescent lighting. What kinds of voltage do I need to sent the fluorescent? Are there any good sources of info. for the circuitry I would need?"

(From: Don Klipstein (don@Misty.com).)

If it is a preheat tube of 22 watts or less, the cheap-and-dirty way to do it is to use a normal preheat fixture. The only change is to add a resistor in series with the ballast. This resistor should be maybe 100 ohms for 20 and 22 watt lamps, slightly higher for lower wattage ones. It should be able to safely dissipate a wattage comparable to that of the lamp. Of course, you are now wasting significantly more power as heat.

The above includes most simple "PL"/twin-tube compact fluorescent lamps with removable bulbs with two pins, as well as most compact fluorescent bulbs with "choke" type ballasts running from 120 volts AC.

Should you need anything more energy-efficient than this, then there is the world of electronic ballasts.

BTW, most low-power-factor screw-in 120 VAC compact fluorescent lamps with electronic ballasts work fine "as-is" with about 160 volts DC or squarewave.

Ballasts and PCBs (The Hazmat Type)

(From: David Morris (allane@ix.netcom.com).)

Ballasts that were made after the late 70's do not contain PCB's. I spoke with an Advance and GE ballast rep. a few years ago about this and I was told the only sure-fire method to tell that there are no PCB's is if the ballast says no PCB's. Any ballast that doesn't say that has a better than 80% chance of having it. The amount in the ballast is VERY minute. Less than a thimble full. It is used to cool a capacitor in the ballast. Since he said the light is about 12 years old, I am quite certain that the ballast does not contain PCB's. In our state, it is legal to dispose of these ballasts in a limited quantity in your local landfill or throw them in the trash. Larger quantities require Hazmat disposal methods. Our company policy is to leave any old ballasts that is not marked 'no PCB's" with the customer for their disposal.

As a side note, I read in one of the Electrical trade rags that the liquid that replaced PCB's is testing out to be more dangerous than PCB's themselves. Go figure!! :-)

As for catching fire, ballasts contain a thermal protector that will cut the power if the ballast gets too hot. Only real old ballasts do not have this feature. Ballasts marked Class P have this protection. It is very rare for one of these ballasts to actually catch fire, although it does happen. More often, they will smoke up the house if they overheat and the thermal protector fails.

Driving Cold Cathode Fluorescent Lamps

(From: David VanHorn (dvanhorn@cedar.net).)

Linear Technology has several extremely detailed app notes written by Jim Williams on this topic. It's more complicated than you might imagine to do it right. Just making the tube light is perhaps only 10% of the job. The rest includes keeping it running a long time without blackening, providing the ability to set the brightness, not loosing all your energy to wiring capacitance, and not creating an EMI nightmare.

Definitely read and understand those app notes, even if you go to another vendor! The good news is that the actual circuit isn't that bad!

What is the E-Lamp?

The E-Lamp is one of those inventions that sounds like a really good idea but still hasn't (as far as I know) made it into wide scale production. In essence, it is an RF excited compact fluorescent lamp. Some of the E-lamp's basic characteristics include.

- Fits into standard household light bulb bases.
- Radio frequency radiation was emitted, then converted to light.
- Dimmable using standard phase control dimmer - no special devices needed.

- Very efficient so runs cool and consumes much less power than incandescent lamps (don't know how it compares to compact fluorescents).
- Desirable white spectral characteristics.
- No filament to wear out (and no wires through glass) so potentially very long life.

Aside from cost issues, there could also be concerns with respect to RF emissions effects on health and interference with other household appliances and electronics.

(Victor Roberts (Vic@RobertsResearchInc.com).)

E-lamps are electrodeless fluorescent lamps. They use a high frequency or RF magnetic field to create a time varying electric field which in turn drives a discharge which is very similar to the discharge in an ordinary fluorescent lamp. Except for the means by which the discharge is created, these E-lamps and identical to all other fluorescent lamps. There is no magic other than the fact that electrodeless excitation allows for the elimination of the electrodes, so electrode failure and wear out are no longer a problem. Also, electrodeless excitation removes the requirement that the lamp be long and thin to achieve high efficacy. Proof of this is beyond the scope of this note. :) Hence, an electrodeless fluorescent lamp can be more easily made in the shape of an incandescent lamp.

There are also electrodeless metal halide lamps and, of course, the electrodeless sulfur lamp.

Notes on Dimming of Fluorescent Lamps

The following provides a variety of dimming methods, some better than others.

Sam's dimming experiments:

OK, I did some experiments using both a dual-lamp Circline fixture and a typical dual-40 W bulb shop light - both with magnetic (rapid start probably) ballasts.

The common wisdom is not entirely correct. You can dim fluorescents. I do not know about the long term reliability or stress on the ballasts but I could achieve dimming down to around 30 to 50 percent brightness (using my standard-issue eye-balls, calibrated annually) with a relatively stable light output - no excessive flicker and no tendency to go out (though to get down to the low end requires starting high and backing off).

I tried both a Variac and a cheap light dimmer with similar results.

(If you want to go below the 30 to 50 percent threshold reliably, however, some means must be provided to keep the filaments hot.)

How about long term reliability?

This was a 'quick' experiment. All I did was observe the light output. A cheap light dimmer just means the kind you get at a home center for $4 or so. Long term reliability is certainly not known. The purpose was simply to show that just because something is stated to be impossible does not always mean that it is - not a suggestion that it is.

Dimming fluorescents 1:

(From altavoz@azstarnet.com).

48" tubes can glow at microamps if fired with 400 volts and require no heater current at all. The mercury is still probably 99% liquid!! I did this with a 9 V transistor battery and an inverter. As you fire them from lower impedances, still using 400 volts and no heaters, you'll see that you can turn down the current and get a better efficiency (output doesn't drop) but you reach a threshold and it drops light output suddenly. When I was working with 12 VDC ballasts, and 24" tubes I had to fire them at 0.65 amps then drop that to 0.4 A. But below 0.4 A they would dim suddenly to a less efficient point.

Of course this is at warm temperatures. At cooler temps you must have the heaters drawing current to boil the mercury.

I have used the cheap dimmers on many inductive loads and as long as you derate them, they will work fine.

I disassemble standard dual 48" fixtures and put the tubes in line to make a 96" fixture that puts out more light! you only need to put the ballast close to one end of the "starter" tube (the one that always starts first) or put the line Neutral close to the tube (they hook together at the ballast).

Dimming fluorescents 2:

(From: John Shotton (J.A.Shotton@bnr.co.uk)).

I have been running four 5 foot (1.5 inch diameter) tubes like this for 15 years.

The circuits (4 off) are resonant start - i.e., there is a second winding on the ballast which connects across the tube in series with an 8 uF capacitor (remember in the UK the supply is 230 VAC). Thus the heaters are energised at all times.

I originally experimented with a moving iron wattmeter (measures true RMS power), a photodetector, and a variac. Allowing for ballast loss (computed from current and resistance), the light output was directly proportional to power consumption. The lamps would dim to around 10% but they wouldn't start at this level.

The permanent installation used a mains transformer connected as an autotransformer with several taps so that I can get around 6 light levels, though they will not start on the two lowest settings and is slow at starting on the next two settings. I can't remember offhand what light output they will self start on, but it must be around 30 to 40%.

As for tube life, the lights are on most of the time when it is dark - from around 5 pm till 1 am. I fitted my third set of tubes about two years ago, and this was not because the second set had failed but because we wanted a change from daylight color-matching to tri-phosphor 2700 °k - I've still got the second set should we decide to revert to the daylight effect.

When I did my original experiments I also tried it with normal ballast circuits, i.e., with a starter across the tubes. I can't remember the results, but I didn't pursue it so they can't have been good. I believe it would work if the heaters were energised at all times from a separate winding.

Dimming fluorescents 3:

(From: David Gibson (dgibson@microconsultants.com)).

My company designed a fluorescent dimmer some years ago. It dims 40 x 40W tubes fitted with high power factor inductor/capacitor control gear as used in Australia and other 220 to 240 VAC countries. Its main claim to fame is that it can cope with the highly capacitive nature of power factor corrected luminaires, and is hence easily retrofitted. A number of large office buildings in Australia are fitted with our/my dimmer.

Unfortunately, the standard ballast used in the U.S.A. (and I presume other 120 VAC countries) uses, I believe, a resonant circuit which cannot be dimmed with our design.

The luminaires it does work with contain basically a tube/choke series combination across the line, plus a power factor correction cap also across the line. The lamp filaments are heated only during turn-on by a starter switch that completes an additional circuit at startup.

The purpose of these dimmers is energy saving. A photocell measures the ambient light, and maintains a reasonable constant light level in the office. Energy saving is possible because lighting systems must be overdesigned to allow for lumen depreciation due to lamp aging, plus the fact that daylight allows lower levels of electric light.

Performance is as follows:

Dimming range: We budget for 40% of light output (60% reduction). In the lab we have achieved down to 26%.

Power saving: At 40% light power is about 35% (yup, you win twice)

Lamp savings: In a 26 story building in Sydney, for which good figures are available, lamp replacement rate was reduced to about 40%, i.e., we more than doubled lamp life.

Overall power savings: Same building, independently audited figures, lighting bill was reduced by 45%. This included secondary savings from reduced air conditioning and a time switching system integral to our design which ensures lights are off at night etc.

Power factor improvement. Undimmed tubes have a power factor of typically 0.85 to 0.9. At 40% light this is 0.99. This is true power factor (see article on power factor on our Web site, URL below).

Line harmonics: During dimming the percentage of harmonics increases as current drops, but the absolute level (total amps) decreases.

(The power companies love it!).

Our design uses a hard-won, patented proprietary dimming method which has nothing to do with triacs. It uses high frequency switching and some very fast and smart firmware.

The same lamps can be dimmed using triacs, but the power factor correction caps must be removed from every fitting. The required triac circuit is slightly modified; the patents belong to a competitor. Its power factor is lousy.

Dimming fluorescents 4:

(From: Andrew Gabriel (andrew@cucumber.demon.co.uk)).

I have made a dimming fluorescent fitting out of a standard fitting (which started out as a switch-start series ballast), and an ordinary phase control (triac) dimmer.

My only reservation is that this is all for standard 200-250 V switch-start fluorescents - when I've seen American books describing fluorescent lamp control gear, it is quite different, presumably because of the lower mains voltage being unsuitable without more complex control gear.

There are three significant things you have to do:

1. The lamp extinguishes at around half power because the filaments at each end are no longer heated sufficiently during one half cycle's bombardment with electrons to emit electrons in the following half-cycle. I overcame this by supplying the filaments with a few volts from a miniature mains transformer with a pair of isolated low voltage secondaries, around 4 volts IIRC for a 5 foot 80W fitting (it doesn't need to be anywhere near enough voltage for a visible glow from them). Also, with this transformer fitted (and the switch- starter removed), the tube actually fires up all by itself without flashing, since it is now really rapid start fitting.

   I also have a switch to disable the dimmer, and when disabled, it also switches the filament transformer's primary to be across the tube rather than the mains. Thus initially when the tube is non- conducting and the tube voltage is 240 V, the filaments are heated, but as the tube starts up and its voltage drops to its running value of around 100 V, the additional filament heating provided by the transformer, which is unnecessary when the lamp is running normally, is all but disabled.

2. The second problem is that all cheap triac dimmers fire the triac with a pulse and expect the triac to continue conducting until the zero crossing point (or more strictly, zero current). However, an inductive load takes time to start conducting, and at the end of the triac firing pulse, the current through the triac will not have reached the minimum holding current when the dimmer is set low, which also results in sudden extinguishing of the tube when dimming down. To overcome this, I added a small incandescent lamp to the output load on the dimmer, in my case it's a 40W spotlight pointing at a painting, so it's a useful additional feature.

   This also allows the lamp to be dimmed completely down to zero. At very dim levels just above zero, some tubes exhibit Faraday rings, rings of alternate light and dark along the tube which might remain still or move along the tube.

   I was expecting the current phase shift due to the inductor to be a problem with a cheap dimmer, but it wasn't.

3. Ensure the power factor correction capacitor is before the dimmer, or you'll destroy the triac. In a

commercial environment, I think I would also include some protection against typical triac failure modes of a one-way open or short, which would result in high levels of DC through the inductor which will overheat it and/or destroy the lamp.

BTW, I did all this 20 years ago as a teenager. However, the fitting in question is still running, and has never required a lamp change in that time, nor is there any blackening at the ends of the tube. It is normally run at full brightness with the dimmer disabled.

Dimming fluorescents 5:

(From: Peter Miller (p.miller@elec.gla.ac.uk)).

I've tinkered a bit... the trick is to keep the filaments at the ends of the tubes warm. You will NOT be able to dim down to zero - probably about 25% at best.

Here is a possible circuit:

```
                        Dimmer
                         +--+  Choke
    AC Live/hot o--------|  |--^^^^^^^^--+--------------+
                         +--+            |              |
                                         |              |
                   +---------------------+              |
                   |                     |              |
                   +-+   +---------------+  +-------+   |
                      )|(                   |       |   |
        Filament      )|(                   |      -|---|-
      Transformer     )| +------------------+     |  ^^^  | Tube
      2 * 6.3V 2A     )|                          |       |
                      )|                          |       |
                      )| +------------------+     |  ^^^  |
                      )|(                   |      -|---|-
                      )|(                   |       |   |
                   +-+   +---------------+  +--------   |
                   |                     |              |
AC Neutral/cold o--+---------------------+--------------+
```

The lamp must be in a earthed / grounded reflector fitting. The metal end caps of the tube must be connected to the reflector. The dimmer MUST be a 'hard fired' dimmer capable of operating an inductive load. The choke is a standard type for the tube in use. Play with an inexpensive everyday tube before using expensive aquaria ones. with a 240 VAC supply a 4 foot 40W tube operates ok. The main difficulty with this circuit is in getting the tube to start - starting is greatly helped by a grounded reflector fitting and connecting the metal end caps of the tube to the reflector (Don't ask - it works!). The transformer can be a standard valve filament transformer - use a separate transformer for each end of the tube if you are unsure of the insulation between the secondaries of any transformer that you buy. As the tube draws less current the voltage across it rises, turning up the heat in the filaments. At start up, maximum voltage is across the lamp and so the filaments are fully on. All dimming ballasts/chokes use some scheme to add extra heat to the filaments at dim running. An undimmed tube draws enough current to keep the filaments warm by itself. There is no glow starter or other starting device in the circuit, so the lamps tend to come on smoothly with no flickering. Shorter tubes are easier to start. New slimline tubes are a real pain to start.

Dimming fluorescents 6:

(From: Bruce G. Bostwick (llbgb@utxdp.dp.utexas.edu)).

This applies to rapid start fixtures.

If the fixture says "RAPID START" somewhere on it or on the package it came in, the internal schematic will be roughly as follows:

```
                       || +-------+---------o
AC line H o---------+ ||(   +----+             to both pins on
                      )||(  (  <-6.3VAC        one end
                      )||(   +--------------o
                      )||(
                      )|| +=---- 2kVAC* -------------------------+
                      )||(                                      _|_
                      )||(   +--------------o                  ///
                      )||(  (  <-6.3VAC        to both pins on
AC line N o---------+ ||(   +----+             the other end
                       || +-------+---------o
```

*The high voltage winding of the secondary is on a branch magnetic circuit that limits the output current to the mercury discharge. Most of the 48" 40W "shop light" type of bulbs use this. Open circuit voltage will be in the kilovolt range, while the voltage across a lighted tube will be somewhat less than that and *exceedingly* non-sinusoidal.

If you're using the big bulbs (F96T12's for example) the ballast will only have the high voltage winding and the cathodes are heated by ionic bombardment from the mercury arc. These take a bit longer to light up when the power is turned on.

If you want instantaneous on/off control, I'd suggest using 4-footers and linking up two ballasts in such a way that the cathode heaters are driven from one which is always on, and the arc is driven from the other which is turned on and off as you desire. They won't last too long that way, but it will work better for show effects. The cathodes could be driven from a pair of low-voltage filament transformers, but be sure to isolate them well -- or you could use a ballast with a blown HV secondary ...

Another suggestion: Use solid-state relays to drive the ballast primaries. These are fairly cheap and provide clean current-zero-crossing switching even with very reactive loads (I've used them for such! ;-) and provide a neat and rugged way to connect the lights to logic controls such as your computer -- great for light sequencing.

Dimming fluorescents 7:

(From: a-freak@freenet.de.)

The magazine "Elektor" developed a dimming circuit for fluorescent lamps running at 230 V which is wired in *parallel* to the lamp at the place where usually the glow starter is located. I tried it and it works well for short lamps of the 18W-type but very unstable with the large ones.

In my opinion this circuit is especially nice if you want to dim up a lamp from zero brightness (lamp shorted, full preheating and maximum current) to full operation (usual values), for example to simulate a sunrise.

Dimming fluorescents 7:

(From: Charles R. Patton (patton@dt.wdc.com)).

Advance (and probably others) made special ballasts for 60 Hz (non-electronic such as with a Variac) dimming. One of the main characteristics was the extra wire for the Variac (or symmetrical electronic dimmer) input. The trick was to keep the filaments warm on the tube, therefore the separate filament power which doesn't get varied so that a larger dimming range was possible. This also makes for much longer lifetimes for the tube because cold electrodes are subject to heavy ion bombardment until they heat up from the normal current (which doesn't exist on a dimmed tube.) As I understand it, some electronic ballasts will power the filament separately for a period of time to get it to temperature, then apply high voltage excitation to light the tube.

Introduction

Gas discharge lamp basics

The use of electrically excited gas discharges significantly predates the invention of the incandescent lamp. Physics labs of yesteryear as well as today have use of a variety of gas filled tubes used for numerous purposes involving light generation including spectroscopy, materials analysis, studies of gas dynamics, and laser pumping. Look through any scientific supply catalog and you will see many different types of gas filled tubes in all shapes and sizes.

Gas discharge lamps are used in virtually all areas of modern lighting technology including common fluorescent lighting for home and office - and LCD backlights for laptop computers, high intensity discharge lamps for very efficient area lighting, neon and other miniature indicator lamps, germicidal and tanning lamps, neon signs, photographic electronic flashes and strobes, arc lamps for industry and A/V projectors, and many more. Gas discharge automotive headlights are on the way - see the section: "HID automotive headlights".

Because of the unusual appearance of the light from gas discharge tubes, quacks and con artists also have used and are using this technology as part of expensive useless devices for everything from curing cancer to contacting the dead.

Unlike incandescent lamps, gas discharge lamps have no filament and do not produce light as a result of something solid getting hot (though heat may be a byproduct). Rather, the atoms or molecules of the gas inside a glass, quartz, or translucent ceramic tube, are ionized by an electric current through the gas or a radio frequency or microwave field in proximity to the tube. This results in the generation of light - usually either visible or ultraviolet (UV). The color depends on both the mixture of gasses or other materials inside the tube as well as the pressure and type and amount of the electric current or RF power.

(At the present time, this document only deals with directly excited gas discharge lamps where an AC or DC electric current flows through the gas.)

Fluorescent lamps are a special class of gas discharge lamps where the electric current produces mostly invisible UV light which is turned into visible light by a special phosphor coating on the interior of the tube. See: Fluorescent Lamps, Ballasts, and Fixtures for more info.

The remainder of this document discusses two classes of gas discharge lamps: low pressure 'neon' tubes used in signs and displays and high intensity discharge lamps used for very efficient area and directional lighting.

Safely Working with Gas Discharge Lamps and Fixtures

Fixtures for gas discharge lamps may use up to 30,000 V while starting depending on technology. And, they are often not isolated from the power line. Neon signs are powered by transformers or electronic ballasts producing up to 15,000 V or more. Thus, the only safe way to work with these is to assume that they are potentially lethal and treat them with respect.

Hazards include:

- Electric shock. There is usually little need to probe a live fixture. Most problems can be identified by inspection or with an ohmmeter or continuity tester when unplugged.

  - Discharge lamps and fixtures using iron ballasts are basically pretty inert when unplugged. Even if there are small capacitors inside the ballast(s) or for RFI prevention, these are not likely to bite. However, you do have to remember to unplug them before touching anything!

    Neon signs using iron transformers are also inert when unpowered - just make sure they are off and unplugged before touching anything!

  - However, those using electronic ballasts can have some nasty charged capacitors so avoid going inside the ballast module and it won't hurt to check between its outputs with a voltmeter before touching anything. Troubleshooting the electronic ballast module is similar to that of a switchmode power supply. See the document: Notes on the Troubleshooting and Repair of Small Switchmode Power Supplies

  - The pulse starters of some high intensity discharge lamps may produce up to 30 kV during the starting process. Obviously, contact with this voltage should be avoided keeping in mind that 30 kV can jump over an inch to anyplace it wants!

- Nasty chemicals: Various toxic substances may be present inside high pressure discharge lamps (sodium and mercury) and neon signs (some phosphors). Contact with these substances should be avoided. If a lamp breaks, clean up the mess and dispose of it properly and promptly. Of course, don't go out of your way to get gut on the broken glass! WARNING: Metallic sodium reacts with water to produce hydrogen gas, an explosive. However, it is unlikely that the inner tube of a sodium vapor lamp would break by accident.

- Ultra-Violet (UV) light: High intensity discharge lamps generate substantial UV internally, often the particularly nasty UV-B variety. Unless designed to generate UV (for medicinal purposes, photoengraving, or whatever), the short wave radiation will be blocked by the outer glass envelope and/or phosphor coating. However, should the outer envelope break or be removed, the lamp will still operate (at least for a while - some have a means of disabling themselves after a few hours or less of exposure to air). DO NOT operate such a lamp preferably at all but if you do, at least take appropriate precautions to avoid any exposure to the UV radiation.

And take care around sharp sheet metal!

- Back to Discharge Lamp FAQ Table of Contents.

Neon Technology

Neon Lights and Signs

Neon technology has been around for many years providing the distinctive bright glowing signs of commerce of all kinds before the use of colored plastics became commonplace.

Neon tubes have electrodes sealed in at each end. For use in signs, they are formed using the glass blower's skill in the shape of letters, words, or graphics. Black paint is used to block off areas to be dark. They are evacuated, backfilled, heated (bombarded - usually by a discharge through the tube at a very high current) to drive off any impurities, evacuated and then backfilled with a variety of low pressure gasses.

Neon is the most widely known with its characteristic red-orange glow. Neon may be combined with an internal phosphor coating (like a fluorescent tube) to utilize neon's weak short-wave UV emissions. A green-emitting phosphor combines with neon's red-orange glow to make a less-red shade of orange. A blue-emitting phosphor may be used to result in a hot-pink color. Neon may be used in tubing made of red glass to produce a deep red color.

Other colors are usually produced by tubing containing argon and mercury vapor. The mercury is the active ingredient, the argon produces negligible radiation of any kind but is important for the "neon" tubing to work. Clear tubing with mercury/argon glows a characteristic light blue color.

Such tubing is often phosphor-coated on the inside, to utilize the major short-wave UV emission of low-pressure mercury. In this way, much of the "neon" tubes in use are a kind of fluorescent lamp.

Phosphor-coated tubing with mercury can glow blue, blue-green, slightly white-ish green, light yellow, bright pink, light purple, or white.

Use of mercury vapor with colored tubing (with or without phosphors) can provide a lime-green or deep blue or deep violet-blue.

Nowadays, nearly all "neon" tubing contains neon or mercury vapor (with argon), whether with or without phosphors and/or colored glass. Well in the past, various colors were obtained (generally at reduced efficiency) by using different gases.

For example, helium can produce a white-ish orange light in shorter length, smaller diameter tubing. Hydrogen in this case makes a lavender-hot-pink color. These gases glow more dimly with duller color shades in larger tubing. Krypton makes a dull greenish color. Argon makes a dimmish purple color. Nitrogen (generally in shorter length tubing) makes a grayish purple-pink color. Xenon, which is expensive, generally glows with a dim bluish gray color, along with the glass tubing giving a slight dim blue fluorescence from very short wave UV from the xenon discharge. Krypton also often causes a dim blue glass fluorescence.

For general information on neon signs and technology including a neon FAQ, see:

- The Internet's Neon Shop
- Neon and Lighting Channel Page

Power Supplies for Neon

Extremely high voltage power supplies are used to power neon signs. In the past, this was most often provided by a special current limited HV line transformer called a neon sign or luminous tube transformer. The output is typically 6,000 to 15,000 VAC at 15 to 60 mA. One such unit can power 10s of feet of tubing. This transformer acts as its own ballast providing the high voltage needed for starting and limiting the running current as well. Warning: the output of these transformers can be lethal since even the limited current availability is relatively high.

As with everything else, the newest neon sign power supplies use an electronic AC-AC inverter greatly reducing the size and weight (and presumably cost as well) of these power supplies by eliminating the large heavy iron transformer.

Small neon lamps inside high-tech phones and such also use solid state inverters to provide the more modest voltage required for these devices.

(From Jeff Zurkow (jeff@atrox.com).)

In the course of looking for a neon sign transformer, I discovered the following line of flyback-type HV power supplies:

- Evertron High Voltage Neon Power Supplies. (Ordering via Neon Central.

For example: the Evertron 2610 is rated at 10 kVAC, 10 mA for $45.50. The model 2610D has dimming for $56.50. There are also 3.5 kVAC and 6 kVAC models that are somewhat less expensive. The 3.5 kV unit runs on 12 VDC, the others on 115 VAC.

The neon bender I visited was kind enough to give me a couple of older units - one made by Evertron (Everbrite Electronics, model 3210) and the other by Transfotek international. One of these (the Evertron) works, but he had a whole pile of dead ones from various makers. He considers all of the electronic ones unreliable (compared to conventional NSTs), but that's probably in 24/7 service. They ought to be OK for intermittent use in laser and HV projects if the output voltage and current are sufficient.

Evertron Model 3210 Gas Tube Power Supply shows the schematic of this unit. It has a pair of power MOSFETs driving a flyback style high voltage transformer, with a whole bunch of open-wound primaries and a potted secondary.

I did plug the thing in and was rewarded with an impressive arc at about 1 cm electrode spacing (bare wires).

The Transfotek unit is completely potted, except for the AC input and on-off switch. And completely dead.

Neon Sign Installation

(From: Clive Mitchell (clive@emanator.co.uk)).

The voltage required to light a run of neon tube is variable according to diameter, gas type, pressure and number of tubes in circuit.

For a 15 kV transformer and neon gas you could run:

- 33 feet of 10 mm tube,
- 45 feet of 12 mm tube,
- 60 feet of 15 mm tube,
- 78 feet of 20 mm tube,
- 102 feet of 25 mm tube.

- Deduct one foot of tube for every pair of electrodes (tube section).

These figures are based on a chart in "Neon Techniques And Handling" which is the traditional neon reference.

The larger the diameter of the tube, the lower the voltage required, and the dimmer it will be. Transformers come with different current ratings. For larger diameter tubes, you can increase brightness by using a higher current.

- Don't attempt to run too much tube on a transformer, since it can cause breakdown of the insulation and destroy the transformer.

- Don't attempt to run too little tube on a transformer, since it can cause overheating and burn-out.

It is absolutely imperative that proper neon sign cabling and insulators are used, and that all local regulations are strictly followed. If you are intending to work with neon tubing, you should learn as much as possible first, since neon poses both a shock and serious fire risk if installed incorrectly.

The lengths quoted above may vary according to the transformer you use. The transformer manufacturers usually provide their own loading charts on request.

Anyone using this information does so at their own risk, and I cannot be held responsible for any horrible smouldering deaths experienced by incompetent dabblers, etc.

(From: Kenny Greenberg (kenny@neonshop.com)).

The neon circuit is not so simple. In a standard AC circuit neon acts like a diac - high breakover voltage followed by fast drop in resistance. Neon sign transformers are designed to 'leak' and thus self-regulate. You have a combined resistive and reactive circuit.

But take heart, it's all been figured out. :-)

There are a few variables:

1. A 'purely' neon filled tube (generally in the red range) has a higher voltage requirement than an argon-mercury tube (whose discharge is usually providing UV for phosphor with a wide range of colors.

2. The voltage requirement varies inversely with the tubing diameter. That is large diameters of a lower voltage requirement than small diameters.

3. The voltage requirement varies directly with tubing length.

4. The number of units (or pairs of electrodes) increases the voltage requirement because the electrodes have a voltage drop.

5. Wiring methods and length will also contribute to the formula but that's a whole 'nuther discussion.

You can download a free Neon Voltage Calculator for Windows.

An old tech method for determining the voltage requirement is to use a Variac on a large neon transformer. Bring the voltage down to where the neon just flickers. This should be at a point approximately 78% of the required voltage.

A better way involves using a milliameter to measure open circuit and closed circuit current and an rms voltmeter to measure actual operating voltage.

Problems With Neon

These fall into two categories:

1. Power supply - like fluorescent ballasts, the high voltage transformers can fail resulting in reduced (and inadequate) voltage or no power at all. Since they are already current limited, overheating may not result and any fuse or circuit breaker may be unaffected. The use of a proper (for safety if nothing else) high voltage meter can easily identify a bad transformer. If a high voltage probe is not available, position (with power off!) the ends of well insulated wires connected to the outputs of the transformer a fraction of an inch apart (about 1/32" per 1,000 V of transformer rating) and apply the power from a safe distance. If a hot arc results, the transformer is likely good (at least when cold).

2. Neon tubes - these may lose their ability to sustain a stable discharge over time as a result of contamination, gas leakage, or electrode damage (either from normal wear or due to excessive current). Check for obvious damage such as a cracked tube or cracked seals around the electrodes or badly deteriorated electrodes. A previously working tube that now will not strike or maintain a stable discharge on a known good transformer will need to be replaced or rebuilt.

Comments on Little Neon Bulbs and Tubes

The comments below relate to the little neon bulbs used as indicators, for voltage regulation or limiting, and other applications in all sorts of electronic equipment.

(From: Mark Kinsler (kinsler@frognet.net).)

Neon lamps can be used for voltage limiters and oscillator elements and just about anywhere else that a non-linear element is needed. The tremolo circuit in the classic Fender guitar amplifier uses a neon lamp relaxation oscillator. The neon lamp is heat-shrinked to a CdS photocell in the volume control circuit.

Less well-known is the fact that you can make a pretty reasonable computer logic element out of them: I believe that this was tried sometime in the 1940's.

Another cool use is as a radiation sensor: you bias the lamp so that it almost turns on, after which any incident radiation: radio waves (as in police radar), light, or gamma radiation will kick the lamp on. There were various circuits in the 1950's that used neon lamps to detect uranium, fight nuclear destruction, or escape the newly-developed police radar guns.

And finally, there's the mystery elevator button. Again, you bias the lamp so that it almost, but not quite, turns on. If you enclose the lamp properly, it'll stay off until you touch it. The electric field variation from your touch will turn the thing on, and it'll stay on. Such lamps are used in some self-service elevators: once the lamp is fired, the low voltage across it is sensed by the ancient logic circuits of the elevator controller and it'll send the elevator to the appropriate floor. These were a lot of fun in the 1960's. I think the controllers used vacuum tubes.

The problem with neon lamps is that they're not so reliable. Their turn-on voltage isn't particularly stable. This means that oscillators have a tendency to drift as the lamps age or when ambient radiation changes. I suspect that the computers are slow and cranky, and the radiation detector isn't anything you'd wish to stake your life or drivers' license on.

Still, they're great fun, and I have a fine time with them. One other use: hang a neon lamp across a telephone line to detect the ring signal. Place it in series with a piezo beeper, and you've got a reliable telephone ringer.

High Intensity discharge Lamps

High Intensity Discharge (HID) Lamp Technology

These have been used for a long time in street, stadium, and factory lighting. More recently, smaller sizes have become available for home yard and crime prevention applications. Like other gas discharge lamps, these types require a special fixture and ballast for each type and wattage. Unlike fluorescents, however, they also require a warmup period.

There are three popular types:

- High pressure mercury vapor lamps contain an internal arc tube made of quartz enclosed in an outer glass envelope. A small amount of metallic (liquid) mercury is sealed in an argon gas fill inside the quartz tube. After the warmup period, the arc emits both visible and invisible (UV) light. High pressure mercury vapor lamps (without color correction) produce a blue-white light directly from their discharge arc. Phosphors similar to those used for fluorescent lamps can be used to give these a color closer to natural light. (Without this color correction, people tend to look like cadavers). Mercury vapor lamps have the longest life of this class of bulbs - 10,000 to 24,000 hours. The technology was first introduced in 1934 and was the first of the commercially viable HID lamps.

- Metal halide lamps are constructed along similar lines to mercury vapor lamps. However, in addition to the mercury and argon, various metal halides are included in the gas fill. The most popular combination is sodium iodide and scandium iodide. A few versions of this lamp have lithium iodide as well. A much less common version has sodium iodide, thallium iodide, and indium iodide. The use of these compounds increases the luminous efficiency and results in a more pleasing color balance than the raw arc of the mercury vapor lamp. Thus, no phosphor is needed to produce a color approaching that of a cool white fluorescent lamp with more green and yellow than a mercury vapor lamp (without correction). Some metal halide lamps have a phosphor that adds some orange-ish red light, but not much, since the metal halide arc does not emit much UV.

- High pressure sodium vapor lamps contain an internal arc tube made of a translucent ceramic material (a form of aluminum oxide known as "polycrystalline alumina"). Glass and quartz cannot be used since they cannot maintain structural strength at the high temperatures (up to 1300 degrees C) encountered here, and hot sodium chemically attacks quartz and glass. Like other HID lamps, the arc tube is enclosed in an outer glass envelope. A small amount of metallic (solid) sodium in addition to mercury is sealed in a xenon gas fill inside the ceramic arc tube. Some versions of this lamp use a neon-argon mixture instead of xenon. Basic operation is otherwise similar to mercury or metal halide lamps. High pressure sodium vapor lamps produce an orange-white light and have a luminous efficiency much higher than mercury or metal halide lamps.

  Since hot liquid sodium often eventually leaches through things and can get lost this way, sodium lamps have a surplus of sodium in them. Proper lamp operation depends on the sodium reservoir being within a proper temperature range.

Mercury vapor lamps are roughly as efficient as fluorescent lamps. Metal halide lamps are much more efficient, generally around 50 to 75 percent more efficient than fluorescent lamps. High pressure sodium lamps are roughly twice as efficient as fluorescent lamps.

Unlike fluorescent lamps, HID lamps will give full light output over a wide range of temperatures. This often makes HID lamps more suitable than fluorescent lamps for outdoor use.

When cold, the metallic mercury or sodium in the arc tube is in its normal state (liquid or solid) at room temperature. During the starting process, a low pressure discharge is established in the gases. This produces very little light but heats the metal contained inside the arc tube and gradually vaporizes it. As this happens, the pressure increases and light starts being produced by the discharge through the high pressure metal vapor. A quite noticeable transition period occurs when the light output increases dramatically over a period of a minute or more. The entire warmup process may require up to 10 minutes, but typically takes 3 to 5 minutes. A hot lamp cannot be restarted until it has cooled since the voltage needed to restrike the arc is too high for the normal AC line/ballast combination to provide.

Problems With High Intensity Discharge Lamps

While HID lamps have a very long life compared to incandescents (up to 24,000 hours), they do fail. The ballasts can also go bad. In addition, their light output falls off gradually as they age. For some types, light output may drop to half its original value towards the end of their life.

A lamp which is cycling - starting, warming up, then turning itself off - is probably overheating due to a bad bulb or ballast. A thermal protector is probably shutting down the fixture to protect it or the arc is being extinguished on its own. However, make sure that it is not something trivial like a photoelectric switch that is seeing the light from the lamp reflected from a white wall or fence and turning the fixture off once the (reflected) light intensity becomes great enough!

Sodium lamps sometimes "cycle" when they have aged greatly. The arc tube's discolorations absorb light from the arc, causing the arc tube to overheat, the sodium vapor pressure becomes excessive, and the arc cannot be maintained. If a sodium lamp "cycles", the first suspect is an aging bulb which should be replaced. Sodium lamp "cycling" used to be very common, but in recent years the lamp manufacturers have been making sodium lamps that are less prone to cycling.

If you have more than one fixture which uses **identical** bulbs, swapping the bulbs should be the first test. If the problem remains with the fixture, then its ballast or other circuitry is probably bad. Don't be tempted to swap bulbs between non-identical fixtures even if they fit unless the bulb types are the same.

Warning: do not operate an HID lamp if the outer glass envelope is cracked or broken. First, this is dangerous because the extremely hot arc tube can quite literally explode with unfortunate consequences. In addition, the mercury arc produces substantial amounts of short wave UV which is extremely hazardous to anything living. The outer glass normally blocks most of this from escaping. Some lamps are actually designed with fusable links that will open after some specified number of hours should air enter the outer envelope. Thus, an undetected breakage will result in the lamp dying on its own relatively quickly.

Troubleshooting a Discharge Lamp Fixture

(From: Greg Anderson (a3a30878@bc.sympatico.ca).)

The following applies directly to high pressure sodium lamps. It may also also be used for metal halide and mercury vapour lamp problems as long as references to the starter are ignored. (Metal halide and mercury vapour lamps do not have starters, except for "instant re-light" metal hhalide lamps.)

The starter produces about 2 to 5 kV spikes to ionize the gas in the lamp. The starter normally has a triac across the ballast and a diac trigger cct. When open cct voltage is across the lamp, the diac fires the triac to short the ballast, the triac then opens. This "kick" produces the voltage spike. Once the gas ionizes, the lamp impedance drops then gradually increases as the lamp warms up. The lamp running voltage is about 1/2 of the open cct voltage

With the lamp removed and power on, you can normally hear a good starter "ticking".

The open circuit voltage is stamped on the ballast and is between about 150 and 350 Vac, depending on lamp wattage and ballast. Also, a capacitor is often connected in series with lamp to improve peaking and ballast action.

Steps to follow:

1. Bypass the photo cell - It may be bad
2. Check connections - water, salt, and bird poop are not good for wiring
3. Check the capacitor, if installed - normally they blow-up when bad
4. Check for open/shorted ballast.
5. Power up and check for starter "ticking"
6. REMOVE starter from cct and measure open cct volts
7. Check/Replace lamp
8. Check/replace lamp socket
9. Replace starter
10. Replace complete fixture.
11. Replace electrician. :)

Repairing a starter is not economically viable and often proves that electronic devices contain smoke and sometimes fire.

Ballasts and Bulbs Should be Matched!

HID bulbs generally need specific ballasts, and any given ballast can usually safely and effectively operate only one type or a few types of HID bulbs.

The bulb wattage must be matched to the ballast. A smaller bulb will usually be fed a wattage close to what the proper bulb takes, and will generally overheat and may catastrophically fail. Any catastrophic failures may not necessarily happen quickly. A larger bulb will be underpowered, and will operate at reduced efficiency and may have a shortened lifetime. The ballast may also overheat from prolonged operation with an oversized bulb that fails to warm up.

See The Discharge Lamp Mechanics Document (rather technical) for why it can be bad to underpower an arc discharge lamp.

Even if the ballast and bulb wattages match, substitutions can be limited by various factors including but not limited to different operating voltages for different bulbs. Examples are:

1. Pulse-start sodium lamps often have a slightly lower operating voltage than metal halide and mercury lamps of the same wattage, and ballasts for these sodium bulbs provide slightly more current than mercury and metal halide ballasts for the same wattage would. The higher current provided by the pulse-start sodium ballast can overheat mercury and metal halide lamps. Mercury and metal halide lamps may also "cycle" on and off in lower voltage sodium ballasts, such as many 50 to 100 watt ones.

2. Metal halide lamps have an operating voltage close to that of mercury lamps in many wattages, but have stricter tolerances for wattage and current waveform. Metal halides also usually need a higher starting voltage. Most metal halide lamps 100 watts or smaller require a high voltage starting pulse around or even over 1,000 volts.

   175 to 400 watt metal halide lamp ballasts can power mercury lamps of the same wattage, but the reverse is not recommended. Mercury lamps 50 to 100 watts will work on metal halide ballasts, but hot restriking of mercury lamps 100 watts or smaller on metal halide lamps may be hard on the mercury lamp since the starting pulse can force current through cold electrodes and the starting resistor inside the mercury lamp.

3. 1,000 watt mercury lamps come in two operating voltages, one of which is OK for 1,000 watt metal halide ballasts. A few wattages of pulse-start sodium (150 watts?) come in two voltages.

   A low voltage lamp in a high voltage ballast will be underpowered, resulting in reduced efficiency, possible reduced lamp life, and possible ballast overheating. A high voltage lamp in a low voltage ballast will usually cycle on and off, operate erratically, or possibly overheat. This will usually result in greatly reduced lamp life in any case.

4. One class of sodium lamps is made to work in mercury fixtures, but these only work properly with some mercury ballasts, namely:

   - 'Reactor' (plain inductor) ballasts on 230 to 277 volt lines.

   - 'High leakage reactance autotransformer' ballasts, preferably with an open circuit voltage around 230 to 277 volts. NOT 'lead', 'lead-peak' nor any metal halide ballast!

   These sodium lamps may suffer poor power regulation and accelerated aging in the wrong mercury ballasts, especially after some normal aging changes their electrical characteristics. Also, these lamps may overheat and will probably have shortened life with pulse-start sodium ballasts.

5. Many sodium lamps require a high voltage starting pulse provided only by ballasts made to power such lamps.

Operation of Discharge Lamps on DC

Sometimes, one may want to run a discharge lamp on DC. There are two possible reasons:

- Only DC power is available.

- To reduce flicker. Sometimes, the lamp performs differently for electricity flowing in one direction than the other. In addition, the positive and negative ends of the arc can make different amounts of light, resulting in a flicker rate equal to the AC frequency rather than twice the AC frequency.

However, end flicker is usually not significant. In HID lamps, the total arc size is generally small. Only if the fixture has a reflector that causes some areas to receive light from only one end of the arc should end flicker be significant. In most multi-tube fluorescent fixtures, the tubes are usually in series pairs with the two tubes in any pair oriented in opposite directions. This generally reduces end flicker effects, especially in fixtures with diffusing lenses.

Bulbs should perform close enough to identically in both directions, unless the bulb is near the end of its life. In such a case, one electrode deteriorates enough to affect performance before the other does. However, this generally indicates a need to replace the bulb rather than to attempt to make it flicker less.

If you want to rectify the AC to provide the bulb with DC, use a bridge rectifier after the ballast. Most ballasts, including all "iron" types, require AC of the proper voltage and frequency to work. Do this only if only two wires feed the bulb. Otherwise, diodes in the bridge rectifier may short parts of the ballast to each other, at least for half the AC cycle. Problems can also occur with fluorescent ballasts with filament windings. Only fully isolated filament windings or separate filament transformers should be used if you rectify the output of a ballast with filament windings. Also, the bridge rectifier must withstand the peak voltage provided by the ballast.

If the power supply is DC of adequate voltage, you need a resistor ballast or an electronic ballast specifically designed to run your lamp from the available DC voltage. "Iron" ballasts only limit current when used with AC. Preheat fluorescent lamps operated from DC supplies and without special ballasts need both the usual "iron" ballast to provide the starting "kick" and a resistor to limit current.

In addition, most discharge lamps are only partially compatible with DC, and some are not compatible at all.

Mercury vapor and fluorescent lamps generally work on DC. However, the life may be shortened somewhat by uneven electrode wear.

Fluorescent lamps may get dim at one end with DC. Since the mercury vapor ionizes more easily than the argon, some of it exists as positive ions. This can cause the mercury to be pulled to the negative end of the tube, resulting in a mercury shortage at the positive end. This is more of a problem with longer length and smaller diameter tubes.

Some fluorescent fixtures made for use where the power available is DC have special switches to reverse polarity every time the fixture is started. This balances electrode wear and reduces mercury distribution problems.

Mercury vapor lamps generally work OK with DC, but some may only reliably work properly if the tip of the base is negative and the shell of the base is positive. This is because the starting electrode does its job best when it is positive.

In addition, if the nearby main electrode is positive, it may cause a thin film of metal condensation that shorts the starting electrode to the nearby main electrode. This may make some brands, models, and sizes of mercury lamps unable to start after some use. The negative main electrode will not release as much vaporized electrode material, since the electrode material easily forms positive ions making the electrode material vapor tend to condense on the electrode rather than condense on nearby parts of the arc tube.

Metal halide and sodium lamps should not get DC. Use these only with ballasts that give the bulb AC. In metal halide lamps, ions from the molten halide salts can leach into hot quartz in the presence of a DC electric field. This can cause strains in the quartz arc tube. At the ends of the arc tube, electrolysis may occur, releasing chemically reactive halide salt components that can damage the arc tube or the electrodes. The arc tube may crack as a result.

There are a few specialized metal halide lamps that are made to work on DC. These often have asymmetrical electrodes and/or short arc lengths. These lamps often also must be operated only in specific positions, and only with the type of current they were designed for in order to achieve the proper distribution of active ingredients within the arc tube and to achieve proper electrode usage. For example, some of these lamps may go wrong in some way or another with AC.

In high pressure sodium lamps, which contain both sodium and mercury, the sodium forms positive ions more easily than the mercury does and drifts towards the negative electrode. The positive end can go dim from a lack of sodium. In addition, if any part of the arc tube is filled with a mixture containing excessive sodium and a lack of mercury, heat conduction from that part of the arc to the arc tube will increase. Furthermore, the hot arc tube may suffer electrolysis problems over time in the presence of sodium ions and a DC electric field.

Low pressure sodium lamps should not get DC for the same reasons. The sodium is likely to drift to the negative end of the arc tube, and hot glass will almost certainly experience destructive electrolysis problems if exposed to hot sodium or sodium ions and a DC electric field.

Special purpose HID lamps such as xenon and HMI

The usual general purpose HID lamps are mercury vapor, metal halide, and high pressure sodium. You can get these at home centers, although usually only in wattages up to 400 watts. These versions of HID lamps are optimized for high efficiency, long life, and minimized manufacturing cost.

However, the arc surface brightness of these lamps is roughly equal to the surface brightness of incandescent lamp filaments and general purpose halogen lamp filaments. For some applications such as endoscopy and movie projection, it is necessary to have a much more concentrated light source. This is where specialized HID lamps such as short arc lamps and HMI lamps come in.

Short arc lamps consist of a roughly spherical quartz bulb with two heavy duty electrodes spaced only a few millimeters apart at the tips. The bulb may contain xenon or mercury or both. Mercury short arc lamps have an argon gas fill for the arc to start in.

In a short arc lamp, the arc is small and extremely intense. The power input is at least several hundred and more typically a few thousand watts per centimeter of arc length. The operating pressure in the bulb is extremely high - sometimes as low as 20 atmospheres, more typically 50 to over 100 atmospheres. These lamps are an explosion hazard!

Mercury short arc lamps are used when a compact, intense source of UV is needed or where one cannot have the high voltage starting pulses needed for xenon short arc lamps. Mercury short arc lamps are slightly more efficient than xenon ones. The pressure in a mercury short arc lamp does not need to be as high for good efficiency as in a xenon one, but is still tremendous.

Xenon short arc lamps are more common than mercury ones, since they do not require time to warm up the way mercury lamps do and have a daylight-like spectrum. A disadvantage of xenon is the requirement of a very high voltage starting pulse - sometimes around 30 kilovolts!

Xenon short arc lamps are used for movie projection and sometimes for searchlights. Lower wattage ones are used in specialized devices such as endoscopes.

HMI lamps are metal halide lamps with a more compact and more intense arc. The arc is larger and less intense than that of a short arc lamp. Typical power input is hundreds of watts per centimeter of arc length, but gets to a few kilowatts per centimeter in the largest ones.

HMI lamps are used in some spotlights. They are used in some endoscopes and projection applications where the intensity of the HMI arc is adequate since they cost less and last longer and are more efficient than true short arc lamps.

There are all sorts of HMI and similar lamps, including HTI lamps and the lamps used in HID auto headlights.

HID Automotive Headlights

First there were gas lamps, then there were electric bulbs, then sealed beam, then halogen. Now, get ready for - drum roll please! - high intensity discharge lamps with sophisticated controllers. High-end automobiles from makers like BMW, Porsche, Audi, Lexus, and now Lincoln are coming equipped with novel headlight technology. No doubt, such technology will gradually find its way into mainstream automobiles - as well as other applications for mortals.

Among the potential advantages of HID headlights are higher intensity, longer life, superior color, and better directivity:

- Light intensity - HID lamps are about 3 times as efficient as halogen lamps. Thus, even when the efficiency of the DC-DC converter is taken into consideration, the lower power input can actually result in much brighter headlights than are possible with halogen bulbs.

This reduced power also leads to cooler operation and less drain on the battery and alternator.

- Lifespan - an HID lamp can be expected to last 2,700 hours or more and thus covered under the bumper to bumper warranty for 100,000 miles. As a practical matter, the HID lamp may outlast the automobile. Since warranty replacement of headlights turns out to be a significant expense, there is strong incentive to see this long lived technology take off.

- Spectral output - the light from the HID lamp is richer in blue (and more like daylight) than halogen bulbs. This turns out to enhance reflectivity of signs and road markings.

- Beam pattern - the small arc size of the HID lamp permits the optical system to be optimized to direct light more effectively to where it is needed and prevent it from spilling over to where it is not wanted.

In order to make this practical - even for a $40,000 Lexus - special DC-DC converter chips have been designed specifically with automotive applications in mind. These, along with a handful of other basic electronic components, implement a complete HID headlight control system.

The HID bulb itself is similar in basic design to traditional HID lamps: Two electrodes are sealed in a quartz envelope along with a mix of solids, liquids, and gasses. When cold, these materials are in their native state (at room temperature) but are mostly gases when the lamp is hot. Starting of these lamps may require up to 20 KV to strike an arc but only 50 to 150 V to maintain it. Lamps may be designed to operate on either AC or DC current depending on various factors including the size and shape of the electrodes. A unique set of ballast operating parameters must be matched to each model HID bulb.

Of all the problems that had to be addressed for HID headlights to become practical (aside from the cost), the most significant was the warmup time. As noted in the section: "High intensity discharge (HID) lamp technology", common HID lamps require a warmup period of a few minutes before substantially full light output is produced. This is, of course, totally unacceptable for an automotive headlight both for cold start (imagine: "Honey, I have to go cook the headlights") as well as when they need to be blinked. The warmup problem was solved by programming the controller to deliver constant power to the lamp rather than the more common nearly constant current that would be provided by a traditional ballast. With this twist along with a special lamp design, the lamp comes up to at least 75% of full intensity in under 2 seconds. The controller also provides 'hot strike' capability for blinking (recall that HID lamps typically cannot be restarted when hot). Thus, restarting a hot lamp is absolutely instantaneous.

While this technology is just beginning to appear, expect inroads (no pun intended) into household, office, store, factory, and other area and work lighting. The combination of high efficiency, long life, desirable spectral characteristics, small size, and solid state reliability should result in many more applications in the near future. The nearly instant starting capability addresses one of the major drawbacks of small HID lamps.

If you have some time and money to spare:

(From: Declan Hughes (hughes@aero.tamu.edu).)

Check out: OSRAM Sylvania Products Inc.

They have a "sample" for sale at $250.00 for one lamp including the 12 VDC electronic ballast. 42 W total power, 35 W light power, 3,200/2,800 lm output (there are two types, D2S and D2R), 2,000 hours rated lifetime, 91/80 lm/W luminous efficacy, 4,250/4,150 K color temperature, 6,500 cd/cm^2 average luminance, 4.2 mm arc length, burning position horizontal +/- 10 deg., luminous flux after 1 sec. = 25%, max. socket temp. = 180 deg C, any errors are mine.

Substitution of Metal Halide Lamps?

The following was prompted by a request for info on replacing an (expensive) 250 watt metal halide lamp in a video projector with something else.

I would not substitute this lamp, for many reasons below:

The metal halide lamp requires a ballast. The ballast should only run a 250 watt metal halide lamp of the same arc voltage. You will have to measure the arc voltage yourself after the lamp warms up, and do this without exposing yourself to the nasty UV that some of these things emit but which does not pass through glass. Arc voltages of many specialized metal halide lamps are not widely published and may or may not be available from the lamp manufacturer.

WARNING: The strike voltage on these may be several kV which will probably obliterate your multimeter should the arc drop out and attempt to restart while you are measuring it! Either the operating or strike voltage may obliterate you should you come in contact with live terminals! (Special metal halides probably usually only need a couple to a few kV. Xenon metal halide automotive lamps need 6 to 12 kV to strike and 15 to 20 kV for hot restrike. The worst are short arc xenon that may use up to 30 kV or more.)

Most metal halide lamps are AC types and some are DC and you can only use AC lamps on AC output ballasts and DC lamps on DC output ballasts. Different metal halide lamps may have different requirements for starting voltage also.

If you match arc voltage, AC/DC type, and the ballast will start the lamp, you might be in business but good chance not. Many projector lamps have specific cooling requirements and some have specific burning position requirements. Metal halide lamps may prematurely fail (possibly violently!) if they overheat, in addition to being off-color. If overcooled, they are more like mercury lamps and will be off-color and have reduced light output. In addition, some metal halide lamps have a halogen cycle in them to keep the inner surface of the bulb clean, and that may not work if the lamp is overcooled and not enough of the chemicals in the bulb get vaporized. This could also even make the lamp fail.

If you get the alternate lamp to operate satisfactorily, the arc may be in a different location from that of the original lamp. The arc may be of a different shape or size than that of the original lamp. This can affect your projection. Your projection may not get much light or may have illumination of only part of the picture.

The arc may have a different color or spectrum, which can affect the color rendering of what's being projected. Metal halide arcs are often not of uniform color, and if the alternate lamp has a less color-uniform arc than the original lamp then your pictures may have strange color tints in them.

As for using a halogen instead of metal halide? You will get less light, as well as problems from the filament having a different shape or size than the original metal halide arc does. Most likely, the filament is larger or longer than the arc and this will reduce the percentage of the light being utilized. Should you try a halogen lamp hack, you will almost certainly have to bypass the metal halide ballast. And halogen lamps emit more infrared than metal halide lamps of the same wattage - you might overheat the source of your image (e.g., LCD panel or transparency).

I would not recommend substituting a projector lamp for all of these reasons. This should only be tried at your own risk and only by those that are very familiar with all of the characteristics of the lamps in question - including being familiar with burning position requirements, cooling requirements, shape and size of the light-emitting region, etc.

Projector lamps in general, and especially specialized HID lamps, should be used only in equipment made specifically to use the particular lamps in question, or by those who know about these things well enough to make their own ballasts and know the other messy things about these lamps. And you may not save much by using a different lamp - specialized metal halide lamps are all expensive.

And for anyone shopping for any sort of projector - look into price, availability, and life expectancy of lamps!

---

Low Pressure Sodium Lamps

(Portions from: Bruce Potter (s60231@aix2.uottawa.ca))

Low pressure sodium lamps are the most efficient visible light sources in common use. These lamps have luminous efficacies as high as 180 lumens per watt.

A low pressure sodium lamp consists of a tube made of special sodium-resistant glass containing sodium and a neon-argon gas mixture. Since the tube is rather large and must reach a temperature around 300 degrees Celsius, the tube is bent into a tight U-shape and enclosed in an evacuated outer bulb in order to conserve heat. As an additional heat conservation measure, the inner surface of the outer bulb is coated with a material that reflects infrared but passes visible light. This material has traditionally been tin oxide or indium oxide.

The electrodes are coiled tungsten wire coated with thermionically emissive material, and somewhat resemble the electrodes of fluorescent lamps. Unlike most fluorescent lamps, low pressure sodium lamps have only one electrical connection to each electrode and the electrodes cannot be preheated.

The gas mixture is a "Penning" mixture, consisting mainly of neon with a small amount of argon. Depending on who you listen to, this mixture is .5 to 2 percent argon, 98 to 99.5 percent neon. More argon-rich mixtures around 98-2 may be favored today since hot glass has some ability to absorb argon from a low pressure electric discharge. Ideally the mixture should be only a few tenths of a percent argon, in order to ionize most easily and do so much more easily than pure neon or pure argon.

A significant surplus of sodium is contained in the glass arc tube since the glass may absorb or react with some of the sodium. The sodium vapor pressure is controlled by the temperature of the coolest parts of the arc tube. When the arc tube reaches a proper temperature, further heating is reduced by the lamp's efficiency at producing light instead of heat.

The arc tube has dimples in it, which are normally slightly cooler than the rest of the arc tube. This causes the sodium metal to collect in the dimples instead of covering a larger portion of the arc tube and blocking light.

The low pressure sodium lamp usually requires 5 to 10 minutes to warm up.

The light of low pressure sodium consists almost entirely of the orange-yellow 589.0 and 589.6 nm sodium lines. This light is basically monochromatic orange-yellow. This monochromatic light causes a dramatic lack of color rendition - everything comes out in an orange-yellow version of black-and-white! This can cause some confusion in parking lots since cars become more alike in color.

Some basically red and reddish color fluorescent inks, dyes, and paints can fluoresce red to red-orange from the yellow sodium light and these will stand out in sodium light with color differing from that of the sodium light.

Another disadvantage of low pressure sodium light is that many objects will look darker than they would with an equal amount of other light. Red, green, and blue objects look dark under low pressure sodium light. Most other sources of light of sodium-like color such as "bug bulbs" have significant red and green output and will render red and green objects at least somewhat normally.

Introduction

This is a collection of jokes and other humorous stories I have collected off the Net over the past few years. Most relate to engineering or science but some on other topics were just too good to pass up.

These should be mostly suitable for general audiences (unless you have a lawyer in the family. :-) They are in no particular order. I just add new ones to the end of the file (most of the time) and bump the version number (when I remember).

In most cases, the actual authors are unknown but I have at least provided attribution to the person who posted or emailed the article where available.

- Back to Humor Table of Contents.

DISCLAIMER

While every effort has been made - really! - to keep this collection of hopefully humorous articles pretty clean and unlikely to offend most people, there is always a chance something slipped through. My apologies in advance for any offense that might be taken. In the several years that most of this collection has been available, I have only received one (1, 0000001, I) complaint which I offered to remedy but never heard back so it can't be all that unsavory!

Having said that, I will not be responsible for any direct or consequential damage that may result from the reading of this collection including but not limited to: complaints from neighbors over excessive noise, costs associated with hernia operations resulting from prolonged and intense belly-laughs, destruction of property caused when the dog, cat, spouse, or other relation was thrown across the room from the couch and landed in the entertainment center, or the time and expense of finding another place of employment having been fired from your former one due to continuous Web page reading and inattention to the duties associated with your official job description.

As you can tell, lawyers had nothing whatsoever to do with the wording of this disclaimer. :-)

A Brief Guide to Scientific Literature

(From: Chris Taylor (chris@labtam.labtam.oz.au).)

Here is an old collection that I rediscovered recently:

```
Phrase                                Translation
-------------------------------------------------------------------------------

It has been long known                I haven't bothered to check the references

It is known                           I believe

It is believed                        I think

It is generally believed              My colleagues and I think

There has been some discussion        Nobody agrees with me

It can be shown                       Take my word for it

It is proven                          It agrees with something mathematical

Of great theoretical importance       I find it interesting

Of great practical importance         This justifies my employment

Of great historical importance        This ought to make me famous
```

Some samples were chosen for study	The others didn't make sense
Typical results are shown	The best results are shown
Correct within order of magnitude	Wrong
The values were obtained empirically	The values were obtained by accident
The results are inconclusive	The results seem to disprove my hypothesis
Additional work is required	Someone else can work out the details
It might be argued that	I have a good answer to this objection
The investigations proved rewarding	My grant has been renewed

Carnot is dead ! Schaeffer disproves 2nd Law

(From: Brandon Davis (HUEP35B@prodigy.com).)

The First Law of Thermodynamics: "You can't get something for nothing"

The Second Law of Thermodynamics: "As a matter of fact, you can't even break even."

Newton's first Law of Motion: "If you kick a can, it will move."

Newton's Second Law of Motion: "If you kick it harder, it will move faster."

Perhaps others know of similar restatements of other important Laws?

The best summary of the first and second laws of thermodynamics I have seen (in 3 statments):

- You can't win.
- You can't break even.
- You can't quit the game.

But surely simple things grow more complex as the cosmos implodes in retrograde time toward the initial collapse of the singularity? Er, or is it that complex things break down to constituent particles as the cosmos eXplodes along linear time lines towards chaos (i.e., entropy). Wait. Where is my local closed system where heat/energy/complexity can make a muddle of the metaverse's puddle? Oh --i know, I will just sink into the quandary of the 19th century, where the only part of probability that was important was babil (babbel) and ...oh, dear, where IS lewis carrol when he's needed?: The

Canonical Collection of Light Bulb Jokes

(From: Clay Belcher (cbelcher@kuhub.cc.ukans.edu).)

Time for a little levity, lighting fans. Or should I say a little light humor. This collection of jokes was originally attributed to: Kurt Guntheroth (kurt@tc.fluke.COM).)but I've been unable to raise him at that address. I've taken the liberty to post this here in a somewhat sterilized version (as the original contained some pretty offensive stuff). Enjoy, and feel free to contribute additional ones.

```
Q:  How many Californians does it take to change a light bulb?
A:  Six.  One to turn the bulb, one for support, and four to
    relate to the experience.

Q:  How many Oregonians does it take to screw in a light bulb?
A:  Five.  One to change the bulb and four more to chase off
    the Californians who have come up to relate to the experience.
A': Nine.  One to change the bulb, and eight to protest the
    nuclear power plant that generates the electricity that powers it.

Q:  How many New Yorkers does it take to screw in a light bulb?
A:  None of your business!
A': 50.  50?  Yeah 50; its in the contract.

Q:  How many Virginians does it take to change a light bulb?
A:  Twelve: one to replace it and eleven to talk about how much
    better the old one was.

Q:  How many yuppies does it take to change a light bulb?
A:  Two.  One to call the electrician and one to mix the martinis.

Q:  How many Psychiatrists does it take to change a light bulb?
A:  Only one, but the bulb has got to really WANT to change.
A': None; the bulb will change itself when it is ready.

Q:  How many software people does it take to screw in a light bulb?
```

```
A:  None.  That's a hardware problem.
A': One, but if he changes it, the whole building will probably fall down.
A": Two.  One always leaves in the middle of the project.

Q:  How many hardware folks does it take to change a light bulb?
A:  None.  That's a software problem.
A': None.  They just have marketing portray the dead bulb as a feature.

Q:  How many Unix hacks does it take to change a light bulb?
A:  As many as you want; they're all virtual, anyway.

Q:  How many Bell Labs Vice Presidents does it take to change a light bulb?
A:  That's proprietary information.  Answer available from AT&T on payment of
    license fee (binary only).
A': Nearly unanswerable, since the one who tries to change it usually drops
    it, and the others call for a planning session.
A": Three.  One to get the bulb and two to get the phone number of one of
    their subordinates to actually change it.

Q:  How many graduate students does it take to screw in a light bulb?
A:  Only one, but it may take upwards of five years for him to get it done.

Q:  How many `Real Men' does it take to change a light bulb?
A:  None:  `Real Men' aren't afraid of the dark.

Q:  How many `Real Women' does it take to change a light bulb?
A:  None:  A 'Real Woman' would have plenty of real men around to do it.

Q:  How many Marxists does it take to screw in a light bulb?
A:  None:  The light bulb contains the seeds of its own revolution.

Q:  How many Russian leaders does it take to change a light bulb?
A:  Nobody knows.  Russian leaders don't last as long as light bulbs.

Q:  How many nuclear engineers does it take to change a light bulb?
A:  Seven.  One to install the new bulb and six to figure out what to do with
    the old one for the next 10,000 years.

Q:  How many pre-med students does it take to change a light bulb?
A:  Five:  One to change the bulb and four to pull the ladder out from under
    him.
```

Q: How many jugglers does it take to change a light bulb?
A: One, but it takes at least three light bulbs.

Q: How many Feminists does it take to change a light bulb?
A: That's not funny!!!

Q: How many supply-siders does it take to change a light bulb?
A: None. The darkness will cause the light bulb to change by itself.

Q: How many economists does it take to screw in a light bulb?
A: Two. One to assume the ladder and one to change the bulb.
A': None. If the government would just leave it alone, it would screw itself in.

Q: How many Valley Girls does it take to change a light bulb?
A: Oooh, like, manual labor? Gag me with a spoon! For sure.

Q: How many data base people does it take to change alight bulb?
A: Three:
One to write the light bulb removal program,
one to write the light bulb insertion program, and
one to act as a light bulb administrator to make sure
nobody else tries to change the light bulb at the same time.

Q: How many Carl Sagans does it take to screw in a light bulb?
A: Billions and billions.

Q: How many Zen masters does it take to screw in a light bulb?
A: A tree in a golden forest.
A': Two: one to change the bulb and one not to change it.
A": One to change and one not to change is fake Zen. The true Zen answer is Four. One to change the bulb.
A'":None. Zen masters carry their own light.

Q: How many folk singers does it take to screw in a light bulb?
A: Two. One to change the bulb, and one to write a song about how good the old light bulb was.

Q: How many surrealists does it take to change a light bulb?
A: Two, one to hold the giraffe, and the other to fill the bathtub with brightly colored machine tools.

Q: How many gorillas does it take to screw in a light bulb?
A: Only one, but it takes a truckload of light bulbs!

Q: How many doctors does it take to screw in a light bulb?
A: Three. One to find a bulb specialist, one to find a bulb installation
    specialist, and one to bill it all to Medicare.

Q: How many [IBM] Technical Writers does it take to change a light bulb?
A: 100. Ten to do it, and 90 to write document number GC7500439-0001,
    Multitasking Incandescent Source System Facility, of which 10% of the
    pages state only "This page intentionally left blank", and 20% of the
    definitions are of the form "A:...... consists of sequences of non-blank
    characters separated by blanks".
A': Just one, provided there's an engineer around to explain how to do it.

Q: How many professors does it take to change a light bulb?
A: Only one, but they get three publications out of it.

Q: How many people from New Jersey does it take to change a light bulb?
A: Three. One to change the light bulb, one to be a witness, and the third
    to shoot the witness.

Q: How many cops does it take to screw in a light bulb?
A: None. It turned itself in.

Q: How many lawyers does it take to change a light bulb?
A: How many can you afford?

Q: How many football players does it take to change a light bulb?
A: The entire team! And they all get a semester's credit for it!

Q: How many thought police does it take to screw in a light bulb?
A: None. There never was any light bulb.

Q: How many Federal employees does it take to screw in a light bulb?
A: Sorry, that item has been cut from the budget!

Q: How many psychics does it take to screw in a light bulb?
A: ---- You should have hit "n"!

Q: How many sorority sisters does it take to change a light bulb?
A: 51. One to change the bulb, and fifty to sing about the bulb
    being changed.

Q: How many frat guys does it take to screw in a light bulb?
A: Three: One to screw it in, and the other two to help him
    down off the keg.
A': Five: One to hold the bulb, and four to guzzle beer until the room spins.

Q: How many Harvard students does it take to screw in a light bulb?
A: Just one. He grabs the bulb and waits for the world to revolve around him.

Q: How many bureaucrats does it take to screw in a light bulb?
A: Two. One to assure the everything possible is being done while the other
    is incomplete pending resolution of some action items. It will be
    continued next week.   Meanwhile...

Q: How many brewers does it take to change a light bulb?
A: About one third less than for a regular bulb.

Q: How many WASP Princesses does it take to screw in a light bulb?
A: Two. One to get a Tab and one to call Daddy.

Q: How many accountants does it take to screw in a light bulb?
A: What kind of answer did you have in mind?

Q: How many civil servants does it take to change the light bulb?
A: 45. One to change the bulb, and 44 to do the paperwork.

Q: How many junkies does it take to screw in a light bulb?
A: Oh wow, is it like dark, man?

Q: How many consultants does it take to change a light bulb?
A: I will have an estimate for you a week from Monday.

Q: How many U.S marines does it take to screw in a light bulb
A: 50. One to screw in the light bulb and the remaining 49 to guard him.

Q: "How many Romulans does it take to screw in a light bulb?"
A: "151, one to screw the light-bulb in, and 150 to self-destruct the ship

out of disgrace."

Q: How many dull people does it take to change a light bulb?
A: one.

Q: How many editors of Poor Richard's Almanac does it take to replace a light bulb?
A: Many hands make light work.

Q: How many Vulcans does it take to change a light bulb?
A: "Approximately 1.000000000000000000000000"

Q: How many members of the U.S.S. Enterprise does it take to change a light bulb?
A: 7. Scotty will report to Captain Kirk that the light bulb in the Engineering Section is burnt out, to which Kirk will send Bones to pronounce the bulb dead. Scotty, after checking around, notices that they have no more new light bulbs, and complains that he can't see in the dark to tend to his engines. Kirk must make an emergency stop at the next uncharted planet, Alpha Regula IV, to procure a light bulb from the natives. Kirk, Spock, Bones, Sulu, and 3 red shirt security officers beam down. The 3 security officers are promptly killed by the natives, and the rest of the landing party is captured. Meanwhile, back in orbit, Scotty notices a Klingon ship approaching and must warp out of orbit to escape detection. Bones cures the native king who is suffering from the flu, and as a reward the landing party is set free and given all of the light bulbs they can carry. Scotty cripples the Klingon ship and warps back to the planet just in time to beam up Kirk et. al. The new bulb is inserted, and the Enterprise continues with its five year mission.

Q: How many efficiency experts does it take to replace a light bulb?
A: None. Efficiency experts replace only dark bulbs.

Q: How many actors does it take to change a light bulb?
A: Only one. They don't like to share the spotlight.

Q: How many Chinese Red Guards does it take to screw in a light bulb?
A: 10,000 - to give the bulb a cultural revolution.

Q: Do you know how many musicians it takes to change a light bulb?
A: No, big daddy, but hum a few bars and I will fake it.
A': Twenty. One to hold the bulb, two to turn the ladder, and seventeen in on the guest list.

Q: How many mystery writers does it take to screw in a light bulb?
A: Two, one to screw it almost all the way in and the other to give it a surprising twist at the end.

Q: How many bikers does it take to change a light bulb?
A: It takes two. One to change the bulb, and the other to kick the switch.

Q: How many running-dog lackeys of the bourgeoisie does it take to change a light bulb?
A: Two. One to exploit the proletariat, and one to control the means of production!

Q: How many existentialists does it take to screw in a light bulb?
A: Two: One to screw it in and one to observe how the light bulb itself symbolizes a single incandescent beacon of subjective reality in a netherworld of endless absurdity reaching out toward a maudlin cosmos of nothingness.

Q: How many light bulbs does it take to change a light bulb?
A: One, if it knows its own Goedel number.

Q: How many dadaists does it take to screw in a light bulb?
A: To get to the other side.

Q: How many mathematicians does it take to screw in a light bulb?
A: None. It's left to the reader as an exercise.
A': One. He gives it to six Californians, thereby reducing the problem to an earlier joke.
A": One. He gives it to five Oregonians, thereby reducing the problem to an earlier joke.
A'": In an earlier article, zeus!bobr writes:

Q: How many mathematicians does it take to screw in a light bulb?
A: One. He gives it to six Californians, thereby reducing the problem to an earlier joke...

In earlier work, Wiener [1] has shown that one mathematician can change a light bulb. If k mathematicians can change a light bulb, and if one more simply watches them do it, then k+1 mathematicians will have changed the light bulb. Therefore, by induction, for all n in the positive integers, n mathematicians can change a light bulb.

Bibliography:

[1] Weiner, Matthew P., <11485@ucbvax>, "Re: YALBJ", 1986

Q: How many consultants does it take to change a light bulb?
A: We don't know. They never get past the feasibility study.

Q: How many Ukrainians does it take to screw in a light bulb?
A: They don't need to, they glow in the dark.

Q: How many poets does it take to change a light bulb?
A: Three. One to curse the darkness, one to light a candle...
... and one to change the bulb.

Q: How many stock brokers does it take to change a light bulb?
A: Two. One to take out the bulb and drop it, and the other to try and sell it before it crashes (knowing that it's already burned out).

Q: How many aides does it take to change the President's light bulb?
A: None, they like to keep him in the dark.

Q: How many magicians does it take to change a light bulb?
A: Depends on what you want to change it into.

Q: How many Macintosh users does it take to change a light bulb?
A: None. You have to replace the whole motherboard.

And a couple more:

(From: Don Klipstein (don@misty.com).)

Q: How many straight male West Hollywood residents does it take to change a light bulb?

A: Either of them could probably do it themselves.

Q: How many journalists does it take to change a lightbulb?

A: Three. One to report on the inspired program to bring light, one to report on the sinister government plot to deprive the poor of darkness, and one to report on the light bulb manufacturer assassinating the old light bulb.

(From: WB or CM Hilbrich (hilbrich@antares.cloudnet.com).)

Q: How many mailing list subscribers does it take to change a light bulb?

A: 1,331:

- 1 to change the light bulb and to post to the list that the light bulb has been changed.

- 14 to share similar experiences of changing light bulbs and how the light bulb could have been changed differently.

- 7 to caution about the dangers of changing light bulbs.

- 27 to point out spelling/grammar errors in posts about changing light bulbs.

- 53 to flame the spell checkers.

- 156 to write to the list administrator complaining about the light bulb discussion and its inappropriateness to this mail list.

- 41 to correct spelling in the spelling/grammar flames.

- 109 to post that this list is not about light bulbs and to please take this e-mail exchange to alt.lite.bulb.

- 203 to demand that cross posting to alt.grammar, alt.spelling and alt.punctuation about changing light bulbs be stopped.

- 111 to defend the posting to this list saying that we all use light bulbs and therefore the posts ARE relevant to this mail list.

- 306 to debate which method of changing light bulbs is superior, where to buy the best light bulbs, what brand of light bulbs work best for this technique, and what brands are faulty.

- 27 to post URLs where one can see examples of different light bulbs.

- 14 to post that the URLs were posted incorrectly, and to post corrected URLs.

- 3 to post about links they found from the URLs that are relevant to this list which makes light bulbs relevant to this list.

- 33 to summarize all posts to date, then quote them including all headers and footers, and then add "Me Too."

- 12 to post to the list that they are unsubscribing because they cannot handle the light bulb controversy.

- 19 to quote the "Me Too's" to say, "Me Three".

- 4 to suggest that posters request the light bulb FAQ.

- 1 to propose new alt.change.lite.bulb newsgroup.

- 47 to say this is just what alt.physic.cold_fusion was meant for, leave it here.

- 143 votes for alt.lite.bulb.

(From: Dan Hicks (danhicks@millcomm.com).)

You forgot:

- 37 empty posts.

- 250 debating the merits of magnetic light bulb filters.

```
- 3 giving you URLs for really sexy adult light bulbs.
```

Pentium Bug Jokes

(From: Henry G. Baker (hbaker@netcom.com).)

The 0.000000000001th new Intel slogan for the Pentium

We give you the most megaflops.

On the tee-shirt of an inline skater in Mountain View: :-)

(Intel Inside logo)

"I asked for a refund on my Pentium, and all I got was this lousy T-shirt"

Some Pentium Q & A and Random Comments

Q: What is Intel's follow-on to the Pentium?

A: Repentium.

Q: What does the element Pentium decay into?

A: Inert silicon with the emission of a press release.

The Pentium doesn't have bugs or produce errors; it's just Precision-Impaired.

Intel business executives have been so stressed by staying up late at night trying to figure out what to do about the Pentium Problem, that they're past the floating point.

I heard that Intel lost one of its divisions today...

(From: Mark Thorson (eee@netcom.com).)

INTEL INSIDE

Intel Inside sat on a wall.
Intel Inside had a great fall.
All the king's lawyers
and all the king's men
couldn't put Intel Inside
back together again.

PENTIUM PROCESSOR

Pentium Processor, puddin' and pie.
Pentium Processor, price real high.
When the bugs came out to play,
Pentium Processor ran away.

(From: John Cooley (jcooley@world.std.com).)

"Here's some of the hardware humor I've had mailed to me since the Intel Pentium floating point divide bug came out that's been such big news lately. It's not every day that we hardware designers get national recognition for *anything* either positive or negative! (Thought I'd post it as a refreshing diversion from the 100,000 serious hardware design oriented posts we see here all year through.)"

John Cooley
- Part Time Sheep & Goat Farmer
- Part Time EDA Consumer Advocate
- Full Time ASIC, FPGA & EDA Design Consultant

The Top Ten Reasons to Buy a Pentium Machine

10. You current computer is too accurate.

9. Want to get into the Guinness Book as "owner of the most expensive paperweight".

8. Math errors add zest to life.

7. You need an alibi for the IRS.

6. You want to see what all the fuss is about.

5. You've always wondered what it would be like to be a plaintiff.

4. The "Intel Inside" logo matches your decor perfectly.

3. You no longer have to worry about the CPU overheating.

2. You got a great deal from JPL.

And the #1 reason to buy a Pentium machine:

1. It'll probably work.

Q&A: The Pentium FDIV bug

```
Q:  How many Pentium designers does it take to screw in a light bulb?
A:  1.99904274017, but that's close enough for non-technical people.

Q:  What do you get when you cross a Pentium PC with a  research grant?
A:  A mad scientist.

Q:  What's another name for the "Intel Inside" sticker they put on Pentiums?
A:  The warning label.

Q:  Complete the following word analogy:  Add is to Subtract as Multiply
    is to:
        1)  Divide
        2)  ROUND
        3)  RANDOM
        4)  On a Pentium, all of the above
A:  Number 4.

Q:  What algorithm did Intel use in the Pentium's floating point divider?
A:  "Life is like a box of chocolates." (Source: F. Gump of Intel)

Q:  Why didn't Intel call the Pentium the 586?
A:  Because they added 486 and 100 on the first Pentium and got 585.999983605.
```

Top Ten New Intel Slogans for the Pentium

```
  9.9999973251   It's a FLAW, Dammit, not a Bug
  8.9999163362   It's Close Enough, We Say So
  7.9999414610   Nearly 300 Correct Opcodes
  6.9999831538   You Don't Need to Know What's Inside
  5.9999835137   Redefining the PC -- and Mathematics As Well
  4.9999999021   We Fixed It, Really
  3.9998245917   Division Considered Harmful
  2.9991523619   Why Do You Think They Call It *Floating* Point?

Things They Never Taught in School

(From: Jim Weir (rst-engr@oro.net).)

And for those of you who went through school thinking that everything above 30 MHz was powdered bat wings and mouse milk,

1. 2 #24 PVC hookup wires twisted tightly is about 10 pf per inch.
2. A file and a disk ceramic capacitor is the original one-set variable capacitor.
3. A wire is just some inductance, capacitance, and resistance floating in a loose formation.
4. A file and a carbon COMPOSITION resistor is the original one-set variable resistor.
5. A 50 ohm line on green glass PC board is about the thickness of the board material.
6. Don't tug on Superman's cape, don't piss into the wind, and don't mess around with The Man.

Virus Jokes

Immediately scan your computer for the following viruses:

- PAT BUCHANAN VIRUS: Your system works fine, but it complains loudly about foreign software.
- COLIN POWELL VIRUS: Makes it presence known, but doesn't do anything. Secretly you wish it would.
- HILLARY CLINTON VIRUS: Files disappear, only to reappear mysteriously a year later, in another directory.
- O.J. SIMPSON VIRUS: You know it's guilty of trashing your system, but you just can't prove it.
- BOB DOLE VIRUS: Could be virulent, but it's been around too long to be much of a threat.
- STEVE FORBES VIRUS: All files are reported as the same size.
- PAUL REVERE VIRUS: This revolutionary virus does not horse around. It warns you of impending hard disk attack: Once if by LAN; twice if by C.
- POLITICALLY CORRECT VIRUS: Never identifies itself as a virus, but instead refers to itself as an electronic micro-organism.

The Fable of the Fox's FAX

(From: Frank Reid (reid@indiana.edu).)

THE FABLE OF THE FOX'S FAX
by Frank
Based *very* loosely on a true story.
(G-rated version; use your imagination.)

Fox faced a fix; Fox couldn't fax, for Fox's fax was fried. "Fax failure forfeits fortunes faxing flax futures," figured Fox, frantically phoning Phoebe the Frugal Fax Fixer from Phoenix, who features fast fax fixes for flat fees of fifty French Francs. "Fix my freaking fax!" Fox fumed furiously.

Phoebe's fastest field fax-fixer, Pheasant, flew to Fox's flat. Pheasant found flocks of faulty fuses, a familiar foible of funky faxes from Formosa. Fetching fistfuls of fresh fuses forced Fox's fax to function with flawless finesse, faithfully focusing phalanxes of photons in phase with faraway photoelectron flux.

"Phooey!" Fox fussed, flipping Pheasant the finger. "I fail to fathom fifty French francs for fifteen-pfennig fuses. Forget fiscal funds for fallacious fax-fix!"

Pheasant fervently feared fowl finagling, for Pheasant failed to find her father following the forementioned fox's fax-fix fiasco four fortnights from February. Pheasant found feathers festooning Fox's foyer, and feared Fox feasted on Father. Pheasant flew forthwith, fleeing Fox's flat.

Pheasant fingered Fox, forwarding fiendishly-forged fax to feds. Federal fuzz ferreted Fox's fingerprints and fined Fox for filching fuses, fomenting forest fires, fencing foreign freon, fleecing folks with fraudulent faxed flax-futures, and felonious failure to file flat flax-fax tax. Fox filibustered futilely, and finally fell afoul of a frizzy female fed who fired flintlocks and fancied fox fur.

Moral: Fare fixers fairly or face fur-fetched frustration.

Fixing a Flux Capacitor

Here is one that hasn't been posted to sci.electronics.repair yet:

Newsgroups: sci.electronics.repair
Subject: Flux Capacitor broken

Greetings:

We found what appears to be a Flux Capacitor that fell out of an alien spaceship in their haste to depart after being approached by BIG BIRD.

The plutonium supply seems to be adequate but plugging the 3 wire cord into 115 VAC doesn't produce any response. However, probing the logic circuits with our HP 16500 analyzer indicates that the P9-1000 they are apparently using to control the display is functional. (It also passes the FDIV bug test - must not be genuine Intel.)

Upon further examination, we note the device marked @@#$%-@#%@$#-11 appears to be burnt. Would like to know of source for this device or equivalent. It seems to be in-line with the main power relay.

We would really like to get our infinite energy/time machine going but are hesitant to jump across this device if it is not just a fuse or if there are further problems. A black hole in the middle of our back yard would be really bad for property values.

Thanks in advance for any assistance.....:-)

Beware Those Transformers

(From: William Letendre (WJLServo@worldnet.att.net).)

Engineerin' Department of our company is on 3rd floor; company's main power XFMR is on utility pole right outside window. This mornin', Scott, engineer (ME) whose desk is next to window asked, "Hey, Bill, how much power is that transformer carryin'?"

Thought it over, answered, "Ah, with a full shift in the machine shop, should be about 200, 300 kW. Why?"

"Hmmmm. So, how strong are the electromagnetic fields from that?"

"Not very. Transformer designers go to fair pains to keep fields inside transformers!"

"Oh. Well, what about those high tension wires? What if one broke? Would that be dangerous? Or, couldn't the transformer just explode?"

"Well, yeah, I guess. Transformers do fail, once in a while. And the high voltage lines are probably up around 4400 volts, IIRC." Was gettin' a little irritated at this point, so added, "Guess if the transformer blew, or, if one of those lines broke and smashed through the window, coroner's report on you would read 'burned beyond recognition,' or maybe, 'grilled like a chop!' So what does this have to do with anything?"

Scott shook his head. "I dunno, boss. I'm not real comfortable sittin' that close to machine carryin' that kind of power. There's an empty desk by the back wall. Mind if I move?"

Rolled my eyes, said, "Sure, go ahead!"

Just about time Scott had his CAD terminal moved, plugged into LAN drop next to back wall, one of the other guys pointed out window, "Hey, check out the transformer!" Damned thing had blue sparks, smoke, comin' out of one of the porcelain terminals. Consolidated Edison was out in about an hour with 3 trucks, overhaulin' transformer.

Dunno what to make of this, but, do know one thing; if we're ever standin' on sidewalk, and Scott sez, "Gee, could we stand a little further from curb?" I won't ask why; I'll just do it!

Engineers Explained

(Forwarded by: Jim Rauchut (rauchut@repairfaq.org), apparently by Scott Adams (from his book: The Dilbert Principle).)

People who work in the fields of science and technology are not like other people. This can be frustrating to the nontechnical people who have to deal with them. The secret to coping with technology-oriented people is to understand their motivations. This chapter will teach you everything you need to know. I learned their customs and mannerisms by observing them, much the way Jane Goodall learned about the great apes, but without the hassle of grooming.

Engineering is so trendy these days that everybody wants to be one. The word "engineer" is greatly overused. If there's somebody in your life who you think is trying to pass as an engineer, give him this test to discern the truth.

ENGINEER IDENTIFICATION TEST

You walk into a room and notice that a picture is hanging crooked. You...

- A. Straighten it.

- B. Ignore it.

- C. Buy a CAD system and spend the next six months designing a solar-powered, self-adjusting picture frame while often stating aloud your belief that the inventor of the nail was a total moron.

The correct answer is "C" but partial credit can be given to anybody who writes "It depends" in the margin of the test or simply blames the whole stupid thing on "Marketing."

SOCIAL SKILLS

Engineers have different objectives when it comes to social interaction.

"Normal" people expect to accomplish several unrealistic things from social interaction:

- Stimulating and thought-provoking conversation
- Important social contacts
- A feeling of connectedness with other humans

In contrast to "normal" people, engineers have rational objectives for social interactions:

- Get it over with as soon as possible.
- Avoid getting invited to something unpleasant.
- Demonstrate mental superiority and mastery of all subjects.

FASCINATION WITH GADGETS

To the engineer, all matter in the universe can be placed into one of two categories: (1) things that need to be fixed, and (2) things that will need to be fixed after you've had a few minutes to play with them. Engineers like to solve problems. If there are no problems handily available, they will create their own problems. Normal people don't understand this concept; they believe that if it ain't broke, don't fix it. Engineers believe that if it ain't broke, it doesn't have enough features yet.

No engineer looks at a television remote control without wondering what it would take to turn it into a stun gun. No engineer can take a shower without wondering if some sort of Teflon coating would make showering unnecessary. To the engineer, the world is a toy box full of sub-optimized and feature-poor toys.

FASHION AND APPEARANCE

Clothes are the lowest priority for an engineer, assuming the basic thresholds for temperature and decency have been satisfied. If no appendages are freezing or sticking together, and if no genitalia or mammary glands are swinging around in plain view, then the objective of clothing has been met. Anything else is a waste.

LOVE OF "STAR TREK"

Engineers love all of the "Star Trek" television shows and movies. It's a small wonder, since the engineers on the starship Enterprise are portrayed as heroes, occasionally even having sex with aliens. This is much more glamorous than the real life of an engineer, which consists of hiding from the universe and having sex without the participation of other life forms.

DATING AND SOCIAL LIFE

Dating is never easy for engineers. A normal person will employ various indirect and duplicitous methods to create a false impression of attractiveness. Engineers are incapable of placing appearance above function.

Fortunately, engineers have an ace in the hole. They are widely recognized as superior marriage material: intelligent, dependable, employed, honest, and handy around the house. While it's true that many normal people would prefer not to date an engineer, most normal people harbor an intense desire to mate with them, thus producing engineer-like children who will have high-paying jobs long before losing their virginity.

Male engineers reach their peak of sexual attractiveness later than normal men, becoming irresistible erotic dynamos in their mid thirties to late forties. Just look at these examples of sexually irresistible men in technical professions:

- Bill Gates.
- MacGyver.
- Etcetera.

Female engineers become irresistible at the age of consent and remain that way until about thirty minutes after their clinical death. Longer if it's a warm day.

HONESTY

Engineers are always honest in matters of technology and human relationships. That's why it's a good idea to keep engineers away from customers, romantic interests, and other people who can't handle the truth.

Engineers sometimes bend the truth to avoid work. They say things that sound like lies but technically are not because nobody could be expected to believe them. The complete list of engineer lies is listed below.

> "I won't change anything without asking you first."
> "I will return your hard-to-find cable tomorrow."
> "I have to have new equipment to do my job."
> "I'm not jealous of your new computer."

FRUGALITY

Engineers are notoriously frugal. This is not because of cheapness or mean spirit; it is simply because every spending situation is simply a problem in optimization, that is, "How can I escape this situation while retaining the greatest amount of cash?"

POWERS OF CONCENTRATION

If there is one trait that best defines an engineer it is the ability to concentrate on one subject to the complete exclusion of everything else in the environment. This sometimes causes engineers to be pronounced dead prematurely. Some funeral homes in high-tech areas have started checking resumes before processing the bodies. Anybody with a degree in electrical engineering or experience in computer programming is propped up in the lounge for a few days just to see if he or she snaps out of it.

RISK

Engineers hate risk. They try to eliminate it whenever they can. This is understandable, given that when an engineer makes one little mistake, the media will treat it like it's a big deal or something.

EXAMPLES OF BAD PRESS FOR ENGINEERS

- Hindenberg.
- Space Shuttle Challenger.
- SPANet(tm)
- Hubble space telescope.
- Apollo 13.
- Titanic.
- Ford Pinto.
- Corvair.

The risk/reward calculation for engineers looks something like this:

- RISK: Public humiliation and the death of thousands of innocent people.

- REWARD: A certificate of appreciation in a handsome plastic frame.

Being practical people, engineers evaluate this balance of risks and rewards and decide that risk is not a good thing. The best way to avoid risk is by advising that any activity is technically impossible for reasons that are far too complicated to explain.

If that approach is not sufficient to halt a project, then the engineer will fall back to a second line of defense: "It's technically possible but it will cost too much."

EGO

Ego-wise, two things are important to engineers:

- How smart they are.
- How many cool devices they own.

The fastest way to get an engineer to solve a problem is to declare that the problem is unsolvable. No engineer can walk away from an unsolvable problem until it's solved. No illness or distraction is sufficient to get the engineer off the case. These types of challenges quickly become personal -- a battle between the engineer and the laws of nature.

Engineers will go without food and hygiene for days to solve a problem. (Other times just because they forgot.) And when they succeed in solving the problem they will experience an ego rush that is better than sex--and I'm including the kind of sex where other people are involved.

Nothing is more threatening to the engineer than the suggestion that somebody has more technical skill. Normal people sometimes use that knowledge as a lever to extract more work from the engineer. When an engineer says that something can't be done (a code phrase that means it's not fun to do), some clever normal people have learned to glance at the engineer with a look of compassion and pity and say something along these lines: "I will ask Bob to figure it out. He knows how to solve difficult technical problems."

At that point it is a good idea for the normal person to not stand between the engineer and the problem. The engineer will set upon the problem like a starved Chihuahua on a pork chop.

The Sex Life of an Electron

(From: Tom The sparky (martinm@wic.net).)

One night when his charge was pretty high Micor Farad decided to get a cute little coil to help him discharge. He picked up Millie Amp and took her for a ride on his megacycle. They rode across Wheatstone Bridge, around by the sine wave, and stopped in a magnetic field by a flowing current.

Micor Farad, attracted by Millie Amp's characteristic curve, soon began to lower her resistance to minimum and his field was fully excited. He laid her on the ground potential, raised her frequency, lowered her capacitance, and plugged in his high voltage probe. He inserted it into her socket, connected them in parallel, and began to short circuit her shunt. Fully excited Millie cried "ohm, ohm, ohm".

With his tube operating at a maximum peak, and her ciol vibrating from current flow, she soon reached her maximum peak. The excess current flow had gotten her hot and Micro Farad was rapidly discharging having drained off every electron.

They fluxed all night trying different connections and sockets until his bar magnet had lost all its field strength. Afterwords, Millie Amp tried self-induction and damaged her solenoid. With his battery fully discharged, Micro Farad was unable to excite her generator. So they ended up by reversing polarity and blowing each other's fuses

About Sears Shop Vac HP Ratings

(From: Kevin AstirCS "1U" KO0B (kferguson@aquilagroup.com).) I note that air compressor manufacturers have taken after the vacuum sweeper folks, and are re-inventing the horsepower. Imagine, 6HP at 15A, 115VAC!

(From: sam).

Have you seen Sears shop vacs lately? I think they are also up to 6 HP. Every week or so, they seem to come out with one that is a little higher in their HP ratings - I guess internal cold fusion or something.

(From: Pin 2 Hot (pinksnd@io.com).)

Let's see, RPM X Torque = Horsepower.

Thus: No-load RPM X Locked-rotor Torque = Sears Horsepower

Notes:

1. testing done at 177V DC, equal to peak of 120V AC (AC-DC motors).
2. Sears Horsepower: How "hoarse" you get trying to talk over one of their shop-vacs while it's on.

Or maybe it's got something to do with vacuuming performance out at the stables.

So You Want a Vacation Day?

(From: contributor's name withheld so HR won't find out :-)). So you want a day off, let's take a look at what you are asking for:

- There are 365 days per year available for work. There are 52 weeks per year in which you already have two days off per week, leaving 261 day available for work.
- Since you spend 16 hours each day away from work, you have used up 170 days, leaving only 91 days available.
- You spend 30 minutes each day on coffee break that accounts for 23 days each year, leaving only 68 days available. with a one hour lunch period each day, you have used up another 46 days, leaving only 22 days available for work.
- You normally spend 2 days per year on sick leave. This leaves you only 20 days available for work.
- We are off for 5 holidays per year, so your available working time is down to 15 days.
- We generously give you 14 days vacation per year which leaves only 1 day available for work, and I will be damned if you're going to take that day off!!!

Sources of Demos (Bill Gates Computer Joke)

(From: Carter B. Schroy (CBS970@AOL.COM).)

Bill Gates died. He was sent to the Afterlife Waiting Room. He was met by St. Peter, who asked him if he wanted to go to Heaven or Hell, and if he'd like to see them before he decided. Bill said yes, and St. Peter snapped his fingers. They appeared on a sunny beach, with people dancing, swimming, and playing volleball. Just basically having a wonderful time. Good food, good music, good people. Bill turns to St. Peter and says, "Wow, Heaven is great!" St. Peter says, "This isn't Heaven, it's Hell. Want to see Heaven?" Mr. Gates nods yes, and they appear in a shady park, with a few old people sitting on benches feeding birds. A gentle breeze blows by, and all is quiet and serene. St. Peter asks Bill, "Well, which would you like?" Bill thinks for a minute, and says, "Well, if this is Heaven, then I will take Hell." Instantly, he was plunged up to his neck in red-hot lava, the screams of other tortured souls filling his ears. He looks up, and sees St. Peter in the waiting room. Bill calls out to him, and said, "Hey! What's going on? Where's the beach? The bikini-clad women? The party?" St. Peter turns from his Macintosh to face Bill, and says, "That was just the demo."

Knowledge, Power, Time and Money Equation...

For all you mathematicians...

After applying some simple algebra to some trite phrases and cliches a new understanding can be reached of the secret to wealth and success.

Here it goes.

> Knowledge is Power
> Time is Money and as every engineer knows,
> Power is Work over Time.

So, substituting algebraic equations for these time worn bits of wisdom, we get:

> K = P (1)
> T = M (2)
> P = W/T (3)

Now, do a few simple substitutions:

> Put W/T in for P in equation (1), which yields:
> K = W/T (4)

Put M in for T into equation (4), which yields:

> K = W/M (5).

Now we've got something. Expanding back into English, we get:

> Knowledge equals Work over Money.

What this MEANS is that:

1. The More You Know, the More Work You Do, and
2. The More You Know, the Less Money You Make.

Solving for Money, we get:

> M = W/K (6)
> Money equals Work Over Knowledge.

From equation (6) we see that Money approaches infinity as Knowledge approaches 0, regardless of the Work done.

What THIS MEANS is:

> The More you Make, the Less you Know.

Solving for Work, we get

> W = M x K (7)
> Work equals Money times Knowledge

From equation (7) we see that Work approaches 0 as Knowledge approaches 0.

What THIS MEANS is:

> The stupid rich do little or no work.

Working out the socioeconomic implications of this breakthrough is left as an exercise for the reader.

You Know You Are Too Serious About Computers If...

- If you did an error-free installation of Windows 95.
- When your modem starts smoking.
- If no one can reach you by phone since your computer is always online.
- If you log-off your system because it's time to go to work.
- If you call in sick because you found a great new WWW site.
- If you can type your top 10 favorite web sites....by heart.
- If you can locate a particular home page without using a search engine.
- If you can write your own html page.
- If you can access more than 20 erotic no-pay sites.
- If you download more than 20Mb from a binary newsgroup...in one session.
- If while reading a magazine, you look for the Zoom icon for a better look at a photograph.
- You comment, while watching a sunset, that the image would be enhanced with 10% more magenta and a higher resolution.
- If while driving down the street, you are confused by the numbers on the houses... they do not appear to be legitimate WWW addresses.
- When someone tells you to remember something, and you look for File/Save command.
- When you discover there is no little car icon with a forward arrow on the dashboard of your car, to make it go.
- When you think the File/Kill command should apply to your system administrators.
- When you find it easier to dial-up the National Weather Service: Weather/your_town/now.html than to simply look out the window.

- When you start using phrases like: Hungry.must-eat.food.now@home.
- If you have a heart attack when you forgot to pay your phone bill and receive a "pending disconnection of service" notice.
- When you order most of what you buy.....online.
- If your fingers quit moving because you've been online for 36 hours.
- When you find yourself engaged to someone you've never actually met, except through E-mail.
- When you log-off from a session in your favorite newsgroup, and your log reads: Online time: 56 hours 24 minutes.
- If your net provider suggests you try a competitor, because you're exceeding 300 hours a month, connect time.
- When you add your third modem and dedicated phone line.
- You access Microsoft's Web page every Sunday morning from Brother Bill's sermon.
- When that 112 GB hard drive is full.
- If 300 Mhz is simply too slow.
- When your desk collapses under the weight of your computer peripherals.
- If you have an "online" light installed on your car to tell you when the engine is running.
- When you discover that in order to drive your car somewhere, you do not have an http:// or ftp:// address.
- If you can actually talk to the computers in your new car, and understand what they say.
- When you modify the programming of your car's computers and actually get better mileage.
- When you can access the Net, via your portable and cellular phone.
- If on the way home from work, you use your portable and cellular phone in your car, to reprogram a Tomahawk missile, in flight, and redirect it to take out the joker in the Cadillac who cut you off.
- If you try to press Alt-F4 to close your car window.
- When you put a CD-ROM in your car's player.
- When someone tells you about a great new program and you're very disappointed to find it's on TV.
- If every sentence you utter begins with, "On the Net..."

- If you put your e-mail address in the upper left-hand corner of envelopes.
- If you have your e-mail address printed on your stationery.
- When you insist on seeing the movie "The Net" for the 63rd time.
- If magazine like "InternetWorld" are of greater interest than "Playboy" or "Playgirl".
- If you maintain more than 6 e-mail addresses.
- If you use more than 20 passwords.
- If you set up your own Web page.
- If you set up a Web page for each of your kids...and your pets.
- If, instead of a phone number, you ask someone for their e-mail address.
- If you don't know anyone who DOESN'T have an e-mail address.
- If, to you, "safe sex" means doing it online.
- If you convince your mom that she HAS to get online because e-mail is so much cheaper than long distance phone charges.
- If you can write a list like this.
- If you can relate to a list like this.

How Mil Specs Live Forever!

(From: Jeff Wisnia, W1BSV (jwisnia@110.net).)

How Mil Specs Live Forever:

The US Standard Railroad Gauge (the distance between the rails) is 4 feet, 8.5 inches. That is an exceedingly odd number; Why was that gauge used?

Because that was the way they built them in England, and the US railroads were built by English expatriates.

Why did the English people build them that size? Because the first rail lines were built by the same people who built the pre-railroad tramways, and that was the gauge they used.

Why did "they" use that gauge then? Because the people who built the tramways used the same jigs and tools that they used for building wagons. which used that wheel spacing.

Okay! Why did the wagons use that odd wheel spacing? Because the first long distance roads in Europe were built by Imperial Rome for the benefit of their legions. Those roads have been used ever since. And the ruts? The initial ruts, which everyone else had to match for fear of destroying their wagons, were originally made by Roman war chariots. Since the chariots were made by or for Imperial Rome, they were all made with similar wheel spacing.

Thus, we have the answer to the original question. The US Standard Railroad Gauge of 4 feet 8.5 inches is derived from the original Mil Spec for Imperial Rome's army war chariots. Mil Specs, like bureaucracies, tend to exist forever.

So, next time you read a Mil Spec and wonder what horse's ass came up with it, you may be exactly right. Because, the Imperial Roman war chariots were designed for maneuverability, as narrow as possible, just wide enough to accommodate the rear ends of two war horses.

(Forwarded by: Kevin Theobald (theobald@capsl.udel.edu).)

Here is an amusing addition from a NASA guy, Howard Winsett:

There is an interesting extension to the story about railroad gauges and horses' behinds. When we see a Space Shuttle sitting on its launch pad, there are two big booster rockets attached to the sides of the main tank. These are solid rocket boosters, or SRBs. Thiokol makes the SRBs at their factory at Utah. The engineers who designed the SRBs might have preferred to make them a bit fatter, but the SRBs had to be shipped by train from the factory to the launch site.

The railroad line from the factory happens to run through a tunnel in the mountains. The SRBs had to fit through that tunnel. The tunnel is slightly wider than the railroad track, and the railroad track is about as wide as two horses' behinds.

So, a major design feature of what is arguably the world's most advanced transportation system was determined over two thousand years ago by the width of a horse's ass.

On Replacing Fuses with Bullets

You have repeatedly been warned: "Do not replace a fuse unless you have thoroughly checked all other components.... The new fuse may just blow the second time around."

Not necessarily. I have seen cases where the second time around, some other component pops off and the fuse survives!

(From: Keith Morgan (morgankk@boat.bt.com).)

Was a .22 caliber bullet the other component Sam mentioned: (this is an article spotted by Gary Davis in the Arkansas Democrat Gazette 25 July 1996, and reported in the UK Private Eye magazine)

"I thank God every hour that we weren't on that bridge when Thurston shot his nuts off, cos we'd both be pushing up the daisies by now," Billy Ray Wallis told reporters from his hospital bed in the Baptist Medical Center, Woodruff County. "When you leave, can you check if anyone got the frogs from the truck? I'd hate anything to happen to them."

Wodruff County deputy Dovey Snyder later gave a more coherent account of that evening's events. "It seems that Thurston Poole, 33, and Billy Ray Wallis, 38, were returning to Des Arc after a frog-gigging trip, when the fuse for the headlights on Poole's pick-up truck burned out. They didn't have a spare, so Wallis took a .22 caliber bullet from his pistol and found that it fitted perfectly into the fuse box next to the steering wheel column. The headlights started working again, and they resumed their journey, with Poole at the wheel.

"Apparently, it never occurred to them that, if the headlight wiring was faulty, then the bullet would soon overheat. They'd gone about twenty miles and were about to cross White River bridge when it got hot enough to discharge itself, striking Poole in the right testicle and partially severing his scrotum. As a result, the vehicle swerved off the road and drove through the front window of a hamburger bar. Poole (who sustained further abrasions from broken glass, and burns from fried onions) kept shouting at diners 'mind my frogs', while Wallis (who sustained a broken clavicle) attempted to steal a chip-fryer in the confusion. I tell you, I've been a state trooper for ten years, but this is the dumbest thing I've ever come across. I can't believe that those two would admit how the accident happened. And all they keep asking about are their damn frogs."

Corporate Down-Sizing Affects Everyone Everywhere

North Pole Memo:

Subject: Famous Reindeer Terminated

The recent announcement that Donner and Blitzen have elected to take the early reindeer retirement package has triggered a good deal of concern about whether they will be replaced, and about other restructuring decisions at the North Pole.

Streamlining is due to the North Pole's loss of dominance of the season's gift distribution business. Home shopping channels and mail order catalogues have diminished Santa's market share. He could not sit idly by and permit further erosion of the profit picture.

The reindeer down-sizing was made possible through the purchase of a late model Japanese sled for the CEO's annual trip. Improved productivity from Dasher and Dancer, who summered at the Harvard Business School, is anticipated.

Reduction in reindeer will also lessen airborne environmental emissions for which the North Pole has received unfavorable press.

I am pleased to inform you that Rudolph's role will not be disturbed. Tradition still counts for something at the North Pole. Management denies, in the strongest possible language, the earlier leak that Rudolph's nose got that way, not from the cold, but from substance abuse. Calling Rudolph "a lush who was into the sauce and never did pull his share of the load" was an unfortunate comment, made by one of Santa's helpers and taken out of context at a time of year when he is known to be under executive stress.

As a further restructuring, today's global challenges require the North Pole to continue to look for better, more competitive steps. Effective immediately, the following economic measures are to take place in the "Twelve Days of Christmas" subsidiary:

The partridge will be retained, but the pear tree never turned out to be the cash crop forecasted. It will be replaced by a plastic hanging plant, providing considerable savings in maintenance;

The two turtle doves represent a redundancy that is simply not cost effective. In addition, their romance during working hours could not be condoned. The positions are therefore eliminated;

The three French hens will remain intact. After all, everyone loves the French;

The four calling birds were replaced by an automated voice mail system, with a call waiting option. An analysis is underway to determine who the birds have been calling, how often and how long they talked;

The five gold rings have been put on hold by the Board of Directors. Maintaining a portfolio based on one commodity could have negative implications for institutional investors. Diversification into other precious metals as well as a mix of T-Bills and high technology stocks appear to be in order;

The six geese-a-laying constitutes a luxury which can no longer be afforded. It has long been felt that the production rate of one egg per goose per day is an example of the decline in productivity. Three geese will be let go, and an upgrading in the selection procedure by personnel will assure management that from now on every goose it gets will be a good one;

The seven swans-a-swimming is obviously a number chosen in better times. The function is primarily decorative. Mechanical swans are on order. The current swans will be retrained to learn some new strokes and therefore enhance their outplacement;

As you know, the eight maids-a-milking concept has been under heavy scrutiny by the EEOC. A male/female balance in the workforce is being sought. The more militant maids consider this a dead-end job with no upward mobility. Automation of the process may permit the maids to try a-mending, a-mentoring or a-mulching;

Nine ladies dancing has always been an odd number. This function will be phased out as these individuals grow older and can no longer do the steps;

Ten Lords-a-leaping is overkill. The high cost of Lords plus the expense of international air travel prompted the Compensation Committee to suggest replacing this group with ten out-of-work congressmen. While leaping ability may be somewhat sacrificed, the savings are significant because we expect an oversupply of unemployed congressmen this year;

Eleven pipers piping and twelve drummers drumming is a simple case of the band getting too big. A substitution with a string quartet, a cutback on new music and no uniforms will produce savings which will drop right down to the bottom line;

We can expect a substantial reduction in assorted people, fowl, animals and other expenses. Though incomplete, studies indicate that stretching deliveries over twelve days is inefficient. If we can drop ship in one day, service levels will be improved.

Regarding the lawsuit filed by the attorney's association seeking expansion to include the legal profession ("thirteen lawyers-a-suing") action is pending.

Lastly, it is not beyond consideration that deeper cuts may be necessary in the future to stay competitive. Should that happen, the Board will request management to scrutinize the Snow White Division to see if seven dwarfs is the right number.

The executives at the North Pole wish you and yours a Merry Christmas and a productive New Year.

Are You a Real Engineer?

(From: Mark Sokos (msokos1@umbc.edu).)

A comment was recently made about the lack of humor on this newsgroup. So, I did an excite search on "electronics humor", and, nothing. Zip. Zero. Nada. (Well, I only checked the first page of listings). So, I did remember snagging this off of the net. It's not quite electronics humor, but it is engineering humor, which I guess is as close as we're going to get.

And yes, it's off topic, so go ahead and flame me.

PS: I'm not going to admit (at least not publically) how many of these I said yes to.

(Author: Jose Herrero (jose@borg.harvard.edu).)

You may be an engineer...

- If Dilbert is your hero.
- If you stare at an orange juice container because it says CONCENTRATE.
- If you want an 8X CDROM for Christmas.
- If you can name 6 Star Trek episodes.
- If the only jokes you receive are through e-mail.
- If your wrist watch has more computing power than a 486DX2-50.
- If your idea of good interpersonal communication means getting the decimal point in the right place.
- If you look forward to Christmas only to put together the kids' toys.
- If you introduce your wife as "mylady@home.wife".
- If your spouse sends you an e-mail instead of calling you to dinner.

- If you can quote scenes from any Monty Python movie.
- If you use a CAD package to design your son's Pine Wood Derby car.
- If you have used coat hangers and duct tape for something other than hanging coats and taping ducts.
- If, at Christmas, it goes without saying that you will be the one to find the burnt-out bulb in the string.
- If you window shop at Radio Shack.
- If your ideal evening consists of fast-forwarding through the latest Sci-Fi movie looking for technical inaccuracies.
- If you have "Dilbert" comics displayed anywhere in your work area.
- If you carry on a one-hour debate over the expected results of a test that actually takes five minutes to run.
- If you are convinced you can build a phaser out of your garage door opener and your camera's flash attachment.
- If you don't even know where the cover to your personal computer is.
- If you have modified your can-opener to be microprocessor driven.
- If you know the direction the water swirls when you flush.
- If you own "Official Star Trek" anything.
- If you have ever taken the back off your TV just to see what's inside.
- If a team of you and your co-workers have set out to modify the antenna on the radio in your work area for better reception.
- If you ever burned down the gymnasium with your Science Fair project.
- If you are currently gathering the components to build your own nuclear reactor.
- If you own one or more white short-sleeve dress shirts.
- If you have never backed-up your hard drive.
- If you are aware that computers are actually only good for playing games, but are afraid to say it out loud.
- If you truly believe aliens are living among us.
- If you have ever saved the power cord from a broken appliance.

- If you have ever purchased an electronic appliance "as-is".
- If you see a good design and still have to change it.
- If the sales people at Circuit City can't answer any of your questions.
- If you still own a slide rule and you know how to work it.
- If the thought that a CD could refer to finance or music never enters your mind.
- If you own a set of itty-bitty screw drivers, but you don't remember where they are.
- If you rotate your screen savers more frequently than your automobile tires.
- If you have a functioning home copier machine, but every toaster you own turns bread into charcoal.
- If you have more toys than your kids.
- If you need a checklist to turn on the TV.
- If you have introduced your kids by the wrong name.
- If you have a habit of destroying things in order to see how they work.
- If your I.Q. number is bigger than your weight.
- If the microphone or visual aids at a meeting don't work and you rush up to the front to fix it.
- If you can remember 7 computer passwords but not your anniversary.
- If you have memorized the program schedule for the Discovery Channel and have seen most of the shows already.
- If you have ever owned a calculator with no equal key and know what RPN stands for.
- If your father sat 2 inches in front of your family's first color TV with a magnifying lens to see how they made the colors, and you grew up thinking that was normal.
- If you know how to take the cover off of your computer, and what size screw driver to use.
- If you can type 70 words a minute but can't read your own handwriting.
- If people groan at the party when you pick out the music.
- If you can't remember where you parked your car for the 3rd time this week.
- If you did the sound system for your senior prom.

- If your checkbook always balances.
- If your wristwatch has more buttons than a telephone.
- If you have more friends on the Internet than in real life.
- If you thought the real heroes of "Apollo 13" were the Mission Controllers.
- If you think that when people around you yawn, it's because they didn't get enough sleep.
- If you spend more on your home computer than your car.
- If you know what http:/ stands for.
- If you've ever tried to repair a $5.00 radio.
- If you have a neatly sorted collection of old bolts and nuts in your garage.
- If your three year old son asks why the sky is blue and you try to explain atmospheric absorption theory.
- If your lap-top computer costs more than your car.
- If your 4 basic food groups are: 1. Caffeine 2. Fat 3. Sugar 4. Chocolate.

- Back to Humor Table of Contents.

Hardware, Software, Management Humor

(From: Dan Kuechle (dan_kuechle@i-tech.com).)

A hardware engineer, a software engineer, and an engineering manager were skiing over the weekend. Upon leaving the resort the brakes failed on their car. They went screaming down the mountain until they drove into a snow bank. At this point they didn't know what to do. They still had half the mountain to descend, and no brakes. The engineering manager said "I will head up a task force to brainstorm the problem, and then come up with a schedule to implement the outcome." The hardware engineer said "I can fix these brakes! I will jack up the car, remove the wheels, and fix them with my Swiss army knife." The software engineer's only comments were "I think we ought to push the car back up the mountain, try it again, and see if it fails the same way"

Why Engineers Don't Write Recipe Books

(From: Redd Emmett R (err557f@cnas.smsu.edu).)

Here's one that a friend of mine sent me, I found it pretty funny.

Why Engineers Don't Write Recipe Books

Chocolate Chip Cookies:

Ingredients:

1. 532.35 cm3 gluten
2. 4.9 cm3 NaHCO3
3. 4.9 cm3 refined halite
4. 236.6 cm3 partially hydrogenated tallow triglyceride
5. 177.45 cm3 crystalline C12H22O11
6. 177.45 cm3 unrefined C12H22O11
7. 4.9 cm3 methyl ether of protocatechuic aldehyde
8. Two calcium carbonate-encapsulated avian albumen-coated protein
9. 473.2 cm3 theobroma cacao
10. 236.6 cm3 de-encapsulated legume meats (sieve size #10)

To a 2-L jacketed round reactor vessel (reactor #1) with an overall heat transfer coefficient of about 100 Btu/F-ft2-hr, add ingredients one, two and three with constant agitation. In a second 2-L reactor vessel with a radial flow impeller operating at 100 rpm, add ingredients four, five, six, and seven until the mixture is homogeneous. To reactor #2, add ingredient eight, followed by three equal volumes of the homogeneous mixture in reactor #1. Additionally, add ingredient nine and ten slowly, with constant agitation. Care must be taken at this point in the reaction to control any temperature rise that may be the result of an exothermic reaction.

Using a screw extrude attached to a #4 nodulizer, place the mixture piece-meal on a 316SS sheet (300 x 600 mm). Heat in a 460K oven for a period of time that is in agreement with Frank & Johnston's first order rate expression (see JACOS, 21, 55), or until golden brown. Once the reaction is complete, place the sheet on a 25C heat-transfer table, allowing the product to come to equilibrium.

Someone's note: Cookie sheet thickness is unspecified :-).

How Data Really Travels

(Author: Anonymous).

If a packet hits a pocket on a socket on a port, And the bus is interrupted as a very last resort, And the address of the memory makes your floppy disk abort Then the socket packet pocket has an error to report.

If your cursor finds a menu item followed by a dash, And the double-clicking icon puts your window in the thrash, and your data is corrupted 'cause the index doesn't hash, The your situation's hopeless, and your system's gonna crash!

You can't say this? What a shame, Sir! We'll find you another game, Sir...

If the label on the cable on the table at your house, Says the network is connected to the button on your mouse, But your packets want to tunnel on another protocol, That's repeatedly rejected by the printer down the hall,

And your screen is all distorted by the side effects of Gauss So your icons in the window are as wavy as a souse, Then you may as well reboot and then you go out with a bang, Cause as sure as I'm a poet, the sucker's gonna hang!

When the copy of your floppy's on the disk, And the microcode instructions cause unnecessary risk, Then you have to flash your memory and you'll want to RAM your ROM. Quickly turn off the computer and be sure to tell your Mom!

Is Hell Endothermic or Exothermic?

(From: Christopher Donham (donham@axon.engr.sgi.com).)

A thermodynamics professor had written a take home exam for his graduate students. It had one question:

"Is hell exothermic or endothermic? Support your answer with a proof."

Most of the students wrote proofs of their beliefs using Boyle's Law or some variant. One student, however wrote the following:

"First, we postulate that if souls exist, then they must have some mass.

If they do, then a mole of souls can also have a mass. So, at what rate are souls moving into hell and at what rate are souls leaving? I think that we can safely assume that once a soul gets to hell, it will not leave. Therefore, no souls are leaving.

As for souls entering hell, lets look at the different religions that exist in the world today. Some of these religions state that if you are not a member of their religion, you will go to hell. Since, there are more than one of these religions and people do not belong to more than one religion, we can project that all people and all souls go to hell.

With birth and death rates as they are, we can expect the number of souls in hell to increase exponentially.

Now, we look at the rate of change in volume in hell. Boyle's Law states that in order for the temperature and pressure in hell to stay the same, the ratio of the mass of souls and volume needs to stay constant.

So, if hell is expanding at a slower rate than the rate at which souls enter hell, then the temperature and pressure in hell will increase until all hell breaks loose.

Of course, if hell is expanding at a rate faster than the increase of souls in hell, than the temperature and pressure will drop until hell freezes over."

English is Such a Crazy Language

(From: Ravi Pillutla (ravi@repairfaq.org).)

Let's face it: English is a crazy language. There is no egg in eggplant or ham in hamburger; neither apple nor pine in pineapple.

English muffins were not invented in England or french fries in France. Sweetmeats are candies, while sweetbreads, which aren't sweet, are meat.

We take English for granted. But if we explore its paradoxes, we find that quicksand can work slowly, boxing rings are square, and a guinea pig is neither from Guinea nor is it a pig. And why is it that writers write, but fingers don't fing, grocers don't groce, and hammers don't ham? If the plural of tooth is teeth, why isn't the plural of booth beeth? One goose, 2 geese. So, one moose, 2 meese? One index, two indices? Is cheese the plural of choose?

If teachers taught, why didn't preachers praught? If a vegetarian eats vegetables, what does a humanitarian eat?

In what language do people recite at a play, and play at a recital? Ship by truck and send cargo by ship? Have noses that run and feet that smell? Park on driveways and drive on parkways?

How can a slim chance and a fat chance be the same, while a wise man and a wise guy are opposites? How can the weather be hot as h*ll one day and cold as h*ll another?

When a house burns up, it burns down. You fill in a form by filling it out and an alarm clock goes off by going on.

When the stars are out, they are visible, but when the lights are out, they are invisible. And why, when I wind up my watch, I start it, but when I wind up this essay, I end it?

Now I know why I flunked my English. It's not my fault -- the silly language doesn't quite know whether it's coming or going.

You Wouldn't Believe These on Amazing Stories

- Police in Wichita, Kansas, arrested a 22-year-old man at an airport hotel after he tried to pass two (counterfeit) $16 bills.
- A man in Johannesberg, South Africa, shot his 49-year-old friend in the face, seriously wounding him, while the two practiced shooting beer cans off each other's head.
- A company trying to continue its five-year perfect safety record showed its workers a film aimed at encouraging the use of safety goggles on the job. According to Industrial Machinery News, the film's depiction of gory industrial accidents was so graphic that twenty-five workers suffered minor injuries in their rush to leave the screening room. Thirteen others fainted, and one man required seven stitches after he cut his head

falling off a chair while watching the film.

- The Chico, California, City Council enacted a ban on nuclear weapons, setting a $500 fine for anyone detonating one within city limits.
- A bus carrying five passengers was hit by a car in St. Louis, but by the time police arrived on the scene, fourteen pedestrians had boarded the bus and had begun to complain of whiplash injuries and back pain.
- Swedish business consultant Ulf af Trolle labored 13 years on a book about Swedish economic solutions. He took the 250-page manuscript to be copied, only to have it reduced to 50,000 strips of paper in seconds when a worker confused the copier with the shredder.
- A convict broke out of jail in Washington D.C., then a few days later accompanied his girl friend to her trial for robbery. At lunch, he went out for a sandwich. She needed to see him, and thus had him paged. Police officers recognized his name and arrested him as he returned to the courthouse in a car he had stolen over the lunch hour.
- Police in Radnor, Pennsylvania, interrogated a suspect by placing a metal colander on his head and connecting it with wires to a photocopy machine. The message "He's lying." was placed in the copier, and police pressed the copy button each time they thought the suspect wasn't telling the truth. Believing the "Lie Detector" was working, the suspect confessed.
- When two service station attendants in Ionia, Michigan, refused to hand over the cash to an intoxicated robber, the man threatened to call the police. They still refused, so the robber called the police and was arrested.
- A Los Angeles man who later said he was "tired of walking," stole a steamroller and led police on a 5 mph chase until an officer stepped aboard and brought the vehicle to a stop.

Some 'Facts' About Electricity

(From: Jussi Kaasinen (Jussi.Kaasinen@hut.fi).)

Read this but be careful: you might not get any sleep tonight because of these shocking facts...

Perhaps the greatest Electrical Pioneer of them all was Thomas Edison, who was a brilliant inventor despite the fact that he had little formal education and lived in New Jersey. Edison's first major invention in 1877, was the phonograph, which could soon be found in thousands of American homes, where it basically sat until 1923, when the record was invented. But Edison's greatest achievement came in 1879, when he invented the electric company. Edison's design was a brilliant adaptation of the simple electrical circuit: the electric company sends electricity through a wire to a customer, then immediately gets the electricity back through another wire, then (this is the brilliant part) sends it right back to the customer again.

This means that an electric company can sell a customer the same batch of electricity thousands of times a day and never get caught, since very few customers take the time to examine their electricity closely. In fact the last year any new electricity was generated in the United States was 1937; the electric companies have been merely re-selling it ever since, which is why they have so much free time to apply for rate increases.

-- Dave Barry, "What is Electricity?"

Funny Ways to Get Rid of Telemarketers

(Most from: SLEEZY (sleezy@usa.net).)

I look forward to telemarketers because I have great fun at their expense:

1. Act hard of hearing and make them repeat things.

2. When asked a questions, answer another one (Them: "Sir, would you be interested in buying our crap?" Me: "Why yes, I would like ice cream.").

3. Act extremely stupid and ask off the wall questions ("So... How long does distance have to be before it's considered long distance?").

4. I hand off the phone to my 13 month old.

5. Start off talking to them but at some point quit talking. After they ask if your still there and seem like they're going to hang up, start talking and get them going again. Repeat as necessary.

6. Act REALLY excited. (WHAT? I'm preapproved for my OWN CREDIT LINE? Off PHone: Oh honey, come quick!!! This nice man says I have excellent credit. OH HAPPY DAY!!!!!) This gets some really strange reactions.

7. Let them go through their entire pitch then at the end say: "Oh, I'm sorry, I thought you were someone else.".

8. Let them go through their entire pitch, then at the end say: "Did you know you have spinach in your teeth?".

9. Sound like a psycho-killer.

10. Tell them you have a bad connection but really are interested. Then speak VERY loudly.

11. Say "I'm sorry, you caught me right in the middle of (favorite sexual act here).

12. If it's a person of the opposite sex, start hitting on them.

13. Every once in a while, bark.

14. Start arguing with yourself.

(The following one suggested by: Courtney Eckhardt (cme@mit.edu).)

15. Wait for an opportune moment and say something like: "I'm sorry, I'm really very interested in whatever you are selling, but you see, I just declared personal bankruptcy.....".

So use your imagination. Add to this list.

The Farmhouse (A Lawyer Joke)

(From: Jim Lagerkvist (jlager@tir.com).)

A rabbi, a hindu, and a lawyer are in a car. they run out of gas, and are forced to stop at a farmers house. The farmer says that there are only 2 extra beds, and one person will have to sleep in the barn. The hindu says, "I'm humble, I will sleep in the barn," so he goes out to the barn. In a few minutes, the farmer hears a knock on the door. It's the hindu and he says, "There is a cow in the barn. It's against my beliefs to sleep with a cow." So the rabbi says, "I'm humble, I will sleep in the barn." A few minutes later, the farmer hears another knock on the door and its' the rabbi. He says that it is against his beliefs to sleep where there is a pig and there is a pig in the barn. So the lawyer is forced to sleep in the barn.

A few minutes later, there is a knock on the door. It's the pig and the cow.

The Parrot

(From: Dave A. Wreski (dawreski@nic.com).)

A magician was working on a cruise ship in the Caribbean. The audience would be different each week, so the magician allowed himself to do the same tricks over and over again.

There was only one problem: The captain's parrot saw the shows each week and began to understand how the magician did every trick. Once he understood he started shouting in the middle of the show:

"Look, it's not the same hat"

"Look, he is hiding the flowers under the table"

"Hey, why are all the cards the Ace of Spades?"

The magician was furious but couldn't do anything; it was, after all, the captain's parrot.

One day the ship had an accident and sank. The magician found himself on a piece of wood in the middle of the ocean with the parrot, of course.

They stared at each other with hate, but did not utter a word. This went on for a day and another and another.

After a week the parrot said: "OK, I give up. Where's the boat?"

How High Do You Jump (Discharging a TV)?

(From: Bert Christensen).

A tech that worked for me many years ago was holding on to a chassis and leaning forward to see something on the other side. He was always rather careless and had hooked up the HV lead in a sloppy >manner. His forehead came in contact with the 30kv. He jumped up into the air, turned around twice, said, "I almost f___ING lled myself, >walked out into the customer waiting area and cried. Ten minutes later he was in working on the same set.

We later drew a scale on a leg of the bench. One inch represented how high you jumped with 1 kV and 25 inches for 25 kV, etc. It was remarkably accurate.

(From: Vic Tosca (tosca@warwick.net).)

That's a KICKER!! I've got the same thing here, but I have it scaled to .808 in/kV. I found that's the accurate formula for the average weight bench tech, including glasses and pocket protector. We also put a bell on the ceiling- anyone that hits it with his head because of a shock gets a day off!

It's located right under the emergency repair tool kit, which consists of a rabbit's foot, a magic wand, a crystal ball, and a hammer. We had to get rid of the hand grenade...insurance laws, y'know. THAT was a *great* tool for tough dogs and irate customers!

Clients love it.

New and Improved Hell

(From: Dave A. Wreski (dawreski@nic.com).)

Author unknown:

An engineer dies and reports to the pearly gates. St. Peter checks his dossier and says, "Ah, you're an engineer -- you're in the wrong place."

So the engineer reports to the gates of hell and is let in. Pretty soon, the engineer gets dissatisfied with the level of comfort in hell, and starts designing and building improvements. After a while, they've got air conditioning and flush toilets and escalators, and the engineer is a pretty popular guy.

One day God calls Satan on the telephone and says with a sneer, "So, how's it going down there in hell?"

Satan replies, "Hey, things are going great. We've got air conditioning and flush toilets and escalators, and there's no telling what this engineer is going to come up with next."

God replies, "What??? You've got an engineer? That's a mistake - he should never have gotten down there; send him up here."

Satan says, "No way. I like having an engineer on the staff, and I'm keeping him."

God says, "Send him back up here or I will sue."

Satan laughs uproariously and answers, "Yeah, right. And just where are YOU going to get a lawyer?"

Don't Lose Those Unpacking Instructions!

A SCSI drive shipped from Bubba's in Louisiana with THIS article in the packaging. No kidding!!!

ACTUAL UNPACKING INSTRUCTIONS

IMPORTANT! READ THIS BEFORE USING YOUR NEW DEVICE!

Congratulations! You have purchased an extremely fine device that would give you thousands of years of trouble-free service, except that you undoubtedly will destroy it via some typical bonehead consumer maneuver.

Which is why we ask you to:

PLEASE, FOR GOD'S SAKE, READ THIS OWNERS MANUAL CAREFULLY BEFORE YOU UNPACK THE DEVICE. YOU ALREADY UNPACKED IT, DIDN'T YOU? YOU UNPACKED IT AND PLUGGED IT IN AND TURNED IT ON AND FIDDLED WITH THE CONTROLS, AND NOW YOUR CHILD, THE SAME CHILD WHO ONCE SHOVED A POLISH SAUSAGE INTO YOUR VIDEOCASSETTE RECORDER AND SET IT ON "FAST FORWARD", THIS CHILD IS ALSO FIDDLING WITH THE CONTROLS, RIGHT? WE MIGHT AS WELL JUST BREAK THESE DEVICES RIGHT AT THE FACTORY BEFORE WE SHIP THEM OUT, YOU KNOW THAT?!?

We're sorry. We just get a little crazy sometimes because we're always getting back "defective" merchandise where it turns out that the consumer inadvertently bathed the device in acid for six days. So, in writing these instructions, we naturally tend to assume that your skull is filled with dead insects, but we mean nothing by it. OK? Now let's talk about:

1. UNPACKING THE DEVICE

The device is encased in foam to protect it from the Shipping People, who like nothing more than to jab spears into outgoing boxes.

PLEASE INSPECT THE CONTENTS CAREFULLY FOR GASHES OR IDA MAE BARKER'S ENGAGEMENT RING, WHICH SHE LOST LAST WEEK, AND SHE THINKS MAYBE IT WAS LOST WHILE SHE WAS PACKING DEVICES.

Ida Mae really wants that ring back, because it is her only proof of engagement, and her fiancee, Stuart, is now seriously considering backing out on the whole thing, in as much as he had consumed most of a bottle of Jim Beam in Quality Control when he decided to pop the question. It is not without irony that Ida Mae's last name is "Barker", if you catch our drift. WARNING: DO NOT EVER, AS LONG AS YOU LIVE, THROW AWAY THE BOX OR ANY OF THE PIECES OF STYROFOAM, EVEN THE LITTLE ONES SHAPED LIKE PEANUTS.

If you attempt to return the device to the store, and you are missing one single peanut, the store personnel will laugh in the chilling manner exhibited by Joseph Stalin just after he enslaved Eastern Europe.

Besides the device, the box should contain:

- Eight little rectangular snippets of paper that say "WARNING".
- A little plastic packet containing four 5/17 inch pilfer grommets and two club-ended 6/93 inch boxcar prawns.

YOU WILL NEED TO SUPPLY: a matrix wrench and 60,000 feet of tram cable.

IF ANYTHING IS DAMAGED OR MISSING: YOU IMMEDIATELY should turn to your spouse and say "Margaret, you know why this country can't make a car that can get all the way through the drive-through at Burger King without a major transmission overhaul? Because nobody cares, that's why."

WARNING: This is assuming your spouse's name is Margaret. And not Pete.

2. PLUGGING IN THE DEVICE

The plug on this device represents the latest thinking of the electrical industry's Plug Mutation Group, which, in a continuing effort to prevent consumers from causing hazardous electrical current to flow through their appliances, developed the Three-Pronged Plug, then the Plug Where One Prong Is Bigger Than The Other. Your device is equipped with the revolutionary new Plug Whose Prongs Consist Of Six Small Religious Figurines Made Of Chocolate.

DO NOT TRY TO PLUG IT IN!

Lay it gently on the floor near an outlet, out of direct sunlight, and water it weekly with a damp handkerchief.

WARNING: WHEN YOU ARE LAYING THE PLUG ON THE FLOOR, DO NOT HOLD A SHARP OBJECT IN YOUR OTHER HAND AND TRIP OVER THE CORD AND POKE YOUR EYE OUT, AS THIS COULD VOID THE WARRANTY.

3. OPERATION OF THE DEVICE

WARNING: WE MANUFACTURE ONLY THE ATTRACTIVE DESIGNER CASE. THE ACTUAL WORKING CENTRAL PARTS OF THE DEVICE ARE MANUFACTURED IN JAPAN. THE INSTRUCTIONS WERE TRANSLATED BY MRS. SHIRLEY PELTWATER OF ACCOUNTS RECEIVABLE, WHO HAS NEVER ACTUALLY BEEN TO JAPAN BUT DOES HAVE MOST OF "SHOGUN" ON TAPE.

INSTRUCTIONS: For results that can be the finest, it is our advising that: NEVER to hold these buttons two times!! Except the battery. Next taking the (something) earth section may cause a large occurrance! However. If this is not a trouble, such rotation is a very maintenance action, as a kindly (something) virepoint from Drawing B.

4. WARRANTY

Be it hereby known that this device, together with but not excluding all those certain parts thereunto, shall be warranted against all defects, failures and malfunctions as shall occur between now and Thursday afternoon, shortly before 2, during which time the Manufacturer will, at no charge to the Owner, send the device to our Service People, who will emerge from their caves and engage in rituals designed to cleanse it of evil spirits. This warranty does not cover the attractive designer case.

WARNING: IT MAY BE A VIOLATION OF SOME LAW THAT MRS. SHIRLEY PELTWATER HAS "SHOGUN" ON TAPE.

- Back to Humor Table of Contents.

An Engineer in Paradise

(From Glenn E Wilkop (Glenn_E_Wilkop@email.whirlpool.com).)

This one comes from our beloved Mr. Tibbs... Enjoy!

A rather inhibited engineer finally splurged on a luxury cruise to the Caribbean. It was the "craziest" thing he had ever done in his life. Just as he was beginning to enjoy himself, a hurricane roared on the huge ship, capsizing it like a child's toy. Somehow the engineer, desperately hanging on to a life preserver, managed to wash ashore on a secluded island. Outside of beautiful scenery, a spring-fed pool, bananas and coconuts, there was little else. He lost all hope and for hours on end, sat under the same palm tree.

One day, after several months had passed, a gorgeous woman in a small rowboat appeared. "I'm from the other side of the island," she said. "Were you on the cruise ship, too?" "Yes, I was", he answered, "But where did you get that rowboat?" "Well, I whittled the oars from gum tree branches, wove the reinforced gunnel from palm branches, and made the keel and stern from a Eucalyptus tree." "But what did you use for tools?" asked the man. "There was an unusual strata of alluvial rock exposed on the south side of the island. I discovered that if I fired it to a particular temperature in my kiln, it melted into forgeable ductile iron. Anyhow, that's how I got the tools. But enough of that," she said, "where have you been living all this time? I don't see any shelter." "To be honest, I have just been sleeping on the beach," he said. "Would you like to come to my place?" the woman asked. The engineer nodded dumbly.

She expertly rowed them around to her side of the island, and tied up the boat with a handsome strand of hand-woven hemp topped with a neat back splice. They walked up a winding stone walk she had laid around a palm tree. There stood an exquisite bungalow painted in blue and white. "It's not much but I call it home."Inside she said, "sit down, please. Would you like to have a drink?" "No, thanks," said the man. "One more coconut juice and I will throw up."

"It won't be coconut juice," the woman replied. I have a crude still out back so we can have authentic Pina Coladas." Trying to hid his amazement, the man accepted the drink and they sat down on her couch to talk. After they had exchanged stories, the woman asked, "Tell me, have you always had a beard?" "No," the man replied. " I was clean shaven all my life till I ended up on this island." "Well, if you'd like to shave, there's a razor upstairs in the bathroom." The man, no longer questioning anything, went upstairs to the bathroom and shaved with an intricate bone-and-shell device that was honed razor sharp. Next he showered, not even attempting to guess how she managed to get warm water into the bathroom. Then he went back downstairs. "You look great," said the woman. "I think I will go up and slip into something more comfortable." As she did, the man continued to sip his Pina Colada. After a short time, the woman, smelling of gardenias. returned revealing a gown fashioned out of pounded palm fronds. "Tell me," she asked, "We've both been out here for a very long time with no companionship. You know what I mean. Have you been lonely...is there anything you really miss? Something that all men and women need? Something that would be really nice right now?" "Yes there is!" the man replied, shucking off his shyness. "There is something I've wanted to do for so long but on this island it was well...impossible." "Well, it is not impossible any more" the woman said. The man, practically panting in excitement, said breathlessly, "You mean you actually figured out some way we can check our e-mail here?"

Hot Water and Ice Makers

(From: Chris Hagwood (hagwood@pobox.com).)

My neighbor just bought a new fridge. He said he was gonna put in an icemaker line, so I stopped by to see how he was getting along. He said he was almost done, but had some trouble early on:

He had called his cousin, who told him to tap into the HOT water line, since "hot water freezes faster--that's a fact" he tells me. So I bit my tongue and waited for him to finish telling me what went wrong. "Did it melt the plastic line?", I thought. No, it seems that he forgot that the same water that was going into his icemaker was going to the "cold water through the door". He would get one glass of cold water, then a glass of HOT! So he had to redo everything on a cold line.

Geez Louis! What people will believe.... "hot water freezes faster"! Insane.

Editor's note: The "Hot water freezes faster" thread, like "NiCds and the memory effect" and "PCs versus Macs" threads are typically never ending. There are simply too many variables to consider in an Internet discussion.

- Back to Humor Table of Contents.

Horsepower Ratings and AC Line Magnets

"How can an electric motor generate 5HP from a 120VAC, 15A wall outlet that puts out only 2.4 HP?"

(From: John M. Feiereisen (feierejm@utrc.utc.com).)

Maybe they were using Ecoblow(tm) power line magnets. Ordinary electricity molecules clump up and do not efficiently energize electrical equipment. The powerful magnetic field of the Ecoblow breaks up these clumps and aligns the electricity molecules through a process known as gullibility-induced victimization, thereby resulting in more efficient scam - oops - operation.

Using an Ecoblow, you can squeeze almost 35 HP out of an ordinary 120 V, 15 A circuit!

A local bakery installed an Ecoblow 3 on the power cord to their industrial size mixer. Heck, the thing spins so fast now, they don't even have use the oven to bake their bread. (Good thing, too, since they burn their bread with it ever since they installed the Ecoflow(tm) gas line magnet.)

I've got an Ecoblow 3 on the power cord to my 128K Mac and now it's about twice as fast as a Sun Ultra 2! An amazing side effect is that I'm now able run codes in 128KB of memory when they used to take a minimum of 64 MB!

I'm currently in the process of coupling an electric motor to an electrical generator. An Ecoblow 3 on the output of the generator will allow me to power the electric motor *and* produce enough electricity to power my house!

Ecoblow - buy one now, because somebody's got to take your money.

- Back to Humor Table of Contents.

All About AC Batteries

From a sci.electronics.misc (or related) newsgroup posting:

"This AC Battery thing is all conspiracy - a US Government cover-up. However, now we have the "Net" and soon the truth will be out about Elvis, Roswell, lost socks and AC 9V batteries."

(From: Bob Myers (myers@fc.hp.com).)

Sigh.

I can't believe what a young, gullible crowd we have here. You guys will swallow ANYTHING.

Any true Old Hand at electronics would know that the AC output from 9V batteries is simply a holdover from the days of portable tube radios. The AC was used to run the filaments, and also served to drive the DC-to-DC converter that was used to obtain the 100-200V of plate voltage from the 9V DC output. (Yes, they tried the obvious route of simply making 200 VDC batteries - still with the necessary AC output, mind you! - but some tragic accidents at a few K-marts (which were ultimately traced to a simple packaging defect) ended THAT standard really quickly, let me tell you.

Today, of course, it's rare to find a product which actually makes USE of the AC output from these batteries, with the exception of some earlier portable CD players which derived the base for the multiple-phase oversampling input oscillation-compensation stage backup clock from it. (And boy, weren't THOSE designs fun, huh?) But once a standard is established, it's hard to get rid of it. Especially with all those production lines already tooled up. Sure, they might save a little in not having to add the cavorite in at the anode insertion process, but it's NOT worth completely rebuilding the line, trust me.

Sure glad I could clear that up for you.

- Back to Humor Table of Contents.

CDs in the Microwave

In response to the following exchange:

"Yes, my microwave-damaged CD's are difficult to repair too. :)"

"What are micro wave damaged CD's?"

(From: DaViD Boulet/Don Harley (dharley@bellatlantic.net).)

The trick is to use a very high-quality line-conditioner for the microwave. I try to microwave my CD's late at night when the electricity is "cleanest" to get the best results. Also, I've found that the newer microwaves with LED time-displays seem to add some euphonic properties to the sound...more relaxed treble, smoother string sound and more liquid midrange. What would be great is if I could get a microwave oven with a detachable power cord so I could use a good-quality MIT power cable. Now *that* would be neat.

I'm hoping that some audiophile company picks up on this and gives a tube-based microwave. Too bad Audio Alchemy went out of business. I heard that they had plans to release an audiophile-designed (tube?) microwave oven before they went under. Any ideas if Camelot might pick up on this? The important thing is that they keep the price under the $1000 to make it affordable to the "normal" starving audiophile.

"Ahh, have you tried STEREO m'waves yet? You have to buy 2 CDs, but the sound is well worth it. Make sure that both microwaves are the same brand so that you can use just 1 remote..."

(From: DaViD Boulet/Don Harley (dharley@bellatlantic.net).)

I like your suggestion except for one thing...I don't believe that remotes should be part of a high-end microwave set-up. In my opinion...one should get up to change the minutes/defrost setting. My experience has shown that, in general, companies who offer remotes with their microwaves seem to compromise in sound-quality. Then again, this effect is not resultant from the remote itself. It just seems to stem from a "philosophy" of consumer-gadgetry that many "receiver" style microwave ovens reflect. My favorite (and best sounding) microwave is plain black...with a simple "on-off" switch and no tone controls.

(From: Pat Crean (pat@crean.com).)

Mine sounded FANTASTIC until the turntable stopped - I'm going to make sure my next microwave has a built-in carousel for uninterrupted listening pleasure!

(From: Ian Stirling 000033C19ADC.NO_UCE@mauve.demon.co.uk).)

Hmm, anyone thought about making a plasma speaker, using a modulated microwave?

(From: Armand (mondo@voicenet.com).)

I tried shaking my MV rapidly and nothing happened-- although my macaroni and cheese did resemble plasma. ;}

(From: Dave).

I doubt that with the grade of microwave-wire you're using...you'd possibly be able to hear the improvement. Why invest hundreds of dollars in a high-end microwave set-up (including disc treatments like the marinating solvent...which I heard at my friend's house and it *really* makes a noticeable difference...especially in the bass--much more dynamic and full) only to shove that signal through a cheap pair of interconnects? IMO, you should have *just* as much money invested in your microwave cables as you spend on the rest of microwave-system.

(From: Derrick Hopkins (dhopkins@infi.net).)

Oh please. If you're going to go with Microwaved CD's(instead of the vastly superior Oven cooked LP's) it doesn't really matter kind of interconnect you use. A micro waved atom is a microwaved atom..period. Even if it's garbled a little, the average person can hear a difference.

When you get past all of the audiophile/gourmet snobbery, you'll realize that a $99 Walmart microwave sounds just as good as a $7000 McIntosh microwave.

Consumer Reports did a huge feature on this back in March '92. A Kmart microwave placed ahead of Carver, Sony, Westinghouse, and Adcom. The only model to beat it was Denon and that's only because it was THX/Redenbokker certified.

(From: DaViD Boulet/Don Harley (dharley@bellatlantic.net).)

First of all...we *all* know that when consumer reports rates microwaves...sound quality is the last thing on their mind. If I recall, they didn't even feel that gold-plated-audiophile microwaves offered any sonic improvement! Consumer reports is only interested in specs and features...

Secondly, your assertion that a 10 year old conventional oven-baked LP can sound *better* than a microwaved CD won't be true much longer. Once we get the next-generation of DVD-based Microwaves with 24-beep/96-calories and multi-panel sound, the debate between analog-ovens and digital microwaves will be over once and for all.

(From: Guillermo Gonzalez (gonzalez@netrox.net).)

Yeah, but my problem remains, that the copper sulfate used in the green marker that I use on my CD's, well, it causes some serious arcing in the microwave...

Alas, what is an audiophile to do?

(From: L. E. Sixma (lesixma@introweb.nl).)

Reheat the lot in a gas-oven for 24 hours at a temperature of 215 degrees Centigrade could do the trick. This is a classic analogue trick. Still you got to be shure that the cookies are taken out in time or else they will be sounding awful. Cassette-spaghetti takes less cooking time and in this case 100 degrees will do for audiophile ear-food.

(From: Nicholas Bodley (nbodley@tiac.net).)

Just a tad off color, but curious. Reminds me of the apparently true story about the red-tailed hawks that would periodically let out a long stream above high-voltage transmission lines and cause arcs that tripped circuit breakers and shut down the lines. This was a significant problem for a while, until they found out how to make the hawks move elsewhere (I've forgotten how they did it). Apparently, the hawks weren't hurt...

- Back to Humor Table of Contents.

The Barking Dog

(From: Jack Kraft (jackjk@iwaynet.net).)

It is common practice in England to ring a telephone by signaling extra voltage across one side of the two wire circuit and ground (earth in England). When the subscriber answers the phone, it switches to the two wire circuit for conversation. This method allows two parties on the same line to be signaled without disturbing each other.

Anyway, an elderly lady with several pets called to say that her telephone failed to ring when her friends called and on the few occasions when it did ring her dog always barked first just before the ring. Pat proceeded to the scene, curious to see this psychic dog.

He climbed the nearby pole, hooked his test set to the lady's line, and dialed the number. The phone didn't ring. He tried again. The dog barked loudly, followed by a ringing telephone. Climbing down the pole the amazed Pat found:

1. The dog was tied to the telephone systems ground post via a metal chain and collar.
2. The dog was receiving 90 volts of signaling current.
3. After several such jolts, the dog would start barking and urinating on the ground.
4. The wet ground now completed the circuit and the phone would ring.

On the Effects of Magnetic Water Softeners

(From: several authors, unknown, for obvious reasons).

> "Testing magnetic softeners can be very dangerous. Should you accidentally over-magnetize the water and unknowingly drink the same, your stomach could burst if you come too near a large ferrous object."
>
> "This happened to a friend of mine. With the philosophy "if one is good, two is better", he put two magnetic water softeners on the same line. Being warm from doing the job, he took a large drink, than

walked by a steel support post in his basement. He was in the hospital for over a month while they did reconstructive surgery on his guts...

Oddly enough, until the magnets were removed, all his faucets constantly oriented themselves toward the north. It was spooky..."

"This really explains a lot for me!

I installed one of these when we first moved into our house 4 years ago. Ever since then we wake up each morning facing north for no apparent reason. If my wife and I sleep facing the same direction (head to toe) we wake up on opposite sides of the bed. If we sleep in opposite directions we wake up clinging to each other in the middle of the bed. Our dishes and clothes always manage to align with north after several days in the drawers too. My 10 month old daughter just started to crawl and she only crawls towards north. We have shale in the ground here and a well. Shale contains lots of iron. We must be magnetizing the iron molecules in the water. The grass that I water always seems to bend north no matter which way I mow. Several floppy disks and video tapes which I stored near an humidifier were mysteriously erased. I seem to bump into large steel objects a lot. Some times I have a hard time getting out of the car, and I never seem to be able to get a compass to work correctly."

In response to the question: "Why are magnetic water softeners so expensive":

"That's probably because you're pricing it as though they were ORDINARY magnets, which of course are fairly inexpensive. But, as anyone will tell you, ordinary magnets do not have any water-conditioning capabilities.

I believe the magnets used in these water conditioners are quantum-mechanic super-heterodyne field effect tachyon-modulated (QMSHFETM) magnets, which of course are more expensive. The manufacturer uses a proprietary process which converts ordinary magnets into the QMSHFETM type, and the process ain't cheap. (This same process, I believe, is what is used to make the 'blue water' that goes into those Laundry CD's and other devices which replace laundry detergent. Hence, these devices are also much more expensive than one would expect for a piece of plastic filled with blue dye.)"

"Of course the price is higher than the materials; the question is, what are the potential benefits worth to you?

After we started using it, our water became so soft we have to add salt to it to get the soap off our skin; my polyps shrank; and my children started getting better grades at school. If Monsieur Henri Paul had passed his wine through a magnetic conditioner, all this would never have happened. So anyway, I recommend it highly at any price.

In addition, I have been watering my flowers with the magnetized water. You've never seen such roses...they're the size of satellite dishes. (I mean those new DSS ones, not the old large ones. Maybe if I planted old roses...) Curiously, the roses all point north. I guess that's because they're magnetized. This makes them useless as satellite dishes, because the geosynchronous satellites are all in the southern sky."

"Yeah, but have you tried putting the conditioned water on dollar bills? Several weeks after getting mine, I left a couple of one dollar bills in my pants in the wash. Boy was I surprised when I took the pants out of the dryer to find two *TEN* dollar bills in the pocket.

> Since then, I've laundered over 70 one dollar bills, netting me a $630 profit, which was almost enough to pay for the magnet. I'm seriously saving up for another one, figuring my dryer will then spit out $100 bills, saving me lots of time!"

(From: Andy Wing).

A magnetic water softener limerick:

> "The MWT pundits won't yield
> Despite no 'hard' evidence to wield
> , of course
> will flog the dead horse
> And insists that it works in the field!

Sorry folks, couldn't resist, puns intended. :-)

Suggestions for Repairing Scratched CDs

(From: Christopher Bedwell (Bedwell@southwest.com.au).)

Try connecting the laser on your CD player to a flux capacitor. That should generate the 1.21 Giga Watts needed to repair the proton electrical photon surface. Hopefully with enought plutonium you can glow in the dark too!!!

Or you could just rub it in a MacDonalds burger! that certainly has enough chemical content residue to melt and re-bond anything.

- Back to Humor Table of Contents.

Warnings about Sucking up Radio Waves

(From: Pat Crean (pat@crean.com).)

You have to be very careful when using devices with good sensitivity.

Remember, the transmitters are pumping a certain amount of power into the VHF/UHF bands with the expectation that there are receiving devices available to absorb it. If too many people use highly sensitive receivers, the excess energy not being absorbed will accumulate until we have an explosion in the affected band that will rival Krakatoa in its effects.

- Back to Humor Table of Contents.

Engineers versus Business Executives

(From: Marcio Domene (mdomene@unisys.com.br).)

Engineers and scientists will never make as much money as business executives.

Now a rigorous mathematical proof that explains why this is true:

- Postulate 1: KNOWLEDGE is POWER
- Postulate 2: TIME is MONEY

