Due principally to repressive legislation, herbalists in North America must once again rely heavily on folk traditions as their major source of learning and inspiration. It should be noted here that much of the valuable herbal lore once utilized widely by native North Americans is now known by only a small

handful of native elders (PC. 1988). It is very fortunate therefore, that Canadian and American herbalists have preserved some of this knowledge in their own practices.

Folk medicine traditions are virtually impossible to legislate against directly, and even in the recent Ontario government recommendations, treatment of oneself and one's family had been specifically exempted from prosecution under the proposed legislation (HPLR, 1989). Direct legislation however, was not the only factor contributing to the decimation of native culture and the virtual loss of their traditional healing knowledge.

The proposals tabled in the Ontario legislature will almost certainly impose or support severe restrictions on the cultivation and/or sale of medicinal plants, should they be passed into law. Furthermore, such legislation will definitely prevent or seriously delay the free development and re-emergence of a professionally oriented system of herbal medicine in Ontario.

Consequently, those who choose to make use of this 'valuable medical resource' (W.H.O., 1975a), will be forced to rely on their own experience and to gather and use only wild plants. This assumes however, that environmental policies in Ontario and the rest of North America will not poison even this source in the very near future.

The Medicinal HerbFAQ

5.3.2 Ayurvedic Medicine - an introduction

by Dr. Duane Weed, D.C. (drweed.delphi.com)

The Ayurvedic system traces its roots to the Himalayan Mountains of India over five thousand years ago. According to legend, a conference was held in a Himalayan cave in which the greatest sages of India--some after having traveled thousands of miles--met to discuss their knowledge of their healing arts. These scholars and teachers possessed traditional knowledge about the medicinal plants of India that had been handed down orally by the tribes of the Indian forests since the beginning of history. At this conference, these sages compared and combined their knowledge into one body which they called the Ayurveda, from two Sanskrit words; Ayus, or "life", and Veda, or "knowledge". "Ayurveda" has been translated as "the knowledge of life", and as "the science of life". It has been suggested that a more appropriate translation would be "the knowledge of life span".

After this historic conference, the Ayurvedic knowledge was passed orally from teacher to student for over a thousand years, continuously growing as each Ayurvedic physician added his insights and experiences. It was finally written down in the first century A.D. by the Ayurvedic physician, Charaka.

By that time--and hundreds of years before the birth of European medicine--Ayurveda had specialists in psychiatry, pediatrics, gynecology, ear nose and throat, ophthalmology, surgery, toxicology, virility, and fertility.

Ayurvedic medicine probably predates any other healing tradition in existence today--even Chinese medicine. Even before the Ayurvedic conference, knowledge of the medicinal plants of India had spread to other continents. Seeds from plants indigenous to India have been found in the tombs of the Egyptian pharaohs. Travelers had carried information about Indian plants through Tibet into China, and Arabs had traded for Indian herbs before the birth of Islam.

At the time of King Solomon, the Queen of Sheba traded herbs and spices of India to the Israelites. Ayurvedic medicine began to be studied by Arab physicians and knowledge of the plants of India was passed on to the Greeks and Romans. By the first century A.D., when Charaka was writing Ayurveda's first written records, Pliny was already describing the plants of India to the Roman Empire in his NATURAL HISTORY. And much more recently, as any American school child can tell you, a Portuguese sailor by the name of Christopher Columbus discovered America in 1492, while searching for a trade route to India to acquire her herbs and spices.

According to Ayurvedic philosophy, health is dependent upon one's ability to live in harmony with one's self and with the external universe. As much attention was given to illnesses of the mind as to illnesses of the body.

The Ayurvedic physician taught that in order to avoid illness and pain, the patient must control the destructive (and self-destructive) nature. Living in harmony with the environment was recognized as essential to one's mental, physical, and spiritual well-being.

Ayurvedic physicians taught that prevention was more desirable than a cure. Their ideal was to develop an individual's natural resistance to disease to the point where one's immune system could function as one's best medicine.

Their goal was to maintain an individual in his or her optimal health throughout life, so that the ultimate goal of life--the awareness of his or her connection with the life principle--could be pursued.

Today's Ayurvedic physicians, like their predecessors, recognize three major body (or physiology) types which they refer to as the three DOSHAS: VATA, PITTA, and KAPHA. One's body type is also referred to as one's PRAKRITI, and is determined by heredity. Most people are actually a combination of types; a VATA/PITTA type for example. Ayurvedic physicians evaluate their patients using such techniques as observation, interview, and pulse diagnosis to determine the patient's body (or physiology) type. They then determine the imbalances that are present in the body and make recommendations according to the patient's body type. Dietary and herbal recommendations make up a large part of their treatments; but many other techniques such as meditation, hatha yoga, aroma therapy, and music therapy are also employed.

Thanks to the Ayurvedic tradition, many herbal combinations based on centuries of accumulated knowledge are available to today's eclectic herbalists and natural health enthusiasts. Ayurvedic herbal formulations, like Chinese herbal formulations, are combinations of many different herbs that work synergistically. Single herbs are rarely if ever employed. Even though there are competent Ayurvedic physicians in practice today, one does not have to see an Ayurvedic physician to use an Ayurvedic herbal combination, as long as the recipe of an Ayurvedic master is carefully followed.

Some of the most common herbs currently used in Ayurvedic formulations are:

Acacia catechu, *Adhatoda vasica* (Vasaka), *Andrographis paniculata*, *Aegle marmelos* (Bel), *Alpina galanga*, *Alstonia scholaris*, *Apium graveolens*, Ashwagandha root, *Azadirachta indica* (Margosa), *Boerhaavia diffusa* (Hogweed), *Boswellia serrata*, *Caesaipinia crista*, *Clerodendrum indicum*, *Commiphora mukul* (Indian Bedellium), *Curcuma longa* (Turmeric), *Cyperus rotundus*, *Enicostemma littorale*, *Fumaria parviflora*, *Glycyrrhiza glabra* (Liquorice), *Gymnema sylvestre*, *Hedychium spicatum*, *Hemidesmus indicus* (Ind. Sarsaparilla), *Holarrbena antidysenterica*, *Inula racemosa*, *Momordica charantia* (Bitter Gourd), *Myrica nagi*, *Ocimum sanctum* (Holy Basil), *Paederia foetida*, *Phyllanthus emblica*, *Picrorhiza kurroa*, *Pimpinella anisum*, *Pistacia integerrima*, *Pterocarpus marsupium*, *Rubia cordifolia* (Indian Madder), *Sida cordifolia*, *Smilax china*, *Swertia chirata*, *Syzygium cumini* (Jamun), *Terminalia belerica*, *Terminalia chebula* (Chebulic Myrobalan), *Tinospora cordifolia*, *Trachyspermum ammi*, *Tribulus terrestris*, *Trigonella foenum-graeceum*, *Vitex negundo*, *Withania somnifera* (Winter Cherry), *Zingiber officinale* (Ginger)

From Robert Hensley (Hensleys.aol.com):

Ayurveda is the world's oldest science of health care. The written tradition dates back around 5,000 years, but the oral tradition in India is timeless.

The basic principles of Ayurveda include:

1. Mind, body, emotions, and spirit are more than connected, they are one.
2. There are 3 fundamental principles of nature: called Vata, Pitta and Kapha, which govern all processes in all levels of our life.
3. Vata governs all movement, Pitta all heat and transformation, and Kapha all growth, structure and lubrication.
4. Everything we experience influences these governing principles.
5. If these principles that guide the processes of our body, mind, etc get "out of balance" due to poor diet, activity, etc. they can become overactive, and disease results.
6. If vata gets out of balance, for instance, it leads to overactive mind, poor circulation, poor nerve conduction, loss of memory, irregular elimination, uncomfortable menses, etc. - all things related to movement.
7. If pitta is out of balance, we can get excessive digestive fire, resulting in heartburn, excess stomach acid, a hot temper, inflammations, etc. -all things related to heat and digestion.
8. If kapha gets out of balance, it can lead to chronic congestion, weight gain, cellulite, cholesterol buildup, acne, oily skin, etc. - all things related to structure and lubrication.
9. Herbs in synergistic combination, diet, routine, meditation, etc are used to restore balance to restore proper operation of the various systems. Balance restores health.
10. Ayurveda does not focus on decreasing symptoms, it focuses on increasing health. Where there is health, there is no room for disease.
11. Symptoms are only used as one of eight ways to determine the underlying imbalance or weakness that has allowed the disease to occur.

Due to foreign intervention in India for hundreds of years, Ayurveda became fragmented, and it

has been revived over the past 35 years by Maharishi Mahesh Yogi. As a result of growing scientific verification at major research institutions, it is the worlds' fastest growing health care system.

The Medicinal HerbFAQ

5.3.4 What is Traditional Chinese Medicine?

From Suzanne E. Sky, L.Ac. (avena.aloha.net)

Traditional Chinese Medicine is a phrase used to describe a complex system of medicine developed in China that has now spread around the world in its various forms. This system is over 3,500 years old. Its fundamental basis is a philosophy which views humans as a microcosm of the universe and inherently connected to it, to Nature and to all Life.

Chinese Medicine is actually a part of what is called Oriental Medicine, because there are many different styles practiced, with the same origins and medical foundation, in China, Japan, Korea and other Asian countries. This medicine spread to America and Europe as practitioners migrated and settled in different countries. Now Oriental Medicine is practiced and taught all around the world.

I. HISTORY & CURRENT USE

The history of Chinese Medicine is very long, complicated, and fascinating. There have always been many different styles of practice and theories of medicine in China. The early Communist leaders destroyed much of the old information but finally decided that Chinese Medicine was a valuable method. The principles were simplified and began to be taught in colleges. Before this, Chinese Medicine was passed down through generations of families, through apprenticeship and training that began at a young age. Now there are several well established Colleges in China that train Chinese Medicine practitioners. Westerners can study there as well. In Chinese hospitals, Chinese Medicine is practiced alongside modern Western Medicine. For example, cancer patients in China receive radiation treatment or chemotherapy, and they also receive Chinese herbal medicine to ameliorate the side effects.

II. WHAT MODALITIES DO CHINESE MEDICINE PRACTITIONERS USE?

Chinese Medicine is a large area of study and practice. Some of the modalities it includes are:

- Herbal Medicine: An advanced and effective system of herbal medicine.
- Acupuncture & Acupressure: Use finger pressure or special fine needles to harmonize and activate the body's own healing ability.
- Moxibustion (moxa): Special therapeutic warming techniques.

- Diet & Nutrition: A unique and effective system which teaches the energetic qualities of food and how it effects us.
- Chi Kung and Tai Chi: Systems of movement and breathing that promotes health. Chi Kung is also an ancient healing method.
- Tui Na: Chinese medical massage

Practitioners are trained in several or many of these modalities and specialize in one to a few areas of expertise.

III. SCHOOLING AND PRACTICE

Many schools in America and Europe are fully accredited and confer Master's Degrees in Oriental Medicine. Schooling takes 4 to 6 years. The requirements include Western science and medical courses along with about 2,000 hours in Chinese Medical Theory, techniques and practice. This includes in-depth study of Acupuncture, Chinese Herbal Medicine, and other modalities. In addition, anywhere from 800 to 1,200 hours of clinical observation and internship are required in an acupuncture clinic. The traditional way of learning, apprenticeship, is still in existence, but is less common today. In America about 20 states certify or license Acupuncturists for practice, through an examination process. There are over 30 schools in America and many schools and practitioners in Europe.

IV. ACUPUNCTURE IS RECOGNIZED BY THE WORLD HEALTH ORGANIZATION

The World Health Organization (WHO) recognizes over 250 illnesses successfully treated by acupuncture and the list continues to grow. Among these are included: PMS (pre-menstrual syndrome), gynecological disorders, anxiety, depression, arthritis and joint problems, colds, flus, sinusitis, cough, bronchitis, headaches, numbness and poor circulation, stress, fatigue, recovery from injuries.

V. QUESTIONS TO ASK YOUR ACUPUNCTURIST

- How and where (or with whom) did they study? (School or apprenticeship)
- How long was their training? Currently some health professionals can attend what amounts to a weekend class and then practice acupuncture under their medical license. They may know where to stick a few needles, but they are not trained in Oriental Medicine.
- What modalities do they use?
- How long have they been practicing?

VI. INTERNET RESOURCES

A great Acupuncture page with lots of resources: <http://www.acupuncture.com/>

The Medicinal HerbFAQ

5.3.5 Flower essences

From Suzanne E. Sky, L.Ac. (avena.wave.net)

Flower essences are liquid preparations, containing only minute traces of actual flowers, which convey the vibrational pattern and essence of specific flowers. Because of this, their action is subtle and extends beyond the physiological. Their action is not biochemical, but is vibrational. These gentle essences enjoy a reputation of being very safe. They have no side-effects and are non-toxic. Some people state they don't 'feel' any change or effect from using flower essences. However, many people find the flowers provide an essential factor in their healing process. Each person responds to flower essences according to their inner rhythm and needs.

Research in the modern field of psychoneuroimmunology shows a clear interrelationship between physical illness, stress and emotional/mental outlook. Flower essences help address issues which often underlay stress and health problems, helping to 'untie' or release these mental/emotional energetic knots. Flower essences can help transform emotions, attitudes or patterns of behavior to enhance one's development, growth and awareness. Flower essences expand our understanding of health care, recognizing the interweaving of spiritual, mental, emotional and physical aspects of wellness. The name most closely associated with flower essences is that of Dr. Edward Bach, the English physician who first discovered them. In the 1930's, he introduced his set of 39 Flower Essences that changed the world of natural medicine forever.

Dr. Bach's Life and Discovery of Flower Essences

Dr. Edward Bach was a remarkable man. He was an early pioneer of natural medicine who discovered results when he treated the person rather than the disease. Born in 1886, Bach entered the medical profession from a sincere desire to help others. Early on in his practice he noticed that the patients personality or temperament was more helpful in deciding which medicine would be most effective than any other factor.

Early in his career, Bach studied bacteriology and became fascinated by the connection between a person's colon flora and their health. He discovered that a vaccine made from the patient's intestinal bacteria, and injected into their blood stream, gave excellent results, especially in chronic diseases. When Bach discovered homeopathy, he modified his method and made homeopathic preparations known as nosodes (remedies made from pathological tissues). He classified the

intestinal bacteria into seven main groups and made preparations still known today as Bach's Seven Nosodes. Soon, he found that when a patient entered his office, he could immediately tell which type of flora would be predominant in that person, and which nosode they would need. From this Bach correlated seven main personality types and began prescribing the Nosodes solely on the basis of the patients personality, rather than laboratory tests. The results were even greater than he expected, and he saw clearly the importance of treating the person rather than their disease.

While Bach had great respect for homeopathy and its founder, Dr. Hahnemann, he refuted the basic premise of homeopathy, that like cures like. Bach states "It is obviously fundamentally wrong to say that 'like cures like'. ...Like may strengthen like, like may repel like, but in the true healing sense like cannot cure like.And so in true healing, and so in spiritual advancement, we must always seek good to drive out evil, love to conquer hate, and light to dispel darkness. Thus must we avoid all poisons, all harmful things, and use only the beneficent and beautiful." (Collected Writings, page 113)

Bach became dissatisfied with using the intestinal Nosodes, desiring to find a natural method which would not require using pathological material. He felt herbs would provide the most suitable material and began investigating the plant world. As Bach continued to work with and observe people, he became even more convinced that a person's temperament and personality were the factors that determined what illnesses they were prone to and what medicines would help them.

The first two plants he discovered and used in his practice, that are still flower essences today, were Impatiens and Mimulus. The third one was Clematis. This was in 1930. Bach was so pleased with the results, he decided to give up his use of nosodes altogether and seek out other herbal remedies to add to his repertory. Dr. Bach gave up his successful, lucrative and prestigious Harley Street office and set out for Wales to discover new healing plants. Little did he know he was about to discover a whole new form of natural medicine and herbal preparation.

Tromping around Wales for many years led him to discover the remaining 36 flower remedies. Bach was very particular in his selection of flowers and where he found them. Each of his remedies is a specific botanical entity, and substitutions are not equally effective. Bach was a sensitive as well as a medical researcher and physician. This blend made him search out only non-toxic plants that offered the highest vibratory patterns. Of the 39 essences we attribute to Bach, 37 are from plants, trees and bushes. One remedy, Rock Water, is from a special spring. The 39th, is a combination of several remedies, used for acute and emergency situations.

Bach found great results using the flower essences with people who came to him from all over. No matter what illness the person had, he only gave remedies in accord with their mental/emotional state of being. Bach himself became ill several times and only recovered after discovering and using the appropriate flower essence. He discovered several essences in this way.

Dr. Bach died in his sleep in 1936, feeling his life work was complete. He stated that the 38 flower essences he discovered would cover every possible area of need. His goal was to discover a safe, effective system of medicine that even the simplest person could use to help themselves, without a doctor. He felt he achieved this goal with his system of the Flower Remedies, which anyone can learn and apply with a little study.

IMPORTANT NOTE

Flower essences work most beneficially as part of a wholistic program of health care, including exercise, nourishing diet, stress reduction, inner work, play, and rest. They are not a substitute for medical attention or professional psychological counseling. If you are ill, please consult a qualified physician.

This entry was much longer - but this is the medicinal herbFAQ, not the flower essence FAQ, so for the full entry go to this page: <http://ibiblio.org/herbmed/neat-stuff/bachflow.html>

The Medicinal HerbFAQ

5.3.6 Aromatherapy intro

From: Marcia Elston <samara.wingedseed.com> - <http://www.wingedseed.com>

What is Aromatherapy? Aromatherapy is a true medical science and is the skilled use of specific essential plant distillates (essential oils), singularly or in combination, for health and well being.

How Does Aromatherapy Work? The essential plant distillates (essential oils) interrelate with the human body within four distinct modes of action, pharmacological (as phytopharmaceuticals), physiological (physically and chemically), psychological (affecting mental states and processes) and incorporeal (spiritual). Our body uses the aromatic molecules (essential oils) both (1.) through our olfactory system which is connected to the limbic system in the brain where our most primal feelings, urges and emotions reside, (2.) and by inhalation and skin absorption of the low weight molecular structure of essential oils. Aromatherapy works best within a holistic approach to wellness.

Is Aromatherapy New? We know from the study of ancient manuscripts that priests in India some 4,000 years ago practiced aromatherapy very much like it is practiced today. Modern Ayurvedic medicine includes an aromatic component that has evolved from this ancient practice. Scent was very important to ancient Egyptians who used plant-oil infusions, gums and resins, as well as aromatic herbs and flowers in rituals, relaxation and skin care extensively in their culture. Modern aromatherapy, as we know it today, was revived in 1910 by the French chemist, Gattefosse, after having been badly burned in a laboratory explosion and plunging his arm into a nearby vat of lavender essential oil. The amazing speed of recovery and lack of scarring led him into a lifetime study of essential oils and their medicinal uses for skincare.

Can I Do This Myself? Most essential oils have been approved as G.R.A.S. (generally regarded as safe when used by various trades at their normal levels of use). However, these standards were developed by the food and perfume industries and were not developed specifically for the use of essential oils in aromatherapy. Aromatherapy, as a medical healing modality, has been in existence in England and parts of Europe for quite some time, and the United States is fast developing a similar model, however there is at present no FDA approval for the use of essential oils medicinally. An individual can use essential oils themselves (self medication) provided they are thoroughly familiar with the uses, safety precautions and contraindications and have available thorough and accurately referenced information on the potential hazards associated with using

essential oils.

SAFETY FIRST! Essential oils are very potent and strong concentrated plant constituents (chemicals). Always keep essential oils out of reach of children and pets. Do not apply undiluted essential oils directly to the skin. Avoid contact with eyes and mouth and other tender mucous membranes. Essential oils should never be taken orally. Essential oils are flammable and should be kept away from fire or flames. Some essential oils can cause dermatitis; always do a skin test with 2% dilution before applying to large area. Some oils are not recommended by use in infants and very young children, pregnant women, persons with epilepsy, hypersensitive individuals, just to name a few. Some essential oils can cause photosensitivity. Some essential oils may not work well when taking prescription drugs. Be well informed before you use any essential oil. The best manual on the market for the safety data of essential oils is *The Aromatherapy Practitioner Manual* by Sylla Sheppard-Hanger. This reference of over 350 plant extracts, in two volumes, includes an index of biologically active phytochemicals, clinical index and taxonomical index and is a must for anyone seriously considering using aromatherapy intelligently and effectively. When not used properly, essential oils can be harmful and they should never be used indiscriminately.

Where Can I Learn More? There are numerous and rapidly emerging educational programs and home study courses being offered throughout the United States and Canada. Here is a short list.

5.4 The Ames Test

>[Does anyone know more about this Ames test?](#)

The Ames test cultures mutations of bugs (usually *Salmonella* spp) that are unable to grow without the amino acid histidine and adds suspected mutagens to the culture medium (after incubating them with liver extract to expose them to lysosomal activity). If the bugs then grow, the mutation is deemed to have reversed (ie they now synthesise histidine) and the test substance is regarded as (ultimately) mutagenic. It is the case that the majority of known chemical carcinogens are also mutagens according to the Ames Test.

The problem is that also according to the Ames Test the prevalence of environmental mutagens is so high that the human population should long ago have been wiped out by cancer if the extrapolations were correct. (The extrapolations being histidine gene mutagenicity equals ultimate carcinogenic action, and salmonella bugs equals people.) This is of course acknowledged by pathologists - but seems not to be understood by the rank and file scare mongers who like to appear to be *scientific* in their attacks on herbalism.

jonno.teleport.com (Jonathan Treasure)

From: Kevin Jones <100621.17.CompuServe.COM>

There are several drawbacks to the Ames test which basically make it worthless on its own.

Firstly carcinogens are divided into those which require to be metabolised in a cell (activated) and those which don't. Obviously the metabolism of a bacterial cell is going to differ from that of a mammalian cell. Compounds which are activated in a bacterial cell may therefore show no activity in a mammalian cell and vice versa.

Secondly carcinogens act by reacting with genetic material. The type which are metabolically activated generally form free radicals which then react with DNA. Many carcinogens have an affinity for a specific sequence of nucleotides. Obviously the number of sequences that are shared between mammals and bacteria are going to be very small! There may well be many chemicals which cause mutations in bacteria but which have absolutely no effect on mammals.

In short, all the Ames test does is show that a chemical produces a mutation in *Salmonella*

bacteria. It might possibly indicate the potential for being carcinogenic in higher organisms - and then again it might not. It also is quite possible that the Ames test could declare a chemical safe which is quite powerfully carcinogenic in mammals simply because it does not affect bacteria.

In any case, relying on the Ames test shows a distinct lack of understanding of the nature of cancer and cell growth. Mammalian cells are programmed to die. Only chemical messages keep them alive and keep a particular gene turned off. It's like a dead man's handle. The moment a genetic error is detected the cell is told to stop dividing. If the error is serious, this gene is turned on and the cell destroys itself. This gene and its backup copy have to fail before a cancer can develop _or_ the chemical messenger system has to become defective and keep it turned off _or_ the self-checking mechanism has to become defective. Many cancers have genetic defects in one or more of these command chains. Presumably it is also possible for an error to develop in the signalling system between the self-destruct gene and the lysosome - the dead man's handle is released but the grenade doesn't go off.

Another gene which codes for ras protein is part of the cell division mechanism. If it is defective the cell goes on dividing. Similarly other parts of the cell division command chain (growth hormone receptor, cytokines etc) can have errors. Some viruses (eg: Epstein-Barr in some circumstances) cause a proliferation of growth hormone receptor on the cell's surface which keeps the cell dividing. The more a cell divides, the more the chance of a mistake and therefore the higher the risk of a cancer developing.

Now the likelihood of being able to show that these specific genetic defects are going to be caused in humans from a bacterial model is laughable. A bacterium is a single-celled organism. It has no use for programmed cell-death!

The Ames test may have some value as an initial screening test, but only as long as its limitations are acknowledged. To rely entirely on it as definite proof that a compound is carcinogenic is not only laughable - it is also bad science!

The Medicinal HerbFAQ

5.5 Trying out the placebo effect

> It's really hard to judge whether the effects were the result of the ..herb.., or whether I just thought these effects were occurring because I was seeking for them to happen (constantly checking myself to see if I notice any change - a bit like the placebo effect I guess).

It's nice to see someone wondering whether they were subject to the placebo effect! Too many people seem to be a bit too convinced by their own personal experiences.

If you are concerned about a placebo effect you might want to try your own little experiment. Get some large empty gelatin capsules from a health food store. Put sugar in half of them and your ginkgo capsule (which should be small enough to fit) in the other (with sugar to fill up the rest of the space. Have a friend label some bottles with numbers (the more bottles your use, the more likely it will be that you aren't just guessing right). The numbers will correspond with whether the bottle contains the sugar or the ginkgo but only your friend will know which is which. Then have your friend put the capsules in the bottles. Complete one bottle and then go on to the next. Don't look at the capsules as you take them and be aware of any subtle ways that you might be discerning the difference (e.g. weight, aftertaste etc.) You might want to use a rating scale of your alertness. Be aware that if you choose the ginkgo, it might simply be a coincidence, so make sure that the difference in ratings is big.

The Medicinal HerbFAQ

5.6 How to find an herbalist / ND

I get a lot of emails saying, eg, "I have Hep C and my dad has Lupus and Crohn's, and my mon's hypothyroidal, what herbs can you recommend for that?" - I don't recommend herbs for that at all, I give a list of referral sites and addresses for alternative healthcare associations. Here it is, gathered over a couple of years:

Try the American Association of Naturopathic Physicians (AANP):

<http://www.naturopathic.org>

Or the American Herbalists Guild (AHG): <http://www.americanherbalistsguild.com>

Canadians can check the Canadian Naturopathic Association (NDA):

<http://www.naturopathicassoc.ca>

Then there's the Ontario Herbalists Association (OHA): <http://www.herbalists.on.ca>

Brits can look for member of the National Institute of Herbal Medicine (NIMH):

<http://www.nimh.org.uk>

Australians have the National Herbalists Association of Australia (NHAA):

<http://www.nhaa.org.au>

If you're in New Zealand check the New Zealand Association of Medical Herbalists (NZAMH):

<http://nzamh.org.nz>

If you still can't find a practitioner near you, you can try the bulletin boards at your local coop / health food store / vegetarian restaurant / other similar place.

The Medicinal HerbFAQ

5.7 Politics and herbal medicine

The growing awareness of herbs is nothing but growing competition to profitable product lines - at least if you're a pharmaceutical company. Which is why pharmacogiants do their very best to spread FUD (Fear Uncertainty Doubt) about herbs and herbal medicine.

A case in point: the German kava debacle, leading to its banning in many countries *without any published details on the adverse effect cases whatsoever*. In fact, these oh-so-dangerous adverse effects were mostly due to meds taken together with or even instead of kava, or due to pharmaceutical-type kava products (50+ % kavalactones, extracted with acetone? That's not a herb, that's a med!).

Adverse effects from kava, the herb, extracted at 1:2 in 95 % ethanol are very rare. In fact, I'd suggest the use of education (don't extract insanely high amounts of "active constituents", and don't use toxic solvents) and common sense (*stop* using kava if you get the telltale scaly skin) instead of legislation, to help clear up the rather few (and quite benign) adverse effects from kava, the herb.

Kava, *Piper methysticum*, is a direct competitor to Paxil and other anti-anxiety agents. It's cheap, can't be patented, and has next to no side effects. Oops.

Another case in point: headlines (and study conclusions) like "<herb> does not work" hide the fact that the med compared in the same trial was way below placebo, too:

<http://jama.ama-assn.org/cgi/content/abstract/287/14/1807> - a better headline would have been "<placebo> better than <herb> *and* <med>!" And this is but a single example of the multitude of skewed research headlines that have been shouted over the rooftops over the last 6 years - ever since St. John's wort made it big on 20/20, back in 1997. FUD. Fight it.

St. John's wort, *Hypericum perforatum*, is a direct competitor to Zoloft and other antidepressants. In addition it's cheap (or even free - pick your own!), can't be patented, and has next to no side effects. Oops.

How to know who's right and who's wrong, then? There's two types of medical journals, the biased ones and the unbiased ones. This is my take on two of the big ones - the ones that get quoted in headlines:

- if the BMJ publishes something on alternative healthcare it's unbiased unless proven biased.
- if JAMA publishes something on alternative healthcare it's biased against unless proven

unbiased.

I'm not saying there aren't quacks in herbal medicine - there are, foremost among them those that take advantage of the desperate (like selling essiac to terminal cancer patients at exorbitant rates) (those people are *despicable*), and the multitude of MLM'ers (multi level marketing biz people) (these people are just clueless and annoying). And don't let me get started on the supplement business ...

However, mainstream medicine and pharmaceutical companies aren't any angels either. Perhaps they believe in what they are doing to alternative healthcare in general and herbal medicine in particular, but that doesn't make them right.

So herbal medicine is under siege. And you generally see only the anti-herbal headlines, because the ones critical to meds and MDs are hidden away as well as they ever can be. How then do you find balancing information? Here's a few links. I hope they are as enlightening to you as they were to me:

- Oops - there goes unbiased medical research: <http://bmj.com/cgi/content/full/326/7400/1167>
- How to make new diseases for fun and profit. Nicholas Regush has collected some very interesting links on his page: http://www.redflagsweekly.com/special_edition.html . Among them these gems:
 - Drug companies and Female Sexual Dysfunction: <http://bmj.com/cgi/content/full/326/7379/45>
 - Ritalin and ADD/ADHD: http://www.house.gov/ed_workforce/hearings/106th/oi/ritalin92900/baughman.htm
 - Paxil and Social Anxiety Disorder (what used to be called shyness): <http://www.policyalternatives.ca/publications/articles/article315.html>
 - Paxil and Generalized Anxiety Disorder: <http://www.guardian.co.uk/Archive/Article/0,4273,4471963,00.html>
- A summary of the tactics pharmacogiants use to discredit herbal medicine: <http://www.rmhiherbal.org/review/2003-2.html>
- Too many doctors prescribe based on favors received from pharmaceutical companies: <http://bmj.com/cgi/content/full/326/7400/1189>
- You've heard of the quackwatch site. Here's something to put quackwatch into perspective: <http://www.quackpotwatch.org/opinionpieces/aaaaaaaa.htm>
- The morbidity and mortality site is downright scary, and *very* hard to find: <http://webmm.ahrq.gov>

The Medicinal HerbFAQ

6.1 Good Books on Herbs and Herbal Medicine

6.1 Good books on herbal medicine

- 6.1.1 [Good books to get started with](#)
- 6.1.2 [Specialty books: women's herbals, men's herbals etc.](#)
 - 6.1.2.1 [Going for broke \(and I wish you luck\)](#)
- 6.1.3 [In-depth books, by organ system](#)
- 6.1.4 [Chinese herbs, or TCM \(Traditional Chinese Medicine\)](#)

Please also check Jonno's Herbal Bookworm page: <http://www.herbological.com> .

And let me know if I've left out -your- favorite book. Be aware, however, that I won't even consider stinkers such as Tyler or Hutchens.

6.1.1 Good books to get started with

Real basics

- **Lesley Bremness: *The Complete Book of Herbs*** - a practical guide to growing and using herbs.
288 pages, paperback, 11.60 x 7.66". Penguin Studio, Sep 1994. ISBN 0140238026.
Listprice USD 22.
A good allround book for the beginner, it includes one-page articles on 100+ herbs, and a wide variety of uses for them (culinary and medicinal uses, cleaning, beauty, etc.). There's also a section on how to grow herbs. Lots of clear plant and how-to color pictures.
- **Richard Mabey: *The New Age Herbalist - How to use herbs for healing, nutrition, body care, and relaxation.***
288 pages, 9.71 x 7.69". Fireside, Nov 1988. ISBN 068481577X. Listprice USD 22.
A beginner's herbal, lots of pictures, not as practical as the others, but still worthwhile.
- **Andrew Chevallier: *The Encyclopedia of Medicinal Plants.***
336 pages, 11.25 x 9". DK Publishing, Dec 2000. ISBN 0789467836. Listprice USD 40.

Like all Dorling Kindersley books it's big on pictures, so it's good for beginners. This one contains one-page articles on 100 plants (lots of pictures for each of these) and very short paragraphs on 450 more (with pictures for about a third of them), in addition to the obligatory history and making remedies bits. If you're out where there's no herb stores you won't like it too much - there's far too many plants from TCM.

- **David Hoffmann: *The Holistic Herbal - A Safe and Practical Guide to Making and Using Herbal Remedies***
288 pages, 9.66 x 7.44". Thorsons Pub, 4th ed., Jan 2003. ISBN 0007145411. Listprice USD 17.
The 1996 edition had 256 pages, of which 200+ half-page articles on single herbs and a section on problems and herbal remedies by organ system. Also includes the usual how-tos - teas, ointments, lozenges, etc. Very visual.
- **John Lust: *The Herb Book*.**
700 pages, 6.84 x 4.2". Benedict Lust Publ., Jun 2001. ISBN 0879040556. Listprice USD 9.
Short notes on the medicinal use of a lot of herbs. Also tables you can look up things in. Some black-and-white plant drawings.
- **Susun Weed: *Healing Wise - Wise Woman Herbal*.**
312 pages, 8.44 x 5.52". Ash Tree Pub., Jul 1989. ISBN 0961462027, listprice USD 13.
In-depth information on seven very common herbs. Some black-and-white plant drawings.
- **Michael Tierra: *The Way of Herbs*.**
416 pages, 9.31 x 6.19". Pocket Books, Aug 1998. ISBN 0671023276, listprice USD 17.00.
A beginner's herbal. No pictures.
Michael Tierra is online at: <http://www.planetherbs.com/>
- **James Green: *The Herbal Medicine Maker's Handbook - A Home Manual*.**
384 pages, 10.62 x 8.48". Crossing Press, Dec 2000. ISBN 0895949903. Listprice 23 USD.
(I have his 40-page booklet on the theme, and find that the allround beginner's herbals cover the topic distinctly better. This almost 400 page treatise might cover ground not found elsewhere, though.)
- **Igor Vilevich Zevin: *A Russian Herbal*.**
250 pages, 8.97 x 6.06". Inner Traditions Intl Ltd., Feb 1997. ISBN 0892815493. listprice USD 15.
For a different view on how to use herbs (still beginner's level) get this book. Some black-and-white plant drawings.
- *No longer in print (my but time flies!):*
 - **Penelope Ody: *The Complete Medicinal Herbal*.**
192 pages, hardcover, 11.75 x 8". Dorling Kindersley Publishing, Jun 1993. ISBN 1-56458-187X. Listprice USD 30.
A good allround book for the beginner, with one-page articles on 120 plants, charts that tell you which herbs to use for which problems, and the obligatory history and making your own remedies bits. A very visual book.
 - **Penelope Ody: *Home Herbal* - a practical family guide to making herbal remedies for common ailments.**
144 pages, hardcover or paperback, 9.75 x 7.75". Dorling Kindersley Publishing, Jun

1995. ISBN 1564588637. listprice USD 20.

A short introduction to making your own herbal remedies, and the ailments to use them for. Lots of clear plant and how-to color pictures.

- **Christopher Hedley and Non Shaw: *Herbal Remedies - A beginner's guide to making effective remedies in the kitchen.***
96 pages, 12.25 x 9.5". Parragon Jan 1999. ISBN 075252416X. Listprice GBP 7 or so.

Very good recipes. It's down to earth and well-written, and you'll get to know (and probably expand) your spice rack in ways you didn't expect when you bought your spices. Lots of clear plant and how-to color pictures. I have both the original hardcover and a later smaller paperback; the content is identical.

Often mentioned, but perhaps not really worth it:

(If you feel I'm wrong in my assessment of these books let me know why you disagree - my email address is hetta@spamcop.net.fix (no fix)).

- **James A Duke: *The Green Pharmacy Herbal Handbook - Your Everyday Reference to the Best Herbs for Healing.***
352 pages, 6.74 x 4.16". St. Martin's Press, Jun 2002. ISBN 0312981511. Listprice USD 7. I have the 1997 edition of this. It's a book written by a researcher, not by a practitioner, and it shows in some of the herbal recommendations. Don't trust it, get one of the books written by a practitioner instead.
- **David Hoffmann: *Medical Herbalism - The Science and Practice of Herbal Medicine.***
672 pages, 10.9 x 8.68". Inner Traditions Intl Ltd., Aug 2003. ISBN 0892817496. Listprice USD 60.
I'm told (I don't have this book) that this is a reprint of the usual Hoffmann database with scientific research thrown in. If that is indeed the case it's not all that much use to the practising herbalist (scientific research on herbs being mostly theoretical), at least if you already have a couple of Hoffmann's works. Add to that that it's very expensive - well, it's not on my list of books to buy anytime soon. If you have this book, are a herbalist, see clients, *and* disagree with this assessment, let me know.
- **Varro Tyler.** Read Jonno's review of Tyler's "*Honest herbal*" and "*Herbs of choice*" to see why Tyler's writings aren't respected by professional herbalists:
<http://www.herbological.com/deconstructing.html> .
If you want a good scientific book on herbs try **Rudolf Fritz Weiss, MD, *Herbal Medicine*** (don't buy the "updated" version, stay with the original from 1988) (listed in entry [6.1.3](#), In-depth books, by organ system)
- ***The Complete German Commission E Monographs - Therapeutic Guide to Herbal Medicines***
This is a very expensive set of committee summaries (380 monographs, Listprice USD 189). Jonno has reviewed the monographs; find his comments here:
<http://www.herbological.com/understanding.html>
- **Simon Mills, Kerry Bone: *Principles and Practice of Phytotherapy - Modern Herbal Medicine.***

448 pages, 9.96 x 7.75". Churchill Livingstone, Nov 1999. ISBN 0443060169. Listprice USD 83.

I'm told this book constantly praises the use of 1:1 extracts as made by Kerry Bone's company MediHerb. If that's indeed the case it should be given away for free, not sold for rather too much money.

Whatever, you're probably distinctly better off buying Simon Mill's earlier work, "Out of the Earth" (also called "The Dictionary of Modern Herbalism"). And stay away from other books by Kerry Bone, unless he's writing with co-authors who have the guts to put their foote down about hidden marketing.

- **Volker Fintelmann, Rudolf Fritz Weiss: *Herbal Medicine - second edition, revised and expanded.***

448 pages, 9.25 x 6.75". Thieme Medical Publ, 2nd ed., Aug 2000. ISBN 0865779708. Listprice USD 59.

Stay FAR away from this rewrite.

Read Jonno's review if you want to know why: <http://www.herbological.com/weiss.html>

Field guides

- **Steven Foster, James A. Duke: *A Field Guide to Medicinal Plants and Herbs of Eastern and Central North America. (A Peterson guide).***

424 pages, 7.22 x 4.48". Houghton Mifflin Co, 2nd revised ed., Dec 1999. ISBN 0395988144, listprice USD 19.

I have the 1990 edition, and it really has very little in the way of text. It's possible that the 1999 edition is distinctly better.

- **Jim Pojar, Andrew MacKinnon: *Plants of the Pacific Northwest Coast.***

528 pages, 8.53 x 5.57". Lone Pine Publishing, Dec 1994. ISBN 1551050404. Listprice USD 20.

You'll find the most common plants of the PNW USA, including photos, drawings, maps, and short paragraphs on usage. It's an excellent field guide - we need more of this caliber. One peeve: botanical works should always mention *Genus species* auct.; there's no auct in this book.

Diving deeper

- **Michael Moore: *Medicinal Plants of the Mountain West.***

351 pages, 9.30 x 6.14". Museum of NM Press, Aug 2003. ISBN 0890134545. Listprice USD 25.

Michael has rewritten the 1979 *Mountain West* book; it's now in the same format, with the same depth of detail and with as many funnies as his extraordinary *Pacific West* book. Go buy it.

- **Michael Moore: *Medicinal Plants of the Pacific West.***

359 pages, 9.23 x 6.14". Red Crane Books, 1993. ISBN 1878610317, listprice USD 22.5.

The single best book on medicinal plants I have seen to date. Don't let the title throw you, it's got universal appeal. I use it, and I'm rather far away from the Pacific west.

- **Michael Moore: *Medicinal Plants of the Desert and Canyon West.***

200 pages, 8.48 x 5.48". Museum of NM Press, Apr 1990. ISBN 0890131821. Listprice USD 15.

A good book on the medicinal uses of some southwestern herbs.

Michael Moore's books on medicinal herbs are very good and fun to read, too. You're in for a treat if you haven't visited his homepage yet - he's got some good practitioner-level booklets online, free for downloading: <http://www.swsbm.com>

● **Michael Moore: *Los Remedios - Traditional Herbal Remedies of the Southwest.***

108 pages, 8.47 x 5.48". Red Crane Books, Oct. 1990. ISBN 1878610066. Listprice USD 10.

If you ever decide to do a book on traditional medicinal uses of your local flora, check this book to see how it's done. It's the only work in this genre (that I've seen) that includes a paragraph labelled "usefulness" with the usual traditional uses.

● **Matthew Wood: *The Book of Herbal Wisdom***

250 pages, 9.05 x 6.05". North Atlantic Books, Sep 1997. ISBN 1556432321, listprice USD 19.

Well worth the price, as Matthew Wood opens a rather different point of view on plants. His tales are sprinkled with personal experience and herbal wisdom. Very very good.

● **Gazmend Skenderi: *Herbal Vade Mecum - 800 Herbs, Spices, Essential Oils, Lipids, Etc. Constituents, Properties, Uses, and Caution.***

496 pages, 8.86 x 6". Herbacy Press, Jun 2003. ISBN 0971320926. Listprice USD 25 plus shipping. Available directly from the publisher: herbacy@aol.com . (better buy it there - Amazon wants USD 50 for it - plus shipping, too, of course.)

Uses are given, dosages aren't - you need to know your plants before you use this book. It's a very good materia medica for practitioners, focusing on the essential; beginners might not do all that much with it, except they'd get solid, practical, sensible cautions for the listed plants, instead of the usual overblown and overly theoretical ones. No pictures.

● **Janice Schofield: *Discovering Wild Plants - Alaska, Western Canada, The Northwest.***

355 pages, 10.9 x 8.45". Alaska Northwest Books, 1998. ISBN 0882403699. Listprice USD 40.

A delightful book, it includes information on a lot of plants found up here in Finland, too. Great pictures, lots of tried and true recipes, sensible medicinal uses - you need this book if you live up north.

● **Janice Schofield: *Alaska's Wild Plants.***

95 pages, 8.02 x 4.55". Alaska Northwest Books, 1995. ISBN 0882404334. Listprice USD 13.

Compared to her excellent *Discovering Wild Plants*: this one is a tenth (or less) of the scope and a third of the price. You makes your choice and you pays your price.

● **Thomas Bartram: *Bartram's Encyclopedia of Herbal Medicine - The Definitive Guide to the Herbal Treatments of Diseases.***

496 pages, 9.10 x 6.12". Marlowe & Company, Sep 2002. ISBN 1569245509. Listprice USD 18.

A lot, and I do mean a LOT, of short notes on herbs, supplements, and diseases, listed alphabetically. Very good as a repertory - a work which gives you treatment options for diverse ailments. No pictures.

- **Maud Grieve: *A Modern Herbal - Vol. 1, A-H, and Vol. 2, I-Z.***
443 + 476 pages, 2 x 9.17 x 6.49". Dover Publ. 1971 reprint of the 1931 original. ISBN 0486227987 (I), 0486227995 (II), listprice USD 13 each.
A fairly good materia medica, especially for its history value. It's online too, scanned and OCR'd in full by Ed Greenwood: <http://www.botanical.com/botanical/mgmh/mgmh.html>

Thorough but easy to understand descriptions of some plants and/or some organ systems

- **Janice Schofield: *Nettles.*** (A Keats good herb guide).
96 pages, 6.77 x 4.18". McGraw-Hill, Jan 1998. ISBN 087983840X, listprice USD 5.
Despite the small format you'll get real in-depth information about that nicest of plants, the stinging nettle. I can personally vouch for Henriette's Potato Mash, with nettles of course. Excellent work!
- **Michael Moore: *Herbs for the Urinary Tract.*** (A Keats good herb guide).
96 pages, 6.77 x 4.18". McGraw-Hill, Jan 1999. ISBN 0879838159, listprice USD 5.
A short but thorough introduction to the urinary tract and what gets it out of and back into kilter.
- **Aviva Romm: *ADHD Alternatives - A Natural Approach to Treating Attention Deficit Hyperactivity Disorder.***
128 pages, 8.49 x 5.54". Storey Books, Jul 2000. ISBN 1580172482. Listprice USD 13.
- **Christopher Hobbs: *Medicinal Mushrooms - An Exploration of Tradition, Healing & Culture.***
264 pages, 9.38 x 6.66". Book Pub Co, 2003. ISBN 1570671435, listprice 19 USD.
It's the book on medicinal mushrooms. Go get it, it's good.
- **Christopher Hobbs: *Natural Therapy for your Liver: Herbs and Other Natural Remedies for a Healthy Liver.*** 128 pages, 2002, ISBN1583331328, listprice USD 10.
- **Christopher Hobbs: *Vitex, the Women's Herb.*** 95 pages, 2003, ISBN 1570671575, listprice USD 8.
Accurate and balanced booklets.
He's online here: <http://christopherhobbs.com>
- **Steven Foster's botanical booklets.** Web site here: <http://www.stevenfoster.com>
- *No longer in print - a shame really:*
 - **Paul Bergner: *The Healing Power of Garlic***
304 pages, 8.25 x 5.50". Prima Publishing, Oct 1995. ISBN 0761500987, listprice USD 16.
 - **Paul Bergner: *The Healing Power of Ginseng and the Tonic Herbs***
288 pages, 8.75 x 5.25". Prima Publishing, May 1996. ISBN 0761504729. Listprice USD 15.
 - **Paul Bergner: *The Healing Power of Echinacea, Goldenseal and other Immune system herbs***
336 pages, 8.75 x 5.50". Prima Publishing, Feb 1997. ISBN 0761508090, listprice USD 15.
 - **Paul Bergner: *The Healing Power of Minerals, Special Nutrients, and Trace***

Elements.

320 pages, 8.50 x 5.75". Prima Publishing, Jul 1997. ISBN 0761510214, listprice USD 15.

These are very good in-depth books both about the herbs and the organ systems involved. Get them if you can.

Paul Bergner is the editor of Medical Herbalism (see the professional level journal list, [ch.6.3.2](#)). He has a website at <http://www.medherb.com>.

6.1.2 Specialty books: women's herbals, men's herbals etc.

Let's get gender-specific:

- **Rosemary Gladstar: *Herbal Healing for Women - simple home remedies for women of all ages.***
304 pages, 9.17 x 7.35". Fireside Books, Nov 1993. ISBN 0671767674, listprice USD 14.
A very good book on herbs and women's health - and at that price it's a steal.
Rosemary Gladstar's website is at <http://www.sagemountain.com>
- **Amanda McQuade Crawford: *Herbal Remedies for Women.***
304 pages, 9.23 x 7.41. Prima Health, 1997. ISBN 0761509801. Listprice USD 20.
A very good book on herbs and women's health.
- **Ruth Trickey: *Women, Hormones & The Menstrual Cycle - Herbal & Medical Solutions from Adolescence to Menopause.***
680 pages, 9.22 x 6.68". Allen & Unwin, 2nd ed., Apr 2004. ISBN 186508980X. Listprice USD 30.
A good book about the hormonal system and what gets it out of and back into balance.
Learn how to remedy, for instance, endometriosis, fibroids, or painful menses with diet, herbs and supplements.
My copy of this book (1st ed.) is misbound (parts are upside down and, obviously, back-to-front), and the publisher promised me a new copy over a year ago. Haven't seen it yet. Tut tut, *bad* publisher.
- **Amanda McQuade Crawford: *The Herbal Menopause Book.***
224 pages, 9.10 x 7.08". Crossing Press, Oct 1996. ISBN 0895947994, listprice USD 17.
Great notes on menopausal discomforts, and how to remedy them.
- **Susun Weed: *New Menopausal Years, the Wise Woman Way.***
304 pages, 8.42 x 5.52". Ash Tree Pub., rev. ed., Nov 2001. ISBN 1888123036. Listprice USD 13.
- **Susun Weed: *Wise Woman Herbal for the Childbearing Year.***
196 pages, 8.42 x 5.52". Ash Tree Pub., Jun 1985. ISBN 0961462000. Listprice USD 10.
- **Susun Weed: *Breast Cancer, Breast Health, the Wise Woman Way.***
380 pages, 8.42 x 5.52". Ash Tree Pub., Mar 1997. ISBN 0961462078. Listprice USD 15.
Susun has her own very wise way of looking at things. You buy one first, and then you go

out of your way to get the others when you or somebody close to you needs them.

Susun is online here: <http://www.susunweed.com>

- *No longer in print:*
 - **Anne McIntyre: *The Complete Women's Herbal*** - a manual of healing herbs and nutrition for personal well-being and family care
287 pages, 10 x 7.75". Henry Holt & Co., Jan 1995. ISBN 0805035370, listprice USD 25.
A very good book on herbs and women's health.
 - **James Green: *The Male Herbal*** - health care for men and boys
278 pages, 9 x 6". Crossing Press, Apr 1991. ISBN 0895944588, listprice USD 15.
The only book about herbs for men that I've seen so far.

Kids

- **Aviva Romm: *Naturally Healthy Babies and Children*** - a Commonsense Guide to Herbal Remedies, Nutrition, and Health.
2000, Storey Books, Pownal, Vermont, USA. ISBN 1-58017-285-7, listprice USD 17.
A good, practical, all-round book for parents.
- **Linda B. White, MD, and Sunny Mavor: *Kids, Herbs and Health*** - practical solutions for your child's health, from birth to puberty.
1998, Interweave Press, Loveland, CO, USA. ISBN 1-883010-53-5, listprice USD 22.
Another look at herbs for kids, this combines the conventional approach with the herbal one.

Pets

- **Mary L. Wulff-Tilford and Gregory L. Tilford: *Herbs for Pets***.
1999, BowTie Press, Irvine, CA, USA. ISBN 1-889540-64-1, list price USD 30.
A blockbuster of a book, this really is worth getting. It includes, among other things, 200 pages of herbal materia medica for pets with glorious pictures, and notes on diet for dogs and cats.

Cancer

There are three books on cancer and herbal medicine for the serious herbalist. These will help you understand the research. They also make it easy to see what's real and what's hype around herbs for cancer:

- **Donald Yance: *Herbal Medicine, Healing & Cancer***.
1999, Keats Publishing, Lincolnwood, Ill, USA. ISBN 0-87983-968-6, listprice USD 22.
- **John Boik: *Cancer & Natural Medicine - A Textbook of Basic Science and Clinical Research***.
1995, Oregon Medical Press, Princeton, Minnesota, US. ISBN 0-9648280-0-6.
- **John Boik: *Natural Compounds in Cancer Therapy***.
2001, Oregon Medical Press, Minnesota, USA, <http://www.ompress.com> . ISBN 0-9648280-1-4.

If you want to get some knowledge about TCM, but keep your western herbalist bias:

- **Steven Foster + Yue Chongxi: *Herbal Emissaries*** - bringing Chinese Herbs to the West.

1992, Healing Arts Press, Vermont, USA. ISBN 0-89281-349-0, listprice USD 17.
Very thorough description of Chinese plants (with growing instructions) for us Westerners.
(I LIKE books with more than 2 pages per plant. These guys use about 6 pages per...)

... or the other way around:

- **Michael Tierra: *Planetary Herbology - An Integration of Western Herbs into the Traditional Chinese and Ayurvedic Systems.***
Lotus Press, Santa Fe, NM, USA. ISBN 0-941524-27-2, listprice USD 18.

6.1.2.1 Going for broke (and I wish you luck)

There's a very good series of books on how to turn a herb enthusiast into a cottage industry: the bootstrap guides(at www.bootstraps.com). They're practical, down to earth, and they tell you not only what plants will sell but also what kind of American bureaucracies you need to look out for. They are:

- **Lee Sturdivant: *Profits from your backyard herb garden***
1995, San Juan Naturals, PO Box 642, Friday Harbor, WA 98250, USA. ISBN 0-9621635-3-8, listprice USD 11.
Starting with a smallish herb garden, this book tells you what you need to know in order to sell fresh herbs to local restaurants and markets.
- **Lee Sturdivant and Tim Blakley: *Medicinal Herbs in the Garden, Field and Marketplace***
1999, San Juan Naturals, PO Box 642, Friday Harbor, WA 98250, USA. ISBN 0-9621635-7-0, listprice USD 25.
The first half of the book gives a view into successful herb businesses, the second part tells you how to grow herbs for the bulk trade - machinery, techniques, hints and tips, and growing and picking specific plants. At the very end of the book you'll find contact information of some American tincture and tea makers, including what plants they need and how to approach them.
- **Lee Sturdivant: *Herbs for sale***
1994, San Juan Naturals, PO Box 642, Friday Harbor, WA 98250, USA. ISBN 0-9621635-2-X, listprice USD 15.
Interesting views into diverse successful herb businesses.