```
As every engineer knows:      WORK
                            --------- = POWER
                              TIME

Since KNOWLEDGE = POWER, and TIME = MONEY, we have:   WORK
                                                    --------- = KNOWLEDGE
                                                      MONEY

Solving for money, we get:        WORK
                              ------------- = MONEY
                                KNOWLEDGE
```

Thus, as KNOWLEDGE approaches zero, MONEY approaches infinity, regardless of the WORK done!

Conclusions: The less you know, the more money you Make.

Note: It has been speculated that the reason why Bill Gates dropped out of Havard's math program was because he stumbled upon this proof as an undergraduated, and dedicated the rest of his carrer to the pursuit of ignorance.

(From: John Woodgate (jmw@jmwa.demon.co.uk).)

But there is a third postulate, at least equally well-known as those:

- Postulate 3: MONEY is POWER

But WORK/TIME = MONEY only if you are paid by the hour: monthly staff do not get overtime pay.

Keeping Electricity Working

(From: Dave VanHorn" (uce@ftc.gov).)

Warning: Do not read while drinking!

This is even funnier if you follow Alt.religion.scientology, but all by itself, it's a hoot.

HUMOR - KEEPING ELECTRICITY WORKING

The loyalist officers in 4th dimensional hiding captured the following post from the alt.religion.electricity newsgroup in an alternate universe. Any resemblance to Earth people living or dead is purely accidental and is due to God playing dice with the various universes.

-- The Pilot

KEEPING ELECTRICITY WORKING - A 21st Century Retrospective

By David MissCambridge, Keeper of the Current

Issue authority granted by the first Church of Edison

As KofC of the CofE, it is with humble pride and pleasure that I announce the upcoming hundredth anniversary of one of our most basic policies, Keeping Electricity Working, issued by our glorious founder on Jan 17, 1898.

It is this policy above all others which has preserved the technology of electricity for us and future generations.

It was here that TOM first identified the evil world conspiracy of financiers, plagiarists, and space aliens that was attempting to pervert his discoveries and deny electricity to mankind.

Consider, for example, the evil Tesla who proposed that the divine current should ALTERNATE! A stupid and ridiculous idea. How would it achieve any useful work if the current simply zig zagged back and forth in the wires? He would have undermined the entire structure of DIRECT CURRENT which moves DIRECTLY to its target and achieves LIGHTNING FAST 100 PERCENT STANDARD RESULTS.

But TAE, by virtue of his superior genius, saw that it wasn't just the yappings of Tesla and Westinghouse, for the same attacks and unworkable ideas were showing up all over the world.

Of course we know that the characteristics of a suppressive person would be to deny the truth of the CofE and seek to deny it financing by undercutting its prices. But it was only TAE himself who could spot the true source of all these SPs, the true suppressive influence behind them.

We now know that it was the Venusians, led by their evil telepathic ruler, XeMoonie, who inspired these diabolical attacks. But by means of our tin foil protective hats and an enlightened legal system, we have driven his influences off of Earth and will keep mankind free of his dreadful doings.

Now remember the key points,

1. Stamp out any experimentation or variation of our workable tech.

2. Buy a fresh foil hat from your local CofE every year

3. Report any squirrel wire twisters to the police immediately.

Remember that only certified CofE graduates may work on anything connected with electricity. We know that the courses are expensive, but the results are proven.

For Electricity is dangerous and anyone who applys squirrel practices to twist wires on their own could be electrocuted or have their house burned down. Your entire neighborhood is at risk if you ignore them. Keeping our homes safe is everybody's job.

And we have a wonderful new TECH BREAKTHROUGH to announce.

By careful study of TAE's research notes, we have discovered that the size of the wire might be increased to carry more current.

Our new double sized copper conductors will be available next year at only $100 dollars a yard. Not only will this bring about obvious savings, but it will allow the average apartment house to support more lighting fixtures.

With this breakthrough, we think that it will even be possible to place lights in stairwells. Just imagine it, your iceman will no longer have to stumble around in the dark with a heavy and potentially dangerous cube of ice for your icebox.

We are working now on a project to carve TAE's writings onto iron plates and bury these in secret vaults all over the world. This will ensure that future civilizations will benefit from his wisdom and knowledge. Send your contributions in now.

Building a better future,

-- Davy

Transistors, Anyone?

I don't think the following questions are quite addressed but anyhow....

"Would you please tell me what transistors do and how they do so? What is the difference between PNP and NPN transistors? What is the concept of using a transistor as a switch? Thanks a lot."

(From: Gareth Alun Evans (gareth@cemetery.demon.co.uk).)

A transistor is rather like the human alimentary canal, after the typical USA diet of burgers and chips; - it constipates, as do semiconductor diodes with no appled bias - the available holes get filled in and nothing can move.

The base current is like a small application of laxative; some of the constipation passes through, until the effect of the laxative wears off. The total throughput depends upon the Mobility. By applying a continuous feed of laxative, then a continuous current passes through. Applying too much laxative results in saturation - i.e., there is a limit to the maximum throughput, depending on the external circuit; in this case, the maximum rate at which you can feed in the burgers at one end. (If you are a customer of MacDonalds, here in Chippenham, Wiltshire, UK then this rate is very low - I have been there twice, and both times, the service was *APPALLING*.)

The difference between PNP and NPN is the direction. In the old days, PNP was used, whereby one injected from the rear end, using a sort of huge syringe - hence PNP - "Put-in Near Poo". More recently NPN is more common, where the laxative is entered via a carrier of some sort, usually chocolate and so we have NPN - "Now Pleasant Nutrient".

Despite the adverse effects, the USA diet of burgers and chips carries on, and recourse has to be made once again to the chocolate. Now the ratio of the carriers of the constipation, the burgers and chips, is much higher than that of the chocolate. Thus they are referred to as the Majority Carriers and the Minority Carriers. If you indulge too much, you find that the vendor will provide you with a paper bag, known as an Excess Carrier.

More recently, there are problems with impurities and you find that the opposite effect occurs. You have no time to reach home before diarrhea takes over. You have no option but to stop the car and nip over a gate into a field. Hence the Field Effect Transistor. This time you have to inject something to STOP the flow. Now, assuming that there was a certain control over events; nothing happened until the Gate was encountered, you then became the Source of flow, and the field itself acted as the Drain. What was originally dirt, became grass, was consumed by the Cow, you ate it as a burger, and it has now returned to the topsoil, an effect known in the trade as Surface Recombination. (Incidentally, did you know that Diarrhea is hereditary? Apparently it runs in the jeans.)

Some of the impurities accumulate in your rear end, and no matter how valiantly you try, you cannot rid yourself of them. Hence In-de-Bum is known as a Try-Valiant Impurity. In the same way, Arsenic, well known for its ill-effects and accumulation in the body tissues is known as a Pent-Up-Valiant Impurity.

Bill Gates' New House

(Forwarded by: Bob Parker (bobpar@ozemail.com.au).)

While the Gateses are moving in from their temporary quarters nearby, final construction of their new house is not expected to be completed until the end of the year. Now if I were a contractor with a sense of humor...

Bill: "There are a few issues we need to discuss."

Contractor: "Ah, you have our basic support option. Calls are free for the first 90 days and $75 a call thereafter. Okay?"

Bill: "Uh, yeah... the first issue is the living room. We think it's a little smaller than we anticipated."

Contractor: "Yeah. Some compromises were made to have it out by the release date."

Bill: "We won't be able to fit all our furniture in there."

Contractor: "Well, you have two options. You can purchase a new, larger living room; or you can use a Stacker."

Bill: "Stacker?"

Contractor: "Yeah, it allows you to fit twice as much furniture into the room. By stacking it, of course, you put the entertainment center on the couch... the chairs on the table... etc. You leave an empty spot, so when you want to use some furniture you can unstack what you need and then put it back when you're done."

Bill: "Uh... I dunno... issue two. The second issue is the light fixtures. The bulbs we brought with us from our old home won't fit. The threads run the wrong way."

Contractor: "Oh! Thats easy. Those bulbs aren't plug and play. You'll have to upgrade to the new bulbs."

Bill: "And the electrical outlets? The holes are round, not rectangular. How do I fix that?"

Contractor: "Just uninstall and reinstall the electrical system."

Bill: "You're kidding!?"

Contractor: "Nope. Its the only way."

Bill: " Well... I have one last problem. Sometimes, when I have guests over, someone will flush the toilet and it won't stop. The water pressure drops so low that the showers don't work."

Contractor: "That's a resource leakage problem. One fixture is failing to terminate and is hogging the resources preventing access from other fixtures."

Bill: "And how do I fix that?"

Contractor: "Well, after each flush, you all need to exit the house, turn off the water at the street, turn it back on, reenter the house and then you can get back to work."

Bill: "That's the last straw. What kind of product are you selling me?"

Contractor: "Hey, if you don't like it... nobody made you buy it."

Bill: "And when will this be fixed?"

Contractor: "Oh, in your next house -- which will be ready to release sometime near the end of next year. Actually it was due out this year, but we've had some delays..."

The Philogiston Theory of Electronics

(Original author's name not available or he didn't want credit.)

(Forwarded by: Atesli (atesli@aol.com).)

A sheet of paper crossed my desk the other day and as I read it, realization of a Basic Truth came to me. So simple! So obvious we couldn't see it! John Kuivinen, Chairman of the Palomar Repeater Committee, (an amateur radio group), I think has discovered what makes integrated circuits work. He says that smoke (yes, you read smoke) is the thing that makes ICs work because every time you let the smoke out of it, the IC stops working. I was flabbergasted!!! Why of course he's right!!!

Smoke makes all things electrical work. Remember the last time the smoke escaped from your Lucas voltage regulator? Didn't it stop working?

I sat and smiled like an idiot as more of the truth dawned. It's the wiring harness that carries smoke from one device to another in your machine and when the harness springs a leak, it lets the smoke out all at once, and then nothing works. Can't you see now why motors have to be large to handle all that smoke, and don't they have smoke all over the inside when they quit working? Think about it!

Microsoft TV Dinners

(Forwarded from: Nicholas Bodley (nbodley@tiac.net).)

Instructions for Microsoft's New TV Dinner Product:

You must first remove the plastic cover. By doing so you agree to accept and honor Microsoft's rights to all TV dinners. You may not give anyone else a bite of your dinner (which would constitute an infringement of Microsoft's rights). You may, however, let others smell and look at your dinner and are encouraged to tell them how good it is.

If you have a PC microwave oven, insert the dinner into the oven. Set the oven using these keystrokes: <\mstv.dinn.//08.5min@50%heat//. Then enter: If you have a Mac oven, insert the dinner and press start. The oven will set itself and cook the dinner.

If you have a Unix oven, insert the dinner, enter the ingredients of the dinner (found on the package label), the weight of the dinner, and the desired level of cooking and press start. The oven will calculate the time and heat and cook the dinner exactly to specifications. Be forewarned that Microsoft dinners may crash, in which case your oven must be restarted.

This is a simple procedure. Remove the dinner from the oven and enter Many users have reported that the dinner tray is far too big, larger than the dinner itself, having many useless compartments, most of which are empty. These are for future menu items. If the tray is too large to fit in your oven you will need to upgrade your equipment.

Dinners are only available from registered outlets, and only the chicken variety is currently produced. If you want another variety, call Microsoft Help and they will explain that you really don't want another variety. Microsoft Chicken is all you really need. Microsoft has disclosed plans to discontinue all smaller versions of their chicken dinners. Future releases will only be in the larger family size. Excess chicken may be stored for future use, but must be saved only in Microsoft approved packaging.

Microsoft promises a dessert with every dinner after '98. However, that version has yet to be released. Users have permission to get thrilled in advance.

Microsoft dinners may be incompatible with other dinners in the freezer, causing your freezer to self-defrost. This is a feature, not a bug. Your freezer probably should have been defrosted anyway.

Is Windows a Virus or a Bug?

(From: John Borchard (jb@dendritics.com).)

Is Windows a Virus? No, Windows is not a virus. Here's what viruses do:

1. They replicate quickly - okay, Windows does that.
2. Viruses use up valuable system resources, slowing down the system as they do so - okay, Windows does that.
3. Viruses will, from time to time, trash your hard disk - okay, Windows does that too.
4. Viruses are usually carried, unknown to the user, along with valuable programs and systems. Sigh... Windows does that, too.
5. Viruses will occasionally make the user suspect their system is too slow (see 2) and the user will buy new hardware. Yup, that's with Windows, too.

Until now it seems Windows is a virus... But there are fundamental differences:

Viruses are well supported by their authors, are running on most systems, their program code is fast, compact and efficient and they tend to become more sophisticated as they mature.

So Windows is not a virus.

It's a bug.

- Back to Humor Table of Contents.

Did They Really Say That?

(Forwarded by: Barry Werner (werner@repairfaq.org).)

Caveat emptor! Read on...

Recently reported in the Massachusetts Bar Association Lawyers Journal:

The following are questions actually asked of witnesses by attorneys during trials and, in certain cases, the responses given by insightful witnesses:

1. "Now doctor, isn't it true that when a person dies in his sleep, he doesn't know about it until the next morning?"
2. "The youngest son, the twenty-year old, how old is he?"
3. "Were you present when your picture was taken?"
4. "Were you alone or by yourself?"
5. "Was it you or your younger brother who was killed in the war?"
6. "Did he kill you?"
7. "How far apart were the vehicles at the time of the collision?"
8. "You were there until the time you left, is that true?"
9. "How many times have you committed suicide?"
10. Q: "So the date of conception (of the baby) was August 8th?"
    A: "Yes."
    Q: "And what were you doing at that time?"
11. Q: "She had three children, right?"
    A: "Yes."
    Q: "How many were boys?"
    A: "None."
    Q: "Were there any girls?"
12. Q: "You say the stairs went down to the basement?"
    A: "Yes."
    Q: "And these stairs, did they go up also?"
13. Q: "Mr. Slatery, you went on a rather elaborate honeymoon, didn't you?"
    A: "I went to Europe, Sir."
    Q: "And you took your new wife?"
14. Q: "How was your first marriage terminated?"
    A: "By death."
    Q: "And by who's death was it terminated?"
15. Q: "Can you describe the individual?"
    A: "He was about medium height and had a beard."
    Q: "Was this a male, or a female?"
16. Q: "Is your appearance here this morning pursuant to a deposition notice
    which sent to your attorney?"
    A: "No, this is how I dress when I go to work."

17. Q: "Doctor, how many autopsies have you performed on dead people?"
    A: "All my autopsies are performed on dead people."

18. Q: "All your responses must be oral, OK? What school did you go to?"
    A: "Oral."

19. Q: "Do you recall the time that you examined the body?"
    A: "The autopsy started around 8:30 p.m.."
    Q: "And Mr. Dennington was dead at the time?"
    A: "No, he was sitting on the table wondering why I was doing an autopsy."

20. Q: "You were not shot in the fracas?"
    A: "No, I was shot midway between the fracas and the navel."

21. Q: "Are you qualified to give a urine sample?"
    A: "I have been since early childhood."

22. Q: "Doctor, before you performed the autopsy, did you check for a pulse?"
    A: "No."
    Q: "Did you check for blood pressure?"
    A: "No."
    Q: "Did you check for breathing?"
    A: "No."
    Q: "So, then it is possible that the patient was alive when you began the autopsy?"
    A: "No."
    Q: "How can you be so sure, Doctor?"
    A: "Because his brain was sitting on my desk in a jar."
    Q: "But could the patient have still been alive nevertheless?"
    A: "It is possible that he could have been alive and practicing law somewhere."

What Happens When Engineers Think Too Much About Christmas

(Forwarded by: Steve Seaman (sseaman@fundy.net).)

It's an oldie, but a goodie.

1. No known species of reindeer can fly. But there are 300,000 species of living organisms yet to be classified, and while most of these are insects and germs, this does not completely rule out flying reindeer, which only Santa has seen.

2. There are 2 billion children (under 18) in the world. But since Santa doesn't appear to handle Muslim, Hindu, Buddhist, and Jewish children, that reduces the work load to 15% of the total - 378 million or so. At an average rate of 3.5 children per household, that's 91.8 million homes.

   One presumes there's at least one good child in each.

3. Santa has 31 hours of Christmas to work with thanks to time zones and the rotation of the earth, assuming he travels east to west. This works out to 822.6 visits per second. This is to say that for each Christian household with good children, Santa has 1/1000th of a second to park, hop out of the sleigh, jump down the chimney, fill the stockings, distribute the remaining gifts under the tree, eat the snacks, get back up the a chimney, get back in the sleigh, and move on to the next house. Assuming that each of these 91.8 million homes are distributed evenly (which we know to be false but for the sake of these calculations we will accept) we are now talking about .78 miles per household, a total trip of 75 1/2 million miles, not counting bathroom stops. This means that Santa's sleigh is traveling at 650 miles per second, 3000 times the speed of sound. For comparison, the fastest man made vehicle, the Ulysses space probe moves at a poky 27.4 MPS; the average reindeer runs at 15 MPH.

4. The sleighs payload adds another interesting element. Assuming that each child gets nothing more than a medium sized LEGO set (2 pounds), the sleigh is carrying 321,300 tons not counting Santa, who is inexorably described as overweight. On land, confessional reindeer can pull no more than 300 pounds. Even granting that "flying reindeer" (see point one) could pull TEN TIMES the usual amount, we can not do the job with 8 or even 9, we need 214,000 reindeer. This increases the weight, not even counting the sleigh, to 353,430 tons. Again for comparison this is 4 times the weight of the Queen Elizabeth 2.

5. 353,000 tons traveling at 650 miles per second creates enormous air resistance. This will heat the reindeer in the same manner as a spacecraft re-entering the earth+s atmosphere. The lead pair of reindeer will absorb 14.2 QUINTILLION joules of energy. Per second. Each. In short, they will burst into flame almost instantaneously, exposing the next pair of reindeer, and creating deafening sonic booms in their wake. The entire team will be vaporized within 4.26 thousands of a second. Santa, meanwhile, will be subjected to centrifugal forces 17,500.06 times the force of gravity. A 300 pound Santa would be pinned to the back of his sleigh by 4,315,015 pounds of force.

6. Conclusion: There was a Santa, but he's dead now.

That Darn Oops Button

Haven't you always wanted a button labeled 'oops' on your keyboard for those occasions where 1 microsecond after posting something to sci.electronics.repair (or a more juicy newsgroups), you realized how stupid it was?

Maybe the 'Oops' button would create a market for those no-longer-needed 'printer buffers'??? :-) Darn, that great an idea shouldn't be in a publicly accessible document. Oops!

(From: Mr Fixit (mrfixit@cyberhighway.net).)

I believe I could retire in style if I can design a ad-on computer button labeled 'Oops'. It would be wired to a small, but high powered electronic box that would go in-line at the modem connection.

Once in place, we usenet users would have a means of dealing with that dreaded situation when we push the 'post' button at the same instant we realize that we shouldn't have pushed it. A quick slap on the 'oops' button would instantly send a high powered jolt down the phone line where it would catch up to the inadvertently sent message and blow it to smitherines, like a Patriot missile intercepting a Scud.

I know I would make regular use of it, as well as Sam, Joe and countless others on this NG alone. And just think of how many NG's there are with their own regretful posters!

Of course, I would have to SPAM all of the NG's to get the word out and start my $millions rolling in. But, knowing me I would probably have second thoughts about being a SPAMMER the instant I push the 'post' button. My knee-jerk reaction would undoubtably be to slap the new prototype 'oops' button on my computer and blast my own SPAM before it could be delivered. The end result being that I would be the only one on usenet with this powerful technology-turned personal toy.

Never mind that this would be grossly unfair to everyone else, the cold reality would be that I just blasted away my comfortable retirement.

Retirement.....that reminds me...I've got toilets, sinks, tubs, floors, walls, windows, doors, etc., etc., to fix. I don't have time to be inventing toys!

So, in lieu of all that, we'll all just have to accept human nature for what it is (occasionally unreliable) and offer Sam a knowing grin, and get on with what we're here for.

Now, what was it we are here for?

Where's that darned 'oops' button now when I need it? Umm, never mind.

Transformer Design - Tomato Launcher

This is actually part of a long thread on sci.electronics.design (much of it between Chuck Parsons and Winfield Hill) but I got tired of extracting and formatting all the relevant stuff!

(From: Chuck Parsons (Chuck@CatenaryScientific.com).)

Well there is nothing I like better than finding the right intuitive model fo something. Intuition is so fast if you can keep out the bad intuition. Many thanks for helping me lay another block in my EE foundation I hope others benefited as well.

While mulling this over last night I tried to come up with a circuit that explored both converters. I came up with a hybrid design that uses both converters in a single transformer. First though I needed a reason for building it, this is what I came up with. I don't claim that the design is particularly good I was just trying to bring some of the issues in to play. I invite anyone who cares to to disparage or (better) improve the designs.

Our story begins many years ago (at least for some of us) when all of us in the sci.electronics.design gang happened to be about 16. Old enough to drive, but young enough that the police might still take us too our parents instead of jail.

Those jerks in alt.pdf_not_gif.big_binaries.wannabies.geese. are getting their due at the hands of our car mounted linear induction motor tomato launcher. It launches 1kg tomatoes. 1 kg tomatoes are rather large, but we have gardening expertise here in sci.electronics and have no trouble procuring our superior ammunition. I have grown 1.1kg tomatoes, and last summer was hours away from picking 4 even larger ones when those &%#@* alt.pdf_not_gif.big_binaries.wannabies GEESE got them.

Careful, but messy, testing has determined that 30 meter per second (108 kph or 67 mph) launch speeds are possible without PPF (premature projectile fragmentation) requiring another trip to the car wash. Naturally we want to come as close to this as possible without exceeding it. The energy of a 1kg projectile traveling at 30 mps is 450 Joules. Our launcher has an impressive 45% efficiency (of course we designed it!) so a launch requires 1000 Joules of energy. We store this energy in 220,000 uF of capacitance at 100 Volts. the caps are discharged all the way to 30 volts during firing, so only 1100 Joules of energy storage is needed to deliver 1000 Joules. Testing has also shown that for small variations in the linear motor input voltage the variation in projectile speed is reasonably linearly related to the voltage variation.

Generation 1 used a simple 20 watt 100 kHz PWM flyback design to generate the 100 volts from the car battery. The ferrite needs to store 200 uJ on each pulse. A ferrite capable of storing 400uJ was chosen to avoid saturation at high input voltages. This design worked great. The 100 volts was accurate assuring reproducible launches whether or not we had the car revving for get away or had the battery just about dead after a long day of field trials. I sketch it here:

```
                           +----------|>|----------+-------+-----o 100 V
Vin 10-15 volts o-----+ ||(                        |       |
                       )||(                       _|_      |
                       )||(                 .22 F ---      |
                       )||(                        |       |
                   +--+ ||(                       _|_      |
       30 V        |       +--+                    -       |
       MOSFET .|---+         _|_                           |
              ||<--.          -                            |
          +---'|---+                                       |
          |       _|_                                      |
          |        -                                       |
          |     +----------------------------------+       |
          +-----| PWM Controller: 0-80% duty cycle |-------+
                +----------------------------------+
```

The inductance of the primary and the avalanche capability of the Mosfet have served to protect the circuit from those nasty 50 Volt transients in the car's ignition system.

Unfortunately after a few successful raids the alters took advantage of the 50 second recharge time to close and return fire from close range.

Generation 2 then using the same ferrite modified the design to use forward conversion allowing an average 200 watts of power transfer and a much quicker 5 second reload time, which is about how long it took Win to pass up those tomatoes from the back seat through the sun roof anyway.

```
                               +---+    +----|>|-------+-------+-----o 100 V
Vin 10-15 volts o---------+ ||(   _|_   |              |       |
                           )||(    -    |             _|_      |
                           )||(         |       .22 F ---      |
                           )||(         |              |       |
                +----+----+ ||(         |             _|_      |
    30 V        |    |         +--------+              -       |
    MOSFET .|---+   _|_                                        |
           ||<--.   --- Snubber                                |
       +---'|---+    |                                         |
       |       _|_  _|_                                        |
       |        -    -                                         |
       |     +------------------------------------------+      |
       +-----| Fixed 100 kHz Controller: 80% duty cycle |------+
```

```
               +------------------------------------------+
```

We had to add a snubber because now the magnetization flux is just being dumped into the mosfet at the end of every cycle. Since we are using the same transformer and frequency as well as maximum duty cycle this energy amounts to just the 20 watts of the flyback converter.

This produced a glorious victory over the alters, plastering them at close range as they closed with their basket of 100 gram wormy tomatoes.

However, there were problems. The Generation 1 circuit could be left on continuously and preloaded allowing instant reaction to sneak attacks when getting in the car in the morning. Leaving the Generation 2 circuit on all night killed the battery, despite nearly 90% efficiency at full load (and full output voltage).

The efficiency at low loads, or low output voltages is poor. Continuous firing is possible until the transformer overheats. At full load _and_ output voltage, the transformer heat load is not bad, but during the output rampup currents are only limited by the leakage inductance (much lower than the full winding inductance), winding resistance and MOSFET on resistance. To minimize the charging time we of course minimized all of these, leading to 100 amp peak currents. Furthermore changes in the input voltage lead to problems in figuring range and aiming accurately. Indeed several second shots while racing away at low gear and high RPMs lead to high battery charging voltages and embarrassing PPF (premature projectile fragmentation).

Generation 3 is to combine the best features of both designs. (The turns on the secondary are reduced 10% to ensure the flyback is the only active energy transfer at full load. This isn't always enough reduction to ensure the output voltage never exceeds 100 volts, but it is a compromise between overcharging at high input voltages and slow charging at low input voltages.)

```
                             +--+--|>|--------+--------+-----+--o Vout: 100 V
  Vin 10-15 volts o-----+ ||(   |             |        |     |
                         )||(   +--|<|--+--+  |       _|_    |
                         )||(           | _|_ | .22 F ---    |
                         )||(   +--|<|--+  =  |        |     |
                     +--+ ||(   |             |       _|_    |
         30 V        |       +--+--|>|--------+        -     |
         MOSFET .|---+                                       |
                ||<--.                                       |
            +---'|---+                                       |
            |       _|_                                      |
            |        -                                       |
            |  +------------------------------------------+  |
            +--| 100 kHz PWM Controller: 0-80% duty cycle |--+
               +------------------------------------------+
```

In this design the snubber disappears because the magnetization energy is captured for use in the output flyback. At low output voltage the design works primarily as forward conversion but at some point the output voltage equals the input voltage multiplied by the turns ratio and the design transfers over to pure flyback. We can once again leave the circuit running continuously. We can get off 10 shots in 50 seconds before the transformer and mosfets overheat, though the output voltage will then be 90 instead of 100 leading to reduced range. The flyback just has to top off the capacitors so if we can 15 seconds instead of 5 (but not 50) between shots we can assure a steady output voltage. The biggest problem is that variation in the input voltage leads to variations in the amount of time spent in flyback versus forward conversion. A second problem is that the flyback, moving charge all the way from ground to 100 volts at the end of the top-off is rather slow. Basically we would like to extend the period of time in forward conversion but we have to adjust the winding turns so that at maximum input voltage the forward conversion output voltage is less than the desired Vout. We can increase the amount of work done in forward conversion as follows, simultaneously greatly improving the charge delivery of the flyback, by giving it a slower rampdown.

```
                            +--+--|>|------+--------+-------+--o Vout 1: 100 V
 Vin 10-15 volts o-----+ ||(   |           |        |       |
                        )||(   +--|<|--+   |       _|_      |
                        )||(          _|_  | .22 F ---      |
                        )||(           -   |        |       |
                    +--+ ||(               |       _|_      |
        30 V        |       +--+--|>|------+        -       |
        MOSFET .|---+          |                            |
               ||<--.          +--o Vout 2: 80 V            |
           +---'|---+         _|_                           |
           |       _|_        --- 2,000 uF, low ESR         |
           |        -         _|_                           |
           |                   -                            |
           |  +------------------------------------------+  |
           +--| 100 kHz PWM Controller: 0-80% duty cycle |--+
              +------------------------------------------+
```

A miracle has happened, with our generation 4 design even in August we don't have enough tomatoes. Maybe we should modify it for zucchini ;-).

Much more - search via Google Groups (formerly Deja.com/Dejanews) for: "sci.electronics.design", and "Re: Transformer design equations - tomato launcher", or maybe just "cherry tomatoes" or "zucchini" for the subject line! :-)

Parts Replacement

So many repair questions take the form:

"Where can I get the microprocessor or flyback or CRT or mainboard or 'most expensive part' because I think THAT must be the problem".

(From: David J. Pittella (ddc_pitt@ix.netcom.com).)

I frequently read or overhear discussions about the repair of products that are controlled by a microprocessor or microcontroller and wonder why technicians are always trying to replace these, typically prior to any testing or troubleshooting?

I wonder if they will ever believe that these devices are typically very reliable and that the lack of a proper voltage, or a failed or dirty sensor or switch be the real fault?

New troubleshooting technique:

1. Replace ALL the biggest chips FIRST, the more pins the better.

2. If step #1 doesn't resolve the problem, see if there is service literature available?

3. If there is no service literature, see if the something called the MAIN BOARD! Just replace anything that could be a MAIN BOARD - that should fix the problem!

4. If steps (1) to (3) don't cure the problem, advise the customer that "parts are no longer available" or "the cost of repair exceeds the cost of replacement".

WARNING: DO NOT attempt to use a voltmeter to make simple voltage tests, or an ohmmeter to possibly check the continuity of the on/off switch!! :-)

You Know You're from Silicon Valley When...

(From: Filip Fuma (filfuma@csi.com).)

- You make $120,000 a year, but can't find a place to live.
- You see nothing but expensive cars because of .
- Your commute time is 45 minutes and you live 8 miles from work.
- You stop asking how much things cost and start asking: "How long will it take?"
- Two-thirds of the people you know are from Boston, Austin, Raleigh-Durham or New York, but you are living in PST.
- You know vast and subtle differences between Thai, Vietnamese, Chinese, Japanese, Cantonese, and Korean food.
- Your home computer contains mostly hardware/software that isn't on the consumer market yet.
- You go to "The City" on weekends but don't live there because you like your car.
- You think that "I'm going to Fry's Electronics" is an acceptable excuse to leave the office for a while. And your boss does too.
- You /lost/never had/don't know how to set the alarm clock. You'll just get to work when you get there.
- You go to an industrial-heavy-metal bar and see two guys get into a fight over what flavor of UNIX is better.
- You own more than 10 articles of clothing that have hardware and/or software companies printed on them. (Bonus for embroidered stuff.)
- You know where Woz Way, Resistor Ave, and Floppy Drive are located.
- You know where Woz is.
- You know Hwy 280 North runs west, and Hwy 680 North runs East.
- Even though Microsoft employs quite a few programmers in the Bay Area, they only work on Powerpoint, and the company is still the embodiment of Satan. (Even if their stock IS worth more than yours.)
- You see a billboard that says "FGPA2ASIC" and aren't fazed.
- When you need the updated Diamond Monster 3D drivers, you just walk across the street.
- You have more bandwidth in your apartment or condo than most major universities.
- You have to hire security to keep the panhandlers off your terrace. (Oakland/Berkeley).
- None of the people you work with are bible thumpers.
- You scan yard sales for back issues of "Dr. Dobbs."

- Your favorite computer reseller speaks only Cantonese.
- Your workplace vending machines dispense "100% natural twig-bars" right next to Jolt cola and Instant Espresso mix.
- No one brings radios into work - they just use RealAudio and listen to the dj.com, rebelradio.com, or other out-of-state stations.
- You don't understand how the carpool lanes work because you normally don't commute during those hours.
- You meet a friend for lunch and the first topic is where they are working now.
- You go to the movies and EVERYBODY claps along with the SciFi theme music.
- You entice prospective employees to join your company by bragging about the speed of your internet connection.
- You've replaced your box of floppies with a box of Zip disks, but that's just until you get your box of Jaz disks.
- You have completely forgotten how to write longhand.

Lawyer One-Liners

Sorry (well not really) for any lawyers reading this. :-)

(Forwarded by: Jim Lagerkvist (jlager@tir.com).)

> Q: What do you call a lawyer with an I.Q. of 50?
> A: Your honor.
>
> Q: What do you call a lawyer whose gone bad?
> A: Senator.
>
> Q: What's the difference between a lawyer and a trampoline?
> A: You take off your shoes to jump on a trampoline!
>
> Q: What do you call 5000 dead lawyers at the bottom of the ocean?
> A: A good start!
>
> Q: How can you tell when a lawyer is lying?
> A: His lips are moving.
>
> Q: What's the difference between a dead dog and a dead lawyer in the road?
> A: There are skid marks in front of the dog.

Q: How many lawyers does it take to roof a house?
A: Depends on how thin you slice them.

Q: Why won't sharks attack lawyers?
A: Professional courtesy.

Q: What do you have when a lawyer is buried up to his neck in sand?
A: Not enough sand.

Q: When lawyers die, why are they buried in a hole 24 feet deep?
A: Because down deep, they are all nice guys!!!!

Q: How do you get a lawyer out of a tree?
A: Cut the rope.

Q: How do you stop a lawyer from drowning?
A: Shoot him before he hits the water.

Q: What is the definition of a shame (as in "that's a shame")?
A: When a bus load of lawyers goes off a cliff.

Q: What is the definition of a "crying shame"?
A: There was an empty seat.

Q: How many lawyers does it take to stop a moving bus?
A: Never enough.

Q: Have you heard about the lawyers word processor?
A: No matter what font you select, everything comes out in fine print.

Q: What's the difference between a porcupine and two lawyers in a Porsche?
A: With a porcupine, the pricks are on the outside!

Q: What do you buy a friend graduating from Law School?
A: A lobotomy.

Q: What's the difference between a catfish and a lawyer?
A: One's a bottom-crawling scum sucker and the other's just a fish.

Q: Hear about the terrorist that hijacked a 747 full of lawyers?
A: He threatened to release one every hour if his demands weren't met.

Q: What does a lawyer and a sperm have in common?
A: Both have about a one in 3 million chance of becoming a human being.

Q: Why is it that many lawyers have broken noses?
A: From chasing parked ambulances.

Q: Where can you find a good lawyer?
A: In the cemetery

Q: What do lawyers use as contraceptives?
A: Their personalities.

Q: What's the difference between a lawyer and a herd of buffalo?
A: The lawyer charges more.

Q: What's the difference between a lawyer and a vampire?
A: A vampire only sucks blood at night.

Q: What is brown and black and looks good on a lawyer?
A: A doberman.

Q: What is the difference between a lawyer and a rooster?
A: When a rooster wakes up in the morning, its primal urge is to cluck defiance.

Q: How many law professors does it take to change a light bulb?
A: Hell, you need 250 just to lobby for the research grant.

Q: Why did the post office recall the new lawyer stamps?
A: Because people could not tell which side to spit on.

Q: Did you hear about the new sushi bar that caters exclusively to lawyers?
A: It's called, Sosumi.

Q: Did you hear about the lawyer from Texas who was so big when he died that
they couldn't find a coffin big enough to hold the body? A: They gave him an enema and buried him in a shoe box.

Q: Santa Claus, the tooth fairy, an honest lawyer, and an old drunk are walking down the street together when they simultaneously spot a hundred dollar bill. Who gets it?
A: The old drunk, of course, the other three are mythological creatures.

Q: What is the ideal weight of a lawyer?
A: About three pounds, including the urn.

Garage Tools

(Forwarded by: blinkys@execpc.com).

HAMMER: Originally employed as a weapon of war, the hammer nowadays is used as a kind of divining rod to locate expensive car parts not far from the object we are trying to hit.

MECHANIC'S KNIFE: Used to open and slice through the contents of cardboard cartons delivered to your front door; works particularly well on boxes containing convertible tops or tonneau covers.

ELECTRIC HAND DRILL: Normally used for spinning steel Pop rivets in their holes until you die of old age, but it also works great for drilling rollbar mounting holes in the floor of a sports car just above the brake line that goes to the rear axle.

HACKSAW: One of a family of cutting tools built on the Ouija board principle. It transforms human energy into a crooked, unpredictable motion, and the more you attempt to influence its course, the more dismal your future becomes.

VISE-GRIPS: Used to round off bolt heads. If nothing else is available, they can also be used to transfer intense welding heat to the palm of your hand.

OXY-ACETYLENE TORCH: Used almost entirely for lighting those stale garage cigarettes you keep hidden in the back of the Whitworth socket drawer (what wife would think to look in there?) because you can never remember to buy lighter fluid for the Zippo lighter you got from the PX at Fort Campbell.

ZIPPO LIGHTER: See oxy-acetylene torch.

WHITWORTH SOCKETS: Once used for working on older British cars and motorcycles, they are now used mainly for hiding six-month-old Salems from the sort of person who would throw them away for no good reason.

DRILL PRESS: A tall upright machine useful for suddenly snatching flat metal bar stock out of your hands so that it smacks you in the chest and flings your beer across the room, splattering it against the Rolling Stones poster over the bench grinder.

WIRE WHEEL: Cleans rust off old bolts and then throws them somewhere under the workbench with the speed of light. Also removes fingerprint whorls and hard-earned guitar callouses in about the time it takes you to say, "Django Reinhardt."

HYDRAULIC FLOOR JACK: Used for lowering a Mustang to the ground after you have installed a set of Ford Motorsports lowered road springs, trapping the jack handle firmly under the front air dam.

EIGHT-FOOT LONG DOUGLAS FIR 2x4: Used for levering a car upward off a hydraulic jack.

TWEEZERS: A tool for removing wood splinters.

PHONE: Tool for calling your neighbor Chris to see if he has another hydraulic floor jack.

SNAP-ON GASKET SCRAPER: Theoretically useful as a sandwich tool for spreading mayonnaise; used mainly for getting dog-doo off your boot.

E-Z OUT BOLT AND STUD EXTRACTOR: A tool that snaps off in bolt holes and is ten times harder than any known drill bit.

TIMING LIGHT: A stroboscopic instrument for illuminating grease buildup on crankshaft pulleys.

TWO-TON HYDRAULIC ENGINE HOIST: A handy tool for testing the tensile strength of ground straps and hydraulic clutch lines you may have forgotten to disconnect.

CRAFTSMAN 1/2 x 16-INCH SCREWDRIVER: A large motor mount prying tool that inexplicably has an accurately machined screwdriver tip on the end without the handle.

BATTERY ELECTROLYTE TESTER: A handy tool for transferring sulfuric acid from car battery to the inside of your toolbox after determining that your battery is dead as a door nail, just as you thought.

AVIATION METAL SNIPS: See hacksaw.

TROUBLE LIGHT: The mechanic's own tanning booth. Sometimes called a drop light, it is a good source of vitamin D, "the sunshine vitamin," which is not otherwise found under cars at night. Health benefits aside, its main purpose is to consume 40-watt light bulbs at about the same rate that 105mm howitzer shells might be used during, say, the first few hours of the Battle of the Bulge. More often dark than light, its name is somewhat misleading.

PHILLIPS SCREWDRIVER: Normally used to stab the lids of old-style paper-and-tin oil cans and splash oil on your shirt; can also be used, as the name implies, to round off Phillips screw heads.

AIR COMPRESSOR: A machine that takes energy produced in a coal-burning power plant 200 miles away and transforms it into compressed air that travels by hose to a Chicago Pneumatic impact wrench that grips rusty suspension bolts last tightened 40 years ago by someone in Abingdon, Oxfordshire, and rounds them off.

JESUS CLIP: "Jesus" every time you drop one of these.

Tesla Coil Caps

Actually, the warnings about PCBs (and I don't mean Printed Circuit Boards) are real!

So you are looking for BIG capacitors...... :-)

(From: Bill Coderre (bc@apple.com).)

Just watch out for PCB-laden oil-filled caps.... Those are usually the ones you find at the junk yard or the surplus place for REAL cheap, big grey cans with lightning protectors on top, usually labeled something like "1 uF @ 100 kV." They're extra cheap if they're already leaking!

Just remember, if you come across a pile of drum caps in an abandoned lot in an industrial section of town - even if the sign on top says "FREE! FREE!" - they are not good for you. Just Say No to PCBs.

I personally wish that Norm Abrams, host of the New Yankee Workshop, would run a show for electronics experimenters, something like the New Geek Workshop:

"Today we're going to be making a tesla coil from champagne bottles, a spark coil from a 53 DeSoto, and this hand-knurled lightning rod. It'll look great next to my Louis XIV-style marquetry and scrollwork Orgone Cabinet!. But first, let's talk about Safety Glasses...."

Customer Translations

(From: Dan (tvman@newwave.net).)

I once had a customer who insisted on "helping" me fix his TV. I politely told him that he had done enough damage to it already."

How about the customer who brought his TV in and said that "it worked fine until" he worked on it. (At least he was honest.)

(From: Michelle Hunt (michell5@ix.netcom.com).)

I had one of those the other day... This guy brought in a little Magnavox 19" and the conversation went something like this:

Him: "I don't know what happened, it just suddenly quit working."

Me: "Was that before or after you dropped it?"

Him: "How did you know I dropped it?"

Me: "It was easy... the cabinet usually isn't broken into pieces like this".

(From: Chris Mann).

How about customer translations such as:

"I think it's got a shorted fuse" - "I don't have a clue as to what's wrong but I know some electronic words so don't rip me off".

"I think it's just a bad connection" - "I know something major happened. I just don't want to think that something major happened."

"I think something's loose inside" - "My child uses it for his piggy bank".

"It fell off the shelf".

"It just stopped working" - "I spilled my drink and it went inside"

Advertising to Dummies

(I was going to use the 'for' word but then a certain publisher's lawyers would come complaining.)

(From: Charley S. McCue (csmccue@midusa.net).)

I once spent 15 minutes trying to convince a customer they had not bought a $20 satellite dish from TV Guide (back when C band was the only option).

(From: Gary Woods (gwoods@wrgb.com).)

That's the ad that I still think is the high-water mark of advertising to stupid people:

"You're not paying cable fees, because this is not a satellite antenna. It uses proven RF technology to pick signals RIGHT OUT OF THE AIR!"

People still bought them thinking they'd get cable or something. We had a copy on the door of the tech shop for a while.

Reminds me of the fellow who offered on a bulk emailer site one million email addresses for only ten dollars. "Generated by sophisticated random number technology", they are all guaranteed undeliverable! People actually sent him orders!

P.T. Barnum was right!

- Back to Humor Table of Contents.

The Hazards of Multimeters

(From: Ed Price (edprice@pacbell.net).)

Let me add my own tale of knowledge gained through stupid experimentation. In 1961, right after I built my Knight Kit VTVM, I was measuring the voltage and resistance of everything I could find. I eventually found an old "Press" style flashbulb, about an inch in diameter. I started out on a high Ohms range, and worked my way down to the 1x range. The lessons I learned involved design of experiments, resistance testing, chemical reaction of magnesium, optical transfer of energy and emergency room procedure. Did you know that those old bulbs had a plastic outer layer which could very effectively fuse to charred skin?

Dirty Harry Callahan was right; "...when properly used, you can REMOVE the fingerprints."

Next time (if somebody asks politely), I'll tell you how I got radiation burns from a pencil.

- Back to Humor Table of Contents.

The Surgeons' Choice

(Forwarded by Fil Fuma (filfuma@csi.com).)

5 surgeons are taking a coffee break:

The first surgeon says: "Accountants are the best to operate on because when you open them up, everything inside is numbered."

The second surgeon says: "Nah, librarians are the best. Everything inside them is in alphabetical order."

The third responds: "Try electricians, man! Everything inside THEM is color coded."

The fourth intercedes: "I like engineers...they always understand when you have a few parts left over at the end."

To which the fifth surgeon, who has been quietly listening to the conversation, says: "You're all wrong. Lawyers are the easiest. There's no guts, no heart, no spine and their head and butt are interchangeable."

VCR Only Works Upside-Down

(From: Clifton T. Sharp Jr. (agent150@ml.org).)

Maybe you should reverse the wires to the vertical yoke windings of the TV as well. :-)

I'll never forget the old 21" round picture tubes and the giant yokes that went on them; the yokes had quick-disconnect spade terminals which connected to the chassis through individual wires. When I had a customer with a sense of humor, or when I worked on my brother's TV, I would first reverse the horizontal winding wires and "work on some adjustments" while waiting for the reaction. They'd say "the picture is backwards, look at the text," and I'd hold my mirror up from behind the set and say, "Looks just fine to me, I can read it." I'd let them remind me about the mirror image or coax me out from behind the set, then I'd shut the set off and instead of fixing the horizontal windings, reverse the vertical. Turning on the set always got "Now it's upside-down!" at which I would rise and lean over the set from the back, chin above forehead, and say "Looks okay to me."

Abbott and Costello Meet Windows 95

(Forwarded by: Barry Werner (werner@repairfaq.org).)

Costello: Hey, Abbott!

Abbot: Yes, Lou?

Costello: I just got my first computer.

Abbot: That's great Lou. What did you get?

Costello: A Pentium II-266, with 40 Megs of RAM, a 2.1 Gig hard drive, and a 24X CD-ROM.

Abbot: That's terrific, Lou

Costello: But I don't know what any of it means!!

Abbot: You will in time.

Costello: That's exactly why I am here to see you.

Abbot: Oh?

Costello: I heard that you are a real computer expert.

Abbot: Well, I don't know-

Costello: Yes-sir-ee. You know your stuff. And you're going to train me.

Abbot: Really?

Costello: Uh huh. And I am here for my first lesson.

Abbot: OK Lou. What do want to know? Costello: I am having no problem turning it on, but I heard that you should be very careful how you turn it off.

Abbot: That's true.

Costello: So, here I am working on my new computer and I want to turn it off. What do I do?

Abbot: Well, first you press the Start button, and then-

Costello: No, I told you, I want to turn it off.

Abbot: I know, you press the Start button-

Costello: Wait a second. I want to turn it off. Off. I know how to start it. So tell me what to do.

Abbot: I did.

Costello: When?

Abbot: When I told you to press the Start button.

Costello: Why should I press the Start button?

Abbot: To shut off the computer.

Costello: I press Start to stop.

Abbot: Well Start doesn't actually stop the computer.

Costello: I knew it! So what do I press.

Abbot: Start

Costello: Start what?

Abbot: Start button.

Costello: Start button to do what?

Abbot: Shut down.

Costello: You don't have to get rude!

Abbot: No, no, no! That's not what I meant.

Costello: Then say what you mean.

Abbot: To shut down the computer, press-

Costello: Don't say, "Start!"

Abbot: Then what do you want me to say?

Costello: Look, if I want to turn off the computer, I am willing to press the Stop button, the End button and Cease and Desist button, but no one in their right mind presses the Start to Stop.

Abbot: But that's what you do.

Costello: And you probably Go at Stop signs, and Stop at green lights.

Abbot: Don't be ridiculous.

Costello: I am being ridiculous? Well. I think it's about time we started this conversion. Abbot: What are you talking about?

Costello: I am starting this conversation right now. Good-bye.

A Pound of Electrons, Please!

(From: Clifton T. Sharp Jr. (agent150@spambusters.ml.org).)

Once on a very very bored day, I and a friend decided to compute how long it would take for a black-and-white TV to shoot a pound of electrons at the screen. If you ever get so bored that you want to duplicate this entirely silly exercise:

1. Take the rest mass of an electron.
2. Convert from nanopicofemtoattograms (whatever) to pounds.
3. Invert to find quantity of electrons in a pound.
4. Determine average beam current of the TV.
5. Convert amps to coulombs per second.
6. Divide quantity in (3) by quantity in (5) to determine number of seconds. Convert to megacenturies.
7. Tell your friends.
8. Do what your friends tell you and get a life.

(Anyone who doesn't see how entirely silly this is and posts corrections to the lousy data should be bolted by aliens to a spaceship and towed through the galaxy until struck by a pound of cosmic rays.)

In Defense of Fuse Eating Equipment

(From: Frank McNally (emcnally@mail.otenet.gr).)

There is absolutely nothing wrong with a TV that eats fuses , most of them do it at some time , What is wrong is that a non technical person should try checking his fuses in a TV that eats fuses . When it has eaten one it is quite likely that it will want to eat another ! and another ! until its appetite has been quenched.

Just how hard did the TV eat the Fuse - was it just a small nibble or the fully grown. "I haven't eaten a fuse for god knows how many years." Bite that left the fuse black and charred.? I have seen Philips TVs that have eaten fuses down to the Glass tube that surrounds them leaving only metal caps in the fuse holder. If the fuse doesn't look burnt, like the TV toasted it before it ate it, the possibility is that the fuse died of old age and thermal shock before it parted company with its end-caps.

A fuse that, like the one that lost its jacket as well as its cool, and must have been eaten alive, before it even had time to think about whether it should holiday in a warm sunny or a cold wintry climate, has definitely wetted the appetite of even the most expensive piece of equipment.

The Ultimate Toaster

(Frowarded by: Jeff Granito (jmg@repairfaq.org).)

Once upon a time, in a kingdom not far from here, a king summoned two of his advisors for a test. He showed them both a shiny metal box with two slots in the top, a control knob, and a lever. "What do you think this is?"

One advisor, an electrical engineer, answered first. "It is a toaster," he said.

The king asked, "How would you design an embedded computer for it?"

The advisor: "Using a four-bit microcontroller, I would write a simple program that reads the darkness knob and quantifies its position to one of 16 shades of darkness, from snow white to coal black. The program would use that darkness level as the index to a 16-element table of initial timer values. Then it would turn on the heating elements and start the timer with the initial value selected from the table. At the end of the time delay, it would turn off the heat and pop up the toast. Come back next week, and I'll show you a working prototype."

The second advisor, a software developer, immediately recognized the danger of such short-sighted thinking. He said, "Toasters don't just turn bread into toast, they are also used to warm frozen waffles. What you see before you is really a breakfast food cooker. As the subjects of your kingdom become more sophisticated, they will demand more capabilities. They will need a breakfast food cooker that can also cook sausage, fry bacon, and make scrambled eggs. A toaster that only makes toast will soon be obsolete. If we don't look to the future, we will have to completely redesign the toaster in just a few years."

"With this in mind, we can formulate a more intelligent solution to the problem. First, create a class of breakfast foods. Specialize this class into subclasses: grains, pork, and poultry. The specialization process should be repeated with grains divided into toast, muffins, pancakes, and waffles; pork divided into sausage, links, and bacon; and poultry divided into scrambled eggs, hard-boiled eggs, poached eggs, fried eggs, and various omelet classes."

"The ham and cheese omelet class is worth special attention because it must inherit characteristics from the pork, dairy, and poultry classes. Thus, we see that the problem cannot be properly solved without multiple inheritance. At run time, the program must create the proper object and send a message to the object that says, 'Cook yourself.' The semantics of this message depend, of course, on the kind of object, so they have a different meaning to a piece of toast than to scrambled eggs."

"Reviewing the process so far, we see that the analysis phase has revealed that the primary requirement is to cook any kind of breakfast food. In the design phase, we have discovered some derived requirements. Specifically, we need an object-oriented language with multiple inheritance. Of course, users don't want the eggs to get cold while the bacon is frying, so concurrent processing is required, too."

"We must not forget the user interface. The lever that lowers the food lacks versatility, and the darkness knob is confusing. Users won't buy the product unless it has a user-friendly, graphical interface. When the breakfast cooker is plugged in, users should see a cowboy boot on the screen. Users click on it, and the message 'Booting UNIX v.8.3' appears on the screen. (UNIX 8.3 should be out by the time the product gets to the market.) Users can pull down a menu and click on the foods they want to cook."

"Having made the wise decision of specifying the software first in the design phase, all that remains is to pick an adequate hardware platform for the implementation phase. An Intel Pentium with 48MB of memory, a 1.2GB hard disk, and a SVGA monitor should be sufficient. If you select a multitasking, object oriented language that supports multiple inheritance and has a built-in GUI, writing the program will be a snap."

The king wisely had the software developer beheaded, and they all lived happily ever after.

Ten Commandments of Electrical Safety

Navy style, at least. :-)

(From: Gordon S. Hlavenka (nospam@crashelex.com).)

```
I    Beware of the lightning that lurketh in seemingly uncharged capacitors,
     lest it cause thee to bounce upon thy buttocks in an unseamanlike manner
     and cause thy hair to stand on end, thereby exceeding regulation length.

II   Cause thou the switch that supplieth large quantities of juice to be
     opened and thusly tagged, that thy days may be long in this earthly vale.

III  Prove to thyself that all circuits that radiateth and upon which thou
     worketh are grounded and thusly tagged, lest they lift thee to radio
     frequency potential and causeth thee to radiate with the angels.

IV   Tarry thou not amongst those fools that engage in intentional shocks, for
     they are not long of this world and are surely unbelievers.

V    Take care thou useth the proper method when thou taketh the measure of
     high voltage so that thou dost not incinerate both thee and thy test
     meter.  For verily, though thou has no NSN and can be easily surveyed,
     the test meter has one, and as a consequence, bringeth much woe unto thy
     supply officer.

VI   Take care thou tamperest not with interlocks and safety devices, for this
     incurreth the wrath of thy department head and bringeth the fury of thy
     commanding officer on thy head.

VII  Work thou not on energized equipment without proper procedures, for if
     thou dost so, thy shipmates will surely be buying beers for thy widow and
     consoling her in certain ways not generally acceptable to thee.

VIII Verily, verily, I say unto thee, never service equipment alone, for
```

```
     electrical cooking is a slow process, and thou might sizzle in thy own
     fat upon a hot circuit for hours on end before thy maker sees fit to end
     thy misery and drag thee into his fold.

IX   Trifle thee not with radioactive tubes and substances lest thou commence
     to glow in the dark like a lightning bug and thy wife be frustrated and
     have no further use for thee except for thy wages.

X    Commit thou to memory all the words of the prophets which are written
     down in the 300th chapter of thy Bible which is the "Naval Ships'
     Technical Manual", and giveth out with the straight dope and consoleth
     thee when thou hast suffered a ream job by thy division LPO.
```

Information Transfer - NOT

(If you are actually an engineer, substitute "Engineering" for "Information Technology", below. :)

(From: Martin (wavefront@bigfoot.com).)

A hot-air balloonist realises he is lost, and so reduces height to ask directions from a man on the ground.

"Excuse me, can you tell me where I am?"

"Yes," says the man below, "You're in a hot-air balloon, hovering about 30 feet above the ground."

"You must work in Information Technology" says the balloonist.

"I do," replies the man."How did you know?"

"Well," says the balloonist "everything you have told me is technically correct, but its no use to anyone."

The man below is now getting pissed off.

"You must work in business as a manager," he says.

"I do," replies the balloonist, "but how did you know?"

"Well," says the man, "You don't know where you are, or where you're going, but you expect me to be able to help. You're in the same position you were before we met, but now it's my fault."

If Cars were like PCs

(Forwarded by: Cye Landy (clandy@columbus.rr.com).)

At a recent computer expo (COMDEX), Bill Gates reportedly compared the computer industry with the auto industry and stated: "If GM had kept up with technology like the computer industry has, we would all be driving $25 cars that got 1000 miles to the gallon."

In response to Bill's comments, General Motors issued a press release stating: If GM had developed technology like Microsoft, we would all be driving cars with the following characteristics:

1. For no reason whatsoever your car would crash twice a day.
2. Every time they repainted the lines on the road you would have to buy a new car.
3. Occasionally your car would die on the freeway for no reason, and you would just accept this, restart and drive on.
4. Occasionally, executing a maneuver such as a left turn, would cause your car to shut down and refuse to restart, in which case you would have to re-install the engine.
5. Only one person at a time could use the car, unless you bought "Car95" or "CarNT". But, then you would have to buy more seats.
6. Macintosh would make a car that was powered by the Sun, was reliable, 5 times as fast, and twice as easy to drive, but would only run on 5% of the roads.
7. The oil, water temperature and alternator warning lights would be replaced by a single "general car default" warning light.
8. New seats would force everyone to have the same size butt.
9. The airbag system would say "Are you sure?" before going off.
10. Occasionally for no reason whatsoever, your car would lock you out and refuse to let you in until you simultaneously lifted the door handle, turned the key, and grabbed hold of the radio antenna.
11. GM would require all car buyers to also purchase a deluxe set of Rand McNally road maps (now a GM subsidiary), even though they neither need them nor want them. Attempting to delete this option would immediately cause the car's performance to diminish by 50 percent or more. Moreover, GM would become a target for investigation by the Justice Dept.
12. Every time GM introduced a new model car buyers would have to learn how to drive all over again because none of the controls would operate in the same manner as the old car.
13. You'd press the "start" button to shut off the engine.

How NOT to Repair a TV

(From: Wes Hilterbrand (replayelectronics@usa.net).)

Here's a humorous (hopefully) little story I wanted to share with everyone.

This is about the people on this earth, and my area especially, that think they can repair stuff without having any clue as to what they are doing. I'm sure most of you know the type.

It happened that a good ol' boy, we'll call him Bubba, had bought a TV, a pretty nice Sanyo DS25030 stereo 25", at a pawn shop I do repairs for. Bubba shortly brought the set back, saying that it quit working. After some questioning, Bubba admitted to connecting the set to 220V(don't ask me how - maybe he thought his reception would be twice as good). The set was in rough condition (more about this follows) and he was told that it may be scrap, but wanted it looked at anyway. The following is my guess as to how the set died - the sequence of events is based on the most obvious things that I found when I looked inside the set. The situations are fictitious - the result of these fictitious situations, however, is sitting on my shop floor.

After Bubba finds out that TVs don't particularly like being fed 220 volts (he was clued in by the loud belch immediately following the feeding), he decides that he can fix whatever ails it. Now he knows that 'lektric'ty is bad for you, so he does unplug the set (Safety first, you know!). Now, instead of finding a 1/4" nut driver or even a socket and ratchet, he uses an angle grinder to cut open the back of the TV. He finds C006, a 470uF 200V electrolytic (that beer-can lookin' thang), blown open. So being the resourceful fellow he is, he wraps approx. 12" of bare 24AWG solid wire around the terminals of the capacitor (about 10 turns) and uses Scotch tape to hold it in place, since he thinks that this part is kinda unnecessary anyway. He plugs the set back in (to 110V this time - he did learn a little), and the main 4A line fuse opens. Again, being the astute repairman, he wraps the fuse with a foil gum wrapper (works ev'ry time!). After plugging the set back in, resistor R001 opens (Why don't this dang thang work?). There are no outward signs that the resistor is open, so Bubba gets discouraged (dang cheap crap TV). He decides he's gonna take it back and claim it's a junk TV. It's a good thing he does, because it probably saves the trailer, outhouse, and dog-lot from burning down.

Well, I picked the TV up yesterday at the pawn shop. The shop owner told me that I didn't need to try to fix it; he was giving it to me. In his exact words, "Anyone stupid enough to open a TV with a grinder is too stupid to own a television anyway." :-)

Cheat Sheet for Stock Market Reporters

(From: Stan Tamulevich stantam@itis.com).)

- Helium was up, feathers were down. Paper was stationary.
- Fluorescent tubing was dimmed in light trading.
- Knives were up sharply.
- Cows steered into a bull market.
- Pencils lost a few points.
- Hiking equipment was trailing.
- Elevators rose, while escalators continued their slow decline.
- Weights were up in heavy trading.
- Light switches were off.

- Mining equipment hit rock bottom.
- Diapers remained unchanged.
- Shipping lines stayed at an even keel.
- The market for raisins dried up.
- Coca Cola fizzled.
- Caterpillar stock inched up a bit.
- Sun peaked at midday.
- Balloon prices were inflated.
- Scott Tissue touched a new bottom.
- Batteries exploded in an attempt to recharge the market.

Some Mice are Just Plain Stupid

(Forwarded by: Andre (A.J.De-Guerin@herts.ac.uk).) Some tech was doing a post mortem on a blown TV chassis (fuse kept blowing.) Examined further, found a dead mouse with its teeth firmly embedded in the mains lead to the switch. Its tail was shorting to ground, hence instantly smoked fuses. Tech extracted mouse, set worked OK.

Mouse demonstrated its own stupidity by:

1. Managing to get into a TV without using proper tools (i.e. its teeth).
2. Doing this while set was energized.
3. Chewing the mains HOT lead when it could have munched any of 22 other cables happily without getting fried.
4. Not taking proper electrical safety precautions.
5. Not using established repair techniques (e.g. using own body as a test probe with no series resistor).
6. Forgetting to use an isolation transformer.

Here's what a smart mouse would have done...

1. Waited until set was switched off
2. Chewed half through flyback HV lead in several places
3. Then wait for the action...

Worst Techs Ever - Take Your Pick

(From: Bill Rosen (brosen@iglou.com).)

By far the worst "tech" I even saw was when I was in the military some thirty something years ago. He would "troubleshoot" boxes that popped circuit breakers (or blew fuses) by holding in the circuit breaker (or putting in a larger fuse) until something smoked and then marking it for "depot" repair. He was great at repairing items that used tubes. He just replaced every tube. It fixed the problem 95 percent of the time. He got transferred at last and I think someone finally got w1 (From: Vince, AA9TL (hamvak@mindspring.com).)

Made him a COOK??? This kinda guy would probably try everything in the pot until he found something that WOULDN'T kill you

(From: Brad Thompson (Brad_Thompson@pop.valley.net).)

During a hitch at Sears as a TV tech, I noted an absence of Phillips screwdrivers. When I borrowed one from the senior tech, he informed me that I should get my own and stash them away where "Bob", another tech, (his real name) couldn't find them.

Apparently, when "Bob" needed a scratch awl or a flat-bladed screwdriver, he'd simply find a Phillips and spend a few minutes at the bench grinder....

"Bob" also once installed a new refrigerator and an icemaker at a customer's house, using only one of two possible screws to fasten the icemaker's "vampire tap" to the cold water line. When the customer returned a few hours later, he found six inches of water in the basement - "Bob's" handiwork had failed.

I wonder what "Bob" does for work today.... He's probably an HMO exec. :-)

(From: Alan Peterman (alp@jps.net).)

For reasons I could never fathom, our AVIONICS shop hired this fellow right out of avionics school. He darn near had to shown which end of the soldering iron to hold.

He once used silicon GLUE, instead of silicon GREASE to pack an aileron servo. That was a fun test flight - I happened to be on it, and when I engaged the autopilot, it promptly blew the circuit breakers - luckily the clutches did their job so we could hand fly the plane.

Then there was the time he wired the lights in a new radio for 12 volts, and put it into a 24 volt plane. Ah well..

Of course we had one mechanic in the power plane shop who often came in somewhat hung over - he forgot to safety wire an oil drain plug on a heart surgeon's plane. Luckily, the plane was a twin so when the plug came off in flight, the doctor was able to land the plane. The shop bought and installed a new engine for him - $18,000 if I remember right.

If you knew the general level of aviation repairmen, you'd be way less happy when flying..

(From: Tobi Scags (tartan54@hotspam.com).)

Just as well he was a heart surgeon, then. He could restart his own when that engine went bang! :)

(From: BillK2 (billk2@aol.com).)

When I started in an engine overhaul shop, airplane yet, all seven of the clamshell balancing machines were down hard. Seems like this fellow replaced the 1/4 amp fuse with a 25 amp fuse in all the controllers. Servos make terrible fuses. A couple of years later I left. Six months after that I got a call from the fellow to see if I had his multimeter. He didn't use it much.

(From: Alan Peterman (alp@jps.net).)

Sounds like the same guy I wrote about. :-)

Airplane Maintenance

WARNING: Don't read if you fly a lot. :-)

(From: Chris (news@zabadak.globalnet.co.uk).)

Here are some apparently actual maintenance complaints submitted by US Air Force pilots and the replies from the maintenance crews. \223Squawks\224 are problem listings that pilots generally leave for maintenance crews.

- Problem: Left inside main tire almost needs replacement.
  Signed Off: Almost replaced left inside main tire.

- Problem: Test flight OK, except autoland very rough.
  Signed Off: Autoland not installed on this aircraft.

- Problem #1: Number 2 propeller seeping prop fluid.
  Signed Off: Number 2 propeller seepage normal.
  Problem #2: Propellers 1, 3, and 4 lack normal seepage.

- Problem: The autopilot doesn't.
  Signed Off: It does now.

- Problem: Something loose in cockpit.
  Signed Off: Something tightened in cockpit.

- Problem: Evidence of hydraulic leak on right main landing gear.
  Signed Off: Evidence removed.

- Problem: Number 3 engine missing.
  Signed Off: Engine found on right wing after brief search.

- Problem: DME volume unbelievably loud.
  Signed Off: Volume set to more believable level.

- Problem: Dead bugs on windshield.
  Signed Off: Live bugs on order.

- Problem: Autopilot in altitude hold mode produces a 200 foot per minute descent.
  Signed Off: Cannot reproduce problem on ground.

- Problem: Friction locks cause throttle levers to stick.
  Signed Off: That's what they're there for.

- Problem: IFF inoperative.
  Signed Off: IFF inoperative in OFF mode.

The Dark Sucker Theory and the Truth About Light Bulbs

(Forwarded by: Martin Griffith wavefront@bigfoot.com).)

For years, it has been believed that electric bulbs emit light, but recent information has proved otherwise. Electric bulbs don't emit light; they suck dark. Thus, we call these bulbs Dark Suckers.

The Dark Sucker Theory and the existence of dark suckers prove that dark has mass and is heavier than light.

First, the basis of the Dark Sucker Theory is that electric bulbs suck dark. For example, take the Dark Sucker in the room you are in. There is much less dark right next to it than there is elsewhere. The larger the Dark Sucker, the greater its capacity to suck dark. Dark Suckers in the parking lot have a much greater capacity to suck dark than the ones in this room. So with all things, Dark Suckers don't last forever. Once they are full of dark, they can no longer suck - just like a vacuum cleaner does if you forget to change the bag. This is proven by the dark spot on a full Dark Sucker. Then the Dark Sucker quits working.

A candle is a primitive Dark Sucker. A new candle has a white wick. You can see that after the first use, the wick turns black, representing all the dark that has been sucked into it. If you put a pencil next to the wick of an operating candle, it will turn black. This is because it got in the way of the dark flowing into the candle. One of the disadvantages of these primitive Dark Suckers is their limited range.

There are also portable Dark Suckers. In these, the bulbs can't handle all the dark by themselves and must be aided by a Dark Storage Unit. When the Dark Storage Unit is full, it must be either emptied or replaced before the portable Dark Sucker can operate again.

Dark has mass. When dark goes into a Dark Sucker, friction from the mass generates heat. Thus, it is not wise to touch an operating Dark Sucker.

Candles present a special problem as the mass must travel into a solid wick instead of through clear glass. This generates a great amount of heat and therefore it's not wise to touch an operating candle.

Also, dark is heavier than light. If you were to swim just below the surface of the lake, you would see a lot of light. If you were to slowly swim deeper and deeper, you would notice it getting darker and darker. When you get really deep, you would be in total darkness. This is because the heavier dark sinks to the bottom of the lake and the lighter light floats at the top. The is why it is called light.

Finally, we must prove that dark is faster than light. If you were to stand in a lit room in front of a closed, dark closet, and slowly opened the closet door, you would see the light slowly enter the closet. But since dark is so fast, you would not be able to see the dark leave the closet.

So next time you see an electric bulb, remember: It's really a Dark Sucker!

The Microsoft Phone

(Forwarded by: Brian Karas (brian@karas.com).)

I heard that the current version only allows you to TALK, and the speaker functionality to HEAR the other party is planned for Phone2000.

Also, the 7,9,5,6,3,4,2,0 and * keys do not work, but Microsoft has a special support phone number: 888-888-8888.

The phone is currently available to beta testers, but you can only call other people with the same build of phone that you have, and each call is limited to 7 seconds, including the time while the phone is ringing.

There is a similar product that works with Linux, the sound quality rivals that of $5,000 audio systems, the range of the cordless model is 20 miles, and it stores the entire phone directory locally. However, you need to hardcode the number you are calling into the phone's microcode (in assembler), then recompile it's kernel.

IBM will have their own version shortly, it's just the Microsoft phone in a grey case, but they've also disables the # key, to distinguish it from the Microsoft version.

(From: David Richards (dr@ripco.com).)

Then there's the OpenBSD phone, which works just like the Linux phone except it eliminates the 42 assorted buffer overflows and 'rootshell' holes (which allow anybody to bill international calls to your phone) and is specifically designed to link against a MD5 triple-DES PGP encryption module that you can only download from a server in Argentina. :-)

Oh, and instead of recompiling your kernel, a runtime LKM holds the number to be dialed...

How to Cure a Parrot with a Bad Attitude

(Forwarded by: Redgie (RodzSkolar@aol.com).)

David received a parrot for his birthday. The parrot was fully grown with a bad attitude and worse vocabulary. Every other word was an expletive. Those that weren't expletives, were to say the least, rude.

David tried hard to change the bird's attitude and was constantly saying polite words, playing soft music, anything he could think of to try and set a good example...

Nothing worked. He yelled at the bird and the bird yelled back. He shook the bird and the bird just got more angry and more rude. Finally, in a moment of desperation, David put the parrot in the freezer.

For a few moments he heard the bird squawk and kick and scream - then suddenly, there was quiet. Not a sound for half a minute.

David was frightened that he might have hurt the bird and quickly opened the freezer door. The parrot calmly stepped out onto David's extended arm and said, "I believe I may have offended you with my rude language and actions. I will endeavor at once to correct my behavior. I really am truly sorry and beg your forgiveness."

David was astonished at the bird's change in attitude and was about to ask what had made such a dramatic change when the parrot continued,

"May I ask what the chicken did?".

One Frustrated Frog

(Forwarded by: Larry Steckler (Lartronics@aol.com)

A guy is taking a walk and sees a frog on the side of the road. As he comes closer, the frog starts to talk. 'Kiss me and I will turn into a princess.' The guy picks the frog up and puts it in his pocket.

The frog starts shouting, 'Hey! Didn't you hear me? I'm a Princess. Just kiss me and I will be yours.' The guy takes the frog out of his pocket and smiles at it and puts it back.

The frog is really frustrated. 'I don't get it. Why won't you kiss me? I will turn into a beautiful princess and do anything you ask.'

The guy says, 'Look, I'm a computer geek. I don't have time for girls. But a talking frog is cool!'

A Little Project

(From: Ralph & Diane Barone (barone@mdi.ca).)

Someone wrote:

> "I need to convert 300,000 Volts DC to 240 VAC, 60 Hz. 80 mA is available from a 300 kV DC source which equals 24 kW. This means 100 Amps capability from the 240 volt 60 Hz output of >some type of converter.
>
> Does anyone have recommendations or schematic diagrams that would provide a conversion for high voltage/low current TO low voltage/ high current as stated above?
>
> Thanks!"

No problem. We have one almost like that where I work (ratings are only slightly different). However, here is the description:

We use SCRs because we are connected to an existing AC power supply and we can let the external supply commutate the SCRs. If you don't have an external AC supply, you will need to use power MOSFETS, IGBTs or GTOs. In our application, each SCR is in an arrangement of 360 devices connected in series parallel (180 series/2 parallel) with the requisite firing pulse isolation transformers (720), RC snubbers (2,160), voltage breakover firing circuits (4,320) and dI/dt limiting series reactors (1,980). Firing pulses come from a custom GE control system which occupies three 3' wide cabinets. From the transformers, we go into our 230 kV AC bus. We have filters on the AC bus to remove the harmonics created by the conversion process. These filters consist of air core (but oil cooled) reactors and a whole wack of capacitors. These filters occupy approx 300 square meters of space in the switchyard.

After the 230 kV bus, we step the power down to 25 kV, then we have another transformer that goes 25 kV to 240 V with a grounded center tap.

If you would like photocopies of our design drawings, please send me five (5) empty 4 drawer filing cabinets and $10,000 to cover copying and shipping. :)

The Ultimate Engineering Test

What we REALLY need here is a test that checks to see if you're competent to deal with REAL-WORLD design issues. I will humbly (yeah, right) now offer a few example questions to get us started:

(Test questions from: Bob Myers (myers@fc.hp.com). Answers from: Sarlock T. (sarlock@twcny.rr.com).)

- Q1. Your management has handed you a set of design specifications which violate all known laws of physics, including several from the "Star Trek" universe. What should you do?

  A1. Lights, lots of blinky lights and special effects, incorporate lasers if need be, and sound you need lots of sound (every time you push a button it beeps) and the power supply has got to hum like it's sucking down 5,000 amps.

- Q2. Supplier A offers components which are technically superior and available at half the cost of supplier B's, but supplier B gives you better T-shirts. Whose party do you try to crash at Comdex?

  A2. Both of them, because the one with the more expensive parts and T-shirts will have better liquor, and the ones with the cheaper parts might have free samples, maybe some cheap liquor to get you started ;)

- Q3. Through basically clumsy application of a test probe and an unfortunate error regarding which terminal was the 400V supply, you have destroyed a prototype representing 300 man-months of effort and an R&D budget equal to that of some developing nations. Who should you blame this on, and how?

  A3. The same people who are conspiring to sell the public short life light bulbs.

- Q4. List, in descending order of generated volume, the top 5 components in terms of producing the most smoke when incorrectly connected.

  A4. Oil Filled Capacitors, oil filled transformers, transformers, electrolytic caps, and hmmm, maybe really big carbon resistors?

- Q5. Give at least three examples of politically-incorrect color-code mnemonics.

  A5. Err... yoiks, I guess I flunk the test, I only know one..

- Q6. How many "Dilbert" calendar pages are required to fully cover the walls of the average R&D engineer's cubicle?

  A6. Unknown, I've never met an 'average' engineer. :)

- Back to Humor Table of Contents.

Battery Powered Human

So, how many AA batteries would it take to power a standard adult human for one day?

(From: Ben Gebeau (bengebeau@hotmail.com).)

A Manganese/Alkaline AA cell it rated at about 2.4 AH. If we assume 1.5 volts average this gives approximately 3.6 watt hours (slightly optimistic). Since there are 3,600 seconds in an hour this is equivalent to 12,960 Joules.

A human consumes about 2,000 calories/day. A dietician calorie is equal to 1,000 engineering calories. A calorie is equal to 4.2 Joules. Therefore this is equivalent to 2,000 * 1,000 * 4.2 = 8.4 * 10E6 Joules per day.

Dividing one by the other you will need about 648 AA cells to power a human for one day.

This assumes that the power from the AA cell will go through the same inefficiencies as the chemical processes in a human. (A human runs at about 20% efficiency chemical energy to mechanical energy). If we can circumvent this inefficiency we would only need 20% of this number of cells - say 130 cells.

Cooking Versus Engineering

(From: ANHCNS (anhcns@aol.com).)

In my month+ of unemployment, I've been keeping busy around the house between the occasional interviews or lead followup. One of the things that has been filling my time is cooking.

I'm not a pro-chef, but I believe it is the result of a 'Transferrable Skill' of Electronics.

Let's compare...

```
      Baking cookies                 Assembling a circuit
  --------------------------------------------------------------------
     First get a recipe              First get a schematic
     then round up ingredients       then round up components
     Mix ingredients                 Bend and cut leads, etch PCB, etc.
     Bake                            Solder
     Enjoy                           Enjoy!
```

(From: Sam)

The true engineer will insist on NIH - Not Invented Here - and do their own design. Likewise, the true chef will create his/her own recipe for each batch of cookies!

(From: Robert Hancock (hancockr@home.com).)

Not to mention that in both activities, you can tell you screwed up by all the smoke and the bad smell. :-)

Sometimes it DOES take a Rocket Scientist

(Source unknown, forwarded by Jeff Gronito (jmg@repairfaq.org).)

Scientists at NASA have developed a gun built specifically to launch dead chickens at the windshields of airliners, military jets and the space shuttle, all traveling at maximum velocity. The idea is to simulate the frequent incidents of collisions with airborne fowl to test the strength of the windshields. British engineers heard about the gun and were eager to test it on the windshields of their new high speed trains. Arrangements were made. But when the gun was fired, the engineers stood shocked as the chicken hurtled out of the barrel, crashed into the shatterproof shield, smashed it to smithereens, crashed through the control console, snapped the engineer's backrest in two and embedded itself in the back wall of the cabin. Horrified Britons sent NASA the disastrous results of the experiment, along with the designs of the windshield, and begged the U.S. scientists for suggestions. NASA's response was just one sentence, "Thaw the chicken."

The Ultimate in New and Improved Speaker Cable!

(From Steve Roberts (osteven@akrobiz.com).)

We here at Infinite Audio have a announcement of our new product line, speaker cables for the wickedly rich.

First of all, our new **Dark Optical Speaker Cable:** Tired of shot noise and 1/F noise interfering with your quiet passages? Our new dark cable relies on the fact that the speed of darkness is indeed faster then the speed of light. Our cable converts your amp output to light, thus when there is no audio, there is dark, to quickly sweep away light noise, long before it can start. $1995 a foot, polishing and termination extra.

Second is our new **Blumlein Series Speaker Cable:** We use a second mirror cable to add capacitance in parallel with the existing cable, then just when you need it for those splendid tweeter blowing highs or that extra megawatt of base, our patented superswitch RCA Tee connector/switch takes the stored energy in your cable and uses it to its maximum by converting from series to parallel. Superswitch's patented tin plating makes the switching decisions far faster then any solid state device could. By using our short pulse energy techniques, you will actually be able to see your tweeter diaphragms move, and move faster. 2300$ a foot, exclusive licensing and secrecy agreement required. Inquire today about our boosted storage version for class D PWM amps!

Finally, **Cryocord**, our revolutionary new cable for home theater installs. Cryocord consists of a 99.9% pure copper core zip cord plated with 14 karat gold then dipped with a layer of of our patented mercury superconductor material. This core is then wrapped with 20 turns of our super low leakage kraft paper insulator and shoved down a long piece of large diameter glass tubing which is ringed by a another silver plated glass tube with a vacuum in it, thus preventing loss of your precious audio signal by the dreaded permittivity and resistivity of dry air. Copious quantities of liquid nitrogen from a 16 meter long 3 meter diameter tank on a semi truck are then pumped through the cable, insuring that your amps see a zero ohm, zero parasitic cable straight to your speakers. Each speaker has its own glasswork, thus greatly reducing crosstalk. Note: If you need to move a speaker, please schedule a visit from Horatio, our friendly glassblower two to three months before you need to move the speaker. Pricing available on request, please bring you current rating in Whos Who and Your listing in Standard and Poor's along with some stock certificates with intact coupons before ordering. Remember with our Dewer covered cables, you can brag about being hollow state through your system!

Seriously, $7K for a chunk of pink pre-soldered ribbon cable with cheap shrink and Far East RCA plugs! Man, am I in the wrong business!!!!! They didn't even bother to make every other strand a ground to reduce crosstalk. ;-) And, they forgot the silver solder for better conductivity.

The Technology of Startrek

Some of my observations, in no particular order:

1. Life and death are a binary process - with one quick low cost test using the Tricorder, the Doc will know if the patient will survive and if not, down to the microsecond when death will occur, unless (1) there is a stasis chamber handy or (2) some alien technology is available.

2. It is generally possible to duck the 24th century hand weapon. I recommend a 1930's vintage submachine gun if you have a choice.

3. Starship weapons couldn't hit the broad side of a barn and targeting servo systems are totally useless.

4. Diagnostics are guaranteed to determine everything there is about the ship's systems. The remedy will always involve improving the efficiency of something.

5. Computer backups aren't used any more frequently in the 24th century than our own.

6. The concept of the 'copy' and 'cp' command was lost sometime after the breakup of Microsoft.

7. Somehow, it is possible to send an entire person (real or holographic) through an alien comm link or wormhole that won't even pass a short audio fragment intact.

8. The Holodeck safety systems can somehow be disabled by the holographic characters. Somehow, this is the first thing to happen in a crisis.

9. The Transporter acts as a high resolution 3-D fax XOR a matter transfer device depending the script's needs.

10. The Enterprise crew will fail to attack a knowingly hostile alien ship at point-blank range that everyone in the audience knows should be vaporized instantly if the rest of the plot would be nullified by its destruction (e.g., the Borg sphere in "First Contact").

If God were an Engineer

I (Sam) must note that I firmly believe in Darwinian evolution as the basis for all life on Earth. However, much of the structure of DNA might just be consistent with creationism if God were an engineer:

Considering the tight (but not unusual) schedule of 6 days for the "Earth Project", any resourceful engineer must do whatever it takes. Note that even for God, I do suspect that the 6 day goal was just a bit optimistic and with the usual delays, it probably did in fact stretch to 3 or 4 billion years in schedule overruns as is typical in these cases.

Any seasoned engineer, having outgrown the NIH (Not Invented Here) syndrome will always attempt to reuse whatever can be reused. Programmers take their old programs and rework them; computer designers base new products on those that have come before. Why should Life be any different? When assigned to create, say, a Better Bug, one should always start with a success story like the cockroach and just make minor modifications (another thing all Engineers know is to change as little possible between revisions). Shorten a leg, lengthen a mouth part, tinker with their mating call, etc., based on all the considerable stack of problem report forms collected over a few billion years.

In the case of Man, being quite complex after all, even if not quite as complex as everyone thought a little while ago, any approach that saves time would be beneficial. So the overworked Engineer would download the best features (in their opinion, lacking realistic input from the Marketing Department or Management, "No chance, adding 2 additional arms would blow the project schedule and budget!") of mice and monkeys and just add the necessary DNA to combine them as quickly as possible. Note that during this process, its not surprising at all that some unfortunate defects (bugs?) have crept into the DNA. And, what about all that junk DNA? Any software programmer knows that when writing a new program, it is expedient to include all the subroutines ever likely to be used - computer memory is cheap but trying to figure out exactly what will be needed ahead of time takes too much time. However, much of that code never actually gets used and ends up in this case as what our greatest minds have declared to be filler. (But, some small amount could also be comment statements!) So, it's not unexpected that Man has only about twice as many genes as a fruit fly. However, if an ear of corn really does have about the same number of genes as Man, some cost reduction should certainly be possible (for the corn at least).

The dinosaurs were one of those Marketing experiments that wasn't entirely successful and the product line had to be cut in conjunction with a down-sizing. Same for wooly mammoths. These had both been pushed over the considerable objections of the Engineering Department unworkable and inefficient and it was thus quite amazing they lasted as long as they did. Insects, on the other hand, have been one of the best collections of critters providing a steady return over the eons.......

So, if God were an engineer, one could almost believe in creationism. :)

The Truth About Electric Circuits

(Forwarded: Tom MacIntyre (tmacinty@ns.sympatico.ca).)

Quote from Dave Barry:

> "Electricity originates inside clouds. There, it forms into lightning, which is attracted to the Earth by golfers. After entering the ground, the electricity hardens into coal, which, when dug up by power companies and burned in big ovens called 'generators,' turns back into electricity, where it is transformed by TV sets into commercials for beer, which passes through the consumers and back into the ground, thus completing what is known as a 'circuit.'"

- Back to Humor Table of Contents.

More Takes on Comprehending Engineers

(Forwarded by: Dave Carpenter (voicebox@dnai.com).)

1. Three engineering students were gathered together discussing God. One said, "God is a mechanical engineer. Just look at all the joints." Another said, "No, God is an electrical engineer. The nervous systems has many thousands of electrical connections." The last said, "Actually, God is a civil engineer. Who else would run a sewage pipeline through a recreation area?"

2. A priest, a lawyer and an engineer are about to be guillotined. The priest puts his head on the block, they pull the rope and nothing happens. He declares that he's been saved by divine intervention, so he's let go.

   The lawyer is put on the block, and again the rope doesn't release the blade. He claims he can't be executed twice for the same crime and he is set free too.

   They grab the engineer and shove his head into the guillotine. As he looks up at the release mechanism, he says, "Wait a minute, I see your problem..."

3. There once was an engineer who had an exceptional gift for fixing all things mechanical. After serving his company loyally for over 30 years, he happily retired. Several years later the company contacted him regarding a seemingly impossible problem they were having with one of their multi-million dollar machines. They had tried everything and everyone else to get the machine fixed, but to no avail. In desperation, they called on the retired engineer who had solved so many of their problems in the past. The engineer reluctantly took the challenge.

   He spent a day studying the huge machine. At the end of the day, he marked a small "x" in chalk on a particular component of the machine and proudly stated, "This is where your problem is". The part was replaced and the machine worked perfectly again. The company received a bill for $50,000 from the engineer for his service. They demanded an itemized accounting of his charges. The engineer responded briefly:

    - One chalk mark: $1.

    - Knowing where to put it: $49,999.

   It was paid in full and the engineer retired again in peace.

   (A common variation on this one is that the "X" marked where to smack the machine with a big hammer. --- Sam)

4. The Top 10 Things Engineering School Didn't Teach

   #10. There are at least 10 types of capacitors.
   #9. Theory tells you how a circuit works, not why it does not work.
   #8. Not everything works according to the specs in the data book.
   #7. Anything practical you learn will be obsolete before you use it, except the complex math, which you will never use.
   #6. Always try to fix the hardware with software.
   #5. Engineering is like having an 8 a.m. class and a late afternoon lab every day for the rest of your life.
   #4. Overtime pay? What overtime pay?
   #3. Managers, not engineers, rule the world.
   #2. If you like junk food, caffeine and all-nighters, go into software.
   #1. Dilbert is a documentary.

5. What is the difference between Mechanical Engineers and Civil Engineers? Mechanical Engineers build weapons, Civil Engineers build targets.

6. Engineers think that equations approximate the real world.
   Scientists think that the real world approximates equations.
   Mathematicians are unable to make the connection...

7. A pastor, a doctor and an engineer were waiting one morning for a particularly slow group of golfers. The engineer fumed, "What's with these guys? We must have been waiting for 15 minutes!" The doctor chimed in, "I don't know, but I've never seen such ineptitude!" The pastor said, "Hey, here comes the greens keeper. Let's have a word with him."

   "Hi George. Say, what's with that group ahead of us? They're rather slow, aren't they?"

   The greens keeper replied, "Oh, yes, that's a group of blind fire fighters. They lost their sight saving our clubhouse from a fire last year, so we always let them play for free anytime." The group was silent for a moment.

   The pastor said, "That's so sad. I think I will say a special prayer for them tonight."

   The doctor said, "Good idea. And I'm going to contact my ophthalmologist buddy and see if there's anything he can do for them."

   The engineer said, "Why can't these guys play at night?"

8. In the high school gym, all the girls in the class were lined up against one wall, and all the boys against the opposite wall.

Then, every ten seconds, they walked toward each other until they were half the previous distance apart.

A mathematician, a physicist, and an engineer were asked, "When will the girls and boys meet?"

The mathematician said, "Never".

The physicist said, "In an infinite amount of time."

The engineer said, "Well... in about two minutes, they'll be close enough for all practical purposes."

10. Back to Humor Table of Contents.

How to make a perpetual motion machine

(Portions from: Stephen Shaw (xstephenx@apple2.org.za).)

The only known way to make a perpetual motion machine is with a cat and a slice of buttered toast. Buttered toast always lands face down when dropped. A cat always lands on its feet when dropped. Therefore, if you tie a slice of buttered toast face up on the cats back you will have a (hovering) perpetual motion machine as both items try to land on their respective correct positions.

The greatest minds pondering the secrets of the Universe have been unable to explain away the violation of laws of conservation of energy but as "they" say: "If it works, use it!" :)

(From: Duke McMullan, N5GAX (DukeMc@mail.com).)

It's a nice idea, but it doesn't work. Evidently the spin states of the bread/cat dipole are unresolved, so it spins in a superposition of clockwise and counterclockwise. All attempts to collapse its collective wave function to date have extracted no useful energy, have gotten butter all over the experimenter's clothes, and usually deep claw marks resulted in the experimenter's arm and hand.

("What did you do to the cat? It looks half dead." --- Schrodinger's wife.)

Patient Advice and Consultation

(From: Lance Dyer (d.lance@sk.sympatico.ca).)

Patient's guardian complained of a washed out vision with prominent white lines across the face when awoken. Secondary complaint of bright red face when going to sleep as well as turning green or red when channels rolled over and prominent white lines in the face as well.

Patient history

- First Name - F27700.
- Second Name - CTC169c-5.
- Family - RCA.
- Birthday - 1993 week 34.
- Age - approximately 8 years.

Consent for treatment signed by guardian.

Diagnosis

9:30 am:

Upon initial diagnosis found patient to be suffering from a malfunction at the junction of the E-C of q2906 luminance buffer. Junction was shorted.

Action taken:

9:45 am:

Patient was immediately scheduled for transistor-ectomy to remove the failed component. Solder pads were cauterized with hot iron and excess fluid removed with sterile solder wick gauze. Diseased part was skillfully replace with donor transistor. Pads were recauterized and an antiseptic 60/40 solder was placed over joints for strength and protection.

Patient Status

9:50 am:

Patient awoke from operation with normal vision and all vital signs checked normal and within acceptable parameters.

Patient transferred to intensive care for monitoring:

10:20 am:

Patient went into arrest. Face flashed, shrunk in height and died. Attempt to restart patient with power button failed. Unit unplugged and expletives expressed to the corpse. Removed guts and began examination again.

Found same malfunction at the junction. Applied power to patient to check vital signs and patient was alive with washed out white face and lines. Patient had relapsed. Repeated transistor-ectomy with another donor transistor, checked vital still normal.

5:30 pm:

Left to go golfing for the day. Patient was still stable at this time.

Would like a consultation and second opinions on whether or not this patient has:

1. An incurable disease of an intermittently shorting picture tube causing cancer of the buffer.

2. A virus or leprosy of the luminance buffer that is attacking it at random.

Sorry my HMO or Health Care provider will not pay for consultation fees but your input is greatly appreciated.

Signed: Dr. Lance R.A.T.S (Radio And Television Service)

Mental Calculation in the Service Shop

(From: Jerry Greenberg (jerryg50@hotmail.com).)

The benefit is to have a good idea of what your answer is going to be.

This is especially true in calculation your customer's reaction when you tell him the bad news, and how much it is going to cost him! You then square that factor, and convert it to the distance that will be required between you and him. Just make sure that you have a very wide service counter between you and him to start with!

The width of the service counter should be at least 1-1/2 his arm length plus 12% of his height. You should be standing at a distance of about 30% more then the sum of his blood pressure + the other mentioned factors. Also, it is important that you are wearing a very good pair of high-grip running shoes, shorts, and a tee-shirt. A good non-slip coating on the bottom of the running shoe soles would also be a good idea. There should be a clear path between you and the opposite direction from him.

Now this is a good logical mental calculation for you.

I think this should sum things up for Y'a!

The System Administrator

This is the individual (usually a human being but perhaps not always) who runs the computer system or ISP you use. They are all alike. Pimply-faced teenagers or if older than 19, pimply-faced teenager wannabees who have never grown up. They have absolute power over their kingdom, whether it's a unix, linux, VMS, or Win NT system, or server farm. This is something not found in many other professions or even most nation states.

Their domain will be an office or cubical with at least 4 of the fastest computers (not accessible to "users") with the best flat panel LCD monitors currently available. If asked a question, the reply will not be a complete sentence or even in English but some obscure technospeak designed to be impossible to understand. When asked to clarify, the response is likely to be a similar sentence fragment selected to indicate that anyone with intelligence greater than that of a typical carrot should have understood the first time. Very often, the first attempt to fix something will not work but when told this, they will never admit the possibility of having made a mistake but will just try something else that doesn't work. Only after several aborted attempts obviously becoming increasingly annoyed at having to cater to a mere mortal, will the concept of actually testing what was done enter their mind. And then, it will somehow have been the user's fault even if protections and variables in 17 locations which could be accessed only by the Sysadmin had to be changed. That is, if they can take time out from playing Doom to actually respond to questions.....

My apologies to those system administrators who are actually real human beings. :)

Reward Offered

(From a posting on the USENET newsgroup sci.electronics.repair by Bob Parker (bobpar@ozemail.com.au).)

A reward of 500 microfarads is offered for information leading to the arrest of Hopalong Capacity. This unrectified criminal escaped from a Weston Primary cell, where he had been Clamped in Ions awaiting the Gauss chamber.

He is charged with the induction of an 18 turn Coil named Milli Henry, who was found Choked and robbed of valuable Joules. He is armed with a Carbon Rod and is a Potential killer.

Hopalong Capacity is also charged with driving a DC motor over the Wheatstone bridge and refusing to let the Band Pass. If encountered he may offer Series Resistance.

The Electromotive Force spent the night searching for him in the Magnetic Field where he had gone to Earth. They had no success and believed Capacity returned Ohm via a Short Circuit. He was last seen, riding a Kilocycle with his friend, Eddy Current, who was playing "Ohm on the Range" on his Harmonic.

Engineering Marketing Hype Translated

(From: nipperchipper (nipperchipper@hotmail.com).)

- NEW: Different color from previous design.
- ALL NEW: Parts not interchangeable with previous design.
- EXCLUSIVE: Imported product.
- UNMATCHED: Almost as good as the competition.
- DESIGNED SIMPLICITY: Manufacturer's cost cut to the bone.
- FOOLPROOF OPERATION: No provision for adjustments.
- ADVANCED DESIGN: Nobody understands it.
- FIELD-TESTED: Manufacturer lacks test equipment.
- HIGH ACCURACY: Unit on which all parts fit.
- DIRECT SALES ONLY: Factory had big argument with distributor.
- YEARS OF DEVELOPMENT: We finally got one that works.
- REVOLUTIONARY: It's different from our competitors.
- BREAKTHROUGH: We finally figured out a way to make it work.
- FUTURISTIC: No other reason why it looks the way it does.
- DISTINCTIVE; A different shape and color than the others.
- MAINTENANCE-FREE: Impossible to fix.
- RE-DESIGNED: Previous faults corrected, we hope....
- HAND-CRAFTED: Assembly machines operated without gloves on.
- PERFORMANCE PROVEN: Will operate through the warranty period.
- MEETS ALL STANDARDS: Ours, not yours.
- ALL SOLID-STATE: Heavy as Hell!
- BROADCAST QUALITY: Gives a picture and produces noise.
- HIGH RELIABILITY: We made it work long enough to ship it.
- SMPTE BUS COMPATABILE; When completed, will be shipped by Greyhound.

- NEW GENERATION: Old design failed, maybe this one will work.
- MIL-SPEC COMPONENTS: We got a good deal at a government auction.
- CUSTOMER SERVICE ACROSS THE COUNTRY: You can return it from most airports.
- UNPRECEDENTED PERFORMANCE: Nothing we ever had before worked THIS way.
- BUILT TO PRECISION TOLERANCES: We finally got it to fit together.
- SATISFACTION GUARANTEED: Manufacturer's, upon cashing your check.
- MICROPROCESSOR CONTROLLED: Does things we can't explain.

A Guide to Abacus Repair

> "My abacus, the most advanced computing device known to mankind, is damaged. What do I need to repair such a highly sophisticated device ? Please help!"

(From: Jeff Liebermann (jeffl@comix.santa-cruz.ca.us).)

You forgot to specify the maker, model, and exact mode of failure. In most cases, the failure is not mechanical but can be attributed to operator error. However, there are some common problems found in the common abacus:

1. Do you have a worm? This is found by running one of the various worm and virus removal programs. They'll help you spot the holes in the main frame bored by the worm. Remedial action depends upon the type of worm. To avoid further infections, please use an anti-worm cover and scan for worms often.

2. When did you last reboot your abacus? Simply shaking the abacus to remove cached numbers often helps with arithmetic errors.

3. Have you installed all the updates and patches necessary for efficient operation? While many of these patches may look like band-aids, cloths pins, hose clamps, sticky goo, and other temporary contrivances, it's the best that the manufacturers can offer.

4. Are you running an open source abacus? If so, you may be missing some dependency or library required to run the abacus. Please inspect the storage area to insure that everything is properly installed. Consult your librarian for the missing libraries.

5. Utilities often interfere with the operation of the abacus. For example, a bolt on fan, cell phone, and CCFL lamp will suck all the power from the abacus. I suggest unloading all your utilities and accessories and see if that helps.

6. Do you have sufficient cooling? The high performance abacus can have considerable friction between the main frame data paths and the beads. If you overclock the abacus and operate the beads faster than the manufacturer intended, heating will be an issue.

Hopefully, these pointers will help you repair or mitigate your undisclosed abacus problem. This is a good thing because when computers are universally banned as a serious detriment to productivity, the abacus will then be the primary computing system.

(From: Sam.)

Also note that accidentally installing some of the beads upside-down can result in subtle errors in lengthy calculations. If the abacus was recently repaired, this may be the problem. Unfortunately, I do not know how to determine if the beads are orientated correctly. :)

In the future, please include the builder's name and approximate date of construction (within a century or two would be adequate). This is the only way anyone can provide specific repair information.

Preface

Author and Copyright

Author: Samuel M. Goldwasser

For contact info, please see the Sci.Electronics.Repair FAQ Email Links Page.

DISCLAIMER

While every effort has been made to assure that the information in this document is accurate and complete, there is no way to guarantee that it will apply to your particular equipment. Depending on the specific design, what works in most cases may result in unacceptable performance, blown fuses or tripped circuit breakers, or overheating and possible fire, damage to the powered equipment or property.

We will not be responsible for improper operation, equipment or collateral damage, or expenses resulting from following the suggestions contained herein.

- Back to Power FAQ Table of Contents.

Introduction

Scope and Purpose of this Document

The following types of questions arise quite often:

- Question: Will my U.S. made TV and VCR work in Europe?

  Answer: A simple step down transformer to convert from 220 to 110 V will probably permit them to work together (i.e., to play previously recorded tapes) but you will not be able to receive any cable or broadcasts.

- Question: I have a microwave oven but will be moving to France. Would I be better off selling it or getting a power adapter?

  Answer: Due to the high wattage of a microwave oven, converting the power will be costly. Sell it and buy a new one at your destination.

- Question: Should I bring by European appliances back to the U.S.?

  Answer: This depends on the specific appliances. See the remainder of this document!

- Question: Will my Onkyo receiver work in Japan?

  Answer: Not without some modifications - which may not be worth it.

We cannot generally provide an answer based on your exact model equipment and the specific standards in use. There are too many variations to deal with in this sort of document. However, the information contained herein in conjunction with the type and specifications of the equipment you own and the power and standards in use at your destination hsould enable you to make an informed decision. Note that if you plan to be moving between countries with different standards, it may pay to invest in appliances and electronic specifically designed for multisystem operation. However, there are all sorts of definitions of 'multisystem' - not all will handle what you need so the specifications must be checked carefully and even then, marketing departments sometimes get in the way of truth in advertising! Again, the information in this document and the links below should aid in this effort.

Related Information

A great deal of specific country information is available at:

- World Electric Guide

including power, plug configurations, telephones, and TV standards.

This should help you issues involved before you reach your destination!

Panel Components - Guide to Worldwide Plug/Socket Patterns and Power Mains has information and photos.

In addition, we deal with general issues related to adapting entertainment equipment and appliances to different power and the implications of reduced or increased voltage and frequency.

Note: this initial release will concentrate mostly on power issues. Later, we will deal with video, communications, and phones systems. For those, the documents: Notes on Video Conversion, Troubleshooting and Repair of Computer and Video Monitors, Troubleshooting and Repair of Television Sets, and Troubleshooting and Repair of Video Cassette Recorders, and others at this site may contain some of the information you seek on these other topics.

- Back to Power FAQ Table of Contents.

Types of Conversion

You Mean it is More Than Just the Type of Plug?

It would be nice if all you had to do was match up a plug and socket to make anything in the universe work together. Unfortunately, while this does work for some things - garden hoses, for example :-) - it rarely is as simple as this for electrical power, video, or communications.

Power Conversion

This relates to what comes out of the wall socket. Nearly every country in the world uses an AC voltage between 90 and 240 V at 50 or 60 Hz. There may be some exceptions (like 600 V at 25 Hz powering portions of the New York City subway system or 28 V at 400 Hz on board an F-18 - but this is not something you are likely to need to deal with!) - if you encounter such unusual situations, we will be happy to add them to this document!

The three important considerations are:

- Voltage - the RMS (Root Mean Square - you really don't need to worry about the term) value of the nominal power line voltage. (OK, if you really care, the RMS value of an AC waveform will be equal to that of a DC voltage which will have the same heating effect. It is the squareroot of the mean (average) of the waveform squared. Got that? :-).

- Frequency - the number of cycles per second now expressed in Hz (pronounced like the Hertz car rental company). Almost all power around the world is AC. There are some exceptions but you will be unlikely to encounter them.

- Plugs and sockets - there are several dozen variations (at least) with and without a safety ground depending on your location. If you purchase *the* adapter that they recommend at the travel store, there is good chance it will not fit when you actually get to your destination! However, there are universal plug and socket adapter sets which may have a better track record.

Video Standards Conversion

This relates to the scan rates, color encoding, and audio transmission of the baseband video signals in use in your country.

- Scan rate - how many total scanning lines are used and how many times per second a complete picture is 'painted' on the picture tube screen. (Note that exsiting TV standards use interlaced scanning - a picture is made up of an even field (all the even numbered lines) and an odd field (all the odd numbered lines) and a picture consists of both of these. The most common (pre-HTDV) are 525 lines at 30 Hz (e.g., U.S. NTSC) and 625 lines at 25 Hz (e.g., U.K. PAL). However, there are others.

- Color Encoding - the way the color information is combined with the basic monochrome (black and white) picture signal. These differ between NTSC and PAL and there are several variations for PAL as well. The effect of a TV with the wrong decoding circuitry will be either a black and white picture or possibly color interference effects.

- Audio - the location of the subcarrier frequency for the sound information among other things may differ as well.

Broadcast (and Cable) Standards

- Radio - AM and FM channel locations and spacing.

- Video - VHF and UHF channel assignments, color encoding, audio carrier, etc.

- Telephone - ???

- Back to Power FAQ Table of Contents.

Voltage Conversion Issues and Common Types of Voltage Converters

How to Get Power for Equipment A to Work with Equipment B

There are a variety of approaches to adapting equipment designed for one power system to another.

- Transformers will always work but may be too heavy or expensive to justify their use.
- Electromechanical approaches go back quite far, are quite efficient, but are heavy, bulky, noisy, not very flexible.
- Solid state converters vary widely in complexity, capabilities, and cost. Some may destroy motors or electronic equipment and this may not be obvious from the product description.

Note that in cases, the proper (or close enough) power may be available already.

- Where 110 VAC is standard, 220 VAC is usually present in the residence since the power originates from a 220-0-220 VAC utility (pole) transformer. In some cases, a suitable outlet will even be present though usually one will have to be added. Whether this is worth the effort and expense for a $30 coffeemaker you picked up in your travels is another matter. :-)

  In industrial or office buildings, 208 VAC will be available (since they use three-phase power but that is another story) and this may be close enough for most applications (though heating appliances won't be quite as zippy as if they were running on the proper 220 VAC and therefore your eggs may take a little longer to cook).

- Where 220 VAC is standard, hotels and other public buildings may provide 110 VAC convenience outlets for foreign visitors. While the frequency will probably still be the standard 50 Hz for these countries, many appliances don't care. See the chapter: "Frequency Issues".
- Many appliances have a voltage selector switch usually near the power cord entrance though some may require changing internal jumpers. See your user manual! This is particularly true of appliances that are typically used overseas like shavers.
- Many types of equipment like laptop computers, camcorders, and computer monitors, use universal switching power supplies that automatically adapt at anything from 100 to 240 V, 50 to 400 Hz (maybe even DC). With these, the nameplate will clearly specify this universal operation. However, you cannot assume this! Applying 240 V to a device that doesn't accept it WILL result in damage or a meltdown.
- Where a power transformer is used as with most audio equipment, there may dual primary windings, possibly with additional taps, to permit the unit to be configured for almost any voltage.

Unfortunately, manufacturers often save a few pennies by using a power transformer in equipment for sale in the U.S. with only a 115 VAC primary. You may be able to determine this by checking the wiring to the primary of the transformer - if each of the line wires goes to a pair of terminals/wires into the transformer, it is likely that the required pair of windings is present and can be rewired in series. If they only go to a single terminal/wire, then this probably can't be done.

True Transformers

This refers to devices that consist solely of a pair (at least) of windings on an iron core. There are no other devices in a transformer beyond possibly a switch, indicator light, thermal protector, and/or a fuse or circuit breaker, and a plug or terminal block for input and socket or terminal block for output.

In the following, we assume that the two voltages are 110 VAC and 220 VAC. Similar comments apply if the ration is not 2:1.

There are several types including:

- Isolated step-up for converting from 110 VAC to 220 VAC.
- Isolated step-down for converting from 220 VAC to 110 VAC.
- Autotransformer step-up for converting from 110 VAC to 220 VAC.
- Autotransformer step-down for converting from 220 VAC to 110 VAC.

Autotransformers are cheaper but do not provide line isolation which may be desirable. In general, a step-up or step-down transformer can be used backwards to effect the opposite conversion - whether this is possible is a construction detail. In addition, a 1:1 isolation transformer can be used as a 1:2 (stepup) or 2:1 (stepdown) autotransformer with a VA rating twice of what it would be when used normally.

The relevant parameters characterizing a tansformer consist of:

- Voltage - The ratio of the number of turns of wire on the output winding(s) and input winding determines the output:input voltage ratio. Electrically, input and output can be interchanged to obtain the opposite conversion. Whether this is supported by the packaging is another story.

- Power/VA capacity: The size of the core and the wire determine the power handling capability. VA is simply the voltage (V) multiplied by the current (A) for the input or output. For a resistive load like a space heater or light bulb, this is the same as true power in watts (W). Due to unavoidable losses in the transformer, the input and output ratings are not quite the same. The transformer must be capable of supplying the required VA of the desired maximum load without exceeding the current rating of the input line.

- Frequency: The relevant values are 50 Hz or 60 Hz. There may be issues of core saturation occurring when attempting to run a transformer designed for 60 Hz on the same input voltage but at 50 Hz. (There is no going the other way.) This isn't an issue if the transformer has been engineered with adequate safety margins but could result in overheating and failure for a 'designed as cheaply as possible. unit. This probably isn't that likely but if the transformer gets excessively hot or has an unusual amount of hum, saturation may be the problem. Running it on slightly reduced input voltage may help but whether this is a viable option depends on many factors and the rest of the equipment may end up being unhappy. See the chapter: Is Frequency Conversion Needed?.

Transformers of adequate capacity can be used with all types of equipment.

However, they are heavy and costly and do not convert frequency. Thus, they may be unsuitable in some situations and there may be cheaper more appropriate alternatives. A *suitable* transformer large enough to power a space heater would weigh about 50 pounds and cost perhaps $200 - much more than the the space heater is worth.

Using a Low Voltage Transformer to Increase or Reduce Line Voltage

Sometimes, it is only necessary to adjust the voltage by 10 or 20 V to be fully compatible. For example, this might be the case when using domestic Japanese gear in the U.S. and vice-versa. Their line voltage is closer to 100 VAC compared to our 115 VAC.

An easy way to change the voltage by 15 V (for example) up or down, is to obtain a transformer with a 110 V primary and around a 15 V secondary. The secondary current rating needs to be at least equal to the load requirements. Wire it up so the secondary is in-phase in series with the AC to the load to boost voltage (as shown below) or out-of-phase to reduce it.

Note: To obtain exactly the correct voltage will require a slightly higher or lower voltage transformer than this simple explanation would indicate since the input voltage will be slightly lower or higher than the transformer's rated input voltage. This is usually not an issue since precise voltage to an appliance or piece of electronic equipment is generally not required.