Not in the same series, this one comes from the other side of the world:

- **Greg Whitten: *Herbal Harvest***
Bloomings Books, The Stables, 21 Isabella Grove, Hawthorn Victoria, Australia 3122.
ISBN 1876473045.
(review by [Rosemary Jones](#);) Just got a copy from the publisher and it seems to answer most questions on the bulk processing of herbs for commercial use. How to build drying sheds and so on. The farming advice is geared towards Australia but could work elsewhere with some modification.
If you're in the US you can order it from Rosemary (healingpgs.aol.com or Healing Pages 1-800-561-2909) and save on freight. Or order it straight from the publisher.

6.1.3 In-depth books, by organ system

- **Simon Y. Mills:** *The Essential Book of Herbal Medicine*.
1993, Arkana, Penguin Books, London, UK. First published under the title "Out of the Earth", by Viking Arkana 1991. ISBN 014-019309X. Listprice GBP 15.00, USD 17.
Excellent in-depth information for the practitioner.
- **Daniel B. Mowrey:** *Herbal Tonic Therapies*.
1993, Keats Publishing Inc., New Canaan, Connecticut, USA. ISBN 0-87983-565-6, listprice USD 15.
Good information on the use of mild tonic herbs, organized by organ system.
- **David Hoffmann:** *The New Holistic Herbal*
1991 (3rd edition), Element Books Ltd, UK. ISBN 1-85230-193-7, listprice 17 USD.
- **David Hoffmann:** *An Elders' Herbal - Natural Techniques for Promoting Health and Vitality*
1993, Healing Arts Press, Vermont. ISBN 0-89281-396-2, listprice USD 18.
- **David Hoffmann:** *The Herbal Handbook: A user's guide to medical herbalism*.
1988, Healing Arts Press. ISBN 0-89281-782-8, listprice 15 USD.
I don't think it really matters which of David's books you get - they seem quite similar, one and all. So go for the newest, or the cheapest, or the prettiest cover picture - but don't go out and buy them all.
An online Materia Medica, by Hoffmann:
<http://www.healthy.net/clinic/therapy/herbal/herbic/herbs/index.html> . Therapeutics to go with that: <http://www.healthy.net/clinic/therapy/herbal/prevent/body/index.html> . - *The healthy.net site is spamming everybody and their uncle. Whatever you do, don't give them your email address; if you do, they'll spam you forever and ever.*
He's also made a good herbal CD-ROM. Review here: section [6.5.4](#).
- **Priest & Priest:** *Herbal Medication, A Clinical and Dispensary Handbook*.
1982, L.N.Fowler & Co. Ltd., Essex, UK. ISBN 01-85243-368-9.
Great notes for the herbal practitioner.

So you're a mainstream medical professional with an interest in herbs? Try these:

- **Rudolf Fritz Weiss, MD:** *Herbal Medicine*.
1988. AB Arcanum, Gothenburg, Sweden / Beaconsfield Publishers, Beaconsfield, UK. ISBN 0-906584-19-1. Expensive!
Translated from the sixth German edition of Lehrbuch der Phytotherapie. Written by one of -the- experts on herbal medicine in Germany, it's a gem for practising herbalists and MDs interested in herbs. Don't buy the "updated" version, stay with the original from 1988.
- **Francis Brinker:** *Herb Contraindications and Drug Interactions*. 2. edition.
1998. Eclectic Medical Publications. ISBN 1888483067, USD 19.95.
It's just what it says on the title, and it's written by a ND who works with herbs. What more can I say? Buy it.

- **Steven G. Ottariano:** *Medicinal Herbal Therapy*. 1999, Nicolin Fields Publishing, Portsmouth, NH, USA. ISBN 0-9637077-6-0, listprice USD 14.95
A pretty good summary for the MD or pharmacist who wants to know more about herbs.
-

6.1.4 Chinese herbs, or TCM (Traditional Chinese Medicine)

- **Dan Bensky, Andrew Amble, Ted Kaptchuk:** *Chinese Herbal Medicine Materia Medica*, 2nd. edition. 1993, Eastland Press, Inc., Seattle, WA. ISBN 0939616157.
The standard Materia Medica for western-trained TCM practitioners.
- **Dan Bensky, Andall Barolet:** *Chinese Herbal Medicine Formulas & Strategies*, 1st. edition. 1990, Eastland Press, Inc., Seattle, WA. ISBN 0939616106.
The companion Formulary.
- Roger Wicke: TCHS vol. 1, The Language and Patterns of Life, USD 55
- Roger Wicke: TCHS vol. 2, Herbs, Strategies and Case Studies, USD 55
These are the two major textbooks for the Rocky Mountain Herbal Institute's Chinese herbology course. Description, table of contents and brief excerpts at:
<http://www.rmhiherbal.org/a/c.publ.rmhi.html>
While Roger, in these books, tries to integrate western physiological understanding of TCM theory where possible, the major focus is on using Chinese herbs according to the traditional TCM clinical rules (any other way simply doesn't work as well, as verified by clinical studies in several countries).

> starting a course of acupuncture and Chinese herbology -- does anyone know any good books on this subject?

- From healingpgs.aol.com (HealingPgs):
Read **Ted Kaptchuk's** *The Web That Has No Weaver*. Most of the Seattle acupuncture schools use this as a first year text and it's a lovely, intelligent explanation of the basics of TCM. The herb book that is most popular with our local acupuncturists is **Dagmar Ehling's** *Chinese Herbalist Handbook*. It's laid out in a very user-friendly fashion. The big herbal reference works for most Western trained acupuncturists are the Eastland Press books by Dan Bensky -- they are probably available through your school bookstore.

The Medicinal HerbFAQ

6.2 Good Books for further studies

So now you feel you've read enough books, but you're still glassy-eyed from reading the 'constituents' -part of the books (or the various ailment descriptions) - time to go shopping for some (literally) (pun intended) heavier stuff:

If you're a practising herbalist:

- Harvey Wickes Felter, John Uri Lloyd: *King's American Dispensatory*, in two volumes. 1898, 18th edition, 3rd revision. Reprinted 1993, Eclectic Medical Publications, OR, USA. Phone 1-800-332-4372. No ISBN number.

<http://www.eclecticherb.com/emp/historicalresearch.html> Listprice USD 285.

This one lists everything they knew about plants (and chemicals used in medicine) back then, and does it exhaustively. It is REALLY good.

It's online here: <http://ibiblio.org/herbmed/eclectic/kings/intro.html> - that's *all* plant-related entries.

If you're a pharmacognosist or pharmacist with an interest in herbs:

- **Norman Grainger Bisset (Ed.):** *Herbal Drugs and Phytopharmaceuticals, A Handbook for Practice on a Scientific Basis.*

Translation of Max Wichtl (Ed.): Teedrogen (see next entry).

1994, CRC Press. Very expensive.

This book has 181 monographs on European herbs with descriptions and photographs of the herbs, with lists of constituents, indications, side-effects, delivery system, method for authenticating the herb (usually a TLC), and the quantitative standards of the European pharmacopoeias where it is listed as official. Although it does not explain mode of action, this is a technical, and scientific book of excellent quality and a must for serious herbal students. It is also expensive as are all CRC books. (kathjokl.aol.com)

- Max Wichtl (Hrsg.): *Teedrogen, ein Handbuch fuer die Praxis auf wissenschaftlicher Grundlage. 2., erweiterte, ueberarbeitete Auflage*

1989, Wissensch.VG., Stuttgart, Germany. ISBN 3-8047-1009-3, listprice DEM 198.

It's expensive in the original, too, but still a good reference for pharmacognosists and pharmacists.

- **Trease + Evans:** *Pharmacognosy*, 13th edition.
1989, Bailliere Tindall, London.

There is a great deal of chemistry involved in this book but again it is an excellent reference if this is the type of information you want. (kathjokl.aol.com)

Then you might want:

- A basic chemistry textbook.
- A good biochemistry textbook.
- A good anatomy/physiology textbook (good to put you to sleep, too).
- The Anatomy Coloring Book.
- The Physiology Coloring Book.
- The latest Merck Manual, which lists main illnesses plaguing mankind - not for us hypochondriacs. You might need a Medicinese - English dictionary to understand it. The Merck Manual (17th edition) is now on the web:

<http://www.merck.com/pubs/mmanual/sections.htm>

The Medicinal HerbFAQ

6.3 Good Periodicals

Also check FTP <ftp://ftp.ibiblio.org>

[/pub/academic/medicine/alternative-healthcare/herbal-references/literature/herb-journals](#) .

Robyn has a list of journals on her page, too: www.rreading.com

You'll find a list of alternative healthcare journals (only one on herbs) here:

<http://www.healthwwweb.com/journals.html>

6.3.1 For enthusiasts (emphasis on color pictures)

- The Herb Companion
The Herb Companion, KS, USA. <http://www.herbcompanion.com>
Bimonthly, USD 20/year or USD 39/2 years (foreign USD 30/year or USD 59/2 years).
Mainly herb gardening and culinary uses of herbs.
- HerbalGram (Journal of the American Botanical Council and the Herb Research Foundation)
American Botanical Council, TX, USA <http://www.herbalgram.org>
Quarterly, USD 50/yr. (Foreign USD 70/yr).
Technical and scientific, ethnobotany, latest medical research.
Do check Jonathan Treasure's in-depth reviews of Tyler's books and the Comm. E. monographs before you let this journal talk you into buying them:
<http://www.herbological.com/>
- Herbs for Health.
Herbs for Health, KS, USA. <http://www.herbsforhealth.com>
Bimonthly, USD 20/year or USD 39/2 years (foreign USD 30/year or USD 59/2 years).
- The American Herb Association Quarterly Newsletter
American Herb Association, CA, USA. <http://www.ahaherb.com>
Subscriptions: USD 35/supporting, USD 20/regular membership per year.
- North East Herb Association Newsletter.
email: [northeastherbal . hotmail.com](mailto:northeastherbal@hotmail.com)

Subscriptions: USD 30-USD 100/yr depending on what you can afford.

- The United Plant Savers newsletter
United Plant Savers, VT, USA. <http://unitedplantsavers.org>
USD 35 - USD 100 sliding scale.
 - The Herb Quarterly
San Anselmo, CA, USA. <http://www.herbquarterly.com/>
Quarterly, ISSN 0163-9900, USD 19.95/year (internet price). (Canada and Mexico add USD 5, other foreign add USD 7).
 - Herbs at Home Magazine,
Ontario, Canada. <http://www.herbsathomemagazine.com/> - (link dead 12Apr04, perhaps the whole mag is gone? -Henriette)
Quarterly, USD/CAD 15/year, USD/CAD 27/2 years.
-

6.3.2 For professional herbalists (emphasis on case studies)

These lead the field:

- Medical Herbalism
Bergner Communications, Boulder, CO, USA. <http://www.medherb.com> - back issues available as single issues, as a bound volume, by online subscription, or on CD.
Subscription by year; 4 issues per; USD 36 (US), 39 (Canada), 45 (overseas). Credit cards accepted.
- The European Journal of Herbal Medicine.
National Institute of Medical Herbalists (NIMH), Exeter, UK, Europe.
Their website <http://www.ejhm.co.uk/> includes full articles of issues 1-3, and TOC of later issues.
Subscription by volume; 3 issues per; GBP 19.50 (UK), 24.50 (EC), 29.50 (overseas). They don't take Visa, but check or money-order is OK.
- Journal of the American Herbalists Guild
<http://www.americanherbalistsguild.com/>
Subscription by year; 2 issues per; USD 45 (US), 60 (foreign).
- The Modern Phytotherapist.
MediHerb Pty Ltd., Qld., Australia. <http://www.mediherb.com.au/>
Subscription by year; 2-3 issues per; AUD 33 (straya), 40 (overseas).
- Australian Journal of Medical Herbalism
National Herbalists Association of Australia (NHAA), NSW, Australia.
<http://www.nhaa.org.au>
Subscription by year; 4 issues per; AUD 220 (full members (practitioners)) + AUD 30 joining fee; AUD 55 (students) + AUD 10 joining fee; AUD 110.50 (supporting members) + AUD 20 joining fee. Overseas + AUD 15 (rates per 0700)

- The British Journal of Phytotherapy - sorry, no info - I'll add an URL if and when they get around to getting one.

This one I don't know:

- The Canadian Journal of Herbalism
Ontario Herbalists Association, Ontario, Canada. <http://www.herbalists.on.ca/journal/>
Subscription CAD 40.00; I don't know how many issues a year or a volume.

Auf Deutsch:

- Zeitschrift der Phytotherapie
Stuttgart, Germany. <http://www.phytotherapy.org/presse/zeitschr.htm> - einige Volltext Artikel, a few full-text articles even in English. The publisher's page is here: <http://www.thieme.de/phyto/index.html>
Not really worth it; unless you're interested in phytotherapy as opposed to herbal therapy, ie. scientific studies as opposed to hands-on experience.
6 issues per year, EUR 62 + Versandkosten.

These are secondary in importance to the practitioner:

- The Protocol Journal of Botanical Medicine - this journal is no more. Do buy used journals, if you can find them.
- The Eclectic Medical Journals
P.O. Box 936, Sandy, OR 97055 USA.
Subscriptions: USD 84/yr for 6 issues.
Comment stolen from an article by Jonathan Treasure: '... the articles in The Eclectic Medical Journals, while giving a useful insight into the grass-roots of the Eclectic movement, hardly justify their annual cost of USD 84 subscription to the average practitioner.'

6.3.3 For universities (emphasis on scientific studies)

- Planta Medica http://www.thieme.de/plantamedica/fr_inhalt.html
- Fitoterapia http://www.indena.com/fitoterapia_profile.asp and http://www.elsevier.com/wps/find/journaldescription.cws_home/620051/description
- Economic Botany <http://www.econbot.org/home.html>

And any other journals which consistently pop up when you do a medline or napralert search (see next section). They should be available at your local university. Subscription rates for these journals run into hundreds, if not thousands of dollars a year, so they are rather out of reach for people, institutions and companies without a sizeable literature budget.

The Medicinal HerbFAQ

6.4 Online commercial databases

6.4.1 Napralert

There's an introduction to NAPRALERT on this www page:

<http://info.cas.org/ONLINE/DBSS/napralertss.html>

Mary Lou Quinn, Managing Director, NAPRALERT, states the difference between Medline and Napralert as follows:

"NAPRALERT is and always has been restricted to world literature regarding natural products. Medline is not restricted. Just as one example, if you query NAPRALERT on the key word AMYGDALIN, you will get only that literature pertaining to the compound AMYGDALIN (otherwise known as LAETRILE).

If you query Medline, not only will you get the above, but you will also get lots of articles dealing with the Amygdala of the brain, anatomy, physiology, etc. It has never been NAPRALERT'S goal to be all inclusive regarding medical science. However, if you want the most comprehensive database on Medicinal plants and Natural products, then NAPRALERT is the way to go."

Quoted from the NAPRALERT information package:

"Napralert (NATURAL PRoducts ALERT) is a relational database of world literature on the chemical constituents and pharmacology of plant, microbial and animal (primarily marine) extracts.

It's housed and maintained by the Program for Collaborative Research in the Pharmaceutical Sciences, within the Department of Medicinal Chemistry and Pharmacognosy, in the College of Pharmacy of the University of Illinois at Chicago, 833 South Wood Street (M/C 877), Chicago, IL 60612, U.S.A.

Phone (312)-996-2246, Fax (312)-996-7107."

And here is what it'll cost you:

You can access Napralert by paying bulk rate (subscribing) or by paying per question. Annual

subscription fee for individual user with no ties to government agencies, small or large businesses, research institutes or libraries: USD 100, of which half gets you manuals, a user ID/password, and limited disk storage space, and the other half gets you answers (at USD 0.75 per reference obtained).

Per question rate: USD 25 + USD 0.75 per reference obtained.

Off-line (snailmail rate): USD 25 + USD 0.75 per reference obtained.

NAPRALERT is also available on-line through STN in the US, Europe and Asia.

6.4.2 Medline

You can get free Medline access here http://www4.infotrieve.com/newmedline/adv_search.asp or here: <http://www.ncbi.nlm.nih.gov/PubMed/>

One has the niftier search engine, while the other will tell you right away if it was 'in vitro' or 'in vivo'. (Why is that important? Section [5.1.8](#) in this FAQ has a nice introduction to the ins and outs of herbal research.)

There is, of course, a caveat with depending on a (a bit skewed) database like Medline: you won't get much outside of the 'white' world; you won't get much outside of English language, you won't get much of the multitude of (occasionally very useful) far-out research. And it helps to add a keyword like 'herb' or 'plant' to your search. Medline is not made for herbalists, it's made for MDs. Live with it, but learn where to get hands-on information, as well. Like the practitioner-level journals I mention in the 'Good Periodicals' -part of this FAQ (section [6.3.2](#)).

Comment by Mark D. Gold (mgold.holisticmed.com):

"I find it (Medline) a very useful tool. But it is important to realize that there are several articles which warn about the "dangers" of herbs (particularly in JAMA) which are little more than inaccurate hatchet jobs."

6.4.3 Ingenta

Another commercial database of scientific journals; it's Carl Uncover in new clothes (well, they merged). Good selection of herbal articles. Enable javascript for the search engine.

<http://www.ingenta.com>

6.4.4 IBIDS

IBIDS is a database where you can search for scientific articles on herbs and supplement. From the NIH (National Institute of Health), Office of Dietary Supplements:

<http://www.nal.usda.gov/fnic/IBIDS/index.html>

The Medicinal HerbFAQ

6.5 Herb programs

6.5.1 Demo or shareware herb programs

In my www space (here: <http://www.ibiblio.org/herbmed/programs/>) and my FTP space (FTP to ibiblio.org, cd to </pub/academic/medicine/alternative-healthcare/herbal-medicine/programs/>) you'll find olde DOS programs, made before even Win3.1 really took off (Herb power, v.2.1; Herb Power, v.3.0; Dr. Weed's E-herbal guide v. 3.0; Healing power of herbs, v.2.0; The Herbal Browser, v.1.0; Herbage, v.1.0; Health, v.5.2). They're all shareware or demoversions which have bigger brothers you can buy. Now, five to six years later (06Jun01), they're really pathetic.

For more recent herbal programs try a search for 'herb', 'plant' or 'botanical' on one of the larger shareware sites, like <http://www.shareware.com/>, <http://itprodownloads.com/>, <http://www.winsite.com/search/> or <http://www.download.com/>

A few links to get you started:

Get the demo of HerbBase, an empty database structure ready for you to fill up:
<http://www.DynamicArray.com.au>

Zentrum Publishing has a few programs, here:
http://www.self-realization.com/alternative_medicine_software.htm (Wellness, v.1.84, Naturheilkunde, v.1.8, Herbs v.1.2, Side Effects v.1.0).

Vitamaster, v.?, is found here: <http://www.vita-master.com/software.html>

6.5.1 Commercial Herbprograms

From Paul Bergner <bergner.concentric.net> 29Jun96:

- Christopher Hobbs' **Herbal Prescriber**. Info: Botanica Press, 10226 Empire Grade, Santa Cruz, CA 95060 (408) 457 9095
- It comes on 5 diskettes, for Windows 3.1 only. About 36.95 USD.
It's the best software yet on medical herbalism. It's thorough, clinically based, and inexpensive. It has therapeutic information from the Eclectic works, and also from German texts that have not been translated into English.

Comment from Henriette: the information certainly is reliable. However, the interface isn't all that good - there is no 'automatic' closing of the current window, so if you want to look at something else, and neglect to click the various 'ok' buttons, you get a 'beep' and nothing else. Frustrating.

CD-ROMs:

- **The Herbalist**, ver.2.0, by David L. Hoffmann, CD-Rom database, listprice USD 54.95, DOS, Windows31, Mac.
Available from Hopkins Technology, 421 Hazel Lane, Hopkins, MN 55343-7116. Phone 612-931-9376 or 800-397-9211.
More info found at <http://www.hoptechno.com/herbmm.htm>.
"The Herbalist" was made before crosslinking really took off, but it has a nice index/search engine. It gives you fast access to thorough plant / ailment information. As a bonus there's pronounciations of some plant Latin - the British way. *HeK evaluation: Excellent*.
This is the best herbal therapeutics program on the market.
- **Traditional Chinese Medicine & Pharmacology**. Hopkins Technology (as above).
Listprice USD 54.95.
More info found at <http://www.hoptechno.com/cherbal.htm>.
Well worth the price, if you do have some basic knowledge about Traditional Chinese Medicine. I can't say how good it is if you really know your Chinese herbs, but for my knowledge of TCM (basic) it's perfect.
- **The Herbal Pharmacy**, ver. 1.2, with Brigitte Mars; CD-Rom database, listprice USD 43, Win95. (*no longer offered on brigitemars.com - 22Dec03*)
Available from Hale Enterprises, 2507 North Broadway, Boulder, Colorado 80304. Phone (303)-938-0840, fax (303) 938-0839.
More info found at <http://www.brigitemars.com>
"The Herbal Pharmacy" consists of a Materia medica (300 herbs) and a Formulary (100 formulas). It is extensively crosslinked, well organized, and includes a score of ways to search for information. There's goodies all over the program: for example, if you add your own notes these will be crosslinked, too. The information is quite reliable - Brigitte Mars has been a practitioner for 16 years. *HeK evaluation: Excellent*.
This is the best herbal materia medica / formulary program on the market.
- **The Interactive Herbal**, with Dr. Terri Willard; CD-Rom database, published by The Follgard Group Inc. The CD is available on the web at <http://www.cdromshop.com/cdshop/desc/p.779810113001.html>
At first glance "The Interactive Herbal" is a nicely done CD-Rom, with some multimedia

and a medium-sized database. However, a closer look is disappointing:

- The "Formulas" section (54 so-called formulas) is severely lacking (there are no amounts given), and not too homogenous (one aromatherapy entry, three homeopathy, 8 TCM, 9 vitamin/nutrient...). *HeK evaluation: Don't bother.*
- The "Diet" section (57 regimens) compounds the frustration by telling you to use these formulas, in almost every single diet regimen. How -can- you, if you cannot make them? It made me wonder who the CD was made for, and what the purpose of it really is - to sell preparations? *HeK evaluation: Don't bother.*
- The "Herb" section gives details on 141 herbs, including herbs both from the western tradition and from TCM; here you'll even find some working formulas. *HeK evaluation: So-so.*
- The "Ailment" section gives thumbnail sketches of 124 ailments or disorders, outlines therapeutic approaches, and recommends herbs, vitamins/nutrients, and formulas. This is the most useful part of the CD. *HeK evaluation: So-so.*

There is no search capability at all. Also, the index of herbs is by common name only, and if you cannot guess that you're out of luck.

The Interactive Herbal needs -extensive- changes before it's as good as its introduction screen promises.

- The **Herbal Remedies** CD-ROM, v.2.1, published by PhytoPharm Consulting GmbH. A German CD-ROM, seen from a phytopharmaceutical viewpoint. USD 99 / DEM 149. The database is divided into two main parts:
 - a Materia medica (which lists, in addition to basic plant information, latin name synonyms -and- variations - quite smart, that.). *HeK evaluation: Good.*
 - a drug information sheet - instead of "Aesculus hippocastanum" we get "Hippocastani semen", with preparations, constituents, and indications. *HeK evaluation: Good.*

In addition to above, the "indications" search page needs mentioning. This contains five alphabetical lists of ailments, with links to above drug sheets. If you wish to see what "BfArM", "ICD10", "Homeopathic", "Asian" or "Other" (no "all" possible, sorry) recommends for, say, "migraine", you'll get a choice of drug information sheets for each. I have not been able to find an explanation for the terms "BfArM" or "ICD10" in the database. If you, once you've selected a drug sheet, click on ICD10, you'll be baffled with further unexplained remarks, like "170", or "N 41". These need to be explained somewhere as they are not self-evident (unless you're a German physician?).

MD's and ND's take note - this one is for you.

- **IBIS 99**, CD-ROM, published by Integral Medicinal Arts Group Inc. (IMA). A program for the practitioner, it's divided into four major parts:
 - Therapeutics - subdivided by modality; among others diagnosis, herbs, nutrition, TCM (herbs and needles), and homeopathics. *HeK evaluation: Excellent.*
 - Materia Medica - the same subdivision as for Therapeutics. In addition to the expected information sheets there's also patient handouts. The herbal information is a weird concoction - some (of the about 300) entries have nothing but the name, others have name, dosage, and cautions, still others have full

information including what to use it for, which part to use, how much of it, etc. If you still need to look up herbs this one won't help too much - except on the interactions, cautions and contraindications side. *HeK evaluation: So-so.*

I can't say how good the TCM, homeopathy or flower remedy parts of the Materia medica are; they're not in my area of expertise.

- Notes - the same subdivision as for Therapeutics. Enter your own notes here; it's easiest to import information from .html files as the editing functions are quite modest. *HeK evaluation: So-so.*
- Patients - keep your patients' visits straight. *HeK evaluation: Excellent.*

Do remember to make backups of the files the program generates for you when you add things to the notes or to the patient info. Otherwise a fatal disk crash (not generated by IBIS - that's a very stable program; but I use Win98...) might mean that you have to re-enter everything from scratch.

All in, I think this is a pretty good package for the practitioner - at least, if you're a herbalist and already know your herbs. At the current price of USD 200 (previously USD 700) it's now affordable. (USD 700 for clinics (3+ workstations); USD 150 for students.)

More info here: <http://www.ibismedical.com/>

- **Interactions 1.01**, CD-ROM, published by Integral Medicinal Arts Group Inc. (IMA). Besides containing good in-depth information about the interactions of some 3-400 drugs, a respectable amount of nutrients, and about 20 of the most talked about herbs, it also includes a short section on herbal pharmacodynamics. *HeK evaluation: Pretty good.* A pretty good package for the price (USD 100). More info here: <http://www.ibismedical.com/>

- **Medical Herbalism Resource Disc**, CD-ROM.

Paul Bergner's excellent journal Medical Herbalism is now available on a CD-ROM, as .html and .pdf -files. Both contain the complete set of back issues. While the links in the html part aren't always correct (the files are there, but the links don't always point to them), the pdf files work very nicely indeed. *HeK evaluation: Pretty good.* Price USD 59.

Considering that the back issues on paper are priced at USD 99/149, and that the information in this format is searchable and well indexed, it's a bargain.

Also included on this CD-ROM, in the same .pdf and .html formats, are King's American Dispensatory (from my site, here: <http://www.ibiblio.org/herbmed/eclectic/kings/intro.html> (used with my permission)) and William Cook's Physiomedical Dispensatory (available on the Medical Herbalism site, see below).

More info here: <http://www.medherb.com/MHHOME.SHTML>

The Medicinal HerbFAQ

6.6 Other online information sources

Among the goodies you'll find herbal mailing list and newsgroup archives, Michael Moore's files, and some nice WWW pages.

6.6.1 FTP sites with info on medicinal herbs: ibiblio herb archives

Try this: <ftp://ibiblio.org/pub/academic/medicine/alternative-healthcare/herbal-medicine/> or <ftp://sunSITE.sut.ac.jp/pub/academic/medicine/alternative-healthcare/herbal-medicine/>.

More here: ftp://ibiblio.org/pub/academic/agriculture/sustainable_agriculture/gardening/ or here: ftp://sunsite.sut.ac.jp/pub/academic/agriculture/sustainable_agriculture/gardening/.

Still more: ftp://ibiblio.org/pub/academic/agriculture/sustainable_agriculture/gardening/gardening-faqs/ or ftp://sunsite.sut.ac.jp/pub/academic/agriculture/sustainable_agriculture/gardening/gardening-faqs/

And you'll find a wealth of herbal information here - unfortunately not very well organized, but if you do have the time to browse you'll find it is a treasuretrove: <ftp://ibiblio.org/pub/academic/medicine/alternative-healthcare/herbal-references/> or <ftp://sunSITE.sut.ac.jp/pub/academic/medicine/alternative-healthcare/herbal-references/>

6.6.2 Interesting WWW pages

I'll only list the most important herbal WWW pages here. You'll find the rest of the good sites from links on Howie's and my pages. And you should use a search engine to look for information on specific plants.

- Michael Moore's homepage: <http://www.swsbm.com> , the Southwest School of Botanical Medicine.

Have a good look at all the goodies; if you are not a beginner, get the big textfiles - Herbal Materia Medica, Herbal Repertory, Herbal/Medical Dictionary, Herbal-Medical Contraindications, Specific Indications, Herbal Tinctures, Herbal Energetics, Plant Folders, Classic Texts, and anything else that might have been added. There's also a -lot- of pictures on site.

Do download the Herbal Energetics - these are summaries of how to prepare and use plants you already know in ways you already know (even though you didn't necessarily know that you can use THAT plant in THIS way before reading the booklet).

- Howie Brounstein's homepage: <http://www.teleport.com/~howieb/howie.html>
Columbine and Wizardry Herbs, wildcrafting school and herb catalog.
Go get a laugh at the Fad herbs, or read up on smoking herbs, or mugwort. Have fun.
- Jonathan Treasure's Herbal Bookworm page: <http://www.herbological.com>
All you need to know about herb books: excellent in-depth reviews, a list of must-read books, a list of stinkers, and a Reality Check.
- The Health World Online site. - *The healthy.net site is spamming everybody and their uncle. Don't go there, and whatever you do, don't email them using a real account; if you do, they'll spam you forever and ever amen.*
- Henriette's Herbal Homepage: <http://www.ibiblio.org/herbmed>
Home of the herbfacts (you're reading part of one right now), you'll also find plant pictures, classic texts, plant names in several languages, archives, links - it's an extensive site.
(Me? Biased? Naah.)

 - 6.7.9 [Smoking herbs document pointer](#)
 - 6.7.10 [Pointer to herbal-medical glossary](#)
 - 6.7.11 [Menopausal discomforts](#)
-

6.7.1 Plants by Mail FAQ pointer

Here you'll find lots and lots of catalogs to get living plants, and some seeds, too:
<http://gardenwatchdog.com>

6.7.2 Carpal Tunnel Syndrome WWW page pointer

Take a look at the Carpal Tunnel Syndrome Home Page at <http://www.ctsplace.com/> and specifically, at <http://www.ctsplace.com/preventative.php>

6.7.3 Hint for Kombucha posters

Please subscribe to the Kombucha list (see [8.1.4](#)). Do not post on alt.folklore.herbs about Kombucha.

You could go visit the Kombucha Homepage, which should answer anyone's questions about the subject: <http://w3.trib.com/~kombu/>

6.7.4 Hint for Essiac posters

You can find a wealth of info on Essiac at this web location: <http://essiac-info.org/>

6.7.5 Thinking of growing herbs for sale?

Visit this site first: <http://www.hort.purdue.edu/newcrop/>

It's the Gateway to the NewCrop Resource Online Program at the Indiana Center for New Crops and Plant Products at Purdue University; it has lots of information about different plants.

Next go for Richters' FAQ pages: <http://www.richters.com/QandA.html>

Then go get the 'herb-growing.faq' at metalab (see [6.6](#)).

6.7.6 Saw Palmetto and Prostate Problems: Newsgroup/FAQ pointer

Try news:alt.support.prostate.prostatitis, where they also have an excellent FAQ posted periodically.

6.7.7 Natural High FAQ pointer

The hyperreal archive is gone - try the erowid vault:

http://www.erowid.org/psychoactives/faqs/natural_highs_faq.shtml

6.7.8 Natural vision FAQ pointer

This interesting document can be found here: <http://www.cia.com.au/vic/faq.html>

6.7.9 Smoking herbs document pointer

THE document on herbal smokes, which also tells you how to stop smoking, is Howie Brounstein's Herbal Smoking Mixtures -booklet. You'll find it here:

<http://www.teleport.com/~howieb/howie.html> .

6.7.10 Pointer to herbal-medical glossary

I got email 'yes but what does MAO inhibitor and adrenergics and cholinergics mean?' ... so here's a pointer to Michael Moore's medicines - English dictionary:

<http://www.swsbm.com/ManualsMM/MedHerbGloss2.txt>

you get there from Michael Moore's Clinical Herb Manuals page:

<http://www.swsbm.com/ManualsMM/MansMM.html>

6.7.11 Menopausal discomforts

A very good place to start is the alt.support.menopause newsgroup. Next, check this page:

<http://www.geocities.com/menobeyond/> . Also see the entry on [wild yam, 2.12](#)

[Home](#) - [Herb FAQs](#) - [Articles](#) - [Classic texts](#) - [Archives](#) - [Links I like](#) - [Pictures](#) - [Plant names](#)

The Medicinal HerbFAQ

8.1 Mailing lists

Mailing lists have a distinct advantage over the online WWW chat pages: you don't have to be online. Just pull down your email from the server, and read and reply at leisure. It's lots cheaper for those of us who pay phone and/or ISP by the minute (this includes most Europeans).

In addition the lists mentioned below there's [Herbal Hall](#), a low-volume, high-quality list for professional herbalists, but that's by invitation only.

Any other lists you think should be here? Any changes in the lists listed?

You can try a search on "herb" on these list listers: <http://groups.yahoo.com/> , <http://www.topica.com> , <http://www.tile.net> and <http://www.lsoft.com> .

8.1.1 The Herblist

(Alive and well. Oct03)

A high-volume list for discussions about herbal medicine and medicinal herbs.

To subscribe: go to the mailman site: <http://lists.ibiblio.org/mailman/listinfo/herb> or write to herb-request@lists.ibiblio.org with only the following text:
subscribe

Be sure to read the Rules before posting: <http://ibiblio.org/herbmed/archives/herblist/rules.html>
Archives found here: <http://www.ibiblio.org/herbmed/archives.html>

8.1.2 The Aromatherapy List

(Alive and well. Mar02)

To subscribe, write to list@idma.com with the following text: join aromatherapy

The problem with this list, as per several emails in December 00 from former aromatherapy listmembers, is that it's become extremely chatty, with next to no aromatherapy posts. If that changes I'd appreciate an update.

Two less contentious and slightly slower lists with aromatherapy:

The Essentials List:

to subscribe: write to essentials@naturesgift.com with just SUBSCRIBE in the subject line, and no text.

8.1.3 The Kombucha List

(Alive and well. Dec00)

To subscribe: write to kombucha-subscribe@topica.com

Website here: <http://lists.topica.com/lists/kombucha/> and here: <http://w3.trib.com/~kombu/>

Pretty good for newbies but mostly the same stuff over and over and over. Good FAQ.

8.1.4 The Paracelsus List

(Alive and well. Oct03)

Subscription is limited to practitioners, educators, researchers and students in alternative and conventional medical fields.

To subscribe: visit this site: <http://lists.ibiblio.org/mailman/listinfo/paracelsus> and follow the instructions, or write to paracelsus-request@lists.ibiblio.org with the following text: subscribe

As part of the subscription approval process, send a biographical note indicating training, practice and interests to the list at paracelsus@lists.ibiblio.org.

8.1.5 The Homeopathy List

(Alive and well. High volume, no chat. Dec00)

To subscribe: write to homeopathy-request@lyghtforce.com with the subject: subscribe

The archives for this list and a FAQ on homeopathy are kept on

<http://www.homeopathyhome.com/web/descriptions/homlist.shtml>

8.1.7 The Culinary Herblist

(Briefly alive in season. Oct03)

This is the list for the gardening and use of culinary herbs:

To subscribe: write to: Majordomo@oregonvos.net with the text: subscribe herbs-l

Archives found here: <http://www.ibiblio.org/herbmed/archives.html>

8.1.9 The Wellpet List

(Alive and well. Dec00)

A list for a holistic approach to animal health.

To subscribe: write to: majordomo@imagicomm.com with the text: sub wellpet

Webpage: <http://www.listservice.net/wellpet/>

8.1.10 The Holisticat List

(Alive and well. Chatty. Oct03).

A chatty list for the use of nutrition, herbs, homeopathy, acupuncture etc. as it relates to cats.

To subscribe: write to: majordomo@vlists.net with the text: subscribe holisticat

OR the text: subscribe holisticat-digest

The list FAQs, archived old posts, articles etc. are available here: <http://www.holisticat.com>

8.1.12 The Apothecary List

(Almost dead. Mar02)

A list for preparing oils, ointments and suchlike. I'm told that the chatters have moved on.

To subscribe: write to: apothecary-request@kjsl.com with the text: subscribe

8.1.13 The HolisticBird List

(alive and well. Oct03)

The HolisticBird list focuses on natural health for birds. Most of the discussions are around bird diseases, nutrition, and herbs, but there is occasional contributions about homeopathy and other modalities.

To subscribe: write to HolisticBird-subscribe@yahoogroups.com, URL:
<http://groups.yahoo.com/group/HolisticBird/>
HolisticBird Newsletter <http://www.holisticbirds.com>
HolisticBird Website <http://www.holisticbird.org>

8.1.14 The Toiletries List

(Alive and well. Many many ads. Oct03)

A list for various aspects of making your own lotions, cremes, soaps, personal care products, and related subjects.

To subscribe: write to: 1Toiletries-subscribe@yahoogroups.com , URL:
<http://health.groups.yahoo.com/group/1Toiletries/>

8.1.16 The Aboutherbs List

(Almost dead. Oct03)

A list focused more on growing and preserving herbs. Animal health and natural beauty are ontopic, as are herbs for health.

To subscribe: write to aboutherbs-subscribe@yahoogroups.com
Website found here: <http://health.groups.yahoo.com/group/aboutherbs/>

8.1.17 The UK Herbal List

(Alive and well. Oct03)

The ukherbal -list for practitioners in Europe is closed, low on volume and high on quality. If you wish to join, and are a practitioner in Europe, send an email with your resume to gcwhite.ntlworld.comx (no x).

8.1.18 The Herbgardening List

(Alive and well. Oct03)

To subscribe: write to herbgardening-subscribe@yahoogroups.com , URL:
<http://groups.yahoo.com/group/herbgardening>

8.1.19 The Forageahead List

(Alive and well. Oct03)

To subscribe: write to forageahead-subscribe@yahoogroups.com

Website found here: <http://groups.yahoo.com/group/forageahead/>

8.1.20 The HolisticPet List

(Alive and well. Oct03)

To subscribe: write to holisticpet-subscribe@yahoogroups.com

Website found here: <http://groups.yahoo.com/group/HolisticPet/>

The Medicinal HerbFAQ

8.4 Newsgroup (and mailing list) netiquette

Here's a good page on snipping as you go: <http://learn.to/quote> .

Another good page is among the FAQs found in <news:news.announce.newusers> , a resource all usenet (= newsgroup) newbies should make themselves familiar with:

<http://www.faqs.org/faqs/usenet/posting-rules/part1/>

The main rule is, contributors to these forums are real live people - so don't be a jerk. And remember, Things get Archived.

All of usenet (except binary groups, but read their FAQs), and most mailing lists are plain text. Email, too, is plain text. That means you should not use any kind of html nor any kind of graphics in your posts and/or emails. Also please note that most people who've been around for a while use email and/or usenet programs that don't even see your nicely formatted text - they see the html code instead. `<ht ml><body bgcolor="#FFFFFF">It's gibberish. Take my word for it.</body></h tml>`

Also, a lot of people (including most Europeans) still pay for their online time and/or their phone by the minute. Yes, European phone companies charge for local calls, too. Some Europeans even pay their ISP (internet service provider) by the byte. Html code and graphics in your posts and emails make for longer downloads, and thus, for higher cost.

So change your habits -- and your email program settings. People on slow lines, people who pay by the minute or by the byte, and usenet and email "oldbies" will thank you for your consideration.

The Medicinal HerbFAQ

8.5 Dealing with spam and trolls

Instead of fretting over commercial posts, we all should take a cool approach to the problem. Whenever I see a message like "Make quick cash!", "Great Anti-Cellulite Cream!", "Don't be Lonely!", "Earn \$50,000 a week!" or something along those lines, I forward the message to the postmaster where the message originated from, explaining why I find the post inappropriate or offensive. Chances are that the postmaster will look into the issue and have a talk with the abuser, if not go ahead and cancel his/her account altogether (has been known to happen).

If the offensive message originated at an academic institution, then I know I am going to get the sucker in a lot of trouble. Universities have strong policies about the misuse of their computer resources. It is likely that after receiving complaints, the offenders will lose their accounts, and in addition experience the wrath of some disciplinary committee.

So, for the good sake of the net, if you see a commercial message posted by idiot.morons.are.us, forward the message with a piece of your mind to postmaster.morons.are.us. You will be doing everyone a favor.

Gloria Mercado-Martin
desidia.community.net

The same goes for trolls. Also, the right thing to do about trolls is to report, killfile, and forget. If you react to a troll on a newsgroup you are feeding it. If you ignore the troll it'll go back under its bridge sooner or later. Trolling: sending off-topic and/or inflammable messages to newsgroups and/or mailing lists. For example, posting anti-herbal messages to a herbal newsgroup.

A note on finding correct abuse addresses: I quite like <http://www.spamcop.net>

You'll find more hints on news:news.admin.net-abuse.* - these newsgroups are very flammable because they attract the wrath of the spammers they fight, but you will find information on how to fight spam, unwanted ads, unwanted binaries in non-binary newsgroups, and UCE (unsolicited commercial email). Have fun!

- Good advice about mononucleosis: [mononucl.html](#) (Howie Brounstein)
- General info on allergies: [allergies.html](#) (Henriette)
- What are pinworms? [pinworms.html](#) (Henriette)

Miscellaneous

- Making tinctures: [tincture.html](#) (Henriette)
 - A tincture is not an essence: [tincture1.html](#) (Henriette)
 - Getting the most out of your herb: [usage.html](#) (Henriette)
 - Flower Remedies [bachflow.html](#) (Suzanne Sky)
 - A list of books you might wish to read: [culibook.html](#) (Chris Reeve)
 - Making herb butter: [butter.html](#) (Henriette)
 - Making an herbal gift basket: [basket.html](#) (Henriette)
 - Making salves: [salves.html](#) (Henriette)
 - Every now and then I get a question on a project for schoolkids. Here's a small selection of them: [herbproj.html](#) (Henriette)
 - Jerusalem artichoke: [helianthus.html](#) (Henriette)
 - Alcohol, vodka, proof and percentages - some definitions and pet peeves: [etoh.html](#) (Henriette)
-

Lots of fun

- The alternative herbFAQ: [funstuff.html](#)
- Then there was a nice silly thread on rec.food.preserving, deserving a wider audience: [vowels.html](#)
- Timid about asking something on the newsgroups? You're not alone: [query.html](#)
- Fun with twining plants: [climber.html](#)

Poking fun at advertisers and hustlers

- Got tired of all the scams? Here's the one to top them all; it'll cure dandruff, death and taxes (among other things), and make you irresistible to the opposite sex: [sbganoni.html](#) (Alan Tillotson)

[Home](#) > Classic Texts

Classic texts: [King's](#) - [USDisp](#) - [Ellingwood](#) - [Felter](#) - [Petersen](#) - [BPC](#) - [DMNA](#) - [Thomas](#) - [Sayre](#) - [Cook](#) - [Potter](#) - [HistVD](#) - [Journals](#)

Classic Herbal Texts

Last updated 03May04 - Have a comment? [Tell me](#).

All scanned works on this site are [copyright](#) © 2000-2004 Henriette Kress - unless otherwise specified.

[Index of plants in the classic texts on this site](#)

Books

- [King's American Dispensatory](#), ([intro page](#)) ([preparations page](#)) ([cool tidbits](#)), by Harvey Wickes Felter, M.D., and John Uri Lloyd, Phr.M., Ph.D., 1898.
- [*The American Materia Medica, Therapeutics and Pharmacognosy](#) ([intro page](#)) ([plant page](#)), by Finley Ellingwood, M.D., 1919.
- [*The Eclectic Materia Medica, Pharmacology and Therapeutics](#) ([intro page](#)), by Harvey Wickes Felter, M.D., 1922.
- [*Materia Medica and Clinical Therapeutics](#) ([intro page](#)) ([part II](#)), by Fred J. Petersen, M.D., 1905.
- [The British Pharmaceutical Codex](#) ([intro page](#)) ([preparations page](#)), 1911. - *added more 03May04*
- [*The US Dispensatory](#) ([intro page](#)) ([preparations page](#)), edited by Joseph P. Remington and Horatio C. Wood, 1918.
- [Drugs And Medicines of North America](#) ([intro page](#)), Vol. I-II, by J. U. & C. G. Lloyd, 1884-1887. (*not yet done*)
- [*The Eclectic Practice of Medicine](#), by Rolla L. Thomas, M. D., 1907.
- [*A Manual of Organic Materia Medica and Pharmacognosy](#) ([intro page](#)), by Lucius E. Sayre, 1917.
- [*The Physiomedical Dispensatory](#) ([intro page](#)), by William Cook, M.D., 1869.
- [*History of the Vegetable Drugs of the Pharmacopoeia of the United States](#), by John Uri Lloyd, 1911.
- [A Compend of Materia Medica, Therapeutics and Prescription Writing](#) ([intro page](#)), by Samuel

O. L. Potter, M.D., 1902.

- [Specific Medication and Specific Medicines](#) by John M. Scudder, M.D., 1870.
- *[Ginseng and Other Medicinal Plants](#) - a grower's and collector's guide. A. R. Harding, 1936.
- *[Tea leaves](#) by Francis H. Leggett & Co, 1900.
- [Flora Fennica - Suomen Kasvio](#) (johdanto) (parhaat palat), by Elias Lönnrot, 1866.
- [Aus Wald und Feld den Tisch bestellt](#), by Walther Schoenichen, 1947.

And this is helpful if you want to read the numbers:

- "Appendix: II: [Tables of Weights and Measures](#)" (the first part), from The Dispensatory of the United States of America, by George B. Wood and Franklin Bache, 1876.

Journals and Periodicals

Ephemera

- John Uri Lloyd: [Alcohol Adversely Criticised](#). OCR'd from a 1922 reprint of articles from 1875 and 1889.
- John Uri Lloyd: [Licorice](#) (picking and processing it in Turkey). OCR'd from a reprint from The Eclectic Medical Journal, 1929.
- *John Uri Lloyd: [The Eclectic Alkaloids](#), 1910.
- *Harvey Wickes Felter: [Biographies](#) of King, Howe, and Scudder, 1912.
- Alexander L. Blackwood: [Observations with Medicago Sativa](#). Lloyd Brothers Leaflet, 1915.
- Elias Lönnrot: [Afhandling om Finnarnes magiska medicin](#). Helsinki, 1832.

*: .html versions of works which are found as .pdf files on [Michael Moore's site](#).

*: cleaned-up and crosslinked .html version of a scan from [Paul Bergner's site](#).

*: .html version of a textfile + images as rec'd from Richard and Margie Druery

Wow, that's a *lot* of text. (59.3+ MB (on ReiserFS), 74.2+ MB (on ibiblio), 7280+ files, and counting.). And there's never enough time, is there? So where should you concentrate your efforts?

- *The later the better* (up to a point) - but however you look at it, King's is still the best, because of the sheer amount of detail. Also, I've linked the journals (and ephemera and such) to and from King's only.
- *Eclectic (and physiomedical) MDs are better than pharmacists* - at least if you're a practising herbalist. But King's was written by an eclectic MD and was extensively revised by both an eclectic MD *and* an eclectic pharmacist - it's not considered the best classic herbal work there is for nothing.

The best recent herbal work? Forget MDs there, they concentrate on more or less irrelevant single constituents (that being what they're used to). Go for books written by herbalists, by people who work with whole plants and with whole people. The ones I've found worthwhile are listed in the

[medicinal herbfaq.](#)

The Fine Print: scanned texts

Yes, it *is* possible to copyright scanned texts, even where copyright for the printed version has expired. If it were not, *nobody* would bother to scan any of these olde ones. Because in that world, the minute you'd put your hundreds of hours worth of scanning, OCR'ing and html'ing online, some busybody would copy it over to his/her site. And/or flog a CD of it. Without even so much as a by your leave. Because they'd be legally entitled to, right? Funny how *right* and *wrong* never seems to enter into it.

Talking of legally entitled: Paul Bergner has the full text of *King's American Dispensatory* (from this site) on his MH Resource CD. That CD also features the full text of Paul Bergner's excellent journal *Medical Herbalism*, and his scan of *Cook's Physiomedical Dispensatory*: http://www.medherb.com/full_text.htm. It's excellent value for your money.

Back to those entrepreneurs. I haven't scanned these works for busybodies to make money off them; I've scanned them because I want to, and because I like the full-text searchability of them. If *you* want the full text of one or the other classic text on your site, why, scan one. Locke's Syllabus Materia Medica might be good; or try anything by the Lloyd brothers, or by Ellingwood. Or Hager's Handbuch, if you can find it in English. Or any of the journals that are repeatedly mentioned in King's. The best years are from 1880 through to 1930 or so. Really, there's lots of good herbal books at your local antiquarian's, or over at <http://abebooks.com> or <http://bibliofind.com>. Send me the URL after you've gotten a good start (say, 100 pages or so online), and I'll link to you. If that's not feasible, well, you *may* copy a few pages (less than ten) of the larger works to your site, but if you do, you *have* to link back to this page from every page you've taken. The URL to link to is <http://www.ibiblio.org/herbmed/eclectic/main.html>.

Classic herbal texts on other sites

- For some historical perspective read this article by Francis Brinker: <http://www.eclecticherb.com/periscop.htm>
- Michael Moore has lots of olde works on his [SWSBM](#) site. (You'll find the ones marked * as .html-files in the upper regions of this page.)
 - Books: *[Felter](#), *[Ellingwood](#), *[Petersen](#), [Fyfe](#), [Culbreth](#), and *[Sayre](#),
 - Periodicals: (*)[Ellingwood's therapist](#), (*)[American Journal of Pharmacy](#), *[Transactions of the Nat'l Eclectic Medical Assoc.](#),
 - *and* others: [Other Manuals](#), [SWSBM](#)
- David Winston has some old works on his site, including [Felter's Syllabus](#) and excerpts from Locke's Materia Medica: http://www.herbaltherapeutics.net/herbal_therapeutics_library.htm
- There's a new trend out there: scan enormous old encyclopaediae and have people spellcheck them online. I've seen two such efforts so far - kudos to both projects:
 - in German: **Meyers Konversations-Lexikon**. 1888-1889. 16 Bände, 16000 Seiten. Hier: <http://susi.e-technik.uni-ulm.de:8080/meyers/servlet/index>
 - in Swedish: **Nordisk familjebok**, Konversationslexikon och realencycopedi. 1876-1899, 20 band; 1904-1926, 38 band; totalt 45000 sidor. Här: <http://www.lysator.liu.se/runeberg/nf/>

- Maude Grieve's Modern Herbal from 1931 should be mentioned here, even if it's almost a modern work: <http://www.botanical.com/botanical/mgmh/mgmh.html>
- Michael Tierra's [Planetherbs](#) site currently boasts one classic work of interest: Eli Jones' "[Cancer - Its causes, symptoms and treatment](#)".
- Culpeper's "The English Physitian" from 1652 is online: <http://www.med.yale.edu/library/historical/culpeper/culpeper.htm>
- Paul Bergner's Culpeper-to-modern Plant Names page: http://medherb.com/culpeper_names.html
- Dioskorides' Materia Medica
 - Julius Berendes' 1902 German translation: <http://www.tiscalinet.ch/materiamedica/>
 - The very first pages of John Goodyer's 1655 middle English translation, from the 1933 Gunther edition: <http://heronbotanicals.com/links/hblinks.html>
- You'll find a library of online Homeopathic works here: http://www.homeopathyhome.com/reference/books_online.shtml - NOTE: homeopathy is not herbalism.
- Resources of the Southern Fields and Forests, being alsoa Medical Botany of the Confederate States by Francis Peyre Porcher, 1833: <http://docsouth.unc.edu/imps/porcher/porcher.html>
- Kräuterbuch von Jacobus Theodorus "Tabernaemontanus" anno 1625 - 1600 pages, 3000 plants (they're still working on it - typing by hand, this kind of text can't be scanned), in German: <http://www.kraeuter.ch/>
- Part of Purdue's Newcrop site: [The Herb Hunters Guide](#) by A.F. Sievers, 1930.
- Köhler's is a good picture book:
 - one version: <http://ridgwaydb.mobot.org/mobot/rarebooks/title.asp?relation=QK99A1K6318831914> (287 images) - and they have the full text of Köhler's online, too.
 - another: <http://pharm1.pharmazie.uni-greifswald.de/allgemei/koehler/koeh-sta.htm> (282 images)
 - another: <http://www.biologie.uni-hamburg.de/b-online/koehler/koeh-sta.htm> (146 images)
- Ooooh. Shiny! Kurt Stüber's pages include *lots* of German botanical works von anno dazumal: http://www.mpiz-koeln.mpg.de/~stueber/stueber_library.html
 - among them a very good German picture book, Otto Wilhelm Thomé, 1885-1905: <http://www.mpiz-koeln.mpg.de/~stueber/thome/index.html>
 - and yet another version of Köhler's (124 images, at 1-2 MB per image): <http://www.mpiz-koeln.mpg.de/~stueber/koehler/index.html>
 - and Siebold's Flora Japonica, 1870: <http://www.mpiz-koeln.mpg.de/~stueber/siebold/flora3/index.html>
- Another German picture book, Fuchs Botanical, 1545: <http://www.med.yale.edu/library/historical/fuchs>

- Paintings from Curtis' Botanical Magazine, running from 1787 to 1807:
<http://www.nalusda.gov/curtis/>
- The Indian Household Medicine Guide, by J. I. Lighthall, 1883:
<http://www.meridianinstitute.com/echerb/Files/classics/lighthall/contents.html>
- There are lots of old (and new) pharmaceutical and botanical texts at the University of Braunschweig; unfortunately, they are scanned .gifs, not OCR'd .html files, which makes downloads expensive and reading cumbersome - unless you have broadband, of course. For pharmaceutical texts, try <http://sun250.biblio.etc.tu-bs.de/pharma.htm>; for botanical ones go for <http://sun250.biblio.etc.tu-bs.de/botanik.htm>.

Among the pharmaceutical works these are worth mentioning:

- Baillièrre et Fils, 1866: Codex medicamentarius - Pharmacopée française.
<http://www.digibib.tu-bs.de/2676-9024/start.htm>
- Friedrich A. Flückiger: Lehrbuch der Pharmakognosie des Pflanzenreichs: 1867. <http://www.digibib.tu-bs.de/2231-2886/start.htm>
1883, 2. Aufl. <http://www.digibib.tu-bs.de/Ab-175/start.htm>
- Wilibald Artus, 1876: Hand-Atlas sämtlicher medicinisch-pharmaceutischer Gewächse, 5. Aufl. 1. Band. <http://www.digibib.tu-bs.de/1425-1298/start.htm>
2. Band. <http://www.digibib.tu-bs.de/1425-1308/start.htm>
- Hermann Hager, Handbuch der Pharmaceutischen Praxis:
1. Theil, 1876. [http://www.digibib.tu-bs.de/Aa-5226-a\(1\)/start.htm](http://www.digibib.tu-bs.de/Aa-5226-a(1)/start.htm)
2. Theil, 1878. [http://www.digibib.tu-bs.de/Aa-5226-a\(2\)/start.htm](http://www.digibib.tu-bs.de/Aa-5226-a(2)/start.htm)
Technik der Pharmaceutischen Receptur, 5. Aufl., 1890:
<http://www.digibib.tu-bs.de/Ab-220/start.htm>
- G. Pabst: Köhler's Medizinal-Pflanzen, 1887, also with the complete text:
Band 1. <http://www.digibib.tu-bs.de/3202-0935/start.htm>
Band 2. <http://www.digibib.tu-bs.de/3202-0948/start.htm>
Band 3 (Ergänzungsband). <http://www.digibib.tu-bs.de/3202-0951/start.htm>
- O. Schlickum, 1886: Kommentar zur 2. Auf. der Pharmacopoea Germanica.
<http://www.digibib.tu-bs.de/2231-3995/start.htm>
- Julius Berendes, 1902: Des Pandanios Dioskurides aus Anazarbos Arzneimittellehre aus fünf Büchern. <http://www.digibib.tu-bs.de/2700-1943/start.htm>
- Edmund White, John Humphrey, 1904: Pharmacopodia - A Commentary on the British Pharmacopoeia 1898: <http://www.digibib.tu-bs.de/2708-3026/start.htm>
- Scans of ancient works, for instance a 1585 Italian translation of an even earlier Portuguese history of medicinal plants: <http://www.abocamuseum.it/bibliothecaantiqua/prodotti.asp>
- Earthly Pursuits: a few old gardening books:
<http://www.earthlypursuits.com/Books/OldBooklibrary.htm>
- More scans of ancient works, these at the Bodleian Library:
<http://www.bodley.ox.ac.uk/dept/scwmss/wmss/medieval/browse.htm>

I've seen parts of Gerard's Herball online, but that's mainly been some [culinary bits](#) (Cindy has *lots* of other older culinary texts online, and links to even more).

[Home](#) - [Herb FAQs](#) - [Articles](#) - [Classic texts](#) - [Archives](#) - [Links I like](#) - [Pictures](#) - [Plant names](#)

Mailing list / Newsgroup archives

Last updated 22Dec03 - Have a comment? [Tell me](#).

Rainy day, with 56 channels and nothing on? Get a couple herbal mailing list or newsgroup archives here and start reading. If you download them all you'll even make it through a month or four of being snowed in, in that mountain cabin.

You'll find a list of all the public herbal forums I'm aware of in the medicinal herbfaq, [part 8.1](#). Have fun! The archive files are also available in my [FTP](#) space, and on the mirror in [Japan](#).

Henriette

The Best of the Herbal Forums

I've long been thinking about making these archives actually useful, as opposed to just archiving it all blindly. So here they are: [the Best of the Herbal Forums](#) -files. That is, the best as I perceive them. You might still want to plod through the complete archives.

There's currently only a few monthly sets online. I'll add more of the older ones as I find time; and I don't expect it'll be all that much work to add new archive files as they accrue, so to speak. After all, I've been doing the [BoRHOD](#) files for - is it three years already? Four, you say? My, doesn't time fly.

Enjoy!

The medicinal herblist (The Medicinal and Aromatic Plants Discussion List) archives

(Formerly the herb@franklin.oit.unc.edu -list. Before that it was the herb@mylist.net -list and the list at herb@vm.ege.edu.tr)

Please read this before posting: [Rules of the Game](#)

Latest archive file available: [log0307.zip](#). Have a look at the other medicinal herblist logs in [WWW](#) space.

You can subscribe, unsubscribe, and set list options on the web. The URL is: <http://lists.ibiblio.org/mailman/listinfo/herb>

Or write to herb-request@lists.ibiblio.org with only the following text:
subscribe

The herb-2 -list

is found here: <http://lists.ibiblio.org/mailman/listinfo/herb-2>

Or write to herb-2-request@lists.ibiblio.org with only the following text:
subscribe

This list has fewer members than the main herblist, but posting rules (like "no html" and "don't quote the full text of the message you're replying to") are practically non-existent.

Alt.folklore.herbs archives

You can subscribe to newsgroups if

- your ISP (Internet service provider) carries them and
- you have a newsreader.

If both are true for you, and your browser is configured as your newsreader, you can see what's generally posted in this newsgroup by clicking here: <news:alt.folklore.herbs>.

The name might throw you - nothing to do with folklore, it's *the* newsgroup for medicinal herbs, even if there's a culinary herb thrown in every now and then. In this [WWW](#) -space you'll find the monthly zipfiles from 1993 to 2001.

This group is **no longer archived**, because 1) there is overmuch quoted text 2) I no longer read afh, and 3) it's all on [googlegroups](#), anyway.

The HerblInfo -list archives

A now defunct list. List archives from 1997 through 2000 here: [WWW](#).

Archives slow: The culinary herblist

A currently very dormant list. List archives from 1996 to 2001 here: [WWW](#). No longer archived.

To subscribe: write to herbs-l-request@orednet.org with only the following text: subscribe

[Home](#) - [Herb FAQs](#) - [Articles](#) - [Classic texts](#) - [Archives](#) - [Links I like](#) - [Pictures](#) - [Plant names](#)

Links I like.

Last updated 25Apr04 - links last checked 22Dec03 - Have a comment? [Tell me](#).

Feel free to link to my site if you like it -- the URL is <http://www.ibiblio.org/herbmed> .

Feel free to send me URLs to check out for inclusion on this page. Note, however, that I don't do reciprocal links.

That means that you'll *really* only find links to sites I like on this page. Note also that I only link to commercial sites if they have no blinking or moving text, no moving pictures, and *lots* of information.

Herbal medicine - [Good Materia Medicas](#) - [Botany](#) - [Culinary herbs](#) - [Other fun things](#)

Herbal medicine, mostly

Herbalists

- Michael Moore - quality information on herbal medicine, including manuals, classic texts, and images: <http://www.swsbm.com>
- Jonathan Treasure's Herbal Bookworm includes critical in-depth reviews of major herbal sellers and herb-drug interaction info, among other things: <http://www.herbological.com>
- Paul Bergner's Medical Herbalism (see medicinal herbfaq [part 6.3](#)):
<http://www.medherb.com> - quality articles and links, geared towards the herbal practitioner
- David Winston's site: <http://www.herbaltherapeutics.net/> - *added 25Apr04*
- I like Charlie Kane's site: <http://tcbmed.com/> - it's got good info on herbs around Tucson, AZ, and nice pictures that remind me of the time I spent in the area. Cool!
- Christopher Hobbs: <http://www.christopherhobbs.com>
- Michael Tierra: <http://www.planetherbs.com> - mostly TCM -style herbal articles
- Howie Brounstein has articles on herbal smokes, fad herbs and wildcrafting:
<http://www.teleport.com/~howieb/howie.html>
- Robyn Klein's recommended reading site: <http://www.rrreading.com>
- Chanchal Cabrera: www.gaiagarden.com
- Rosemary Gladstar's Sagemountain site: <http://www.sagemountain.com>
- Brigitte Mars: <http://www.brigittemars.com>
- Tieraona Low Dog: <http://www.fihm.com>
- Susun Weed: <http://www.susunweed.com>

- Alan Tillotson: <http://www.oneearthherbs.com> - Ayurvedic herbal medicine, with an emphasis on herbs for the eye.
- Jaime De La Barrera: <http://www.infoherb.com>
- Todd Caldecott: <http://www.wrc.net/phyto/>
- Joshua Muscat's SanFran BotMed Clinic site: <http://www.sfbmc.org/>
- Hall Newbegin is cool, and he sells herbs'n'soaps'n'stuff: <http://www.juniperridge.com>
- J Mark Taylor: http://www.arcadyholistic.ca/yhnc_m.htm
- Graham White: <http://www.gcwhite.co.uk/herbs.htm>
- Jeanne Rose: <http://www.jeannerose.net>

Herbalist organizations:

- The National Institute of Medical Herbalists (NIMH) is online: <http://www.nimh.org.uk/>
- The European Herbal Practitioners Association (EHPA): <http://www.users.globalnet.co.uk/~ehpa>
- The National Herbalists Association of Australia (NHAA): <http://www.nhaa.org.au>
- The American Herbalists Guild (AHG) is found here, these days: <http://www.americanherbalistsguild.com/>
- The Ontario Herbalists Association (OHA): <http://www.herbalists.on.ca/>
- The International Register of Consultant Herbalists and Homoeopaths: <http://www.irch.org>
- New Zealand Association of Medical Herbalists (NZAMH): <http://nzamh.org.nz/>

Databases

- Go for Jim Duke's Phytochemical and Ethnobotanical Databases: <http://www.ars-grin.gov/duke>
- Or try Dan Moerman's Native American Ethnobotany Database: <http://herb.umd.umich.edu>
- The [herbmed database](#) used to be useful, but now it says "licensed content" for most entries, and "database error" for the rest. Sad, that - but it's simply not worth a visit anymore.

Other

- Try the Herb Research Foundation, with their slant towards scientific phytotherapy: <http://www.herbs.org> - *you need to read Jonno's review of [the Honest Herbal](#) before you decide to buy any of Tyler's work, and read Jonno's review of the [Comm. E Monographs](#) before deciding to buy that exceedingly expensive set of committee compromises.*
- The Herb Society of America has nice pages: <http://www.herbsociety.org>
- The Present Moment site has some good herbal articles:

http://www.presentmoment.com/article/toc_health..html - check, for example, the horehound article. Heh.

- The Merck Manual, 17th edition, is online at:
<http://www.merck.com/mrkshared/mmanual/sections.jsp>
- A comprehensive glyceimic index page is found here:
<http://diabetes.about.com/library/mendosagi/nmendosagi.htm> - you need this if you have blood sugar problems.
- A site with tapes of conferences: <http://www.botanicalmedicine.org/> and a conference calendar: <http://www.botanicalmedicine.org/conferences/index.htm>
- The herbalchem site dives into the chemistry of herbs: <http://www.herbalchem.net/>
- Most of the Suite101 article collections are worthwhile, especially if you're new to herbs. Check, for instance, these: [historical plants](#) - [herbal medicine](#) - [herbalism](#) - [herbal healing](#) (Susun Weed) - [botanical](#) - or just do a search for "botanical medicine" here:
<http://www.suite101.com>

[Herbal medicine](#) - [Good Materia Medicas](#) - [Botany](#) - [Culinary herbs](#) - [Other fun things](#)

Good Materia Medicas

- In addition to Michael Moore's own Materia Medica (manuals) you'll find olde Eclectic tomes (other manuals, Felter, Ellingwood, Fyfe, Culbreth ...) on his site:
<http://www.swsbm.com>
- A nice materia medica with accompanying therapeutics: <http://www.herbs2000.com>
- Nope. Healthy.net is *still* spamming.
- David Hoffmann's Materia Medica is found here:
<http://www.npicenter.com/library/herbal/materiamedica>
- All herb-related bits of King's American Dispensatory (1898) are here:
<http://www.ibiblio.org/herbmed/eclectic/kings/intro.html> (yes, it's part of this site.)
- A Himalayan herb site: <http://www.himalayahealthcare.com/herbfinder/english.htm>
- A Modern Herbal (1931): <http://www.botanical.com/botanical/mgmh/mgmh.html>
- The Raintree Tropical Plant Database includes information on about 100 plants:
<http://www.rain-tree.com/plants.htm>
- The TCM Herbal Database from The Rocky Mountain Herbal Institute has info on about 220 commonly used Chinese herbs: <http://www.rmhiherbal.org/ai/pharintro.html>
- Healthnotes, widely available on the web; try
<http://www.pccnaturalmarkets.com/health/Index/Herb.htm>,
http://www.gnc.com/health_notes/Index/Herb.htm, or any of the other clones. Note that the Healthnote Files are slanted towards a "scientifically correct" way of thinking, ie. pharmaceutical industry; therefore the herbal files are overcautious and more or less

theoretical.

- Holisticonline has a rather comprehensive database here:
http://www.holisticonline.com/Herbal-Med/Hol_Herb_Directory_Index.htm
- Christine Haughton's files have been moving around a lot; let's hope they'll stay here for at least a little while: <http://www.purplesage.org.uk/>
- Phytotherapy: the herbal monographs of the Australian Naturopathic Network,
<http://www.ann.com.au/herbs/herbal.htm>
- More phytotherapy: practitioner-level information at <http://www.phytotherapies.org> (if you're a practitioner you can register and gain access to the info.)
- Mary O'Connell has compiled information on some Southwest Medicinal Plants:
<http://medplant.nmsu.edu/plantindex.htm>

Auf Deutsch

- Thomas Schoepke hat eine Botanische Datenbank inkl. den Anwendungsmöglichkeiten von Nutzpflanzen: http://www.pharmakobotanik.de/systematik/1_ti_reg/reg-arzn.htm
- Die Heilpflanzen-Suchmaschine: <http://www.heilpflanzen-suchmaschine.de>

Botanical things

- Need to find a new scientific name from an old book, or see which plants are actually identical nowadays?
 - The GRIN taxonomy database is very good indeed, even if it does have a few interesting gaps here and there:
<http://www.ars-grin.gov/cgi-bin/npgs/html/taxgenform.pl>
 - If you're looking for plants found wild *somewhere* in the US, your best bet is the plants database at <http://plants.usda.gov/> - they're lumpers (yay!), but a tad too keen on adding the newest botanical binomials ASAP. Europeans are generally splitters (boo hiss!) but usually we wait a bit before introducing shiny new latin names, which often means we don't have to introduce them at all -- because botanists just can't make up their minds.
 - Here's an excellent site for algae: <http://www.algaebase.org/SpeciesSearch.lasso>
 - For the *Fabaceae*, the best database is Ildis: <http://www.ildis.org/LegumeWeb/>
 - Then there's tropicos: <http://mobot.mobot.org/W3T/Search/vast.html> - do pay attention to the "Author" part of the botanical name. While it does give a lot of synonyms it's not always clear on *which* of the results given is the currently correct botanical binominal. They also have way too many circular references (plant a? Nah, that's b these days. Nah, that's c these days. Nah, that's a these days. *Argh*, says I.)
 - The IPNI database can be helpful: http://www.ipni.org/ipni/query_ipni.html - current botanical binomials are given in comments only, which of course means that a lot of the entries don't have them.
 - The best Swedish botanical database is of course Den Virtuella Floran; if you're even close to being able to understand Swedish go have a look:
<http://linnaeus.nrm.se/flora/welcome.html>
 - CNIP is a good botanical database for Brazil:
http://150.161.125.13/db/pne_acc/st_geog.shtml
 - Lichens. The Index Fungorum also covers lichens - yay! Still no data on *Variolaria dealbata*, though. <http://www.indexfungorum.org/Names/NAMES.ASP> - *added 25Apr04*
 - Scott's botanical links: <http://www.ou.edu/cas/botany-micro/bot-linx/>
 - Russian wild nature (plants, fungi, animals); pages in Russian and English:
<http://rwn.boom.ru>
 - DELTA Descriptions of flowering plants, a treasuretrove for botanists:
<http://biodiversity.uno.edu/delta/angio/index.htm>
 - Flora Celtica, folkloric use of a lot of plants:
<http://rbg-web2.rbge.org.uk/celtica/dbase/genera/GENERA.HTM>
 - Some nice pictures by botanical family: <http://www.keiriosity.com/>
-

Culinary and gardening sites, mostly

- The Gardening Launch Pad: <http://gardeninglaunchpad.com>
- The GardenGuide pages: <http://www.gardenguides.com>
- The Weekend Gardener / The Official Seed Starting Homepage / Herb Seeds: <http://www.chestnut-sw.com/seeds/herbseed.htm>
- Here's an extensive site with a lot of information on culinary herbs and spices - just browse around: <http://www-ang.kfunigraz.ac.at/~katzer/engl/index.html>
- The Sustainable Farming Connection, a nice site for farmers: <http://ibiblio.org/farming-connection>
- Here's a very good site on soap-making: <http://www.millersoap.com>
- And here's a good selection of info on natural health and beauty: <http://www.geocities.com/HotSprings/Spa/3893/>

Not plants at all, but still fun

- Missing your daily dose of Calvin and Hobbes? At the official site they have reruns, from 10 years ago: <http://www.ucomics.com/calvinandhobbes/>
- Frazz rocks. It's the new Calvin and Hobbes. I'm itching to see it in print though: <http://www.comics.com/comics/frazz/>
- Schlock is extraordinary. It includes one of the best strip gags in any comic ever: <http://www.schlockmercenary.com/d/20010813.html> - but read it from the first strip to the current one, it's great.
- I spend some of my copious free time on <news:rec.humor.oracle.d>. Here's some gems from that ng: <http://ibiblio.org/herbmed/rhod/main.html>
- Recent columns by Dave Barry, at the Miami Herald: http://www.miami.com/mld/miamiherald/living/columnists/dave_barry/
- One of the greatest rants of all time (you *go*, Russ!): <http://www.eyrie.org/~eagle/writing/rant.html>
- Great site for website design: [Sarah's Kinda Helpful Web Site](#)

I've been entertained by the unitedHeroes folks for years, or at least it seems so. They do wacky or mysterious web serials (as in, written adventures). It's all free of charge, and it's also all great fun. Here's their tidbot:

No javascript? Oh well, here's the plain URL then: <http://www.unitedheroes.net>

Lovely Linux links

- Geek news:

- <http://slashdot.org/> - news for nerds.
- <http://www.theregister.co.uk/> - The Register: "biting the hand that feeds IT".
- Linux specific:
 - <http://www.suse.de/de/index.html> - SuSE.
 - newsgroup: <news:alt.os.linux.suse> - very helpful.
 - <http://www.kde.org/> - one of the desktop environments of linux distros - ooh, shiny! I *love* the file preview in the file manager.
- MySQL:
 - <http://dev.mysql.com/doc/mysql/en/index.html> - the online version of the manual is much better than the one included in your linux distribution, because it includes reader comments - examples, caveats, etc. Very helpful.
 - newsgroup (in German): <news:de.comp.datenbanken.mysql> + FAQ: <http://mysql-faq.sourceforge.net>
- PHP:
 - <http://www.php.net/manual/en/> - this manual, too, includes reader comments in the online version. Extremely good.
 - <http://pear.php.net/> - what CPAN is for perl, PEAR is for PHP - even if it's still young. Start with the manual.
 - newsgroup (in German): <news:de.comp.lang.php.datenbanken> + FAQ: <http://www.dclp-faq.de>

Henriette's plant photos

Last updated 17Jan04 - Have a comment? [Tell me](#).

26Nov03, major site update: I've added authors to the botanical binominals (prompted among other things by the [Illicium anisatum](#) confusion), added common names in languages other than English (mainly Finnish, Swedish and German, but there's some French and Italian, too), updated outdated latin names, put both names and image info into a MySQL database, and added a few PHP scripts which pull info from said database. The single picture pages don't take info from the database yet - that's an upcoming project. My heartfelt thanks to David Robley and [JR Conlin](#) for their help with PHP and MySQL.

[The plant name search](#)

which also includes links to URLs across this site,
and links to all the plant pics on this site.

Index pages: [pics.php](#)

Arne Anderberg, *Jan De Langhe*.

The Fine Print: my photos

Henriette's plant photos are licensed under a [Creative Commons License](#),
with the addendum that German-language sites need to ask first, as a
 German company holds exclusive German language-area internet rights to a
 lot of my pictures.

Personal use

You may copy pics for your own personal use, but you may not change them in any way. Note, personal use is just that. It does not include posting these photos to your favorite mailing list, webforum, or similar - that's republishing them, which is anything but personal. So you like these pics, and want others to see them, too? Post the URL, not the photo. Or, if you *have* to post the photo, non-commercially, of course, you *must* include this: "Photo copyright Henriette Kress, <http://www.ibiblio.org/herbmed>" with every posted image.

Non-commercial website use

Link and/or copy away. Two Three Four things to remember:

1. The pics may not be changed in any way. Three reasons for that: they contain embedded info (you can see it if your photo editing program can read IPTC), I want my name and URL to be legible, and I've made artistic decisions along the way, which changes would, umm, change. So don't. Thanks.
2. Do put this: "Photo copyright Henriette Kress, <http://www.ibiblio.org/herbmed>" right next to every picture you've used. Note, that should be a working link, not just text.
3. If you deeplink please link to the single picture .html pages instead of the images. Thanks.
4. German-language sites should ask first - a German company has exclusive German-area internet rights to a lot of my pics. Don't be in a tearing hurry, though, I'm not always in town.

That goes for *non*-commercial website use only. Commercial use, see below.

Other non-commercial use

Feel free to use my pics in your school homework projects and such. But don't change the pics in any way, and remember to put

"Photo copyright Henriette Kress, <http://www.ibiblio.org/herbmed>"

right next to every picture you've used. If it's show-and-tell type use like teaching and such, remember to add that same line to your handouts.

Commercial use

Rights to use pictures in online and print publications are one of the ways I put butter on my bread. [So ask me -- or make me an offer.](#)

Use in journals

If it's a journal for professional herbalists (EJHM, Medical Herbalism, and the like), use away. If you need larger pics just ask me - for those, I request a copy or two of the journal in return (unless I subscribe, in which case I expect the subscription be extended a tad). I'll also require photographer credits. Don't be in a tearing hurry, though - I'm not always in town.

Others? See commercial use. Yes, I do favor professional herbalists. I am one.

Technical details:

All photos here are taken with my Canon AE1 Program -camera, with a 35-70 mm zoom lens. I usually do slides, as I do [herb talks](#) (and herb walks, but I don't need slides for that). The oldest pics were copied to Kodak Photo-CD's, a couple of negatives in between were scanned with a negative scanner, older pics were scanned with a Polaroid SprintScan 35/LE, and newer pics are scanned with a Nikon LS-1000, using vuescan under Linux.

Pictures: [P01 \(a-anem\)](#) - [P02 \(anem-az\)](#) - [P03 \(b-ce\)](#) - [P04 \(cf-cyn\)](#) - [P05 \(cyp-eru\)](#) - [P06 \(erv-go\)](#) - [P07 \(gr-lar\)](#) - [P08 \(las-malv\)](#) - [P09 \(malv-ni\)](#) - [P10 \(nj-phys\)](#) - [P11 \(phyt-rho\)](#) - [P12 \(rhp-sco\)](#) - [P13 \(scp-thym\)](#) - [P14 \(thyn-z\)](#) - [Unknown](#) - [Misc](#) - [People](#) - [Fungi](#)

[Home](#) - [Herb FAQs](#) - [Articles](#) - [Classic texts](#) - [Archives](#) - [Links I like](#) - [Pictures](#) - [Plant names](#)

Plant name database

Data last updated 23Apr04 - Have a comment? [Tell me](#).

The plant names - you always did want to know what *Achillea millefolium* is called in Finnish, didn't you? Here's your chance ...

A bit of background on the Jan04 update: from Jun03 through Nov03 I went through all my pictures and gave them the currently correct botanical binominals, complete with genus, species and author, adding common names in any of a number of languages I speak, and a few that I don't. That exercise brought home to me just how many errors the old dinosaur of a plant name database contained, so I decided to do something about it. Here it is:

[The all shiny and new plant name search](#)

which also includes links to URLs across this site (not all that many yet, but that's changing),
and links to all the plant pics on this site.

That means that the delimited textfiles, uploadable into any good spreadsheet or database program, are no more.

Those of you who actually asked instead of just copying things wholesale from this site, do ask again; the lot is in MySQL now, which probably is what you use anyway. It's currently 9440 latin names (including 2368 synonyms) and 28266 common names.

[Healthy Herbs](#)

Juli Kight

herbsforhealth.guide@about.com

Juli Kight is dedicated to introducing others to the diverse world of using herbs and plants to enhance, protect, and maintain health and well being.

Professional Experience: Juli is a member of the [Herb Research Foundation](#), the [Flower Essence Society](#), the American Herbalists Guild and a student of the [Michael Tierra's East West Planetary Herbalism](#). She has been working with herbs for about 15 years.

From Juli Kight: "This site features herbs with information on practical methods to use them, where to purchase herbs and extracts, what herbs you can find along the road, natural born killers (herbs to stay away from), plant based eating habits, projects you can do with your plants, and controversial herbs. We will explore all facets of medicinal plant use from traditional Western and Eastern uses to flower essences and homeopathy."

[Healthy Herbs](#)**Tonic Herbs**

Gifs by Juli

Dateline: 12/05/98

[Overview](#)[More Information/Links](#)[Books on the Subject](#)**Overview**

Tonic herbs strengthen and improve specific organs, systems, weaknesses or the body as a whole. They are generally gentle herbs that can be gently stimulating.

There is a difference between tonics and stimulants. Stimulants tend to stimulate an organ or system eventually ending up in depletion, thus "coming down", "crashing" or exhaustion you experience after using them for a period of time. Tonics, gently build and do not exhibit the instant effects of stimulants. You will not experience the "crash" when you stop using them. Tonics like American ginseng will gently build your energy and at the same time help you remain calm and focused during stress, also allowing for better sleep.

Tonic herbs can be described as "normalizers" which nurture and nourish. As Paul Bergner quotes "Taking a tonic is like putting money (chi) in the bank. Taking a stimulant is like withdrawing the money, at some point, your account becomes over-drawn." Lesley Tierra states that tonics "strengthen and promote the overall body processes or particular organs to function better; use to improve any organ or system function and to strengthen and build blood or energy."

If you ever get that feeling that you're not feeling your best, but then you're not feeling sick, perhaps a tonic is all you need.

Chickweed - Stellaria media

Herb

From [Juli Kight](#),
Your Guide to [Healthy Herbs](#).

Overview: Revered as a nuisance to most gardeners, this inconspicuous little plant grows world wide and in abundance. It is usually one of the first plants in spring and in the heat of summer it can be found in cooler, damp shady areas. It makes a wonderful addition to fresh spring salads.

Actions And Properties:
Topical anti-pruritic (itch)
Anti-rheumatic
Astringent
Emollient

Hypotensive
Vulnerary
Constituents:
Mucilage
Saponin glycosides
Coumarins and hydroxycoumarins
Flavonoids
Triterpenoids
Carboxylic acids
Vitamin C

Uses:

Chickweeds best uses are for skin issues and as a tonic. Topically, chickweed addresses skin ailments from minor rashes and itching to eczema and psoriasis. It is also effective against relieving pain from bug bites. Young green tops in spring are excellent in salads and used like spinach for tonic purposes.

Warnings:

None found at this time.

Healthy Salads

Add healing potential to your salads my making a few adjustments with your greens.

We are half way through the summer and I'll bet you are tired of salads based on [iceberg lettuce](#).

Not only is iceberg lettuce lower on the nutritional value scale than other lettuces or salad greens, commercial heads may contain sulfites to prevent it from turning brown.[1] You can increase the healing potential of your salads by adding a variety of fresh herbs and greens.

Changing your salad from plain iceberg lettuce to a variety of vegetable and herbal greens not only awakens your taste buds, but also serves as a healthy tonic as well as supplying more nutritional values. It completely changes the flavor profile leaving your salad choices less boring, and less susceptible to loading them with all the wrong fixings. You will also feel more satisfied and nourished instead of hungry an hour later, leading to snacking.

It is easy to make the change by purchasing specialized salad mixes available in the produce section at your grocery store. My favorites are the spring or field herb blends. This allows you to try a little at a time to see what you do or don't like. Try mixing some new greens in with your basic iceberg until you find a taste you like. I still use iceberg myself because I like the added crunch and there are some nutritional values to it.

Below are some herbs to ideas to add to your salads. Be sure to check out the links below for even more unusual ideas and recipes.

- [Borage](#) - Several ways to use. Rich in minerals and an adrenal tonic.
- [Chervil](#) - Rejuvenation.
- [Chicory](#) (French Endive).
- [Dandelion](#) - Cleansing, diuretic.
- [Lavender](#) - Ways to use, good with fruit salads.
- [Lemon balm](#) - Nice aroma, add to salads to cut down on vinegar or lemon juice.
- [Monarda](#) - Add flowers for a unique flavor and look.
- [Mustard Greens](#) - Add sparingly for congestion, aches, digestion and circulation to mention a few. Plus it adds some spunk to your salad.
- [Parsley](#) - Chop a little fresh parsley for flavor, digestion and inflammatory conditions.
- [Raspberry](#) - Internal astringent. If you don't like berries on your salad, raspberry walnut dressing is a good alternative.
- [Salad burnet](#) - For a fresh spicy taste. Internal astringent.
- [Sorrel](#) - Folk cancer remedy. Adds a lemony taste.

Spring Cleansing

From [Juli Kight](#),
Your Guide to [Healthy Herbs](#).

As we spring clean our homes, so should we spring clean our bodies.

If there is any best season to rejuvenate and cleanse your body, spring is it. Over the fall and winter months you have probably increased your intake of fats, holiday sweets and processed foods while fresh organic produce plummeted. Toxins have built up from being held up indoors most of the time, air has been filled with garbage from home heating systems and fireplaces and you've definitely had a lack of sunshine. You are probably feeling sluggish or a little "off" and your skin is dull. It's time to shake the cob webs out and turn on the lights.

I am not a fan of drastic cleansing and detox programs so they will not be addressed in this feature. If you are considering this route I recommend doing it gradually and under supervision of a specialist as it can be harsh and result in unpleasant side effects or even increase illness. Cleansing should never be done when you are weak or ill. You can get great results by changing your diet and taking spring tonic and cleansing herbs over the next couple of weeks which will make you look and feel like a million bucks. Some detoxification programs target specific areas such as excess phlegm, inflammation or nerves.

The liver is the major organ for detoxification. It's role is to remove toxins and chemicals from our system. It is also a key player in fat metabolism. Excess weight, digestive problems and general poor health can be caused by liver dysfunctions. Heavy "sticky" foods eaten in excess will increase impurity and toxin levels. Most of us increase these foods during the colder months leaving us sluggish and unhealthy by the end of winter. A simple liver flush done twice per year is easy without ill side effects.

Your herbal arsenal for liver cleansing is simple. They can be

purchased if not wildcrafted just about anywhere. They can be found and used in combination as well.

Herbal Suggestions:

[Milk Thistle](#) - inhibits liver damaging factors. Also has the ability to rebuild new liver cells for all ready damaged livers. Can also build a protective layer of cells so toxins can not enter.

[Dandelion](#) - Helps clear obstructions and stimulates the liver. Assists with toxin elimination through urine.

[Turmeric](#) - Cleanses and regenerates liver cells.

[Bupleurum](#) - Increases circulation to the liver.

[Burdock Root](#) - Stimulates liver and bile.

Red Clover - Blood purifier.

How To Make Super Sea Glow Recipe

from Shannon Winczura

A salt glow recipe contributed by reader Shannon Winczura.

Difficulty: Easy

Time Required: 40 - 60 min.

Here's How:

1. Arrange blankets on massage table with the electric blanket between the two flannel sheets.
2. Turn on the electric blanket to heat.
3. Mix the salt, vegetable oil and rose oil together.
4. Have the person lay on the blankets.
5. Apply the salt mixture to the skin.
6. Wrap the blankets around the individual and have them rest for 15 minutes.
7. After 15 minutes, have the individual shower to remove the salt and dead skin cells. Pat dry.
8. While the individual is in the shower, apply a clean sheet to the table and prepare the moisturizer.
9. Lightly massage a light moisturizer into the skin

Tips:

1. The skin will absorb moisture in the delicate state that it is in after all the skin will be very thirsty.

What You Need:

- 2 c. Sea / Mineral Salt

How To Make Indulging Sugar Scrub

From [Juli Kight](#),
Your Guide to [Healthy Herbs](#).

Forum Post by LINZEE1522. I just created this recipe for sugar scrub. Everyone who tried it loves it! You can use it at the sink or shower, for your hands or as a body exfoliator.

Difficulty: Easy

Time Required: 20 min.

Here's How:

1. Add dry ingredients and mix well.
2. Add oil and glycerin
3. Mix until wet, and ingredients stick together.
4. If its to crumbly, add a little more glycerin and fragrance.
5. Put in jar or plastic container. Enjoy!

Tips:

1. I like to add some yummy scented body cream, about 1/4 tsp.
2. I recommend that you apply some lotion after using this it will make you feel even more velvety!

What You Need:

- 3 T. Raw Sugar
- 2 T. White Sugar
- 2 T. Brown Sugar
- 3 T. Epsom Salt
- 1 T. Kosher (sea) Salt

How To Make Salt Glow Scrub

From [Juli Kight](#),
Your Guide to [Healthy Herbs](#).

A wonderful blend of sea salt and oils to exfoliate and smooth skin.

Difficulty: Easy

Time Required: 15 Min.

Here's How:

1. Mix all ingredients in a jar.
2. Seal jar when not in use.
3. Stir mixture well before applying.
4. Massage in circular motions towards the heart.
5. Leave on for a few minutes then rinse off.

Tips:

1. Do not use on face.
2. You can also use it with a body shampoo more for exfoliation.
3. Choose base oils such as sweet almond, kukuki nut, hazelnut etc. according to skin type.
4. Choose essential oils appropriate for intended purpose.
5. Do not rub over irritated or broken areas of the skin.

What You Need:

- 2 c. sea or mineral salt

- 1 c. vegetable oil/blend
- 15 drops essen. oil/blend

Grow Medicinal Herbs In Containers

From [Juli Kight](#),
Your Guide to [Healthy Herbs](#).

[Page 1 - Pro's and Con's of Container Gardens](#)

[Page 2 - Selecting Herbs](#)

[Page 3 - Planting Guide](#)

I like growing herbs in containers for several reasons.

You create changeable groupings.
Smaller plants are more visible and can compliment each other.
Growing conditions and exposure to pests can be more easily controlled.

They are closer to you where you can really appreciate them instead of being buried in the garden away from the living areas. You can be quite creative and have beautiful miniature living gardens full of color.

There are only a few disadvantages to having a container garden however, once it's growing it is well worth the effort. They are:

They need to be watered more as they dry out very fast.
May require additional feeding.
Large pots are heavy and require a dolly or two people to move.
You may be limited in what you can grow in reference to size, however, I like to push the limits and try many in containers.
If you are planning a roof-top, deck or porch garden, make sure you know your weight limitations. Containers full of wet soil

and plants can get extremely heavy. One gallon of water weighs 8.34 pounds.

The containers can be just about anything as long as they have a drain hole. Keep in mind that the more porous the container material is, the faster it will dry out. If it is moisture retentive or does not have adequate drainage, the roots will most likely rot. Interesting containers I have used where metal baskets and even plastic milk crates. I just simply lined them with plastic, filled it with potting soil then punched holes in it for drainage and the plant plugs. My favorites are ceramic and clay pots however they get very heavy to move so I use primarily light weight imitation clay pots for the large ones.

Butterfly And Hummingbird Herbs

From [Juli Kight](#),
Your Guide to [Healthy Herbs](#).

Create a healing space using herbs which attract butterflies and hummingbirds. This can be a space in your garden or a space created by a container herb garden. A few years ago while living in Minnesota I had been planting various and unusual herbs, roses and growing geraniums into standards. We had two warm seasons and had been seeing a lot of unusual life in the garden that I normally had not seen including hummingbirds. One early morning after putting the dog out, I stood on the porch among the plants and saw what I thought was a really unusual hummingbird. Then I noticed the antenna, and really had to look closer to make sure that is what I was seeing, and was captivated. Apparently we were being visited by some sort of hummingbird or Sphinx Moth and I have not seen one since. Now that I live in Central Texas and still very much a novice at this, I have noticed huge amounts of butterflies and moths as well as hummingbirds and have decided to add more plants to attract them.

Butterfly plants provide nectar for adult butterflies and food for the offspring. It is important to learn how to garden organically to make it a safe haven and supporting area for these little life forms. Many nectar plants are shared by both the butterfly and hummingbird. According to [Hummingbirds.net](#), hummingbirds lack the sense of smell and go by "visibility and nectar production". I had noticed they seem attracted to reds especially.

Find out which butterflies and moths are native to your area. You can do this by going to the [Butterflies Of North America](#) web site. This site offers distribution maps, butterfly and moth identification by region and information on the species. For hummingbirds visit Hummingbirds.net [Species list](#) by state.

For selecting plants for butterflies, visit the [Butterfly Website](#) which offers a list by species, then gives both nectar and host plant suggestions. Some easy herb selections include: Lavenders

The Fragrant Garden

A fragrant healing garden can do more for you than you think.

Many of us lead busy and complicated lives, forgetting the beauty of simplicities in life. A fragrant herb garden can calm, stimulate, heighten the senses, heal and add beauty and life to even the smallest of garden spaces. Fragrant herbs combined with other garden and wildflowers create what is sometimes referred to as a [sensory garden](#).

What is an aromatic herb? One which possesses a strong and usually pleasant odor. Not all will agree that all plant aroma's are pleasant, and one plant may not smell the same to different people. Some aromatic herbs will exude a heavy scent on their own, some are more mild and are activated by brushing by or running your hand lightly through it. Scents range from mild to pungent floral, citrus, spicy, fruity and blends. Let's not discount fragrant bedding plants, perennials, shrubs and trees either for this purpose. I believe any plant that is aromatic and pleasing to you has emotional and psychological healing properties.

Aromatic gardens are personal [healing spaces](#). The plants you select are pleasing to you whether it be for the scent, texture or visual effects. For example, I have just started my aromatic healing space for a small patio. Along with a varied fern selection to soften the area, I have added scented geraniums (rose and old spice), [rosemary](#) and various patio roses, all in containers. My plans are to add some basil and thyme, nutmeg and ginger scented geraniums, lavender and some [fragrant vines](#).

The more open your fragrance garden is, the lighter the scent will be if any especially on breezy days. Partially enclosed areas or areas behind wind breaks work well. You can create areas of quiet air using vines, trellises, shrubs and small trees. Add comfortable seating or a hammock, a wind chime, small fountain and you have a wonderful place to relax, rejuvenate and focus.

I personally like to purchase my plants first hand instead of on-line. Its fun to take a few hours and just smell the different varieties and see how they effect your mood, emotions etc. Only you know if you like the scent of that particular plant. If you purchase your chosen scent online, make sure you are getting the same plant variety you tested in person. For example, southernwood can smell like tangerines, or camphor depending on the variety. There are several types of rose geraniums such as Attar of Roses, Gray Lady Rose or Snowflake Rose, each with their own subtle differences which you may or may not like.

Below are links to help guide you in creating your fragrant healing garden with ideas, plants to use and plans.

FDA Issues Regulation Prohibiting Sale of Dietary Supplements Containing Ephedrine Alkaloids and Reiterates Its Advice That Consumers Stop Using These Products

The Food and Drug Administration (FDA) today issued a final rule prohibiting the sale of dietary supplements containing ephedrine alkaloids (ephedra) because such supplements present an unreasonable risk of illness or injury. The rule will become effective 60 days from the date of publication.

"This FDA rule reflects what the scientific evidence shows - that ephedra poses an unreasonable risk to those who use it," Health and Human Services Tommy G. Thompson said. "The regulations prohibit the sale of dietary supplements containing ephedra, and we intend to take swift action against anyone who puts consumers at risk by continuing to sell such products after the prohibition takes effect."

"In December, we advised consumers to stop using ephedra products, and we asked responsible companies to stop selling them," said FDA Commissioner Mark B. McClellan, M.D., Ph.D. "We intend to use this regulation to make sure consumers are protected by removing these risky products from the market."

Under the Dietary Supplement Health and Education Act (DSHEA) of 1994, FDA may remove a dietary supplement from the market if it presents a significant or unreasonable risk of illness or injury when used

according to its labeling or under ordinary conditions of use. FDA's final regulation presents a framework for applying this unique statutory standard.

To meet the standard required by the dietary supplement law, the FDA gathered and thoroughly reviewed evidence about ephedra's pharmacology; peer-reviewed scientific literature on ephedra's safety and effectiveness; adverse event reports; and a seminal report by the RAND Corporation, an independent scientific institute. The FDA also reviewed tens of thousands of public comments on the agency's request in March 2003 for information about ephedra-associated health risks.

In recent years, dietary supplements containing ephedrine alkaloids have been extensively promoted for aiding weight control and boosting sports performance and energy. The totality of the available data showed little evidence of ephedra's effectiveness except for modest, short-term weight loss without any clear health benefit, while confirming that the substance raises blood pressure and otherwise stresses the circulatory system. These effects are linked to significant adverse health outcomes, including heart attack and stroke. "Until the final rule prohibiting the sale of ephedra-containing dietary supplements takes effect, FDA reiterates its warning to consumers: 'Do not take these products. They are simply too risky,'" said Dr. McClellan.

Ephedra, also called Ma huang, is one of the plants that are a source of ephedrine alkaloids, including ephedrine and pseudoephedrine. When chemically synthesized, ephedrine and pseudoephedrine are regulated under the Federal Food, Drug, and Cosmetic Act as drugs. In contrast to the DSHEA-regulated dietary supplements that contain ephedrine alkaloids, the safety and effectiveness of drug products containing ephedrine alkaloids in drug products have to be proven by the manufacturer.

The issuance of this final rule continues a process that started in June, 1997 when FDA first issued a proposal that required a statement on dietary supplements containing ephedrine alkaloids warning that they are hazardous and should not be used for more than seven days. FDA also proposed to restrict the amount of ephedrine alkaloids in dietary supplements and to prevent combining ephedra with other ingredients that have a known stimulant effect.

FDA modified this proposed rule in 2000, and in February 2003 it announced a series of measures that included taking enforcement actions against firms making unsubstantiated claims regarding enhanced athletic performance for their ephedra-containing products. FDA also issued warning letters to firms promoting these products as alternatives to illicit street drugs. Many firms have complied with FDA's warning against making such claims. FDA has also followed up with seizures and injunctions and joint enforcement actions with the Federal Trade Commission and the Department of Justice. (More detail on these actions can be found at <http://www.fda.gov/ola/2003/dietarysupplements1028.html>.) As a result, most ephedra-containing dietary supplements advertised for enhanced sport performance have been removed from the market.

Additional information relating to ephedra is available online at www.cfsan.fda.gov/~dms/ds-ephed.html.

Guide Picks - Top 3 Essential Oils

If you are going to pay top dollar for essential oils, why not get the best? Here are my top picks for quality.

1) [Oshadhi Essential Oils](#)

By far my favorite oil for quality. I like the care and hand crafting from farm to store shelf that is practiced.

[Read Review](#)

[COMPARE PRICES](#)

2) [Aroma Terra Essential Oils](#)

My second favorite brand of essential oils. It is a top quality product using CO2 extraction. Cost is comparative to Oshadhi. Aroma Vera does not have the history or hand crafted quality that Oshadhi has. They do offer custom blending and a wonderful selection of personal products.

[Read Review](#)

[Manufacturer's Page](#)

3) [Frontier Natural Products Co-op](#)

Frontier does not manufacture their oil. They are a co-op so they purchase it from other oil producers and require quality standards. They also offer certified organic oils. The benefit of this is price. Oil prices are a little easier on the pocket book. Frontier oils are easily found in many health food stores. They also offer Aura Cacia brand essential oils.

- [How do I change my membername?](#)
- **Q. How do I contact the Guide of a site?**

A. To contact any Guide on our site, click on the Guide's name located on the top left corner of the particular site. You will then be brought to a page containing their e-mail address or other information that you can use for contact purposes.

[back to top](#)

- **Q. How do I unsubscribe from newsletters?**

A. To unsubscribe from any newsletter, a link is provided at the bottom of the newsletter itself, including instructions on how to be removed. You can also remove yourself from newsletters by visiting: <http://talk.about.com>

[back to top](#)

- **Q. How do I update my e-mail address on newsletters?**

A. To update your e-mail address on any About newsletter, you will need to unsubscribe the old address first, then resubscribe with the new address you wish to use. This can be done by following the instructions at the bottom of the last copy of the newsletter you received or directly from the GuideSite by clicking on Newsletter. You can also remove yourself from newsletters by visiting: <http://talk.about.com>

[back to top](#)

- **Q. How do I submit my website to About.com search?**

A. If you are interested in placing a link on our site, please e-mail the Guide directly. The Guide will then consider your link for inclusion. Please note that requesting a link does not guarantee a listing on any About site. For a complete listing of About Guide Sites, please visit: <http://a-zlist.about.com>.

[back to top](#)

- **Q. How can I get permission to reprint information/graphics from About.com?**

A. In order to get permission, you will need to contact the Guide of the particular site with the following information:

Name of publication or Web Site that wants to reprint.
Name of and complete contact info for individual to which license is being requested.
URL(s) of material on the Guide Site to be reprinted. (3) Max.

Please allow 3-4 business days for your information to be reviewed. Someone will then follow up with further instruction.

EPHEDRA BANNED TODAY

As of April 6, 2004, ephedra and supplements containing ephedrine alkaloids are banned and prohibited for sale in the United States. For more information see [FDA Issues Regulation Prohibiting Sale of Dietary Supplements Containing Ephedrine Alkaloids and Reiterates Its Advice That Consumers Stop Using These Products](#). At this time it does not

ban Chinese herbal remedies or tea which are regulated as food.

Hayfever

From [Juli Kight](#),
Your Guide to [Healthy Herbs](#).

Hayfever

Definition: The acute seasonal form of allergic (pollens (weed, tree, grass etc.)) rhinitis, recognized by sneezing, nasal discharge, nasal obstruction, itching/tearing eyes, and pruritus. Can be present anytime plants are pollinating. Food sensitivities seem to be a contributing factor [1].

Most places in the United States get a break from pollen assaults during the winter months. Here in Central Texas, we are plagued with [Mountain Cedar Allergies](#) which pollinates November through March. Cedar allergies not only carry the classic hayfever symptoms, but can also manifest downright flu symptoms such as sore throat and ears, facial discomfort and lethargy.

Help For Hayfever Sufferers:

Select herbs with the following actions:

Anti-inflammatory, [anti-catarrhals](#), expectorants, anti-spasmodics, astringents, bitters, [adaptogens](#) and anti-histamines.

Herb Suggestions:

[Urtica \(Stinging nettle\)](#)

[Euphrasia officinale](#) (Eyebright)

[Plantago \(Plantain\)](#)

[Solidago virgaurea](#) (Golden rod)

Quercetin (derived from [Sophora Japonicas](#)) - Anti-inflammatory, inhibits histamine release.

Aralia racemosa - American Spikenard
Gnaphalium uliginosum (Cudweed) - British Herbal Pharmacopoeia
Hydrastis canadensis (Goldenseal)
Ephedra

Homeopathic Suggestions:

Luffa operculata (Spurge cucumber)
Allium Cepa (red onion) - Burning of the nose, watery red eyes, throat inflammation.
Apis (honey bee) - Facial redness and swelling, burning eyelids.
Arsen Alb - Burning eyes and tears, relentless sneezing, restlessness.
Natrum Muriaticum (sodium chloride) - Dry red eyes.
Pulsatilla (wind flower) - Eye and lid inflammation, itching and burning, thick discharge
Ambrosia - Itchy eyes, sneezing, dull mind.
Nux vomica - Headache, stuffed up with nasal drip, sneezing, irritability.

Other Supporting Suggestions:

Use [essential oils for respiratory symptoms](#) in conjunction with other aids.
Vitamin C - A powerful anti-histamine, helps eliminate histamines from the body.
Zinc - Inhibits histamine activity.
Diet - Reduce dairy and meat intake.

Selecting Herbs For Itchy Skin

From [Juli Kight](#),
Your Guide to [Healthy Herbs](#).

Selecting herbs and essential oils for itchy skin should include both external and internal approaches.

Most itchy skin is an allergic reaction to either an external contaminant or a food reaction (see [Itchy Skin](#) for types of dermatitis.)

Here are some herbs to consider taking:

Alteratives-The "blood cleansers". -

These herbs work slower by cleansing the blood of toxins and should be used long term. They work gradually to "alter" existing conditions which could be aggravating your skin conditions. (See [Alterative Herbs](#).)

Adaptogens-The "stress defenders". -

Stress can definitely aggravate skin conditions. These herbs help your body deal with on-coming environmental, emotional and physical stresses your body encounters on a daily basis. They are also used long term with gentle actions. (See [Adaptogenic Herbs](#).)

For itch relief- Use anti-itch herbs and essential oils as well as anti-inflammatories.

Aloe gel - Can be used as a base for combinations.

Witch hazel

“Adaptogens”

Glossary

From [Juli Kight](#),
Your Guide to [Healthy Herbs](#).

Definition: [Adaptogenic herbs](#) help you adapt to changes in life, environment and may increase stamina and sports performance. They are gaining ground as treatments for stress and fatigue. An important mediator of the stress system.

Consist of two main chemical groups: Terpenoids and aromatic compounds.

In order for an herb to be classed as an adaptogen:

1. It must cause only minimal disorders in the body's physiological functions
2. Must increase body's resistance to adverse influences
3. Must have an overall normalizing effect, improving all kinds of conditions and aggravating none.

These originally were set during Lazarevs studies of a chemical substance called dibazole. His student I.I. Brekhman changed the focus to natural substances.

Adaptogens are split into two categories, primary and secondary. Primary are the well known most studied herbs such as eleuthero, schizandra and reishi. Secondary show some normalizing effects, but have not been studied as much or support the adrenal system.

References

[Adaptogens](#) - Earlier and more recent aspects and concepts on their mode of action (very scientific and detailed).

Also Known As: Whole body tonics

Lycopene

Phytochemical

From [Juli Kight](#),
Your Guide to [Healthy Herbs](#).

Description:

Lycopene has been found to be the most powerful antioxidant of the dietary [carotenoids](#). It is basically responsible for the red coloring in some fruit such as tomatoes. It is believed to protect against several cancers, macular degeneration, heart disease and much more (see resources below).

Sources:

What are the best sources? Surprisingly, processed tomato products. Processed products provide a better availability of lycopene to the body which is increased when heated and consumed with oil. If you can not eat tomato products, lycopene can also be found naturally in pink grapefruit, guava, papaya and apricots. Lycopene supplements are also available.

Lycopenes have also been discovered in rosehips [3].

Studies:

Tomato paste has the best absorbency rate of lycopenes into the blood system, nearly four times as much as fresh tomatoes. [1]

Tomato juice contains 50 percent more lycopenes than paste in equivalent weight portions and at least three times more lycopene per gram of edible product than a slice of tomato. The juice was found to be poor in contributing to the blood concentration unless consumed with oil. [1]

Lycopene Content [2], [3] :

Tomato paste - 42.2 mg/100 g

Spaghetti Sauce - 21.9 mg/100 g

Chili Sauce - 19.5 mg/100 g

Ketchup - 15.9 mg/100 g

“Polysaccharides”

Glossary

From [Juli Kight](#),
Your Guide to [Healthy Herbs](#).