```
                   +-----------+
                   |           |
     AC In o-------+--+        |
                     o )|| +----+
                       )||(
105 VAC Line   Primary )||( Secondary
                       )||( o
                       )|| +---------o AC Out
     AC In o-------+--+
                   |                          120 VAC to Load
                   +-----------------o AC Out
```

Thyristor Based Converters

These are the low cost devices available at Radio Shack or a travel accessories store that weigh almost nothing and have huge power ratings. They operate by switching the power on to the load at the appropriate time during each cycle of the AC voltage (120 or 100 times a second) resulting in approximately the proper power being delivered to the load.

Thyristor based converters are for converting from 220 VAC to 110 VAC without changing frequency with major restrictions:

- WARNING: These are suitable ONLY for resistive loads like light bulbs, space heaters, and frying pans WITHOUT induction motors, transformers, or electronic controls.

- They are designed to provide approximately the correct *power* conversion factor for resistive loads (and possibly universal motors). The maximum voltage may still be close to that of the input - 220 V. This will instantly (or at least quickly destroy electronics and may destroy induction motors, transformers, and other similar loads rated for 110 VAC only slightly more slowly.

- The output is very spike-y unlike the smooth sinusoid of the normal power line AC. This in itself may result in addition problems including radio frequency interference (RFI) and equipment buzz or hum.

Since all a thyristor (triac) can easily do is turn on - it has to wait until the end of the cycle to turn off - to get the same effective power from a 220 VAC input as a 110 V input will require a higher peak voltage with a duty cycle of much less than 100 percent. Capacitors in the power supply of typical electronic like to charge to the peak - BLAM! The high peak voltage can result in breakdown of underrated insulation and have other undesirable effects on devices like induction motors and transformers. Even equipment for which these are supposedly designed can be destroyed or may represent a safety risk since there can be much higher voltages inside than normal.

Motor Alternators

Before the development of solid state power devices, these represented an efficient, if bulky way of converting both voltage and frequency. A synchronous induction motor is coupled to an alternator (AC generator) on the same shaft. By designing with the appropriate number of poles for each, this could easily, if noisily, perform both voltage and frequency conversion.

Solid State (AC->DC->AC) Converters

These provide efficient conversion of both voltage and frequency in a light weight compact package. The best of these generate an output nearly identical to the power obtained from the wall socket and operate as follows:

- Rectify and filter AC input to provide direct current (DC).

- Chop the DC at a high frequency controlling both polarity and amplitude to synthesize a replica of the desired power (sinusoidal) waveform.

- Use a transformer to step this up to the required voltage
- Provide a filter to remove the high frequencies from the output.

The waveform before smoothing would look similar to the following:

```
    ||                  ||
  ||||||              ||||||
 ||||||||            ||||||||
||||||||||          ||||||||||
||||||||||          ||||||||||
          ||||||||||          ||||||||||
          ||||||||||          ||||||||||
           ||||||||            ||||||||
            ||||||              ||||||
              ||                  ||
```

After smoothing, the result would be very similar to a sinusoid.

This more costly approach enables arbitrary voltage *and* frequency conversion but as we will se later, this is rarely needed. For an idea of how to design such a converter, see the section: Design of High Efficiency Power Inverters.

Cheaper models simply generate a square wave or modified sinewave at the appropriate frequency:

Squarewave:

```
 _________           _________
|         |         |         |
|         |         |         |
|         |         |         |
|         |         |         |
          |         |         |         |
          |         |         |         |
          |         |         |         |
          |_________|         |_________|
```

Modified sinewave:

```
    _____                 _____
   |     |               |     |
   |     |               |     |
   |     |               |     |
___|     |____       ____|     |____
```

```
                          |       |                  |      |
                          |       |                  |      |
                          |       |                  |      |
                          |_______|                  |______|
```

The nice thing about the modified sinewave is that its RMS and peak values match that of the true sinusoid (as well as other advantages in terms of harmonic content). If you don't know what this means, don't worry, Your life doesn't depend on it. One implication, however, is that heating loads and electronic devices which rectify and filter the input power will see the same effective voltage.

For many devices including all resistive loads, either of these approaches is adequate. However, devices with motors and/or transformers will be much happier with smoothed sinusoidal power. Switching power supplies (except universal types) will be underpowered with the simple squarewave inverter and may overheat running near full load.

Design of High Efficiency Power Inverters

Here is a general recipe - season to taste. :) (From: James Meyer (notjimbob@earthlink.net).)

1. Make a DC to DC converter using any one of several standard designs available almost anywhere. Pick a design using switch-mode control and a high frequency transformer. The input voltage you already know. Make the output voltage adjustable over a 0 to 170 volt range by way of a low-level input signal of maybe 0 to 10 volts. The output current will be whatever you want for the 120 volt AC output current. You'll probably want to have a transformer in there to isolate the output from the input, but it will be a small one because the frequency will be very much higher than 60 Hz.

2. Build a signal generator that puts out a 0 to 10 volt signal that looks like a half-wave rectified 60 Hz waveform. Use that to control the DC to DC converter.

3. Then use an H-bridge switch on the output of the 0 to 170 volt converter to get alternate plus and minus output. Use a square wave that changes state at each 0 volt output point of the input signal to drive the H-bridge.

Using this approach, you can step the input voltage up to the peak of the sine wave that you want at the output with a decent converter that can be very efficient and produce little waste heat.

The H-bridge MOSFETs are also only switches so they can be efficient. Plus, you're switching currents at the output voltage level which is a lot smaller than the current at the DC input.

You'll get a sine wave at the output and the whole thing should be simple and fairly cheap. The high frequency switching converter will be the hardest part to get going because of the wide adjustable output voltage range required, but I think it will still be easier than the "brute force" method.

Some Power Converter Companies Here are a few random

companies that offer power converters. I am in no way endorsing their products and have no direct knowledge of their quality or performance. Listed in alphabetical order.

- **Stark Electronic**
- **Voltage Valet**
- **Walkabout Travel Gear**
- **Todd Systems**

What Appliances will be Damaged by Reduced Voltage?

Here is a summary of various appliance types and how they are affected by the severely reduced voltages possible during a brownout:

- **Resistance heating elements/incandescent bulbs/ and similar will not be damaged and will actually last longer. Of course, light and/or heat will be reduced.**
- **Constant horsepower loads like refrigeration compressors will be severely stressed and may burn out.**
- **Shaded pole motors will run slow but will probably not be damaged. Many of these are designed to survive a stalled condition as well.**

  Examples: fans and some blowers, can openers, pencil sharpeners.
- **Capacitor run and other larger induction motors without a starting switch will run slow with reduced torque. However, if they stall, overheating and burnout is possible.**

  Examples: some blowers, dishwashers.

- **Motors with a starting switch may not reach starting winding cutout speed and result in motor damage - burnt out starting winding.**

  Examples: washing machines, cloths dryers, circulator and other larger pumps, large furnace blowers, stationary shop tools.

- **Universal motors will run slow with decreased torque and reduced cooling. There may be a range of speeds over which they will overheat.**

  Examples: vacuum cleaners, electric leaf blowers, many other portable line powered tools

- **Switching power supplies will run hot and may fail.**

  Examples: TVs, some VCRs, computers (PCs and laptops), monitors, and some peripherals,

- **Linear power supplies will probably just not regulate well resulting in hum in audio or hum bars in video.**

  Examples: Stereo receivers, CD players, cassette decks, phones, some fax machines, some printers.

- **Anything with relays may have problems with the relays not operating reliably or cycling.**

  Examples: heating and cooling systems, garage door openers, etc. but most of these will have other components more severely affected.

For appliances with more than one type of device like a microwave oven, all factors must be considered. For this example, the oven will heat at a reduced power level (which is safe) but the cooling fan(s)

will also run more slowly resulting in possible overheating and failure of the magnetron. A convection space heater may overheat for similar reasons.

How Big a Difference in Voltage Before a Converter is Needed

> "I would like to bring a variety of small to medium-sized Japanese electrical products (100V 50/60 Hz) with me when I move back to the U.S. (e.g., lights, rice-cooker, cassette player, VCR...) Individual transformers like those sold in travel shops are quite expensive. Is it possible buy a large number of small stepdown transformers -- or to make them as kits? Any advice would be greatly appreciated."

First, for some of these like the VCR, the 15% difference between 115 VAC and 100 VAC may not matter. The only way to be sure is to check with the manufacturer.

For others like the rice cooker, it too may be ok if it uses a thermostat to control its heating element.

However, the simplest way to reduce 115 to 100 VAC is to buy or construct an autotransformer.

To construct one, you need a stepdown transformer with an output of about 15 V (for this example) and a secondary current rating at least equal to your total current needs. Then, the primary is connected to the line and the secondary is wired anti-phase in series with the loads and the line.

For devices using AC adapters, I would just replace the AC adapters with a US version.

Effects of Improper Voltage on Resistive Loads

- Incandescent light bulbs. Light output will increase or decrease by a greater relative percentage than the voltage change. Life will be impacted dramatically. The life function for an incandescent light bulb is roughly (V/Vo)^^14. This is the actual voltage divided by the nominal voltage raised to the 14th power! A 5 percent increase in voltage will decrease life by about 50%.

With greatly excessive voltage (i.e., running a 110 V light bulb on 220 V), burnout will be nearly instantaneous - the bulb may even explode.

With reduced voltage, the light output will be reduced and life will be extended dramatically as well. However, efficiency decreases faster than voltage so it doesn't make sense to use bulbs on lower voltage unless they are in a hard-to-reach spot as the energy cost dominates. Extending the life of a 25 cent bulb just doesn't save money in the end especially if a higher wattage or additional bulbs must be used to make up the light reduction.

- Space heaters (excluding fans) and heating appliances like rice cookers, deep fryers, toaster, etc. Power is proportional to the square of the voltage. Reduced voltage will result in less heat or longer cycles (if thermostatically controlled). Excessive voltage will result in more heat or shorter cycles. However, there could be fire risk if the appliance is not designed with adequate insulation and safeguards to handle the extra power.

  With greatly excessive voltage, heating devices will blow a fuse or internal thermal protector, the AC fuse or circuit breaker, or burn out.

Effects of Improper Voltage on Constant Power Loads

- Induction motors. These are found in refrigeration equipment (fridges, freezers, air conditioners, dehumidifiers), air compressors, washing machines, dryers, some stationary shop tools, pumps, and many other domestic and industrial applications.

An induction motor is a nearly constant speed drive. Reduce the voltage and it will still try to maintain almost the same speed. Where the load is constant, this means that it will draw greater current to compensate for the reduced voltage (remember: P = constant = V*I). This will result in excessive heating and stress. The equipment may fail to start properly at all or cycle on its thermal/overcurrent protector. Its life may be shortened or it may burn out quickly.

Excess voltage isn't good either since the construction may result in magnetic core saturation which will also result in overheating, added noise (hum), and lower efficiency.

- Regulated switchmode power supplies

  These share many of the characteristics of induction motors in that they will attempt to maintain the same power to the load. Thus, at low line voltage, they will draw additional current and internal parts may be stressed to the point of (possibly catastrophic) failure. Unlike induction motors, this is much more difficult to predict as it is highly design dependent.

  Usually a slight reduction or increase in voltage will not affect the performance or longevity. However, unless specified as a universal input (90 to 240 VAC) or where specific recommendations are available, remaining within a 10 percent window is best. This is especially critical on the low side when running near full load.

  Running a non-universal switching power supply from a squarewave inverter result in overheating and subsequent failure near full load. The reason is that the peak value of the input waveform is about 7/10ths of that from the normal AC line and the current must increase to compensate.

Effects of Improper Voltage on Transformer Loads

While the ideal transformer (the one they may have taught you about in EE101) doesn't care about its actual input voltage, real transformers do. If the voltage increases significantly above what it was designed for, the core may saturate. This means that the magnetic field in the core cannot increase any further and the result is to effectively short circuit the input (above a certain voltage on the waveform). At the very least, this will result in excessive heating and hum or buzz. The transformer may burn out if a fuse doesn't blow first.

How much excess voltage is acceptable is not something that can be determined without testing. Some transformers are designed very conservatively (bigger cores, more copper, etc.) while others just barely get away with running on the nominal line voltage.

Certainly, 2:1 will be too much for almost any transformer. You may get away with a 25% increase without too many problems.

It is possible to test for this by slowing increasing the input voltage while monitoring input current. Up until saturation, it will increase linearly with voltage. As saturationg sets in, a small increase in voltage will result in a large increase in current and increased buzz or hum as well.

Reducing voltage to a transformer is not a problem unless the load will then demand more current - which may result in excessive heating and failure.

Effects of Improper Voltage on Motor Loads

- As noted above, induction motors are constant speed devices so that the current will tend to decrease as voltage is increased and increase as voltage is decreased. There can also be core saturation effects just as with transformers.

- Universal motors - those found in vacuum cleaners, portable shop tools, and so forth - will run with a speed that it related to input voltage (unless feedback regulated). On low voltage, the speed will be lower and your vacuum cleaner won't suck as well. Since it uses bypass air to cool the motor, it may overheat also. On higher than normal voltage, it will run faster adding wear and tear to the bearings. Blowers and flywheels may disintegrate if not designed for the added centrifugal loads.

- Fan motors - these are shaded pole induction type usually and so lossy to begin with that speed will vary with voltage. Again, bad things may happen at too low or too high voltage but they will probably survive modest changes.

- Back to Power FAQ Table of Contents.

Line Frequency (50/60 Hz) Issues

Is Frequency Conversion Needed?

The question of 50 Hz vs. 60 Hz always comes up in conjunction with international power. However, except for equipment with induction motors (e.g., fans, compressors), or where the line frequency is used for timing (electric or line powered electronic clocks), the line frequency may be irrelevant.

Effects of Improper Frequency

- Clocks/timers run slow or fast. Devices that depend on synchronous motors or count the cycle of the line voltage directly like desk or alarm clocks, clocks in clock radios, appliance timers, anti-burglery timers, and so forth, will run fast or slow by the precise ratio of the correct to actual line frequency. In nearly all cases, this will be either 5/6 or 6/5 based on the ratio of 50 to 60 Hz and vice-versa.

In the case of synchronous motors, there is nothing you can do - the speed is determined by construction and the gear ratios.

Those that are entirely electronic may have a switch or jumper (probably inside) to select the AC frequency - 50 or 60 Hz.

Many devices use an internal quartz crystal for the clock or timer and will not be affected at all. Devices like VCRs may or may not use the power line for timing. Of course, battery operated equipment will always use an internal quartz crystal as there is no connection to the power line.

- Transformer core saturation - excessive heating. Reducing the frequency of the input to a transformer also increases the likelihood of core saturation. Therefore, going from 60 Hz to 50 Hz may be a problem for your stereo (which likely uses a power transformer) if its design is marginal. As with voltage, there is no way to know except by testing unless the nameplate specifically states a frequency spec - 50/60 Hz.

- Induction motor speed and torque. As noted, these are nearly constant speed devices dependent on power line frequency:

  - Going from 50 Hz to 60 Hz: motor will run fast with reduced torque.

  - Going from 60 Hz to 50 Hz: motor will run slow with reduced torque.

- Note that most modern electronic equipment (with the possible exceptions listed above) does not depend on the power line frequency for anything. This includes CD players, cassette decks, servo-drive turntables, TVs (unless there is an on-screen line timed clock), VCRs (ditto), computers, monitors, printers, fax machines, etc.

Equipment that Will Probably not Care About the Line Frequency

The following are generally insensitive to frequency (50/60 Hz):

- **Appiances with only heating elements (e.g., toaster, radient space heater) and incandescent light bulbs.**
- **Devices with universal motors (e.g., vacuum cleaner, electric drill).**
- **Fluorescent lamps using electronic ballasts (including many compact fluorescents).**
- **TVs, VCRs, computers, monitors, universal AC adapters, other devices using switching power supplies. (The a clock may run at an incorrect rate if it depends on the power line frequency.)**

However, note different TV standards will likely result in your TV and VCR working together but not able to receive or record broadcasts or cable.

Some equipment explicitly states the acceptable voltage and frequency range. In the case of a universal power adapter, this may range from 90 to 260 V DC or AC up to 400 Hz - or more.

Equipment that May Work with a Different Line Frequency

The following will probably work when going from 50 Hz power to 60 Hz power and may work going the other way. However, transformer cores designed for 60 Hz may saturate on 50 Hz and run hotter and/or blow internal fuses and cooling fans will run slower - this should be checked to make sure there is no hazard:

- **Audio equipment (e.g., receivers, CD players, tape decks, servo locked turntables). However, since the broadcast channel spacing may differ, tuning may not operate correctly.)**
- **Devices using wall wart AC adapters with actual transformers**

(these are massive as opposed to universal AC adapters which weigh almost nothing) (e.g., calculators, boomboxes, telephones and answering machiens, external modems and CDROM drives, dust busters hand vacs). However, the phone system may not be compatible.)

- Printers, fax machines, and other computer peripherals which use a power transformer in their power supply.

- Microwave ovens (power is related somewhat to frequency, cooling fans and turntables will run slow on 50 Hz).

- Fans and blowers (will run slower on 50 Hz).

- Convection space heaters (shaded pole fan motor will run faster on 60 Hz). If designed for 60 Hz and run off 50 Hz, it will run slower possibly resulting in overheating.

Equipment that May have Problems on Different Line Frequency

The following may have problems:

- Audio equipment using AC motors like some turntables and reel-to-reel tape decks. Speed will be incorrect. Mechancial adapters may be available.

- Clocks and devices with built in clocks or timers. Many of these depend on the power line frequency for timekeeping. They will therefore run at a 5/6 or 6/5 rate when the frequency changes. (This may be desirable - your day could last 20% longer! :-)).

- Electric shavers depending on a resonant linear motor (vibrator). The frequency difference may be enough to kill the resosnance and result in weak or no blade motion. (Remingtons used to use this technique; I do not know what manufacturers still do.)

- Large fixed power devices like refrigeration compressors.

- **Equipment with a combination of resistive heating elements and/or induction motors and/or electronics. One or more subsystems may have performance or overheating problems.**
- **Fluorescent lamps and fixtures using iron ballasts.**

- **Back to Power FAQ Table of Contents.**

Recommendations for Specific Equipment

General Considerations

The sections below summarize the major issues with respect to common appliances and consumer electronic equipment. Following these are those which relate specifically to moving overseas or vice-versa.

Television Sets and Video Cassette Recorders

A voltage converter - preferably a true transformer or modified or true sinewave inverter will be needed to adapt the voltage unless the unit has a universal power supply.

Modern TVs do not care about power line frequency at all as they do not have any power transformer. Really old sets may run into core saturation problems but these are mostly dead by now.

Note: the video frame rate is not tied to the power line in any way. Therefore, a U.S. TV with a 60 Hz (actually 59.94 Hz) frame rate will work just fine in a country with 50 Hz power assuming the voltage is correct. However, it will not be compatible with broadcast or cable or likely a VCR purchased in that country - see below.

VCRs may use a small power transformer in the power supply so

changing from 60 Hz to 50 Hz may result in overheating though probably not likely.

However, taking a VCR and TV from the U.S. to a European country, for example, may not be worth it. They will work fine with each-other (as long as the voltage is proper) but the video standards in foreign countries are not compatible with those in the U.S. Therefore, it may be better to buy new equipment overseas unless you are taking your prized collection of videos and will obtain other equpiment to deal with broadcast and cable. There are also services for copying video cassettes from one standard to another and these may represent an alternative to lugging the equipment with you.

Small Appliances

Specific recommendations will depend on the actual devices inside the appliance - motors, heating elements, timers, and so forth.

- For appliances containing ony heating elements - no fans or other motors - any type of voltage converter will be suitable. For example, the very inexpensive and light weight thryistor type of 220 VAC to 110 VAC type should work fine with a waffle iron.

- Where motors are involved, a true transformer will be best but may be excessively heavy or expensive.

- With timers, the line frequency will also be important.

- If the appliance is powered by a wall adapter outputting DC, a substitute wall adapter may be the best option.

Clocks

Electric clocks using a synchronous motor would require a motor or gear transplant - not worth it. Of course, you could just live with shorter or longer days :-).

Clocks using the power line to drive an electronic display may have a jumper to select 50 or 60 Hz. Even this may not be worth the effort to locate as it is likely not going to be labeled.

Fluorescent Lamps

For those using iron ballasts, both voltage and frequency will be significant. Though it may be possible to come up with a formula which incorporates both, the best thing to do is to only use the line voltage for which the unit was designed.

Where the frequency isn't the same, the current through the lamp may differ, most likely too high in going from 60 Hz to 50 Hz, too low the opposite way. If the current is too high, there could be shortened lamp life at the very least or even a serious fire hazard. If the current is too low, the lamp may not remain on in a stable manner, flickering, or constantly restarting. Initial starting could also be affected.

If they use electronic ballasts, the frequency probably won't matter. Some "universal" types, can accommodate an input voltage from 90 to 250 VAC up to 400 Hz or even DC.

In all cases, it is best to consult with the manufacturer if the product label doesn't explicitly indicate "50/60 Hz" operation. When in doubt, leave them behind since there is really no way to be sure of the safety issues.

Audio Equipment

These include tuners, amplifiers, receivers, tape decks, CD players, etc.

Except for the tuner or tuner portion of the receiver, the only issue is power. Audio equipment almost always uses a transformer type power supply so the comments in the previous chapters should apply. A voltage converter will be needed to go from 110 VAC to 220 VAC or vice-versa. In this case, it really should be a true transformer.

Anything else is quite likely to introduce unaccceptibel interference in the form of a hum or buzz even if it doesn't result in any damage to the equipment. As noted, going from 60 Hz to 50 Hz could intruduce problems of transformer core saturation in marginally designed equipemnt as well.

Radios, Tuners, Receivers

In addition to the power issues (see the section: Audio equipment, station frequencies and channel spacing differ from country to country.

Microwave Ovens

If the voltage is different, sell where you are located and buy a new one at your destination. The power involved would require a large, heavy, expensive voltage converter - preferably a true transformer. It doesn't make sense for a $150 microwave.

Line frequency doesn't affect the performance of a microwave that much (perhaps a 5 percent increase in cooking power from 50 Hz to 60 Hz) but the timer and clock will likely be affected and may not be easily adjusted - not at all in the case of a mechanical timer though there may be a jumper for an electronic timer. However, the turntable and cooling fan motors will also be affected and attempting to account for all the variations is probably just not worth it!

PCs and Laptop/Notebook Computers

Check your equipment. Most PC power supplies have a switch to select between 110 VAC and 220 VAC. Some have universal power supplies that will work within a range of voltage between 90 and 240 V AC (up to 400 Hz) or DC. The latter is generally true of laptop/notebook power packs.

Similary, monitors may use a switch or jumper to select voltage or have a universal power supply.

PCs and monitors do not use the line frequency for anything - not even the real time clock.

Laser Printers

These may use a switching or transformer based power supply. This is not the real problem. What is, is the power for the fuser - several hundred watts. Therefore, if using a true transformer for voltage conversion, a large one will be required.

Some may have universal power supplies - check your instruction manual!

Non-Laser Printers

These will usually use a power transformer type power supply so a voltage converter will be needed. The frequency will only matter with respect to transformer core saturation. Nothing in a printer depends on line frequency.

Taking Equipment Overseas (or Vice-Versa)

When does it make sense to take an appliance or piece of electronic equipment to a country where the electric power and possibly other standards differ?

For anything other than a simple heating appliance (see below) that uses a lot of power, my advise would be to sell them and buy new when you get there. For example, to power a microwave oven would require a 2kVA step down (U.S. to Europe) transformer. This would weigh about 50 pounds and likely cost almost as much as a new oven.

Note that some places like Japan may even have varying power specifications in different parts of the country. Isolated areas such as islands may have their own power generators with very erratic and voltage and frequency. The following discussion assumes power

from a large (national) grid.

There are several considerations:

1. **AC voltage - in the U.S. this is nominally 115 VAC but in actuality may vary from around 110 to 125 VAC depending on where you are located. Many European countries use 220 VAC while voltages as low as 90 or 100 VAC or as high as 240 VAC (or higher?) are found elsewhere.**

2. **Power line frequency - in the U.S. this is 60 Hz. The accuracy, particularly over the long term, is excellent (actually, for all intents and purposes, perfect) - better than most quartz clocks. In many foreign countries, 50 Hz power is used. However, the stability of foreign power is a lot less assured.**

3. **TV standards - The NTSC 525L/60F system is used in the U.S. but other countries use various versions of PAL, SECAM, and even NTSC. PAL with 625L/50F is common in many European countries.**

4. **FM (and other) radio station channel frequencies and other broadcast parameters differ.**

5. **Phone line connectors and other aspects of telephone equipment may differ (not to mention reliability in general but that is another issue).**

6. **Of course, all the plugs are different and every country seems to think that their design is best.**

For example, going to a country with 220 VAC 50 Hz power from the U.S.:

For electronic equipment like CD players and such, you will need a small step down transformer and then the only consideration power-wise is the frequency. In most cases the equipment should be fine -

the power transformers will be running a little closer to saturation but it is likely they are designed with enough margin to handle this. Not too much electronic equipment uses the line frequency as a reference for anything anymore (i.e., cassette deck motors are DC).

Of course, your line operated clock will run slow, the radio stations are tuned to different frequencies, TV is incompatible, phone equipment may have problems, etc.

Some equipment like PCs and monitors may have jumpers or have universal autoselecting power supplies - you would have to check your equipment or with the manufacturer(s). Laptop computer, portable printer, and camcorder AC adapter/chargers are often of this type. They are switching power supplies that will automatically run on anywhere from 90-240 VAC, 50-400 Hz (and probably DC as well).

Warning: those inexpensive power convertors sold for international travel that weigh almost nothing and claim to handle over a kilowatt are not intended and will not work with (meaning they will damage or destroy) many electronic devices. They use diodes and/or thyristors and do not cut the voltage in half, only the heating effect. The peak voltage may still approach that for 220 VAC resulting in way too much voltage on the input and nasty problems with transformer core saturation. For a waffle iron they may be ok but not a microwave oven or stereo system. I also have serious doubts about their overall long term reliability and fire safety aspects of these inexpensive devices..

For small low power appliances, a compact 50 W transformer will work fine but would be rather inconvenient to move from appliance to appliance or outlet to outlet. Where an AC adapter is used, 220 V versions are probably available to power the appliance directly.

As noted, the transformer required for a high power heating appliance is likely to cost more than the appliance so unless one of the inexpensive convertors (see above) is used, this may not pay.

Fortunately, the standard for the CDs themselves is the same everywhere in the explored universe Yes, even Australia :-). Thus, there should be no issues of incompatibility. The differences will relate only to the power supply.

First, check your user's manual (which you of course have saved in a known location). It may provide specific instructions and/or restrictions.

Most component type CD players use a simple power supply - a power transformer followed by rectification, filter capacitors, and linear regulators. These will usually only require a small step up or step down transformer to operate on a different voltage. Since power requirements are minimal, even a 50 VA transformers should be fine. WARNING: never attempt to use one of those cheap lightweight power adapters that are not true transformers to go from 220 V to 110 V as they are designed only for heating appliances. They will smoke your CD player (or other equipment not designed to handle 220 V to 240 V input).

Some CD players may have dual voltage power transformers which can be easily rewired for the required voltage change or may even have a selector switch on the rear panel or internally.

The frequency difference - 50 or 60 Hz should not be a problem as nothing in a CD player uses this as a timing reference. The only slight concern would be using a CD player specified for 60 Hz on 50 Hz power - the transformer core may saturate and overheat - possibly blowing the internal fuse. However, I don't really think problems are likely.

For portable CD players, if your wall adapter does not have a voltage selector switch, obtain one that is rated for your local line voltage or use a suitable transformer with the one you have. As with power transformers, a frequency difference may cause a problem but this is not likely.

Microwave Ovens

Microwave ovens are high power appliances. Low cost transformers or international voltage adapters will not work. You will need a heavy and expensive step down or step up transformer which will likely cost as much as a new microwave oven. Sell the oven before you leave and buy a new one at your destination.

Furthermore, for microwave ovens in particular, line frequency may make a difference. Due to the way the high voltage power supply works in a microwave oven, the HV capacitor is in series with the magnetron and thus its impedance - which depends on line frequency - affects output power.

High voltage transformer core saturation may also be a problem. Even with no load, these may run hot even at the correct line frequency of 60 Hz. So going to 50 Hz would make it worse - perhaps terminally - though this is not likely.

- Going from 50 Hz to 60 Hz at the same line voltage may slightly increase output cooking power (and heating of the magnetron). The line voltage could be reduced by a small amount to compensate.

- Going from 60 Hz to 50 Hz may slightly decrease output power and possibly increase heating of the HV transformer due to core losses. Using a slightly lower line voltage will reduce the heating but will further decrease the cooking power.

The digital clock and timer will likely run slow or fast if the line frequency changes as they usually use the power line for reference. Of course, this may partially make up for your change in output power! :-)

> "I have the following question for you specialists:
>
> Can I buy a TV in any west-european country and use it in any other west European country? For example, buying a TV in the Netherlands and use it in Greece or buying in France and using in England.
>
> Any help would be appreciated as I do not really trust the sale people at the store."

Neither would I.

Along with the multiple audio/video formats, there may be differences in channel frequency assignments between the various countries.

Channel 5 in country X may not be on the same actual frequency as Channel 5 in country Y or Z. The channel spacings or modulation may also be different.

(From: Phil Nichols (in5379@wlv.ac.uk).)

Plus, in different countries the audio signal can be transmitted at a different frequency relative to the vision signal. Great! Perfect picture, no sound!

I believe most continental European countries use PAL B (narrow vision bandwidth; sound carrier 5.5MHz higher than vision carrier), whereas the UK and Ireland use PAL I (wider vision bandwidth; sound carrier 6MHz higher than vision carrier).

The wisest thing is to decide which countries you are most likely to want to visit with your TV, find out what transmission system they use, then go looking for a TV which can use that/those system(s).

Almost all TVs in west Europe are compatible (PAL-B/G), except

Britain (PAL-I) and France (SECAM-L). Greece is also using SECAM, but on very few channels and not all the time.

(From: Wolfgang Schwanke (wolfi@berlin.snafu.de).)

This is correct, but maybe not the whole story.

There are differences in the broadcast bands used. At least Italy uses different channel allocations than the rest of the PAL-B/G crowd. Germany uses frequencies on cable that are unused elsewhere, which only special tuners can get. Also, there are different methods for transmitting stereo sound (NICAM vs. analogue).

New TVs nowadays (sold in Europe anyway) are often all-world-standard all-frequency-bands, because it's easier for the manufacturer to make a "one for all" set instead of having so many different designs for every country. But don't rely on it.

(From Jeroen Stessen (Jeroen.Stessen@philips.com).)

Oh boy, here goes another long story:

PAL-plus is an attempt to extend the life-cycle of terrestrial PAL transmissions by including compatible wide-screen (16:9) transmissions. It is an advanced variant of the letterbox format, this means that when you receive a PAL-plus widescreen program on an older 4:3 receiver you will see black bars top and bottom. It was originally developed in Germany (university of Dortmund in cooperation with German terrestrial broadcasters and some setmakers). Later a large consortium of European and Japanese setmakers took over and finished the job. Strangely, the German broadcasters seem to use PAL-plus only very rarely.

The PAL-plus standard comprises three extensions to the PAL-standard:

1. **Vertical helper. In order to compensate for the fact that 1/4 of the**

video lines are not used, which would deteriorate vertical resolution for the widescreen viewer, the missing vertical information has been coded into the black lines in a manner as to be nearly invisible on a 4:3 receiver (you see some dark blue). The 16:9 PAL-plus receiver combines 432 visible lines plus 144 helper lines into 576 new visible lines.

2. Colour-plus. The PAL colour carrier is modulated in a slightly different way (making use of correlation between 2 fields) in order to give a cleaner Y/C separation in the PAL-plus receiver.

3. Signalling bits from which the receiver can conclude whether the transmission is 4:3/16:9/PAL-plus and adapt the display format accordingly. The bandwidth of these bits is low enough to survive recording on a VHS recorder.

In order to enable a poor-man's PAL-plus receiver, the standard permits using the mark "PAL-plus" if at least the vertical helper reconstruction is included. Colour-plus is optional, so you will find sets on the market with only half of the PAL-plus extension.

PAL-plus may also be combined with teletext, ghost cancellation reference, digital Nicam stereo, VPS, PDC and what-you-have more. Theoretically it can be broadcast over a satellite channel too, but it was not designed for that and some aspects of a satellite channel do indeed give interesting technical problems.

There are also sets marketed as "PAL-plus compatible". These are mostly widescreen sets without any PAL-plus processing at all, but they allow switching of the display format between 4:3 and 16:9. They may well do that automatically, based on the signalling bits.

There are 2 methods for displaying a 4:3 letterboxed signal on a 16:9 display, without using the PAL-plus helper lines:

1. Increase of the vertical deflection amplitude to display only the centre 432 lines.

2. Vertical interpolation without using the helper, to convert 432 lines into 576 lines and display on a 576 lines display.

Both modes may be called "movie expand". Only when you really convert to full-resolution widescreen will it be called "widescreen".

And there are 4 methods for displaying a regular 4:3 signal on a 16:9 display (regular PAL, has nothing to do with PAL-plus):

1. Decrease of the horizontal deflection amplitude, this gives black bars left and right.

2. Horizontal interpolation, to convert N pixels to 3/4*N pixels. Both modes may be called "4:3" or "normal"

3. Non-linear horizontal deflection waveform, called "Panorama mode" by JVC, works by increasing the S-capacitor value.

4. Non-linear horizontal interpolation, called "Superwide" by Philips, works with an advanced sample-rate convertor.

With both modes, the left and right edges of the picture will be stretched to fill the left and right bars, but the aspect ratio of the centre part of the picture will hardly be affected.

Interesting, ain't it ?

(From: Allan Mounteney (allan@amounten.demon.co.uk).)

RE: Is there a TV set that covers international standards?

The answer is YES.

Reason I know is that I was with a company that made computers with TV-OUT for world wide use and wanted something that could show that the TV Out worked for various countries.

This ONE and ONLY one we could find Three years ago came from Germany and covered PAL, SECAM and the American NTSC systems and came with a note that said from the time of making/selling that set it would not work in just one small country in South America. All features (including audio) were adjustable from the front panel menu and it was a Grundig 17" job. I am advised that there is a load of others on the market now.

The company who seemed to know all about these international sets and gave us good service at that time was Andrew McCulloch Ltd in Cambridge UK. Phone: 44(0)1223-351825

Items of Interest

TV, Shortwave, Power Worldwide

(From: Mark Zenier (mzenier@netcom.com).)

A book, "The World Radio TV Handbook" published by Billboard that covers TV, along with where all the world's shortwave radio transmitters are, and what sort of power comes out of the wall plug all around the world. It has a new edition each year and costs around $25 to $30.

About the Vertical Scan Rate

TVs never ever used the line frequency for vertical rate. The vertical rate is not even equal to line frequency, actually 59.94 Hz (NTSC). It was set originally to 60 Hz to minimize the visibility of interference between the deflection and power transformer. When NTSC added color, it changed to 59.94 Hz. And, TVs no longer have power transformers.

Determining Unknown Connections on International Power Transformers

Most likely, you can figure this out if you can identify the input connections.

There will be two primary windings. Each of these may also have additional taps to accommodate various slight variations in input voltage.

For the U.S. (110 VAC), the two primary windings will be wired in parallel. For overseas (220 VAC) operation, they will be wired in series. When switching from one to the other make sure you get the phases of the two windings correct - otherwise you will have a short circuit! It is best to test with a Variac so you can bring up the voltage gradually and catch your mistakes before anything smokes.

An multimeter on the lowest resistance scale should permit you to determine the internal arrangement of any taps.

With any luck, the transformer wiring will even be labeled on the case!

Running Three-Phase Motors on Single-Phase Power

This may be an issue if you picked up a South Bend lathe with a 10 foot bed at a garage sale for $1 or more realistically with professional shop equipment like large saws or planars.

A three-phase motor will run on single-phase power once started - but at somewhat reduced output power (horsepower). The very simple approach (compared to complete conversion) is to just provide a means for starting. The motor will then run at the correct speed (assuming the line frequency is the same) but will not be able to develop full torque before stalling. Actually converting single-phase to three-phase will likely be more expensive than replacing the motor.

There is some info at the Building a Phase Converter site.

A Note on Voltage in Europe

(From: Michael Salem (4ms2u$ms@michaels.demon.co.uk).)

Until recently voltage in the UK was 240 VAC nominal, +- 6%. Voltage in most of the rest of Europe was 220 VAC. A few years ago voltages throughout Europe were harmonized to 230 VAC. This caused very little disruption; no change to power stations or distribution systems, no equipment problems caused by the change.

Why so trouble-free?

It was a politicians' change: Voltage didn't change at all (at least in the UK). The permissible voltage in the UK used to be between 226V and 253V (240+/-6%). It is now 230V -6% +10%; i.e., anything between 216V and 253V. The actual voltage is exactly what it always was, it's just *called* 230V. Presumably as power stations and distribution equipment age and are replaced the actual voltage will decrease; but I have certainly measured the maximum permissible 253V in June 2000.

DISCLAIMER

The devices, equipment, circuits, and other gadgets described in this document may be dangerous. Much of it deals with potentially lethal voltages. Getting electrocuted could ruin your whole day. Using an inadequate or improperly designed or fabricated high voltage probe to measure high voltage can be equally dangerous.

We will not be responsible for damage to equipment, your ego, blown parts, county wide power outages, spontaneously generated mini (or larger) black holes, planetary disruptions, or personal injury that may result from the use of this material.

For really high voltage equipment, also see: Tesla Coils Safety Information.

WARNING: The microwave oven is perhaps the most dangerous equipment you are likely to encounter around the house. The high voltage (up to 5,000 V) along with the high current (1 A or more) availability make this an instantly lethal combination. It is highly recommended that NO measurements be made on a powered microwave oven. Only after the plug has been pulled and its high voltage capacitor has been safely discharged should you even think about touching or probing anything. Most troubleshooting can be done with at most an ohmmeter. See the document: Notes on the Troubleshooting and Repair of Microwave Ovens for more information. By comparison, TVs, monitors, and even large helium-neon lasers, are tame. While still very dangerous, they don't have quite the deadly quality of the microwave oven!

- Back to HV Probe Design Table of Contents.

Introduction

Scope and Purpose of This Document

There are all sorts of times when being able to determine the value of a high voltage DC source is desirable. Most multimeters have a maximum range of 750 or 1,000 V. (One exception is the workhorse Simpson 260 which has a 5,000 V range). Whether testing a TV with a dim picture, a helium-neon laser power supply that does work quite right, or troubleshooting some home-built high voltage project, the ability to measure 10, 20, 30, or more kV can come in handy.

This document provides information on constructing very basic high voltage probes suitable for measuring the high voltages found in consumer electronic equipment like TVs, monitors, and microwave ovens (though the latter is not recommended for safety reasons).

These simple approaches will work for DC and low frequency AC voltages but no effort is made to compensate for stray capacitance - which will seriously limit high frequency response. However, some of the issues are discussed.

If you will be making HV measurements regularly, by all means invest in a real HV probe for your multimeter. A commercial HV probe will still be a far better long term investment than some cobbled-together unit. However, for occasional HV testing, what is described below can be built and used safely but probably won't have the accuracy, consistency, or frequency response of a good commercial probe. Aside from purchasing a HV probe new, these do show up surplus as well as on eBay, possibly at greatly reduced prices. Even if a model isn't available for your particular multimeter (which is likely), it should be possible to adapt almost any commercial probe to work with it, requiring at most a scaling factor when taking a reading.

SAFETY

Read the associated document: Safety Guidelines for High Voltage and/or Line Powered Equipment before attempting to work with high voltage systems. High voltage can jump amazing distances when you least expect it. The direct or indirect consequences of this can ruin your entire day or a whole lot more.

High Voltage Probe Design

Basic Considerations

CAUTION: DMMs may not be particularly forgiving of voltages on their inputs exceeding their specifications. Autoranging DMMs may be even more likely to blowout as they are selecting the correct range - if there even is one. Depending on your electrical and mechanical components, the chance of excess voltage due to arc-over, leakage, or component breakdown may be a major consideration. My analog VOM has survived many close encounters with HV. You should not assume the same for the typical low cost or even expensive DMM. There is a reason for the high cost of commercial HV probes - these kinds of factors are incorporated (hopefully) in their design.

A simple high voltage probe for a DMM or VOM may be constructed from a pair of resistors. This is suitable for DC measurements but without compensation, will have a unknown AC response due to the very high impedance and stray capacitance forming a filter - low pass or high pass depending on the amount of stray capacitance and input capacitance of your meter or scope. However, this simple design is sufficient for the majority of consumer electronics work which are mostly DC measurements. I have not characterized the AC response of this probe design. However, if there is AC riding on your high voltage, it may mess up your readings if there is no compensation provided as it may act as a high pass filter.

To design the voltage divider, the input impedance of the meter must be taken into account. There is a minor but significant difference between DMMs and VOMs.

- DMM: Z-in is usually constant, often 10M ohms.
- VOM: Z-in is the voltage range (full scale) times the ohms/volt rating of the meter.

Here is the basic circuit:

```
  High Voltage <------/\/\/\/\/\---------+-------------> + to DMM/VOM
                         R1              |                    |
                                         \                    \
                                      R2 /                 R3 /
                                         \                    \
                                         /                    /
                                         |                    |
  Ground Clip  <-------------------------+-------------> - to DMM/VOM
```

R1 together with R2||R3 form a voltage divider where R3 is the internal resistance of the DMM or VOM on the scale for which the probe is designed.

While R2 is not strictly needed, it is recommended that it be included and approximately equal to the Z-in of the meter on the scale you will be using. The reason to include R2 is to insure that high voltage never can reach the meter. The ground clip should be securely connected to the metal chassis of the device being tested - the frame of a microwave oven or CRT grounding/mounting strap of a TV or monitor - before it is powered up. Both R1 and R2 should be located in the probe head.

The only difficult part is locating a suitable resistor for R1 that has high enough resistance and physically is long enough such that arc-over is avoided. The only difficult part is locating a suitable resistor for R1 that has high enough resistance and physically is long enough such that arc-over is avoided. Caddock, OhmCraft, Victoreen, and Vishay are among the major companies that manufacture suitable resstors. But don't expect them to pay much attention to you for an order of 5 resistors! However, it may be possible obtain free samples if you explain what you're doing - and their lawyers don't get involved! If this doesn't work out, electronics surplus outfits occasionally come up with odd lots of strange components such as these and they even show up on eBay from time-to-time.

The high value high voltage resistor can also be constructed from several equal lower value resistors in series if they are all approximately the same size. Another possibility is salvaging the focus divider networks from dead flybacks or TV/monitor voltage multiplier assemblies. Even if the unit was discarded as being faulty, where there are no internal shorts in the HV rectifier or resistive network itself, the entire unit can be used intact.

In addition to basic safety precautions when working around high voltages, some form of equipment protection should be considered in provide an arc-over path to ground should there be arcing over the surface of the resistor as well as if the resistor should somehow decrease in value. There is no telling what can happen under less than ideal damp or dirty conditions.

A 'corona', 'arc', or 'discharge' ring could be placed around the resistor near the low voltage end securely connected to the ground cable. The idea is that any arcing over the surface should find this as its destination before obliterating your meter.

A variety of devices could be placed across R2 to limit the maximum voltage present in the event of a breakdown. Suitable devices include neon light bulbs (NE2s without resistors); zener, avalanche, or ordinary diodes; or other semiconductor junction devices. Traditional surge suppressors like MOVs and Tranzorbs may work but their off-state impedance may be too low compared to R2). The neon bulb is good since its impedance is essentially infinite until its breakdown of 90 volts or so is reached. In some cases, these devices will be destroyed (semiconductors may short) but they will have served their protective function and are a small price to pay to prevent you and your meter from being blown.

Frequency Response

Probe compensation similar to that used on oscilloscope probes can be implemented. However, the determination of the capacitor values is beyond the scope of this note. To put it simply, the ratio of the capacitance C1:C2 (where C1 is across R1 and C2 is across R2||R3) needs to be equal to the ratio of R2||R3 to R1 (or equivalently, to the inverse of the voltage divider ratio). C2 includes the stray capacitance and input capacitance of the meter or scope probe. The capacitor across R1 would need to sustain the HV so that is another complication. Since a 10x scope probe usually has an input impedance of 10M, the same design as used for the DMM would work with a scope. Although I have not pursued this issue, it sounds like based on the ratio (1000:1 would mean that C1 would need to be extremely small, probably smaller than the stray capacitance of the R1 and the associated wire) you would need to add a capacitance for C2 and that there will be enough stray capacitance such that no physical C1 will be needed.

If you are only interested in DC measurements, putting a .1 uF capacitor across R2 should smooth out any 50/60 Hz or higher frequency ripple.

The implementation of full probe compensation is left as an exercise for the motivated student.

- Back to HV Probe Design Table of Contents.

Simple High Voltage Probe Design Examples

50,000 V Maximum Using a 10Mohm Z-in DMM

By my rule above, I will select R2 to be 10M ohms. Fine adjustment of calibration could be made by making R2 out of a combination of a fixed resistor and a multiturn pot.

To minimally load the circuit under test, R1 should be as high as practical. Practical here means (1) low enough so that leakage over its surface is not a problem, (2) low enough that a reasonable voltage can be developed across R2||R3, and high enough so that loading of equipment being tested will not change the readings by more than a few percent.

R2||R3 is 5M ohm. Selecting R1 to be 4,995M ohm will give a 1000:1 ratio so that 50,000 volts will read out as 50 V on the DMM. 4,995M ohm is high enough that loading of a 250M ohm focus network should not be an issue (5%). 1000:1 is a nice easy to remember ratio. You could go to something higher if loading is still a concern but then leakage current over the surface of R1 becomes an even greater concern. Even 5,000M ohm is about as close to an open circuit as you can get - any contamination whatsoever will change the calibration significantly. You may find that using a resistance around 1,000M will result in less of a problem and accept the circuit loading that this value implies.

For all practical purposes, you can use 5,000M instead of the exact value of 4,995M. The error of about 0.1 percent will be less than the error spec of most portable DMMs and much less than the error spec of any VOM. And, you probably aren't going to risk your expensive precision bench multimeter on this lunacy anyhow!

50,000 V Maximum Using a 30kohm/V VOM

This is a little more complicated because you need to pick a range and then calculate the Z-in for that range. for example, for the 100 V range of a 30kohm/V VOM, the Z-in will be 3M ohms. For the same 5,000M ohm R1 and 10 M ohm R2, you would get a reading of 23 V (roughly) on the 100 V scale for a 50 kV input. The divide ratio in this case is about 218.

It is a simple matter to determine a scale and an R2 such that the actual high voltage measurement is easily calculated from the meter reading. What you want is the ratio of R1 to R2||R3 to be a nice round number. Note that switching ranges will produce some peculiar behavior due to this current division between R2 and R3. A unique R2 must be selected for each range of interest. You are already using nearly the maximum sensitivity of the meter and switching to a lower range will only slightly change the position of the needle unless you construct a range switch box as shown below.

- Back to HV Probe Design Table of Contents.

Sample Circuit

I have constructed a high voltage probe from the surplus bleeder resistor from a defunct video terminal. For the probe tip, I used a discarded probe from a VOM. The resistor and probe tip were mounted inside an insulating plastic tube with R2 included at its base. A ground cable with an allegator clip provided the connection to the chassis. A second pair of wires with banana plugs connected to the meter via a switchbox which could select between a DMM or a couple of different scales on a VOM. Potting the entire HV head is a good idea to minimize the possibility of arc-over. Remember that 50,000 V can jump several inches (2 inches in dry air approximately). See above text for other suggestions on equipment/you protection (which is not shown).

This circuit uses only a 203M ohm high voltage resistor. Since the internal resistance of a typical focus divider network is 200-300M ohm, this probe would obviously load such a circuit excessively.

```
                                      .

- SW1 - SPDT Center Off Toggle Switch.
- All resistors except R1 are 1/4 watt 2%.

- 50,000 V maximum based on the particular R1 I had laying around. 1000:1 voltage division.

- SW1-1 = Radio Shack DMM on 3, 30, or 300 V scale (10M Zin).
- SW1-2 = VOM, 25 V scale (30K ohms/V, 750K Zin).
- SW1-3 = VOM, 100 V scale (30K ohms/V, 3M Zin).

Modifications to use a higher value R1 are straightforward.

Calibration

Unless you have a calibrated HV supply, a working TV for which you have the service manual makes a good starting point. The proper high voltage is usually specified to within 5-10%. If you have a line-transformer based HV supply (e.g., neon sign transformer, rectifier, capacitor), then this would be pretty accurate based on your power line voltage. For a DMM with a constant input resistance, you can use a low voltage (like a few hundred V) on a lower range and extrapolate for the HV range. However, for a VOM, you cannot use this technique since changing ranges also changes the parallel resistance of R2||R3. You are already using nearly the full sensitivity of the meter.

More Information on High Voltage Probes

Construction of High Voltage Probes

(From: Duane C. Johnson (redrok@pclink.com).)

1. When you make the resister strings make sure that the maximum voltage rating of the resisters is not exceeded. Most resisters have a maximum rating of 200 volts. In this case I would not exceed 100 volts per resister.

2. Don't place the scope directly in series with the higher resisters. The first resister should be in parallel with the scope and and ground or the scope chassis.

   This detail is important for safety reasons. If the connection to the scope becomes disconnected then their will not be a dangerous shock hazard as would be the case if the scope was in series.

(From: Larry G. Nelson Sr. (nr@ma.ultranet.com).)

You can do this with a high voltage resistor divider network. That is what is in a high voltage probe you would buy. This can be very dangerous to you and your equipment in the event of a failure. Please be very careful. I suggest a fuse at the probe input and an MOV across the resistor to ground that will connect to the scope and use a plexiglass tube to put it all in to contain the bits if anything blows up.

(From: Kevin Astir (kferguson@aquilagroup.com).)

With respect to preventing high voltage arcing and corona, *do not* use RTV.

Places that carry the GC line will have some 'anti corona discharge dope' often called 'Q-dope'. This is *the* stuff to use at HV. You can clean it off with acetone when you discover that you didn't clean flux off good enough and have an arc underneath. Epoxy and RTV have no such advantage, and RTV releases corrosive acid while curing to boot.

Heed the warnings of other respondents WRT resistor voltage. As they said 100 V per for garden variety resistors will yield a safe margin. 200V is typical max rating.

There are special HV resistors (up to 10 kV or so) made, available into the G Ohm range. I don't know of a hobbiest source however. If you know anyone who works in nuclear instrumentation field they may be able to snag one for you. (HV used as detector and PMT bias in radiation detectors). This is what will be inside "real" HV probe from Fluke, or Tektronix.

Finally, I have a lot of experience, and am fairly blase' around HV, but in addition to "normal" 115V AC rules, (no rings, one hand in pocket, etc.) I *never* work on HV stuff (not even a TV or hi-pot test) alone. And, I make sure the 'observer' knows CPR, even if I have to wait 2 days to fix TV, so girl friend can 'help'.

High Voltage Probe Frequency Response

(From: Winfield Hill (hill@rowland.org).)

You can calculate this for yourself. The parasitic lead-to-lead capacitance of a typical small resistor is 0.05 to 0.2pF. The capacitance from the *middle* of the resistor and from any connection node between series resistors, to ground, may range from 1pF to 5pF or more depending upon your choice of a shielding scheme. Longer glass resistors intended for high voltages have lower lead-to-lead capacitance, but higher distributed parallel capacitance.

As a worst case, imagine a 1000M ohm probe made with a 2-inch long resistor. To start, place the capacitance to ground from the midpoint. If you assume 5pF of parallel capacitance, you'll see you're in trouble even at 60Hz!

- HV probes with usable high frequency response may have cleverly arranged shields which can be connected to ground, the attenuated signal output, and the input. Some shields may overlap and may be adjustable, to provide an adjustable capacitive divider that can swamp the remaining effects of the resistor's capacitance.

- These probes can be very accurate at DC and high frequencies, but the skill of the designer is tested in the transition between resistive and capacitive divider action. They can be very badly behaved in this transition region. Basically the "center" of the resistor experiences a bypass to ground (a severe dip in gain) or due to other HF components, a severe peak in gain. This can easily be 50% and cover a decade. Typically it'll happen at 20 to 100 kHz.

  One solution invokes the capacitance from a few carefully-placed concentric sleeves connected to the input and the signal output, plus an overall shield or guard connected to ground.

- Poorly designed probes can suffer from mid- or high-frequency errors and from severe pickup sensitivity to nearby rapidly-changing voltages. For example, I've seen probes that provide an output even when the measuring tip is grounded!

The classic low-voltage probe architecture of a pair pf RCs doesn't work for HV scope probes, unless (1) you're willing to have an overly high capacitive loading, or (2) you don't care about mid-frequency or pulse-shape response accuracy. This is because the RES1 value will be very high, 100M or more likely 1000M ohms, and physically long and large. So the real circuit is like:

```
+------------ CAP1 -------------+
|                               |
```

```
Probe tip o--------- Rs -*- Rs -*- Rs -*- Rs -------- etc
                         |      |      |
                         Cs     Cs     Cs
                         |      |      |
                        Gnd    Gnd    Gnd
```

Because the Rs are so high, the probe becomes a good antenna, and a shield is mandatory. Therefore the Cs "stray" capacitance is higher than you might think. I think you see the problem.

One solution is to make C1 very large, but it's just a matter of specs - if you want 1% performance over the whole range, C1 is a severe load. There is a good overall solution, which I think is fairly clever (after thinking of it, I discovered the experts had beat me to it!).

High Voltage Probes for AC Measurements

(From Winfield Hill (hill@rowland.org).)

The usual method is simply to use a capacitive divider, a small 1 kV capacitor, etc., or make the HV capacitor yourself for really high voltages, like 5 to 20 kV, use an air neutralizing capacitor, etc.

Say for example, its a 3pF capacitor. With shields. With another more conventional capacitor, say 3000pF for the bottom of the attenuator, followed with a voltage buffer if desired, and you've got a nice wide-band 1000:1 HV probe installed in the system, good for mucho kV.

More on Measuring High Frequency High Voltage

(The following was prompted by a request to measure the pulses in a capacitive discharge ignition system.) (From: Winfield Hill (hill@rowland.org).) You want to measure the voltage pulse or spike, so you'll need a high voltage high-frequency probe. Many popular HV DC probes are not suitable, such as the Fluke 80K-40 probe. Fluke does have a high-frequency HV probe, the PM9100, which is a 200 MHz, 4 kV probe. For voltages higher than 4 kV, use a Tektronix P6015A probe (buy one on eBay), or you can make a probe yourself.

First let me strongly say that designing HV AC probes which include a resistor for DC measurements is not trivial. See my comments:

- http://fstewart.ne.mediaone.net/DaEtiHhoaNews.shtml#ssE0B35885A28B1949
- http://fstewart.ne.mediaone.net/DaEtiHhoaNews.shtml#ss1F147631D050E473

Also, read the rest of this document including my other comments on this subject in the previous sections.

You can see details of an impressive 500 kV five-foot probe design, Rob's High Voltage Probe Page. Lacking a shield, this probe is suitable only for DC or low-frequency AC use.

For your purposes a simple ac-only probe should suffice. Happily they are relatively easy to make. The basic principle is to make a capacitive divider. For example, a 3pF HV input capacitor with a 3000 pF load capacitor will make a 1000:1 divider with perfect high- frequency response. You can use a home-made 3 pF, 30 kV air capacitor.

Used with a standard 1M scope input the probe will have a 3 ms droop time constant and low-frequency roll-off of 53 Hz. This is suitable for measuring all kinds of fast HV signals like auto ignition pulses, camera-flash triggers and discharges, TV flyback transformer outputs (before the HV diodes), Tesla-coil primary voltages, atomic-trap ring voltages, etc. A 30 kV input will present a safe 30 V to the scope.

```
     3pF     3000pF
  O---||--+--||-- GND
   \      |   _______________
    ''--> '--)______________)-- scope
  oops!
```

Sounds simple, but there are a few problems. A big one is labeled oops! on the drawing above, namely unplanned capacitive paths from your HV signal to the divider junction. To prevent this you'll need some cleverly designed shields.

Because your 3 pF capacitor must be able to withstand 30 kV, it'll be much larger than you would at first imagine. For example, I have used two 1/4-inch thick 4-inch diameter discs placed 1/2-inch apart, IIRC, held in place by metal bars to a long ceramic rod located off to one side. Both discs had 1/4" rounded sides to prevent corona discharge. The "lower" disc was grounded to act as a shield. The low-voltage sense electrode was a thin copper shim-stock disc with a slightly smaller diameter, stuck to the ground disc with double- sided mylar tape. A hole in the ground disc allowed a coax cable connection to the copper sensing disc.

```
                                              ,------------- HV
                                             /
     ,---------------------------------------+--,
    |                                           |
     '------------------------------------------'

        ________________________________________
     ,------ | -------------------------------,
    |        |                                |
     '------ | -+-----------------------------'
             |   |__________
             '--)__________ cable
```

Keep in mind that you should get zero output with the HV probe tip grounded - with the wrong shield layout this is a tough requirement.

A smaller design might use two concentric metal tubes, with an outer shield and an inner low-voltage electrode. The HV would be presented on a wire held in place in the center, making only 3pF of capacitance to the inner tube. Holding the wire in place with a sturdy tip mount without unduly increasing the capacitance would be a design issue.

Calibrate the probes with low voltage AC signals and an AC RMS DVM.

A second issue is protecting the scope. You have to absolutely sure your homemade 30 kV capacitor will not have a small breakdown event and destroy your scope! One solution is to make a 1:3000 divider so the output is limited to 10 V and use a diode-protected opamp follower. Also, with the 10M resistor the droop time constant is better, 100 ms and the low-frequency -3dB point is lower, 1.6 Hz.

```
     3.33pF  0.01uF
  O---||--+--||-- GND          pair of diodes to +/-15V
          |  __________            |     FET opamp
          '--)_________)- 10k -+-+---|\  follower
             coax      |       |     | >--+-- 50 ---o To scope
                      GND     10M  ,-|/   |
                               |   '------'
                              GND
```

Commercial High Voltage Probes

(From: Frank Miles (fpm@u.washington.edu).)

Both Tektronix and Hewlett Packard sell HV probes rated at 5kV and up. Bandwidths are (at least) into the 100kHz area, probably more. I imagine there are others.

The older Tek probes even had ports to refill with now-banned chemicals. The newer ones don't, but are more expensive.

Frequency response is a significant concern. Designing and manufacturing a decent HV probe is definitely non-trivial if you need flat frequency response. Many parts have significant voltage coefficients, too, as well as breakdown voltages.

(From Winfield Hill (hill@rowland.org).)

A significant part of the design effort (and cost) deals with, the problem of how to go smoothly from a resistive divider at low frequencies, to a capacitive divider at high frequencies, while keeping a constant attenuation value at mid-frequencies. This isn't easy. Consider for example, that an overall shield is clearly needed and must properly prevent the high-Z end of the probe from simply acting as an antenna (as some HV probes do! i.e. ground the tip of the probe and *still* see large signals at the output). This shield acts as a capacitance to ground for the HV resistor, routing some of the high-frequency current which is supposed to go to the output, to ground. Hence at some middle frequency there's a dip! This is solved in various ways - with shields connected to the probe tip (but inside the ground), capacitors bypassing the resistor, special resistor construction, etc. Most solutions can just as easily cause a region with a response hump, as well as a dip, or even both. BTW, these problems are much harder if one seeks to make a probe with very low capacitive loading and high frequency response. The Tek P6015A probe is 3pF, and you'll also note it has a veritable raft of response adjustments on the scope-input end.

Much of the cost of the probe is knowing how to do all this!

Incidentally, a low-cost intermediate-range HV probe is the Fluke PM9100, which is a 4kV 100:1 probe with a 200MHz bandwidth. Also the Tek P5100 is rated to 2.5kV. Most of these probes also have a derating above some d frequency.

Most of this mess you can avoid entirely by not attempting to make the probe measure DC (or at least not the whole frequency range).

(From: Sam.)

The person who contributed the following comments may not be totally unbiased but the information is still valid.

(From: Cicel Clenci (cicel@cic-research.com).)

I used many different probes on high voltage measurements and found out that their performance is terrible when exposed to even relatively low common mode voltage transients (100 V or more). Even when using differential probes like Tektronix's P5200 or P5205 measurements can be influenced by common mode voltage transients. You will get glitches on the output that are not there, these will confuse the engineers. One big problem is the high input capacitance of the probe. In order to get the best common mode rejection of the various transients and an accurate representation of the input waveform, you must reduce the input capacitance. 4 pF or 3 pF input capacitance is too high, when dealing with high voltage fast transients, and the compensation is not as easy as it might seem. Look for 0.5 pF or lower input capacitance. There are many issues that need to be addressed when designing high voltage (differential probes). Just take a look at CIC Research HV Probes Page for probes that outperform Tektronix's or LeCroy's probes.

DISCLAIMER

The procedures described in this document require access to potentially dangerous voltages, proximity to the CRT and its implosion risk, and other possible dangers lurking inside a television set. Furthermore, while your symptoms may fit those described below, there is guarantee that resoldering the tuner or IF module WILL fix your problem. The actual cause could be elsewhere.

We will not be responsible for personal injury resulting from attempting these repairs nor damage to the equipment that may result from lack of soldering experience or inadequate desoldering or soldering equipment.

- Back to Sony Solder FAQ Table of Contents.

Introduction

Scope of This Document

Problems with bad solder connections, mostly in and around the tuner and IF boxes are very common with several series of late model Sony TVs. The repairs are straightforward though perhaps tedious and on some models, removing the tuner and IF boxes from the mainboard can be real fun.

Some of the common symptoms include:

- Picture turns to snow or shows other reception problems.
- Inability to tune blocks of channels.
- Channels change randomly as if TV doesn't like what you are watching.
- Loss of picture - just raster and high pitched whine.
- Noisy or muted sound, volume buttons have no effect.
- Controls have no or unexpected affect (console or remote).

Note that many other manufacturer's TVs are also susceptible to similar symptoms with similar causes.

The articles in this document have been compiled over the last few months from postings on the USENET newsgroup sci.electronics.repair.

Contributions are welcome to increase the coverage of this set of notes as well as those for the very similar set of problems and solutions for late model RCA and GE TVs: "RCA/GE TV (CTC175/176/177) Solder Connection and EEPROM Problems".

Proper attributions will be made for all providers of solutions. I apologize if I have incorrectly referenced you or left your name off. I will be happy to make any necessary corrections in the next revision. Please email me with any additional sections. I would very much like to improve the details of the repair procedure if possible.

Corrections and additions to any specific symptom or solution are also welcome.

I have no connection with Sony Electronics or any other manufacturer of consumer electronics. These articles have been included unedited except for some spelling, grammar, and format cleanup.

Safety

Before removing the case on any TV or monitor, make sure you understand AND follow the safety guidelines provided in the document: Safety Guidelines for High Voltage and/or Line Powered Equipment.

- Back to Sony Solder FAQ Table of Contents.

Solder Connection Problems and Solutions

Symptoms of Cracked Solder Connections

Here are some typical sets of symptoms resulting from bad solder connections in and around the tuner of this series of late model TVs. Most of these problems are characterized by erratic behavior of one form or another. However, total failure of reception is possible:

> "I have a two-year old Sony Trinitron TV. When it is turned on, picture perfect. But it can only last about 30 mins, then it looks like it has difficulty to receive signal. On its hardly seen screen, you can see all channel display only one TV station signal (I am using cable). After I turn it off for a while and turn it on again, I got good picture again. The time it last depends on the time I turn it off. Occasionally, if it past the first 30 mins, it seems it will be good forever."

> "I have a Sony KV-27TS20 tv that upon power up will drift back and forth from a clear picture to a whining static fill mess. This happen for about five minutes then the clear picture stays."

> "My Sony 27" (Model KV-2782R) is having a problem with the tuner (I think). When the TV comes on, I have no control over any of the functions. The channel changer, display controls, TV/Video selector all have no effect on the TV. I can, however, see the source (VCR/Laserdisc) that is plugged in to my Video 1 jack, but the picture is very dark."

> "I have these 2 practically identical (at least on the outside) 13" TVs, and they both have the same problem: they act like if someone was messing with the antenna - the picture comes and goes, or just 'jumps' vertically every couple of seconds, the sound sometimes goes away too (turns into just noise). On the KV-1395 the problem sometimes stops - either the picture is already good at power-up or it just acts up for about 20 seconds and

tunes in, the other one is totally unwatchable.

I assume that this is a common problem with these and some other Sony TVs - I remember long time ago someone had posted repair tips on Sony tuners, but I could not find them on the FAQ sites."

One more detail: At power on both the TVs cycle through channels 2-6, with no picture on screen. You have to select a channel for the picture to come on. Is this normal with these models?"

"I'm having a problem with my KV27XBR55 (mines in the XBR series). I realize now that the problem started many months ago when I heard the sound degrading (I thought the sub-woofer had blown). But after moving recently the sound got very bad just before the picture dropped out too.

If I unplugged the set for a while (minutes to hours) it would work for several minutes to several hours after plugging it back in. And... (forgive me! :) a well place thump on the cabinet could get either some video/audio static or actually restore the picture and sound.

I thought the jarring of the move may have loosened some circuit boards or connectors, so I opened the back and reseated every card/connector I could easily reach. That seemed to work but the next day it died again.

When it's having its "problem" I can get a picture by selecting a video input (like the VCR) but no sound."

"This TV works fine for a few minutes, but after warming up it demonstrates a tuner problem. When a channel is switched to, it will take ~5 seconds to lock into the station. Then it will not stay locked in, but instead drift to an adjacent channel for the audio.

I have been reading here for several months, and based on other postings of similar problems, thought I could try to fix this. I read the pertinent parts of Sam's FAQs, and I photocopied parts of the Sams' Photofacts.

The photo of the A-Board shows one tuner box, while I have a box labeled RF-AGC [IFB-450M 1-464-598-11 AE7C20] and Tuner [1-463-603-13 BTP-201 D7011BY]. Adjusting the blue turn knob in the top of the RF-AGC did not improve the problem. I have not adjusted the white turn knob that is in the RF-AGC box. It is difficult to get to because of the proximity of the adjacent Tuner box.

My questions are:

- Should I adjust the knob inside the RF-AGC?
- Should I solder out the Tuner box and replace it?

- Should I solder out the RF-AGC and replace it?
- What will a tuner and/or RF-AGC cost and where can I get one?

I admit to being a novice, but I have enjoyed reading the troubleshooting advice that is discussed here. Although I could take this to a shop, I would like to try and fix it myself." Do not touch any of the adjustments! Problems that happen suddenly or have significant consequences are rarely due to adjustments drifting!

None of the modules need replacing but if you screw up :-) the IF is about $90 and the tuner is about $100. Resoldering all suspect joints will cure your problems.

> "Would like to know if any users have discover why the tuner or TV signal fails to work until the set has been on for about 10 minutes. This problem shows up on the VHF channels - the UHF channels will work. A number of the same vintage sets are starting to show the same problem. Any suggestions would be most welcome."
>
> "I turn it on, and after 5 minutess, it goes to static. I can't even play a tape in the VCR (which the signal runs through first)."
>
> "I have a 4 year old SONY TV with a trinitron tube. When the TV is switched on, it does not receive a few station. For some stations it just snows, on others it shows a very distorted view of some other channel. The problem goes off automatically after 4-5 minutes and then there is no problem as long as the TV is on. The lower frequency channels take the longest time to come back. It is a cable ready TV and when we are viewing cable, the lower channels have the same problem. Most of the time the higher band cable stations are ok from the start.
>
> We are thinking that it may be a problem with the tuner. It does not look like heating problem as the problem is there only during the startup. Can it be a problem of the tuner PLL? or is it something simpler?"

This may be an actual electronic problem but would still recommend doing the resoldering first.

"Does anyone know how I can go about fixing a tuner problem with the Sony TV? The tv signal will come in and out, the signal will come in only for about 30 seconds and is gone for about 15 mins. I have checked all electrical cables, cable TV and antenna cables too.

I have tried contacting Sony, they seem don't care about their consumer services. I have emailed them and contacted their Sony Store dealers, and they would only say it would best to buy a new Sony. I personally will not buy another Sony every again.

"I have a Sony 32" console type TV and the model number is KV-32TW75. The TV set is about three years old. It worked perfect until few month ago. When the set is direct connected to antenna through the UHF/VHF terminal, it worked perfect for about 1 minute then lost all the signals and had no picture. Then I connected the antenna to a VCR first, and connected both the UHF/VHF and video output from the VCR to the TV, it worked all the time. I thought maybe the signal was weak, by turning on the VCR may increase the signal so I didn't pay that much attention. Yesterday it started getting very poor picture quality. I disconnected the video input it got no picture at all. With the video input connected, it doesn't make any difference with or without the UHF/VHF input connected and the picture quality is way low. By connecting only the VCR UHF/VHF output to another TV (this one is a 19" sony with no video input terminal), the picture is perfect. Anyone have any idea what cause this problem and how can I fix it? Thanks in advance.

"This small electronically tuned Sony (Sony KV-13TR14) has this problem:

After about a minute of power on, picture snaps to another (cable) channel for an indeterminate amount of time and then snaps back to the original channel where it operates okay for periods of time (a few seconds to a minute or so). This goes on for several minutes then usually stops and doesn't happen again until the set is turned off, etc.

The local cable company told me that this model Sony had "a bad 'board' grounding problem" or some similar 'grounding' flaw.

I wrote to Sony asking if they were aware of a manufacturing problem with this model and they replied no.

Of course its out of warranty and there's the judgment of taking to the repair store or just buying new.

I'd sure like to repair this myself and any help greatly appreciated."

"I have two Sony TVs that seem to have tuner problems.

The first one is a 13" TV about 4 years old. After about 1 hour of use, the VHF channels go away and all I get is a scanning type picture and a high pitched whine. The UHF and Video input still work. (I do not have cable.) Turning the set off for a while will fix the problem. Also, the TV has the problem faster when it is hot out.

The next one is a 27" TV about 5 years old. When I first turn it on, it works fine for 1 minute or so. Then the VHF channels start to dissapper in the same way as the other TV. This starts at channel 9 (the top VHF station) and works its way down. The problem only affected channels 9 and 7 but not 4 and 2 go out too. After 5 or so minutes they are all back. UHF and Video input still work.

Would you suggest re-soldering the tuner modules for these TVs?"

"I'm wondering how easy it is to replace a tuner module for my 13" Sony. Repair shop said

> that it is a very expensive part and is very difficult to replace. I'm skeptical about the expense because the same shop replaced a tuner module on another tv I had and they listed the part as $5. If it's easy, any ideas about where I can find a replacement part?
>
> A replacement tuner for a Sony 13" tv is a little expensive. I would suggest that you check the solder connections in the IF block before investing in a new tuner."

General Repair Considerations

Caution: See the document: Troubleshooting and Repair of Consumer Electronic Equipment before attempting to repair or replace the tuner module. You *must* have proper soldering equipment and desoldering tools. Attempting to remove, solder, or replace the modules(s) without these *will* result in a mess and a very expensive bill when you finally take your TV to a professional.

Someone brought me a TV to look at. After a little prodding, it was learned that he had lent it to a friend and it died after six months or so. The 'friend' then attempted to replace the tuner module based on the description on a refused estimate from a TV service shop. He did not have proper soldering equipment - perhaps only a Weller 100W soldering gun. Needless to say, the TV did not work - nearly every pad on the PC board under the tuner had been destroyed. I had to run wires from the pins on the tuner to the their destinations on the mainboard. It was not fun. Luckly, no permanent damage was done but it could have easily been a lot worse.

You need to remove the two metal boxes (if there are two - one is the tuner and the other is the IF). On some sets like the 13 inch models, these are readily accessible once the rear cover is removed. On some 19" sets, the pins that need to be desoldered to remove the modules are partially blocked by the plastic bottom frame that holds the mainboard.

Once these are pulled, snap off the *bottom* shield of each and go over all solder connections - both through-hole and surface mount. You may be able to pinpoint some hairline cracks. The pins that go to the mainboard on the tuner and a coil on the IF module seems to be popular locations for problems. Also check the solder connections to the metal case shield and the fingers that need to make contact when the cover is snapped in place.

Don't touch any of the top-side components. Take care not to introduce any solder bridges or overheat anything. However, you may need more than a 15 watt iron to adequately heat some of the (shield) connections.

Descriptions of the Solutions

Here are some of the responses - many from experienced techs who fix (too) many of these sets:

(From: Davetech (dnesbitt4@ vcom.is.net).)

If that is the one with an IF (VIF?) module beside the tuner, shoot some freeze spray into the module while it is playing. I had a Sony last week that turned out to have a bad solder joint in that module, and freezing it pinpointed it. It too, was "searching" through the channel.

(From: Gary Klechowitz (klechowi@execpc.com).)

On Sony TV/monitors of the early 90s there were problems with solder connections in the AGC module. This module was a solder-on board enclosed in a metal box very much like the tunner. There were tunable coils inside and one or two of the legs from the coils would crack free from the circuit. This caused a gray screen effect but also caused the audio to drop out as well. This may be a similar problem. Look for any delay line modules. They are in small plastic cases sometimes orange colored and solder edgewise onto the main board. Inspect the solder connections there as well. If I remember right there was a delay line that had three legs and one of the solder connections would crack and you loose things like low level B & W. That would cause your problem.

(From: Jeff Rigby (jeffg2@ix.netcom.com).)

If a sound and picture problem then look for bad connections in the tuner and the IF module. The IF module generally has bad connections at the pin connections for the Coils (IF, AFT, Disc). The tuner has bad grounds on the outer edge of the tuner board. This problem is generally temperature related=> it will work when cold or hot but in one condition or another will give problems.

As a check, with the back off and the set operating lightly tap the IF can and the tuner and see if the picture or sound changes.

Sound *only* problems are usually due to surface mount caps on the MPX decoder board.

Video only problems are a surface mount capitor problem in the comb filter board.

Both of the above are temperature related and usually get better as they heat up.

(From: Tom Cat (kanduit@juno.com).)

Remove IF 450, solder connections around AFT coil... and any other connection that looks bad... (very common problem).

(From: Mr. Caldwell (jcaldwel@iquest.net).)

Open the IF assembly and resolder the coils, tuner should not need resoldering but if the problem persists you can resolder the ground connection in it if it does.

(From: Brian Leeman (bryboe@mint.net).)

I have run into a few of these...

In every case it has been due to one of the grounding "fan" leads that runs from the PCB to the metal case having a cold joint.

It has always been the lead that fastens to the top of the case directly to the left of the AGC trimmer (looking at the trace side).

These problems are gravy for techs, but it is a shame how poorly Sony executes the manufacture of their consumer electronics. Talk about mass produced junk...

Sorry for the rant, but if you work on this stuff, you have to agree!!

(From: Mister M. (mister-m@ix.netcom.com).)

You should start by checking for these symptoms. If the signal goes to snow then tap on the tuner to see if the signal returns. If it does then proceed to pull the tuner out and pop the shield to solder all grounds around the perimeter of the tuner. (being very careful with the solder splashing). If your signal seems to drift out and come back not snow but a smeared picture or a detuned like symptom then pull out you IF201 if block pop the shield and look for a AFT coil. Resolder and your back in business.

(From: Viawest (viawest@azstarnet.com).)

Invariably, the Sony KV-13TR14 and most of the ones near it are famous, and plaqued with bad solder joints. be very careful not to cause any solder bridges when resoldering the pc board. you must remove the shields from the tuner assembly to accomplish this repair. By the way, check the rest of the board *before* tearing your tuner apart. Sometimes it is a bad spot other than in the tuner itself - usaually the power supply.

(From: Raymond Carlsen (rrcc@u.washington.edu).)

It sounds like you're describing the classic "tuner with bad solder connections". You'll have to remove the tuner and pop the covers. Resolder all the grounds around the outside of the little PC board. Also solder the ground tabs where the metal can pokes through and grounds the foil in half a dozen spots around the middle of the board. Look at the top side of the board to see where the metal goes through the PC. Work carefully! Don't get any solder "bridges" in there. Use a large enough (and hot enough) iron that will fully heat the connections without having to heat them for too long a time, but not so large a tip that will cause bridging. Re-install the tuner and pull the little can next to it. The PC connections that run from the board to the chassis need to be gone over. Resolder any connections that look flaky. Re-install that sub-board and you're done. That should take care of it. I've never had to do one twice.

Successes from Non-Techs

(From: Bill Somrak (cooncat@ncweb.com).)

Well, thanks to all those that suggested that I look at the I.F. assembly for poor grounds and soldering.

I pulled the unit from the main board last night, removed the tin covers on both sides. On the side with the coils and chips in it, there wasn't much to be done, so I left that pretty much alone. The other side was mostly surface mounted stuff. I didn't see anything that was grossly under soldered. Several joints looked "cold". All I did was touch up as many ground connections as I could .. re-solder the cold looking ones, re-do the two chips. I also bent out the little tabs that are on the covers of both sides of the unit .. these tabs apparently make contact with ground spots on the unit. After all this I resoldered the unit back onto the main board .. crossed my fingers, plugged the set back in and powered it up.

Success! No matter what channel I tuned to, the set came on (with picture) instantly. I powered it down several times to let it cool down again, and tried the experiment over and over ... never a failure. So, this morning, before going to work, I put the cover back on the 13" Sony and its working as well as the day I got it (1991). I did note that this is the ONLY Sony that I've had problems with. It was assembled in Mexico (strike 1???), and the I.F. tuner was made in Korea (strike 2???). I wonder if other's have found "non-Japanese" made Sonys to have less than the expected reliability?

- Back to Sony Solder FAQ Table of Contents.

Miscellaneous Problems

Erratic Picture and Sound

> "At start-up, picture comes on OK, then goes dark - loud Crash-Boom sounds from set. After turning off - letting sit - on -- repeats -- several times, seems to stabilize, stay on, and function Ok. I'd appreciate any advice so I know if the repairman has a clue."

This may be tuner/IF related but other bad connections could be involved.

(From: Mr. Caldwell (jcaldwel@iquest.net).)

What should be done anyway:

- Resolder all the TO220 package regulators on the main board.
- Resolder the Horizontal Output Transformer.
- Remove open and resolder the IF pack coils.
- Remove the power supply itself and resolder the output diodes.

There is a capacitor in the power supply that's caused some problems, it's the 22V/27V line I think, a 1000uf@25v or 1000@50v. I've just been replacing it with a 1000uf@50v.

If you do all of this you should not have much else to worry about with this TV.

Noisy Audio

> "I bought a Sony TV (model KV-27TS27) in 1992 and had some problem with the tuner right after the warranty expired but fortunately my Visa card's extended warranty covered some of the repair cost. Now the sound is getting very noisy and I suspect the audio module is not working properly. The TV is not covered by any warranty and I'd like to take care of it myself. I wonder if any one out there knows where I can order an audio module for my Sony TV."

(From: Mr. Caldwell (jcaldwel@iquest.net).)

The MPX 'IC' is a custom mini ceramic PCB with components masked onto it. It is easy to spot and as it is a DIP but you can see the components on the 1" x 1" ceramic 'board'. Capacitors on this board leak and cause a failure in the audio. It will do all sorts of weirdness and then fail.

Call Sony and politely gripe.

(From: John D. Carder (jonetek@aloha.net).)

I buy the Sony SBX1637 MTS module from Matt Electronics for about $7 compared to Sony's price of $68! I have never had a repeat failure yet.

Intermittent Audio

> "My Sony KV-32TS20 television (4 yrs. old) has developed an audio problem. The stereo LED no longer lights ups and I get intermittent popping/crackling along with the audio. I have tried switching between mono and stereo and the audio sounds the same in either mode (sounds like mono in both modes to me). This set had the infamous Sony tuner solder joint problem in the past which was resolved by resoldering the tuner to main ckt. board connections. Now I resoldered the audio section solder joints on the main circuit board but the audio problem remains."

(From: Mr. Caldwell (jcaldwel@iquest.net).)

Defective IC on audio pcb. Little green part with tiny caps on it smack in the middle of the board with the a/v jacks on it. It's a ceramic PCB, about 1" square and it will have corrosion because the capacitors start leaking.

Periodic Audio Noise

> "I have a SONY KV-A2522U (U.K.) TV. About every hour or so it gives out, through the R. hand speaker, a very loud thunder like noise. (and just as loud) Even when the volume

is set low? If I tap the set with my hand the noise stops. Telling me it's a loose connection?"

(From: Steven Turner (steven.turner@amigabee.org.uk).)

Very common fault this. Locate the Metal heat sink running front to back resolder all the IC pins on the heat sink. That will fix it.

Intermittent Picture

(From: John de Rooy (solaris@dds.nl).)

A few months ago someone gave me a Sony 27" KVE2911d television, which was repaired by Sony about 8 months ago. The set came up ok with sound and stereo LEDs but no picture at all. After warming up about 15 minutes the picture returned and stayed until switching off.

I talked to a Sony technician about this case and told him the set was already repaired by them 8 months ago for a lot of money and asked for help. While I think the Sony service is very poor by luck this time he told me about the bad solder connections from the tuner and IF boards.

I was very happy with this information and started taking off the cover for a check! But bad luck! Sony already had resoldered every connection of the tuner and IF boards. After a long time trying to locate the problem (only 15 minutes a day to measure!), I found out the problem was on the small CRT board located on the neck of the CRT. I resoldered the entire crt board (10 minutes of work) and the set has been OK since then.

- Back to Sony Solder FAQ Table of Contents.

Service Information, Costs, Reliability

Getting Out-Of-Warranty Repairs

If you are not inclined to tackle these sorts of repairs for whatever reason, you may still have recourse with Sony. If pressed, they will often cover at least part of the cost of the repair.

(From: Mr. Caldwell (jcaldwel@iquest.net).)

Call Sony Customer Service and explain the problem to them and see if they may cover parts. It's more than likely the tuner and while it can be resoldered and repaired in most cases you can do nothing wrong by asking Sony to cover some of the costs. A 3 year TV isn't that old.

Call Sony and see if they'll pay for the parts and then call a Sony service center and get an estimate and THEN tell them you've got authorization for the part from Sony. ;-)

Warning About Sony Tuner Repair on Certain Models

(From: Gary Warner (warner1@airmail.net).)

Lately I caused myself a lot of grief quite innocently. I thought it might stop a problem before it happens to share this:

On a Sony KV-27S15 I needed to replace the tuner. The tuner is on the "A Board". Looks easy enough to get out but, one end of the board won't clear a metal frame that runs across the center of the main PCB. It's only a small part of the frame and was easily bent out of the way. Unknown to me, bending the frame caused the "solder land" that's under the frame where I bent it, to twist and cause an open connection all around the land. After replacing the tuner and the "A Board" I plugged the unit up, turned it on and POW, the power supply and the horizontal output were all bad.

After a day of troubleshooting I found that the crack had opened the only ground reference for the "feed back" loop of the transformer in the power supply (pin 12 of T603). The power supply lost it's ability to regulate and it ran at "full throttle".

What an embarrassment for me as this was an in-home tuner replacement and now I "Blew up the set". Anyway, everything is okay and the customer understood when I explained all this to them. It was one of those hard lessons that I thought some of you could appreciate and might avoid yourselves.

BTW, the tuner was bad like the tuners in the JVC's, where it intermittently looses the tuning but it's not a physical (connection) or thermal problem. My guess was the PLL IC was checking out. Until now, this model was free of any tuner problems for me.

Sony Service Bulletins

(From: Lynn H. Blakely (lynns@arkansas.net).)

I thought you should know about the service bulletin #203R3. This covers a lot of different models. It shows where to solder the grounds and they have a new cover to replace the original one for the tuner. Also, many of these and similar models have sound problems these can be repaired many times by replacing the SBX1637-11 module. The Sony part #8-746-371-20.

Also see the section: Noisy Audio.

Preface

Author and Copyright

Author: Samuel M. Goldwasser

For contact info, please see the Sci.Electronics.Repair FAQ Email Links Page.

DISCLAIMER

Some of the procedures described in this document require access to dangerous voltages, hazardous laser radiation, moving mechanical parts, and other potential risks to personal safety and damage to equipment and property. The authors and contributors to this document will not be held responsible for any direct or collateral damage which might result from following the suggestions or recommendations contained herein including but not limited to: shock, burns, electrocution, vaporization, meltdowns, torn flesh, destruction of the equipment, and local or planetary wide power disruptions or implosions.

- Back to Printer/Copier/Fax Repair FAQ Table of Contents.

Introduction

Most of the articles in this document have been compiled over the last few years from postings on the USENET newsgroup sci.electronics.repair. I cannot vouch for the accuracy of all of the recommendations they contain but have edited out anything I felt was totally bogus. I apologize if your response is not here - it could have been that I missed the posting and will welcome contributions.

Note that many of the problems and solutions are listed with respect to specific models. Even though your model and problem may not be included, there is a good chance your problem is covered but with respect to some other model printer or copier. Therefore, search for a generic description of the symptoms and you may get lucky.

Since the operation of laser printers and photocopiers is very similar, check both chapters to see if your problem is covered when dealing with either type equipment.

There is also a chapter on fax machine problems though it is pretty sparse at the moment.

Eventually, this document may be expanded into a full "Notes on the Troubleshooting and Repair of Printers and Photocopiers". For now, be happy that it exists at all! :-)

As always, comments, suggestions, and corrections are welcome.

Portions of this document also appear at PrinterCartridgesInk.com under "Printer Advice". As far as I know, this was done without my permission but since he included the appropriate attribution and copyright notices, I'm not complaining. The formatting may even be a bit better. :)

See the document: Troubleshooting and Repair of Consumer Electronics Equipment for general information on tools, test equipment, tips, techniques, and much more.

SAFETY

Also see the document: Safety Guidelines for High Voltage and/or Line Powered Equipment.

While printers are not generally considered dangerous pieces of equipment (compared to TV, monitors, and microwave ovens, at least), some types - laser printers in particular - present a variety of hazards that should not be underestimated. In addition, photocopiers - particularly larger high speed machines - need to be treated with great respect while servicing.

There are minimal dangers in servicing most printers. However, there may be exposed line voltage near the line cord and long hair or neck-ties may be sucked in along with paper! Laser printers have their lasers but these are generally located such that accidental exposure to the beam is minimized. The toner in copiers, plain paper faxes, and laser printers may be harmful if inhaled and is a potential fire/explosion risk if carelessly vacuumed. Each of these possible safety issues is discussed below with additional specific information in the chapters for the equipment to which it applies. All in all, working on printers is relatively low risk.

The first set of items applies to all line operated printers:

- The input power is 110 VAC (or 220 to 240 VAC depending on where you live). If it is necessary to work inside with the power on, identify the location of any exposed terminals and cover them with plastic electrical tape or block accidental access in some other way. This is much more dangerous than the high voltage present in laser printers and photocopiers (see below).

- Some equipment of this type uses switchmode power supplies. Their internal voltages may exceed 300 VDC, include large capacitors, and the entire front-end is likely line-connected. Aside from staying away, if power problems are suspected, one must take extreme care in troubleshooting these types of power supplies both for personal safety and because it is extremely easy to destroy them (and possibly the powered equipment) due to a misplaced probe. If there is NO large power transformer near the power input but one or more smaller transformers (possibly with HV warning labels) amid-ships on the power board, you probably have a switcher! See the document: Notes on the Troubleshooting and Repair of Small Switchmode Power Supplies for more information.

- Moving parts can grab dangling neckties (yes, I know, you haven't worn one of these in 17 years!) and jewelry - remove any you may be wearing.

- There will be all sorts of sharp sheet metal and other parts to gouge flesh. Avoid sudden uncontrolled movement.

- Dot matrix and thermal print heads may be HOT - stay clear.

- The inks, while probably not toxic, are certainly indelible, so don't wear anything you care much about!

The following apply to laser printers and photocopiers:

- In addition to the AC line input, the fuser lamp is usually powered from the line. Thus, dangerous voltage may appear (come and go as the fuser cycles) at contacts deep inside the machine - possibly hidden from view but not touch. The main motor drive may also use line voltage.

- The main drive motors and gear trains in this equipment are quite powerful, especially in large photocopiers. There is no telling what can get sucked in due to carelessness.

- The fuser is very HOT (heat-wise) and can cause a nasty burn. It remains hot for a long time after power is removed.

- There are several high voltages used to charge the various corona wires. For most modern equipment, the maximum current available from these is extremely small (less than 1 mA) so actual danger is minimal. However, some older copiers may have more dangerous high voltage power supplies. Don't assume all are the same! Interlocks are *supposed* to prevent operation except when printing but they can be defeated.

- Powdered toner is not something you want to inhale (in addition to getting all over EVERYTHING). Also see the additional toner warnings at the start of the chapters on laser printers and photocopiers.

- The photosensitive coating on the imaging drum may also be toxic if it should flake off or become powdered. Avoid direct contact.

And finally, for laser printers and laser photocopiers:

- The laser in all but very old (or high performance phototypesetters and other specialized imaging systems which this document does not address) are IR - invisible. So, you cannot detect it by eye - an IR tester circuit, IR detector card, some camcorders, or other means will be needed to determine if the laser is actually working. The beam will also be well collimated and thus especially hazardous to vision since it will be focused to a fine point on the retina.

  Fortunately, under normal conditions, the laser beam will not be turned on unless all interlocks are closed and a page is actually being printed and/or will be in constant motion as a result of the scanning mirror (which reduces the risk considerably). (It is virtually impossible to get to the laser beam before the scanning mirror without total disassembly.) However, certain failure modes could result in a stationary beam which ignores the interlocks so take care whenever working on a laser printer with the covers removed.

- If your printer does use another type of laser (like helium-neon), there may also be a high voltage power supply for that which can really bite.

- Back to Printer/Copier/Fax Repair FAQ Table of Contents.

Printer and Photocopier Technology

Dot matrix printer operation

These are the only type of impact printers still in wide use. A set of steel pins - typically between 9 and 24 - strikes the paper through a fabric or carbon film ribbon. The pins are activated by solenoids which are controlled by the printer's control logic. Multiple passes may be used to increase the effective number of pins and improve print quality (letter versus draft mode).

For text, an internal character generator (ROM) converts ASCII codes to pin firing patterns. For arbitrary graphics, the actual bit map is read out and used to control the pin drive.

The paper, carriage, and sometimes ribbon movement use stepper motors. These, their drivers, or interconnect cables, are common problem areas.

Daisy wheel printer operation

These may still turn up at yard sales and flea markets but have virtually disappeared due to slow speed and limited flexibility with respect to graphics. In their defense, for basic text, their quality is superb for a low cost printer.

Instead of pins, these use a wheel with all the possible characters molded on 'leaves' around the perimeter. The wheel spins to the correct character position and a hammer than taps the leaf to impress the character (via a ribbon) on the paper. Carriage and printhead movement is similar to that of dot matrix printers.

(From: Peter (hedgieus@yahoo.com).)

Some history/trivia:

The daisy wheel printer (interestingly) was patented before World War II! It was GE or a GE engineer, but only commercialized by Diablo, which was later bought by Xerox in its expansion to California. Later spinoff was Qume, and then lot of companies got into it, some Japanese, some local (California). Daisy wheel technology was killed by the laser printer becoming cheap and having better quality. Original impetus for it was speed: IBM Selectric was able to print at 10 char/s (good for 110 baud modems!). It moved the whole ball (big inertia). Daisy wheel only moves one spoke, (to print one character) and got 30 chars/s.

Near the end of the era, 'on the fly' printers got as fast as 80 char/sec.

Ink-jet printer basics

(From: Tony Hardman (AHED_CIJ@f54x19.demon.co.uk).)

There is a US publication called 'The Hard Copy OBSERVER' from Lyra Research Inc. Tel: (617) 322-0708.

This discusses the latest technologies and who does what. It may not cover the print head technology very much but is a good read if you are into print technology in general.

There are many companies that sell variable print processes. One I have heard of is RALFLATAC. They do a brochure that does an excellent brief of most technologies available for printing. They have UK (and many other sites in europe) and US sites. UK Tel 01732-583661, US Tel (704) 684-3931.

I have no idea if you can easily get copies of either publication from them so here goes a very very brief description.

Ink jet printing has two main types, continuous ink jet (CIJ) and impulse printing (DOD) (drop on demand). Each of these can be a single jet, or an array of jets.

- CIJ as a single jet is used on product identification (sell by dates, serial numbers) on high speed industrial applications.

  CIJ is a continuous jet of ink cycling round a system and occasionally (when required) a drop is deflected out of the stream onto the paper. The stream is modulated to break it into a consistent drop size. The deflection works like the beam on an oscilloscope. If you charge 1 drop and pass it between two high voltage plates it is deflected. This system also requires cunning mechanics, but the support electronics is much more complex, and probably one of the reasons for its performance limitations being not up to what you might expect. The calculations of the aerodynamics of drops being deflected is no small task, even if look up tables are used.

- DOD is often an array of small jets used on desk top printers.

  DOD works in principal like an old Dot Matrix pin printer. Instead of firing a pin at a ribbon, a drop of ink is fired at the paper. The drop is fired by either a piezo crystal squeezing the ink out of a small tube, or by boiling the ink and the vapor forces the ink out of the chamber. The key to both of these processes is in the mechanical design of very small components if 300 dpi is required. The control electronics is a bit cunning, but I figure it is the easy bit.

A primer on priming

The priming station of a typical ink-jet printer (e.g., HP DeskJet 500C) includes a rubber seal ('boot') and small pump to actually suck on the end of the print cartridge to free up nozzles (there are 50 or more in a typical print cartridge) that have dried up or become clogged. It may fire all the nozzles at some point during this process as well. It also includes rubber 'flappers' which the end of the cartridge pass over to wipe off excess ink.

Priming and cleaning are normally done automatically upon power-on and possibly between pages. However, additional cycles may be needed at times.

With the water based ink, even if the printer is powered off properly which seats the cartridge(s) on a rubber seal, some evaporation occurs so priming will often be needed after it sits idle for a while. Note: Don't kill power to an ink-jet printer as soon as your printout pops free - it needs to position the printhead and cartridge(s) on the rubber boots. Wait until the printhead stops moving and clunking. Some (older) printers don't even have a seal in which case letting it sit idle is even more likely to result in problems.

If there has been ink spilled into the priming area, it may clog up the little hose connecting the priming station to the pump - I have used a wooden toothpick to clear the hole though this may be risky if it should break off. With care, a wire rounded off at the end so as not to puncture the tubing can also be used. Complete disassembly and washing of the parts is probably the best but is probably a pain.

A bit of ink-jet history?

(From: John Nagle (nagle@netcom.com).)

The original ink jet printer of this type was the Teletype Inktronic, which introduced the concept of video-type distortions to printing. It appeared around 1970, and was so bad nobody tried again for years.

(From: Tony Hardman (AHED_CIJ@f54x19.demon.co.uk).)

I guess that is why it was used in industrial applications I guess. Were the 'video-type distortions' a deliberate feature or just a coincidence of how they turned out?

Who are/were Inktronic???(apologies to anyone connected with them) I guess that may have been spin off development from some work contracted out by IBM, but it was so....?? (costly/low res/unreliable - choose one) they lost interest. Although one of the very early machines still runs well on a textile mill. It had a large number of jets side by side, and may be multi color too. I've only seen the patents so don't know exactly what it looks like.

I thought original ink jet printer was a chart recorder developed in the last century. It was just a nozzle on deflection mechanism, and was not modulated so it was always printing. It was a lighter mechanism than actually trying to move a pen and so had some performance advantages over other technology available at the time...

The same reason CIJ still sells world wide, even when high resolution DOD is biting at its heals.

Inkjet types (at least from a Xerox perspective)

(From: Peter (hedgieus@yahoo.com).)

Here are history/trivia. (I used to work at Xerox marking technology group, working on ink-jets and daisy printers.)

- Type 1 (or "push") ejects continuous stream (under pressure). The discovery goes back to Hertz (one who has the unit named after him) and theory is described in the book: The Theory of Sound, by John William Strutt, 3rd Baron Rayleigh.

  Type 1 was commercialized first for printing postal labels and other similar applications. It was a big machine - 5x5x5 meters! Clumsy but fast. This was before laser printers. IBM published detailed (and definitive) research paper on this - circa 1985.

- Type 2 (or pull) uses electrostatic field to extract the drop. It was never commercialized.

- Type 3 (push-pull) or DOD is what we use in small printers now. Xerox put lot of money into developing this in the seventies, than (just when it achieved some 10 kHz (drops/second/nozzle) in the lab, (considered necessary minimum for viable printer) Japanese companies introduced first machines on the market. (I think first was NEC or Ricoh) and Xerox dropped the project. (Manufacturing people in Webster estimated that they can never produce it at profit, facing this competition.) Later, Xerox was using Sharp inkjet heads and printers, under Xerox label. Some research was then revived, (I suppose in cooperation with OEM supplier (Sharp).

Response times of resistance heater elements in ink jet printers

The ink drops that make up the 'image' on the paper from an ink jet printer are expelled by microscopic resistance (thin film or the like) heaters with response times in the 10s of microseconds if I recall correctly. When living in the macro world, it is often counterintuitive to realize that a resistance element can have such a fast thermal response.

(From: John Eaton (johne@vcd.hp.com).)

The trick is that a lot of the energy that you pump into the resistor leaves the printhead with the fired dot. One way to detect Out_of_Ink is to mount a thermistor on the printhead and watch for a sudden rise in temperature as you are firing.

How many colors can an ink-jet printer can produce?

> "I use a HP680C in the office, and it have two cartridges, one for black and one for color (yellow/cian/magenta?). If the printer fire one drop of each ink at a given point, we can have only 6 different colors (ignoring white and black). If it can fire two or more drops at a given point, maybe we can have more colors, but I suspect that the printer use this to control quality of the presentation, not the number of colors. Anybody knows for sure? With dithering it can make more colors, with reduced resolution."

Like most print processes you only have a limited selection of inks to use. Full colour can be derived from three primary colors, just like a monitor. For monitors, these are Red, Green, and Blue because monitors emit light resulting in an additive color process. Inks, on the other hand, absorb light so printing is a subtractive process. The resulting inks should then be cyan (blue+green or -red), magenta (red+blue or -green), and yellow (red+green or -blue).

Therefore, the colors used in common ink-jet printers are not really capable of producing true full spectrum photorealistic quality results since they are red (not magenta), blue (not cyan), and yellow. These are optimized for nice saturated primary colors when used independently. Also see the section: Why are red, blue, and yellow inkjet primaries?.

In addition, the combination of the three primary colors should be capable of being combined to produce black but due to misregistration and the pigments used, this black would be somewhat muddy and brown. Therefore, a separate black ink cartridge is normally used for black printing.

(From: Tony Hardman (AHED_CIJ@f54x19.demon.co.uk).)

With printing there are more problems than solutions and I do not know which method HP use in their printing.

If you can vary the drop size, you can change the drop spread on the paper. This can be done by firing bigger slugs of ink, or multiples of the drop at the same position. As you can figure the ink will either spread and make a bigger drop, or stay the same size and become denser. Depending on the resolution you want these could both improve colour density. This depends on two key components.. The ink, and the paper.

The problems with laying down multiple drops on paper is that if you do a large block the paper will curl up and the overall image becomes worse. This is why you can pay 1$ a sheet for 'quality' paper.

Another problem with this is speed. Firing two drops in the exact same place is difficult... Unless the head is stationary but that is not good either. You may notice that most DOD printers in high resolution mode do a number of passes over the same place. This does allow dithering and other techniques for resolution / colour enhancement. They usually only print while going in one direction for improved mechanical control.

In the 1600 printer there is a heater to assist with the drying times and reduce the curling problem.

Inks are a problem too. They can dry at different times because of the different dyes used, or they may not mix how you expect if you place two colours on top of each other. Its only ink ... but to get the best balance of surface tension, drying time, viscosity, colour, stability.... and more is not as straight forward as it might seam. I have noticed that the water based inks are improving, and there are some that do not run if they get wet (after drying on the paper).

I think the spec in your manual may suggest what method they use.. The printer resolution (best) is 600dpi (I guess), and I recon the best full colour resolution is lower. Also the print head is only 300dpi so you must do two passes to get 600dpi black (single black ink cartridge). This suggests a partial step of 1/600 inch between the passes. What happens when you print black using the colour head? How many passes, how much slower? The resolutions quoted may also be 600 * 300, or what ever. If they make blocks of colour from a potential 600dpi machine, the resultant image is probably only 75dpi (possibly less). This still might be called 600dpi, because the drop placement uses this resolution, but it is not 600dpi at full colour. The resolution of quality picturers / poster is several thousand dpi, but not a variable image (not ink jet).

In the Lyra publications they did publish the real print head specifications for the machines they review. They also include some of the methods of colour printing.

After all this I have noticed that I have not answered the question of how do HP et all get their colour resolutions. All I have mentioned is a few of the parameters that the designers have to deal with.

Why are red, blue, and yellow inkjet primaries?

For a subtractive printing process, the 'optimum' primary colors for a 3-ink system would be closer to magenta, cyan, and yellow. However, these are not generally used. Why?

I don't know the precise answer but it is no doubt a tradeoff between cost and which colors are used most often. For non-photo printing, the straight red, blue, and yellow are far more useful since they can be use by themselves or in simple combination to produce a wide range of vibrant, if not realistic colors. For example, pure red is far more likely to be used for simple graphics than magenta. To make something that looks like pure red using magenta and yellow requires a precise combination - not easy to do with an inkjet printer!

About inkjet printer ink

No, you can't refill your HP DeskJet cartridges with fountain pen ink!

(The following is from someone who also sells inkjet refill kits so this may not be an entirely unbiased writeup.)

(From: John Connolly (toner@idirect.com).)

There are at least 10 ingredients in inkjet ink, starting with triple distilled, de-ionized water, dye or pigment color of a known particle size, humectants such as glycol to minimize evaporation (and head clogging), surfactants to balance the surface tension and paper wetting, resins to get good paper adhesion, biocides and fungicides and buffering agents for the correct pH. These considerations ensure that properly reverse engineered inks not only work, but produce a print comparable to the OEM. For printers like Epson, with fixed permanent print heads in the printer, expensive repairs are also avoided.

To make matters worse HP has rigged their most popular black cartridges for the Deskjet 500 & 600 series to curb refilling, with air bladders, constantly changing maze/ venting assemblies at the bottom, and logic to change the signals to the micro-resistor jets on the 3rd or subsequent reinstallation of the cartridge. The color cartridges for these MUST be refilled before air locks occur, particularly in the yellow chamber.

Some people still manage to get an acceptable refilling success rate with these Deskjets, but we feel it is a bad introduction to refilling for the first time refiller. Deskjet series 700, 800 & 900 are better bets to refill.

But, the current Lexmark, Canon, Xerox and Epson cartridges are by far the easiest to refill.

Image Control's refill kits for the Canon 4000 series refill the BCI-21 black 40 times, or the BCI-21, 12 times EACH color.

More details on inkjet inks, a description of our refill kits which are larger than most offered, references and printer/cartridge tips are available at Image Control's Web Site.

Laser printer and photocopier operation

Copiers and laser printers have a lot in common. The major difference is in how the image is formed on a photosensitive drum:

- A copier uses a bright light and lens to focus an image of the original (actually, a strip at a time which is scanned in most modern low to medium performance copiers) onto the drum. Adjusting the lens-to-original and lens-to-drum distance is used to vary the reduction or magnification.

- A laser printer uses a low power sharply focused laser beam to scan one line at a time on the drum. Modern laser printers use infra-red solid state laserdiodes similar to those used in CD players and optical disk drives while older ones used helium neon lasers.

  The digital image is generated from a bit map stored in the printer's memory and modulates the laser beam. Scanning is mechanical - a high speed motor spins a multifaceted deflection mirror to get the X-axis and the paper moves to get the Y axis.

  LED printers use a large array of LEDs as the image source but are otherwise similar to laser printers.

Plain paper fax machines use similar techniques in their printing mechanism.

Beyond this, copiers and laser printers are nearly identical (at least in principle) except that copiers use a positive process (dark areas in the original result in marks on the paper) and laser printers commonly use a negative process (a spot of light results in a dark mark on the paper).

The most sophisticated machines are now actually scanner-laser printer combinations with buffer memory so that multiple copies can be made without rescanning the original, sorting and collating is more flexible, scaling and rotation can be done digitally, and other features not possible with simple copiers.

(Portions from: Copenhagen Cowboy (cowboy@fastlane.net).)

The photosensitive drum is the heart of the laser printer or copier. In larger machines, it may be a separately replaceable unit. In most laser printers and smaller copiers, it is part of the 'toner cartridge' and is a throw-away (or may be recycled).

The drum is coated with a photosensitive material which has an extremely high resistance when in darkness. It's resistance drops to a low value when illuminated.

All of the following takes place as a continuous process as the drum rotates. Note that the actual photosensitive drum in most copiers and laser printers has a circumference that is much smaller than the length of the printed page. Therefore, only a portion fits at any given time and the charging, exposure, transfer to the paper, cleaning, and erasing is a continuous process:

- The drum's surface is charged to a high positive voltage (typically 5 to 6 kV) by a set of charging corona wires in close proximity to the drum.

- The exposure process differs for copiers and laser printers:

  - For copiers, a swath of the original is focused onto the drum. As the drum turns, a quartz lamp and strip mirror moves along the original and second strip turning mirror moves at half this speed. The result is that the entire original's image is kind of 'peeled' onto the rotating drum. (Look through the glass platform that supports the original of a copier as it is copying and you will see what I mean.)

  - For laser printers, the negative image of the page stored in the printer's buffer memory (the laser is turned on where the print is to be black) is read out and scanned onto the drum one line (i.e., 1/300th or 1/600th of an inch) at a time.

  Where the light hits the drum's surface, its resistance drops dramatically and the charge in these areas is dissipated.

  At this point, a swath of the image of your ultimate copied or printed page resides as areas of electrostatic charge on the drum. This is a 'latent' image and must be 'developed'.

- As the drum continues to turn, the latent image rotates past the 'developer unit' which contains a mixture of developer and toner. For the most part, developer is not really used up during the printing process but some is lost and may need to be replenished from time-to-time (depends on design).

  - Developer is a material which includes powdered iron or other powder which is attracted by a magnet.

- Toner is the actual 'ink' and consists of very finely powdered thermo plastic particles. These are 'fixed' in the fuser by literally melting the image onto the paper.

  Depending on design, the developer material may be separate or actually combined with the toner.

  A magnet in the developer unit which is as long as the page is wide causes the developer along with trapped toner to stand out following its lines of force off of its long N-S pole pieces. This forms a kind of brush of toner and developer material which is in contact with the drum as it rotates with its latent image. Normally, the developer material brush is C-shaped, and toner particles are carried in the C-shape (the back of the 'C' is against the drum).

  Here is where the developing processes of copiers and laser printers differ:

  - For copiers, the relative charges of the drum and toner are set up so that toner is drawn to the unexposed (dark parts of the original) portions of the drum resulting in a positive image on the paper.

  - For laser printers, the relative charges of the drum and toner are set up so that toner is drawn to the exposed (where the laser beam was turned on) portions of the drum resulting in a negative image on the paper.

- The drum continues to rotate around and comes in contact with the paper.

  Below the paper is another corona, the 'transfer corona'. Another high voltage is applied to the back of the paper (once again, around 7 or 8 kV DC) to draw the toner from the drum to the paper. (Remember, all this is going on in a continual cycle and it is all in motion).

- Depending on the manufacturer of the machine, you may or may not have a third corona, the 'separation corona'. This is needed to separate the paper from the drum, but not disturb the toner on the paper (the separation corona is usually 4 or 5 kV AC (if it was DC, you would separate the paper, but have *very* smeared toner all over the page as to make it unreadable). The separation corona usually has guides over it to keep the paper from 'dipping' down too far into the corona shell.

- Paper is then transported to the fuser which 'fixes' the toner to the paper via heat (to soften the toner particles) and pressure (to embed them in the paper fiber). There are parts in the fuser which also keep the paper from sticking to the hot rollers. A thermostatically controlled quartz tube lamp provides the heat inside the anti-stick (Teflon coated) fuser roller.

- Finally, your copy or printed page is ready!

- However, we are not done as there is still some toner on the drum - it is not possible to get it all off electrically) so there is usually a rubber or plastic blade which rubs in direct contact with the drum. This 'drum blade' scrapes the toner off the drum, and the 'recovery blade' catches it to keep it from falling back into the machine. A 'used toner auger' transports the used toner (which is now changed both physically and electrically and is also contaminated with paper dust (don't reuse your used toner) because it can eventually damage the developer unit, cleaning blades, fuser sections and other parts of the mechanism.

- Now that all the toner has been scraped off the drum, there is still some residual charge on the drum from the previous exposure process. You can't scrape the static charge off the drum, so the cleaned drum is now fully exposed to a bright light to discharge the drum surface and prepare it again for a new charge, which comes right after the discharge lamps.

That is the basic process. Many variations are possible and depending upon the machine and manufacturer, some of this may be a little different. Where a (disposable) toner cartridge is used, many of these components are replaced with the cartridge - typically the drum, toner itself and developer (usually combined into a single powder), developer magnet (really neat!), cleaning blades, some of the corona wires.

There is also some photocopier information at:

- Diverse Devices

Laser printer operation summary

(Portions from: Zaki (zg@ix.netcom.com).)

In general the principle of electrostatic laser printing is as follows:

1. Charging a photoconductive selenium (or other) coated drum.

2. Discharging the drum with the laser steering engine in accordance with the input image rasterized pattern. (the laser is modulated to generate a predefined pixel pattern on the face of the drum - the focal plane).

3. The rotating drum attracts toner to the charged pattern (latent image) generated by the laser.

4. The toner is transfered from the drum to the moving papaer to generate a full image.

5. The paper carrying the toner moves through the heater to fuse the toner to a fine non-erasable image.

The laser steering engine is combined of the following components:

- Infra-red diode laser, 3 to 4 mW in basic units, up to 30 mW or more for high performance printers.

- Beam expander to form the required size of the collimated input beam which generates the beam spot size in the focal plan.

- Cylindrical lens to reshape the laser elliptical beam to a round one.

- Spinning polygonal mirror to deflect the laser over the focal plan.

- F-Theta lens to flatten the inherent circular plan of a rotating mirror. This lens is a very special lens which only few in the optical community know how to design and fabricate. The one that you own is particularly special because it is a Sectioned F-Theta lens which are typicaly more expensive (most of them are spherical).

  If you need to scan or to print in high resolution 500 dpi or higher, you end up using a glass F-Theta lens.

Cleaning and Handling of Photosensitive Drums

Where the drum is located inside a replaceable toner cartridge, there is no need for special handling. However, where the drum is a separate unit, the following applies. Or, if for some reason, you need to disassemble (gasp!) a cartridge:

(From: David Kuhajda (dkuhajda@locl.net).)

Whatever you do, do NOT use alcohol on an organically based drum, it will ruin it. The alcohol causes the material to crystalize. I use to do copier service and this was stressed a lot by the manufacture as they switched from the old selenium drums to the new opc drums. Direct sunlight will immediately destroy the drum. A couple of minutes under normal lighting is no problem, just place it in a dark area and put a black cloth over the top of the drum while it is out. If you are replacing the drum cleaning blade or cleaning the crud off the blade, make sure you powder up the drum completely and the blade before reapplying power. The toner actually is a slight lubricant and the rubber cleaning blade directly on the drum will also ruin it. Just print a few low text copies after reassembling to allow the blade to reseat properly.

(From: hapticz@email.msn.com.)

Short periods (less than 5 min) under fluorescent lighting is safe.

Direct sunlight kills them immediately.

Just have a clean brown paper bag to shove it into while it sits on the table outside the machine.

Often more damage is done to them physically during insertion/removal. just be careful.

Xerox used to clean the 10" diameter drums with 90% isopropyl alcohol and some kind of "Kim Wipes" in our office, that was years ago though.

Book on laser printer maintenance and rapair

(From: Michael (ncacaver@aol.com).)

Get the book: "Easy Laser Printer Maintenance and Repair by Stephen J. Bigelow".

Your local library should have it or be able to get it. Stephen J. Bigelow has several other books on printer repair, both laser and non laser types. All are very good.

Discussion on laser diodes in laser printers

> "I just acquired the optics from a dead laser printer and have been trying to understand it. There are two functions I have yet to grasp. One is something which it has but for which I see no need. There seems to be a heater (Contains mica) and a thermometer, with PCB markings like "T1" and H2" or something similar. If these the laser is temperature controlled, why? There seems to be a control photodetector to monitor the laser diode so temperature control appears like overkill unless the photodiode itself has too much temperature dependence and the drum exposure is very critical."

(From: Jonathan M. Elson (jmelson@artsci.wustl.edu).)

There is a heater inside the fuser roller. This is what melts the toner into the paper. It is thermostatically controlled, and then has a safety thermostat in case the control fails.

There are two photodetectors for the laser. One compensates for dimming of the laser over years of use, the other picks up the beam at a particular angle of the polygon mirror, and synchronizes the raster electronics to the polygon rotation.

> "The other thing is something I cannot find, the aperture defining the nice well-formed pixel. So far I must admit the study has been a bit superficial but the aperture ought to be pretty obvious if there is one!"

The laser is the aperture. With an optical path of 0.5 m or so, the laser is a pretty good approximation of a true point source. A simple lens makes it look like a very good point source.

> "Finally, how are the correction lens made? They look like slices out of the middle of some fair sized lenses, but that would be a very wasteful way to make them. Can they be diamond formed to nearly the final shape and with such good finish so only a simple polish completes them. Grinding the old-fashioned way on a sliver of glass looks doomed to generating all sorts of defective approximations to a sphere. (As far as I can tell they are glass, or some wonderfully hard plastic I would like to know more about!) Can they be molded to sufficient precision? (The sides are ground or sawn.) Thanks to anyone who can bring me up to date on lens fabrication technique."

I think they mold these lenses to near correct shape, then grind and polish to the desired aspheric shape with specialty machines for that purpose. (Note that almost all eyeglasses are aspheric for astigmatism correction.) Yes, these lenses are glass, I've had a few printers apart myself.

Types of toner

(From: Lionel Wagner (ck508@FreeNet.Carleton.CA).)

There are two basic kinds of toner: magnetic and non-magnetic. If your laser printer has a Cannon 'engine' it most likely uses magnetic. NEVER use the wrong type. The imaging process is extremely delicate and specific toners are important. Use of toner that is slightly different could result in all black or all white copies.

So you put in the wrong type of toner?

> "I have a 3M Model 6312 copier. I believe it is a re-badged Lanier. I didn't pay much for it but it worked well. When the toner warning light came on, I made the mistake of adding the wrong kind of toner. I removed the wrong toner as much as I could by vacuum. Is there anything I should do before adding the right type of toner? Did I do serious damage to the system? What to do if the warning light remained on even with the right type of toner added? Any suggestion will be greatly appreciated."

(From: Lionel Wagner (ck508@FreeNet.Carleton.CA).)

If your copier uses non-magnetic toner, it is mixed with iron powder, called the Developer. Both have to be removed and all residue vacuumed out. If the copier uses magnetic toner, less of it will remain in the machine. Try to get as much as possible out. Do not scratch the roller on which the toner sits.

WARNING: See the section: Warnings about vacuuming laser printer toner before using a household vacuum cleaner to do this!

- Back to Printer/Copier/Fax Repair FAQ Table of Contents.

Dot Matrix and Daisy-Wheel Printers

So you took your printer apart....

> "I stupidly took apart my Panasonic KX-P1123 to attempt a head swap (the cable was too short!), now that

> it's back together it just beeps when I try to print. The only things I touched were the rod that the head assembly slides on and the toothed belt also had to come off (I don't think it's a timing belt.. there's no clear markings suggesting that). When I try to print, the head moves to the center, there's no pin action and it starts beeping at two second intervals (and won't stop). It's not the paper sensors because they seem to work properly...any ideas?"

(From: Filip M. Gieszczykiewicz (filipg@repairfaq.org).)

Greetings. A few:

1. Make sure you didn't trap and crimp any wires .. there SHOULD be a 'Column 0' sensor - either a photo-interrupter or a switch. The print head will activate it during the self-init.

BTW, move the carriage all the way to the right, close the cover and turn it on - does the print head move or does it just sit there and beep?

2. Ensure that you have the ribbon cable correctly hooked up between the printer & head .. some [smarter] printers can tell... I am not sure about that one, but some printer have an optical (IR) sensor that detects ribbon presence (or am I spoiled with fixing $$$ printers? :-)

3. This should be obvious - but does the print head move FREELY all the way from the left to right and back? Don't forget to oil (not too much!) the rails!

4. Did you reconnect all the cables? Is the front-panel (display+buttons) attached?

More depends on the answers and results of the above. BTW, most newer dot-patrix printers just need 2 screws to be removed to release the head. I know the Epson LQ-1050 works like that (and many of that Stars as well). Anyones needs parts from the former? I have one with a dead head (and it's not economical to repair).

Print head repair

> "I have a few Epson dot matrix print heads with stuck or sunken pins. Does anyone have experience with disassembling these things for cleaning/repairs? It looks like you just have to pop a few clips to get them apart."

(From: Chris Serrano (brace@loop.com).)

I resurrected one by hanging it pins downs in an ultrasonic cleaner. A lot of old dried up ink floated right out and the stuck pin became obedient again.

(From: Filip M. Gieszczykiewicz (filipg@repairfaq.org).)

Greetings. If one does not have the use of an ultrasonic cleaner, I have found a different way to get these suckers working again.

Go to your local plumbing store and look in the chemicals department for 'CPVC-PVC-ABS CLEANER' (used to clean plastic pipes). This stuff is a combination of groovy chemicals Methyl Ethyl Ketone and Acetone. It will 'melt' most plastics so be sure the print-head's any plastic parts are safely taken off.

Pour some of this stuff into a GLASS container and put the print head, business-end first, in it and leave it there for a few minutes. When the stuff turns dark-purple (all the ink and goo from the print head) you are done. Let it dry (few minutes) and then oil it with LIGHT OIL. Note: Do NOT use WD40 - we're interested with something that sticks around for a few months... WD40 just leaves a 'protective layer' with almost zilch lubricating properties (it's a Water Displacer (WD), after all).

I have done this for a few DataSouth DS-180, Infoscribe 1000s, and Xerox [monster] printers that see a box of 132 column paper a month (each) for a number of years with excellent results. Note: YMMV... these printers have rugged print heads (7/9 pin)... I don't know how a 24-pin Made-in-China feather will respond.

Ribbon does not advance after replacing flex-cable

Have you actually confirmed that your 'new' ribbon cables are making proper contact - with an ohmmeter? Assuming that the thing worked better before the cables were cut, then there are only two possibilities: your replacements aren't quite right or something was damaged by the 'event' or through later actions.

Print head stepper

Confirm that you simply don't have bad solder connections around the plug to the motor. This is common in printers and will result in erratic or incorrect motor movement.

(From: Ralph Wade Phillips (ralphp@gcstation.net).)

What's common in some older Okidata 32x's and 39x's is that the lithium battery *above* the stepper driver will spring a leak, and drop the lithium compound onto the legs of the stepper. I do not know for sure if it's corrosive, conductive, or just plain nasty, but it kills the stepper deader'n'snot.

I'd LOVE to find a replacement - I've got a service customer that has about 2,500(!!!) 320's and 321's in the field, and I am not looking forward to having to exchange all those boards over the next several years.

Motor driver blows fuses

The following was in response to a dot matrix printer blowing the power fuse whenever the paper advance motor was driven. A 74LS273 was getting hot as well:

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

I'm going to guess (based on what I've seen in other printers) that there's a set of power transistors (either H-bridge drivers or 1 per coil, depending on the motor) that drive the stepper. These transistors are driven from the printer's microcontroller via an output port - in this case the '273.

Now, if a TTL chips is getting very hot, then either something is drawing too much current from it, or something is overvoltaging one of the pins. A particularly unpleasant failure mode is when a PNP power transistor, with the emitter tied to the V++ rail (the 20V + rail that supplies the motors) decides to short and apply said voltage to the output of whatever device is driving it. If you're unlucky, the next stage is that the output port device breaks down as well, and the CPU data bus gets 20V or more on it. The result is blown chips all over the printer. Please don't ask how I found that out ;-)

My guess is that there's at least one shorted transistor in the stepper motor drive circuit. If the system uses an H-bridge driver (an equal number of NPN and PNP transistors) then if one transistor shorts, its companion is connected across the power rails. When it turns on, the supply is effectively shorted.

I think you'll have to trace out the driver circuit for the stepper motor. Figure out what drives what. Test the transistors, and then replace the defective ones _and_ that '273, which is probably now blown.

Ribbon on electronic typewriter does not advance

> "My wife has a "Smith Corona" Model SD800 electronic typewriter that will not advance the ribbon. Everything else seems to work fine. We have been unable to find a local repair for this unit. I think I can fix it with some advice from someone familiar with these machines."

Can you determine if it is a mechanical or electronic problem? For example, with the ribbon removed, does the gear or post that drives it appear to try to turn or not at all?

Modern electronic typewriters are a combination of keyboard, microprocessor, and printer. Therefore, the same sort of troubleshooting approachs can be used as for computer printers.

Common electronic problems include bad connections to the motor that advances the ribbon (cold solder joints, cracks in traces on flex cable to carriage), bad motor driver chip, or bad motor.

Mechanical problems include stripped or broken gears, misalignment preventing advance mechanism from engaging, and defective ribbon cartridge.

(From: Roger D. Waddell (rwaddell@peachnet.campus.mci.net).)

This problem is usually caused by a broken 'E' clip on the bottom of the print hammer solenoid. The clip holds on a lever that works in conjunction with the ribbon/correction feed solenoid near the right front of the print carrier.

When the clip breaks, the lever falls out of position and never trips the lever that assists in feeding the ribbon.

I have seen this problem many times!!

Apple Imagewriter II squeal

> "My Imagewriter II, after many years of faithful service (~8), is starting to squeal. It squeals when the carriage moves. It still prints perfectly fine, but....a new noise can only mean trouble. Does anyone have any experience with this problem and his solution? I imagine it would take only a drop or two of lubricant. But where?"

(From: Chris Jardine (cjardine@wctc.net).)

I would suggest that you might have a problem with the ribbon mask. A few years ago I was the service manager at an Apple dealership. I can't tell you how many ribbon masks I replaced for many different problems, including wierd noises. It could also be a problem with the carriage drive motor. I can't remember which side of the printer it is on, but, it is below the gear/pulley that drives the toothed belt. You might try some very fine (maybe silicone) oil there and you might want to clean and then re-oil the carriage guide bar (the shiny round bar) and the bushings on the carriage that ride on the bar. The only other possibility would be a problem in the gears below the ribbon that are responsible for driving the ribbon.

Compaq Pagemarq 15 printer service mode

(From: Darren Mckillop (Darren.Mckillop@gecm.com).)

Try powering on while holding escape, this will put you into service mode. Press the up arrow to start the engine test, if this works you may have a problem with the xerox controller board.

Try disconnecting all the n/w cables and reseating the cables on the system board. Remove this by the two thumbscrews at the back and slide out as far as you can then pull the cable off.

I have a Compaq Pagemarq 15/20 service manual that I am selling, but I am in the UK, where are you?

Epson FX-286e printer problems

> "I just received the above printer in a non-working condition. It exhibits the following symptoms:
>
> When power is applied, the head appears to try and move, but will not unless you manually get it started. Then it goes to its home position. You then hear three beeps, and nothing else can be done to elicit any response from the printer. The power LED comes on, but the paper-out will not, regardless if there is paper installed or not. The paper detect switch is working properly (checked with ohmmeter by inserting/removing paper while across switch). Also, I hooked up a resistor and +5 V to the paper-out LED, and it lit up ok. I have also mapped out the stepper motor leads, and resistance checks show that it appears to be ok.
>
> MY question is if perhaps I lost one of the outputs for one of the stepper phases. The controller seems to be one large power-ic from what I've traced out."

Could be. Do you have a scope? You could check the phases.

> "I know if you keep voltage across one phase, you can lock a stepper. If you lose power to one phase, will the other phases keep it going provided you manually start it like I'm doing?"

Also check for bad connections to the stepper from the logic board - I have seen these on printers.

It doesn't explain your other problems, however. Once initialized, even though the print head doesn't move properly, I would expect the printer to work in other respects.

(From: Joe Wagg (jwagg@fs.cei.net).)

The 3 beeps tell you there's a carriage error, probably from an incorrect number of steps needed to reach the home position. Since you've already checked the motor, the next step is to check the motor drivers. Using a meter with a diode check function, put the red lead on ground and the black lead on each phase coming from the board (disconnect the motor first). The readings should be within 20 percent of each other, not open or shorted. Also make sure the motor, pulleys, and carriage are all relatively clean and move freely. The other symptoms are caused by the carriage error, which halts the cpu to prevent damage. Clear up the carriage error and the other problems should go away. You should also make sure that all socketed chips are properly seated and don't have dirty contacts.

Paper debris clogging Epson LQ-570

> "I have an Epson LQ-570 series dot-matrix printer that has developed an intermittent paper feed problem over the past year or so. It uses a push tractor for sprocket-feed paper, and paper tends to bunch up under

> the platen. There doesn't seem to be an obvious way to remove the platen to see what the paper's catching on, indeed the FAQ on Epson's website says it can't be removed, and to bring it in to the dealer for repair."

(From: Asimov (Asimov@juxta.mn.pubnix.net).)

Remove everything that is normally accessible. Then flip the printer on its back and play a vigorous drum roll all over it. This should dislodge a huge amount of "holes". Didn't you always wonder where those perforations went? Well, some of them make it into clogging up under the platten.

Flip the printer on its side and with a thin brush dust the remaining grime away. If the jam didn't clear up you might try manually inserting a stiffer paper (postcard, greeting card, etc) a few times before dismantling the platen assembly any further.

IBM X-24 Proprinter print head jumps around

> "Got a problem with a real nice 24 pin dot matrix printer I bought used. Was working fine for awhile then all of a sudden it will be printing fine an the printhead intermittently will jump to the center of the carriage and start printing from there. Also, when you turn it on, many times the printhead jams over to the right side of the carriage and the gears grind and you have to cycle it on and off to get it to start up right. Then you now almost for sure it will have problems printing. Help, any ideas? Do I just change a control chip? How do you scope out something like that? Can I get a manual somewhere? I want to keep the printer."

Also check for bad connections. If the printhead motor is a servo (DC instead of stepper), you have an intermittent feedback problem, again could be bad connections or bad parts.

(From: Ralph Wade Phillips (ralphp@gcstation.net).)

First off, have you changed the RIBBON? Second, clean the print head carriage rails. They need a VERY LIGHT coat of VERY LIGHT oil, then wiped clean.

Usually, when I see this, either the printer is just plain wore out, or the ribbon is snagging. Since the ProPrinter family drive the ribbon off of the carriage drive, if it ever snags, you'll get these symptoms.

NEC P5200 Printer problem

> "I have a NEC printer that has an intermittent CE (ribbon cartridge empty) problem, only the cartridge is new and good. Anyone knows what senses this condition and what part could be affecting this? NEC wants $20.00 just to talk to me. Thanks for any help."

(From: Paul Weber (webpa@aol.com).)

Look at the old ribbon. Does it have a short piece of transparent tape at the end of the ribbon? If so, the printer probably has an optical end-of-ribbon sensor; a LED/phototransistor pair that looks through the ribbon. Does it have a short patch of aluminum foil tape (probably on the back side of the ribbon) ? If so, there is probably a pair of contact fingers that rub the back of the ribbon as it feeds. Look for bent contacts or debris in the ribbon holder mechanism.

Look at the ribbon holder mechanism in the printer. Is there switch or contact pair that could sense the motion of the ribbon cartridge's feed reel? If so, check for free movement and cleanliness. Does the ribbon holder move with the printhead on this machine? If so, check that the ribbon cable connecting the carriage with the remainder isn't damaged and is connected properly at both ends.

OKI Microline 391 Elite Problem/Error

> "I am having a problem with a OKI Microline 391 Elite. I opened it up and cleaned out the dust and paper from inside. On putting it back together and powering up, The SEL light, the COURIER font light, LW and 10 cp light are all flashing and the stepper motor for the platen is jigging back and fore about once every 3 secs."

(From: Glenn Allen (pclogic@xtra.co.nz).)

These printers generally need just a clean out and put back together.

I would try to reseat the main logic board first, also try cleaning the edge connectors. There is a plastic joining bracket between the print head cable and the main logic board.

If you are getting bad carriage movement then check that the carriage can move freely back and forth, also check the black teethed guide lying on the bottom for clogged teeth. The print head ribbon can be removed for better testing. if the carriage doesn't move freely then you may need to adjust it's position by loosening the two screws on either side of the print head carriage and then adjusting back and forth until good movement is achieved.

Star SD15 printer self-test problem

> "This printer has a problem I am lost with. When I power it up and attempt to have it perform the self-test printout (FF on power up), the print head moves back and forth, the paper feeds, but the pins don't actually fire. However, if I connect the printer to a computer, the printing is just fine."

You are complaining? :-) Usually, it is the other way around!

(From: Ralph Wade Phillips (ralphp@gcstation.net).)

Eh? On the SD-15, the FF SelfTest is for checking HEAD MOVEMENT only. It sounds like it passes just fine!

Try holding down LINEFEED button instead. :-)

Ink-Jet Printers

HP DeskJet problems

This of course also applies to other HP printers as well!

Hewlett Packard has on-line information and documentation at:

- HP Support.

Types of HP ink-jet technology printers

(From: Paul Grohe (grohe@galaxy.nsc.com).)

The PaintJet printers are 180 DPI and the DeskJet printers are 300 DPI. The resolution of the PaintJet is about that of a poor 24 pin printer. The PaintJet and ThinkJet printers are also PCL, so you can use a HP laser printer driver set to 150 DPI.

There seem to be currently four levels of HP ink-jet printers:

1. ThinkJet/QuietJet: The original. Small see-through bladder cartridges. These are small, compact, quiet, form-feed printers. Text quality was about that of a 9 pin (I still love the little ThinkJet printer; damn near indestructible, small, and built-in Epson emulation). (BTW, look in the 1989 HP Optoelectronics handbook for the datasheet of the miniature ThinkJet cartridge). Original cartridges needed special paper for best printing. Replacement cartridges that print on plain paper are now available.

2. PaintJet: The first color printers. Cartridges are bigger, 'squarish' and usually are mounted horizontally. Resolution is the same as their 'little brothers', the Thinkjets (180 DPI). There are black, combined color and separate color cartridges (and sizes) available for the different printers. Printers were generally form-feed.

3. DeskJet/DeskWriter: 300 DPI. BIG improvement. Cartridges mount vertically. Black and combined color cartridges are available. Printers are sheet feed and plain paper printing.

4. DeskJet 800 series: 600x300 DPI B&W, 300x300 DPI color. Cartridges are tall and narrow and mount vertically. Damn near laser quality w/special paper.

Dissertation on HP DeskJet repair

These comments are in response to: "Repair Brief #49 - Part 1: HP DeskJet Professional Printer - Dead" and its followups. My text is indented. See those articles for details. The quick summary is that I picked up this printer at a garage sale and first had to dry it out and repair some cold solder joints before it would print at all.

(From: Paul Grohe (grohe@galaxy.nsc.com).)

I've dealt with a few of these buggers before! ;^)

Is yours a DeskJet, DeskJet Plus, or any of the DeskJet 500 or 600 series?

> I believe it to be an original DeskJet.

If not, then ...well....then I may as well tell you this anyways because you will probably run into these some day....(some of the below can apply to other ink-jet printers).

> Now, how to do a self test? Fortunately, the complete HP users' manual was part of the deal. "Hold the FONT button while turning on power". OK, no problem.

Try holding down 'FF' during power-up, you may get a different test page. One of the pages should have a jet-test pattern (A slanted diagonal line separated by 11 vertical marker lines and little jet ID numbers).

The first page of the standard self test results in that pattern.

I first tried the cartridge that looks exactly the same as the one that came with the printer (though the part number is different). Then, I tried another somewhat larger one that apparently has identical connections.

The different part numbers are the 'standard capacity' and the 'high capacity' cartridges. They're interchangeable.

> Going back and forth, they are consistent. I am not sure if one of the two missing lines are the same on both cartridges. Could something be marginal or is the priming not working? However, all other nozzles seem to be rock solid. Reseating the connectors to the print head makes no difference. If I knew which drivers were involved I could look at the signals but it will be difficult to trace the circuitry from the driver board to the actual nozzle.

I assume you have cleaned the contacts (with a Q-tip, on both cartridge and socket). Use a magnifying glass and check *each* of the gold 'bump' contacts. Repeated cartridge swapping, or improper insertion, can cause a crack to form around the base of the 'bump' and the pad (or the pad and the trace). The 'bumps' can also be 'flattened' by cartridges that were forced in at too much of an angle. There should also be some 'give' or 'sponginess' to the contact area to assure even contact with the cartridge.

Check for broken/bad traces in the flex-cable that goes from the driver board to the cartridge. Ohm out the cable between the supply commons and the individual driver lines (at the PCB) with the cartridge in place. I think the jet resistance was about 50 ohms (It's been a while). There were four separate jet sections (commons). All four commons were tied to the +20V supply through four separate (12 ohm?) series current limiting resistors. The driver outputs seemed to be grounded emitter, open collector (w/clamp diode?). The jets themselves are driven individually and are not multiplexed.

To test, I printed an all-black page (with an empty, but installed cartridge) and watched for activity on each of the lines at the PCB end. Good pulses are 'bi-levelish'. Normally negative going 20V, with pulses down around 15 V, and going all the way near ground for that particular jet. The commons 'bounce' because of the shared series current limiting resistor, causing the numerous smaller pulses around 15 V (caused by the firing of other jets sharing that common). A bad connection will show up as a weak or distorted pulse. An open or broken line will show up as 0 V. I theorize that a bad driver would show just the smaller 'line bounce' 15 V pulses and a shorted driver would show 'GND' (and also would blow out that jet!).

The current involved to drive the 'jets' is a pulse of short duration and pretty high current. Any poor connections will cause excessive I/R drop and the jet may not fire hard enough. A sign of this is drops (dribbles) of ink that form on the head during printing.

While you are in there, check and clean the rectangular rubber seat that the cartridge rests on in the 'parked' position. Dry ink can cake up on it, causing a faulty seal and resulting in dried-up cartridges ($$$!). The rubber seat pulls off and is easily cleaned with a wet paper towel (wear gloves, or you will suffer the dreaded 'black finger syndrome'). Also clean the 'nose wiper' that sticks up about a centimeter to the left of the cartridge seat. This always cakes up and can cause printing problems.

To manually prime an uncooperative cartridge, you do not have to suck on the business end. You can gently blow into the top vent (located on the top of the cartridge, inside the green arrow) to prime it. But be careful!; If the jets are severely plugged, ink may blow out the check-valve on the bottom (under the plastic 'flap' with the 'maze-like' area). Very messy! Have a towel ready!

The old DeskJets were (and still are) notorious for paper feed problems as they age. This is caused by the three big paper pick-up rollers drying out and becoming hard and smooth. Roughen them up with some rough sandpaper. The HP FTP site has a article about this in the DeskJet DOC directory. A free kit is available from HP (to qualifying S/N#'s) that 'dresses' the rollers (basically forces the rollers to turn and sandpapers them).

OH! Biggie! Another big 'failure mode' of the early printers is that the paper sensor lever will jump out of position and jam if the printer has suffered some rough handling (especially if it was turned upside-down or on it's side). The paper sensor lever (pivot) is located on top above the middle roller. The other end breaks the beam of a photosensor. The 'interrupter' end will move over just enough to wedge itself above the photosensor. This is cured by simply raising the lid and wiggling it until it drops back into position (I have 'fixed' many an alleged 'broken' printer this way). The 'interrupter' end seems to have been made larger on the later printers to prevent this.

From time-to-time, the cartridge's nose should be wiped clean with a soft, moderately damp cloth (~ every 100 pages). Keep the 'business' end pointed down when handling/cleaning the cartridge (Yes, this means hold it above you and clean it from the bottom!). This keeps the galleys and jets primed.

> Comments: I suspect the original problem resulting in the dead printer to have been a cold solder joint on the DC power connector which I repaired. I don't really think that the nozzle problem was caused by the water since the print head driver board was never wet. Since the data connection to the print head driver board is a 20 pin cable, this must be a common bus and thus it is unlikely that any failure on the main logic board could manifest itself as a single or pair of bad nozzles. Stay tuned.

I concur. If just *one* jet is not firing, then it is on the driver/flex- cable/connector/cartridge side. All the nozzle decoding is done on the driver board, so the 20 pin interconnect cable is okay. The DC (well..really 20VAC) power connector does take some abuse in normal service, this could have aggravated the cold joint.

Don't forget to check the buttons for water damage/contamination.

> Been there, done that. The FONT button was Coke-logged.
>
> Do you know what the difference is between the DeskJet and PaintJet cartridges? There is at least one contact that is open on a DeskJet cartridge and wired to something on a PaintJet cartridge.

I also have a color PaintJet 300 with a possible "dead" driver line, but I focused my attention to the ailing DJ500, so I did not have a chance to "buzz-out" the PaintJet cartridge. From looking at it, it looks like the PaintJets are multiplexed in some way (there are more jets/contacts than wires in the flex-cable). I never got around to fixing/looking into it (it's still sitting there).

BTW 1; The DeskJet, DeskJet Plus and DeskJet 500 (non 'C' models) are basically the same (except for some internal fonts). The DeskJets speak PCL, so if a driver for a DeskJet is not available, you can use a basic HP LaserJet driver (but the margins may be cut off, as the DeskJets print area is not as big).

> The missing line problem turned out to be bad connections between the flex cable and the gold contacts on the print cartridge due to the flex cable shifting position on its indexing pads.

These things are so damn simple that not much can happen to them. I have yet to run across one with a severe electrical problem. They are always minor mechanical failures (or missing power bricks...$35 from HP).

> As noted previously, the HP DeskJet series in general is a well engineered design with only a half dozen basic components. While my (DeskJet) printer is one of the oldest models, the fundamental design has not really changed dramatically in the last several years as evidenced by the fact that print cartridges for some much more modern printers work just fine in this old machine.

All the DeskJet/DeskWriter printers, up to and including the 6X0 series, use the same B&W cartridge as the original

DeskJet. Those cartridges will still be available for some time. Your printers life is not over any time soon!

> The print quality with a new cartridge is nearly laser-quality. Yes, HP seems to come out with a new, faster, cheaper, color. etc. printer every few weeks. But, looking inside newer printers shows that their basic design and construction is quite similar.

The DeskJets are good, sturdy and reliable printers (as long as they are well maintained) You did clean the rubber cartridge seat and flap. Right?.

BTW 2: For maximum cartridge life, make liberal use of the "draft" setting for "not-so-important" printouts (or, er, um, drafts!). It also prints faster because it "swipes" once per line instead of twice.

BTW 3: Use the cheap 'Shark' brand inkjet paper for best results. Pretty near laser quality! Regular copy paper tends to bleed, but is fine for general use.

Can you tell I have a 'few' of these printers around???? ;^)

> Just when I thought all was well....
>
> At random times, the print will fade out and require priming by mouth to restore operation. This can be anywhere from a few lines to a few pages. Until it quits there is no evidence of a problem. Blowing into the vent hole will restore operation. This happens with more than one cartridge. It appears as though the ink is just not refilling after being vaporized.

Is the cartridge full? As you get down to the last 20% or so of the cartridges capacity, it tends to start doing this. I guess there is not enough pressure "from above" to force the ink down. If you can start seeing through the cartridge, you are probably near this point.

> CAUTION: I found out the hard way that you really do not want to stick anything into the vent hole - ink all over the place as the vent valve must have been damaged by this mischief. I 'salvaged' the cartridge with a blob of silicone sealer. I don't know what the long terms implications of this 'repair' will be.

In troubleshooting the printer, you tend to "burn up" cartridges a *lot* faster than in normal use.

> I cleaned out the priming tube which was *totally* clogged with dried ink and it seems to be much happier now.

This can be a symptom of the print head not seating firmly when in the "parked" position. Use a dental mirror and make sure the seat presses firmly against the head. One cause of this can be turning off the printer before it has a chance to run through all of it's "housekeeping" cycles at power-up, reset (re-boot), or after printing. During certain parts of the cycle, the head is moved slightly, or the cover is moved. Turning off the printer too soon may leave the head exposed. Always let it finish, then turn it off (warn others about this).

If you haven't already, just pull the thing apart and give it a good overhaul (get your favorite pair of Torx bits ready!). Clean all the rubber tires, seals and "nose wipers". Wipe off the slider bar to remove any old lubrication. If there was a serious ink leak and the printer was involved in some "circus acrobatics", some of the ink can get on the slider bar and contaminate the factory lubrication, causing it to become "pasty". I wipe the slider bar clean with a cloth then apply a *light* coating of a light, teflon-type machine oil with a cloth (I use "Tri-Flow", a spray-on type usually found in bike shops).

BTW 4: In the winter months, with it's low humidity, the rollers will shrink even more, causing even more paper feed problems. This is also compounded by the fact that the paper sometimes develops a static charge and tends to "stick" together. Sometimes it pulls two or three sheets in at once, or the paper sticks firmly together in the tray and the weak, dry rollers cannot pull the paper in. Just remove the stack of paper and "fan" it out to loosen it (especially if it has been sitting there unused for a couple of weeks).

These printers are, like some other things we won't mention, 'Use `em or loose `em'! They work best with frequent use. They do not like sitting around for months unused. Three months seems to be the limit before a 'good' printer will start to dry up from no use.

> Before I 'discovered' the priming problem, I has visions of a serious electronic problem like an intermittent resulting in the nozzle drive pulses getting messed up at random times.
>
> How is pulse width determined in these things?

I never really investigated the timing of the pulses. I'm not sure how they vary the pulse width. I looked at the pulses when it was doing the first page of the self test, which is mostly text, and all the pulses seemed to be the same width.

Happy printing!

> The conclusion: After several years of faithful service (the most serious problem being that I really used the printer so infrequently that the cartridges invariably dried up!), I was given an HP DJ1000C with a couple of broken plastic tangs to which the pressure roller springs were attached. Some overzealous paper unjamming had caused thses to snap - not really a quality problem. Thanks to some stiff wire and Duco(tm) cement, the printer is better than new forcing retirement of my trusty $5 original DeskJet. :)

HP ThinkJet printer repair 1

(From: Paul Grohe (grohe@galaxy.nsc.com).)

The ThinkJet is VERY simple. The ThinkJet printers (and clones) do not employ any type of printhead covers or 'priming stations', so the cartridges are prone to drying out if not used for a while. A quick 'priming' is usually required, even after only a week or two of non-use.

The cartridges also tend to leak if placed in odd positions or subjected to rapid temperature changes. Make sure the cartridge has not drooled on itself and caused ink to cake down on the contacts in the holder. Clean the gold contacts *gently* with a cotton swab moistened with rubbing alcohol.

BTW: Like motor oil, fresh ink is great for cleaning up old, dried-up ink.

The ink is contained in a rubber bladder inside the plastic shell. There is a hole in the 'butt-end' of the cartridge. *Gently* stick a bent paper clip in and push on the bladder to prime it. A drop of ink should form on the printhead. Use a piece of tissue to wipe the drop off and re-install the cartridge.

Note that there are two types of HP ThinkJet printheads. One is the older, original type meant for printing on special 'ThinkJet' paper, and the newer 'Plain Paper' ones meant for, well, plain paper! ('PLAIN' will be printed on the side of the cartridge).

The older cartridges printing will appear very light if printed on plain paper. Make sure you have the 'Plain' type. Note that even with a 'plain' paper cartridge, the printing is lighter than a Laserjet or DeskJet, especially in draft or single pass modes. Don't expect razor sharp printouts. This was the first Inkjet printer!

As for the missing jets, eyeball the cartridge contacts and see if they appear straight and aligned correctly. The contact area could have slipped and may be out of alignment (although rare).

The flex cable/connector assembly is held in place with a pair of plastic bars. The "bars" have two pins that snap into the 'carriage' (they also provide alignment).

If the contacts appear to be out of alignment, carefully pull out the plastic bars to release the contact pad, realign the holes and press them back into position. Make sure the rubber 'bumps' behind the contacts are clean and undamaged.

(This makes more sense when you actually see it :^))

Be careful! Nothing needs to be forced.

HP ThinkJet Printer repair 2

> "I have an HP ThinkJet 2225C printer. I just replaced the print cartridge. It still doesn't print dark enough, and even after I primed the cartridge a few times, it still also misses a dot at the top and the second one from the bottom.
>
> I'm wondering, could the voltage to the cartridge be too low?"

(From: Kevin).

I have seen on rare occaisions the cartridge bad out of the box! Try wiping down the cartridge head & contact points on the printer with a Q-tip & alcohol. Sometimes blowing in the vent holes will force ink out the head, wipe off excess and try it. You may have to repeat the procedure a few times. If this doesn't work get another cartridge. You may want to try swopping the bad cartridge into a working unit or taking a working cartridge and putting it in the suspect printer.

(From: Frank Reid (reid@indiana.edu).)

I agree with all Kevin said. I use blue window-cleaner (e.g. Windex) instead of alcohol; the ink is very soluble in that stuff, and it penetrates the tiny holes in the printhead. After cleaning, hold a rag over the printhead and sling it downward a few times (as if throwing, but don't let go), such that centrifugal force pushes some ink out. If that doesn't work, try blowing on the upper vent.

On a few rare occasions I've encountered bad connections at the fixed end of the printhead cable, fixed by reseating the connectors. Also, if the cartridge has leaked, there may be ink on the gold pads in the moving end of the printhead connector, causing bad contact. Clean as above.

Some of the later models, including the type which takes two cartridges (3-color and black), have screws at the end of the carriage rod which allow adjusting the clearance between printhead and paper. Those may need adjusting if the ink is smearing. If too light, it's probably a printhead problem.

(From: Richard M. (Digitech@bogus.net).)

It is a water based ink. There is no need for any solvent other than water. Warm water works well. Use it all the time on my 1200C and DJ750C... BTW, I never have to touch my Epson. Use lint free cloths to tamp dry. NEVER wipe.

(From: R. Wagner (rwagner@ncn.net).)

I found the cable from the computer to the print head had some open places close to the head. The want 35 dollars for a new one. I went to the auto parts store and got some a rear window defroster repare kit. I got it working but for how long I dont know.

HP DeskJet paper feed problems

(From: John T. Black (cz667@cleveland.Freenet.Edu).)

The paper feed problem afflicts the HP DeskJet 550C and 560C, DeskJet 520 and DeskWriter 520 printers produced between June 1993 and March 1994. The affected units have serial numbers beginning with 'US3' through 'US43.'

The problem seems to be that the rubber rollers become slick over time and then the paper doesn't always feed properly. Last year HP offered a free paper-feed cleaning kit to fix the problem. Try contacting HP at 800/656-2324 or 510/657-1473 (FAX) to find out if the free kits are still available.

(From: Allen E. Amey (a_amey@ix.netcom.com).)

Try contacting the manufacturer. I have heard that HP has a free kit for the 500 series printers. The kit dresses the rollers and is supposed to be a fix for the type of problem that you are experiencing. BTW, using alcohol can actually compound the problem by prematurely drying out the rollers.

(From: FaxRepair (faxrepair@aol.com).)

I believe the only replacement part would be the entire paper pickup assembly which may need to be replaced because the gear train is damaged from ink having dripped onto it. Once the gear train is out of timing there is no known cure. Clean the rollers with rubbing alcohol and a soft cloth. If it doesn't pick up the paper after cleaning the rollers, then remove the entire print assembly and look for signs of ink on the gears at a location directly below the ink cartridge's home position. On a few occasions I have had success by flushing the gear mechanism with warm water to wash away dried ink.

(From: James E. Burke, Jr. (jeburke@ibm.net).)

I fixed one for a friend a couple of months ago. Parts are not available (well, you can get them, but they're too expensive).

In the one I fixed, it was a broken plastic part that caused the misfeeds. To get to the part, I had to disassemble the whole printer.

If you decide to to this, check the two 'fingers' that are behind the print head when it's in the parked position. The hook on the tip of one of them was broken off. I found the broken part inside the printer and glued it back on with JB Weld (twice--first time backwards). The pair of 'fingers' are identical so you could probably swap parts from one of the other machines instead of attempting the repair of the "fingers".

(From: Paul Grohe (grohe@galaxy.nsc.com).)

I have the same problem.

The rollers dry up and become glazed-over and smooth. You need to 'rough' them up.

Try sandpapering the wheels with coarse sandpaper (100 to 200 grit).

You'll need to trick the paper sensor. Take the cover off and lift-up on the black paper sensor lever. Then hold the piece of sandpaper firmly against the wheel and hit 'FF'. You'll need to do this repeatedly, as the wheels will only spin a sheets' worth each time.

Do this until the wheels feel 'sticky' again.

It also helps to keep the paper tray full at all times (but not overloaded).

Unfortunately, they'll never be like new.

(From: Frank Reid (reid@indiana.edu).)

I've had very good results cleaning the rollers with naphtha or mineral spirits, no sanding. It removes the glaze from the clay content of the paper, and makes the rollers softer.

(From: (Egiglious Giggles" (chsoccer@prodigy.net).)

The thing I have come across, is the spring which is directly under the roller itself. The purpose is to allow tension on the roller for pulling the paper in one sheet at a time. If you look directly in the middle under the roller from the front there is a guide that is spring tensioned. You have to take the roller assembly apart to get to it. But, if cleaning the rollers doesn't do the job, this is probably the culprit.

(From: Tony Dunlap (tdunlap@odot.dot.ohio.gov).)

The "Glaze" that gets on the rollers is often due to the rag content of many cheaper papers (especially "Recycled"). To clean the rollers:

1. Remove the paper and paper tray.

2. Send a short test page to the printer with the paper out. This will cause the form-feed light to blink.

3. Wet the rollers one at a time with a cloth (not a paper towel) dipped in alcohol, while pressing the paper feed button.

4. While it is wet, rub it with something rough and non-porous (I modified a toothed chip extractor that came with a pentium upgrade kit), again while pressing the paper feed.

5. Wet it again with a fresh part of the cloth dipped in alcohol.

6. Dry it with a fresh part of the cloth.

7. Put it back together and let it print the test page.

Cartridges drying out on early HP DeskJets

Note that unless the cartridge is almost empty anyhow, it can usually be revived by patting off the caked ink with a damp lint-free cloth and then gently blowing in the vent hole on top until a drop of ink appears at the print head. Sometimes this may have to be done more than once. NEVER poke anything into that vent hole or you will have a mess!

(From: Paul Weber (webpa@aol.com).)

HP had a free upgrade kit for the 560 to solve this, maybe for the 500 as well. It was a replacement for the silicone rubber park-position nozzle seal. Also remember that the 500 came with a cartridge storage box with an elaborate rubber seal in the bottom; they encouraged you to remove the cartridge from the printer and put in the box whenever it wasn't in active use to prevent dry-outs. Finally, HP cartridges have expiration dates - and they mean what they say: If they're out dated, they work poorly or not at all.

HP DJ340 shuts off during printing

(This may also apply to other battery powered printers.

> "Whenever I send a heavily formatted print job to a DJ340 printer, it prints 1/3 to 1/2 a page and then power shuts off! This so far has happened in TTAX97 and Netscape 4.03. OS is Win95 and I'm using the latest driver for this printer. The printer otherwise prints test pages and simple jobs OK."

(From: Paul Grohe (grohe@galaxy.nsc.com).)

I know this sounds silly, but how old are the batteries?

My guess is that the battery is probably getting weak. Heavy graphic content and "fancy" fonts users (of which TTax and Netscape qualify) will "swipe" the head more per line than the "text and lines" of the test pages. Moving that print head uses a lot of power!

Does the unit work on the adapter - without the battery? If not, then it relies mainly on the battery for power, and the adapter just charges the battery in between jobs. A weak battery could be drained after a short time.

If it works without the battery, then the battery could be going bad, causing the charger to dump too much current into the battery and "rob" some of the power from the printer.

There is a "Troubleshooting" note in the printers "FAQ" on HP's site.

- HP Support.

It basically says to check the batteries and make sure you are using the correct power supply.

Try replacing the battery. If you bought it at a local store, take it back and see if they have another battery to check it with.

HP DeskJet 520 - Crunch!

> "I just picked up an HP DeskJet 520 printer that doesn't work. On startup, the print head moves right an inch, then all the way left, where it slams into the left side of the carriage and grinds away for about a tenth of a second before stopping."

(From: Tech Guy (patrickmcardle@sprintmail.com).)

You may wish to check the undercarriage (no pun intended).

The printhead location sensor microswitch may be on the fritz The printer uses this switch to determine the starting point of the printhead after which it uses assumed location by how far the data has sent the head every time the unit gets a reset code, it checks this switch and if the signal is not detected, it may slam the head to either rail end or not move at all. If this is the case you can make sure that the platen is not clogged with label or paper debris. Gently move the head by hand to the right. If you shine a bright light into the area where the printhead usually calls "home" you may be able to see this switch (it may however be located under a cover triggered by the belt) if the switch is defective, replace it. If in fact it is jammed by debris, simply clear it and you may have solved the problem. Beyond this, you may have a logic problem (bad chip or other component) I make a good practice of doing a thorough cleaning of all machines that have left my shop to reduce the possibility of other problems during my warranty period. (it also makes the customer think that they have gotten something for their money)

I have replace a switch or a fuse on many machines, charged my base fee and heard the response upon their pick-up by customers that, "I can tell right away that you have found and fixed the problem" without even so much as a demo.

(From: michae98@ix.netcom.com).

There is a clear plastic strip strung between the both ends of the printhead pathway. This strip of plastic has microscopic vertical bars which the printhead can read and sense what position its in the pathway. The strip may be contaminated with excess ink which may confused the printhead. Take a soft cloth or Q-tip dampened with water and wipe of the strip (the ink is water soluble) and the printer should work.

(From: Raymond Carlsen (rrcc@u.washington.edu).)

Closely examine the toothed belt that drives the printhead. Look for a few missing teeth at one end. I managed to make one work again by shifting the belt over a bit (past the bad teeth). If that's it, the belt should of course be replaced.

HP DeskJet 560C Detailed problem description and possible solutions

> "I have a HP DeskJet 560C, Model C2168A that is behaving badly. When I power it on initially, it appears to run through a diagnostic self-test (as evidenced by the sequence of LEDs on the control panel). It gets to the point where it moves the print head and that is where things go bad. I think it is attempting to report some sort of error code because it then flashes some of the LEDs in a repeating pattern (more on that later).
>
> First let me describe mechanically what it is doing. When it gets to the point in the power-up routine where it moves the print head, it should do the following:
>
> 1. Move print head to the extreme right.
>
> 2. Prime the print head (???), a stepper motor on the right raises a mechanism to contact the print head.
>
> 3. Position the print head in a ready position.
>
> OK, here is what it is doing (please forgive my feeble attempts to describe in words what is happening):
>
> 1. I hear three distinct sounds (whirring of various stepper motors I think) before the print head moves.

2. The first two sounds seem normal from what I can remember when the printer used to work.

3. The third sound is the loudest and doesn't sound at all normal. It sounds as if the stepper motor that does the priming is oscillating back and forth between two "steps" (the sound is like a stripping gear).

4. The print head moves approx. 1" to the right.

5. The print head immediately moves approx. 1.5" to the left (note, this sequence of print head movements happens bang-bang (no delays between movements).

The end result is that the print head winds up about 0.5" to left of the position it was in when the unit was powered on. If I continue the power on sequences enough times it will end up at the extreme left and will be accompanied by a much uglier, more sinister sound of the print head slapping against the leftmost guard (as if the printer is attempting to throw the print head through the case).

Now let me describe the sequence that happens with the LEDs. The control panel has 9 LEDs arranged in three columns of three LEDs each. The leftmost column of LEDs lies between the "CLEAN" button at the top and the "Font" button at the bottom. The middle column of LEDs lies between the "Alignment Test" button and the "Status" button. Finally, the rightmost column of LEDs lies between the "Install Print Cartridge" button and the "Quality" button. Here is some ASCII art:

```

===========================================================================
```

I have numbered the LEDs (using my own numbering scheme) so that I can reference them below.

Here is the sequence that the LEDs progress through each time the unit>is powered on. The sequence is always the same.

	LEDs On	Duration	Description
1.	123456789	2.5 secs	Happens immediately when I switch the power on. Then LEDs 234789 turn off.
2.	1 56	0.5 secs	This is a flash (longer than a blink). Then LED 5 turns off.
3.	1 6	2 secs	Then LED 7 flashes on.
4.	1 67	0.5 secs	This is a flash. Then LED 7 turns off, LED 5 blinks on.
**5.	1 56	----	Here LED 5 just blinks on then off.
6.	234 789		This starts the alternating sequence where I believe the printer is trying to report an error code.
7.	1 6		This is the rest of the alternating sequence. The printer then repeats these two patterns forever (LEDs 234789, followed by 16).

** Step 5 is the point where the printer starts moving the print head."

(From: Jason D. Pero (JDP6640@ritvax.isc.rit.edu).)

The grinding sound from priming area is the jammed lever black stick that is pushed towards a bit towards right. If it good, it should be in upright position. If stuck too very right, unstick it by pushing it back to upright position towards left. This stick can be seen between the carriage rod and the printhead's purging rubber nipples and wipers. Also clean (gently!) the clear plastic strip with that fine black lines on it. First the clear strip must be removed first before doing this operation: The sensor is behind the printhead riding the clear strip, remove it by unengaging two triangular fingers inwards from outside and pull the sensor unit outwards towards back. Dust off inside that sensor gap and snap it back in.

Finally clean and oil both carriage rod and the angled underside area where the bearing block contacts upward onto it. Oil that carriage motor carefully and all stepper motors.

That should solve everything. This have happened to my 520, and my friends' 540 and 560C. Pretty common problem! Usual action when misbehaving is slamming either stops or do a "rushed start/stop" and some odd scary noises. All complains with pretty, interesting alterating flashes from the LED's on the control panel.

Pure or almost pure alcohol stuff is best as it does not melt anything or rub marks off and some 2 in 1 heavy duty oil "blue band" can. Top and bottom white shells comes apart easily after unengaging four snaps, doing one at a time and pulling gently and with a small flat screwdriver. Top off, the engine is free. disconnect with care to both ribbon cables one for carriage motor, and the flat white ribbon, or in some models that uses dual printheads, unplug another stepper motor. All connections you need to worry about is only from the mainboard side. Then the print engine lifts out without any fastening hardware.

WELL DESIGNED 5xx series compared to many printers past and now! I have a 520 chugging away after this fix and real cheap for that printer from a owner who does not want it.

Only problem is cost of cartridges. :($50 of two versus $13 can of toner powder for an Okidata 400 that will last thousands of papers. Only problem is Oki. 400 LED laser thinks (processing graphics) very slowly. Is there a hack to swap the proper circuit boards from other similar Oki 400/800 series to make it work faster and more useful than a pokey 186 cpu equipped Oki 400???

Your comments and suggestions on which brand of refill inks that is perfect for those cartridges. I know how to refill it right after experimenting on a bad cartridge and successfully refilling one good cartridge from a bad cartridge (dead jet out of 48 jets I think).

(From: Glenn Allen (glenn@manawatu.gen.nz).)

It is not a stripped gear is it?

The old DJ500 used to have 2 levers on the right hand side at the back that went up and down. Sometimes these got stuck and noises could be heard. Normal paper feed problems here.

A problem with a DJ850 was that paper got stuck and to get it out I had to remove the paper feed motor on the drive shaft, when put back it would bang the left hand side of the case. Needles to say it needed the cog setup back to right place it expects when powered on.

Those printers have an index strip that the printhead follows doesn't it? Is this clean, i.e. Not ink all over the place.?

Lastly if you are repairing and turning your printer up and down, check you do not lose the rubber cap where the printhead sits, and clears the guns, If you do your cartridges will become clogged in no time.

Also clean the print head shaft, any gunk on it will cause the printhead head to stick thus giving error light or worst powers down the printer.

Cartridge detection on HP DeskJets

(From: Fred Keen (fkeen@repeatotype.com).)

The HP printers test for the presence of a cartridge by checking the electrical voltages on the contacts between the cartridge and the cable. The slightest amount of dirt on the contacts can give a false reading making the printer think that no cartridge is present. If cleaning the contacts does not work you will have to buy a new cartridge.

HP Deskwriter 660 printer problems

> "My HP Deskwriter is just over the warranty of one year and when I print text instead of white lines through the type which would indicate to clean cartridges or replace them, I get black thin lines almost smearing slightly the text."

(From: Dennis Bathory-Kitsz (bathory@maltedmedia.com).)

1. Take out the cartridges and clean their sides, which pick up hair.

2. Clean the cartridge-cleaning mechanism itself on the right, especially the foam pad.

3. Take out the cartridges and clean the bottom of their carriers.

For this last, there may be some diagrams accessible via the HP Support Page.

Little plastic parts in HP DeskJet printers and HP service policies

(From: Wayne Van Beelen (wbvanb@nbnet.nb.ca).)

The bad news is that the plastic these parts are made of seem to be a Teflon hybrid and even the best epoxy doesn't last real well.

The even worse news is that DeskJets are disposable, just like Bic lighters.

HP will NOT sell you any internal parts.

They will not sell them to your dealer.

They will not even sell then to a so called HP service center.

All DeskJet service takes place in Corvallis, Oregon. A second possible location is Mississauga, Ontario but I think they just forward printers to Corvallis.

Here's the deal as I've been told; you pack up your printer and courier it to Mississauga, ($40 Cdn.), pay $175 Cdn. for a refurbished version of your Deskjet, and then pay another $40 Cdn. to ship the refurb back to you. That's $255 Cdn for a used printer when there are any number of new printers that can be had for a comparable price (and would also have a warranty).

That, to me, means DeskJets must be disposable because nobody in their right mind would pay that much for a three or four year old printer. It's bad enough when you consider 540's, which back then had a 3 year warranty, think about all the poor suckers buying newer HP's with only a 1 year warranty...

That's got to be enough harping on my part, the short of it would be that if you've got it working and your cartridge parks okay, it might be best to leave it alone. You won't get any worthwhile out-of-warranty help from HP. Check on parts availability on any future new printers you might ever buy. You can't assume that they won't forget you the day your warranty expires.

HP DeskJet 560C - stripping gear sounds and more

> "Does anyone know where the problem might lie with my HP printer? The problem is that when it is turned on, it goes through the reset sequence until it reaches the park zone, then it seems to miss a gear or something by the sound of stripping gears, then the lights flash alternately. My workaround to this is to turn it on, let it start across on it's reset sequence, turn it off, then right back on, and it will initiate just fine. Another anomoly is that when printing large color graphic files, occasionally, it will make it part way through the page and just stop with the same flashing error. After resetting it, it of course will print garbage unless I resend the data to the printer all over again. Any ideas? I've left a message on the HP site, but there has been no response."

Call HP - After much hassle they finally admitted it was a defect and replaced it with a new 600 series. I had the same problem - but had to call Idaho to get results.

HP600C DeskJet produces too much black ink

In addition to cleaning the cartridge, replacing the cartridge, cleaning the ink "well" and rubber wiper used for wiping cartridge head, using "approved" paper, printing in econofast mode (less ink), and setting up "transparency" print mode (gives more time for drying), one thing is often overlooked:

(From: Ralph Wade Phillips (ralphp@techie.com).)

Did you also clean the cartridge HOLDER? See HP's web page for more details, but I've seen SEVERAL of the 600 family that have "dust" collected under the cartridge holder. Since the black hits at a different angle than the tricolor cartridge, it is more prone to hitting the dust buildup, causing excessive smearing.

- How to clean HP DJ600 printer to prevent black ink streaks.

BTW, beware of flipping the entire printer over to unlatch the top - you may get a shower of the last n years excess ink from the holding tank!

HP DJ power supplies/wall adapters

It seems that this is one part that HP may not totally gouge you on!

(From: Paul Grohe (grohe@galaxy.nsc.com).)

Go to this page below, scroll down to the "power module options" section, and pick the correct adapter part number for the UK.

HP DeskJet 500 Printer - Printer Product Specifications.

Then do a net search for that part number, or, contact HP directly. Last time we ordered some, they were about $35US from HP.

HP 600 series DeskJet printer smears even with new cartridge

(From: Bill Rothanburg (william.rothanburg@worldnet.att.net).)

I had a similar problem with a HP 693C. The problem was the spacing between the paper and the carriage. A suggestion: if you're not mechanically adept, don't tackle this, get someone who works on printers to lend a hand.

I have not taken my 600C apart, and will not do so unless it fails, so the following information is based on the 693C, a similar printer.

The top cover is held in place by some latches, and a couple of screws under the paper tray. Be careful while tipping the printer, there is a catch-basin for the ink, and if this spills you will have ink dripping inside the printer. Remove the upper cover. Be careful with the thin cable to the electronics board. At this point you should be able to check for any gobs of ink that have turned to paste. Clean the dried ink off of everything, especially the bottom of the carriage, and print a test page. If it still smears, it's time to try adjusting the carriage height.

On the 693C the carriage slides on a rod that runs the width of the printer. The anchors consist of a screw through a slotted hole. On the one I fixed, the screws had obviously been loosened (they're torx screws, and it was obvious that something such as a jeweler's screwdriver had been used on them). Anyway, loosen the screw at one end, lift the rod slightly, and retighten. Print a test page, and repeat if it still smears. Of course, if it now smears only at the other end, it's time to switch ends.

I'm sure at the factory they use a gauge to adjust this to within a micron but the empirical approach worked for me.

HP DeskJet 692C - Random lockups

(From: Jess Askey (jess@magenta.com).)

I did a search when BOTH of my HP692C DeskJet printers started getting flaky. I didn't find much except for a post mentioning that cleaning the small plastic 'barcode' may solve most problems. While this is exactly what HP customer service suggested as well, it didn't solve my problems.

What the printers were doing, were randomly locking up. They also started making a 'knock' sound while they were printing. But, the 'knock' sound was more prevalent than the actual 'locking up' problems. But they would still lock up more than twice a day.

What I found was happening was that the stepper motor belt was skipping a tooth when the print head was changing directions. There is a black plastic tensioner arm on the left side of the printer that holds the belt tight and this was getting yanked in enough to let the stepper belt have some slack.

What I did to fix this was to take the spring out from behind the black tensioner arm and stretch it out to put more tension onto the stepper motor belt.

Both of these printers have had heavy use, they both are just over 1 year old right now too. I only moderately stretched the first spring and it still made the 'clicking' noise every so often. On the second one, I probably stretched it about 1/2" to 3/4" in it's fully relaxed position, but I think when putting it back into place it probably bent back a small amount. This worked well, the belt did not feel overly tight and I have not had ANY problems whatsoever. :-)

HP 820Cxi DeskJet Problems

(From: Vic Zane (vic@webworks2000.net).)

I've been having a problem with the black cartridge in my HP 820Cxi printer getting all gummed up with ink on the bottom, making lousy print. Clean it off, and it comes right back. It also was missing a horizontal line or two - thin but noticeable. The "clean" instructions with HP troubleshooting didn't help at all. Interesting that they say there is another thing you can try, but don't do it except with NEW ink cartridges! At $30 or so each, I wasn't interested in trying that except as a last resort.

The other day, after cleaning and refilling, I got an error message telling me that my black cartridge was no longer usable, and that continued use would possibly damage the printer. I purchased a new cartridge, and replaced. The old cartridge again had the buildup of ink on the bottom. So now I got the same "unusable" message, with recommendation that the cartridge be returned for replacement. And again, the bottom was loaded with ink. Obviously this was not just leakage from a faulty cartridge.

Information found on the web indicated that HP has only one repair location, and will not sell repair parts to even their dealers. Probable repair costs, added to shipping two ways, lead me to believe that I would be money ahead by either repairing it myself, or junking the printer. It has been in service (I am a retiree using it at home) for just over three years.

There should be information on this printer accessible on-line which is not included with their on-screen maintenance information:

- HP Support.

I also referred to this document at a Sci.Electronics.Repair FAQ site.

I removed the cartridges, and stood them upright on a multi-thickness pad of paper towel that was moistened with distilled water (from dehumidifier), figuring that this might open any ink jets with dried ink in them. A flashlight helped to see the area at the far right of the printer, where the cartridges park. Those wipers were a real mess. The Q-tip swab technique proved quite unhandy, but with a larger wad of cotton on the tip of a long and narrow needle nose pliers, I was able to clean them. There is a well to the left of the wipers that appears to have a spongy material in it - well soaked with black ink. When I tried to clean it, it just depressed down into the well and stayed that way. The pads that rest against the cartridge bottoms when in the park position were inaccessible, as they retract when the carrier moves away.

The paper toweling soaked up a little ink (I had some plastic under it). I wiped the cartridge bottoms, then replaced them in the printer. Alignment worked well - no skips or smudges. But I kept getting the error message telling me to cancel printing and align whenever I started printing, until the computer had been shut down and restarted.

The printouts are now first class, and there are no more error messages. The "unusable" cartridges both work fine. Of course it has only been one day so far though!

(From: Someone who wishes to remain anonymous.)

I can only add that the cover comes off quite nicely by unscrewing the two screws found on the top of the printer toward the back and by wedging back with wads of folded paper the four plastic clips on the printer's bottom. With the cover off you have good access to the area that needs cleaning. Also, I used rubbing alcohol rather than water. The ink well is just that. There is no spongy material there. Mine was just full of waxy ink that had accumulated there over time. Needless to say, I dug that all out. Hopefully the printer should work well for another two or three years.

HP DeskJet 1200C power supply repair story

(From: Marc Geyskens mgeysken@innet.be).)

A while back, I got this broken down printer, most of the time the power supply wouldn't kick in after pressing the standby switch. After checking elementary things, I got stuck on the PCB that holds the standby switch, on it reside passive components, a few LM431 and a UN3854 all of the components where ok except for the LM and UN chips. Since I had no schematic and no sheet on the UN3854 I turned to the chip directory which led, via a few stops, to the Unitrode site and yes, a data sheet for the UN3851. Plugged my scope (power supply on isolation transformer) onto the ucc line for the UNxxxx, noticed that the voltage was almost 0 raising slowly to 12 V and then fast to 20V after that time the PS worked normal. So I traced the supply back to a FET 2SK537 on the power supply mainboard which is part of a protection, its gate pulled up by a zener ZD1 and a resistor of 680k from 400V and pulled down by a transistor in case of the transformer's output voltage gets to high. Well, it was the 680k resistor, infinitive resistance yet not a scratch on it.

Thanks to the Chipdir site, and the Unitrode people.

HP PaintJet problems

> "My HP PaintJet printer has a problem! When I turn the printer on, the print head moves as if it's cleaning the head but thats it! The "on" light stays on but the "SET TOF", "LF", and "FF" buttons don't work. I've tried a test page by holding down the "FF" button and turning on the printer but it won't print. It just goes through the head cleaning stage again and then stops. If I turn the printer off and manually move the print

> head to the other end of the carriage and then turn it back on again the print head will move back to it's home position."

(Responses from: Paul Grohe (grohe@galaxy.nsc.com))

I am assuming you have the original tractor-feed "PaintJet", and not the sheet-feed 300XL.

It sounds like you have a problem with the "paper out" detector.

Is the second lamp on, even when there is paper loaded?

Here's a clue: If the other light is *on* after you do the self-test key sequence, then it thinks there is no paper loaded, so it does not print. The buttons are useless at this point, too. I have confirmed this with my PaintJet by removing the paper, and it does exactly what you describe. During normal "self test" printing, the paper out lamp is off.

It is very common with DeskJets and PaintJets to have their "paper out" detectors jam after rough handling.

Looking down into where the paper goes in, there is a little black lever sticking up (about 8cm to the right of the left end of the platen). This is the paper detect lever. The other end is a "flap" that goes between a photodetector.

Make sure this lever moves freely.

Open up the case (don't worry, it is very simple). Pull the big platen knob off. Then there are two rubber "wedges" stuck in two oval-ish latch holes on the bottom under the front "lip". Pull out the wedges and squeeze the latches. The cover then lifts right off (nothing is connected to it).

With the cover removed and viewing the printer from the front, look at the bottom left corner of the circuit board. You can see the "flap" end of the paper detect lever and photosensor, right above the "made in USA" sticker. Make sure it moves freely and that it is situated between the two detector "blocks" (I have seen these levers "wedge" themselves against the outside edge of the detector).

My guess is that you will either find paper jamming the lever, the lever itself mechanically jammed, or a piece of paper wedged in the sensor.

While you have the top off, notice that there is a long, plastic strip with fine lines on it running along the front. This is used for sensing the head position. Move the head over and make sure that strip is clean and that no ink has spilled anywhere on it. Also clean out any paper dust or spilled ink.

Don't be afraid to plug in the printer to test it with the cover off. The input voltage is only 20VAC, so you will not get shocked. Just be careful of the orientation of the power plug and watch out for the moving parts.

BTW1: The PaintJet printer is very stupid. It will 'print even with the cartridges removed or the platen motor unplugged, so there are no other sensors that could be causing a problem.

> "The symptoms are that first the color cartridge got weak and stopped working and now the same has happened to the black cartridge. It's not out of ink or clogged and the contacts are all clean."

The 3630 (aka: "PaintJet") was one of, if not *the* first, color ink jet printer. As such, it was plagued by the usual "first-of-it's-kind" problems. HP learned from their mistakes on this one!

We have a few of them around here, and your experience is not unusual. They tend to "dry up" more often than the newer printers. I seriously doubt it is an electrical failure.

Even though the cartridge appears "full", the ink gallies will clog if not used after a certain amount of time. After a week or two, you will need to clean and prime the cartridges.

This printer does not have the automatic "priming" that the DeskJets have. Instead, you have to remove the cartridges and manually prime them with the "plunger" located under the "flap" on the top-left. Then "wipe" them with the rubber "nose-wiper" located on the underside of the cartridge access door.

There is (supposed to be) a slide-out card located on the bottom of the printer with the "cleaning and priming" instructions (The little tab with the "i" on it).

The PaintJet also lacks a rubber-sealed "cover" for the cartridge head when it is in the "park" position. This greatly adds to the "dry-out" problem.

The head connector also creates some problems. The 3930 uses two rows of individual long, gold-plated "fingers" to make contact with the cartridge. These "contacts" can bend back, or become mis-aligned, due to improper cartridge insertion or wear.

Take a look at these "fingers", and just make sure they are even and straight. Don't bend them too much, as they are brittle. Also make sure there is no leftover ink on the contacts. Don't press

It should be easy to fix. However, you may go bankrupt replacing the cartridges.

There are ink "refill" kits available, however, the problem is usually with the clogging of the internal passageways and jets. So new ink won't help much.

My suggestions:

Check the contact "fingers".

Try "priming" and "cleaning" the cartridges.

Try replacing the cartridges with known good ones (or new).

If you will not be using the cartridges for a while, remove them and place them in a sealed container or baggie for storage (place them in the same position as they are in the printer).

> "What other printers are compatible with the PaintJet if I cannot get mine working and I need to use existing software"?

The "PaintJet" is a 180 DPI, "PCL" language printer. Just like the "newer" DeskJets.

If your unit has a parallel or serial interface, you can use any one of the older DeskJet printers (500/600 "C" series, DJ plus) - any that use the "PCL" language) or almost any laser printer (HPII compatible - B&W only). However, the newer printers are 300DPI printers, so the printouts will be 30-40% smaller.

If it is a HPIB interface, look for a HPIB ThinkJet.

Unclogging non-HP inkjet printers

These printers have the printhead separate from the ink supply.

(From: John Hudak (jhudak@sei.cmu.edu).)

Here are a few suggestions:

- Do a Google search on inkjet printer repair. You should find companies that make 'cleaner cartridges' that replace the ink cartridges. Invoke the clean cycle on the printer with the cleaning cartridges (follow both the printer manufacturer and the cleaning cartridge manufacturer instructions. This should remove the blockage. You may have to cycle it many times and/or let it sit overnight and then do cycles in the morning.

- Some companies also sell a syringe kit in which you fill a syringe with cleaner and flush out the print head. In my opinion, this is the best approach.

- Buy a HP in which the print head is integral to the ink cartridge. This eliminates the problem, and a side benefit is that the print quality is always good.

(From: Richard J. Scott (rjscott@telus.net).)

I have a Cannon BJC400 inkjet printer which I only use when I get home every week or so. Of course the ink clogs up the cartridge as always.

In my frustration, when I couldn't even blow the ink through this time, I took about 4 ounces of windshield washer fluid added about 1 ounce of isopropyl alcohol got it near boiling in the microwave and set the cartridge into it for about 1 hour. Bingo it came clean on blowing through the breather hole and printed beautifully. Nice cheap fix!!!

Intermittent light/no print from Canon BJ330

> "I have a canon BJ330 that starts printing light and prints nothing. This only happens approx once every 2 months. The unit has ink and it still thinks it's printing but there is no ink on the paper. This has happened a couple of times and so far I haven't figured out what it is that I do to 'correct' the problem.
>
> I was thinking that there must be a way to clean the printhead that is not in the service manual. Which I do not have, anyway."

On my DeskJet, I just blow gently into the vent hole on the ink cartridge. I then wipe off blob of ink that forms on on the head and it works like a charm - if you don't get ink all over everything. Perhaps, try the following first:

(From: russrite@magmacom.com).

Remove the sponge from the purge cap carefully, try washing in water carefully, and reinstall it:

- Remove the top cover to expose the printer power on the printer when the printhead moves away from home position SHUT OFF the power

- You will see a rubber rectangle cap towards the bottom of it is the sponge (called an 'Ink Absorber')

Canon BubbleJet information

Parts Now! has a set of articles mostly on laser printer engines, but there is one for Canon BubbleJets. These can be found at:

- Parts Now Service Today Archives.

Canon BubbleJet printers not printing after cleaning

(From: Handy (handy@redshift.com).)

Take out the cartridge that you want cleaned. Find that hole that ink comes out of, squeeze the cartridge until ink comes out of that hole - actually drips. Put it back in the machine, clean it at least FOUR times. Usually on the fourth time for some reason, it works. Just clean the one that you think needs cleaning.

Canon BJC 600 problems

(From: Rob Connelly (connelly@ix.netcom.com).)

I have found that sometimes the BJC 600 series gets confused and needs to be reinitialized. If you haven't already done so, unplug it from the wall, wait 60 seconds for the internal supply capacitors to completely discharge, then plug it back in and try again. When you remove it from the AC line it goes through a complete warm up cycle and resets itself.

Also, the contacts that mate with the print head are notorious for oxidizing. You might want to carefully clean them (lightly) with a pencil eraser and some isopropyl.

If these remedies don't work, the Canon 1-800 number will put you in touch with their tech department, and they are really quite good at determining what the problem is over the phone.

(From: Al Savage (asavage@iname.com).)

When I was working on printers, we'd see a few of the 600s in with corrosion on the ribbon cable end under the printhead. NewKote apparently had a venting problem with their copykat ink cartridges, where in some situations ink would spurt (leak? drip?) and somehow corrode the ribbon cable.

I never tried to replace one and see if it could actually be repaired with just the cable, but I did try vigorously cleaning the cable end: no conclusive repair.

BJC 600 print head error - lights flashing

> "Upon powering up the printer the two lights flash indicating a print head error. However by cleaning the electrical contacts (with alcohol) on both the print head and the printer the printer works,,, temporarily. Within a day or two the problem resurfaces. When the printer does print it prints excellent quality. The nozzles seem to be is good working order."

(From: Al Savage (asavage@iname.com).)

Although printhead failures are common on the 600 series, so is failure of the ribbon cable to the printhead. This is an acknowledged problem from Canon, when aftermarket ink reservoirs are used (i.e. Pirana or NewKote). Somehow the ink gets up to the cable/printhead interface and corrodes it. When I was working on them (about 18 months ago) Canon and NewKote were pointing fingers at each other. It appeared to be a reservoir venting problem.

Epson Stylus Color IIS error light problems

> "The error light on the Epson Stylus color IIs keeps blinking. The color cartridge is new. The black and white prints perfect."

(From: Robert J. Brancatelli (bronco@mkol2.dseg.ti.com).)

Most likely, the new color cartridge is not seating all the way. Move the print head to where you normally do to swap the heads. Now, without removing the color print head, lift the most forward lever up as far as it will go, then bring it down to reseat the ink cartridge.

Cleaning totally clogged colour head in Epson Stylus Color 500

(From: Colin Guillas (rguillas@nrn1.nrcan.gc.ca).)

I have an Epson Stylus Colour II printer which had similar problems- this time, which the magenta head.

After running about 50 cleaning cycles, and having no improvement, I disassembled the unit (I am WAY out of warranty already ;-) and manually mopped out the cleaning apparatus- the rubber heads were VERY gummed up, so I wipe them off... the suction tubes were clogged, so I squeezed them out, the sponges were full, so I mopped them up with a kleenex. I then put on a pair of elbow length kleenex gloves, and pulled the cotton cleaning tray/absorbent reservoir out of the base of the unit, and rung it out into the toilet. There was a three year accumulation of wasted ink in there- this printer gets extremely heavy use, but it was amazing at the amount of ink that gets wasted, compared to what goes on paper! I would guess that it's about 30/70, 70% ending up on paper. Incredible wastage. I just don't buy cheap refills. I buy better ones with guarantees on them. I also replace the cartridges that I am refilling every four to six refills. There will be an accumulation of 'junk' if you don't.

The cure to my problem? Pay the price for the genuine epson cartridge and do another fifty cleaning cycles. It worked for me. I had to wring out that @#$%liner again....

(BTW, If anyone else has an epson inkjet, I recommend that they get the liner replaced or at least wrung out. It's a horrible mess which can overflow if you use an awful lot of ink... mine was saturated... you may have a nasty surprise next time you decide to move the printer- all down the front of your shirt. ;-)

Epson Stylus 800 print quality

> "I have an Epson Stylus 800 printer which is only used infrequently. I seem to have a problem with some of the jets clogging up after a while producing a banding effect and/or a blurring of text.
>
> The built in cleaning cycle does not clear the problem. Running the head over a pad soaked in Isopropyl Alcohol clears the problem, but after a week or so things start getting bad again.
>
> The user manual does not mention the need to change any cleaning pads. How does the cleaning cycle work and are there any checks or adjustments which might improve things?"

(From: Paul Grohe (grohe@galaxy.nsc.com).)

Inkjet printers do not like 'infrequent' use. They need to be 'exercised' every once and a while. Use 'em or loose 'em!

I'm not familiar with the Epson products, but on the HP DeskJets, there is a little rubber "seat" that the cartridge sits on when it is 'parked'. If it is gummed-up or damaged, it can cause the cartridge to slowly dry out.

The HP's have a little oval-shaped rubber 'do-hikey' that seals the area around the ink jets. It generally gets gummed up with dry ink, and does not seal completely anymore.

Check and see if there is something similar that covers the print head when it is not in use.

The "banding" can also occur as the cartridge starts getting towards the end of it's life. Also try cleaning the contact areas with a soft cloth. Poor contacts can cause similar problems.

If large ink droplets are forming on the head during printing, this is a sign of poor contacts or a physically damaged head.

However, most of the time it is caused by "clots" in the areas supplying the jets, or in the jets themselves. Sometimes soaking the jets in a tray of alcohol or water for a while can dissolve these "clots", but the success rate is not that great. Better to fix the root of the problem.

BTW: Avoid turning the cartridge upside-down. Always hold it so gravity pulls the ink down to the jets and keeps them primed. Turning it upside-down can allow air to be drawn back into the jets.

Then again, it may be time for a new cartridge!

Epson Stylus Color 800 printer seems to operate but no printing

(From: Al Savage (asavage@iname.com).)

Sorry to be the bearer of bad news, but the both the purge pump and the printhead in the Stylus series (300, 400, 800, ColorII) are very trouble prone. I've scrapped a couple dozen of them. The cost of a replacement printhead is more than the printer on sale.

They do print nicely when they're working, though. My experience is that they don't work for very long.

Epson Stylus Color 800 clogged print head

(From: Alan G. Pope (agpope@phonetech.com).)

PROBLEM: Dryed black ink clog-up in the tube leading from the black ink cartridge to the print head. Black ink flow totally halted. New cartridges won't work.

BACKGROUND: Epson uses very fast-drying, water-soluble, inks in this printer, and if the printer sits idle for some length of time the ink feed tubes and the print heads become clogged with dry ink. Epson issues dire warnings about potential damage to the printer if attempts are made to flush these parts with any solvent, and recommends factory repair only.

On the advice of someone who has vast experience with such problems, I successfully used the following repair. procedure.

REPAIR PROCEDURE: Use a clean small hypodermic syringe with NO needle. Press on to the syringe nozzle, a 3/4 inch long piece of model airplane gas engine fuel tubing. This tubing is available cheaply from your local model hobby shop. It is a pale light blue colored plastic tubing. The MEDIUM size is the right one. The bore (ID) of the tubing is less than 1/16 of an inch. It makes a very tight fit when pushed onto the syringe nozzle.

Remove the cartridge from the printer, and pull the power plug immediately to prevent any further printer movement.

Load the syringe with 2-3 CC's of scalding hot water, preferably distilled water available at your grocery store. Then press the other end of the tubing down over the little black nozzle in the bottom of the cartridge holder. It must be a very tight fit.

Forcibly inject the hot water into the printer. If the clogging is really severe, you may have to press the syringe plunger very hard. Continue injecting until the syringe is empty, while making sure that the tubing does not slip off the syringe or the printer nozzle. Repeat this injection procedure 1-2 more times with more hot water if necessary.

Once the hot water goes through easily, the clog has been dissolved. It may be necessary to wait 24 hours for the water to evaporate, but in my case it was not. I simply replaced the black ink cartridge, and ran the Epson's head-cleaning utility several times until the black ink started coming through. Running the nozzle-check utility, to make a test pattern print, will let you know when the ink flow is OK.

This same procedure should work equally well for the colored inks of this printer. I suspect that the procedure will also probably work for some other Epson inkjet printers as well.

Use this procedure at your own risk. All I can tell you is that it worked beautifully for me. There was NO printer damage.

Non-use and refill of BJC-620 ink cartridges

(From: Roy (royf@iname.com).)

The people who talk about clogging, etc. must have never seen a BJC-620, in which the printhead and ink tanks are separate. I've had a 620 for about 16 months and having printed almost nothing on it (have a laser for most needs) have noticed that the ink tanks last about 5 months. My third set of cartridges at $40 per set have just recently gone dry. (Actually only the color ones are dry. The larger black one lasts longer.) I foolishly threw away the first set of empties, but I still have two sets. I decided that I've sent enough money to Canon and searched the web for a more economical solution. What I found was Bob Nedved and his re.ink.kit refill kit at:

- Re Ink Kit Home Page.

where, for $74.50 I got an amount of bulk ink equivalent to about $800 worth of new cartridges. Included also are 4 syringes and 4 small screws. The procedure is to make a small hole in each tank tank and seal it with a screw. To refill, you remove the screw, inject a few cc of ink, replace the screw, and clean the syringe with a little alcohol or distilled water. Filling the first cartridge was a little messy, but once you get the hang of it, it's a snap. The kit doesn't completely eliminate buying new tanks, because the tanks themselves eventually need to be replaced, but it sure does cut the annual maintenance cost, whether you only use the printer a little or if you use it a lot.

(From: Bill Sloman (sloman@sci.kun.nl).)

Epson uses a piezo-electric print head, and an alcohol-based ink. If you don't like paying for Epson's ink cartridges, use Pelikan's (I think that is the brand I use - it is certainly one of the old-fashioned ink manufacturers). They seem to use a higher molecular weight alcohol than Epson, so the cartridges last me more like six months than three in the old (1993) Epson Stylus Q800.

HP and Canon use a water-based ink, that is actually heated to boiling in the print-head to spit out droplets - so the print head corrodes rapidly, which is why their "ink cartridges" contain an new print-head and only about 15 ml ink, as much as the print-head can reliably spit out.

Inkjet Printer Cartridge Type and Reliability

Here are a couple of opinions. (From: Al Savage (asavage@iname.com).)

Having worked at Epson, Canon, and HP warranty service centers, I tell anyone who asks me for advice about buying an ink jet printer to always choose one where getting more ink also gets you a fresh printhead. The number one service problem with all inkjets is printhead clogging failures. On the Stylus 800 series, for example, the printhead retail cost was $170, and the labor was about half an hour. On the Canon BJC-600, the P/H cost was $250, but the head could be changed by the owner. And with so many folks using third party ink that works like it was brewed up in someone's bathtub (NuKote, Piranha (sp?), etc.), printhead failures scrapped more inkjets than any other three causes combined.

Cheap, owner-replaceable printheads help keep cheap inkjet printers out of the landfill.

(From: Roger Hamlett (roger@ttelmah.demon.co.uk).)

I disagree with the comments about chosing one where getting ink gets you a printhead. I have a bin full of 'dead' HP cartridges, that have resisted various attempts to get them printing again, yet also have an Epson here, that is four years old, and has never given any problems. The bill for cartridges on the HP, (allowing for the part use), would have paid to replace the printer a couple of times over.

Ink cartridge expiration dates

(From: Paul Weber (webpa@aol.com).)

One other thing about HP inkjet printers (DJ 550, 560, 850): Before you buy an ink cartridge, look at the expiration date on the box. Don't buy it unless you expect to use it before the printed date. That number really means that the cartridge will NOT work after the date...no matter how it is stored. Water and/or hot water rejuvenation rarely works on cartridges that are outdated. The reservoir evidently turns to crap and won't wick the water in or the ink out.

Dead Cannon, Compaq, HP, and similar power supplies

Apparently, these power supplies may blow their internal fuse either as a result of an overload, or possibly for no reason at all. In this case, a new fuse will be all that is needed. Of course, it's also possible that there is a fault in the power supply or in the printer which will cause the new fuse to blow but it's worth trying a new fuse before more complex troubleshooting.

(From: Jim Steel (procomputer@telisphere.com).)

Repair instructions.

The power supply is encased in a bonded 2-piece ABS plastic housing. There is a fuse inside but no way to access the fuse without splitting the case.

Splitting the case:

Unplug the power supply and secure the power supply in a utility vice. Use a short-blade utility knife or linoleum knife to slowly and carefully and cut along the seam where the 2 halves of the power supply are joined. Don't try to cut the seam all at once. Work a little at a time until the case halves can be separated.

Replacing the fuse:

On a power supply with an unsoldered fuse socket, simply replace the fuse and test the power supply. Alternately, a leaded fuse may be soldered in.

On a power supply with the fuse soldered into the fuse socket, leave the fuse in the socket and solder in a leaded fuse. (A leaded fuse has lead wires extending from each end of the fuse.)

On a power supply with a leaded fuse, unsolder the old fuse solder in a new leaded fuse.

Testing the power supply:

Ensure that the power supply and printer work before bothering to close the case.

Closing the case:

ABS plastic cement may be used to bond the power supply case halves. Alternately, electrical tape may be used to hold the case halves together.

- Back to Printer/Copier/Fax Repair FAQ Table of Contents.

Laser Printers

Note: also see the chapter on Photocopiers as the operation and problems of the two types of equipment are very similar.

On-line laser printer resources

- There is a complete textbook on laser printers: "A Laser Printer Book" by Steven Burrows, on-line at: http://cp.ru/goods/Inform/prl/books/00-toc.html.

  While this doesn't have much electronic repair information, it certainly would seem to cover just about everything else including some discussion of common image quality and mechanical problems. Note that this on-line book was present awhile back and disappeared. Now it's back but for how long, I have no idea. So, download what you need and save it!

- Parts Now! has a set of articles on specific laser printer print engine maintenance, repair, parts interchangeability, etc. These can be found at:

  - Parts Now Service Today Archives.

- MacIntosh Printer Manuals has many popular inkjet and laser printers.

Warnings about vacuuming laser printer toner

This is less likely to be something you would do in a big way with a laser printer compared to an office copier but if you are contemplating it, see the section: Warnings about vacuuming copier toner. There are several considerations including the risk of explosion and/or fire.

Refilling toner cartridges

If you can stand the mess, refilling some types of laser printer (and photocopier) cartridges can be worthwhile IFF the basic mechanism and photosensitive drum are in good condition. Even if you only get one more use out of a cartridge, the savings can be substantial. I have had mixed results buying reconditioned cartridges, but you know what your own have been doing in their spare time! However, it isn't quite just a matter of dumping new toner into a used cartridge:

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

Firstly the health/safety warning. Toner, because it's a very fine powder, is (a) carcinogenic, and (b) explosive. However, provided you don't make clouds of the stuff, you should be OK. It can't be *that* harmful, as some photocopiers take 'loose' toner, and some printers have separate toner/drum/waste toner units.

I've fixed mechanical problems on the SX and CX cartridges. I also once moved a good drum from an empty cartridge to an almost-new cartridge with a scored drum (don't ask...).

There are 2 things you need to do to refill one - empty out the waste toner tank and (obviously) add some new toner.

The SX cartridge is easy to dismantle. Unclip a little triangular plate on the side, pull out 4 plastic pegs, and the case comes off. The plastic bung for filling the toner tank is obvious. To empty the waste toner, you have to take the cartridge apart, remove a plate (2 screws) and empty the toner into something. I worked inside a plastic bag last time I opened one of these cartridges.

These printers use a combined toner and developer. The toner mix must be magnetic for the printer to work at all.

I've seen bottles of loose toner for some photocopiers. I have not idea which brands would be suitable (if any), but I might experiment sometime.

As for inspection/testing:

Well, the main test is probably drum sensitivity (but this won't change unless you are swaping drums). Now, if you get that wrong, all that happens is that the image is too light or too dark. There are some little plastic clips on the side of the cartridge that operate microswitches in the printer. And there are only 3 settings!. Believe it or not, I've found some remanufactured cartridges that work better when these blocks have been moved - in other words, the drum sensitivity wasn't checked properly.

Everything else should be mechanical inspection - condition of bearings/gears, leaks, primary corona, etc. Nothing that's impossible to do at home. Of course it's rather different if you're selling remanufactured cartridges - in that case you need to be sure the parts will last another 4000 pages or whatever. But if you're fixing up your own printer, and don't care if you have to fiddle with something else in 1000 pages time, then there's no real problem.

About the worse that can happen to the printer is that the cartridge dumps toner all over the insides. I've had that happen -

once. And it wasn't from a cartridge that I'd had in bits. It was from a remanufactured cartridge. That, together with the incident where a CX cartridge had had the door assembly incorrectly assembled, which caused damage to the transfer corona assembly, convinced me to avoid remanufactured cartridges that I'd not rebuilt myself, or at least checked.

You do need to avoid mixing waste toner (which will probably have a higher concentration of developer) with the new toner. Empty out the waste toner tank, but don't add the contents to the new toner. But if the toner you are adding is similar (or better still the same) as the original stuff, there is no problem from the residual toner in the cartridge.

Plenty of printers (Ricoh engine?) use 'loose' toner + drum/belt as separate parts. In those, you do add new toner on top of the old, and it all mixes up. Now, why should Canon printers be so different?

Cleaning laser printer optical path

As noted below, the optics are delicate and easily damaged. Use an air bulb to first blow off any loose dust/toner. Then use isopropyl alcohol and a cotton swab or lens tissue to *gently* clean the exposed surfaces. DO NOT disassemble any optics components - the alignment may be critical.

(From: David H. (textool@aol.com).)

It's always a good idea to clean the entire optical path from the laser (diode) forward. Most of this is inside the scanner module and there may also be a long external mirror.

With time these surfaces become coated with a film of toner/dirt and the laser beam reaching the drum gets weaker and diffused. Print quality suffers and later "beam detect" or "scanner failure" errors will occur, which may be intermittent at first, but eventually they will shut the printer down completely.

So open up the scanner module and gently clean all the prisms, mirrors and lenses. I say gently because the mirrors are front coated and the lenses may be plastic which can be scratched by aggressive cleaning with cotton swabs. Clean the external mirror if there is one. There is also a beam detection sensor which will have it's own small lens or prism which must be cleaned. Good luck.

In my experience dirty optics has been the they most common failure in 4+ year old laser printers with Canon engines.

Laser printer drum damaged by extended exposure to light?

(From: DenFrodo (denfrodo@aol.com).)

Yes, with extended exposure. I remanufacture toner cartridges for a time. Long term exposure to light will effect the photoconductive layer. We even cover areas of some (scratched) after-market drums and exposed them to sunlight to see how it effected them. It takes extended exposure to show an effect. No, the printer will not detect the problem and the printer will probably print dark for the basic 'positive' image (a dark area is exposed to light) laser printer. A scanner or copier might print light (reflective light of the 'white' surface exposes the surface of the drum. Good Luck.

Repeating images on laser printer

This likely means a faint ghost of the main printout at a distance equal to the circumference of one of the rollers or photosensitive drum.

Depending on where the problem originates, this could be a bad wiper (cleaning) blade, faulty corona, or incomplete fusing.

- If the distance between successive images is equal to the circumference of the photosensitive drum, it is a wiper blade, erase lamp, or corona problem.

  A residual latent image or residual toner is sticking to the drum and not being properly cleared.

- If the distance between successive images is equal to the circumference of one of the fuser rollers, then the fusing may not be complete due to damaged rollers or an incorrect temperature setting.

It is easy to determine where the problem is located: Interrupt a printout in mid-stride (where part of the paper is between the toner/developer and fuser. If the un-fused image has ghosting, it is a fault in the area of the drum. Also see the section: Previous copy doesn't erase from drum.

Black evenly spaced lines on laser printer or copier

(From: Edward Klotz (eklotz@www.flash.net).)

90% of the time it is the toner cartridge (or drum), If it is still exactly the same condition with the new cartridge, here is one exception: The fuser assembly has a rubber roller, I had one with an indentation in one spot, allowing toner to pack in the indentation & actually transfer a small character impression onto the fuser roller and then transfer it to the paper several times on each sheet. The fuser is very easy to remove(2 screws at the back). I temporarily worked the indent out of the soft rubber, but eventually replaced the fuser assembly.

(From: Dave Lee (leedj@uwec.edu).)

According to "Image Defects, Repetitive image defect ruler in LJ4", the cause would me the "Primary Charging Roller", is 1.5 inches or 38 mm around. Start with that, swap with another printer is possible, or order one, try Parts Now, Inc, 800/886-6688 or The Printer Works, 800/235-6116 or Global Printer Service, 800/588-3554.

Optics disassembly?

> "I would like to remove the mirror in order to clean it well. It mounts on a plastic bar that runs the width of the printer. The bar mounts by screws (2) at either end. I am worried that I will need some kind of aligning jig to get it back properly."

The short answer is: DON'T. Some aspects of the alignment are impossible to adjust/correct/reinstall without factory jigs and test equipment. The best you can hope for at home is trial-and-error. Most of the optics is probably solidly glued in place anyhow so disassembly is difficult or impossible - but it doesn't move much either! The long mirror itself is probably less critical than the rest but there is no real need to disturb it.

To clean the optics, use (low pressure) compressed air, alcohol and lens tissue, or as a last resort, alcohol and cotton swabs (Q-tips). However, some lens and mirror coatings may be easily damaged - test in a corner first.

(From: Pete (PTCull@lbl.gov).)

You are correct in being worried. Alignment marks closest to the muffin fan side of the engine should be noted before removal of the Beam-to-Drum Assembly. Better yet, just blow the mirror clean with a filtered compressed air source, leaving the mirror mounted.

Unless the mirror is very contaminated, I really wonder if you'll see the improvement you believe you might? Some of these mirrors have very soft surfaces and only should be touched with lens cleaner or cotton swabs.

If you still choose to remove the mirror from the engine, check to see if the two extreme sides of the page seem even when referenced to the top edge, using the "Engine Test print".

HP LaserJet FAQ

If your problem is with an HP LaserJet, before reading further, check the following three sources of information:

- The "HP LaserJet Information" document at this site is a comprehensive collection of common problems and solutions as well as a listing of error codes and likely causes.

- The Printer Works has a very complete listing of HP LaserJet error codes and possible remedies as well as some other model specific laser printer information. There are exploded diagrams for most Canon engines there as well!

- All Laser Services also has an error code listing along with some repair info. (Mostly HP but includes other printers using the same print engine as well as a few totally different printers.)

- Also see the section: Frank's repair notes: HP-IIP, HP-IIIP, Apple Personal Laser Writer.

Guide to disassembly and reassembly of HP LaserJet II and III

(From: Alexandre Souza (taito@terra.com.br).)

I used to fix lots and lots of HP II and HP III here in Brazil. So, with time, I developed a "checklist" for HP II and III repairing, that is safe enough to keep the printer working for years (4 years and NO defects whatsoever) and customers were happy. I'll include things not necessary for Americans (Brazil is HOT. Hotter than USA!) because friends all over the world may need this info.

What you need: Isopropyl alcohol, toner sucker, good screwdrivers, cotton, cotton swabs, screw picker (that little handy tool to pick/put screws in tight places), some rags - and lots of space!

I'll take the HP III as an example, The HP II is equal, with very minor differences. Please apologize me for any incorrections, since I'm telling everything from memory.

1. Be prepared to do a complete tear-down of the printer. Dismantle it to the last screw. This is a day-long work, so better you are prepared to do it. If you let for the following day, you WILL forget where the assemblies go, and will make your job a trip to hell.

2. Take the body cover entirely off. You will take total 6 screws, one of them in the back of the printer. You take it off pivoting it on your direction. It is a clumsy process, don't know why HP didn't made it easier.

3. Take the front "shield" off. The "front shield" is a big sheet of metal that covers the entire front of the printer. 5 or 6 screws, 2 ol the sides, 2 on the front, 1 or 2 on the top.

4. Take the Power Supply off. You need to unscrew 2 screws on the front of the printer, and one on the back of the power module, besides the main motor. Also, disconnect the cable of the motor from the power module.

5. Look at the solenoids of the power module. It is very common to have the solenoids' felts inside it became a messy glue. Take the metal flap off (take care with the coil) and clean everything that seems messy. Take 2 or 3 small squares of electrical tape, and put in the nucleus of the solenoid. Do it on both, replace flap. Don't forget the coil! Check the solder of the power module.

6. Now is time to take the ozone filter support out. This is a black plastic piece with 2 screws - one on the top, and another near the motor. Clean everything with compressed air and a rag. Be sure the filter is unobstructed. Better if you CHANGE the filter, but these are impossible to be found in Brazil. So you clean it. Or you will have some messy ex-gears. You have been warned.

7. Take the fuser out - it has 4 screws on the corners. Take care of it, there is a big and expensive lamp inside, and you don't want to buy a new one, eh? We will not disassembly the fuser module if not needed. But if you open the cover, pick the cleaning pad out and see black lines on the fuser roller, it is time for a cleaning!!! Dismantling the fuser is a complicated matter, but here we go: First of all, study how every piece fits its place. You should begin the dismantling by the right side, taking great care with the lamp. Take off the plastic pieces at the sides of the fuser, take the lamp out, so you are free to work. Store the lamp in a quiet place (no one should even touch it he he he) and don'ts touch the glass with your fingers - do it by the ceramic sides, or the wires. Clean the lamp with cotton embedded in isopropyl alcohol and set aside. Take off the locks of the gear on the right side of the fuser roller, there is an equal lock on the left. Take off the fuser roller, and PLEASE don'ts scratch it. You will see 2 thermistors on the fuser assembly, covered with yellow plastic. Clean it with cotton swabs and alcohol. If they are damaged (plastic is broken, missing a piece, has a hole, etc) CHANGE IT. If the surface of these thermistors isn't smooth, it WILL mark the surface of the fuser roller and WILL DAMAGE it. And this is not a cheap part. Everything clean, assembly it again, doing backwards what you did to unassembly. Remember this is a GOOD time to change the fuser roller.

8. Take off the AC module, where almost all the CX engine problems are located :o) This is the aluminum "tower" besides the fuser assembly, and where the AC cable comes in. Dismantle everything, change the little little little heat accumulator (yep, it is so little that should be called "heat accumulator") from the black TRIAC besides the mains power connector, and put a good heatsink with heat paste there. Also, clean THOROUGHLY the upper fan assembly, because when it fails, it can make things hotter. Hot enough to melt the fuser gears. :o) Remember: ERROR 50 = TRIAC open. A TIC 226 fits the bill on place. Of course there are other causes for error 50. But I've never seen that in Brazil.

9. Time to go to paper path! Take the 4 screws that locks the registration assembly in place. The registration assembly is the module where you have the big green handle. Clean everything and note if the "L" of the front is straight. If it doesn't make a 90 degrees angle, fix it. Also, change the separation pad. It is the culprit of 99% of the pickup paper problems. What? You live in Brazil and cannot buy new separation pads? So clean the black mess that was a long time before a hard rubber, and put some kind of rubber or cork on it. Also, take about 10 cm of isolating tape and cover the lower half of the "separation pad" you did. The printer will not give ONE pickup error for YEARS. BTW, I never had one return of this method. When you put the registration assembly back, don'ts forget the small yellowish piece on the front roller is assembled pointing the frontal part of the printer!!! This is very important!

10. Take the pickup roller out and clean it thoroughly. Use turpentine to make it softer, it will last years! Of course, if you have a replacement unit, better to use that.

11. Using a cotton swab, alcohol and LOTS OF PATIENCE, clean the corona wire. Be careful as you can, not to break the diagonal wires that surround it.

12. Do a GOOD cleanup on the inside of the printer. Use compressed air (with a dehumidifier) and don'ts throw air in the scanner assembly. Better never mess with that. Only open the scanner assembly if you HAVE a problem with

it. Hope you never have.

13. Of course you already took the toner cart off, eh? Well, you have a black metal plate, with instructions of putting a cart there. Slide that plate to right, and move it up. You will see a very nice and delicate frontal mirror. Use only cotton and alcohol to clean that, and after only cotton to polish it. Make it clean, and close the lid. Of course, you don'ts want to let it exposed. A nick on this mirror, and there goes your print quality away.

14. You have 2 contacts on the left part of the printer cover. They touch the fuser assembly below. Do a continuity test there, you should find some ohms, but continuity. If you don'ts find it, you have a broken "erasing lamp" inside the printer cover. 2 screws keep you far from them, better change it now

15. Close the printer cover, turn the printer upside down, take out the plastic pan on the bottom of it, take the metal pan, clean everything including the lower fan. Of course, a lower fan broken, is a laser printer broken. NEVER, I said NEVER run the printer with the lower and upper fan disconnected, OK? Do you remember what I said? You have been warned 2.0 :o)

Well, this completes my "HP Refurbishing method". To reassemble it, you do the following:

- Bottom aluminum pan
- Bottom plastic pan
- Turn the printer up
- Registration assembly
- Pickup Roller
- AC Power module
- Ozone Filter Support (the black plastic thing)
- Fuser Assembly
- DC Module (don'ts forget the main motor cable!!!)
- Frontal shield
- Top cover (don'ts forget the cable for the front panel)

And so you have a healthy HP III. It will last for YEARS if you did it right. don'ts forget to put a fresh new cart of toner and it will last forever. Of course, you want to clean everything externally too.

The common disclaimers apply here. Do it at your own risk. I've fixed some 500 HP LaserJet IIs and IIIs, and never had a problem, return or anything doing that. Your mileage may vary. Greetings for Brazilian friends, and for all around the world that uses that guide. :o)

Guide to disassembly and reassembly of HP LaserJet 4

(From: Alexandre Souza (taito@terra.com.br).)

I fell in love with this printer but this puppy got some Coke in her fuser and messed things a little. So I was obligated to do a complete disassembly of it, to clean up the mess and change a gear. So, here we go:

1. Open the right lateral cover, pick it out.

2. Take the top cover out, 2 screws on the back, one on the top, beside the little green brush. You have 2 plastic locks on front, be careful with them

3. One plastic lock on top, and you take the left panel out

4. On the back of the printer, take the big panel out - you have the plastic hinge besides the parallel and serial connectors (best done than said) and one small "lock" on the right pin of the door (the power supply side). Take the lock out, and slide the plastic door out the printer.

5. 2 more plastic locks, and you take the small front panel (where you put cartridges) out. The only remaining panel is the MP tray, that I didn't needed to take out.

6. Take the formatter door out. You have a small plastic pin on the middle of the hinge of it, push it and slide the door out.

7. Take the formatter out. You will have 2 screws on the left, behind the formatter door hinge, one or 2 screws on the top, one in the right.

8. You are seeing the main motor. 4 exposed screws, and it is out. Take GREAT care with a hole below the left screws, if you don'ts close it (and open before using the printer) one of the left screws ALWAYS falls by this hole on the power supply. And you don'ts want it, want you?

9. Behind the motor board, you will find 2 screws, it frees the main gear unit. This is the most fantastic thing I've ever seen - 2 screws and all the gears, inside a module, come out. I LOVE HP! :oD

10. Behind the printer, take 2 screws on the base of the fuser assembly, take it out, push up and back the fuser assembly.

11. 2 screws on the printer connectors, let you take out the cooler fan on top of it. It also has a small plastic lock on the left side of it

12. Take the black ventilation colum out. This is divided in 2 parts. Take care. Take the ventilation grid on the bottom of it, and clean it thoroughly.

13. 2 plastic locks on the BACK of the assembly that transports the paper to the top of the printer (sorry, don't know the HP name) and it is free.

To disassemble the fuser:

1. take the FRONT plastic part out. Note there are 4 plastic locks on the front, and another one on the lower right, besides a gear.

2. Unconnect a lug terminal on the bottom of it. Take GREAT care, this is the wire that comes from the lamp.

3. Free all the wires from their locks, and take the two screws of the frontal thermistor (the bigger one) on the top of the fuser. Also, unconnect the small 2 wires with a connector on lower left.

4. Unscrew the RIGHT plastic part, freeing the lamp, and with greatest care of all, unscrew the LEFT plastic part. TAKE CARE with the wires and the lamp. One wrong movement and the lamp is gone.

5. Take the lamp out, now you can play it safe with the fuser.

6. Take the right top and bottom gears - they are free.

7. Take the fuser gear. You have a small lock you have to take out.

8. Take the same lock in the left side

9. Take out the metal cover of the fuser - you have 2 small locks between the plastic back with the green sticker (that has 2 coils that go to this cover), just pull it back and here comes your metal cover. Clean the thermistors!!! don'ts forget to change it if they are scratched, dented or damaged!!!

10. Unscrew the fuser roller bushings from the main fuser module

11. Find a way to make the lower rubber roller stay far from the fuser roller, and pick it out of the module. So you can pick out the black rubber roller too

12. Clean everything with isopropyl alcohol

13. Reassembly everything in reverse order.

This is my method of "Refurbishing" the HP4+. Note I have one with 400,000 pages printed and NO problems. The gear I changed was INTACT (as the others on the main gear module) with only 2 broken teeth caused by the roller, that was completely locked!!! It was SO Glued with coke that a small gear on the fuser, after unassembling, was completely unable to move, before taking it out with great force, and cleaning with alcohol. After that, it was free as a bird. Go figure...

Just a little fun: This one cost US$30. :o) Spent more US$40 to fix. The parts were more expensive than the printer itself he he he :o)

Testing the erase lamps on an HP LaserJets

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

There's a very quick test for the erase lamps in these printers (SX engine). Open the cover, and swing it right open. There's a plastic post that comes down from the cover at the back left with 2 contacts in it. It goes into a slot on the left side of the fuser when the printer is closed.

Check for continuity between the 2 contacts in the cover. I have no idea what the right resistance would be, but it's less than 1k. If it's open-circuit then most likely one of the lamps is burnt out. There are 5 of them, in series.

If the lamps are good and there are still erase lamp problems, then remove the fuser, take the cover off the left side of it (1 screw on top) and unscrew the PCB under it. Check the 2SD1414 power transistor Q331 on this board (it's the erase lamp driver). If that doesn't do it, check the components around it. R335 (1.8 Ohm) is the current sense resistor in Q331's emitter circuit, L331 is a filter choke in series with the lamp supply, and Q331 is a current sense transistor that removes the base drive from Q331 if the thing overcurrents.

I suppose it could be a problem with the cable back to the DC controller or even the DC controller itself, but that's unlikely.

If you've still not found the problem, though, post again and I'll think again.

HP LaserJet error code 51

> "On self-test, pulls in paper, pauses, indicates "51 err." Then pulls paper through mechanism while "02 warming up" is displayed. Nothing prints, except for 2 horizontal black bars about an inch apart with grey in between them, about 1/3 from top of page. Since we stole this fair and square, and since we have a number of good (but _not_ laser printer) techs around, I'm wondering where we might dig. The book simply says error 51 means we should call HP service."

(Note: In the discussion below, the specific cable and parts IDs may not match your model.)

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

It's called a 'beam detect error'. Let me explain what that means:

The laser beam is reflected off a spinning hexagonal (I think) mirror, and scanned across the drum. At one end of the scan the laser is turned on, and the reflected beam hits a fixed mirror (not the drum) and is reflected down an optical fiber to a photodiode on the DC controller board. The electronics on that board detects the pulse from that photodiode and provides a sync signal for the data sent to the laser

So the fault can be the laser, the scanner motor, assorted optical bits, the photodiode, or bits on the DC controller board. I think we can eliminate the motor for the moment, as that tends to give Error 52s.

Look at the PrinterWorks Web site (http://www.printerworks.com/) for exploded diagrams. Also read the section: SAFETY since you will be inside the printer near high voltage and possible exposure to laser light.

The official fix is to replace the scanner, the cables (electrical and fiber optic) between the scanner and the DC controller, and then the DC controller until the fault goes away. But you can often fix things

Start by pulling the casing. Over the paper tray there's a flat black box. Start be reseating the 2 cables (one under the flap) that go to this unit.

If you have an IR detector (as used for testing remote controls) then undo the screw on the scanner - not the fixing screws that hold the scanner in place - remove the grey optical fiber, and hold the sensor over the channel that the fiber fitted in to. Do not look up this channel - it can output laser light. Turn on, and try to print a test page - which will fail.

If you get IR light out of the scanner unit:

Reconnect the fiber at that end, remove the base of the printer, and arrange some way to prop it upright with the interlock switch pressed in. Unplug the fiber from J201 (a DNP-like connector) on the DC controller board. Put your IR sensor on the end of that and test again. No IR light now, time to replace the fiber.

Reconnect the fiber to J201 and hook a logic probe or 'scope to TP208 on the DC controller. This is the output of the photodiode amplifier. Do you get pulses here? If not, check the photodiode and the transistors Q202, Q204, Q208. If you do, then, alas the problem is most likely in a custom chip, and it's time to replace the DC controller.

If you get no light from the scanner, then it's time to inspect it:

Carefully trim back the moulded clips that hold the cover on the scanner and open it up. Clean the optics with a soft brush or lens tissue. The mirrors are front-silvered of course. There's a little shutter in the laser beam, opened when a toner cartridge is locked in place - is this opening correctly when you close the printer? If not, find out why not.

Unplug the cable from the laser PCB, power up the printer and try a test page. Does the scanner motor rotate? If not, we'll debug that.

The last possibility is that the laser isn't coming on for some reason. Debugging that is going to be interesting (read Sam's laser diode notes next :-), and I'll do the same) and I'll try to talk you through that when I know it's necessary. (Note: Sam's laser diode notes -- Diode Laser chapter of Sam's Laser FAQ.)

(From: Tom Dunn (dunnt@cco.caltech.edu).)

Error code 51 indicates loss of laser beam for over 2 seconds. Check -5 V, also make sure there is no interlock mechanism damage, and +5 V at J451-1 on Laser Drive PCA. You may need new laser unit. Good hunting.

(From: John Holcepl (john_holcepl@nls.net).)

This is a very common error on a HP Series II. An error code 51 is loss of beam detect. The cause is a bad cable between the DC Controller and the laser/scanner assy. P/N RG1-0908-000CN. Sometimes just reseating the cable will make this error go away but it will come back eventually.

(From: Eric Liber (liberes@westinghouse.com).)

Here is the description of the possible 51 errors:

51 ERROR (Loss of Beam Detect)

- 2686 Only:
    1. Bad laser unit or improper laser power setting.
    2. Replace Laser Diode Assembly.
    3. Replace Scanner Assembly.
- II, III Only:
    1. Replace Cable, Laser/Scanner to DC Controller cable (P/N RG1-0908-000).
- II, IID, III, IIID Only:
    1. Inspect the Fiber Optics Cable for cuts or kinks.
    2. Replace Laser/Scanner Assembly.
    3. Replace DC Controller.
- IIISi/4Si Only:
    1. Visually check or replace toner cartridge.
    2. Inspect Fiber-Optic Cable between Laser/Scanning Assembly and DC Controller.

3. Reseat connectors J002 on the DC Controller and J601 on the Laser Drive PCA.

4. Replace Laser/Scanning assembly.

HP LaserJet I fuser swapping and other tidbits

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

What you need to do (if you're going to remove the whole assembly) is to remove the (brown) cover that's flat on the printer chassis just behind the 'tower' at the front that contains the interlock switch and AC control boards (where you removed the fuser heater wires from). Under that cover there's a little 4-way connector that links the fuser thermistor back to the engine control PCB (DC controller). Unplug that.

Then you can remove the 4 screws that hold the fuser in place, lift it up a bit, and free the heater wiring from the channel in the baseplate. The whole fuser then comes out.

These fusers can be stripped and rebuilt - I've done it. If the old one still heats up, keep it for the heater lamp that's in it - that lamp does fail, and it's not that hard to replace. It's a quartz-halogen bulb, so you shouldn't touch the 'glass'. The safest place to store it is in the old fuser.

These printers are that bad. I've had one stripped down to individual components (even dismantled the optical assembly), and have it running now. But the SX engine (LJ2, etc) are a lot easier to dismantle into modules (and in some cases harder to replace individual components on...)

HP LJ Series II bad bearing noise and other comments

> "Got one that started making unpleasant noises about two weeks ago. It is in a church office environment, so they have to turn it off unless they need it for a short while. I took part of the cover off and decided it wasn't the top fan or the small motor on the right side. The sound comes from the right rear at the grilles at the bottom of the machine. It sounds like a bad bearing or something rubbing a fan."

(From: Ralph Wade Phillips (ralphp@techie.com).)

Bad lower fan. Part number RH7-1056. I'd check at http://www.pcservice.com and register and order XX-RH7-1056 (it's under $20) and just replace that fan.

I'd also consider replacing the upper fan (go look for it with the search engine - it's about the same $ for the generic 3rd party version) since a failure there will ALSO cost you the fuser gears, thereby costing a fuser assembly.

As to removing the bottom cover - Eh? Put the top back on, flip it over, and remove those screws you see around the rim. Remove all cartridges also. Slip the metal cover off, and viola - There she is!

Big warning - Do NOT run the machine with the lower fan disconnected. This is known to damage the DC controller board (at least a $60 part, EXCHANGE - over $300 purchase!), and can cause massive problems later down the road ... Take a look at http://www.printerworks.com and look (and print, if possible!) their exploded parts diagrams. Yes, books are available, but will outrun the $150 the church is paying for it (worth it, though, with as many LJ2/LJ3/QMS/LWII and other SX-based printers out there, IMAO.)

(From: Al Savage (asavage@iname.com).) Probably the most-commonly-replaced part is the lower fan on the 33440A. Yes, it's very noisy when bad, right up until it becomes extremely quiet .

Well, buying 10 year old hardware and then wanting to depend on it not breaking isn't very realistic. As reliable as the LJII/III is, they DO break, especially lower fans, the 14T fuser gear, paper pickup roller, pickup photosensor, AC power supply, registration assy. It's just that they'll commonly print half a million pages in the process, and many contemporary printers aren't designed for a service life a third as long.

To replace the lower fan, have a vacuum cleaner with a brush handy (or an air compressor). Remove toner cartridge/drum unit. Close lid, remove all cables (power, data), flip printer upside down. On a LJII, you're looking at steel square pan; on a LJIII, you're looking at a large plastic tray and you have to remove four Phillips-head screws to get it off first.

On both models: remove any optional memory card(s) by first removing the access hatch for them on the left side. This hatch is the one *without* the 1/4" hole in it. Remove any circuit board you find under there: they just pull straight out.

On the back of the printer, remove any optional I/O card (HP JetDirect, Appletalk, etc) that may be installed next to the normal Centronics data port. This isn't always *necessary* but when it isn't it just makes things easier. Once again, just remove two screws and pull on the I/O card.

Now you can remove the lower pan. Nine Phillips head screws later, lift the front edge of the pan, wiggle it to get it off over the Centronics port cable clips.

Vacuum the pan out -- it will be filled with dust bunnies -- and any dust you see collected on the mainboard. You can now see the lower fan. It's a squirrel cage design. Remove the short wire harness and the four screws to remove it. Note the position of the small bracket under two of the screws, as you will need to put that bracket back!

Reassemble in reverse order. One screw on the lower pan does NOT go in the left rear corner, but that's only a problem is you have the upper plastic off as well. You can't put it in wrong if the upper half is still assembled.

The fan is about $20 wholesale, often close to $40 retail. Do NOT attempt to disassemble and clean it. I've tried several times, and no matter what I try it will either still be noisy, or will fail again within months.

HP LaserJet II just dies and no sign of power after a short while

(From: Larry Sabo (sabo@storm.ca).)

> "I have an HP LaserJet II that will just die after a short time. There are no power lights, not even an error message. If I leave it for a short time it will come back on after a power cycle. It is totally random."

Check the daughter board in the PSU at fault. On mine it had deteriorated solder connections on *both* ends of the connecting pins. Remove it, resolder the pins on the daughter board, then remount it. It's worked like a charm ever since.

HP LaserJet II with dark bands on first page

(Problem and solution from: Ken Eckert (eckert@sfu.ca).)

I have a LJ II that has the following problem:

> "The problem is a dark horizontal band starting at line 1, about 1/2" wide, indistinct edges. Repeats down the page at same length as the optical drum circumference. Problem is present only on page 1 of a print job. All other pages are clean. When the engine is stopped at the beginning of the print process a large

> amount of toner is present on the OPC in a band. Band gets darker and larger the more time between successive print jobs is incurred.
>
> Swapping cartridges has no effect."

The problem turned out to be the chassis wiring harness from the DCA controller to the HV module. There was a bad connection between the HV module and the chassis connector only when the module was inserted. I ended up extracting and soldering all the crimped pins in the connector. I suspect that it was probably the HV reset line that was the problem.

HP LaserJet II output jam

> "I found a junked HP Laserjet II which initially jammed pulling in the paper. I have fixed that. It still jams on the output, though. It prints nicely, so it seems worth fixing. If I open the back tray, the sheet exits 90% before stopping with the "paper jam" error. With that tray closed, I get the accordion paper jam in the fuser area. I do not detect any rotation of the upper rollers to feed the paper out of the top. When opened, I can roll them by hand easily. I see no obvious gear wear or broken teeth. I also see deep scratches in the grey fuser, which is probably unrelated. The toner does not have any fusing problem that I see in a band down the page."

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

I think you've got 2 problems here - the false paper jam with the tray open, and a problem with the drive to the top rollers.

Let's look a them in that order.

There's only one paper sensor in the SX engine that I know about, and that's part of the fuser. On the PCB at the left side of the fuser there's a slotted opto-switch with a lever that detects paper in the fuser. There's also a single transistor on said PCB that buffers/amplifies the output from the opto-switch, Q332, I think. This sensor must change state one way (to indicate paper has got to the fuser) shortly after the registration clutch operates and then change state the other way when the paper has got out of the fuser.

You might start by reseating the cable at J206 of the DC controller board (just in case it's bad connections) and then look at the sensor (mechanically and electrically) on the fuser PCB.

Silly question: If the paper tray switches (on the DC controller board) aren't operating properly, could the printer think it was feeding a shorter piece of paper than it actually has, and then give a paper jam error? It's always possible... Alas I don't know the coding for these 3 switches (SW201-SW203)

The other problem is almost certainly mechanical. Look at the gears on the right hand side of the fuser (stripped teeth do occur here) and in the top cover of the printer. Shouldn't be too hard to find where the drive has failed. I suppose you could remove the outer casing and AC block, re-insert the fuser and close the cover, and look at things while turning the machine by hand.

HP LaserJet IIp won't go past 'warm up'

> "I have an HP IIP that goes through the "05 Self Test" mode but hangs when it gets to "02 Warm Up." The only thing I ever hear run is the fan. I am not getting any error codes otherwise. If I try to send a print job to it in this state, it seems to take it and the On Line indicators light up, but it won't print. Based on what I've read in the FAQ and in the archives, I'm guessing it is the DC Controller. I re-seated the connections

> going to the DC controller PCB and the power supply and everything else visually looks good. I do not have a service manual for this unit.
>
> Can someone tell me how to test the DC controller to see if it is defective or maybe shed a little light on what may be causing the unit not to make it to the "ready" mode?"

Any number of simple faults can result in the warmup sequence not completing. Check these first before suspecting a blown power supply or controller.

It may indeed be as simple as a burned out bulb or broken door interlock.

(From: Dave Lee (leedj@uwec.edu).)

Here is what I found in my notes concerning your very same problem, Hope it helps......

New "Service Today" from Parts Now, volume IV, number 1, issued in Feb 95 is devoted to the "LX" engine units, IIP/IIP Plus/IIIP Series, the Cannon LBP-4, Apple Personal LaserWriter. Lots of good stuff, error 50's, error 41's, fuser upgrades, "moaning", other squeaks etc.

Here is what it says:

> If hung on "02 Warming Up", trouble may be caused by cables on the door wear and tear. Also look at DC Cnt PCA, dual I/O, formatter PCA. Now also look at the solenoid for the MP pickup roller assembly. This can cause the 'hung 02 Warming Up' error if an open occurs in either the solenoid cable, or solenoid coil. To check, remove the formatter PCA in order to access the DC Controller PCA. Locate J209 on the DC Controller; pins 1 & 2 are the solenoid. Measure across the top of these pins, the correct reading is 200 ohms +- 10%. Replace the paper path door cable assembly, Part #RG1-1608-000 if the solenoid has high resistance.

(From: Jeff Churchvara (jeffc@pond.com).)

Experience would have diagnosed this one in about 10 seconds. I just didn't know what I was looking at.

I started reading the FAQ and figured the worst. At first, I did not have the service manual to go over this code. When I finally did get a copy, I started checking the voltages and did not have +24 V at the DC Controller PCA.

All of what I was reading said to defeat the door interlock. At first, this didn't make sense to me because the bar that should be attached to the door was instead, laying on top of the switch and wasn't even moving when the door opened. I didn't know enough not to look any further.

Once I realized the bar should've been attached to the door, I started looking for it's correct mounting. The screw holding the bar must have loosened up and over time it broke the mounting nut right out of the door.

I ended up resetting the nut (threaded sleeve) by adding a screw from the outside. Then I pinched it in place with a second screw when I re-anchored the bar. This made the bar pull away when the door opened and then correctly contact the interlock switch when the door closed.

I forgot the basics of troubleshooting when I posted this one and was making it more difficult than it actually was.

Thanks to all of you who responded and kept me looking in the right direction.

Totally blank printout on laser printer or copier

(From: Ed Paolo (edpaolo@intac.com).)

Check to see if the image of the printout to be, is on the image drum. If it is there and isn't being transfered to the paper then something like the high voltage corona wire or hight voltage supply isn't charging the paper.

(From: FAXFIXR (justdfax@cdepot.net).)

There are two corona wires, the charge corona and the transfer corona. The charge corona is the one you should look at. It is located in the toner cartridge so the easiest way to check is try another cartridge, even one that is out (or almost) of toner. If you don't have another, then you can check yours. If you look at the cartridge in it's operating position, there is a black mylar plastic film that covers a slit on top from end to end. The mylar covers the corona wire but allows you to insert the little green tool, found inside the copier, to wipe the corona. If the tool is there, stick the pad into the slot and wipe it back and forth. If you hear a slight screeching sound (like a violin) then the corona is there. If it's not there, then the cartridge must be replaced.

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

(The following was written for HP LaserJet III but it is generally applicable to other laser printers and photocopiers.)

For starters, try a new toner cartridge. I've found these can cause all sorts of problems...

Now, blank pages are due to one or more of :

1. The drum is not getting exposed by the laser
2. The EHT power supply isn't transferring toner onto the drum
3. The EHT power supply isn't transferring toner from the drum to the page.

Start it printing a test page (the 'engine test' switch on the DC controller is useful for this). When the paper is still going through the printer, turn it off, open the lid and pull back the cover over the drum in the cartridge. Is there a 'latent image' on the drum? If so, check the EHT power supply and transfer corona assemblies.

Check that you plugged the cables into the scanner properly. They don't always make good contact. This will normally cause a 'beam detect' problem - I forget what the error is for that (51? 52?). It's possible that there's an O/C in the cable, of course.

If you have an IR detector (of the type used for testing remote controls), unplug the optical fibre from the DC controller and point the end at the IR detector. Again print a test page. If the laser and scanner are working, you'll get some IR (laser light, so take care) out of the end of the fibre.

There is a mechanical shutter in front of the laser in the scanner that's opened by a lever under the scanner when the cover is closed with a toner cartridge in place. The idea is to prevent any laser light getting out if the printer is run with the cover open/no cartridge. Is this working correctly. Did you get the scanner correctly on top of it.

Bearing replacement on HP LaserJet II to fix error code 41

(From: Andreas Mohr (a.mohr@mailto.de).)

My (donated) Laserjet II series printed black horizontal lines after about the third sheet. It then occasionally spit out "error 41".

Solution:

The ball bearings of the scanner unit were defective (now I know that my printer was MUCH louder than other HP 2s). That caused the scanner unit to get "out of sync" and print black lines and occasionally spit out "error 41".

I just replaced the ball bearings and everything was fine again.

As far as I know, no Laserjet error codes service page mentions this yet. (They only say that "the scanner unit may be defective", but not HOW that may be.)

HP LaserJet series II - error code 50 Service and clicking

(From: Peter Strezev (jup001@airmail.net).)

I had a LaserJet series II with exactly the same symptoms: 50 SERVICE and that very clicking sound. I fixed that printer last week after quite a bit of troubleshooting.

First: the clicking sound comes from a mechanical relay in the PSU, which controls, together with an SCR solid-state relay, the sequence in which power is applied to the heating lamp in the fuser. The sound itself is not a problem, it is a symptom. You probably have a bad thermistor in the fuser assembly, or the signal path from the thermistor to the control board is corrupted.

If you are good with electronic troubleshooting, try the following:

- Remove the fuser assembly from the printer. Locate a 7-pin connector on the left side of the assembly (I am assuming the same orientation, in which it was while inside the printer). Turn the fuser upside down, so that the connector is on the top. Using an ohmmeter, measure the resistance between pins 3 and 4, counting from the one closest to you. The meter should read a few hundred KOhms (if you take off the plastic cover, which covers the thermistor and thermoswitch, you could access the thermistor and try to heat it with a soldering iron. The resistance should come down to a few K Ohms or less if the thermistor is OK).

- If you got correct readings, measure the resistance between the corresponding pins in the socket, where the connector goes to when the fuser is installed. It should be quite high, about a M ohm. In my case, I found only 30 Ohms, and this was the source of the problem. What it turned out to be, the little cable underneath the printer, which carries a bunch of sensor signals from the fuser to the control board. Two wires responsible for the thermistor data turned out to be shorted by an excessively tight cable tie. It might not be the same in your case, but who knows...

(From: Mark Wolfe (markw@wwa.com).)

Just to speed things up a little, override the printer open switch, and remove the plastic cover from the right end of the fuser to get at the power connector for the bulb. Turn the thing on, and read this connector, should see about 115 VAC, if you don't, check Q101 in the Power Supply. The problem you had sounded like a rarity, as it's usually the halogen light in the fuser, or Q101 in the power supply. Yours was the sensors going back to control Q101. Anyway, if you ever have one of the power supplies opened, it looks as if HP intended this triac to fail with it's whimpy heat sink. Hope this helps.

I had the same thing happen to me on a IID, check the connections on the fuser. I swapped fusers with my III, and both printers worked, swapped them back and both printers worked. The power connector on the right end of the fuser seemed a bit loose, could've had a bad connection. Anyway, IID is still going, and this was in august when I did this.

(From: Chris Holmes (holmesc@sedgehill.lewisham.sch.uk).)

I dont know if Error code 50 is the same as Service 50 on the HP Laserjet II but if it is you are in luck.

I once had this and spent about an hour and a half stripping cleaning and reassembling it, and it worked! When I got back to civilisation I checked the manual. The official HP action for Service 50 is - switch off for 10 Mins!

Still i'm sure the clean did it good.

(From: Frank Reid (reid@indiana.edu))

A fuser-heating fault in HP Laserjet II or III (or the Apple equivalent) causes a capacitor on the dc controller board to charge. Discharge takes 10 to 30 minutes. If you repair the problem and restart the machine before the capacitor discharges, the error indication remains.

(From: Stuart Elflett (stuarte@OntheNet.com.au).)

Does the 50 error now stay on constantly, e.g. if you turn the machine on after a 30 minute wait, does it still say 50 error without doing its self test?? If so, I'd head towards the D.C. Controller. If the bulb in the fuser comes straight on, and the delivery rollers don't turn a little before hand, I'd be looking at the AC Supply. Is your fan spinning?? A stalled fan can often result in a 50 error. Is the fuser heating up?? If you're technically minded, you could remove the fuser and check the bulb for continuity.

Parts are commonly available almost world wide now.... you could check my links page for some sites that provide parts.... there's plenty more out there that aren't on my list..... try a web search for Laser Printer Parts....... They're not too expensive, as long as you get exchange parts where possible!! A manual would be a good purchase if you intend doing the work yourself, however they are still relatively expensive compared to parts!!

(From: David Gardner (gardneda@www.gc.cc.fl.us).)

Error 50 is called a fuser error, which it is, but I have found that it can also be caused by a bad High Voltage power supply or by a bad cable that runs from the power supply to the fuser.

Notes on HP LaserJet II error code 50

(From: ROO7L@aol.com.)

When confronted with a code 50 - after checking lamp, lower fan operation, thermal cutoff, wire connections etc. I always, as a precaution against call-backs, 1. remove solder from wire ends at thermistor, clean and resolder with silver solder, 2. replace 1k ohm resistor under pin connector (thermal protector board on end of fusing unit), 3. replace Q101 (triac on power supply board) and add more heat sink, 4. replace D155 on dc control board. 5. restake all wire end connectors with stake type wire connections. All of these are prone to happen and you can cut them off at the pass by taking care of these common offenders while you have the machine open. The voice of experience, I hate call backs!

HP LaserJet II - Top of the line printing shifting in multipage printing

(From: M K Ramadoss.)

Problem: In multipage printing, the first page will print fine. But, the top line of the second and subsequent pages will be shifted about 1/2".

Cause: There is a solenoid on the right side of the printer which stops the toothed gear. You can see this if you open the printer cover exposing the inside of the printer. On the solenoid there is a thin piece of foam which becomes sticky with age and temperature inside the printer. When the second and subsequent pages are printed, the solenoid the metal flap sticks to the solenoid and hence the timing of the feeding of paper is messed up and hence the shifting of printing.

Fix: This is very simple. In the hardware section of your store you will find thin felt squares or rounds with self-adhesive back normally used on the bottoms of lamps etc to prevent them from sliding as well as scratching polished surface of table etc. All you need is one such piece (about 1/2" round) which is stuck on the solenoid side of the solenoid. Thin felt is preferred. (Cost of a sheet of felt rounds/squares at Walmart is less than $1.00. All you need is one round).

HP LaserJet II bad bearing sounds

This also applies to many other laser printers using the Canon SX or similar print engine.

> "Developed frequency-changing whine of bad bearings. Not really sure whether a fan motor or main motor."

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

A service manual probably wouldn't be a lot of help. The SX printers (HP LJII, Apple Laserwriter 2, etc.) are very modular, and AFAIK, the official way to repair them is to replace the defective module. Of course it's possible to repair them at a much lower level than that, which is what I do to my pair.

There are 3 motors:

1. Lower fan. A tangential blower in the lower case next to the DC controller (Engine controller) PCB. This runs all the time that the printer is turned on. (Maybe the cover needs to be closed - I can't remember which 24 V line it runs from)

2. Upper fan. This sits on top of the AC block in the rear right corner (near where the mains cable plugs in). It runs when the machine is printing, and drops back to a slower speed when the machine is idle.

3. Main motor. This is a stepper motor that drives all the mechanics in the printer through a gear train. Needless to say it only turns when the machine is actually printing.

By finding out when the noise occurs, it's possible to figure out what is causing it.

Firstly the good news. I have never had a main motor bearing fail. They're ball races anyway (Yes, you can strip the motor down and rebuild it). I've never had noise from the gear train either.

Now the bad news. Fan failure is common. The bearings are bronze bushes, and they fail. Sometimes lubrication helps a lot, sometimes things are just too far gone.

Lower fan. Remove the toner cartridge and paper tray. Turn the printer upside-down and remove the screws that hold the base cover on. Remove the cover. The fan is obvious, and is held down by 4 screws (there's a bracket at one side that comes off as well), and it plugs into the smaller of the PCBs in the machine. Remove it. You can then unscrew the motor from the fan and slide the motor + blades out. Then pull the blades off the motor, remove the circlip, and pull the motor apart. Examine the shafts and bearings. If they're not too badly worn, a drop of oil (3-in-1 or similar) will probably cure the fault. Otherwise you need a new fan - parts are impossible to obtain.

Upper fan. Remove the paper tray and toner cartridge. Undo the screws and remove the outer casing. Remove the 2 screws and lift out the fan duct + ozone filter (on top of the AC block). The fan is under it and is held down by 3 more screws and a 2-pin plug on the upper (fuser protection) PCB in the AC block. There are at least 3 different upper fans in use, so I can't give directions for dismantling them. But in general, the motor can be unscrewed from the side of the fan, and the bearing on the other side pulled out. Inspect them as above, and try a drop of oil.

Editor's note: If you buy a replacement for this, it will likely be a 24 VDC muffin style fan (like in your PC, except that is 12 VDC). HP or Apple will likely charge you $70 or more for this part!

(From: Frank Reid (reid@indiana.edu).)

If the upper fan fails, the fuser assembly will overheat and do about $200 damage. Cleaning the bronze bushing often solves the problem.

An obscure and obnoxious squeak sometimes comes from the anti-static brush on the end of the upper fuser roller (end opposite drive gear). A bit of high-temperature grease on the nearby felt pad will fix it.

HP LaserJet II fuser overheating

(From: Glenn Allen (pclogic@xtra.co.nz).)

I had this problem on my HP LJII. I traced it to D155 shorted on the Fixing Heater Saftey PCB , this is in the same casing as the AC Power Assembly where the power cord plugs in. There was some sort of corrosion there.

I replaced it with a IN4148 diode as it is only a signal diode.

HP LaserJet II triac replacement

(From: John (jneff@uidaho.edu).)

We have been replacing these with a SK10466 (800 V, 8 A, Vgt 2 V, Igt 50 mA).

(From: dhickey@knox.edu).

If it is in the AC Powersupply, try a NTE 56006.

Also check for 2 open resistors.

HP LaserJet Series II intermittent

> "My new (to me) HP Laserjet Series II printer seems to have a power supply problem, although its previous owner said his supplier/servicer suggested the problem was 'probably due to a fryed mainboard' and promptly sold him a new printer. Lucky me. :-)

It works fine for a while, then starts to cycle between "12 Printer Open" and "00 Ready" before the fan in the power supply area drops in speed at the same time. I notice that the lamp on my desk flickers occasionally, even when the printer shows "00 Ready". Tapping the cover at any time immediately brings on the "12 Printer Open" message and fan speed drop-off. The cycle eventually ends with a "67 Service" message."

(From: Larry Sabo (lsabo@freenet.carleton.ca).)

The cause of the problem was an intermittent connection in the DC power supply, where the daughter board is attached to the pcb with a right-angle connector. I got so tired of removing and reassembling the power supply, I just jammed an empty plastic scotch tape role to hold it in position, and it has worked like a charm ever since.

HP LaserJet IIP printer error code 12

(From: Michael (action@netdoor.com).)

Your problem is likely to be the "Density Control PCB" that if you had the top cover off the unit, it would be a little board with a lot of wires (mainly purple, I think) going to it. It is in the front on the top.

About $40. Not saying that's it for sure, but I've seen it three times in the last 4 months.

(From: Frank Reid (reid@indiana.edu).)

I agree, but it could also be the assembly of photoelectric sensors and their wiring harness (about $25). Before replacing components, clean the sensors with compressed air and re-seat their connectors on the DC Controller board.

(From: Greg Smith (n6nyx@cox.net).)

Check the 10 uF electrolytic capacitor on the Density Control PCA board to clear Error 12 Open or No EP.

The capacitor on my printer went open-circuit big time! It started off with an intermittent error message. Percussive maintenance brings it back for a while, then it dies for good! The capacitor is only rated at about 16 V. I put in a 10 microfarad, 50 volt unit to replace it and still had plenty of room to clear obstructions after I bent it over a bit!

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

I am not sure how the printer detects that the cover is closed - there are 2 obvious ways : from the +24 V interlock switch or from the toner cartridge microswitches. Since, I believe, it'll claim the cover is closed even without a toner cartridge in place, I think it's the former.

OK, things to check:

Firstly, there should be a little peg on the cover (on the right hand side under the edge) that goes into a slot on a metal housing on the LV power supply module. This presses a microswitch inside that housing. This peg often breaks off.

If that's not it, then take off the bottom cover from the printer and stand the printer on one side. It's safe to power it up like this. Connect a voltmeter between the 2 outside pins (1 and 14) on J212 (a long 14 pin socket on the DC controller board). Power up. If you don't get 24 V here, you have a LV power supply problem.

Now connect the meter between pins 2 and 13 on the same connector. If you don't get 24 V now, then the problem is almost certainly the microswitch in the LV power supply, or the peg that operates it, or something like that. You can probably fix that by taking out the LV power supply, taking it apart and examining the switch and its connections.

If you do get 24 V there, then assuming the printer uses the +24 V sensing as the method of detecting when the cover is one, the problem is possibly R817, R818 or C760 on the DC controller board. If it's not those, then it's IC218, a custom microcontroller.

As I said, it _might_ use the toner cartridge switches to detect when the cover is closed. Take off the upper casing, the frame round the front, and the LV power supply module. On the side of the power supply there's a PCB with the paper sensors, the clutch solenoids, and the cartridge switches on it. Check the latter (SW301 and SW302) and the spring leaf that operates them.

HP LaserJet IIP with 12 Open or no EP error

> "I have tried to reseat the EP-L cartridge and opened and closed the fuser door many times, but can't seem to get this printer to work."

(From: Erik Welander (erikwelander@hotmail.com).)

I have written a detailed description of how to repair the "Error 12 OPEN or no EP-L" problem of the Lasejet IIP that seem to be very common on this printer (cost of approximately $1 for the capacitor). This, and some general maintenance advice can be found at: [HP Laserjet Maintenance and Repair].

(From: Terry (tmredding@worldnet.att.net).)

Sometimes the spring tabs on the left side of the printer that are the sensor for the cartridge get bent or are dirty. Also you get this error if the fan is not working.

(From: Dave Lee (leedj@uwec.edu).)

Most times I find that its the Density PCA that causes the problem. Sometimes its just dirt/dust in the two sensors on the right side above the toner cartridge, blow these out and give it a try. Density Board is avail through most laser parts houses, these are the ones I use:

- Global Printer Services, Phone: 800-588-3554
- Parts Now, Inc., Phone: 800-886-6688
- The Printer Works, Phone: 800-235-6116

HP LaserJet IID Error 13

(From: John H. Meyer (John_Meyer@compuserve.com).)

(I finally found the cause of the problem described below: One of the voltage outputs on the main power supply was blown. Had the power supply refurbished and everything works perfectly.)

> "LaserJet IID gives Error 13 message immediately upon warmup. (This is paper jam message.) The paper path, however, is totally clear. I've taken things apart and cleaned the exit sensor and paper path. Unit is quite clean. I've downloaded information on Error 13 and have tried everything except replacing DC controller card ($200-$400 part). I took the unit to two different repair places. One tried swapping out the fuser assembly -- that didn't help, and that was all they were willing to do for their free diagnosis.

MicroAge charge me $$ for a few hours troubleshooting and tried swapping out the main motor. No help. They also claim to have electrically checked the exit sensor. They said that the only thing left was to replace the DC controller card, but they didn't have one to swap in, so I'd have to pay up-front for the card.

I didn't do this. Instead, I took the unit back home and pulled the DC controller card. I tested all the discrete parts (simple diode tests on the transistors), and they all test OK. Two questions:

1. Does anyone have other suggestions of things to try?

2. Does anyone have a recommendation on where else to get a DC controller card for less money?"

(From: Dave Lee (leedj@uwec.edu).)

Had almost the same problem about a year ago, problem was the AC Power Module, just needed reseating. ACPM is located in right rear corner, just under ozone filter and upper cooling fan. Fuser assembly must also be removed to get to one of the 4 screws that hold the ACPM to frame. Remove the ACPM and then put back in place, thats all I had to do. Has been working since Feb 1995.

But another thought about this, are you sure that something isn't jammed where paper from botton tray comes up just in front of the registration assembly. If you remove the reg. assembly, there is a clear plastic guide that is held in place by 2 screws. Remove this and check to see if maybe something is jammed by that sensor.

As far as a good price on DC Controller board, I would call Parts Now, Inc. at 1-800-886-6688 or The Printer Works, 1-800-235-6116. I know that Parts Now sells either repaired or used or exchanged boards, probably a LOT less than what you were quoted.

(From: John Meyer (john.meyer@worldnet.att.net).)

Thanks for very complete reply. Your message sparks a lightbulb. When I first took the cover off when this problems initially surfaced, I took the power unit apart from the top (took of the little fan, and then started disassembling it). When I put it back together, things worked. I then put the top main cover back on, and things didn't work again. Nothing has worked since. However, I never took the whole assembly out and therefore never got to the connector. I'll try this and let you know what happens.

I don't use the bottom tray because the bottom paper path is prone to jamming, and has been for years. However, it is possible that someone (I have a four year old boy) may have jammed something in there. I have looked for such a jam and haven't seen it, but based on your input, I will try again.

(From: Dave Lee (leedj@uwec.edu).)

As far as the jamming from bottom tray goes, 2 areas to look at:

1. Remove the registration unit, its the first assembly inside the printer. Open cover, its the part with the hinged assembly with a small green handle. (Not the fuser, this is right inside the printer). Remove both paprer trays, registration assembly is held in by 4 screws. Under that is clear plastic guide held in by 2 screws. Remove this guide, and you should be able to inspect path from bottom tray for an obstruction. Also check the clear plastic guide, something may be caught in the guide.

2. Paper pickup roller for bottom tray may be glazed or very dirty. Clean with damp rag (water will work) although some "Fedron" cleaner is best but hard to find.

Do this after you get the error 13 fixed so you don't compound the problem.

HP LaserJet IIP and LaserJet series 2 error code 52

> "I have a HP LaserJet IIP, which does not print, but displays Error Code 52. Don, a man who is willing to help me fix mine, has a HP LaserJet series 2 that works. How similar are theses two machines? Is there any chance that one can swap parts to find the problem?"

(From: srob@iprolink.co.nz and Michael Schuster (schuster@panix.com).)

Totally different. Different cases, electronics, toner cartridge and system.

(From: Lewis King (echo@infogo.com).)

Error code 52 is 'Scanner Malfunction' and there have been posts on the USENET newsgroup sci.electronics.repair that indicate that this is fairly common and is usually the cable leading to the scanner mechanism. These printers, and the CX before them, use insulation displacement connectors. Quite often the connection gets flaky and pressing down on the wires where they enter the connector will fix a problem (worked on my Xante Accel-a-writer when it was telling me I needed a new DC controller board).

The part you need is the scanner motor... I can't remember the part number, but it is the same as the scanner motor for a IIP+ and a IIIP. The scanner motor has three screws holding it in, in the box where the laser attaches to the side. As you pull off the scanner you will notice a square microprocessor on it's board. the bottom side of that board will probably have a dark spot where that processor got too hot. I fixed about 50 of them that way.

I will find out what the error code means and get back to you.

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

That sounds like the classic scanner motor failure on these printers. It's a very common fault, alas.

The 'Official' repair is to replace the scanner assembly (the entire unit - the black plastic box - on top of the printer), and if that fails to cure it, then change the DC controller board. But you can normally fix it a lot cheaper than that.

Here's how (I believe) the unit should work:

There's a frequency generator (FG) coil on the motor PCB, just like the one in a VCR. The signal is fed down the cable to J203 on the DC controller and then converted to a TTL signal by IC202A (LM393 comparator). It enters the gate array (IC206) and comes out again when it is fed to a TC9142 chip (IC203) which compares it to a reference clock also from the gate array. The error output from the PPL is conditioned by IC201b (LM358) and fed back to the scanner motor. There is feeds the control input of the TA7259 (IC401) chip which drives the motor windings.

First check that the cables are connected to J203 and J401 (inside the scanner unit). The most common fault is that IC401 has failed and probably burnt out R401 (8R2) with it. Fortunately, this chip is not custom - in the UK it's available from (e.g.) Grandata, so a VCR spares place might have one.

If you've still not got it working, get back to me, and I'll talk you through the test points on the PLL on the DC controller board. Hopefully the gate array is still good, since I've not found a source of those.

Oh yes, how to dismantle the scanner to replace the chip.

Firstly remove the outer casing from the printer. Then unplug the 2 cables on the scanner unit - one on J451 (on the laser PCB) and one on J401 (under the little flap on top). Undo the clamp screw in the back right corner, swing up the clamp and remove the beam detect fibre cable. Then remove the 4 screws and lift out the scanner unit.

Now, *carefully* cut back the melted-over studs and lift off the top cover. Keep dust to a minimum (obviously). Remove the circlip on the scanner motor spindle on the bottom of the unit. Remove the rotor and hexagonal mirror, taking care to note where all the washers go. Remove the small screws and lift out the PCB.

(From: Flemming (flemming.gottsche@get2net.dk).)

Where the scanner cannot maintain proper speed. Replace electrolytic capacitors on scanner board. All capacitors are 10 uF/16 V. Also replace the current measurement shunt resistor (R301) on scanner board. It has a value of about 1 Ohm. All these parts are in the black plastic box below processor.

HP LaserJet II scanner information

(From: Jon Fick (JFick@pcilightingcontrols.com).)

The following Web site has some helpful hints about scanner chip/board replacement, and also has a scanned datasheet for the chip for those that want to substitute flatpack/dippack types.

- PIC Circuits.

HP LaserJet IIP error code 51

> "I have here a HP Laserjet IIP which gives errocode 51. The manual says something about a beam-detection. Do you guys 'n girls think this is to repair for relatively little money?

(From: Osceola Electronics (osceola@netonecom.net).)

On my IIP+, I had to take it all apart. I had to remove the main board and open the main cover to the laser area and clean the fiber-optic pickup and lens.

HP IID error code 50

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

A problem on the DC controller (in particular C210) can cause intermittent ERROR 50's

Mechanical failures of the fuser will not cause ERROR 50 (AFIAK). After all, the fuser temperature is maintained even when the mechanism is not turning. A broken gear in the fuser will cause paper jams, but not much more.

If you've got the machine in bits on the bench, and you are *sure* the fuser is not overheated, try shorting C211 on the DC controller board momentarily with the power off to clear the error.

HP LaserJet IIP+ error code 50

"My owners manual tells me that if this error persists after a 15 minute power interruption then service is required. Is it feasible for me to perform this service myself? What is the risk factor that my printer will be FUBAR if I attemp this?"

(From: Don Hickey (dhickey@knox.knox.edu).)

It could be one out of a number of items that are actually bad. Most likely it is the fuser assembly. However it could also be the Ac Power Supply, Dc Controller or the cable going from the fuser to the dcc. Most of the time the lamp on the fuser burns out or one of the thermal switches.

(From: (Frank Reid (reid@indiana.edu).)

Test for continuity through the large terminals on the fuser. That will tell you if the lamp and thermostat are good. If they are, then the problem is in the AC power supply (cubical box under the upper fan). Remove the printer case, observe the fuser lamp upon power-on. If it lights immediately and then goes off with an audible click, the triac in the power supply is shorted. ECG 5620 is a replacement. Be careful desoldering the plated- through holes.

HP LaserJet IIP - 52 error

"The problem with the machine is as follows:

1. I bought the printer used from friends a year ago. They sold it because the printer would crash when they sent it a large print job. I do that very rarely, and thus this happened very infrequently. I would just shut off the power and then turn it back on and it would print the same job just fine.

2. In December the printer would go through the initial diagnostic routine, but when the first print job came it would at first sound fine, but then make a longish whining noise and then display the error message "Printer Error 52" (I looked that up in the Users' Manual: "This error message indicates a scanner malfunction.") I reset the printer, and then it would work fine.

3. The problem as described in 2) gradually occurred more frequently: I would have to reset the printer several times for it to print. After it started to print it would work fine until I turned the printer off for some time.

4. Finally even after letting the machine warm up for hours it would not print at all, even though it went through the diagnostics on power-up.

5. Model Number of the laser printer is: HP33471A, manufactured: April 1990 Serial Number: 3049J01EOB

(From: Charles Kyle (kyle@citynet.net).)

I have repaired a lot of the HP IIP printers with error 52. It has always been the scanner motor assembly. The assembly can be repaired by replacing the motor driver IC and possibly a burnt resistor or by ordering the scanner motor assembly.

Laser Impact carries the scanner motor assembly for the HP IIP. The part # is RG1-1771-000. it is easy to replace and costs about $60. Their phone number is (800)879-5882.

"I have a HP Laserjet IIP printer that no longer works and I need some help diagnosing. The printer does not print any text pages but instead gives an error 52 on the LCD screen. The owners manual says that an error 52 is a scanner malfunction. However the authorized service center said that this error was a memory error. The cost of having them fix the printer is more than the printers worth."

(From: Rich (richcar@flash.net).)

The service center gave you the wrong info. It is a bad scanner motor or a bad dc controller. I have found, that on a lot of laser printers for this error and others, that if you re-seat all connections internally, to all PCB's, the problem will go away. (About 50% of the time) If this doesn't work you can check the voltages on the dc controller itself. The dc controller is the PCB under the formatter, (If you were looking down on top of the printer) and directly above the scanner assembly.

```
 J212 on the dc controller
------------------------------------------------
 Pin 1: Gnd (blue)
 Pin 2: Gnd (blue)
 Pin 3: +24 * (red)
 Pin 4: +24 * (red)
 Pin 5: Gnd (blue)
 Pin 6: +12 (orange)
 Pin 7: Gnd (blue)
 Pin 8: +5 (brown)
 Pin 9: Data signal (yellow) (shouldn't matter)
```

* Paper path door closed or pwr supply interlock defeated

These are the voltages the dc controller uses. (From the pwr supply) The scanner assembly. is the most expensive part and on exchange you can get one for about $150-200. But don't quote me on that. Contact Printer Works or PC Service Source to find out. I don't have their numbers but you should be able to get them from the 800 directory. 800-555-1212 >

HP Laserjet IIP error 52 - chip replacement

(From: Jon Fick (fickpci@aol.com).)

I was finally able to fix the printer by replacing the chip on the scanning motor board rather than replacing the whole board. That's a $10 fix rather than a $80 fix!

The surface-mount chip and an associated surface-mount resistor apparently run hot in this application, and over time, darken the back of the printed circuit board.

- The resistor color bands indicate that it is 1 ohm. It measured 0.8 ohm so I left it in place. I was able to obtain some data sheets for the chip. Although the data sheet diagram is written in an oriental language it appears that the resistor could indeed be a low value in that location so I didn't change it.

- The chip part number is HA13456AMP. It is a surface mount device, a quad package. It's leads are meant to be soldered, not plugged. With Solderwick and a small iron the old chip came off easily. Be careful of the heat, though, because it appears that the surface of the board can become slightly delaminated. I also used a stereo microscope so I could be exacting as I applied the heat.

I covered the scanner rotor before attempting anything because I didn't want to have to clean the mirrors afterwards.

I also have the same chip in a different package that might actually be more robust. It is the HA13456A, a long DIP package with triple-width ground tabs in the middle of each side. It is electrically equivalent from what I can tell and might be a good substitute if the flat pack fails early.

The printer came right up, and self test immediately printed two pages!

The chip came from: B & D Enterprises International, PO Box 460, Main & Liberty Streets, Russell, Pennsylvania, 16345.

Their worldwide number, as well as tech support (really helpful) is: 814-757-8300 (800-458-6053 in the USA).

Their 24-hour fax number is: 814-757-5400

VISA, MASTERCARD, AMERICAN EXPRESS are accepted worldwide.

Each chip was $7.55. They have a $15 minimum order, so I ordered two, partly to make the minimum order, and partly to have a spare.

Laserjet IIP PS board

(From: Brian Mathews (icontech@volcano.net).)

I have repaired many of these power supplies and I usually replace the triac, two resistors (22 and 150 ohms?) and the eight pin DIP (usually marked SHARP).

HP LaserJet III problems

> "This LaserJet III has me stumped. It has a persistent error 50. I tried everything in the service manual, but to no avail. If anyone has an idea how to fix this, it would be most welcome"

(From: Ted Szypulski (szypulsk@esslink.com).)

Sounds like an open fuser lamp, like mine was. I have an LJ4. HP would only sell a rebuilt fuser assembly. My cost was $150.00. The fuser assembly on the 4 comes out the rear real easy. There are two captive screws to loosen and then it just unplugs. I removed mine and took it to another LJ4 just to be sure that was the problem before buying a new one. My testing with an ohm meter also proved the fuser lamp was open.

I hope the LJ3 is similar and this is of some help.

Smudged vertical line on HP Laserjet III

(From: Dan Bourque (danbou@nbnet.nb.ca).)

The common problem with these printers is that the fuser drum gets scratched by the heat sensors of the fuser assembly which gets dirty with toner. Take a look at the drum of the fuser if the protective coating was scratched to the metal. If this is the case then the fuser needs to be replaced (around $80.00 for refurbished). If the protective coating is not scratched to the metal then the fuser can be removed and disassembled to clean the heat sensors. Use alcohol and Q-tips to clean.

To print a test page hit the On_Line button to put it off-line and then press test button for about 5 seconds.

Shifted print on HP LaserJet III

> "The LaserJet III in my office has acquired the annoying habit of shifting its printed output about half an inch down on the paper. This sometimes cuts off the page numbers. It typically will never happen on the first few pages. Once shifted, it stays that way, until I turn it off. I'm kind of clueless, the manual doesn't mention anything like this."

(From: Frank Reid (reid@indiana.edu).)

Replace the pickup roller. Clean the transfer rollers with naphtha or mineral spirits. If that doesn't work, replace the transfer assembly (set of metal and rubber rollers after pickup roller; removable by 4 black screws). Inspect the solenoids on the DC power supply: The rubber pads sometimes become sticky and hold onto the armatures, thus messing-up the timing. If that happens, scrape the old pad off, clean the armature and core with solvent, and replace the pad. I use squares of double-sided foam tape and then use naphtha to remove the glue from the outer side. If you remove the old pads but don't replace them, the printer will be more noisy, and permanent magnetism in the solenoid cores may affect timing.

(From: Joop van der Velden (joopv@solair1.inter.NL.net).)

Two possibilities: a mechanical problem with the paper transport, or a escape sequence reprogramming the printer paper format(ting)

Try to print some test pages from the printer itself (no pc connected) If that gives the same problem, try cleaning the paper path and transport an paper separation mechanism.

(From: Randy McVittie (rmcvittie@octrf.on.ca).)

I thought it might have been the pick-up roller, at least that is what the manual was pointing me towards, but other people's 2 cents worth said to look at the solenoids SL301 and SL302 on the Paper Control PCA.

There is a piece of foam tape on the core of these solenoids, and it had become kind of sticky, preventing the solenoid from snapping back when power was removed. Then I had severe paper jam problems I guess you need some amount of spacing here. So I put a few layers o of electrical tape in the same spot and now I had great registration. 3 layers of tape was my magic number, your mileage may vary.

This area was not even mentioned as a source of problem in paper registration troubleshooting chart in the HP manual.

HP LaserJet III powers on but appears dead

> "When I flip the power switch on, I can hear it power up, but the none of the lights comes on and the LED panel is also dead."

(From: David J. Pittella (ddc_pitt@ix.netcom.com).)

Since you say the unit 'powers up', I assume you hear the engine power up (fan, drive motor, etc). Assuming this is a Lajerjet III (not IIIp or IIIsi, etc.), you can do an engine test by removing a small cover on the bottom of the right side, removing this cover will expose a metal plate with a hole in it. The hole exposes a switch on the DC controller which will print simple line test pattern. This will at least confirm that the engine is working.

The front panel LCD display and status LED's are driven by the formatter board. The formatter gets its +5 power from the DC controller via (2) screws that secure the formatter to the CD controller. If you remove the bottom plastics and bottom pan, the formatter is the large main board. The DC controller is the smaller board with several connectors attached to it.

I am also making the assumption that the cable leading from the formatter to the front panel is attached at both ends?

You may also want to remove any options, (memory, optional I/O) as one of these options could be preventing the formatter from initializing and possibly lead to a blank display. BUT, the best guess here is that the formatter is not getting power - check those screws between the DC controller and formatter!

HP LaserJet III cold fuser

(From: Flemming (flemming.gottsche@get2net.dk).)

Where the fuser is cold and the relay trips, check Q153 for leakage (C-B) which results in current leaving the base and charging C158. When C158 is charged to about 3.3 V, Q153 is turned on and the relay trips.

The relay that is tripping is RL101, which actally is located on another PWB than the transistor. This relay has a very distinct sound, which has been mentioned over and over again in postings to various news-groups. Both PCBs are placed in the rear right corner of the HP LJIII.

HP LaserJet III paper jam

> "I have two LaserJet IIIs that complain about a paper jam on power up, right after the self test (i.e. before I've even had a chance to send anything to the printer)."

(From: Terry (tmredding@worldnet.att.net).)

The most likely cause of this problem is the exit sensor arm or photointerrupter or the dc controller board. Standing in front of the printer with the top cover up it will be in the far left lower corner.

(From: Wong Sy Ming (siming@singnet.com.sg).)

HP LaserJet III paper feed problem

My LJIII wouldn't feed paper past the registration assembly. Sounds like a mechanical problem right? No, it was not mechanical but rather it was electronic problems. At first I replaced the two drive transistors on the solenoid board thinking that one of them burned out but that didn't solve the problem.

Then, the whole thing came apart as I traced the connections for one of the solenoids back to the DC controller board. Guess what? One of the PCB traces near the 78324 IC (large square one) was corroded away. I quickly soldered a wire across it and now it works perfectly! Now I wonder what could have caused that...?

HP LaserJet III error 50

"My HP Laserjet III is giving a "50 Service" error. So something is wrong with the fuser. But the lamp is not burned out. Also, the fuser roller is pretty clean.

When I turn on the printer, the light in the fuser comes on for a second. Then there's a click from the power supply (or around there), and the light goes off.

The 05 Self Test message comes up.

Then Warming up (takes a while).

Then, both online and page feed lights go out and "50 Service" appears.

The power supply and fan are working and the ozone filter is clear."

(From: Geir Knutsvik (geirk@netpower.no).)

What about the fuser? Does it make heat? I have in some cases have faulty opto electronics for sensing paper and drawers result in Error 50.

In worst case it cold be the main pcb ...expensive... check dc controller.

(From: Mark Wolfe (markw@wwa.com).)

5 bucks says it's Q101 in the power supply (crosses to NTE 5620). I've seen quite a few where this was the problem. Check the power connector at the right end of the fuser, it's under a plastic cover. There should be about 115 VAC there during the warm up, you'll have to stick something in the cover open switch to get it to power up. If there is 115 VAC, it's the lamp in the fuser. If there isn't 115, it's save to say it's Q101 which is the triac that supplies the fuser. Get a new heatsink with the new triac. Cost here with tax to fix the problem is $7.07 + my labor. :)

(From: Terry (tmredding@worldnet.att.net).)

This error can be caused by missing 24 v, bad Thermistor, Fuser Bulb or Thermoprotector. Replacing the fusing assembly is quite easy by removing the 4 silver screws that secure it.

Notes on HP LaserJet III error code 50

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

[Error 50, SX Engine]

Remove the fuser (4 screws hidden down holes - it helps to remove the plastic cover from the left hand side (1 screw).) At the right hand side there's a 2 pin plug that goes into the AC block. Test for continuity between the 2 pins on the fuser. If it's open, then it's either the fuser lamp or the overheating-protection thermal switch that's open. It's pretty easy to trace the connections and test them separately if you can figure out how to dismantle the fuser (I can talk you through it).

If the fuser is OK, then remove the outer plastic casing, and the AC block under the upper fan [at the right rear of the printer. Remove the two screws securing the black plastic ozone filter housing, pull that housing straight up and off. Three vertical screws secure the base, plus one horizontal one on the outside rear. Then pull the AC block straight up. The fuser must be removed prior to removing the AC block].

Most of the time the thing that fails is the Triac, Q101 on the lower board in the AC block. This means the fuser can't heat up.

Here are a few notes on what goes on in the AC block (totally unofficial, BTW).

Lower board:

R101, L101, C101, C102, C103 form a mains filter. The output of that goes to CB1 (circuit breaker) with VZ1 connected across the output of that lot as a spike suppressor. The output of that goes to the 2-pin plug (J104) and thence to the DC power supply. Watch out for J104 if you run an AC block out of the printer as it carries live mains.

The fuser control circuit on the lower board isn't complex either. The live side of the mains (output of CB1) goes to T101 (current sense transformer) primary. The other side of the primary goes to the contacts of RL101 (fuser protection relay). There's a snubber SQ101 across the relay contacts. The other side of the relay contacts goes to one pin of J103 and thence to the fuser lamp. The other pin of J103 (and thus the other side of the fuser lamp) is returned to the neutral side of the mains via the triac Q101. This is triggered by SSR101. Oh, there are a couple of resistors (R102 and R103) in the triac gate circuit, and suppression components L102 and SQ102.

There's a 10 pin connector between the lower board and the upper board. The pinout seems to be:

```
Pins 1,2    T101 current sense transformer secondary
Pins 3,4    RL101 relay coil
Pins 5,6    Solid State relay (SSR101) input (6 +ve)
Pin 7       Fan control
Pin 8       Fuser drive from the DC controller
Pin 9       Ground
Pin 10      +24 V (input)
```

The last 4 pins are connected to the 4 pins of J101 which is connected to the DC controller. Shouldn't be hard to trace those.

Upper board:

This virtually never fails, so I'll simplify the description by missing out resistors, etc. You can trace the signal flow from this description anyway.

The fan control is trivial - the fan control input drives Q159 with the fan as the collector load.

The fuser control signal is AC coupled (C157) to Q157. The output of that is rectified/smoothed (D157/C156) and drives Q156. The collector load of Q156 is SSR101 on the lower board.

There's also a protection circuit, which works as follows. Normally Q153 is on which turns on Q152 and Q151. This turns off Q155 which has the protection relay as its collector load.

If the fuser control circuit fails so that Q156 stays on too long (which would cause the fuser to overheat), then C153 is discharged by D155 and the collector of Q156. This turns off Q153, Q152, Q151 and turns on Q155, energizing the protection relay and turning off the fuser.

If the fuser takes too much current then the output of the sense transformer T101 becomes large enough to trip the comparator IC151 (LM393). This turns on Q154 which discharges C153. The rest of the circuit operates as above.

(From: Jon Martin (jon.martin@unisys.com).)

There is a partial Schematic of the AC power supply at: Fuser Controller RG1-1438.

The fuser thermistor comes in on pin 4 or J206. There's an 18k resistor (R237) to +5 V, and a 4.3K resistor to ground via SW205 (which is open when the base cover is on the printer -- the idea is to shut the fuser down if you power up the printer when dismantled). Then there's a 3.3K resistor in series (R747). And then a 4.7 uF cap (C210) to ground to smooth the signal out a bit. Finally we get the AN0 input on the main microcontroller IC218.

The fuser drive signal comes out on port PD2. This is buffered by IC219e ('04) and IC211e ('07) before going to pin 2 of J208 and then to the AC block.

There is one more bit of circuitry to consider -- the overheat shutdown. If the fuser overheats (or the machine things it has), then a signal comes out on port PD3. This turns on Q210 (2SC1815) which charges C211 (100 uF) via R749 (330 ohms). There's a 4.7M resistor (R748) in parallel with C211, which gives a time constant of many *minutes*. That's why to have to leave the printer off if the fuser seems to have overheated. Anyway, the voltage across C211 is monitored by the AN3 input on the microcontroller

So, what to check? C210 is a favorite, it goes leaky. If that's not it, check (with the printer assembled and therefore SW205 open -- you have to solder wires onto the points so you can look at the signals) the following

1. The voltage across C210 (should be around 2 V I think). If wrong, check the fuser thermistor and connections, the R's and C's between it and the microcontroller, etc

2. The voltage across C210. If it's more than 0 V, then switch off, discharge C210 (short the leads together), try again. If it rises again, find out if Q210 is being turned on (Check the base voltage -- it's an emitter follower). If so, then either the microcontroller is faulty, or there's a problem you should have spotted in (1) :-). Check Q210, the R's and C's, etc.

3. Any pulses at the input to IC219e (pin 11 of IC219). If not, then again, suspect the microcontroller if you've got this far. If you do have a signal there, check it again at the output (pin 10) of IC219e, then the input of IC211e (pin 11) and the output of IC211e (pin 10 -- this should be a 24 V level signal, not TTL). If you get a signal at the output of IC211e, then make sure it gets to the AC block. If it does, then the fuser should work.

If the microcontroller is faulty then as far as I know, the only place to get a replacement is off another DC controller board.

Paper jams on HP LaserJet IIIP

> "More and more I get HP Laserjet IIIP printers here with all the same problem: 13 Paper jam. Every time I look at the driving-mechanism and move it with my hand, but it all seems to work fine. I suspect there's a common cause to all this. I think it's got something to do with the electromagnet in the tray, but I'm not sure."

(From: Frank Reid (reid@indiana.edu).)

If the paper is getting crunched accordion-style, the 'drum-drive clutch' is probably broken. It's a couple of small white gears inside the right-side cover of the machine. The plastic tends to crack in a ring, separating the gear from the shaft.

To confirm, mark the green drum in the toner cartridge: If it doesn't turn, then the clutch is surely at fault. Apple "Personal Laser Writer" and some other brands use the same print-engine.

If the machine won't pick up paper at all but the pickup rollers are good, look for a bent piece of metal preventing movement of the bar that raises the stack of paper just prior to pickup.

A third possibility is stripped plastic gears on the fuser assembly.

(From: Lars Arvidsson (arvid@plea.se).)

My guess is the paper intake rubber reel, you see it if you pull out the paper tray. It gets old and dry, and it needs to be sticky to get a grip on the sheet. It gets worse at dry weather, cold and dry. Try to clean it with alcohol, then coat it with some balsam turpentine (don't know if this is the right translation, it's a liquid used for diluting artist oil paint).

Allow it to be absorbed for a few hours, then wipe of the excess. The reel is sticky again...or just replace it - but that's no fun. ;-)

(From: Rick Norton (RKNORTON@worldnet.att.net).)

I repaired an HPII with a similar problem using automotive belt dressing on the rubber pickup surfaces. Spray a small amount on a rag and wipe on surface. Allow to dry for 15 minutes. The printer has been working for 3 years without a problem.

(From: Dr. John Betts (Dr@browser.demon.co.uk).)

Don't ignore a more mundane cause - that paper is stuck inside the fuser, particularly if someone has used inferior grade labels.

HP LaserJet IIIP power up problems

> "I have a HP Laser Jet IIIp, The problem is when it is switched on, the printer can do one of two things; the panel lights up and displays 05 Self Test and then switches off after around 3 Seconds, and other times nothing happens at all."

(From: Pete (PTCull@lbl.gov).)

If you have a voltmeter, J212 on the DC Controller is a good place to start checking. Blue wires are earth/ground, brown is +5 VDC, orange is +12VDC, and the red wires have +24VDC.

However, it sounds like a nice time for known good spares or another known good LX engine to borrow known good assemblies from.

HP LaserJet IIIP - error code 52

> "I have inherited a dead HP LaserJet IIIP printer and would like to hear your thoughts on its chances.
>
> The machine goes through its warm up routine OK but if I do an internal font printout or print from a PC then it sits quitely for about ten seconds, then raises in pitch for a second and simultaneously displays: 52 ERROR.

> The manual states that this error is a 'scanner fault'.
>
> I have dismantled the unit down to the laser and rotating mirror but can see no obvious faults. Perhaps the motor that drives the mirror is burnt out or the laser is dead??
>
> HP have quoted me a repair price equivalent to a new Oki!!!

(From: Frank Reid (reid@indiana.edu).)

That symptom can often be cured by re-seating the cables between the laser assembly and the dc controller (smaller board under bottom cover). Also check the optical fiber running from the laser scanner housing to the dc controller: Sometimes it goes bad or the end gets dirty. If you can shine a flashlight through it, it's probably ok.

(From: Ralph Wade Phillips (ralphp@prysm.net).)

About 50% dead laser and 50% bad DC controllers (photoreceptor dies, or interface chip it drives is dead ... gives SAME error!)

Without a spare printer for parts, it'll cost you about a new printer for parts ... sigh.

(From: John Fiskio-Lasseter (johnl@yin.earlham.edu).)

Not necessarily. There are a number of places where you can simply buy the parts themselves, often refurbed - even a DC controller and laser assembly together would be cheaper than getting another printer.

Adam, at a guess, I'd say that you really are looking at a failed laser/scanner assembly. Of the possible causes, that's the part that gets the most wear and tear, and the most likely to fail under normal operating conditions.

A few places to try for parts:

- Hewlett-Packard: Part # ID: 1-916-783-0804, Sales: (800) 227-8164.
- The Printer Works: 1-800-235-6116. (These people have the coolest catalog in the business!)
- Laser Impact: 1-800-777-4323.

Both PW and LI will do repair, parts sales, and exchange parts sales, and you may find them a good bit cheaper than Hewlett-Packard.

Also note that the engine parts from all other HP LaserJet II's and III's are interchangeable with yours. So are the engine parts (except the DC controller) from the Apple LaserWriter II printers. Other printers based on the same Canon SX engine are: QMS 410, Brother HL-8e, and several others that I can't remember off the top of my head.

(From: Steve Pepin (steve.pepin@mogur.com).)

You may not need to dump the printer or even pay for a new scanner assembly. I had exactly the same problem with mine and it turned out to be only the cable that attaches the scanner assembly to the main PCB. It's only a $28 part and you can possibly simply repair the one you have. I don't know how mine failed, but that is what our local HP service center replaced.

(From: Frank Reid (reid@indiana.edu).)

Correct! I repair at least 100 of those things per year. The connections fail far more often than the $canner. The problem can usually be solved by removing and re-seating the connectors on both ends of the cables that connect the scanner and laser to the 'dc controller' board (smaller board under bottom cover).

(From: TAltmeyer (taltmeyer@aol.com).)

Sometimes the driver-IC for the mirror motor is defect. It's a circuit from Hitachi HA1XXXX, i can't remember the number exactly. A half year ago i had such a printer with error 52 and i replaced the chip and all was fine.

The chip is a little bit difficult to get but if your're encouraged enough you can get it (after a lot of telephone talking) from your local hitachi distributor. It's much cheaper than a complete unit :).). The scannerunit itself was made by Canon (as the complete printerdrive is made by Canon)

HPLaser Jet IIIsi - 'User Maintenance' message?

> "What cause a working HPIIIsi coming up with 'User Maintenance' message in the lcd window. If you pop up the cover and reclose, the message goes away and printer keeps on printing fine."

(From: Jim Hunt (jhuntjr@b-c-i.com).)

I believe this is the message you get after printing 200,000 (I might be wrong) copies which is a reminder to replace the fuser unit. This comes in a kit with new pickup rollers and several other pieces. It is pretty easy to replace

HP LaserJet 4 - intermittent error code 50

(From: Brian Mathews (icontech@volcano.net).)

I have seen this problem quite a few times and I check the fuser lamp to find it was manufactured by USHIO. After replacement with a Toshiba lamp (not an endorsement, just what the supplier sends) the problem is gone. I haven't ever had this problem and not found that brand of heat lamp in the fuser......

HP LaserJet 5L grabbing more than one sheet of paper

(From: Shaun Harwood (shaun.harwood@virgin.net).)

I'm a field engineer and deal with quite a lot of printers. What is quite a common cause for this problem is damp paper or using the printer in a damp room. Try a brand new ream (direct from store) and try using in a warm room and see if the problem goes away. I've been having this problem a lot lately as the weather has turned a bit - most of my customers store the paper in store rooms and it gets a bit damp. Incidentally HP printers in particular seem to be suffering from this quite a bit. >

HP LaserJet 5 SIMM codes

(From: David B. Gustavson (dbg@SCIzzL.com).)

Here are the empirically determined SIMM codes for the HP LJ5: (o for open circuit, g for grounded jumper)

```
 Pin 70 69 68 67
------------------------------------------
```

```
o  o  o  o  treated as an empty slot
o  o  o  g  53.00.02 error
o  o  g  o  53.00.02 error
o  o  g  g  53.00.02 error
o  g  o  o  53.14.03 error
o  g  o  g  16 Meg RAM
o  g  g  o  2 Meg RAM (=LJ5 70ns)
o  g  g  g  4 Meg RAM
g  o  o  o  53.14.03 error
g  o  o  g  16 Meg RAM
g  o  g  o  53.14.03 error
g  o  g  g  4 Meg RAM (=LJ4 80ns)
g  g  o  o  53.14.03 error
g  g  o  g  16 Meg RAM
g  g  g  o  53.14.03 error
g  g  g  g  4 Meg RAM
```

Since there are several codes that have the same RAM size, it's possible that they correspond to different RAM speeds or other differences that might matter. I connected my $129 16MB 70ns 32-bit-wide 72 pin SIMM in the g o o g pattern, and so far it seems to work OK.

If anyone has more info, such as speed or other characteristics that ought to match the ambiguous codes, I'd be very interested. Some of these codes correspond to the RAM/ROM PostScript SIMM, but those seem to be driven from a logic array and might have more complex behavior. In particular, no static code was interpreted as such a PS SIMM, but that might be because it already found one in another slot.

With a duplexer, the LJ5M barely functioned with the original 6MB RAM, had to run it at 300 dpi or it would just not bother to duplex. Borrowing 4M from my old LJ4M raised it to 10M, which raised the performance ENORMOUSLY. 16M raises it to 22M, which is surely major overkill, but for $129+tax at Fry's, why go for less.

So far the software on my Mac is refusing to control the duplexing features, e.g. the "which edge is the binding edge" choices are always disabled, but turning it on at the printer works (unselectively). But maybe this is due to some beta printing environment stuff I'm using.

HP LaserJet random behavior - no ground

Aside from surge supressors not being effective (to the extent that they ever are) without a proper safety/earth ground, here is another example of possible symptoms:

(From: Leif Gastgivar (lgastgiv@technis.syh.fi).)

I bought a new HP Laserjet 5L printer and I just plugged the printer into the socket. After a time the printer started to print out pages by its own. I checked out the manual but I couldn't find out the problem. But after a wile I find out, that the printer wasn't connected to the ground. After I fixed the problem, it will have been working properly.

Determining if HP LaserJet partial print problems are scanning or logic

This would apply if, for example, an HP-LJ3 prints only left side of the page.

If the boundary is sharp and constant, logic is likely but not always.

If the boundary is fuzzy and/or ragged, blockage in the optical path is more likely - a label or Post-It(tm) note that escaped, or even a wad of dust or other debris.

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

Does the printer have an 'Engine Test' switch (a button on the DC controller PCB on the LaserJet 2, and one on the side of the LaserJet 1)?

This will cause it to print a test page (of vertical lines normally) even if the formatter board (the thing that translates the incoming data into a bit stream to send to the laser) is defective.

If you can find such a button (it's hidden on the side of the lower cover on the Laserjet 2), press it and see what happens. If you only get half a page, then the fault is almost certainly optical (Check for defective mirrors, etc as mentioned earlier in this thread). If you get an entire page of lines, then the fault is in the formatter board. I have no info at all on any formatters other than the Apple Laserwriter 2NT one, alas

(From: Ralph Wade Phillips (ralphp@gcstation.net).)

On one side of the bottom, there's a cover that can be removed after removing one screw. After that, the button is visible through a hole.

Only push this AFTER it warms up all the way - it's ignored until the engine is ready!

LaserJet IIID and others: paper not picked up correctly

> "The printer will print perfectly on both sides if the paper is fed into the sheet feeder. If the paper is fed from either of the paper cassettes, the paper not picked up from the cassette. There is a mark on the paper where it appears the roller has been rubbing on the paper."

(From: Al Savage (asavage@iname.com).)

Piece of cake. Replace the pickup rollers. You can clean them, but it won't last.

Now, the bad news: it's not real easy. Or, like most things, it's really easy once you've done it a couple of dozen times.

The rollers themselves are about $5 these days, and have been redesigned to eliminate one problem they used to have: you can't put them on backwards anymore!

LaserJet IIID: remove all exterior plastic: three screws up top accessed after opening the lid. One screw horizontally near AC power cord receptacle. Release nasty catch of top lid from side plastic at just above AC receptacle. Try hard not to break top lid while doing this. :)

Now you can access two screws retaining front edge of side panels to front panel. Remove two vertical screws holding left side panel to rear of printer chassis, near fuser.

Unhook front panel operator panel cable, remove front panel assy.

Remove six small screws retaining front chassis subframe to (scanner, HVPS, DC PS), plus about five larger screws holding power envelope feeder subframe to front.

Remove DCPS on right front of chassis: remove three vertical large screws (two in front, one at right rear). Disconnect main motor harness from DCPS. Disconnect gray fibre optic cable from black clip at left front edge of DCPS, or it will be damaged, and you'll add another large batch of screws to remove/replace! Then remove DCPS by grasping firmly and pulling straight up. This takes considerable force, as there are connectors at the bottom that you are separating.

I recommend removing the registration assy prior to removing the paper pickup assy, but it can be done without. To remove the registration assembly, remove four vertical screws (three black, one chrome, most likely on III series) from reg assy, which is the part with the green "handle" just inside the paper path, as you look straight down into the printer. The left rear (shiny) screw will likely have a short ground wire under it on a III. With the DCPS out, the reg assy will just lift straight out. Note carefully the bronze ground lug at the left front of the reg. assy. It must be rotated forward at reassembly or the forward black roller (small diameter, 9" long) on the reg assy won't be grounded, and you'll get all kinds of odd print quality problems. Look at it now, BEFORE removing the reg assy, to see how it's supposed to look.

Using long #2 Phillips, remove two small screws retaining the pickup assy (the shaft with the grey PU roller on it, plus the black or white spring clutch on the right end of the shaft) black plastic bearing blocks. Lift up PU assy, slide 2" to right (the reason you had to remove the DCPS), then swing left end rearward to where the reg assy used to be, and remove.

To replace the PU roll: remove E clip on left end of shaft, slide off all the washers, spacers, etc, noting the order carefully. Roll just falls off!

On reassembly, don't forget to reconnect the main motor's wire harness to the DSPS. One of my common problems.

If you're going to do the lower PU roll, do it now, prior to reassembling the top half. Remove the lower side plastic panels -- one horizontal screw in back for each side.

After removing the sides, remove the E clip on the left side of the lower pickup assy, then remove the bronze shaft bushing. Don't lose it.

On the right side, remove the three small horizontal screws on the clutch plate, disconnect the clutch's harness from the chassis harness and harness hold-down clip, then rotate the clutch plate and slide the lower PU assy out the right side.

Replacing the PU roll is identical to doing the top one at this point.

Now you know why I charge 1.5 hours to do top & bottom rolls. Plus, I pull the lower pan and vacuum it out, Fedron the reg assy, and replace upper/lower fans if needed.

The IIID is the best laser printer HP ever made, barring the Si series. Well worth the effort and expense, even if you have to replace the fuser too. I like them a lot.

Done right, a proper PM of a IID or IIID involves removing the upper unit from the lower to properly clean the skewed feed roller, but that's another 30 minutes, plus cleaning the refeed assy. You can "kinda" clean that lower feed roller (not the PU roller) if you have small hands and a long Q-tip, but it really isn't a good job.

PS: oh, yeah. I wrote this all from memory, and I haven't done one in a couple of weeks, so I just *might* have overlooked something. But the major steps are there. Keep track of the various screws, they're not all interchangeable.

Laserwriter LS

> "I have a Personal Laserwriter LS; am getting 'fuser assembly malfunction' error. Does anyone have

> experience w/this, know the likelihood that I need to replace the entire fuser assembly, or how I can find out? Also, is there a place to get a used assembly, and is it difficult to make the repair myself? Stores charge $200 parts and labor for the replacement, and this printer's not worth that investment."

(From: Frank Reid (reid@indiana.edu).)

The fuser lamp often fails in that model. The replacement is Apple part number 890-0427. I think it costs roughly $25.

Apple technical information

The following Web site provides links and a search capability for Apple computer products including Apple printers:

- AppleCare Tech Info Library.

Apple Lserwriter I/O

> "I just picked up an Apple Laserwriter II NTX which appears to be working. The problem is I need to find out what this thing has for I/O, and what the dip switch settings are. It appears to have a 50 pin centronics connector, along with a DB25, an appletalk port and one other port."

(From: Erik Johansson (erijo105@student.liu.se).)

The ports are a Phonenet Appletalk connector, a 50 pin centronics-like scsi connector (to connect a font cache hard disk), 25 pin female D-sub serial connector (wired as a DTE so the cable should be the same as when connecting to computers, not a computer and a modem) and a RS-422 8 pin miniDIN connector (also for serial communication).

The jumper settings:

```
 Switch1 Switch2           Function
---------------------------------------------------------
   Up      Up     8 pin AppleTalk (Serial Port Disabled)

  Down     Up     25 pin RS-232 and 8 pin RS-422
                  Serial Ports 1200 baud

   Up     Down    25 pin RS-232 and 8 pin RS-422 *
                  Serial Ports 9600 baud

  Down    Down    25 pin RS-232 serial port 9600 baud;**
                  pin RS-422 serial port 0 baud

 Switch3 Switch4   Function
-----------------------------------------
  Up       Up     PostScript Batch

  Down    Down    HP LaserJet
  Up      Down    PostScript Interactive

 Switch5 Switch6   Function
----------------------------------------
  Down    Down    No Handshake
```

```
Up      Up      ON/XOFF
Down    Up      Etx/Ack
Up      Down    DSR
```

Apple LaserWriter and LaserWriter Plus paper jams

(From: Ralph Wade Phillips" (ralphp@techie.com).)

I suggest that you cruise on over to The Printer Works and check out the blowup parts list for the LaserWriter and LaserWriter Plus mechanical (Canon CX engine - also LaserJet, LaserJet 500, LaserJet Plus, and several, SEVERAL other printers). That will make the text easier to follow. (Use the search facility for the printer model - that will include the "Parts Identification Diagrams".)

To repair the MOST common problem with consistent jams at the paper INLET, you have to strip the printer down to where you can remove the Registration Shutter Assembly. Due to how the LaserWriter I/O board is connected, you'll have to remove the I/O board (the big one with the Plus ROMS on it), and the case it's in (Note: DISCONNECT the board from the computer's wiring harness, do NOT try to remove it from the case. The case should come off also - leave it mounted there.) After that, you can see the registration shutter mounting screws, along with the wiring harness for the shutter solenoid AND for the cartridge installed/sensitivity microswitches. Remove the shutter assembly. You'll have to either dismantle it and clean the solenoid out, quite possibly having to replace the rubber bumpers, or you'll have to replace it.

I have left out the most obvious steps of removing the upper housing and several other steps - they should be obvious from the parts diagrams for the printer.

Apple LaserWriter prints double/repeated images

The characteristic is faint repeated printing a couple of inches down the page as well as from the previous page.

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

- Try a new toner cartridge. I _think_ there's a problem that will cause this.

  (The wiper blade which is inside the toner cartridge on these printers may be warped/defective --- sam).

- The preconditioning lamps are not coming on (more likely).

On a Laserwriter 2 series (the most common one IMHO):

With the top cover open, look for 2 ping contacts in a little white pillar attached to the cover on the left-hand side. When the cover it closed, it makes contact with 2 similar contacts on the PCB on the left side of the fuser. Check for continuity (but not 0 resistance) between the 2 contacts _on the cover_. If it tests O/C, remove the toner cartridge (you did that, right?), then the little metal plate (grey metal, held on by 1 screw) behind it, then undo the 2 terminal screws under this, undo 2 more screws on the large grey metal assembly, and remove it. Inside this are 5 bulbs in series, one of which has probably blown. You can get replacements from the PrinterWorks

If those bulbs are OK, then check the power transistor on the PCB on the left end of the fuser.

Apple LaserWriter IIg runaway scanner never stops

(From: Dave Lee (leedj@uwec.edu).)

A good possibility is the cable from the scanner to the DC controller. It might just need to be re-seated. Might need replacing.

Apple Laserwriter IINT error codes

> "Where can I find the meaning of the flashing error codes on a Laserwriter II NT printer? It is flashing both the paper jam and the paper out light. The fuser doesn't heat up."

(From: Ralph Wade Phillips (ralphp@gcstation.net).)

It means that the fuser isn't getting to proper heat. This might be a blown fuser, might be a bad AC Input Block, might be a bad DC controller.

Before I fought TOO hard, I would pull the fuser assembly and check the 115 VAC inputs for continuity. If you don't have any, then I'd say you most likely have an open fuser lamp, and it will need to be replaced.