Definition: The form in which most natural carbohydrates occur. Starch, glycogen, and cellulose. Non-digestible polysaccharides - Dietary fiber. May lower risk of diseases of the colon. Attenuate blood glucose and insulin levels. Reduces the risk of Type 2 diabetes. Lowers risk of coronary heart disease.

Actions can include:

[Adaptogenic](#)
Immunomodulator
Demulcent
Emollient
Sweetener
Vulnerary
Expectorant
Hypoglycemic

It is believed that the protein bound polysaccharides are responsible for the immunomodulating and anti-cancer activities of medicinal mushrooms.

References

Maitake (Grifola frondosa)

Herb - Mushroom

From [Juli Kight](#),
Your Guide to [Healthy Herbs](#).

Overview: The Maitake mushroom is a highly regarded Japanese mushroom in both the culinary and medicinal world. Wild Maitake have been over harvested in Japan however it can be found in Northern temperate forests of Europe, North America and parts of Asia. Maitakes [unusual appearance](#) resembles a hens tail.

Actions And Properties [1], [2], [3]:

Adaptogen

Tonic

Anti-cancer

Total cholesterol lowering

Reduces tryglyceride levels

Lowers arterial blood pressure

Immunomodulator

Anti - HIV

Anti-hypertension

Anti-obesity

Liver damage - prevention and recovery

Constituents:

Beta-glucan [polysaccharides](#) - These are the most important constituents being researched. They are unique and differ than other mushroom beta-glucans [3].

Uses:

The main focus of maitake today is on it's anti-cancer and immune system capabilities. The best results in cancer studies are shown against breast, lung and liver cancers. It is also used to balance blood cholesterol, sugars and pressure. One promising study showed maitake improved T-cell activity and killed AIDS however much more research needs to be conducted.

Warnings / Safety:

Since Maitake effects blood pressure in animals, persons using medications for diabetes and blood pressure should consult with their physician first. No other warnings have been found at the time of this

RSS

What is RSS?

Rich Site Summary (or Really Simple Syndication) is an XML-based format for content distribution. Below, About.com is offering an RSS and JavaScript feed with headlines, descriptions and links back to this GuideSite for the full story. This allows you to easily feature or check out the latest headlines from About.

There are two main ways to take advantage of these feeds.

First, you can use them to feature the latest headlines from About on your Web site. All you have to do is paste a short snippet of JavaScript into the code of your page. Here's how:

A) Simple Version:

1. Cut and paste the following lines of JavaScript into your html page.
2. Optional: You can control the number of links that are displayed on your site by changing the number shown here:
<script>ShowHeadlines(10)</script>

```
<script language="JavaScript" src="http://z.about.com/6/js/b.txt?s=healthyherbs"></script>  
<script>ShowHeadlines(10)</script>
```

B) Advanced Version:

For people who want to write their own display html using JavaScript

1. Cut and paste the following block of JavaScript into your html page.
2. Write/Modify the ShowHeadlines Function to customize your display of the data.

```
<script language="JavaScript" src="http://z.about.com/6/js/b.txt?s=healthyherbs"></script>  
<script>  
function Items(t,u,d){while(d.indexOf("\")!=-1){d=d.replace("\", "");}  
document.writeln('<a href="'+u+'" title="'+d+'>'+t+'</a><br>')  
function ShowHeadlines(c){  
var i=0; //counter  
var l=this.zIBlgI.length-1; //length of the item array  
c=(c)?(c*3)-1:29; //calculate how many links to display[default 10]  
if(c&&l>c)l=c; //make sure items to display is less than number of items  
  
var h;  
h=('<a href="http://about.com">')  
h=('</a><br>')
```