If you have continuity, I'd change out the AC Input Block, and work from there.

The DC controller being dead is rare, but it *can* cause the same symptoms.

(From: Mark Wolfe (markw@wwa.com).)

Do what the other guy said, but instead of replacing the AC Power Block, check the triac at Q101 inside the ac power block. Common failure on this engine. When you do fix it, put a good heat sink on the thing.

Apple Laserwriter IINT 'clicks' with intermittent fuser error

> "I have a LaserWriter IINT with an intermittent fuser error. When the printer is switched on, sometimes it cycles normally and works fine; but sometimes, the startup cycle sound is followed by a soft click, and a few moments later the green light gives way to double blinking red. I have attached a voltmeter to the fuser lamp contacts; when the soft click is heard, no voltage reaches the fuser."

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

The click is almost certainly the fuser protection relay dropping out. This relay is located in the AC input block assembly at one end of the fuser, under the main cooling fan.

This relay is on the lower board in that module, and is driven by the protection circuit (a few transistors, not hard to trace out if needed) on the upper board. It operates if the fuser drive signal from the DC controller is active for too long at a time - it prevents the fuser from overheating if one of the CPUs on the DC controller goes crazy

OK, things to check:

1. Look for dry joints on both boards in the AC input block. They are *very* common here.

2. Check the thermistor in the fuser. Clean it, check for dry joints, check that it is pressing against the fuser roller.

3. Reseat all the connectors on the DC controller board associated with the fuser and AC input block.

4. If that doesn't cure it, you'll need to hang a scope off the fuser drive signal (one of the 4 wires from the DC controller to the AC block - the other 3 are ground, +24 V and fan speed control) and see if the fault is in the DC controller (Signal does stick high) or the AC block.

Diagnosing a blank vertical strip problem on Apple Laserwriter IINT

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

There aren't many (if any) electronics faults that can cause this, thankfully...

First press the test button on the side of the bottom casing round the back. Does the test printout also have this strip missing? If not, then you've got a very strange problem with the formatter board, and I'll have to think again...

Secondly, take out the cartridge and shake it, and put it back in. If that doesn't help, then try a new toner cartridge.

If you've still got problems, then the most likely problem is something in the beam. SX engines (which you have, and CX engines and...) print black where the drum is discharged by the laser [1]. Start by removing the toner cartridge. There's a black metal strip in the top cover above the toner cartridge. By fiddling with it you can move it slightly, exposing a front-silvered mirror. Inspect that for bits of paper, etc. Clean it _very_ carefully.

Next area to look at is the laser scanner itself. If you know what you are doing, take off the outer casing (screws round the outside, some under the lip that the lid closes onto, and 2 on a metal bracket at the left side of the fuser) and look at the scanner block. This is the black thing mounted over the paper tray. Unplug the cables (one to the laser PCB itself, one to the scanner motor under the little flap on top), undo the small screw to release the optical fiber, and undo the 4 screws that hold the scanner in place. Lift it out. Look at the slot on the front edge for any paper, etc. I don't know if I recommend you opening the scanner (Canon DO NOT, but I've done it), but you can carefully trim back the heat-moulded studs and open the cover. Look for debris inside. Handle it with great care, of course.

(From: Ken Eckert (eckert@sfu.ca).)

One problem that gives this printout is loose screws on a plate in the top cover above the toner cartridge. The screw(s) fall out and get stuck in the toner shutter window that that the laser goes through. I've had a couple like that, I made it a habit to tighten those screws whenever I work on one of these Canon engines.

Upgrading Apple LaserWriter to LaserWriter Plus

It may be possible to upgrade your Apple LaserWriter if you have a partially dead LaserWriter Plus.

(From: Ralph Wade Phillips" (ralphp@techie.com).)

There are two ways. One is to swap the eight or sixteen ROMS from the Plus into the same sockets on the LaserWriter, !AND! to swap the programming shunt assembly (a set of four jumpers in a 16 or 24 pin DIP socket), placing it in the exact SAME place. The easier way, if you have both printers, would be to remove the upper cage and swap THAT. This will mess up the page count, however, that's not such a big deal nowadays (not on a CX engine - after all, does it REALLY matter on a '88 Dodge Aries K that it's got 213K miles or 127K miles? ...)

Toner All Over Paper on Various Brother Laser Printers

(From: Robert Wilson (rfwilson@intergate.ca).)

Both my 300 dpi Brother 641 (sold as the 630 in the USA), and my friend's 600 dpi version of the same printer, had a problem where toner ended up all over the page. What a mess.

The problem was that there is a long thin spring that is rotated at one end, and propels the used toner (scraped off the drum) back to the point where toner enters from the toner container. It acts like an Archemedes' Screw, gradually transporting used toner back again for reuse. It also transports fibers of paper that have been scraped off, and therein lies the problem. Brother stupidly "closed" the end of the long spring (its last coil is bent to be in contact with the coil before). The result is that paper fibers (once they reach the end of the spring), get caught in the closed end of the spring and cannot get out.

The fibers build up until they jam the end of the spring and it can no longer rotate. The drive mechanism doesn't know this, and keeps rotating the spring until it breaks (usually right at the driven end).

The solution is to disassemble the printer drum (not all that hard, but not for the faint of heart!), remove the spring (it's about 15 inches long), and bend the end so it engages into the drive gear again. Then, eliminate the original problem by opening the last coil at the far end, so fibers can get out.

Resetting "REPL.DRUM" error on Sharp JX-9460

This will probably work for other laser printers as well though the details may vary. Use at your own risk!

(From Owen Solberg (osolberg@infinex.com).)

If your Sharp JX-9460 laser printer has decided it is time to give you the "REPL.DRUM" message on the LCD screen, but the print quality is still fine, then all you need to do is fool the page counter to think a new drum has been put in. Here's how:

1. Open the cover and remove the photo-drum.

2. Look down into the area under where the drum was. On the right hand side, you will see two circular metal contacts. You will also see two "slots" on the far right side. These slots mesh with plastic tabs on the drum cartridge.

3. At this point you will need two paper clips. Use the first one (unbent) to insert into the FORWARD-MOST slot. You don't have to push it very far. You will hear a click and the LCD panel will probably go from saying "COVER OPEN" to saying "REPL.DRUM." Keep holding the paper clip in the slot while you:

4. Touch the 2 ends of another paper clip BRIEFLY to the two circular metal contacts. (you will have to unbend the paper clip a little.) It will spark a little. Don't worry, it is only 4 volts. But I wouldn't hold it there for too long.

Anyway, the theory behind this is that the new cartridge comes with a fuse in it which is blown by the 4 volts the first time you insert the cartridge. That is what resets the counter. Better than spending $190 on a new drum, right?

TI MicroLaser Plus laser printer reports 'Main Motor Err'

> "I have a Texas Instruments Microlaser Plus laser printer which after I turn it on, reports that the self-test passed but then displays an error on the LCD: 'Main Motor Err'.

> This laser printer uses the Sharp JX9500 engine and I was able to find out how to get it into diagnostics mode. I selected "Test Print" and it returned "Service (C2) 01". The stepper motor appeared to be working correctly along with the fuser lamp."

(From: All Laser Service (laser@ix.netcom.com).)

The lubricant used on the gear train tends to gum up and the motor strains to the point that you receive a main motor error. Take the complete gear train apart and clean it. You will need to disassemble all the gears and clean both the gears and the axles. Also take a look at the developer and drum cartridges as they are driven by this gear train. If they are jammed this will also cause your problem.

Fuser problem/printer parts

(From: Robert Blackshaw (blckshaw@clark.net).)

> "I have a ti-microlaser printer that worked great until a gear in the fuser assembly cracked. This gear drives the rollers in the fuser. If anyone can tell me if there is a place to get used parts or a kit of the common parts that fail in the fuser etc. it would be a great help. Also looking for any other info on this printer such as: schematic, user manual, and part numbers for the photoconductor unit, developer unit and toner cartridges."

Try The Printer Works at http://www.printerworks.com.

I fixed an HP Laserwriter II (same engine as the NT) with exactly the same problem, a $0.49 gear on the fuser assembly. On top of it all their catalogs are like service manuals with exploded diagrams of everything.

Swapping fuser parts

> "I have a couple of Scrap Brother HL-8 Laser printers.
>
> Both have defects in the Toner Fixing unit (Fuser roller?). Which is the unit that melts the toner onto the paper.
>
> One unit has VERY BAD scratches on the Toner fix roller itself, which causes a bad streak on pages.
>
> On the other unit the heating element on the Toner fixer has blown. The big question is can I take the heater from one, and place it in the roller of the other? Anyone done this? A new roller unit will cost me 90 quid, so a couple of hours to actually do it is worthwhile, as a working laser printer will be the result."

(From: JStev55598 (jstev55598@aol.com).)

No problem if you are careful when swapping over the fuser lamp you will have a working printer which is a darn site cheaper than a re-con unit. One thing to bare in mind is what made the lamp fail in the first place. Although it has usually got to the end of it's natural life sometimes a failure in the temperature sensor or a power supply fault can cause the lamp to overheat.

When turning it on for the first time after replacing the lamp check that it switches on and off after it's initial warm up . You can sometimes see the lamp when it is on through a vent in the side of the printer by the end of the fuser roller.

Panasonic KX-P4410 CHNG DRUM error code 027

(From: David Moisan (dmoisan@shore.net).)

The drum sensor on my 5400 is an opto-interrupter that sits over an opaque flag that's connected to a bucket inside the waste-toner compartment on the drum. When the bucket is full, the flag blocks the sensor and causes the CHNG DRUM indication.

Carefully drill a hole to get the toner out and BE CAREFUL OF THE DRUM SURFACE. I killed mine doing this. What sucks is that when this happened I was getting the indication and I only had 4400 pages on it (it's a 6000 page life span, supposedly).

when you're done, power up the printer while depressing ENTER. The display should tell you "DRUM COUNTER RESET" or something like that. Another fun thing I really love about the printer is how the developer mechanism--the magnetic drum that picks up toner--is permanently mounted in the printer. Lots of fun if the scraper is removing toner in one spot and you can't clean it. :((A slip of paper *somewhat* works.) I only found this out after tearing my printer down *completely* and removing every last bit of old toner.

After 3 years, I'm *not* happy with my printer any longer. Though it's had a new drum, it has *never* worked the same since it was changed out. White streaks on the output where there's not enough toner. And smeared characters where there's *too* much toner. *sigh*

It goes against our dogma here to say this, but I am very tempted to throw my printer out the window. (And I say this as a Panasonic owner who loves his 27-inch TV.) It's not repairable, I'm tired of tearing down the printer for a fault I can't possibly fix. And I'm tired of blowing another $70 on a drum that will die before I know it. Not when I can get a new printer for about the same price, 600 DPI and at least 12,000 pages before I have to spend big bucks on a drum. Like Curly Sue, when it was good it was very very good but when it's bad....

Panasonic 4420 laser printer error code E31 and other comments

(From: Al Savage (asavage@iname.com).)

E31 is the most common reason for a 4420 to fail.

The manual says that 'fusing unit failed to reach x degrees in 90 seconds' or words to that effect. Makes you think of fuser problems, right? Bulb, thermal fuse, thermistor? Well, only about 1 out of 10 times.

The problem is solder blown off two pins in the AC power supply, located on the front left side of the printer (after removing plastic cover) as you face the front. Easy fix, if you're moderately handy.

E31 and dirty feed rollers (and paper pickup roller) are about the only things that fail on a 4420. Well, you do need to replace the developer and drum every so often, and they're pretty expensive, but they're long-lived, too. Much lower cost-per-page than any HP product.

I happen to think the 4420 was Panasonic's best-made laser printer. The 4450 is over twice as fast, at 11 pages/minute, but you can't really run laser label through it. And it's MUCH harder to service.

Copy counter fuses

> "I have a Panasonic KX-P4420 laser printer. It locked up with a message about 36K service.
>
> I issued the incantation to reset this message. It now works again, but the display is flashing 'Change DEV' and 'Change Drum'. This makes it more difficult to use the menu system. I'd like to turn them off.
>
> From the dealer's explanation, I gather that there are fuses in both the developer and the drum. When you install a new one, the machine senses the fuse, resets the counter then blows the fuse. If this is true, I should be able to bridge the fuses with another and reset the counters. Maybe even a resistor will do it. Or maybe even a reset switch somewhere?
>
> Can anyone tell me how to reset the error messages for the developer and the drum? I'm willing to disassemble the thing to do this."

(From: Jeff Roberts (jroberts@axionet.com).)

- To turn off change drum message turn machine on while depressing "<" key
- To turn off change dev message turn on machine while depressing "^" key

(From: Mark Wilson (mawilson@worldnet.att.net).)

There must be something additional to that. I tried it on my 4420 and it did not work. Can anyone shed additional light on this??

(From: Jeff Wilkinson (laser@ix.netcom.com).)

The fuse on the drum unit burns out when you first install it. This momentarily shorts the input to a counter IC and resets the counter. I would be very careful about shorting it with a piece of wire, even though the circuit is current limited it is just not a safe practice. Of course you could always replace the drum! The same is true for the developer unit. The developer and drum unit should have been replaced at both 18K and 36K pages as they have reached there useful life expectancy. E-mail me if you want more info, I believe I have the value of the fuse required here someplace.

(From: Mark Wilson (mawilson@worldnet.att.net).)

I believe there is a module with a microfuse, similar to the one on the toner cartridge. If this is so, you have to replace the microfuse (preferred) or short it with a piece of wire (not recommended). The fuse burns out after so many pages, triggering the drum message. When the drum is replaced, it has a new (intact) fuse.

Laser Printer info

> "Is there any info available on the net on how Laser Printers work, & how to fix them? I've worked on a few, & am learning the hard way, but could use all the help I can get."

(From: Robert Blackshaw (blckshaw@clark.net).)

Lotsa luck! I have an HP LaserJet 500+, an Apple Lasewriter Plus, and a Xante AcceleWriter which were DOA and which all now see active duty. The only piece of information that I have that is very useful is the HP Printer Service Manual P/N 02686-90920 that I got *after* solving the LaserWriter Plus' problems.

I went through Border's Books and other computer book shops looking for anything covering laser printer internals with no luck at all. It's your brain and logic, and luck.

One thing that will cause you grief on the older CX engine based printers are those *insulation displacement* connectors they used. Occasional no contact problems are usually solved by pressing the wires into the plug.

Strange running time meter/copy counter

> "I have disassembled (read: cannibalized for parts) an old Cannon laser printer a few months back. I found a mysterious part in it. Perhaps somebody can enlighten me as to what it was thrown in for...
>
> It looks just like a standard fuse, as found in power supplies. The usually-glass part is made of white plastic. There is a window on one side, made of a clear material(glass, plastic?) And there is a scale next to the window, 0 to 10.
>
> In the window is some substance that looks like mercury from end to end, but there is a "break" somewhere in the middle (around 3 or 4 on the scale)."

(From: Tony Duell (ard@p850ug1.demon.co.uk).).

The substance is mercury, AFAIK, and in the 'gap' there's a small amount of some electrolyte. Passing current (very low current) through the device electroplates mercury from one column to the other, thus making the gap appear to move along the tube.

It can be used in 2 ways - if a constant current is passed through it, it records the total time that the unit has been in use. That is the more normal way to use it.

However, in the CX, it's fed with a short pulse of current at the start of each page. Thus, a small amount of mercury is transferred for each page printed, and the device does, indeed, operate as a page counter.

Laser Printer prints heavy on one line about 2 inches from bottom

> "What could be causing my Brother HL8e laser printer to smear/or blur one line of text about 1-2" from the bottom of the page. At this point, 90% of the page has already fed through the printer with no problem. Can't see any botched labels or other obstructions. It doesn't always do it, but at least 50% of the time if there is text at that point on the page, there will be a heavier print on that line. I don't know if you would call it blurring, it's kind of like it's printing twice double at that point. Is it the rollers? Which rollers should I replace?"

(From: Frank Reid (reid@indiana.edu).)

If changing the toner cartridge doesn't fix it, the lower (rubber) fuser roller may be bad. Those (at least in HP printers) sometimes don't pinch the paper tightly enough during fusing, causing smears.

The fuser has a teflon-coated hollow metal roller with a heat lamp inside, and another roller which pinches the paper against the hot roller during fusing. The lower roller is made of high-temperature silicone rubber. Those sometimes go bad as described above, but if you have replaced the whole fuser assembly recently, it probably isn't the problem.

Look for any rollers between the pickup roller and the fuser, and clean them with naphtha or mineral spirits. If there is a black roller with foam-like surface, that one is electrically conductive and is part of the mechanism that places electrical charge on the paper. Clean it with alcohol and do not get fingerprints on it. Clean everything in the paper path: If there is a corona wire (instead of the conductive roller), clean it with a Q-tip dipped in alcohol.

Image tilted/skewed/crooked on old IBM laser printer

> "I have an ancient IBM Laserprinter E P/N 1039229 that has an aggravating problem: the printer prints fine except that the image is skewed on the page. There are no problems with the image itself other than the fact that it is a little crooked. I suspect that the take up wheel (D-shaped with rubber coating) is the culprit because the paper does not jam. Anyone have any experience with this? I don't want to replace the wrong part!"

Bad rubber is a very likely possibility. There are rubber restorer chemicals - don't know how well they would work. Sanding the top layer may help. Replacement would be best if you can locate parts.

Fuser Roller collects toner on laser printer

> "I have an AST TurboLaser/PS (also known as an DEC LN03, a Brother, etc, etc.). When I bought it someone had let a ring of melted toner collect on the fuser roller until it had burnt through the coating and ruined the roller. So I replaced it and ran a few thousand copies through the printer. Now I notice that the roller is beginning to collect a bit of toner again. Just how does someone clean that roller without pulling the coating off? I tried the usual wiping with a paper towel and that removed some of it but there is still a hint of it left and a few more copies begins to let it accumulate again."

(From: FAXFIXR (justdfax@cdepot.net).)

I would bet the "picker fingers" or "separation claws" are in need of replacing. They are the claw type pieces that ride on the roller and prevent paper from sticking to the roller. The end that rides on the roller will build up a coating of toner and crud and will wear a groove thru the teflon coating of the roller. Once the teflon coating is gone, toner builds up in the groove and shows up on each page as a faint line.

HP original laser printer 2686A: bargain or boat anchor?

> "This printer is (i'm told) supposed to print a test page full of assorted characters yet only prints multiple parallel lines. Also, i'm unsure of the proper hookup to Win95, parallel or serial interface. To clarify, I bought this thing used from someone who 'knew nothing about it' and the HP web site volunteers little information."

(From: Gerald Chafee (GChafee@worldnet.att.net>).)

If I remember right the original Laserjet has a "test switch" located towards the back that only tests the print engine and is supposed to only print parallel lines. I think that you can take the printer off-line from the front panel and get some sort of printout by holding down a self-test switch on the front or a combination of switches. Somewhere I have a service manual for this unit and I will try to look it up.

BTW, the LJ I's were invariably a serial port only printer which made them a pain to interface. They do give a good print for such old technology, but you only have 1 or 2 resident fonts and I believe there was no graphics capability. You had to use cartridges to get any other fonts.

(From: Mike B. (osiris@avana.net).)

It's printing correctly. If I remember, there are two ways of testing this thing. You are hitting the 'test print' button on the side. This is the parallel lines test. There is another test button on the front panel that when hit, causes the cascading alphanumeric printing sequence.

With Win95, you should be able to use the HP Laserjet driver with no problems. Since you have Model #2686A, I think the 'A' stands for parallel connection. In that case, just connect it like any other parallel printer, and make sure that you have the proper Win95 drivers.

Why doesn't the HP site help much? :-). They just want to sell you one of their new, whiz-bang models :0

This printer is a great workhorse. I believe you will still find lots of support for it from other places. There is a place called Laser Connection that supports/services these printers.

Okidata printer that's streaking

(From: Dan Fraser (dmfraser@rogers.wave.ca).)

These printers need a new drum every 4-5 toner refills. They are designed that way to fool you into buying them as the toner is cheap. Then they get you later at drum time. The drum is a consumable and does NOT last the life of the printer. Resign yourself to a new drum every 4-5 toners or so. That's the system.

(From: Chris Laudan (chris.laudan@zetnet.co.uk).)

Yup, agree with this. The cleaner unit has a fine clear plastic strip that removes old toner from a roller, in time this develops fine kinks or scratches which let old toner stay on roller, hence streaks. If this strip is OK and machine says need new cleaner unit, you *can* carefully empty cleaner unit and carry on, but you must be careful not to damage strip doing this. Best to replace unit as above,

First page smudges on OKI OL400

> "Sounds like my second hand (sorry, previously owned) OKI OL400 has a problem with the fuser roller, too. Up till now I've just printed two first page copies of everything I needed 'clean'.
>
> Please does anyone know if the fuser roller is an integral part of the OKI OL400/800 Image Drum Cartridge replacement kit? If not, any ideas on the part number, please?"

(From: Al Savage (asavage@iname.com).)

Note that an OL400 is nothing like an OL400e. Almost no parts interchange including the drum/developer assemblies.

(From: Brian Hughes (bkhughes@gisco.net).)

The problem you're both describing is caused by the "wiper blade" in the drum cartridge, not the fuser! OKI doesn't sell the part and says when you have this problem you must replace the entire image drum assembly $$$$

The cure is really quite simple: I remove the entire drum cartridge and place it on newspaper under subdued lighting (you don't want to "shock" the drum). The corona wire assembly can be recognized by the sliding blue knob on top; I release the left side with a small screwdriver tip and remove it. After removing the two screws I have just uncovered, I lift the blade free. Gently wiping the accumulated toner off the blade allows me to see the rubber better. If I see that the blade has "curl", I can then weight it down on my bench for a while to reverse the curl before I reassemble it. Sometimes all it takes is the cleaning. I have done this with my own "preowned" OL400, and now enjoy like-new printing.

The one that stumps me is where to find a fuser lamp, OKI will only sell the fuser assembly (major part!).

DISCLAIMER: Due to the possible health hazards of toner dust, I have only told you what I have done...it is your choice, and your responsibility to take precautions should you disassemble your printer.

(From: George Hurley (ghurley@voicenet.com).)

That smudge on the first page is your OL400 telling you that your image drum is getting old - they're about $240 from Staples, or $180 rebuilt. HOWEVER, the actual cause of the smudge is the failure of the toner wiper blade inside the image drum assembly. This acts like a windshield wiper and scrapes excess toner off the drum. When it hardens with age, it stops working as well as it should. This blade can be replaced at fairly low cost - I bought one for $25 and suspect that I overpaid, and it took about ten minutes to replace the old one. You'll eventually need a new drum assembly, but this repair should squeeze another 10-15,000 pages out of the drum.

I forget who I bought the blade from, but LaserImpact should have one. You can reach them at 1-888-809-4155 - if you ask for tech support, they can probably give you instructions on how to do it.

Resetting 'Replace Drum' message on OKI OL400

The following may apply if the printer produces quality output but insists on the error message. Of course, if the printouts are faded, etc., it may indeed be time for proper maintenance.

(From: Jason Kuetemann (jason.tracey@sympatico.ca).)

Press the 'RECOVER/RESET' button while turning the printer ON. This will reset the counter.

(From: Steve TR I have this model, too. Don't fall for that drum error. It only goes by a page count and the drum will continue to yield quality images for at least another 200-500 pages! Also, you can hold down the MENU 1 key to get into a service menu where you can reset the drum count and total page count for the printer.

Laser printer test equipment

At least one company offers a device specifically for testing of laser printers. This is obviously not going to be something you will want if you deal with 1 laser printer every few months. However, where dozens of printers a week are involved, check out: http://www.LaserWizard.com/.

Frank's repair notes: HP-IIP, HP-IIIP, Apple Personal Laser Writer

(From: Frank Reid (reid@indiana.edu).)

All of these use the same Canon print-engine.

- Paper jam: Paper is crunched accordion-style near the toner cartridge, does not reach output rollers:

  The toner-cartridge drum is not rotating due to a failed "drum-drive assembly." You can mark the periphery of the light-sensitive drum to confirm that it is not rotating.

  Remove the top and right covers of the printer. The drum-drive assembly is a white plastic gear/clutch attached to the gear that drives the toner cartridge. Inspect for cracks, replace if necessary. OEM part # RG1-1777- 100, Apple Part # 890-0609. You must partially dismount the entire gear assembly to replace the drum-drive assembly, however, sometimes the new clutch can be slipped onto the old shaft (which does not wear out): Not all shafts are identical.

- Paper jams or gets wrinkled as it exits the top of the machine; works OK if the selector is set for front delivery:

  The upper output-rollers deteriorate (perhaps due to ozone) and become mushy: Replace the roller (Apple "face-down delivery assy." part # 971- 0043 does not fit HP machines, but you can remove the roller and replace that only.)

- Paper jam: Paper does not progress past pickup rollers:

  Inspect the pickup-rollers. If the gray rubber is smooth and shiny on the tips of the cams, replace the rollers. Replace obviously-worn rollers as part of preventive maintenance during other repairs.

- Paper jam: Paper will not feed from front of machine:

  When paper feeding begins, a mechanism lifts the paper stack so that the pickup rollers can grab the top sheet. Inspect the lifting mechanism: Sometimes parts at the sides become bent, preventing it from working.

- 50 Service:

  The fuser lamp often burns out because the seals fail and let air into the lamp (resulting in opaque purple/yellow deposits inside the quartz tube). Replacement is easy, requiring minimal disassembly of the fuser. Rarely, the lamp-control circuit in the power supply fails.

- 51 Service:

  The laser-scanner motor commonly fails. Replacement is simple but getting at the scanner requires removing several layers of sheet-metal and circuit boards, the black plastic cover of the scanner housing, and the plastic lens: That may take an hour on your first attempt, 15 minutes with experience. Typically, the IC which drives the scanner motor overheats and visibly discolors the circuit board. HP-IIP, -IIIP and APLW all use the same scanner.

  Normally, you can hear the scanner motor running; it whines like a tiny jet-engine starting, a few seconds before the machine begins to feed paper.

- "Door open" or "No EP" indication, although door is closed and toner cartridge is installed:

  Inspect photoelectric sensors, clean with compressed air. If problem persists, re-seat the appropriate connectors on the dc controller board, or replace the entire sensor harness. Failure of the circuit board that holds the contrast control can also cause this indication.

- Groaning sound while feeding paper:

  Replace the separation pad (~1x5cm bar with cork-like surface). No tools required.

- Prints are mostly black, characters barely visible:

The high-voltage terminal on the toner cartridge is making bad contact. Placing washers under the two mounting-points of the (white plastic) high- voltage insulator on the cartridge will often extend the terminal enough for good contact.

- Printer equipped with optional bottom paper-tray delivers one page followed by a blank page, then halts unless door is opened and closed. Possible "41 Service" message (misleading! - means laser-scanner error):

  The detachable paper-feeder contains two solenoids. Under the armature of each is a rectangular black foam pad. If the pads become sticky (as in the HP-II), the paper-feed timing is disturbed. Remove the solenoids, replace the pads. I use double-sided foam tape, then use naphtha to thoroughly remove any glue from the upper surface.

  I never encountered this problem until November 1995, then saw several cases in rapid succession: The entire lot of HPIIP-type printers may be reaching an age where this failure is common, so I now inspect the solenoids for stickiness as part of the preventive maintenance of any printer I repair.

  Also inspect for broken solder connections on the pins which connect the paper to the printer.

- Paper stops just prior toner cartridge:

  (From: Edward Klotz (eklotz@www.flash.net).)

  The worn D-roller assembly can be replaced in about 15 minutes. May as well replace the separation pad also (5 more minutes, fixed at least 6 with new D-roller assemblys from LASER impact out of Texas - about $28 last time I purchased). Also ozone filters are available, very inexpensive (may save a repair down the road).

Tony's entry into laser printer repair

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

You may be interested to know how I got into laser printer repair. It's a long story, but here goes...

I was given a non-working Canon LBP8A1. I pulled the case and started fiddling about and discovered a PAL on the formatter board with a stuck output. The cure was obvious -- replace the PAL.

Alas Canon didn't like that solution. No parts were available, and no manuals. At about this time I discovered that the original printer for a computer that I happen to love - the PERQ - was a CX-VDO -- the same printer without the formatter. And I managed to obtain the PERQ interface board, admittedly non-working.

So I totally dismantled the printer in the hope that I could figure it all out. I had a pile of screws, gears, lenses, mirrors, bearings, etc. And PCBs covered in unidentifiable chips.

A lot of work with data books (and questions to newsgroups) identified most of the chips. A lot of hacking about got me enough of the pinout of the CX DC controller connector to guess roughly what was going on.

Then I had some luck. The guy who'd given me the PERQ card remembered that the CX-VDO had a ribbon cable from that connector to the outside world. And Bob Davis, who had obtained all sorts of stuff when PERQ Systems folded, dismantled his personal machine and ohmed out cables, etc.

Slowly it all went back together. I figured out how to align the scanner unit using the IR detector I use for testing remote controls. I figured out how to test (and repair - there was a defective chip and a shorted capacitor) the main PSU. And I worked out how the status LEDs were connected.

I made up what I thought were the right cables, put it all together and fired it up. The test page was fine. I was getting there. Put the PERQ card together, plugged it all it. It sort-of worked. The page was black apart from a 16 pixel strip at the left. But Bob had been helpful and had sent me info on the operation of this card. I was my fault. I'd missed out a jumper which connected a clock to the data FIFO. After that it worked fine.

I now believe that these printers *can* be repaired at home, no matter what Canon say. And if Canon won't help people, then somebody else should...

Repairing plastic paper feed strip in Canon PC10, etc. or CX laserprinters

(From: Curtiss Priest (BMSLIB@MIT.EDU).)

Serach at: Google Groups for the subject heading: "Repairing plastic paper feed strip in Canon PC10, etc. or CX laserprinters".

- Back to Printer/Copier/Fax Repair FAQ Table of Contents.

Photocopiers

Note: also see the chapter on Laser Printers as the operation and problems of the two types of equipment are very similar.

Warnings about vacuuming copier toner

> "I know there are special vacuum cleaners for use in picking up toner in laser printers. What is the problem with using a cheap ordinary vacuum cleaner? Is there a fire hazard? Thanks for any comments."

(From: (jollyrgr@mc.net).

If you vacuum toner with an ordinary vacuum, a static charge from the toner will build up in the vacuum and shock you. Toner works by static charge. Moving it, as in vacuuming, causes it to give up its charge to the vacuum. Without having a complete ground throughout the entire vacuum can cause charge to build up to quite a high potential. Be safe, use a toner vacuum.

Now if the paper does not get fused, the toner can be rubbed off. This toner, and any spilled toner still retains some charge. As it is moved though an ordinary vacuum, charge is transfered to the various parts of the vacuum. (Much in the same way charge is transfered to a person walking across a carpet in dry weather). When the charge builds up, it has to find a way to ground. In the case of the person walking across the room, the charge is discharged when they touch a metal object such as a light switch cover or door knob. In the case of the vacuum, its the vacuum that builds up the charge. When the person using the vacuum touches the charged portion, the charge is transfered to them (ZAP!!). If the person is holding the part of the vacuum that is getting charged, they get charged as well. Only now they get zapped when they touch something else. A friend of mine worked in a print shop at one time. He spilled a bottle of toner. Instead of getting the toner vacuum used on the copy machines, he used an ordinary shop vac. The metal pipe was attached to a rubber hose. As he vacuumed the toner it was he that got charged. It was when he touched the grounded portion of the vacuum as he was turning it of that he got shocked.

Toner vacuums have all their parts grounded (pipe, hose, canister, motor ect.). These parts are all connected by wires to the ground terminal on the power cord, shunting any built up charge immediately to ground. So it is not the conduction of the toner to the electrical ac line but from the charge the toner itself has.

(From: jlager@tir.com).

I don't know about any fire hazard, but I DO know what that stuff will do to an ordinary vacuum cleaner from lessons well learned! Toner/Developer is the finest stuff you may ever see, and will instantly clog all the pores of a regular vacuum bag. You'll go broke just buying bags. And... don't wash any of your clothes/rags with hot water that it has penetrated because it will make the stuff solidify. All my advice is based on repairing copiers over the years.

(From: Ed Wright (motogump@cris.com).)

The point here is that vacuuming toner, which is carbon black and latex, will create a static charge. Using a vacuum that is not intended for this purpose can cause the following. You can blow sensitive components on circuit boards, expecially bias boards on the developer units of the larger copiers and the transfer belt power packs of the smaller machines. Another worrisome possibility is an explosion. I have seen two old toner capable vacuums ignite the toner dust as it went through the vacuum. I admit this is a very rare phenomenon but I would think it would be even more likely in a vacuum not designed for sucking up toner. I would suggest reading on the side of your toner bottle. Most bottles caution about disposing of toner by incineration, the stuff is explosive if the air/fuel mixture is right. It probably wouldn't do much harm but I bet it would play hell with your office.

(From: Le Baron O. Ferguson" (ferguson@math.ucr.edu).)

Thanks for the response. I think I should state for everyone reading that I am now convinced that there IS a serious fire hazard. One person who responded (by email) has seen two of them "light up."

Comments on copy problems

(From: Copenhagen Cowboy (cowboy@fastlane.net).)

Copy problems can be hard to figure out, but given the evidence the copier gives you, you can now probably determine what to check.

Black or dark lines are mostly caused by dirty optics (not enought light getting to the Drum) Blank copies might be a broken corona wire, or even failed High Voltage board. Black copies can mean a bad exposure lamp (broken or burnt out) or failed exposure lamp thermal fuse. Black copies with even blacker images in them could be overtoned (too much toner in the developer unit) or bad drum ground (the drum cannot discharge {the voltages have nowhere to go, so they just stay on the drum). Bad drum grounds usually pull developer, and you get the grit on the copies.

General image quality problems - Clean the optics first!!

The office here has a Xerox 5310 (Rebadged-Sharp) and it's been getting progressively worse with respect to overall image quality. A new drum ($140) has helped but things go down the crapper too fast for comfort. (~90 thousand copies, 4th drum now.)

So, I cleaned the optics. That was it! 2 mirrors were CLOUDED with white dust. Geeeee, do ya think that could do it? ;-)

Light-path in each is going to differ but I'll give you this one as an example. The 5310 can enlarge and reduce and the table does NOT move, i.e., more hoopla under the glass :-)

                         |  DRUM |                       ..
```

Legend:

dddd - represents the paper document you are copying
A - Moving assembly that holds the exposure lamp and (1) first mirror.

B - Moving assembly containing 2 mirrors: (2) second mirror and (3) third mirror.

L - Movable assembly containing enlarge/reduce lens.

C - Movable assembly (covered by black sheet-metal cover that also covers the top of the Lens) containing (4) fourth and (5) fifth mirrors.

D - Fixed (6) sixth mirror that directs light onto the drum.
P - Erase lamp assembly.

Layers:

LEV 1 - External to the copier, look for whiteout and layers of smudges.

LEV 2 - Glass pane (see LEV 1)

LEV 3 - Scanning layer, exhaust fan to keep dust from settling... Does that for about 2 minutes and then starts accumulation of very fine dust on all mirrors. :-)

- Some assemblies are covered to 1) keep the stray light and 2) reduce dust accumulation - do NOT skip them in cleaning. *Especially* Assy C!

LEV 4 - Structural sheet-metal separates Scanner from drum/toner assembly below.

LEV 5 - Toner and Paper transport layer

See the document: Notes on the Troubleshooting and Repair of CD Players and CDROM Drives for appropriate chemicals and materials for cleaning mirrors (and lenses) In a pinch, a bit of my [clean] 100% cotton T-shirt works well - followed by a good blow with duster can and soft, [fake] camel-hair brush. The object is to have a mirror as clean as the minute it was made.

Apply a half dozen drops of non-detergent light oil onto the felt 'washers' on any movable assemblies' rods, if present. Might want to dampen a piece of cloth with oil and wipe the rods. This helps to prevent drips, etc.

I would remove the glass (LEV 2) completely from the machine and give it a good scrub from BOTH sides with the usual chemicals (ammonia-content is superior, IMO) for 2 reasons: 1) to keep ALL overspray from rest of machine and 2) to do a really GOOD job... not half-assed worried about overspray :-)

Don't skimp on corona wires... many machines include a plastic/felt wiper than prevents injury to the wires, USE IT. I keep a supply of scavenged wires for times when it goes 'TwhanNNnnnG' for the last time... :-|

Density control - some machines, the 5310 included, have a density adjustment under the front cover. This is in addition to the DARK-NORM-LIGHT control on the front panel. I find that after this cleaning, it can be turned back to somewhere near the middle. This cleaning is often needed if even *that* adjustment doesn't compensate for crappy copy :-)

After this cleaning, the copy will *overall* have whiter (read: less toner wasted) background... this will improve contrast and lead to greater toner cart life. We get them recharged, BTW, for ~$49 or so... New it's $120 from Office Depot. ARGHHHHHHHHHHHHHHHH....

Diagnosing 'blank copy' problems

> "I have just cleaned a Sharp SF 755 which was quite dirty but now will not copy at all! No error codes paper hot on exit, all seems well but the paper is blank."

(From: Bruce L. Miles (henry31@prodigy.net).)

Two things to try:

1. Peek inside and see if you can detect a latent image on the drum. If an image of your test document exists on the drum, then the main corona unit is working at least.

2. Perform a 'Skyshot Test'. Leave the cover off the glass and take a picture of, well, the sky. It is a good idea to cover the leading edge (left side) of the copy glass with a piece of paper so that the fuser doesn't try so hard to jam on a solid sheet of heavily tonered (blackened) paper.

If the skyshot print comes out white (it should be entirely black since the amount of light hitting the drum compared to reflection from actual copy is nil), and you DID have a latent image on the drum, the prime suspect would be the transfer corona - it is not receiving the high negative voltage needed to pull the positively charged toner off the drum and onto the paper. The culprit could be the corona wire being broken, the corona assembly not making a good connection into its high voltage socket, or even some weirdness going on with the high voltage power supply - i.e., supplying proper voltage to the main corona, but nothing to the transfer corona.

Copies too dark 1

> "I have an old Savin model 7010 copier that works just fine except it prints to dark. I have to keep the

> "lighter darker' control to max "lighter". I have replaced the (expensive) OPC cartridge and cleand all the wires and mirrors etc. It works best right before it runs out of toner, of which it uses up to fast. Any info will be appreciated!"

(From: Thierry Thdereck (thdereck@aol.com).)

There also other reason a copier is darker than it should:

- The lamp is old and has not enough light on the drum,
- You may also have wrong voltages (currents) which polarize the drum,
- The voltage on the toner developer may be incorrect ...

So you may have lot of work if you don't know the right setups before having good copies.

Copies too dark 2

> "Canon NP-2015s ... prints very dark, with "water stained" appearance. All controls full light gives a 'readable' copy with a dark grey background. I have been told everything from 'wrong toner' to moisture in the toner. The guy who brought it to me doesn't know. Before I vacuum out the toner & stick a $25 cartridge in it, could this be a bias problem?"

(From: Bernard Morey (bmorey@aardvark.apana.org.au).)

Have you tried cleaning the corona wires? There are generally two modules. Pull out and clean with cotton-swabs (Q-tips).

(From: Lionel Wagner (ck508@FreeNet.Carleton.CA).)

If your dark grey background is not uniform, you will have to vacuum out ALL the old toner, and thoroughly clean the roller that transfers it to the drum. Do not use abrasives, as the surface of the roller is very critical. If this restores even grey background, you can think of adjusting the bias voltage.

Copies too light

Aside from a misadjusted 'darkness' control, improper voltages, dirty corona wires, and worn drum, don't overlook the trivial: your paper may be incorrect or damp.

(From: Morton Lee Cohen ya484@@vtn1.victoria.tc.ca).)

I am a former copier tech. that worked on Konica copiers. To get good results from your copier, a periodical maintenance should be perform on the copier, every so many copies or once a year, depending on which event occurs first.

During a PM, the optics, corona wires, drum gets cleaned. The Fixing unit gets cleaned, and serviced. The Developer gets replaced. And adjustments are performed, if needed only.

The developer transports the toner to the charged area of the drum and developer gets weak over time. Developer is made up of iron filings.

Previous copy doesn't erase from drum

> "I recently purchased a Mita DC-111 copy machine, and I finally it to make copies, now I have on big problem. When I do more than one copy, the drum doesn't fully erase itself, thus leaving ghosted images on the remaining copies that are made. I don't know much about copiers, and I really just lucked into getting it to actually make copies. Any help would be appreciated.

(From: Jeff Roberts (jroberts@axionet.com).)

Make sure it is the drum that is not cleaning by measuring the distance between the origional image and the ghost image on the page. that distance will be the circumference of the drum if that is the cause. The drum assembly should come out as a unit. Take it out and make shure to quickly remove the drum from the unit and put it in a dark place so that it doesn't become light shocked. then look for a blade of some sort, it may be neoprene or rubber. it is usually on a actuater assembly that can push it out to make contact with the drum and then retract it back (possibly a solenoid/cam) this blade does the cleaning by scraping the excess off the drum. If it is hard or brittle it will have to be replaced but cleaning it with a 70% solution of rubbing alcohol may be enough. After cleaning it rub some toner along the edge to re-lubricate it and reassemble and try that. Also check that the drum unit is not clogged up, the waste toner goes somewhere and if it uses a sump and the sump is full then it will ghost no matter how clean the blade is.

(From: Vance Harlow (musk@aol.com).)

On copy machines and laser printers with long life drums (ones where toner can be refilled without replacing the whole drum assembly) the wiper blade will usually fail long before the drum does on machines that are not used frequently or used to print one or two copies at at time. If the service department is not aware of the problem, or the manufacturer doesn't supply the blade as a separate part, you'll usually end up getting stuck for a whole new drum assembly when all that's needed is a wiper blade (this is the rubber or plastic blade that bears on the image drum, not the felt wand, BTW).

Usually the clue will be that the first few copies are bad, but then quality improves. If that's what's happening, usually replacing just the wiper blade will cure it.

Since the blade costs only $10 or so, it can be worth giving it a try before replacing the drum assembly. This has worked on both my Canon 1010 copier and various OKI and GCC laser printers.

Finding the blade can take some doing - when I called the local Canon distributor, they couldn't give find a part number, even though I'd bought a couple years earlier and knew it existed as a replacement part. Luckily, one the the service techs was able to dig up the number. OK doesn't list them at all - they only sell the the whole assembly. But you can get the blades for most laser printers, and some copiers, from American Ribbon and Toner or Computer Friends. Since the drum assembly on the old Okis like the 400 and 800 series, and the GCC/Mac versions lists for $250 or so, one frequently runs into them with bad drums for $0-25. I've revived a half dozen of them simply by replacing the blade - knowing this trick is like having a free source of laser printers! the OKI blade pops right in with only minor disassembly; the Canon is a bit more trouble.

Computer Friends also has a teflon wax for reconditioning drums - they claim it will protect the coating, fill in small scratches and treble the life of a throw away drum, and vastly prolong the life of long life drums. I've tried it so far only on an old 1010 drum, with mixed results so far (worked great at first, but now copies are getting dirty - don't know if it's the wax acting up, the drum going despite the wax, or other problems. They also sell the Oki drums for about $40, and drums for many other printers but not copiers.

Copy quality degrades with use

(From: Lionel Wagner (ck508@FreeNet.Carleton.CA).)

If you are lucky, cleaning the optical path: mirror and lens will help. Cleaning the corona wires is a routine necessity. Use two Q-tips, one on top, the other on the bottom, of the fine wires and travel the length. Soak the Q-tips in lighter fluid, my favorite all-purpose cleaner.

Probably the photo-sensitive drum has aged. A sure sign of this is a difference in density between the first and last copy of a long (50 copy) print run. This is particularly noticeable after the copier has not been used for some time.

(From: BRADS TV (bradstv@aol.com).)

I have found that dirty mirrors and optics will cause smudging, dark copies and generally poor quality copies. Try cleaning these mirrors in the optical path. NOTE these mirrors are first surface or front silvered mirrors and they scratch easily. Also look carefully for the complete light path from the exposure lamp all the way to the drum, you will find several mirrors mounted at angles to direct the image to the drum . You are right in the fact that the drum can cause poor copies but cleaning first might be the first step. Brad

Copier error codes

Most modern copiers produce an error code of some sort when, you guessed it, they detect an error. However, there is no standardization. So, other than posting to sci.electronics.repair or checking this FAQ, how does one determine their meaning?

(From: Sid Ashen-Brenner (sashen@midusa.net).)

Affordable Photocopiers (http://www.photocopiers.com) may have a Service sheet for about $15.00 that would contain the codes for your copier. I got the one for my Mita DC 1255 from them. They also sell parts and supplies at a fairly reasonable rate.

Canon PC25 copier problems

> "The lamps goes on my Canon PC-25 but I get nothing but black copiers. I'm told the problem could be a broken corona wire. Where is the corona wire located? What does it look like? How do I determine if it's broken and how is it replaced? Thanks in advance."

(From: Lionel Wagner (ck508@FreeNet.Carleton.CA).)

I doubt the cause is a broken corona wire. If this were the case you would get white copies, instead of black. Check the bias lamps are coming on. They are a string of small lamps located 'downstream' from the transfer corona (located at the bottom of the drum).

> "I have an elderly Canon PC25 Copier, which still runs well apart from two problems.
>
> The first is an intermittent fault which makes it turn out blank paper, usually on switching on but occasionally during a run. I assume this is a faulty joint on a circuit board because opening the machine and slamming the top down usually cures it for the moment.
>
> The second is that the light/dark slider has to be at one end of its range to get satisfactory copies.
>
> Are these common faults on this model with a recognized cure? Although it is expensive to run, I seldom

> need enough copies to justify purchasing a new one."

(From: Lionel Wagner (ck508@FreeNet.Carleton.CA).)

You're right about the bad connection fixed by the vibration of closing the cover. Your exposure control is probably at darker than normal to compensate for aging of the photo-sensitive drum. Some compensation is possible by adjusting the high voltage or (I prefer) the toner wheel bias voltage. I'm assuming your corona wires are clean, of course.

The mysteries of developer

> "My owner's manual never mentions developer anywhere. This copier uses toner cartridges which mount above the dispenser and drop toner into a mechanism which distributes it to the drum. There is a white plastic bottle which catches excess toner and eventually fills up and needs replacing. They say to replace the bottle, but I just empty it, wipe it off and reinstall it. Only the toner cartridge and the bottle are mentioned in the useless owner's manual."

(Responses farom: Nate Morrison (nmorriso@plains.nodak.edu).)

Well, that's all they think you need to know. They want you to call the dealer if the copies are crappy.

The reason you should just toss the used toner bottle is the dust--it is messy and not good for your respiratory tract.

Some copiers use developer; others don't. How long it lasts before it runs out is basically in how the copier is engineered. Some gets carried away every time you make a copy. Pretty soon there isn't enough to carry toner to the drum anymore.

> "So, if my copier needs developer, how do I obtain it? Where does it go? I suspect that I purchase a bottle of these 'iron particles' and dump it into the slot where the toner drops into, but I don't want to do *anything* until I know the right thing to do."

If you need developer, you can get a kit from the local service shop. You'll pay plenty, to be sure, but not as much as if someone came out and did it for you. It might not be a bad idea to invest in a service manual - I got one for our Minolta for around $20.

> "Why is this rather simple maintenance procedure kept a secret from the owner? Is Mita trying to make money for their authorized repair outlets?"

Well, that's another of those reasons they want you to hire the serviceperson at a ludicrous rate. (the local place gets $99/hour!) You have it pegged.

Another reason is that they want to promote the idea that _their_ copier is service-free. Telling any prospective buyer that in 50,000 copies it will require professional service is NOT a selling point. :-) The copier is designed so you can change toner and paper and that's it. Anything else is always "see your authorized dealer" in the useless owner's manual.

Problems with Ricoh copier

> "Some time ago I got a big and heavy RICOH xerox copier and I have got a problem with it:
>
> The output of the device is very poor: Passages which should be black are only light grey. If the contrast is turned on to the maximum the whole sheet gets grey. The copies look as if there would be only a little bit

> of toner on the drum. In order to solve the problem I already checked the optics, the corona wires and voltages and I filled up the toner. My question now is whether it is possible that the drum is defect? What else could cause such a failure?
>
> Since the device is quite old (1988) spare parts are not easy to get, but the mechanics looks quite well so I do not want to loose the device."

(From: Copenhagen Cowboy (cowboy@fastlane.net).)

I am a Copier Repair Tech and have a few suggestions for you. First, what does a Blackout look like? What I mean is, make a copy with the lid up, and check to see how Black it is. Note to see if there is any "Grit" on the paper. Most likely if there is no Grit, and the Black area is Grey, then I would suggest changing the Developer (or you might even have a Developer Drive Problem [gears and stuff]). If there is a fine layer of Developer on the page, you probably have a Drum Grounding problem.

Toner sensors?

I took one of those apart and found something that looked like a piezo element with 3 wire connections to concentric rings. I looks to me like some sort of resonator but I have not attempted to analyze the circuit.

My wild guess would be that the frequency changes with low toner or something like that.

(From: Morton Lee Cohen (cx163@FreeNet.Carleton.CA).)

Probably the disks stir the toner for even dispersion, and break a photogate to tell the controller PCB that there is toner there. Some Cannon laser printers/photocopiers use magnetic sensing of the toner level. Most Okidatas use the photogate sensors with magnetic toner agitators.

Comments on copier cleanliness

Copiers are about the ickiest equipment to dismantle with all that black toner over everything!

(From: Morton Lee Cohen (cx163@FreeNet.Carleton.CA).)

There is toner over a lot of places in copiers, not so much due to customer problems, but due to lazy service technicians, trying to raise their average call per day ratios. Service Technicians often get calls to do Periodical maintenance on copiers late in the day and rush to leave an account at 5pm, so many overlook non-important parts of the copier to clean during a maintenance of a copier.

And as far as the toner sensor goes, lots of times toner cakes on the sensor and the copier never tells the customer that it needs toner, when the copies start getting light, that the copier starts pulling developer from the developer tray, and that it gets messy.

Not all copiers are created equal and not all service technicians are created equal, either also. Some will always be better than others. But the best policy is always to tell the truth. My telling the truth, you tell the customer where the problem exists.

Never lie, because if you lie, one always has the remember what they lied about. From the writers of Star Trek - The Next Generation. And I practice that in dealing with customers and myself.

Gray tinge on Xerox 5260 Copier

> "Earlier this year, I inherited a Xerox 5260 personal copier. It works well except all the copies have a grey tinge to them, even when the auto-exposure control is set to light. The grey background is visible over all the page, and gets noticably darker when the auto-exposure control is set to dark. Is it time to replace the copy cartridge?"

(From: Lionel Wagner (ck508@FreeNet.Carleton.CA).)

Your toner/developer wheel bias voltage may be wrong. When light strikes the photosensitive drum it does not completely discharge it. The toner/developer bias voltage must precisely match the residual charge or grey background will result.

Streaky copies

(From: Bernard Morey (bmorey@melbourne.DIALix.oz.au).)

Well, I discovered that streaky copies are caused by dirty corona wires (fixed easily, although 1 unit was held by a screw-in plate, rather than the usual pull-out method) and that dirty corona wires seems to be caused by excessive toner deposition (haven't figured that out yet).

(From: Lionel Wagner (ck508@FreeNet.Carleton.CA).)

If the streaks are white, in black areas, clean or replace the corona wires. If the streaks are narrow black and run the entire length of the page, replace the soft plastic wiper blade on the drum (and hope the drum is not scratched). Black smudges are related to the toner/developer purity. Replace both.

Toshiba parts

> "Can anyone tell me where to get old / deleted spares for Toshiba photocopier model No BD-3110, or where to get the following for the mentioned copier. TEC High Voltage Unit (HVT-T)..Model No AFT-375-A

(From: Filip M. Gieszczykiewicz (filipg@repairfaq.org).)

Greetings. Give URL: http://www.europa.com/~tait/copiers.htm a go. They have all the usual stuff (rollers, picker fingers, lamps, masters, etc) for many Copiers. My $200 order is in the mail. :-)

[dig dig]

Drat, they don't list prices for anything but toner for that one. Their number is 1-503-293-8071 but you might want to try something closer to home (than Portland, Oregon - 1/2 world away :-) because the shipping *will* kill you...

Canon PC20 cold fuser

> "I'm trying to repair a Canon PC20 copier, on which the main problem is a cold fuser.
>
> The fuser lamp has blown, but it looks as though it might have overheated before doing so : in two places the tube has expanded as though it got very hot while under compression from the spring endcaps. The

> 47R sacrificial resistor in the fuser lamp relay circuit (I think it's there to stop the control circuit holding the lamp on permanently) has also gone open circuit.
>
> What would cause the lamp to overheat ? The thermistor (which was coated in toner) appears to work : it measures about 300K at room temperature and falls a few 10K with finger heat, so it's not open circuit (though it might be incorrect). I'd like to check out the rest of the copier before buying spare lamps etc. - can anyone tell me what the thermistor should measure (hot & cold) so I can test the control circuit and fool the copier into working?"

The thermistor may be working. It sounds like a bad triac or whatever is used to actually switch power. Get a 300K pot as a sub for the thermistor during testing.

(From: Adrian Godwin (agodwin@piresearch.co.uk).)

I had a go with this : about 4K fools the control board that the roller is hot, and allows the rest of the cycle to run. However, this _doesn't_ cause the heater power to switch off - in fact, only turning the resistance almost to zero has any effect, and at this point it appears that the controller attempts to burn out the 47R resistor.

This might make sense, except that as far as I can see there's no way that the control board COULD turn off the heater power without burning this resistor : the fuser lamp is powered through a relay which is excited by the main 24 V supply via this 47R resistor. There's no way that I've seen so far that the controller can turn off the lamp other than to short out the relay (which burns the protective resistor). So I wonder if there's no control - just a monitor for the copier control board and an overtemperature safety circuit that disables the fuser lamp (and simultaneously disables themain motor control triac). This surprises me, as I have a Canon SX-based printer where the lamp power cycles (though not using a relay, as it's quiet).

(From the editor).

There must be a triac or other mechanism for cycling power to the lamp - its temperature must be tightly controlled regardless of line voltage fluctuations and ambient temperature. (--- sam)

Broken Sharp Copier

> "My Sharp copier is dead again, it's an old one. It is flashing "U1" which I think means internal lithium battery is dead, but it won't reset. Somebody emailed me the secret code once, but I have since

(From: FAXFIXR (justdfax@cdepot.net).)

The prefix is always CROP (clear, repeat, zero, pause) and the code for a U1 reset is 13 then press the copy button. So it would be C R O P 14

Resetting Sharp Z-25 copy count

This may be necessary if you run the copier past the recommended life of the drum but still get acceptable performance. You then need to trick the copier into thinking a new drum has been installed. Other copiers may require similar treatment as well.

(From: YonyMar (yonymar@aol.com).)

You need to reset the counter inside the copier. When you buy a new drum, it resets the counter, however it can only do this once. Unplug the copier and remove the drum and toner cartridge, at the back of the machine where the drum would slide in look for a small metal lever, push it in with your finger to reset the counter. The counter numbers are covered by a black plastic cover.

Sharp SF-71 copier will not reset

> "I have an old Sharp SF-781 copier which will not reset. The diagnostic code "H1" is flashing on the display and the copier will not reset to the operation condition, using the keyboard clear sequence.
>
> I have been able to reset the "H1" code before, but this time no luck."

(From: copymann@usa.net).

H-1 means an open thermal fuse on the upper fuser roller. Remove the cover on the fuser rollers and you will see a ceramic fuse located on the top plate. Check the fuse for continuity. If bad replace it with one with the same temperature rating, (or close to the same) Sometimes you can find them a radio shack. If not email me and I will send you one. If you order the fuse from sharp it is pretty expensive. If the fuse is good check the lamp in the upper fuser roller or the upper lamp triac. 99% of the time it is the fuse.

Sharp SF-7100 copier drum replacement

> "I have a Sharp SF-7100 copier. When I call about a replacement drum, people tell me it uses a Master. What is a Master? Can I install it myself. Does anyone have a service manual for this copier?"

(From: Lionel Wagner (ck508@FreeNet.Carleton.CA).)

The Master is the SURFACE of your photo-sensitive drum. In a brilliant design concept, Sharp allows you to easily replace a thin (in your case) cardboard sheet, that effectively gives you the performance of a new drum at a fraction of the cost. There is no wiper blade, residual toner is removed by polarity reversal and is re-absorbed in the developer. Cardboard Masters for your machine are in short supply. Let me know if you can find some. You may wish to upgrade to an aluminum backed Master used in model SF760, but they are much more expensive.

General Problems

Panasonic 1124 power supply problem

The following, of course, also applies to many other printers and other electronic equipment, for that matter.

> "I have a Panasonic 1124 printer which keeps blowing the only 250V 3A fuse on board. The fuse burns as soon as the power is turned on.
>
> I unhooked the components which connect to the logic board - i.e., printhead and tractor feed.
>
> Is it possible that the problem is in the power supply? If it is, what can it be? (The bridge rectifier consists of four hefty diodes)."

(From: Bruce A Haugh (yrp456@freenet.mb.ca).)

With the power supply disconnected from the rest of the printer circuits, blows the fuse, the problem is with the power supply. I have a Raven PR-9101 (made by Panasonic) that has the exact same symptoms. Turns out that one of the secondaries on the power transformer has shorted. You'd need schematics to confirm voltages.

(From: Robert McCallum (simply@sk.sympatico.ca).)

I've fixed quite a few panasonic printers and yes 90% of the time when the machine is dead, it's one or more of the bridge diodes.

(From: Kerry Messana (messana@capital.net).)

It's fairly simple to diagnose where the problem is originating. If you unplug (if possible) the output cable from the power supply and it still blows the fuse then the power supply is at fault. As for what could be wrong, well, I am not familiar with the particular supply. If it is a linear supply a good place to start is the bridge circuit. If it is a switching supply you could also start there but there are more possibilities further on.

(From: John A. McCulloch (advp@notnow.com).)

Another very common problem with the whole Panasonic 11XX series of printers is the zener diode and pass transistor. When the diode shorts, the transistor blows, and I mean *blows*!

Cannon LBP-8 A1 Printer 40 and 22 errors

(From: GTRIST (gtrist@aol.com).)

The 40 and 22 errors normally refer to a problem with the cabling etc. Make sure that you have it cabled properly. Also, it can be a bit tricky changing from parallel to serial I/O. Make sure that it is indeed selected.

- Back to Printer/Copier/Fax Repair FAQ Table of Contents.

Fax Machines and Scanners

Fax/scanner striping

> "One of my fax machines produces some black stripes in copy mode and on the documents received on another machine. Are these stripes caused by a malfunction of the optical diodes bar, some other electronic failure or by dirt?"

(From: Paul Grohe (grohe@galaxy.nsc.com).)

Probably by dirt or a paper shreds stuck in the optical path.

A common cause is Liquid Paper. Somebody makes a correction and sticks the not-yet-dry correction into the fax. Then the still-wet correction fluid makes a streak on the pickup window as it passes by. Subsequent faxes will now have streaks.

I had the same problem. It turned out that the ink from a faulty page stamp had dripped down onto the mirror.

Generally, the paper is moved and the optical path does not move. So if there is something blocking the optical path, it will show up as one continuous image, or stripe. The "blockage" can be a paper shred, ink, dust or even a loose wire.

The image is usually bounced off a long, wide mirror and then into the CCD pickup somewhere in the bottom of the machine. If anything is in this path, it will cause that problem.

Open er' up and just look around inside for dirt and loose debris. Then inspect the *ENTIRE* optical path. BUT DON"T REMOVE ANYTHING!!! You don't want to mess up any alignments.

If the fax is old, or is in heavy use, you'll probably find that it is in need of a good cleaning. Clean the mirror and blow out any dust or junk.

Also check the automatic paper cutter (if it has one) for paper shreds.

Brother Fax machine feed problems and cleaning

(From: (Al Savage) asavage@iname.com).)

I suggest you look carefully at the paper feed mechanism. Brother has a reputation with me for feeding the scanned documents poorly, resulting is overscanning the same area two or more times, which results in "stretched" text or graphics. If this seems to match your symptom, cleaning the feed rollers will probably cure this.

The downside is that a couple of the Brother fax machines that I've had to clean force you to do an unbelievable amount of teardown work to get to some of the feed rolls. Fortunately, I don't work on them anymore .

Brother IntelliFax 950M transmits black messy lines

> "I have a Brother IntelliFax 950M plain paper fax that transmits with black lines or dots. When making just a copy the prints are just as bad. The prints are tiny square dots that make up these lines. It looks like digital problems and not dust on the lens. I'm not very familiar with plain paper faxes. It looks like a scanning failure. I'm guessing at a scanner or some other circuit board. Receiving faxes are ok. Has any one had experience with the Brother Intellifax 950M? Also, Brother has a part called a NUC printed circuit board. Would this be some sort of scanner?

(From: MECHSHOT (mechshot@aol.com).)

This problem is a known fault because Brother assembled these units with what turned out to be defective scanners. They would fail after some time, typically withing 2 to 3 years. I know, we have 3 that failed and they were all built around the same time. The good news is Brother will supply the part (worth about $120) if you pay for the labor (usually around 55-85). Contact Brother Customer Service (the 800 number is in your owner's manual) and they will refer you to an authorized service center. Get a bunch (if possible) of different shops in your area, they charge different labor costs. You must supply your machine's serial number to see if it is eligible for this program.

Then customer service will make out work order, send it along with part to center of your choice.

All of the centers I spoke to were aware of this problem and were confident once fixed, the units were very good and reliable afterwards. Check local office equipment repair houses for more info too. Hope this helps.

Hewlet Packard LaserJet FAX (HP C1740A)

> "This machine is copying and sending fax with a line about 3 cm across straight down the paper. This is a thick black colour. Any ideas as to the cause? I have already checked that there is no paper jam or any block to the sensor.

(From: Robert Macy (robert.macy@engineers.com).)

I'm not familiar with the HP LaserJet FAX, but I assume the LJ scans in a page and then sends it, or copies it. Since the black stripe is unique to sending or copying a document (does not appear on incoming faxes), the problem is in the HP's acquisition system.

It can either be the illumination of the page over that small section (no light, looks black) or it can be a whole section of the linear CCD went out (the whole section is losing any charges built up, looks black) or it can be the memory where the image is shifted into (dead RAM section, looks black).

I don't know how the HP illuminates its pages. Is it a flourescent tube across the page, or a row of LED's? Knowing HP's penchant for reliability I would almost assume the engineers went after LEDs. And the section that lights up that 3cm width could have died. However, if it's illumination that died, usually the edges are "soft".

If it uses flourescent light (remember I said I'm not familiar with this scanner), then it sounds like the CCD, or memory, has gone funky on you.

If the memory where the image is stored has a section that died, then you could end up with such a stripe also. Even my ScanMan Plus by Logitech has occasionally put a black strip on the first 10% of the pixels. To solve that I have to do a full power OFF reset (not reboot, but full power OFF)

You can look for the illumination uniformity with your eyes. Just make sure there is no section that's darker by a noticeable amount (not necessarily black, but just a lot dimmer)

Put a sheet of white paper in the machine and put a scope on the output of the CCD & sync from the line reset. Make sure that the CCD is supplying active light information across its whole field of view. If not, you can go from there.

If the data coming out of the CCD looks good, then it's probably the memory holding that line. You can probably change the line storage RAM and fix it.

These are just guesses based upon how I perceive the HP LaserJet to work. Hope somebody that *knows* this unit jumps in with more specific help.

Paper sense problems with Brother Fax

> "I have a Brother 470 FAX machine that appears to have a broken micro-type switch that detects there is paper WITHIN the front feeder.
>
> Also sometime it jams paper at the rear. It looks like it cuts the paper off (the copy or document report) a little short and the roll of FAX paper pulls it back towards the roll. Thus when the roller advances the paper next time it gets jammed as it isn't in the feed slot?"

(From: "NO UTN" (utn@pi.net).)

My experience with brother fax:

There are 2 detectors at the output of my Brother Fax, do not know type but it uses a roll of thermal paper.

Detector 1 simply uses an IR LED and IR receiver to sense the paper.

Detector 2 is on the cutter, when cutting paper the motor turns by means of a worm-wheel a wheel that moves a handle that lets the cutter move. On the wheel is a detection switch, there is a ring on the wheel from which one part is taken away to be able to detect the home position. If cutting starts the wheel has to be turned in a maximum time, if not the wheel is turned back and cutting stops. The Fax gave and error message. Solution: put some oil at the motor and it works again.

- Back to Printer/Copier/Fax Repair FAQ Table of Contents.

Miscellaneous Problems and Procedures

Cleaning the fuser roller

Of course, the stuff mentioned below is probably banned now.

(From: uiop@cyberramp.net).

When I worked servicing copiers for Canon, we took the roller out, the wiped it down with tri-chlor-ethane, which did a great job.

(From: Joseph Patrick (jpatrick@edge.net).)

The best way to clean a fuser is to use a very light coat of silicon oil. This is used on the heated fuser as well as the pressure roller.

The function of the fuser is to bind the ink to the paper through heat and pressure it should not accumulate any ink during normal use, it doesn't remove or collect toner normally, unless the surface is dirty or deteriorated. The teflon on the main fuser should be slightly shiny much like the surface on a Silverstone(tm) frying pan.

The item you were thinking of is the drum wiper blade which is a part of the drum assembly and is usually responsible for streaks / smudges that persist on the photo drum's surface and make permanent smudges on copies.

I learned of the silicon oil treatment from a 3M service rep. I was using alcohol in the copiers I serviced up to that time. He showed me the way to do it by wiping the fuser components with a non linty rag with a little oil on it until the rollers were completely clean then drying them with another cloth. The job naturally was done with the rollers fully dis-assembled but in his case could be done with minimum removal just so the rollers could be turned and reached without touching the drum assembly, the oil would kill it.

Streaks on laser printer output

(From: Bruce Tomlin (btomlin@crl.com).)

There is also a drum cleaner blade which cleans excess toner off of the drum between pages. On a regular copier, this would show as streaks or even a double image that only shows when you print more than one page at a time.

HP plotter communications problems

> "I'm repairing HP plotter 7550 and there are some chips that I suspect to be broken. They are related to serial communications (thats what is broken). The chips are labeled as 1820-3321 and 1820-3322. I suspected that they could be 1488 and 1489 but changing them did not fix the problem"

(From Paul Grohe (grohe@galaxy.nsc.com).)

Been there, dunnit...

The serial interface on the 7550's is...well...weird!

Without the proper cable, the interface will seem "dead" or unresponsive.

First, you need to use the *male* 25 pin connector, not the female one (which you may automatically assume).

It requires a specially wired serial cable (you can build it yourself). A standard modem cable with a F-F adapter will not work. There are a few handshake lines that need to be wired. Note that you will also need to get a *female* plug for the plotter end of your serial cable.

There are also some menu setups required.

HP has a diagram of the needed cable and menu setups on their FTP site. Get these two documents:

- ftp://ftp.hp.com/pub/plotters/support_doc/cable.txt
- ftp://ftp.hp.com/pub/plotters/support_doc/7550a.txt

Everything you need, short of RTFM, is in these files.

(These no longer exist. If anyone knows what happened to them or has the info, please send me mail via the Sci.Electronics.Repair FAQ Email Links Page. --- Sam.)

There are some other plotter docs at:

- HP Support.

The 7550 suffers from paper pickup rollers that dry/wear out and have trouble picking up the paper from the tray. If you look at the rollers, there is a flat portion. The edge of the "flat" part wears down and becomes rounded, causing it to no longer pick up paper. Try to keep the paper tray as full as possible. Overfilling the paper tray will cause it to pick up multiple sheets, and that can cause a real mess!!

Check the paper feed slot and pinch rollers for shredded paper.

Also, check and make sure the screw that holds the pen carousel together is tight. If this screw becomes loose, it will cause pen loading problems.

It's a "helluva" plotter when it works!

Okidata FAX machine - Printer Alarm 4

> "I am currently working on a Okidata fax machine Model Okifax 2100. The display reads: PRINTER ALARM 4[TEL], CONFIRM AND 'STOP'
>
> If anyone has seen this problem and would be kind enough to share the fix it would be greatly appreciated."

(From: Darrin Acreman (darrina@profax.com.au).)

In all Oki plain paper machines, 'Printer Alarm 4' is caused by the fuser section failing to reach the correct operating temperature. The most common cause is a blown thermal fuse in the fuser section.

- Back to Printer/Copier/Fax Repair FAQ Table of Contents.

Unresolved Problems

Packard Bell laser printer - strange bug

(From: Jordin Kare (jtk@s1.gov).)

> "Just picked up a used Packard Bell laser printer with some problems and could use help...
>
> Print engine is not one I'm familiar with. It's an 8 ppm engine that uses separate drum and developer assemblies. The drum assembly is attached to the top section, which hinges upwards. The developer assembly is attached to the bottom section, and uses a replaceable cylindrical toner cartridge similar to that used in older Canon NP-series copiers. The whole developer assembly can also be removed.
>
> Paper tray mounts underneath unit, and paper follows an "S" shaped path through printer, stacking face-down on top. Front panel has a ~16 char. LCD display and typical button/LED set (ON LINE, Form feed, Menu, Test, Reset).
>
> (Sorry, don't have the model # to hand. Printer was built in late 1993.)
>
> Printer executes power on self test OK, warms up, and goes on line.
>
> Problem 1: Take it off line and push test, and the motor whirs briefly, then stops. The LCD display then reads: 'ERROR 74-M: MOTOR'. Reset has no effect; printer must be power cycled to get it to restart.
>
> Interesting variation: The top section is held down by two large catches at the right and left sides of the printer. The 'hooks' are released by a button on the top section. It's possible to get only the right-side hook to catch, leaving the left side 'loose' and raised by about 1/4 inch. In this condition, the printer will start up and work fine (except for problem 2 below) for many pages. Eventually, it will stop with ERROR 74-M

again. Pushing down the left side will cause an immediate ERROR 74-M.

I assume there's something binding or sticking a bit in the various rollers, such that the motor draws too much current or otherwise triggers an error when the top is latched down. Releasing the top on one edge reduces the pressure on the various rollers and thus the load on the motor. But I can't find any obvious points of sticking.

Problem 2: When the printer *does* work, with the cover popped, the leading edge of the page, down to the first line of print, is dark grey. The grey is faint on the first page or after a restart or long idle, but uniformly dark on all pages thereafter. It tends to be striped along the page (varying darkness as you move left-to-right; uniform as you move top-to-bottom). The grey disappears at the first line of text. There's also a slight "ghost"; text printed near the top of a page is repeated faintly further down the page, apparently displaced by one rotation of the drum.

This seems most likely due to a bad cleaning blade or clearing corona. Anyone have any suggestions other than replacing the drum assembly? Also, anyone recognize this print engine, so I can track down parts via sources other than Packard-Bell?"

Service Information

Printer, copier, and fax Web sites

Unfortunately, these tend to come and go! The following include some with info, error codes, message boards, and links. Some make their moeny on parts and repair kits to beware of those that may be overpriced.

- Photocopiers.com - Supplies, Service and Maintenance
- Smarka - Copier/fax/printer buy, sell, info, tips, etc.
- FixYourOwnPrinter.Com
- Office Machine Buyer's Guide
- HP Laserjet Maintenance and Repair.
- HP LaserJet Printer Error Messages
- HP Parts Surfer
- Laser Wizard - Service courses
- Max Patch Ink - Inkjet tips and free utilities
- Parts Now
- Parts Now Print Engine Information
- Printer Works
- Fax Service Systems
- Bell Copiers
- Ames Supply
- All Laser
- Tips About Inkjet Printers And Refilling Cartridges
- Resources for Epson Inkjet Printers
- MacIntosh Printer Manuals

- Depot America - HP and Lexmark printer parts, technical info, and links

USENET newsgroups

In addition to the USENET newsgroup: sci.electronics.repair, there are a variety of computer related newsgroups including comp.periphs.printer, comp.laser-printers, and comp.sys.hp.hardware which are relevant to printer related problems. However, sci.electronics.repair is probably still best for hardware type print problems (not drivers or applications).

Copier forums

This is a newsgroup style bulletin board for copier selection, troubleshooting, repair and appears to be a good archive if you should need to find something not in this document - hard to believe, but possible :-). However, it is separate and distinct from any Usenet affiliation as far as I can tell.

- The Copier Network - Copier Service Forum.

HP LaserJet parts

(From: Dave Lee (leedj@uwec.edu).)

Dor HP Laser printers, try:

- Parts Now, Inc, 1-800-886-6688.
- The Printer Works, 1-800-235-6116.

Laser printer cartridge rebuild info

(From: terwes11 (terwes11@email.msn.com).)

I've been recycling cartridges for a few years now. Summit Laser Products (formerly Chenesko Products) has comprehensive product and technical information.

Although they are not aimed at hobbyists and do-it-yourselfers their emphasis on service is refreshing. Currently their minimum order is $60 with about 6%discount above $250. They can probably point the private consumer to stores which do handle single-unit sales.

Another distributor for the pro is Oasis Imaging (1-800-322-8992, New Hampshire for regional office).

Here are a couple of places who used to handle small orders. I haven't been in touch with in years, though:

Steven Michlin's LaserLand (orders 800-60-TONER) in Michigan Computer Friends (orders 800-547-3303) in Oregon had "starter kits"

Finally, RECHARGER Magazine intended for the remanufacturing industry only. Each issue is full of products and companies.

Printer parts

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

I've heard good things about a company called 'The PrinterWorks' for HP (and other Canon) laserprinter parts. They have a web page with an on-line catalog and search facility at:

- The Printer Works, 3481 Arden Road Hayward, CA 94545 USA. Phone: 1-800-225-6116.

All kinds of parts are available even down to that little brush stored inside your HP LaserJet Series II: The SX engine parts catalogue shows that the part on page 350 (feeder assembly) as part number RF1-1177-000. It costs $1.23 plus shipping. Or, that 27/21 tooth fuser driver gear (RS1-0287-000). It costs $1.10 in quantities of 1.

(From: Dave Lee (leedj@uwec.edu).)

- Parts Now, Inc., Madison, WI. Phone: 1-800-668-6688.

I have used them for the last 4-5 years for HP Laser and ink jet parts. They also do some Panasonic parts. Great tech support, good prices, same day shipping, etc. They have treated me very well. Also, service information on a variety of printers.

(From: Paul Strider (pstrider@phys.ufl.edu).)

- PC Service Source, 2350 Valley View Lane, Dallas, TX 75234. Phone: 1-800-727-2787 Fax: 1-972-406-9081.

(From: George Hurley (ghurley@voicenet.com).)

- LaserImpact. Phone: 1-888-809-4155.

They'll even fax or mail you a diagram of printer subassemblies so you can identify the exact part you need.

(From: Dave Noseworthy (davenos@pesl.com).)

- Katum Corporation.

Katum is a business machine (i.e., copier/fax/page printer, etc.) part supplier to office equipment dealers. If they won't sell direct to you, I'm sure they'll indicate a local dealer.

(From: SargW1 (sargw1@aol.com).)

- Laser Products Co., 1010 E. 18th St., Kansas City, MO 64116. Phone: 1-816-421-7830.

(From: Sid Ashen-Brenner (sashen@midusa.net).)

- Affordable Photocopy, Inc.

You may be able to get a Service Sheet with the error codes (among other information). They also sell parts & supplies.

HP DeskJet Parts

(From: Jeff (jkinc@erols.com).)

Try this link for HP and other printer parts:

- Parts Now, Inc..

They have a free tech line. Much better than HP.

LaserJet II: Where is the fuse?

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

There are 3 fuses/breakers to my knowledge:

The mains circuit breaker is in the AC block (right hand side of the fuser). It's hidden by the fan duct, but that's quite easy to remove if you have the casing off. The breaker is a little rectangular object with a button on top, on the lower PCB. Press down the button and try again.

The Low Voltage PSU contains the other 2 fuses. One is in the mains side, and is a normal 20mm cartridge fuse. If you remove the casing and the bracket round the front of the printer (6 screws), you can see this fuse on the PSU PCB. This fuse is a listed spare part at 'the Printerworks', which is strange, since the only time it should fail is if there's something majorly wrong with the PSU, and no other PSU spares are available.

The other fuse is a thermal one, clamped to the heatsink in the top right corner of the PSU PCB (looking at it from the component side). This one protects the 24 V pass transistor that on the same heatsink. I've never had to replace this one, so I don't know what the rating is.

If all the fuses are good, then you need to do some more troubleshooting. Firstly, check for mains at the 2-wire connector to the LV PSU. If that's missing, then you need to remove the mains input block (easy, once you've removed the fuser), and sort it out. It's _very_ simple, and should pose no problems.

If mains is present at the input to the LV PSU, check its outputs. Remove the base cover, and sit the printer on the right hand side. The LV PSU output is on the 14 pin connector in the middle of the engine control (DC controller) PCB. The front 2 pins are ground, the next 2 are +5 V, and the rearmost one is +24 V. If they're missing, you have a PSU problem.

Good luck in that case - Canon flatly refused to supply me with any spares for the PSU. They claimed that it would be dangerous to repair it. Quite why it's more dangerous than any other SMPS that I've worked on remains to be seen.

LaserJet III: Where is the fuse?

> "I am looking for the fuse of an HP LJ III. I shorted an exposed wire to ground at the fuser unit with my screwdriver. It was exposed because someone broke the cover of the fuser unit. Now the printer gets no power, the front display does not light, the fan does not come on. I looked for the fuse in all obvious places to no avail. Any hint is appreciated.

(From: Patrick Mulvey (pmulvey@li.net).)

A number of the fuses that are in the laserjets are hard to spot. There is a small component on the boards that is a small black disk. You will have to follow the wiring from the fuser back to the board and look for this small component (fuse).

I have on one occasion lost power to the paper feed motors installing a card access device (defective harness shorted the motor to ground), and found the "fuse" after looking everywhere. Looks like a disk cap but leads are on opposite side of the disk and its mounted parallel to the PCB. Hope this helps...

Copier and laser printer manuals

(From: Gerald Chafee (GChafee@worldnet.att.net).)

I have had good luck purchasing manuals from a company called "Wright-Moore Corp, P.O. Box, 66019, Indianapolis, IN. 46266-6019. I have bought a ton of Toshiba parts and manuals for less than a quarter what any Toshiba repair parts distributor quotes and I know that they are a distributor for Mita. The only possible problem is that they want to deal with someone that has a business license (read resale or Tax ID certificate). If you know someone that will let you use their name and / or address, Wright-Moore doesn't care if it is copier or laser printer connected. They do have an 800 number which I don't have in front of me but is listed with 800 directory assistance.

Canon information

Canon has a faxback service at 1-800-526-4345. Quite a bit of technical information is apparently available for their printers.

Epson printer switch settings

(From: Kim (103114.1526@compuserve.com).) Some info can be found at:

- Epsom DIP Switch Settings.

Hewlett Packard information

HP actually has a fair amount of printer maintenance and troubleshooting information on-line but no schematics:

- HP Support.
- HP parts info.
- HP Parts Surfer (Includes exploded diagrams with parts numbers).

Printer schematics?

> "Working "on my own" Okidata microline 590. Need a print of mother PCB and regulator PCB. A copy of the schematic will save time and let this OLD TV tech enjoy life.... Thanks"

(From: Joe Wagg (jwagg@fs.cei.net).)

Good luck. Even the Okidata service manuals don't have schematics. The easiest and most cost effective way I know to fix these printers is to send the board off to be repaired. I'm not sure about the price, but the logic board for that model is probably around $100, assuming you send yours in to be repaired. This way you get a known good board with a guarantee. I suggest using Laser Impact, address below. Hope this helps.

(From: Uncle Monster (unclemon@bellsouth.net).)

Try "Ted Dasher & Associates" (http://www.dasher.com), 1-800-638-4833. Ted sells refurbished HP equipment out of Birmingham, AL, He may sell you the parts, info or a trashed printer with the parts you need.

DISCLAIMER

Improper use, testing, or repair of gasoline powered equipment can result in explosion, fire, injuries including loss of limbs or worse, as well as total destruction of your spouse's prized flower bed.

We will not be responsible for damage to equipment or property, your ego, or personal injury or worse that may result from the use of this material.

---

* Back to Small Engine Repair FAQ Table of Contents.

Introduction

Can you see above the weeds?

Most problems with gasoline powered rotary lawn mowers as well as other small engines have simple and inexpensive solutions. For example:

* A mower that is hard to start, runs roughly, or dies at the first opportunity may just need a new spark plug or to have its carburetor cleaned.

* A mower that won't start after its blade hits an obstruction may just need one or two 25 cent locking keys replaced.

This document addresses some of the most common ailments and provides detailed instructions for their diagnosis and cure. In addition, it provides detailed maintenance guidelines to prolong the life and happiness of your lawn mower(s) and other yard equipment.

For electric lawn mower and other electric yard tool problems, refer to the document: Notes on the Troubleshooting and Repair of Small Household Appliances and Power Tools which includes chapters on basic electrical theory (relax, no rocket science) and electric motor testing and repair information.

We will deal with problems the weekend gardener is likely to run into (sometimes, literally!) as well as semi-detailed overhaul instructions. One or more of the books listed in the section: References can be used to supplement this document and can provide much more detailed troubleshooting and repair procedures.

Even if you don't know the difference between a carburetor and a crankshaft, you may still be able to do some of your own work. (Hint: if you drop one of these on your foot, the crankshaft will hurt a lot more!) We begin with an introduction to small engine technology and have more-or-less separate chapters on basic maintenance, intermediate troubleshooting and repairs, and more extensive overhaul procedures.

I welcome comments, additions, hints, corrections, funny or other stories, etc. As the title implies, it is oriented toward the gasoline engine powered rotary lawn mower. However, much of the general information applies to a wide range of yard and shop equipment powered by small 2 and 4 stroke gasoline engines.

SAFETY

Despite all the dire warnings (don't forget that the lawyers need to make a living!) it is possible to use, store, maintain, and repair gasoline powered equipment safely. Mostly, the necessary precautions are just common sense - for example, don't smoke around gasoline (well, don't smoke at all but that is not a part of the charter of this document!).

The following represent the basic precautions to take when performing maintenance or service procedures on gasoline powered equipment and dealing with gasoline in general:

* NEVER work on a gasoline powered engine indoors unless it has been totally drained of gas and given time for the residue to evaporate. Gasoline, in particular, is extremely explosive. It is not the liquid but the vapors - at a wide range of concentrations. The various solvents used for cleaning carburetors and degreasing engine parts are also very flammable. The vapors are also not exactly beneficial to good health.

* ALWAYS store gasoline in an approved gasoline can. These will be red in color. They are not the same as (blue)

kerosene cans! The round metal or thick plastic type sturdier than the rectangular thin (sheet metal) cans which may collapse in cold weather. NEVER NEVER store gasoline in glass or plastic bottles. NEVER store gasoline indoors or anywhere else that any vapors can build up or in a location near an open flame (gas or oil heater, etc.).

- ALWAYS stop the engine before refilling the fuel tank. If possible, add gasoline when the engine is cold - a splash on the hot cylinder could catch fire. Rinse off spills with water or wait till they evaporate before starting the engine.

- NEVER attempt to run a gasoline engine indoors. In addition to the general fire and explosion hazard, internal combustion engines produce significant amounts of carbon monoxide - a colorless, odorless, deadly gas.

- NEVER ever smoke while working on gasoline powered equipment even if you are willing to kill yourself slowly by smoking.

- DISPOSE of used engine oil in a safe manner - don't just dump it down the drain or in the trash. Your local service station or recycling center may accept engine oil or recommend a place for its environmentally friendly disposal. Used engine oil is also a carcinogen. Therefore, avoid excessive skin contact during servicing procedures.

- AVOID going near the spark plug wire when the engine is running or even if you are just pulling on the starter cord. The high voltage is not really particularly dangerous since the available current is extremely small but it will not be pleasant and the reflex reaction may make you do something you will regret.

- ALWAYS disconnect the spark plug wire and tie it safely away from the spark plug terminal (several inches minimum) when doing any work on the engine's moving parts. You don't want any chance of the engine starting on its own. An even better alternative is to remove the spark plug entirely. Even an engine that normally takes 10 pulls to start can do funny things that might lead to unpleasant accidents. Despite the fact that it will not start now no matter what you do, the underlying problem could actually be a flooded carburetor or something else which may correct itself while you are working. Never take chances.

  Note: Modern mowers have at least two systems for stopping blade rotation fairly quickly and keeping it stopped if the dead-man bar is released. These will be either an engine kill and blade brake (on most inexpensive mowers) or a blade brake/clutch which keeps the engine running but stops the blade (on high-end machines).

- NEVER work on or with gasoline powered equipment when overly tired - it doesn't take too many mistakes to ruin your entire day.

- Under no circumstances should the dead-man bar be tied down unless the spark plug wire is removed and safely tied away from the spark plug terminal. Even removing the gas tank isn't necessarily enough to prevent accidental starting. Many types of carburetors contain a reservoir (float chamber) which may still hold sufficient gas for several minutes of operation.

- Older mowers (or other yard equipment) may have no blade brake and only a momentary contact for stopping the engine by shorting the spark plug terminal to the frame. These mowers are on a hair trigger and just rotating the blade can start them up when you least expect it.

Tools and supplies

While you probably did not purchase your lawn mower specifically for the joys of repairing it, there is always a chance that despite all your precautions, the blade will strike a rock that just happened to grow out of the ground when you weren't looking. Therefore, it makes sense to be prepared.

Basic servicing of small engines doesn't require a $500 tool caddy. However, some basic hand tools and other items will be needed.

- A good quality set of socket wrenches is essential. For small engine work, a 3/8" ratchet and a set of sockets from 1/4" to 1" as well as a special spark plug socket. Usually a deep 13/16" type - check for your particular engine(s) will suffice.

  A basic set from Sears (Craftsman) should be fine and will come with a lifetime replacement warranty as well! If you have never invested in a socket set, now is the time. Forget about those $4 specials, however, as they are generally worse than useless. A word to the wise: you really must have a socket set to do any kind of work on small engines. Slip-joint pliers or worse yet - ViseGrips(tm) - just will not do!

  While open-end or box-end (closed) wrenches may be used for certain bolts, some simply are not accessible without a properly sized socket (like cylinder head bolts).

- An impact wrench may come in handy for removing those really stuck bolts and screws. These accept standard screwdriver bits and sockets (via an adapter) and convert a hammer blow to rotary motion. First try penetrating oil like Liquid Wrench(tm) and normal tools though.

- A variety of good quality screwdrivers - both straight and philips.

- Needlenose and utility pliers.

- Wire cutters and strippers.

- Ball-peen hammer or other metal hammer.

- Rubber mallet.

- Funnel, drain pan, plastic milk jug for used oil. These can be discards from the kitchen.

- Old rags, cotton swabs, paper towels, etc. for cleaning. An old but soft paint brush for getting dust and dirt our of various places.

- Wood blocks for propping things up or securing the blade or flywheel when loosening or tightening. Other drift (scraps) of wood and soft metal.

- Torque wrench. An adequate model that will work with your 3/8" sockets can be purchased for around $10. Setting the torque - tightness - on certain engine bolts is critical to proper operation and long life.

- Feeler gauge - a set of precise thickness strips or wires for setting spark plug and point gaps. The .020" and .030" sizes should suffice for basic maintenance.

- Flywheel puller - build or buy. See the sections starting with: Flywheel removal. If purchased, it must be one designed for your model engine, not just something you picked up in the hardware store marked 'flywheel puller'! Briggs and Stratton, Tecumseh, and others sell tools specifically for their engines. This is the easiest way to remove the flywheel.

- Carburetor cleaner - this comes in a spray can. It is also probably as flammable as gasoline, toxic, and will eat plastics and painted surfaces. Therefore, use only in a well ventilated area or outdoors and take appropriate precautions.

- A tube of thread-lock comes in handy as well as some anti-seize compound like graphite grease for the muffler/exhaust bolts and spark plug.

- Back to Small Engine Repair FAQ Table of Contents.

Lawn Mower Basics and General Maintenance

Gas, electric, or manual?

Many people who have never used a gasoline engine powered piece of yard equipment are intimidated by all the warnings with respect to the explosive nature of gasoline. They then opt for an electric lawn mower instead of gas. For many, this is the correct choice. There are a different set of precautions to follow but they are fewer and seemingly less of a threat.

Electric equipment is in some ways more environmentally friendly generating no pollution (though the electricity had to generated somehow). Once the equipment is unplugged, there is nothing to worry about with no gasoline to store. Little maintenance is needed and there is never any issue of disposing of used engine oil - since there is no engine oil. Electric equipment is also usually - though not always - somewhat quieter.

The main disadvantage of line powered electric equipment is that it is tethered to an electric outlet by the power cord. This can become quite a nuisance after a short while. Battery powered equipment has tended to less powerful and more finicky to deal with than similar equipment powered from a line cord. And, electric mowers tend to be less powerful than similar equipment using a small gasoline engine.

Where your yard is relatively small (say, less than 50 feet to an electric outlet from the farthest point), a corded mower may be a good choice. It will be less expensive than typical battery powered mowers and most gasoline powered mowers, and virtually maintenance-free. Just make sure you use a proper outdoor heavy duty extension cord - probably one size LARGER (lower AWG wire size number) than what the manufacturer recommends. This will assure minimal loss of voltage due to its resistance - and every bit of power you have available will help! A somewhat lighter duty outdoor cord can be used for the first few feet if that makes maneuvering the mower easier. The main thing to watch out for is accidentally cutting the cord by running over it. Mowing in a back-and-forth pattern while moving away from the outlet helps. If you do cut the cord - don't panic. At most, you will need to shorten it a couple of feet and install a new socket on the end of what is left AFTER pulling the plug! If the outlet is now dead, at most you have tripped the circuit breaker or GFCI, or blown the fuse. Of course if you make a habit of this, your cord could get to be quite short. :-)

Battery powered yard equipment and power tools have improved greatly over the years. Some of the newer models are quite capable of cutting a modest size yard (e.g., 1/4 acre, manufacturers specifications may still be a bit optimistic) on one charge with ample power for moderately thick grass. But, there is quite a bit of variability in cutting performance and battery life so shopping around, consulting Consumer Reports, and making sure you get a return option if you are not satisfied are all well worth the effort - to save effort in the long run.

It is interesting, however, that quite capable battery powered tractors for example, have been around for a long, long time.

See the section: Comments on electric mowers for more information.

Having said all that, the fact of the matter is that the vast majority of lawn mowers used for modest or larger lots are gasoline powered.

Of course, if you have a postage stamp size or even a small suburban lot, a manual reel mower may be your best choice - and you get some good exercise as part of the deal as well.

Also see the comments in the Chapter "Items of Interest" on electric and manual mowers.

Types of lawn mowers

Depending on the size of your lot, glowing conditions, and your energy level, one or more of the following options will fit you like a glove:

- Reel mowers - manual type are still available and suitable for small lots. Safe, non-polluting, quiet, low maintenance, and low cost substitute for aerobic workout.

- Rotary mowers (gasoline powered) - Most common type, convenient, relatively low maintenance, some pollution, generally noisy.

- Rotary mowers (electric, AC line or battery powered). Convenient, low maintenance, non-polluting, usually quieter than gasoline powered mowers, limited by cord length or battery charge.

- Teenage kid - low maintenance but variable performance and possible reliability problems.

- Landscaping service - expensive but consistent and may occasionally mow your valuable flower bed as weeds by mistake.

- Cow, goat, or other herbivore - mowing performance quite variable, fencing required, excellent source of fresh fertilizer. The extended warranty is essential! :-)

The first two of these are described in more detail is subsequent sections of this document. For the last, well you should already know if *that* is appropriate for your life-style!

Large mowers (those which carry you) may be of either the rotary or reel type, usually gasoline or diesel powered but some electrics have been produced. For information on riding mowers, lawn tractors, garden tractors and estate tractors (also known as compact diesel tractors), see the Small Tractor FAQ.

Consumer Reports regularly provides reviews and ratings of most common types of lawn mowers. These articles are a good place to start as they include a great deal of the basic information needed to decide on the lawn mower type best suited for your property. They compare a selection of typical models based on features, safety, price, and their tests of performance and operator convenience. If you do not subscribe to Consumer Reports, your local library will likely have access to several years of back issues.

For even more advice, see Consumer Reports Books' Yard and Garden Equipment Buying Guide. It is sold at bookstores and newsstands and is also available directly from Consumer Reports Books using the order form in the back of every issue of Consumer Reports.

Reel mowers

These may be manual or engine powered. A spinning set of sharp spiral cutting blades working against a fixed 'bedknife' snips off grass like a scissors. In principle, reel mowers can produce an exceptionally consistent manicured lawn. However, small reel mowers may have serious cutting height limitations and also result in a wavy uneven appearance.

- The common (some would say old fashioned) manually operated push reel mower is simple in construction, easy to operate (if you have the energy), safe, quiet, compact to store, and modern ones in particular are quite light in weight. However, blade sharpening is something best left to an expert. If your lot is small and/or you like the exercise, a manual reel mower may be for you.

- Small engine powered reel mowers do exist but I do not know if they are still readily available. I have seen them at garage and estate sales. While I have never seen an electric powered reel mower, this would seem to make a lot of sense for battery operation as the power requirement of a reel mower are much less than for a rotary type.

- I don't know if commercial battery powered reel mowers exist but it would make sense as they should be much more efficient than rotary mowers.

    (From: Nigel Cowburn (nigel@hkem.com).)

    "A neighbor of mine had a homemade car-battery-powered reel mower. He used his actual car battery and worked out a mowing time that allowed him to start his car again after mowing."

  (From: Sam.)

  I suppose he had to factor in the height of the grass to guarantee that his car would start. :)

- Professional landscapers often use large engine powered versions of these machines which may have multiple cutting heads and are self propelled, ride-on, or pulled behind a tractor.

See the Reel Mower FAQ for additional information on this type of beast. An Internet search should also turn up a number of informative Web sites.

Rotary mowers

These may be gasoline or electric (AC line or battery) powered. A spinning blade or blades whirls at the selected cutting height and lops off the tops of you grass by side impact. This is most definitely brutal treatment of your poor defenseless grass! The length of the cutting blade determines how much of a swath is cut on each pass - typically 18 to 24 inches for a walk-behind mower; up to 36 inches or more for a riding mower. Mowers with large swath widths may use two or more smaller blades instead.

The uniformity, consistency, and just general appearance of a lawn mowed with a rotary lawn mower is not quite up to the standards of that of a professional reel mower. You will never get the perfect manicured look though some models may come close. However, the simplicity, lower cost, and need for less and more easily performed maintenance will generally overcome the desire for perfection unless your lawn is featured regularly in "Better Homes and Gardens" magazine.

Gasoline powered rotary lawn mowers are by far the most common type used by homeowners and many professional landscapers as well. Most walk-behind mowers use a manual recoil (pull) starter though electric start is available on more sophisticated (and more expensive) models and generally standard on riding mowers and lawn tractors.

The main disadvantages of a gasoline powered mower are the need to deal with the handling and storage of gasoline and routine engine maintenance at the end of the mowing season to assure easy starting next season and to prolong engine life. However, most of this is pretty straightforward. See the section: General preventive maintenance. Small gasoline engines also do contribute to air pollution but new mowers must meet more stringent EPA requirements as of September, 1996.

Electric rotary mowers are also available in both plug-in and cordless (battery powered) versions. However, since gas mowers are generally more powerful and not limited by the length of a power cord or charge of a battery, they continue to dominate the market. Electric mowers are, of course, non-polluting but the electricity had to be generated somehow.

Dead-man control

All rotary mowers manufactured within the past 15 years or so must have a dead-man control to stop the blade quickly (within a couple of seconds) if the handle is released or the operator falls off of the seat of a riding mower or lawn tractor. While not foolproof, this feature greatly reduces the chances of serious injuries due to accidental slipping or falling - or attempting to make adjustments while the blade is spinning.

WARNING: Never defeat the dead-man control for any reason unless there is no chance of the mower starting.

- For gasoline powered mowers, this means that the spark plug wire had been pulled and tied a safe distance (a few inches minimum) away from the spark plug terminal or the spark plug has been removed entirely. Even draining or detaching the fuel tank is no guarantee that the engine will not start as the carburetor often contains a few minutes of fuel reserve.

- For electric powered mowers, this means that the wall plug has been pulled or the battery disconnected and the wire tied or taped to prevent any accidental contact.

Always restore the dead-man control to normal operation before attempting to start the mower.

Types of rotary mowers

In addition to options with respect to gasoline or electric power, rotary mowers can be classified based on such things as: walk-behind vs. ride-on, to bag or not to bag, and rear or side discharge or mulcher:

- Walk-behind mowers may be either of the push type - you provide the power to move the mower; the engine or motor spins the blade - or self propelled where the engine (usually only for gasoline types) drives the front wheels via a fixed or multiple speed transmission. Typical engine power is from 3 to 6 HP with the trend nowadays toward the higher end of this range especially for self propelled models.

- Side discharge mowers eject the grass clippings from the right side (usually) to the rear. These are probably the most common type in use today due to their low cost. Some perfectly serviceable new mowers of this type sell for $100 or less. Optional grass catcher bags permit some of these to be converted to side-baggers if desired but the bags tend to be much smaller and thus less convenient than those for rear bagging mowers to prevent them from becoming side-heavy when the bag fills up.

- Rear baggers eject the grass clippings into a bag mounted behind the mower. Bags tend to fill quite quickly - especially if you keep putting off your mowing assignment - and need to be emptied or changed frequently. The weight of the grass clippings in the bag also contributes to the mass of the mower - which you have to push if it is not self propelled.

  WARNING: Rear baggers should never be operated without a bag unless the opening is fully blocked or the proper deflector is installed. Grass cutting performance will then be similar to that of a mulching or (side) discharge type mower respectively but since this is a compromise, the resulting appearance of the cut lawn may suffer.

- Mulching mowers do not discharge the clippings but continue to chop them up under-deck until they are small enough to cease being sucked up by the airflow. The best will result in almost no detectable evidence of grass clippings though the worst may leave big clumps behind. The appearance of the lawn from a mulcher may be as good or very nearly as good as that from a bagger but this is not assured. Some mowers - both discharge and bagging types - can be converted to mulching mowers by using a special cover to block the discharge port and possibly a different mulching blade.

  Side discharge and bagging mowers can often be converted to mulching with the use of a mulching kit which includes a means of blocking the discharge port and possibly a special mulching blade. However, performance of one of these may not be as good as that of a mulching mower since the airflow requirements differ and these are largely determined by the design of the deck.

- Riding mowers are basically larger versions of the self propelled bagging mower with a seat for the operator, steering wheel, and more controls for cutting rate and forward speeds. The engine is typically in the 8 to 10 HP range and is mounted in the rear beneath or behind the seat.

- Lawn tractors may be even more sophisticated than riding mowers with larger blades and additional options for non-lawn mowing tasks. The engine is higher power - 12 to 18 HP or more - and is mounted up front under a hood as in a real tractor.

WARNING: Most lawn mowing accidents result from reckless or careless use of riding mowers and lawn tractors, not walk-behind mowers. These are not as stable as an automobile especially when their large bags are full of heavy, wet, grass clippings and may tip over on inclines that would not be a problem with someone in control of a walk-behind lawn mower. They are best and safest for use on large flat open lots. A walk-behind mower - perhaps even a manual reel mower - should be used for sloping or irregular areas and for mowing or trimming around obstructions like trees, shrubbery, landscaping timbers, posts, fences, planters, boulders, and so forth.

Putting a mower into service for the first time

If this is a new purchase, you should have a users manual - READ IT!!!

Above all, understand the very important SAFETY information.

If there is some 'simple assembly required', take your time and follow the instructions step-by-step. Despite the apparent efforts of the designers of the mower and the manual writers to make everything as obscure as possible, it will probably go together without undo difficulty if you use the proper tools. With some, all you need to do is unfold the handle taking care not to pinch any control cables - oops - and you are ready to go to work. Happy times are here again!!

IMPORTANT: For 4 stroke engines, make sure there is oil in the engine!!! Learn how to check it and fill it to the proper level if there is none or it is low. See the section: Checking the oil.

WARNING: Running an engine without oil can ruin it in a few minutes and your warranty will not likely cover such stupidity. Since the lawn mower may be shipped without any oil, it is your responsibility to check this and then add the proper amount of the correct type of oil to the crankcase!!!

For 2 stroke engines, special oil (not the usual 10W-30/40 type motor oil, nor WD40 or 3-In-One!) must be mixed with the gasoline in the correct proportions IN THE GAS CAN - not the fuel tank of the mower! See your users manual! Forgetting to use the proper mixture can ruin a 2 stroke engine in a matter of minutes and your warranty will not likely cover such stupidity. Adding the oil to the fuel tank is not recommended because thorough mixing cannot be assured.

If you have yard equipment with both 2 stroke and 4 stroke engines, clearly label the two gas cans to indicate which equipment each is used in.

Gasoline

Use only fresh unleaded gas. Regular octane rating (87) is fine - small engines operate at relatively low compression ratios so knocking should not be a problem. There is likely no benefit to using anything higher. In fact, I've heard that small engines may actually be harder to start and run poorly on expensive high octane gas due to their low compression ratio. Gas that is over a month old may have lost some of its more volatile fractions resulting in hard starting, possible varnish formation, and other undesirable effects. At the end of the season, dump the unused (unmixed, not from a two-stroke engine!) gas into your car (preferably when its fuel tank is at least half full so your old gas gets mixed with fresh gas). This way you won't be tempted to use it at the start of the next season.

If the tank detaches easily as with many Tecumseh/Craftsman engines, just lift it off and drain the gas into a gasoline safety can reserved for this purpose. If the tank doesn't come off easily, I typically use a cooking baster to do this (you know, the thing you use when baking turkeys!) although the gas tends to destroy the rubber. There are similar devices or gas siphons available at auto parts stores that survive better.

For 4 stroke engines, gasoline is used as-is since there is a separate oil supply. For 2 stroke engines, you must mix the proper amount of the correct 2 stroke engine oil (outboard motor oil or whatever is recommended by your engine's manufacturer). Fill your '2 stroke mixture' gas can with about half the amount of gas you are preparing and add the proper amount of 2 stroke engine oil. Put on the top and slosh this around to thoroughly mix the oil in with the gas. Then add the remaining gas to the total amount for which your oil measurement was made.

How do you tell if a lawn mower you just inherited has a 2 stroke or 4 stroke engine? The vast majority are 4 stroke - look for an 'oil filler cap'. On many, this is clearly marked with words like 'oil' or 'oil fill' or with a suitably ambiguous icon. Removing it will reveal a dipstick. (Note that unlike the engine in your automobile, this is both the test and filler location.) However, on more basic models, it may be near the base of the engine and be unmarked. In addition, there will generally be markings as to the need for the gas/oil mixture somewhere on the cover. The only major manufacturer of lawn mowers I know of that has used 2 stroke engines in recent designs extensively is Lawnboy.

If you are unsure of the correct mixture ratio - they typically range from 16:1 to 32:1 gasoline:oil by volume - 16:1 is probably a safe choice. The worst that can happen is that the spark plug may be more likely to foul (and you will pollute more than necessary) but at least you won't risk damaging the internal parts from lack of oil. It is of course best to determine and use the recommended mixture ratio.

Where to buy gasoline

Your nearest auto service station will sell you small quantities of gasoline. As noted in the section: SAFETY, you must use an approved gasoline safety can which will be red in color. These come in sizes from 1 to 5 gallons or more and may be made of plastic or metal. A convenient size is 2 to 2-1/2 gallons. The fuel tank on a typical walk-behind mower will be between 1/4 and 1/2 gallon.

WARNING: When filling your gas can, place it on the ground a few feet from your vehicle - never fill it inside the trunk or truck-bed. See the section: Where to fill gas can.

However, a gallon of gas goes a long way with a walk-behind lawn mower. I don't have exact numbers but a gallon will probably do several acres of mowing (assuming you aren't chopping foot high grass!).

If you must transport gasoline in a vehicle, make sure the container is secured in an upright position and tightly capped (both the filler spout and vent openings). Provide adequate ventilation so there can be no possibility of fume buildup in the trunk or passenger compartment.

Where to fill gas can

Always remove the gas can from vehicle before filling it. In addition to common sense 'what ifs' with respect to spills and fume buildup, there may be an added risk of the buildup of static electricity:

Also see the section: Explosion risk when filling a metal gas can.

(From: Joyce (joduren@ix.netcom.com)

Please be careful about filling the gas can. I saw something on one of those PBS How to do it shows (or was it in the newspaper?) that said that people are filling their plastic gas cans with them still in their trunks or hatchbacks. They said this is dangerous because the can isn't grounded or something and a static electricity spark could make the thing to explode.

Gasoline additives or stabilizers?

The use of a proper stabilizer can often substitute for the task of draining the gas between seasons by preventing the formation of insoluble gum that would otherwise eventually clog up your carburetor.

> "Isn't there a gasoline additive you can add to the gas which will keep it 'fresh' for up to 24 months? I've seen it at Home Depot, though have never used it. I think a tube was less than $1.00."

(From: Floyd Reed (floyda@ix.netcom.com).)

Being an old small engine mechanic from way back, I suggest that you don't use any additives to keep your gasoline 'fresh'. Dispose of old gasoline (end of season) by dumping it in the (nearly full) fuel tank of your car, then refill your gas can at the beginning of the mowing season. It should last you the season. With this method, you spend no extra on additives (that are no good for an engine), you don't waste 'old' gasoline, and you don't dump raw gasoline into the environment.

(From: Dan Weise (dan_yz@cin.net).)

I have found the commercial product Stabil the best thing since sliced bread. It prevents the gasoline in the gas tank from gumming up. I'm too busy to run around emptying gas tanks in the fall.

Instead, I shoot in a squirt of Stabil, run the engine for 5 minutes, shut the gas valve off (unless it's a suction carb mounted on the gas tank) and the engines start next spring.

That was *not* the case before Stabil. I can't count the number of times I've disassembled a carb and sprayed Gumout trying to unclog the main jet or the idle jet. Or had the float stick down and flood everything in sight. All because of gummy gasoline.

I've used Stabil for about 10 years with great success.

I also use that Slick 50 teflon stuff, but have no idea whether it does any good or not. But for the investment in an engine, I can't see that it hurts. The intermittent duty of many engines makes them more vulnerable to oil run-off than vehicles that are used daily.

Before you start mowing

Note: while written with gasoline powered rotary mowers in mind, most of these comments apply to electric models as well.

- Reread the section: SAFETY, particularly with respect to the storage and handling of gasoline.
- Make sure you understand the operation of your mower. In particular, how to stop it! On most modern inexpensive mowers, the engine should stop as soon as a dead-man safety bar is released. This is supposed to both kill the ignition to the engine and apply a brake to the blade (usually to the flywheel). On more sophisticated machines, releasing the bar disengages the blade but does not stop the engine - do you know how to stop the engine?
- Check, and if necessary, set the cutting height. (I will leave it to the gardeners to determine optimal height. Around 2 to 2-1/2 inches is probably acceptable unless you are mowing a putting green.) This is usually accomplished either with levers on each of the wheels or by removing and reinstalling each of the wheels into one of several holes. A few mowers use a single control for all wheels - very convenient. Always make sure all (4) wheels are set at the same height.
- Check the oil and if necessary. top it off.
- Remove any obstacles or debris in your path - rocks, stones, wood blocks, branches, etc. These are a safety hazard and killers for your lawn mower. If the blade hits something small, it can become a high speed projectile traveling at up to several hundred feet per second - this is a substantial fraction of the muzzle velocity of a handgun. If the blade

tip contacts something larger, the engine will stop and serious damage may be the result. See the section: Why you really don't want to attempt to move an immovable object. Mark immovable obstructions with Dayglow orange paint or something else you won't miss!

In some cases, obstructions like tree roots cannot be moved. In this case, you will either have to mow around them or raise the cutting height of the blade to clear.

- Make sure all protective devices are in place on the mower. Rear baggers must have a bag or proper cover installed (many are automatic). Side baggers must have a bag or deflector installed. Change bags only with the blade stopped - and preferably the engine stopped as well.

- Wear proper clothing and sturdy fully enclosed shoes with non-slip soles. Avoid mowing when the ground is wet and slippery.

- Wear proper eye protection - plastic eyeglasses or safety glasses - to protect your eyeballs from flying debris.

- Use some kind of hearing protection - ear plugs or muffs. Even just a wad of cotton or tissue will greatly reduce the noise level to your ears.

- Keep curious kids and pets a safe distance away.

- Avoid mowing a highly sloping area in the up and down direction as the mower can slip or you can slip. Even with the safety blade brake, it takes a couple of seconds for those knife edges to come to a stop. If you must mow such an area, do it from side-to-side and be careful of side-bagging mowers that may tend to tip over particularly when their bag is filled with grass clippings. Better yet - only plant rocks on highly sloping areas!

Starting the mower

Most mowers and other small pieces of gas powered yard equipment use a self retracting recoil type starter. You pull on a handle attached to a cord wound around a one-way clutch affair. Pulling on it rotates the engine's crankshaft and the clutch allows the engine to run without pulling you back into the mower! If yours has an electric starter, then you don't need to tug on anything - plug it in and push a button or turn a key. Of course, finding an outlet at the far end of a large yard may prove to be a challenge. With larger equipment like riding mowers, power is usually provided by an on-board rechargeable battery. In either case, there will be some kind of backup recoil or rope starter should the electric start be unusable or inconvenient.

For the following, we will assume you pull a self-retracting starter rope. With an electric starter, replace the words: 'pull...times' with 'crank for several seconds'.

Move the mower or other equipment to the place where it will be used - no sense in dragging a chugging lawn mower through the neighborhood. Position it on a solid level surface. Make sure there are no loose stones, twigs, branches, logs, etc. underneath to get sucked up and thrown about once you succeed in getting the engine started (if you ever do).

When attempting to pull on the starter cord, it may be helpful to put one foot on the mower deck to brace it. Whether this is needed will depend on the design of your mower and in what direction the cord exits from the starter.

You or the starter motor supplies the power to get it started. However, at the low speed of starting, special modifications may be required to the fuel system for the engine to catch. These may take one of the following forms:

- Primer - a rubber bulb or pushbutton squirts a little extra gas into the intake pipe. Your engine manual will detail the procedure and number of 'pushes' required under various conditions - typically between 1 and 12. Too few and nothing will happen. Too many and you will flood the engine (excess gasoline will prevent it from starting). See the next section.

A typical starting procedure for an engine with a primer might be:

  - Set the throttle control (if any) to the START or HIGH position.
  - Push the primer 5 times.
  - Pull the starter cord once or twice (if it doesn't start on the first one).
  - If it still doesn't start, prime 2 more times.
  - Pull the starter cord again.
  - Set the throttle control to the desired speed once it starts.

- Automatic primer - a chamber in the carburetor which fills with the engine stopped and provides an additional squirt of gas when starting.

  Automatic choke - temperature and engine vacuum control the fuel-air mixture.

  A typical starting procedure for an engine with an automatic primer or automatic choke might be:

  - Set the throttle control to the START or HIGH position.
  - Pull the starter cord once or twice (if it doesn't start on the first one).
  - Set the throttle control to the desired speed.

- Choke plate - a control on the carburetor which partially closes off the air intake and forces additional suction to increase the amount of fuel drawn into the cylinder. Normally, the choke is closed when starting cold and gradually opened in the few seconds after the engine starts. It is left fully open once the engine is running and may not need to be closed when starting warm.

  A typical starting procedure for an engine with a choke might be:

  - Close the choke (usually on carburetor).
  - Set the throttle control (if any) to the START or HIGH position.
  - Pull the starter cord once or twice (if it doesn't start on the first one).
  - If it still doesn't start, open the choke half way.
  - Pull the starter several more times until it starts (hopefully).
  - Gradually open the choke to keep the engine running smoothly.
  - Set the throttle control to the desired speed.

If the appropriate procedure is not successful, the engine may be flooded. You can give it 15 minutes or so for the gas to evaporate and try again or, if there is an IDLE or LOW speed position, open any choke and pull the rope several times in this position which should clear out the excess gas. Then repeat the recommended starting procedure.

If none of this works, you may have a starting problem and should refer to the section: Lawn mower will not start. Probably, you forgot to fill the gas tank!

A primer on priming

Many small engines have replaced the choke with a primer - a rubber bulb or button that is supposed to be pushed several times before attempting to start the engine. Under the right conditions, this is a very effective approach. However, here are a couple of things to keep in mind:

- The number of times the manufacturer recommends for pressing the primer is just an average - in many cases, more is better and won't hurt. (The instruction manual probably even says something like: "If the engine doesn't start and run after N pushes of the primer, do it N more times and try again"). While it is possible to flood the engine with too much priming, it would probably take more than just 2 or 3 times the recommended number of pushes.

- If the ambient temperature is low, priming will be less effective. The engine may run for a few seconds and then die since its interior parts having heated up enough, requiring repeated priming and starting. If the engine then runs fine, there is probably nothing actually wrong. If you work at it, this might be a good excuse to put off the first mowing of the season. :)

Where behavior seems to have changed, first confirm that environmental conditions are the same and the gasoline is fresh before blaming the engine on starting problems.

If the engine operates normally once started (assuming you can get it started by some other means like squirting some starting fluid into the cylinder), then dirt may have made its way into the priming mechanism. Disassembly and cleaning may be all that is needed. However, there really isn't much to it: Pressing the primer just pushes some air into the carburetor, which squirts some gas via the main carburetor jet to the intake pipe. There really isn't much that can wrong as long as the rubber primer bulb and connecting tubing (if the primer isn't on the carburetor itself) is in good condition.

Stopping the engine

On most inexpensive lawn mowers manufactured within the last 10 or 15 years, releasing a dead-man bar on the handle both kills the engine and applies a brake to the blade (well, actually the flywheel of the engine). In this case, there is nothing to think about - just release the handle and it will stop within a second or two. These are quite reliable. The usual problem is that you forget to engage the dead-man bar and attempt to start the mower despite the basic fact that this is quite impossible!

More expensive equipment will have a blade brake clutch meaning that while there is still a dead-man bar but instead of killing the engine when released, it disengages the blade (clutch) and brings it to a rapid stop (brake). This is more convenient especially with a balky engine. There will then be a separate engine stop switch - possibly combined with a speed/throttle control.

Equipment with an electric starter may have an ignition switch just like an automobile and there will be three positions: STOP, RUN, START.

Some older equipment just has a stop contact that grounds the spark plug. Pressing on a lever connects the spark plug terminal to the engine chassis and kills the spark. While this is fairly reliable, it may be a momentary contact meaning that the engine may be on a hair trigger and even rotating the blade a fraction of a turn may cause the engine to take off again. Thus, disconnecting the spark plug wire or removing the spark plug is even more critical when working on this sort of equipment.

Suppose it fails to stop?

What should you do if the engine stop switch has no effect? Probably the safest and surest is to use a wooden stick to pop the spark plug connector off of the spark plug terminal. This **will** stop the engine.

The most likely cause of such misbehavior is a stop wire that has become disconnected or has broken. This is easily remedied.

Maintenance Guide

General preventive maintenance

Here is what you should do at the end of the mowing season:

- Change the oil. If you do nothing else in this list, at least change the oil. Old dirty oil will shorten the life of your engine and affect its starting and running performance eventually.

- Drain the fuel tank (see the section: Gasoline for tips on doing this). Put this and any fresh (unmixed) gas remaining in your gas supply can into your car's fuel tank (preferably at least half full to dilute it) so you won't be tempted to use it next season. Or, discard it in an environmentally friendly manner. Then run the mower until it stops from lack of gas which will use up the gas still remaining in the carburetor (at most a couple of minutes). Purging the engine of old gasoline is particularly important for float type carburetors. Otherwise, evaporation and oxidation may result in the formation of insoluble gum which will eventually clog up your carburetor.

  Also see the section: Additional comments on winterizing - draining versus the use of fuel a stabilizer. The use of stabilizer is convenient but I think draining is preferred as it is safer not storing garden equipment over the winter loaded with gasoline.

- Inspect the air filter (and fuel filter if present). If dirty or clogged, clean or replace as appropriate.

- Remove and inspect the spark plug. The curved electrode and tip should be smooth and light gray or brown in appearance. If they have deteriorated or are damaged in any way, replace the spark plug. Engine repair books usually recommend replacing the plug in any case - they are inexpensive, under $2. Use the proper small engine spark plug - not one you found in the corner of your toolbox or removed from your automobile! A bad spark plug is a major cause of a hard-to-start engine. Check the spark plug gap (new or used) with a feeler gauge - it should be .030" for most small engines. Carefully bend the curved electrode to adjust - do not file the center electrode!

- Squirt a teaspoon or so of fresh engine oil into the spark plug hole so that it coats all sides of the cylinder. WD40 will work as well since its purpose is protection and not lubrication. Then crank the engine a couple of times to distribute it. The oil will protect the cast iron cylinder liner and piston rings from rust during the off-season.

- If you reinstall the old plug, it is generally good practice to replace the metal washer. Install the spark plug finger tight and then tighten another 1/2 to 3/4 turn or to 15 to 30 ft-lbs with a torque wrench using the proper deep (spark plug) socket.

- Clean above and below deck to remove dirt, leaves, and other debris. Pay particular attention to the area around the cylinder under the shroud (blower housing). Remove any leaves or other debris that might impede the all important air flow.

- While underneath, inspect the blade for serious damage that would require resharpening or replacement. It doesn't have to be honed like a scalpel but there should not be too many deep nicks and it should not wobble noticeably or be bent or have bent or distorted tips.

- If you have a battery for electric start, make sure the water reservoir (if not the maintenance-free type) is topped off, the terminals are clean and tight, and that it is fully charged.

- Put a light coating of oil on any exposed unpainted steel parts. Check any front wheel drive components - chains, idlers, pulleys, and clean and lubricate if necessary. Dribble a few drops of light oil into any throttle, choke, safety interlock, or other cables.

- Store the mower in a dry location supported off of the floor on wood blocks if there is any chance of flooding.

Then, when it comes time to start mowing again (yes, I know, you can't wait), all you should have to do is add fresh gas (don't use last season's). The mower should start on the first (well, maybe, second) pull. There may be some white/blue smoke for a few seconds from it burning off the oil coating on the cylinder walls but this should quickly disappear.

The Lawn-mower-shop.com Web site has great deal of useful information including diagrams of popular carburetors and links to small engine manufacturers.

Here is another recommendation:

(From: Bill Harnell (bharne@adss.on.ca).)

Change the oil at the *end* of the season. No need to leave the acid charged oil in the crankcase over the winter to corrode the engine.

Then add a couple of teaspoons or so of Stabilit to the gas tank. Run the engine for approximately 5 minutes and while you're at it, inject some fogging oil through the carburetor to thoroughly coat all of the interior surfaces. Directions are provided on the fogging oil container.

Wipe the frame and handle with an oily cloth and oil all pivot points lightly. Clean the crud from under the deck - you do that frequently all summer - right? Remove all the grass clippings from around the flywheel and the cylinder fins.

Then store it in the shed or garage.

It will start on the first or second pull every spring.

BTW, you should be able to get both Stabilit and fogging oil at any reputable engine service center.

Checking the oil

The following applies only to 4 stroke engines. For 2 stroke engines, special oil must be mixed in proper proportion with the gasoline.

The proper amount of oil is critical to the happiness of your engine. Too little and it may overheat, cause excessive wear, and in extreme cases (but not unusual), cause engine parts to seize and fail - very expensive. Make it a habit to check the oil regularly. Doing this after about every 5 hours of operation is generally recommended. More frequent checks - such as before each time you mow - are fine as well. A typical small engine in reasonably good condition does not use up a lot of oil but checking oil is easy and will not hurt.

Oil should be checked when the engine is cold or after waiting 10 minutes for it to drain back into the oil sump after running the engine.

Place the mower on a level area.

- If there is a dipstick - remove it, wipe it with a rag, and then reinsert it as directed on the information sticker or on the stick itself - usually threaded fully back in place and then removed to read. If the level is below or near the empty mark, slowly add the proper new oil to bring it up to just below the full mark.

- If there is just a filler plug near the base of the engine, the correct level is just below the top - almost to overflowing. If lower than 1/4" or so below the lip, add new oil to top it off. (There may be exceptions to this but filling to near the top should be safe if you do not have your lawn mower engine manual handy.)

If the oil level is high - you just bought the lawn mower or were careless in filling it last time - drain enough oil to bring the level back down to the full mark. Too much oil can result in problems as well - oil spraying out of various orifices or getting into other places where it should not be like the combustion chamber.

If you find the oil level over the full mark or higher than it was before, gas may be leaking into the oil due to a flooded carburetor - a stuck inlet needle or bad float. If this is the case, the oil will need to be changed once the underlying cause of the leakage is determined. (This is only likely with float type carburetors such as those used on the Tecumseh engines used in a variety of Sears/Craftsman models equipment.

If the oil is very low and you have been performing regular maintenance, there may be a leak or your engine may need a ring job. Excessive oil under the deck - on the shaft or blade adapter - would indicate a bad bearing or oil seal. Noticeable blue smoke while running would indicate that excessive oil is getting by the rings into the combustion chamber.

Typical oil capacity is just over 1/2 quart (usually about 1-1/4 pints).

About engine oil

For the common 4 stroke engines such as Briggs & Stratton or Tecumseh, you don't need to buy specially high priced engine oil. The type likely used in your automobile will work fine and will be much less expensive. Although small engine manufacturers may recommend SAE 30 oil, they usually also state that 10W-30 or 10W-40 are acceptable substitutes - and these are what your car probably uses. New oil should have at least the SG rating though if you have some SF in your garage, that will be fine also (for your lawn mower, not your car!). However, there are situations like equipment that must run in extremely cold weather (probably not a problem with grass mowing!) where specific alternative oil recommendations should be followed.

The capacity of a typical small engine is just over a 1/2 quart. This will probably cost you about 50 cents - a very worthwhile investment!

However, some people do swear by synthetic oil. I remember it worked pretty well on my bicycle as well :-):

(From: Daniel Pope (dpope@l-a-net.net).)

Synthetic Motor Oil in the crankcase and Marvel oil in the gas is the only way to go!

I have a $1,900 MTD tractor style mower with B&S engine (L head twin). It has over 800 hours and 9 years on it and I mean rough hours (bahaya grass and hot weather). The engine does not use a drop of oil (changed every 30 hours) and the compression is the same as when new. These other guys can have there $5,000 fancy mowers. I'll use that money to buy a truck.

Oil change

If you don't do anything else to prolong the life and happiness of your small engines (and your automobile, for that matter) it should be an oil change at the recommended interval. Oil loses its lubrication and cooling effectiveness with use and this will gradually take its toll on your precision engine parts. Even a simple lawn mower engine is machined to very precise tolerances and any contamination will increase wear. Ultimately, its performance - starting and running - will suffer and its life will be shortened.

Since there is typically no oil filter, all the grit, metal particles, and other undesirable stuff continues to circulate with the oil to find its way in between precision engine parts.

For small engines, the oil change interval is usually specified to be about 25 hours of use. More frequent oil changes may be desirable if the equipment is operated in an extremely dusty environment.

A typical mowing season for a modest size lot is around this amount of time so an oil change once a season is probably satisfactory. I recommend this be done at the end of the season so that the old contaminated oil does not sit in the crankcase during the winter months and you will not (conveniently) forget to do this at the beginning of next season when you are eager to get at that straggly lawn.

An oil change isn't really a big deal

The oil change procedure is a lot simpler than for an automobile as everything is readily accessible and there is no oil filter to worry about.

- You will need a funnel, low wide container or drain pan for the used oil, and a container like a plastic milk jug for temporary storage of the used oil for disposal.

- Spread adequate newspaper on the ground to collect any drippings.

- Run the mower for about 2 to 3 minutes to allow the oil to circulate and warm up so that it is less viscous and will flow more easily. Stop the mower and remove the spark plug wire.

- If the fuel tank is less than about 1/3 full, then you will probably not have any problems, otherwise you will have to drain some gas or remove the fuel tank so that gas does not spill out of the breather hole in the cap.

- If there is an oil drain plug, you can use this to drain the oil. However, it is usually more convenient to just turn the mower on its side, carburetor side up. This is usually acceptable for the short time that will be involved. Immediately check for any oil leakage - if there is any, we will need to avoid tipping the mower as much - look for the drain plug.

- Wipe around the oil filler cap with a clean cloth or paper towel to remove the dirt and grime that has likely collected there. The oil filler will either be on or near the bottom of the engine or at the top of the shroud (Eager 1 type). If it is not right at the bottom, there will be a dipstick attached to it.

- Place your wide mouthed drain pan under the oil filler cap and remove the cap. The oil will flow into your pan. Let it continue until the dripping stops - probably 10 minutes or so.

- Set the mower upright on a level surface. Wipe any drips on the engine and deck up with a clean rag or paper towel.

- Use the recommended oil for your engine. SAE30 is usually specified by the engine manufacturer but they will usually state that 10W-30 or 10W-40 (SG rating) are acceptable substitutes. These 'multi-weight' oils are widely available and inexpensive. Typical small engine oil capacity is just over 1/2 quart. Start low and incrementally add oil until just below full on the dipstick or at the top of the oil fill hole if there is no dipstick. DO NOT overfill. Give it time for the relatively viscous oil to find its way into the crankcase. Tipping the mower back and forth a bit will help this process.

- Replace the filler cap. Wipe up any additional drips.

- Replace the spark plug wire. Then, start and run the engine for a couple of minutes. Wait a few minutes, then recheck the level. Top it off if needed.

- Transfer the used oil from your drain pan to the storage container and dispose of it in an environmentally safe manner.

Blade sharpening

The blade in a rotary lawn mower doesn't need to be sharp as a carving knife or scalpel but serious dents and nicks will result in a less than perfect lawn (to say the least!). In addition, a seriously unbalanced blade can result in excessive vibration and eventually, possible internal damage as well.

First, drain the gas or remove the gas tank. If you will be filing steel, you get sparks. Sparks are not the greatest thing to have around gasoline vapor. Enough said. Disconnect the spark plug wire and tie it safely away from the spark plug or remove the spark plug entirely. Turn the mower on its side.

CAUTION: Immediately check for oil leaks at the oil filler pipe or elsewhere. If there are any, you will need to work on the mower just propped up by 45 degrees or so. Or, use this as a good excuse to perform an oil change and drain the oil (even if the engine is cold, most of the oil will drain out but it will take a little longer). Just don't forget to refill the crankcase with fresh oil once you have completed work on the blade!

Check that the blade isn't bent. Locate a reference point on one side and note the height of the blade tip at that location. Rotate the blade 180 degrees and check the height of the opposite blade tip. There should be no significant difference - say no more than 1/8" or so. If it is greater, the blade is bent or the crankshaft is bent. Either will require further investigation as running the mower under such conditions will probably result in excessive vibration and can be dangerous.

Assuming this is fine, inspect the blade:

Slight nicks and dents can be cleaned up with a file while the blade is still installed on the mower. Unless you have run into a curb, this is probably all that is needed on an occasional basis. Removing this small amount of metal will also not unbalance the blade enough to worry about. Refer to the section: Non-violent blade removal if it needs to come off the mower.

If the damage is severe, consider replacing the blade entirely - they are not that expensive (usually under $10). Otherwise, you can use a file, a bench grinding wheel, or a grinding wheel mounted in an electric drill (there are special attachments for this specific application).

Since the rotating blade also contributes to the proper air flow, you do not want to upset the shape. Grind in such a way that the original blade angle is preserved. It doesn't need (or want) to be razor sharp. A 1/64" edge is fine. Anything finer will quickly be dulled by little bits of stone and dirt in any case. Safety is not the main concern here - if any part of your anatomy contacts the whirling blade, you **will** be in trouble no matter how dull or sharp the blade might be!

Attempt to remove approximately equal amounts of metal from both ends and in roughly similar areas if possible. If there are a few large nicks, it isn't necessary to remove them completely - your lawn (and neighbors) will never know the difference.

Check the balance by positioning the blade at the center hole location on a pencil or other rod - you don't need a fancy blade balancer but can use one if you like. If it tips one way or the other, remove more material from the heavy side a little at a time.

Replace the blade along with all its mounting hardware. Make sure you get all parts in the same relationship as they had originally. The blade must have its sharpened edges pointing downward. Don't forget the install the key if it is separate and DO NOT substitute a hard steel key for the soft metal one that should be used. See the section: Why soft metal keys must be used. If the locking key or blade adapter key appear damaged in any way, replace it.

Non-violent blade removal

For just some minor touch up, there is no real need to remove the blade. For major grinding and balancing, removal will be needed. Removal will also be required to inspect for a damaged or sheared blade lock key and to replace it if necessary.

In either case: disconnect the spark plug wire and tie it safely away from the spark plug terminal (several inches minimum) or remove the spark plug entirely to prevent accidental starting.

If the nut holding the blade on is just on very tight, use a block of wood to prevent the blade from turning. Use a good quality socket wrench or box-end wrench of the correct size - an adjustable or even open-end wrench may not be enough. The nut usually unscrews counter-clockwise. However, check this out first! A careful inspection of the threads on the end of the crankshaft will reveal the direction. Or, determine the direction of rotation which will be designed to tighten, not loosen the blade. Most, if not all, single blade mowers rotate the blades clockwise as viewed from above which will therefore use a normal right-hand thread nut.

CAUTION: Make sure that if the wrench slips, your flesh will not contact the blade or other sharp sheet metal - liberal use of rags or newspapers is a good idea. Arrange your position and the mower so you are pulling towards you - this is a more stable controllable arrangement.

(From: Graduate student of school of hard knocks.)

> "I'd wish I'd read this a few years ago. I used an open-end wrench and it 'flexed' off of the bolt. Needless to say, my next week wasn't a lot of fun with 10 stitches in my hand."

Use some penetrating oil (e.g., liquid wrench or WD40) on the nut and threads if there are signs of rust or corrosion. Allow it to soak in for a few minutes before attempting to remove the nut.

You will prevail. A hammer or other more violent approaches should not be needed.

Once the nut is loose, unscrew it the rest of the way by hand and remove any washers or mounting plate and note their exact position and orientation. The blade and adapter should come off easily. Some penetrating oil (e.g., WD40) may help if it is difficult to remove.

If your adapter/blade doesn't pop off after removing the nut or bolt, it may be mounted using a taper like the flywheel. This is somewhat unusual on a walk-behind lawn mower but might be present on a larger machine like a lawn tractor. A wheel puller is best for dealing with this situation but first see if it isn't just gummed up or rusted in position - try the WD40.

Inspect the key or locking tab for damage. You may have:

- A rectangular blade adapter with a welded-on soft metal ring with a tab protruding into a slot in the crankshaft.
- A blade adapter that locks to the crankshaft with a rectangular or D-shaped (Woodruff) soft metal key.

If the adapter's tab is broken off or the key is sheared or damaged, then replacement of the entire blade adapter or just the key (depending on your mower's design) will be needed upon reassembly. For now, if you will be sharpening the blade, replace all the hardware in the correct positions (except the blade) and finger tighten the nut so you won't lose anything.

WARNING: Do not install a hard steel key in place of the recommended blade lock key as you will lose the protection that the soft metal provides and the next incident may be the last... See the section:Why soft metal keys must be used.

Once you have reground the blade or obtained a replacement, reassemble in reverse order and then tighten the nut to the proper torque.

(From: Gib Gahan (gahan@esinet.net).)

Another way to remove a stubborn blade is to take it to your friendly garage or tire changer and have them put an impact wrench on it. Saves knuckles, tempers, etc. Just don't put the blade back on without a touch of oil or anti-seize compound and of course, don't use an impact wrench!

Carburetor adjustments

If your engine is relatively new (made within the last 10 years or so) and has only one speed, then there may be no adjustments (like the one discussed in the section: [Cleaning Craftsman (Tecumseh) carburetors](). It will either work or it won't - in which case it needs cleaning or parts replaced. Or your overhaul was less than 100% effective. You can tell if your carburetor is of this type as there will be no adjusting screws on the carburetor. For Craftsman types, there will be a solid hex nut on the bottom holding the float bowl in place. There may or may not be a primer button.

For adjustable types, it is best to refer to your engine manual. However, here is the general procedure. Some of the specific numbers may differ for your engine, however.

In all cases, before touching any adjustments, make sure your air filter is in place, and clean (or new). Fill the fuel tank about half full with fresh gasoline.

There are three adjustments on a typical carburetor:

- Main mixture - Bottom of Craftsman (Tecumseh) float carburetors.
- Idle mixture - Side into body of Craftsman (Tecumseh) float carburetors.
- Idle speed - Sets relaxed position of throttle plate.

Initially, carefully and gently turn the two mixture controls in until they just seat.

Note: "In" means clockwise (the way you would tighten a normal screw) and "out" means counterclockwise (the way you would loosen a normal screw).

CAUTION: do not force them - you are not trying to tighten anything - as you will damage the needles and seats which will require replacement of the needles or entire carburetor. Then back them out 1 to 1-1/2 turns. Set the idle speed screw 1 to 2 turns beyond where it contacts the throttle plate. Refer to your engine manual for specific recommendations! These settings should allow the engine to start and run, though perhaps not entirely smoothly or with great enthusiasm.

- Start the engine and allow it to reach normal operating temperature - a couple of minutes. Make sure any choke is off once it is started and running stably. This will also flush any old deteriorated gasoline from the carburetor!

- With the engine throttle control set for the maximum recommended rpm, very slowly rotate the main mixture screw counterclockwise (loosen) until the speed begins to drop off due to too rich a mixture. Then, rotate the screw very slowly clockwise (tighten) until the engine begins to cut out. Very slowly means a fraction of a turn at a time - then wait a few seconds for the adjustment to have an effect. Note the number of turns between these two positions and set the screw in the middle of this range.

- Repeat this procedure with the engine throttle control set to the idle or slow speed position but using the idle mixture screw instead.

- If there is a high speed adjustment - possibly on the throttle control itself or the throttle control bracket, it is best to set it using a tachometer. However, it is possible to do a very good job by comparing the speed by ear to an identical type engine that is set correctly. See the section: [Setting engine speed]().

  WARNING: if in doubt, set it low. It is better to end up with a scraggly lawn than bodily injury or a blown engine! Note that by ear, 2 stroke will always sound faster than 4 stroke engines for the same output speed because they have twice as many explosions per rotation of the crankshaft!

- Set the idle speed adjustment just high enough that the engine idles smoothly and isn't about to cut out. A tachometer can be used to set it to specifications but there is no risk is just adjusting it to idle smoothly.

- Test the engine under load. It should respond to load pickup immediately. An engine that dies is set too lean. An engine that runs roughly when picking up load is set too rich. Make a small adjustment (i.e., 1/8th turn) and test again.

Notes on Briggs & Stratton tune-up

(This assumes foam type air filter that needs have a film of engine oil in it to trap dust.)

(From: (Willjim@gte.net).)

Once the air filter is saturated it must be wrung out. I typically place them in a paper towel and squeeze. Then possibly a second paper towel. No oil should be dripping out of the filter when gently squeezed. Chilten's B&S engine section says to simply squeeze the filter of excess oil - no mention of a paper towel, etc.

In adjusting the carburetor, Chilten says about 1-1/2 turns but 2 turns is my standard.

I get the engine running first - warm it up to general operating temp. No applied choke, air cleaner installed. Adjust the main jet if you can get it to run at rated speed - preferably under load (turn in to the lean studder, out to the rich studder then back in about 1/2 way between these extremes). Then adjust the idle, at idle - at no load - using the same operation as the main jet. You may then go back and repeat/refine the process a second time as the idle adjustment may affect the main a bit.

For the 92000 in particular (typical but refer to your specific engine model for exact specifications), from Chilten's second edition, "Repair & Tune-Up Guide for Small Engines" (successor to [2]):

- Plug type: 1.5"/2.0"
  - Champion CJ-8/J-8
  - Autolite A-7NX/A-71
  - A.C. CS-45/GC-46).

- Plug gap: 0.030"

- Point gap 0.020"

- Armature air gap:
  - 2-leg 0.006" - 0.010"
  - 3-leg 0.012" - 0.016"

Setting engine speed

Many inexpensive mowers don't even have a speed adjustment screw. Spring tension and the linkage to the governor set speed - period. Note that actual speed is rarely that critical for engine driven equipment as long as it is within safe limits. See the comments below on string trimmer speed settings. However, what options do you have where there is a need to set the precise engine speed?

- Use a tachometer designed for small engines. If you do a lot of small engine work, this may be a worthwhile investment. For most of us, it would gather dust.

- Use a tachometer designed for automotive engines. You may already have one of these if you do your own tune-ups. Sure, right, that went out of style about the same time as emissions controls! OK, maybe your father did his own tune-ups :-).

  Since an automobile engine spark plug fires on every other revolution of the crankshaft rather than every revolution as with most single cylinder 2 and 4 stroke engines, it will probably be necessary to multiply the reading by a factor of 2.

(Even though there is a power stroke every other revolution for the 4 stroke engine, the ignition system is usually active on every revolution. However, there are a few exceptions to this rule.)

- If you have electronic test equipment such as almost any oscilloscope or frequency counter, it is a simple matter to couple its input to the spark plug wire on its insulation (not to the plug itself!). Then, the speed is equal to the pulse rate for most single cylinder 2 stroke and 4 stroke engines.

- Compare it by ear to another engine of the same type (2 stroke or 4 stroke) that is correctly set (i.e., you didn't muck with it!). This is actually a remarkably accurate way of setting the speed.

For equipment where a shaft with a known speed ratio to the engine crankshaft is available (i.e., a power take-off or trimmer head), an optical stroboscope of one form or another may be used. You will just need to paint or tape some stripes on the rotating part to put under strobe illumination:

- A fluorescent lamp powered by a magnetic ballast (not an electronic ballast) flickers at 120 Hz (in the U.S., 100 Hz in countries with 50 Hz power) and may be all you need to accurately set speed.

For example, for something like a string trimmer which has a direct coupled hub, strobe disks with 2, and 3, and 4 radial lines will appear stationary under fluorescent illumination for 3,600, 2,400, and 1,800 RPM respectively.

There can be ambiguity but if you are already in the ball park, this sort of approach may be all you need.

- Use a stroboscope which is calibrated in RPM or Hz. You may be able to borrow one from a high school physics lab or Disco!

(From: Philippe Habib (phabib@netcom.com).)

Go to a hobby shop that sells radio controlled airplanes. Plunk down $30 or so and get an optical tach. Paint 2 strips on the (crankshaft) hub of your equipment to simulate a propeller, and you're done.

(From: J. Matthew Good (jmg14213@ix.netcom.com).)

You shouldn't need a tachometer on a trimmer. Two stroke engines in the size and power range of line trimmers can't overspeed as they don't have the power with a line head installed. Just set the carburetor up so that it 'two-fours' at wide open throttle and you should be all set. If it needed to be adjusted with a tachometer, it would have some kind of governor on it.

(From: Mowerman (mowerman2687@my-dejanews.com).)

B&S engines have a spring in the governor arrangement. You want to change tension on the spring to change the speed. (This is basically true of most other small engines as well but the details will differ.) The spring is attached to a metal tung in the linkage at front of motor, this is made of a tinny metal so you can easy bend this tung. To lower speed you want to lessen the tension on the spring. You can do this while the motor is running at top speed but it would be safer to do the bending while mower is not running. By pushing in tung you will lessen top speed gently as it doesn't take much to alter that speed. Often this tung gets knocked in while mowing around bushes or other protruding material and "hey presto" your engine is only idling. It is a design problem that briggs should be working on, however I love B&S engines with their simplicity and ease of maintenance.

Adjusting the carburetor on a 2 stroke engine

This is generic advice but probably a good place to start. It assumes that there are 2 adjusting screws - idle and high speed mixture.

(From: foxeye@www.compumise.com).

I would start with them both backed out from the closed position to 2 turns open, for starters. One should be idle mix and the other should be high speed. Crank the motor, get it warmed up. You may have to fiddle with the throttle and or choke until its warmed up. Then slowly turn in the low speed jet, until it starts to die, then back it out another 1/4 to 1/2 turn. Then hold the throttle wide open, and slowly turn in the high speed, until it really starts to smooth out and rev high, and start screaming, then back this out until it starts to run rough or slow down, and then turn it back in to midway between these two positions. Keep playing with the low speed needle until you get rapid immediate response from the throttle, and good idle with the idle adjustment. Then play with the high speed needle, but always back it out from the setting about 1/4 turn or so, from where it runs the smoothest. This setting of backing it out will allow more fuel when under a load, and keep your 2 cycle motor from running too lean. Put a load on it and just tweak the settings just a hair at a time. If you're in the ball park it won't take much adjustment either way to make a difference. Better on the rich side than lean side. Also make sure your oil / gas is mixed at the proper ratio. 99% of 2 cycle motors are adjusted the same, no mater what brand they are. Most will start and run with both screws open 2 turns initially. Just don't close the high speed off any more than necessary no matter how well it runs.

Troubleshooting Guide

Instant troubleshooting chart - most common problems and possible causes

The following chart lists a variety of common problems and nearly all possible causes. Diagnostic procedures will then be needed to determine which actually apply. The 'possible causes' are listed in *approximate* order of likelihood. Most of these problems are covered in more detail elsewhere in this document.

While this chart lists many problems, it is does not cover everything that can go wrong. However, it can be a starting point for guiding your thinking in the proper direction. Even if not listed here, your particular problem may still be dealt with elsewhere in this document.

(Portions of the following from: Chilten, Small Engine Repair 2-12 HP, (1).)

- Problem: Engine will not start or is hard to start.
  Possible causes:

  1. Fuel tank is empty or shutoff valve is closed, or fuel line or fuel tank cap vent is clogged.
  2. There is water in the fuel.
  3. Carburetor is overchoked.
  4. Carburetor is improperly adjusted or needs service.
  5. Ignition system or its wiring is defective or ignition switch is off.
  6. Deadman or other cutoff switch is open or defective.
  7. Spark plug is fouled, improperly gapped, or damaged.
  8. Engine compression is poor.
  9. Operator needs to read user manual. :)

- Problem: Engine starts easily but dies after a few seconds.
  Possible causes:

  1. Fuel tank is empty or shutoff valve is closed, or fuel line or fuel tank cap vent is clogged.
  2. Carburetor is overchoked.
  3. Carburetor is improperly adjusted or needs service.

- Problem: Engine misses under load.
  Possible causes:

  1. Spark plug is fouled, improperly gapped, or damaged.
  2. Breaker points are pitted or improperly gapped, breaker arm is sluggish, or condenser is bad.
  3. Carburetor needs adjustment or service.
  4. Fuel line, fuel filter, or fuel tank cap vent is clogged, or fuel shutoff valve partially closed.
  5. Valves not adjusted properly or valve springs weak.
  6. Exhaust ports blocked (2 stroke).

- Problem: Engine knocks.
  Possible causes:

  1. Magneto is not timed properly.
  2. Carburetor is set too lean.
  3. Engine has overheated.
  4. Carbon buildup in combustion chamber.
  5. Flywheel is loose.
  6. Connecting rod is loose or worn.
  7. Cylinder is excessively worn.

- Problem: Engine vibrates excessively.
  Possible causes:

  1. Engine is not mounted securely.
  2. Blade or other driven equipment is unbalanced.
  3. Crankshaft is bent.
  4. Counterbalance shaft is not timed correctly.

- Problem: Engine lacks power (possibly after warmup).
  Possible causes:

  1. Old gas, bad spark plug, very thick/dirty oil.
  2. Choke is partially closed.
  3. Carburetor needs adjustment or service.
  4. Ignition not timed correctly.
  5. Air filter is clogged.
  6. There is a lack of lubrication.
  7. Valves are not sealing properly.
  8. Piston rings are not sealing properly.
  9. Head loose or head gasket blown or damaged.
  10. Exhaust ports blocked (2 stroke).

- Problem: Engine operates erratically, surges, and runs unevenly.
  Possible causes:

  1. Fuel line or fuel tank cap vent is clogged.
  2. There is water in the fuel.
  3. Fuel pump is defective.
  4. Governor is not set properly, sticking, or binding.
  5. Carburetor needs adjustment or service.

- Problem: Engine overheats.
  Possible causes:

  1. Magneto is not timed properly.
  2. Carburetor set too lean.
  3. Air intake or cooling fins are clogged.
  4. Shroud or blower housing missing.
  5. Excessive load.
  6. Insufficient or excessive oil.
  7. Improper oil viscosity (4 stroke) or mixture (2 stroke)
  8. Valve clearance is too small.
  9. Excessive carbon buildup in combustion chamber.

- Problem: Crankcase breather passing oil.
  Possible causes:

  1. Too much oil in crankcase.
  2. Engine speed is excessive.
  3. Oil fill cap or gasket is damaged or missing.
  4. Breather mechanism is dirty or defective.
  5. Piston ring gaps are aligned.
  6. Piston rings are worn.

- Problem: Engine backfires.
  Possible causes:

  1. Carburetor set too lean.
  2. Magneto is not timed correctly.
  3. Valves are sticking.

Lawn mower will not start

This is probably the most common problem you are likely to encounter. The cause is very often the same - lack of maintenance.

Note that the assumption here is that it cranks - the crankshaft and blade rotates in a normal manner but the engine never catches. Some larger (Briggs and Stratton) engines may have a low-oil cutoff switch which will stop the engine if the oil level is inadequate. However, this is not likely on a push mower.

- In the case of a recoil starter, you are able to pull on the cord and the crankshaft with the blade rotates and it feels normal but the engine does not start. If it feels like nothing is engaging, then the starter mechanism or clutch may be broken. Of course, if the cord breaks, then the problem is obvious! See the section: Recoil (pull) starter repair for more information.

- In the case of an electric starter, the engine cranks but never catches. If there is no response to the button or key, then the outlet may not be live, the battery may be weak or dead, or there could be a bad connection or bad starter motor. If the motor spins but doesn't engage the engine, the overrunning clutch or gear could be broken.

If you are unable to pull the cord (or the auxiliary starter on one with electric start), there may be a clump of grass stuck between the blade and the deck or there could be serious internal damage, especially if you just encountered an immovable object. See the section: Lawn mower will not start after the blade hit an obstruction. However, you didn't forget to engage the dead-man bar, did you? On most inexpensive mowers this safety interlock is needed to both enable the ignition system and release the blade brake.

Lawn mower is hard to start

Most of the time, the possible causes and solutions will be similar to those where the engine doesn't start at all. So, see the following sections for more information. However, here are some specific issues dealing with engines that do start eventually and then run fine:

- **Cockpit error:** If you have a user manual, read it! The starting procedure for all engines is not the same. Make sure you are following the recommended starting procedure. This may not always be best but it is a starting point (no pun....).

- **Number of priming cycles:** The instructions on priming are often optimistic. In colder weather, twice as many presses of the primer may be necessary. However, overpriming and flooding is also possible. Don't overdo it.

- **Condition of gasoline:** Old or contaminated gas will make any engine harder to start. If the problem is with an engine using last year's gas, drain the old gas and add fresh gas (not from the batch sitting in the can since last year!).

- **First start of the season:** If no maintenance was done at the end of the last mowing (or whatever) season, the first time the engine is started may be tough. However, this may be a one-time problem. Hopefully, maybe. :) Even if all the recommended maintenance was done, the first start may not be perfect. And, for float-type carburetors, after filling the fuel tank, wait a minute or so for the gasoline to fill the float bowl before pulling the cord!

Determining why it won't start

Think: *FAST* - Fuel, Air, Spark, Timing. Diagnosing a balky engine is not difficult but a step-by-step methodical procedure will make it a lot less traumatic. Despite all the warnings, serious problems rarely develop on their own. Most likely, there is a simple, easily remedied cause.

Fuel

Obviously, the engine won't run without gas!

- Is there some in the fuel tank? If it is near the bottom, add enough so that there is no doubt about there being enough to reach the outlet pipe regardless of any slant on which the lawn mower is located.

- Make sure any shutoff valve is open.

- Check for a clogged fuel filter, if there is one. There may be a sediment catching screen at the bottom of the tank as well.

- If your engine uses a primer bulb, does it feel like it is doing something? There is a distinctly different feel when it is actually squirting a little gas into the intake pipe. Check that the rubber hasn't deteriorated but if many pushes still doesn't do anything (and you're sure there is gas in the tank and the engine hasn't flooded from TOO MUCH gas), the carburetor and/or fuel line may need cleaning.

- If you are using gas from last season, discard it and start fresh. While old gas will usually work in an engine in good condition, this is not always the case, especially with one that has seen better days. The more volatile fractions evaporate leaving behind higher flash point gas. Why add another unknown factor to the puzzle?

- There may be water in the gas. If the carburetor has a drain plug, operate it to rid it of the bottom layer which would have the water. If there is no drain, repeated pulling on the starter cord should eventually clear any reasonable amount of water.

Once you have exhausted these obvious problems, determine if gas is reaching the cylinder as follows: Perform the normal starting sequence and then, assuming it shows no signs of wanting to start, immediately remove the spark plug. If fuel is reaching the cylinder, the spark plug should be damp with gas and there should be a very distinct odor of gas from the spark plug hole. If there is none, then there could still be a blockage in the fuel line or the carburetor may need cleaning.

A flooded engine, most likely due to extended unsuccessful attempts at starting or a defective carburetor (float valve stuck open or gas-logged float) will result in inability to start as well and a distinct odor of gas. You might find raw gas coming our of various orifices - air filter as well as exhaust. (Note that in severe cases, enough gas gets mixed in with the oil to significantly increase the level in the crankcase and reduce the effectiveness of the oil. This will require an oil change.

Air

The optimal air:fuel ratio is around 14:1. This must be lower for a cold engine and thus a choke plate or other means to increase the richness of the mixture is usually provided. A choke plate restricts air intake forcing more gas to be sucked into the cylinder. A primer bulb effectively squirts gas into the intake pipe to augment the normal carburetor action. Some carburetors have no choke and no primer but incorporate a small gas reservoir which fills when the engine is off and provides some extra when starting.

To much air results in a mixture that is too lean, burns too quickly, and can result in engine damage over extended periods of operation.

- Check that any choke is not stuck in the open position and not doing its job.
- The carburetor may need adjustment or cleaning.

Too little air results in a mixture that is too rich - there will be loss of power and possibly black smoke from the exhaust. This could be due to several factors:

- Check the air filter. For testing, it can usually be removed to see if the engine will start. However, do not run it for an extended period of time without a properly functioning air filter in place. Some are designed to be washed and reused while others must have their elements replaced.
- Check that any choke is not stuck closed. Though needed to start cold, if the choke remains closed, the engine will not restart and will quickly stop (truly choke!) due to an overly rich mixture.
- A defective carburetor may also cause the mixture to be too rich or too lean.

Spark

All common lawn mower engines require a precisely timed spark to ignite the air-fuel mixture in the cylinder. The existence of a spark can easily be tested as follows:

WARNING: make sure there is no gas in the vicinity when performing the following test!

Remove the spark plug wire and insert the blade tip of an appropriately sized and well insulated (plastic) screwdriver inside the boot or clip in place of the spark plug. While holding the *insulated* part of the screwdriver, position the metal part of the blade about 1/8th inch from the block or frame.

An alternative technique is to use an old, but good, spark plug whose gap has been increased to about 1/8 inch or one specially made for exactly this purpose. In this case, simply connect the spark plug wire to the test plug and hold its threaded part against the cylinder head or other part of the chassis (away from the gas tank!!).

Note: Just positioning the spark plug wire a short distance from the spark plug terminal is not recommended as the results of this test will then depend on the condition of the spark plug as well since the spark will have to jump two gaps.

Have a buddy crank the engine at normal starting speed so that you will be able to hold the screwdriver or test plug steady and be close enough to see any spark clearly. Shield the gap from the sun or bright light if necessary.

You should see a nice healthy spark jump the gap several times on each pull (actually, once per rotation of the crankshaft/blade on both 2 and 4 stroke engines). Note: 4 stroke engines ignite the air-fuel mixture on every other rotation of the crankshaft. The extra sparks fire harmlessly into the exhaust gasses and are wasted. Can you believe it?!

CAUTION: if you are not well enough insulated, *you* will jump several times per rotation of the crankshaft/blade if the ignition system is functioning properly! Hey, that *is* a valid test!

If this test confirms the spark, it is still possible that the spark plug is fouled or bad. See the section: Checking the spark plug.

If there is no spark, then there is a problem with your ignition system.

Lack of spark

If your mower is less than 15 years old, there is an excellent chance that if uses an electronic ignition system. These are very reliable as there are no points or condenser to go bad and no need for routine tune-ups.

However, a number of other problems can result in lack of spark:

Make sure stop switch/stop wire is in appropriate position - confirm with a multimeter, check that flywheel is being spun by starter and that flywheel key is intact to assure proper timing, check condition of points/condenser and setting (if applicable), test magnet (on flywheel) for strength, check the gap between flywheel and magneto core. If these are all fine, test or replace the magneto.

In more detail:

1. Check for a faulty or misadjusted STOP switch. This may be activated by releasing the dead-man bar or by a throttle control lever (STOP, RUN, START). Inspect the cable, linkage, and wiring for damage or for something that may have come loose. Make sure you have the controls set properly to run!

2. Check that your starter is actually spinning the flywheel. If the flywheel is not rotating properly when you pull the cord or turn the electric start key, then there is a problem with the starter, not the ignition system. Or, the flywheel is not tight due to a sheared flywheel key or improperly torqued flywheel nut.

3. Check for a flywheel that is loose and not seating properly on the taper. This could result in no spark if the air gap between the flywheel magnet and magneto core is then incorrect. However, due to the close spacing, you would probably feel and hear serious scraping in this case.

Items (2) and (3) are likely if your just attempted to move a curb with your mower blade (or if someone inadequately tightened the flywheel nut during some previous maintenance).

4. Check for bad connections or defective wiring including faulty or water logged insulation. If you just gave the mower a shower, wait ample time for it to dry out. High humidity may result in more problems if the insulation is not in good condition as well.

5. Check for a weak (or missing) flywheel magnet. Both of these faults are extremely unlikely unless you have been hammering and whacking the crankshaft and flywheel in an effort to remove the flywheel. (This is not recommended - see the section: Flywheel removal.)

6. (a) Electronic ignition - There is likely a single potted module which includes the circuitry and ignition coil. If anything goes wrong with this module, replacement is the only option. Once the wiring and resistance of the secondary has been checked, there are really no addition tests that can be performed on an electronic ignition module without special equipment. A defective ignition module will have to be replaced.

6. (b) Breaker point ignition - Possibilities are bad, dirty, corroded, or loose points or points that are grossly out of adjustment, a bad condenser, or a bad magneto coil. See the section: Maintenance of point-type ignition systems.

See the section: Testing the magneto.

First, check that the dead-man bar is properly disengaging the stop switch when pulled and/or throttle control is properly disengaging the stop switch when in the start or run position.

For anything beyond this, disassembly will be needed to identify and replace any defective parts.

If the no-spark condition happened after the blade hit an obstruction, (1) or (2) are likely. See the section: Lawn mower will not start after the blade hit an obstruction.

Checking the spark plug

Use the proper socket to remove the spark plug and inspect it for damage and general appearance:

- Light gray or brown and smooth - this is the normal appearance. The mixture is correct and there likely no major problems with the engine.
- Excessive black carbon - the mixture may be too rich or the spark plug may be the wrong type for your engine.
- Damage to the electrodes - the mixture may be too lean, timing may be set incorrectly, or the spark plug may be the wrong type for your engine.

The best thing to do at this point is just replace it with a new spark plug and worry about the old one later. Actually, nearly every small engine maintenance book will recommend changing the spark plug every season anyhow.

Testing the magneto

The magneto, like the ignition coil on an automobile, contains two windings:

- A primary with a few turns of heavy wire.
- A high voltage secondary with thousands of turns of super fine wire.

In an automobile, the battery supplies the primary current; in a magneto, the magnet on the flywheel moving past the core at high speed acts as a generator and induces current in the primary.

As the magnets spin past the pole pieces of the magneto core, the points are closed and current builds up in the low voltage winding (and flux builds up in the core). At or slightly before Top Dead Center (TDC), the current (and flux) should be maximum and at this instant the points open. The flux then collapses (and the condenser (capacitor) across the points acts as a snubber allowing the current to bypass the open points and preventing arcing at the point contacts). This rapid decrease in flux results in coupling of the stored energy to the turn high voltage winding and results in up to 10,000 V or more at the spark plug.

(For EE types, this is somewhat similar in basic operation to the flyback converter in a switchmode power supply except that the moving magnet supplies the input power instead of the rectified AC line and the points act as the switch instead of a power transistor.)

The secondary will always be accessible for testing but the primary of an electronic ignition may be not be due to the electronic components:

- Secondary: 3 K ohms (maybe a little higher but not open). Much lower would indicate a shorted winding.

- Primary (if non-electronic and accessible): very low - guessing less than an ohm.

Wires can break due to corrosion or vibration. This would result in an open winding - infinite resistance. Shorts can develop between adjacent windings or to the core. This may be detectable as reduced resistance but without knowing exactly what it should be, there is no way of knowing if a slight discrepancy represents a problem or just slight variations in design or manufacturing.

A more complete test would involve checking the 'Q' or doing what is called a 'ring' test and even more for an electronic ignition. This requires special equipment. Therefore, it is best to swap in a known good unit. They are not that expensive.

Timing

For power to be developed, the ignition of the compressed air/fuel mixture must take place at exactly the correct instant - just before the piston reaches Top Dead Center (TDC) on the compression stroke. With automotive engines, there are mechanisms to advance the spark at higher revs but simple lawn mower engines do not have this complication, at least.

Timing is set on older mowers with point type ignition systems by adjusting the point gap and generally only changes due to wear. However, these changes are gradual and unless the points come loose for some reason, will not likely suddenly prevent the mower from starting. On newer electronic ignition systems, there is basically no adjustment as the position of the electronic ignition coil/module fully determines ignition timing and this is fixed.

However, timing can be grossly messed up if the flywheel key gets sheared and the flywheel then rotates a fraction of a turn on its mount on the crankshaft. The result may be a mower that does not start, backfires or runs erratically, lacks power, won't run and/or start when hot, etc. This is very likely to happen should the blade strike a rigid object causing the mower to stop instantly. In this case one or both of the blade lock key and flywheel key have sheared to (hopefully) protect the very expensive internal parts from damage.

There are likely not going to be any timing marks for that old timing light you have sitting gathering dust somewhere. The only test really is to inspect the flywheel keyway to determine if damage has occurred.

See the section: Lawn mower will not start after the blade hit an obstruction as this is the most likely cause of a sheared flywheel key.

Lawn mower will not start after the blade hit an obstruction

The following description applies to most small rotary lawn mowers with direct driven blades. The vast majority of these use either Tecumseh (as found a variety of Sears/Craftsman equipment) or Briggs & Stratton engines. However, similar comments apply to others as well including Lawnboy two stroke engines and the more modern Honda and other overhead valve type of engines.

The assumption is that the engine started and ran normally prior to the incident. Now, no matter how many times you yank the starter rope or run the electric starter, it will not start at all, bucks, kicks back, backfires, or fails to develop enough power to keep going on its own.

If the blade struck a solid boulder while the engine was set on 'high', more severe damage is possible as even with soft metal keys locking the blade and flywheel to the crankshaft, the inertia of the rotating blade is acting sideways against the crankshaft in addition to suddenly stopping its rotation. This can result in a bent crankshaft. The end of the crankshaft with the blade adapter could be bent without affecting the bearings or internal parts. This would need to be tested for as well. Not that such an occurrence is that much better - the crankshaft would still have to be replaced but at least the bearings in the crankcase will not be damaged.

If the starter will not turn the crankshaft (assuming you remembered in your haste to engage the safety bar) - it is seized or will only rotate part of a revolution before hitting against something solid inside - then you probably have serious internal damage that will require a complete strip down and replacement of some (expensive) parts. If it turns but much more tightly than you recall (assuming you do have the safety bar engaged!) then the crankshaft may be bent - again very expensive. Repair may not be worth it.

However, in most cases, what has happened is that either or both of the blade lock key and/or flywheel key have sheared to protect the crankshaft from serious (and terminal) damage.

If the blade lock key broke, the blade will no longer turn rigidly with the crankshaft and provide the inertia required by many small engines with undersized flywheels. In this case, the engine may try to start but die out with a few "putt-putts" or even kick back on the starter cord. (As a side note, attempting to use a lawn mower engine as a replacement on a piece of equipment that doesn't have something to substitute for the blade's inertia may not work for this reason.)

If the flywheel key broke, the ignition timing will likely be totally wrong and the result may be no ignition, backfiring, kickback, or weak or total loss of power.

To diagnose, proceed as follows:

First, pull off the spark plug wire and tie it securely away from the spark plug terminal (several inches minimum) or remove the spark plug entirely so that there is no chance of the engine accidentally starting. Even though it will not start now no matter what you do, the underlying problem could actually be a flooded carburetor or something else which may correct itself while you are working. Never take chances.

Drain the gas or remove the fuel tank. This will prevent gasoline from spilling out the gas cap vent hole or flooding the engine through the carburetor since you will need to tip the mower to get underneath.

Set the mower on its side (carburetor side up).

CAUTION: Immediately check for oil leaks at the oil filler pipe or elsewhere.

The mower can usually be set on its side for a few minutes without harm but if these occur - you will have to work with it tipped less than 45 degrees or so - propped on wood blocks. Or, use this as a good excuse to perform an oil change and drain the oil (even if the engine is cold, most of the oil will drain out - it will just take a little longer). Just don't forget to refill the crankcase with fresh oil once you have completed your work!

Using an old rag and/or proper work gloves, grasp the blade and attempt to rotate the blade and crankshaft.

CAUTION, despite your lack of maintenance, the blade may be sharp!).

The blade and crankshaft should rotate together. If there is slippage, the key has broken and will require replacement of just the key or the entire blade adapter plate depending on design. If it appears to be intact, then you can assume the flywheel key has broken. The blade key may be broken as well but it is not likely the reason for your failure to start. You should remove the blade to determine this for sure before restoring the mower to service in any case. See the section: Non-violent blade removal.

You can possibly avoid removing the flywheel for inspection of the key by unscrewing the sparkplug, rotating the crankshaft so the piston is at TDC, and noting the location of the magnet on the flywheel relative to the magneto coil pole pieces. The magnet should be pretty close to the magneto in that position. If this is not the case or just to be sure, the flywheel will have to come off to inspect and possibly replace the key.

To get at the flywheel key itself, some disassembly is required.

Flywheel removal

Remove the shroud (blower cover) if you have not done so already. This is usually fastened with 4 screws and hopefully does not involve any head bolts - if so, you will need to tighten them to the proper torque using a torque wrench once you have remedied the problem. You may need to remove the fuel tank (if you have not done this already) and other trim pieces as well.

You should now see the top of the flywheel. In most cases, a large nut fastens the flywheel to the crankshaft. (However, in some designs, part of the starter mechanism is actually used and this is supposed to require a special wrench to remove. However, using a piece of wood as a buffer and tapping the ears in a counterclockwise direction will work also. Refer to your engine manual for details.) Use the proper socket to loosen this nut (counterclockwise). It may be necessary to brace the flywheel securely to gain enough leverage. Make sure this is done against something that can stand the force. Once loose, remove it by hand and then remove any washers or other parts that are under it. Make a note of how these were positioned including which side is up on some cupped washers.

You should now see the keyway. The slots on the crankshaft and flywheel should be aligned. There are two common types of keys:

- A rectangular or D shaped piece of soft metal that locks the flywheel and shaft. You should be able to see if the two identically sized slots are still aligned.

- A piece of soft metal with an L-shaped cross section. The slot on the crankshaft is narrower than the slot on the flywheel and is slightly offset (thus, the L). Again, it should be obvious if the two slots are still aligned.

You may even find that the flywheel is relatively loose on the crankshaft if rotating the blade while holding the flywheel stationary is possible. Either the blade key or the flywheel key or both are broken in this case.

You will have to remove the flywheel to replace the key if it is broken or damaged.

If the flywheel is loose at this point, then the following will not be needed as it can be lifted off.

There are several approaches to flywheel removal:

- The best way by far is to use a special puller designed for your particular engine. Briggs & Stratton and Tecumseh flywheels usually have 2 or 3 holes placed around the center of the flywheel which are used with special puller blocks. These have self tapping bolts which you thread into the holes and then tighten down nuts to pop the flywheel off of the crankshaft. I have made my own blocks for this purpose from scrap steel. If you have a drill press, it is not difficult. Alternatively, you can purchase these from the engine manufacturer. The use of a puller really does reduce the use of 4 letter expletives and virtually eliminates the chance of damage to the flywheel or crankshaft by the alternative techniques.

```
         ___              ___
        |___|            |___|<-------- Self tapping bolts or pretap holes.
         | |              | |
        _|-|_            _|-|_
       | |-| |          | |-| |<------- Tighten nuts to release flywheel.
    ___|_|-|_|__________|_|-|_|___
   |      |-|              |-|     |<--- Plate or block - 1/4" or thicker steel
   |_____|-|______________|-|_____|
         |-|  .-.----.-.  |-|
         |-|  | :----: |<-|-|---------- Flywheel nut - loosen slightly.
         |-|  |_:----:_|  |-|
   ______|-|___ :----: ___|-|______
   //////:-:///|:----:|///:-://////
   //////:-:///|:----:|///:-:////// <-- Flywheel comes with predrilled holes.
   //////'-'///|:----:|///'-'//////     (taper not shown - ASCII limitations!)
   //////| |///|:----:|///| |//////
```

Bolts are screwed into holes in flywheel. Then, plate bears against the flywheel nut (slightly loosened) and the nuts are tightened alternately until the flywheel pops off.

WARNING: do not use an ordinary gear, clutch, pulley, bearing, or other puller unless this is specifically mentioned as a recommended technique in your engine manual. The flywheel could be damaged - possibly not immediately obvious - but the result could be catastrophic failure once the engine is put back into service.

- A 'knock-off tool' is a special closed-end nut that you thread onto the crankshaft in place of the normal flywheel nut. You then are supposed to pry under the flywheel with a pair of large screwdrivers while tapping the knock-off tool with a soft hammer. Aside from the fact that as described, this requires 3 hands, this may or may not work easily. Depending on conditions, the flywheel may pop off at the first tap or may stubbornly refuse to budge no matter how much you whack. If not done properly, it is possible to bend the crankshaft - very expensive. Some people also worry that the shock will damage internal parts or even partially demagnetize the magnet on the flywheel. Thus, my preference for the puller unless the first couple of taps releases the flywheel.

- Many engine books will simply recommend threading the flywheel nut back on flush with the end of the shaft and tapping this with a hammer as above (with the 3 hands). The risk here is that the threads may be damaged in addition to the possibility of bending the shaft or causing other damage. Use a piece of soft metal - aluminum, brass, or lead - to protect the end of the shaft and nut. In any case, only use this approach as a last resort.

Flywheel removal on Briggs & Stratton engines

The following applies to most B&S engines with the square starter shaft. This procedure will be needed to gain access to the points and condenser (on engines without electronic ignition), oil seal, etc.

(From: Foxeye (foxeye@www.compumise.com).)

The square shaft which turns one direction but not the other is the recoil starter pawl. This can be pulled straight up from the round cup that it sits in. There should be a couple of steel balls inside. Some models have a large internal snap ring that holds this in the cup. Remove ring, and pull it straight up. Use a magnet to remove the steel balls. Once you have this starter pawl removed, and the steel balls, hold the flywheel, stationary, and using a block of wood, bump one of the lugs on the outside of the starter cup in a CCW direction.

Once you break it free of its torque, it should be able to be spun off CCW. Remove this starter cup, and the beveled bellville washer under it. Now your ready for your flywheel puller. A strap wrench can also be used to turn this starter cup loose. When installing the starter cup, make sure it is clean and free of grease and oils. A drop of oil or a light coating of grease on the crankshafts stub end (over which the starter pawl goes) is usually recommended. The starter cup only needs to be snugged down, and you don't have to go overboard trying to torque it to ungodly tightness. Snug is sufficient.

Drop in the starter pawl, into the cup over the stub of the crank, and drop in the steel balls, replace larger flat cover over this assy, and insert snap ring if there was one.

Flywheel inspection

Once the flywheel is off, inspect the keyway on the crankshaft and flywheel for damage. Serious damage will require replacement of the affected parts. Slight burrs can be removed with a small file. If there are any cracks in the flywheel radiating from the hole, the flywheel MUST be replaced as this is a serious safety risk - the flywheel could literally explode when run at full speed. However, don't be concerned by surface flash - lines that look like fine cracks resulting from the molding process. To confirm that these are not cracks, there will be no visible penetration inside the shaft hole and fine sanding will quickly remove all traces of this flash.

Assuming there is no serious damage, a new flywheel key should be all you need - about 25 or 30 cents. To confirm that this is all you need, replace the flywheel without the key but line up the two slots as they would be if a key were present. Tighten securely (but it doesn't need to be to the full torque as this is just a test). This should permit the mower to start and run normally but I would not recommend using the mower to actually cut grass until you replace the flywheel key.

To install the new one, insert the key into the slot in the flywheel first and then slip the entire affair onto the crankshaft (I like to use a bit of WD40 for protection as well). The flywheel should seat securely with no detectable free play - it should be on straight and not rock back and forth at all. If this is not the case, the key may be in upside-down or there may be something or some particles of dirt or metal blocking it. Replace the washers, dirt screen, etc., and then hand thread the flywheel nut as far as it will go. Tighten to the specified torque (typically, 30-33 ft-lbs).

Note: There may be a cupped washer between the nut/screen and flywheel. This must be installed cupped-side facing the flywheel or else you will be probably be replacing the flywheel key again very soon :-(.

WARNING: Do not install a hard steel key in place of the recommended flywheel key as you will lose the protection that the soft metal provides and the next incident may be the last... See the section: Why soft metal keys must be used.

Then, replace the shroud, fuel tank, etc. If head bolts had to be removed, it is probably a good idea to slightly loosen all of the head bolts and then retorque them to the proper value in the recommended sequence for your engine.

Why soft metal keys must be used

Normally, the soft metal keys lock the blade and flywheel to the crankshaft. However, should the blade strike an obstacle and stop suddenly, one or both key(s) will shear and reduce the likelihood that the very expensive crankshaft or other parts will be damaged. The reason is that the substantial inertia of the crankshaft and that of the flywheel will tend to try to keep them rotating. Something has to give and you want it to be the 25 cent key and not the $75 crankshaft! However, this isn't foolproof as explained in the section: Why you really don't want to attempt to move an immovable object.

Note that the soft metal flywheel key can also be damaged without totally shearing which may result in slightly incorrect timing. Symptoms may include a mower that is hard to start, runs rough or lacks power, or cannot be restarted when hot. Therefore, always replace the key if there are any signs of damage or wear.

Engine dies or won't restart when hot

(From: Wild Bill (kwag98@tcis.net).)

There can be numerous reasons for the engine to quit running when it gets up to operating temperature.. expansion of metal parts where bolts/screws aren't tight enough, breakdown of the condenser for the ignition points (if equipped), or a possibility of a crack somewhere. An overall inspection of the tightness of fasteners would be a good place to start.

- If the miss is a miss, the problem probably has to do with ignition or the fuel mixture. Check the tightness of the carburetor mounting bolts and where the intake manifold/air-fuel mix tube fastens to the engine block.

- If instead, the miss is popping through the exhaust, this might be caused by a bad exhaust valve or valve seat.

- If there is puffing or popping near the engine head, the head bolts might not be tight.

- If the engine spins over too freely when it's hot.. indicating much lower compression, check the torque of the head bolts.. if they were loose, the engine should now restart.

- If it won't restart until it's cooled down, the exhaust valve (and/or valve seat) may be the problem. If you can remove and disassemble the engine yourself, this isn't expensive to have corrected. If not, the shop labor for tear-down and reassembly will be fairly costly. A common reason for exhaust valve failure is that grass clippings become embedded in the cooling fins around the exhaust port area.

- If the engine is just failing to fire the spark plug when it's hot, there's a good chance that it's time to change the (points and) condenser. This can usually be confirmed by quickly removing the spark plug after it quits running, and grounding the sparkplug base securely to the engine (away from fuel vapors).. then spin the engine to see if there is a hot blue spark with an audible snap, snap noise.

(From: Walt Conner (jerrbear@midwest.net).)

As soon as the engine shuts down, turn the flywheel by hand or DISCONNECT the plug wire and turn the blade by hand to see if there is any compression. I have had several B&S engines that did not have enough valve clearance and when hot, the valve stem expands in length enough that the valve does not properly close. After cooling, engine will be OK. Also could be a bad condenser or the other faults listed above.

(From: Michael Stevenson (mike@gi4xsf.freeserve.co.uk).)

Problems with the ignition coil can make an engine impossible to start when warm (or even stop running when it warms up), apparently this happens on motorbike engines quite often and is caused by a break in the HT coil.

A carbon track forms inside the coil where the wire is broken. When the engine is cold the carbon track has a low resistance and it conducts well enough so the spark is strong enough to start the engine, when the engine is warmer the track resistance is greater and the spark less strong. This problem gets worse over time as the carbon track gets bigger and bigger, the only remedy is to change the coil or electronic ignition module.

Smoke signals

For the most part, smoking is just as bad for a small engine as it is for you. Excessive smoke from the engine may be an indication of problems with the carburetor, rings, or gasoline:

- Black smoke is a symptom of an overly rich fuel-air mixture. This could be caused by a choke that is partially closed, a faulty carburetor, or the need for a carburetor adjustment. Make sure the choke if fully open. See the sections on carburetor adjustment and carburetor cleaning.

- White or black smoke may also result from yard debris, oil, or other contaminants on the exterior of the cylinder as the temperature after a few minutes of operation will reach several hundred degrees F even with proper cooling. Stop the engine and let it cool for a few minutes. Then, check around the cylinder, cylinder head, and under the shroud for grass clippings, leaves, oil or other spills, dead rodents, etc.

- 2 stroke engines will always produce some fine white/blue smoke since the lubricating oil in the fuel mixture is being burnt along with the gasoline. However, excessive white/blue smoke could indicate an incorrect ratio of gasoline to oil or a mixture which has been sitting around for a while - the more volatile gasoline evaporates leaving behind the oil. It could also be an indication of contaminated fuel.

- 4 stroke engines should produce virtually no smoke while running. At first startup of the season, there may be a few seconds of white/blue smoke resulting from the oil squirted into the cylinder at the end of last season (you did the preventive maintenance, right?) burning off as well as white smoke/steam from accumulated moisture. If you tip the mower on its side routinely (to clean out grass clippings, for example), oil may seep into the cylinder resulting in white/blue smoke at startup as well.

  White or blue smoke while running may be an indication of an excessively worn cylinder or rings or a clogged or inoperative breather (the breather assures that there is always negative pressure in the crankcase - if not, oil can get forced up into the cylinder). Or, you may be using the fuel mixture for your 2 stroke weed whacker by mistake!

Lawn mower smoking after oil change

(From: Wild Bill (kwag98@tcis.net).)

I'm assuming that you were trying to use the drain plug at the bottom of the engine, not where the oil is added. Draining is done most effectively when the plug on the bottom is removed and the mower is placed level again, over a catch basin and left to sit.

Oil has gotten into the combustion chamber area. The muffler (if it now contains oil) can be washed (flushed out) in a safe solvent, and allowed to dry.

When tipping a vertical shaft engine to get to the drain plug, keep the sparkplug end of the engine higher than the rest of the engine.. and follow the safety precautions.

Tipping the crankcase end up will put oil at the combustion chamber end of the engine, and seep into the combustion chamber.. and sometimes through the crankcase passage into the carburetor area. In cases where a lot of oil gets into the combustion area.. the engine might not rotate (due to a hydraulic lock), until the oil has returned to the crankcase.

If this should happen.. allow the engine to sit for an hour or so, with the sparkplug end elevated, and most of the oil will return to the crankcase.

If the air/fuel intake area has become flooded with oil, you might need to have the engine serviced.. the carburetor might need to be removed to evacuate the oil from that area.

When the oil gets into the combustion area, the sparkplug is usually soaked.. and after cleaning or replacement, the engine will smoke (for a short time) like a fog machine. This will often foul the plug again, and create a lot of carbon in the combustion area. There isn't an effective way of removing the excess carbon aside from removing the cylinder head. For an old mower, that might not matter much.. for a new one that you'd like to get years of trouble-free service from, you might want to consider having the head removed and the oil & carbon cleaned out.

About squeals and other animal noises

While some may describe the engine of an antique automobile as 'purring', this will not likely apply to most gasoline powered lawn mowers. It would seem that noise reduction is just not a high priority design issue with lawn mower engineers or marketing types. However, even if not exactly quiet, the sound made by a healthy mower should not be similar to that of a pig being tortured.

- A screeching or squealing sound may be the result of worn bearings or inadequate lubrication. This could be due to lack of oil (!!) or a problem with the oil distribution system (pump, passages, slinger, etc.). It could also be a problem with auxiliary mechanical parts - power take-off, front wheel drive, or a starter clutch that fails to disengage.

- Banging or rattling noises may be due to parts that have worked loose due to vibration or by being inadequately tightened (by someone else, of course). The entire engine may be bouncing around on its mount. Or, the flywheel, blade, attachments, or chassis parts may be vibrating. Even if everything appears secure, there is quite a bit of energy associated with an engine running full throttle and parts can work loose.

- A low frequency shuddering or vibration may be due to debris under the deck. Check for wads of matted grass, twigs, branches, and 3 foot logs, caught in the baffles or exit chute. Sometimes, globs of this stuff fall off and get slung by the blades with all sorts of associated strange sounds.

A combination of the above are also possible. For example, a loose flywheel could result in it scraping against the magneto yielding a sound like a cat being squeezed to death (or that of a first year violin student) but possibly only at high revs :-).

Of course, a badly worn engine can also result in piston and rod slap and other mechanical noises as internal parts with excessive clearances whack one another. A complete engine overhaul may be in order or just tolerate it and plan for a new mower when the final day arrives (or your neighbors take up a collection).

Lawn mower fuel tank leaking

Fuel tanks can leak for a variety of reasons including defects in manufacturing, abuse, corrosion, etc. However, before you buy a new tank, a couple of notes:

1. If this is on an Briggs and Stratton engine there are known problems with some models - check with your local small engine repair shop as it may be under a (hidden) warranty.

2. A tank that is filled to the top may appear to be leaking when in fact it is just seepage from the cap vent hole. It may even attempt to fool you into replacing the tank by appearing to come from the seam!

If the tank is truly leaking, DON'T use the mower and drain the gas - you don't want to take chances with a possible engine fire or worse.

Lawn mower too loud

Small engines - especially those on cheaper mowers - are usually loud, no question about it. However, if yours sounds like it is about to explode or take off, there may be something actually wrong.

Obviously, if it is backfiring every other stroke, you have a problem with the ignition timing, mixture, valves, etc. What this section deals with is just the normal noise assuming the engine runs properly - and how to reduce it. Else, you need to perform the proper maintenance first.

- Make sure everything is tight - it may be the engine rattling against the deck or something simple like that.

- Your muffler could be worn out - probably rusted out. Inspect it and if in doubt, just replace. They only cost $3 or so.

Some lawn mowers discharge under the deck. This should reduce the noise level but the proper (probably spark arresting) muffler must be used or else you risk igniting dry grass or whatever as you mow!

- It may be possible to purchase an after-market quieter muffler - check with the suppliers listed in the section: Mower and engine parts sources.

Note that for a 2 stroke engine, the muffler is particularly critical for proper operation and substitution may be more difficult.

Lawn mower wheels

Wheels tend to get banged about and damaged or may just become loose and unstable due to wear. Wheels and wheel bolts are readily available at home centers (or Sears for Craftsman mowers).

- If really frozen, the use of penetrating oil like WD40 or Liquid Wrench should permit the old bolts to be removed using one or two wrenches (sockets preferred).
- In some cases, adding some metal washers on the axle may help to reduce wobble on a worn wheel which is too loose.
- The best type use ball bearings and will outlast the mower but I wouldn't expect to see this on anything less than the gold-plated model! However, ball bearing wheels can be installed as replacements.
- Use of WD40 can help to ease the pain of switching the cutting height of lever operated wheels.

Intermediate Level Maintenance and Repair

Cleaning Craftsman (Tecumseh) carburetors

Simple float carburetors are found on a variety of equipment including many engines made for Sears by Tecumseh. The basic procedures applies to the float carburetors of other manufacturers as well.

If you have been following the recommended preventive maintenance procedures, this may never be needed. But, face it, you do not! The most important PM that is not likely done by 90 percent of mower owners is to drain the gas at the end of the season. With float type carburetors in particular, the result is a buildup which eventually clogs the very fine passageways in the carburetor. What happens is that the gas in the carburetor bowl gradually evaporates leaving behind the gunk and varnish. New gas then flows in from the fuel tank which then evaporates leaving behind more gunk and varnish, and so on and so on and so on. This eventually, well, gums up the works by interfering with float movement and clogging the precision metering holes. Thus, the need for cleaning. Symptoms include difficulty in starting, flooding, surging, lack of power, difficulty in restarting when hot, etc.

The following procedures are specifically for the common non-adjustable carburetors used on the vast majority of Craftsman mowers manufactured in the last 10 years. Carburetors with adjustments and/or a choke are slightly more complex and may differ in other ways. Refer to a small engine repair book or your engine manual for further information.

Carburetor removal

- Drain the fuel, close the shutoff valve if any, or remove the gas tank. On the common Craftsman mowers, the tank either slips off or is fastened with a couple of screws. The gas line should pull right off. Inspect the fuel line for damage or cracking and replace it if these are severe.

- Remove the air filter, inspect, and set aside. The small plastic enclosed air filters twist off counterclockwise. If it is clogged and of the paper type, replacement will be needed. If it has a foam element, this can be reused if it doesn't fall apart. Remove the foam element, clean in soap or detergent and water, dry, and then coat it with a few drops of fresh engine oil. Work the foam with your fingers to distribute the oil. For other types, see your engine manual.

- Use a large philips screwdriver to loosen the two screws fastening the intake manifold to the cylinder block. If the gasket separates easily and cleanly, then it can be reused though a dab of non-hardening sealer is advisable once you have tested the mower to be sure that your newly restored carburetor is functioning properly. If it tears or is damaged in any way, then it should be replaced.

  If the bolts are really tight, an open end wrench may be of help but common sockets may not fit around the bottom bolt. Thin walled sockets may work.

- Disconnect the throttle linkage and governor spring noting which holes they go in. IMPORTANT: If you get this screwed up you could have a runaway situation on your hands when you go to restart it. This can destroy the engine in a few seconds!

- Disconnect the rubber tube from the primer bulb, if any. It should pull off. If it tears near the end, there is probably enough slack so that a new tube is not required.

- Disconnect the speed control and stop switch wire, if any. Note how they are installed.

The carburetor can now be moved to the convenience of your workbench.

WARNING: there is still likely a significant amount of gas inside the float bowl. Initial disassembly at least should be done outside so that you can dispose of this safely. Working outside is advisable in any case as the common carburetor cleaning solvents are both flammable and bad for your health.

Disassembly

Most carburetors on Craftsman mowers are variations on a common float design. Newer mowers tend to have no adjustments and no choke - which greatly simplifies cleaning and adjustment. With respect to adjustment, there is none - it either works or it doesn't. If it doesn't, your cleaning was not thorough enough, some parts need replacement, or the problem is not in the carburetor.

- Under the bowl is a large hex head bolt. On the non-adjustable carburetor, this is closed on the bottom. It is also not a simple bolt but includes the precision main fuel metering hole which will need to be cleaned thoroughly. Use a proper socket to unscrew this bolt (counterclockwise). Drain any residual gas from the bowl. CAUTION: I've heard of people breaking the bolt by either attempting to loosen it the wrong way or overtightening upon reassembly to stop leaks.

- There is a fiber washer under the bolt. There may also be a fiber washer on this nut inside the float bowl. Don't lose these or get them mixed up.

Turn the carburetor upside-down.

- Carefully remove the bowl and O-ring. Inspect these for damage. (Note: there is probably a dimple in the bottom of the bowl in the lower level side. This is normal and probably there to keep the float off of the bottom where gunk and varnish collect because you didn't drain the gas.)

- The float will now be visible. Rotate it to the fully up position. The inlet needle will come up with the hinged part of the float. It is held in place by a wire clip but will now be free. The inlet needle is actually a four sided metal rod with a polished conical tip. Remove the needle and clip.

- Use a pair of needlenose pliers to pull out the hinge pin which will free the float. Careful - the float is made of relatively thin brass and is susceptible to damage.

Check the throttle plate for free movement - there should be absolutely no hint of binding or tightness. If there is, then this will need to be disassembled as well and cleaned:

- Use an open-end wrench to loosen the intake pipe and then remove the nuts and bolts. The manifold will probably come free with the gasket intact. Don't lose the metal strip to which the governor spring attaches. Check for dirt and other debris and set aside.

- Use a 1/8" straight blade screwdriver to remove the screw in the center of the throttle plate. Note the position of the hole in the plate and the orientation of the plate. (The hole should be toward the engine side with the carburetor body upright. Mark it before removal if in doubt.)

- Tap the carburetor if needed to remove the throttle plate.

- Pull the throttle shaft out of the carburetor body. Take care not to lose the spring with the felt and/or metal washer. Note their positions.

Cleaning the carburetor parts

Use carburetor cleaner and lint free cloths or paper towels to remove all built up brown or green gunk, varnish, and other contamination from the metallic parts. Pay particular attention to the machined passages and metering holes.

WARNING: Carburetor cleaner is both flammable and the fumes are toxic. Do all cleaning away from open flames and outdoors if possible. Wear eye protection. The stuff will also eat plastics including some plastic eyeglass lenses.

Take care where non-metallic parts are still in place as extended contact with harsh solvents may degrade their properties (inlet seat and primer bulb, if present). Low pressure compressed air may be used to blow out passages but only use this on the fuel line from inside the carburetor body - else you may end up with the inlet seat clear across the driveway never to be found again.

DO NOT use wires or metal instruments to clear any of the passages as their size is critical.

The small hole in the hollow bolt on the bottom is most critical. Make sure it is cleaned down to the shiny brass and that this hole is unblocked and fully open:

```
     _     _
    | |   | |
    | |   | |
    | |   |_|
    | |    _  Hole in nut (approximately .025") - use carburetor cleaner
    | |   | |  and wooden toothpicks to clear it out down to shiny brass.
    | |   | |  DO NOT use metal wires!
   _| | _ | |_
  |    \_/    |
  |___________|
```

If you are absolutely sure there is no hole in the bolt (some models may forgo this), check further up on the central tube - there may be a tiny hole about 1/2" from the bottom. There has to be a hole somewhere for the gas to be sucked up through the carb!

I first use carburetor cleaner inside and out with cotton swabs to remove all traces of gunk from the inside. Use as many as needed till no more discoloration shows up. Then, use the broken end of a wooden toothpick or popsicle stick to clear the .5 mm diameter hole in the side. In severe cases, this hole may not even be immediately visible due to the varnish and gunk buildup.

If this hole is narrowed or clogged, the engine may start but then die in a few seconds. Gas enters the reservoir in the nut slowly or is forced in by priming but the normal suction cannot replenish it quickly enough.

Fine steel wool may be used on the float hinge pin if it is rough or there is evidence of rust but do not use anything abrasive on any of the other parts. Persistence with carburetor cleaner and cloths or paper towels should prove sufficient.

Inspect the inlet needle and seat. The needle should have sharp uniform edges and no visible damage to the conical tip. Any damage half way down the conical part - where it actually contacts the seat - will result in leakage and flooding. The seat can be removed if damaged by pulling it out with a hooked wire - careful - you do not want to scratch the body! If removed, do not reuse but install a replacement. The new seat goes in groove side first (lubricate with a drop of oil) and can be pressed home with a blunt rod.

If the throttle plate was disassembled, clean these parts with carburetor cleaner. Use a cotton swab to get into the bearing surfaces in the carburetor body.

DO NOT attempt to disassemble the carburetor beyond this point - the pressed in main fuel nozzle is precisely fitted and is not removable. The welch plug (pressed in disk) should not be removed unless you suspect contamination in the primer chamber (if any).

Carburetor rebuild kits are available and are economical where almost any parts need replacement.

(From: Jim Williamson (Willjim@gte.net).)

If soaking the carburetor in cleaner:

When you remove each part from the dip tank rinse it with warm/hot water (as hot as your hands can reasonably stand). The parts that have passages - force water through the passage. This does two things: (1) rinses the internal passage of the cleaner and any old junk (2) gives you a VISUAL check that water is coming out the other end of the passage. The visual check is the key here - you could use compressed air to rinse the passages but you don't see the exit stream. On a clean passage the exit stream will be nice and solid indicating no particles hanging up in the passage.

Now as for the hot water - this is to help dry the parts off - evaporation. Sometimes once I've rinsed the parts off I'll use compressed air to further dry the passages - or at least manually blowing through them.

Critical considerations for proper operation

- The inlet needle and seat must be in good condition or else the carburetor will flood due to leakage or result in erratic operation due to uneven gas flow. If there is any evidence of damage, these parts will need replacement. The 4 edges of the needle should not be worn (the sharpness would change about 2/3 of the way from the pointed end). If the edges are noticeable rounded, replace the needle. There may be varnish deposits on the needle, rubber seat, and the metal casing in which it is installed. These must be totally removed using carburetor cleaner and soft (wooden or plastic) tools.

- The float height adjustment should be fairly accurate. With the float and inlet needle reinstalled (and the seat replaced if it was removed), invert the carburetor - the float should sit just about horizontal. For more precision, a .210" (#4) drill bit should just fit between the body and the non-hinge end of the float.

- The machined passages must be free and clear and not damaged - never use wires to clean them. Use compressed air, carburetor cleaner, wooden sticks, etc. However, do make sure that they are fully open. There are no blind passages in these carburetors so a strong light should permit you to see that they are unblocked (the following are typical - your model may differ slightly):

    - Air bleed, inlet side angled down toward main jet.
    - Passage to primer chamber, inlet side.
    - Slot towards center at edge of welch plug (may not be present).
    - Pair of main fuel passages in central cylinder in main body.
    - Main metering hole in bowl bolt.

- The hole in the bowl bolt is the main metering orifice and it is critical to the proper operation of the carburetor. This area also tends to collect a lot of crud. It will yield to repeated use of carburetor cleaner, cotton swabs (Q-tips), and wooden sticks. Continue cleaning until you are down to shiny brass. Just don't become impatient and use any wires or sharp tools to speed the process!

- Any primer should be air-tight for it to function properly and for the engine to run properly. Any leaks will result the primer being partially or totally ineffective. In addition, the engine will run rich and contaminants may enter the carburetor. Check for damaged rubber parts or hoses that have fallen off.

  If the primer bulb is on the carburetor, there is a 'welch plug' (a metal disk pressed into a mating cavity) sealing the primer chamber. On the side toward the center, there is a tiny rectangular hole that must be open - it often gets clogged and may not even be readily apparent. Do not attempt to remove the welch plug unless you seriously suspect something is inside. If pressing the primer bulb results in a blast of air out of the hole, it's probably fine. Where the primer is separate from the carburetor, there is usually no welch plug.

- The float must be air (and gas) tight. Shake it - if there is any gas inside, the float will need replacement. (It's possible there may be metal particles or other debris sealed inside at the time of manufacture - this will cause no harm.) Put the float under water - there should be absolutely no evidence of bubbles and leakage. Pinholes sometimes develop in the thin brass and while these can be soldered, this practice is not recommended.

- The large O-ring must seal properly. If it leaks, the engine will run rich and contaminants may enter the carburetor bowl. Replacement is usually recommended whenever the carburetor is disassembled. However, if it is in perfect condition, you can try to reuse making sure that the mating surfaces are clean and smooth. Use some engine oil on the O-ring to assure a tight seal.

Reassembly

Once all parts have been cleaned and inspected - replaced where needed, proceed as follows:

If you removed the throttle assembly:

- Reinstall the throttle shaft along with its spring and felt and/or metal washer. Hook the spring onto the ridge on the carburetor body. Make sure it moves freely. DO NOT lubricate.

- Attach the throttle plate to the shaft with the original screw. Make sure the plate is correct side out and that the hole is positioned on the right facing the upright carburetor from the throttle plate side. As you tighten the screw, slightly rotate the throttle shaft to allow the plate to seat properly - jiggle it a bit at the same time. When properly installed, the plate itself limits the return movement of the throttle. It should be fully closed at this point.

Confirm that the throttle plate moves freely between a fully closed and fully open position - there should be no hint of binding or stiffness.

- Reattach the air inlet pipe with gasket using the two sets of nuts and bolts. Don't forget the metal strip for the governor spring if your carburetor uses this. Tighten securely - 4 to 6 ft-lbs if you use a torque wrench.

Now for the main event:

- Install a new seat if you removed the old one. The new seat goes in groove side first (lubricate with a drop of oil) and can be pressed home with a blunt rod.

- Install the float using the hinge pin.

- Insert the inlet needle hooking the retaining clip on the tab near the float hinge. Check for free movement of the float.

- With the carburetor body inverted, check the float height adjustment. It should seat almost horizontally. For a more precise test, use a 0.210" (#4) drill bit as a gauge across the outer ring of the carburetor body - the float should just touch this. Bend the tab on the float to adjust. (Note: unless you replaced some parts, this setting will probably be fine.)

You can test for proper operation using low pressure compressed air (i.e., by blowing into the fuel hose), or water or gas. Water is safest but you must make sure to dry everything thoroughly before final assembly. To do this, temporarily reassemble the bowl with the hex head bolt. With the carburetor upright, dribble water into the fuel hose until it accepts no more - perhaps an ounce or two. There should be no leakage - the level of water in the hose should not change at all once it stops. If there is any leakage, there is still a problem with the inlet needle or seat - or the float is gas-logged.

- Install the large O-ring around the carburetor body. Use a small amount of engine oil to aid in assuring a good seal.

- Place the bowl over this assembly making sure that it does not pinch the O-ring. Orient it so that the deep part is almost opposite the float hinge (it should actually point directly away from the engine when the carburetor is mounted.)

- Install the hex head bowl bolt and fiber washer. Tighten securely (but there is apparently no recommended torque for this bolt). CAUTION: I've heard of people breaking the bolt by either attempting to loosen it the wrong way or overtightening upon reassembly to stop leaks. If gas leaks out in the area of the bolt head, the fiber washer may be missing or damaged. For testing at least, a non-hardening gasoline resistant sealer like Form-A-Gasket B(tm) can be used.

Carburetor installation

With the carburetor positioned in its approximate location on the engine:

- Reinstall the throttle and governor linkages Where there is no speed adjustment or idle position, the direct governor linkage goes in the hole closest to the engine and the spring hooks onto a fixed vertical metal strip with only one hole at one end and the lower hole in the governor lever at the other. Thus, in operation, the spring attempts to keep the throttle open and the governor pulls on the throttle to close it. Increased spring tension results in higher speed. Don't get these backwards when you go to reinstall the carburetor on the engine!!! See the section: Throttle/speed control linkages on Craftsman/Tecumseh engines.

- Reattach the primer tube, if any.
- Reattach the stop switch wire, if any.
- Install the carburetor onto the engine with a new gasket if needed. Tighten securely (6 to 8 ft-lbs).
- Double-check that the throttle linkage and governor spring are in the proper holes and nothing is binding - you should be able to move the throttle back and forth without any sticking or tightness. It should return to the full counterclockwise position instantly as a result of the governor spring tension.
- Do not replace the air filter at this time.
- Reinstall any throttle selector or cable. Confirm that it operates properly - usually STOP, LOW, HIGH. STOP should engage the stop switch. LOW should leave the governor spring tension where it was. HIGH should increase the governor spring tension slightly. If there is an IDLE position, the throttle plate should be almost closed.
- Reinstall any trim pieces that were removed.
- Reinstall the fuel tank and fuel hose with clamp, if any. Open the fuel valve, if any.

Throttle/speed control linkages on Craftsman/Tecumseh engines

The following is for one model! NOT ALL ENGINES ARE SET UP THE SAME! It is best to consult your engine manual. Getting it wrong is not something you really want to do! :(

The user speed control (if any) pulls on a spring which is attached to the 2nd hole from the top on the governor lever. For engines with no speed control, there is a fixed plate or tang to which the spring is attached. Some amount of adjustment is possible by bending this plate.

The carburetor throttle plate has several holes in it. The one that is probably used is that closest to the little cutout (which I can't show with ASCII art) and the tip of the throttle plate return spring. You can probably confirm this by looking for which hole has the paint worn off!

```
             __                              _

```

See: [Neil's Tecumseh Throttle and Carburetor Linkage Page]() for some slightly better diagrams. :)

Initial tests

Add a small amount of gas to the fuel tank - perhaps half a glass or so. Just enough to assure that it will reach the carburetor even if the mower is slightly tilted or jostled.

Inspect around the fuel hose and carburetor body for fuel leaks. If gas starts dripping from the air inlet or anywhere else, there is still a problem with the inlet needle and seat. Disassembly will be required.

Only a few seconds are needed for the gas to fill the carburetor bowl.

Assuming there are no leaks, install the air filter and reattach the spark plug wire or reinstall the spark plug. Attempt the normal starting procedure - prime if recommended.

The engine should start on the first pull! Immediately move the throttle selector to LOW if you have this option. Confirm immediately that it stabilizes at a reasonable speed - stop it quickly if it sounds like the mower is preparing for takeoff - your governor connections are incorrect or binding. If it runs at a fast speed with the speed selector set at LOW, the governor spring is probably in the wrong hole. Check it.

Listen and feel for any significant unevenness, surging, or other unusual behavior. Stop the mower, wait a few seconds, and restart. It should restart with a single pull without priming.

Mow for a few minutes. Stop the engine and confirm that it restarts without priming. Listen and feel for any indication of lack of power or other unusual behavior.

Go take a dinner break. Then confirm that the engine will now start - priming may be needed since it will now be cold.

Maintenance of point-type ignition systems

In most cases, missing or total lack of spark will be due to dirt, pitting, or corrosion of the points or a failure of the condenser. Timing may affected as well by excessive wear. The following procedures should restore the ignition system to good health:

First, test for spark. If there is a spark, try replacing the spark plug since this is the most likely cause of ignition problems. With a spark present, there could still be ignition system problems but this is much less likely.

You may be able to test the points to some extent if you can get to the wire that connects to the magneto or the STOP switch. A multimeter on the low ohms scale will the permit you to watch the opening and closing of the points.

If this confirms that the points are operating the condenser could still be defective, the breaker arm could be sluggish, or the point gap could be grossly out of adjustment.

To proceed further:

- Remove any trim pieces and the shroud/blower housing to access the flywheel, magneto, and points assembly under the flywheel.
- Check the flywheel magnet to magneto core air gap. While it is extremely unlikely that this increased, it is an easy test. The correct value is usually .015 inches but some engines use other gap spacings. A non-magnetic feeler gauge is best for this. If it is much larger than specified, adjust it and test for spark again.
- Remove the flywheel. See the section: Flywheel removal.

- Test the flywheel magnet. No actual strength is usually published but if it attracts a steel screwdriver from at least a 1/2" distance and seems strong, the magnet is likely fine. If it is weak (or missing, though this is mostly a theoretical possibility!), the flywheel will need to be replaced.

- Remove the cover over the breaker points assembly, if any.

- Inspect the points. There should be no serious pitting, corrosion, evidence of arcing or sparking. Nor should they be welded together!

  If any of these problems are present, replace the points and condenser as well - a bad condenser may be the cause of the points failure it is not really possible to fully test it.

  You can also test for electrical operation of the points using a multimeter on the low ohms scale while rotating the crankshaft (you will have to use the blade - careful) or operating the breaker arm manually.

  Or better yet, just replace the points and condenser. The cost is minimal (probably under $5 for a rebuild kit) and you have already done most of the work.

- Note the mounting arrangement and remove the old points and condenser and install the replacements. Do not tighten the locking screws at this time.

Setting the point gap and ignition timing

Perform the following whenever the breaker points assembly is replaced or where a timing problem is suspected.

- Rotate the crankshaft so that the cam that operates the points is at the highest location and the points are wide open.

- Adjust the point gap setting to specifications using a feeler gauge. This is nearly always .020 inches.

- Set the crankshaft position. This is usually done statically and does not require a timing light (Darn!).

  - On many engines including Tecumsehs, there is a timing dimension in the engine specifications. This is the distance of the piston below Top Dead Center (TDC) at which the points should just open.

    While measuring piston position with a scale through the spark plug hole, rotate the crankshaft until the piston is precisely at TDC and note this distance. (There are special timing gauges for this purpose with lock screws to hold the setting but a little ruler will work just fine.)

    Now, turn the crankshaft in the opposite direction from normal rotation (usually counterclockwise as viewed from the flywheel end) until the piston moves down .25 inches or so and then turn it slowly in the normal direction of rotation until the piston position is precisely at the timing dimension listed in your engine specifications.

  - On some engines there will be timing marks on the flywheel and engine block or the manual may tell you to line up the one edge of the flywheel magnet with one of the magneto pole pieces.

    The flywheel should be temporarily re-installed without tightening the nut.

    Rotate the crankshaft until the timing marks are precisely aligned.

    Carefully remove the flywheel without disturbing the crankshaft position.

- Adjust the timing. Loosen the locking screw on the points assembly. Rotate the points assembly until the points just open (use a thin piece of cellophane or a multimeter on the low ohms scale. Lock the position by tightening the set screw.

- Double check that your settings have not shifted.

- Replace the cover over the points assembly, if any.

- Reinstall the flywheel and associated hardware and tighten to the specified torque (30 to 33 ft-lbs). Make sure the cupped washer, if any, has its cupped-side facing the flywheel. (Defer tightening to full torque if the engine is not presently mounted solidly on the equipment. Just don't forget!)

- Check, and if necessary, adjust the magnet to magneto coil spacing using a non-magnetic (preferably) feeler gauge or shim stock (typically .015 inches though some are .005 to .008 inches, see your engine manual).

- Replace the shroud/blower housing and any trim pieces that were removed if no other servicing is to be performed on the engine.

Recoil (pull) starter repair

- Broken starter ropes or failure to retract are both repairs that are fairly easy. However, the spring can be nasty as it is under tension (or should be when reassembled). This can be risky if you are not familiar with the internal construction as you disassemble the unit.

  The cause of a broken cord is obvious. The cause for a failure to retract could be a broken spring, tangled or frayed rope, or some other mechanical failure. A broken spring will require total disassembly of the starter mechanism - fortunately there really isn't that much involved.

  With some designs, it is possible to replace the cord without fully disassembling the starter mechanism - by threading the cord in and tying a not in the end - but after rotating it several turns to put the proper tension on the spring. This is relatively safe but may be frustrating as 3 hands are sometimes needed.

  Where safe disassembly is not obvious, I would recommend that you refer to a book on lawn mower or small engine repair from the library or the service manual for the mower, if possible. You may be able to find specific step-by-step instructions which will minimize your risk of injury from an encounter with an uncontrolled spring.

- When the rope pulls out and retracts normally - but doesn't do anything else - the most likely cause is a problem with the one-way clutch. This may be part of the spring-rope assembly - usually removable as a unit - or attached to the flywheel. The most common problems are gummed up lubrication or a broken spring or other damaged or worn parts. For common engines:

  - On Briggs & Stratton starters, the clutch is often part of the flywheel nut assembly. The entire unit can be easily removed and replaced if it fails to engage reliably.

  - On Tecumseh starters, pawls in the starter assembly engage a serrated cup held in place by the flywheel nut. Check for damaged parts or gummed up lubrication.

WARNING: Take extreme care should you need to disassemble the portion of the starter that includes the mainspring - that can be nasty.

Broken lawn mower handle

Should the tubular handle on your mower break at some point (yes, I know this should be unlikely but I know of two people who have managed to do it!), the use of a splint is probably the best approach. Obtain a length of steel pipe with an inside diameter just a hair larger than the outside diameter of the handle. About 8 to 12 inches should be enough. Even electrical conduit may work. Use this to splice the joint. Drill holes through both the pipe and handle and secure with sheet metal screws. This will maintain the required strength and keep the handle the same length as it was originally so you will not have to become a midget to mow your lawn.

Diaphragm carburetor problems

> "I Recently inherited a BobCat Snow Blower from the 60's or 70's. It has a Lausen 3.5hp (HR35P-2403P). I just installed a Tecumseh Rebuild Kit#631893. The unit runs way too rich, I run out of gas in 10 minutes, the muffler starts to glow red. I cannot get it to idle. I installed a new needle, seat/jet and diaphragm. During the rebuild I did not remove the welch plugs. I tried swapping the idle screw with the high speed screw (not sure which is which). One screw has a smooth taper while the other has a taper with a step to it (no evidence of scoring). Could I be missing a key piece that regulated fuel flow? The rebuild kit did not come with directions, so I just installed everything in reverse."

The idle mixture screw is the one with the step.

I assume you have any choke off, throttle connected properly with spring return, etc.

What happens if you close both idle and main jets? Does it starve? I would expect that you should be able to stop fuel flow totally. If this is not possible, your needles or something else is incorrect/worn or fuel is somehow bypassing the jets which is also wrong.

Did you compare the old and new parts to make sure they gave you the correct kit?

It also recommend removing the Welch plug and blowing compressed air through the passages to clean.

It might also be a problem in the diaphragm spring pressure but without seeing it, no way of knowing. The diaphragm acts against atmospheric pressure. There is a spring on the inlet needle which if missing would run very rich. Chilten has a detailed diagram - really no way of knowing if your assembly was done correctly. Also, warns again using harsh cleaners on non-metallic parts and clearing all vent holes.

However, I rather suspect that comment about running rich is not correct as an engine running very rich would lack power if it continued to run at all. Your throttle may be stuck wide open and it may be over revving.

Your public library should have some Chilten or other books like those listed in the section: References. These should include diagrams of the diaphragm type carburetor.

Metal gas tank repair

Yes, you have to remove the gasoline first! And, make sure all traces of vapors are gone - if it smells like gas, it may very well explode!

(From: Greg Fretwell (JRFC31A@prodigy.com).)

The best way is to braze it, but before you get your torch out take a bottle of ammonia to the car wash and have them steam the tank out, pour in some ammonia and rinse. Repeat a few times. Ammonia will remove the residual gasoline and make it safe to weld on. This is the procedure required by the welding shop that fixed my tank. They needed to see the receipt from the car wash before I could even bring the tank on the property.

(From: Doug Younker (dougy@ruraltel.net).)

I have gotten lucky and have been able to solder repair leaks in small engine tanks using my 140 watt soldering gun after leaving the tank to preheat in the sun all afternoon while I was at work. You have to be patient to do so...

- Back to Small Engine Repair FAQ Table of Contents.

Engine Overhaul

When does this information apply?

This chapter deals with the following:

- Indications for the need for an overhaul.
- Engine disassembly down to the last nut.
- Inspection of major parts for wear and damage.
- Basic replacement or repair of any broken or damaged parts.
- Engine reassembly.
- Post overhaul testing.

For detailed instructions on valve grinding, cylinder reboring, or main bearing reaming, for example, you should refer to one or more of the books listed in the section: References. However, this chapter will give you the general feel and basic information needed to perform many common types of simple overhaul operations and to evaluate the need for more drastic action - such as a trip to the new lawn mower store!

Depending on your particular problem(s), only a subset of these sections may apply. For example, inspection and cleaning of the valves and combustion chamber - even valve regrinding (but we said we weren't going to talk about that!) can be done with a minimum of engine disassembly.

Do you need an overhaul?

Many common problems can be remedied without going into the deep dark recesses of the engine. However, some will require either a partial or total overhaul. Eliminate all other possibilities from consideration before considering an overhaul - it will not be a fun afternoon (or weekend, or week, or month,....).

The following are indications that at least a partial overhaul may be needed:

- Mechanical damage - broken, damaged, or bent parts resulting in inability to start or even turn the crankshaft for starting or excessive vibration while running. In most cases, this will be obvious - the mower died very suddenly - possibly with a loud clunk or p-ting and now the crankshaft hits something really really solid inside when attempting to pull the starter.

- Low compression - this is due to wear or abuse (lack of oil) of parts like the rings or valves or due to a blown head gasket. Perform the compression test described in the section: Compression testing. Symptoms would be difficulty in starting and unusually little resistance when pulling the starter cord, and perhaps, loss of power once you get it started. If rings are bad, there may be excessive oil consumption and blue exhaust smoke. If only the valves are involved, only the cylinder head may need to be removed.

- Excessive oil leaks - a failure of the oil seals (the lower one on mowers at the PTO/blade end, most likely) will result in oil dripping or pouring from under the mower deck. The blade will be coated with oil and there will be a puddle where the mower is stored. Of course, if this is severe enough or neglected, you may end up with much more serious problems when the internal parts fail due to lack of lubrication. Replacing an oil seal is not difficult. The old seal is removed by piercing its thin metal shell with an awl or ice pick and carefully prying it out. Take extreme care not to scratch or dent the mounting surface or crankshaft. This may be possible without extensive disassembly. The new one is then pressed on. In fact, installing the new seal is best done with the crankshaft in place as there will be less likelihood of damage to the new seal and it can then be driven in straight. There is a special tool for this but a piece of pipe that just fits over the crankshaft cut off square will work just as well. Remove any burrs on the crankshaft to prevent damage to the new seal and take care that any rubber lip on the seal does not get folded over.

- Excessive noise - knocking, banging - while an engine powered piece of machinery is not exactly quiet, there should not be unusual or excessive mechanical noises. Such noise can be an indication of an excessively worn engine or of some part that is about to fail. Should you strip the engine based on this? I cannot say - it is a judgement call. It something about the sound suddenly changed, then investigating the cause is certainly warranted.

In some cases, multiple problems may be present and/or there may just be excessive wear of parts like the cylinder, rings, and piston. Under these circumstances, the cylinder may need to be rebored to accept a replacement oversize piston and ring set. The cost of the parts and labor (you really don't want to rebore a cylinder) will likely be more than you want to spend. This is when a new engine or mower is the best option.

Comments on engine rebuilding

While the specific question dealt with a medium size snowblower engine, the comments should apply to other yard equipment as well.

> "Is it economical or feasible to properly rebuild a 7 HP Tecumseh engine on a snowblower? Compression seems fine. Has been burning oil to some degree for the last 3yrs, but this year its' burning a lot - maybe 1/2 pint oil for each gal of gas. Until last year, was using 5W30. This year, switched to straight SAE30. I could get a new Tecumseh SnoKing engine for about $350 including shipping."

(From: Mother (jmg14213@earthlink.net).)

As a finalist in the All-American Engine Repair Championships formerly held at the Outdoor Power Equipment EXPO (an industry trade show) in the Tecumseh division, and as a Briggs and Stratton Master Service Technician, it has been my experience that:

1. Yes it is POSSIBLE to rebuild one successfully, although if it is not an HH model with cast iron bore, it probably will not hold up (single H models are aluminum bore).

2. It is not cost effective to do so.

3. Short blocking this engine requires special tools if it is more than ten years old, as the ignition timing is not fixed, as it is on newer, solid state models.

4. Engines from companies like Northern Hydraulics may be adaptable to your unit, but will likely not just bolt on.

If this engine is on a top of the line product, such as Ariens, Snapper, or BearCat, it is probably worth repairing, as a new comparable product is big bucks (and overpriced).

If this engine is on a mid-range product, such as Toro, Simplicity, John Deere, Husqvarna (European product, not USA built), etc., then repair is probably still a good option, due to the overpricing of similar replacement products.

If it is on a Murray, Noma, AMF, Dynamark, Ultra, Sears, MTD, YardMan, White, Husqvarna (USA built by Murray/Noma), or other discount store brand, go buy a new machine. The cost of a new unit is not much more than the cost of the engine repairs, and then you won't have a worn out piece of discount store equipment to break down again in three weeks when something else goes bad...

Compression testing

Special compression gauges are available at auto parts stores or small engine parts suppliers. These will catch and hold the highest pressure reached so you don't need to be in two places at once.

Note that this procedure may always yield a very low reading if there is a compression release mechanism on your engine - which is very likely. In this case, the crankshaft must be spun in the opposite from normal direction by the flywheel (counterclockwise when viewed from the flywheel end, with the starter removed).

- If the compression gauge has a screw thread, install it in the spark plug hole so it snug - it doesn't need to be really tight. If it just has a rubber boot, have a buddy hold it in place in the spark plug hole as you perform the following tests.
- Pull the starter cord several times or use the electric starter in the normal manner.
- New Tecumseh engines should have a compression reading of at least 80 psi. If your reading is at least 60 psi (or the specification found in your engine manual), then compression is acceptable.
- If it is less than expected, squirt a small amount of engine oil in through the spark plug hole so it coats all around the edge of the piston and cylinder.
- Repeat the compression test.
- If the pressure reading is now acceptable, then the rings need replacement or the piston/cylinder are excessively worn. If there is little change, there is a valve problem.
- If the measurement is very low under both conditions, there may be a blown head gasket or damaged (punctured) cylinder or head. (Or your engine has a compression release mechanism which is reducing the reading - see the note above).

For Briggs & Stratton engines, the manufacturer simply recommends spinning the crankshaft by the flywheel in the opposite from the normal direction with the normal spark plug installed. A sharp rebound (as it compresses the trapped air since the compression release mechanism is not active in reverse) indicates good compression. Little or no rebound indicates low compression and need for service.

Should you even bother?

Only you can decide if the time and effort will be worth it. If you enjoy a challenge, then engine overhaul may be for you. However, this is probably not going to be your idea of fun. Doing something like this for the first time *will* result in scraped knuckles and the liberal use of 4 letter expletives. If the mower was a Hechinger's $100 special and has seen several seasons of use, then it may be time for a new one.

If you are not the detail oriented meticulous type, you may be better off leaving this sort of overhaul to a professional or buying a new engine or mower. Most parts must go back in exactly the same orientation as they were originally - including matching of timing marks on the crankshaft and cam gears. Even the piston is not symmetrical - though this is not obvious except by taking detailed measurements. Nonetheless, it will not work well if at all, or will wear quickly if rotated 180 degrees upon reassembly.

Furthermore, once a wear pattern has developed, it is generally a good idea to replace parts in exactly the same position - the direction of the piston (wrist) pin or location of the intake and exhaust valve lifters. Violating this rule won't result in immediate failure but could lead to excessive wear and reduced life

What this means is that you cannot assume anything about the parts you remove. Even if they look identical at first glance, they may have a definite right and wrong orientation and/or may want to be replaced in exactly the same location. Even lowly head bolts may be of different lengths. Make notes and diagrams. Most of these will be pretty simple but they will save your hide in the end!

Bearing surfaces are very finely ground and polished - just dinging the crank pin journal surface against a steel part will put a nick in the relatively soft bearing which will need to be carefully removed as best you can - affecting as little else as possible - with very fine emery cloth.

In addition, if you don't like to get your hands dirty and oily, forget it. You will have disgusting black crud under any surviving fingernails for days. This is a messy operation! The outside of the engine will be coated with decayed grass clippings, dust, and dirt. The inside of the crankcase will have the remnants of old used motor oil (also a carcinogen) and the combustion chamber will be coated with filthy carbon deposits.

At the same time, cleanliness is critical when reassembling as any particles of dirt or metal will find their way between rotating parts resulting in excessive wear or worse.

Having said all that, overhauling a small engine is not like overhauling an automobile engine. In the words of a colleague: "It's just a frick'n lawn mower". What this means is that you can get away with tolerances, imperfections, and mistakes in dealing with a small engine that would be unacceptable for the health of your Chevy or Porsch.

Special tools

For most of the procedures described below, the basic set of items listed in the section: Tools and supplies will suffice. However, some of the following more specialized tools may be needed depending on how far you go:

- Micrometer - many of the measurements of wear to engine parts requires determining the diameter of shafts or bearing surfaces. Except for the piston, most of these can be accommodated by a micrometer with a maximum opening of 1 to 1-1/4 inches. However, in many cases, what is important is not actual diameter but clearance - and this can be determined with the inexpensive 'plastigauge' or a substitute.

- Plastigauge - these are disposable pieces of calibrated plastic used to determine the critical clearance between the rod bearing and crank pin journal.

  You place one in between the rod bearing and crank pin journal and tighten to specifications. When removed, simple measurements on the markings on the squashed plastigauge will very precisely determine the clearance, taper, and out-of-round specifications for your bearing. It is also possible to obtain most of this information by using slips of paper or foil of known thickness but this will not be as accurate or convenient.

- Flatness gauge - a good machined straight-edge and a set of feeler gauges will suffice for checking the mating surfaces of the cylinder and head.

- Ridge reamer - the 1/8" or so above where the piston slides in the cylinder will develop a buildup of carbon. In addition, if the engine has seen really heavy use, the metal in this area will be higher (less worn) than the section below. In order to remove the piston, this ridge must be eliminated or else it either won't come out or you risk breaking the rings.

Fortunately, the metal ridge is rarely a problem on lawn mower engines and the carbon ridge can be removed with a simple homemade tool which is just a soft metal (i.e., aluminum or brass) piece with a straight edge or inside right angle. You probably will not need an expensive commercial ridge reamer tool. You will not need one at all unless you will be removing the piston.

- Piston ring compressor - when reinstalling the piston and rings, it is virtually impossible to squeeze the rings together to fit into the cylinder without some help. Commercial piston ring compressors are available for about $5 or you can make your own from a large hose clamp and strip of sheet steel (say, 1" x 12" x .020"). This tool is not needed unless the piston is being removed from the cylinder.

- Piston ring expander - this allows the easy removal of piston rings from the piston. With care, you can do this by grabbing the two sections of the ring and guiding it off the piston by hand. In any case, unless you will actually be removing the rings from the piston, this tool will not needed.

- Valve spring compressor - in order to remove and reinstall the valves, their rather powerful spring must be squeezed together tightly. This is almost impossible to do without this tool. I have done it with an improvised clamp designed for holding lab equipment but it was barely up to the task and not fun. However, unless you are going to remove the valves, this tool will not be needed.

- Rubber mallet - the engine overhauler's 'persuader'. In particular, to break free the crankcase/oil sump joint and for reinstalling the piston using the piston ring compressor. A small one will be more than enough.

- Scrapers - to remove built up carbon deposits and stuck gasket material - start with a strip of aluminum. For stubborn deposits, a flat edge paint scraper or straight blade screwdriver will come in handy. Take care not to scratch any machined surfaces. Coarse steel wool can then be used to finish up after the major deposits have been removed. For fine work, an X-acto knife also is useful.

- Wood blocks (4" x 4" x 8" typical) for supporting the engine on your workbench.

- Rags, paper towels, and more rags. Just make sure to dispose of oil soaked material safely. Plenty of old newspaper to protect the ground or table top.

Prepare your work area

Once the gasoline and oil is drained, all overhaul work can be done indoors. Without gas, there is little risk and working indoors is generally much more convenient. Therefore, you need to decide where to set up for the overhaul. The best location will be relatively dust free, well lit, and not likely to be required for other purposes. Your engine may be remain in a disassembled state for some time if you need to obtain replacement parts. Also, even with its bodily fluids removed, an old engine will stink. Therefore, the dining room table is probably not the ideal choice!

Lay out a healthy layer of old newspapers to protect the workbench from oil and solvent drips and damage from heavy tools and parts.

Engine overhaul procedure

The following description applies directly to a large number of Craftsman mowers using Tecumseh engines (most do). However, with minor modifications, it is also applicable to most other mowers using 4 stroke engines.

Mechanically, 2 stroke engines are very similar. In many respects, they are simpler having no camshaft operated valves or oil pump. There is no oil to drain or change. However, needle bearings are used in key spots which complicate matters slightly. Refer to one of the books listed in the section: References for detailed 2 stroke overhaul procedures.

Prepare the engine for removal

While for certain repairs it is quite possible to work on the engine while still mounted on the mower or other yard equipment, it will almost always be much more convenient to disconnect and remove the entire engine to the convenience of your workbench. There are generally only a handful of actual connections. A typical small engine is remarkably light and compact once stripped of the mower deck!

- Disconnect and secure the spark plug wire.
- Drain the gasoline or remove the fuel tank and store in a safe place.
- Drain the oil from the crankcase/oil sump. While this is not essential for all overhaul operations, it will eliminate any risk of oil pouring out or going where it should not when you turn the engine over or on its side. In addition, this further reduces the risk of explosive fumes which might result if excessive gasoline has contaminated the oil. Finally, now is a good time for an oil change! Refer to the section: An oil change isn't really a big deal. (However, you won't be refilling until later.) Don't reuse the old oil even if you recently changed it and dispose of it in an environmentally friendly manner.
- Brush or vacuum off the exterior of the engine above and below the deck and then wipe it down with an old rag to remove decayed leaves, grass clipping, dirt, oily grime, dead (or live) rodents, whatever. The cleaner it is when you actually start work, the better off you will be and there will be less chance of contaminating the interior.
- Detach (and label if there is any doubt about how they are connected) any throttle or dead-man control cables.
- Remove the blade (or anything else driven by the crankshaft). See the section: Non-violent blade removal. Don't lose the locking key if it is separate!
- Remove any auxiliary drive (self propelled) or power take off. This may be a belt or chain above or below deck.
- Disconnect any electric start wiring from the mower.
- Check for and remove anything else that would prevent the engine from being detached from the equipment.

Remove the engine

At this point, the engine should be free of all its attachments to the mower except for its mounting. For a typical rotary mower, there will be three large bolts accessible from under the deck. Removing these with the proper socket will allow the engine to be lifted and moved to your workbench. You will probably be surprised at how light it is! I recommend just screwing the bolts back into their threaded holes finger tight. That way they will not get lost and the threads will be protected. Also, Protect the threaded end of the crankshaft with a bit of rag or paper towel fastened with an elastic band.

Engine disassembly

The following sections provide the detailed procedures for disassembly and initial inspection for major damage. As noted, these apply directly to most Tecumseh engines but most other 4 stroke engines are very similar.

Removal of the accessories

Now it is time to get down to business! As noted, depending on your situation, not every step will be needed.

- Remove any trim pieces which cover the engine. Depending on how much you paid, the engine may be nearly bare or have multiple plastic doodads covering up what is essentially that same bare engine!

- Remove the gas tank if you have not done so already. A spring loaded screw clamp may be used to attach the fuel line to the tank - use a pair of pliers, socket, or screwdriver as appropriate to loosen it.

- Remove the oil filler pipe, if any. This is usually fastened to the shroud/blower housing with one or two small screws. Thread these back into their holes finger tight so they will not get lost.

- Remove the shroud/blower housing. This is usually fastened with 4 small bolts (they may be different sizes - replace in the threaded holes so they will not be lost. If there is a primer tube running to the carburetor, disconnect it at whichever end is convenient.

- Remove any electric starter components - starter motor, gears, etc.

Carburetor

- Detach the throttle control (may not be present on all models). Two screws hold it to the carburetor. Replace these screws so they will not get lost. (Yes, I know this is getting kind of repetitious!)

- Disconnect the stop wire if there is one.

- Use a large philips screwdriver to loosen the two screws fastening the intake pipe to the cylinder block. If the gasket separates easily and cleanly, then it can be reused though a dab of non-hardening sealer is advisable. If it tears or is damaged in any way, then it should be replaced.

  If the bolts are really tight, an open end wrench may be of help but common sockets may not fit around the bottom bolt. Thin walled sockets may work.

- Disconnect the throttle linkage and governor spring noting which holes they go in. IMPORTANT: If you get this screwed up you could have a runaway situation on your hands when you go to restart it. This can destroy the engine in a few seconds!

The carburetor can now be set aside or disassembled and cleaned. (See the section: Cleaning Craftsman (Tecumseh) carburetors.

WARNING: there is still likely a significant amount of gas inside the float bowl. If turned on its side or upside-down, this gas will come gushing out. Therefore, it is best to set the carburetor aside in an outdoor area in an upright position. Plug the intake manifold and fuel pipe with wadded up paper towels or rags to prevent the entry of dirt.

Muffler

Note that in addition to decreasing the noise from your engine, the muffler serves a very important spark/flame arresting function. Therefore, it is important that it be in good condition.

Some mufflers simply screw into the cylinder using pipe threads. Others are mounted with a couple of bolts.

- Remove the muffler. Use penetrating oil (e.g., Liquid Wrench or WD40) if the mount is heavily rusted or corroded and does not yield to normal efforts.

- It is ok to ruin the muffler in the process. Mufflers are inexpensive and you probably needed a new one anyhow. Just do not damage the cylinder threads as the metal is relatively soft.

- If the muffler comes off intact, inspect for serious corrosion, holes, or other damage and figure on replacing it if needed.

Flywheel

- If you will need to remove the crankshaft or get under the flywheel to check or adjust the points (non-electronic ignition), then now is as good a time as any to remove it. See the section: Flywheel removal.

- Inspect the flywheel and set it (and associated washers, starter clutch, etc.) aside in a safe place - away from steel filings that will be attracted to the powerful magnet!

- Thread the flywheel nut back onto the shaft and then protect it with a rag or paper towel secured with an elastic band.

Ignition

This can be left in place but will be susceptible to damage.

- Inspect the high tension lead for cracking or broken insulation. Temporary repairs using several layers of electrical tape may be made but replacement is best for long term reliability.

- Inspect the stop wire and any others for similar damage and repair or replace parts as needed.

- The electronic (e.g., Goldkey or Magnetron) ignition can be removed as a unit since there is nothing under the flywheel except possibly a (plastic) sleeve/spacer. Inspect the potted unit for cracks or other damage.

- For point type ignitions, the magneto coil along with the components under the flywheel (points, condenser, cam) can be easily removed if the flywheel has been pulled. Inspect for worn, pitted, welded, or corroded points and other damage.

Cylinder head

- Use the proper size spark plug or deep socket to remove the spark plug counterclockwise. Inspect the spark plug and threads in the head for damage.

- Use the proper size socket to remove the (usually 6 to 10) head bolts counterclockwise. It is best to loosen each a half turn at a time in an alternating pattern until they turn freely to minimize possible stress on the head. They will be fairly tight but should not be frozen. Check each one after removal as some may be longer than others and then must go back in their respective holes. Hold the head with one hand as you remove the last couple bolts - it should pop right off.

- Separate the head and head gasket from the cylinder. This should occur easily without requiring your persuader.

- Inspect the head, head gasket, and cylinder mating surface for major damage. While it may look really ugly, once the carbon is removed, the metal should be virtually like new.

- Remove built up carbon from the head, valves, piston, and cylinder. This is best accomplished by chipping it away with a soft metal tool like a scrap of aluminum. Take care if you use a steel paint scraper or screwdriver not to scratch the relatively soft cylinder or piston. WD40 will often help to loosen this carbon buildup. Most of the carbon will probably be on the exhaust valve and on the exhaust valve side of the head and piston.

Valves

You should only need to do this if you are replacing or grinding a valve. In most cases, the valves are undamaged but may appear in poor condition due to carbon buildup - which can be removed in-place fairly easily.

- Remove the valve cover on the side of the engine next to the valves.

- Use a feeler gauge to check the gap between the valve lifter and valve stem with the valve lifter in the relaxed - lowest - position. A typical value is .010 inches. Excessive clearance will require replacement of the valve or valve lifter. There could also be too little clearance - which is also bad - but the valves stems can be ground down to repair this problem which is either a defect in manufacturing or a result of a cam shaft replacement which is oversize.

- Use a valve spring compressor to remove pressure on each valve.

- The retaining clip or split cup should now be free. Remove these.

- The valve should now slide out.

- Loosen the valve spring compressor and remove the spring and any other hardware. Don't interchange the intake and exhaust valve springs.

- Remove the built up carbon deposits from the valves and valve seats using a soft metal scraper. Some WD40 may help to loosen the caked on carbon.

- Inspect the valves for serious burning or pitting especially on the seating (angled) surfaces. Once free of any carbon, they should be smooth and undamaged.

- Similarly, inspect the valve seats for serious burning and pitting.

- Inspect the springs for rust or other damage. Stand them on a flat surface and check for serious droop/tilt. Measure their free length and compare with your engine specifications.

Oil sump/crankcase cover

We are now going into the lower section. I can hear you saying "Joy!".

- Check the crankshaft for burrs at the blade lock key or other key and/or where any front wheel drive pulley setscrew was tightened. It is essential that these be carefully removed with a fine file before you attempt to remove the cover to avoid damage to the main bearing. In addition, any rust and/or dirt buildup must be removed with steel wool, sandpaper, or emery cloth to allow the shaft to pass through the main bearing without damaging the bearing or oil seal. Remove all traces of rust and grime but don't go overboard - it doesn't need to shine. Wipe with a very slightly damp cloth to remove **all** abrasive residue.

- Set the engine flywheel-side down on wooden blocks so that the flywheel mounting shaft is clear of the table.

- Once again, wipe down the underside of the engine, especially around the crankcase/oil sump mounting bolts and the seam where the cover will separate from the engine block.

- Remove the 6 to 10 hex head crankcase/oil sump mounting bolts and set them aside.

- Use a soft rubber mallet if necessary to help free the cover. If mild persuasion doesn't work, check for any bolts you may have missed.

- As the cover comes free, gently lift and turn at the same time. It should slide right off the crankshaft. If there is any resistance, you probably didn't find all the burrs or rust. Go back, identify, and correct the problem. Don't force it as you will end up with scratches on the bearing surface and/or damage to the oil seal.

- The gasket will likely tear in the process of removing the cover and will need to be replaced. It is not worth trying to repair it. You will have to scrape the remnants of the old gasket off of both mating surfaces before installing the new one (later).

- Check for any washers that may come free with the cover. There will be at least one on the crankshaft. It may be sticking to the bearing surface on the cover.

- Usually, the flyweight governor is just left in place unless parts need to be replaced. Inspect it for damage to the gears, flyweights, or cup. Individual parts can be replaced if needed (and if you can get them!). The post is a press fit and should not be disturbed unless damaged.

Camshaft/camgear

- Remove the camshaft driven plunger type oil pump. This is in two sections which have a definite relationship (the flat faces out). Inspect for damage and set aside.

- Carefully rotate the crankshaft until the timing marks align. These will be a line, dot, or hole on the camgear and crankshaft gear. For most engines, these should line up perfectly with each other at one position of the crankshaft. However, on some Craftsman engines, they are offset by one tooth. Check and note this before removing the camshaft/camgear!

- With the timing marks aligned, valve pressure should be released (if you removed the valves, this won't matter) on the camshaft and it should slip out easily.

- Inspect the camgear for chipped or broken teeth and wear. There should be no chipped teeth and no detectable wear on any of the gear teeth. Chipped teeth or significant wear will require replacement.

- Inspect the cam lobes for wear or wear. There should be no detectable wear and no damage.

- Check the compression release mechanism on the camgear for damage and free operation. The weight should snap back to the shaft when released. The little lift pin should move smoothly.

- Remove each of the valve lifters and inspect for wear. There should be no significant wear. Note which went where so that they can be replaced in the same location. Most are of the same length but once a wear pattern is established, replacement in the same location is desirable. Sometimes, they are of different lengths and then this is more critical.

Connecting rod

- Rotate the crankshaft so that the rod bolts or nuts are accessible.

- Bend out any lock plate that may be associated with the rod bolts or nuts. Many Tecumseh engines use 'Durlock' rod bolts with integral locking serrations and there is no lock plate and no lock washers. Note: Durlock bolts, lock plates, or lock washers should always be replaced with new ones if removed and not be reused. You really don't want the rod coming apart!

- Use the proper size socket to loosen the rod bolts or nuts counterclockwise. Start with small equal increments on each of them until loose to equalize stress.

- Remove the bolts or nuts and cap. Note the orientation of the cap and rod. If yours is the slant type, this is easy.

Otherwise, look for match marks, casting numbers, or other identifying marks and make a diagram in any case.

- Where bolts protrude from the rod, immediately cover these with some bits of rubber tubing or tape to prevent them from hitting and dinging the crank pin journal or other precision surfaces.

Piston

- Remove any carbon ridge you find at the top of the cylinder. This will catch the rings and prevent you from removing the piston or if force is used, break the rings. Usually, it is a simple matter of scraping with a piece of soft metal like aluminum. On rare occasions with a really well worn engine, enough of a metal ridge will also be present to require the use of a ridge reamer tool.

- Push the piston up and out of the cylinder bore. The rings will expand but will not pop off unless they are actually broken.

- Replace the rod cap and finger tighten the nuts or bolts. This will help to protect the bearing surfaces from accidental damage.

- Inspect the piston for damage. There may still be significant carbon deposits but once these are carefully scraped off, the piston should be fairly smooth. There may be some vertical scoring but a modest amount of this is not serious.

- Inspect the rings and ring grooves for damage. It is usually not necessary to actually remove the rings from the piston to do this - which should be avoided if possible to minimize the chance of breakage. The outer surface of the rings should have an almost polished appearance with no significant pits, scratches, or corrosion. There should be no chips or other visible damage.

- If you must remove the rings, use a ring expander if possible and make sure you note the exact orientation - top/bottom and location - for each.

- If you are removing the piston pin, note the orientation of both the rod and pin as they must be returned in the same relationship. Pistons are not symmetric! Look closely and you will see that the pin is offset a fraction of an inch to one side. This is done to optimize the center of force on the rod bearing and rotating crank pin journal.

- Use a pair of needlenose pliers to remove the 'circlip' from one side. The piston (wrist) pin usually floats (moves easily) in between the two circlips but a slight lip of metal (probably resulting from the pin banging back and forth) may prevent it from being easily removed. Very slightly scraping around this lip will free it up or you can remove the other circlip and then use a drill or arbor press to push the pin out far enough to free the rod. There is no need to remove the pin entirely. Then, there will be no question as to the direction upon reassembly.

Crankshaft

- Lift while rotating the crankshaft out of the top bearing. There should be no resistance (unless you forgot to remove something).

- Inspect the crankshaft to determine if it is bent. Any deviation from perfection is cause for replacement. The proper way to do this is with some V-blocks and a run-out gauge. However, you won't have these tools so a visual inspection is the best you can do. However, unless your blade kissed a boulder, a bent crankshaft is not likely.

- Inspect the small gear for broken teeth and wear. There should be no chipped teeth or detectable wear of the gear teeth. If there are chipped teeth or significant wear, then this gear and the camgear will need replacing.

  Note: the small gear on the crankshaft may be a press-fit and may not be considered serviceable by itself without replacing the entire crankshaft. However, I have been able to remove it non-destructively by gently tapping on each side using a soft metal bar (e.g., brass) and a small hammer. (When I had to do this, the guy at the engine parts store was surprised that I was able to get it off without damage.) Heating the replacement gear will expand it and reduce the force needed to press-fit it onto the crankshaft. Similar gentle tapping will then work once the gear is aligned with the indexing pin.

- Check for any washers at the flywheel end of the crankshaft and set these aside. There are probably none.

Breather

- The breather allows the pressure inside the crankcase to vent to the outside and should result in negative pressure inside as this contains a (leaky) one-way valve.

- The breather cover is under where the flywheel is located.

- Remove the screw to remove the cover plate. There is a gasket but it will probably separate cleanly.

- Check the spring and valve disk for rust, dirt, and wear. They will likely be fine. Make sure the small vent hole is clear.

- Replace the cover as there is nothing else to do in there.

Oil seals

- Do not remove the oil seals unless you intend to replace them. If oil leakage has not been a problem and you don't think any damage resulted from removing the crankshaft, leave them alone. It should be possible to replace the oil seals after reassembly if oil leakage turns out to be a problem.

- It is very unlikely that the flywheel side oil seal would be defective or damaged.

- The PTO/blade oil seal can be damaged by neglecting to completely remove burrs from the crankshaft before removal of the crankcase/oil sum cover.

- To remove the oil seals, use a screwdriver to pry them out from the crankcase/oil sump cover and/or the flywheel side of the crankcase. Take care not to gouge the mounting surfaces.

Detailed inspection

A complete overhaul can restore a small engine to like-new condition. Any parts that are found to be damaged or out of tolerance are repaired or replaced.

Determining this requires a visual inspection and taking measurements of all critical dimensions of bearings, cylinder, piston, and rings. Some of the inspection is subjective - how badly scored a bearing surface is before it must be replaced or reground. A few score marks around the circumference of a bearing surface will not adversely affect operation or wear. How few is a few? Perhaps if less than 10% or so of the surface is affected. You are not going to spend as much to repair the mower as it cost in the first place in any case so don't lose sleep over it.

Measurements may come up marginal as well. For example, if the limit listed in your engine specifications is .0015" and you measure .002" will this be a serious problem requiring the replacement of expensive parts? Probably not. You may get less than optimal life out of the engine but it will probably still work fairly well and for a long time. So many other factors can affect life that this may have no effect at all.

The following items should be visually inspected. If any significant wear is indicated, precise measurements should be made:

- Crank pin journal and rod bearing. Inspect for wear, pitting, and scoring on both the crank pin journal and the inside bearing surface of the rod and cap. On a new engine, both of these surfaces are nearly mirror smooth. On a well worn engine, there may be significant scoring due to particles from the oil getting trapped. An engine that has failed due to a severe lack of lubrication may result in some pretty spectacular failures of these parts. Minimizing wear and the change of catastrophic failure is the primary reason for performing regular oil changes.

    - A few score marks around the entire circumference of the journal are unimportant as long as they represent a small percentage of the surface area.

    - Scratches, pitting, or score marks that run side ways are more serious. If slight, polishing with very fine emery or crocus cloth may be all that is needed. If they catch a fingernail, this may not be enough.

    - A serious out-of-round condition is unacceptable.

  Follow the instructions that came with the plastigauge to take measurements. Consult your engine specifications for acceptable limits. Use judgement in determining whether slight out-of-spec measurements will necessitate replacement or major rebuild.

  If you had a rod failure due to lack of oil (remember what we said about the importance of oil - see the section: Rod disasters - or why the oil and governor are kind of important) - then there could be a variety of types of damage that will make these measurements academic. The rod my have broken in half or the cap may have literally exploded into multiple pieces. In many cases, the crank pin journal will escape relatively unscathed but needless to say, you will need a new rod and cap - not cheap!

- Main bearing - PTO (blade) end. Inspect for severe scoring, corrosion, or other damage. It may no longer be mirror smooth but should not appear excessively worn.

- Main bearing - flywheel/magneto) end. Inspect for severe scoring, corrosion, or other damage. This will probably appear almost like new even on an old engine as there is a lot less load on this end and it is relatively well protected and well lubricated.

- Cylinder. Inspect inside the cylinder for excessive wear and scoring. If it appears fairly smooth without much scoring, it is probably ok but only exact inside measurements would confirm.

- Piston. Examine the sides for vertical scoring. There will probably be some but as long as the piston is not mostly score marks, it is probably fine. Only exact measurements would confirm. Check for damage to the lands - the surfaces between the ring grooves. If any are cracked or broken, the piston will need to be replaced.

- Piston (wrist) pin. This should be mirror smooth. There should be no detectable free play if you try to jiggle the rod.

- Rings. Inspect for damage, pitting, and scratches. The outside surfaces should be pretty much mirror smooth. Use an appropriate sized feeler gauge to check clearance between the rings and piston grooves.

- Oil passages. Inspect and use compressed air if necessary to clear the various oil passages in the crankcase/cylinder, camshaft, connecting rod, and crankshaft. The typical small Tecumseh engine has a hollow camshaft which is part of the oil pump and drilled passages in the crankcase. The oil path is from the plunger/barrel oil pump up through the center of the camshaft, over top via the passages in the crankcase to lubricate the main bearing (flywheel/magneto end) and also to drip on the connecting rod and crank pin journal. Some larger engines also have drilled passages in the crankshaft and connecting rod. There is even an oil pressure test port normally sealed by a small screw. A typical pressure measurement on an engine running at full speed is 7 psi but you won't measure this so just make sure everything is clean and clear.

Engine reassembly

Once you have performed whatever magic is required to repair or replace broken or damaged parts, here are the steps that will transform your pile of parts into a (hopefully) working engine.

If any filing, sanding, or grinding was involved, make sure all traces of abrasives have been removed from every part. The best approach is to clean with soap and water or mild detergent and dry thoroughly. Then immediately coat all ferrous parts with engine oil to prevent rust.

Where the internal moving parts are involved, liberal use of fresh engine oil will also make things to go together smoothly and help protect the surfaces from damage due to initial lack of lubrication.

- Oil seals: If you removed the oil seal(s), clean the inside surfaces where the seals go and install new ones by pressing them in straight and square with a block of wood and rubber mallet or better yet, use a drill press or arbor press. Make sure you get the correct side facing out! Installing the new oil seals after the crankshaft has been replaced may be easier. There is a special tool for this but a piece of pipe that just fits over the crankshaft cut off square will work just as well. Remove any burrs on the crankshaft to prevent damage to the new seal and take care that any rubber lip on the seal does not get folded over.

- Breather: If this was removed, replace valve plate, spring, gasket, and cover. However, this is probably already assembled.

- Valves: Use a valve spring compressor to fully compress the spring for the intake valve and install the valve, any washers, and retaining clips. Do the same for the exhaust valve. Install the valve cover. <>
- Piston rings: Replace any that were removed. Use a piston ring expander if available or your hands to expand the rings and slip them over the piston and into their proper grooves. Note orientation and position! Avoid scratching the relatively soft piston. Do not expand more than needed - the rings are fragile.

  Note the typical arrangement (from top to bottom):

  - Compression ring (solid).
  - Compression ring (solid).
  - Oil ring (slotted with internal expander spring).

  But, you drew a diagram, right?

  Note: if new rings are installed, you should deglaze the cylinder wall with fine emery cloth in a cross-hatch pattern (diagonal strokes). This is needed break in the new rings. Then very thoroughly clean the cylinder to remove all traces of abrasive residue.

- Piston pin and connecting rod: Put a few drops of engine oil on the pin, position the rod, and then slide the pin into place. Use a press if it is a tight fit. Use new circlips to secure the pin. Make sure you get the orientation of both the rod correct! It is also desirable to install the pin in the same orientation as it was originally. If the pin was never entirely removed, this should not be a problem.

For the following, position the crankcase flywheel/magneto side down on some wooden blocks so that when the crankshaft is installed, it's end will be clear of the table-top.

- Crankshaft: Using a gentle rotating-while-inserting, place the crankshaft into the flywheel/magneto-end bearing. Use engine oil to prevent scratches. Take care not to bend over the lip of the oil seal.

- Piston into cylinder: Coat the piston and cylinder wall with engine oil. Orient the rings around the piston so that the gaps are staggered by 90 degrees and not above the pin location. Suggest from top to bottom: 45, 135, 225 degrees. Use a piston ring compressor (commercial or home-made). Tighten until the rings are fully compressed and then release just a hair. Position the piston in the correct orientation - rod with respect to crankshaft - and gently tap into cylinder using a wood block and rubber mallet. If it hangs up, the compressor is too loose. If it does not move at all, the compressor is too tight.

  CAUTION: Do not use a metal hammer - there is a good chance you will crack the fragile aluminum piston.

  CAUTION: Don't let the bottom of the rod or rod bolts hit the crankshaft! Put a wad of rag inside to prevent this.

- Rod and cap to crankshaft: Coat the crank pin journal with engine oil. Position the crank pin journal and rod bearing so that they are in contact. Place the rod cap in position - noting match marks. Using a new lock plate, lock washers, or rob bolts, as appropriate, hand thread the nuts or bolts on as far as they will go. Jiggle the cap to adjust and then tighten some more by hand.

  CAUTION: double check that you have the match marks aligned. If correct, the bearing formed by the rod end and cap will fit the crank pin journal perfectly - seated fully - with no free play even when only finger tight. If you attempt to fully tighten the rod nuts or bolts and the cap is backwards, you may ruin the rod and cap by distorting the soft metal.

  Now, use a torque wrench to tighten the nuts or bolts to the proper torque as listed in your engine manual. Alternate between the two nuts or bolts tightening in small equal increments until the proper torque is reached. Where a range is specified, aim for the middle.

  Where a lock plate is involved, torque to the middle of the acceptable range and then tighten the nuts or bolts just enough further to align a flat with the edge of the plate. Then, bend the plate over to lock it in place. DO NOT reuse an old lock plate.

  It may be a tight fit to get a torque wrench inside the crankcase. Here are a couple of comments:

  - I use a basic 3/8" deflecting beam type torque wrench - nothing fancy. To this, I add a 3/8" to 1/4 inch adapter (short) and a 1/4" socket.

  - Position the piston/crankshaft to provide the most clearance for each nut or bolt. These will differ.

  - This can also be done with an open end wrench and spring scale but the torque wrench is so much easier!

  It is just possible to get both the clearance and angle to use the torque wrench effectively. With a ratcheting torque wrench it would be easier but this is not essential.

  THIS ASSEMBLY IS MOST CRITICAL and is probably the single most important place to get the torque just right. Too tight and (especially for aluminum alloy rods/caps) you will strip the threads and/or distort the precision fit. Too loose and the bolts will eventually work their way out. You really don't want the cap to pop off while the engine is running at full power!

- Valve lifters: Install the valve lifters in their respective holes.

- Camshaft/camgear: Carefully rotate the crankshaft until the timing mark faces the camshaft bearing location. Slip the camgear in place so that the timing marks exactly align (or if your engine is one of those exceptions, so they are off by one tooth - see your engine manual if in doubt). For most Tecumsehs:

The camgear timing mark (if not marked) is in line with the center of the hobbing hole (small hole in the face of the gear).

  - The corresponding timing mark on the crankshaft is either a beveled tooth on its gear or in line with the keyway.

  - If the engine has a Craftsman type (float) carburetor, advance camshaft 1 tooth clockwise (except for the Craftsman variable governed fuel system, whatever that is!).

- Oil pump: Install the two piece oil pump. The flat must face out.

- Crankcase/oil sump cover (temporary): Install the washer(s) that go on the crankshaft. Without using a gasket, install the crankcase/oil sump cover. Use a gentle twisting motion and take care to avoid damaging the oil seal. Slip the ball end of the oil pump plunger into its cavity in the cover before it is fully lowered. With a little jiggling, the cover should seat properly. Thread a couple of the mounting bolts in hand tight to hold it in place.

- Test for free rotation: Use the blade adapter and key as a means of grasping the crankshaft and rotate it through two complete revolutions. There should be no binding of parts though you will feel the resistance of the piston as it moves up and down in the cylinder and the valves as they are lifted once in every two revolutions (which you will also see from above).

- Remove the cover. Double check that the mating surfaces are free of old gasket material and dirt. Use a new gasket. Again, take care not to damage the oil seal and line up the ball on the end of the oil pump plunger so that it fits in its cavity in the cover as it is slid into place. Install all the bolts and tighten in a staggered order incrementally to the proper torque.

- Cylinder head: Position the cylinder head and new head gasket and install all the head bolts finger tight. If any are of a different size, make sure they go in the proper locations so that they do not bottom out or engage too few threads. (Tecumseh bolts seem to be all the same size.) Tighten the head bolts in the recommended sequence in 3 or 4 equal increments to the torque specified for your engine.

  Engine repair manuals always recommend using a new head gasket. The old one has shaped itself to the texture and imperfections of the head and cylinder and you could never match this up perfectly upon reassembly. The result can be leakage of hot combustion gases and ultimate failure of the gasket and possible damage to the mating surfaces.

  However, if you have not done anything to the head or cylinder surfaces and the gasket is in essentially perfect condition, you can risk reusing it but I won't guarantee long term reliability! My general recommendation is that you use a new head gasket once you are sure that everything works properly and thus there will be no need to remove the head again. Unless the old one is damaged, it will work fine for testing purposes.

  A typical Tecumseh bolt tightening sequence is shown below (except 8 HP). Check your service manual for the specific recommended procedure for your particular model engine.

```
    Flywheel/magneto end
     ___________________

     /\| | | | | | | |=|=0 |__|
___/____\|_|_|_|_|_|_|_|_|_|___\___
-----------------------------------
         PTO/Blade end
```

For the following steps, position the engine on wooden blocks blade/PTO side down.

- Ignition: Install the components (if any) that go under the flywheel (e.g., points, condenser, cam). Install the magneto coil or electronic ignition module. Temporarily position it so that it is as far away as possible from where the flywheel will go. Tighten the bolts.

- Set the point gap and ignition timing (point type ignitions systems only). See the section: Setting the point gap and ignition timing.

- Flywheel: Place any inside spacers proper side up onto the crankshaft. Position the flywheel key in the keyway and then install the flywheel onto the shaft. Jiggle it a little to seat solidly. It should not now move from side-to-side at all. Add the washers, starter cup, and flywheel nut. Screw the nut on by hand and then tighten securely (but not to full torque necessarily at this time) using a socket wrench. Torque to specifications once the engine is mounted as this will be a lot easier.

- Set the flywheel magnet-magneto gap (if you have not done this already): Place an appropriate spacer (e.g., .015 inches) between the flywheel magnet and magneto pole pieces. Loosen the magneto coil mounting bolts. The magnet will draw the pole pieces tight against the spacer. Tighten the bolts to the recommended torque.

- Install the spark plug with a new washer (and a dab of anti-seize compound). First, thread the plug in by hand to get it started and then tighten to specifications (15 to 30 ft-lbs typical).

- Install any electric starting components.

- Install the muffler. A dab of anti-seize compound will make removal of exhaust system components much easier at a later time should the need arise.

- Carburetor: Position the carburetor assembly in its proper location.

- Reinstall the throttle and governor linkages: Where there is no speed adjustment or idle position, the direct governor linkage goes in the hole closest to the engine and the spring hooks onto a fixed vertical metal strip with only one hole at one end and the lower hole in the governor lever at the other. Thus, in operation, the spring attempts to keep the throttle open and the governor pulls on the throttle to close it. Increased spring tension results in higher speed. Don't get these backwards when you go to reinstall the carburetor on the engine!!!

- Reattach the primer tube, if you removed it at the carburetor end.

- Reattach the stop switch wire, if any.

- Install the carburetor onto the engine with a new gasket if needed. Tighten securely to the proper torque (6 to 8 ft-lbs).

- Double-check that the throttle linkage and governor spring are in the proper holes and nothing is binding - you should be able to move the throttle back and forth without any sticking or tightness. It should return to the full counterclockwise position instantly as a result of the governor spring tension.

Engine installation

It will be easier to tighten the flywheel nut to the recommended torque once the engine has been reinstalled on the mower. Therefore, now is a good time to install the engine to the mower deck:

- Remove the three mounting bolts from the bottom of the engine. Position the engine on the mower deck and install these bolts finger tight. Then, use a socket wrench to tighten securely.
- Tighten the flywheel nut. Brace the flywheel against something solid and tighten the flywheel nut to the recommended torque (30-33 ft-lbs).
- Shroud/blower housing: Position and install using the proper bolts.
- Oil fill pipe: Put a little engine oil on the O-ring. Position the fill pipe into the oil hole in the base of the crankcase/oil sump cover. Make sure the O-ring seats inside the oil hole. Tighten the screw(s).
- Gas tank: Slip the gas tank into its mounts and tighten any screws. Connect the carburetor fuel hose to the gas tank.
- Trim pieces: Reinstall any trim pieces.
- Reattach any dead-man and throttle cables to the engine.
- Install any front wheel drive components - pulley to crankshaft (using proper key) and belt, or chain drive.
- Install the blade adapter and blade. Tighten to the recommended torque.
- ADD OIL!!! Add fresh engine oil to just below the top of the oil filler hole or just below FULL on the dipstick. This will be about 1-1/4 pints.
- Use the starter cord or electric starter to crank the engine a few times. This will help to distribute the oil.
- Add a small amount of gasoline to the fuel tank - say, a half a glass.

Initial post-overhaul testing

Assuming you didn't make any mistakes, the engine should start on the first pull. As you start it, look and listen for any abnormalities and immediately stop it if any are detected:

- Engine overspeeds due to screwed up governor or linkage.
- Unusual knocking or banging due to parts hitting one another.
- Excessive black, white, or blue smoke from exhaust (or 3 foot flames, I suppose).
- Overheating.
- Leakage of oil or gas.

Assuming nothing appears wrong, run it for a while at slow speed (if you have the option). Continue to be on the lookout for anything unusual. After a few minutes, stop it.

Let is sit for 10 minutes or so and then check, and if necessary, top off the oil.

Now, restart and run it at high. Mow a few lawns.

Congratulations! Hopefully, your engine will now serve you for many more years - or until the blade hits the next curb!

Items of Interest

Explosion risk when filling a metal gas can

Although rare, there have been reports of fires resulting during fuel transfer. Simple precautions can minimize this risk.

Here is how to fill a gas can to minimize the danger of fire:

- Turn off your vehicle's engine.
- Use only an approved container.
- Do not fill any container while it is inside a vehicle, a vehicle's trunk, pick-up bed, or on any surface other than the ground. This includes pickup trucks, sports utility vehicles, vans and others.
- Remove the approved container from the vehicle and place it on the ground a safe distance away from the vehicle, other customers and traffic.
- Keep the nozzle in contact with the can during filling.
- Never use a latch-open device to fill a portable container.
- Follow all other safety procedures, including No Smoking.

More information can be found on: Chevron's Technical and Safety Publications Page.

Why you really don't want to attempt to move an immovable object

The rotating blades and mass of the internal engine parts pack quite a punch. Speeding along merrily mowing away one doesn't think about this. However, if the blade should hit an obstruction, you may have no choice.

There are various safeguards to protect the mower from damage should a blade tip hit something but these don't always work. Why?

There is protection for the upper and lower parts of the crankshaft after all:

- The soft metal blade lock key can prevent damage due to excessive torque on the blade-end of the crankshaft when the mass of the engine parts continue to attempt to rotate after the blade hits something solid. The blade adapter then breaks away allowing the crankshaft to rotate freely. A 25 cent blade lock key or a $4 blade adapter will remedy this.

- The soft metal flywheel key will protect the upper part of the crankshaft and flywheel from damage should the blade and crankshaft stop suddenly and the inertia of the flywheel attempts to keep it rotating. A 25 cent flywheel key will remedy this.

In many cases, both of these will break free at the same time.

However, if the shock is severe enough, much more serious damage can result. Here is why: When one end of the blade hits a curb, for example, the inertia of the mass of the blade alone (rotating at high speed) will attempt to push the shaft sideways. This is pretty much independent of the rest of the engine.

In the diagram below, the blade is rotating clockwise. When the left-hand tip hits the curb, the right-hand side due to the inertia of the entire right-hand half of the blade wants to continue to move (down in this diagram) with the 'X' as the fulcrum. The entire left-hand half section of the blade contributes relatively little. This results in a net significant sideways (downward in the diagram) bending force on the crankshaft. The unavoidable arrangement of the fulcrum at one end and the shaft in the middle makes the situation even worse as the force resulting from the blade tip (the right hand one in this example) is amplified by the up to 2:1 mechanical advantage of the lever arm (the tip is twice as far from X and the shaft).