[Home](#)

```

- [Skin - Dermatitis](#)
- [What's Hot Now](#)
- [Herbal Encyclopedia A to Z Spring Cleansing](#)

That takes care of easily displaying these feeds on your Web site.

Next, let's move onto another use of RSS, and that's news aggregation.

Using one of the many popular news aggregators (see below for links), you can have the latest headlines from this GuideSite (or any other site with an RSS feed) delivered directly to your desktop. This makes checking out your favorite sites quick and easy.

Name	RDF location	RSS location	Description
Healthy Herbs			Most recent Healthy Herbs Headlines

If you're interested in reading more on RSS, try [What is RSS and How Do You Use It?](#) or [Sharing Your Site with RSS](#) or the [RSS specification](#). About.com is currently using the RSS .91 format.

[Feedster](#) and [Syndic8.com](#) have a large directory of available feeds. There are many newsreader applications which use RSS files. Here are some popular ones:

-  My Yahoo!
- [NewsGator](#) Microsoft Outlook
- [Headline Viewer](#) Windows
- [NetNewsWire](#) MacOS X
- [Amphetadesk](#) Windows, MacOS X and earlier, Linux
- [Bloglines](#) Web-based
- [Radio Userland](#) Windows, MacOS X and earlier (newsreader is part of software)
- and [others](#)

If you decide to syndicate any About sites, we'd appreciate attribution to About.com, either as text ("from About.com") or with this [85 x 31 graphic](#). These feeds are free to use, but we ask that you do not publish the full text of our articles. Please click on the orange XML button above to get the corresponding feed.

Horny Goat Weed - Epimedium sagittatum

From [Juli Kight](#),
Your Guide to [Healthy Herbs](#).

The mechanism of how horny goat weed works for increasing sexual desire is still unknown at the time of this writing. It is believed that horny goat weed may be able to restore levels of testosterone and thyroid hormones. The herb has been traditionally used for liver and kidney tonification as well as sexual dysfunction. It has improved the life of chronic renal failure patients in a Chinese study. It is found in formulas for psychological and physical impotence.

Common Name - Horny Goat Weed

Scientific / Latin Name - Epimedium Sagittatum

Pin Yin Name - Yin Yang Huo

Parts Used - aerial parts harvested in spring and autumn.

Actions and Uses - Libido enhancement, anti-fatigue, adaptogen,

Thermal Qualities - Warm

Taste - Pungent, sweet

Chinese Uses - Yang tonic for yang deficiency

Itchy Skin

From [Juli Kight](#),
Your Guide to [Healthy Herbs](#).

If you are like me, the summer season can bring out a malady of itchy skin problems ranging from contact dermatitis to allergic reactions and poison ivy. Many times the heat, sun and sweat of summer can aggravate conditions. Dermatitis means skin inflammation and there are several types which encompass a wide range of ailments.

Types of Dermatitis

Contact Dermatitis - Caused by exposure to an irritant which results in mild rash which may or may not itch limited to an area of skin. The most common dermatitis which is normally a mild allergic reaction to plants, fruits, vegetables, cosmetic ingredients, detergents, fabric chemicals and some soaps.

Atopic (eczema) Dermatitis - Chronic itching, scaling, swelling or blistering of the skin. It tends to be genetic and can be caused by allergies, asthma and stress.

Nummular Dermatitis - Common in people 55 or older who live in dry environments, take very hot showers or have dry skin. Red itchy patches of weeping, scaling or encrusted skin. This condition can be aggravated by stress.

Seborrheic Dermatitis - Usually on the scalp and other hairy parts of the body as well as the face and genitals. Yellowish or reddish greasy scaling associated with over production or blockage of the oil glands. It can be aggravated by stress.

Stasis Dermatitis - Skin irritation and unhealthy growth around ankles which is caused by poor circulation.

Page 2 discusses the first step of relieving the discomfort and itching. Page 3 will be added next week focusing deeper on the root causes and prevention of reoccurrences.

Movable Type 3.0 Beta Testing
04.17.2004

We'll be starting the Movable Type 3.0 public beta test next week, the week of April 19. It's taken longer to get to this public beta because we made the decision to extend the alpha process to catch as many bugs as possible before introducing MT3b to the general public.

The alpha testing started about one month ago on March 17, 2004. As anticipated, the alpha uncovered a number of issues that are now fixed, and we thank our alpha testers for their hard work in testing out the software.

If you had applied to be part of the alpha and we missed you, we apologize. As a result of the kinks we encountered during the alpha tester selection process, we've made improvements to the way we'll be handling notifications and tester involvement.

We now have the opportunity to let a larger number of testers in for a beta phase of testing, to test out more platforms and configurations. In addition to the larger number of testers, for the beta we'll be removing the restriction that the software must be installed on a non-public site.

The beta will be run in phases, so as not to introduce any beta-level bugs into a wide audience of people at one time. This means that we will gradually increase the number of people participating each day. All who

submit a completed survey will be allowed to participate in the survey (assuming they provide us with an valid email address). If you don't receive email inviting you to the beta right away, don't worry--you'll be included in the later phases.

Once you're introduced into the beta testing, you will receive an email message notifying you where to download the distribution of Movable Type 3.0b1.

You'll then be able to install the software, provided that you agree to the beta testing license.

We will ask that you report any bugs that you may discover to us using our bug reporting software.

The beta for Movable Type 3.0 will begin during the week of April 19, 2004.

If you'd like to participate, please [fill out this questionnaire to sign-up for beta testing](#).

More TypeKey Information
03.19.2004

Today, [we've released more information about TypeKey](#), which should serve to answer some of the initial questions potential users may have.

While designed first with comment registration in mind, TypeKey will not be limited to usage in Six Apart products. For developers, we plan to offer documentation on integrating TypeKey authentication into your own applications shortly after the service launches.

Look for more information about TypeKey in the coming weeks at [typekey.com](#).

Posted by Mena at 04:31 PM | [Permalink](#)

Testing Begins & More Info about 3.0
03.16.2004

We're taking our first steps towards the release of Movable Type 3.0. The pre-beta version has just finished its initial two rounds of alpha testing and we're now opening the testing to a larger audience (we've picked 300 random addresses from those who

applied and will be adding more as time progresses).

The testing that we're conducting will not only help ensure a stable final release but will also give us an opportunity to receive feedback on feature implementation from both users and developers.

Starting today, we'll be giving all of our users much more information on what to expect in Movable Type 3.0.

The official 3.0 release will contain a significant change to the existing interface that embraces web standards, usability and localization. This will also be reflected in a new set of default templates that will implement more of the best practices that both Movable Type and TypePad have become known for.

With a suite of comment management features and versatile comment registration--utilizing a centralized authentication service we're calling TypeKey--Movable Type 3.0 will give you more control than ever before over the public face of your website. We've spent a lot of time planning a comment registration system that will fit the needs of different types of webloggers, and we have focused our attention on a system that will encourage registration and *open* communication.

In addition to providing authentication for comment registration, TypeKey's open nature will enable developers to build applications upon the infrastructure, utilizing its authentication hooks. Since TypeKey and comment registration are such a significant addition to Movable Type 3.0, we'll be going into more detail about these features later this week.

In addition, our support for the Atom API and syndication feeds will allow Movable Type users to utilize the richer content model offered by the new format, including the use of clients that communicate through the API.

And for developers who like to get under the hood, we've added many new hooks into the application, allowing plugins more control over data, configuration, and user interface.

COMING UP:

If you haven't been added to the testing list yet, don't worry. We've got lots of you who we want to add to the list once the initial bugs have been worked out, so we can get your valuable feedback without being distracted by minor issues. If you submitted the contact form requesting to be on the beta, keep an eye on your mailbox over the next few weeks.

And stay tuned over the coming days, as we outline some of the other major new areas of improvement in Movable Type 3.0. With the help of our dedicated testers, we're hoping to make this our best version of Movable Type ever.

Posted by Mena at 12:17 AM | [Permalink](#)

Alpha Testing to Begin Soon
01.30.2004

We're starting to coordinate our round of alpha testing for Movable Type 3.0 that will occur prior to the public beta. If you're a Movable Type authority, plugin developer, web standards advocate or just a Movable Type user with an active commenting community and want to be involved in this round, please drop us a line using the Movable Type contact form.

In this message, please let us know:

1. What version will you be upgrading from?
2. How many total comments are in your installation? (per weblog)
3. Will you enable comment registration? If no, why not?
4. The URL for your weblog(s)

If you're not comfortable installing alpha software, you may want to wait for the public beta. Our schedule calls for alpha testing to begin in the next two weeks.

Thanks as always for your interest in Movable Type!

Posted by Mena at 09:20 PM | [Permalink](#)

Version 2.66 Released
01.14.2004

In recent weeks, open comment systems, and Movable Type weblogs in particular, have become a target for comment spam and comment flooding (automated scripts that send many comments at a time to a weblog entry).

As a stopgap before we release comment registration in Movable Type 3.0, we've released version 2.66 of Movable Type, which includes some protection against comment flooding. We've included a throttling measure so that comments from the same IP address can only be posted every N seconds, where N is configurable ([documentation on the setting that controls N](#)). We've also added a measure to automatically ban an IP address based on an abnormal number of comments from the same address in a short period of time. Of course, there are no perfect defenses, and if you're truly concerned about the comments on your weblog, the best defense is prevention by closing old comment threads.

Also in 2.66, we've changed the behavior of `<$MTCCommentAuthorLink$>` to use [redirects when linking to URLs given in comments](#). The goal of this is to defeat the PageRank boost given to spammers by posting in the comments on a weblog.

You can download the 2.66 upgrade from the [download page](#) and follow the [standard upgrade instructions](#).

Update: We've released 2.661, an update to 2.66, to fix a problem with invalid XHTML in the comment redirect script, along with using comment IDs instead of URLs to fix an open redirect problem.

Good Sites for MT Junkies
12.27.2003

Those of you who are hardcore Movable Type users and can't get enough news, tips, and tricks for your blog might want to check out the [Resources and Newsfeeds](#) page from the invaluable [Movable Type Plugin Directory](#). Listing dozens of sites that track the latest developments in the community, along with many individuals who are creating new plugins and

discovering new ideas, there's plenty of inspiration for your own experimentation with Movable Type.

Posted by anildash at 11:02 PM | [Permalink](#)

Movable Type 3.0

12.22.2003

We realize that official news has been scarce over the last 6-9 months. During this time, our company has grown from two people to seven, and we have launched [TypePad](#). Now that we have hired more engineering resources (and we are still [looking for more](#)), we are able to focus again on our Movable Type product line. As mentioned in [this post on the Six Log](#), we're focusing on releasing more personal features in the basic Movable Type package, and concentrating features for businesses, organizations, and large content-driven sites into Movable Type Pro (which, needless to say, has been delayed).

The next version of Movable Type will be version 3.0, a significant and free upgrade. Many oft-requested features will be integrated into this release, including:

- Comment registration. As a response to both comment spam and to the increased usage of Movable Type on large community sites, we'll be adding the option to restrict comments to registered users.
- Improved comment and TrackBack management features.
- New API hooks for plugin developers. Plugins will now be able to hook into many more pieces of Movable Type, including adding callbacks for saving and removing objects, building application methods with integration into the UI, and hooking into the publishing process. This opens up possibilities for plugins to add even more advanced functionality than they're able to do now.
- User interface rebuilt using CSS. We've seen with TypePad that a CSS-based interface gives users very fast application response times, and gives us a flexible interface for making application-wide changes, and we want to give

this same speed and flexibility to Movable Type users.

- Support for the Atom API. We've already added Atom syndication feed support in version 2.65 of Movable Type, and we'll be adding publishing support for the API in 3.0.

In addition to the above, we'll be integrating some features into 3.0 that we're not yet ready to announce, but which we know will be very exciting to MT users. Additionally, for those interested in posting from mobile devices, we expect this to be a welcome release.

Movable Type 3.0 will be a free download and upgrade. We have full-time engineering resources devoted to this new version, and we plan to have a beta release in early Q1 of 2004.

[Our Story](#)

Our Story

Welcome to About, the Human Internet, where real people help you get whatever you want from the Web.

Each site in our unique network is run by a professional Guide who is carefully screened and trained by About. Guides build a comprehensive environment around each of their specific topics, including the best new content, relevant links, How-To's, Forums, and answers to just about any question.

The insight and perspective that our Guides bring to each area of interest is what makes the About experience much more enjoyable and interactive than other destinations.

The About network consists of hundreds of Guide sites neatly organized into 23 channels. The sites cover more than 50,000 subjects with over 1 million links to the best resources on the Net and the fastest-growing archive of high quality original content. Topics range from pregnancy to cars, palm pilots to painting, weight loss to video game strategies. No one has greater depth and breadth than About.

A Brief History

In February of 1997, Scott Kurnit and a dedicated team launched The Mining Company, the first information network to integrate the Internet's most productive agent - people. The company quickly grew in size and scale and in 1999 the company was renamed About, to reflect its breadth of content, services and ease of use. Today, About is visited by one in five online users each month, making it one of the most popular destinations on the Net.

Who are the About Guides?

The Guides are the heart and soul of our business.

Coming from all different backgrounds and from all over the world, our Guides know their subjects as well as anyone. Together they have gathered and created hundreds of thousands of pages of content to share with users. Whether they're providing insight and guidance, initiating discussions, moderating chats or writing articles, it is their knowledge, commitment and passion that enable About to provide our millions of regular users with the most human online experience.

About Guides live and work in over 20 countries and celebrate their interests in hundreds of topics. Guides are selected for their ability to provide the most interesting information for users, their commitment to finding the best sites, and for their passion for their subject and the Net.

Overview

Are you ready to become an online leader of a community of people who share your interests? Apply to become an About Guide!

About Guides are fully empowered to do all of these things. Each Guide's mission is to create an easy, intuitive and gratifying experience for people interested in their topic.

Each Guide is carefully screened and trained by About. All Guides must successfully complete the About training program and maintain our high standards in user services and community leadership. Guides write original informative articles, provide the Web's best links for their topics, and give their readers what they need to know. This relationship between Guides and users makes About a dynamic service that truly responds to the needs of anyone who visits.

We ask our Guides to be opinion leaders, sharing your perspective and insight into the topic. What do your users need to know? How can you help them avoid the pitfalls of researching information and purchasing products online?

Our Guides are real people - just like you. They include professionals, educators, students and stay-at-home moms. Our Guides are as diverse as the sites we offer. We believe that one of the key components of our success is the fact that each Guide is a person, as well as an online expert. See for yourself -- every site has a photo of the Guide and a bio.

As diverse as they are, Guides do share a few characteristics:

- A true knowledge of and a passion for their topic
- Commitment to creating informative, "what you need to know" features
- A dedication to building and updating a comprehensive links directory
- The ability to bring their site to life
- Strong writing and editing

development strategy and managing the size and quality of an online audience

- Demonstrated ability to increase online traffic, along with knowledge of techniques for driving traffic to specific parts of a site
- Solid understanding of advertising and direct marketing, including Customer Relationship Management.
- Hands-on experience with direct response emails campaigns (privacy statements, email marketing campaigns, etc.)
- Ability to accurately project the cost of audience development efforts
- Excellent analytical and communication skills both verbal and written
- College degree with relevant course work

Ad Operations Positions

About.com is actively seeking an assertive self-starter who is able to handle multiple tasks to fill the position as Traffic Manager in our online advertising sales group working in our NYC headquarters. This hire will be responsible for reviewing banner ad submissions for adherence to technical specifications, booking into our Adserver and managing campaign progress.

Specific Responsibilities will include:

- Manage insertion order implementation post-sale.
- QA creative submissions.
- Insert and update creative in DART.
- Manage campaign progress.
- Assist Account Executives with traffic questions.
- Reconcile campaigns across Ad Delivery and Back Office systems.

Required qualifications:

- Minimum of two years online ad trafficking experience - knowledge of DART strongly preferred.
- Solid skills in Microsoft Excel and HTML.
- Demonstrated Customer Service experience.
- Incredible attention to detail.
- Ability and willingness to learn new skills quickly.
- Experience with most major rich media.

ABOUT ONLINE PRIVACY POLICY

About is strongly committed to protecting your privacy and providing a safe online experience for all our users. This Privacy Policy applies to information collected online through About's Web site, which includes all of the About.com Guide-Sites and governs online data collection and usage by About. Please read the complete About Online Privacy Policy below and contact us if you have any questions.

COLLECTION AND TRACKING OF PERSONAL INFORMATION

So that we can provide you with the most efficient and enhanced service, we request information about you. We collect personally identifiable information such as names, email addresses and demographic information such as age, gender and zip code. We also may collect your [IP address](#), browser type, domain name, access times and referring Web site address. This information is collected both during registration on a site or in response to specific requests, for example when signing up for a newsletter, entering a sweepstakes or contest or answering a survey. Information collected at one About Web site will be available within the About family of Web sites.

Sometimes we will give you the opportunity to opt in to offers from third parties not affiliated with About. If you decide to accept these offers, we will provide, with your consent, your information to the third party. However, you should note that this Privacy Policy does not apply to information users consent to give to third parties not affiliated with About. Any information users give to another party is governed by the rules of that party's privacy policy, which may differ from this Privacy Policy. About is not responsible for information given to other parties. Please review their privacy policies prior to providing any information to third parties

WHAT WE DO WITH COLLECTED INFORMATION

We use personal information so that we may display custom, personalized content to our visitors and send newsletters, emails, features, promotional material, surveys and other updates to our users. A user may, at any time, opt out of receiving such information. We also use

collected information to evaluate and administer our service, respond to any problems that may arise and to gauge user trends to determine what part of our services are most popular with users.

We may extend offers to users on behalf of our partners about a particular product or service that may be of interest to you, but we will never give out your name or personal information at any time without your permission. As result, although About may receive a fee from our partners for this service, About sends all the offers so that your personal information is never shared with any outside third party.

We may, at times, produce reports for advertisers containing aggregate information about our users such as demographic, age and online usage information. This allows us to work more closely with advertisers to provide content and offers that are most relevant to our users. We will never include any personal information of our users in these reports.

We allow users of our Web site to send articles or links by email to other parties who may be interested in them. We do not retain any email addresses (unless you are a member who already has voluntarily provided your email address) of either the sender or recipient of such articles or links after they are sent.

We reserve the right to use or disclose any information without notice or consent as needed to satisfy any law, regulation or legal request; to conduct investigations of consumer complaints or possible breaches of law; to protect the integrity of our site and our property; to protect the safety of our visitors or others; to fulfill your requests; or to cooperate in any legal investigation.

You should be aware that if you voluntarily disclose information online (whether through About's services or any other service available online), personal or otherwise, that information can be collected and used by others. For example, if you use chat, forums, bulletin boards, your e-mail or if you post personal information online, you may receive unsolicited messages from others. About has no control over this use of your personal information.

USE OF COOKIES

Your browser offers so-called "cookies" which, if you allow their use, store small amounts of data on your computer when you visit a Web site. Cookies do not contain any personally identifiable information about you and therefore cannot be used to identify you personally. Cookies simply assist us in tracking which of our features you like best. Cookies also enable us to customize our content according to your preferences. You have the ability to accept or decline cookies by modifying your browser and our Web sites are viewable even if you disable the cookie function on your browser. However, if you disable cookies, some advanced and customized features of our site, as well as other Web sites, will not be available to you.

Some of the banner ads displayed in our Web sites are provided by outside companies. These ads contain cookies. While we use cookies in other parts of our Web

sites, cookies received with banner ads are collected by our advertisers and we do not have access to this information. We use a reputable third party to serve some or all of the advertisements that are placed within our sites and they may use information (not including personally identifiable information) about your visits to our sites and other sites to assist in serving advertisements to you. If you would like to know more about the information gathering practices and 'opt-out' procedures of our third party ad server, please see <http://www.doubleclick.net/us/corporate/privacy>.

USE OF WEB BEACONS

Some of our Web pages may contain electronic images known as Web beacons, which are also called single-pixel gifs. These images allow us to count users who have visited those pages and to deliver co-branded services. We also may include Web beacons in promotional e-mail messages or newsletters in order to count how many messages have been opened and acted upon. Web beacons are not used to access your personally identifiable information but they are a technique we use to compile aggregated statistics about our Web site usage. Web beacons collect only a limited set of information including a cookie number, time and date of a page view and a description of the page on which the Web beacon resides. Some of our Web pages may also contain Web beacons placed there by our advertising partners to help us determine the effectiveness of our advertising campaigns.

CONTROLLING YOUR PERSONAL INFORMATION

A user may, at any time, change, correct, modify or delete any personal information they may have provided to About by visiting the Member Center located on the About homepage. Users can also unsubscribe from any newsletters or opt out of various promotional emailings at any time by visiting the Newsletters section in the Member Center or clicking on "unsubscribe" links in each of our newsletters or emails.

SECURITY OF YOUR PERSONAL INFORMATION

All About employees are made aware of its privacy practices through periodic communications and training. We limit access to private and confidential data only to those employees with a specific need to retrieve this information and we store data on multiple service systems, in controlled, secure environments. To maintain the highest level of security, we conduct internal reviews of our security measures on a regular basis.

CHILDREN'S PRIVACY

Some portions of the About Web site may be used by children under the age of 13. About is strongly committed to protecting the safety and privacy of children who visit our Web site.

About has a system in place to effectively screen its users to ensure compliance with this Privacy Policy and the Children's Online Privacy Protection Act of 1998 (COPPA). COPPA and its accompanying regulations establish United States federal law that protects the

[Spring Cleansing](#)

privacy of children using the Internet.

Our site and services may collect information about children under 13, including e-mail forum participation and chat rooms. Use of such activities requires initial registration by the participant. Children under 13 who wish to register are asked to have a parent or legal guardian do so for them. The parent must provide a credit card number for verification that he/she is an adult. Upon verification, the parent can choose in which activities he or she would like the child to participate. Parents can change the selected activities at any time.

Only after verifying age, do we collect and maintain the name, date of birth and email address of children who register. With proper proof of identification (including name and credit card verification), parents can review their child's personal information, ask to have it deleted and refuse to allow any further collection or use of their child's information.

We use cookies to check the age of registered users who enter chat rooms. We do not permit users under 13 into chat rooms unless their parents have consented to their participation.

About.com includes many topical areas that all users may access. When a parent provides verifiable consent to allow his or her child to use chat and forums and to receive newsletters or other materials where a child may provide personally identifiable information, the child will also have access to those relevant services throughout the About site, including areas that may not be directed toward children. In particular, if you allow your child to participate in chat or forums, your child will have access to all chat and forum areas on About.com. Many chat areas are not monitored and private chat is permitted. Chat areas may contain information or language unsuitable for young children and visitors of all ages may participate. If you authorize your child to participate in these features, we encourage you to monitor their use closely. We also allow guests to participate in chat and forum areas at About.com but use techniques to prevent unregistered children under 13 from participating in areas unsuitable for them. Parents can change these options at any time.

Except as authorized under COPPA, About.com will NOT:

- collect online contact information from a user under 13 without prior verifiable parental consent, which includes an opportunity for the parent to prevent use of the information and participation in the activity. When we do not obtain prior verifiable parental consent, online contact information will be used only to directly respond to the child's request and will not be used to contact the child for other purposes.
- collect personally identifiable offline contact information from users under 13 without prior verifiable parental consent.
- distribute to third parties any personally identifiable information collected from children known to be under 13.
- give the ability to children to participate in forums

or chat rooms without prior verifiable parental consent.

- entice a child under 13 by the prospect of a special game, prize or other activity, to divulge more information than is needed to participate in such activity.

We will also place prominent notice wherever personally identifiable information is collected requesting the child to ask a parent for permission to proceed.

If you have any questions regarding the privacy and safety of children on our site, please visit us at <http://home.about.com/gi/pages/pform.htm>.

CHANGES IN CORPORATE STRUCTURE

In developing our business, we might sell certain assets or the company, or parts of it, may be sold, merged or otherwise transferred. In such transactions, user information, whether personally identifiable or otherwise, may be one of the transferred assets.

INDEX

18. ALSIKE CLOVER

Trifolium hybridum

(pea family)

TOXICITY RATING: Low.

ANIMALS AFFECTED: All grazing animal may be affected.

DANGEROUS PARTS OF PLANT: All green parts (when dewy).

CLASS OF SIGNS: Gastrointestinal irritation, photodermatitis (sunburn or sunscald).

PLANT DESCRIPTION: These perennial legumes (fig. 18) are commonly grown for pasture or hay and may be found as escapes in fields, roadsides, and waste areas. They have the familiar three-parted clover leaf. The flowers are axillary, not terminal as in red clover, and are pink to white in a clover head.

SIGNS: This is not a commonly reported toxicity, and is usually not serious even if toxicity occurs. It is unknown if the wet clover causes problems by contact or ingestion. The typical signs associated with alsike clover are gastrointestinal distress, including mild colic and diarrhea. Photodermatitis ("sunburn") is also possible, especially on the parts of the body that contact the wet grass (lower legs, mouth). Liver damage has been suggested, but not well-verified. This syndrome, which can be caused by plants in addition to alsike, is sometimes called "dew poisoning" or "trifoliosis".

In rare cases, the sunburn may spread to the entire body, especially in lightly pigmented areas. Newly shorn sheep may be particularly at risk. Large amounts of alsike must be consumed before serious body-wide sunscald develops.

FIRST AID: Remove the animals from the pastures especially in the early morning when the

plants are dew-covered. Animals severely affected by sunscald need to be kept out of the sun until recovered (turn them out at night). Care for gastrointestinal and sunburned areas symptomatically. Call a veterinarian if signs are severe or if the animal does not recover in a day or two.

SAFETY IN PREPARED FEEDS: Alsike clover is safe when dry, therefore prepared feeds containing alsike is safe for consumption.

PREVENTION: Keep sensitive animals off alsike pastures in the early morning or during wet weather. Provide other feed if animals are consuming large quantities of the clover and if they are showing clinical signs. Keeping the pastures mowed will lessen the effects of the toxicity for sensitive animals.

NOTE: Red clover (*Trifolium pratense*, pea family), buckwheat (*Fagopyrum esculentum*, dock family), and alfalfa (*Medicago sativa*, pea family) can sometimes cause similar poisoning. However, white clover (*Trifolium repens*, pea family) poisoning, when it occurs, causes cyanotic or estrogenic (hormone) symptoms, especially in swine. All of these plants sometimes cause bloating, especially when the animals are put out in lush growth that they are not accustomed to eating.

INDEX

10. AZALEA, RHODODENDRON

(*Rhododendron* spp.)

(heath family)

TOXICITY RATING: Moderate. These plants grow wild in the East and cause significant problems there, the danger from these plants in Indiana is much less.

ANIMALS AFFECTED: All animals may be affected.

DANGEROUS PARTS OF PLANT: all parts, especially leaves.

CLASS OF SIGNS: Stomach irritation, abdominal pain, abnormal heart rate and rhythm, convulsions, coma, death.

PLANT DESCRIPTION: These perennial shrubs have tough, glossy, smooth-margined evergreen leaves. The large, showy flowers are in terminal clusters and have five white, pink, or red petals (fig. 10). Some horticultural varieties have yellow or orange petals. Common and local names for these plants include "lambkill" and "calkill". These plants have been used by people to commit suicide.

SIGNS: These plants, as well as mountain laurel (*Kalmia* spp.) contain grayanotoxins (glycosides) which affect the gastroenteric (stomach and intestines) and cardiovascular systems. The older name for this toxin was andromedotoxin.

In order for toxic signs to manifest, 0.2% by weight of green leaves needs to be ingested. Gastroenteric signs develop first, generally within 6 hours of ingestion, including salivating, vomiting (in capable species), diarrhea, abdominal pain, and tremors. Disturbances in cardiac rate and rhythm may then be noted. If sufficient quantities were consumed, convulsions may occur, followed by coma and death. Not all affected animals will die, and livestock may recover without treatment, depending upon amount ingested.

FIRST AID: Prevent further ingestion and provide supportive care. Veterinary attention is needed if ingestion was recent, or if clinical signs are present.

SAFETY IN PREPARED FEEDS: These plants are not safe in hay nor in any other prepared feed.

PREVENTION: Animals should not be allowed to graze these plants. Keep hungry livestock away from areas where these plants grow. Pets may nibble or taste the leaves out of curiosity or boredom, and this is not advised, but seldom leads to clinical toxicosis. Honey made from the nectar of these flowers is also toxic and should not be consumed, so exercise caution when placing beehives.

INDEX

39. STAR-OF-BETHLEHEM, SNOWDROP, NAP-AT-NOON

Ornithogalum umbellatum

(lily family)

TOXICITY RATING: Moderate to low. While very toxic, exposure is not commonly reported.

ANIMALS AFFECTED: Cattle, sheep, horses, and potentially any grazing animal.

DANGEROUS PARTS OF PLANT: All parts, especially bulbs.

CLASS OF SIGNS: Stomach and intestinal irritation, abdominal pain, irregular heart rate, death (rarely).

PLANT DESCRIPTION: This perennial (fig. 39), a close relative of wild garlic (but without the smell), reproduces mostly by clumps of bulbs. The central flower stem grows 4 to 12 inches long. The leaves are about as long as the stem and have a light green midrib. Star-shaped flowers, six white petals with green stripes on the back, appear in spring. Usually the tops die back after flowering and before the fruit, a capsule, can be produced. Originally introduced to Indiana as a garden plant, star-of-Bethlehem has now gone wild along roadsides, in fields, and in woods, especially in the southern and western parts of the state.

SIGNS: Star-of-Bethlehem contains cardiac glycosides in all parts of the plant, with the bulbs containing a higher percentage of the toxin. This is not a commonly reported toxicosis, but it can be severe if encountered and if enough of the bulbs have been consumed. The bulbs may become more readily accessible after plowing, frost heaving or other such activity, thus increasing the risk of toxicosis. The toxic component (and therefore the toxic signs) are very similar to foxglove (*Digitalis*). The first signs are stomach and intestinal irritation, which is followed by abnormalities in the heart's rate and rhythm, and this can progress to fatal cardiac arrhythmias.

FIRST AID: If animals are observed eating Star-of-Bethlehem, contact a veterinarian immediately,

since evacuation of the gastrointestinal tract may be attempted to remove the toxin. Beyond this, therapy is symptomatic and supportive, often necessitating a veterinarian's care.

SAFETY IN PREPARED FEEDS: The toxin remains after the plant has dried. Since the toxin is powerful, there is no level that can be considered safe when feeding processed feeds containing Star-of-Bethlehem.

PREVENTION: Do not let animals graze Star-of-Bethlehem, and avoid incorporating this plant into hay and other feeds. It would be advisable to eliminate the plant from pastures, especially if they grow in any significant numbers.

INDEX

48. BLACK LOCUST

Robinia pseudo-acacia

(pea family)

TOXICITY RATING: High to moderate.

ANIMALS AFFECTED: Horses are particularly at risk, but all animals ingesting the plant may be poisoned.

DANGEROUS PARTS OF PLANT: Leaves, especially wilted leaves, young shoots, pods, seeds, inner bark.

CLASS OF SIGNS: Depression, poor appetite, weakness, paralysis, abdominal pain, diarrhea (which may be bloody) and abnormalities in the heart rate and/or rhythm. Death is possible.

PLANT DESCRIPTION: These moderate-sized trees with rough bark often bear two short spines at the base of each leafstalk (easiest to see on young leaves). Leaves are alternate and pinnately compound with oval, entire leaflets (fig. 48). The fragrant flowers are creamy white, sweet-pea-like, and arranged in long drooping clusters. The fruit is a flat brown pod which contains kidney-shaped beans (fig. 48A). Black locusts are common in well-drained woods, thickets, and waste areas, especially in the southeastern part of the state. They are often planted along highways and fencerows as ornamentals and for erosion control.

SIGNS: This discussion will center on the effects in horses, the species most likely to be poisoned by black locust. Horses may ingest the bark or leaves when hungry and no other forage is available, or if they are confined or bored in the vicinity of the tree.

There are several toxic components in black locust including the toxic protein robin, the glycoside robitin, and the alkaloid robinine. The toxins affect the gastrointestinal tract as well as the nervous system. Clinical signs can manifest as soon as one hour after consumption and can include

depression, poor appetite, generalized weakness to paralysis, abdominal pain, diarrhea (which may be bloody) and abnormalities in the heart rate and/or rhythm. With sufficient amounts ingested, death may occur within a few days, although black locust is not always lethal. Some animals recover despite showing clinical signs, an indication of the dose-dependent nature of the toxin.

Honey locust (*Gleditsia triacanthos*, pea family) has been implicated in causing similar toxic signs, but the information on this is not clear. Prickly ash (*Zanthoxylum americanum*, citrus family) superficially resembles black locust in vegetative aspect and has been blamed for loss of sheep.

FIRST AID: If horses are observed eating black locust, contact a veterinarian immediately, since emergency measures to rid the gastrointestinal tract of toxin may be implemented. Beyond this, therapy is aimed at preventing further exposure and keeping other animals away from the trees, and treating clinical signs symptomatically. Recovery may take days to weeks. Be extra cautious around affected horses to prevent human injury, and these horses should not be ridden until all clinical signs have resolved.

SAFETY IN PREPARED FEEDS: Reports are not clear on this matter, but given the potentially toxic nature of black locust, it should never be allowed to contaminate feeds, especially those destined for horses.

PREVENTION: Do not confine horses in an area where black locust grows. If this is unavoidable, provide enough palatable feed so that the horses leave the trees alone. Some horses are wood and bark chewers, however, and for these horses it may be necessary to fence off the trees or utilize a different pasture to prevent toxicosis. Paints and sprays to prevent wood chewing may be tried, but long-term success with these treatments may be difficult.

INDEX

45. BLACK WALNUT

Juglans nigra

(walnut family)

TOXICITY RATING: Moderately toxic, depending upon length of exposure.

ANIMALS AFFECTED: Horses, dogs, possibly other animals.

CLASS OF SIGNS: Laminitis, breathing problems, gastroenteritis.

PLANT DESCRIPTION: These familiar trees are recent additions to the list of poisonous plants. Little information is yet available about their toxicity. Black walnuts are large (60-80 foot) forest trees often

planted as ornamentals. The bark has characteristic broad, round ridges. The leaves are alternate, pinnately compound, 1 to 2 feet long, with 13 to 23 sharply toothed, tapered-pointed leaflets (fig. 45). Often there is no terminal leaflet. The fruit is a very rough nut enclosed within a clammy glandular husk, 2 to 4 inches in diameter (fig. 45A).

SIGNS: Horses are most often affected. When horses are bedded on wood shavings containing more than about 20% of black walnut shavings (which tend to be dark in color), clinical signs of laminitis (inflammation of the laminae in the hoof) can occur within 12 to 18 hours of contact, but 24 hours may elapse before signs manifest. Consumption of the shavings may cause signs of laminitis as well as mild colic. Affected horses become unwilling to move or have their feet picked up, are depressed, may exhibit limb edema and signs of laminitis. Difficulty in breathing (increased rate and depth) may be noted. Horses on pasture may show mild respiratory signs from pollen or fallen leaves. Poisoning in dogs is reported occasionally when the seed hulls are consumed, causing stomach upset and diarrhea (gastroenteritis).

The toxin causing equine laminitis has not been clearly identified. It was once thought to be

juglone, but this is not believed to be the toxin. Juglone is produced by the tree which limits the growth of other plants in the vicinity. Walnuts are also lethal to earthworms.

FIRST AID: Remove black walnut shavings immediately; cooling the hooves and legs with a hose can help. Call a veterinarian if signs are severe or if shavings were consumed. Prompt removal of shavings typically results in complete recovery. Respiratory signs in horses usually do not require treatment unless severe or long-lasting. Stomach upset in dogs will resolve when hulls are no longer eaten.

SAFETY IN PREPARED FEEDS: Reports are not clear concerning the safety of black walnut leaves in processed feeds. The bark and seed hulls are toxic, and these should never be incorporated into any feeds. In the interest of safety, any part of the black walnut plant should not be allowed to contaminate feeds.

PREVENTION: Do not use shavings containing black walnut, limit access of horses to pastures with walnut trees. Purchase bedding shavings only from reputable dealers. Do not let dogs eat walnut hulls.

INDEX

41. BOUNCING BET, SOAPWORT

Saponaria officinalis

(carnation family)

TOXICITY RATING: Low.

ANIMALS AFFECTED: All animals have the potential to be affected.

DANGEROUS PARTS OF PLANT: All parts, especially seeds and roots.

CLASS OF SIGNS: Mouth, stomach, and intestinal irritation.

PLANT DESCRIPTION: A very common and familiar weed of summer and autumn throughout the United States, bouncing bet (fig. 41) is found in colonies along roadsides and railroad tracks, in meadows, and waste areas. It is a knee-high, spreading, perennial weed with jointed stems. The leaves are opposite, simple, toothless, and slightly hairy. Phlox-like, flat-topped flower clusters consist of white or pinkish-white to red blossoms that have five petals, each with a slight notch at the tip.

SIGNS: Bouncing bet contains saponins, substances that when mixed with water produce a soap-like foam. These saponins produce gastrointestinal irritation upon ingestion. Animals will typically avoid eating this plant, however they may ingest it if extremely hungry and no better feed is available, or if parts of the plant (especially the seeds or the roots) are incorporated into prepared feeds. The plant needs to be consumed for several days before toxic signs are noted, which can include: mild depression, vomiting (in those species that can vomit), abdominal pain, diarrhea (which may become bloody). Overall, this toxicosis is not encountered frequently.

The seeds of corn cockle (*Agrostemma githago*) contains saponins and cause toxicity similar to that of bouncing bet. In the case of corn cockle, the poisonings occurred when seeds contaminated prepared feeds. Swine are particularly susceptible to this toxicity.

FIRST AID: If the animals are eating the plant in the pasture, either remove the animals or eliminate the plants. Provide better forage, since most animals will not eat this plant unless there is little else to eat. If the feed is contaminated, it may need to be discarded, since the continual presence of the saponins will perpetuate the gastrointestinal irritation. Call a veterinarian if animals are severely affected and do not recover within 12 to 24 hours, or if the animals were observed eating a large amount of the plants.

SAFETY IN PREPARED FEEDS: Feed and hay contamination with bouncing bet (especially the seeds) is the primary route of poisoning. The toxicity remains with drying and upon storage, and the feed is not safe for consumption.

PREVENTION: Maintain pastures in good condition, keeping weeds mowed. This alone will discourage most broadleaf plants from growing, including bouncing bet. Exercise caution when preparing hay or other feeds, so that no seeds or other plant part becomes incorporated into the mixture. When buying feeds, only do business with reputable suppliers.

INDEX

23. BRACKENFERN, BRAKE FERN

Pteridium aquilinum

(fern family)

TOXICITY RATING: Moderate.

ANIMALS AFFECTED: Ruminants (especially cattle), horses, sometimes swine. Any grazing animal is susceptible.

DANGEROUS PARTS OF PLANT: All parts, especially the roots.

CLASS OF SIGNS: In horses and swine: Weight loss, weakness, gait abnormalities, abnormal heart rate and/or rhythm, inability to rise, death.

In ruminants: Bleeding disorders (bruising, hemorrhaging, anemia), breathing difficulties, weight loss, death.

PLANT DESCRIPTION: The broad, triangular leaves (fronds) of this perennial fern rise 2-3 feet tall (sometimes to 4 feet) from a thick, brown or black, horizontal rootstock. Each frond divides into three main parts, and each of these is twice subdivided (fig. 23). The edges of the leaves usually turn under. Late in summer the lower edges of mature fronds bear powdery clusters of brown spores (fig. 23A). These ferns are common in open, acid woodlands, burned-over areas, and

open pastures in dry, sandy, or gravelly soil. Stands of bracken may be so dense that they crowd out all other plants. Although brackenfern grows statewide, it is more common in the northern prairie and lake regions.

SIGNS: Toxic signs vary between ruminants (cattle, sheep and goats) and monogastric animals (like horses and swine):

Horses: The toxin in brackenfern is thiaminase, an enzyme that destroys thiamine (vitamin B1). The horse then essentially suffers from a vitamin deficiency of thiamine, which causes myelin degeneration of peripheral nerves (a loss of the fatty insulation layer to nerves that primarily control muscles). Poisoning can occur at any time of year, but is more likely in the late summer when other forages are scarce and the level of thiaminase is at its peak. Bracken is not considered palatable, but horses will eat it if no other forage is available, or they will consume it in hay or bedding, where it remains toxic. Some horses are believed to acquire a taste for it, and these horses will consume it even if other forages are available.

Horses need to consume bracken for one to two months prior to manifesting clinical signs. After this time horses may then be fed bracken-free forage and yet still develop clinical signs within 2 to 3 weeks. The first signs in horses is weight loss after a few days on bracken. Later, weakness and gait abnormalities are present, which progress to staggering, hence "bracken staggers". Affected horses may stand with their legs widely placed and their back arched. Muscle tremors and weakness is apparent when the horses are forced to move. Early in the course of the syndrome, a slow heart rate and abnormalities of the heart rhythm may be noted. Near the end of the clinical course, the heart rate and temperature rise, and the animals cannot get up and may have spasms and an upward arching of the head and neck. The syndrome runs its course, with death occurring within 2 to 10 days of the onset of signs, but it can be treated.

Swine would show signs similar to those in horses.

Ruminants, especially cattle: Thiaminase does not adversely affect ruminants since the ruminal bacteria degrade the enzyme. However, other toxins in bracken affect ruminants, most notably ptaquiloside, a lactone toxin that affects the bone marrow. The toxin is present in all parts of the plant, but is concentrated in the rhizomes, and is toxic in fresh as well as dried plants.

Consumption of bracken results in the depression of bone marrow (and thus red and white blood cell and platelet production), and the plant has a direct or indirect anti-coagulant property. Cattle show signs after grazing bracken for 1 to 2 months, although death may occur within this time frame as well. Affected cattle have an increased temperature, weight loss, and exhibit increased bruising and bleeding. From the excessive bleeding, cattle are anemic, and can die within a week of showing signs. Young cattle may develop swelling in the larynx and have difficulty breathing. Sheep may be poisoned in a similar manner, but are apparently more reluctant to consume bracken.

The plant is also reported to contain carcinogenic substances, but instances of cancer in animals resulting from bracken fern ingestion is not well reported.

FIRST AID: Horses: If horses are observed eating bracken, immediately remove them from the pasture, or in some way prevent access to the plant. Hay with bracken in it should never be fed. If large amounts were consumed, and especially if clinical signs are present, call a veterinarian

immediately. The antidote is daily injections of thiamine for up to two weeks. Do not wait until the animal cannot rise, by then it may be too late. Provide similar first aid to swine.

For ruminants: Immediately remove cattle from bracken pastures, or fence off the bracken areas to limit access. Do not feed hay or bed animals on straw that contains bracken. A veterinarian can assist with treatment of affected animals, but this may be cost prohibitive. Evacuation of the rumen and intestinal tract is usually not of value, since the poison accumulates in the system for many days, and there may be little or no toxin remaining in the digestive tract to be removed once clinical signs appear. Treatment is concerned with alleviating the clinical signs and providing supportive care. Blood transfusions may be attempted, but the prognosis is poor for clinically affected animals.

SAFETY IN PREPARED FEEDS: Bracken remains toxic when dry, and is never safe for consumption.

PREVENTION: Grazing animals should not be allowed access to bracken fern, especially if they have developed a taste for it. Provide supplemental feed if the pasture is low in adequate forage. Never use hay or bedding material that contains bracken.

NOTE: Sensitive fern (*Onoclea sensibilis*, fern family), may also be poisonous. Horses reportedly have become nervous and uncoordinated after eating this common fern of marshy areas.

INDEX

44. OHIO BUCKEYE HORSECHESTNUT

Aesculus glabra *Aesculus hippocastanum*

(horsechestnut family)

TOXICITY RATING: Moderate to high.

ANIMALS AFFECTED: All animals may be affected, especially grazing animals and those consuming the honey.

DANGEROUS PARTS OF PLANT: Buds, nuts, leaves, bark, seedlings, and honey.

CLASS OF SIGNS: Two effects: gastrointestinal and neurologic: excessive salivation, gastrointestinal irritation, vomiting in those species that can vomit, abdominal pain, diarrhea. Neurologic signs can include staggering, trembling, breathing difficulty, dilated pupils, collapse and paralysis, which can proceed to coma and death.

PLANT DESCRIPTION: The thick twigs of these medium-sized trees have glistening buds in spring and bear opposite leaves composed of five leaflets in a finger-like arrangement (fig. 44). The yellowish flowers rise in large, upright, dense, candle-like clusters at branch ends during June. The prickly fruit contains 1 to 3 nutlike seeds, glossy and leathery brown with a pale scar on each that gives the tree its name. These trees commonly grow in rich, moist woods or along river banks and are often planted as ornamentals.

SIGNS: The toxins in Buckeye and Horsechestnut affect the gastrointestinal tract as well as the nervous system. The saponic glycoside aesculin in addition to suspected alkaloids cause the toxic signs. Initially, gastrointestinal signs manifest, which can include salivation, vomiting (in those species that can vomit), abdominal pain, and diarrhea. If enough was ingested, neurologic signs may develop, including trembling, staggering, and difficulty in breathing. Toxicity may then progress to collapse, paralysis, coma and death.

These trees are among the first to leaf out in the spring, and hungry animals on pasture may be tempted to eat them if no other forages are available.

FIRST AID: If animals are observed eating Ohio Buckeye or Horsechestnut, contact a veterinarian immediately; emergency measures can be used to remove plant material from the digestive tract. Once clinical signs are present, and if it has been several hours after the plants were consumed, supportive care is all that can be provided, since there is no antidote for this toxicosis.

SAFETY IN PREPARED FEEDS: Reports are unclear concerning the safety of Ohio Buckeye or Horsechestnut in processed feeds. Therefore, in the interest of safety, consider these plants as toxic and do not feed processed feeds if contaminated.

PREVENTION: If animals are to be pastured with these trees, be certain that adequate, nutritious forage is available. In this way, the animals are likely to avoid consuming toxic quantities of these trees.

INDEX

4. BULB-BEARING PLANTS OF HOUSE AND GARDEN

TOXICITY RATING: Moderate. Incidents of poisoning by these plants is rare, but special care must be taken, especially with lily of the valley.

ANIMALS AFFECTED: Pets are primarily at risk, cattle have been poisoned by iris.

DANGEROUS PARTS OF PLANTS: Bulbs, rootstocks, whole plants.

CLASS OF SIGNS: Stomach upset, vomiting, diarrhea. For lily of the valley, additional signs may include irregular heartbeat, convulsions, and death.

PLANT DESCRIPTIONS:

1. *Convallaria majalis* (lily-of-the-valley, lily family). A familiar low-growing garden perennial, forms dense clumps from slender rootstocks called "pips." The lily-like leaves are parallel-veined (fig. 4A), and from them rise flower stalks that bear small white blossoms all on one side. The flowers are bell-like and fragrant and rarely develop into the red to orange-red berries.

2. *Hippeastrum vittata* (amaryllis, amaryllid family). A houseplant (fig. 4B) that blooms in only a few weeks after forcing in the wintertime. At first one or two 1 to 3 feet tall, naked stalks appear, each bearing from one to four large, six-petaled, red, blue, white, or bicolored flowers. Later several sword-shaped, fleshy leaves develop from the base of the plant.

3. *Hyacinthus* spp. (hyacinth, lily family). These potted or garden plants grow from a 1 to 2 inch diameter bulb (fig. 4C). The 8 to 12 inch long leaves are narrow, somewhat trough-shaped, and fleshy. The small fragrant, white, pink, or blue lily-like flowers are borne on a leafless stalk that is taller than the leaves.

4. *Iris* spp. (iris or blue flag, iris family). These commonly grown garden perennials also occur

wild in wet

meadows, marshes, roadsides, lakeshores, and stream banks. Branching, fleshy rootstocks bear clusters of long, sword-like leaves in which the base of each leaf is folded over the base of the next higher leaf (fig. 4D). The flowers, blue with a yellow heart in our wild species but purple, blue, yellow, or reddish-brown in cultivated varieties, have three upright "standard" petals and three pendant "fall" petals. The fruit is a dry capsule.

5. *Narcissus* spp. (daffodil, jonquil, narcissus; amaryllid family). Springtime in Indiana is officially proclaimed by the yellow trumpets of daffodils (fig. 4E). These perennials produce lily-like leaves and slender stalks that each bear a conspicuous orange, white, or yellow flower with six petals, parts of which fuse to form the trumpet.

SIGNS: This group of plants is divided into two sections. The first section includes lily of the valley, and the second section includes the other bulbs.

Lily of the valley is the far more dangerous plant, producing a mixture of many cardiac glycosides, especially convallatoxin. Toxic signs in pets after they chew on the plant would include stomach upset, vomiting, irregular heartbeat, convulsions, and death if sufficient quantities are consumed. The toxin in lily of the valley acts in a similar manner to the toxin in foxglove, a plant from which digitalis, a powerful cardiac medication, is derived.

The bulbs or corms of tulip, daffodil, jonquil, narcissus, amaryllis, and iris produce primarily gastrointestinal signs (vomiting and diarrhea) after consumption, and are not as toxic as lily of the valley. Pets are more likely to come into contact with these plants than are horses or livestock, however, livestock (cattle) have been poisoned when grazing wild-growing iris and eating the rootstocks.

Concerning pets, dogs are the most likely to consume the bulbs, and the usual time for poisoning is when the bulbs are removed from the ground or stored prior to planting. This is not a common poisoning, but some animals, once they find the stored bulbs, will consume them. While unlikely, some animals will dig the bulbs up in the yard and eat them. The toxic components in these bulbs is not well identified, but may be a mixture of alkaloids, having an irritant action on the gastrointestinal tract.

FIRST AID: For lily of the valley, contact a veterinarian immediately. If the animal is vomiting, allow it to continue to do so, since this will remove the toxin from the gastrointestinal tract. If the vomiting is severe or persists, a veterinarian needs to be contacted. In cases where the pet has eaten a large quantity, emergency treatment is imperative. For the other bulbs and for iris, vomiting and diarrhea should resolve in a few hours. If the signs continue, or if the pet is weak, sick, pregnant, nursing, or old, a veterinarian can provide supportive care until the toxin is eliminated.

SAFETY IN PREPARED FEEDS: It is unlikely that these plants would be incorporated into animal feeds. On the rare event that this occurs, the toxins would remain, and the feed is then unsafe for consumption.

PREVENTION: Do not allow livestock to graze where iris grows, especially if there is insufficient forage available. For pets, do not allow access to stored bulbs, and restrict access to bulb beds and

4. BULB-BEARING PLANTS OF HOUSE AND GARDEN

newly planted bulbs. Never pen or place an animal within reach of these plants, especially lily of the valley, since the pets (including birds) may nibble them out of boredom.

INDEX

2. COMMON BURDOCK

Arctium minus

(daisy family)

TOXICITY RATING: Low. Burs cause local irritation and possibly intestinal hairballs, and most animals avoid ingesting these plants. Serious illness and death are rare.

ANIMALS AFFECTED: All animals may be affected. Pastured animals and outdoor dogs are particularly at risk. Poultry may get burs lodged in the esophagus.

DANGEROUS PARTS OF PLANT: Burs.

CLASS OF SIGNS: Skin, eye, mouth, nose, and ear irritation; stomach irritation; hairballs.

PLANT DESCRIPTION: This familiar biennial weed (fig. 2) of waste places and roadsides grows from a fleshy taproot and produces large, heart-shaped, hairy leaves and red-violet flower heads surrounded by numerous hooked bracts that form a bur-like cup.

Burdock is often confused with cocklebur (a far more dangerous plant). Burdock burs are rounder and have softer, more Velcro-like hairs than cocklebur. Cocklebur burs are oblong and have hooked spines on the bur, and have, on the end of the bur, two spines which are larger and not as strongly hooked.

SIGNS: These burs, and those of cocklebur, crimson clover, rabbitfoot clover, sandbur, and buffalobur may lodge in the skin, eyes, ears, mouth, throat, or stomachs of grazing animals (and sometimes pets). Direct irritation may result, with swelling and pain, or the bur may form the center of a "hairball", a mass of plant matter, hair, and debris that can cause digestive tract irritation and possible obstruction. These burs also tend to lodge in the fur, manes, and tails of animals.

2. COMMON BURDOCK

FIRST AID: Remove all visible burs (some may need to be cut out of the hair). If the irritation is minor, provide supportive care. If the eyes, ears, nose, mouth, feet, or hooves are involved, or in cases of digestive upset or inability to eat, a veterinarian needs to be contacted. Burs and hairballs may require surgical removal.

SAFETY IN PREPARED FEEDS: Only poor quality hay and feeds would contain these burs. If the number of burs is small or only in certain sections of the hay (which should be discarded), few problems may result. If there are many burs, especially if the animals are forced to eat these feeds, problems are likely to develop.

PREVENTION: Prevention consists of removing these plants from the pasture. Mowing is effective in reducing the number of flowers and burs that will develop.

INDEX

30. BUTTERCUPS

Ranunculus spp.

(buttercup family)

TOXICITY RATING: Low. Most animals avoid buttercups, and seldom ingest enough to cause any serious toxicity.

ANIMALS AFFECTED: All animals that chew on or ingest the plant can be affected.

DANGEROUS PARTS OF PLANT: Fresh leaves and stems.

CLASS OF SIGNS: Oral and gastrointestinal irritation are the primary signs (oral irritation, salivation, abdominal pain, diarrhea which may be bloody).

PLANT DESCRIPTION: Buttercups arise from fibrous roots, thickened rootstocks, or bulbs to form a rosette of basal leaves and often a low stem with alternate and divided (three-parted) leaves. The axillary, solitary flowers have five green sepals, five glossy yellow petals, and numerous reproductive parts and seeds. Buttercups usually are found in moist woods, meadows, fields, pastures, and sometimes along roadsides and in drier sites. Bristly buttercup (*Ranunculus hispidus*, fig. 30A) is typical of the wet site species; celeryleaf buttercup (cursed crowfoot, *Ranunculus sceleratus*, fig. 30B) is typical of the small-flowered, dry-site species.

SIGNS: The toxin in buttercup is protoanemonin, a volatile yellow oil, which causes intense oral irritation and gastrointestinal irritation. Problems in livestock tend to occur most often in the spring, herbivorous pets may be poisoned at any time if they have access to the plant. The plant is not palatable, and causes almost immediate oral irritation, so animals tend to avoid it. The toxicity of buttercup varies greatly among the different species and during the course of the growing season. Seldom is buttercup reported as a significant threat to animals. In experimental feeding

trials with greater quantities of buttercup, prostration, coma and death have been reported, but these signs are rarely reported under field conditions.

FIRST AID: No treatment is necessary unless severe gastrointestinal signs are present (colic, bloody diarrhea) or if a large quantity was observed to be eaten. Minor oral irritation will resolve on its own.

SAFETY IN PREPARED FEEDS: Reportedly, the toxin is volatilized ("evaporates off"), so processed feeds and hay may be safe for consumption. However, consumption of any significant quantity of contaminated feeds is not recommended.

PREVENTION: Buttercup is a common pasture contaminant, and tends to not cause problems as long as there is sufficient quantities of good forage available. Eradication is not usually necessary, since animals tend to avoid this plant on their own. If it has become a problem, mowing or eradication are recommended.

NOTE: Marsh marigold (*Caltha palustris*), a closely related plant found in similar habitats, also contains protoanemonin and causes mouth and stomach irritation as well as generalized distress when cattle, sheep, or horses eat the fresh tops. Hay has been considered safe for consumption. First aid is the same as for buttercups.

INDEX

11. CASTORBEAN, CASTOR OIL PLANT

Ricinus communis

(spurge family)

TOXICITY RATING: High. Death is likely with consumption of even small amount of castorbean.

ANIMALS AFFECTED: All animals may be affected.

DANGEROUS PARTS OF PLANT: The seeds are the primary source of toxin, but the rest of the plant may be considered to be slightly toxic as well.

CLASS OF SIGNS: Stomach irritation, diarrhea, abdominal pain, increased heart rate, profuse sweating, collapse, convulsions, death.

PLANT DESCRIPTION: This stout, robust shrub-like plant with reddish to purple stems may reach 12 feet in height. A perennial in its native tropics, it is grown as a garden annual in Indiana. The large (4 to 30 inches across), umbrella-like leaves (fig. 11) have 5 to 9 pointed, finger-like lobes. Long purple leaf-stems are attached near the centers of the leaf blades. Greenish-white or reddish-brown flowers are produced in narrow, upright clusters. The fruit is a three-lobed, green or red capsule with a soft, spiny

exterior. One large, mottled, attractive seed (fig. 11A) develops in each lobe. Some people think the seeds look like well-fed ticks.

SIGNS: The phytotoxin ("plant toxin") in castorbean is ricin, a water soluble protein, which is

concentrated in the seed. Also present are ricinine, an alkaloid, and an irritant oil. As a side note, commercially prepared castor oil contains none of the toxin. There is great species variability in susceptibility to ricin toxin, with humans and horses being the most at risk (25 grams of castorbean seed is lethal for the horse). Due to the powerful toxin however, it is best to keep all animals (livestock and pets) away from this plant.

The seed is only toxic if the outer shell is broken or chewed open. Seeds swallowed intact usually pass without incident. Signs of toxicity may not manifest for 18 to 24 hours after ingestion. The animal first shows signs of depression and a mild increase in temperature. Later, gastrointestinal signs predominate, including vomiting in humans and other species that can vomit (horses cannot vomit), profuse diarrhea (which may be bloody), colic and abdominal pain. The affected animal may then go into convulsions, collapse and die, with death generally occurring within 36 hours of consumption. The toxic signs are the result of severe gastrointestinal irritation, anaphylaxis and shock. This toxin is closely related to the toxin in rosary pea (a section on this plant is also included in this book).

FIRST AID: If animals are observed eating castorbean, call a veterinarian immediately, since emergency measures need to be undertaken. If consumption occurred several hours ago, a veterinarian will be able to provide supportive care and treat for shock, but death may still result from this powerful toxin.

SAFETY IN PREPARED FEEDS: The seeds may become incorporated into hay or grains. The seeds are never safe to eat, especially by horses or livestock, since these animals could easily crack the seed coat. After making castor oil, the remaining seed cake is sometimes used for animal feed. This needs to be boiled or heated to remove the toxin.

PREVENTION: Do not allow seeds or any other part of the plant to be incorporated into animal feeds. It is advisable to not let castorbean grow in the vicinity of pastures used for grazing or forage production. Do not allow pets access to this plant. To decrease the chances of intoxication, snip off the flower heads before they develop into seeds; this will protect children as well as pets.

INDEX

7. CATNIP

Nepeta cataria

(mint family)

TOXICITY RATING: Low

ANIMALS AFFECTED: Cats.

DANGEROUS PARTS OF PLANT: Stems, leaves.

CLASS OF SIGNS: Behavioral changes.

PLANT DESCRIPTION: Catnip (fig. 7) has all the characteristic earmarks of a member of the mint family: stems square in cross-section, leaves opposite and fragrant, and small flowers in tight clusters at the ends of branches. This perennial herb may grow up to 3 feet tall and be highly branched. The gray-green to green leaves are heart-shaped with scalloped edges and are often crowded toward the top of the plant. The flowers are white, dotted with purple, two-lipped, and produce four tiny, dark nutlets per flower.

SIGNS: Only cats are affected, and some cats are affected more than others. Aromatic oils and the monoterpene, nepetalactone, cause the signs. Cats will rub and sometime ingest the plant, and then act "drunk" or "wild" for up to an hour or more. No lasting toxicity is reported. If excessive amounts are ingested, vomiting and diarrhea can result, but the signs are self-limiting. Catnip can be considered as a legal recreational drug for cats!

7. CATNIP

FIRST AID: None is required.

SAFETY IN PREPARED FEEDS: Not applicable.

PREVENTION: Catnip is safe, however avoid excessive ingestion since vomiting or diarrhea may occur.

INDEX

46. WILD BLACK CHERRY

Prunus serotina

(rose family)

TOXICITY RATING: High.

ANIMALS AFFECTED: All animals may be affected. Ruminants (cattle, sheep, goats, deer) are more at risk than monogastric animals (dogs, cats, pigs, horses) and birds.

DANGEROUS PARTS OF PLANT: Damaged leaves pose the greatest risk. All parts are potentially toxic.

CLASS OF SIGNS: Anxiety, breathing problems, staggering, convulsions, collapse, death (which may be sudden).

PLANT DESCRIPTION: This cherry may grow as a tree or shrub. Bark of young branches and twigs is scaly and reddish-brown with prominent cross-marks ("lenticels"). Leaves (fig. 46) are alternate, simple, elliptic-pointed, leathery in texture, and finely toothed on the margins. Flowers are showy, fragrant, and white, hang in drooping clusters, and produce dark-red to black cherry fruits (fig. 46A). The wild black cherry commonly grows in fence rows, roadside thickets, and rich open woods.

SIGNS: Black cherry contains cyanogenic precursors that release cyanide whenever the leaves are damaged (frost, trampling, drought, wilting, blown down from the tree during storms). Most animals can consume small amounts of healthy leaves, bark and fruit safely; however when hungry animals consume large amounts of fresh leaves or small amounts of damaged leaves (as little as 2 ounces), clinical cases of poisoning will occur, and many animals may die. This is especially true if there is no other forage for the animals to consume, or in the case of pets, when confined and/or bored, the chances for toxic levels of ingestion can occur. The conditions of cyanide poisoning