```
    Blade tip   /
  hits curb.  X-------____________________________________
    Ouch!   / |                                           |   Inertia of this
          /   |                   - O -                   | | side of blade
        /     |____________________________________       | | attempts to
                                    |   |   |   |  -------  | continue in same
                                    V   v   v   v   v   v   v direction.
                            Net sideways force
                              on crankshaft
```

While the rotating mass of the engine is attempting to shear the blade lock key, the inertia of the blade is trying to push the crankshaft sideways. The net result could be a severely bent crankshaft - a very expensive repair. An 8 to 10 degree bend is not unusual for a typical Craftsman-class mower running at full power. Any detectable bend in the crankshaft requires replacement - it is not safe to attempt to straighten it. A bend resulting in the blade tips wobbling by more than a fraction of an inch, there will be unacceptable and dangerous vibration when the mower is run. In addition, the original trauma (as well as attempting to run with a bent crankshaft) can damage other parts like the main bearings and connecting rod. The blade lock and flywheel keys will likely be broken as well but these are insignificant in comparison to the cost of major replacement parts and the labor involved in their installation.

The time and effort needed to disassemble the engine is significant and the crankshaft is probably the single most expensive part of the engine. In fact, purchasing a new crankshaft may be more expensive than an entire new lawn mower! It is quite possible that unless you have access to low cost replacement parts from a salvage yard and have the free time to do the work, repair may not make sense.

Therefore, don't let this happen to you. Your curbs and rocks don't grow that quickly and do not generally require mowing!

How about a crankshaft friendly blade?

It is too bad that most lawn mower blades are made of heavy rigid steel (though I do recall a mower that used a super thick nylon cord - sort of like a weed whacker on steroids). The chance of serious engine damage from curb kissing would be greatly reduced if a blade were used which had less inertia and increased flexibility. Then, no matter how hard you tried to whack something solid, only the blade lock and/or flywheel keys would shear and thus spare the expensive engine parts.

Apparently, some mowers are made with swing tip blades:

(From: Roderick Carmichael (carmic@nex.net.au).)

> "I use a top notch Supa-Swift with a gravity cast alloy chassis and swing-tip blades (Australian invention, no bent cranks on our mowers mate!)"

Why are these not common in America? Conspiracy to sell replacement parts by the small engine manufacturers? :-). You would have to really work at bashing a curb to bend a crankshaft with such a mower.

Another possible approach - applicable for both new lawn mower designs as well as field upgrades - would be to replace the heavy steel blade with one made of nylon with a molded-in steel edge. An auxiliary flywheel might have to be added (under the deck) to provide the needed inertia (normally supplied by the steel blade) for the engine to start and run properly and to help the mower plow through tall grass. However, since this additional flywheel could never be stopped abruptly due to hitting a rock or curb, its inertia would never contribute to a sideways bending force on the crankshaft. The greatly reduced mass and increased flexibility of a reinforced nylon blade should virtually eliminate the possibility of a bent crankshaft from such unfortunate incidents. See the section: Why you really don't want to attempt to move an immovable object.

(From: Mowerman (mowerman2687@my-dejanews.com).)

I have been reconditioning lawn mowers for many years and find it fascinating what design goes into some of this equipment. Like arrangements to prevent the crankshaft from bending if the blade hits something. Most engines have an aluminum key at the flywheel but this will not stop shaft bending most of the time. Mower manufacturer uses many methods. Lawn boy has a tapered shaft at blade level and so the shaft has no key and the blade slips if hit. Some other mowers had steel washers and fiber washers nearest the blade like a clutch I seen this on some antique mowers. The best idea is disc with small flail blades or short blade with flail at end. Manufacturers in New Zealand and Australia use this method on their domestic mower mostly and it works well. Victa of Australia was one of the first ones around here with this idea. I am sure you have them over there to no doubt. I hope this information will be to some help.

Crankshaft-friendly blade sighted

(From: Thomas Prufer (Prufer@compuserve.com).)

I recently came across a description of a blade assembly similar to the one suggested by you to make bending the crankshaft difficult. This is in the Royal Horticultural Societies' "Encyclopedia of Gardening". In the tools and accessories section, under the "lawn mowers" subsection, a caption says: "Plastic disk. This cheap replacement part cuts the grass by rotating horizontally". The inset shows rotary, cylinder, and "Flymo" mowers. A picture of the part shows a disc almost the diameter of a regular blade, with one blade joined to the circumference by a pin so that centrifugal force keeps it radial. This blade is short and narrow compared to the plastic disc; no telling if it is plastic or metal. There is no further reference to this part in the text. In my translation, it is on page 465.

If only they had included a name or supplier!

Another reason not to mow rocks!

(From: Forbes Family (fbsfam@clear.net.nz).)

I have recently purchased a new rotary lawn mower and appear to have started wrecking it in the first two weeks of use! Problem is, my property has lawns that run alongside a gravel driveway, and its often very hard to guarantee there are no stones lying in the grass before you start mowing. Not surprisingly I often hit small stones. These usually cause no harm, but today some teenagers were mowing my lawns and hit a real monster that measured approximately three inches by two by one, and weighed more than half a pound! Although the mower seems still to work OK, the impact has created a three inch long tear in the mower's cast aluminum body. Not a nice thing to have happen to a new machine!

Despite the stone's size, I was surprised at the size of the resulting tear in mower's more than 1/4 inch thick aluminum casing. I hadn't imagined a rotary mower blade powered by a 5 HP Briggs and Stratton motor could produce such force!

It would be interesting to hear from others who have survived similar experiences and to get an idea from any budding engineers on whether its perfectly reasonable for a stone this size to do such damage to the body of my mower - or whether it's more likely the body casting had a manufacturing defect that made it split prematurely?

Rod disasters - or why the oil and governor are kind of important

A combination of low oil (well, actually, almost no oil) and probably too high RPMs resulted catastrophic failure of the connecting rod and cap on my garage sale Eager 1 Craftsman mower. I had just completed cleaning the carburetor and was testing it when p-ting!! and it stopped dead - the rod had broken and it was dead-dead. Extremely embarrassing since there was no excuse for such a disaster.

The primary cause was likely a lack of oil - I should have checked it before attempting to run the engine for more than a few seconds. I have no idea whether someone had actually drained the oil for who knows what reason or it was just very low. In addition, I may have accidentally put the governor link back in the wrong hole permitting the engine to run at an abnormally high (and dangerous) speed.

There was no warning. The rod cap just exploded into e pieces (and this was at normal speed) and took a nice chunk out of the interior of the crankcase. Based on a post mortem of the rod, it appears as though one of the cap screws just loosened and backed its way out totally - there was no evidence of thread damage that would be expected if it were ripped out - and fell into the sump. With only one screw holding the rod and cap together, eventual failure was inevitable. Due to the offset design of the cap, this probably worked for a while since most of the force is on the rod.

Discoloration indicated excessive heating but no obvious bearing damage was evident that could be attributed to the lack-of-oil condition. The bearing was not in pristine condition but the type of scoring seemed to be more due to just poor general maintenance - lack of regular oil changes - than to this incident in particular.

Lessons: Check the oil level no matter what if there is any question or you are working on an engine of unknown history. Double check the governor linkages - take notes during disassembly - and be aware of what a normal speed sounds like for your type of engine (2 stroke or 4 stroke). If in doubt, install the link in the hole that would result in lower RPMs - closer to the carburetor. You can always move it later.

I forgot the oil and now it's stuck

OK, so you didn't read this document first or just got distracted while changing the oil and you ran the thing with no oil until it came to a screeching halt. Assuming nothing actually broke - it just won't turn at all, there may still be hope without a complete refurb (which in reality probably means a new mower):

(From: David Thomas (dthomas@NO.cityutil.com).)

The following assumes it is (was) a small push mower with a vertical shaft engine and that you drained the oil the preceding fall.

What little oil that was left in the bushing areas on the crank have burned down to tar. The piston may or may not be seized. Either way you'll need to break the engine down (pulling the flywheel is the hardest thing about it) and clean the tar out.

If this is beyond your abilities, try spraying penetrating oil on the crank around the bushing areas both on top (may still have to remove the flywheel to get to this area) and bottom as well as around the piston as the other gentleman suggested. (If you can't remove the head, pull the spark plug and spray penetrating oil or WD40 inside the chamber using one of those straw things that comes with the can so that you can direct the spray around all the walls of the cylinder, put the plug back in so it doesn't all evaporate and then set the engine so the piston is pointed straight up and let it soak a few hours.)

Last choice is to fill the crankcase with about a pint or two of penetrating oil (and spray inside the combustion chamber as stated above) then slosh it around the engine, turning the engine every which way and upside down, let it soak for a couple of hours repeating the sloshing every so often and changing the position of the engine so that you alternate soaking each bushing area and the bottom of the piston and then try the pull rope again. Be *sure* to disable the spark 'cause you *sure* don't want it to start with that light oil in the crankcase.

If it does free up, drain out the light oil and add the normal recommended oil before trying to start it. If it starts (it will smoke like the devil while it burns that light oil), let it run at idle speed until it warms up then shut it down and change the oil. It may still burn oil and smoke since the piston walls are probably scored badly so check the oil every time before starting it even after a short break until you get a feel for how much its going to burn.

(I had one engine that I did this with that used all most as much oil as it did gas. I had to clean the crud out of the spark plug before each mowing.)

(From: Brian Fistler (brian_34_@yahoo.com).)

If it's a Tecumseh engine, throw it away... Even if you get it running, it'll probably throw a rod soon (not like it wouldn't even if you hadn't seized it... :-)

If it's a Briggs, try putting oil in it first, then remove the spark plug and spray a liberal amount of WD 40 in there... You might have to let it set for a day or so, then, LEAVING THE SPARK PLUG OUT try turning the engine using the blade... Once you get it freed up, most likely it's run fine and probably last a few more years...

When I was a kid, my best friend and myself used to "work" on Briggs engines, we'd tear them down, fix broken ones from the junk yard, and most fun of all was "torturing" one... After seizing it up by finding out what would, and would not keep the thing running by spraying it in the carburetor (i.e., using hair spray, WD-40, paint thinner, etc...) We finally found that a certain spray engine degreaser of the era *would* run the engine, it would not run it for *long* because it removed the oil from the cylinder walls, and the engine would seize up...

That gave us an excuse to tear the engine down and find out how to get it going again... After the 3rd or 4th time seizing the engine with various products, we just decided to cut a hole in the side of the block and put a piece of Plexiglass there, so we could get easier access...

We ran that poor engine with every possible thing in the crank case, including pure water... (Side note: Water didn't seize the engine, as long as you didn't allow all of it to evaporate)

When the engine would seize up, all we ever had to do was put oil back in the case, spray a little WD-40 in the spark plug, and hit the blade a few times with a hammer to get it starting to turn...

That motor kept us entertained for an entire summer... :-)

So you got oil in the cylinder

> "I tilted my Toro to work on it and now can't start it because oil flooded into the cylinder. I already cleaned up the plug. Is there anything I can do to clean out the oil without taking the engine apart?"

Possibly, just letting it sit for awhile (in the normal position!) will allow the oil to drain back into the crankcase sump.

If oil is really trapped between the piston and the head, then you may be able to just tip the lawn mower so that the spark plug hole is down (a buddy may come in handy) and drain the oil out through there.

Alternatively, you should be able to suck most of it out with a kitchen baster and narrow extension tube (make sure it is made of something that won't scratch the interior of the cylinder and the piston) through the spark plug hole.

You don't have to get every last drop. What is left should not prevent you from starting the engine - it will just belch gobs of white/blue smoke for a few seconds after it kicks over as the remaining oil burns off. Keep in mind that squirting a half an ounce or so of engine oil into the cylinder is recommended when winterizing to protect the cylinder from rust so it should not be a problem.

In fact, I would expect that pulling the starter a few times will clear most of it in any case. It is possible that you have other problems - hopefully you didn't turn it over carburetor side down!. (In this case, the air filter may need to be removed and cleaned or replaced.) It may even be that your initial attempts to start it with an oil in the cylinder have resulted in a flooded the engine (excess gas) and waiting will clear that as well.

Some of the following information may be model specific but most applies to any engine that has gotten oil in the cylinder and/or carburetor due to tipping:

(From: J. Matthew Good (jmg14213@ix.netcom.com).)

First, my guess is that it is a Briggs QUANTUM or SIGNATURE SERIES engine, with the paper air filter. Go buy a new filter, as that one full of oil is shot.

Next, remove the plug and secure the plug wire away from the opening. Crank the engine a few times to clear the liquids out of the cylinder. Reinstall the plug. Now take a 1/2 inch box wrench and loosen (don't remove) the plug/nut on the bottom of the carburetor until gas flows clear through it, and retighten it. This should get the oil out of the carburetor. Now, check the oil.

Since you lost so much into the carb, and air filter, and it only holds 2 and 1/2 cups total you will probably need to add oil. If not, you may have gas in the oil as well. Drain the oil into a pan for recycling by tipping the mower air filter up, and dipstick tube down. Fill with clean SAE 30 HD oil. DO NOT use 5W30, 10W30, 10W40, or any other W oil. Just SAE 30 HD from any discount store will be fine. Do NOT use SAE 30 ND, it does not have the needed detergents.

Now you have the liquid out of the cylinder, the oil out of the carb, the gas out of the oil, the air filter OFF, and you are ready to start the engine. If it has a CHOKE, set it for full choke, if a primer, press it 3 times. Pull the rope until it starts. Let it JUST RUN until the smoke clears, don't mow or anything else until the smoke clears and you reinstall the NEW air filter.

The reason I guessed it was a Quantum is that this is the only engine I know of that automatically puts oil in the air filter if you tip it for sharpening. That's why the first thing I do to any Quantum that comes in for service is remove the air filter and put it in a safe place.

(From: Lloyd E. Sponenburgh (lloyds@fiscalinfo.com).)

Actually, a judicious tilt *away* from the carb will coat the underskirts of the cylinder and piston with oil so as to make starting *easier*. This improves compression. It's an old salesman's trick to show just how easy it is to start the engine.

So you put gasoline in the oil filler hole

Don't panic, just get it out of there. Drain the oil/gas mixture completely and refill with the proper new engine oil. If you want to be doubly sure, run the engine for a minute or so to mix any of the remaining contaminated oil with the new oil, then drain and refill again. It really shouldn't have done any damage if you get it out of there reasonably quickly (I don't know what effect gas might have on the oil seals over time though).

Oil starvation from mowing at too steep an angle?

4 stroke engines require oil to continuously coat the various moving parts during operation. There are two types of systems used in most small engines: splash lubrication and forced oil lubrication.

- Splash lubrication - there is an 'oil slinger' driven (via a gear) from the crankshaft. It dips into the oil sump and literally slings oil onto (hopefully) the moving parts in such a way that it makes its way down into the critical bearing surfaces.

  For the slinger to operate, it must dip into the oil! At too steep an angle, the slinger may be whipping up fumes and no oil!

- Forced lubrication - there is an oil pump (as with an automobile engine) and oil passages drilled through various parts to channel the oil directly to the bearing surfaces. (However, on the typical small lawn mower engine, there is no oil filter and no idiot low oil warning light or automatic shutoff - thus the need for periodic oil changes!)

  At too steep an angle, the intake of the oil pump may be exposed sucking fumes instead of oil!

With the oil filled to the correct level (yet another reason to check the oil every time you mow!), the oil starvation angle should be greater than anything you are likely to safely encounter unless you have a very hilly lawn. However, if you do mow steep slopes for more than a few seconds (e.g., to turn around), it would be worth determining if this could be a problem for your engine.

Two stroke engines do not have this problem since the oil is mixed with the gasoline. As long as the fuel feed is working, the engine should be happy and the mower will mow! However, I do not like 2 stroke engines because of their generally higher production of smoke and pollution.

(From: Walt Conner (jerrbear@midwest.net).)

Oil starvation can happen. If you must mow on a very steep slope, look to see which side the valve cover plate is on. This side of the engine will also have a semi-circular bulge in the crankcase while the opposite side will be pretty well flat. The side with the bulge will have the oil slinger located below the bulge. Keeping this side down slope should keep you in oil anywhere you can stand.

When failure occurs, usually the connecting rod is first to go, sometimes the top main bearing seizes. Either occurrence usually means it's time for a new mower.

For really hilly mowing, you may want to consider a model that uses a 2 stroke engine such as Lawn Boy.

Additional comments on winterizing - draining versus the use of fuel a stabilizer

Not everyone agrees with the recommendation to drain the fuel at the end of the season as described in the section: General preventive maintenance.

(From: Dwayne (Dwayne@mddc.com).)

There is some argument that draining all the fuel from the system is bad, allowing the carb to dry out and the inside of the fuel tank to rust. That was the case on my motorcycle; the guy who had it always drained the fuel for storage and it ruined the tank. I always just add fuel stabilizer to the tank, fill it completely, and run it for a short time and have never had problems.

(From: Matt Howell (howell@ll.mit.edu).)

Fuel stabilizer's purpose is to prevent souring, and hence, the need to drain the fuel system before storage. In my experience, my equipment starts right up each season with stabilizer in the fuel. I would suggest you clean/rebuild the carburetor. Repair kits are cheap, and easy. Good luck!

(Editor's comments).

I have cleaned and rebuilt too many Tecumseh carburetors (mostly from neglected Craftsman lawn mowers). The cause in most of these was almost certainly gasoline left in the fuel tank between mowing seasons. You might get away with it for a couple of years but eventually the goop will prevail. I would definitely recommend draining the gas with these. The fuel tanks are plastic in any case and there are only a few steel parts in the carburetor and rusting of these is not that likely. A fuel stabilizer may not prevent the buildup of gunk and varnish as a result of the slow but inevitable process of fuel evaporation in the carburetor and replenishment from the fuel tank.

For other types, I would still recommend draining the fuel tank and running the engine until the carburetor is dry. I believe that this will result in the best long term reliability in most cases. Now, if you live in a swamp and mow the seaweed.... :-)

Testing a used lawn mower before you buy

A used mower at a bargain price may not turn out to be such a bargain if you have to do extensive repairs. There are two types: the living and the dead.

If the owner claims the mower will start and is prepared to demonstrate, this is usually a good sign! However, first, take a moment to check the following:

(Disconnect the spark plug wire, and tie it safely away from the spark plug terminal to prevent accidental starting if you are doing anything more than looking.)

- Check for significant oil leaks particularly around the main bearing at the blade/PTO end. This could indicate a defective oil seal or extremely worn main bearing.

- Check the oil both for level and condition. If the oil level is low and/or really black and icky, the owner probably did not follow the recommendations in this document! The oil should also not smell of gasoline.

  CAUTION: the oil will be hot if you check it after the engine has been running for more than a couple of minutes.

If there is gasoline in the fuel tank and it will start without undo effort, then there is an excellent chance that the engine is in good condition.

- How much effort does it take to start? If 10 pulls on the starter cord are needed, this probably means that some maintenance, at the very least, will be required.

- Check for unusual vibration and noise which could indicate an unbalanced, bent, or broken part. The blade of a rotary mower can be replaced easily and inexpensively if it is bent but any internal problems will be costly or time consuming to remedy.

- Check for any unusual unevenness, surging, or sputtering. If there is more than one speed, see how smoothly the engine switches between speeds. Put it under load if possible (offer to mow some foot tall weeds) to see how well the engine deals with actual conditions that will be encountered during normal use. Problems here usually indicate at most that the engine needs some long overdue maintenance but it might help your bargaining position.

In most cases, if the engine starts reasonably easily, there will be no really serious problems. The ignition system may require a tune-up or the carburetor may need cleaning and/or adjustment. Even a hard-to-start mower may very likely restored to tip-top shape with this type of intermediate level maintenance. Of course, the blade may have to be sharpened or replaced.

If the engine doesn't work - no gas in the fuel tank and no handy gas can is usually a tip off of this - how can you be fairly sure that there are no major mechanical problems? Note that the objective here is not to identify **the** problem but to have a good idea of whether repairs will be really expensive or difficult. Thus, we won't even bother checking the carburetor or spark as problems in these areas are minor compared to those caused by internal mechanical damage. Here are some simple tests you can do without tools and without overly upsetting the people running the sale or junk yard:

WARNING: disconnect the spark plug wire and tie it safely away from the spark plug terminal if you will be doing anything under the deck. Yes, I know, there is nothing in the fuel tank but it doesn't hurt to be safe. Use a rag or proper work gloves if you attempt to rotate the blade directly.

- The single most important test is to determine if the pull starter will rotate the engine without binding or unusual noises. If it doesn't turn at all or with great difficulty - and there isn't a clump of grass stuck between the blade and housing, there may be severe internal damage including broken parts or seized bearings. However, make sure that the blade brake is disengaging before walking away - it could be that simple (you did remember to grab the dead-man bar or set the throttle control to RUN, right?). There is also a very slight possibility that the starter itself is simply tangled or rusted and that the engine itself is fine. In this case, you should be able to rotate the blade and it should rotate the crankshaft.

- For a 4 stroke engine, you should feel the resistance of compression once every two rotations of the crankshaft (blade). If there is a tough spot every rotation, the valves are not working probably due to broken teeth on the crankshaft gear or camgear. (For a two stroke engine, there should be compression on every rotation.)

- If it turns too easily with minimal resistance (and the blade is actually rotating, not just the starter) - you should have an idea of the effects of proper compression on a typical mower - then there may be stuck valves, worn piston rings, or other internal mechanical damage.

- If possible, perform this simple compression test: Spin the crankshaft is the opposite direction from normal. A sharp rebound on the compression stroke indicates decent and probably acceptable compression. Little or no rebound means that the compression is probably low. (This is actually the only compression test Briggs & Stratton recommends.)

- If the cord pulls out with no resistance and doesn't rotate the blade, the starting clutch may just be broken - a very minor repair. Then, you will have to check for binding by rotating the blade itself (carefully).

- If you found the starter cord broken, this could be minor and simply due to wear or forgetting to engage the safety bar once too often - or major resulting from attempting to start a broken and seized mower.

  I picked a mower off the curb once where the cord was broken due to guess what - a clump of grass stuck between the blade and deck. Apparently, the cord was quite worn and the mower stalled on the clump of grass. The next yank likely resulted in a stream of 4 letter expletives and the mower was put out in the trash. Extracting the grass clump and replacing the cord yielded a rear bagger in perfect operating condition.

  Another mower found in the trash was not as fortunate requiring the replacement of the gear on the crankshaft and the camshaft/camgear assembly due to broken gear teeth ($35 - it was a learning experience), carburetor overhaul, and a tune-up.

Assuming the engine doesn't flunk any of these tests, then you may end up with a functioning mower with relatively little additional cost and effort.

Discussion of 2 stroke engine rebuilding

> "I am in the process of refurbishing an old Eska 7.5 H.P. outboard boat motor. The engine (a 2-stroke Tecumseh) runs fine when under load at full throttle.
>
> I can only get the engine to idle at a high RPM. If I lower the idle speed, the engine will eventually die.
>
> Once the engine is started and idling, any attempt to put it into gear will cause the engine to die. Sometimes it will stay running and I can get the throttle revved up at which point the motor will push the boat and run just fine. When I lower the engine speed (approaching the dock) the motor will eventually die.
>
> I am totally stumped. I've completely rebuilt the carburetor (new seals, etc.), replaced the condenser, points, and spark plug. I've set all adjustments to factory specs yet it still won't idle or go into gear."

(From: Al Savage (asavage@iname.com).)

Although I haven't worked in the field in 15 years, two stroke theory doesn't change much .

Is your high idle (out of gear, unloaded) smooth? It shouldn't be. Two strokes without electronic mixture controls are almost always calibrated to be slightly rich when unloaded, as the nature of all three induction systems (piston port, reed, rotary valve) is such that adding a load leans the effective mixture. Something to do with flow dynamics, I didn't need to know, as I don't design them.

You've covered the common problem area -- ignition. I suspect you have an air leak somewhere. Upper or lower crankshaft seal, reed plate gasket, intake gasket, and upper housing gasket are common areas, in that order.

Mind, this is generic two cycle troubleshooting advice; I don't pretend to know the model you're working with.

To track these things down in the shop, we'd build custom block off plates and pressurize the crankcase to a few inches, then watch the gauge to see the leakage rate. Not terribly practical unless you're rebuilding, but you sometimes found porous castings and cracks that way.

When I'm feeling adventurous I'd spray starting fluid (with a tube nozzle attached) around all the seams with the engine running to see if the run behavior changed. Not recommended; too dangerous.

Does your 2 stroke engine use reed valves?

Since a bad reed valve can be the cause of a variety of problems, knowing if you even have these can be useful - not all 2 stroke engines use reed valves.

(From: John Barry (jb@zedak.keepyourspam.com).)

One easy way to tell is to note where port is behind carburetor. If it just "dumps" into crankcase, like diametrically opposite cylinder, most likely it's got a reed-valve. If the passage from the carb connects to the cylinder at a point closer to the crank center-line than the exhaust port, perpendicular to cylinder axis and perpendicular to crank, it's mostlikely piston-ported. If the carb passage is parallel to the crank eventually (starts out perpendicular on Rotax engines), most likely you have a rotary-valve engine; this is usually the case for serious specific-output.

Some problems with Briggs and Stratton engines

(From: Mike Brandt (mwbran1@uswest.com).)

A quite common problem with these engines is the gasket between the carburetor and engine. It is usually a thick fiber gasket and sometimes gets blown out if engine ever backfires. This is more common with age, as the nuts holding carb on do sometime get loosened. Also gum buildup can and does clog the main and low-speed jets at times which means removing carburetor. Cleaning out with a good carburetor cleaner then blowing out all passages. This happens quite often here where they add 10% alcohol to gasoline. Gas goes bad a lot quicker than without alcohol!

Comments on Briggs and Stratton repair

The following was in response to a posting on alt.home.repair about a 12 year old lawn mower. Of course, if properly maintained, such an engine may still have quite a bit of life left in it :-).

(From: foxeye (foxeye@www.mindspring.com).)

The best method is if you do not have a flywheel puller is take it to the nearest Briggs dealer and have them remove it. Since you do have a puller, just put some tension on the flywheel with the puller you already have, and then hit the top of the puller (the threaded shaft that centers on the crankshaft end) with a heavy hammer (16 to 24 oz.) should do it. Sometimes all it takes is a sharp blow with tension exerted on the flywheel to break it free. One or 2 raps should be enough. If it fails at that, there are still other ways to remove it.

Some have points and condenser some do not. There is a points/condenser replacement kit that makes it solid state available for less than $10.00 called Atomic Ignition. Also rust on the magnet of the flywheel and the ignition coil laminated portion can also cause it to have no spark. The measurement is critical for the ignition coil to flywheel space (called air gap) for proper ignition as well. Unless very badly corroded and worn, the points can usually be cleaned up and readjusted. Its not uncommon for the little fiber plunger that operates the points on some models to get stuck.

You should pick up a manual, for proper dimensions, and bolt torque. Even though it may list special tools for some repairs, there is usually a work-around in most cases. I would not really spend to much money on this motor, as the age is against it, but a new one from a source like Northern Hydraulics can be had for $99 to maybe 125.00. I picked up a 5hp highwheel lawn mower with a Briggs I/C motor at the end of last summer at a local builders supply and garden center for $130.00 new in the box.

Experience with Briggs & Stratton carburetor

(From: Dan Hicks (danhicks@millcomm.com).)

Last Monday, while I was mowing the lawn, our 21-year-old Snapper mower quit on me. I could start it up but it would run for a few seconds and then quit again. After futzing with it in the yard for several minutes I took it back to the garage, and, after several more attempts at getting it going, I decided it was likely getting too much gas.

I disassembled the carb and cleaned it good. It's a "PulsaJet" model with the carb mounted on the gas tank. The diaphragm looked good -- no visible holes.

I reassembled things and the thing started and ran well enough to finish mowing, but it didn't have much "oomph".

During the week I got a new diaphragm, and I got around to installing it today. What a difference!! It used to take several tries to start the mower, now it starts on one pull. And it has more power than it's had in years.

Hard to say what may have been wrong with the diaphragm, but likely it had some microscopic holes in it.

McCulloch chain saw hard to start

> "This weekend I picked up a 14" McCulloch chain saw and have had a hell of a time getting it started. I am no novice at this as I already have a gas trimmer and blower. I am sure my fuel mixture is right and have done just about everything else by the book. In how many pulls do I consistently start a cold McCulloch chain saw. I should mention that I HAVE started it but can't believe it should be this hard."

(From: DanDee I had the same problem with mine!

If yours is like mine , it has a throttle latch knob to use during starting. Mine never worked. After pulling myself silly trying to start it, I just decided to hold the throttle trigger open manually and it starts every time very easily.

You may want to give it a try if you haven't tried it already.

Riding mower stops periodically

(From: Mike Odryna (modryna@ix.netcom.com).)

You might want to check the oil level. Some of the Briggs & Stratton engines have a low oil pressure cut off. Some of these cutoffs are very sensitive. They will stop the engine when it's less than a cup low on oil. As far as I know, you can't adjust it either.

How do you get the blade off a tractor mower?

(From: Lloyd E. Sponenburgh (lloyds@fiscalinfo.com).)

Typically, you remove the entire mowing deck, then manipulate the deck, rather than the whole mower.

Alternatively, shops often LIFT the whole tractor, and work from underneath. I built a beam-supported block and tackle affair in my barn to do just that... it's lots faster than taking the deck off a stupid Murray. Those pieces of trash require that you remove about a dozen fittings and nuts to get a deck off.

Now, my Wheel Horse, on the other hand, requires only ONE hand-released fastener, and off-she-comes!

About Wico magnetos

These are separate units (not part of the flywheel assembly) and may be found on larger (usually horizontal crank) engines.

(From: Al Savage (asavage@iname.com).).

The design is such that it uses an impulse spring to fire at low speed (less than 10 rpm, yes 10). It does a complex wind spring/release spring action until the engine fires. Other than the straightforward "replace the points/condenser" maintenance, I don't think I ever had to have the mechanical section apart, they're that reliable. I do think I had to clean up a couple of them, and relube them though.

If you rotate the engine by hand (careful!) you should hear the impulse spring release, with a very audible bang. With the high tension lead hooked to your spare-plug-on-the-head, you should be able to have at least 3/8" spark; less is probably not enough.

If you don't hear that loud bang from the mag, while very slowly cranking the engine by hand (two turns per bang on that impulse unit), you probably have a mechanical problem. If you hear the bang, but can't get the mag to fire repeatably, I'd refurb the points and condenser. It's a bit tricky, and I haven't even seen one in 15 years, much less worked on one in twenty, but there are many still in service and parts should be readily available.

Oh, yes. I worked most of my teen years in small engine repair. So I *do* know whereof I speak. On that vintage equipment, anyway.

What is inside a small engine electronic ignition module?

The advantage of these systems is that there is no maintenance as there are no points to wear out or gum up. Timing is fixed by the relationship of the flywheel magnet and sensor. There are also no adjustments except to set the magneto coil pole piece to flywheel air gap.

Replacement modules are available for many small engines to take the place of their original point type ignition system. These can be designed in several different ways but all must emulate the behavior of the point type ignition replacing just the magneto coil/pole piece assembly and without requiring alterations to the flywheel.

- One design uses the flywheel magnet passing the coil pole pieces to induce a moderate voltage - a few hundred volts - and store this in a capacitor. A sensor coil then triggers a solid state switch which dumps the charge in this capacitor into a high voltage transformer (ignition coil) to produce the spark.

- Another possible approach is to provide a coil in which current builds up until the moment when the points would have opened and a transistor switch to interrupt the current flow at that instant. So, perhaps something like a switchmode power supply or TV horizontal output transistor with a current coil like the ordinary magneto coil and a network to control base drive to the transistor so it turns on and off at the proper times. Some designs may use a separate sense coil to control this more precisely.

  If you are really curious, check out **U.S. Patent #4163437: Transistor ignition circuit**. There are diagrams of several possible variations on the basic circuit. (The US Patent & Trademark Office currently has a search facility with free access to complete text and graphics.)

Not that any of this profound knowledge does you any good for repair as these things are usually quite well potted and impregnable.

Capacitor discharge ignitions systems

(From: Matthias Meerwein (mmerwei@eis.k8.rt.bosch.de).)

I once fixed a CDI unit for a 3-cylinder Evinrude 2-stroke outboard motor. The storage capacitor (1 uF, 400VDC) had a short. Quite simple to replace, but digging the PCB out of the silicone RTV sealing compound inside the ignition box was a real pain! But considering that Evinrude charges real big bucks (about 800 DM = 500$) for the ignition box, it was worth the effort. Another possible cause of failure of the CDI are the SCRs. Also, check the charging and trigger windings as well as the cables and connections.

Which manufacturer makes what brand names?

The following could be retitled: Sales people don't have a clue of what they are talking about most of the time or make something up to please the customer (and pad their commissions). I'm not sure how much of the following can be trusted though in all fairness, it may be that manufacturers switch around like musical chairs. :)

(From: Tom Bellucco (bellucco@netacc.net).)

I recently moved into a new house with a very large lawn and went shopping for a riding mower / lawn tractor. This is what I was told by various people, both in and out of mower sales:

- Toro makes Toro and Lawn Boy.
- MTD makes all of the store brands (i.e., a mower that might have the Home Depot name on it), along with MTD, Dynamark, YardPro, Weed Eater, Noma, and Sears Craftsman.
- Murray makes MTD.
- MTD makes the low end (non-commercial) John Deere tractors.
- John Deere makes all John Deere.
- MTD makes White.
- White makes White.
- American Yard Products makes MTD, Noma, Dynamark, YardPro, Weed Eater, Sears Craftsman, and all store brands.

Now THAT'S confusion! I'd like to hear what anyone out there knows or has been told. It ought to be interesting to hear what other stores are telling people.

Note: The guy that told me that MTD makes John Deere sells Toro and Ariens. He has publicly stated that he HATES John Deere (I won't post his exact words). I never realized how defensive a guy gets about his tractor -- you should have seen the reaction I got when I told a guy his John Deere was made by MTD! I probably got a worse reaction than if I said something bad about his wife!!!! Anyway, he got right on the horn to his John Deere dealer and was promptly told that John Deere makes all John Deere products.

(From: Duane (djdubay@ix.netcom.com).)

Hmph... That *is* confusing. Just make sure that sucker says *Briggs & Stratton* on the blower cover!

(From: John P. Curcio (jpc@philabs.research.philips.com).)

According to my Cub Cadet dealer (from whom I purchased my snow blower), Cub Cadet, White, and MTD all come from the same factory. The only differences are color and features. They are located somewhere in Ohio, near Cleveland, if I recall correctly.

(From: Carol (carol@willard-oh.com).)

I live just up the road from the MTD plant - never saw a John Deere. I don't think they do that one.

(From: Peter Szymonik (Xorg@msn.com).)

John Deere makes *all* of their riding mowers. The walk-behinds are assembled by a "third party", and many Deere dealers don't carry the walk behinds for that reason, and because the walk behinds had electrical problems.

(From: BELJAN E (lvpy67c@ix.netcom.com).)

HUH??? That doesn't sound right at all. MTD makes that, MTD, Ariens, White, Cub Cadet, Yard Man, and Lawn Chief. Murray, another famous store brand makes some of them. Dynamark was and probably still is its own.

John Deer is John Deer.

(From: DeWayne McKay (dmckay@geotec.net).)

You have several people misled on who makes what lawn equipment. I've been in the repair business for about 12 years now. Murry is made by Murry. John Deere is made by John Deere. There are several hundred names that can be found on the side of an MTD product, but MTD does not make any AYP, Noma, Dynamark, or Sears product. Sears in the late 80's was made by AYP and Murry depending on model. Now they are only made by AYP. The new line called Scotts is partially made by AYP. And, as for John Deere: The cheaper smaller tractors are AYP and the bigger tractors are made by John Deere. Huskvarna mowers are also made by AYP except a few high-end commercial models. Also the bottom-end or should I say cheap trimmers and chain saws from Huskvarna are made by Poulan. Have you ever heard of Gilson? They built a lot of the Sears products in the 70's and 80's and also built Lawnboy's tractor line and some of the Ford line in the late 80's.

Comment on modern manual mowers

(From: Peter Szymonik (Xorg@msn.com).)

Sears still sells push mowers, I bought one this summer and use it for the trim areas, works great. The only downside is that you have to go to a professional mower shop to get the blades sharpened correctly.

Comments on electric mowers

(From: Leslie Gerstenfeld (lgerst1@umbc.edu).)

I bought a Ryobi Mulchinator in '94 (cordless electric). I found it cheapest at Home Depot, I think it was about $325. I really like it.

Pros:

- Cordless, no gas, no oil, no tune-ups, no starter cords. It starts literally with the touch of a button.

- Comes only as a "mulching" mower, so there is no bagging, and the mulching action really works - it shreds the grass into 1/2 inch pieces that you don't see on the lawn. I had previously purchased a Black and Decker corded mower (which I think is also available as cordless), MM450 I think, and it had a mulching "conversion" kit that blocked the bag chute, but just caught lots of grass and didn't really mulch.

- Ryobi says it will cut 1/2 acre on a charge, which I find a bit of a stretch, but it does cut my 1/4 acre of grass (on 1/2 acre lot) without any problems.

- It has a 'Remaining Charge' gauge that works pretty well, though its not very progressive, it kind of jumps in 1/4 'tank' increments.

- Designed to be stored either upright (normal orientation), or upended - the handle folds down over the main deck and you can tip it on end; it takes up very little space this way.

- Cutting height is easily adjusted with one lever located by one of the rear wheels.

- Recharges in 11 hours. The instructions say to always leave it plugged in, even through the winter.

Cons:

- Fairly heavy as mowers go since it has on-board batteries, but I don't have any problems using it.

As for the big issue - how does it cut. Well, it cuts pretty well, but it certainly can't take down anything like a gas mower can. As the grass gets higher, it starts to leave a bit along one edge of the cutting strip slightly higher.

If you are the type who knocks a foot off your grass every few weeks, this isn't the right mower. But if you mow regularly, it works pretty well.

(From: Carol J J (caroljj@ix.netcom.com).)

I have used Black and Decker electric mowers for over 20 years. I Love them. We have a small property and a 100 foot extension cord is all we need. Since my husband is disabled, my young sons and I have done all the mowing for years. There are no worries about pouring or storing gasoline, no pulling like crazy to get it started. The blade is easy to replace. The grass bag is awkward but okay. My latest is a mulcher. It switches between regular and mulching easily. The mulch works well, not as good as a Snapper, but we're not paying Snapper prices either.

(From: Nann Blaine Hilyard (hilyard@pol.org).)

I bought a Black & Decker cordless electric mower for $150 at Menard's last year. It is lightweight and very easy to use. I have not calculated the energy cost (we keep it quietly charging between mowings, though we unplug it in the winter) versus a gas mower, but I don't have the strength to pull the cord for a gas mower so the extra electricity doesn't bother me.

(From: Geoffrey G. Shepherd (gshepherd@seanet.com).)

When my old Craftsman gas mower gave up this summer (gas leak) (what, you didn't read this FAQ?? :-) --- sam), I decided it was time to replace it with a new electric mower (my brother-in-law has the old mower now and is working on it for his own use). I ended up purchasing a Black & Decker CMM-1000 5 HP Cordless Mulching Mower from the local home improvement warehouse for just over $350.

So far, I'm quite happy with it. It mulches better than the Craftsman did, and rear-bags when I want to add to the compost pile. It mows my entire city lot on a charge (in fact, the built-in meter still reads full charge when I'm done - admittedly, my house takes up a large portion of the lot). I also like how it adjusts height with one clever lever. It's fairly quiet, and my clothes don't smell like gasoline when I'm done. Call B&D at 1-800-762-6672 and they can send you literature and a free video on the CMM-1000.

My only complaint with it is the weight. It seems to weigh about the same as the gas mower it replaced - it might even be few pounds heavier. But that's OK - I can use the exercise.

(From: Steve Hill (hills@inficad.com).)

I spent 3 years with a push reel mower. If the blades where sharp and the grass short then it was fine. If the blades where dull or out of adjustment or if the length of the grass to be cut at all long, it would leave the lawn a mess. I'd have to make 2 or 3 passes to get decent results. Also some types of weeds with resiliant stems where very difficult to cut.

Finally, last year I bought a Black and Decker cordless electric. It was magnificent. It was a mulching mower so my raking days where over and it gave much better results. Also, it was very quiet and was always ready to go in an instant. All of my neighbors with gas mowers were very jealous.

(From: William Lee (w-lee2@nwu.edu).)

I have had a Ryobi for 4 years and found it to be adequate for our small lawns. It takes me about 20-30 min.to do everything. In my opinion, it does not cut as well as a "good" gas powered mover that has a sharp blade. The batteries do degrade over time, although I'm am still working on the originals. It had an charger problem the first year, but that was fixed without charge. The blades are non-standard and I have an extra so that I can have a resharpened blade ready to go.I do enjoy not having to "listen" to the noise of a gas engine! Good luck!

(From: Andy Dennie (adennie@instinctive.com).)

As a former reel mower user and a current cordless electric mulching mower user, I can comment on both of these items.

I used a reel mower for about a year and a half. I found that it worked well if I cut the grass pretty short, but when I did that I got more weeds. I tried raising the blade height, but then it didn't cut as well.

This year I got a Ryobi Mulchinator cordless electric mower. So far I have been pretty happy with it. The charge is good for about 1-1.5 hours, supposedly, but it only takes me about 45 minutes, so I don't know what its limit is really. It's louder than the reel mower, but quieter than a gas mower. While charging it can stand on its nose and the handle can be folded up so that it takes very little floor space in my garage (this was important for me). One minor inconvenience is that you have to leave it plugged it all the time (at least that's what they recommend), so it is helpful if you have a plug near the place where you will store it (you don't want to be tripping across a long cord all the time). This didn't turn out to be a problem for me. Another thing is that you're not supposed to store it in very cold weather (bad for the battery I guess), so I had to move it inside recently for the winter.

(From: Jim (jstrohm@texas.net).)

The only problem we've had with our plastic-decked B&D is that it tends to collect grass when it's wet, and clogs frequently. We've chunked a few rocks with it, but with no damage.

We haven't actually tried to cut rocks with it, and my experience is that a rock will penetrate the deck of any mower if it hits right. You should pick up the rocks before you mow, not try to hide from the shrapnel.

In general, electric mowers are best suited for smaller lawns with less vigorous growth and without extensive landscaping to tangle the cord. A frequently sharpened blade makes a tremendous difference on electric mowers.

(From: Robert Smits (rs@ham.island.net).)

I've had experience with both electric mowers and gas mowers. I live in an area where the grass can grow quite quickly and thickly, and the B&D electric one just doesn't have the oomph to cut long, thick grass. (Even when you make sure you're using as short a heavy duty cord as is practical - to avoid voltage drop in the cord). My 5HP gas model just whizzes through the same stuff, and not having to hassle with the cord is really an advantage - my lot size is just under an acre.

The battery operated electrics may run out of steam quite soon if you have a larger lot, and count on replacing the battery pack every few years.

(From: Roger Fillingim (rfilling@uab.edu).)

I've had two electric mowers, both cordless - a Ryobi and a Black & Decker. The B&D was rated as a 5 HP engine, although I have no way of knowing whether it delivered the same power as a 5 HP gas mower. I used my electric mowers on a small lawn. I would agree that the electrics don't do as well on a overgrown lawn, but other than that my electric, especially the B&D, were great. I still have the B&D, but I'm in an apartment right now so I don't have much use for it. But, when our new house is completed, I plan to use it again.

While charge time and power are potential downsides of electric, not having to change the oil, fill up with gas, pull a starter cord, etc... are substantial benefits in my opinion. Also, electric lawn mowers are much quieter and more environmentally friendly. If your yard is not too large and you mow fairly regularly, electrics are an option to consider.

(From: Pat Kiewicz (kiewicz@mail.wwnet.com).)

I hung up my reel mower for my Black & Decker rechargeable electric, for the very same reason. My mower also can bag grass for those occasions when due to circumstances beyond my control I must cut grass that is too tall or too damp or when I want grass clips for mulch or composting.

It runs on a lead-acid battery (same technology as your car battery) and can survive the winter in an unheated garage. I have to go rechargeable if I want to go electric as my lot stretches back 200 feet or more from the nearest plug. The battery should last a good, long time if not abused. (How often do you have to replace your car battery?)

I believe the most recent issue of National Gardening Magazine has an article on electric mowers, with comparison between the features of different brands and models.

(From: user@execpc.com (C. Ligh).)

I bought the Toro 24V rechargeable $349 based on the free video tape Toro provided describing all its features and options. The problem with the rechargeable is run time.

I have a 10,000+ sq feet lawn and after about 35 minutes mowing the battery level lights went out. The owner's manual states: one should stop and recharge after the lights are out or the batteries' life will be shortened. Anyway there was still power left and I finished the lawn in about 65 minutes. With the prospect of replacing the batteries every year and run time shortened after every use, I returned the mower.

Toro does offer a 30 day return. You might want to give it a try when you have grass. Get the corded model if you don't have too many trees and save a $100.

When ever my 13 years old Honda dies, I'll probably get a corded electric mower. But I do miss the quietness of a electric and absence of exhaust fume.

P.S. There is a 36V rechargeable, but it's a $100+ more. So, will replacing the two batteries = $200?

(From: Michael Lamb (michael.lamb@nciinc.com).)

I own an electric mower now. It's a beefed-up Sunbeam. I found it on the side of the road and did a bit of 'customizing' to it. I like it MUCH better than the gas thing I had for years. The cord is a bit of a bother but when I think that I'm polluting far less and it uses far less power (costs about 25 cents less energy to cut the yard compared to the old gas one) AND it doesn't stink and be a pain to start and a health hazard and is quieter too. I might get a new cordless eventually but the $375 price tag is a bit much. I tried one out and think they are pretty nice, far lighter than a gas mower. Besides the one I have does very well for now. A friend of mine bought a B&D cordless, she likes it and has no problem doing her yard and her neighbors too! (she likes cutting grass)

(From: ap052137@idirect.com).

Have really enjoyed the convenience of a cordless mower. Bought it in 1992 and went to replace the battery. It is a model 3300m and got the shock off my life when the first place I tried quoted me a price of approx $236 cdn. I got in touch with B&D and they directed me to another dealer where I got it for $93. However, this dealer told me that the new price list does indeed show $236 cdn for new stock. Goodbye B&D the next time the battery needs replacing. I can buy a complete gas or ac unit for the amount of money.

(From: Mike).

The problem you state does not exist for only B&D lawn mowers, but *any* rechargeable product. Batteries do not last forever, and typically account for more than 50% of the cost in any tool. Often times the batteries are a standard size and you can get relatively inexpensive replacements at electronic stores. As an example, most cordless drills use sub 'C' cells which run about $1.75 a piece from Tanner Electronics in Dallas, Tx. For comparison, B&D wants $20 for their replacement (four batteries).

At the risk of sounding like a zealot...the people that think they are "saving the environment" with their electric lawn mowers are fooling themselves. In the first place, all you've done is moved the pollution from your backyard to somebody elses, and soon we're going to extend this fallacy to cars (oh, joy...smog in the country). In the second place, the process used to produce Cadmium plating is so toxic that even the US military is phasing out its use, while most foreign (non-US) governments outlaw its production entirely. "Green factor" wise, we're all probably just as well off with oil burning tub-thumpers.

I predict in the not so distant future (10-20 years) we'll see the end of NiCad powered appliances either because governments ban them, tax the daylights out of them, or nobody will be dumb enough to build the batteries anymore. At the very least, expect to see mandatory recycling programs for *all* types of batteries (not just lead-acid). Regardless, prices will sky rocket.

Ok, soap box mode off :).

(From: J. Matthew Good (jmg14213@ix.netcom.com))

First, battery powered lawn mowers use Lead - Sulfuric acid batteries, just like in your gas powered car, only smaller. Second, these batteries are one hundred percent recyclable. Yes, that is 100%.

To the original poster: The only problem with battery mowers is that you must follow the directions about over- charging. Also, they are sealed, as most of them are installed laying on their sides, so ordinary replacement batteries would leak.

Ryobi has replaced the pair of batteries in their machine with a single 24V unit which lists for about $95 US, PLUS FREIGHT. From what I've seen, they are lasting anywhere from 2 to 3 years for most users. To make it last longer, charge only until the indicator says it is fully charged, then unplug it. On a Ryobi, the light turns from red to green to indicate full charge, and supposedly goes into float charge. Don't take a chance, when it turns green, or whatever Black and Decker's equivalent is, Pull the Plug.

(From: Ronald Kramer (kramerr@oasys.dt.navy.mil).)

This is my third year with a so-called 5HP Black and Decker battery electric. I think they are crap! I couldn't mow the lawn due to rain this weekend once again so the grass got to be twice the cutting height. This requires that I cut without the bag which causes the grass to clump. I then have to go over the area again with the bag. For my 12500 sq. ft. yard takes 4 days because I have only 50 min of charge. So when I finish I have a yard of grass at different heights and it is time to start mowing again.

(From: Jeff Canavan (Canavan@foodfac1.rutgers.spamfree.edu).)

I recently had the decision to make regarding a new lawn mower. I went with all electric stuff for the yard; corded combo weedwacker/edger, 16" chainsaw and Black and Decker CMM1000 rechargeable lawn mower. Searching through prior usenet posts with Dejanews.com, I found mostly good comments about the lawn mower and thought I'd give it a try. It comes with a 30 day money-back offer, so if I really hated it, I could return it to get a corded one or a fume belching fossil fueled model. After plugging it in overnight, I mowed the grass for the first time last Sunday, (it hadn't been mowed for 7+ weeks) After mulching the 1/2 acre of shin- to knee-high grass and weeds, the charge indicator was still in the green zone halfway between the Fullest and the yellow. The box states 1/2 acre range, including driveway, walkways, and house. It must be conservative or I got a really great set of batteries.

Discounting all ecological debates regarding macro pollution issues;

Pluses:

- No gas or combustion fumes to take away the fresh cut grass smell (Do ANY gas mowers have catalytic converters?).
- No starting hassles.
- No gasoline to store, spill, or deal with.
- No oil to change, ever.
- Quieter than gas mowers.
- A real metal cutting blade, (some corded model have nylon cords).
- Better cutting power than most corded models, (5hp).
- No power cord to trip on or wrap around trees (I have many).
- Mulches or bags mulch, (I tried it with leaves, it worked well).
- One lever to control cutting height for all wheels

Pluses, neutrals, or minuses, (depending on your view of yardwork):

- Won't cut wet grass well, (i.e., wait for a nice evening)
- Limited run time, (If it won't cut all your grass at once, I'd consider something that would, unless you don't mind waiting for a recharge).

Minuses:

- Expensive, I paid $359 at Home Depot.
- Only a 19" cut, smaller than most gas mowers, corded ones are equal or greater.
- As heavy as gas mowers, corded models are lighter.
- Require a dedicated outlet to store and charge.
- Long term battery life (?) & Battery replacement costs ($?).
- Push mower, not self propelled.

(From: Frank Wilder (frank.wilder@intrlnk.com).)

We have an 18" rechargeable Black & Decker electric and we really like it. We bought a refurbished unit at a Black & Decker outlet.

Pros:

- Can use during Ozone Action Days

- Easy to start -- just engage the switch. (It's always entertaining to watching the neighbors with the gas mowers try to get them started).
- Quiet -- you can cut your grass early in the morning or late in the day and not bother anyone. I also use my walkman while cutting and I don't have to have the volume all the way up.
- It cuts my yard (1/3 acre) with plenty of charge left over. Every so often I run the batteries all the way down before recharging. It runs for another 45 to 60 minutes after I am done, but this is with the mower sitting on the driveway (no load on the cutting blade).
- Very little maintenance.

Cons:

- Mine only cuts an 18" track, but some may cut wider.
- Mine only cuts a small yards (< 1/2 acre)...but each mower is different.
- What do you do when the batteries ware out? and how long will that be?
- Mine doesn't allow you to raise the deck as high as I would like to.

I am happy with the one I have but I can't wait to upgrade to a bigger one. The newer B&D lawn mowers look really great.

(From: Dave Clark (Dave_Clark@dg.com).)

Country Home Products, the people who make the DR Field and brush mower offer a cordless lawn mower that has a removable battery. The battery has a built in handle and lifts out of the mower housing for easy replacement and charging. If it is half the quality of the DR Brush mower it is a great mower, and a great company to do business with. They are located in Vermont, and you can get their number from 800 information (1-800-555-1212).

I don't own the mower (yet) but am considering it for my mothers house. I do own the DR and I love it. I have no interest in this company - but I am a very satisfied customer.

(From: Topher Eliot (eliot@alum.mit.edu).)

I'm happy with my Sears electric. I discovered on trick for dealing with the cord: use a heavy duty, long cord (100', 12-gauge in my case) with a short light cord at the end (20' 16 gauge). This allows moving back and forth a moderate amount without having to move that heavy cord.

BTW, I don't think I really needed that 12-gauge; in retrospect a 14-gauge would have been better.

Comments on mulching mowers

(From: Jeff (kahlua53@aol.com).)Kahlua53

Mulching mowers are nice, you don't have to bag any of the grass that you cut. Mulchers do need a bigger engine, that's why if they are used to mulch make sure it is at least a 5 hp 21" or less (6hp for a bigger cut). Mulching adds moisture and acts as fertilizer for the lawn. The bad thing is that you need to cut the lawn every four to five days. If the grass gets too long the mower can't cut the grass as well as it should (also it's not good for the grass if you cut off more than a inch at a time that is when the mower is set at 3 inches). So for that reason it would not look that good if it was to rain a lot and you could not cut the grass. As for me I have both types that works out very well.

Comments on inexpensive lawn mowers

True or false?:

> "Throw away mowers will always cost you more in the long run. Murrays and MTDs are bargain basement mowers, and you most definitely get what you pay for."
>
> "The problem with Murrays and MTDs is that they use the cheapest engines and components available. If you manage to get the engine to last, the rest of the mower will fall apart around it. Remember, the reason K-Mart, Lechmere, Caldor, and other mass merchandisers sell these machines, is because they want you to come back every 2-3 years to buy a new mower from them."
>
> "Murray is a bargain basement brand sold by mass merchandisers who want you to come back for a new mower every 2-3 years, and Tecumseh engines at about the same. :-(If you manage to get the engine to last, the deck will fall apart around it. On the bright side, at least they are cheap."

Some responses:

(From: Jan Hickman (janry@ix.netcom.com).)

Yea!! My bargain basement (cost under $100 when new) Murray is over 10 years old and I'm cutting .4 acres with it. You can bet when it wears out (if it ever does) I'm gonna buy some mega bucks mower!! But if you do take that bet, let me in on the other side of the action. Keep the blade sharp, the air filter clean, topped up on oil and they will run for a looooong time.

(From: Don Sterner (No@junk.email).)

Well, my Murray has a quality Briggs & Stratton engine which is still running fine. My problem is that the deck has rusted and is now a shell of its former self. There is barely enough metal left to hold the blade shafts in place. The mower is only 2 1/2 years old, but we do live on salt water (next to it, really). All of our property is well above the water line - the mower has never been wet with salt water. I've made it a practice to always hose the mower down after use and I keep it under cover when not in use. The only replacement decks I can locate cost nearly as much as a new mower.

Our previous mower (a Craftsman) was returned to Sears within 6 months after it had lost much of its paint and was covered with rust.

(From: BELJAN E (lvpy67c@ix.netcom.com).)

My MTD mower holds up fine, and I have the killer lawn. It burns out virtually every lawn mower's engine, whether it is Briggs or Tecumseh. I bought my MTD and it is a self propelled with 3.75 hp Briggs & Stratton Sprint engine. I would buy the same mower again, the problem is I probably wouldn't need to! The mower is so durable, it is unbelievable (I should note it is last years front cog drive which now is 4 hp quattro, and it is still sold with the 3.75 HP engine as Lawn Chief.) It survived a year and still doesn't burn oil! That is a major accomplishment. The only trick is to put Marvel Mystery Oil into the gas and oil. I also have a 16 year old Snapper and it still goes. Regardless, MTD is well worth it. You get a cheap mower that in my estimate unless you abuse it will last 5 years or more with good maintenance. $100 or so for 5 years of use (and it isn't hard to maintain them) is an excellent deal. A $600 mower could last less than that.

(From: Floyd Reed (floyda@ix.netcom.com).)

If you take care of amy mower, you can expect a reasonable amount of service out of it, usually comparable to the price. True, Murray mowers are cheaply built, but they build an awful lot of mowers... with different name brands. Most still carry a substantial warranty. As for Tecumseh engines, years ago they were the more expensive engine, placed on the more expensive machines. They were the only engine of this type and size to incorporate an actual oil pump. I never did care much for them as they liked to burn exhaust valves and blow head gaskets. The carburetors left a little to be desired also. They were good for my small engine repair business. I am out of the business now and have not taken one apart for a long time and do not know how they are being made today, but I'll bet if you take care of them and change the oil regularly as well as keep the air cleaner clean, you will receive respectable service out of it.

(From: Jan Hickman (janry@ix.netcom.com).)

My Murray with a 3.5 HP Tecumseh engine is over 10 years old. The only parts replaced have been the wheels, the spark plug once and the blade a couple of times. The lawn area I cut is approximately 1/3 acre. Will I ever buy a $500 quality lawn mower? Not as long as I can get one to last like this. And by the way - it's not luck, it taking care of them. I know several people whose bargain basement brands last several years and they all have one thing in common. They take care of them."

(From: Patrick J. McQuiggan (PMCQUIGGAN@cardinalfinancial.com).)

I've had a Murray since 1990. No problems whatsoever. Also 1/3 acre. Use it regularly. Follow maintenance advice. Engine is Briggs & Stratton 5 hp and it is self propelled. A bargain.

(From: Bijan Mobasseri (mobasser@vu-vlsi.ee.vill.edu).)

I am amused with the high power recommendations here: Honda, Toro, Snapper, Lawnboy, some costing $600. In 1989 I bought a walk-behind Murray for $99. This morning, as in all Saturdays, I pulled it out of the shed, gave it ONE pull and as always it started. It is still running on the original plug (Tecumseh engine) and the only thing I have replaced is one $5 wheel.

Comment on high wheeler and wish list

(From: Edward Rice (ehrice@his.com).)

I've got a non-propelled high-wheel, it's okay. Nothing very exciting. My lawn is hilly but not bumpy, and I had gotten the high-wheeler to assist in shifting over edging and over flag walkways, and it's okay for that - but not so great that I'd bother with a high-wheel design in the future.

What I would *love* to get in the future, and maybe that 'weed whacker on steroids' is what I really need, is something that would let me go casually over edging, so the blade is cutting grass on one side and safely *not* cutting 1 to 2" river stones on the other side. This is made worse because the left-hand wheels on the stone (typically, with a right-throw mower) jiggle up and down enough that the occasional stone does get whupped.

I'd also be interested, if anybody makes one, in an *offset* mower, in which the left-hand wheels were not to the left of the mower housing. By increasing the wheelbase and putting one fore and one aft, I would love for the left side of the mower to be cantilevered out with nothing under it but the blade, to let me get really close for edging. I don't want a specialized edger - I want a mower that can do the job through the simple expedient of getting the left-side wheels out of the way!

Comments on plastic decks

(From: Joe Kowalski (builder@proaxis.com).)

I bought a new Honda with a plastic deck. I like it. The plastic is not like regular plastic; in fact, it has proven bulletproof. It is very lightweight. I mowed many rocks, keys, etc. with no problem. It was a concern of mine when I bought the unit ($660), but the salesman convinced me that it was 'put through hell' to prove its vitality.

Comments on Briggs & Stratton versus Tecumseh engines

These two manufacturers produce the vast majority of small engines used in low to medium priced yard equipment.

I have always preferred Tecumseh engines over Briggs & Stratton though perhaps this is more of a touchy-feely thing than representing any really fundamental difference between the two. The float carburetors (e.g., Craftsman) do tend to gum up if the gas is not drained at the end of the season but they are easy to clean and rebuild. (Also, I have picked up several mowers dirt cheap at garage sales where the only problem was a gummed up carburetor - 15 minutes work to remedy.) Change the oil regularly and Tecumseh engines will keep going for a long time.

(From: BELJAN E (lvpy67c@ix.netcom.com).)

> "What a JOKE!!! Try rebuilding a '72 carb sometimes, the floats are terrible, I finally slapped a '91 4 HP carb on the 4 HP '72 and it works now!!!! Some newer ones can be saved, but 10 years of sitting with *leaded* gas, that spells the end."

Hehehe... A guy just sent me a couple of carbs that were probably closer to '72 than '91. A new needle, seat, and hinge pin (in one case) was all that was needed (beyond the gallon of carburetor cleaner!). :-)

(From: BELJAN E (lvpy67c@ix.netcom.com).)

> "It depends on how the gas was in, if you drain the float, you should be able to get it clean. Another trick is to put Marvel Mystery Oil in the float assembly and let it sit there a week, in 99% of cases, that will get it running. On the '72 carb, The gas formed crystals around all of the parts, I put all sorts of carb cleaners in, and I replaced the rubber seal, float, needle, and all replaceable parts, it didn't work. I pulled the carb off (this happens to be a '72 Tecumseh off a Sears engine. My guess is that is was overhauled so I got it starting on one pull with starting fluid). I took a '91 Sears (Tecumseh) carb off and bolted it onto the engine, since this is a power reel mower, the engine isn't easily replaced, the new carb is from a primer type non-choke engine, so I made a rubber plug in the hose to the air filter assembly to spray starting fluid into the carb to start it. Now it works fine. It looks strange but runs great!"

(From: Thomas N. Harding (harding@coypu.cig.mot.com).)

> "I would like to add that Tecumseh engines are easy to rebuild. Most folks would be surprised how few parts are in them."

(From: Steve Ordinetz (steveord@xtdl.com).)

> "Several years ago I worked with a guy who rebuilt small engines as a sideline, and he was partial to Briggs & Stratton because parts tended to be pretty standard from year to year, while Tecumseh were less interchangeable between similar engines of different vintage."

(From: Terry Highley (terry.highley@daytonoh.ncr.com).)

> "I agree 100%!!!"

(From: BELJAN E (lvpy67c@ix.netcom.com).)

> "Ha! I have had no trouble forcing Tecumseh engine parts to fit on same horsepower engines, and they all worked fine, I had spent over 30 minutes starting one with stale gas once though!"

Comments on Honda overhaul

(From: Israel Kantorowicz (kant@sqi.com).)

I recently damaged the engine on my Honda mower, so here is my experience (Seattle area):

The engine is well built and fairly easy to work on. Their manual specifies a bunch of special tools, but I was able to take the engine apart and put it back together with just "ordinary" small engine tools. The only problem I had was with the flywheel. It has no threaded holes, and needs to be held around the periphery with something like a belt-wrench while torquing the center bolt. For the same reason, a large gear-puller is required to remove the flywheel from the crankshaft. I did not attempt anything ambitious like replacing valve seats, though. All threads on this engine are metric, of course.

The manual (available from dealers) is very clear and well illustrated. Carb rebuilding is not covered, however. Part numbers are listed in a special "parts manual", not in the regular one.

Note that Honda appears to have a policy of not letting anybody but their dealers get in touch with their central tech support. They don't publish their phone number, and there is no email address either. I could not find the timing mark on the crank, and the dealer could not or would not help, so guessing was the only option left... I don't know if other small engine makers are any better in this respect, but I am used to customer support meaning something entirely different in my line of work.

No trouble getting parts, but they all had to be "special ordered" from out of state, taking about a week to arrive. They seem very expensive to me. A rod was $50+, a set of piston rings, valve springs, or head gasket $20+ each, and the crank (which I luckily ended up not needing) was supposed to set me back about $185. My relatively minor repair ended up being about $125 in parts (taxes, oil, and band-aid for bruised knuckles not included).

The mower has served me well, and the only problem other than caused by my own fault was premature wear of the blade clutch lining. The plastic deck seems to take rock hits much better than an aluminum deck that I owned some time ago, and there is no paint to peel of from it.

Walk behind versus riding mower or tractor

(From: Stephen M. Henning (shenning@fast.net).)

The forward speed is about the same for a walk behind and a rider, about 3 mph. The main variable is the width of the mower. Let's say we have a 42" mower. If the overlap is 4", then we have 38" cut.

Then the time to do one acre with a 42" mower is:

220 ft. x 220 ft. / (3.17 ft x 4.4 ft/sec x 60 sec/min) = 58 minutes.

In summary:

- 24" mower is 110 minutes per acre
- 36" mower is 69 minutes per acre
- 48" mower is 50 minutes per acre

You can go faster with a rider, but the quality of cut degrades. The walker gets slower for a large lawn since one gets tired and takes more breaks and tends to slow down on the turns.

I would recommend only a tractor that had a cast iron engine and a rear discharge mower. I had a tractor with an engine with aluminum heads. The first engine failed and I replaced it and the second failed. They both warped and eventually failed. I got a tractor with a cast iron engine and it never quit. Eventually it got so old that when the fuel pump failed, it could not be replaced. Now I am using a WheelHorse/Toro with a 17 HP Kohler 2-cylinder cast iron engine. It is a great machine and has worked flawlessly over 12 seasons. The 17 HP is excessive for mowing or pushing snow, but the 2-cylinder engine is great. I can mow for 5 hours and not get the least bit fatigued. However, with 1-cylinder engines the vibration was so great that my toes and fingers would become numb in less than an hour. I had to take a break every hour to recover.

For the mower, get a steel rear discharge mower. The first mower I got was a cast aluminum mower. Every rock the mower picked up knocked a chunk out of the housing until there was nothing left. Then I got a steel mower, but the aluminum engine gave out and it was not prudent to get a third engine for the steel mower. I did get a tractor with a cast iron engine that could use the steel mower and this combination lasted 20 years.

Now on the WheelHorse/Toro I got a rear discharge mower because it does not throw objects like the side discharge machines. Also, when the grass clippings are too heavy to leave on the ground, I can collect them with a simple sweeper and not need a motorized collection system. Also, it doesn't throw clippings on the flower beds and walks or make passing motorists think they are going to be attacked. It is also easy to mow next to shrubs and trees on either side of the tractor. You don't have to always mow with the discharge to the mowed or unmowed side, depending upon what you are trying to accomplish.

A lawn mower for the security minded

Smarter (and lower maintenance) than the average cow...

> "This is a lawn mower that is solar powered and stays within a buried wire boundary. It also 'learns' the layout of your yard and will even put itself away at night. Does anyone have one of these devices? It sounds great, but at $1,500, I would like some real world product feedback."

(From: ranck@joesbar.cc.vt.edu).

I don't have one, but apparently the CIA has two. They use them in a courtyard that is completely surrounded by one of their buildings. The robo-mowers were seen as a better solution than having to have a security officer escort some person in/out and watch them mow.

The miracles of JB Weld

-------------------- OK, I have no idea of whether the following repair will actually hold up but I supposed there is nothing to lose by trying:

(From: Andrew Bowers (falcon_@geocities.com).)

I just did something cool!

My friend Dan gave me a 3.5 HP Briggs & Stratton horizontal shaft engine, which burned oil like crazy. I took it completely apart, (Dan had started to, but he hadn't taken the actual block apart, he had just taken the carburetor, muffler, and flywheel cover off) and found a _deep_ gouge in the cylinder wall. The rings were fine, except there was a chunk missing from the oil ring. Here comes the "miracle" part. Most people would have just chucked the engine, or kept it around for parts. I grabbed my thing of JB Weld ("the world's finest cold weld"), mixed some up, and filled in the gouge. The next day, I sanded the patch smooth, and put the engine back together. Started on the first try. Still burns oil (due to the missing segment on the oil ring; the auto parts store I went to didn't have piston rings, can you believe that?), but runs pretty good. (Well, the injectors in the carburetor keep getting clogged, and it won't start, so we're going to get a new, *plastic* gas tank).

Interesting lawn mower repairs

(From: Sean Smith (seansmith@racemark.com).)

When I was 17 and still living at home, mowing the lawn was part of my chores. Well, I didn't have a running lawn mower and my Mom insisted that I mow the lawn. She pretty much stated that she didn't care how I did it, as long as it got done.

So, I figured that I needed to get one of them running, and I couldn't for the life of me figure out what the exact problem was but I wasn't getting spark, so I figured that it had to be the magneto. Well, I didn't have the resources to get a new one, so I did the next best thing, I rewired it!

Mom comes out to find me mowing the lawn with a car battery and a coil strapped to the thing. Ran a line from the condenser to a spare coil I had for my VW Bug and strapped an AC/Delco to the thing and away I went. It was a bit heavy but it was better than nothing. I still wish I took pictures of it.

(From: Charles Gilley (gilley@bravewc.com).)

My coolest repair was rebuilding my B&S after letting the oil run out. After I put it back together and with great anticipation, I began to pull and pull and pull.... I was impressed. It was silky smooth, but the darn thing would not start. I sat down to rest, glanced at the bench... to see the valve lifters still sitting there.

Sigh.....

Importance of having the correct valve clearance

(From: Derrick Setchell (D.Setchell@eastman.ucl.ac.uk).)

My father-in-law owned a Flymo with a 3.5 HP Briggs & Stratton. He'd had it for nearly twenty years, but never used it much because it was "hard to start", especially when hot. He has other mowers and neither of us had found time to investigate it. Why he didn't return it for warranty investigation at the start is lost in the mists of time.

This year, he felt it was taking up space in his barn and was going to throw it away, so it was rescued by yours truly. I thought the motor might be a useful standby in case the even older Aspera (European Tecumseh) on my own rotary packed up. That's been a fine engine, by the way. The B&S was in a pretty good state considering, but sure enough took up to fifteen pulls to start when cold and would not re-start at all if fully warmed up. It did look like it'd been HOT, with the usual blockage of ventilation spaces by clippings, but otherwise well preserved.

I gave it a complete carb and magneto overhaul which improved cold starting somewhat, but not the hot. I also felt it was a bit "gutless", so then investigated the combustion chamber and valves. This poor machine had virtually NO valve clearance when cold, on either lifter. The valves were still in pretty good order, so my assumption is that it was shipped that way from the factory. Once it got hot, the compression must have been zero, though it didn't obviously seem to be.

A thorough clean, careful adjustment of the valve stems with a diamond hone (out of the engine !!) to provide the upper limit of the specified cold clearances and back together it went. What a contrast ! It now starts first pull, hot or cold, and runs like it should have done when it left the factory. My guess is the magneto and carb were fine all along in this lightly-used engine. Next time I'm going to look at those valve clearances earlier in the sequence, even if the engine isn't old....

Internal Combustion Engines

Small engine technology

If you have some idea of how your automobile engine operates - or a Model T Ford for that matter - then you know the basic operating principles of your small engine as well. In fact, your Craftsman Eager 1 has a lot more in common with a Model T than a Honda Accord. However, strip off, the electronics, pollution control devices, and engine powered accessories, and the basic mechanical construction is very similar, though the lawn mower engine is not manufactured to quite the same tolerances and with the same quality materials as an automobile engine.

Nearly all small engines up to 20 HP or so are single cylinder affairs - one piston, one spark plug, no distributor, forced air cooled - about as simple and straightforward as it gets.

If you have never been under the hood of your automobile, then the description in the following sections may be of some help.

The next chapter: "Engine Diagrams" provides an explanation of each of the 4 strokes of a 4 stroke engine. However, if you cannot get the hang of my fabulous ASCII graphics, check out the following site:

The How Stuff Works Web site has some really nice introductory material (with graphics) on a variety of topics relating to technology in the modern world. Of relevance to this document is an article on "How Car Engines Work" which is really mostly about the basic principles but WITH some real animated graphics!

Types of engines

Unless otherwise noted, most of the descriptions and procedures in this document apply to both 4 stroke and 2 stroke engines. However, there are fundamental differences in the proper fuel and oil that is used with each type.

The small 4 stroke engine has a separate oil sump just like the engine in an automobile. Therefore, gasoline and oil are separate. Oil changes are also required.

WARNING: a new lawn mower or other piece of yard equipment will very likely be shipped without oil or just a minimal oil fill. Check it first and add oil if necessary. Running an engine without oil for a few minutes can cause serious - or terminal - damage. Even if your mower was assembled by the store where you bought it, don't assume they filled it with oil and tried it out!

The 2 stroke engine requires that the gas and special oil be mixed prior to use in specific proportions. Leave out the oil - or get your gas cans mixed up - and you will quickly ruin a 2 stroke engine due to lack of lubrication if plain gas is used by mistake. Clearly label the gas cans for each type and instruct anyone using them in the proper fueling technique.

Portable tools like chain saws, weed whackers, and backpack type leaf blowers use 2 stroke engines as these need to operate in a variety of positions.

Stationary or wheel-about equipment including most lawn mowers, rototillers, shredders, backup electric generators, and large blower/vacs, use 4 stroke engines.

Another distinction is that engines smaller than about 2 horsepower are generally 2 stroke while those larger than 2 horsepower are generally 4 stroke but there are exceptions. Lawnboy lawn mowers tend to have 2 stroke engines and there are some types of equipment with very small 4 stroke engines. Of course, if your engine has a cap marked 'oil' then it is a 4 stroke.

Larger pieces of yard equipment like riding mowers and lawn tractors use 4 stroke engines that are really very similar in most respects to their smaller cousins - much more so than to the engine in your automobile, for example. Similar servicing procedures apply. In fact, if you read the respective chapters in any of the engine repair books for engines (listed in the section: References) under 5 horsepower and those between 5 and about 20 horsepower, the only significant differences will be in the size of the various engine parts!

Parts of a 4 stroke engine

You may be surprised at the large number of individual parts which comprise the engine even on a $100 mower. The following description is for a typical single cylinder 4 stroke engine as would be found on most rotary mowers, rototillers, shredders, backup electric generators, larger snow throwers and leaf blowers, and even modest size riding mowers and lawn tractors:

- Fuel tank and fuel line. This may be on the side, above, or below the engine intake. A fuel pump may be present - either as part of the carburetor or a separate unit if it is not gravity fed. There may be a fuel cutoff valve and fuel filter and/or filter screen) as well.
- Shroud or blower housing. Since these engines are all forced air cooled, (no radiator, water jacket, or thermostat) the proper air flow is extremely important as air is much less efficient than water at removing the substantial heat energy generated by a running engine. This piece of sheet metal precisely guides the airflow. The engine should not be run for any length of time with the shroud or blower housing removed.
- Oil filler pipe. On many engines, this is just a hole near the base fitted with a screw-in plug. On fancier models, there is an actual extension tube with a dipstick usually fitting into that hole in the base and sealed with an O-ring.
- Starter. Like an automobile engine, some means must be provided to supply an initial rotation.
    - Pull or recoil starter. This is by far the most common on small pieces of yard equipment. A self retracting cord wrapped around a one-way clutch acts on the crankshaft directly. Less common variations include wind-up starters and a simple rope wrapped around a drum.
    - Electric starter. A small motor - usually powered from a wall socket - drives the edge of the flywheel via a self releasing gear. On larger equipment, as in an automobile, an on-board battery provides the electricity. The battery is recharged by an alternator while the engine is running.
- Air filter. The air used by the engine should be free of dust and larger particles. Most yard equipment will include one of several kinds of air filters - paper, foam, or oil bath. However, engines used exclusively in equipment used in low dust environments like snow throwers and outboards may lack an air filter. Types of air filters include:
    - Paper air filter. This is similar to the filter in a vacuum cleaner. The pleated paper element must be replaced when clogged.
    - Foam air filter. This uses a piece of foam rubber lightly coated with engine oil and can be washed in detergent or soap and water when dirty and recoated though replacement will be required if it is badly deteriorated.
    - Oil bath filter. This contains an oil reservoir and filter element. These can be drained and cleaned. Refill to the 'full' mark with the same type of oil as used in the engine crankcase. The oil bath air filter is much less common than the paper or foam type.
- Carburetor. The function of the carburetor is to provide a precise air-fuel mixture to the engine under a variety of operating conditions including:
    - Starting. A higher ratio of fuel to air is needed when starting and/or the engine is cold.
    - Idle. Just enough flow is maintained to keep the engine from stalling.
    - High. Full flow is provided with engine speed limited by feedback from the governor.

- Load pickup/acceleration. The proper air-fuel ratio and amount of fuel must be maintained when the equipment is placed under load or encounters an increased load and when switching from IDLE to HIGH, for example.

  Several functions are incorporated in a carburetor:

- Fuel control - float, diaphragm, suction. A variety of means are provided to maintain a nearly constant supply of fuel despite varying levels of gas in the fuel tank.

  Craftsman and Lawnboy carburetors use a float similar to the system used in automobile engine carburetors (when they still used this technology). A hollow float maintains a constant level of fuel in a reservoir called a float bowl by acting against an inlet needle valve. The fuel tank will usually be above the level of a float carburetor though a fuel pump could also be used. See the section: Basic operation of a float type carburetor for a more detailed description and diagram.

  Where equipment may be operated in any position, a diaphragm carburetor is used. A flexible disk (diaphragm) with atmospheric pressure on one side and intake pressure on the other is used to maintain the proper air-fuel ratio (this is a gross simplification!).

  Briggs & Stratton engines usually have a suction lift carburetor with a built-in fuel pump. Some simple ones don't even have a fuel pump but depend on suction alone to pull gas from the tank. In both cases, the fuel tank is usually below the carburetor. If there is no fuel pump, the fuel tank should generally not be less than 1/3 full for proper operation.

- Venturi. If you look into the air intake of a carburetor, you will see a narrowing of the passageway. This is called a venturi and results in higher velocity air flow and lower pressure at the center of the narrow section. Just as when you blow across a soda straw submerged in a liquid, or use a bug or lawn sprayer, this lower pressure will suck up the liquid and inject it into the moving air stream. In the care of gasoline, evaporation is almost immediate.

- Throttle. A plate that can rotate to close or open the outlet from the carburetor to the engine intake pipe controls the flow of the air-fuel mixture to the engine. When fully closed, the engine will stop. When slightly open, the engine will idle. When fully open, maximum power is developed. To limit rotation speed with little or no load and to maintain proper speed under load, a governor acts on the throttle plate to keep it at the proper setting under all normal operating conditions.

- Choke. A plate that can rotate to partially close off the air supply is placed in the air intake side of the carburetor. This is usually set manually when starting, particularly in cold weather, to make the mixture richer - more fuel with respect to air - as needed. The carburetors most newer equipment have automatic chokes or other methods of accomplishing the same objective.

- Flywheel. The flywheel in a small engine serves several functions:

  Provides some or all of the inertia so the engine can coast through the 3 non-power strokes of the full cycle (4 stroke). However, with rotary mowers in particular, the blade provides some of the inertia due to the use of a lower mass (lighter, so this is not all bad!) flywheel.

  - Provides the electrical energy for the most common magneto based ignition system. A powerful magnet mounted on the edge of the flywheel passes by a coil (and possibly other stuff) once per rotation. This is part of the ignition system and either provides the high voltage for the spark directly or charges a capacitor which is then discharged (by a solid state switch triggered by the flywheel magnet rotating past a sensor) into an ignition coil at the proper time to generate the spark.

- Includes the fan blades which provide most of the essential cooling airflow.

- Links to the starting mechanism. For recoil or other manual starters, the starting device attaches to the center of the flywheel. For electric start, the flywheel will have a large gear along the outside that is engaged by the starter motor gear (with an overrunning clutch).

- Engine/blade brake. Releasing the dead-man bar engages a brake pad that is usually applied to the outside of the flywheel.

  A soft metal key locks the flywheel to the crankshaft. This is designed to shear (break) to protect expensive engine parts should the engine stop abruptly (due to blade of a rotary mower striking an obstruction, for example). In this case, the flywheel inertia will attempt to keep it moving and it is better to shear the key than to fracture the flywheel or crankshaft.

- Blade adapter. This fastens the two ended cutting blade to the crankshaft. A key part (no pun intended, well almost) is the locking key. This may be a half circle (called a Woodruff key), rectangle, or part of the blade mount bracket itself. Its purpose, like the flywheel key, is to break cleanly should the blade strike an obstruction thus protecting - hopefully - the expensive engine parts from damage. However, see the section: Why you really don't want to attempt to move an immovable object for the reasons this isn't always successful and using your mower to trim rocks and curbs really should be avoided. Therefore, it is essential that the key be made of the proper material - a soft metal. Never replace a broken key with one made of steel 'because it is stronger'.

  For other types of equipment, various adapters are used to couple the driven device to the engine crankshaft. These may include gear reducers or multispeed transmissions, belt or chain drives, or a direct connection to a blower, vacuum, or pump impeller, or electric generator or alternator. As with the blade adapter, a soft metal key or shear pin will likely be used for protection.

- Spark Plug. The ignition source for all small gasoline engines is a high voltage spark. There is nothing magical about a spark plug - it is just an insulated electrode with a specific size gap poking into the combustion chamber. However, damage or fouling (gumming up with carbon or other combustion residue) is one of the most common causes of a hard or impossible to start engine. Not all spark plugs are created equal despite their simple function so the recommended replacement type should always be used. In addition, most automotive spark plugs have a longer reach - more threads - and will likely bash the piston at TDC.

- Magneto ignition. These used to use mechanical contact points - controlled by a cam on the crankshaft to determine the timing. Nowadays, most are fully electronic and require no maintenance.

  - Point type. The magnet mounted on the flywheel induces a current in a coil with pole pieces mounted in close proximity to the flywheel. When this current is near its peak, a set of contacts operated by a cam on the crankshaft - the breaker points - open interrupting the current and diverting it to a condenser (capacitor). The current drops abruptly and induces a high voltage in another coil wound on the same core. This coil is connected to the spark plug terminal. It will be 10 kilovolts or more to jump the spark plug gap even under the more difficult conditions during maximum compression. The exact time - angle of the crankshaft - at which the points open is the critical setting. This is usually adjusted by moving the piston to a specific dimension below Top Dead Center (TDC) or aligning timing marks on the flywheel and crankcase and setting the points to just open at this location.

  - Electronic type. These can be designed in several different ways but all must emulate the behavior of the point type ignition replacing just the magneto coil/pole piece assembly and without requiring alterations to the flywheel. See the section: What is inside a small engine electronic ignition module?.

- Engine block. The casting which includes the cylinder, crankcase, intake and exhaust ports and valve guides and seats. The other major part of the engine structure is the crankcase cover/oil sump.

- Cylinder. This is the, well, cylindrical component in which the piston moves. Most small engines are made of either aluminum (most common these days) or cast iron. In most cases, the aluminum type will have a cast iron liner for long life where the piston actually slides. With regular oil changes, there will be virtually no wear.

- Cylinder head (or just head). The cap which encloses one end of the cylinder. On most small engines, the only component mounted in the head is the spark plug which screws into a threaded hole. However, on the most modern (and expensive) small engines (as well as all automobile engines), the valves will also be mounted above the piston in the cylinder head. Fins on the head increase its surface area - absolutely necessary for these air cooled engines to keep their cool

- Crankcase. This encloses the lower working parts of the engine and also contains the oil supply. The flywheel/magneto end main bearing is mounted in one end of the crankcase. The crankcase cover/oil sump seals the crankcase and also includes the PTO/blade end main bearing. Also see the section: Bearings and bushings.

- Valves. These look like metal mushrooms and seat against metal rings mounted in the engine block casting. They are spring loaded in the closed position, slide in valve guides (bored holes), and operated by valve lifters from cams on the camshaft.

    - Intake valve. This valve is opened only during the intake stroke. It is subjected to less stress than the exhaust valve as it is cooled by the fresh air-fuel mixture. The intake valve may be stamped with an I.

    - Exhaust valve. This valve is opened only during the exhaust stroke. It is subjected to more stress than the intake valve since the hot exhaust gases pass out through its opening. The exhaust valve may be marked with an E.

  Note that in most small engines, the valves are not mounted above the cylinder (in the head) as they are in automobile engines. Rather, they are mounted on the side of the cylinder in the engine block. This is done for reasons of cost requiring fewer parts and simpler construction. The cylinder head is then just a casting with cooling fins and a threaded hole for the spark plug. The disadvantage of the side valve engine is lower efficiency and higher pollution. The newest (and currently most expensive) lawn mowers and other yard equipment are incorporating the better overhead valve technology. Eventually, environmental protection laws may force this on all small engine operated devices. However, both types can apparently be made to meet the emissions standards mandated for all new mowers sold after September 1996.

- Valve lifters (tappets). These also look like metal mushrooms with the wide part riding on the cams of the camshaft. Their ends press on the ends of the valve stems to open them during the appropriate part of the cycle.

- Compression release. This mechanism reduces the compression somewhat at low rpms (to make starting easier) by opening the exhaust valve slightly early. A weight disengages the compression release once the engine starts.

- Piston. The piston is a cylindrical close ended plug that slides in the cylinder and is acted upon by the hot gases during combustion. In small engines, it is usually made from an aluminum alloy. Power is obtained by the piston driving the off center crank pin journal on the crankshaft via the connecting rod.

- Piston rings. Springy split rings of cast iron (usually) which fit in grooves or slots around the piston. When the piston with rings is installed in the cylinder, the rings expand and tightly contact the cylinder wall forming a remarkably good seal.

- Piston pin (or wrist pin). The piston is attached to the connecting rod via a polished steel pin (actually a tube) which fits closely in a bearing in the connecting rod.

- Connecting rod (or just rod). A rod with bearings at both ends. Small 4 stroke engine rods are usually made of an aluminum alloy and have no special bearing inserts at either end. 2 stroke rods will have needle bearings due to the type of lubrication available.

- Crankshaft. The main rotating part of the engine. See the diagram in the section: Crankshaft anatomy.

    - Main bearings. The crankshaft is supported at each end by the main bearings. Most inexpensive 4 stroke engines use plain bearings without inserts - just the finely polished steel crankshaft surface rotating in equally finely finished surfaces of the engine block casting. 2 stroke engines may use needle bearings in these positions. Some engines use ball bearings.

    - Crank pin journal. The offset surface where the connecting rod bearing rotates. The is the bearing with the most stress as the full force of each power stroke is applied here. It is the location where damage will likely show up first due to contaminated oil or lack of oil.

    - Counterbalance weights. These two massive weights are part of the crankshaft casting opposite the crank pin journal. They help to reduce the vibration of the engine by partially counteracting the forces of the piston and connecting rod as they move back and forth. Larger engines may have additional rotating balancer shafts which can be designed to do a better job of minimizing vibration than just the counterbalance weights on the crankshaft.

    - Crank gear or timing gear. A small gear mounted on the crankshaft which rotate the camshaft at half the crankshaft speed to control valve timing. The crank gear has half as many teeth as the camgear.

    - A precision taper is located at the magneto/flywheel end for mounting the flywheel and starter components.

    - A cam (possibly removable) may be present under the flywheel location for operating the breaker points on a point type ignition system.

    - An auxiliary PTO gear may be present. This is a worm gear or other mechanism for providing a secondary, usually lower speed, higher torque, power output. A typical speed reduction ratio is 8:1. This may be used to power a front wheel drive sprocket, for example.

- Camshaft. This includes the two cams which operate the valves and runs at 1/2 the speed of the crankshaft. In addition, it may have a compression release mechanism to reduce starting effort and in the case of many Tecumseh vertical crankshaft engines, is part of the oil pump as well.

- Oil/lubrication device. Several types of mechanisms are used to distribute engine oil to all the critical parts in a small engine:

    - The piston rings (oil ring mainly) scrape oil off of the cylinder walls which passes through holes in the oil ring grooves of the piston to lubricate the piston pin at the top of connecting rod.

  All other important parts are lubricated typically by one of the following devices:

    - Oil dipper. An extension to the connecting rod dips into the oil sump on each rotation of the crankshaft and provides lubrication by literally just splashing oil onto where it is needed. (Horizontal crankshaft engines only.)

    - Oil slinger. A pinwheel like affair rotated off of the crankshaft or camshaft flings oil onto where it is needed. (Horizontal or vertical crankshaft engines.)

- Oil pump. A camshaft driven pump distributes oil to the important parts via various passages in the camshaft, engine block, and possibly the crankshaft and connecting rod as well. (Horizontal or vertical crankshaft engines.)

- Governor. This provides the feedback to the carburetor throttle plate to regulate the engine speed (usually for anything but idle speed). Thus, the speed is maintained relatively constant despite changes in load and a engine temperature

  - Air vane governor. The air flow provided by the flywheel/blower passes by a plate which is coupled to the carburetor throttle plate acting against a spring force.

  - Flyweight governor. A spinning gear assembly with a pair of weights is driven by the camshaft. As the centrifugal force of the weights increases, they move a sleeve which presses against a lever whose shaft passes through the crankcase. This lever then operates the carburetor throttle plate against a spring force.

  With both types, increasing the spring force will increase the engine speed.

- Breather. Since the crankcase is otherwise sealed with the piston moving up and down or in and out, some means is required to maintain a negative pressure or else oil might be forced out various places like the bearings an oil seals. The breather is a leaky one way valve which easily passes air out but is mostly blocked in the other direction.

- Muffler. The muffler mounts on the exhaust port and serves two important functions:

  - Noise reduction. As its name implies, the muffler muffles or reduces the loud noise resulting from the explosions of the air-fuel mixture.

  - Spark/flame arresting. The internal baffles of the muffler prevent most sparks or flame from existing the engine even if it backfires.

- Oil seals. These are spring loaded rubber rings which prevent the escape of oil through the main bearings to the outside.

Engine operating principles

These are internal combustion engines which means that the burning of the fuel-air mixture itself powers the engine. External combustion engines use the heat from combustion to expand or boil a working fluid as in a steam engine. Other examples of internal combustion engines are the rotary Wankel engine and gas turbines (jet engines).

The type of engine in your lawn mower or automobile operates on what is called the 'Otto' cycle (if you care). A complete 'cycle' is needed to supply one power impulse to the output shaft. All engines must provide the following regardless of whether they are 2 stroke or 4 stroke, rotary, or turbines (though turbines or jet engines operate in a continuous rather than pulsed manner):

For the following, refer to the section: The four strokes of a four stroke engine in living ASCII art.

1. Intake stroke. Air is mixed with fuel (gasoline for piston engines) and drawn into the combustion engine.

   4 stroke: The air-fuel mixture is sucked into the cylinder through the open intake valve as the piston moves downward on the intake stroke.

2. Compression stroke. The air-fuel mixture is squeezed into a smaller space. This heats it to some extent and prepares it to be burnt. (Note: in a diesel engine, this heating alone causes the mixture to ignite and there is no spark needed). Compression ratios for small engines are typically low compared to automobile engines.

4 stroke: Both valves are closed. The piston moves upwards thus reducing the space above it and compressing the air-fuel mixture.

3. Power stroke. The compressed air-fuel mixture is ignited at a precise time by the ignition system (spark).

   4 stroke: Both valves are closed. The heat produced by the rapidly burning gases to expand and drive the piston downward and because it is connected to the crankshaft, drives the load as well.

4. Exhaust exhaust. The burnt combustion products are driven out of the cylinder. These consist of carbon dioxide, carbon monoxide, water vapor, oxides of nitrogen, some unburnt hydrocarbons, and numerous other mostly harmful compounds.

   4 stroke: The exhaust valve is open. The piston moves upward and pushes the exhaust gasses out through the muffler. A relatively massive flywheel attached to the crankshaft provides the inertia to allow the engine to coast through the non-power strokes (1-3). However, this is not always enough by itself - the blade on a rotary lawn mower is often required as well and a rotary mower may not start easily if at all without the blade in place and tightened securely.

Note that the terms '2 cycle' or '4 cycle' are often used incorrectly when what is meant is 2 stroke or 4 stroke. The cycle is the entire sequence of events including intake, compression, power, and exhaust. The complete cycle for a 4 stroke engine is two complete revolutions of the crankshaft. The complete cycle for a 2 stroke engine is one rotation of the crankshaft. This means that a 2 stroke engine produces a power stroke on every rotation of the crankshaft while a 4 stroke engine does this only on every other one. Thus, a 2 stroke engine will be more powerful than a similar size 4 stroke engine. However, on the down side, 2 stroke engines tend to be less efficient in fuel utilization and pollute much more than 4 stroke engines.

Bearings and bushings

The shafts of rotating parts normally are mounted in such a way that friction is minimized - to the extent needed for the application. A bearing is any such joint with more specific terms used to describe the typical types found in lawn mowers - or small motors, automobile engines, or 100 MW turbines.

The bearings to be concerned with in a lawn mower or small engine are:

- Main bearings - supports the crankshaft at the blade/PTO end and at the magneto/flywheel end.
- Crank pin journal - links the bottom of the connecting rod to the rotating crankshaft. This single location is most critical as it is subject to the largest forces from the piston.
- Piston pin journal - links the piston to the connecting rod and is subject to the full pounding of the piston but only rotates back and forth through a small angle.
- Gear reduction - additional bearings may be used inside a gearbox. For example, a snow thrower or rototiller require lower speed high torque outputs to drive the auger and tines respectively.
- Auxiliary power takeoff - a lower speed output for front wheel drive or other secondary purpose.
- Wheels - although this is a must less critical application, higher quality bearings will make for easier and smoother operation and longer life.

A variety of bearing types are available. For most inexpensive rotary lawn mowers, plain bearings are most popular due to their simplicity and low cost.

- Plain bearings consist of an outer sleeve called a bushing in which a polished shaft rotates. The bushing may be made of a metal like brass or bronze or a plastic material like teflon. In the case of many small engines, the aluminum alloy casting of the crankcase and cover are simply then bored and reamed to a fine finish to accept the ground and polished shaft. There is no actual bushing. However, if these bearings ever need repair, the hole(s) in the casting would need to be enlarged and a bushing would then be pressed into place and finish reamed.

  The shaft of a small engine is made of steel though other materials may be found depending on the particular needs. Where a metal bushing is used, there must be a means provided for lubrication. In a small engine, this is provided by the engine oil via a variety of means. For example, a typical Tecumseh lawn mower engine lubricates the blade end/PTO main bearing by direct immersion in the oil sump, the magneto/flywheel main bearing via machined passage fed from the camgear driven oil pump, and the crank pin journal by oil sprayed or dripped from above.

  Under normal conditions, a plain bearing wears only during start and stop cycles. While the shaft is rotating at any reasonable speed, there is absolutely no metal to metal contact and thus no wear. With a properly designed and maintained bearing of this type, a very thin oil film entirely supports the shaft - thus the importance of regular oil changes to assure clean oil with effective lubricating properties.

  To put this into perspective, the clearance between the connecting rod and crank pin journal of a typical small engine crank pin journal may be 0.0005 inches or less - one half of one thousandth of an inch. This is roughly 1/10th the thickness of a sheet of computer paper! The same engine may be considered worn to its limit when this clearance increases to .0015 inches. Your automobile engine's crankshaft is entirely supported by these types of bearings as well - and the tolerances are even finer.

  If oil is lost even for a short time, serious metal-to-metal sliding contact results in significant wear and possible destruction of one or both bearing surfaces. Particles in dirty oil can get trapped and embedded, usually in the softer outer bushing resulting in scoring and additional wear. It is your responsibility to assure that your engine oil is maintained at the proper level and changed regularly. Any warranty is not likely to cover failure due to negligence.

- Frictionless bearings are usually of the ball, roller, or needle variety. An inner ring called a race rotates supported by a series of balls, rollers, or elongated rollers called needles inside an outer race. An optional 'cage' positions the rotating objects uniformly around the periphery. There is virtually no friction even at stand-still with these bearings. However, rolling metal to metal contact is maintained at all speeds so they are not quite as wear free as a properly maintained and constantly rotating plain bearing. Loss of lubrication, while not as immediately destructive as with a plain bearing, will still result in accelerated wear and premature failure.

  - Ball bearings may be found in the main bearings of yard equipment where significant sideways loads are encountered. Lubrication is provided by engine oil, gear oil in a separate gearbox, or by being packed with grease either as a maintenance item or for the life of the bearing at the factory.

  - Roller bearings may be used on larger engines where significant loads of all types are encountered. Since the contact between rollers is a line rather than a point as it is with balls, they can support much greater loads. Lubrication needs are similar to those of ball bearings.

  - Needle bearings are found in 2 stroke engines and may be used for the main bearings as well as the crank pin journal. The 'needles' are really just long rollers - a ratio of 5:1 to 10:1 is typical of length to width - and there is no cage to position the needles, they are packed in around the shaft as many as will fit. Due to the type of lubrication - oil mixed with the gasoline - plain bearings are generally not suitable for this application.

Crankshaft anatomy

The diagram below shows the major parts of the crankshaft:

- Main bearings support both ends and whatever is driven by the engine.
- The crank pin journal is the surface upon which the piston's connecting rod bearing acts to rotate the crankshaft.
- The crank gear drives the camgear/camshaft assembly which operates the valve lifters/valves and possibly the oil pump as well.
- The flywheel is actually mounted on a machined taper (not shown) held on by a large nut. The starter engages a clutch mechanism which may also be mounted with the flywheel. For point-type ignition systems, a cam to operate the contact points is usually located on the crankshaft under the flywheel.
- The blade or other driven equipment is mounted on the other end with an adapter (not shown) held on by another large nut.
- Auxiliary equipment like front wheel drive may be powered from a worm gear which is part of the PTO end of the crankshaft (not shown).
- The counterbalance weights help to smooth the operation of the engine.

Basic operation of a float type carburetor

The diagram below shows a schematic of a typical float type carburetor with the engine running at high speed. The choke plate is fully open and the throttle plate is opened the proper amount be feedback from the governor to maintain the speed set by the user throttle control.

- Air is sucked through the venturi by the intact stroke of the piston. The lower pressure created by the faster moving air draws gasoline up through the main nozzle and into the air stream. This aerosol of gasoline vaporized almost instantly.
- The air bleed allows the pressure inside the float chamber to equalize as fuel it drawn off
- The float maintains a more or less constant level of liquid gasoline in the float chamber by opening the inlet needle valve when the level drops. The fuel supply is either above the level of the carburetor or there is a separate fuel pump (usually operated by crankcase pressure pulsations or a direct mechanical linkage).
- The main nozzle either has precisely machined orifices to set the ratio of air to gasoline in the mixture or has an adjustable needle valve for this purpose (not shown).
- Closing the choke forces more gasoline into the mixture and makes it richer.
- The throttle plate is used to vary the amount of the air-fuel mixture to the engine but maintains nearly the same ratio of air to fuel over a wide range of engine speeds.
- The user throttle (speed) control adjusts the spring force against which the governor must act to close the throttle plate. Increasing the spring force increases the engine speed.
- Operation at idle speed depends on a separate system of an idle nozzle and idle speed adjustment (not shown) and does not depend on governor feedback to control the throttle - which is kept open just a small amount.

The four strokes of a four stroke engine in living ASCII art

You will just love the most excellent, accurate, and to-scale (:-).)ASCII renditions below but at least it will display on any computer using a fixed width font and not require half your disk space allocation for storage!

Note that the valves, normal operated by a camshaft driven off of a small gear on the crankshaft, are not drawn in their usual position for a common small (side valve) engine to improve the superb clarity of these drawings.

Intake stroke (1)

Air-fuel mixture is sucked into the cylinder by the by piston moving down driven by inertia of flywheel (and blade).

- Intake valve: open.
- Exhaust valve: closed.
- Piston: moving down sucking in fresh air-fuel mixture from carburetor.

Ignition

Compressed air-fuel mixture is ignited just before piston passes Top Dead Center (TDC) and starts down again.

- Intake valve: closed.
- Exhaust valve: closed.
- Piston: just short of Top Dead Center moving up.

```
                                ZAP!

                      Main bearings
```

Power stroke (3)

Heated expanding gases drive piston downward and apply power impulse to crankshaft via connecting rod (clockwise rotation).

- Intake valve: closed.
- Exhaust valve: closed.
- Piston: moving down driven by combustion of air-fuel mixture.

5. Back to Small Engine Repair FAQ Table of Contents.

Service Information

References

The best reference is the manual that likely came with your engine. This will have the specific information needed to service it as well as the recommended preventive maintenance tips. Many engine manufacturers now have the user and service manuals for specific engine/equipment models on-line as well as extensive general maintenance and troubleshooting information, and parts identification and ordering.

- Briggs & Stratton
- Lawnboy
- Kohler
- Tecumseh

- Sears has many of its mower diagrams and other information on-line. For servicing of Sears/Craftsman equipment, this may be more then adequate. You may need the complete model number to access them. Here is a road map to get through the Sears Web site (at least as it configured now, Summer 2001, provided by: Frank Clason (patdc@nts-online.net).)

  - Start at Sears Home Page (same link as above).
  - Go down the left hand side of the page and click on PARTS.
  - Go down to item #2 and input the model number - make sure it is complete.
  - Click on GO and then on CONTINUE.
  - Go down to the diagram that says "OR select the area...".
  - Click on the item under the column that says VIEW DIAGRAM for your area of interest.
  - Click on CONTINUE.

  This should bring up the schematic (diagram) of interest. I was really surprised to find the diagrams - they appear to be quite useful and could come in real handy in the future.

- LAWN-MOWER-SHOP.COM has a variety of information on basic maintenance and troubleshooting including: Tune-up procedure and checklist, starter repair, a troubleshooting guide, links, carburetor diagrams, and more.

The Lawn-mower-shop.com Web site has a great deal of useful information including diagrams of popular carburetors, rope starter repair, and links to small engine manufacturers. There is even a "slide-show" illustrating complete disassembly of a typical small engine. This may be all you need for many popular engines.

The following are good for general information but may not have the specific information for your equipment. However, the combination of the original user or service manual and a small engine repair book is probably all you need.

1. Small Engine Repair, 2-12 HP
   Richard J, Rivele, Ed.
   Chilten Book Company, 1993
   Radnor, PA 19089
   ISBN 0-8019-8323-1

   (There are also several other versions of this book covering small engines up to 20 HP. For the most part they

are very similar with some additional information provided where appropriate for each size range.)

2. Chilton's Repair and Tune-up Guide for Small Engines, 1-1/2 to 20 HP
   Chilten Book Company, 1979
   Radnor, PA 19089
   ISBN 0-8019-6810-0 (Paperback: ISBN 0-8019-6811-9)

3. The Complete Handbook of Lawn Mower Repair
   Paul Dempsey
   TAB Books
   Blue Ridge Summit, PA 17214

4. Small Gas Engines: How to Repair and Maintain Them
   Paul Weissler
   Sterling Publishing Company
   Two Park Avenue, New York, NY 10016

5. Simple Gasoline Engine Repair
   Ross R. Olney,
   Doubleday and Company, Inc., 1972
   Garden City, NY

6. Walk-Behind Lawn Mower Service Manual - Third Edition
   Intertec Publishing Corporation
   P.O. Box 12901, Overland Park, Kansas 66212

7. You Fix It: Lawn Mowers
   Carmine C. Castellani & Clifford P.Seitz
   ARCO Publishing, Inc., 1975, 1976
   219 Park Ave. South, New York, NY 10003
   ISBN 0-668-02705-3

8. My Lawn Mower Hates Me - An Original Manual for Hand and Power Mowers
   Tom Cuthbertson and Rich Morrall
   10 Speed Press
   Box 4310, Berkeley, CA 94704

9. Handbook of Lawn Mower Repair
   Franklynn Peterson
   Emerson Books, Inc., 1978
   Buchanan, NY 10511

10. Repairing and Maintaining Yard Equipment and Power Tools
    Mort Schultz
    John Wiley & Sons, Inc., 1994
    605 Third Avenue, New York, NY 10158-0012
    ISBN 0-471-53500-1 (cloth:acid-free paper), ISBN 0-471-53501-X (paper)

11. The Repair & Maintenance of Small Gasoline Engines
    George R. Drake
    Reston Publishing Company, A Prenice-Hall Company, 1976
    Reston, VA 22090
    ISBN 0-87909-724-8

12. Small Gasoline Engines: How to repair and maintain them
    A Popular Science Book
    Paul Weissler
    Times Mirror Magazines, Inc., Book Division, 1975
    ISBN 0-06-014564-1

13. Fix It Yourself - Power Tools and Equipment
    Time-Life Books, Inc., 1989
    Alexandria, VA
    ISBN 0-8094-6268-0, ISBN 0-8094-6269-9 (lib. bdg.)

14. Small Engines - Mowers, Tillers, Chain Saws
    The Editors of Time-Life Books
    Time-Life Books, Inc., 1982
    Alexandria, VA
    ISBN 0-8094-3910-1 (retail ed.), ISBN 0-8094-3911-X (lib. bdg.),
    ISBN 0-8094-3912-8 (lib. bdg.)

15. Small Gas Engines and Power Transmission Systems,
    A Repair and Maintenance Manual
    Walter E. Billiet
    Perntice-Hall, Inc., 1982
    Englewood Cliffs, NJ 07632
    ISBN 0-13-814327-7 (hardback), ISBN 0-13-814319-6 (pbk.)

16. Garden and Yard Power Tools - Selection, Maintenance, and Repair
    Walter Hall
    Rodale Press, 1983
    Emmaus, PA
    ISBN 0-87857-446-8 (hardcover), ISBN 0-87857-447-6 (paperback)

17. How to Repair Briggs and Stratton Engines, 3rd edition
    Paul Dempsey
    Tab/McGraw Hill, 1994, $14.95

    (From: Jim Nelson (jgn@ameritech.net).)

    This is an excellent book about B&S engines.

    I don't know any old galoots who can teach me this stuff, so I always end up at the bookstore. This book I had to buy to identify the missing controls on a B&S driving a mortar mixer I bought cheap.

Links to engine and equipment manufacturers

The Doc System Small Engine and Power Equipment Resource site has links to most of the major companies as well as some detailed procedures for basic maintenance and tips on purchasing replacement parts.

On-line small engine discussion group

This is a free (well sort of, it is advertising supported which presumably means you probably have to tolerate banners and such but hopefully no SPAM).

From the charter:

> "Small Engines is an open forum intended as a resource for individuals studying small engines, business owners, home owners or anyone for that matter. The basic purpose of the list is to serve as a forum for discussions and distribution of information. Subscribers are encouraged to post questions, comments, or announcements of interest to the list about small engines and which pertain to work or theory or ideas about the current development or past of small engines. Discussions include: electrical systems on equipment, what works and how to do things, the effects of small engines on the environment and a lot more."

Check out: Yahoo Groups: Small Engines Discussion Group.

Mower and engine parts sources

Most of the common maintenance and repair parts that are likely to be needed are readily available and relatively inexpensive. Your place of purchase may be most convenient but not necessarily the cheapest.

Many engine parts are fairly specialized and non-interchangeable unless the replacement part really is identical. However, even different model engines may use the same parts. For example, the identical connecting rod, piston, piston pin, camgear/camshaft and oil pump, valves, valve lifters, ignition components, and flywheels are used in several different 3-5 HP Tecumseh engines. Even the same crankshaft may be used in multiple models but slight variations like whether there is an auxiliary power take-off or not can complicate matters.

Carburetors, magnetos and other ignition components from similar sized engines from the same manufacturer may be substituted in many cases. I have even heard of people adapting a larger carburetor to a small engine (with varying levels of success).

Here are some of the alternatives for obtaining replacement parts:

New parts and supplies - walk-in

- Home centers: 2 stroke and 4 stroke engine oil, spark plugs, mower blades, wheels, some front wheel drive components. They also have tune-up kits as well as other service parts like air filters, mufflers, and flywheel keys. These seem to be mostly for Briggs & Stratton engines but I did find some Tecumseh parts at a Builder's Square. Home centers are also a good source for name-brand tools. Stay away from the bargain tools as their quality is often mediocre.

- Auto supply stores: engine oil, carburetor cleaner, anti-seize, sealer, hardware, some tools.

- Sears retail stores: 2 stroke and 4 stroke engine oil, spark plugs, mower blades, wheels, front wheel drive components, air filters, mufflers, and blade adapters for Craftsman equipment. However, all the general items like oil and spark plugs can be used on most other engines and the repair parts will be compatible with much other equipment powered by Tecumseh engines.

  Sears is, of course, where you get Craftsman tools which in the past have been of very high quality. All hand tools also come with an unconditional lifetime warranty.

- Sears parts centers: these are separate from the retail stores and generally serve an entire region. They will have all engine parts for Craftsman and other Sears equipment down to the last nut are available but you will have to have the complete equipment model number (134.XXXXXX) for non-engine related parts and/or the complete engine model number (143.XXXXXX) for engine parts so they can look up the part numbers.

Having samples of the parts you need is a good idea as well.

Sears now has a Web site: Sears PartsDirect which allows direct ordering of over 4 million parts (so they claim) based on the parts list (which they provide on-line) for each product model number.

Parts availability is guaranteed for something like 15 years for most Sears brand equipment. Since the Tecumseh engine design has really not changed substantially for a lot longer than this, parts will likely be available even for an old mower. However, the person at the parts counter may look at you as if you are from Mars if you are interested in some of the very low level engine replacement parts like circlips or rod bolts. It would appear that not many people do this sort of stuff anymore.

- Yard equipment dealers and service shops: most parts for brands of equipment they sell and repair. Complete equipment model and engine identification information and samples of the parts you need will prove essential.

  For Sears/Craftsman products in particular, the first 3 digits of the Sears part number identify the actual manufacturer of the equipment. With these in-hand, you may be able to bypass Sears entirely and buy parts directly

New parts and supplies - mail order/Web

An increasing number of small engine manufacturers are providing on-line sales of repair manuals, general maintenance items, and "how to" books and videos. One example is Briggs and Stratton. However, they may not have more specialized items like head gaskets and connecting rods.

There are a large number of parts supply companies. Only a few are listed below. (I have absolutely no affiliation with any of the following companies. Some of the descriptions are from the company's site or what they emailed me. Listed in alphabetical order, more-or-less.)

- Battery and Electric Co. (BECO) has a secure online catalog featuring some of the most popular lawn mower and small engine parts, and we do offer consumers a form to request information on any parts not found online, including hard-to-find McCulloch parts. BECO is a distributor of all major OPE parts lines, and also offers a lower cost alternative in quality aftermarket Prime Line parts. We also offer new engines by Briggs and Stratton and Tecumseh in our online catalog. Online orders are by credit card (Visa, Mastercard and Discover). BECO has been in business since 1920 offering quality parts and service to the Carolinas, and we have now been on the Web for about a year.

  - Web: http://www.becoparts.com/
  - Payment terms: Visa, Mastercard, and Discover

- Manufacturer's Supply lists all kinds of parts and accessories including those for small engines, lawn mowers, snowmobiles, logging/chainsaws, ATVs, and other engine powered equipment.

  - Phone: 1-800-826-8563
  - Fax: 1-800-294-4144
  - Web: http://www.mfgsupply.com/
  - Email: webmaster@mfgsupply.com

  The site has an on-line catalog (under construction) and search capability. A free 200 page print catalog may be requested as well. (I have been informed that they are currently out of these (May '97) but you will be put on their mailing list for a summer release.) They also have a 600+ page catalog (major portions of which will be put on their web site in the near future) with all sorts of fabulous replacement parts, tools, and other maintenance items - for the princely sum of $3.

- M & D Mower Repair. Product lines include those from Briggs & Stratton, Tecumseh, MTD, and others. Their web site provides access to the following:

  - Safety information.
  - Monthly tips, FAQ-like help, and an 'ask the mechanic' service.
  - Original engine service manuals and special tools.
  - Equipment and engine parts including complete engines and shortblocks. - After-market replacement parts for most popular brands of engines and outdoor power equipment.

  - Web: M & D Mower Repair: http://www.M-and-D.com/

  Orders are accepted via secure email, Fax or snail mail. Payment may be made using MasterCard, Visa, or Discover. The minimum S&H fee is around $4.

- Oscar Wilson Engines & Parts, Inc. has a web site which indicates that they are distributors for a large number of companies including Briggs & Stratton, Kawasaki, Kohler, McCulloch, MTD, Tecumseh, and others. There is no on-line catalog. I do not know if they will help with parts identification or whether you really need to have an exact part number to order.

  - Voice phone: 1-800-873-6721
  - Fax: 1-800-873-6720
  - Web: http://www.oscar-wilson.com/
  - Email: oscar@i1.net
  - Payment terms: cash, check, Mastercard, Visa, Discover, Open Account.

Used parts

It doesn't make a lot of sense to search the countryside for a clogged air filter or slightly worn engine oil :-) but it may be possible to save a substantial amount of money if you can locate a previously owned replacement for that bent crankshaft!

- Salvage yards: these are probably the most reasonable priced sources for major engine components if you can locate a compatible model and are willing to do the necessary leg work. Since only a hand full of really different engines are used on the majority of rotary mowers, this may not be that hard. Of course, the condition of such parts can be quite variable. And, it will likely be your entire responsibility to locate exactly what you need! Buying a complete engine by the pound to obtain a rod or piston may end up being cheaper than buying just a new part and just about as good in many cases. For internal parts, take along a copy of the Chilten or other engine repair book which lists engine cross references so that you will be able to determine if a part will be compatible without stripping the engine! (Of course, if the previous owner neglected the routine maintenance, the engine had a long hard life, or oversize repair parts were installed, you may be out of luck anyhow.)

  Yard equipment dealers may take old (non-working) mowers as trade-ins and be happy to sell or give away the remains for parts. Of course, if all you need is a bolt, you will have to dispose of the rest of the carcass!

- Garage or yard sales: if you are in no hurry and enjoy this weekend pastime, mowers in various stages of decay and disrepair are often available. I have paid $2 to $10 for non-functional mowers requiring relatively little in the way of repair - usually this is carburetor cleaning or perhaps a tuneup. The beginning and end of the mowing season are probably the best times for this search. At the beginning of the season, people discover that their mowers won't start, shove them in a corner, and go out and spend big $$$ for a brand new mower that will be in the same sorry state in a couple of years. (They, of course, have not read this document.)

(From: BELJAN E (lvpy67c@ix.netcom.com).)

> "About 10 minutes, replace the points, spark plug and a spritz of starting fluid and 90% are fine after that!"

At the end of the season they say "never again" and move to an apartment or hire a landscaper.

I paid $35 for a Sears Craftsman mower in perfect condition (I guess grass mowing was not something the seller enjoyed) about 17 years ago and it is still going strong with only minimal maintenance.

Comments on buying used mowers

Caution: Mowers older than about 20 years or so will not have the safety features of modern ones (dead-man bar for engine kill and/or blade-brake clutch). Therefore, it may make sense to avoid really old mowers without these safety features even if they are in perfect condition.

Garage and yard sales, tag sales, flea markets, and auctions, are also excellent sources for tools. Very high quality tools often show up at reasonable prices but there is a lot of junk out there so know what you want and how to distinguish an easily salvageable tool from one that is a pile of congealed rust.

(From: Mark Manville (manville@vega15.cs.wisc.edu).)

What I did when we bought our first house was to just go around to garage sales and look for an inexpensive used mower. I figured I would need to cut the lawn for a while before I was really sure of what I needed anyway. Besides, after the down payment, closing costs, and other expenses, there was not much free cash to speak of. Such a mower could perhaps take you through the first year or so, until you have more experience, time, and cash. You may even get lucky like I think we did and get one that you can stick with for a while. We got a 22" Sears self propelled that works pretty well - it's old, but at $30 I count it as a bargain, even if breaks down after one year."

(From: Erik Beljan (lvpy67c@ix.netcom.com).)

I would like to comment on buying used lawn mowers. Do not trust what you are buying. You never know what the quality of the engine is and there is no way to guarantee it. I found a Roper Rally 22 inch lawn mower last fall, and had an interesting ordeal which shows what you might be getting. I took it home only to find the engine was seized (found by attempting to pull the starter cord). I took the sparkplug out and put a mixture of Duralube All Purpose Spray, Marvel Mystery Oil and Liquid Wrench into the cylinder. I put the spark plug in and let it sit a few minutes. I took the plug out and yanked the blade from the underneath. It snapped free. I then cranked it about 10 times, to clear the cylinder (if fouled the old plug that was in the mower) I cleaned the plug off with some carb and choke cleaner, sprayed some into the cylinder and carb. I proceeded to start it again. It kicked to life with a huge cloud of smoke. It blew smoke everywhere for about 5 minutes. I shut it off and parked it under a tree overnight so I could take a closer look the next day.

The next day I took a better look at it only to find that the top of the flywheel was full of poplar tree cotton, which I removed. I looked at the oil which was a dark thick black color. I poured a large dose of Marvel Mystery Oil into the oil and started the mower. I ran it for a few minutes (it burned considerable oil), shut it off and changed the oil. I dumped the old oil out and filled it with a 50 50 blend of SAE 30 oil and Nu Lube oil stabilizer (a thickish oil treatment like STP thins out more though). I filled the gas tank and put about 4 oz of Marvel Mystery Oil in the gas. I started it and ran it for 10 minutes. No smoke, sounds like new. I am using it now this spring with the only modification of a new spark plug and air filter. The thing runs fine, but it is likely that the engine is in terrible shape internally (I am not bothering to take it apart, but can it can be seen by the excessive oil burning if I don't put some Nu Lube in the oil).

If I sold it to you today without telling you what I did to it, you would never know, there are no outward signs of what it was like. The Nu Lube seals the clearances nicely, stops the oil from burning, keeps the spark plug from oil fouling, keeps the oil looking clean and quiets the engine quite a bit. If I were the purchasing party I would not want to receive this engine if I would have known its condition. This story goes to show that for minimal work you can make an engine run in so it seems to be in decent shape, even though it might not be.

Small Engine Specifications

Typical mechanical specifications

The following are some of the key dimensions and other specifications for several common Tecumseh engines. Where two numbers are listed, they are the upper and lower service (wear) limits as appropriate. One of these will be close to the expected dimension on a new engine; the other represents the point at which you are supposed to replace the part due to wear. All values are in inches unless otherwise noted.

```
        Specification        LAV/H30   LAV/H40   LAV/H50    V/H70    VM/HM100
-------------------------------------------------------------------------------

Horsepower:                     3         4         5         7          10

Displacement (cubic inches):  7.75      10.5      11.5      15.0      20.2

Bore:                         2.3125    2.625     2.75      2.75      3.187

Stroke:                      1-27/32   1-15/16   1-15/16   2-17/32   2-17/32

Timing Dimension:              .060      .035      .035      .050      .070
(before TDC)

Point setting:                 .020      .020      .020      .020      .020

Width of oil ring grooves:	.125 .127	.156 .158	.1565 .1585	.188 .190	.188 .190
Ring end gap:	.007 .020	.007 .020	.007 .020	.007 .020	.007 .020
Top piston land clearance:	.0105 .0145	.0165 .0215	.024 .027	.023 .028	.029 .034
Piston skirt clearance:	.0025 .0040	.0045 .0060	.0045 .0060	.0045 .0060	.028 .053

Typical torque specifications

For proper operation and long life, you cannot just tighten critical nuts and bolts by feel. You really don't want the connecting rod cap to come loose while the engine is running! The following are just samples - check your engine manual for exact values!!! The most critical are the connecting rod bolts or nuts and the cylinder head bolts.

Location	Torque ---> Inch-pounds	Foot pounds
Cylinder head bolts:	160 - 200	13 - 16
Connecting rod bolts (Durlock rod bolts):		
2.5 - 4 HP small frame:	96 - 110	7.9 - 9.1
5 - 6 HP medium frame:	130 - 150	10.8 - 12.5
7 - 10 HP medium frame:	150 - 170	12.5 - 14.1

Cylinder cover or flange to cylinder:	65 - 110	5.5 - 9.0
Flywheel nut:	360 - 396	30 - 33
Spark plug:	180 - 360	15 - 30
Magneto stator to cylinder:	40 - 90	3.3 - 7.5
Starter to blower housing or cylinder:	40 - 60	3.3 - 5.0
Housing baffle to cylinder:	48 - 72	4 - 6
Breather cover to cylinder:	20 - 26	1.7 - 2.1
Intake pipe to cylinder:	72 - 96	6 - 8
Carburetor to intake pipe:	48 - 72	4 - 6
Air cleaner to carburetor (plastic):	8 - 12	1
Tank plate to bracket (plastic):	100 - 144	9 - 12
Tank to housing:	45 - 65	3.7 - 5
Muffler bolts to cylinder:		
1 - 5 HP small frame:	30 - 45	2.5 - 3.5
4 - 5 HP medium frame:	90 - 150	8 - 12
Electric starter to cylinder:	50 - 60	4 - 5

These are the Runners Up

Well, not really. The articles in this document are based on email I have received about other people's experiences while troubleshooting, repairing, breaking - and learning, as well as random comments about the FAQs, repair in general, or the state of the universe. They have not become "Assorted Repair Briefs from OTHER sources [than Sam]" for one reason or another, mostly obvious, but that is no reflection on their significance or the lessons to be taught by their content. For the most part, I have only made editorial changes and have retained the original flavor of each of these interesting and sometimes amusing articles.

Repair Story #1: MacGyver-In-Training

Author: Norval F. T. Tennant, Copyright © 1996,1997, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or valten_f@toj.com.

Happy Holidays

Hope you had an enjoyable Christmas and that the approaching new year will see the fulfillment of all your dreams. I discover Sci.Electronics on the web about a week ago. Since then I have downloaded and read most of your articles. Presently I am reading your repair briefs. I am finding it very informative and hilarious too (ha ha heh heh).

I have been fiddling around electronics for sometime now and earlier this year started a course with N.R.I. Schools in Micro Processors and Micro Computers. Presently I am an Information Systems Manager at a hotel but I really love electronics. I have fix quite a few equipments. (Have not had any complaints of fire after my repairs either) . However I am still a novice - Pro Wannabe and I believe that with guidance from guys like yourself and others someday I too might become a pro.

Hey any chance of me renting your knowledge for a month or two?. Oh well I didn't think so either but just checking. Man, I have quite a number of appliances laying around the house. Mostly for friends. Well you see they seem to think that whatever broken equipment they have, MacGyver can fix it.

MacGyver - Yeah thats what they call me. That was from a television series some years ago staring Richard Dean Anderson or was it Robert Dean Anderson, Well lets just say "Something Dean Anderson". Now he was something else. I once saw that guy broke an egg and empty its contents in a car radiator to stop a leak. Well Thats television for you.

Oh about that equipment - Yeah I do have quite a few. VCRs, televisions, computer monitors, CD player and even an electronic scale.

Well a part of my problem is that unlike you I cannot go to the library to get a copy of a Sams'. What are you inquiring about .... Service manual for a Panasonic PV2822?. What the hell is that. You see I am living in Jamaica. Where? Oh that's a little Caribbean country about 90 miles south of Cuba. Its total area is about 4411 Sq. Miles with a population of around 2.6 million. Home of the now famous reggae music. Also produces world renown Blue Mountain Coffee. Has produced some world class athletes in track and field the likes of Herb McKinley, Donald Quarrie, Bert Cameron. Did I say has produced?. That was a slip of the tongue. We are still producing - Merlene Ottey, Deon Hemmings etc. etc. Hey we even have a bob sled team, but listen it has never snowed in Jamaica. Ha. Ha. Well there are quite a few achievements to make us proud but to have Sams' Photofacts in the library, We are not there yet. Still a third world country....perhaps one day.

Probably when we have become close friends then we can work something out but for now - grope grope in the dark. Do you think if I share some symptoms you might be able to help? Well I do not own a scope. Have never seen one except in magazines. I have download something from Sci about them thought, will read that later. I have a DVM, pliers, screw drivers, etc. The basic tools really. Well let me tell you about a patient:

Panasonic PV 2822 Video

Complaint - Good sound but no picture. Snow on T/V (local term - T/V snowy). Tried cleaning video head - no change.

Well that sounds like the video heads might have done its days I thought. First thing I did was to remove cover. Lift main board to get to head. Close scrutiny shows head appears to be worn and the color seem sort of brownish not shiny bright. I wonder what they use to clean head. Some of those cassette cleaners not any good. How about some manual cleaning. Some isopropyl alcohol and tissue from the bathroom and some gently rubbing on head, tape guides, pinched roller, etc.

Now to test. Circuit board not screw back in position but set so that nothing will short against any metal parts. Connect to TV. Plug into A/C line. No Variac or Isolation transformer that Sam refers to so often. Need to address that but for now .. .Power switch press. Display lights up. Channel 2 on display. No local station uses that channel and cable is not attached. Menu appears on TV, "Numeric key to set date and time etc. etc.

Now for a cassette. That is inserted. Safety tab on cassette is removed so play come on automatically. All mechanics seems okay, tape properly wraps around drum and alas picture, best I have seen on this TV since I fix it 2 years ago. I was attempting to tweak it then, when I use a minute metal screw to adjust - what is that part called .. IF or RF transformer for cleaner picture I reasoned. Well the darn screw driver crack the core or was it the person using the screw driver? Well the picture has been somewhat snowy since perhaps one of these days I will fix that but back to video at hand.

Picture cool, sound awright just screw it back together and hook it to the better working TV and watch a movie. Just got 2 movies to borrow from my cousin. Well Stop, Eject and power. Off goes connector to tv and out goes power cord. Oh did I mention a small spark from the socket the first time I plug in into the ac line. I have seen that every now and then I wonder if the socket terminals are somewhat corroded well I will check that one of these days....

Time to screw up (no pun intended) VCR. Enter my 4 year old stepson and his 5 year old uncle. "Hi dad You said you were going to allow us to help you fix video". Man why do young kids have such good memory. This I told them earlier on when they were refusing to go for their bath. "Well your time now" I said go get two phillips screw drivers. Well they know were the tools are kept sometimes I have to ask them were my tools have disappeared to.

Well it is a good thing they only visit during holidays or I think I would be mad by now but then again probably I already am. Well they are back and they look ready to screw. No No Not that type of screw Sam. These are kids, oh boy!. Well I carefully inserted the the main board back into its position making sure all wires are intact. I inserted all the screws putting about two turns on each with my finger. Okay guys your turn. I showed them how to finish inserting screws a few minutes later they were through. No No I did not leave them to do it by themselves another few years perhaps but for now I was right there. Well with the main board out the way I replace the cover and with the boys help screwed it in place.

Now to go watch the movies. Movies in a few minutes I announced to the rest of the household. I hooked up Video to properly working TV, plug into A/C line again that little spark - different socket this time - Well this is an old house. Power, display lights up and menu comes up on t/v well now insert cassette. In goes cassette, on comes play, sound but wait NO PICTURE. FAINTLY detected ghost wiggle but NO PROPER PICTURE. EVERYONE NOW TAKING THERE SEATS. Wiggling of cable bring no change. Well I must have missed something when WE WERE SCREWING it together. Well off comes cover, up comes board, close visual inspection reveals nothing amiss. Well what the &$#@ went wrong. By now I am back to snowy Tv set still no picture. Gently prodding of circuit board yields no change. Another quick clean of head - Nothing. A hour and a half later still nothing. By this the theater - I mean the living room is empty. Someone making a wise crack about me working on the projector. Well What am I not checking. When Power is applied the startup menu is displayed - Set date time etc on t/v. Did I check the channels from the video No. Well antenna is attached to video and local channel is selected on video, vcr/tv switch is check vcr selected. Well what do you know still no picture. Whenever a channel is selected for which their is no signal there appears to be horizontal lines on t/v however once one with a signal is selected good sound put faint ghost and lots of snow. Did I say it never snow in Jamaica.

Well it is getting late and I have to be up early for work in the morning so I not going to stay up with Mr VCR anymore. Why did you have to do that to me I ask?. Well now I know that I am really tired because I sure I hear it mumble something about me allowing kids to poke around in his belly. Well just my imagination probably.

Well Sam that was yesterday. Have not looked at it today. But I have been thinking - That fact that there is no picture at all neither from the tuner circuits or from the video circuits then the problem is in a circuit that is common to both could it be power problem?.

Knong Kong Heht Hett - Now what is that. Ah my little 15 months old niece. Heh heh Hoh hah - Sam she is wearing her Mother's Shoes. Well I think she is here to continue her computer class we started the other day.

Sam I have to say bye for now. Hoping to here from you soon. Anxiously awaiting your advice. In the meantime I continue to read your articles. This young lady is pulling on my pants trying to get on my lap. Now where did I put that Dr. T's Sing-A-Long CD. "Raat raat" - No baby, Not a rat. It is call a mouse, Kids .....

Samtron SVGA monitor model SC441V

Well well!. Today is the start of a new year so after awaking, yawning and stretching I decided to check my mail and what do you know - Heh Heh there is a reply from Sam. Now I know why they call that other service SNAIL MAIL.

Sam it was nice to hear from you. I have noted all your recommendations and will be posting a few questions to Sci.Electronics shortly. Well after reading your chapter on "Incrediblely handy widgets". I decided to construct the Visual Load Indicator - . Like yourself I wired a dual outlet box in series so both the equipment under test and the lamp can be plug in. My problem now is understanding what wattage bulb to use for what equipment.

You see I constructed it last night - NEW YEARS EVE - Well who cares, I was doing what I like. I was at my own New Year's Eve Ball. The equipment I was testing it on was a 14" Samtron SVGA monitor Mod# SC441V. This patient was busted up somewhat, but I will tell you about that some other time. For now I had just replace a voltage regulator - STR 58041 = ECG 7078 (Yeah I have an ECG Cross Reference manual 96 version). This had a short between pins 2 & 3. Base and output if I remember correctly. I also replace two C1008 transistors with 2N2219A, A 1K resistor 1/4 watt and a RPG15G diode - This is rated at 600 prv 3amp so I used one rated at 1000 prv 3amp. This was only for test purpose as I will try to located a original or one of similar ratings.

No I have not noted any shorted are open capacitors as yet. Well time to test. The monitor is rated at 70 watts 0.5 - 1 amp. My newly made visual indicator is connected and I am using a 40 watt bulb. My bulb holder is one of those with a switch on it. Am I wearing rubber boots? Yes and one hand struct deep down in pocket. Wait Wait What is this?. A huge hole in my pocket - On so that was how my $500 bill escaped. Sam 500 Ja.$

is about $15 in Uncle Sams currency. Well you gain some, you lose some, that's life. Still I will show this torn pocket.....

Now back to the matter at hand. Burr Rum Burr bum (Is that how a drum sound Sam). Well drum roll and all and POWER. Now what do you know?. Awright Sam Awright - I am just learning not as experience as you but one of these day .... Yes bulb shines brightly. Well Sam did say If bulb glows bright then shorts probably exits - now what could that be. Now give this a little thought and ... Okay if degausing cable is still connected then that might provide a low resistant path for current back to bulb... One way to find out. Power Off, degausing coil disconnected. Power on. No glow from bulb, no wait there is a faint glow on the filament. Now what still no sign of life from my patient SAM err err I meant My patient SAMTRON. Now what would Sam the man with Gold in his name have done. Well I remembered him changing the wattage of the bulb a few times I wonder if.... . Can't see any harm in that. Well I do have a 100 watt bulb. Now that is fetch and quickly replaces the 40 watt. Power. Ahah bulb is glowing but not brightly AND THERE IS A HORIZONTAL LINE ON MONITOR THAT IS SLOWLY OPENING VERTICALLY. AND there is also letters on the screen. Not quite legible but there. Oh I did hook the monitor to a old 386 PC that had no hard drive or key board. Yes is has memory. About 2 mb. The rest will be added later. You know me one of these days ......

Well I suppose this monitor needs more current so I will just disconnect this visual tester and plug it in ac outlet. My Next gadget must be an isolation transformer and also a variac. I already have a few transformers and also a line conditioner. I could probably convert that to a variac. I could asked on Sci about a circuit diagram or perhaps Sam can help. Back to monitor. Degauss is connected and monitor plug in to ac. Power. Yes Yes monitor lights up beautifully. It i s a bit bright but that is soon corrected with a little adjustment to the brightness control on the front of monitor. Now I see the booth up and error message on monitor as 386 tries to booth without a hard drive or floppy drive. Now to let this run for awhile. How about rebooting computer. Okay. Power Off. BUZZZZ Buzzz. Now What the hell is that. The back of monitor is still off so visual inspection is easily done. Power Off. Plug pulled from a/c. That sound seem to be coming from somewhere in the vicinity of the newly installed regulator and that many legged transformer that it is close to. In fact in is connected to a heat sink that have a portion hovering over the transformer. A quick check using a finger as heat detector on newly install parts - CAREFUL NOT TO TOUCH ANY METAL PART - FILTER CAPACITOR NOT DISCHARGE ALSO STAYING FAR FROM HV CIRCUIT - revealed nothing until i came to the newly install diode. The one with the 1000 PRV Instead 0f 600. Well that is rather hot. Well what does this supply. From tracing the circuit I saw 24 volt written on PCB and it goes to quite a few components. Well I suppose one of them has a problem that is causing my little silicon friend to over work and sweat - I mean heat up too much. Well let me just check this voltage. All connected and power up. Monitor lights up. With my DVM I checked - 23.9 volts after a few seconds buzzz buzzz. Power off. Diode is quite hot. Well it is almost midnight now. My fiancee seems to be asleep and hey she is hugging a pillow. Well I've got to start the New year right - think I better get to bed and replace that pillow. She did say she wanted to be up when the New Year arrived so she won't mind if I wake her Plus Sam did say NOT TO WORK WHEN I AM TIRED - Well at least not on any thing electrical. Well that was last night and the rest is history. This morning I got your letter and now I reply. Later I will attend to patient SAMTRON. NO Success then to Sci.

How do I determine what wattage bulb to used on equipment under test?. Gotta say bye for now. Looking forward to hearing from you soon. All the best for New Year.

Now what is that sound. Oh Oh 15 month old niece. Sam I have not fully recovered from that last lesson. Gotta find somewhere to hide , Gotta find somewhereeeee ....

January 3, 1997

Hey Sam - How about under a section entitled "NEVER DO THIS" - Ha Ha. Well as one of my mentors whatever you chose to do is okay with me. I have taken a little break from repairs for a couple days. I have to keep Mr. Mantzanas (Director of Education - N.R.I.) happy, so I am catching up on a few lessons. I am presently studying Logical Operations and Functions. You know all those logic gates - AND, OR, NOT, NAND, NOR etc etc. Sam these Boolean Algebra are really a brainful. Do you know any EASY WAYS of remembering all these various laws? - Commutative, Associative, Distributive, Laws of Absorption etc.

About your comments on that diode!. Well the only difference between the original and the one I installed is the PRV. Well this is based on data in ECG Manual. I check on the original and also the replacement. It is in the secondary supply. On the other hand - Would a problem arising from the switching function of this diode results in that buzzing sound that I am hearing?. Sound only appear after unit is turned on for a few seconds. In fact the first time I heard it was when I disconnect the signal cable from PC to monitor. Well I guess I could double check that.

Until I hear from you "TEK CARE AND WALK GOOD" - (Jamaican dialect) - Means "Be careful and watch your step".

MacGyver

Repair Story #2: Watering a TV

Author: Andrew Bock, Copyright © 1997, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or abock@mars.ark.com.

I just wanted to pass on thanks for info on monitors. I read your 'Why I do This' note and agree with your philosophy.

I have fixed countless VCRs, TVs etc just to stop them from going into the dumpster. Todays society is so much a toss it in the bin generation. If people don't want it back when I give them an idea of its cost I fix it anyway and donate it to charity or some poor starving student. If I can ever help you proofread or sort info let me know as I have time at work between trouble calls. I too have tried just about everything (cars, motorbikes, lawn mowers, built a house). I work as a tech maintaining air traffic radar and navigations systems.

In exchange for your info I offer this story:

One of the guys I work with brings in his brothers big screen TV that's belly up. When quizzed he doesn't really want to talk about it or whats wrong with it. So now we are really interested. It turns out that it has had water spilled in the back. Well we had all ran across this before so after much guffawing and insulting of his lineage the story comes out. His brother had the customary spider plant on top of the TV. Well sometime not long after he bought it the bottom third of the screen folded over and left a black bar at the bottom.

Because of the size of the TV he just left it that way for more than a year. Then one day he watered the plant a little too exuberantly and smoke came out of the back. He quickly unplugged it and left it wisely to dry out. Well when he plugs it back in several days later it is cured of its fault! The TV works perfectly for a month. Then the fault comes back, but he knows what to do. You guessed it, he gets out the watering can and pours water! In the back of his LIVE TV set. Why he didn't end up as a pair of smoking sneakers was only luck. Needless to say the comments on his genetic structure flew fast and furious.

Enjoy and keep up the good work.

Repair Story #3: Chinese CD Player with an Attitude Problem

Author: Mark Kinsler, Copyright © 1997, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or kinsler@bobcat.ent.ohiou.edu.

Patient: RCA model 1050 M-F (maybe that means it only is guaranteed to work on weekdays? :-).

Symptoms: Ejects discs instead of playing them.

Testing: Same behavior with multiple discs.

So we finally bought the world's cheapest CD player, which is an RCA model 1050 M-F. Fabrique en Chine, as one would expect. Worked fine until I decided to horse around and try to play the free CD that came in the mail from Microsoft the other day. Not surprisingly, it didn't play. Lots more surprisingly, our audio CD's won't play now, either, and Natalie won't believe that I didn't wreck the thing by trying to play a computer CD in it.

The symptoms are: You put a CD in and push the button to close the drawer. CD starts to spin up and then the drawer opens. The drawer never, in normal use, opens automatically. So I took the cover off and lugged machine over to the kitchen table, where it worked fine. Put cover back on, still worked fine. Re-installed it to Natalie's ancient Montgomery Ward receiver and it started with the music critic act again: put in a CD, it pushes it out again.

I didn't think that the fool drawer motor was connected into the microprocessor circuit. Does anyone have any ideas? Help?

(From: Vlad (vlad@chaos.bme.ohio-state.edu).)

> "I'm also a happy owner of a similar CD player.

> When I was inside it :), I noticed that the drawer is kept in locked position with a tiny plastic hook, and instead of metal spring to move the hook to locked position, they used plastic. At first, I could not believe this thing could work at all. The cover (or drawer?) is pushing a little switch, when it is locked. It has no other connections to anything important. If you can locate this little switch, you could try to press it and play the CD. Or try just to keep the cover closed with a hand ant try to play. Perhaps, this stupid cover locking mechanism does not functioning right."

The situation has progressed as follows: With the deck on the kitchen table and playing normally, I poked and prodded everything with the power on and the cover off. I noticed that one of the ribbon cables from the CD mechanism to the circuit board was sensitive to my prodding: when I'd push it with my finger, the sled would start to search and focus and stuff. Solder joints and everything looked fine, and the problem seemed to clear up after I removed and replaced the ribbon cable plugs. Plugged it back into the amplifier, and out the drawer comes--the machine won't play a thing. Back on the kitchen table, the thing plays fine.

I notice that the ribbon cable seems sensitive again. I don't know how long it took me to figure out that it was sensitive when I poked it with my finger but not when I poked it with a pen. (Not that long, actually--I used to be fairly accomplished at audio repair before CD's came out, and I'm suspicious of everything.)

To make a long story shorter, I've got an rf shielding problem. We have, it turns out, a strong AM radio station near the house, and the problem showed up after I plugged the power wiring of the stereo system in somewhat differently. In fact, the CD player works like a loop antenna. If I rotate it 90 degrees in its location on the shelf, it works better--hesitantly, skipping, but still trying.

The drawer mechanism is presumably involved because this thing has a remote control and simple pushbuttons to control things like the power and the drawer. These buttons activate interrupts to the microprocessor, which then executes the desired command. Apparently the rf is getting to the microprocessor and scrambling things.

I noticed late last night that the machine had settled down remarkably, and that the ribbon cable wasn't particularly sensitive to my massage techniques. I'm very glad I also noted that the radio station had gone off the air for the night as well: this morning, the drawer was up to its old tricks again.

I will discuss the problem with the dealer, but I don't expect much help in that direction. Then I will get at it with various remedies like 0.05 uF disk capacitors from power and audio cables to ground.

I haven't put the steel case back on the machine yet, though it's apparent from the construction of the player that they paid considerable attention to shielding and that they expected the case to be in place. I will apply my capacitors and maybe some ferrite beads and then put the case back on.

Sheesh.

Natalie was convinced that what I should do is to move the thing the next shelf up, away from the TV set. I had to explain to her that that wouldn't do any good because the TV set wasn't affecting the CD player by its unplugged presence. Back to work:

Having determined that the problem was shielding and bypassing, I checked my cabinets of little plastic storage drawers. Only the faded labels on these give evidence that they were once organized. They're now filled with random junk of a vaguely electronic nature. However, I found some 3-legged ceramic disk capacitors with ferrite beads on two legs. These were from a Radio Shack surplus capacitor assortment and were obviously meant for rf suppression purposes. I put one on each of the audio outputs, grounding them to the board ground. I also stuck one on the audio cable shield. Just for good measure, I stuck a big old 2kV 150 pf ceramic disk capacitor across the power line, which was already equipped with series inductors. I tightened everything that looked like it had anything to do with shielding and checked the continuity of everything thereof.

Stuck the case back on, paying particular attention to the single screw that connected the case to the ground. Set it on the shelf, plugged it in, put in the test CD. Spun right up!

And two seconds later, the drawer pushes open. Did it again, and again.

So what the hell. I took the books off the next shelf up and put the CD player up there. Plugged it into receiver and power.

That's the Bach Double Violin Concerto playing in the background.

From Sam:

> So, you are saying the TV picks up the AM radio station and does something to affect the CD even though the TV is unplugged????? Did unplugging the audio cable have any effect? Yes, I know it would be tough to listen to it that way but maybe the drawer would stay shut :-).

Could have been anything, actually. Among other things, I just rebuilt Natalie's closet. It shares a wall with the living room, and I put in two long pieces of 3/4" steel electrical conduit for her to hang her stuff upon. These could change the radiation pattern effectively. I also re-routed the TV cable under the floor. With the hills in this area, you can get the strangest rf on earth. Apparently I stuck the CD player in a local Bermuda Triangle.

Natalie is delighted, I must say.

Plugging the cables in did indeed affect the symptoms. A bit of experimentation showed that the cable shields seemed to be carrying in more rf than the core conductors: no effect when just the center pin of the RCA plug was inserted, but we got hunting and stuff when the shield made contact. Just touching the plug shield to the jack shield without the pin's being inserted caused disturbance.

BTW, I tried the Microsoft disk again. No sound, but no skipping.

From Sam:

> Right, the CD player is too new to gobble up CDROM discs or else the company has ties to Sun Microsystems instead of Wintel.

Repair Story #4: Magnavox Portable CD Player

Author: BELJAN E, Copyright © 1997, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or lvpy67c@ix.netcom.com.

Well, I just wasted nearly half my night on this piece of junk. Problem was that it wouldn't read CDs, but if you turned it upside down it would. The pickup would then slip out of alignment and start clacking. It took me an hour to get it apart (This is a Magnavox AZ6822) because of the stupid screws, I couldn't find screwdrivers to reliably get them out. When I got it apart, the design inside was simple enough, and I decided to take out the transport. I removed the transport, which is nicely supported by springs that fall all over the place. Well, I got the thing out, and you cant even tell what is wrong with it, because it isn't related to the circuitry. Well, I figured out that as you know, the lens slides along a metal bar, well at one end, a little plastic clip was missing. I figured this was logical since the unit was dropped about 5 times on concrete. Well, there I was, No clip, pickup mechanism out, what was I to do. Well, I found a seemingly unlikely solution. A piece of a broken Rod Antenna, the end was crimped, so I cut it off with tin snips. Well, what do you know, same thickness and width of the clip. I cut it to size, and put it in. Reassemble, and Bingo works like a charm, reads the CDs, plays fine. This was absolutely the worst CD player design I ever saw. Easy to scratch discs, eats batteries, but it took 5 falls on concrete to break it.

Repair Story #5: Toshiba TX-902 Car Radio/CD Player

Author: Peter Strezev KJ5CN, Copyright © 1997, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or jup001@airmail.net.

Editor's note: This one is a great example of persistence despite what would appear to be a hopless cause - a piece of equipment that has been previously butchered!

This car radio I bought at a garage sale in a hope to install it in my daughter's car if I could fix it. Evidently somebody had worked on it before because I could see signs of sloppy soldering job here and there, a few burned traces jumpered with wire, and also the 2 flexible wires between the LCD panel to the CD mechanism were not there at all. I fixed the obvious damage and used flat ribbon cable to hook the CD mechanism up.

At this point, the radio part started working. Attempts to play a CD did not succeed though: the disk gets "sucked" in normally, just sits there without rotation for a few seconds and then is ejected.

The laser is working: to check that I took a junk CD and sanded out a small portion of it where the pickup is located to make it transparent. This method works great by the way: I could easily see from a safe angle the tiny deep red spot inside the disk material without even having to turn the lights off.

From the following, I came to the conclusion that the the YM7121 chip was bad. I spent hours carefully checking everything else step by step (by the way, thanks for the great web page that you maintain: I found plenty of very useful information there).

Check on the focus search signals showed that none are generated. This led me to checking the IC in question, which is the main CD controller. I have the schematics, so I was able to compare the voltage levels on the pins of this chip to the ones indicated on the diagram. Only the VDD (no wonder) and some of the input signals are within the expected values. Rest are wildly off mark. But this is not all. The VCO test pin shows no oscillation at all (yes, I used a scope), and even the 16.9 MHz XTAL oscillator is not running. I checked every of the few components around the crystal and the crystal itself, everything is fine, so evidently there is something wrong with the oscillator amplifier inside the chip.

My last experiment was to take the crystal off the board and put together a quickie 74LS00 oscillator around it. Once I had this working, I tried to feed the 16.9 MHz signal into the XTAL IN pin of the YM7121. My hope was that if something went bad with the feedback in the OSC amplifier in the chip, I might get the chip to work by feeding it an external clock. No such luck :-{.

The output of my oscillator gets quite heavily loaded, everything else remains the same. At this point I accepted the grim fact that the YM7121 is fried. I agree with you, this is the last thing to happen, but I can suspected that whoever worked on this unit before might have burned it by accident.

So I need to replace a Part Number is YM7121C, 80-pin PQFP package.

I have not quite given up yet, so I will keep playing with it until I either return it to life, or say to myself "enough is enough". I placed an order for the replacement chip with Fox International Ltd (yes, I was surprised myself to find a place where you can actually order something like that).

It is an 80 pin WFP surface mount part. Yes, I do have certain experience with SMT rework which I have done on computer boards, so replacing the chip is not gonna be a problem.

But the best experience I had was with the hybrid metal/glass CRTs. That is, the ones which had a bare metal cone as the 2nd anode, and the glass parts (the screen and the electron gun assembly) welded to the metal on each side. Great way to learn about the safety issues when you have one third of the set having a dozen of kilovolts on it :-) :-). Just to add to the issue, most of these sets had a transformerless power supply. Nasty...

Let me update you on the CD player status. First, my determination to fix it was not because I want it so bad, but because of the great learning experience I have been getting in the process. Also, I am sure you are familiar with that feeling of satisfaction when you bring a seemingly hopelessly dead thing back to life.

You probably already figured out that I had some major progress. Yes, the thing is now working, flawlessly.

I got the replacement chip last week ($27 plus shipping, to answer your question) and replaced it on Sunday. Sure enough, it did not start to work right away. Even though the 16.9 MHz oscillator seemed to be doing something (remember, with the old chip it did not oscillate at all), the frequency was somehow 2 times higher (33.8), and looked very noisy on the scope. Nothing else worked, the DC voltages on most pins were still wildly off the expected values. After fighting with it for some time, I suddenly remembered the golden rule:

"if too many things seem to be so wrong, that you fail to even understand, how they could be so wrong, check the ground connections".

I started testing the pins on the YM7121, which were supposed to be on VDD and GND. Surprise: pin #77, which should be at the GND according to schematics, in reality is not. So are a few components around this pin which used the same PCB trace.

After rechecking my diagnose, I bridged the trace to the nearest ground, and turned the thing on. Viola! The VCO came on. Quick adjustment of the PLL free run frequency to make it 4,35 MHz, power off, reconnect the pickup, power back on. Yes, the disk starts spinning, I hear the buzzing of the focusing coil and even bits and pieces of sound start coming through. Next adjustment: E-F balance, brings only a marginal improvement.

OK, let's see what we have on the RF test points. The scope shows an eye pattern, but very shaky and jittery one. Suppressing my doubts I start tweaking the optical alignment screws. At some point the inner tracks start playing much better, but with lots of skipping and re-search attempts. The outer tracks are much worse no matter how carefully I try to find the proper alignment.

OK, maybe this is because all this time I had the CD mechanism upside down (this is the only way to reach the PCB and all adjustment points).

Turning the mechanism the right side up makes matters a lot worse: even the disk index search fails 100%, alignment screw does not help at all.

This tells me that something is wrong with the turntable adjustment.

Accessing the turntable requires a lot of disassembly (all these tiny screws and springs), but finally I am able to measure the turntable height. Yes, there is a problem: the manual shows that the height should be 5.0 +/- 0.05 mm, while I measure only 4.7 mm. Figuring out how to adjust the height takes quite a while, but finally I am on my way back assembling the thing together.

Power on: this time everything starts playing just great even before I re-adjust the alignment. Final adjustments on the first and the last tracks: great, the eye pattern is now clean and stable, the player works great the right side up, and even turning it upside down does not change anything.

Conclusion: Obviously, the chip I cruelly cut out and replaced, was not guilty at all, but hindsight is always 20/20. The fault in the PCB trace underneath the chip is probably a microscopic one, since I did inspect this part of the board when I removed the old chip and did not find anything unusual.

Repair Story #6: Sony TV with Power Problems

Author: David Klementovic, Copyright © 1997, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or djk@trsvr.tr.unisys.com.

Editor's note: The following is an excellent example of methodical, logical troubleshooting, taking appropriate precautions, and monitoring behavior leading to a successful diagnosis.

BTW, the gradual deterioration of performance/change in current is a good indication of a component drifting. This is going to most likely be a capacitor - bad solder connections, coils, and transformers don't drift but usually change their characteristics suddenly.

Good work!

My client asked me to repair his 5 year old Sony television which failed to power on. I put it up on the service cart, plugged in the line cord and tried to power it on. I heard a tic-tic-tic sound coming from the switching power supply board F. A quick check of the power supply was done with the ohmmeter but nothing obviously shorted or open.

Then I removed plug F61 from the power supply board, pressed the power on button on the set and the switching power supply began to work, I could hear the audio amplifiers working through the speakers. Something in the television chassis was loading the power supply down. I metered the brown wire on plug F61 (B+ supply) and found it shorted to ground. Then I tested the horizontal output transistor Q503 and it was shorted.

I inspected the flyback and other high voltage components and seeing nothing else shorted replaced Q503 (2SD1941) horizontal output and Q502 (2SC2688-lk) horizontal driver with exact replacements. Now, I know that frequently horizontal output devices are over-stressed by some other defect in the chassis so I prepared for this possibility by removing B+ jumper wire JW-41, inserting a 5.6 ohm 10 watt resistor in its place and clipped my voltmeter leads across the resistor. This gave me the ability to monitor the current being consumed by the flyback transformer.

I powered up the set slowly using a variac and an isolation transformer, the picture was good. I adjusted the variac for 125 volts AC, set the customer picture controls on the Sony to midway, (brightness, sharpness) and the Trinitone to LOW. I tuned to a music video channel on cable in order to observe the raster changing frequently from dark to light, and recorded a voltage drop across my 5.6 ohm resistor of 2.2 volts with a dark raster to 3.98 volts with a white raster.

After 10 minutes of operation, the voltage across the resistor began to climb even though the raster was fairly dark at the time. At 5 volts the right side of the raster began to shrink, and after about the loss of 3 inches of raster from the right side I powered the set off, alas there was more trouble in this set for me to debug. I inspected for problems with the scan-derived B+ voltages, pin cushion correction circuitry, deflection yolk and retrace tuning capacitor, nothing found defective! The trouble- shooting breakthrough came when I replaced a 0.47 mfd electrolytic capacitor (C525) which coupled the horizontal drive signal into the base of the horizontal driver transistor and C537, a 4.7 mfd electrolytic capacitor in the horizontal driver circuits. These two capacitors had weak- ened and had resulted in the eventual failure of the horizontal output transistor. I checked the horizontal waveform on the base of the horizontal output transistor and it looked OK. So I removed the 5.6 ohm resistor, soldered B+ jumper JW41 back in the circuit and tested the set for 6 hours.

The Sony worked fine and has continued to work for my client for 3 months now. Thank you for listening.

Repair Story #7: Beware the Nasty High Voltage!!

Author: Zapper, Copyright © 1997, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or zap@mhv.net.

I had to replace all three crt's in a mag projection TV. The "new" crt's were rebuilts. I usually do the blue and green first. Remove one, drain it, new crt, fill, reinstall,, fire up the set and "rough-in" the alignment, then move on to the green...do all the same then the red last. Yeah I know, should do the green last, but I have had both blue and green out before to change the fluid so red was really my reference....

so anyway.... I the green jug is in and the sets fired up... I reach up to grab the yoke to position it and WHAM-SNAP I get bit by HV. right from the anode cup... Not just one snap mind you, but snapa-snapa-snapa-snapa !!!!

Shit, I have done this the same way for years....Well you never know when its gonna getcha, heheheheheheh

Repair Story #8: The School of Hard Knocks!!

Author: A. R. Duell, Copyright © 1997, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or ard12@eng.cam.ac.uk.

The only way to learn is to make mistakes. I've been learning electronics for over 25 years now (!), and I still make mistakes. I fact, the last mistake I made when repairing something was last night - I unsoldered and replaced a 40 pin chip in a Tektronix computer before realising the fault was simply bad keyboard contacts (!).

Of course, as my skills have progressed, I make fewer mistakes that cause more damage to the equipment. I learned years ago never to overrate a fuse unless there were _very_ good reasons, and I learned somewhat more recently that it was a good idea to test a PSU into a dummy load before connecting the rest of the machine. I learned both those things the hard way. If I'd simply read them, I'd probably still be making the same mistakes.

People who are learning often make things a lot worse. I think most regulars here will agree with that. But that doesn't mean they shouldn't learn. Yes, it does mean they shouldn't (IMHO) 'be helpful' and try to fix other people's stuff for money. What they should do instead is obtain old stuff that would be thrown out anyway (and there's a heck of a lot of it about), and have a go at fixing it. If you make it worse, you've not lost much (and you've probably added a lot of spares to the junk box, and learned what not to do next time), and if you fix it, well, you've learned something as well, and got a working whatever.

I have lost count of the perfectly repairable VCR's and Stereos that I've written off because of secondary damage caused by well-meaning 'buddies'.

The worst one of those I ever saw was a Solartron DMM. The real fault was simply bad contacts on the switch-bank, but the idiot who had it before me had randomly replaced FETs with bipolar transistors ('the old ones didn't test right'), zeners and constant-current diodes with 1N4148s, etc. The result was that the _very_ expensive custom chip had died. Yes, it was worth repairing, but only just.

Repair Story #9: Chris's HeNe Laser Adventure

Author: Chris Chagaris and Samuel M. Goldwasser, Copyright © 1997, All Rights Reserved.
Comments or Suggestions to: Sam or pyro@grolen.com.

This is a on-going project on finding information and restoring a strange HeNe laser acquired by: Chris Chagaris (pyro@grolen.com). Research to determine the specifications and requirements involved postings to sci.optics, email correspondence, and a bit of luck - seeing a photograph of the mysterious laser in a book on holography.

Here is the original description (slightly reformatted):

(From: Chris Chagaris (pyro@grolen.com).)

I have recently acquired what I have been told is a 35 mW Helium Neon laser head. However, it is unlike anything I have ever seen before. (See the diagram, below.)

```
                Capillary tube/external starting electrodes

   Starting pulse  o-------+----------------------+
                         _|_                    _|_
    ||     //===================================================\\     ||
    ||   //=====. .==================. .=================. .=====\\   ||
                |||                  | |                 |||
  Mirror        '|'  25K             | |           25K   '|'        Mirror
         Anode 1 +---/\/\---o +HV    | |   +HV o---/\/\---+ Anode 2
                      .---------------' '--------------.
                   ---|-+                            +-|---
                      |  ) Main                Spare (  |
                   ---|-+                            +-|---
                      '---------------------------------'

              Gas reservoir with heated cathodes and getters
```

Jodon Laser Head shows the construction in more detail.

- It has no external markings except for "CAUTION LASER LIGHT" on one end and "DANGER HIGH VOLTAGE" on the other end.
- The exterior is a grayish/green rectangular metal box 4" x 4" x 32" long with a ventilated top and bottom. It has four adjustable metal feet on the bottom and a 1-3/8" dia. x 7/8" long silver bezel on the output end.
- The resonator tube itself consists of a 2 mm I.D. capillary tube approximately 27" long (with about 12 wiggler magnets along the axis).
- Attached in the center is a glass reservoir that is 30 mm in diameter and about 13 inches long mounted underneath.
- This large glass tube has what are some sort of filaments at each end with four electrodes on each. Only one side is connected to the input power wires (black and green) using only two of the electrodes.
- The only other markings are on this reservoir, and from what I can make out are "SM-7225-2 HN-7175 10-15-6".
- A white input wire (anode?) runs to ballast resistors (25K) connected to electrodes near each end of the capillary tube.
- A red input wire is connected to what looks like some sort of trigger transformer - one inch in diameter by 1-1/4 inches long with a 2-1/2" long x 3/8" core in the center (ferrite?).
- The other two input terminals of this transformer are connected to the black input wire which is also grounded to the case.
- The output of the trigger transformer is connected to two fuse clips externally attached 4-1/2 inches from each end of the capillary tube. There is about 300 ohms resistance between the input and output of this device.

Here is one reply Chris received by email from someone else named Marco. As you will see, this turns out to be a dead end.

(From: Marco.)

> "Hi Chris,
>
> This seems to be a really old one, or from other location than west Europe, Japan, and the USA.
> The 'SM' could be an abbreviation for Siemens, they had manufactured lasers from 1966 to
> 1993; until last year Zeiss/Jena has taken over the production; and since 1997 Lasos has

overtaken the production by a kind of management buy-out. You can send them the number, it will be possible that they know it. Contact Dr. Ledig. I will also look around if I can help you further.

HeNe lasers with a heated filament are no longer built. To see if it still runs you can attach a 3.3 V supply to the filament and see if it glows red, not more, to much heat will destroy it. You could use transformers from tube amplifiers for the filament and an old HeNe laser power supply for the anode.

This laser will need around 5,000 V and 10 mA I think. If you could only get a smaller power supply, you may not see any laser beam, but you can see if it will trigger."

(From: Sam.)

Here are my 'guesses' about this device. (I have also had email discussions with Chris.)

I agree with much of what Marco had said.

- This IS likely quite old. Unlike modern HeNe lasers, it uses a heated cathode instead of the common aluminum 'can' cold cathode. Perhaps the last number is a date code: 10-15-6. The '6' could either be the first part of a date that is rubbed off (e.g., '68) or the last digit ('66, '76). It is almost certainly before the mid seventies as HeNe tubes I have seen from that era were very similar to modern ones in construction.

- I expect the anode voltage (on the white wire) to be in the 2 kV to 3 kV range. Based on the diagram, the actual discharge length is about 12 to 14 inches in two sections, not the entire length of the capillary tube. The current may be higher than a modern tube because the bore is wider (2 mm). Perhaps, 10 to 15 mA for each section (20 to 30 mA total).

- With the wide bore, it may be multimode, not TEM00.

- A microwave oven transformer would be ideal for the main supply if it were not so dangerous. And it IS - don't be tempted. A voltage doubled boosted tube type TV power transformer should be able to provide 1,000 VAC resulting 2,800 V DC - this may be enough. At the expected current, an inverter might be tricky (at least for testing) as up to 100 W may be required.

- The trigger transformer probably operates like one for a large photoflash or flash lamp pumped laser. I would guess discharging a capacitor of a few uF at several hundred volts into it will work. However, if I were building the power supply, I might just ignore the trigger transformer and use a more conventional approach - a voltage multiplier or HV inverter. One less unknown to worry about. However, each of the two anodes would need to have its own feed from the starter.

- With too small a power supply, there would likely be at least a flash of laser light at the instant that the discharge was initiated - if the tube is still functional. This would occur even if the power supply was inadequate to sustain the discharge.

- I would power the filament from a low voltage transformer using a Variac and, as noted, not push it!

Unfortunately, Chris has determined that regassing will be required and he is equipped to do this but there will be some delay in the results.....

(From Chris (a few months later).)

Well, tonight while looking through the "Holography Handbook" I spied what looked suspiciously like that elusive laser I have. It said it was made by Jodon Engineering Associates of Ann Arbor, MI. I immediately called them and was fortunate to have the engineer (Bruce) who has built their tubes for the last 18 years answer the phone. I told him of my plight and read off the numbers that were on the plasma tube. Sure enough, it was one of their early lasers. They have been manufacturing HeNe's since 1963. He provided me with many of the details that I had been searching for.

- The laser is rated at 15 to 25 mW output.

- The capillary tube is 2 mm in diameter.

- The heated cathode requires 6.3 volts at 2.05 amps, (and, there are two sets, one is the spare), the getter assembly (a spare here too) can be fired using a variable supply rated at 6 VDC @ 10 amps.

- He wasn't sure about the operating voltage but assured me that my variable 4,000 volt supply would be more than sufficient. The current requirements are 9 to 11 mA on each leg (two anodes).

- The optimal fill pressure with a 7:1 mix should be 1.85 torr.

- He also explained the reason for the wiggler magnets along the capillary tube. These are used to suppress the 3.39 um line which competes with the 632.8 nm line and can rob up to 25% of its power.

I explained that I planned on trying to re-gas this antique and he offered to help with what ever information I needed. It is truly refreshing to find someone in the industry that is willing to help the amateur without an eye on just making a profit.

I finally located a small supply of HeNe gas, just yesterday. While visiting North Country Scientific to purchase a pair of neon sign electrodes (in Pyrex), I mentioned my need for a small amount of laser gas for my laser refurbishing project. (This was formally Henry Prescott's small company that supplied all the hard to find components for the Scientific American laser projects.) Lo and behold, there on a shelf, covered with dust, were a few of the original (1964?) 1.5 liter glass flasks filled with the 7:1 He/Ne gas mix. He let them go at a very decent price!

(Hopefully, those tiny weeny slippery He atoms have not leaked out! --- sam)

Now, about the magnets:

The magnets are of rectangular shape, one inch long, 3/4 inch in width and 3/8 inch thick. There are a total of 26 magnets placed flat against the top (14) and flat against the bottom (12) of the plasma tube as viewed from the side. All but the ones on the very ends of the plasma tube are attached exactly opposite from one another, top and bottom. (See Jodon Laser Head for placement and field orientation).

They are placed with the long side (1") parallel to the plasma tube with the north and south poles along this axis.

They appear to be of ceramic construction and not very powerful. Sorry, I don't have any means of measuring the actual field strength.

The current status of this project is that the laser needs to be regassed. Chris is equipped to do this and has acquired the needed HeNe gas mixture.

To be continued....

Photos of a similar but much larger Jodon HeNe laser (3.39 um IR in this case) can be found in the Laser Equipment Gallery (Version 1.41 or higher) under "Jodon Helium-Neon Lasers".

Repair Story #10: Paul's Sony 27XBR15 Saga

Author: Paul Grohe, Copyright © 1997, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or rohe@galaxy.nsc.com.

Prolog:

Date: Thu, 20 Nov 1997.

Hi All,

Sony experts...help!! I'm puzzled! Any hints???

The details:

This is a circa 1990 27" Sony with dual-tuner PIP, "ANU-1" chassis (same basic "guts" as the non-PIP 27XBR10's).

Last weekend I was flippin` channels when the screen just went blank between flips. The set seems to be functioning completely normally..except no picture! Tuner works, sound okay, PIP seems functional, video inputs switch, high-voltage okay, filament lit, remote works, "sleep" lamp is off and I could hear the H & V scan change as the channels changed.

Wrestling the set up on to the bench, I narrowed down the "bottleneck" to the Y/C/J "Jungle" chip.

After convincing myself that the chip was bad, I ordered another one ($30!). To make a short story longer....It did not help.

The suspect was the 48 pin "IC301" (CXA1313S) Jungle chip on the main "A" board. The chip contains the H & V stripper circuits as well as all the digitally adjusted Y/C to RGB conversion and switching circuitry. The RGB outputs of the chip then go directly to the neck board drivers.

There are three video inputs to the chip, the Y/C input, the RGB input for the OSD and another "ext" RGB input for the PIP circuitry. I can see correct tuner/aux video signals at the Y/C input pins, and good OSD and PIP video RGB signals. However, the RGB output pins just show a positive going ~50uSec pulse. No "video" at all.

The problem is that all the usual video "adjustments" are performed by multiple D/A's in the chip. There are no coils or pots to adjust.

The sync sections of IC301 seem to work, as I can see it "lock" as a video signal is applied. All the sync signals are there and look okay. Voltages and waveforms around the Sync and Video *inputs* of the chip are very close to what the manual shows.

The neck board and CRT seems okay, as applying appropriate voltages *directly* to the neck-board inputs results in the expected Red, Green or Blue rasters (with retrace lines). The raster appears at about 3.8V and is full-brightness by about 5.5V. Going too-far trips the X-ray protection (as expected).

The biggest error is the DC level at the chips RGB outputs. The manual claims 3.9VDC. Right now the outputs are 0V with a 3.5V, 50uSec positive going pulse (V-rate). There should be 1.5Vp-p of video signal on these outputs. I am assuming that I should see the video signal between 4 and 5.5V.

The manual claims 2.4V for the "ABL" input, and I measure 2.5V. More discrepancies:

- The "filter" pin #27, measures 0.6V, instead of the 7.8 V claimed (can anyone confirm this? Could it be 0.78 V?).

- The three "AKB-R, G & B" pins should be 6.1 V, but measure 3.9 V.

  I'm getting the feeling that the chip is being "told" to misbehave.

Questions:

- Would there be any failures *anywhere else* that would cause this chip to blank the screen? The protection circuits (X-Ray & ABL) do not seem to be activated and the "Sleep" light is off.

- Is this chip, IC301 (CXA1313), known to fail?

- The "VM" mute lines shows a 7.5mSec, 2.5V "fuzzy" square wave - is this normal??

- EEPROM failure??? All the channel settings are correct.
- Anybody else seen this problem???

Any thoughts appreciated!

Help!!!

Here is update #1

Date: Sat, 22 Nov 1997 09:30:36 GMT

I want to thank everyone who has responded!!

First off; NO, it is not the regulators. Been there, dunnit months ago.. All supply voltages are "normal" and steady.

Alan Harriman sent me a copy of a previous post from "cyberchaos" about "IK Shutdown". It hit the nail-right-on-the-head. There *is* a reason why the chip would shut off the video!

This is a copy of the earlier post by "cyberchaos@aol.com":

-- begin quote --

> "Other than power supply problems, this is the second most common circuit to give people problems on our sets made in the last 5 years. If you have high voltage and vertical deflection (as you indicated) the unit is probably in what we term as 'IK blanking'.
>
> The jungle IC sends a 60us pulse in the vertical blanking area in order to monitor CRT cathode current, thus maintaining white balance. Each color drive output has its own pulse in this area (Red=line 17, Green=line 18, and Blue=line 19. These pulses are them matrixed and returned to the jungle IC to be monitored. If one or more of the pulses does not return (or is very low) the jungle IC will keep the video off. Bad video drivers, weak CRT cathodes or faulty IK pulse return circuits will cause this symptom".
>
> Here's how to find the cause: Even though the video is off, the Jungle IC is sending the pulses to the CRT board. Measure each of the cathodes with a scope. At vertical rate you should see a 60us pulse at each cathode about 20-50 volts in amplitude. What we're looking for is one of the cathodes to either have an extremely large pulse (in comparison to the other two) at about 150 Vp-p or having no pulse at all".
>
> If one cathode has no pulse, troubleshoot the driver circuitry for that color.
>
> If one cathode has a very large pulse, the cathode is weak or the return pulse is not making it back to the Jungle IC. To tell if the CRT is bad, turn up the screen control and see if you get a raster with one of the primary colors missing. It should be the color that you saw the large pulse

on. If the raster is white or is slightly dominant in one of the primary colors, the CRT is probably OK. Troubleshoot the IK return buffer transistor and associated components for that driver.

If all 3 cathodes have a large pulse (150VPP) Then check the following:

1. The IK buffer transistor which is sending the combined pulses out of the CRT board (all three must be present here and at least 700mvpp).

2. The screen control is turned too low.

3. G1-G2 short or leakage. this will be evident by G2 voltage dropping drastically while the CRT board is mounted on the tube and raising when removed."

-- end quote --

It looks like this is what is happening, but it is the result of another odd problem on the neck board.

The green cathode shows a "normal" pulse, but the red and blue show a strange 11 cycle pulse train where the "IK" pulse should be.

Cathode waveforms:

"Good" green cathode:

```
----+    <- 60uSec ->   +------------- 200V
    |                   |
    |                   |
    |                   |
    |___________________|           ___80V

______________________________________ 0V
```

The red and blue cathodes show a really "weird" pulse train during their "IK" interval.

```
    |-| 5 uS apart, 1 uS wide.

----|-|-|-|-|-|-|-|-|-|-|------------- 200V
    | | | | | | | | | | |
    | | | | | | | | | | |  (11 pulses)
    | | | | | | | | | | |
    | | | | | | | | | | |           ___80V
```

```
______________________________________ 0V
```

The eleven narrow pulses are triangular, stable, 5uSec apart and 1uSec wide. They roughly occupy the same "area" as the "normal" pulse.

Simplified output stage:

```
        +200V
          o
          |
          /
          \ 8.2K
          /
          |           B     1K
        A +----|>|----+----/\/\-----o To cathode
          |           |
          +----||-----+
          |  680 pF   |
          |         |/ E
          +---------|    PNP
          |         |\ C
        |/ C          |
 9V o---|    NPN      |
        |\ E        __|__
          |         _\_/_
          |           |
        |/ C          |
  In o--| NPN        E \|  (PNP)
        |\ E            |--o gated 173 V
          |          C /|
          o            |
       to 'I'          o
       source    to protection
                 summing node
                  and buffer
```

Here is where it gets weirder.... On the driver transistor collector, there is a "normal" 200-80-200V pulse at point "A". But on the "CRT" side of the diode (point "B"), the "weird" pulse-train appears. The waveforms remain the same even if I isolate the CRT cathodes; so it does not seem "load" dependent.

Removing or bridging the 680pF cap makes only a slight difference. The transistors and diodes look "okay" on a curve tracer.

The IK feedback pulses reflect this "pulse train" waveform. The green interval shows a 0.6Vp-p level, but the "pulse train" shoots up to 3.5V. I can also see the amplitudes rise as the load of the scope probe is applied to the cathode.

Here is an example of feedback waveform at the "IK" pin 25

```
|||||||                                - 3.5V
|||||||
|||||||         | 1.2V "spikes"
|||||||_________|_______               _ 0.6V
                        |
                        |
"R"      "G"      "B"     -------   - 0V
```

I discovered this late last night, so I left it at that, saving the "digging" for later.

Tonight, I was in the middle of tracking down the cause of the "weird" pulses, when I pulled a "bonehead" stunt. I accidentally clipped the scope ground clip onto the 1000V "G2" line, instead of the ground next to it. This stunt blew the 1000V rectifier diode and flameproof resistor. So until I get some new parts, I'm "SOL" for now. Hopefully I can pick some up replacements tomorrow.

So, Stay tuned! (If your %#@%!# TV works!)

Here is update #2

With a quite possible happy ending.

Date: Sun, 30 Nov 1997 01:43:02 GMT

Now that the Holiday Hoopla is over, I had time to take another crack at the set.

I was going nuts trying to track down the source of these funny "pulse trains" in the video circuits. I did not want to call them "oscillations, because the pulses were too regular and did not "vary", as you would expect a feedback-type oscillation to act.

Suspecting "flakey" parts in the neck board, I swapped parts between the "good" channel and the "funny" channels. No difference - no better, no worse. I was stumped!

I then began to suspect the Jungle chip and it's associated parts again. I began swapping/bridging the various components around the chip...again. When I bridged C309, the "AKB-R" capacitor, the strange "pulses" for that channel went away. So I did the same for the other two "AKB" capacitors. When I touched in the last cap, BINGO!, the picture came back on! Yippee!

The three caps (C309,310,311) are 0.1uF film caps hanging off IC301 that are used as integrating capacitors for the "IK" sampling circuit. It seems a little strange that two of the three caps would go "bad", but stranger things have happened!

The removed caps all measure the same on the bridge (C & ESR @ 1kHz). Unfortunately, my "junk" box is out of similar 0.1uF film caps, but I will get some next week. Right now I am using ceramic "bypass" capacitors. I cannot announce "success" quite yet.

So, If you have no video, and see set of thin "pulses" on *any* of the RGB input lines, "IK" line and cathodes, try bridging/replacing C309, C310 and C311.

Hopefully I will be able to button-up this set by next week.

Cheers, Paul Grohe

Date: Mon, 1 Dec 1997 04:31:18 GMT

(Indented text from: Michael Caplan (cy173@freenet.carleton.ca).)

> "As you noted, the three caps are at IC301, in the same area as the video outputs to the RGB. I believe the caps are on pins 19, 21 and 23, and the RGB outputs are pins 20, 22 and 24."

Yep. That's it. The caps are 0.1uF to ground.

> "I am puzzled by the causal relationship -- I wonder how or why the defective capacitors caused the IK pulse at the CRT cathode to be a train of pulses while, as I recall, at the collector of the first video amp on the CFT board the pulse was "normal"."

I believe I was looking at the good, green channel. Subsequent tests showed the pulses on both sides on the blue and red channels. Should have' mentioned that!

The "current detection" circuit outputs are all summed into one junction, and all three video amplifiers share a common current source. It could be feed through.

However, each color is "pulsed" individually, not at the same time, so the "runt" pulses from one color can't simply feed-through to another....strange.

> "Perhaps there is someone more familiar with the SONY IK system who might enlighten us."

Please do! Or, does anyone have a datasheet for the Sony CXA1313S "Jungle" chip?

When I did the initial checkout of the jungle chip, I *did* bridge each cap *individually*. Because I was not aware of the function of the "IK" system at the time, I did not know what to watch for! It finally took bridging ALL THREE caps at the SAME TIME to restore normal operation.

More puzzling to me is why the caps went bad at the same time. Any spike big enough to kill the caps should have killed something else! If IC301 was "zorched", the new one should have worked.

"Sometimes a little "break" and lots of perserverence help."

Or, a more powerful force: "Honey...Isn't the TV fixed YET!?!?!?"

Repair Story #11: This Throwaway World - a Telephone Tale

Author: Ron Dozier, Copyright © 1997, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or dozier@udel.edu.

Problem: Callers and callies complaining about excessive noise on telephone line.

Diagnosis: Noisy Radio-Shack phone

Possible remedies:

- Buy another phone.
- Fix phone.
- Have phone fixed.

Constraints: Cost, holes in wall accommodating that phone.

Experience buying another Phone:

- Retails for $50.
- On sale for $30, salesman doesn't immediately know that.
- Salesman tries to sell another phone.
- He also tries to sell extended warranty: 3 years $15.

Conclusions about buying another phone.

- Sale - got lucky.
- One year of phone service for $50.
- Three years of phone service for $50+15 (retail prices).
- Buy a schematic - I refer to them as insurance policies $10.

Have phone fixed:

- $35 + parts. Guarantee - unknown

Fix phone myself:

- How does one fix phones?
- Buy a service manual - $10.
- Ah Ha - Good ideas for testing phones, bad component values 10H choke? - Na.
- Buy Xformer 600-600 100 mA DC, LM317THV and 43 ohm resistor,
- Wire as 30 MA current source and add 40 VDC power supply. Neat. $15.00
- Try on passive phone, Observe on scope. Can't blow them up as easy. Works. Touch tones work. Can see dirty contacts, etc.
- Try bad phone. Yea! Great! Noise!
- Use troubleshooting chart - oops - noise not listed as a problem.
- Use brain - determine TEA1062A IC is bad.

Time passes (next day)

- Try to order part from local Radio-Shack. Can't e-mail RS and ask why they don't want me to buy their products.
- Last item I bought only 15 items were available for replacement part on a currently sold item. (mini cassette recorder)
- Went to IC distributor down the street - NO luck.

Internet search:

- Chipdir - Chip made by Phillips, distributed by Marshall.
- Listed at Marshal as not in stock and costs $1.00. $10.50 seems to be added to all orders. Backordered no more than 182 days (so the site tells me).
- Look at data sheet: Radio shack phone missing 100 uF CAP on power supply to blown IC. (Probably missing on purpose: expensive part, makes phone break). More protection is needed for pulse dialing, but you need to order publication X to find out what it is.

So for $30 (sale phone) + $10 (insurance policy a.k.a. service manual) + $15 (testing gizmo) + $12.50 (ordered TEA1062A) + unknown wait, I now have:

Total: $62.50

- New phone that needs a CAP that would void warranty.
- An education in troubleshooting phones without a phone line.
- An old phone that contains all the parts that won't go bad on the new one. (remember I bought an Insurance policy)

All I really needed was:

- A service manual - With the phone would be nice.
- A part that costs $1.00.
- Know how to test a phone.

My nature forces me to puzzle solve. It's fun. It's entertainment. It's frustrating. It's my nature.

It's no wonder why you throw it away.

Repair Story #12: AIWA Model RX-N373U Mini Stereo Repair Tip and Comments

Author: HA11747ANT and Jerry G., **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or ha11747ant@aol.com or jerryg@total.net.

(From: HA11747ANT (ha11747ant@aol.com).)

Patient: AIWA RX-N373U mini stereo receiver.

Symptoms:

When you turn on the power, the receiver comes on and immediately shuts off, blanking the digital display. After about 10 seconds, the display comes back on flashing "12:00 AM" (if clock was set in receiver). When the display comes back on, pressing power will repeatedly do the same thing over again.

The cause:

I found (after about 3 hours of troubleshooting the power supply and microprocessor) found the main power amp module IC203 (STK-4162II) bad. How I found this was not easy. I finally resorted to jumpering the relay's driver transistor (Q108) between the emitter and collector, energizing the relay, which switches on the main power amp's supply rails. The display went black immediately, and did not come back on until 10 seconds after I removed the jumper. While the relay was energized, I went to the speaker outputs and checked for DC offset, low and behold, the left channel was at the full negative supply rail (-39 volts)! The right channel was OK. I haven't put in a new module (I wont be able to do that until Monday), but hopefully that will repair this receiver. If I went to the module itself and disconnected it's speaker outputs from the main board, the receiver would come on normally.

My Comments:

This one was definitely a strange one. I was rather upset (learned more words to my vocabulary which I won't repeat here), after going for 3 hours to find a bad STK module. What kills me is the rather strange protection circuitry used in this receiver, if there's a fault in the power amp, the damn receiver won't even come on properly to reveal the fault. It kind of pi**es me off to see stupid circuitry designs like this. I thought the Pioneer RX-series "blow line" was stupid, but this one takes the cake. In my 25 years of repairs, I've never seen something as retarded as this. I would have to call it an "overdesigned circuit", yet the simple speaker relay protection I've seen in many units would suffice.

(From: Jerry G. (jerryg@total.net).)

Do you think that if the receiver was allowed to stay on, and the speakers were left connected, they would be destroyed? If the STK chip is putting out DC to its output, this is very dangerous for the speakers!

When I troubleshoot these types of units, I never connect the speakers. I use a sample and hold voltmeter. I get a full DC from the supply for a bit less than a hundred milliseconds if the chip is shorted...

Technics has a few receivers that don't have a protection at all for the DC outside of the chip itself. I have had a few cases where the speakers actually caught fire!!! One model that I had a few cases on was the SA 350 series. I have been told it is know for this!

In fact I have one here at the moment that destroyed a pair of expensive Tanoy speakers. The customer went to the manufacturer and got nowhere with them. They didn't want to know about it! She dumped the receiver on me. I fixed it, but I later on will be adding some very large non-polar coupling caps on the output. This will fix the DC problem if the chip blows again!!! Then the receiver should be safe for speakers if the output chip blows again...

Most of the time these chips blow when the user tends to put the volume too high for the rating of the receiver, and there is some distortion. This makes it run too hot, and will eventually break down. Another problems is when the customer goes and buys 4 ohm speakers for a unit that is designed for 8 ohms only. And, the classic problem that causes breakdown is that people sometimes don't connect the speakers properly. Some of the strands may touch each other, or the wires are not on properly.

Repair Story #13: JVC 7300U VCR -- Fixed (Almost)! And Adding Remote Control

Author: Joe, Copyright © 1997, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or pichej@shaw.wave.ca.

I'm providing this for anyone else as a few pointers which might help fix a senior VCR :)

Problem #1 -- Tape play would abort in mid stride.

> Closing one of the switches on the bottom would start the machine in playback mode. Tracing the mechanicals back led me to the tape transport motor and belt. If I hand cranked it through, it would complete the cycle. Simple fix.. Replace belts with better ones from my old toasted VCR.

Problem #2 -- No RF out.

I had all the signals in, but no output. I scrapped the old RF converter, and inserted one from an old Sega Master system that half worked. Now RF out worked.

Problem #3 -- No video, from either RF or video in.

Problem traced to a wire that had sheared off of the circuit board. Simple resolder job.

Problem #4 -- Scrambled video out.

Lucky guess. I had an approximate idea were video was being processed because of the last problem. 3 pots were in the area. I found that I could adjust them to get a washed out red hazy picture that was viewable (best). Figuring that my finger would do something to the picture,

I found that putting it across one of the pots improved the picture to perfect state! Then I tried a 1k resistor, same effect. Soldered it on, works pretty well.

If some one would like to explain why it worked, I'd love to hear why!!

Problem #5 -- Uneven record speed.

Replaced a magnetic pickup on the video head with one out of my old JVC VCR. I probably buggered it up when I was tracking down problem #1, with the head spinning, and screws out of the transport.

Sh*t happens :-)

Problem #6 -- No RF in (did work before).

Channel selector flickers on and off, no RF in signal. Probably won't fix it either. I use a cable box to pick stations. (57 channels and nothings on).

Likely a loose wire, broken connector.

Problem #7 -- Won't record.

Records scrambled, and aborts. Like it used to look in #5. If I play back, get a good video signal off of the tape (good picture), then record, it works. Not straight off. Probably one of the pots I screwed with is off. Picture is a bit overly bright.

Project #1 -- Add a remote control to a dinosaur.

I found a radio electronics magazine (Aug 1995) that covers building a remote control unit using a PIC. I think I'd like to add this to the VCR. Use the IR remote control and module from my old VCR, and add remote play, stop, fast forward, rewind, pause, and record. A latch, and a transistor or two, and it might be real practical :-).

Repair Story #14: Quasar VCR Problems and Service Center

Author: The Tooth Wrath, **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or nelsonr1@means.net.

This is my mother's VCR, a Quasar VH400.

I took it to Zap-City (true name suppressed) TV and Electronics after it started refusing to load tapes. I was quoted a $25 non refundable diagnosis fee, and was told that given the symptoms the repair would likely run $25 in addition to this fee. A few days later, they call my mother and tell her the repair will be $125.

Since I can buy a new VCR for that, she wasn't going to pay that, but I wasn't going to let Zap-City have the VCR for free so I went and picked the carcass back up. I set it on a shelf when I got back home, and it sat there for a couple of months, and then one day I decided to see if I could diagnose and repair it myself.

I can fix most mechanical VCR problems if I can find the trouble, but this had appeared to be a sensor problem, so I had thought it better to leave the repair to a VCR shop, and chose Zap-City, a factory authorized service center for this Quasar VCR.

I thought the repair quote from Zap-City was obscene, and told the joker there that I believed I was at least entitled to a detailed diagnosis for my $25, and he refused. He made some remark about the trouble being in the tape transport was all.

So two months later, when I hauled it out to take another look at it, I suspected I might have made an error in my assessment of the problem being a sensor problem, and I decided to examine the tape transport.

I was thinking I would find a stripped or broken gear somewhere, since the joker at Zap-City had said the problem was in the transport. I figured I could find the problem gear and make a new one with fine sand casting and curable clear plastic epoxy.

The only way I found to move the tape transport from full disengage to full engage was to turn a worm gear by hand. It took 72 turns, which was a pain in the butt. This is one reason I gave up so easy the first time.

Then it hits me, I can hook up a big 6 volt flashlight battery to the tape transport motor, and use that to drive it back and forth so I could do a full gear inspection. Worked pretty well, too. I removed the entire transport and ran it back and forth about 50 times, looking for the problem gear. But all the gears appeared to be working perfectly.

Then I noticed it.... There is a little return spring that carries the tape to the sound head, and it had been bent, (The VCR started acting up immediately after it ate a tape.)

All I had to do was to remove this spring, use a needle nose pliers to bend it to give it more tension. I reassembled the unit, and it has been working perfectly ever since.

Damn, Zap-City wanted $125 to replace a bent return spring, I guess they think their time and 'expertise' are far more valuable then the rest of you normal people's...

Anyway, since I got it back, when it records the sound on playback is really low, pretty near inaudible when an older used tape is used for he recording.

Prerecorded tapes and tapes it made earlier play back at normal volume. The picture and tracking are perfect, and I aligned and centered the sound head.

I notice there is a resistor to the right of the tape transport which has obviously been overheated, to the point where I cannot read the value to be able to replace it. Could this be the problem component? At any rate, I would appreciate it if someone could tell me the value of this resistor, and/or give me any input on what the problem might be.

I would also appreciate it if someone who knows Matsushita's email address would give it to me. I would like to narc on Rite-Way, but I can't find any email links on Matsushita's worthless Web pages.

(From: sam) In all fairness, Zap-City, like you, probably didn't have any idea what the problem was when they issued the quote. They just knew that it wasn't obvious and thus they didn't want to deal with it!

Repair Story #15: What a Nice VCR

Author: Paul Jones, Copyright © 1998, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or pjones@caltel.com.

A friend gave me a nice VCR.

It had a fried SMPS. I spent $15 on a kit from SK. It didn't have the 82 uF cap which of course had blown its top! I finally got it working even though the test instructions were erroneous.

Fired it up and the video head bearing is really noisy. I went to a bearing house figuring $10 at most. Nooooo! "Yes, we have them at our Tracy, CA warehouse at $38 each", he mumbled something about precision bearings. I said I didn't think the VCR maker had paid that much. They checked some more and said they could get them out of Atlanta, GA for only $7.81 ea plus shipping and gouging. I said thanks and left. I then tore apart a swap meet machine I paid $10 for and lo and behold same bearings. I gently removed them and then installed them in the other machine. No more picture!

Read FAQ (should have before!) I didn't mark position of motor.

Lots of tweaking, finally got it back. Whew! I guess it was worth it....

Repair Story #16: Now I Wonder Where Those Parts Went?

Author: Charles N. Horton, Copyright © 1998, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or carolus@mit.edu.

Here's one that should be right up your alley, if you can get past my lousy description of the problem. A girl I know wanted me to fix her combination TV/VCR, which had eaten her tape. I agreed, somewhat reluctantly, to open the case. So we managed to get the VCR out (score one for Zenith -- they made the board with the VCR assembly easily removable; whether this is good engineering or cynicism I'm not sure :) and looked at it.

Oh yeah, the symptoms: When plugged in, the machine would power up (sometimes without even needing to be switched on!) for a short time, maybe a few seconds, then turn itself off. The VCR made a rather unhappy sound during that time, as though it were trying to eject the tape. The tape was quite mangled; the heads were away from it and the tape door was closed, but the tape had gotten caught in the door and crumpled.

Secondary goal: fix the VCR. Primary goal: get the _____ tape out :)

Back to the story... So the only thing about the VCR assembly that didn't look fine, aside from the unspeakably cheap Third World construction (one metal piece was attached with TAPE!) was a capacitor. Around the base of this capacitor was some hard white stuff. It looked like it might have come out of the capacitor, although given the general care that went into assembling the VCR I thought it could have been insulation. What do you think? This capacitor was in the general region of the power supply, BTW.

Now, to vent for a moment: This TV reached the ripe old age of 2 years before dying. When we opened the case, there were already 2 pieces free inside it: an anonymous piece of clear plastic, and some sort of little metal piece that had liberated itself from some mechanism. The person across the hall from this girl has a VCR, also two years old, that has stopped recording. I have a Sony tape deck that I've had for a couple years, and one of the two tape bays doesn't work.

We also have a Panasonic VCR circa 1980 that still works fine (no repairs in its 18 years, except one lamp that burns out every few years -- which is user replaceable with a soldering iron), a BiC tape deck from before I was born that works better today than my Sony did when it was *new*, and so on...

From sam:

The white stuff may just be adhesive especially if >it is dry and hard. Though, that glue (when it turns brown) is known to >short stuff out! The little prism thing may be THE problem - part of the tape-in sensor or one of the end sensors. Figure out where it goes and at least some of the VCR problems may be solved. I am waiting for the next installment.....

Repair Story #17: Where the VCR Saved a Computer Monitor

Author: Paul Millington, Copyright © 1998, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or pm@digitalnebula.com.

Please help!

Problem: Broken VCR circuit board from shock of computer monitor landing on top of VCR while moving electronics in car during rush-hour traffic (sudden stop.) Plus, it is my friends $1400 VCR that I broke. Circuit board broke into 2 pieces. Copper tracers(?) broke. Need to reconnect tracers.

Status: I have etched away all the green stuff, and epoxied the 2 halves together.

Solutions: The only things I have found so far to fix it are "Pretinned solid bus wire", 24-gauge, $1.79 from Radio Shack, or a "Etch your own PC board" kit, $13.99, from Radio Shack also.

Available tools: Radio Shack solder gun, wire strippers, and about $50.

Questions:

- What is the best way to repair it?
- What is the most economical way to repair it?
- How should I do it?
- Is there a good Web site or manual out there that would help me?

(From Sam: After several replies to this plea for help on the newsgroup sci.electronics.repair, we have the following mostly success story.)

Update: May 14, 1998

The VCR is fully functioning again--well almost. The only thing not working is the channel up and down front panel control and also the channel up and down controls through the remote. However, channels can still be selected directly by using the remote to input it, such as "11." Usually the best way anyway. I figure it is just a lose connection somewhere else on another board, but I didn't see anything.

The procedure used in repairing the VCR:

First, the broken circuit board was epoxied together, which ended up looking like it had never been broken. I made sure that when i epoxied it together, that i could still see the traces well. Next came the long, tedious part. In all, i had to make about 25 broken trace jumps. I used #30 wire-wrap from Radio Shack, 0.022 silver bearing solder, Rosin Soldering Paste Flux, and a 15 W solder iron. I probably should have used a magnifying glass too, but didn't have enought money to get one. I just followed the broken traces back on each side of the break to the closest soldered pin (please note i don't know the proper technical definitions) and placed a very small dab of Flux on the point with the end of a paper clip. In most cases, i just re-heated the old solder and placed the wire-wrap end into that, so i hardly used any of the solder i had purchased. This was mainly due to the fact that the pins were so close together that i didn't want to risk shorting anything. Finally, to add strength to the epoxied joint, i cut up one of my old credit cards, and epoxied a small piece to each side of the board.

When i was finished, it kind of looked messy with all the wires, (25 of them or so) going in various directions over the circuit board. I tried to flatten them out as good as possible and then applied some electrical tape over a couple locations to help hold the wire in place. I wouldn't call it a work of art, but at least the VCR is working again. I noticed that the point where the break occurred also had a small plastic support going from the front panel display to the circuit board. I had to break this off (well, i tried to shorten it but is broke) because that was the same place the credit card support was added. I figured that was also a cause for the break in the first place--over 10 years of use, this location probably became weak whenever someone pressed the eject button. And there is no eject button on the remote, so this probably had caused small stress fractures in this area, which eventually broke when the 17" computer monitor landed on it in the car.

All in all, I probably spent 12-15 hours to get to this point. It turned out to be a good decision for me to repair it because it would have cost anywhere from $600-$1500 to replace it (it was a top-end Hitachi from 1988, with digital effects, Picture-in-Picture, S-VHS, Hi-Fi, Level control, and many other hard to find features that most current VCRs don't have.) Not to mention that I probably would have just been playing Jedi Knight with that time anyway. So it was a good learning experience. My friend has his VCR back and is satisfied with its condition, although i would like to get the channel up/down buttons working for him. Boy, am I lucky (or unlucky for breaking it in the first place.) Wish me luck in Saturday's $110,000,000 Powerball.....

Repair Story #18: The Saga of the Mini-Scope

Author: Stephen J. Conner, Copyright © 1999, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam s.j.conner@strath.ac.uk.

A while ago I was presented with a mini battery-powered scope, an irresistible toy by any accounts. 'For the engineer who has everything'...

Made by a British firm in the Seventies, it had dual traces and 20 MHz bandwidth. The whole thing ran off six 'D' size nickel-cadmium batteries. It had a cute 4" screen and was about 9" by 14" deep by 5" tall. Like most British instruments of that era, all the transistors were in sockets!

The previous owner was a scrounger like myself, and he had given up on it as a bad job. But it was such a dinky piece of equipment it might as well have worn a T-shirt saying 'Please Fix Me.' I made up my mind to do whatever it would take to get the thing working. I didn't know it, but I was in for an epic battle!

Act One

Before getting stuck in I inspected the service manual. (Yes, it came with a service manual.) On one of the schematics pages, a large arrow had been drawn on the EHT tripler, with the helpful legend 'Burning here!' Further down the margin was a note; 'Replacement EHT unit costs 75 pounds!' Uh-oh! (US readers; 1 pound = about 1.5 dollars)

Opening the scope, I was greeted with a grisly sight. A square inch of insulation on the EHT multiplier had turned into brown bubbly crust, and black streaks were burnt along the EHT lead. Out of a sense of morbid curiosity I attached a bench power supply to the battery terminals and applied power. A miniature lightning storm broke loose inside the scope and the current meter shot up to a silly number of amps. Horrified, I pulled the plug.

This proved that the power supply was healthy, so I decided to continue. I unscrewed the multiplier unit, a potting-resin brick with flying leads, and dangled it as far away from conducting objects as its leads would allow. Then I repeated the experiment.

This time, apart from a bit of crackling as the EHT built up, nothing nasty happened. Actually, nothing happened at all. The thing was obviously live though; the heater was glowing and the multiplier was sizzling away nicely. I turned brightness up as far as it would go; nothing. Consulting the manual, I tweaked the sub-brightness and blanking trimmers on the tube base board. Bingo! A trace! Unfortunately though, it didn't blank during flyback. Nevertheless I was able to verify that the Y amps and timebase were working. Things were looking better by the minute. For the present though, something needed to be done about that EHT unit.

As far as I could tell, the components inside it all seemed to be working. So I decided to repair the insulation. I had vaguely heard of a substance called 'conformal coating', a clear rubbery resin that would withstand high voltages. Perfect! Unfortunately I didn't have any. With the impatience of youth I ransacked the chemical cupboard until I came across a tube of the clear, rubbery sneaker repair compound, Free Sole. Yes! Free Sole looks just like conformal coating, I reasoned, so it must be able to withstand high voltages! Oblivious to the flaw in this logic I applied a generous coating of Free Sole to the destroyed insulation. As I waited for it to cure I pondered how I could check its insulating properties. Maybe if I plugged my brother's hiking boots into a socket...

Next day I re-assembled the scope. The Free Sole had developed a lot of air bubbles and it didn't look good. Would it hold up when the 8,000 volts kicked in? I threw the switch. For a few seconds there was silence. Then a vicious crackling developed. Bummer! I must have got a bad tube of Free Sole. Still it was better than before; the power supply wasn't actually being overloaded. Seizing a roll of electrical tape I wrapped the EHT unit until it was mummified. I still wasn't too confident, but I had heard that oil was a really good insulator. I couldn't fill the scope full of oil, but grease! That would do the trick. Applying a generous coating of Carlube around the damaged area I screwed the EHT unit back in, and the crackling eased off to the occasional tiny click.

Now the EHT was working I could mend the blanking. Using another scope I found that the blanking signal went into a transistor buffer stage... but never came out. The transistor was obviously history. It was near the EHT unit, so it was probably zapped to death. I didn't have an exact equivalent, so I replaced it with a 2N2222. (The service manual mentioned 'high frequency'.) Now the trace unblanked, but only at the beginning of the sweep. Afterwards it faded out.

The blanking was dealt with on the tube base in two ways; a small capacitor fed the start of the unblanking pulse straight to the grid, while the rest of the pulse went down a resistor chain and was amplified up again. This complex coupling was necessary because most of the tube base circuitry sat at an impressive -1,600 volts relative to chassis. Yikes! How would I troubleshoot that? My multimeter could only stand 1,000 volts. But - the display went up to 1,999. Surely, I thought, 1,000 V would be a worst-case value, and the 'average' multimeter could take more. In any case I'd be careful not to apply the test leads to any points more than 1,000 V apart. Suddenly one of my probes slipped... and for a split second the meter showed 1,720 V. Then there was a bit of a bang. Not bad though, the last one exploded at only 750 V when I was working on some tube equipment. From then on I resolved to work on the tube base only when unpowered. (The moral of this is - not all battery-powered equipment is safe to work on!)

Eventually I tracked down the fault to two 0.1% resistors on the tube base which had failed open-circuit. It was the first time I had ever seen that. In a bizarre coincidence, the dead digital multimeter contained exactly the right values of resistor to replace them. They weren't 0.1% but so what, I figured. (I would regret this later.)

Now the scope was ready to go into service. It worked fine for a few days, and then suddenly it began to crackle and the screen flashed. The scumbag had already cost me one multimeter! I gave it a few ill-tempered bashes with Mr. Fist but to no avail. Then the trace disappeared completely.

Opening it revealed that a little piece of metal filings had got into the tube base. Sitting on the chassis, its pointy end stuck out towards the circuit board. This created a lovely spark gap. I only noticed this because it lit up! The transient voltages caused by the sparking had obviously fried something. In disgust I hurled it to the darkest corner of my junk pit.

Act Two

2 years passed, and I finished university. I now had an honours degree in electrical and mechanical engineering! 'That' oscilloscope would not defy me now!

Before I started I made a x100 high-voltage probe for my latest multimeter. Foolishly I used 10M 10% carbon resistors which are non-linear at high voltages. I also modified a scope probe by taping a 4n7 5 kV ceramic capacitor to the end. I then investigated the tube base again.

After a few evenings of exploration I tracked the problem down to the most expensive component on the board... a high voltage, low-power FET. It didn't appear in any of the data books, and with its white ceramic case and gold pins it looked like an antique. The manual said that it 'formed a long-tailed pair with the CRT to regulate supply current' - great. Since the characteristics of a MOSFET and a CRT couldn't possibly match anyway, I wouldn't have to worry about finding the exact equivalent. Picking a device with suitably high breakdown voltage and low leakage I hurtled to my local electronics store.

Back in the workshop I bent the thing into a pretzel shape to get the Gate, Drain and Source leads in the right holes. After a bit of adjustment the blanking worked perfectly. Now, I had to deal with that monstrous collation of Free Sole, electrical tape, grease, and burnt plastic. I ripped it out and took it down to the basement. With a PCB drill and a burr, I machined off all the Free Sole and burnt potting resin. I kept on drilling the resin away until I came across the internal connection for the EHT lead. Then I cut off the lead, chopped out the burnt bit, and soldered it back on. To help it out I stuck a piece of 10,000 volt GTO sleeving (I think it stands for 'Gas Tube, Outdoor') over the lead. I then made a cardboard-and tape pot for it and potted it up again. It looked as good as new!

Firing it up again I was greeted by more sparking, and a flickering screen. My potting job was bombproof, so I suspected something else. Turning all the lights out, I peered into the guts. Now this scope had an unusual EHT lead arrangement. Instead of the single captive length of cable ending in a big sucker, it had a cable attached to the EHT unit and another cable coming from the tube. The leads joined in a plastic connector - and blue flashes were coming from deep within! Gotcha! I switched off and, opening the connector, I stuck a screwdriver in to discharge the EHT. Blam! Yikes! Being the suspicious type I waited a minute and did it again. Blam! Yikes! That's dielectric memory for you. The EHT lead to the tube had come adrift inside the connector, and the tube current was having to jump the gap. Soldering it back on I fired up again.

Now a sinister frying noise came from the innards. Apart from this, the scope was fine, but I didn't like it... the noise reminded me of that scene from 'The Taking of Pelham 123' where the bad guy steps on the third rail. By just waving a scope probe near the guts I could pick up spikes of interference from the discharge. Using this method I tracked it down to that plastic connector again. I cut it out, soldered the leads together and ran them through a thick plastic tube which I zip-tied in place. Silence!

The scope is still running, and I now use it as my main oscilloscope. Sometimes when it gets hot the blanking won't work, because of those resistors I put in that weren't 0.1% - but so what. I still love to play with electronics. To save you some hassle, here are the lessons I learnt;

- Free Sole and conformal coating are not the same substance.
- Do not hit things if they don't work.
- Resistors sometimes blow - even if they don't run hot.
- Don't replace close-tolerance components with rotten ones.
- Don't do metalwork and electronics on the same table.
- When you exceed the maximum voltage rating printed on your DMM - it blows up.
- Always discharge HT circuitry twice before touching it.
- Battery-powered equipment can zap you too.

Repair Story #19: MGC XGA Multisync Color Monitor

Author: Bill Lahr, Copyright © 1999, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or mr.bill@pcmagic.net.

I was given this monitor by a friend. It was a good one, would support 1024x768 which was a far cry from the plain vanilla VGA monitor I was using on my CDROM burner. (It was an old Compaq that was salvaged from a dumpster. A $2 video output IC had fixed it.) When turned on, with no video input, the MGC made a loud noise, kind of a hiss or crackling sound, like frying bacom, coming from the Switchmode Power Supply transformer. The display was also unstable unless the brightness was fully on. If I plugged it into the video port on my notebook, it would quiet down. It was also quiet when plugged into the video card in my CDROM burner, but only if the brightness controls were set as high as possible, and if a light background was on the screen. Bring up a darker page, or lower the brightness, and the hissing noise would reappear and the display would jiggle and show noise in the horizontal.

I suspected a problem in the Switchmode Power Supply, but they can be rather complicated and difficult to track down without a schematic. I subscribe to Electronics Now, and Sam had included a schematic from a "no-name" monitor in an article on the SM power supply. I examined the schematic, and my monitor, and as luck would have it, they were identical!

I took some oscilloscope readings, and with video present, and all signals appeared normal. With no video, there was evidence of ringing (oscillation) in the positive half of the waveform on the drain of the power MOSFET. I checked all the capacitors and diodes in that section of the board, but everything was fine. Next I put the scope on the gate of the MOSFET. With no video, the gate drive signal went crazy. I knew the Pulse Width Modulator IC was okay, because the monitor worked. The DC output voltages were okay when there was video signal, but with no video signal, they increased. The B+ would go from +92 V to +133 V.

I removed each of the electrolytics on the secondary side of the SMPS transformer. All the ones in the higher voltage sections were fine, but when I got to the 6.3 V line, one of the two 470 uF electrolytics, the one nearest the diode rectifier, was bad. Looking at the schematic, I could see what happened.

There is an opto-isolator used to control the Pulse Width Modulator top regulate the output voltages. The DC supply for the LED in it comes from the 6.3V line. Since one of the capacitors was open, some 45 kHz AC ripple was present on the LED. This "signal" was passed through the opto-isolator to the PWM, which in turn amplified it and fed it to the gate of the MOSFET. The MOSFET generated noise in the transformer, which passed even more of it to the 6.3V line, eventually making its way back to the PWM until the SMPS transformer was nearly saturated. I replaced the bad 470 uF capacitor and the monitor works perfectly again.

Repair Story #20: Saved from the Deep Six

Author: Bill Lahr, Copyright © 1999, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or mr.bill@pcmagic.net.

A friend of mine, who lives on a small boat, noticed the new owner of the boat next to his putting boxes of "junk" on the dock. He struck up a conversation and was told the "junk" was on its way to the dumpster. My friend asked if he could have it for me, since he knew I like to repair electronic equipment, or scrap it for parts. There was no objection, so he showed up at my door with a large, wet cardboard box. Inside was an

RCA VCR that didn't work. It was a fairly expensive one, where half of it slid out and could be powered by a battery pack for use with a camera as a camcorder. Somebody had spilled varnish on it and the buttons were stuck on the front panel. I took it all apart, cleaned it up, replaced one drive belt, and it worked.

In the bottom of the cardboard box was a rectangular box made from metal. It was brown and disgusting looking, and was wet from being left out in the rain. I didn't know what it was, but noticed an embossed area near the bottom that said "IBM" followed by a number. I examined it and noticed a handle on one end. There were two small buttons on the sides near the handle end, so I pushed them and the front section of the case lifted up to expose an LCD display, two 3.5" floppy disk drives, and a keyboard! It said "IBM PC Convertible." It was a notebook computer!

It was in sad shape, and I poured seven ounces of water out of it. Most people would have given up at that point, but I wanted to see if I could fix it. It took a few minutes to figure out how to take it apart. The battery pack was no good, but was composed of 8 nicad "C" cells, so I knew I could rebuild it if necessary. The keyboard lifted out, and I could unplug the ribbon cable. The LCD panel lifted out of a socket. Two screws held each of the disk drives in place, so I removed them and pulled the drives out. Once they were free, I was able to lift the rear portion of the case to expose the motherboard and three smaller cards. I unplugged the boards, then removed the stiff paper insulator under them. I dried the keyboard, circuit boards, disk drives and case with a heat gun. One of the drives was frozen, so figuring I had nothing to lose, I squirted some WD-40 in it and worked the motor back and forth by hand until it loosened up. When everything was dry, I put it all back in the case and plugged in the display.

There was an IBM power supply in the cardboard box. It was wet, but looked okay. It plugged into a socket on one side of the computer case. I noticed a red button next to it and pushed it, but it didn't make any noise so didn't think anything happened, until I looked at the LCD display. There was a drawing of the computer showing a floppy disk moving toward the left hand drive! It worked! It was waiting for me to put in a disk with the operating system!

The next step was to make a boot disk for it. Since the CPU was an 80C88, I knew the drive would have to be only 720K. Luckily my main computer at that time was a 486-100 running DOS 6.22 and Windows for Workgroups 3.112E I had a few spare low density floppy disks, so I made a boot disk with 6.22 to try it. The notebook booted right up, no problem. Knowing that the kernel for 6.22 is larger than DOS 3.3, I dragged out an old 5.25" floppy with the older OS on it. I popped in the boot disk with 6.22 on it and turned off the attributes for the three boot files. Then, I copied the three boot files from the 5.25" disk to the 3.5" floppy. Finally, I ran Norton Speedisk on the 3.5" floppy to remove any blank spaces between the files. Put the 3.5" disk into the notebook and it booted up perfectly in DOS 3.3. (This little trick for creating boot disks comes in handy sometimes.) Once I knew it worked, I made a few disk copies and set them aside, then went to work finding software that would run on it. It could not handle much in the way of graphics, but I did find a word processor, some utilities, modem program, database, spreadsheet, etc., that would run from dual floppies.

Since the notebook worked, I invested $20 in some surplus nicad C-cells and rebuilt the battery pack. It would run for 30-45 minutes on a full charge. The keyboard was filthy, so I pulled all the keycaps off and washed them. The mechanical keyboard switches were okay, so I didn't have to remove and clean them. The case was filthy from years of diesel fumes and cigarette smoke, but "409" cleaner, some Q-Tips and a lot of soft rags did a nice job. When I finished it, the case looked almost new. It was hard to believe it even worked, given the condition it was in when I got it. It even had a port adapter and a video adapter, plus a small printer, that snapped onto the back of the computer. I even got a 9" monitor with it, but it was DOA. The printer was no good, all rusty inside and not repairable. The video adapter didn't work either, but the port adapter did. I was able to print with no problem, and the modem port worked with my old ISP, using text mode, so I could use it for e-mail if I needed to. It is only an 8088, so it is really slow, but it works, and makes a neat conversation piece.

Repair Story #21: About the Caps in Those Panasonic VCR SMPSs

Author: Ray Chandos, Copyright © 1999, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or rchandos@ivc.cc.ca.us.

Re: Repair Brief 97 (See: Sam's Repair Briefs.) I've got you beat!

How about a 1 week repair time to locate the same bad capacitor in a Panasonic PV-4700. After reading your account, just for the pure entertainment value, and studying your reverse-engineered schematic, I thought "this sure sounds familiar" and went back to the bench to review my reverse-engineered schematic, and check the two filter caps on the 5-V (measuring 3.9 V) output. As I had done previously, I applied the LCR meter (B+K digital) across each one and, as previously, measured about 700 uF. Great, I thought. Each cap is 330 uF, and they're in parallel (except for L3, the horizontal element of the pi filter--like a short, right?--in between) so that's about right, if they're both a little high, I thought. Then, for the heck of it, I unsoldered one lead of C16 and found it was low (under 300 uF) and had a high dissipation factor. I next did the same on C15 and found it was completely open! Replaced them and the regulation came back and the VCR ran. Apparently, that inductor drives the LCR meter nuts. I'm guessing it works by measuring reactance, and the inductor had plenty of that.

I had scoped the outputs, but that didn't help me, for some reason. What I saw there was the 5-V output going up all the way to +5 V for a second, at which point the colon on the display would give one blink and one of the motors would whirr, then the 5 would drop down to 3.9 and everything would go dark until you unplug and repeat. The switcher would continue to switch, but the voltages were off, so it was a problem of regulation.

No blown zeners, but a $24 SAMS VCR facts on the way...(VCR-256) If you ever need to borrow it, let me know. When it arrives, I'm going to see what's inside IC2. Unlike the model you sketched out, this one has one of those stick-of-gum type modules between the regulated output voltages and the opto-coupler. But there's inputs to it from both sides of the above pi filter, for some reason. So the filtering must be critical to the regulation, although, again, I didn't see any obvious ripple or hash on the 3.9-V output, although I didn't switch over to AC coupling and crank up the scope sensitivity to look for anything. (I will next time.)

I found two other crappy caps on the hot side and changed them earlier. I'll probably do the kit and change them all, or the @#$% thing will be back in a month.

Repair Story #22: Uncle Jay Comes Through Again

Author: Jay Vickery, Copyright © 1999, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or jmv@digitalexp.com.

One of my best friends in the world brought over his kids' CD player the other day. A 1990 Pioneer, model PDM630. I gently explained to him that he could get a new one cheap and I'd even go in halves on it and make it an early Christmas gift or something. The only problem was, his kids had given it to him and told him to: "Take it to Uncle Jay. He can fix it, he can fix anything!". I don't know where they got that idea. All I have ever done, was fix their Tvs, Nintendos, VCRs, satellite receiver, hot water heater, pool pump..... Anyway, now I was under the gun.

I put a disk in the single cartridge, upside down, but I caught it. :) The machine loaded the disk, waited a couple of seconds, and unloaded it. Pulled the cover off, looked for obvious problems, didn't see any. Put the disk in again, it loaded, the carriage moved down, but the disk did not spin! AHA!.

Along about then, I remembered the S.E.R FAQ and started digging. I downloaded the entire CD Repair FAQ.

I skimmed the text, found the Pioneer Test Mode part. Great! I entered test mode, loaded the disk, turned on the spindle, ran great. Ok, now we are getting somewhere. Must be a bad switch not telling the machine that the disk is loaded. Nope, all switches check out good. I check a few other things, finally sit back to think about it for a while. Figured I would clean the lens while I was thinking. Removed the four shoulder screws from the rubber grommets, and laid the assembly back.

Looked carefully for the lens. And looked and looked and looked. Finally realized that that round hole in the plastic behind which I could see the "speaker voice coils " was the hole that the lens was supposed to be in.

On the plus side, I can look down through the hole, and see the mirror real well. :)

There's no sign of the lens in the machine, of course, so I'm heading to the Pioneer site to get a number to order a new assembly.

It'll probably cost me more than a new machine, but by God, Uncle Jay will come through again!!

Repair Story #23: Rob's Experiences

Author: Robert Dvoracek, Copyright © 2000, All Rights Reserved. **Edited by**: Samuel M. Goldwasser

Comments or Suggestions to: Sam or lgtngstk@uti.com.

I have been reading some of the electronic horror stories at your Website and got inspired to relate a few of my own. You could say that I'm a junior technician, being only 18, as a point of interest.

1. My neighbor across the street had heard that I could fix stuff (lawn mowers, cars, electronics, computers, bicycles, doors, fax machines, furnace blowers, halogen lamps, predict weather, etc). So she decided to loan me her brand new TV that had no picture. I immediately took it over to the deck (I was outside) and plugged it in. The picture was compressed into a horizontal line. So, I tried my first line of troubleshooting - hit the damn thing from various angles - and presto, the line would expand to the whole screen and quickly turn back into the horizontal line. I promptly unplugged it and took off the cover. With the nearest ^wooden^ rake handle, I began to prod the mainboard in various places to try and localize the problem. It seemed to be the worst around an inductor or transformer or something near the flyback and HOT, probably the one for the horizontal driver. So, it began to tap the mainboard with the rake handle using much finesse until the picture "stuck". Then I hit it some more until I couldn't get it to screw up again. After zipping it back together I returned it to her. The whole shebang took all of 15 minutes, and she's been enjoying her new TV for several months now. I figure that the transformer or inductor had a loose connection inside and that the arcing from being jarred heated the loose connection until it fused itself back together.

   In short, I fixed a TV with a RAKE HANDLE while simultaneously breaking the all time record for shortest TV repair (arguably).

2. I received a small thermal FAX machine from my stepfather with a paper feed problem. After a few lines, the paper would stop and it would make a ticking sound. After I opened it up, I found the gear for the platen had a missing tooth. Solution - get a new gear? What? Not a chance. It was a manufacturer that I'd never even heard of before and there were no phone numbers on the machine. So the solution - splice in a gear tooth. Anyone out there ever heard of this being done before? Me neither, but here it goes. I had some styrene sheet lying around that I got at a hobby shop. I took the old gear and, using a small file or hacksaw blade, made a notch in it about the width of the styrene sheets as close to dead on center of the missing tooth as I could get. Then, I cut a piece of styrene to fit in the notch that was a little taller than I needed it to be (excess can be filed off) and JB Weld/Krazy Glued it in place. Don't worry if the styrene piece doesn't fit perfectly, because chances are that you screwed up the notch like I did and ended up with a rounded off bottom, just fill in the gap with JB Weld. Reguardless, make sure the piece sticks straight out from the gear hub. After the whole mess dried, I got a really small file and CAREFULLY filed down the new gear tooth as close as possible to the others. To assure of smooth operation, I test fitted the adjacent gear and rolled it over the new tooth and then filed it accordingly until the gears meshed more or less perfectly. After reassembling the FAX machine, needless to say, the thing worked perfectly. If you try this, make sure to use a stronger plastic for higher stress gears, like high density polyethylene (HDPE) or something.

3. THIS ONE'S GOOD!!!!! (the former statement reflects the author's opinion and is in no way intended to sway opinions or other o words) Do NOT read the following if you have a sensitive stomach or just got back from Old Country Buffet or something.

   I found a complete Macintosh Performa 631CD in the garbage, including monitor, keyboard, CDROM, etc (no mouse). Just one problem: The entire thing was full of cat pee! :^() Was I going to let that stop me? Hell no! I know macs suck, but I needed the practice, being a computer technician. Besides, I had a little theory to prove: You can wash a mainboard in soap and water and the thing will still work, as long as you let it dry thoughly. Did it work when I was done? Stay tuned to find out. So, I commenced the dirty deed, making sure to wash my hands !VERY! !WELL! before meals. I started on the case top and all that (you know, those macs are a real pain to take apart). The plastic parts came out smelling like roses, but the metal parts had started to corrode from the action of uric acid. After tedious scrubbing, they came out reasonably clean. The disk drives were pretty much shielded from the cat's vile spray, but the mother board took a direct hit to the processor via the cooling fan. Those Apple engineers put the blasted thing right on top and the cat's aim was true. After removing the mother board, I discovered a puddle in the bottom (I hope you haven't just ate lunch :o). The power supply's heat sink was sitting right in it. Yet another qualm about the mac design: the power supply isn't a separate module like in the ATs. Anyway, to make a long story longer, I carefully washed the heatsink in soap and water, being careful not to wet any transformers or coils that will probably retain the water and short out - why take a chance, they weren't peed on anyway, fortunately.

As for the cooling fan, I basically just drenched it in water numerous times - this is one of the parts that took a direct hit, remember - to make sure and rinse out any pee residue. Okay, okay, on to the good part: mainboard. I pryed out the processor with a screwdriver as there was no zif socket (mac strikes again). I washed the processor twice with soap and water without a care, knowing all processors are hermetically sealed. I then ran the mainboard under a stream of hot running water for about a half hour and soaped it up several times, making sure to get all the little crevices - there are a lot of little crevices. I then let it tumble dry overnight in the clothes dryer (just kidding about the dryer part). The next day (yes, the whole ididerod took two days), I took apart the monitor, which wasn't too bad, and washed the outer shell. I don't know what i'd have done if the monitor board was full of pee. After letting it dry, I commenced reassembling the whole mess (it was quite a mess, it took up the whole bathroom and part of the living room (those darn macs have so many odd parts crammed in there - that's why they're so heavy)). - another big section cut out here - After it was together and after hooking everything up and finding the power switch, yet another annoying thing about macs, it's in the back and feels just like a nearby piece of plastic so you end up pushing on a useless piece of plastic every time you try to turn the thing on, UGH!, I finally arrived at the moment of truth. With its famous elevator music type of startup sound, it came on!!! :-) :-) :-) :-) :-) :-). That is the first and last time that I was happy to see that insidious smilyface icon staring back at me from out of the deralict void (gosh I feel dirty:-). So, to sum up, you can actually wash a computer with soap and water, when you know what you're doing. If anyone else out there has done this before, I have $20 waiting for them.

Repair Story #24: Sione's Blown VCR

Author: Sione Vaka, Copyright © 2000, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or sione.vaka@ttil.to.

Patient: Emerson VCR model VCR3002A, American system. A friend of mind said he was going to dump the machine and I asked if I can have it.

Background Information: Here in our country, Tonga, (in the South Pacific) our main electricity is 240 VAC, 50 Hz just like New Zealand, Australia, etc. Since there are so many Tongan people in the States they tend to send electronic equipment such as TVs, VCRs, Hifis, and many many more. The bad thing is that they have to be used with a stepdown transformer since USA only uses 110 VAC. This is one of the major causes of equipment failure here in our country is that sometimes people forgot to use the transformer!

Fault Symptom: My friend told me that his wife accidentally plug in the VCR straight to the 240 VAC and smoke coming out from the back of the VCR. The VCR is completely dead.

Testing: Plug in to the mains using step down transformer but completely dead.

I removed the top cover and found the fuse has blown. One leg of the rectifier has been burned. I checked the power transistor with my DMM and confirmed there is permanent short between B-C-E. I also check for open fusable resistors but none of them were bad. Off to the electronic shop and buy one rectifier type S6056 (cost $3.00 = US$1.74) same type as the burned one, a power transistor type (cost $5.00 = US$2.91). I connected up these two components and ready to test. Plug in mains with the top cover off and still the VCR completely dead. Expect for any smoke but none. Turn power off and check the fuse is not blown so as to the rectifier. I measured the power transistor while it is still connected in the circuit board and I come up with something strange. The B-E is shorted. I remove the power transistor out of the circuit and measured again. I found B-E is no longer shorted (high resistance). Now I am confuse If this is normal or not. I emailed Sam and asked for his assistance. He replied with some helpful information saying that normally testing the power transistor in-circuit on VCR SHOULD NOT be shorted. Now I suspected a component in the vicinity of the power transistor is shorted that causes the B-E shorted. I measured a small transistor which drives the base of the power transistor but confirmed to be OK. I finally found out a zener diode just around the power transistor which was shorted. I removed the Zener diode and test and still confirmed to be shorted. While the zener Diode is still out of the circuit board, I checked again the B-E of the power transistor and confirmed now is no longer short. This brings me good luck on this problem. I replaced the Zener diode with an identical one and now ready to test again. Hold my breath, cross my fingers, turn the power on and bingo!! The VCR comes alive.

I connected the VCR to a TV and loaded a tape. Everything was just fine except some adjustments on the audio head and the cleaning of the video head. Now I have a working VCR!

Comments: This is a great experience for me to come across such kind of problem. As I mentioned before this kind of problem is usually happen here in our country due to voltage difference but I am more confident if I meet this kind of problem again.

Repair Story #25: Alan's First Monitor Repair

Author: Alan Pearson, Copyright © 2001, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or alanp@linux.pearson.uk.

Patient: Mag MX17 in good physical condition.

I am experienced in electronics and repair, but never TVs, monitors etc. I had been away from it for a year or two and got back in with this beautiful monitor. It had been lying round for 2 years because I didn't have a chance to look at properly.

Symptoms:

It lit up its LCD dislay, said no signal, and after 5 secs powered down.

So, first thing to examine was the power supply. I found no -7V. So, I traced the circuit board traces and found an open resistor. Then put a meter on where the -7 V went to and ground and found a short. Further tracing located a shorted transistor, a 2SD799 (Q506) main board.

I replaced it and powered the beast back up. Still the same symptoms. I removed the PS from unit and metered output voltages. Mistake 1: The PS should have been loaded by a light bulb or something. With a light bulb load, the PS was indeed power cycling. This eliminated a short on the main board or something (well mostly). Metered again (Mistake 2: Used a highly inaccurate DMM which read +210V for a +185V source). So, I thought the voltages were very high.

After taking a lot of advice from Bill (MANY THANKS!), I was told to check the 91K resistor in the PS. It was open. Replaced and metered again. Voltage still high. My crap meter! Anyway, days later I dug out my trusty AVO 8 meter, and it gave ACCURATE readings that showed the PS all okay!!

So I put it back together and all I got was a very bright vertical line in middle of screen. Consulted the FAQ (thanks Sam!! big time) and discovered this was due to the horizontal deflection not working. I traced the yokes back from the tube and found a blown transistor, 2SD4924 (Q503). Bill also enlightened me on this and told me to check R514 on the main board as well. Surprise, it was open open! Replaced this and the transistor and checked the other power transistors, and all common faults for this unit. Found Q909 short as well (2SD799) and replaced. Bill many thanks for pointing me at that resistor. Saved me days of heartache.

I reassembled the unit and powered on. Just a very bright white screen. (Well, that's progress, first nothing, then a line, now a white screen. :) --- Sam) At this point it is worth mentioning that this unit had been in for an estimate of repair years earlier, (not by me) and someone else had been inside. So, I turned down main brightness of flyback transformer, and got a picture (not much of one but one). Check all PS voltage again and correct.

It took hours to discover the correct location of about 5 plugs in the unit which the previous tech had put back in the wrong places, and 2 I couldn't remember. When the brightness was turned up, the unit clicked a relay and then said no signal. This turned out to be the brightness was connected to the place for the input selector switch. Then the convergence was messed up, and a lot of other stuff. Eventually figured out the correct connections (I don't have a service manual for this beast) through, logic and common sense.

Then I got a picture. But I had to go and realign every POT on the beast to get the picture right (focus, pincushion, convergence, position, brightness the whole bloody lot).

Now she runs beautifully with one exception: A line was burnt in the middle of the tube, where the horizontal had failed. I only had the unit on for max 10 secs at a time when it was like this (and then only 3 or 4 times), so I conclude it wasn't me. Apart from that I am the happiest man alive ! Successful repair, and I learned a bucket load.

Some recommendations based on my experience:

1. See if some other person has been inside, and if so take NOTHING for granted. Preference would be to get a service manual at this stage. Tell tale signs are resoldered components, wiring not looking routed correctly etc. If someone else was inside, chances are he couldn't fix it, and didn't put it together again correctly or messed it up trying, or the estimate to fix it was too high, and he reassembled it wrong.

2. Mark all cables you remove in some way so you know where they go. Even if the connectors are different. It will save you lots of heartache later on.

3. Mark positions of pots you play with before you play with them.

4. Check all marking printed on the board for help with things like cable location, alignment etc. This is partly how I was able to connect the cables again correctly (to CRT should goto CRT!!).

Anyway, the monitor is working with a small vertical burn only noticeable on white backgrounds, but it is my monitor and I am very happy with it. One of the best 17" monitors I've used.

Repair Story #26: Keypad Determination

Author: David Forbes, Copyright © 2002, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or dforbes@azstarnet.com.

Patient: GE (Samsung) JES633WN microwave oven with worn keypad.

I just finished replacing my 1995 GE (Samsung) JES633WN microwave oven's keypad. It works now and it didn't cost anything to fix. It did take a few hours, however.

The problem was that the keypad had developed some open traces from rubbing plus water damage. I tried to fix them with Tech-Spray conductive ink and overcoat, but the overcoat ate through the original silver and rendered it unfixable.

So, I called GE to ask the price of a new keypad. $99 including shipping, one week delivery. Ouch. I politely told them where they could put their $3 Mylar keypad with a $96 markup.

Then I got to work replacing the keypad with my own version that's repairable and looks (and works) just like the original. I used a bunch of those low-cost 6 mm square tact switches like you find behind VCR front panel buttons. These were in my junk drawer from 1993, so they were free.

The Samsung model has the PC board mounted a good 3/4" behind the keypad, leaving lots of room to add a thicker keyboard mechanism. I'm glad for that space, as it allowed me to install a piece of perfboard to hold the tact switches. This perfboard is mounted behind the keypad's plastic bezel, spaced from it with 4-40 nuts on the mounting screws that I added. This gives the right switch depth with standard flat-button tact switches.

The first job was to drill holes in the plastic front bezel for the switches. I had already peeled off and separated the halves of the original keypad in my repair attempt. Using the inside piece of the membrane keypad as a guide, I drilled a 7/16" hole in the center of each switch position with a Unibit.

Then I cut a piece of perfboard to size of the keypad and cut away the necessary bits to allow it to fit around the PC board screw bosses. I also cut down the gussets on the screw bosses to make the job go faster. Once the perfboard fit, I installed the tact switches into the perfboard hole grid to fit in the 7/16" bezel holes. Some switches were rotated relative to the others to get the best centering in the big holes (the switch pin pattern is 0.2" x 0.3".)

Next I held the perfboard behind the bezel and drilled a couple #4 mounting holes at top and bottom of the array. I put 4-40x3/8" flathead screws and nuts in these holes to hold the perfboard to the bezel while drilling the other mounting holes. I used a total of ten mounting holes, countersunk into the bezel for the screw heads.

The correct spacing of the tact switches has the tops of their buttons flush with the top surface of the bezel where the touchpad cover sheet goes. If they stick out they will be pressed too easily, and if they are recessed they will be too hard to press. I used one hex nut between bezel and perfboard to get just the right spacing on my keypad. Yours may vary - use washers as needed.

Once I had the perfboard mounted behind the bezel with the switches installed, I wired them up with 24 ga. stranded hookup wire according to the chart so conveniently provided on the oven's built-in service guide stored in an envelope above the cooking chamber. If your oven doesn't have such a chart, just peel apart the keypad and trace out the lines from each key to its outside and inside membrane connector pins.

I replaced the original 13-pin flex connector with two 6-pin Molex KK series connectors that I had on hand. Pin 7 on the keypad flex-cable is tied permanently to pin 13 on my oven, so I added a wire for that job onto the PC board.

Then I stuck the original keypad cover sheet over the switches, installed the controller PC board, plugged in the Molex connectors, put the oven together, tested it and it worked fine. Hooray.

Repair Story #27: Bogen PA Amplifier - Broken by Design

Author: George R. Gonzalez, Copyright © 2003, All Rights Reserved. **Edited by**: Samuel M. Goldwasser
Comments or Suggestions to: Sam or grg2@comcast.net.

Patient: Bogen tube-type PA amplifier, dead.

Sometimes you wonder how some products ever made it out of the design lab.

Sometimes there's so much wrong, you wonder if the item is a joke.

Someday I may relate the story of the no-name amplifier, but today's story is from a quite respected company, Bogen.

I acquired this Bogen PA amplifier, 50 watts out allegedly, pair of 8417s for output.

Nicely built, heavy-duty transformers.

Nothing works, so I put it on the bench.

I look it over.

The bad news: Output tubes have white getters, don't hold vacuum anymore.

The only visible good news: the pilot light is okay.

I don't have any 8417s, so I go to the computer to look them up. The number doesn't sound familiar.

I look up the tube specs, and whoo-boy, they have a heck of a transconductance, 23,000 micromhos!

I do a Google search, and find several references like "these tubes sometimes run away". Hmmm..... let's be careful...

I go to order some new ones, and no matter where I look, they're pricey-- $50-80 each. I finally find some on eBay for a somewhat reasonable price.

Meanwhile I look over the amp for obvious things wrong.

The cathode current balancing pot doesn't want to turn! It's not rusty, what's going on?

I open up the pot and see something unusual-- it's a wire-wound 30-ohm pot with a the wire wound around a gray plastic form. The form is badly MELTED and DEFORMED. How the ^#!$%!^? Let's see, 30 ohms, maybe takes 5 to 10 watts to melt it this badly, that's----- 400 to 800 milliamps!! No wonder the tubes gave up. I replace the pot.

The tubes apparently ran away to a very high current level. I check the bias circuit, looking for a bad voltage regulator, or a bad bias adjust pot.

No problems there.... there is no bias regulator OR bias adjust pot. Just your basic capacitor stealing a bit of the high-voltage AC and rectifying it, then dropping it down with some fixed resistors.

Hmmm, a pair of the most sensitive tubes ever made, and the designers don't make the bias adjustable! It's set by a couple of resistors, at about -15 volts. Luckily, this is just about right according to the cathode current I measure.

But if the line voltage goes low, so will the bias, and it doesn't take much of a drop to make these tubes conduct like crazy.... I make a mental note to add a Zener, or more appropriate for the era, a neon bulb, to regulate the voltage. And oh yes, I make a mental note to sell any Bogen stock I have.

A week later the tubes arrive, I plug them in, put a 8 ohm resistor and scope on the output, sine wave in. Time for FUN!

I turn up the line voltage slowly--- cathode currents are low and stable, whew. Everything looks good. I turn up the sine wave, and at about 20 watts out, the amp starts some ragged oscillating in the MHz on the sine-wave peaks. In about 5 seconds the tubes start running away! Good thing the Big Red Switch is nearby.

I look at the circuit to see what may have gone wrong with the oscillation-snubbing components. We'll there's nothing wrong with them, because they don't exist. There's NO snubbing resistors, not on grids, screens, cathode, or plates. No roll-off capacitors on the plates either. These are some of the highest gm tubes ever made, and apparently Bogen made NO ATTEMPT to tame the tubes!!

Argghh... I have no idea what the optimum value for grid-snubbers is for this tube, so I wire in a ballpark value, 2.2K. The combination "red red red" is a bit garish, but what the heck, we're somewhat peeved and desperate.

With the grid resistors in place there's no more trace of MHz oscillation at 20 watts. But when I crank it up to near-clipping, the fuzzies reappear and the tubes run away again. This time I'm soo befuddled I don't hit the switch until the cathode current has passed 500 milliamps! Well, at least we know these pricey tubes have plenty of cathode emission, or at least had it.

I think ahead about protecting these tubes in case they ever run away in the future when I'm not watching. The line fuse isn't going to do it, as it hasn't in the past. I ponder the desecrating effect of drilling two 1/2 inch holes to mount a pair of cathode fuse holders. Hmmm, better do it, originality be danged..

There's no easy way to add screen-snubbers without drilling holes and mounting terminal strips, so I look to taming the plates. I add a roughly in the ballpark plate-to-plate taming capacitor, 1,100 pF. Well actually, two 2,200 pF 1 kV capacitors in series. There's lots of voltage up there.

Now there's no oscillation on the peaks, and the tubes don't start any spiraling current death marches. But there's something else- the leading edge of the sine-wave has a big scallop cut out of it. How can this be?

A lot of probing around with scope probes and capacitors reveals nothing interesting. This is the worst of times, when everything looks okay except the output, and nothing you try seems to help.

For lack of anything better to try, I decide to measure the heater voltage.. I know, I know, the 6.3 volts on the heaters can't be far off, and even if it was it wouldn't scallop the sine wave this way, but let's waste 15 seconds anyway. I should use the voltmeter to measure the heater voltage, but I change my mind and use the scope. You see the new test leads on the meter have really hard to squeeze alligator clips, while the Tektronix scope probe is much easier to use. Plus I can use the mental practice of trying to divide the p-p voltage by 3 in my head. So due to pure lazyness, I use the wrong tool for the job. And due to this mistake, all the answers pop out at me!

The scope reveals that the heater voltage has a non-negligible amount of signal on it! I'm really puzzled now, wondering how 500 mV of signal gets into the heater lines, wondering how the designers never noticed this, wondering why I'm getting steamed at the shortcomings of a 45 year old design.

I decide to attack the symptom and put a .22 uF capacitor from heater to ground. The signal disappears from the heater voltage, and the output sine wave now looks perfect! Apparently there was feedback from the output tubes to the preamp tube, back through the heater wires!

What the bellepety-bleep! What the friggity-frig! How did this ever get past the designers? I solder in a 0.47 uF capacitor into the heater circuit. Lots of playing around with various frequencies and levels of sine waves, and I *think* the amplifier is finally stabilized.

(I should try it with some square waves too now that I think of it, but the square wave generator is out in the garage, which is at about 98 degrees, 90% humidity right now.)

So that's it so far. Had to get this off my chest. How could the designers have come out with such a shaky design? I put a nice sedate load on it, and it ran away every time! An expensive-looking amplifier, with many critical components apparently never designed into it.

If anyone has any ideas out there how this could have ever worked right, please contact me.

(From: Sam.)

Note that it's still possible that the modifications described above are just masking a more fundamental problem that is still present since it's likely the PA amplifier provided years of reliable service before being put on a shelf for a few decades. :)

Acknowledgements

Much of this list was compiled from entries in the ECG Semiconductor Master Replacement Guide and from

replies to postings on the sci.electronics.repair newsgroup.

Data for a several of the parts (those marked with *) has been generously provided by: Colin M. (colinmc@mail.zynet.co.uk).

> "Note that a number of chips produce the same output voltage at two pins: These outputs are separate. Separate DC inputs are also required. Our thanks to Sanyo Semiconductor (Europe) GmbH for supplying data on these devices and to Eugene Trundle for technical advice.
>
> Original data taken from a reference pulished by Television magazine. Scanned in by Colin McCormick. All errors to be blamed on Logitech Direct OCR software."

Device Pinouts Contributions

This list was compiled from replies to postings on the USENET newsgroup: sci.electronics.repair and will be updated as new requests come in. Contributions are welcome. Please email in a format similar to those listed below. If you provide additional comments, your name and email address will be listed as well.

DISCLAIMER

While every effort has been made to assure that the pinout information in this document is accurate, errors are possible and sometimes the databooks themselves are even in conflict.

We will not be responsible for damage to equipment, your ego, blown parts, county wide power outages, spontaneously generated mini (or larger) black holes, planetary disruptions, or personal injury that may result from the use of this material.

- Back to VCR Regulator Pinouts Table of Contents.

Introduction

Scope and Purpose of this Document

This document provides pinouts for some of the common hybrid multiple output voltage regulators used in a large number of VCRs. A good source for this information is the ECG Semiconductor Master Replacement Guide (or the SK/NTE or other similar databooks).

Does My VCR Use a Hybrid Voltage Regulator?

VCRs typically use one of these types of power supplies:

1. Power transformer with linear regulator using 78/79XX parts or discrete components. The power transformer will be large and right near the AC line cord.

2. Power transformer with hybrid regulator like STK5481 or any of its cousins - multioutput with some outputs switched by power on. Again, the power transformer will be large and right near the AC line cord. The regulator will be a black box with multiple pins soldered to a circuit board and will be mounted on a heatsink usually in the vicinity of the power transformer.

3. Small switching power supply. Most common problems: shorted semiconductors, bad capacitors, open fusable resistors. In this case there is usually no large power transformer near the line input but a smaller transformer amidships. See the document: Notes on the Troubleshooting and Repair of Small Switchmode Power Supplies for info on these types of supplies.

4. Combo of the previous (for example, a power transformer feeding a switching supply) - these are less common.

When to Suspect the Regulator

Failure of one or more outputs of the power supply can result in symptoms anywhere from a totally dead VCR to problems in one subsystem such as the tuner or display. Multiple systems failures are a likely indication of a power supply problem as well.

Safe Troubleshooting of Hybrid Regulators

WARNING: Read, understand, and follow the recommendations in the document: Safety Guidelines for High Voltage and/or Line Powered Equipment before attempting any power supply repairs. While most of the devices listed here operate at low voltages, there may be exceptions. And, you may be in the vicinity of exposed line voltage terminals when probing the hybrid's pins.

Testing

First identify a suitable ground for your multimeter. With the VCR unplugged, test for continuity between the ground pin of the regulator and the chassis or a metal shield. Don't use the hybrid's ground pin as clipping anything to it increases the chance of an unfortunate short circuit.

Check the outputs with the VCR both on and off if possible. The on/off should change with the power unless the unswitched output is dead and thus everything is dead.

If any are low or 0, the regulator is most likely bad. Failure of these regulator blocks is a very likely cause where a VCR exhibits multiple system failures. While it is possible for an excessive load to be dragging down the power supply output, failure of the hybrid regulator is a lot more likely.

However, also check the input voltage - typical values are 20 - 30 V DC. Defective rectifier diodes or filter capacitors can result in a low voltage or high ripple input which can result in low, noisy, or unstable outputs.

For erratic problems or those that only occur under certain operating conditions, monitor the outputs on an oscilloscope (a storage scope would be nice) to see if they dip or have any noise on them.

VCR Hybrid Voltage Regulator Pinouts

STK791

```
VCR Regulator.

(From Ken Koskie (aw345@lafn.org).)

The voltages should be approximately the same in all modes: Off, EE, Play,
and Record.

Pin 1: VI1 6.7 V
Pin 2: VI1 6.7 V
Pin 3: 0.0V
Pin 4: 0.0V
Pin 5: VO  6.8 V
Pin 6: NC
Pin 7: GND
Pin 8: VI2 18.5 V
```

STK5331

```
* Three output series regulator in an eight-pin package:

Pin 1: +5.1 V output
Pin 2: +6.05 V input
Pin 3: Load resistor
Pin 4: Load resistor
Pin 5: +12.3 V output
Pin 6: on/off
Pin 7: +30 V max input
Pin 8: Chassis
```

STK5332

```
VCR Positive Voltage Regulator: 13 V at 1 A, 6.05 V at 1 A, 5.1 V at .5 A.

Pin 1: VO3 +5.1 V
Pin 2: VO2 +6.05 V
Pin 3: VI2
Pin 4: Vb
Pin 5: VO1 +13 V
```

Pin 6: Gnd/SW
Pin 7: VI1
Pin 8: Gnd

STK5333 - ECG7036

VCR Positive Voltage Regulator. 15 V at 1 A, 5.8 V at 1 A, 5.1 V at 1 A, 8 Pin SIP.

Pin 1: GND
Pin 2: VO3 +5.1 V
Pin 3: VO2 +5.8 V
Pin 4: VI2
Pin 5: Vb
Pin 6: VO1 +15 V
Pin 7: SW
Pin 8: VI1

STK5338

* Three output series regulator in an eight-pin package.

Pin 1: Chassis
Pin 2: 5.1 V output
Pin 3: 5.8V output
Pin 4: 30V max. do. input
Pin 5: Load resistor
Pin 6: 12.3V output
Pin 7: On/off switching
Pin 8: 30V max d.c. input

STK5339

* Three-output series regulator in an eight-pin package.

Pin 1: Chassis
Pin 2: +5.1 V output
Pin 3: +5.8 V output
Pin 4: +30 V max input
Pin 5: Load resistor
Pin 6: +12.3 V output
Pin 7: On/off switching
Pin 8: +30 V max input

STK5342 - ECG7035

VCR Positive Voltage Regulator. 12.3 V @ 1A, 6.0 V @ 1A, 5.3 V @ .6 A.

Pin 1: VO3 +5.25 V
Pin 2: VO2 +6.0 V
Pin 3: Vb
Pin 4: Vb
Pin 5: VO1 +12.3 V
Pin 6: Cutoff
Pin 7: VI1
Pin 8: GND

STK5372 - ECG1883

VCR Positive Voltage Regulator. 12.1 V @ .8 A, 12 V @ .8 A, 5.3 V @ 1 A.
8 pin SIP.

Pin 1: VO3 5.3 V (switched)
Pin 2: Cutoff (control input for 12 V output)
Pin 3: VI2 (input for VO3, 10 V typical)
Pin 4: VO2 12 V (switched)
Pin 5: VO1 12.1 V (and input to VO2)
Pin 6: Vb (control for VO1)
Pin 7: VI1 (input for 12 V outputs, 18 V typical)
Pin 8: Gnd

STK5421

* Four-output series regulator in a fifteen-pin package.

Pin 1: +12.3 V output
Pin 2: Load resistor
Pin 3: +12 V output (unswitched)
Pin 4: Decoupling
Pin 5: +30 V max input
Pin 6: Link to pin 5
Pin 7: +30 V max input.
Pin 8: +16 V output (unswitched)
Pin 9: Link to pin 8
Pin 10: +9.55V output
Pin 11: Load resistor
Pin 12: Chassis
Pin 13: On/off switching

Pin 14: Decoupling
Pin 15: Decoupling

STK5422

* Four output series regulator in a fifteen pin package.

Pin 1: +12V output
Pin 2: Load resistor
Pin 3: +12V output
Pin 4: Decoupling
Pin 5: +30 V max input
Pin 6: Link to pin 5
Pin 7: +30 V max input
Pin 8: +13 V output
Pin 9: Link to pin 8
Pin 10: +9.5 V output
Pin 11: Load resistor
Pin 12: Chassis
Pin 13: On/off switching
Pin 14: Decoupling
Pin 15: Decoupling

STK5431

Pin 1: Out 5.1 V
Pin 2: NC
Pin 3: Out 12 V
Pin 4: Ctrk 12 V
Pin 5: In 12 V
Pin 6: In 5 V
Pin 7: In 15 V
Pin 8: In 9.5 V
Pin 9: Out 15 V
Pin 10: Out 9.5 V
Pin 11: Ctrl 9.5 V
Pin 12: Gnd
Pin 13: Ctrl 4 V
Pin 14: Ctrl .6 V
Pin 15: Ctrl 15 V

STK5436 - ECG1876

Pin 1: VO4 +6V
Pin 2: NC

Pin 11: IB2
Pin 12: GND
Pin 13: On/Off
Pin 14: Bypass
Pin 15 Bypass

STK5441 - ECG1734

VCR Positive Voltage Regulator. 12V @ 2A, 9V @ 1A, 5.5V @ .5A. 15 Pin SIP.

Pin 1: VO3 +5.5 V
Pin 2: NC
Pin 3: NC
Pin 4: NC
Pin 5: NC
Pin 6: VI2
Pin 7: VI1
Pin 8: VO1 +12V
Pin 9: VO1 +12V
Pin 10: VO2 +9V
Pin 11: Bias
Pin 12: GND
Pin 13: Cutoff
Pin 14: Bypass
Pin 15: Ripple Filter

STK5451 - ECG1735

VCR Positive Voltage Regulator.   16V @ 1A, 12V @ 1A, 12V @ 1.5 A, 11.9 V @ 1.5A.

Pin 1: 11.9 V Output 4
Pin 2: Control Volt
Pin 3: DC Input 2
Pin 4: Reference input
Pin 5: 12V Output 3

Pin 6: Reference input
Pin 7: 16V/12V Output 1/2
Pin 8: Reference input
Pin 9: DC input 2
Pin 10: DC input 1
Pin 11: Hi/Lo volt switch
Pin 12: GND
Pin 13: on/off control
Pin 14: Heater switch (??)
Pin 15: Reference input

STK5461 - ECG7027

VCR Positive Voltage Regulator. 12V @ 1A, 12V @ 1A, 5.1V @ .5A. 15 Pin SIP.

Pin 1: VO3 +5.1 V
Pin 2: NC
Pin 3: NC
Pin 4: NC
Pin 5: NC
Pin 6: VI2
Pin 7: VI1
Pin 8: VI1
Pin 9: VO1 +12V
Pin 10: VO2 +12V
Pin 11: IB2
Pin 12: GND
Pin 13: Cutoff VO1
Pin 14: Cutoff VO2
Pin 15: IB1

STK5464 - ECG7023

VCR Positive Voltage Regulator. 12V @ 1A, 12V @ 1A, 5.3V @ 1A. 12 Pin SIP.

Measured input voltages (your mileage may vary): VI1 = 18 V, VI2 = 8.5 V

Pin 1: VO3 +5.3 V
Pin 2: NC
Pin 3: NC
Pin 4: NC
Pin 5: VI2
Pin 6: VI1
Pin 7: VI1
Pin 8: VO2 +12V
Pin 9: VO1 +12V

Pin 10: VO1/VO2 Cutoff
Pin 11: GND
Pin 12: Vb

STK5466 - ECG1821

VCR Positive Voltage Regulator.

Pin 1: VO3 +5.3 V
Pin 2: NC
Pin 3: NC
Pin 4: NC
Pin 5: NC
Pin 6: VI3
Pin 7: VI1 and 2
Pin 8: VI1 and 2
Pin 9: VO2 +12 V
Pin 10: VO1 +12 V
Pin 11: NC
Pin 12: GND
Pin 13: On/off
Pin 14: On/off
Pin 15: Vb (probably around 13-14 V)

STK5467

* Three output series regulator in a twelve pin package.

Pin l: +5.3 V Output
Pin 2: NC
Pin 3: NC
Pin 4: NC
Pin 5: +30 V max input
Pin 6: +30 V max input
Pin 7: Link to pin 6
Pin 8: +12.1 V output
Pin 9: +12.1 V output
Pin 10: Pin 9 output cut off
Pin 11: Chassis
Pin 12: Load resistor

STK5471 - ECG1822

VCR Positive Voltage Regulator. 12 V @ 1.5 A, 12 V @ 1.5 A, 5.3 V @ .5 A.

10 Pin SIPP.

Pin 1: Iout 3 for 5.3 V
Pin 2: Vout 3 control
Pin 3: Iin 3
Pin 4: Iout 2 for 12 V (emitter)
Pin 5: Ib 2 (base)
Pin 6: Iin 2 (collector)
Pin 7: Iout 1 for 12 V (emitter)
Pin 8: Ib 1 (base)
Pin 9: Iin 1 (collector)
Pin 10: GND

It appears as though Pin 1 is the output of an IC regulator for the 5.3 V.
Pin 3 is the Vin - 20 V typ. Pin 2 is some kind of on off control.

Pins 4-6 and 7-9 are the emitter, base, and collector for the two
12 V outputs. These are simple Darlington transistors setup to
drive the outputs in an emitter follower configuration.
Vin typ of 30 V.

Deduced from schematic in ECG.

STK5477 - ECG7034

VCR Positive Voltage Regulator. 12v @ 1A, 12V @ 1A, 5.1V @ 1A.

Pin 1: GND
Pin 2: VI2
Pin 3: N/C
Pin 4: VO3 +5.1V
Pin 5: VO2 +12V
Pin 6: VB
Pin 7: VI1
Pin 8: VO1 +12V
Pin 9: VB
Pin 10: VI1
Pin 11: N/C
Pin 12: GND

STK5481 - ECG1823

Pin 1: Ib3
Pin 2: VI2
Pin 3: VO4 +5.3 V
Pin 4: VO3 +12.1 V

Pin 5: VO3/VO4 ON/OFF
Pin 6: VO2 +12.2 V
Pin 7: Ib2
Pin 8: VI1
Pin 9: VO1 +12.0 V
Pin 10: Ib1
Pin 11: VI1
Pin 12: GND

STK5482

* Four output series regulator in a fifteen pin package.

Pin 1: Chassis
Pin 2: +30 V max input
Pin 3: +5.1 V output
Pin 4: +12 V output
Pin 5: Bias/+12V output switching
Pin 6: +30 V max input
Pin 7: +5.8 V output
Pin 8: Bias/pin 7 output switching
Pin 9: Link to pin 2
Pin 10: Load resistor/pin 7 output switching
Pin 11: +13/+15V output
Pin 12: Pin 11 output switching
Pin 13: Link to pin 6
Pin 14: Pin 11 output switching
Pin 15: Chassis

STK5486 - ECG7038

VCR Positive Voltage Regulator. 13V @ 1A, 12.2V @ 1A, 6V @ 1A, 5.1V @ 1A, 5.1V @ 1A, 15 Pin SIP.

Pin 1: VO5 +5.1 V
Pin 2: NC
Pin 3: VO4 +5.1 V

Device Pinouts Contributions

This list was compiled from replies to postings on the USENET newsgroup: sci.electronics.repair and will be updated as new requests come in. Contributions are welcome. Please email in a format similar to those listed below. If you provide additional comments, your name and email address will be listed as well.

DISCLAIMER

While every effort has been made to assure that the pinout information in this document is accurate, errors are possible and sometimes the databooks themselves are even in conflict.

We will not be responsible for damage to equipment, your ego, blown parts, county wide power outages, spontaneously generated mini (or larger) black holes, planetary disruptions, or personal injury that may result from the use of this material.

- Back to Chip Pinouts Table of Contents.

Introduction

Scope and Purpose of this Document

This document provides pinouts for some of the common integrated circuits found in audio and video entertainment equipment like TVs, VCRs, and cassette decks and computer monitors. A good source for this information is the ECG Semiconductor Master Replacement Guide (or the SK/NTE or other similar databooks).

Note: the companion document: VCR Power Supply Hybrid Regulators contains similar information for many of the common parts found in VCRs with linear power supplies.

Much more info on most of these parts can be found on the Net via Chipdir and other semiconductor reference pages. See the links in Sam's Neat, Nifty, and Handy Bookmarks. Consumer electronics sites may have some of the hard-to-find datasheets. For example, for Sanyo datasheets (STK), more info can be found at:

> Datadart.com Sanyo Reference Page.

When to Suspect the One of These Chips?

The following are valid reasons for investigating the health of one of these parts:

- Scorch marks, discoloration, melted or bubbling plastic, device split in half, gobs of smoke, 6 foot flames.

- Excessive heat. While some of these chips or hybrids like power amplifiers will run hot, they should not be so hot that an egg would fry instantly.

- Functional fault. Since many of these parts have quite specific tasks to perform, the symptoms should provide some hint as to whether it is possible for the particular device to be at fault. For example, your monitor no longer syncs properly would point to the sync separator.

Safe Troubleshooting

WARNING: Read, understand, and follow the recommendations in the document: Safety Guidelines for High Voltage and/or Line Powered Equipment before attempting any repairs on equipment that operates directly from the wall outlet (not low voltage wall adapter).

Testing

First identify a suitable ground for your multimeter. With the equipment unplugged, test for continuity between the ground pin of the chip or hybrid and the chassis or a metal shield. Don't use the part's ground pin as clipping anything to it increases the chance of an unfortunate short circuit.

First, check for power to the Vcc or Vss (or whatever) pins. A large percentage of failures will be due to lack of power or incorrect voltages. The suspect device may or may not be at fault. In many cases, a fusable resistor has sacrificed itself possibly due to a short in the suspect part or elsewhere (or opened for no good reason).

However, note that the 'typical Vcc' or other supply voltages listed in this document or the device's datasheet may not be what your equipment actually uses. Therefore, a voltage that is moderately different than the one listed for the device may be normal.

Once good power is confirmed, test the inputs and outputs. Obviously, an oscilloscope is generally needed for these.

Where multiple identical devices are present, substitution is usually an acceptable troubleshooting technique but there is some risk involved as faulty circuitry can blow your 'good' part.

- Back to Chip Pinouts Table of Contents.

Chips Starting with Numbers

4N33 - ECG3083

```
Opto isolator - Photo Darlington output.

Pin 1: Anode
Pin 2: Cathode
Pin 3: N.C.
Pin 4: Emitter
Pin 5: Collector
Pin 6: Base
```

6N138 - ECG3093

```
Optoisolater with split Darlington output.  Vcc = 18 V max., 8 pin DIP.

Pin 1: NC
Pin 2: LED Anode
```

```
Pin 3: LED Cathode
Pin 4: NC
Pin 5: Gnd/Q2 Emitter
Pin 6: Q2 Collector
Pin 7: Q1 Emitter/Q2 Base
Pin 8: Vcc/PD Anode/Q1 collector.
```

93C66

```
Serial EEPROM.  512 x 8 or 256 x 16 bits.  8 pin DIP.

Pin 1: CS chip select, active high
Pin 2: CLK, serial clock, xfer on positive edge
Pin 3: DI, data in
Pin 4: DO, data out
Pin 5: Vss (ground)
Pin 6: ORG  (x8=vxx or x16=vcc)
Pin 7: NU (not used?) or TEST
Pin 8: Vcc 5 volts for C, other versions (LC) can runs +2 to +6v
```

- Back to Chip Pinouts Table of Contents.

A

AN6359 - NTE/ECG1812

```
VCR Servo Interface.  Vcc - 5 V.  20 pin DIP.

Pin 1:  Mode select B
Pin 2:  Gnd
Pin 3:  Mode select C
Pin 4:  Mode select X 1/2
Pin 5:  PAL/NTSC select
Pin 6:  B optput
Pin 7:  A output
Pin 8:  Error input
Pin 9:  Ref input
Pin 10: Amp input
Pin 11: Error output
Pin 12: Rec/Play select
Pin 13: Rec 2/4/6 H select
Pin 14: Mem
Pin 15: FG divide select
Pin 16: PB ctrl input
Pin 17: FG output
Pin 18: Vcc (5V)
Pin 19: FG input
Pin 20: Mode select A
```

AN5515 - ECG1684

```
TV vertical deflection.  Vcc = 24 V typ.  7 pin SIP-HS.

Pin 1: Ground
Pin 2: Output
Pin 3: Vcc for output
Pin 4: Input
Pin 5: Trigger pulse input
Pin 6: Pulse amp out
Pin 7: Vcc
```

- Back to Chip Pinouts Table of Contents.

B

BA336

```
Audio Level Sensor, used for a 'skip track' function, 9 pin SIP:

Pin 1: Pulse Width
Pin 2: Sense Timing
Pin 3: Input
Pin 4: NFB
Pin 5: GND
Pin 6: Muting
Pin 7: Noise Filter
Pin 8: Output
Pin 9: Vcc (Min: 4.2V, Max: 12V)
```

BA5115

```
Pin 1: PB level adj
Pin 2: PB output
Pin 3: LP (eq switch)
Pin 4: PB +input
Pin 5: Bias filter
Pin 6: Vcc
Pin 7: Rec output
Pin 8: Rec amp in
Pin 9: Rec/EE control
Pin 10: Mute control
Pin 11: Line output
Pin 12: Ground
Pin 13: ALC level
```

Pin 14: ALC off
Pin 15: ALC att/recv
Pin 16: Line amp in
Pin 17: PB/EE control
Pin 18: Line input

BA6209 - ECG1716

VCR Motor Driver with braking. Vcc max = 18 V, I max = 1.2 A.

Pin 1: GND
Pin 2: Vout 1
Pin 3: Vz1
Pin 4: Vreg
Pin 5: Fin
Pin 6: Rin
Pin 7: Vcc1
Pin 8: Vcc2
Pin 9: Vz2
Pin 10: Vout 2

I would guess that you should be able to monitor Fin and Rin (forward and reverse, I would assume) and determine if the commands are correct. Vout 1 and 2 should probably be opposites of each other for forward (e.g., +,0) and reverse (e.g., 0,+). They would be the same for stop.

I have no idea what the Vzs are or the Vreg.

BA6247

Pin 1: Ground
Pin 2: Motor drive
Pin 3: Motor drive
Pin 4: Logic
Pin 5: Logic
Pin 6: Logic
Pin 7: Vcc 12 V
Pin 8: Voltage divide
Pin 9: Voltage divide
Pin 10: Motor return

BA7001

Audio power amp, single channel.

Pin 1: NC
Pin 2: Control Input
Pin 3: Ground
Pin 4: Output

```
Pin 5: NC
Pin 6: VCC
Pin 7: Input 1
Pin 8: Input 2
```

- Back to Chip Pinouts Table of Contents.

C to L

C4558C

```
Dual op-amp.

Pin 1: Out 1
Pin 2: -In 1
Pin 3: +In 1
Pin 4: -Vcc
Pin 5: +In 2
Pin 6: -In 2
Pin 7: Out 2
Pin 8: +Vcc
```

CNY75GB

```
Optoisolator, NPN phototransistor.

Isolation voltage, Vmax = 5300 V, gain = 100, Vcemax = 80 V.

Pin 1: LED K
Pin 2: LED A
Pin 4: Phototransistor E
Pin 5: Phototransistor C
Pin 6: Phototransistor B
```

DS8884

```
High voltage display driver for gas filled tubes.

Pin 1: Current Prog. In
Pin 2: A in
Pin 3: B in
Pin 4: C in
Pin 5: D in
Pin 6: D.pt.
Pin 7: comma in
Pin 8: comma out
```

Pin 9: GND
Pin 10: d.pt out
Pin 11: g out
Pin 12: f out
Pin 13: e out
Pin 14: d out
Pin 15: c out
Pin 16: b out
Pin 17: a out
Pin 18: Vcc

HA12002

Speaker (or spike) protector/voltage/temp/overload IC.

Pin 1: Relay driver
Pin 2: GND
Pin 3: Temp detect
Pin 4: Audio sig. in
Pin 5: AC detect
Pin 6: Overload detect
Pin 7: Bias
Pin 8: Pos feedback

kA2206/LA4183 - ECG1667

Dual AF PO, 2.3 W, 9 V (4.7 W bidge BTL).

Pin 1: BTL out
Pin 2: Out 2
Pin 3: Bootstrap 2
Pin 4,5: Pwr amp GND (tab)
Pin 6: Neg feedback 2
Pin 7: In 2
Pin 8: Decoupling
Pin 9: Preamp GND
Pin 10: In 1
Pin 11: Neg feedback 1
Pin 12,13: Pwr amp GND (tab)
Pin 14: Bootstrap 1
Pin 15: Out 1
Pin 16: Vcc

L200C - ECG1942

Positive adjustable voltage regulator. Output: 3 to 36 V, 2 A.

Pin 1: Input
Pin 2: Limiting

Pin 3: Ground
Pin 4: Reference
Pin 5: Output

LA6324 - ECG987

Quad op-amp.

Pin 1: Out 1
Pin 2: -In 1
Pin 3: +In 1
Pin 4: +V
Pin 5: +In 2
Pin 6: -In 2
Pin 7: Out 2
Pin 8: Out 3
Pin 9: -In 3
Pin 10: +In 3
Pin 11: -V (or GND for some)
Pin 12: +In 4
Pin 13: -In 4
Pin 14: Out 4

LA7823 - ECG1647

TV Horiz/Vert Osc/Driver/Sync Sep/AFC. Vcc 12 V typ, 16 pin DIP.

Pin 1: Flyback pulse in
Pin 2: AFC Out
Pin 3: Horiz Osc In
Pin 4: Horiz Osc Out
Pin 5: Holddown In
Pin 6: Gnd
Pin 7: Vert Drvr Out
Pin 8: Vert Drvr In
Pin 9: Vert Out Center Voltage
Pin 10: Vert Osc
Pin 11: Vert Osc
Pin 12: Sync Sep Out
Pin 13: Vcc - Vert
Pin 14: Video In
Pin 15: Blanking Out
Pin 16: Vcc - Horiz

LA7824 - NTE7123

Sync Deflection Circuit for color TV. Vcc = 12 V typ. 16 pin DIP.

Pin 1: AFC Comparison Sawtooth Wave Input

Pin 2: AFC Output
Pin 3: Time Constant Circuit
Pin 4: Horizontal Output
Pin 5: Holddown Input
Pin 6: Gnd
Pin 7: Vertical Drive Output
Pin 8: Vertical Drive Sawtooth WaveInput

Pin 9: Vertical Output Middle Point Voltage
Pin 10: Time Constant Circuit
Pin 11: Vertical Trigger Output
Pin 12: Horizontal, Vertical Sync Sep Output
Pin 13: Vcc13 (Vertical)
Pin 14: Video Signal Input(Positive)
Pin 15: Composite Blanking Pulse Output
Pin 16: Vcc16 (Horizontal)

LA7831

TV Vertical Deflection, typical Vcc = 24 V.

Pin 1: NC
Pin 2: NC
Pin 3: GND
Pin 4: Vertical output
Pin 5: Vertical output stage Vcc
Pin 6: Input
Pin 7: Osc
Pin 8: 24 V Vcc
Pin 9: Pump up output
Pin 10 NC

LA7836 - SK10085

TV vertical deflection, 13 pin SIP.

Pin 1: +Vcc1
Pin 2: Vert Trig In
Pin 3: Vertical height control
Pin 4: 50/60 Hz Vert size control signal input
Pin 5: Ramp Waveform Generation
Pin 6: AC/DC Feedback Input to Vertical Output Section
Pin 7: Vcc7
Pin 8: Pump Up Output
Pin 9: Vertical Blocking
Pin 10: Gnd
Pin 11: Vertical Output
Pin 12: Power Supply for Vert Out
Pin 13: Ripple filter

(From: Tuck, Ryan (investbanker@webtv.net).)

I did a ton of research myself only to find that if you want to replace an LA7835, LA7835-TV, LA7836, LA7837, or LA7838, you are better off using the LA7838 for any of them or paying more for an ECG7104 or ECG7039 instead of crosswiring a SK10085 (which does work. Philips lists the LA7820 listed as being replaceable by an ECG7084 but I have seen it listed elsewhere as an ECG7840 or another transposition of those last three numbers I can't remember.

LA7837 - ECG7104

```
TV vertical deflection, 13 pin SIP.

Pin 1: +Vcc1 = 12 V typical
Pin 2: Vert Trig In
Pin 3: Time constant
Pin 4: Vertical amp control
Pin 5: Vertical size control input
Pin 6: Ramp waveform generation
Pin 7: Vertical output FB
Pin 8: Vcc8 - 24 V typical
Pin 9: Pump up output
Pin 10: Osc stop
Pin 11: Gnd
Pin 12: Vertical Output
Pin 13: Power Supply for Vert Out
```

(Also see note under LA7836 - SK10085.)

LA7838 - ECG7039

```
TV vertical deflection, Vcc1 = 12 V, Vcc8 = 24 V, 13 pin SIP.

Pin 1: +Vcc1
Pin 2: Vert trigger in
Pin 3: Time constant
Pin 4: Vertical amp control
Pin 5: Vertical size control
Pin 6: Ramp generator
Pin 7: Vert output AC/DC feedback
Pin 8: +Vcc8
Pin 9: Pump-up out
Pin 10: Osc stop
Pin 11: Ground
Pin 12: Vert output
Pin 13: Power supply for vertical out
```

(Also see note under LA7836 - SK10085/A>.)

LA7850 - ECG7086

TV/monitor deflection processor.

Pin 1: Horiz trig in
Pin 2: Phase adj time constant
Pin 3: Sync pulse time constant
Pin 4: FBP trig in
Pin 5: Sawtooth gen cap
Pin 6: Comp volt gen cap
Pin 7: Afc out
Pin 8: Horiz osc time constant
Pin 9: Discharge res
Pin 10: Vcc1

Pin 14: Ground
Pin 15: Vert drive out
Pin 16: sawtooth gen
Pin 17: Mid point volt control in
Pin 18: Vert osc time constant
Pin 19: Vert trig in
Pin 20: Vcc2

LA7851 - ECG 7062

Vertical Deflection Circuit/Sync/H V Osc/X-ray Prot. Vcc = 12 V. 20 pin DIP.

See LA7850 - ECG7086 for pinout (electrical specs
may differ slightly).

LM325

Dual Regulator, 14 pin dip.

Pin 1: +Boost
Pin 2: NC
Pin 3: +Vin
Pin 4: -Vin
Pin 5: -Current Limit
Pin 6: -Sense
Pin 7: -Vout
Pin 8: -Boost
Pin 9: NC
Pin 10: Reference
Pin 11: GND
Pin 12: NC
Pin 13: +Current Limit
Pin 14: +Sense

LM1881

Sync separator.

```
Pin 1: Composite Sync (out)
Pin 2: Composite Video (in)
Pin 3: VSync (out)
Pin 4: GND
Pin 5: Burst/Back Porch (out)
Pin 6: Reset
Pin 7: Odd/Even (hi/lo) (out)
Pin 8: Vcc
```

Chip Pinouts Table of Contents.

M to P

M51522A

Dual Audio Preamplifier by Mitsubishi Electronics.

```
Pin 1: Input 2
Pin 2: Feedback 2
Pin 3: Output 2
Pin 4: Ground
Pin 5: V+
Pin 6: Output 1
Pin 7: Feedback 1
Pin 8: Input 1
```

M54543L - ECG1628

VCR loading/bi-directional motor driver.

(From: Deon Maree (edm@pixie.co.za) I think the M54544L is the same as the M54543L)

```
Pin 1: Vcc
Pin 2: Driver Vcc
Pin 3: Output 2
Pin 4: Input 1
Pin 5: Ground
Pin 6: Input 2
Pin 7: Output 1
Pin 8: Driver Vcc
Pin 9: Vcc
```

MC34166

```
Switching power regulator.

Pin 1: Voltage Feedback
Pin 2: Switch Output
Pin 3: Gnd - Heatsink
Pin 4: Pwr Input
Pin 5: Compensation
```

NE5044N

```
Programmable 7 channel RC encoder.

Pin 1: IP1
Pin 2: IP2
Pin 3: IP3
Pin 4: IP4
Pin 5: IP5
Pin 6: IP6
Pin 7: IP7
Pin 8: GND
Pin 9: FR RC

S to STK

SAA7321

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

Pin 1: CDR (Right channel Damping capacitor)
Pin 2: DER (Right channel De-emphasis network)
Pin 3: VRefR (Right channel reference)
Pin 4: VssAR (Right channel analogue ground)
Pin 5: VssA (Analogue ground)
Pin 6: VssAL
Pin 7: VRefL
Pin 8: DEL
Pin 9: CDL
Pin 10: INTL (Left channel Integrator output)
Pin 11: VddAL (Left channel +5V)

Pin 12: OALI- (Left channel Op-amp Inverting input)
Pin 13: OALI+ (Left channel Op-amp non-inverting input)
Pin 14: OALO (Left channel Op-amp output)
Pin 15: VddRef (+5V for reference)
Pin 16: VRO (Voltage reference output)
Pin 17: VRC (Voltage referece decoupling capacitor)
Pin 18: Test4
Pin 19: DAO (Serial data output (I2S) from the attenuator/clipper stage)
Pin 20: CLO (Serial bit clock output)
Pin 21: WSO (Word Select output)
Pin 22: Vdd1 (+5V)

Pin 23: Vdd2 (+5V)
Pin 24: Xtal2 (Crystal oscillator connections 11.2896MHz)
Pin 25: Xtal1
Pin 26: Xsys (System clock output from this oscillator)
Pin 27; Vss (ground)
Pin 28: Vss
Pin 29; Test1
Pin 30: WSI (I2S Word Select Input)
Pin 31: CLI (I2S Clock input)
Pin 32: DAI (I2S Data Input)
Pin 33: N/C

Pin 34: DEC (Demphasis control input)
Pin 35: Mute* (Active low mute input)
Pin 36: Att* (When low, attenuate outputs by 12dB)
Pin 37: Test2
Pin 38: tes3
Pin 39: VddA (Analogue +5V)
Pin 40: OARO
Pin 41: OARI+
Pin 42: OARI-
Pin 43: VddAR
Pin 44: INTR

Where signal names are uncommented, look for a similar name with L/R
swapped. It'll be the same signal in the other channel.

I2S input port is 16 bits, 44.1kHz. I2S output port is 4 times oversampled.

STK054 - ECG1028

20 W Audio Amp.

Pin 1 - -Vcc
Pin 2 - Out
Pin 3 - +Vcc
Pin 4 - Bootstrap
Pin 5 - NC
Pin 6 - NC
Pin 7 - FB
Pin 8 - In
Pin 9 - Gnd
Pin 10 - NC

STK082

Audio Power amp, 35 W, Vcc = +/- 30 V typical.

Pin 1: Input
Pin 2: Gnd
Pin 3: Neg FB
Pin 4: Vcc-
Pin 5: Phase
Pin 6: Vcc-
Pin 7: Output
Pin 8: Vcc+

Pin 13: Output 2
Pin 14: Power Gnd 2
Pin 15: Input Bias 2
Pin 16: Gnd 2
Pin 17: NFB 2
Pin 18: Input 2.

STK5633 - ECG1742

130 volt regulator.

Pin 1: DC input (case)
Pin 2: Base
Pin 3: Common
Pin 4: Output

STK6982B - ECG1736

```
Four phase constant current step motor driver.  Vcc: 24 V, Il: 1.5 A typ.
18 pin SIP.

Pin 1: Vcc
Pin 2: Motor A common
Pin 3: Diode
Pin 4: Motor A
Pin 5: Input A
Pin 6: Motor A low
Pin 7: Low Input A
Pin 8: Re1
Pin 9: V ref
Pin 10: Ground
Pin 11: V ref
Pin 12: Re2
Pin 13: Motor B
Pin 14: Input B
Pin 15: Moto B low
Pin 16: Low B Input
Pin 17: Motor B common
Pin 18: Pause
```

- Back to Chip Pinouts Table of Contents.

STR

STR380 - ECG1548

```
Hybrid TV Voltage Regulator, 123 V, 1 A.

See the section: "STR381 - ECG1546" for pinout.
```

STR382 - ECG1553

```
Hybrid TV Voltage Regulator, 127 V, 1 A.

See the section: "STR381 - ECG1546" for pinout.
```

STR381 - ECG1546

```
Hybrid TV Voltage Regulator, 130 V, 1 A.  TO3 3 pin.

Pin 1: +DC Input
Pin 2: Output
```

Pin 3: Common
Pin 4: Base

Bottom view:

```
            Common
            3 o
        4 o       o 2
        Base    Output
```

Case is input - probably about 160 V.
Base is probably nearly the same as output.

STR11006 - ECG7092

Pin 1: V out/sense
Pin 2: Base drive
Pin 3: Input
Pin 4: Ground
Pin 5: Current detect

STR30115 - ECG1896

Hybrid TV Voltage Regulator, 115 V, 1 A. 5 pin SIP.

See the section: "STR30135 - ECG1778" for pinout.

STR30120 - ECG1839

Hybrid TV Voltage Regulator, 120 V, 1 A. 5 pin SIP.

See the section: "STR30135 - ECG1778" for pinout.

STR30123 - ECG1776

Hybrid TV Voltage Regulator, 123 V, 1 A. 5 pin SIP.

See the section: "STR30135 - ECG1778" for pinout.

STR30125 - ECG1897

Hybrid TV Voltage Regulator, 125 V, 1 A. 5 pin SIP.

See the section: "STR30135 - ECG1778" for pinout.

STR30130 - ECG1777

```
Hybrid TV Voltage Regulator, 130 V, 1 A.  5 pin SIP.
```

See the section: "STR30135 - ECG1778" for pinout.

STR30135 - ECG1778

```
Hybrid TV Voltage Regulator, 135 V, 1 A.  5 pin SIP.

Pin 1: Common
Pin 2: Base
Pin 3: +DC Input
Pin 4: Output
Pin 5: NC
```

Note: Pins 3 and 4 are the collector and emitter of the output transistor in a darlington configuration. Pins 2 and 4 are the two base emitter junctions in of the darlington pair.

STR50041A - ECG1894

```
TV Voltage regulator, 41.8 V, 1.1 A.  5 lead formed SIP.

Pin 1: Vout sense
Pin 2: Base drive
Pin 3: Input
Pin 4: Common
Pin 5: Soft start
```

STR51041 - ECG1895

```
TV Voltage regulator, 41.8 V, 1.1 A.  5 lead formed SIP.
```

See the section: "STR54041 - ECG1796" for pinout.

STR53041 - ECG1840

```
TV Voltage regulator, 41.8 V.  5 lead formed SIP.
```

See the section: "STR54041 - ECG1796" for pinout.

STR53043 - ECG1841

TV Voltage regulator, 43 V. 5 lead formed SIP.

See the section: "STR54041 - ECG1796" for pinout.

STR54041 - ECG1796

TV Voltage regulator, 114.5 V. 5 lead formed SIP.

Pin 1: Vout sense
Pin 2: Base drive
Pin 3: Input
Pin 4: Common
Pin 5: Vout control

STR5412

This is a 103 volt regulator typically used in live chassis TV SMPS.

Pin 1: Collector of chopper (NPN)
Pin 2: Base
Pin 3: Ground
Pin 4: Emitter
Pin 5: B+ adjust (if required)

STR58041

Hybrid voltage regulator, output 115 V.

Pin 1: V out sense
Pin 2: Base drive
Pin 3: Input
Pin 4: Common
Pin 5: V out control

STR80145

(From: yonymar@aol.com).

The STR80145 is used in computer monitors. It is called a "Hybrid Auto-Switch Module-Doubler". It allows monitors to operate at 110v or 220v without having to use a selector switch. At 220v AC the IC allows the bridge rectifier to function normally and pass the rectified AC to the filter caps, at 110v AC the bridge rectifier voltage is sent to this IC to be doubled to the equivalent of the 220v operation, automatically. The rest of the circuit operates as if the input were 220v AC.

```
Pin 1: Delay
Pin 2: T1
Pin 3: T2
Pin 4: Gate
Pin 5: Common
```

- Back to Chip Pinouts Table of Contents.

TA7120

```
Audio Preamp.

Pin 1: Preamp Res
Pin 2: Input
Pin 3: Feedback
Pin 4: Gnd
Pin 5: Bypass
Pin 6: Output
Pin 7: Vcc
```

TA7136AP - ECG1464

```
Audio Preamplifier IC, Vcc = +/- 15v typical, Vg - 92 dB, 7 pin SIP.

Pin 1: Feedback
Pin 2: Input
Pin 3: Feedback
Pin 4: (-)Vcc
Pin 5: Bias
Pin 6: Output
Pin 7: (+)Vcc
```

TA7203 - ECG1154

```
AF Power Output, 2 Channel, 2 W/channel, 14 pin DIP-W, Vcc = 14 V typical:

Pin 1: Decoupling
Pin 2: Decoupling
Pin 3: Ch 2 in
Pin 4: Feedback Ch 2
Pin 5: Phase compensation
Pin 6: Phase compensation
Pin 7: Ch 2 out
Pin 8: Vcc
```

Pin 8: Ch 1 out
Pin 10: Phase compensation
Pin 11: Phase compensation
Pin 12: Feedback Ch 1
Pin 13: Ch 1 in
Pin 14: GND

TA7204 - ECG1153

AF Power Output, 4.2 W, 10 pin SIP HS, Vcc 12.5 V typical.

Pin 1: GND
Pin 2: AF out
Pin 3: Vcc
Pin 4: Bypass
Pin 5: Feedback
Pin 6: Feedback
Pin 7: Bypass
Pin 8: Feedback
Pin 8: Input bypass
Pin 10: AF input

TA7222AP - ECG1278

AF PO 5.8 W. 10 pin SIP-HS.

Pin 1: Vcc
Pin 2: Ripple reject
Pin 3: Muting control
Pin 4: AF signal input
Pin 5: FB filter
Pin 6: Gain adjust
Pin 7: GND
Pin 8: GND
Pin 9: AF output
Pin 10: Bootstrap

TA7267 - ECG7064

VCR loading/Bidirectional motor driver, 1 A. Vcc = 18 V (typical).

I would expect the normal output voltage to be close to whatever you have for Vcc (just a guess).

Pin 1: In 1
Pin 2: In 2
Pin 3: Out 1
Pin 4: Ground
Pin 5: Out 2

Pin 6: Ve
Pin 7: Vcc

TA7291S

Bidirectional motor driver.

Pin 1: In 1
Pin 2: Vcc
Pin 3: Out 2
Pin 4: NC
Pin 5: GND
Pin 6: Vs
Pin 7: Out 1
Pin 8: Vref
Pin 9: In 1

Not sure if the second (or first) In1 is a typo - this is from ECG7043.

TA7313AP - ECG1465

AP PO, .5 W, 8 ohms, Vcc = 6 V (typical), 9 pin SIP.

Pin 1: Hi Freq Comp
Pin 2: Input
Pin 3: Feedback
Pin 4: Hi Freq Comp
Pin 5: GND
Pin 6: Out
Pin 7: Vcc
Pin 8: Bootstrap
Pin 9: Ripple Filter

TA7317P

Speaker protection IC:

Pin 1: Power on-off detection/Over current detection (typical voltage -0.6V)
Pin 2: Direct voltage detection input (Typical voltage 0V)
Pin 3: Gnd
Pin 4: Gnd
Pin 5: Substrate (Typical voltage -0.8V)
Pin 6: Relay drive output/Typical voltage low 0.9v
Pin 7: Gnd
Pin 8: Muting circuit/Typical voltage 2.8v
Pin 9: Regulator input/Typical voltage 2.8v

This IC senses over current or a DC offset on the output to the speakers.
In the event of a offset it will operate a relay to remove any connection

between the amp and speakers so to prevent DC flowing through the speakers and damage them.

TA7559P - ECG778A

Dual op-amp.

Pin 1: Output one
Pin 2: Invert input 1
Pin 3: Noninvert input 1
Pin 4: V neg.
Pin 5: Noninvert input 2
Pin 6: Invert input 2
Pin 7: Output 2
Pin 8: V pos.

TA75902P - ECG987

Quad op-amp.

Pin 1: Out 1
Pin 2: -In 1
Pin 3: +In 1
Pin 4: +Vcc
Pin 5: +In 2
Pin 6: -In 2
Pin 7: Out 2
Pin 8: Out 3
Pin 9: -In 3
Pin 10: +In 3
Pin 11: . (I assume -Vcc or Ground?)
Pin 12: +In 4
Pin 13: -In 4
Pin 14: Out 4

TA8201AK - ECG1832*

* May not be identical mechanical or electrical equivalent but should work in majority of applications (!!).

12 W, AF PO. Vcc = 13.2 V, RL = 4 ohms. 7 pin inline.

Pin 1: Input
Pin 2: NFB
Pin 3: Ripple rejection
Pin 4: Gnd
Pin 5: Out 2
Pin 6: Vcc
Pin 7: Out 1.

TAA611A12 - ECG1113

2.1 W Audio Amp, 15 V Vs max. Rl = 8 ohms. 14 pin DIP.

Pin 1: Bootstrap
Pin 2: NC
Pin 3: Frequency Compensation
Pin 4: Frequency Compensation
Pin 5: Feedback
Pin 6: NC
Pin 7: Input
Pin 8: Ground
Pin 9: NC
Pin 10: Ground

TDA1175P

Vertical output IC, PowerDIP16, supply voltage +35 volts max, +10 V min.

Pin 1: Ramp out, 1 V
Pin 2: Supply voltage
Pin 3: Flyback
Pin 4: Ground and heatsink
Pin 5: Ground and heatsink
Pin 6: Power amplifier output
Pin 7: Power amp supply voltage, range -0.5 to +10 V
Pin 8: Reg voltage, +6.7 volts
Pin 9: Height Adjustment
Pin 10: Sync input
Pin 11: Oscillator

Pin 12: Ground and heatsink
Pin 13: Ground and heatsink
Pin 14: Amp input, 2.27 volts
Pin 15: Compensation
Pin 16: Ramp generator

TDA1541A

(From: Tony Duell (ard@p850ug1.demon.co.uk).)

Pin 1: Latch Enable(split mode)/Word Select(multiplexed modes)
Pin 2: Bit clock input
Pin 3: Data input (left chanel data in split mode)
Pin 4: Right channel data in split mode, otherwise not used.
Pin 5: Analogue Ground
Pin 6: Right channel audio output
Pin 7-13: Decoupling. Connect to ground via separate 0.1 uF cap on each pin.
Pin 14: Digital ground
Pin 15: -15V supply
Pin 16,17: Oscillator capacitor (connect 470pF between these 2 pins)
Pin 18-24: Decoupling (7 more 0.1 uF capacitors)
Pin 25: Left channel audio output
Pin 26: -5V supply
Pin 27: Digital mode select input
Pin 28: +5V

Modes:

Pin 27 = -5V: Separate channel data streams on pins 3 and 4. Pin 1 = latch enable

Pin 27 = 0V: Time multiplexed offset binary data on pin 3. Pin 1 = word select (low = left, high = right)

Pin 27 = +5V: Time multiplexed 2's complement data on pin 3. Pin 1 = word select again.

TDA1670A/TDA1675 - ECG1862

TV vertical deflection output, 35 V max Vs, 15 pin SIP-HS.

Pin 1: Amp output
Pin 2: Amp supply

Pin 1: -In
Pin 2: +In
Pin 3: -Vs
Pin 4: Out
Pin 5: +Vs

Pin 3 connected to case.

TDA2577 - ECG1632

Horizontal, Vertical Oscillator, Sync, Driver. Vcc1 = 12 V typical.

Pin 1: Vertical Drive Out
Pin 2: Vertical Feedback
Pin 3: Vertical Frrequency Adj
Pin 4: Vertical Sync Sep
Pin 5: Video Input
Pin 6: Horizontal Sync Sep
Pin 7: Horizontal Sync Sep
Pin 8: Slow Phse Det
Pin 9: Ground
Pin 10: Vcc
Pin 11: Horizontal Drive Out
Pin 12: Horizontal Flyback Input
Pin 13: Mute Out
Pin 14: Phase Det.
Pin 15: Horizontal Frequency Adjust
Pin 16: Start Circuit Stab
Pin 17: Sandcastle Out
Pin 18: Coincidence Det

Aside from those that have obvious meanings, I do not know what the
other signals do.

TDA2578A

Synchronisation circuit with vertical oscillator and driver stages.

Pin 1: Vertical Drive output
Pin 2: Veritcal feedback (e.g. from sense components, bottom of yoke circuit)
Pin 3: Vertical oscillator timing components
Pin 4: Vertical sync separator R/C network
Pin 5: Video input
Pin 6: Horizontal sync separator input
Pin 7: Sync slicer output (connnect to 6 via RC network)
Pin 8: Slow (horizontal) phase detector RC timing components
Pin 9: Ground
Pin 10: +12V
Pin 11: Horizontal Drive output
Pin 12: Horizontal flyback pulse input
Pin 13: Mute and 50/60Hz indentification
Pin 14: Phase detector 2 timing capacitor
Pin 15: Horizontal oscillator timing components
Pin 16: Startup current input
Pin 17: Sandcastle pulse output
Pin 18: Coincidence detector timing capacitor

TDA3505

Chroma Control Circuit.

Pin 1: Red Signal Out
Pin 2: Storage Cap Cutoff Green
Pin 3: Green Signal Out
Pin 4: Storage Cap Cutoff Blue
Pin 5: Blue Signal Out
Pin 6: Vcc

TDA3654 - ECG1754

TV vertical deflection, 26 V typ.

9 pin SIL (the TDA3654Q has the pins bent to a sort of 'DIL' pinout - either
can be easily converted to the other shape).

Pin 1: Vertical drive input
Pin 2: Ground
Pin 3: Vertical drive input (may be linked to pin 1)
Pin 4: Ground
Pin 5: Output
Pin 6: Output stage power (Diode to V+, capacitor between 6 and 8)
Pin 7: Protection (to shut down CRT if sacn fails)
Pin 8: Flyback (capacitor to pin 6)
Pin 9: V+ (supply voltage)

TDA4190 - ECG1633

TV sound IF, tone, volume, FM detector, preamp, Po = 4 W, Rl = 16 ohms,
Vs = 24 V typical. 20 pin DIP.

Pin 1: Turn iff muting
Pin 2: Sound IF input
Pin 3: IF decoupling/VCR switch
Pin 4: IF decoupling/VCR switch
Pin 5: Gnd
Pin 6: Gnd
Pin 7: Detector (FM)
Pin 8: Detector (FM)

Pin 22: SECAM ID Ref
Pin 23: SECAM ID Sel
Pin 24: Sandcastle In
Pin 25: Switch Voltage In/Out NTSC 4.4
Pin 26: Switch Voltage In/Out NTSC 3.5
Pin 27: Switch Voltage In/Out SECAM
Pin 28: Switch Voltage In/Out PAL

TDA4601

SMPS controller. Vcc = 15 V typ.

Pin 1: Reference
Pin 2: Zero detection
Pin 3: Feedback
Pin 4: Sawtooth Generator
Pin 5: Shutdown
Pin 6: Gnd
Pin 7: Sink output
Pin 8: Source output
Pin 9: Vcc

TDA4605

SMPS controller.

Pin 1: Regulation input
Pin 2: Primary current simulation
Pin 3: Primary voltage monitoring
Pin 4: Gnd
Pin 5: Output
Pin 6: Supply voltage
Pin 7: Soft-start
Pin 8: Zero crossing detector

TDA8340

(From: Alex Suhisky (a1ex@q-net.net)
  and Peter Radlberger (p.radlberger@blackbox.at).)

Television IF amplifier and demodulator.

```
Supply voltage (pin 11)                              - 12V,
Video output voltage (peak-to-peak, pin 12)      - 2.7 V
AFC output voltage swing (peak-to-peak, pin 5)  - 10 V
```

Pin 1: Balanced IF input
Pin 2: IF amplifier decoupling
Pin 3: Tuner AGC starting point adjustment
Pin 4: Tuner AGC output

Pin 5: AFC output
Pin 6: AFC on/off switch and sample-and-hold capacitor
Pin 7: Reference carrier pi/2 rad.phase shift
Pin 8: IF picture carrier passive regeneration
Pin 9: IF picture carrier passive regeneration
Pin 10: Reference carrier pi/2 rad.phase shift
Pin 11: Positive supply (Vcc)
Pin 12: Video output
Pin 13: Gnd (Vee)
Pin 14: IF AGC capacitor and VCR switch

Pin 3: S2       Output 2        Open collector, active low
Pin 4: S1       Output 1              "
Pin 5: E10
Pin 6: E9
Pin 7: E8
Pin 8: E7
Pin 9: E6
Pin 10: E5
Pin 11: E4
Pin 12: E3
Pin 13: E2
Pin 14: E1
Pin 15: DATA    Data input
Pin 16: Vp      Pos. supply
```

Encoder: Pin 15 to Vp, Output: tie pins 3&4 together, this is your output, open collector. E1-E10 set code (connect to either Vp or gnd).
Key V+ to transmit.

Decoder, pin 15 to Vp, E1-E10 set code, pins 3&4 open collector outputs
active when code matches. Third unsucessfull try disables input! (three
strikes and your out!)

Illegal codes are E1-E10=High or E1-E9=High with E10=low.

TL494 - ECG1729

Pulse width modulator control circuit. Vcc = 15 V typical. 16 pin DIP.

Pin 1: Non-inverted in
Pin 2: Inverted in
Pin 3: Feedback
Pin 4: Dead time control
Pin 5: CT
Pin 6: RT
Pin 7: Ground
Pin 8: Collector 1
Pin 9: Emitter 1
Pin 10: Emitter 2
Pin 11: Collector 2
Pin 12: Vcc
Pin 13: Output control
Pin 14: Vref
Pin 15: Inverted in
Pin 16: Non-inverted in

U to Z

UA78GU(1C) - ECG953

Adjustable regulator, 5 to 30 V, 1 A.

```
               -----
               | O | <-Common (heatsink tab)
               -----
               |   |
               -----
                ||||
                1234
```

Pin 1: Common
Pin 2: Input
Pin 3: Output
Pin 4: Control

UA2240CN - ECG893 - SK7712

Programmable Timer/Counter. Vcc = 5 V typ.

Pin 1: Fo (out)
Pin 2: Fo/2 (out)
Pin 3: Fo/4 (out)
Pin 4: Fo/8 (out)
Pin 5: Fo/16 (out)
Pin 6: Fo/32 (out)
Pin 7: Fo/64 (out)
Pin 8: Fo/128 (out)
Pin 9: Ground
Pin 10: Reset
Pin 11: Trigger
Pin 12: Mod/sync
Pin 13: Timing/rc network
Pin 14: Time-base (out)
Pin 15: Regulator (out)
Pin 16: Vcc

UC3842AN

Switchmode power supply controller. 8 pin DIP.

Pin 1: Comp
Pin 2: Vfb
Pin 3: Isen
Pin 4: Rt/Ct
Pin 5: Gnd
Pin 6: Out
Pin 7: Vcc
Pin 8: Ref (+5)

UDN2993LB

Pin 1: Load supply
Pin 2: Enable(A)
Pin 3: Phase(A)
Pins 4-7: Gnd
Pin 8: Out(1A)
Pin 9: Out(2A)
Pin 10: V(ea)
Pin 11: V(eb)
Pin 12: Out(2B)
Pin 13: Out(1B)
Pin 14-17: Gnd
Pin 18: Phase (B)
Pin 19: Enable (B)
Pin 20: Logic supply

ULN2003A - ECG2013

7 Input Darlington Driver 500mA

Pin 1: In 1
Pin 2: In 2
Pin 3: In 3
Pin 4: In 4
Pin 5: In 5
Pin 6: In 6
Pin 7: In 7

Pin 8: Gnd
Pin 9: Common connection point for the cathodes of the internal free
wheeling diodes connected to each driver output.

Pin 10: Out 7
Pin 11: Out 6
Pin 12: Out 5
Pin 13: Out 4
Pin 14: Out 3
Pin 15: Out 2
Pin 16: Out 1

ULN3718M

Pin 1: Decoupling
Pin 2: Power Ground
Pin 3: Signal Ground
Pin 4: Output
Pin 5: Vcc
Pin 6: N/C
Pin 7: N/C
Pin 8: Input

ULN3751Z

Pin 1: Non-inverting input
Pin 2: Inverting input
Pin 3: Substrate/-Vs
Pin 4: Output
Pin 5: +Vs

uPA53C - ECG2084

5 Input Darlington Driver, 500mA.

Pin 1: NC
Pin 2: In 1

Pin 3: In 2
Pin 4: In 3
Pin 5: In 4
Pin 6: In 5

Pin 7: Gnd
Pin 8: NC

Pin 9: Out 5
Pin 10: Out 4
Pin 11: Out 3
Pin 12: Out 2
Pin 13: Out 1
Pin 14: NC

uPC177C

Quad Comparator.

Pin 1: Output 1
Pin 2: Output 2
Pin 3: Vcc
Pin 4: Neg input 2
Pin 5: + input 2
Pin 6: - input 1
Pin 7: + input 1
Pin 8: - input 3
Pin 9: + input 3
Pin 10: - input 4
Pin 11: + input 4
Pin 12: Gnd
Pin 14: Output 3
Pin 13: Output 4

uPC1238 - ECG1378

AF Power Out, 10W, Vcc = 12V typ. TO220, 5 pin.

Pin 1: Non-inverting input
Pin 2: Inverting input

```
Pin 3: -Vcc
Pin 4: Output
Pin 5: +Vcc
```

X24C44

```
8 pin DIP.

Pin 1: Chip enable
Pin 2: Serial clock
Pin 3: Data input
Pin 4: Data output
Pin 5: Vcc
Pin 6: Store
Pin 7: Recall
Pin 8: Vss
```