have also been discussed under Johnsongrass.

Healthy cherry leaves contain prunasin, a cyanide precursor that in itself is non-toxic. When the leaves are damaged, the prunasin molecule is split and free cyanide (also called prussic acid or hydrocyanic acid) is liberated. Many plants, especially those in the rose family, have the potential to produce toxic levels of cyanide under certain conditions. Chokecherry (*Prunus virginiana*) is also toxic. There are reports of peach sprouts, leaves, and pits poisoning sows. Apricot pits and apple seeds are toxic as well. Arrowgrass (*Triglochin maritima*) contains a cyanogenic glycoside and has caused poisoning in livestock. Johnsongrass, discussed earlier, has a similar toxicity.

Cyanide prevents the body from being able to utilize oxygen at the cellular level, so although the animals physically can breathe, their tissues and cells "suffocate". After consumption, signs will manifest within a few minutes, but sometimes up to an hour may pass. The animals will try to breathe more rapidly and deeply, and then become anxious and stressed. Later, trembling, incoordination, attempts to urinate and defecate and collapse is noted, which can proceed to a violent death from respiratory and/or cardiac arrest within a few minutes to an hour. If an affected animal is still alive 2 or 3 hours after consumption, chances are good that it will live.

FIRST AID: The clinical signs of cyanide poisoning tends to come on quite rapidly, and the animals may be found dead without much warning. If the animals are exhibiting toxic signs, call a veterinarian immediately. There is an antidote, but it needs to be given intravenously and within a few minutes of the onset of signs, and it is often impossible to get help in time. Prevent the animals (especially the unaffected animals) from eating any more of the grass or feed. Do not handle or stress affected animals any more than absolutely necessary, since this will worsen the signs. Also, affected animals are extremely stressed and may be dangerous to work with, therefore exercise caution so no human injury results.

SAFETY IN PREPARED FEEDS: Cyanide is lost to the air with time, so processed feeds containing cherry may technically be free of the toxin. However, green chop and silage containing cherry will still retain large amounts of cyanide aside from being feeds of poor quality. Dried products would also not be of high quality if they contain cherry, but the cyanide levels will be much lower. Caution is still advised when feeding cherry-contaminated feeds.

PREVENTION: Do not allow animals to have access to damaged cherry leaves, especially if they are hungry and there is no other forage available. Do not place fallen branches or tree trimmings where animals can graze them. Exercise caution with animals on pasture after storms, during droughts or after a frost since these conditions will increase the chances of toxic levels of ingestion. For pets, do not house or confine animals in the vicinity of cherry, since boredom will increase the likelihood that the plant will be eaten. For most species of cherry, the fruit is safe for consumption. It is the leaves and bark which pose the greatest risk.

INDEX

8. CHRISTMAS PLANT

Poinsettia pulcherrima (*Euphorbia pulcherrima*)

(spurge family)

TOXICITY RATING: Low.

ANIMALS AFFECTED: All animals can be affected, but pets are more likely to come into contact with *Poinsettia* than are livestock.

DANGEROUS PARTS OF PLANT: Leaves and stems primarily, but all parts may be toxic.

CLASS OF SIGNS: Skin, mouth, eye, and stomach irritation.

PLANT DESCRIPTION: People commonly display this potted plant (fig. 8) in houses and offices in the wintertime. These 1 to 4 feet tall plants with yellow stems bear alternate, coarsely toothed, smooth, green leaves. The top leaves turn red. Although many people mistake them for petals, they function as "bracts", calling attention to the true flowers which are tiny, yellow, and clustered at the top of the plant. The inconspicuous fruits are small, green, three-lobed, fleshy capsules.

SIGNS: The milky sap (a latex) is irritating to skin, eyes, and mucus membranes. Once considered extremely poisonous, toxicity is more likely to manifest as irritation, discomfort, rash, and stomach upset. Nausea and vomiting may occur if sufficient quantities are consumed. Typically, animals will show head-shaking, salivation, and pawing or rubbing at the mouth or eyes.

FIRST AID: Wash sap off the animal to prevent further ingestion. Call a veterinarian if the eyes are affected, or if signs do not resolve in a few minutes.

PREVENTION: *Poinsettia* should not be allowed near curious animals.

INDEX

32. COMMON COCKLEBUR

Xanthium strumarium

(daisy family)

TOXICITY RATING: High.

ANIMALS AFFECTED: All animals may be affected. Cattle, swine, sheep, and poultry are more at risk than horses and pets.

DANGEROUS PARTS OF PLANT: The seeds and seedlings contain the highest quantity of toxin, yet the whole plant can be considered toxic. The seed burs can cause mechanical damage.

CLASS OF SIGNS: Gastrointestinal irritation, weakness, breathing difficulty, behavioral changes, cardiac abnormalities, death.

PLANT DESCRIPTION: The angled, sometimes red- or black-spotted stems of cocklebur grow 1 to 3 feet high. Leaves of this many-branched annual are alternate, hairy, rough-textured (sandpaper-like), somewhat heart-shaped, toothed, and lobed (fig. 32). Flowers are inconspicuous with male flowers in terminal spikes, female flowers in clusters in the leaf axils. The fruit is a hard, oval, prickly bur about 3/4 inch long containing two seeds (fig. 32A). Because seeds germinate best after being soaked in water, the plants are usually found along the shores of ponds where water has receded. The edges of farm ponds may be lush with young cockleburs. Seedlings have small strap-shaped leaves 1/4 inch wide by 1 1/4 inches long (fig. 32B). They also pop up in gardens, fields, roadsides, and other areas of nearly full sunlight.

SIGNS: There are several types of toxins in cocklebur, one being a glycoside, carboxyatractyloside, which causes hypoglycemia (low blood sugar) and a group of sesquiterpene lactones which can cause vomiting (in those species capable of vomiting), weakness, tremors, weak pulse, a loss of appetite and convulsions. Liver damage may also result from these toxins,

and death is likely if a sufficient dose was consumed (ingestion of green plant at approximately 0.75% of body weight). The seed bur can cause mechanical damage (please refer to the section on Foxtail barley). The most common time for toxic signs is late spring and early summer for the seedlings, later in the summer for the burs, and at any time seed-contaminated prepared feeds are ingested. As the cocklebur plant matures, the toxicity decreases (except for the seeds). The seedlings are extremely dangerous, and typically sprout in wet areas, such as alongside streams, at the edges of ponds, in receding floodplains, etc. Animals will tend to avoid cocklebur, even the seedlings, as long as there is sufficient forage available. Species that are less discriminant eaters (cattle, swine) are particularly at risk where cocklebur grows. Once toxic signs develop, death may follow within 48 hours. Some animals may recover, but this may take some time (weeks).

Other conditions of toxicity can occur when seeds are incorporated into prepared feeds. Feeds that may become contaminated include hay (especially if cut later in the growing season when cocklebur has gone to seed), silage, or grains (corn, beans). If the feeds (especially the grains) are highly processed, it may be difficult to arrive at an accurate diagnosis of cocklebur toxicosis. The seed is highly toxic, and any species may become poisoned upon consumption.

FIRST AID: If animals are observed eating cocklebur, contact a veterinarian immediately. In the meantime, prevent further consumption of the plant by all animals. Keep animals quiet until the veterinarian arrives.

SAFETY IN PREPARED FEEDS: The seedling, when dried, retains its toxicity, therefore feeds with dried seedlings are not safe for consumption. Mature plants are less toxic, but consumption is still not advised. Feeds that contain burs and/or seeds are a mechanical threat as well as a toxic one, therefore these feeds are also not safe for consumption at any dosage.

PREVENTION: Pasture management is essential to prevent poisonings by cocklebur. Mature, seed-bearing plants should be removed from the pasture to prevent seeding and germination. This is particularly important if the pasture contains any wet areas that are subject to seasonal drying. If removal of the plants is impractical, fence off areas where seedlings are likely to germinate and/or provide for supplemental feed to decrease interest in the seedlings. For prepared feeds, exert extra caution when harvesting for hay, silage, or grains and do not allow any cocklebur to be included. Buy prepared feeds only from reputable dealers.

INDEX

3. THE AROID FAMILY

Aglaonema: CHINESE EVERGREEN

Anthurium: ANTHURIUM

Arisaema: JACK-IN-THE-PULPIT, GREEN DRAGON

Caladium: ELEPHANT EARS

Colocasia: TARO

Dieffenbachia: DUMBCANE

Monstera: CUT-LEAF PHILODENDRON, CERIMAN, MEXICAN BREADFRUIT

Philodendron: PHILODENDRON

Scindapsus: DEVIL'S-IVY, POTHOS

Symplocarpus foetidus: SKUNKCABBAGE

Syngonium: TRI-LEAF WONDER, ARROWHEAD VINE, NEPHTHYTIS

TOXICITY RATING: Moderate. Pets may sample these commonly available plants with a nibble

or two, but rarely ingest any quantity sufficient to cause serious problems or death. Risk increases with hungry or bored animals housed in close proximity to these plants.

ANIMALS AFFECTED: Any animal that chews or ingests the leaves will be affected. In Indiana, nearly all of these plants would be grown as houseplants, therefore pets (including birds and reptiles) are primarily at risk.

DANGEROUS PARTS OF PLANT: Roots, leaves, stems.

CLASS OF SIGNS: Mouth and throat irritation, salivating, possibly stomach irritation, diarrhea (rarely).

PLANT DESCRIPTION: All 2,000 species of this family of plants should be treated as potentially toxic. A few are eaten, such as poi and taro (*Colocasia esculenta*) in Hawaii, but only after the poison is eliminated by cooking. Seven species of aroids occur naturally in Indiana, mostly in wet areas. Jack-in-the-pulpit and skunkcabbage are the most common and best known of these. Dumbcane (fig. 3), pothos, and philodendron are potted plants of offices, restaurant lobbies, and homes.

Aroids are perennials, many arising from corms or rhizomes. Some may be vines. The large net-veined leaves, which may have white or colored spots, are borne on leaf stalks that sheathe the stem. Most of these plants have simple leaves, but jack-in-the-pulpit has three-parted foliage (fig. 19). The aroid flower is a fleshy green, white, or yellow spike (spadix) borne inside a wraparound hood or bract (spathe). The fruits are brightly colored berries, borne in tight clusters, not often produced by the house plant species.

SIGNS: The plant cells contain needle-like crystal of insoluble calcium oxalate which penetrate the skin and mouth causing discomfort. In addition, the plants contain proteolytic enzymes which release histamine and kinins, causing swelling and an itching or burning sensation. Affected animals will shake their head, paw or rub the face and mouth, may salivate or foam at the mouth, may seek water, or may have visible swelling. Very severely affected animals may experience oral swelling to the point that swallowing and breathing become impaired. Typically, animals are not severely affected, since a few bites of the plants are often a sufficient deterrent to further consumption. Occasional reports of these plants causing kidney failure in cats have not been well-verified. Effects in cats appear to be limited to the signs described above. Some of these plants have been used with humans to prevent individuals from talking by causing excessive tongue swelling, hence the name "dumbcane".

FIRST AID: For minor irritation, provide supportive care and prevent further exposure. For more severe signs, if the animal does not improve within a few minutes, or if swallowing or breathing is impaired, consult a veterinarian immediately.

SAFETY IN PREPARED FEEDS: These plants are not likely to be incorporated into hay or other feeds, but if so, the toxins are likely to remain.

PREVENTION: Animals should not be allowed to consume these plants. Offer small amounts of fresh grass or other safe plant material (depending on the species), or remove the plant from the pet's environment. Some pets do not "learn their lesson" and may return to chew on these plants. In these situations, it is best to remove the plant from the pet's environment.

INDEX

21. DUTCHMAN'S BREECHES, STAGGERWEED

Dicentra cucullaria

SQUIRRELCORN, STAGGERWEED

Dicentra canadensis

CULTIVATED BLEEDING HEART

Dicentra spectabilis

(poppy family)

TOXICITY RATING: Low. The plant is unpalatable and is not eaten when better forages are available. Also, larger quantities need to be consumed to show clinical signs, and only rarely is consumption of *Dicentra* lethal.

ANIMALS AFFECTED: Cattle are primarily affected, horses and sheep also appear susceptible. Due to the nature of the toxic component (morphine-like derivatives), all species are likely to be susceptible at sufficient dosages.

DANGEROUS PARTS OF PLANT: Leaves, stems, roots.

CLASS OF SIGNS: Salivating, breathing difficulty, abdominal pain, collapse, convulsions, neurologic signs (running with head held up).

PLANT DESCRIPTION: These delicate perennials with finely-cut, fern-like leaves bear 1 to 10 showy flowers on slender stalks. The 4 to 10 creamy white flowers of Dutchman's breeches (fig. 21A) have spurs like bloomer legs. The white-flowered squirrel corn (fig. 21) and pink-flowered bleeding heart plants bear heart-shaped petals with teardrop-shaped appendages at the bottom. Small, yellow, pea-like tubers are scattered along the underground stem of squirrelcorn. The wild staggerweeds are common spring wildflowers in established woodlands.

SIGNS: This plant is one of the first to grow in the spring. It is considered to be unpalatable, but may be consumed if no other forages are available. The plant contains isoquinoline alkaloids, such as apomorphine, protoberberine, and protopine. Debate exists over whether the plants cause immediate signs, or if the plant needs to be consumed over several days before signs develop. Clinical signs begin with salivation and difficulty in breathing. Later, colic (abdominal pain) and possibly diarrhea may be noted. The animals may run with held up high, become uncoordinated, and may collapse and exhibit convulsions. Some have reported a loss of milk production in affected animals. Other disorders resembling *Dicentra* poisoning may also occur in the spring, making a diagnosis difficult. Death with *Dicentra* poisoning is rare, and animals tend to recover on their own in a few hours after they are removed from the plant. A plant called *Corydalis* (fitweed) will cause similar signs in animals (similar toxic component).

FIRST AID: Remove all animals from the plant and provide adequate safe forage. Signs tend to resolve in a few hours. For seriously affected animals, or those who are very young or ill, a veterinarian can provide basic emergency care and provide relief.

SAFETY IN PREPARED FEEDS: Precise information could not be located. Consider *Dicentra* unsafe in hay and other prepared feeds.

PREVENTION: Provide adequate feed for pastured animals, especially in the early spring. Animals will avoid *Dicentra* if better feed is available. If animals continue to eat this plant, consider fencing off the area where *Dicentra* grows to limit access.

INDEX

51. Easter lily

Lilium longiflorum

Lily family

TOXICITY RATING: High.

ANIMALS AFFECTED: The only reported toxicity is in cats.

DANGEROUS PARTS OF PLANT: Leaves primarily, stems and flowers may also be toxic.

CLASS OF SIGNS: Gastrointestinal irritation (vomiting), depression, lack of appetite.

PLANT DESCRIPTION: (I need to get this to you)

SIGNS: This is a newly reported toxicosis, apparently lethal only to cats. Upon consumption of Easter lily (the exact amount is unknown), the cats begin to vomit within an hour or so. The cat then becomes depressed over the next half day, presumably as the toxin begins to affect the kidneys. Within 48 to 96 hours after consumption, the cat will tend to show signs of clinical kidney failure: increased urination, depression, stomach upset, dehydration. Death tends to occur within 5 days.

FIRST AID: If a cat is seen eating Easter lily, contact a veterinarian immediately. If emergency treatment is begun within 6 hours of consumption, the chance are good that the cat will recover. This generally consists of emptying the gastrointestinal tract of the affected cat and intravenous fluid therapy in a hospital setting. If more than 18 hours has elapsed, the cat may not survive, even with emergency care.

PREVENTION: Easter lily is a popular plant at certain times of the year, and extra caution must be used when bringing these plants into the house where cats can get at them. Make sure the plant is kept away from cats, especially ones that like to nibble on things. If nibbling plants is unavoidable, have a selection of safe plants available (grass or catnip are two possibilities).

INDEX

5. ENGLISH IVY

Hedera helix

(ginseng family)

TOXICITY RATING: Low. Although reported to be very toxic in a few scattered reports, this is not a frequently encountered toxicosis.

ANIMALS AFFECTED: Cats, dogs, birds, other pets.

DANGEROUS PARTS OF PLANT: Leaves, berries.

CLASS OF SIGNS: Oral irritation, stomach irritation, diarrhea, breathing problems, coma, death.

PLANT DESCRIPTION: The vines that give many colleges their "halls of ivy" appearance may be poisonous. These woody vines, also used as groundcovers, have alternate, palmately-lobed, dark green leaves with lighter green veins (fig. 5). Flowers are uncommon but are borne in small umbrella-like clusters and produce small black berries.

SIGNS: A saponic glycoside, the aglycone hederagenin, is found in the leaves and berries. This is an uncommon poisoning, but incidents have been reported in dogs, cats, and pet monkeys, especially when the green berries were eaten. The most common signs relate to mouth and stomach irritation, but coma and death may occur if large quantities are consumed.

FIRST AID: There is no specific antidote. If animals are observed eating English ivy, contact a veterinarian immediately, especially if a large quantity of the plant was consumed. A bite or two of a leaf is not likely to cause a serious problem, but this should be discouraged.

SAFETY IN PREPARED FEEDS: There are no clear reports on this, but consider English ivy unsafe in prepared feeds.

PREVENTION: Keep animals, especially curious nibblers, away from English ivy. Exercise caution for indoor animals as well, since English ivy grows up the sides of buildings and can grow through window openings.

INDEX

14. ERGOT

Claviceps purpurea

(fungus)

TOXICITY RATING: Moderate. While ergot itself is extremely dangerous, modern feed production practices are vigilant in not allowing ergot into grain mixtures. Pasture poisoning remains the most likely source for toxicosis.

ANIMALS AFFECTED: Any animal consuming affected grain or grass seed heads: primarily swine, cattle, sheep, and goats. Poultry and horses may also be affected.

DANGEROUS PARTS OF PLANTS: Fungal bodies in the seed heads of grains and grasses.

CLASS OF SIGNS: Behavioral changes, lameness, abortions, convulsions, gangrene, death.

PLANT DESCRIPTION: Ergot (fig. 14) is a fungus parasite of the heads of grasses. In mid- to late-summer, entire grains are replaced by the black, hardened bodies of the fungus. Each body is up to 1 inch long, larger than the normal grain, and protrudes conspicuously from the head. One to a half dozen ergot bodies may develop on one head of grass. Ergots on wheat are straight. On rye they usually are curved. Ergot is found wherever its host plants grow. Rye is the most frequently attacked grain. Other grain, hay, turf, and weedy grasses may be affected, including wheat, oats, wild rice, Kentucky bluegrass, perennial ryegrass, redtop, smooth brome, orchardgrass, quackgrass, reed canarygrass, etc. When grain or hay is harvested, ergot bodies may fall to the ground and be left behind to infect the next season's crop.

SIGNS: The amines and the alkaloids in ergot (ergotamine being one of the major alkaloids) produce a number of clinical signs relating primarily to vasoconstriction and psychoactive effects. The ergot toxins are very similar structurally to lysergic acid (LSD). Wheat and rye contaminated with ergot has affected humans, and the resulting disorder is called St. Anthony's Fire. It is also believed that the one of the reasons for the Salem witch trials was due to the abnormal behavior of

persons affected with ergot toxicosis from contaminated rye flour. Ergot has been used in herbal medicine to control hemorrhage during childbirth, and is used currently as a drug to help control migraines.

Animals may be affected by ergot from eating small amounts over a long period of time, or eating greater quantities in a short period of time. Chronic toxicity is more common, with signs manifesting within several weeks of ergot consumption, and field exposure to ergot is more common than processed feed or flour exposure.

The clinical signs can vary, but often begins with swelling of and pain in the extremities, especially the hind legs, due to the constriction of blood vessels. Later, sensation is lost in the affected areas, and dry gangrene can develop. Eventually, the affected areas may slough ("fall off"), with typical losses including claws, hooves, teats, ears, or tail. In addition to the vascular effects, neurologic signs are often seen, such as apprehension, nervousness, and convulsions. Some animals may show signs of depression. Death can occur, but only with significant quantities ingested. In sublethal cases, once the source of ergot is removed, recovery from neurologic signs is likely, but recovery from the vascular effects and gangrene is not likely. Ergot poisoning has been implicated in cases of abortion in large animals.

FIRST AID: Remove animals from the source of ergot, whether in feed or pasture. Call a veterinarian if nervous signs are present. In cases of dry gangrene, the affected portion will be likely to spontaneously amputate. A veterinarian can advise and assist. Always exercise caution when working around animals that have nervous and behavioral changes to prevent human injury.

SAFETY IN PREPARED FEEDS: Ergot remains toxic in feed and should never be fed. Most feed producers are aware of ergot, so it is rare to have it contaminate commercially prepared feeds.

PREVENTION: Screen grains carefully prior to feeding or planting. Affected pastures may produce ergot each year under the right environmental circumstances (typically after wet, cool spring growing seasons). Commercially prepared feeds will not contain ergot. Pasture managers need to be able to identify ergot and limit animal access to affected fields. Keeping the pasture grasses mowed to prevent seed head formation will greatly decrease the presence of the ergot fungus. The fungus is likely to be present in the pasture, so infestations may occur in any year with the right environmental conditions.

INDEX

15. TALL FESCUE

Festuca arundinacea

(grass family)

TOXICITY RATING: Moderate to high, depending upon individual circumstance.

ANIMALS AFFECTED: Horses, cattle, possibly other ruminants.

DANGEROUS PARTS OF THE PLANT: Seed head, stem and leaf sheath.

CLASS OF SIGNS: Reproductive problems, "poor doers", lameness, dry gangrene, fever, death.

PLANT DESCRIPTION: This grass (fig. 15), often cultivated in wet pastures for forage or for turf, is a perennial, 3 to 4 foot tall clump grass with medium-wide leaves that are rough-ribbed on top. It has no rootstocks (rhizomes). The heads are open and many-branched. Escaped plants may be found along roadsides and in waste areas, especially in the southern half of the state.

SIGNS: Toxicity is the result of an endophytic ("inside the plant") fungus, *Acremonium coenophialum*, which is believed to enable the grass to be more hardy and outcompete other grass species. The grass itself is not toxic. The fungus is passed in the seed, and is not transmitted directly from plant to plant.

In horses, pregnant mares are most at risk when eating fescue, since the alkaloids produced by the fungus inhibit prolactin release. Mares will have an increased risk of prolonged gestation, abortion, stillbirth, dystocia (difficult birth), foal mortality, retained or thickened placenta, no milk, and mare death (in foaling, or from a retained placenta).

In cattle, several syndromes have been reported, including fescue toxicosis (summer slump), fescue foot and abdominal fat necrosis. Summer slump causes slower gains, decreased milk production, poor appetite, retention of winter coat, reproductive problems, and elevated

temperature. Diarrhea may also be present. Summer slump tends to occur in the warmer months, but has been noted at any time of year, and is the most common of the three syndromes. Fescue foot tends to develop in the late fall and winter, and the extremities (typically tail, ears, and rear feet) undergo necrosis ("death"). Another name for this type of necrosis is "dry gangrene". Fat necrosis develops when areas of fat inside the abdomen die.

Additional note: Fescue can accumulate nitrates under conditions of overfertilization (see the section on oats for more information on nitrate toxicosis).

FIRST AID: There is only supportive and symptomatic treatment once signs appear. A veterinarian can advise on treatment of more severely affected animals. Pregnant mares will be likely to need assistance when foaling and in the post-foaling period. Foals that survive will require supplemental colostrum. Management and prevention are the best means to minimize losses.

SAFETY IN PREPARED FEEDS: The toxin remains active in hay.

PREVENTION: There are several options, depending on the farm situation. Fungicides do not work, so animal and pasture management are the only viable alternatives. Pastures can be tested for the presence and degree of fungal contamination, and reseeded may be required. If reseeding the pasture is not feasible, keeping the pasture short will prevent seed formation. Feeding other forages, such as other warm season grasses or legumes, will be of benefit. Fescue pastures can also be diluted with legume planting (red or white clover). Heavy fertilization may make the problem worse, especially in cattle. If fescue has to be used for mares, at least avoid feeding fescue hay or pasture during the last 30 to 60 days of gestation to minimize problems. Endophyte-free strains of fescue exist, although they do not grow as well as tall fescue with endophyte.

INDEX

1. FOXTAIL BARLEY, SQUIRRELTAIL BARLEY, WILD BARLEY

Hordeum jubatum

(grass family)

TOXICITY RATING: Moderate. Irritation from the awns is likely, but serious illness and death are rare.

ANIMALS AFFECTED: All animals can be affected. Grazing animals and outdoor dogs are especially at risk.

DANGEROUS PARTS OF PLANT: Seedheads (awns).

CLASS OF SIGNS: Skin, mouth, ear, nose, and eye irritation; stomach irritation, abscesses.

PLANT DESCRIPTION: This perennial weedy grass (fig. 1) of fields, waste places, and roadsides gets its name from the long bushy flower spikes. Each long, slender, wiry bristle bears small teeth or barbs that point backwards like tiny fishhooks.

SIGNS: The seed heads (especially the awns) of this and several other types of grasses can cause mechanical irritation to the skin, eyes, ears, nose, mouth, and stomach of animals. The grasses can cause problems in pasture as well as in prepared feeds like hay. Embedded seed heads can cause local irritation and infections, or become more deeply embedded in tissues and migrate in the body. Irritation and infection often develop, necessitating removal of the plant matter. Signs depend on location of the seed awn, and can include head shaking; sneezing; nasal or ocular discharge; rubbing at the ears, eyes, or mouth; difficulty in chewing or swallowing; or signs of digestive disturbance. Yellow or green foxtail, rye and millet can cause similar problems.

FIRST AID: For minor irritation, supportive care is all that is required. Minor irritations will resolve in about a day. If any of the following are noted, a veterinarian needs to be contacted: if signs are severe, if signs of irritation do not resolve, if the eyes or ears are involved, or if the

animal cannot eat. Infections and abscesses require veterinary care, and some awns may need surgical removal.

SAFETY IN PREPARED FEEDS: Small amounts incorporated in hay and other feeds may not cause much harm, most animals will avoid eating these plants if better quality feed is available (good hay and feeds do not contain many seed heads of these grasses). Hay and other feeds containing large quantities of these seed heads are not safe for consumption, especially if animals are forced to eat these feeds.

PREVENTION: These plants are common weeds in pastures and along roadsides. If problems occur with these plants, consider mowing to reduce seedhead formation or otherwise removing them. The foxtail that commonly grows in the western U.S. (*Setaria*) is especially problematic and animals should have little or no contact with this grass.

INDEX

25. GREEN FALSEHELLEBORE, WHITE HELLEBORE, INDIAN POKE

Veratrum woodii

(lily family)

TOXICITY RATING: Moderate to high, depending on individual circumstance.

ANIMALS AFFECTED: Sheep are affected primarily, but chickens and cattle may also be at risk.

DANGEROUS PARTS OF PLANT: All parts, especially roots.

CLASS OF SIGNS: Gastrointestinal irritation, salivating, weakness, trembling, heart problems, breathing difficulties, birth defects.

PLANT DESCRIPTION: These perennial herbaceous plants (fig. 25) have stout, erect, unbranched, 1-8 feet tall stems arising from short, thick rootstocks. There are clusters of large, broad, alternate leaves that to some people resemble garden cabbage or skunk cabbage. These leaves are parallel-veined and pleated like a skirt. Green to greenish-white, inconspicuous flowers occur in large terminal clusters. *Veratrum woodii* grows in woods or on hillsides and bluffs, most commonly in the central and southern parts of the

state.

SIGNS: False hellebore can cause toxicity in grazing animals or more commonly, cause birth defects. Both of these syndromes are more common in sheep than in other species. It is possible that the toxins causing birth defects are not the same toxins that affect the grazing animals. Since toxicity of grazing animals is exceedingly rare and usually not lethal, this section will briefly cover the grazing animal toxicosis, and will focus on the teratogenic effects of false hellebore.

The toxic component in false hellebore is a mixture of alkaloids (primarily jervine, cyclopamine,

and cycloposine). In grazing animals that consume a toxic dose, salivation, gastrointestinal irritation, weakness, incoordination, decreased heart rate, and breathing difficulties may be noted. Rarely, animals may convulse and die.

More important are the effects that false hellebore has on fetuses. The toxins are known teratogens, causing developmental problems with lambs in utero. Specifically, if a pregnant ewe eats false hellebore on the 14th day of gestation, the lamb may die or have severe developmental problems. The problems in the lamb affect mostly the brain, skull and face, and the lambs can be born with a "monkey-face", or with the eyes in the center of the face ("cyclops") or hydrocephalus, or failure of the head to develop. These lambs are usually born dead or tend to die shortly after birth. In some cases, the ewes gestation is prolonged and the lamb grows too large, necessitating assistance at delivery or a C-section. It is possible that only one of a pair of twin lambs will be affected.

In addition to the well researched aspects in lambs, false hellebore, when ingested at any time prior to the 32nd day of gestation can cause many birth defects and death of the fetuses.

FIRST AID: For grazing animals, treatment is symptomatic. Call a veterinarian if signs are prolonged or severe. Nearly all animals will recover once removed from the plants. For affected fetuses, there is little that can be done other than to assist the ewe in delivery, since some of the lambs are large and/or malformed.

SAFETY IN PREPARED FEEDS: False hellebore reportedly remains toxic when dry, therefore feeds containing this plant should not be fed, especially to sheep.

PREVENTION: False hellebore is a big problem in western ranges, but can affect animals in Indiana. The danger is particularly high with sheep. It would be best to keep all pregnant ewes away from false hellebore until after their 33rd day of gestation. In addition, plants are more toxic in the spring, and toxicity decreases through the growing season. The roots and rhizomes are considered to be more toxic (lethal), with the leaves containing more of the teratogenic (birth defect) compounds. Therefore, be cautious with animals who appear to be eating this plant, and attempt to limit all access to false hellebore as much as possible.

INDEX

28. POISON HEMLOCK

Conium maculatum

(parsnip family)

TOXICITY RATINGS: Moderate to high.

ANIMALS AFFECTED: All animals may be affected. Grazing animals, swine and animals that may eat the seeds (especially poultry) are more at risk than pets.

DANGEROUS PARTS OF PLANT: All parts, especially young leaves and seeds.

CLASS OF SIGNS: Nervousness, trembling, incoordination, depression, coma, death, birth defects.

PLANT DESCRIPTION: This biennial herb (fig. 28) grows 3 to 8 feet tall and has a smooth purple-spotted stem and triangular, finely divided leaves with bases that sheathe the stem. Fresh leaves and roots have a rank, disagreeable, parsnip-like odor. The small but attractive white flowers, arranged in umbrella-like clusters, open in early summer. The fruit is tiny, flattened, and ridged. Underground is a fleshy, unbranched white taproot (fig. 28A). Unlike wild carrot (*Daucus carota*, parsnip family), there are no hairs on the stems or leaves of poison-hemlock and no branching, feathery bracts beneath the flower clusters. These plants are commonly found along roadsides, edges of cultivated fields, railroad tracks, irrigation ditches, stream banks, and in waste areas.

SIGNS: The toxic components include the volatile alkaloids coniine and gamma-coniine. A lethal dose for a horse is 4 to 5 pounds of leaves, cattle may be poisoned with 1 to 2 pounds, and sheep with a half pound or less. Humans are often poisoned, mistaking the roots for parsnips, the leaves for parsley, or the seeds for anise.

Affected animals show signs within 2 hours of eating the plant, and tend to become nervous, and will tremble and become uncoordinated. After the excitement phase, the animal becomes

depressed. The heart and respiratory rates slow down, the legs, ears and other extremities become cold, colic and/or bloating may occur. Even at this stage, the animal may not die, but may remain like this for several hours to days, and then recover. In lethal cases, the animals tend to die within 5 to 10 hours after the onset of the clinical signs, typically from respiratory failure (in which case the mucus membranes will appear blue). A mousy odor has been reported to emanate from affected animals.

The primary time of year for poison hemlock is spring, often when there is insufficient forage available. At this time, the plant may also be more palatable. The toxicity increases throughout the growing season, and the roots become toxic only later in the year. Once dried, the toxicity is considered to be reduced but not eliminated.

Poison hemlock can also cause birth defects in ruminants and swine, with cattle and swine more susceptible than sheep and goats. The most often reported birth defects are cleft palate and spinal abnormalities. The gestational ages that have been associated with birth defects are: for goats, days 30 through 60; for cattle, days 40 through 70; for pigs, days 30 through 60. The birth defects resemble those seen with lupine, with lupine being the more dangerous plant.

FIRST AID: If animals are seen ingesting poison hemlock, call a veterinarian immediately. Treatment consists of eliminating the toxin from the gastrointestinal tract and providing supportive care. If the animals become comatose but do not die, they will require intense nursing care until they recover.

SAFETY IN PREPARED FEEDS: Reportedly, poison hemlock has a decreased toxicity when dry, but hay that contains a large proportion of poison hemlock may still cause problems (besides, it would have a low nutritional value). Recommendations are to feed little or no hay that contains poison hemlock. Seeds may contaminate grain-type feeds, making these feeds unsafe for consumption.

PREVENTION: Most animals will avoid poison hemlock if other forages are available. Tiny amounts may be consumed with little problems resulting, but significant consumption, especially of the seeds, will produce clinical signs and possibly death. Eliminating the plant from the pasture is the best solution; treatment with herbicides may be tried. Be sure all plants are dead prior to re-introduction of animals, since treated plants may be more palatable. Poison hemlock may be difficult to eradicate.

INDEX

27. SPOTTED WATER-HEMLOCK, WATER-HEMLOCK, SPOTTED COWBANE

Cicuta maculata

(parsnip family)

TOXICITY RATING: High. This is one of the most toxic plants in the U.S.**ANIMALS AFFECTED:** All animals can be affected, but cattle are especially at risk.**DANGEROUS PARTS OF PLANT:** The roots contain the highest concentration of toxin, but all parts are toxic.**CLASS OF SIGNS:** Nervousness, breathing difficulties, muscle tremors, collapse, convulsions (seizures), death (which may be sudden).

PLANT DESCRIPTION: The perennial stem of water-hemlock (fig. 27) may grow to 7 feet from its cluster of 2 to 8 fleshy or tuberous roots. Stems are smooth, branching, swollen at the base, purple-striped or mottled, and hollow except for partitions at the junction of the root and stem (fig. 27A). A yellow, oily liquid smelling like parsnips exudes from cut stems and roots. Leaves are alternate, two to three times pinnately compound, and toothed, with the leaf veins extending to the leaf notches. Leaf petioles partially sheath the stems. The small white flowers are borne in flat-topped, umbrella-like clusters at the tips of stems and branches. Seed pods are small and dry with rounded, prominent ribs. Water-hemlock is found in swampy areas and marshes, wet meadows and pastures, and along streambanks and low roadsides.

SIGNS: This plant is considered to be one of the most toxic plants in the United States since so little of it needs to be consumed to cause death. Humans have been killed after only one or two bites of what they thought were "parsnips" (water hemlock root resembles a parsnip). Cattle are the primary species affected, hence the name "cowbane", especially in early spring when the plants are smaller and apparently more palatable and the roots are easily pulled up. Animals may also be poisoned if water hemlock is plowed under or if ground is reclaimed, since this may expose the root. Toxicity decreases through the growing season, and the toxicity of above-ground parts may

be negligible when dry. The roots however are toxic at all times, even when dry. Animals have been poisoned by drinking water that had been contaminated with trampled water hemlock roots.

The toxin is cicutoxin, a yellow, viscous resin with a carrot-like odor, which affects the central nervous system. The toxic dose (the dose needed to cause clinical signs) and the lethal dose are nearly the same, with a little more than 1 gram of water hemlock per kilogram of body weight able to kill sheep, and 8 ounces (approximately 230 grams) will kill a horse.

Once the animal has ingested even a small amount of the plant, signs will develop within an hour, and as soon as 10 to 15 minutes. The syndrome is typically very violent. Stimulation of the central nervous system begins with nervousness, and dilated pupils. Later, muscle tremors occur, the animal has difficulty breathing, falls down and goes into convulsions. Death, from respiratory paralysis and terminal convulsions, is a typical outcome, occurring within 30 minutes of the onset of signs. If a sublethal dose is consumed, and the animal survives for 4 to 6 hours (or in one report, over 2 hours), the animal may recover, but may suffer from temporary or permanent damage to heart and/or skeletal muscle.

FIRST AID: If animals are seen eating water hemlock, especially the roots, get all animals away from the plant, and call a veterinarian immediately. Emergency measures (emptying the stomach or rumen and the use of medications to control seizures) may be tried, but death may still occur. The seizures cause severe damage to the heart and skeletal muscle, and this damage can be avoided if the seizures are controlled. However, this is rarely possible under farm and field conditions since the toxin acts so quickly.

SAFETY IN PREPARED FEEDS: The above-ground parts of water hemlock decrease in toxicity over the growing season and lose additional toxin with drying. Therefore, the hay may not cause clinical toxicosis, but it is still advisable not to feed hay, or other prepared feeds, that contain water hemlock. The root is never safe, and remains toxic when dry, and should never be fed.

PREVENTION: Do not allow livestock (especially cattle) to graze in areas containing water hemlock. Prevent access to these areas or completely remove the plant (most importantly the roots) prior to introducing livestock, especially in the spring or when the roots may be exposed due to plowing, ditch maintenance, or other such activity. Never allow water hemlock to be incorporated into hay or other prepared feeds.

INDEX

29. FIELD HORSETAIL SCOURINGRUSH

Equisetum arvense *Equisetum hyemale*

(horsetail family)

TOXICITY RATING: High for horses, moderate for other species.

ANIMALS AFFECTED: Horses are the species most affected, cattle and sheep may be affected, but this occurs rarely.

DANGEROUS PARTS OF PLANT: All parts, both fresh and dried.

CLASS OF SIGNS: Weight loss, weakness, gait abnormalities, abnormal heart rate and/or rhythm, inability to rise, death.

PLANT DESCRIPTION: Two types of shoots 1 to 3 feet tall merge from horsetail's underground rootstock. Both types are round, hollow, stiff, and jointed. The stem sections easily pull apart. The first type of shoot (fig. 29A) is tan, appears early in spring, and ends in a terminal, cone-like structure. The later, green, sterile shoot (fig. 29A) bears whorls of pine-needle-like branches and looks like a horse's tail. Scouringrush sends up long, tapering, cane-like shoots 1-6 feet tall. These stiff, evergreen shoots terminate in spore-producing cones. Leaves are reduced to teeth-like scales arranged in whorls around the joints of the stems (fig. 29B). The plants commonly grow on shaded, moist soil in meadows, along roadsides, in ditches and thickets, along stream banks, at the

borders of swamps, and on railroad embankments.

SIGNS: The toxic signs associated with horsetail are essentially the same as for bracken fern, since the toxin is the same: thiaminase. Horsetail does not contain the bone marrow toxin found in brackenfern. See the section on bracken fern (horses) for more details.

FIRST AID: A veterinarian needs to be called to assist in the treatment of thiamine deficiency. For more discussion, see brackenfern.

SAFETY IN PREPARED FEEDS: Consumption of horsetail in feeds is the most likely route of poisoning, but fresh plants are also toxic (but considered unpalatable).

PREVENTION: Do not allow horsetail to be incorporated into feeds, especially if these feeds are intended for horses. Do not feed contaminated hay.

INDEX

19. JACK-IN-THE-PULPIT, INDIAN TURNIP

Arisaema triphyllum

(aroid family)

TOXICITY RATING: Low.

ANIMALS AFFECTED: All animals may be affected.

DANGEROUS PARTS OF PLANT: Bulbs, stems, possibly leaves.

CLASS OF SIGNS: Oral and gastric irritation, mouth and throat swelling on rare occasions may be severe enough to affect breathing.

PLANT DESCRIPTION: These herbaceous perennials (fig. 19) pop up in spring in Indiana woodlands. They grow 1 to 2 feet tall from a tuberous root. The large leaves are three-parted, smooth-margined, and net-veined. Each plant produces one bloom beneath the leaves on a short stalk. The "jack" is a fleshy green spike ("spadix") bearing a number of inconspicuous male and female flowers. The most noticeable

part of the bloom is the "pulpit", a modified leaf ("spathe") that wraps around and hides the spadix. It may be all green or striped with red or reddish-violet. In late summer the spathe falls away, revealing a cluster of bright red berries.

SIGNS and FIRST AID: See the section for the Aroid discussion. Rarely is enough of this plant consumed to cause a problem, but the potential exists, especially in spring when other forages are not readily available and if the livestock have access to a wooded area. Signs are self-limiting, and a veterinarian only needs to be contacted if signs do not resolve or if breathing is affected.

PREVENTION: Jack-in-the-Pulpit grows in wooded, shaded areas in the spring, so limit animal access to these areas when plants begin to emerge.

INDEX

36. JIMSONWEED, THORNAPPLE

Datura stramonium

(nightshade family)

TOXICITY RATING: High. The plant and seeds are extremely toxic, this plant is abused as a hallucinogen in humans, and deaths in humans and animals have been reported.

ANIMALS AFFECTED: All animals (including pets and poultry) may be affected.

DANGEROUS PARTS OF PLANT: All parts, especially seeds.

CLASS OF SIGNS: Dilated pupils, agitation, trembling, delirium, may appear to be experiencing hallucinations, convulsions (which may be violent), coma, and possible death. Abortions and birth defects have also been reported.

PLANT DESCRIPTION: This stout, coarse annual (fig. 36) grows to 5 feet tall with strongly-scented, coarsely toothed, green or purplish alternate leaves. The large trumpet-shaped flowers are white or purplish and are formed singly at the forks in the stems. The fruits are hard, spiny capsules (fig. 36) which split open along four lines at maturity to release numerous tiny black seeds. Jimsonweed commonly grows in cultivated fields, waste areas, barnyards, abandoned pastures, roadsides, and feedlots. Other *Datura* species (angel's-trumpets) are grown as ornamentals.

SIGNS: Animals will avoid eating Jimsonweed whenever possible. Even when forages are scarce, animals are reluctant to consume this plant. For animals, the danger lies primarily in the consumption of seeds that contaminate prepared feeds (hay, silage, grains, processed feeds). The plants may become palatable after the application of herbicides, thus greatly increasing the risk of toxicosis.

Once the plant is consumed, signs become apparent within a few minutes up to several hours. The

alkaloids in Jimsonweed act on the central nervous system as well as the autonomic nervous system that controls bodily functions. Animals may seek water to drink, have dilated pupils, become agitated, may exhibit increased heart rate, tremble, become delirious, may appear to be experiencing hallucinations, have convulsions (which may be violent), become comatose, and possibly die. Consumption of Jimsonweed during gestation may result in abortions or birth defects.

Jimsonweed contains many toxic components, in particular the alkaloids, including atropine, hyoscyamine, and hyoscyne (scopolamine). As much as 0.7% of the fresh weight of the leaves may be the toxic alkaloids, which is a very large quantity. The seeds are the greatest risk, with alkaloid concentrations believed to be greater than the leaves and stems, and even the nectar is toxic.

FIRST AID: Prevent further exposure to the plant or contaminated feed. Exercise caution when working with affected animals to avoid human injury. Contact a veterinarian if signs are severe, since there are medications that can counteract the effects of the toxin. Also, if consumption was recent, contact a veterinarian quickly, since it may be possible to evacuate a large amount of the plant from the digestive tract before the toxicosis becomes severe. For less severely affected animals (a veterinarian will be able to assist in determining this), the clinical signs will resolve within a day or two, so keep animals quiet and undisturbed.

SAFETY IN FEEDS: Jimsonweed remains toxic when dry, therefore feeds are not safe for consumption. The small black seeds are very toxic and may contaminate prepared or processed feeds. Toxic signs will occur even when good forage is fed, and there is no reported "safe" quantity of Jimsonweed that can be fed.

PREVENTION: Do not allow animals to graze on Jimsonweed. Provide adequate forage whenever animals are in contact with the growing plants. If the plants are treated with herbicides, make sure they are completely dead prior to introducing animals to the pasture. Use caution when harvesting feeds, especially near the edges of fields where Jimsonweed is likely to grow. In this way, incorporation of the plant or the seeds into the feeds will be prevented. When buying processed feeds, only work with reputable dealers.

INDEX

43. JOHNSONGRASS

Sorghum halepense

(grass family)

TOXICITY RATING: Moderate to high.

ANIMALS AFFECTED: All types, especially ruminants.

DANGEROUS PARTS OF PLANTS: Leaves and stems, especially young plants.

CLASS OF SIGNS: Breathing problems, staggering, severe anxiety, convulsions, coma, death (may be very sudden).

PLANT DESCRIPTION: Johnsongrass (fig. 43), a coarse perennial grass, produces large, scaly rootstocks and grows in dense stands up to 6 feet high. Seed heads are large and loose. This plant grows commonly in the fields, fencerows, and ditch banks of the southern part of the state and is rapidly spreading northward. Once grown for dike stabilization or for hay, it is now classified as a "noxious" weed.

SIGNS: The toxic signs resulting from ingestion of Johnsongrass are due to the presence of cyanide in the leaves and stems. This toxicity is identical to that resulting from the ingestion of wilted or damaged cherry leaves. In normal, healthy Johnsongrass plants, the levels of free cyanide

are low, and the plant can be consumed safely. Other members of this grass genus have been bred as grain or forage plants (milo, Sudan grass, etc.) and also have the potential to produce cyanide, although not as much as Johnsongrass. The young shoots are the most dangerous, and when wilted, trampled, herbicide treated or frost damaged, a great deal of free cyanide is liberated in the leaves. Upon ingestion, the animals quickly develop signs related to cyanide poisoning. Mature plants have much lower toxicity, and well-cured hay is relatively safe for consumption.

The most common occurrence of Johnsongrass toxicity is on pasture after the plants have been damaged somehow. Cyanide prevents the body from being able to utilize oxygen at the cellular level, so although the animals physically can breathe, their tissues and cells "suffocate". After consumption, signs will manifest within a few minutes, but sometimes up to an hour may pass. The animals will try to breathe more rapidly and deeply, and then become anxious and stressed. Later, trembling, incoordination, attempts to urinate and defecate and collapse is noted, which can proceed to a violent death (respiratory and/or cardiac arrest). If an affected animal is still alive 2 or 3 hours after consumption, chances are good that it will live. Under rare circumstances, a chronic cyanide toxicity can develop, which causes weakness and partial paralysis, but this is not a common occurrence. In the southwestern U.S., a syndrome affecting the urinary bladder and nervous system in horses has been reported after consumption of sorghum grasses. This disorder is called equine sorghum cystitis ataxia, and the animal is uncoordinated, has urinary incontinence (dribbles urine uncontrollably), and foals of affected mares may be aborted or be born with birth defects. The disorder can also cause death.

Johnsongrass, like other plant species, can accumulate toxic levels of nitrates, depending on fertilization practices. Nitrates are extremely toxic and can also cause death, especially in cattle, sheep and goats. Look in the section on oats for more discussion of nitrate poisoning. The signs of nitrate poisoning may be confused with cyanide poisoning.

FIRST AID: The clinical signs of cyanide poisoning tends to come on quite rapidly, and the animals may be found dead without much warning. If the animals are exhibiting toxic signs, call a veterinarian immediately. There is an antidote, but it needs to be given intravenously and within a few minutes of the onset of signs, and it is often impossible to get help in time. Prevent the animals (especially the unaffected animals) from eating any more of the grass or feed. Do not handle or stress affected animals any more than absolutely necessary, since this will worsen the signs. Also, affected animals are extremely stressed and may be dangerous to work with, therefore exercise caution so no human injury results. Similar recommendations exist for nitrate poisoning, although death usually doesn't occur as quickly as with cyanide.

SAFETY IN PREPARED FEEDS: When Johnsongrass is dry, the level of cyanide is extremely low, so properly cured hay is safe for consumption. If the grass is used for silage or green chop, the levels of cyanide may still be quite high and potentially lethal. If the grass has accumulated toxic levels of nitrates, the hay, silage and chop will continue to be toxic. This may be fed in small amounts along with an adequate supply of good forage, although it would be best to discard feeds that are high in nitrates.

PREVENTION: Johnsongrass and other sorghums may be grazed safely throughout most of the growing season. Extra care must be taken when the grass is young, especially if damaged somehow. Animals should not be allowed access to the grass if these circumstances occur. Care

43. JOHNSONGRASS

must also be taken when fertilizing johnsongrass (as well as many other types of grasses) so as to not accumulate toxic levels of nitrates. Do not use johnsongrass as green chop or silage.

INDEX

38. COMMON ST. JOHNSWORT, KLAMATH WEED

Hypericum perforatum

(St. Johnswort family)

TOXICITY RATING: Low to moderate.

ANIMALS AFFECTED: Cattle, sheep, goats, horses, and swine.

DANGEROUS PARTS OF PLANT: All parts.

CLASS OF SIGNS: Sunburn, skin slough, eye irritation.

PLANT DESCRIPTION: This perennial herb (fig. 38) grows 1 to 1 1/2 feet 1/2 to 1 inch long and flat-topped clusters of golden yellow flowers 3/4 to 1 inch broad which bloom from midsummer to late fall. The five petals often have distinctive black dots around their edges (fig. 38A) and the leaves may have similar dots (fig. 38B). St. Johnswort commonly grows in droughty, poor, or over-grazed meadows, pastures, fields, and waste areas, usually on dry, gravelly, or sandy soils in full sunshine. Other species of *Hypericum* occur in Indiana, some as garden plants. Although the evidence of their toxicity is not as clear, it may be prudent to avoid them, too.

SIGNS: The toxin in St. Johnswort is called hypericin. When animals ingest the plant, the hypericin is absorbed from the intestinal tract and goes into the circulation. Hypericin is photodynamic, able to convert sunlight into energy (primarily heat), causing cellular damage and sunburn (which can be severe). Cattle and sheep are the most sensitive to this toxin, but swine and horses may also be affected.

St. Johnswort is not palatable and is eaten only when better food is unavailable. Animals must consume the plants for 4 to 5 days or more before clinical signs are noted. The affected skin first

becomes swollen and tender, then reddened. This occurs primarily on the lightly pigmented areas (pink or white skin), and on the areas of the body that receive more sunlight (head, neck, back). The skin can be burned to the point where large areas of skin peel off. This is extremely painful, and predisposes the animal to infection. Affected animals are reluctant to have the areas examined, and may act abnormally and not want to eat due to the discomfort. Occasionally the eyes will be affected, causing redness and inflammation of the eyelids and the eye itself. These animals may not be able to see.

There are many plants that can cause sunburn either by contact or ingestion. In addition to St. Johnswort, some types of clover, vetches and buckwheat (*Fagopyrum*) have caused sunburn and skin scald in animals.

FIRST AID: The first steps are to prevent further consumption of the plant and to get the animals into the shade or a barn. Emergency evacuation of the gastrointestinal tract is not required since the toxin takes several days to build up in the body and cause signs. If the sunburn is mild, conservative treatment and supportive care is all that is required. Animals will resent handling, and horses will not be able to be ridden for at least 1 to 2 weeks. Keep animals in the shade, consider turning them out at night only. For more severely affected animals, including animals whose eyes are affected, or where the skin is blistered or sloughing, a veterinarian needs to be contacted, and antibiotics and anti-inflammatory medications provided.

SAFETY IN PREPARED FEEDS: The toxin in St. Johnswort remains active even when the plants are dry, therefore hay or processed feeds will still be toxic and should not be fed. However, if the hay needs to be fed under extreme circumstances, keep all animals out of direct sunlight for up to one week after the contaminated feed is no longer being used.

PREVENTION: Animals will voluntarily avoid St. Johnswort if more nutritious and palatable forage is made available. If the pasture contains large stands of this plant, it may be best to mow, spray, or re-seed to improve the pasture quality and eliminate potential problems. If the plants are to be sprayed, keep animals off the pasture until the plants are completely dead, since herbicide treatment often increases plant palatability.

INDEX

20. DWARF LARKSPUR, STAGGERWEED, POISON WEED

Delphinium tricorne

CULTIVATED LARKSPUR

Delphinium ajacis

(buttercup family)

TOXICITY RATING: Moderate for Indiana. These plants are a more serious threat in the western ranges.

ANIMALS AFFECTED: Cattle are the primary animals affected; toxin can also affect other ruminants as well as horses.

DANGEROUS PARTS OF PLANT: All parts, especially seeds and young leaves.

CLASS OF SIGNS: Nervousness, incoordination, staggering, salivating, bloating, abnormal heart beat, breathing difficulty, paralysis, convulsions, death.

PLANT DESCRIPTION: These short annual or perennial herbs (fig. 20), 1/2 to 4 feet high, bear alternate, deeply-lobed ("crowfoot") leaves and elongate clusters of spurred white, blue, or purple flowers in the spring. Roots grow in tuberous clusters. This weed commonly grows in rich open woods, along

streams, in old fields, along roadsides, and on sand hills. Wild larkspur is most common in the southern two-thirds of the state, but the equally poisonous cultivated larkspur may be found in gardens statewide.

SIGNS: Larkspur is primarily a problem in western ranges, especially with cattle. Apparently, the

plant is palatable, which increases the risk of clinical toxicosis. The toxicity of larkspur varies, with the highest periods of toxicity occurring during early growth, and when the plant goes to seed. The toxin is a mixture of alkaloids, including ajacine and delphinine, and blocks communication between nerves and muscles (like curare). Signs appear within a few hours of ingestion. Approximately 1/4 pound of larkspur per 100 pounds body weight may be lethal for cattle. A higher dose is needed before sheep and horses show clinical signs.

FIRST AID: There is no antidote for larkspur poisoning, and treatment is supportive. A veterinarian needs to be called if the animals are bloated, or if consumption was very recent (the veterinarian may be able to empty the stomach or rumen). Affected animals should not be handled any more than necessary, since stress will worsen the signs.

SAFETY IN PREPARED FEEDS: Larkspur remains toxic when dry, therefore hay and other prepared feeds will be toxic.

PREVENTION: Do not let animals (especially cattle) graze larkspur, particularly during the early growth and seed stages. Keeping pastures mowed will greatly reduce the number of larkspur plants.

INDEX

6. LUPINE, BLUEBONNET, QUAKER-BONNETS

Lupinus perennis (wild)

Lupinus polyphyllus (cultivated)

(pea family)

TOXICITY RATING: Low to moderate in Indiana. In the western rangelands, where lupine grows plentifully, the risk of toxicosis would be high. Different species of lupine have different toxicities. According to reports, *L. leucophyllus* (velvet or wooly-leaved lupine) is the most toxic and should never be grazed since all stages of plant growth are toxic.

ANIMALS AFFECTED: Sheep are primarily affected, but all animals are susceptible.

DANGEROUS PARTS OF PLANT: All parts, especially pods with seeds.

CLASS OF SIGNS: Breathing problems, behavioral changes, trembling, birth defects, coma, death.

PLANT DESCRIPTION: Lupines (fig. 6) are herbaceous perennials grown in gardens or found wild along roadsides, in fields, and in open woods. Wild lupines are common only in the prairie and lake counties of Indiana. In the rangelands of the West, they are a leading cause of livestock poisoning. Several stems often grow from one creeping root and reach 12 to 30 inches in height. The leaves are alternate and pal-

mately compound with 7 to 11 spear-tip-shaped, softly hairy segments. Elongate spikes of blue, purple, white, magenta, or bicolored pea-like flowers in early summer are followed by 1- to 2-inch, fuzzy, pea-like pods.

SIGNS: Toxicity in lupine is believed to result primarily from the alkaloid D-lupanine. The signs of lupine poisoning can develop within an hour or may take as long as a day. The signs are related

to the nervous system and resemble the signs seen with excessive consumption of nicotine (tobacco): twitching, nervousness, depression, difficulty in moving and breathing, and loss of muscular control. If large quantities were consumed, convulsions, coma, and death by respiratory paralysis may occur. In cows that graze lupine, skeletal birth defects in calves can occur, and the syndrome is called "crooked calf".

FIRST AID: There is no antidote. Allow affected livestock to rest quietly, especially if they are unfamiliar with human contact. Handling, trailering, or other stress on the animals after they have been grazing lupine will make the signs worse and can increase losses.

SAFETY IN PREPARED FEEDS: The alkaloids in lupine remain after the plants have dried, so prepared feeds are unsafe for consumption, especially if the feeds contain lupine seed pods.

PREVENTION: Do not allow hungry animals access to lupine, particularly when in the seed stage, if other forage is not available. If lupines are prevalent in the pasture, become familiar with the particular species, since toxicities vary. Do not handle, process, or ship animals that are heavily grazing lupine since this type of stress will increase the number of animals that will become sick and/or die. Livestock can graze lupine without incident as long as excessive ingestion is avoided and animals are not handled or trailered while on lupine pastures (and if the animals are not pregnant). In cattle, to avoid birth defects, do not allow grazing between days 40 and 70 of gestation.

INDEX

50. Red Maple

Acer rubrum

(maple family)

TOXICITY RATING: High, death is common.

ANIMALS AFFECTED: Horses only.

DANGEROUS PARTS OF PLANT: Leaves, especially when fallen, damaged, or wilted.

CLASS OF SYMPTOMS: Breathing difficulties, jaundice, dark brown urine, death.

PLANT DESCRIPTION: Red maple is a tree of medium size, occurring naturally or planted as an ornamental. Young bark is a smooth gray color, older bark is dark and broken. Leaves are 3 to 5 lobed, with shallow notches between lobes. Underside of leaves are white. Leaves are green during the growing season and turn red in the fall. Buds, twigs, flowers, and petioles are red. The sap is not milky.

SIGNS: The toxin has not been identified, but is believed to be an oxidant due to its effects on red blood cells. Only horses are known to be affected. The ingestion of wilted or fallen leaves causes massive destruction of red blood cells, and the blood can no longer carry sufficient oxygen. Ingestion of 1.5 pounds of leaves is toxic, and ingestion of 3 pounds is lethal. Wilted or dry leaves remain toxic for about a month. Fresh and undamaged leaves have not been implicated, but ingestion is still not advised. Clinical signs develop within one or two days and can include depression, lethargy, increased rate and depth of breathing, increased heart rate, jaundice, dark brown urine, coma, and death. Approximately 50% to 75% of affected horses die or are euthanized.

FIRST AID: The first step is to prevent further consumption by the horse (and any other horses on the same pasture). There is no specific treatment, and contacting a veterinarian is advised. The veterinarian may use methylene blue, but this is not often effective in horses, but can be tried early in the course of the disorder. Treatment is symptomatic and supportive and can include mineral oil and activated charcoal to prevent further absorption in the stomach, oxygen, fluid support, and blood transfusions.

SAFETY IN PREPARED FEEDS: Reports are lacking, but red maple should not be considered safe in hay, especially if it is freshly baled.

PREVENTION: Do not allow horses access to red maple. Most poisoning occur in the late summer and fall when leaves fall into pastures, or at any time when fallen limbs are placed in pastures. Apparently the leaves are palatable, thus increasing the risk of toxicosis. Do not incorporate red maple leaves into hay bales.

INDEX

35. HEMP, MARIJUANA, HASHISH, HASH

Cannabis sativa

(nettle family)

TOXICITY RATING: Low. Animals tend to avoid this plant, and toxic encounters are rarely fatal.

ANIMALS AFFECTED: All animals, pets as well as horses and livestock, may be affected.

DANGEROUS PARTS OF PLANT: Leaves, stems, flowers, seeds.

CLASS OF SIGNS: Behavioral changes, trembling, incoordination, gastrointestinal signs, sometime breathing difficulty.

PLANT DESCRIPTION: This coarse, roughly hairy, herbaceous annual, at least 3 to 6 feet tall, has opposite leaves on the lower part of the plant, alternate leaves above (fig. 35). The leaves are made up of from 3 to 7 coarsely-saw-toothed, rough-to-the-touch, long, narrow leaflets borne in a finger-like arrangement. Male and female flowers are found on separate plants, the male flowers on branch tips and the female along the length of the branches. Hemp may be found in weedy pastures, fence rows, brushy stream banks, and illicit plantings.

SIGNS: Nearly all animals will voluntarily avoid marijuana. Toxic cases are usually encountered when the plant is mixed in prepared feeds or bedding materials, or if the animal is forced into consuming or inhaling smoke from the plant. Signs can include nervousness and disorientation which can progress to depression, trembling, vomiting (in those species that can vomit), and sometimes diarrhea and breathing difficulties. Fatalities are rare. Animals more likely to be poisoned are pets (especially dogs and birds), and perhaps swine, but all species are susceptible.

The primary toxic component is tetrahydrocannabinol, a resin. In addition, alkaloids and glycosides are present in marijuana. Toxicity varies greatly in the plants. The top leaves and flower buds of the female plants contain the highest toxin concentration, with the rest of the plant as well

as male plants being toxic to a lesser degree.

FIRST AID: In nearly all cases, effects will wear off within a few hours with little or no permanent damage done. In cases of massive (or malicious) poisoning, contact a veterinarian as soon as possible. Emergency evacuation of the gastrointestinal tract may be necessary with followup supportive care. In cases where an animal (most often a dog) has consumed marijuana in baked goods (typically brownies), chocolate toxicosis may be additive to marijuana toxicosis. A veterinarian needs to be contacted in both cases of toxicoses.

SAFETY IN PREPARED FEEDS: Marijuana remains toxic when dried, therefore prepared feeds will still be toxic.

PREVENTION: Do not allow animals to have contact with the plant or any "preparations" where it might be contained and do not allow malicious intoxication.

INDEX

26. MILKWEEDS

Asclepias spp.

(milkweed family)

TOXICITY RATING: Low to moderate. Milkweeds are unpalatable, and have variable toxicities. Death is not likely unless large quantities are consumed.

ANIMALS AFFECTED: All animals may be affected. Sheep are most at risk, but cattle, goats, horses, poultry, and pets are also at risk.

DANGEROUS PARTS OF PLANT: Stems, leaves, roots.

CLASS OF SIGNS: Gastrointestinal irritation (primarily vomiting and diarrhea), incoordination, tremors, heart problems, respiratory difficulty, death.

PLANT DESCRIPTION: Milkweeds, such as common milkweed, *Asclepias syriaca* (fig. 26), get their name from the thick, sticky, milky sap that oozes out of cut or torn leaves, stems, and fresh pods. The usually solitary stems of milkweed grow 1 to 5 feet tall and bear opposite (sometimes whorled), sometimes fleshy leaves with entire margins. Flowers emerge in umbrella-like clusters and range in color from pink to rose-purple to orange or white. The fruit (fig. 26A) is a pod with "tufted" seeds. A dozen species of milkweeds grow in Indiana woods and swamps, but most commonly in dry soils of fields and road-

sides. Dogbanes (*Apocynum* spp.), which are easily confused with milkweeds, are found in the same habitats and may cause similar poisoning.

SIGNS: There are several different types of milkweeds with varying degrees of toxicity, with the whorled milkweeds being the most toxic. Milkweed plants are considered unpalatable and are eaten only when other forages are not available, and may also be found in hay and processed feeds. The primary toxicants are cardiac glycosides that cause gastrointestinal, cardiac and respiratory

problems and can cause death if enough is consumed. Resins (especially galitoxin) in the milky sap may also contribute to the toxicity of milkweed. In ruminants, the first signs are incoordination, muscle tremors and spasms, bloat, increased heart rate, breathing problems, and occasionally death. Horses are very reluctant to eat this plant, and its toxicity is only rarely reported: colic, diarrhea, abnormal heart rate and rhythm, rarely death. In animals that are capable of vomiting (pigs, dogs, cats, humans), this is the first sign to develop and is beneficial in that further absorption of the toxin is lessened. Horses cannot vomit, and vomiting is not generally observable in ruminants (if vomiting occurs, the contents still remain in the rumen), therefore toxic signs will be worse in these species.

FIRST AID: There is no antidote if an animal consumes milkweed. It is important to limit further ingestion of the plants or contaminated feed. If the animal recently consumed a large amount of the plant, a veterinarian should be called so that the gastrointestinal tract can be emptied and supportive care provided. Small tastes of the plants tend to result in minor oral irritation, and serve as a deterrent to further consumption, and these little nibbles typically do not require treatment.

SAFETY IN PREPARED FEEDS: Milkweed is toxic both fresh and dried, therefore hay, silage, green chop, and processed feeds that contain milkweed are never safe for consumption.

PREVENTION: Animals will avoid milkweed as long as there is sufficient forage available. Care must be taken to avoid incorporation of milkweed into prepared feeds and hay, and these feeds should be discarded.

INDEX

34. MUSTARD FAMILY

Brassica (wild mustard)

Thlaspi (pennycress)

Lepidium (peppergrass), etc.

TOXICITY RATING: Low to moderate.

ANIMALS AFFECTED: Cattle, horses, sheep, poultry.

DANGEROUS PARTS OF PLANT: All parts, especially seeds.

CLASS OF SIGNS: Oral and gastrointestinal irritation, photosensitivity, breathing difficulty.

PLANT DESCRIPTION: Mustard family members have a pungent, sulfurous odor or taste. They may be annual, perennial, or biennial, with a basal cluster of leaves and alternate leaves on the stem that are usually smaller and shorter-stalked than the basal leaves. Flowers of most mustard species are yellow, but some are white, blue, or purple, and all have four petals in a cross-like arrangement (fig. 34A). The seedpod (silique) is dry and may be broad and flat (fig. 34B) or skinny and much longer than it is wide (fig. 34C). The mustard family includes weeds such as yellow rocket, black mustard (fig. 34), tansy mustard, peppergrass, and pennycress. These are found in fields, pastures, lawns, roadsides, waste areas, and sometimes in woods. Cultivated

mustards, which may be harmful if eaten in large quantities, include cabbage, rape, broccoli, turnip, rutabaga, horseradish, and radish.

SIGNS: Mustard plants are capable of causing several types of problems. The most common is oral and gastrointestinal irritation primarily the result of the isoallyl thiocyanates and irritant oils. The plants are not palatable and tend to be avoided unless there is little else to eat or if the seeds have been incorporated into processed feeds. Clinical signs could include oral irritation, head shaking, salivating, colic, abdominal pain, vomiting (in those species capable of vomiting), and possibly diarrhea. Swine and younger animals (lambs and calves) appear to be more susceptible to the irritant effects of mustard seeds in processed feeds. In order to cause toxicity, fairly large amounts need to be consumed over a period of time.

Mustard plants can cause other problems, although these are not reported as often. Photosensitization has been reported in cattle after rape (*B. napus*) was consumed. There are also reports of abortions, goiter and blindness due to mustard consumption, but these are not major problems. Mustard plants may accumulate nitrates under certain fertilization conditions, and thus cause nitrate toxicosis.

FIRST AID: There is no antidote for mustard poisoning. Supportive care and providing adequate quality forage is necessary. For more serious signs, or if animals do not recover when mustard feed is withdrawn, consult a veterinarian.

SAFETY IN PREPARED FEEDS: Mustard plants retain their toxic components upon drying. The seeds in particular contain a high concentration of toxins, and may be incorporated into grain mixes or hay. Care must be taken to insure that these plants and seeds do not contaminate feeds, since they are toxic in any quantity. If small amounts have been incorporated into hay, animals are likely to voluntarily avoid the plants. However, if the hay is highly contaminated and there is no other forage available, the animals will eat the mustard out of necessity and suffer toxic signs as a result. Therefore, avoid feeding mustard, but if this is not entirely possible, provide for additional and more nutritious forage.

PREVENTION: Do not feed hay or other feeds that contain mustard plants or seeds. Do not let animals onto pastures that are overgrown with mustard plants without providing adequate edible forage. Use caution when feeding animals (especially swine) crop harvest leftovers from plants in the mustard family.

INDEX

31. STINGING NETTLE WOOD (BULL) NETTLE

Urtica dioica *Laportea canadensis*

(nettle family)

TOXICITY RATING: Low. Local irritation is the most common sign which shortly resolves on its own.

ANIMALS AFFECTED: Any animal that brushes against or consumes the plant can be affected. Short-haired hunting dogs and other dogs that run through the underbrush are more likely to encounter this plant.

DANGEROUS PARTS OF PLANT: Stems, leaves.

CLASS OF SIGNS: Facial, skin and oral irritation, salivation, pawing at the mouth, possible ocular irritation.

PLANT DESCRIPTION: These herbaceous perennials are common on moist ground in flood plains, woodlands, and along stream and river banks. They often occur in colonies so large that they are the only herbaceous plant present. The tough unbranched stems grow 2 to 5 feet tall from fibrous roots and are covered with stinging bristles. The leaves are opposite, thin, egg-shaped, toothed, and tapered at the tip. They measure 2 to 6 inches by 1 to 2 inches in stinging nettle and 3 to 8 inches by 3 to 5 inches in wood nettle. The 3 to 5 main veins from the base make the leaf (especially in wood nettle) strongly resemble the leaves of white snakeroot. However, the stinging hairs on the lower surface of the leaves prove the plant's identity. The tiny, green or greenish-white flowers droop in axillary clusters in stinging nettle (fig. 31) and stand upright in branching clusters at the top of the stem in wood nettles.

SIGNS: The small, hollow hairs in stinging nettle contain several irritating substances such as histamine (the mediator of some allergic reactions), serotonin, acetylcholine and formic acid (ants

contain a high concentration of formic acid). These substances, coupled with the hairs ability to scratch the skin and mucus membranes, results in almost immediate burning, itching and irritation. Typically, signs are present for a few minutes to a few hours, and resolve on their own. If oral contact was made, the animal may shake its head, salivate, and rub its mouth. Skin irritation is possible, especially with short-coated dogs, and ocular (eye) irritation is also possible. It is possible that the animals attempts to comfort itself and relieve the irritation may cause more damage than the plant itself. On very rare occasions (and only after significant amounts were consumed or contacted) will more severe systemic signs manifest (trembling, weakness, disturbances in heart rate). Nearly all animals (including humans) learn to stay away from nettle.

FIRST AID: Limit further exposure as much as possible. Remove affected animals from the areas where the plants are located, and monitor the animals so they don't self-traumatize. Recovery should occur within a few minutes to hours. If animals continue to have difficulty, or if more serious signs develop, or at any time if the eyes are affected, contact a veterinarian.

SAFETY IN PREPARED FEEDS: There is little information on the safety of nettle in feeds. However, due to its irritant potential, inclusion of this plant into hay or feeds is not recommended.

PREVENTION: Use caution in marshy or wooded areas where dense stands of nettle may be located. Prevent animals from contacting the plants as much as possible.

INDEX

42. BLACK NIGHTSHADE

Solanum nigrum

CAROLINA HORSENETTLE, BULL NETTLE

Solanum carolinense

BITTER NIGHTSHADE, CLIMBING BITTERSWEET

Solanum dulcamara

(nightshade family)

TOXICITY RATING: Moderate. While the plant itself is very toxic, it is also unpalatable, and rarely does an animal consume enough to cause a serious or potentially lethal poisoning. Toxic risk is higher if the plant is included in processed feeds.

ANIMALS AFFECTED: All animals, including pets, may be affected.

DANGEROUS PARTS OF PLANT: All parts are potentially toxic, the berries are often higher in toxicity.

CLASS OF SIGNS: The nightshade plants cause problems with the gastrointestinal tract and can also affect the central nervous system. Signs can include abdominal pain, vomiting, diarrhea, incoordination, weakness, depression, apparent hallucinations, convulsions, and possible death.

PLANT DESCRIPTION: Black nightshade is a low-branching annual (fig. 42A), 1 to 2 feet tall with triangular stems that bear oval, thin-textured, alternate leaves with wavy margins. The tiny white flowers, borne in drooping clusters on lateral stalks between the leaves, resemble tomato flowers. The berry fruit is green when immature, purplish-black when ripe. Bitter nightshade

resembles black nightshade except that the stems are climbing, the lower leaves are lobed at the base, the flowers are purple, and the ripe fruit is red. Horsenettles (fig. 42B) are similar but have coarser, prickly stems, larger white to purplish flowers in loose clusters, and yellow fruits that look much like small tomatoes. All three species commonly grow in open woods, old fields, waste areas, pastures, along roadsides, and around farm buildings.

SIGNS: Clinical signs of poisoning in the nightshade family tend to reflect gastrointestinal irritation and/or effects on the central nervous system. The plant is not palatable and is eaten only when animals have no other forage available. The plant may be a contaminant in hay, where it will still cause toxicity. Pets may eat the green, red, or black berries and be poisoned. The major toxin is solanine, an alkaloidal glycoside, and along with other glycosides and atropine have numerous and powerful effects on the body.

Gastrointestinal signs can include: vomiting (in those species that can vomit), poor appetite, abdominal pain, and diarrhea which may become bloody. Central nervous system signs can include depression, difficulty breathing, incoordination, weakness, collapse, convulsions, and possible death. In one report, one to ten pounds of plant material was potentially lethal for a horse.

A chronic toxicity has also been reported, where the animal eats small amounts of the plants each day. These animals tend to present with general unthriftiness, depression, and diarrhea or constipation.

FIRST AID: If a large amount of nightshade plant was consumed, contact a veterinarian immediately, since emergency measures may need to be undertaken. In most cases the animals will avoid eating this plant, so clinical cases are rare. Curious or bored pets are particularly at risk, and a veterinarian should be contacted if these animals are seen eating a nightshade plant. Treatment is largely symptomatic until the clinical signs wear off (which can take a day or two, sometimes longer). Death is rare in animals, but has occurred in people who have abused these plants.

SAFETY IN PREPARED FEEDS: The nightshade plants lose some toxicity with drying, but the toxin is not eliminated. Therefore, feeds containing nightshade are not considered to be safe. If there are just a few plants in hay bales, the animals may voluntarily avoid the nightshade if provided with enough nutritious and safe hay. In the case of hay then, careful observation to see that the nightshades are being left may make it allowable to feed the rest of the affected bales. If the feed is more highly processed (silage, chop, pellets), the feed is not safe at all since the animals will not be able to avoid the nightshade plants.

PREVENTION: Nearly all grazing animals will avoid eating plants in the nightshade family unless they are extremely hungry and there is little else to eat. The exception to this is if nightshade plants are incorporated into prepared feeds and the animals eat them unknowingly, therefore only feed quality feeds and only purchase from reputable dealers. Pets may be attracted to and eat the berries, so always keep pets away from nightshade plants, especially if the pet is confined, bored or unattended.

NOTE: Other *Solanum* species contain the same poisonous principle. These include buffalobur (*Solanum cornutum*), the ornamental Jerusalem cherry (*Solanum pseudocapsicum*), and the common white potato (*Solanum tuberosum*). Sprouts and sunburned (green) or spoiled potato

tubers should not be mixed in feed because they also contain solanine. Vines of tomatoes (*Lycopersicon esculentum*, nightshade family) contain similar glycoalkaloids. Toxicity is also related to that seen with Jimsonweed.

INDEX

47. RED OAK

Quercus rubra

(beech family)

TOXICITY RATING: Moderate high.

ANIMALS AFFECTED: All animals may potentially be affected, but the primary risk is to cattle.

DANGEROUS PARTS OF PLANT: Buds (fall), young shoots (early spring), sprouts, acorns.

CLASS OF SIGNS: Poor doer, poor appetite, weight loss, diarrhea or constipation, increased drinking, increased urination, edema, death is possible.

PLANT DESCRIPTION: Oaks are trees with leaves that turn brown but hang on through the winter. In the southwestern U.S., Gambel's oak, shinnery oak, and post oak frequently cause poisonings. In our part of the country, red oak has produced problems. Red oak is a large tree of well-drained woodlands, parks, and home plantings that bears broad-bladed leaves with deep lobes ending in bristle-tips (fig. 47). The

fruit is the familiar nut borne in a scaly cup and called an acorn (fig. 47A).

SIGNS: This discussion refers primarily to cattle, the species most often affected by oak toxicosis.

It also seems that cattle less than 2 years of age succumb to oak toxicosis more than do older animals, however older animals are still at risk. Other species at risk include sheep and possibly deer. Goats and swine are more resistant to poisoning, and horses are rarely affected (likely due to a unwillingness to consume oak). Pets rarely consume sufficient quantities to do harm. Many species of oak have been implicated in the poisoning of livestock, with red and black oak exhibiting greater toxicity than white oak.

While short-term acute poisoning by oak has been reported, the most commonly encountered oak poisoning is of a chronic nature. Oak is most dangerous early in the spring when the leaves and buds are the highest in toxicity and when there is little else to eat. The fall is another at risk period, when acorns and leaves fall and better forage dies back. Therefore, management plays a key role in preventing oak toxicosis.

The toxins in oak are called gallotoxins and are converted in the body to tannic acid, gallic acid and pyrogallol, all of which are very toxic to the kidney. It is the resulting kidney failure that causes the clinical signs. Typically, a significant amount of oak needs to be consumed over a period of time before clinical signs appear. Signs can develop over 2 to 14 days, or signs may be present with the animals becoming progressively worse over many weeks. The number of animals affected in the herd can vary greatly, but of those showing clinical signs, up to 80% may die. Signs of oak poisoning can include depression, lack of appetite, a gaunt and emaciated appearance, poor or rough hair coat, dependent edema (fluid buildup under the skin under the neck, abdomen or on the legs), digestive disturbances (both diarrhea and constipation have been reported, with mucus covered or tarry stools), increased drinking, passage of copious amounts of urine which may contain blood, and death.

FIRST AID: The most important step is to get the animals back on to plentiful and nutritious feed, and to limit stress, shipping and handling during the recovery period. Also, make sure that plenty of fresh water is always available, since affected cattle cannot maintain their own water balance very well while recovering. Since this is a long-term chronic toxicity, there is little in the way of an antidote to relieve signs. Severely or more chronically affected animals may not recover, but the less affected animals may, and may return to previous rates of gain and milk production. A veterinarian will be able to assist in management, and will be able to assist in emergency measures if large amounts of oak were recently consumed. Beyond this, treatment is supportive and symptomatic.

SAFETY IN PREPARED FEEDS: The toxin in oak remains when dry, so no feeds are safe that contain oak.

PREVENTION: Oak toxicosis is easily preventable with proper livestock and pasture management. Animals tend to eat oak only out of necessity, therefore by providing adequate and nutritious feed in the spring when the oak leaves bud out and again in the fall when leaves and acorns drop, the incidence of toxicosis should be minimized or eliminated.

INDEX

13. CULTIVATED OATS

Avena sativa

(grass family)

TOXICITY RATING: Moderate.

ANIMALS AFFECTED: Cattle, swine, sheep, goats, poultry, horses.

DANGEROUS PARTS OF PLANT: All parts.

CLASS OF SIGNS: Breathing difficulty, skin irritation, paralysis, convulsions, death (rarely).

PLANT DESCRIPTION: This widely cultivated annual grass has escaped into waste places. The plants grow up together in small tufts. The fruiting structure is a terminal, loose panicle (fig. 13).

SIGNS: Oats may cause up to three separate problems, depending upon the conditions:

a) Oats can accumulate excessive amounts of nitrates, especially when heavily fertilized. Many grasses and forages can accumulate toxic levels of nitrates depending upon fertilization practices. This is a serious problem, especially in cattle. The signs are then consistent with nitrate toxicosis: the blood turns a brownish color due to the action of nitrate on hemoglobin. The blood is not capable of carrying oxygen efficiently, and animals show signs of hypoxia: increased respiratory rate, anxiety, collapse, convulsions, and death. Nitrate toxicosis is less often reported in non-ruminants (horses, swine, etc), but can occur. The primary signs in these species is stomach and intestinal irritation, although an inability of the blood to carry oxygen may develop and require treatment.

b) Oats can also induce a photosensitivity reaction in animals, although the exact mechanism (direct contact and/or ingestion) is uncertain. The skin becomes increasingly susceptible to damage by ultraviolet radiation, and the typical presentation in affected animals is sunburn on the lightly

pigmented parts of the body. Both fresh oats and oat straw can cause a skin reaction.

c) Moldy oats (called smutty oats), which result from the improper curing or storing of oat hay, can cause paralysis, convulsions or death if sufficient quantities are ingested.

FIRST AID: In all three cases of possible toxicoses, the first and most important step is to remove the oats from the animals.

a) For nitrate toxicosis, it is best to call a veterinarian, especially when cattle or other ruminants are affected. There are emergency measures that can be performed, but severely affected animals still may die. Horses, swine, and poultry are less likely to be affected, but if clinical signs develop, they may require treatment as well, although it may be impractical to attempt treatment on swine or poultry.

b) For photosensitization, allow the animal access to shade. The animal may need shade for a week or two until the sunburned areas heal. Animals on pasture can be turned out at night and stabled during the day. Remove oat straw if used for bedding. The sunburn may be severe enough to prevent normal function, such as seeing, eating, walking, allowing young ones to nurse, etc. In these cases, a veterinarian needs to be called to provide supportive care until the lesions heal. In addition, a veterinarian needs to be called if the sunburned areas are extensive or if they appear infected, or if the animal is depressed and unwilling to eat.

c) For moldy oats, discard affected feed and provide proper forage. If clinical signs develop, call a veterinarian.

SAFETY IN PREPARED FEEDS: Ideally, oat hay with excessive levels of nitrate should not be fed. If feeding this hay cannot be avoided, the animals should receive a well-balanced and adequate diet, since these animal will be less likely to show toxic signs. Nitrate contaminated feed should only make up a small portion of the total ration. Since the cause of oat photosensitivity is unknown, consumption of oat hay or grass may induce the clinical syndrome. Moldy oats are not safe for consumption and should be discarded.

PREVENTION: Ideally, the oat feed should be discarded. If this is impossible, know that properly fed cattle can consume forages higher in nitrate than can poorly fed cattle, therefore, feed cattle an adequate and balanced diet, especially if high nitrate forages are to be included in the diet. Do not over-fertilize oats or any grass forage, to reduce the likelihood of this common toxicosis. Photosensitive individuals may need to have oats permanently removed from their diet. Moldy oats should never be fed.

INDEX

52. Oleander

Nerium oleander

Apocynaceae (Dogbane family)

TOXICITY RATING: High. Ingestion of even small amounts can kill.**ANIMALS AFFECTED:** All animals can be affected.**DANGEROUS PARTS OF PLANT:** The entire plant is toxic. Most animals are poisoned by consuming leaves, fresh or dried.**CLASS OF SIGNS:** Gastrointestinal irritation, cardiac abnormalities, death (may be sudden).**PLANT DESCRIPTION:** This plant grows outdoors in warmer regions, and in Indiana is grown as a houseplant. Oleander grows as a shrub or sometimes to the size of a small tree. The leaves are lance-shaped, thick and leathery, and grow opposite each other. Sometimes, leaves may grow in whorls. The leaves are 8 to 10 inches long, although smaller specimens will have shorter leaves. Flowers are showy, approximately 1 to 3 inches in diameter, and grow in large clusters at the ends of the branches, and can be white or any shade of pink or red.**SIGNS:** Oleander contains the toxins oleandrin and nerioside, which very similar to the toxins in foxglove (*Digitalis*). This is a tropical plant, but is grown as an ornamental and as a houseplant in Indiana. Apparently the plant is not palatable, but will be eaten by hungry animals. It is reported that dried or wilted leaves may be slightly more palatable than fresh leaves, and the leaves are still toxic when wilted or dried. In one report with horses, it was indicated that approximately 1/4 pound of leaves (about 30 or 40 leaves) could deliver a lethal dose to an adult horse.

Clinical signs may develop rapidly, and the animal may be found dead with no prior warning. In other cases, depression coupled with gastrointestinal distress is evident: vomiting (in those species that can vomit), diarrhea (which may be bloody), and abdominal pain. Irregularities in the heart

rate and rhythm will occur: the heart may speed up or slow down, and beat erratically. As the toxicosis progresses, the extremities may become cold and the mucous membranes pale. Trembling and collapse can occur, followed by coma and death within a few hours.

FIRST AID: If animals are observed eating oleander, contact a veterinarian immediately. The toxin acts quickly, and is lethal in small amounts. Emergency measures may be used to empty the gastrointestinal tract of remaining plant matter, and medications may be administered to control the effects that the toxin has on the heart. Despite emergency care, the animal may still die, but the sooner treatment is begun, the better the prognosis for survival.

SAFETY IN PREPARED FEEDS: Oleander is extremely toxic, even in small quantities, and the toxin is not eliminated by drying. Therefore, feeds containing oleander are never safe for consumption.

PREVENTION: Be able to identify oleander and exercise extreme caution when pets (and humans) are in the vicinity of these plants. The plants should never be placed where animals can have contact with them. Extra care needs to be taken in cases where leaves can fall into a pasture or in the vicinity of a confined, bored or hungry animal.

INDEX

33. REDROOT PIGWEED

Amaranthus retroflexus

(pigweed family)

TOXICITY RATING: High. The plant is quite common and very toxic.

ANIMALS AFFECTED: Cattle and swine are the animals most likely to be affected; goats and sheep can also be poisoned.

DANGEROUS PARTS OF PLANT: Leaves, stems, roots.

CLASS OF SIGNS: Breathing problems, trembling, weakness, abortions, coma, death.

PLANT DESCRIPTION: Redroot pigweed (fig. 33) is a large (to 5 feet tall), coarse, annual with red stems and simple, egg-shaped, wavy-margined, alternate leaves. The green, inconspicuous flowers are borne in short, compact clusters along with green spines. Seeds are small, shiny, and black. Fields, barnyards, and waste areas are the favorite habitats of this weed.

SIGNS: Pigweed contains a nephrotoxin that causes kidney failure, and also contains soluble oxalates and is capable of accumulating nitrates. Therefore, toxicity can be due to any combination of these toxicoses.

Animals need to consume pigweed in fairly significant quantities over several days before signs appear. Typically, onset of signs is 3 to 7 days from the onset of ingestion. Animals will usually avoid pigweed if there are better forages available. Common incidences of poisonings have occurred when swine have been raised in confinement and are then turned out into a pigweed-infested pasture in the late summer to early fall. Under these circumstances, the swine consume large amounts of the plant quickly, with 5-90% of the animals becoming affected, with 75% or greater mortality among the affected animals. Modern management practices have largely eliminated this type of poisoning, but it can still occur. In cattle, pigweed toxicosis resembles oak toxicosis.

In affected animals, early signs include weakness, trembling and incoordination. This progresses to an inability to stand and paralysis, yet the animals may still be alert and able to eat. Near the end of the clinical course, the affected animals may go into a coma, and have edema under the skin of the abdomen and the legs, have a bloated abdomen, and die. The course of the disease is approximately 48 hours and is primarily consistent with kidney failure. Cases where animals consume smaller amounts of plants over long time periods have not been well studied, but this is also believed to cause toxicology problems.

Treatment with herbicides may render pigweed even more palatable, therefore make sure all treated plants are dead prior to introducing animals.

FIRST AID: If pigweed is being rapidly consumed, limit further access and ingestion of the plants. A veterinarian will be able to provide supportive care for the different toxicants contained in pigweed, but the animals may still succumb to the nitrates, soluble oxalates or the kidney toxin.

SAFETY IN PREPARED FEEDS: Pigweed is not safe in hay or other prepared feeds.

PREVENTION: To prevent pigweed poisoning, do not allow animals to have access to affected pastures, especially if the animals are hungry. Spray or mow plants down, making sure they are dead before animals are on pasture. Provide for supplemental feed if pasture quality is poor, since well-fed animals are less likely to consume pigweed.

INDEX

40. COMMON POKEWEED, POKEBERRY, POKEROOT, INKBERRY, POKE

Phytolacca americana

(pokeweed family)

TOXICITY RATING: Low.

ANIMALS AFFECTED: All animals may potentially be affected.

DANGEROUS PARTS OF PLANT: All parts, especially roots and seeds.

CLASS OF SIGNS: Gastrointestinal irritation (colic, diarrhea which may be bloody). Rarely: anemia, possibly death. Birth defects and tumors may also be possible.

PLANT DESCRIPTION: Pokeweed (fig. 40) is a tall (to 10 feet), smooth-stemmed, perennial herb with a large, fleshy taproot (fig. 40A). Stems are succulent, purplish, and bear alternate, lance-shaped, shiny leaves with smooth, curled margins. The small, white to greenish flowers hang in long, drooping, grape-like clusters. Each flattened, spherical, green berry turns dark-purple or ink-black and usually contains 10 seeds. Pokeweed commonly grows on recently cleared land, in open woods, barnyards, pastures, fence rows, and roadsides.

SIGNS: Animals do not voluntarily eat this plant unless there is no other forage available. If the animals are forced to eat pokeweed (especially if it has been incorporated into processed feeds), the primary signs relate to the irritant effects of the saponin toxins, in particular phytolaccigenin. Salivation, abdominal pain, diarrhea (which may become bloody) can be noted. Horses and ruminants do not exhibit vomiting, which is seen in humans, dogs, cats, and pigs. Signs usually resolve within a day or two. Only if large doses are consumed will the animal display more serious signs: anemia, alterations in the heart rate and in respiration, and in very rare cases, death.

Noted in the human literature but not well published in the veterinary literature is the mutagenic and teratogenic properties of pokeweed, that is the ability to induce mutations (and possibly

cancer) and birth defects. For humans, even handling the plant is considered dangerous, so it would seem wise to not only prevent human contact with the plant, but animal contact as well. Despite this, the plant is eaten as a spring vegetable in the southern U.S. after cooking it first in several changes of water. Consumption of the plant is not advised.

FIRST AID: For gastrointestinal irritation, provide better feed and symptomatic care, and signs should abate in about 24 hours. Discard all feeds containing pokeweed, since the plant is never safe for consumption. For severely affected animals, or if it is known that a large amount was consumed, consult a veterinarian promptly for emergency care.

SAFETY IN PREPARED FEEDS: Reports are not clear, but consider pokeweed as unsafe in hay and other feeds.

PREVENTION: Pokeweed should be removed from pastures and barnyards. Exercise caution when doing so, since the plant is toxic to humans as well. Good pasture management, with mowing and weed removal, will suffice in keeping pokeweed under control.

INDEX

24. GROUNDSEL, RAGWORT

Senecio spp.

(daisy family)

TOXICITY RATING: High. *Senecio* is very toxic both fresh and in hay, affected animals often die.

ANIMALS AFFECTED: All grazing animals may be affected, but horses and cattle are particularly susceptible. Young, growing animals are more susceptible than mature animals, and fetuses may be affected in utero.

DANGEROUS PARTS OF PLANT: All above ground parts, with higher concentrations in the seeds.

CLASS OF SIGNS: "Poor doer", weight loss, unthriftiness, poor hair coat, anorexia, behavioral changes, sunscald, liver failure, jaundice, death.

PLANT DESCRIPTION: There are several species of ragworts. In Indiana they are perennial herbs about 1 foot tall (rarely to 3 feet tall). Basal leaves are spoon-shaped and stem leaves are alternate and pinnately cut into narrow segments. At the top of the plant are clusters of yellow composite (daisy-like) flowers with yellow ray petals. Most ragworts grow along roadsides, in pastures, and in wet or waste areas. *Senecio aureus* (golden ragwort) blooms in early spring in woodlands or meadows statewide (fig. 24).

SIGNS: Poisoning from ragwort may be chronic or acute, with the chronic form more commonly encountered. The disease is also called "seneciosis" or "pictou" disease. The toxic principle is a mixture of pyrrolizidine alkaloids which adversely affect the liver. The plant grows in late winter through the spring and tends to be incorporated in first cutting hays. Animals may not show signs

until the fall or winter after eating this hay for some time. In horses especially, the clinical signs may develop months after ragwort hay is no longer being fed, making an accurate diagnosis difficult.

In the rare acute toxic case (20 or more pounds consumed in a short period of time for a horse), the animals may become very excited and violent, with gastrointestinal signs (colic, diarrhea), dilated pupils and increased heart rate, and sudden death. Chronic toxicity is far more likely to be encountered. The animals must consume the plants fresh or in hay for weeks to months before clinical signs appear. The toxin is cumulative, and continues to damage the liver until enough of the liver is affected to cause clinical signs. Approximately 50 to 150 pounds of ragwort needs to be consumed by a horse before signs appear. Cattle are more resistant to the toxic effects than horses and reports have indicated that cattle may be fed small amounts of ragwort hay without ill effects. There are reports that sheep are relatively resistant to this toxin.

In chronic cases, the first clinical signs are weight loss, "poor doer", unthriftiness, and a decreasing appetite. These and all clinical signs are reflective of the gradual loss of liver function. Later, nearly total anorexia, jaundice, behavioral changes (depression, drowsiness, confusion, aimless wandering, "sleepy staggers") and an uncoordinated gait may manifest. Some animals will head press, where the animals lower their head and press it and/or their neck against a sturdy object. Some animals have been noted to stumble over objects and to appear blind. Since the liver is responsible for degrading diet-derived plant pigments, these pigments are not destroyed, and enter into the circulation. The pigments react with light and can cause photosensitization and sunscald, especially to the more lightly pigmented areas. Near the end of the course of the disease, abdominal fluid may build up ("ascites"), and fluid may build up under the skin in the "lower" parts of the body (throat latch, under the abdomen, legs), and the animal may develop diarrhea. Loss of blood's ability to clot (another important liver function) may be present as well, with bruising and hemorrhaging noted (which may occur in the urinary tract and present as red to black colored urine). Just prior to death, the animal may collapse and go into convulsions. Once clinical signs become apparent, the chances that the animal will recover are very unlikely.

In cattle, other signs can be noted in addition to those listed above. The muzzle may become dry and scaly, and animals may strain to defecate, causing the rectum to prolapse. Affected animals will produce milk with an unusual odor. It is not known, but it is suspected, that this milk may be toxic.

FIRST AID: Once clinical signs are present, recovery is less likely. Newer and experimental treatments exist, but the prognosis is poor for survival. Remove all ragwort hay from animals and provide proper feed. A veterinarian may be able to provide some treatment or referral to an animal hospital for care of valuable animals, but even this treatment option has a low rate of success, especially for severely affected animals.

SAFETY IN PREPARED FEEDS: All plants that contain pyrrolizidine alkaloids remain toxic in hay, silage and other feeds. Horses should never be allowed to consume any feed containing ragwort. Ruminant (cattle primarily) may be able to tolerate small amounts of ragwort hay if it is fed intermittently and enough good forage is made available. The recommendation for cattle is that ragwort hay be fed at 10% or less of the body weight over the course of a year. This would amount to 50 pounds per year for a 500 pound animal. If at all possible, the ragwort hay should never be

fed, even to cattle.

PREVENTION: Learn to recognize ragwort both fresh and in hay, and only deal with reputable feed dealers. Never feed ragwort to horses, and it is advisable not to feed it to cattle. If ragwort hay must be fed to cattle, follow the guidelines listed above.

NOTE: Plants that also may cause similar signs due to the presence of pyrrolizidine alkaloids: Stinking willie (*Senecio jacobea*), common groundsel (*S. vulgaris*), fiddleneck and tarweed (*Amsinckia* spp), rattlebox (*Crotalaria*), Hound's tongue (*Cynoglossum officinale*), heliotropium (*Heliotropium* spp) and salivation Jane (*Echium lycopsis*). Ragwort poisoning is a major problem in the western United States and may be increasing in the East. The greatest risk in Indiana seems to be in the southwestern counties where cressleaf groundsel (*Senecio glabellus*) grows. Another species, prairie ragwort (*Senecio plattensis*), occurs in the northern half of the state. Ragwort growing in alfalfa fields has been reported.

INDEX

9. RHUBARB, PIE PLANT

Rheum rhaponticum

(dock family)

TOXICITY RATING: Low, unless animals are fed the leaves intentionally.

ANIMALS AFFECTED: All animals may be affected, those being fed garden trimmings are particularly at risk (cattle, swine, sheep and goats).

CLASS OF SIGNS: Staggering, trembling, breathing difficulties, weakness, diarrhea, increased drinking and urinating, death.

PLANT DESCRIPTION: This herbaceous garden perennial (fig. 9) develops from a heavy rootstock. Its leaves grow from the base of the plant on stout, shiny, red stalks. Heart-shaped and 1 to 2 feet long by 1/2 to 1 1/2 feet wide, the leaf blades have a smooth and shiny surface, darker above, with five main veins and wavy margins. The hollow stems end in greenish-white flower clusters in late spring.

SIGNS: The leaves contain oxalic acid, soluble oxalates, and citric acid, although the stems are edible. Some oxalates are insoluble and cause local irritation but the oxalates in rhubarb (and other species, such as sorrel or dock, *Rumex*) are soluble, and cause systemic problems, especially in the kidneys, or they can affect the electrolytes in the body, such as the balance of calcium and magnesium. Poisoning can be acute, when large amounts of oxalates are consumed quickly, or may be chronic, where smaller amounts are eaten over a longer period of time. Low blood levels of calcium and kidney failure are commonly reported findings in soluble oxalate toxicity.

Affected animals will appear depressed, and may stagger and tremble and be weak. Often, they will drink and urinate more as kidney function declines. Diarrhea may be noted, and affected animals may die if the electrolyte balance is extremely deranged or if the kidneys fail.

FIRST AID: There is no specific antidote for oxalate toxicity. If an animal is observed eating a large quantity of rhubarb or other oxalate plant, call a veterinarian immediately. If the plants were ingested a day or more previously, only supportive care can be given. A veterinarian will be able to provide assistance, although death may result from electrolyte imbalance or from kidney failure.

SAFETY IN PREPARED FEEDS: Rhubarb is not safe in hay, nor is any other oxalate-containing plant.

PREVENTION: Ruminants have some ability to adapt to oxalate plants if they are introduced to them gradually, since the rumen bacteria will detoxify the oxalates to a certain degree, although feeding these plants is never recommended. Do not allow animals to ingest large amounts of oxalate plants quickly, and it is best to not allow the feeding of oxalate plants at all. Do not incorporate weeds or rhubarb leaves into feed for animals, especially ruminants and swine, since these animals are not finicky eaters. Always make sure that animals have sufficient water, since oxalate toxicity is worsened if animals go thirsty.

INDEX

53. Rosary Pea , Precatory beans, crabs eye, jequirity bean

Abrus precatorius

legume or pea family

TOXICITY RATING: High. Even one bean can kill.

ANIMALS AFFECTED: All animals may be affected, although the primary risk is to pets.

DANGEROUS PARTS OF THE PLANT: The beans are the primary risk.

CLASS OF SIGNS: Severe gastrointestinal irritation, vomiting, diarrhea, abdominal pain, collapse, death.

PLANT DESCRIPTION: Twisting perennial vine, grows naturally in tropical climates. Rosary pea is established in certain areas of southern Florida. The leaves are alternate and compound, with 8 to 15 leaflets. The flowers are small, and can be any shade of white to red to purple. The seed pod is about 1 and 1/2 inches long, containing several seeds, bright red with a black spot.

SIGNS: The toxic signs resulting from rosary pea ingestion are very similar to those of castorbean, except rosary pea contains a more powerful toxin. It is reported that one seed if well-chewed can kill an adult human. The toxins are a protein called abrin and a glycoside called abric acid, which cause severe gastrointestinal signs: vomiting (if the species can vomit), diarrhea (which may be

bloody) and abdominal pain. This progresses to weakness, shock and death within a short period of time.

The plant does not grow in Indiana, but sometimes seeds are imported to make jewelry and rosaries. If the seed is swallowed without damage to the seed coat, poisoning is unlikely, and the seed will tend to pass without incident. In cases where the seed coat is chewed or opened (as in drilling to make jewelry), toxic signs and death are likely.

FIRST AID: If rosary pea was ingested, contact a veterinarian immediately. Prevent further exposure and get other animals away from the source. Emergency measures may be used to eliminate the toxin from the stomach and intestines. Once gastrointestinal signs appear, it may be inadvisable to try to evacuate the stomach and intestines for fear of doing even greater damage, but a veterinarian will decide this. Beyond this, care is symptomatic and supportive of the digestive upset, weakness, and shock. Affected animals are likely to die even with care.

SAFETY IN FEEDS: The seed is toxic in feeds, and is never safe at any level of feeding. Discard all feeds if contaminated with rosary pea.

PREVENTION: Rosary pea should never be allowed around the home or pasture for the safety of animals and humans alike. If jewelry or rosaries are made of rosary pea, discard them immediately.

INDEX

22. WHITE SNAKEROOT, WHITE SANICLE, RICHWEED

Eupatorium rugosum

(daisy family)

TOXICITY RATING: High. White snakeroot will be eaten, especially in the late summer and fall, and is often lethal.

ANIMALS AFFECTED: Cattle, horse, goat, sheep, swine. All grazing animals can be affected by white snakeroot, and the toxin passes in the milk, so nursing animals and humans are also at risk.

DANGEROUS PARTS OF PLANT: Leaves and stems, possibly flowers. Roots seem to have a lower toxicity.

CLASS OF SIGNS: Trembling, sweating, depression, stiff gait, heart failure, jaundice, toxic milk, death (may be sudden).

PLANT DESCRIPTION: White snakeroot (fig. 22) grows from fibrous, matted roots as a smooth, erect, perennial herb 1 to 3 feet high with opposite, oval, pointed-tipped leaves with sharply-toothed edges. The upper surfaces of the leaves are dull, the lower surfaces shiny with three prominent main veins. Small white flowers in compound terminal clusters are conspicuous in late summer. White snakeroot is found in woods, damp and shady pastures, and occasionally in thickets and clearings (especially at the edges of wooded areas) in all 92 Indiana counties.

SIGNS: Clinical signs include: depression, stiff gait, periods of sweating, normal or subnormal body temperature, labored or shallow respiration, muscle tremors, trembling, partial throat paralysis, jaundice, passage of hard feces, prostration, death (death may be sudden with no prior signs). Onset of signs is typically 2 days to 3 weeks. Death occurs within 1 day to 3 weeks, with horses typically succumbing in 1 to 3 days. Even if the horse does not die from this toxin, it may suffer permanent heart damage and be unsuitable for work or pleasure purposes. The toxic component is tremetol, and the toxic dose of the green plant is approximately 1% to 10% of the body weight of the animal at one time or over several doses. The toxin is cumulative, so one large

dose or multiple smaller doses over time can kill. The toxin is excreted in the milk, so lactating animals are slower to show signs of toxicity, but the nursing animals will then be affected by the toxin. Humans who drink raw milk from affected animals can also be poisoned, sometimes fatally (the disorder was called "milk sickness" in colonial times).

The primary danger occurs in late summer throughout the fall, especially in overgrazed pastures or where there is insufficient food. Poisonings in early winter where the animals eat stalks that extend above the snow have also been reported. The edges of woods or thickets are common locations for white snakeroot. Dry years are also associated with more reports of toxicity, perhaps due to inadequate pasture forage.

FIRST AID: Supportive care is required, since there is no specific antidote. Many affected animals will die or be permanently disabled. Remove all animals from the pasture or fence off the wooded areas, especially in the fall through winter. Continue to milk lactating animals, and discard milk. A veterinarian will be able to provide supportive care to animals showing signs, but death is likely once clinical signs develop.

SAFETY IN FEEDS: Drying decreases but does not eliminate the toxin, therefore hay with white snakeroot in it is unsafe for consumption.

PREVENTION: Learn to recognize and avoid white snakeroot. Do not allow animals to graze this plant under any circumstance. To do this, fence off wooded areas, provide supplemental feed (especially in the late fall and winter), or treat the snakeroot with herbicides. Be cautioned that treatment with herbicides may make the plant more palatable, so allow several weeks to pass between spraying and allowing animal access (be sure the plants are completely dead). The problem may recur the following year, so plan ahead to avoid animal loss. Under no circumstances should raw milk from affected animals be used for animal or human consumption.

INDEX

37. SPURGES, EUPHORBIA

Euphorbia spp.

(spurge family)

EXAMPLES:

Euphorbia cyparissias, cypress spurge, fields and gardens (fig. 37A)

Euphorbia esula, leafy spurge, noxious weed

Chamaesyce maculata (*Euphorbia maculata*, old name), prostrate spurge, weed (fig. 37B)

E. marginata, snow on the mountain, garden plant

E. splendens, crown of thorns, houseplant

E. lactea, candelabra cactus, houseplant

E. tirucalli, tinsel tree, milk bush, houseplant

E. pulcherrima, poinsettia, houseplant

TOXICITY RATING: Moderate. Spurges are highly unpalatable, and are rarely consumed in quantities sufficient to cause serious toxicity, but are very irritating upon contact.

ANIMALS AFFECTED: Any animal consuming spurge or coming in contact with the sap may be affected.

DANGEROUS PARTS OF PLANT: All parts.

CLASS OF SIGNS: Gastrointestinal irritation, dermal and ocular irritation, poor doer, weakness.

PLANT DESCRIPTION: These spindly annuals or herbaceous, sometimes succulent or even cactus-like perennials with milky, acrid sap have simple, alternate or opposite, entire or toothed leaves. The tiny flowers are clustered in small, cup-like structures themselves resembling white-petaled flowers in some species. The fruit, three-lobed and three-seeded, is borne on a stalk extending from the cup-like flower structure. Spurges grow in old fields, open woods, roadsides, waste areas, and around homes as cultivated or escaped plantings. Some are houseplants.

SIGNS: Spurges contain sap that is highly irritating upon contact, especially to the eyes and mouth, and upon prolonged exposure to skin (legs and head primarily). Irritation, redness, pain and swelling will result, and salivation and head-shaking if the oral mucosa is affected. Blistering and open sores are possible with spurge sap, and some plants have historically been used as a chemical brand for cattle. If the plants are swallowed, stomach and intestinal irritation can occur, with vomiting (in those species that can vomit), abdominal pain, and diarrhea.

FIRST AID: Prevent further contact and ingestion of spurge. If a large quantity was consumed, if an eye is affected, or if the animal cannot eat, contact a veterinarian immediately. For minor irritation, provide supportive care, since the signs are usually self-limiting within about 12 to 24 hours.

SAFETY IN PREPARED FEEDS: Spurges remain toxic when dry, therefore feeds are not safe for consumption. If small amounts have been incorporated into hay (where the plants are still recognizable), animals may voluntarily avoid consuming spurge if there is enough good feed available. Caution must be used in more highly processed feeds where consumption is unavoidable, such as silage, chop, and pellets.

PREVENTION: Animals should not be pastured where spurges grow. Mow or spray to eliminate them, since skin irritation can occur just by the animal's contact with the plant. Do not feed spurge-contaminated feeds, especially the more highly processed ones where consumption cannot be prevented. Small amounts of spurge in hay may be safe for most animals since they typically will avoid eating it, although all efforts should be made to provide clean feed.

16. YELLOW SWEETCLOVER WHITE SWEETCLOVER

Melilotus officinalis *Melilotus alba*

(pea family)

TOXICITY RATING: Moderate.

ANIMALS AFFECTED: All animals that eat affected hay may be poisoned.

DANGEROUS PARTS OF PLANTS: All above-ground parts when present in moldy hay.

CLASS OF SIGNS: Bruising, spontaneous bleeding.

PLANT DESCRIPTION: These coarse biennial herbs (fig. 16) have alternate, three-parted, toothed leaves and bear white or yellow flowers in long, slender, spike-like clusters in the leaf axils. The numerous small, pea-like, white or yellow flowers fall soon after blooming. Pods are small, egg-shaped to round, inflated, and contain 1 to 4 seeds. Sweetclover grows along roadsides, fence rows, and in old fields. It is cultivated as a forage crop and soil builder. The plants favor alkaline or calcareous soils.

SIGNS: Clinical signs are related to the anticoagulant ("prevents blood clotting") activity of dicoumarol (also called dicoumarin). Coumarin, present in sweet clover, is converted to dicoumarin during improper curing of sweet clover hay, or when the plant is excessively stressed (frosts, drought). Fresh, undamaged sweetclover is safe for consumption.

Signs are related to the consumption and inadequate production of vitamin K, responsible for blood clotting, therefore excessive and uncontrolled bruising and bleeding will occur. The bleeding may be noticeable (through the nose, mouth or a wound), or may occur under the skin as large bruises, but can also occur inside the body, making an accurate diagnosis more difficult. The toxin can be passed in the milk, therefore nursing animals may be affected. The moldy hay needs to be consumed for 2 weeks or longer before signs manifest and this toxicosis is most often seen in winter after several weeks of moldy sweetclover has been consumed and is typically a herd problem.

Affected animals are weak, anorexic, may exhibit visible bleeding, have pale mucus membranes, increased respiratory rates, rapid and weak pulses, and may die. Often more than one animal is affected at a time.

Dicoumarin and related drugs are used in human medicine as "blood thinners" and are commonly used in rat and mouse poisons (which if ingested by any other animal can cause excessive bleeding and death if not treated).

FIRST AID: Remove all moldy hay from the animals. A veterinarian needs to be called if animals are bleeding, although once bleeding starts, it may be difficult to save the animal. Treatments can include blood or plasma transfusions (which may not be available or practical with large numbers of livestock) or treatment with vitamin K1. Vitamin K1 therapy requires a minimum of 12 to 24 hours to be effective, therefore severely affected animals may not survive this time period.

PREVENTION: Toxicity can be prevented by properly curing sweet clover hay, especially by allowing the stems to dry before baling. Extra caution must be taken with second year growth, since it contains a higher concentration of toxin. Affected hay may remain toxic for years. Moldy sweet clover hay should not be fed, but if it has to be fed, alternating with a non-moldy quality hay every few days will minimize clinical signs. Moldy sweet clover hay should be withheld for 4 to 6 weeks prior to anticipated parturition ("giving birth") or surgical procedure, to lessen the chances of these animals bleeding to death. Discard milk from affected animals to prevent signs developing in nursing animals.

INDEX

12. COMMON TANSY

Tanacetum vulgare

(daisy family)

TOXICITY RATING: Low.

ANIMALS AFFECTED: All animals may be affected.

DANGEROUS PARTS OF PLANT: Leaves, stems.

CLASS OF SIGNS: Salivating, colic, abdominal pain.

PLANT DESCRIPTION: These old-fashioned garden plants (fig. 12) were introduced from Europe and are now found in old gardens or along roadsides, creek banks, and waste areas. They are perennial herbs from a short, stout rootstock and bear alternate fern-like leaves with saw-toothed margins. The yellow, strong-scented, bitter-tasting flowers are in flat-topped clusters at the tops of the plant.

SIGNS: This is not a commonly reported toxic plant. Animals rarely ingest it, and this plant rarely occupies significant acreage in pastures. Illness and death in humans has been reported due to attempts at medicinal uses of concentrated plant extracts. Toxic signs may include salivating and abdominal pain (colic), with the possibility of convulsions and abortions occurring. The oil tanacetin is believed to cause the clinical signs.

FIRST AID: The risk of serious illness and death is slight with this tansy. Provide adequate and proper forage if the animals are eating this plant, and do not let pets nibble on the leaves or flowers.

SAFETY IN PREPARED FEEDS: Information is lacking on this, however, consider the plant toxic in prepared feeds.

PREVENTION: The risk of toxicosis is low with tansy, however if a pet begins to chew this plant, consider keeping the pet and plant separated (especially if the pet is confined in the plant's vicinity). If tansy occupies a significant amount of a pasture, consider mowing or otherwise eliminating the plant, or keeping the animals and plants separated.

INDEX

17. TOBACCO

Nicotiana spp.

(nightshade family)

TOXICITY RATING: Low to moderate, depending on the situation.

ANIMALS AFFECTED: All animals may be affected, but pets in contact with tobacco products are at risk as are pigs allowed to forage on harvested tobacco fields.

DANGEROUS PARTS OF PLANT: Leaves.

CLASS OF SIGNS: Gastrointestinal irritation, trembling, staggering, weakness, breathing problems, heart problems, collapse, birth defects, death.

PLANT DESCRIPTION: These tall annual plants grow from fibrous roots and produce large, hairy leaves and terminal clusters of tubular, 2 inches long, white, red, lavender, or yellow flowers on short stalks. Many-seeded capsules may appear in late summer. The tobacco species with colorful flowers (fig. 17) are grown as garden ornamentals. Those with yellow-green flowers and the largest leaves are an economic crop in the southern counties of the state.

SIGNS: The toxin in tobacco is nicotine, an alkaloid with an irritating effect on the stomach and intestines and also the nervous system. This toxin is related to the toxins in poison hemlock and lupine. Concerning nicotine concentrations, an average cigarette can contain between 20 and 30 mg, and 120 mg for a cigar. One report indicates that for a human unaccustomed to tobacco, 4 mg can cause clinical signs, and 60 mg at one time can cause death.

Pets can easily be poisoned by tobacco products in the home, either accidentally or maliciously. The primary route of poisoning is by ingestion (eating tobacco products or drinking tobacco-tainted water), but inhalation of smoke is also possible. Clinical signs nearly always are present, but only rarely is a lethal dose ingested. The initial signs of poisoning can develop within

10 to 15 minutes or may not manifest for several hours. At first, the irritating effect that tobacco has on the stomach and intestines will cause salivating, vomiting (if capable), and diarrhea. Shortly after the digestive signs develop, neurologic signs appear. Initially, nicotine stimulates the nervous system, with depression of the nervous system occurring at a later time. Early signs include nervousness, shaking, trembling, a stiff and uncoordinated gait, weakness and collapse. Cardiac abnormalities may be noted as well as breathing difficulties, to the point of respiratory paralysis (the cause of death in lethal cases). Tobacco is also teratogenic, causing birth defects if the mother animal was pregnant when the toxicosis occurred.

In large animals, pigs are the most likely to suffer tobacco poisoning, since they are allowed to forage on harvested tobacco fields. In addition to the gastric and neurologic signs, birth defects have been well documented when pregnant sows ingest tobacco. The most common defects are limb deformities in the piglets.

FIRST AID: For pigs and other large animals, it is unlikely that a lethal dose would be consumed. Keep the animal quiet and undisturbed and clinical signs should resolve within a few hours, although birth defects may still occur. For more severely affected large animals or in cases where it is known that a large quantity was ingested, call a veterinarian as soon as possible, since emergency evacuation of the gastrointestinal tract may be necessary. For pets, contact a veterinarian if any ingestion has occurred. With their smaller size, pets will show clinical signs more rapidly and more severely than large animals. In addition, the effects of nicotine can come on rapidly.

SAFETY IN PREPARED FEEDS: Tobacco remains toxic when dried, therefore processed feeds containing tobacco are not safe for consumption.

PREVENTION: Do not allow pets to be in contact with tobacco or tobacco products. Do not let animals drink from puddles or cups that have leached tobacco juice in them (such as when a water-filled cup has been used as an "ashtray", or spittoons), since this water can have extremely high concentrations of nicotine. Forced ingestion or inhalation is inhumane and potentially lethal. Concerning sows, there is disagreement over whether there exists a "danger window" for consumption of tobacco during gestation (currently there exists two thoughts, that on days 10 to 30 of gestation the piglets are susceptible, and another that indicates that anything after 30 days is dangerous). Until more clarity is brought to bear on the issue, do not let pregnant sows graze on tobacco.

INDEX

49. ENGLISH YEW JAPANESE YEW

Taxus baccata Taxus cuspidata

(yew family)

TOXICITY RATING: Extremely toxic, death is likely.

ANIMALS AFFECTED: All animals (livestock, pets and birds).

PLANT DESCRIPTION: Several species of yew are planted as ornamental shrubs or hedges. They are woody perennials with flat 1/2-1 inch long evergreen leaves (fig. 49) lighter green on the underside and broader than pine needles. The "berry" (technically called an aril) is grape-sized, juicy, and bright scarlet, with a hole in the end which makes it look cup-like.

CLASS OF SIGNS: Sudden death is the typical sign. Occasionally: breathing problems, trembling, weakness, heart problems, stomach upset.

SIGNS: "Found dead" is the typical presenting sign. Very rarely will animals show signs up to 2 days later: trembling, slow heart rate, difficulty breathing, gastroenteritis (stomach upset and diarrhea). The plant is exceptionally toxic, with one mouthful able to kill a horse or cow within 5 minutes. Toxicity is compounded by the apparent palatability of yew. Many animals are poisoned accidentally when yew trimmings are thrown into the pasture or when yew is planted as an ornamental within browsing reach. Infrequent reports of dogs chewing the leaves resulted in gastroenteritis, seizures, and aggressive behavior.

The toxin is taxine, a mixture of alkaloids, that slow down cardiac conduction. As little as 0.1 to 0.5% of the fresh plant per body weight is lethal. Death is due to cardiac and/or respiratory collapse.

FIRST AID: First aid is usually impractical, since the animals die so quickly. Prevent other animals from being exposed and use caution around animals showing clinical signs to prevent

human injury. If animals are still alive, contact a veterinarian. Cardiac drug therapy may be attempted, but success is unlikely.

SAFETY IN PREPARED FEEDS: Yew is toxic even when dry, therefore hay with yew in it is never safe in any amount.

PREVENTION: Never allow yew plants or trimmings within reach of horses, cattle, sheep, goats, pigs, birds, or any other animal likely to eat plants. Dogs and cats rarely chew on this plant, so it is not necessary to remove it from ornamental gardens. Toxicities in dogs occurred when puppies were confined to a pen with yew and chewed the plant out of boredom. The fleshy red "berry" is not considered toxic, but consumption is not advised.

THE POISONOUS PLANT GARDEN

The University of Illinois Poisonous Plant Garden will help individuals become familiar with plants that are potentially hazardous to a range of animal species including human beings. The garden includes over ninety species of plants native to Illinois or commonly used as ornamentals or house plants.

Toxic effects of plants vary with the species, health status, and age of the individual(s). Time of year, humidity, growth conditions, growth stage, and other factors also play a role in the hazards posed by toxic plants.

The Poisonous Plant Garden is located just northwest of the College of Veterinary Medicine Basic Science Building, near the corner of Lincoln Avenue and St. Mary's Road in Urbana, Illinois. The Garden is open to the public free of charge throughout the year.

STRUCTURE OF DATABASE

The following is a brief explanation of the structure which will aid you in your navigation around the database.

Within the Toxic Plant Database Homepage and at the bottom of this page you will find links to two alphabetical lists of plant names, one by common names and the other by scientific names. When you select a plant in either of the lists, you will be guided to the description of that plant. The description contains a representative plant image at the height of its growth and a brief description for identifying the plant. This section may also contain links to other images of the same plant at different growth stages.

From the description, you can access 5 other parts of the same plant entry as shown below:

(1) Distribution

This section describes the geographical and the type of area in which the plant is commonly found.

(2) Conditions of poisoning

This section describes how animals are most often poisoned, i.e., time of year, weather conditions, etc.

(3) Control

This section contains general information about controlling the growth of the plant to prevent poisoning.

(4) Toxic principle

This section identifies the chemical principle of the plant which causes the poisoning.

(5) Clinical signs

This section describes the signs displayed by animals that may have been poisoned by the plant.

Alfalfa

(*Medicago sativa* L.)

Description

Alfalfa is an excellent forage crop when harvested and stored properly. However, the plant can cause "hepatogenous photosensitivity syndrome" if water-damaged (Monlux AW . J Am Vet Med Assoc, Vol. 142, 9, p. 989-994, 1963).

Kentucky Coffee Tree

(*Gymnocladus dioica* (L.) Koch)

Other common names include: American coffee berry, Kentucky mahogany, nicker treet, stump tree.

Description

Kentucky coffee tree is a large round-barked tree belonging to the legume family and reaches heights of 60 to 100 feet. Its short trunk, 1 to 2 feet in diameter, divides into several large branches that end in contorted, stout twigs. Twice-compound leaves are arranged feather-fashion in 3-7 pairs of leaflets which are more or less ovalish without marginal teeth and 2-4 inches long. The tree is most easily identified in fall and winter for its large deserted leaf scars. The leaf which emerges late in spring is made up of a hundred or more separate oval leaflets arranged on the branches of the rib.

The flower, which blooms in May, is inconspicuous, greenish-white in terminal racemes, and has a tubular base about 1/2 inch long. Male and female flowers are found on the same tree. The fruit is a thick, flat pod, containing 4-7 flat broad seeds with a sticky pulp between them. The pulp dries at maturity and the seeds become olive-brown, 1/2 - 3/4 inches in diameter.

Bracken Fern or Brake Fern

(*Pteridium aquilinum*)

Description

Bracken fern is a typical fern. Its large triangular fronds are divided into three main parts with each part bipinnately subdivided. These fronds are 2 to 4 feet long by 1 to 3 feet wide. They are borne at the tips of erect, rigid, straw-colored, smooth stalks 1 to 3 feet tall. The stalks rise at intervals from stout black underground rootstocks sometimes a yard or more long.

Spores are borne in late summer at the edges on the lower sides of mature fronds, and the edges fold under to form the spore cover. The rootstocks also spread the fern.

Castor Bean

(*Ricinus communis*)

[Additional images of Castor Bean](#)

Description

Castor bean is a herbaceous annual which can reach to nearly 15 feet tall when growing in open spaces in warm climates. Large leaves are alternate, palmately lobed with 5-11 toothed lobes. Leaves are glossy and often red or bronze tinted when young. Flowers appear in clusters at the end of the main stem in late summer. The fruit consists of an oblong spiny pod which contains three

seeds on average. Seeds are oval and light brown, mottled or streaked with light and dark brown and resemble a pinto bean. The plant itself is fast growing, but the seeds require a long frost-free season in order to mature.

Clover, Alsike and Other Clovers

(*Trifolium hybridum* L. and other species)

Description

Alsike clover is a many-stemmed herb 1 1/2 to 2 1/2 feet high, much like the common red and white clovers, of which it is a hybrid. Its stems and leaves are not hairy. Its leaves, like those of all other clovers, are made up of 3 leaflets grouped at the ends of the long leafstalks. There are no crescents in the leaflets. Its flowers, borne in rather compact, stalked heads, are usually pink but range from red to white. Its seeds are smaller than those of red clover and are dark yellow-green.

The flowers of [Red clover \(*Trifolium pratense* L.\)](#) are usually rose purple or magenta. The stems

and leaves of American strains are generally hairy.

Cockleburs

(*Xanthium pennsylvanicum* L. and other species)

[Additional images of Cocklebur](#)

Description

The cocklebur plant is a coarse herbaceous annual about 3 feet high. They have erect, stout stems and spreading branches that are angled and often red-spotted. The leaves are alternate, rough to the touch, and broadly triangular to heart-shaped. Cockleburs produce two kinds of flowers. One kind, in short terminal branches, produces only pollen; the other kind, in clusters in the axils of the leaves, produces seed. The fruit is a small, hard, 2-chambered bur, oval in shape and about 3/4 inch long. It is covered with strong, hooked spines. This plant reproduces only by means of its seed.

The seedling, the plant's most dangerous stage, is very different from the mature plant. It consists of a slender, straight whitish green stem 1 to 3 inches tall. Capping this stem are two strap-shaped

green leaves, each about 1 1/4 inches long and 1/4 inch wide. Leaves produced after these first leaves gradually assume the characteristic shape of those of the mature plant. Proof of the identity of young seedlings may be found in their attachment underground to the easily recognized burs from which they sprout.

Ground Ivy

(*Glechoma hederacea* L.)

[No Image Available]

Description

Ground ivy is a low, prostrate perennial herb with slender 4-sided stems that hug the ground, root at their joints, and often cover areas of many square feet. Its leaves, two at a joint, are raised on slender stalks. They are roundish and have scalloplike teeth on their margins. Its small bluish flowers, found in the axils of the leaves, appear from April to May and even into July.

Crown-of-Thorns

(*Euphorbia mili*)

Description

A low-growing evergreen shrub with very thorny grooved stems and branches. The stems are purplish brown and are 1-2 feet tall on average, but can reach 3 feet in a warm climate. The thorns are sharp pointed and are 1/2 inch long on average. The ovate leaves are 1-3 inches long, few in number, and are found mostly at the growing ends. The cyathia, a type of inflorescence characteristic of the genus *Euphorbia*, are born in small umbels and have showy, ovate and bright red bracts. The small flowers are produced in clusters of 2-8 at the tips of green flower stem about 1 inch long. Genus *Euphorbia* includes other commonly available plants such as poinsettia (*E. pulcherrima*) and snow-on-the-mountain (*E. marginata*).

Jimsonweed

(*Datura stramonium* L.)

Other common names

Jamestown Weed, Thorn Apple, Devil's Trumpet, Mad Apple, Stink Weed

[Additional images of Jimsonweed](#)

Description

Jimsonweed is a stout, coarse annual herb 2 to 5 feet tall, with spreading branches. It has a pale-green stem and large, ovate, green or purplish, strong-scented leaves, coarsely toothed on their margins. Its flowers are large, white, and tubular, 2 to 4 inches long, and set on short stalks in the axils of branches. Its circular seeds, about 1/8 inch across, are contained in a hard, prickly capsule which, when ripe, splits lengthwise into four parts.

Ergot

(*Claviceps purpurea* (Fr.) Tul.)

[No Image Available]

Description

Ergot is a fungus that lives as a parasite in the blossoms of grasses. When the grass heads are nearly mature, it appears as jumbo grains protruding from the heads. Ergot grains, which are fungus bodies and not seeds, are several to many times the size of the grass seed. They are dark violet to almost black and are curved, hard, and hornlike. Ergot varies in abundance from year to year.

Poison Hemlock

(*Conium maculatum* L.)

Description

Poison hemlock is a coarse biennial herb with a smooth, purple-spotted, hollow stem and leaves like parsley. It grows 3 to 6 feet tall and in late summer has many small white flowers in showy umbels. Its leaves are extremely nauseating when tasted.

Although sometimes confused with water hemlock, poison hemlock can be distinguished by its leaves and its roots. The leaf veins of the poison hemlock run to the tips of the teeth; those of the water hemlock run to the notches between the teeth. The poison hemlock root is long, white, and fleshy. It is usually unbranched and can be easily distinguished from the root of water hemlock, which is made up of several tubers.

Water Hemlock

(*Cicuta maculata* L.)

[Additional images of Water Hemlock](#)

Description

This 2-10 feet tall herbaceous perennial or biennial native of the Umbelliferae family is very difficult to separate from other species of the same family. It has a tuberous root with 2-8 oblong tubers which are 1.5-3 inches long and about 1/2 inch thick at the thickest point near the middle and stem end. The purple-streaked stems are stout and erect with much branching. The stems are solid when very young, but become hollow with nodes where the leaflets are attached. The stems are chambered with horizontal diaphragm of pith tissue which are more closely arranged at the base of the stem. The horizontal plates of piths are most easily visible by cutting the stem base lengthwise.

The alternate leaves are pinnately 2-3 times compound. The leaves of most species are lanceolate, 2-5 inches long, and sharply toothed. The base of the long petioles clasp the stem.

Flowers are white and tiny (no more than 1/8 inch across), have 5 petals, and appear in loose compound umbels at branch ends in mid summer. Umbels measure from 2 to 8 inches across and become somewhat spherical in fruit. Fruits are ovoid and ribbed on the outer surface.

New growth begins from tubers as well as from seeds.

Hyacinth

(Hyacinth orientalis)

Hyacinth

(Hyacinth orientalis)

[Additional images of Hyacinth](#)

Description

Hyacinth is one of all the early spring blooming flowers most favored by home gardeners. It is a bulbous herb of the lily family with its origin in the Mediterranean region and cultivated in many color varieties. Green leaves, 7-8 per bulb, all arising from the ground level, are fleshy, glossy, narrow with smooth margins, 4-12 inches long and about 3/4 inches wide without marginal teeth. Flowers, borne in a dense raceme on a 6-8 inch long stem, are bell-shaped, and eventually open into 6 reflexed tepals. The flower is most well known for its fragrance. Fruits are globose and have 3 divisions. The bulb is 1-1/2 to 2 inches in diameter, light purple or cream colored, and covered with dry skin-like layers.

Hydrangea

(*Hydrangea* spp.)

[Additional images of Hydrangea](#)

Description

The cultivated species, *Hydrangea macrophylla* Ser. (= *H. hortensis*), is a deciduous shrub which can reach to nearly 6 feet. The common cultivated species is grown widely in gardens and as potted plants. The flowers among the cultivated species include white, pink, mauve, bluish purple, to blue. The forms of the flower clusters and the leaves of the cultivated species are similar to those of the cold-hardy wild species (*H. arborescens* L.).

Wild hydrangeas, *H. quercifolia* Bartr. and *H. arborescens* L. , are shrubs which reach 3.5 to 10

feet in height. The stems are light green when new, turning light brown and woody with time. Leaves are alternate, 4-10 inches in length, dark green above, lighter or pale green on the underside. The leaves of *H. quercifolia* Bartr. are deeply lobed, while those of the other species (*H. arborescens* L.) are broadly rounded with apex tapering to a point. Flowers appear in clusters or heads, mostly with 4 petals in white or cream color, blooming from June to July. The capsular fruit is less than 1/8 inch in length and has many small, thin brown seeds.

Lantana

(*Lantana camara* L.)

Description

Lantana (yellow sage) is a native of tropical Americas and West Africa. In the northern states including Illinois, it is grown as a garden annual reaching 12-18 inches tall. In the south, from Florida to California, it grows as a perennial shrub of 3-6 feet tall. In the tropics, it may grow even taller. Leaves are opposite, ovate, 1-5 inches long and 1-2 inches wide, with very small rounded teeth, somewhat rough and hairy. Leaves are aromatic when crushed. Flowers are borne in dense clusters 1-2 inches across on the axils near the top of the stem. Each flower is tubular with 4 lobes flaring to about 1/4 inch, initially yellow or pink gradually changing to orange and deep red. Often, the different colored flowers are present on the same cluster. Fruit is fleshy, greenish-blue to black, and berry-like with each containing one seed.

Dwarf Larkspur and Other Larkspurs

(*Delphinium tricornis* Michx. and other species)

[No Image Available]

Description

Dwarf larkspur is an erect, little-branched herb 1 to 3 feet tall. Its leaves, alternately placed and slender-stalked, are deeply divided into 5 to 7 nearly separate lobes, each lobe itself again rather deeply lobed or toothed. Its stout stem ends in a flower-bearing part that carries several blue or white, spurred blossoms 1 to 1 1/2 inches long. Three short-pointed rather fragile, widely spreading pods about 1/2 inch long develop from each blossom. These pods contain numerous small, dark seeds.

The rocket larkspur (*Delphinium ajacis* L.), which is cultivated and sometimes escapes, may be recognized from the above general description. It is supposed, in common with all other larkspurs, to be poisonous.

Mayapple

(*Podophyllum peltatum* L.)

[Additional images of Mayapple](#)

Description

Mayapple is a perennial herb of the Barberry family. Leaves are umbrella-shaped and are about 8 inches wide with 5-9 lobes. Plants that have a single leaf do not flower, while those with two leaves develop a single flower in the axil of the leaf stalks. The flower appears at the end of the downward-curved flower stalk about 1 inch long. The flower, with 6 or more white petals and about 1.5-2 inches across, blooms in April to May, and is eventually replaced by a green ovoid fruit. The plant withers away by mid-summer.

Although the creeping, fleshy rhizome has been used to prepare medicine commercially, it is poisonous by contact. The green leaves and unripened fruit are poisonous but the fruit becomes

edible as it ripens and turns greenish-yellow in color.

Nightshade

(*Solanum* spp.)

Description

About 1,500 *Solanum* species exist in the world, and they include some of the most common garden plants such as potato (*Solanum tuberosum* L.) and eggplant (*Solanum melongena* L.). One of the species, Jerusalem cherry (*Solanum pseudocapricum* L.) is grown as a house plant for its compact form and small round berries which turn bright red at maturity. The tomato (*Lycopersicon esculentum* Mill.) is also a related plant. Included in this entry are descriptions of Black Nightshade, Bittersweet Nightshade, Silverleaf Nightshade, and Horse Nettle. Other related species may be found under their own names.

Bittersweet Nightshade (*S. dulcamara*)

Bittersweet nightshade is also known as European bittersweet or climbing nightshade. This plant grows from rhizomes and is a slender climbing or trailing perennial reaching 6 feet in length. Leaves are alternate, ovate, simple or deeply lobed, 1-1/2 to 4 inches long, and pointed at the tip. Flowers are deep purple or bluish purple with flower stalk arising between the leaf nodes or opposite the leaves. Nearly round fruits turn red when mature and stay on the vines through mid winter.

[Black Nightshade \(*S. nigrum*\)](#)

Black nightshade is an annual herb with a tap root. Stems are erect and much branched reaching 3 feet tall. Leaves alternate, ovate or lanceolate, and long-stalked. The flower has 5 white petals, sometimes with a yellow inner star, and ranges from 1/4 inch to 3/8 inch across. Berries are round

and about 1/4 or so inches across, green, and turn purplish to black when ripe. Immature berries and foliage are toxic, but ripe fruits are reportedly edible.

Plants commonly known as back nightshade may include two native species, American Black Nightshade (*S. americanum* P. Mill.) and Eastern Black Nightshade (*S. ptycanthum* Dun.), as well as *S. nigrum* which was introduced from Europe and is widely naturalized. *Solanum ptycanthum* may be more commonly found in the midwest since *S. americanum* appears to be more concentrated in the southern states.

[Horse Nettle, Bull Nettle \(*S. carolinense*\)](#)

A perennial with a deep taproot and rhizome below ground. Its stem and leaves have yellowish spines and sometimes are hairy. Leaves are alternate and ovate with irregularly wavy or lobed margins. Flowers appear in June to August, are light purple to white, 3/4 to 1 inch across, and in short racemes near the top of the plant. Petals are united with 5 points at the margin. Fruits are globose, about 1/2 inch in diameter and yellow when mature. Yellow or brownish seeds are numerous, and irregularly circular, about 1/8 inch across.

Silverleaf Nightshade or White Horse-Nettle (*S. eleagnifolium*)

This perennial herb gets its common name because of its silvery appearance caused by the numerous fine hairs. Its thick, lanceolate leaves are wavy and roughly indented (sinuate). The stems and parts of the leaves have short stiff spines. The flowers appear at the end of branches and have petals which are pale to deep blue or lavender in color.

Poke or Pokeberry or Pokeweed

(*Phytolacca americana* L.)
(= *P. decandra* L.)

[Additional Images of Pokeweed](#)

Description

Poke is an erect, branched, smooth herb with coarse, succulent, purplish stems; at maturity it is 3 to 10 feet tall. Its leaves, borne on short stalks, are alternately placed and ovate and are without teeth on their margins. Leaves grow up to about 5 inches long. Poke bears small white flowers on short flowerstalks along separate branches at the growing tip of the plant and in the axils of the leaves. Each flower becomes a dark purple berry, flattened and spherical. The berries contain crimson juice and about 10 seeds each.

A perennial, poke comes up year after year from an enormous taproot but it is spread only by seed.

Rhododendron

(*Rhododendron* spp.)

[Additional images of Rhododendron](#)

Description

Rhododendron is a genus of a shrub with about 800 species worldwide. Its ovate evergreen or deciduous leaves are alternate, 1/2 - 8 inches in length depending on variety, with smooth untoothed margins. They are dark green with a glossy upper surface and a dull underside. Large trusses of bell-shaped flowers bloom from spring to early summer. Plants are available with flowers in colors such as white, purple, deep rose, red, yellow, and orange. Rhododendron and its closely related azalea have been hybridized for many uses in gardens and rarely reach above 3-5 feet tall in northern states including Illinois.

White Snakeroot

(*Eupatorium rugosum* Hout.)
(formerly known as *Eupatorium urticaefolium*)

[Additional images of White Snakeroot](#)

Description

White snakeroot is an erect, branched herb usually about 3 feet tall but varying from 1 to 5 feet. It has slender, round stems and branches bearing pointed, oval, oppositely placed leaves. These leaves, 3 to 5 inches long and petioled, are sharply toothed on the margins. Each leaf has 3 main veins that show prominently on the underside. The roots are fibrous, coarse, and shallow.

In late summer, numerous small heads of minute white flowers appear at the top of the stem and the ends of the branches. These flower heads, except that they are white, are almost exactly like the flower heads of the familiar ageratum of gardens. Later the flowers are replaced in the heads by small black seeds each with a crown of soft white hairs.

Because the leaves of white snakeroot resemble those of the nettle, other plants with nettle-like leaves are often mistaken for it. Two such plants are the nettle-leaved sage and the nettle-leaved vervain. Even without flowers or fruit, these plants can be easily distinguished from white snakeroot. The nettle-leaved sage, a rare plant in some southern Illinois counties, has square stems; white snakeroot stems are round. The nettle-leaved vervain, a common weed throughout Illinois,

has lance-shaped leaves; white snakeroot leaves are broad at the base but narrow quickly in a wedge-shaped part to the petiole.

Wild Onion

(*Allium* spp.)

[Additional images of Wild Onion](#)

Description

Wild onion (*A. validum* or *A. canadense*) is a bulbous herb of the Amaryllis family and is a close relative of cultivated onion (*Allium cepa* L.). It has a distinct onion odor. It has slender grass-like leaves and reaches about 2 feet in height when flowers appear in late summer. Leaves are narrow, long, and with parallel edges arising from the small underground bulb. Flowers, varying in color, depending on the species, from white to pink, appear at the top of a leafless stem and eventually become bulblets which drop to the ground and propagate.

It is thought that the name Chicago is derived from the smell of wild onions:

"Indians, mainly Potawatomi, who were the most powerful tribe around the south end of Lake Michigan, hunted, traded furs, and occasionally camped in the area they called "Checagou," evidently referring to the garlic wild onion smell which permeated the air."

Encyclopedia of Illinois, 2nd. Edition. Somerset Publishers, New York, 1994. p. 138.

Bouncing Bet

(*Saponaria officinalis* L.)

[Additional images of Bouncing Bet](#)

Description

Bouncing bet is a herbaceous perennial, 1-3 feet tall, which grows from rhizomes. Its close relative, cow cockle (*Saponaria vaccaria* L.), is an annual. The stems are erect and jointed with opposite elliptic leaves which are 3-4 inches long and 1/2 to 1-1/2 inches wide at the middle. The leaf margins lack teeth.

The flowers come in clusters of cylindric sepals and bloom from June to September, displaying 5-6 petals notched at the apex. Petal colors range from white to pink. The fruit is a capsule about 1 inch long and 1/4 inch thick containing many somewhat round black seeds. The seeds have minute bumps on the surface.

Bouncing Bet

(*Saponaria officinalis* L.)

Distribution

Originally from Europe, bouncing bet and the related species, cow cockle (*Saponaria vaccaria* L.), grow in open unused areas, along roadsides and railroad tracks, and waste grounds throughout the U.S. Bouncing bet is found in nearly all counties of Illinois, while cow cockle is limited only to scattered counties in northern and central Illinois. Bouncing bet and cow cockle are considered weeds, although they are attractive plants.

Bouncing Bet

(*Saponaria officinalis* L.)

Conditions of poisoning

The abundance of bouncing bet along roadsides and in other wastelands makes it easily accessible to animals allowed to graze in such places. Although the entire plant is poisonous, the seeds contain the largest concentration of the toxic principle.

[Description](#) | [Distribution](#) | [Control](#) | [Toxic principle](#) | [Clinical signs](#)

Bouncing Bet

(*Saponaria officinalis* L.)

Control

Screenings of grain should be checked for large quantities of *Saponaria* seeds. Animals tend to avoid contaminated feed because the plants apparently are distasteful. Animals should not be grazed where *Saponaria* species is abundant, especially when the pasture grasses are present in short supply or are exceedingly dry.

[|Description](#) |[Distribution](#) |[Conditions of poisoning](#) |[Toxic principle](#) |[Clinical signs](#)|

Bouncing Bet

(*Saponaria officinalis* L.)

Toxic principle

Bouncing Bet contains large amounts of saponins, which froth when extracted with water. The saponins are soluble in water and alcohol. The sapotoxins of these saponins are similar or identical to those of corn cockle (*Agrostemma Githago*). Hydrolysis of the saponins yields sugars and sapogonins, a group of physiologically active substances.

The toxic material is contained in highest concentration in the seeds. Most animals refuse to eat the seeds and avoid grains or screenings containing them. Feeding of the plant itself to sheep in an amount of 3% of the body weight caused death within 4 hours; the plant weight being expressed on a dry-weight basis.

Last updated: April 2, 1996

Please direct all comments or requests for information to [M. Williams](#).

Bouncing Bet

(*Saponaria officinalis* L.)

Clinical signs

Poisoning caused by bouncing bet is usually mild, as animals tend to avoid the feed that contains this plant. The poison irritates the digestive tract and may cause vomiting, signs suggestive of nausea, and diarrhea. Slowed or rapid breathing as well as unsteadiness, ataxia and coma also are associated with poisoning by this plant.

Toward a Biodiversity Knowledge and Innovation Network (BKIN) for Canada

[If you would like a copy of a document, please send an email to: [CBIF](#)]

Strategic Report from Canadian Biodiversity Network Conference, Ottawa March 1—4, 2001.

Implementing a BKIN [February 2002]

The need to formally "organize" the stakeholders into a "community" or "association" and how a BKIN Secretariat can manage that network, setting out the rationale for a biodiversity knowledge and innovation network and recommendations for its structure, mandate, and preliminary budget requirements.

The Urgent Need for a BKIN [February 2002]

Describes the impacts already being experienced by not having a well-functioning biodiversity knowledge and innovation network. These impacts also show where a BKIN could be useful to support decision-making in these areas.

The Requirements for a BKIN [February 2002]

This document indicates the infrastructure that is required to establish and maintain a strong biodiversity knowledge and innovation network.

The Biota of Canada Information Network: Documenting and Analysing Canada's Living Capital for Science and Society
Final report on the inaugural workshop of the 5NR Biota of Canada Information Network project, Ottawa March 2-3, 2000.

As a member of the [Global Biodiversity Information Facility \(GBIF\)](#), Canada is exploring new ways to improve the organization, exchange, correlation, and availability of primary data on biological species of interest to Canadians. By enhancing access to these data, CBIF provides a valuable resource that supports a wide range of social and economic decisions including efforts to conserve our biodiversity in healthy ecosystems, use our biological resources in sustainable ways, and monitor and control pests and diseases.

CBIF has developed the following tools to help users find the information they need.

Species Access Canada

Species Access Canada is the Canadian component of a global project to allow Internet access to information associated with the billions of specimens housed in the world's natural history collections. The Canadian network currently incorporates collections on five servers; many more will be added over the next few years.

Users can search these collections by species name, source collection, collector, or location.

Note: If you have a specimen database you would like added to Species Access Canada, please contact [CBIF](#)

Integrated Taxonomic Information System

ITIS is a catalogue of common and scientific names that will eventually include all species found in Canada, the United States and Mexico. The database also contains synonyms.

Search results pages for individual species include the taxonomic hierarchy for the species (genus, order, family, etc.). They also provide links to search engines, automatically searching on the pertinent terms for the species you select.

The Biological Observations, Specimens and Collections Gateway

The BiOSC Gateway is a global metadata search engine that cross-walks multiple distributed biodiversity networks and facilitates access to their combined holdings. As of early January 2002, the BiOSC Gateway contained approximately 2.4 million biological records. The gateway associates a biological names harvester with a multilingual taxonomic authority file (ITIS*North America), providing international users with access to biodiversity records by scientific names, vernacular names, synonymy, country of collection or geographic coordinates. Each individual metadata record (either an individual specimen or a single observation) is hyperlinked directly to its primary source on its native biodiversity network, ensuring that end-users access detailed records exclusively via the facility of the owners who remain in full control of their records. Interactive world maps are provided for those biological records that are associated with explicit latitude and longitude coordinates.

[More information about BiOSC](#)

SpeciesBank

Butterflies of Canada is the pilot project in this section of CBIF's web site. Identifying information, photographs, distribution maps, and more are available for all butterflies found in Canada.

Canadian Biodiversity Information Facility

Introduction - Canadian poisonous plants

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

- [Intended audience](#)
- [What the Information System does](#)
- [What the Information System does not do](#)
- [Illustrations](#)
- [Acknowledgments](#)
- [Project history](#)

The CANADIAN POISONOUS PLANTS INFORMATION SYSTEM presents data on plants that cause poisoning in livestock, pets, and humans. The plants include native, introduced, and cultivated outdoor plants as well as indoor plants that are found in Canada. Some food and herbal plants are also included that may cause potential poisoning problems.

Plant poisoning is caused by chemicals in plants that have undesirable affects upon animals and humans. Some poisons must be ingested whereas others, such as chemicals in poison-ivy, only require contact to elicit response in sensitive humans. Some chemicals must be modified before they are poisonous to animals, such as prunasin and other cyanogenic glycosides. These chemicals must be hydrolyzed by plant enzymes or by rumen organisms.

Plants that cause dermatitis are discussed in this program if the reactions are severe. The more obscure dermatologic plants are not included. For more information on plant-induced dermatitis [see Mitchell, J. C., Rook, A. 1979. [Botanical dermatology](#). Greenglass Ltd, Vancouver, B.C., Canada. 787 pp.].

Other excluded plants are those that only cause mechanical injury, poisonous blue-green algae, and plants causing hay fever.

While the Information System is oriented primarily to a Canadian audience, much of the information is useful elsewhere. Certainly the plants grown in and around homes can be grown throughout the temperate regions of the world. Indeed, many house plants are

tropical in origin. Other plant species included here have been introduced to North America as well as other temperate regions of the world. The information on the native plant species is applicable wherever they grow in North America.

Information included in this program has the following limitations:

- much literature on poisonous plants is anecdotal and therefore of limited reliability
- many plants are only mildly poisonous or cause symptoms in unusual circumstances such as when prodigious quantities of material have been consumed
- the author has attempted to find the most current literature available on each included plant species (up to the 1993 publishing date of the original document). However, in many cases, current information refers to works published early in that century.

Scientific name

Rhamnus frangula
Medicago sativa
Aloe barbadensis
Trifolium hybridum
Amaryllis belladonna
Amaryllis vittata
Sambucus canadensis
Ilex opaca
Phoradendron flavescens
Datura innoxia
Astragalus adsurgens
Astragalus lentiginosus
Brassaia actinophylla
Colchicum autumnale
Persea americana
Brassica campestris
Prunus serotina
Hyoscyamus niger
Robinia pseudoacacia
Solanum nigrum
Quercus velutina
Juglans nigra
Rudbeckia serotina
Lobelia siphilitica
Caulophyllum thalictroides
Iris versicolor
Echium vulgare
Kalmia polifolia
Pteridium aquilinum
Vicia faba
Gutierrezia sarothrae
Fagopyrum esculentum
Ranunculus bulbosus
Ceratocephalus testiculatus
Lupinus burkei
Euonymus atropurpureus
Caladium bicolor

bur buttercup	<i>Phacelia campanularia</i>
Burke's lupine	<i>Rhododendron macrophyllum</i>
burningbush	<i>Laportea canadensis</i>
caladium	<i>Taxus canadensis</i>
California bluebell	<i>Astragalus canadensis</i>
California rose-bay	<i>Aloe arborescens</i>
Canada nettle	<i>Euphorbia lactea</i>
Canada yew	<i>Euphorbia lathyris</i>
Canadian milk-vetch	<i>Lobelia cardinalis</i>
candalabra aloe	<i>Ricinus communis</i>
candelabra-cactus	<i>Ranunculus sceleratus</i>
caper spurge	<i>Physalis alkekengi</i>
cardinalflower	<i>Allium schoenoprasum</i>
castor-bean	<i>Chrysanthemum indicum</i>
celery-leaved buttercup	<i>Solanum dulcamara</i>
Chinese-lantern	<i>Xanthium strumarium</i>
chives	<i>Hymenoxys richardsonii</i>
chrysanthemum	<i>Symphytum officinale</i>
climbing nightshade	<i>Senecio vulgaris</i>
cocklebur	<i>Humulus lupulus</i>
Colorado rubberweed	<i>Asclepias syriaca</i>
common comfrey	<i>Ligustrum vulgare</i>
common groundsel	<i>Vicia sativa</i>
common hop	<i>Papaver rhoeas</i>
common milkweed	<i>Codiaeum variegatum</i>
common privet	<i>Euphorbia milii</i>
common vetch	<i>Rudbeckia laciniata</i>
corn poppy	<i>Cyclamen persicum</i>
croton	<i>Euphorbia cyparissias</i>
crown-of-thorns	<i>Narcissus pseudonarcissus</i>
cut-leaved coneflower	<i>Zigadenus venenosus</i>
cyclamen	<i>Kalanchoe daigremontiana</i>
cypress spurge	<i>Dieffenbachia bausei</i>
daffodil	<i>Dicentra cucullaria</i>
death camas	<i>Asclepias verticillata</i>
Devil's-backbone	<i>Hyacinthoides nonscripta</i>
dumbcane	<i>Ilex aquifolium</i>
Dutchman's-breeches	<i>Hedera helix</i>
eastern whorled milkweed	<i>Taxus baccata</i>
English bluebell	<i>Senecio integerrimus</i>
English holly	<i>Rhamnus cathartica</i>
English ivy	<i>Sambucus nigra</i>
English yew	<i>Euonymus europaeus</i>
entire-leaved groundsel	<i>Veratrum viride</i>
European buckthorn	<i>Iva xanthifolia</i>

European elder	<i>Digitalis purpurea</i>
European spindletree	<i>Rumex acetosa</i>
false hellebore	<i>Daphne cneorum</i>
false ragweed	<i>Allium sativum</i>
February daphne	<i>Dictamnus albus</i>
fiddleneck	<i>Dieffenbachia amoena</i>
field horsetail	<i>Heracleum mantegazzianum</i>
five-hooked bassia	<i>Gloriosa superba</i>
flamingo lily	<i>Thermopsis rhombifolia</i>
fly honeysuckle	<i>Laburnum anagyroides</i>
foxglove	<i>Allamanda cathartica</i>
garden-sorrel	<i>Lathyrus sativus</i>
garland daphne	<i>Sarcobatus vermiculatus</i>
garlic	<i>Chelidonium majus</i>
gas plant	<i>Descurainia pinnata</i>
giant dumbcane	<i>Physalis peruviana</i>
giant hogweed	<i>Glechoma hederacea</i>
glory lily	<i>Viburnum opulus</i>
golden-bean	<i>Vicia villosa</i>
golden-chain	<i>Philodendron scandens</i>
golden-trumpet	<i>Apocynum cannabinum</i>
grass pea	<i>Aesculus hippocastanum</i>
greasewood	<i>Armoracia rusticana</i>
greater celandine	<i>Cynoglossum officinale</i>
green tansy mustard	<i>Hydrangea macrophylla</i>
ground-cherry	<i>Papaver nudicaule</i>
ground-ivy	<i>Brassica juncea</i>
Guelder-rose	<i>Lobelia inflata</i>
hairy vetch	<i>Arisaema triphyllum</i>
heart-leaved philodendron	<i>Wisteria floribunda</i>
hemp dogbane	<i>Taxus cuspidata</i>
horse-chestnut	<i>Solanum pseudocapsicum</i>
horseradish	<i>Datura stramonium</i>
hound's tongue	<i>Sorghum halepense</i>
hydrangea	<i>Clivia miniata</i>
Iceland poppy	<i>Gymnocladus dioicus</i>
Indian mustard	<i>Kochia scoparia</i>
Indian-tobacco	<i>Chenopodium album</i>
Jack-in-the-pulpit	<i>Lupinus polyphyllus</i>
Japanese wisteria	<i>Euphorbia esula</i>
Japanese yew	<i>Dirca palustris</i>
Jerusalem-cherry	<i>Convallaria majalis</i>
jimsonweed	<i>Oxytropis sericea</i>
Johnson grass	<i>Delphinium bicolor</i>
Kaffir lily	<i>Ginkgo biloba</i>
	<i>Mangifera indica</i>
	<i>Cannabis sativa</i>
	<i>Triglochin palustre</i>
	<i>Equisetum palustre</i>
	<i>Podophyllum peltatum</i>

Kentucky coffeetree	<i>Delphinium menziesii</i>
kochia	<i>Aconitum napellus</i>
lamb's-quarters	<i>Menispermum canadense</i>
large-leaved lupine	<i>Ipomoea tricolor</i>
leafy spurge	<i>Dieffenbachia seguine</i>
leatherwood	<i>Leonurus cardiaca</i>
lily-of-the-valley	<i>Helenium flexuosum</i>
locoweed (<i>Oxytropis sericea</i>)	<i>Narcissus poeticus</i>
low larkspur	<i>Cicuta virosa</i>
maidenhair tree	<i>Avena sativa</i>
mango	<i>Aesculus glabra</i>
marijuana	<i>Nerium oleander</i>
marsh arrow-grass	<i>Allium cepa</i>
marsh horsetail	<i>Papaver somniferum</i>
May-apple	<i>Papaver orientale</i>
Menzies larkspur	<i>Maclura pomifera</i>
monk's hood	<i>Asimina triloba</i>
moonseed	<i>Euphorbia tirucalli</i>
morning glory	<i>Alstroemeria ligtu</i>
mother-in-law plant	<i>Euphorbia peplus</i>
motherwort	<i>Philodendron cordatum</i>
naked-flowered sneezeweed	<i>Prunus pensylvanica</i>
narcissus	<i>Cypripedium acaule</i>
northern water-hemlock	<i>Euphorbia pulcherrima</i>
oats	<i>Rhus radicans</i>
Ohio buckeye	<i>Suckleya suckleyana</i>
oleander	<i>Rhus vernix</i>
onion	<i>Conium maculatum</i>
opium poppy	<i>Phytolacca americana</i>
Oriental poppy	<i>Pinus ponderosa</i>
Osage-orange	<i>Solanum tuberosum</i>
pawpaw	<i>Abrus precatorius</i>
penciltree	<i>Symphytum asperum</i>
Peruvian lily	<i>Lactuca scariola</i>
petty spurge	<i>Primula obconica</i>
philodendron	<i>Amaranthus blitoides</i>
pin cherry	<i>Agrostemma githago</i>
pink lady's-slipper	<i>Oxytropis lambertii</i>
poinsettia	<i>Raphanus sativus</i>
poison ivy	<i>Brassica napus</i>
poison suckleya	<i>Prunus virginiana</i>
poison sumac	<i>Trifolium pratense</i>
poison-hemlock	<i>Acer rubrum</i>
pokeweed	<i>Quercus rubra</i>
ponderosa pine	<i>Amaranthus retroflexus</i>
	<i>Phalaris arundinacea</i>
	<i>Rheum rhaponticum</i>
	<i>Centaurea repens</i>
	<i>Amelanchier alnifolia</i>
	<i>Anagallis arvensis</i>
	<i>Triglochin maritima</i>

potato	<i>Onoclea sensibilis</i>
precatory-pea	<i>Rumex acetosella</i>
prickly comfrey	<i>Kalmia angustifolia</i>
prickly lettuce	<i>Cypripedium reginae</i>
primula	<i>Asclepias speciosa</i>
prostrate pigweed	<i>Scilla siberica</i>
purple cockle	<i>Lupinus sericeus</i>
purple locoweed	<i>Lupinus argenteus</i>
radish	<i>Symplocarpus foetidus</i>
rapeseed	<i>Lupinus pusillus</i>
red chokecherry	<i>Amaranthus hybridus</i>
red clover	<i>Helenium autumnale</i>
red maple	<i>Galanthus nivalis</i>
red oak	<i>Sorghum bicolor</i>
redroot pigweed	<i>Heliotropium curassavicum</i>
reed canarygrass	<i>Dieffenbachia maculata</i>
rhubarb	<i>Cicuta maculata</i>
Russian knapweed	<i>Apocynum androsaemifolium</i>
Saskatoon (a serviceberry)	<i>Daphne laureola</i>
scarlet pimpernel	<i>Dicentra canadensis</i>
seaside arrow-grass	<i>Hypericum perforatum</i>
sensitive fern	<i>Ornithogalum umbellatum</i>
sheep sorrel	<i>Urtica dioica</i>
sheep-laurel	<i>Chrysothamnus nauseosus</i>
showy lady's-slipper	<i>Thlaspi arvense</i>
showy milkweed	<i>Sorghum sudanense</i>
Siberian scilla	<i>Euphorbia helioscopia</i>
silky lupine	<i>Helianthus annuus</i>
silvery lupine	<i>Lathyrus odoratus</i>
skunk cabbage	<i>Monstera deliciosa</i>
small lupine	<i>Delphinium glaucum</i>
smooth pigweed	<i>Glyceria grandis</i>
sneezeweed	<i>Tanacetum vulgare</i>
snowdrop	<i>Senecio jacobaea</i>
Sorghum	<i>Lonicera tatarica</i>
spatulate-leaved heliotrope	<i>Symphoricarpos albus</i>
spotted dumbcane	<i>Astragalus miser</i>
spotted water-hemlock	<i>Nicotiana tabacum</i>
spreading dogbane	<i>Ailanthus altissima</i>
spurge-laurel	<i>Tulipa gesneriana</i>
squirrel-corn	<i>Astragalus bisulcatus</i>
St. John's-wort	<i>Rumex venosus</i>
star-of-Bethlehem	<i>Solidago mollis</i>
stinging nettle	<i>Parthenocissus quinquefolia</i>
stinking rabbitbrush	<i>Dicentra formosa</i>
	<i>Menziesia ferruginea</i>
	<i>Rhus diversiloba</i>
	<i>Cicuta douglasii</i>
	<i>Zigadenus elegans</i>
	<i>Trifolium repens</i>

CanExplore

Your doorway to the world of sustainable development

CANCELLATION of CanExplore Search

As of December 31, 2002, CanExplore will no longer be available. Agriculture and Agri-Food Canada has been supporting CanExplore but will cease to host the search engine site due changes in the four Federal Government departments involved.

Please refer to the individual Web sites of these four departments as follows:

[Agriculture and Agri-Food Canada](#)

[Environment Canada](#)

[Fisheries and Oceans Canada](#)

[Natural Resources Canada](#)

Thank you.

Materials on this Web site were produced and/or compiled by the Canadian Biodiversity Information Facility (CBIF) for the purpose of providing Canadians with direct access to information about the programs and services offered by the Government of Canada.

The material on this site is covered by the provisions of the [Copyright Act](#), by Canadian laws, policies, regulations and international agreements. Such provisions serve to identify the information source and, in specific instances, to prohibit reproduction of materials without written permission.

Non-commercial reproduction

Information on this site has been posted with the intent that it be readily available for personal and public non-commercial use and may be reproduced, in part or in whole and by any means, without charge or further permission from CBIF. We ask only that:

- Users exercise due diligence in ensuring the accuracy of the materials reproduced;
- CBIF be identified as the source department; and,
- The reproduction is not represented as an official version of the materials reproduced, nor as having been made, in affiliation with or with the endorsement of CBIF.

Commercial reproduction

Reproduction of multiple copies of materials on this site, in whole or in part, for the purposes of commercial redistribution is prohibited except with written permission from the Government of Canada's copyright administrator, Public Works and Government Services Canada (PWGSC). Through the permission granting process, PWGSC helps ensure individuals/organizations wishing to reproduce Government of

Canada materials for commercial purposes have access to the most accurate, up-to-date versions. To obtain permission to reproduce materials on this site for commercial purposes please contact:

- Public Works and Government Services Canada
- Canadian Government Publishing Directorate
- Constitution Square Building, 4th Floor, 350 Albert Street
- Ottawa ON K1A 0S5
- Canada
- or copyright.droitdauteur@communication.gc.ca

Third-party materials

Some of the materials and graphical elements found on Government of Canada Web sites are subject to copyrights held by other organizations. This is particularly true of sites that are jointly operated by a Government of Canada institution and an external organization as part of a collaborative arrangement. In such cases, some restrictions on the reproduction of materials or graphical elements may apply and it may be necessary to seek permission from the rights holder prior to reproducing the material.

To obtain information concerning copyright ownership and restrictions on reproduction on this site, please [contact us](#).

Privacy notices

The Government of Canada and CBIF are committed to providing visitors with web sites that respect their privacy. This page summarizes the privacy policy and practices on CBIF's web site.

- CBIF web pages do not automatically gather any specific personal information from you, such as your name, phone number or e-mail address. We would only obtain this type of information if you supply it by sending us an e-mail or registering in a secure portion of the site.
- All personal information created, held or collected by this department is protected under the federal *Privacy Act*. This means that at any point of collection you will be asked for consent to collect your information, and you will be informed of the purpose for which it is being collected and how to exercise your right of access to that information.
- CBIF employs software programs to monitor network traffic to identify unauthorized attempts to upload or change information, or otherwise cause damage. This software receives and records the Internet Protocol (IP) address of the computer that has contacted our Web site, the date and time of the visit and the pages visited. We make no attempt to link these addresses with the identity of individuals visiting our site unless an attempt to damage the site has been detected.

- CBIF does not normally use "cookies" to track how our visitors use this site or to determine sites previously visited. The system will notify you before any cookies are used so that you may refuse them. (A "cookie" is a file that may be placed on your hard drive without your knowledge by a Web site to allow it to monitor your use of the site.)
- Information on individual visitors is used by CBIF employees who need to know the information in order to respond to your request or to ensure the security of this system. We only share the information you give us with another government department if your inquiry relates to that department. We do not use the information to create individual profiles, nor do we disclose this information to anyone outside the federal government.

Questions or comments regarding this policy, or the administration of the *Privacy Act* in CBIF may be directed to the Privacy Co-ordinator by [e-mail](#). If you are not satisfied with our response to your privacy concern, you may wish to contact the [Office of the Privacy Commissioner](#). >

Conditions for use of data

Disclaimers

- Data are provided on an "as is" basis -no responsibility by the network or by the caretakers of the original data is accepted for uses or misuses.
- Data are not to be used on a for-profit basis - use of the data for commercial or for-profit applications are permitted only via written permission from the managers of the data network and from the component data caretakers.
- Data are provided on an end-user basis - that is, data are provided to users, but are not to be passed on to third parties or otherwise redistributed.
- Proper acknowledgment of the data network and source institutions is expected; in textual form, the following format should be used: "Biodiversity data were drawn from the distributed data network entitled Species Analyst, a project of the North American Biodiversity Information Network, and participating institutions." Acknowledgment of individual institutions should also be included.
- Data are provided under the understanding that their use will be generally consistent with the philosophy of not causing detriment to wild species.
- Data are provided in this facility under the general, overarching principle of free and open access to biodiversity information and technology.

Provisos

- *Issues of data quality* - Although interested in assisting data caretakers to improve data under their care, this data network serves simply to make information available. We refer users with special concerns regarding data precision or quality to the original data caretakers. Areas of special concern include taxonomic determinations and geographic referencing.
- *Use of negative information* -Biodiversity data generally constitute positive information only; that is, absence of a record does not always mean absence of a particular species from a particular point in space and time. Because biodiversity sampling is notoriously spotty, biased, and incomplete, understanding the positive-only nature of the data is critical to their proper understanding.
- *General* -Neither the creators of this biodiversity information network nor the institutions that it links guarantees either the accuracy, reliability, or completeness of the data or information provided, or the reliability and functionality of the computer tools provided, and neither accepts any liability in this regard.

Integrated Taxonomic Information System (ITIS) Taxon based biological information system

[New Query](#)[Advanced Searches](#)[Data Quality](#)[Search Help](#)**BIOSC Gateway**[New Query](#)[About BiOSC](#)

Biological Observations, Specimens and Collections (BiOSC) Gateway
Biodiversity Knowledge, Global Knowledge

Search by scientific name and/or geography

Hints:

- **enter scientific name only**
- **leave the name input field blank to see all collections from a given geographic area**
- **enter at least three letters if searching *All* geographic areas**

Search: Kingdom the

name

from the geographic region:

Search within a bounding box
(only some collections are GIS referenced)

Hints:

- enter the centroid coordinates
- use whole numbers or decimal degrees (e.g. 45° or 45.076°)
- use negative numbers for latitudes south of the equator (e.g. -45°)
- use negative numbers for longitudes west of the 0 ° meridian (e.g. -79°)

Latitude

Longitude

The prototype BiOSC Gateway demonstrates the power of *interoperability* between different biodiversity networks. Supported networks currently include:

- [Distributed Generic Information Retrieval \(DiGIR\) \(DiGIR\)](#)
- [European Natural History Specimen Information Network \(ENHSIN\)](#)
- [The Species Analyst \(TSA\)](#)
- [The World Information Network on Biodiversity \(REMIB\)](#)

These networks utilize differing techniques to store and display data. When you click on any of the country links the resulting information is being returned directly from the institutions holding these data. For more information [about BiOSC](#) visit the Canadian Biodiversity Information Facility.

Hints: To properly see the information returning from the ENHSIN network, please use Microsoft Internet Explorer Version 5.x, Netscape 6.x or view Page Source from your browser.

The Biodiversity Knowledge and Innovation Network (BKIN) was established in response to a recommendation by representatives of governments, universities, zoological and botanical gardens, museums, environmental and wildlife nongovernmental organizations, aboriginal groups and sectoral and high-technology industries at the Canadian Biodiversity Network Conference held in March 2001 in Ottawa. This conference was held to develop a national strategic approach for a biodiversity knowledge network in Canada [[see full report in PDF format](#)].

Participants in BKIN

Participants in BKIN include the following organizations, which were represented on the steering committee for the Canadian Biodiversity Network Conference, 1–4 March 2001.

- [Agriculture and Agri-Food Canada](#)
- [Biodiversity Convention Office](#), Environment Canada
- [Canadian Advanced Technology Alliance](#)
- [Canadian Biodiversity Information Network](#), Environment Canada
- [Canadian Federation of Agriculture](#)
- [Canadian Forest Service](#), Natural Resources Canada
- [Canadian Information System for the Environment](#), Environment Canada
- [Canadian Museum of Nature](#)
- [Canadian Nature Federation](#)
- [Canadian Wildlife Service](#), Environment Canada
- [Dow AgroSciences Canada](#)
- [Ducks Unlimited Canada](#)
- [Ecological Monitoring and Assessment Network](#), Environment Canada
- [Elanco Animal Health](#)

- [Eskimo Lakes Inc.](#)
- [Fisheries and Oceans Canada](#)
- [Goodfellow Agricola Consultants Inc.](#)
- [Miistakis Institute for the Rockies](#)
- [Ministère de l'Environnement du Québec](#)
- [Montréal Botanical Garden](#)
- [National Research Council Canada](#)
- [The Nature Conservancy of Canada](#)
- [NatureServe Canada](#)
- [Parks Canada](#), Canadian Heritage
- [Royal Ontario Museum](#)
- [Secretariat of the Convention on Biological Diversity](#)
- [Texar Corporation](#)
- [University of Alberta](#)
- [University of British Columbia, Zoology Department](#)
- [University of Calgary](#)
- [University of Guelph, Department of Computing and Information Science](#)
- [Wildlife Habitat Canada](#)
- [World Wildlife Fund Canada](#)

More information

Système canadien d'information sur la biodiversité

Introduction - Système canadien d'information sur les plantes toxiques

[Introduction](#)[Recherche interactive](#)[Liste de toutes les plantes toxiques par nom scientifique](#)[Liste de toutes les plantes toxiques par nom commun](#)[Les principaux sites Web sur les plantes toxiques](#)

- [Audience suscitée](#)
- [Ce que le Système d'information permet de faire](#)
- [Ce que le Système d'information ne permet pas de faire](#)
- [Illustrations](#)
- [Remerciements](#)
- [Historique du projet](#)

Les plantes provoquent des empoisonnements parce qu'elles contiennent des substances chimiques qui ont des effets indésirables sur les animaux et les humains. Pour produire un tel effet, certains poisons doivent être ingérés; dans d'autres cas (herbe à puce), il suffit d'un simple contact sur la peau pour produire une réaction chez les personnes sensibles. Certaines substances chimiques (prunasine et autres glucosides cyanogénétiques) ne deviennent toxiques pour les animaux que si elles sont transformées, c'est-à-dire hydrolysées par les enzymes végétales ou par les organismes présents dans le rumen.

Les plantes qui provoquent des dermatites ne sont traitées dans ce système que si elles produisent des réactions sévères et non si leurs effets sur la peau sont peu marqués. On trouvera plus d'information sur les dermatites d'origine végétale dans Mitchell, J. C., Rook, A. 1979, [Botanical dermatology](#), Greenglass Ltd, Vancouver, B.C., Canada. 787 pp.

Les plantes qui ne produisent que des blessures mécaniques, les algues bleu-vert toxiques et les espèces qui provoquent le rhume des foin ont également été exclues.

Bien que ce Système d'information s'adresse avant tout à un public canadien, il sera également utile dans d'autres pays. Bien entendu, les plantes d'intérieur ou qu'on fait pousser près des habitations peuvent aussi être cultivées dans toutes les

régions tempérées du monde. De nombreuses plantes d'intérieur sont même d'origine tropicale. D'autres espèces végétales traitées dans ce système ont été introduites en Amérique du Nord et dans d'autres régions tempérées du monde. L'information relative aux espèces végétales indigènes est pertinente dans toutes les régions de l'Amérique du Nord où elles sont présentes.

Pour ce qui est de l'information qui figure dans ce système, il convient de noter les points suivants :

- une grande partie de la documentation sur les plantes toxiques est de nature anecdotique et présente donc une fiabilité limitée.
- beaucoup de plantes sont peu toxiques ou ne produisent des symptômes que dans des circonstances inhabituelles (p. ex. consommation d'énormes quantités)
- l'auteur s'est efforcé de trouver les documents les plus récents qui étaient disponibles sur chacune des espèces traitées (jusqu'à 1993, date de publication de la première version). Cependant, dans beaucoup de cas, l'information la plus récente est tirée d'ouvrages publiés au début du XX^e si.

Canadian Biodiversity Information Facility

Intended audience - Canadian poisonous plants

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

The Information System is intended for use by veterinarians, doctors, and poison control personnel. The information is based entirely on literature references. Biologists are asked to excuse the convenient separation of animals and humans, which allows more rapid access to information for veterinarians and poison control personnel.

Canadian Biodiversity Information Facility

What the information system does

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

The Information System is intended for USE AS A RESEARCH TOOL that provides access to information on poisonous plants and their effects on animals and humans. The program contains information on:

- plant nomenclature (common and scientific names)
- distribution of wild plants (rendered graphically by province and territory)
- cultivated and food plants of concern
- toxic plant parts
- toxic chemicals (if known)
- additional descriptive information on many of the poisonous plants
- references from which information was extracted (up to the 1993 publishing date of the original document)

Veterinarians

Veterinarians can find information on poisoning of livestock and pets for:

- animals that have been poisoned by a particular plant and on all plants that have caused poisoning in a particular animal species
- symptoms of recognized diseases (such as chewing disease)
- symptoms of poisoning for each animal species that may be poisoned

Medical doctors//Poison control

Medical doctors and poison control centre personnel can obtain details on:

- human poisoning by a particular plant and on all plants that have caused poisoning in humans

- symptoms of recognized diseases (such as milk sickness)
- symptoms of poisoning by each plant species

Canadian Biodiversity Information Facility

What the information system does not do

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

This Information System does not provide the following:

- a means for identifying poisonous plants. A decision was made to leave out this feature because of the complication and time involved in developing a complete identification system to separate all the poisonous plants from nonpoisonous plants that may be encountered. Other computerized systems under development may provide on-screen identification of poisonous plants. For example, Debbie Metsger has been doing research into the development of computer identification systems with specific reference to ingested house plants in Canada, including poisonous plants. She may be contacted at:

[Debbie Metsger](#)

Department of Botany
Royal Ontario Museum
100 Queen Park Cres. West
Toronto, Ont. M5S 2C6

Also, please see our web page to [other important WWW Poisonous Plant sites](#).

- a diagnostic tool for medical situations. In some cases, additional information has been provided on treatments that have been reported as effective, but this inclusion by no means implies any comment of their use. For more information, you should always get a copy of the original published references.

Acknowledgements - Canadian poisonous plants

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical
name](#)[All poisonous plants by Common
name](#)[Important WWW Poisonous
Plants sites](#)

The author wishes to thank the following individuals from Agriculture & Agri-Food Canada (AAFC):

- Gerry Mulligan (retired) who started the initial literature projects on poisonous plants and with whom the author has co-authored three publications on the subject including "Poisonous Plants of Canada"
- Scientific editing was provided by Jane Buckley and Frances Smith. Any remaining errors are the responsibility of the author.
- [Guy Baillargeon](#) who encouraged the author to start the Internet project, for continued help and ideas on computerizing this information, and for some French translations.
- Walter Majak, Harriet Douwes and [Ruth McDiarmid](#) [who supplied the chemical diagrams], all of Kamloops Research Station, Kamloops, B.C.
- Dr. Donna Hutchings, Microbiology, CFIA, Ottawa, Ont.
- [Debbie Metsger](#), Department of Botany, Royal Ontario Museum, Toronto, Ont.

French Translation:

1. Stephen Bolcso of the Research Branch, AAFC for helping to find funding for the French translation,
2. the translation was done by Jean-Pierre Artigau, Traductions Artigau, Inc, Alymer, Qc,
3. finishing touches by Françoise Guilbault of Research Branch.

Project History

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

During the 1980's Gerry Mulligan (retired) and I (Derek Munro) produced two technical bulletins and a publication on poisonous plants in Canada. In 1990 I started work on a database version of the poisonous plants using DBase software. This was published as a *runtime* version for DOS computers. With the introduction of the World Wide Web I converted the DBase version into an Internet product using UNIX shell scripts and delimited text files (thereby simulating a relational database system). The latest incarnation has been ported into Oracle SQL database enabling extra query possibilities, enhanced performance, and XML (eXtensible Markup Language) output for application developers.

Publishing History:

- Mulligan, G.A & Munro, D.B. 1983. Vascular plants poisonous to livestock in Canada 1. A preliminary inventory. Contribution 1983-23E. Research Branch, Agriculture & Agri-Food Canada. 33 pp.
- Mulligan, G.A. & Munro, D.B. 1984. Wild and cultivated plants poisonous to humans in Canada. A preliminary inventory. Technical Bulletin 1984-15E. Research Branch, Agriculture & Agri-Food Canada. 22 pp.
- Mulligan, G.A. & Munro, D.B. 1990. Poisonous plants of Canada. Publication 1842/E. Ministry of Supply and Services Canada. 96 pp.
- Munro, D.B. 1993. Canadian Poisonous Plants Information System. Information Systems No. 1993-1B Agriculture & Agri-Food Canada (Manual 15 pp + 3 DOS diskettes)
- Munro, D.B. 1996. Canadian Poisonous Plants Information System Internet version 1. (no longer available at <http://res.agr.ca/brd/poisonpl/>)
- Munro, D.B. 2000. Canadian Poisonous Plants Information System Internet version 2. (<http://www.cbif.gc.ca/poison/>)

Welcome to BoDD

the Botanical Dermatology Database

WWW Launch Date: 08 August 1994
 This page last updated: 05 January 2004
[\[Server statistics; Sites with links to BoDD\]](#)

From the time of its WWW launch in August 1994 until January 1997 access to BoDD was restricted. Access restrictions were then removed. Anyone may now access the database. You may enter BoDD via the index links below. If you find BoDD useful, please consider supporting the project with a donation. Follow the [Support BoDD](#) link to discover how you can contribute to the upkeep of the project.

BoDD is an electronic re-incarnation of BOTANICAL DERMATOLOGY by John Mitchell & Arthur Rook, which was originally published in 1979 by Greengrass Ltd, Vancouver [ISBN 0-88978-047-1]. This updated on-line version is made available to you with the kind permission of the original authors.

This database is under continuous development. You may view the indexes, text, and image files but you may not systematically download the database, nor reproduce the html

code, text or images for profit or gain without express permission from the copyright holder. Educational users should make proper acknowledgement of the source of any information derived from BoDD.

If your browser is capable of displaying forms, please use the [BoDD Search Engine](#) to enter BoDD. For other users, only the [Plant Families Index](#) provides access to the whole database. The [Main Index](#) is under construction and will in due course provide a variety of alternative entry modes.

Constructive criticism, corrections, etc. will be gratefully received.

Notes on poisoning: *Abrus precatorius*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Precatory-pea (*Abrus precatorius*) seeds contain a chemical called abrin, which is highly toxic. A single well-masticated seed can kill an adult human (Kingsbury 1964).

In Canada the seeds of this plant are imported into the country on necklaces and perhaps on other decorative items. These attractive seeds are shiny, red, and black and about 5-8 mm long (Hoy and Catling 1981).

Notes on Toxic plant chemicals:

Abrin is a lectin of *Abrus precatorius* and is a ribosome-inactivating protein. This chemical is regarded as one of the most deadly plant toxins known.

LD-50: 0.56 micro gm/kg in mice (Stirpe and Barbieri 1986). Kingsbury (1964) states that a toxicity dose is about 0.00015% of a human subject's weight. A single well-masticated seed can kill an adult. Abrin causes large-scale disruption in lymphoid tissues, with apoptotic cell death. Apoptotic bodies have increased in the small intestine of experimental rats (Griffiths et al. 1987).

Canadian Biodiversity Information Facility

Notes on poisoning: *Acer rubrum*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Red maple (*Acer rubrum*) is a native tree found in eastern Canada. Leaves of this plant have poisoned horses in the New England States and Georgia. Divers et al. (1982) noted that three of four horses died in one case. Experimental symptoms of hemolytic anemia indistinguishable from the field case were induced in a pony. This problem should be suspected in horses in which acute hemolytic anemia occurs after they ingest red maple leaves.

Horses are poisoned sporadically in the northeastern United States after they ingest red maple leaves. Signs of toxicity are similar to those seen with the *Brassica* anemia factor after animals ingest plants of the genus *Brassica* (such as canola, kale, cabbage). Tennant et al. (1981) noted 33 cases of hemolytic anemia in horses in the New England States in the late 1970s. These cases were attributed to red maple leaves.

Image or illustration

Acer rubrum:

Images: images.google.com

Notes on Poisonous plant parts:

The wilted leaves of red maple (*Acer rubrum*) have caused poisoning and death in horses. This toxicity is most prevalent from June through October. Cases become symptomatic 3-4 days after ingesting the leaves (Divers et al. 1982).

Wilted leaves administered to a pony at the rate of 3.0 g/kg of body weight caused illness and death within 1-5 days. Freshly harvested leaves did not cause any symptoms. Dried leaves remained toxic for 30 days (George et al. 1982).

Notes on Toxic plant chemicals:

The chemical that causes hemolytic anemia poisoning in horses is not yet known for red maple (*Acer rubrum*). The chemical probably works as an oxidant. In Georgia, ponies poisoned by red maple leaves died rapidly when fed dried leaves after mid September, whereas ponies fed leaves collected earlier in the summer had a more prolonged illness. This finding suggests that the toxin increases in quantity during autumn (George et al. 1982).

Notes on poisoning: *Aconitum napellus*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Monk's hood (*Aconitum napellus*) is an outdoor ornamental herb. The plant contains poisonous alkaloids, which have proved toxic in humans when accidentally ingested (e.g., aconitine; see Fiddes 1958). Few cases of animal poisoning occur (Kingsbury 1964).

References:

Fiddes, F. S. 1958. Poisoning by aconitine. Report of two cases. Br. Med. J., 2: 779-780.

Notes on poisoning: *Aesculus glabra*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Ohio buckeye (*Aesculus glabra*) is not native to Canada but is occasionally planted as an ornamental tree in southern Ontario. It is winter-hardy in Ottawa. Cattle have been poisoned in the eastern United States, where this tree is a native species. Symptoms are mostly gastrointestinal and neuromuscular (Kornheiser 1983). This plant is unlikely to cause livestock poisoning because it is rare in Canada. The fruits of this plant may be attractive to children and could cause poisoning if ingested.

Notes on poisoning: *Aesculus hippocastanum*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Horse-chestnut (*Aesculus hippocastanum*) is an introduced tree that is found in the southern parts of Ontario and Quebec. It has poisoned cattle, horses, and pigs, causing sickness and death (Reynard and Norton 1942, Muenscher 1975). Human poisoning has also occurred.

Image or illustration

Aesculus hippocastanum:

Images: images.google.com

Notes on Poisonous plant parts:

Horse-chestnut fruits, leaves, and flowers contain the chemical aesculin. Young leaves and flowers are especially toxic to cattle (Reynard and Norton 1942). Children occasionally ingest the fruit but few authenticated cases of poisoning are found in the literature, although death has been reported (Lampe and McCann

1985).

Toxic parts:

flowers
leaves
mature fruit

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Reynard, G. B., Norton, J. B. 1942. Poisonous plants of Maryland in relation to livestock. Univ. MD. Agric. Exp. Stn. Bull., A10. 312 pp.

Notes on Toxic plant chemicals:

Aesculin is a saponin (7-hydroxycoumarin 6-glucoside) that yields aesculetin (6,7-dihydroxycoumarin) upon hydrolysis. Aesculin is related to hydrocoumarin found in spoiled sweet-clover hay (Cooper and Johnson 1984). LD-50 measurements from nut extracts were as follows (Williams and Olsen 1984):

10.6 mg/g of body weight for chicks
10.7 mg/g of body weight for hamsters.

Toxic plant chemicals:

aesculin

Canadian Biodiversity Information Facility

Notes on poisoning: *Agrostemma githago*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Purple cockle (*Agrostemma githago*) is a naturalized herb found across southern Canada. The seeds are contaminants of wheat seeds and they are considered to be poisonous to poultry, cattle, and humans. Human poisoning is rare. Feeding trials have been conducted with ground seeds, which are unappetizing to poultry (Quigley and Waite 1931).

References:

Hardin, J. W., Arena, J. M. 1969. Human poisoning from native and cultivated plants. Duke University Press, Durham, N.C., USA. 167 pp.

Image or illustration

Agrostemma githago:

Images: images.google.com

Toxic parts:

seeds

References:

Heuser, G. F., Shumacher, A. E. 1942. The feeding of corn cockle to chickens. Poul. Sci., 21:86-93.

Quigley, G. D., Waite, R. H. 1931. Miscellaneous feeding trials with poultry. Univ. MD. Agric. Exp. Stn. Bull., 325: 343-354.

Notes on Toxic plant chemicals:

Purple cockle (*Agrostemma githago*) contains the saponin githagin, which is toxic mainly to poultry. The toxin is destroyed in seeds at 50 C. The following quantities have been found to be toxic in experiments with animals:

calf 0.0025% of body weight
poultry 0.0025%
pig 0.0010%
dog 0.0009%

Most feeding experiments have been conducted on chickens (Quigley and Waite 1931; Heuser and Schumacher 1942).

Notes on poisoning: *Ailanthus altissima*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Tree-of-heaven (*Ailanthus altissima*) is an ornamental found in the warmest parts of Canada. Exposure to the leaves may have caused dermatitis in humans and it is suspected of being a poisonous plant as well. However, convincing documentation of poisoning is lacking. The tree has been suspected of causing gastroenteritis. (Muenscher 1975, Mitchell and Rook 1979).

Canadian Biodiversity Information Facility

Notes on poisoning: *Allamanda cathartica*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Golden-trumpet (*Allamanda cathartica*) is an indoor ornamental vine that is suited to greenhouses. It is considered poisonous, but firm evidence is lacking. The plant was once used as a cathartic. Ingesting the fruits may cause upset stomach (Kingsbury 1964; Hardin and Arena 1969).

There is a case of a young boy who was sucking the end of the stem of this plant. He subsequently became nauseated, and developed a high temperature and swollen lips. Some individuals develop a rash from the plant sap (Morton 1962).

References:

Hardin, J. W., Arena, J. M. 1969. Human poisoning from native and cultivated plants. Duke University Press, Durham, N.C., USA. 167 pp.

Canadian Biodiversity Information Facility

Notes on poisoning: *Allium canadense*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Wild onion (*Allium canadense*) is a native herb found in parts of eastern Canada. This plant can cause gastroenteritis in young children who ingest parts of this plant. Chronic ingestion of the bulbs reduces iodine uptake by the thyroid gland, which can lead to problems. No specific treatment is suggested other than to prevent dehydration (Lampe and McCann 1985). Livestock have also been poisoned by ingesting wild onions, and some have died (Pipal 1918). Horses have developed hemolytic anemia from ingesting wild onion leaves (Scoggan 1989).

Toxic parts:

bulbs

leaves

References:

Scoggan, R. D. 1989. Wild onion toxicosis and other hemolytic anemia toxins. Equine professional topics. Univ. Ill. Urbana-Champaign Ext., 14(1): 1-2.

Notes on Toxic plant chemicals:

The three onion species (*Allium* spp.) mentioned in this information system contain S-methyl-L-cysteine sulfoxide (SMCO), which is a sulfur-containing alpha-amino acid. The empirical formula is C₄-H₉-O₃-NS. The common garden onion (*A. cepa*) contains the following:

- 100 mg/kg wet weight of SMCO in the leaves,
- 1600 mg/kg wet weight of SMCO in the bulbs (Benevenga et al. 1989)

Toxic plant chemicals:

S-methyl-L-cysteine sulfoxide (SMCO)

Notes on poisoning: *Allium cepa*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Cultivated onion (*Allium cepa*) has caused hemolytic anemia in livestock including cattle, horses, and experimentally in sheep. Death can occur in severe cases. The formation of Heinz bodies in the red blood cells is a common occurrence. Heinz bodies consist of a precipitate, denatured hemoglobin caused by oxidant attack (Hutchinson 1977).

Thorp, F., Harshfield, G. S. 1939. Onion poisoning in horses. J. Am. Vet. Med. Assoc., 94: 52-53.

Notes on Toxic plant chemicals:

Onions (*Allium* spp.) contain various toxins that can cause problems. N-propyl disulphide, an alkaloid, has been implicated as the toxic chemical (Hutchinson 1977). More recent studies have shown that S-methyl-L-cysteine sulfoxide (SMCO) is involved in forming Heinz bodies and hemolytic anemia. This chemical is less toxic in nonruminant animals (Benevenga et al. 1989).

(Note: calcium oxalate crystals have been found in the dry outer skin or scale leaves of this plant (Sarma and Terpó 1980)). Garlic (*Allium sativum*) is a cultivated plant grown for its bulbs.

Notes on poisoning: *Aloe barbadensis*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Aloe (Aloe barbadensis) is the common "Aloe vera" found in extracts that are used in cosmetics and medicinal products. The latex from under the skin can cause a cathartic action because it irritates the large intestine; anthraquinones color alkaline urine red. An excessive dose may cause nephritis (Lampe and McCann 1985). Contact dermatitis can also result from contact with this plant.

Notes on poisoning: *Alstroemeria ligtu*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Peruvian lily (*Alstroemeria ligtu*) is grown as a cut flower by the florist industry. Cut flowers are also flown into North America from Holland. This plant causes contact dermatitis to workers who may be sensitized to the chemical tuliposide A, which is also found in tulip plants. This chemical readily penetrates vinyl gloves. Nitrile gloves may prevent the allergic reaction of workers sensitive to this chemical (Marks 1988).

Santucci, B., Picardo, M., Iavaroni, C., Trogolo, C. 1985. Contact dermatitis to *Alstroemeria*. Contact Dermatitis, 12: 215-219.

Notes on Toxic plant chemicals:

The lactone 6-tuliposide A occurs in both the Peruvian lily and in

tulip plants. A human who becomes sensitized to one of the plants generally becomes cross-reactive to the other plant. In a series of tests, it took about 3 years for workers to become sensitive to Peruvian lily (Santucci et al. 1985).

Cattle

General symptoms of poisoning:

[blood brownish](#)

[death](#)

[gait, unsteady](#)

[mucous membrane, brown](#)

[nervousness](#)

Notes on poisoning:

In one case in New Zealand, cattle were poisoned and one died as a result of suspected nitrate poisoning after ingesting smooth pigweed. The mucous membranes were brown and the blood was dark. The animals were unsteady. Postmortem findings showed the rumen to be full of the plants, but no obvious lesions were present (Duckworth 1975).

Canadian Biodiversity Information Facility

Notes on poisoning: *Amaranthus retroflexus*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Redroot pigweed (*Amaranthus retroflexus*) is a naturalized herb that is found across much of Canada. This plant can cause a variety of toxic problems, including perirenal edema in pigs. However, the nature of the toxic compound is not known. This plant can also accumulate oxalates to as much as 30% of dry weight. Redroot pigweed is capable of accumulating toxic concentrations of nitrates (Osweiler et al. 1985).

Notes on Toxic plant chemicals:

Nitrates have the following LD-50 values (Crawford et al. 1966):

LD-50 1.0 g/kg body weight in cattle

LD-50 0.5 g/kg body weight in other ruminants.

Acute poisoning occurs when forage nitrates exceed 1.0% nitrate (dry weight) or 1500 ppm in water (Osweiler et al. 1985). All *Amaranthus* spp. mentioned in this information system can accumulate toxic quantities of nitrates.

Notes on poisoning: *Amaryllis belladonna*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Amaryllis (*Amaryllis belladonna*) is an ornamental plant commonly sold for its winter flowers. Ingesting the bulbs has poisoned humans. The toxic alkaloid, lycorine, is the principal toxin, although small quantities of related alkaloids are also present (Lampe and McCann 1985; Fuller and McClintock 1986).

References:

- Fuller, T. C., McClintock, E. 1986. Poisonous plants of California. Univ. California Press, Berkeley, Calif., USA. 432 pp.

General poisoning notes:

Saskatoon, a serviceberry (*Amelanchier alnifolia*), is a shrub native to western Canada. The shrub has an hydrogen cyanide (HCN) potential high enough to kill cattle and mule deer. Mule deer that ingested 1 kg of fresh weight per day were poisoned and died within 24 h of the appearance of clinical signs. Experiments with cattle also showed the poisoning potential (Majak et al. 1978, Majak et al. 1980).

Image or illustration

Amelanchier alnifolia:

Images: images.google.com

Notes on Poisonous plant parts:

Saskatoon contains a large quantity of prunasin, which has a hydrogen cyanide (HCN) potential exceeding the level required to cause of poisoning in cattle. HCN occurs in the twigs before the leaves appear and during the bloom period. The level of HCN

potential is highest in new-growth twigs, especially during dry years (Majak et al. 1981).

Toxic parts:

flower buds
leaves
seeds
twigs
young shoots

Notes on poisoning: *Amsinckia intermedia*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Fiddleneck (*Amsinckia intermedia*) is an introduced plant found in parts of western Canada. Ingestion can cause severe diseases in horses, swine, and cattle. Hepatic cirrhosis results from ingesting the seeds of the plant. The symptoms are termed walking disease in horses and are known as hard liver disease in swine and cattle. These diseases were present mainly in California and the Pacific Northwest. With the advent of herbicides, the problems have mostly disappeared (Woolsey et al. 1952, Cheeke and Schull 1985).

Canadian Biodiversity Information Facility

Notes on poisoning: *Anagallis arvensis*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Scarlet pimpernel (*Anagallis arvensis*) is a naturalized plant found across parts of southern Canada. The plant contains several toxins that have poisoned livestock, and an irritant in the plant hairs can cause allergies in humans. The occurrence of poisoning appears to depend on unknown conditions, which may account for the conflicting literature reports. However, the plant has been implicated in enough cases of poisoning to be treated as a potentially toxic plant (Cooper and Johnson 1984, Fuller and McClintock 1986).

Canadian Biodiversity Information Facility

Notes on poisoning: *Anthurium andraeanum*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Flamingo lily (*Anthurium andraeanum*) is an indoor ornamental plant that produces striking flowers. Ingestion can cause painful irritation of the mouth and throat. Other species of the genus *Anthurium* may be cultivated in Canada, and all these plants should be regarded as containing calcium oxalate crystals, an irritant.

References:

Notes on poisoning:

Apocynum

androsaemifolium

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Spreading dogbane (*Apocynum androsaemifolium*) is a native herb found across Canada. This plant has been reported to cause serious poisoning potential in cattle, horses, and sheep after ingestion (Johnson and Archer 1922). This information was credited to a report from the Arizona Experiment Station and to an article that was erroneously stated to be about *Apocynum*. However, that article actually concerned *Nerium* (oleander) poisoning of livestock. Therefore, the various signs and symptoms attributed to dogbane poisoning since 1922 are usually based on this mistake (Kingsbury 1959).

Notes on poisoning: *Apocynum cannabinum*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

1909). Hemp dogbane (*Apocynum cannabinum*) is a native plant found across Canada. Fuller and McClintock (1986) report that two horses died after ingesting alfalfa hay that contained large quantities of hemp dogbane. The tops of the plants (up to 1 m tall) were found in the hay.

References:

Fuller, T. C., McClintock, E. 1986. Poisonous plants of California. Univ. California Press, Berkeley, Calif., USA. 432 pp.

Nomenclature:

Scientific Name: *Apocynum cannabinum* L.

Vernacular name(s): hemp dogbane

Scientific family name: *Apocynaceae*

Vernacular family name: dogbane

Go to ITIS*^{ca} for more taxonomic information on: [Apocynum cannabinum](#)

Notes on poisoning: *Arisaema triphyllum*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Jack-in-the-pulpit (*Arisaema triphyllum*) is a native plant found in wet soils in parts of eastern Canada. The plant contains calcium oxalate raphide crystals, as do many other members of the family Araceae. When ingested, these crystals can cause severe pain and burning in the lips, mouth, and throat (Lampe and McCann 1985).

Notes on poisoning: *Armoracia rusticana*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Horseradish (*Armoracia rusticana*) is a cultivated plant that can persist after cultivation. The plant contains glucosinolates, which can cause toxicity in livestock. Irritation of the mucous membranes can occur in humans who grind the roots to produce horseradish condiment. See the notes under *Brassica oleracea* for more information on these chemicals. Under normal circumstances horseradish is safe.

References:

Notes on poisoning: *Asclepias verticillata*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Eastern whorled milkweed (*Asclepias verticillata*) is a native plant found in fields in parts of southern Canada. It has caused poisoning in experimental feeding tests in sheep. Large quantities of fresh plant were administered with a balling gun at about 2.2% of body weight, causing symptoms of poisoning (Marsh and Clawson 1921). The early literature is rife with contradictions in determining the scientific names of various milkweeds. *Asclepias verticillata* was termed *Asclepias verticillata* var. *geyeri* in Marsh and Clawson (1921). For more information on *Asclepias* taxonomy see Woodson (1954).

Sheep

General symptoms of poisoning:

[agitation](#)

[bloat](#)

[breathing, labored](#)

[convulsions](#)

[death](#)

[depression](#)

[opisthotonos](#)

[pupil dilation](#)

[temperature, elevated](#)

[trembling](#)

[weakness, posterior](#)

Notes on poisoning:

Experimental feeding of fresh eastern whorled milkweed caused poisoning in sheep. The animals fell down and went through characteristic running movements. The head and jaws occasionally moved compulsively. The pulse was often weak. Ingesting 2.2% of body weight was necessary to produce serious poisoning in sheep. Animals do not normally eat these distasteful plants or other milkweeds (Marsh and Clawson 1921).

Notes on poisoning: *Astragalus bisulcatus*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Two-grooved milk-vetch (*Astragalus bisulcatus*) is a native plant found on rangelands in western Canada. This plant can accumulate quantities of selenium high enough to cause toxicity in cattle, horses, sheep, and swine. High quantities of selenium cause acute toxicity, with symptoms including staggering, diarrhea, prostration, and abdominal pain. Plants that contain a selenium content of less than 200 ppm cause chronic toxicity. James et al.(1983) used this plant (selenium content of 180 ppm) to conduct feeding experiments on sheep. They found that the symptoms and microscopic lesions of tissues collected from the sheep were similar to those caused by locoweed poisoning and not selenium poisoning. This finding suggests that other toxic compounds in addition to selenium may be present.

Swainsonine is also found in this plant, which may explain why, in experiments, sheep exhibited symptoms more appropriate to locoism than to selenium poisoning (Cheeke and Schull 1985).

Notes on poisoning: *Astragalus canadensis*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Cattle have been fatally poisoned when fed on rangeland containing Canadian milk-vetch (*Astragalus canadensis*).

Experiments with sheep indicated that plant material must contain NO₂ at 250 mg/kg of body weight to produce toxic responses and 275 mg/kg body weight for a lethal dose. In week-old chicks, the LD-50 = 2 g of plant ingested (Williams and James 1975).

Notes on poisoning: *Astragalus lentiginosus*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Astragalus lentiginosus is a native plant found in south-central British Columbia. Ingesting the plant causes a variety of problems. Plants contain the alkaloid swainsonine, which can cause locoism. The common symptoms are impairment of the nervous system, depression, and excitement when disturbed. Teratogenic effects have also been noted in lambs and foals. At high altitudes (above 2120 m), cattle suffer from congestive heart failure (swainsonine influences the vascular system). This plant is a major poisonous range plant in the western United States. It is not abundant anywhere in Canada (Cheeke and Schull 1985, Panter et al. 1988).

Van Kampen, K. R., James, L. F. 1972. Sequential development of the lesions in locoweed poisoning. *Clin. Toxicol.*, 5: 575-580.

Notes on Toxic plant chemicals:

Swainsonine, the chemical involved in locoism, is found in several plants occurring in Canada, including *Astragalus bisulcatus*, *A. lentiginosus*, *Oxytropis lambertii*, and *O. sericea*. This indolizidine alkaloid causes locoism in cattle, horses, and sheep; it also causes teratogenic deformities in lambs, calves, and foals. In addition, at high altitudes (above 2120 m) it contributes to congenital heart failure in calves and cows (Cheeke and Schull 1985).

Toxic plant chemicals:

slaframine
swainsonine

[sperm, detached tails](#)
[sperm mobility, poor](#)
[testicle degeneration](#)
[ventricular\(right\), edema](#)

[ventricle\(right\),round](#)
[weakness](#)

Notes on poisoning:

Astragalus lentiginosus caused fetal abortion in sheep and clinical signs of locoism in pregnant ewes. It also caused fluid accumulation in the placenta, altered cotyledonary development, and decreased fetal heart rates causing cardiac irregularity. At necropsy the fetuses had hypertrophy of the heart, right ventricular dilation, rounded apex of the heart, and generalized edema (Panter et al. 1987).

Notes on poisoning: *Astragalus miser*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Timber milk-vetch (*Astragalus miser*) is a native herb that is found in southern British Columbia and southern Alberta. This plant causes acute and chronic toxicity in cattle and sheep. Experimental poisoning has been caused in other livestock. Honey bees that forage on the flowers of timber milk-vetch were also poisoned (Majak and Pass 1989).

References:

Image or illustration

Astragalus miser:

Images: images.google.com

Notes on Poisonous plant parts:

Timber milk-vetch contains miserotoxin. This toxic principle is found primarily in the leaves and reaches its highest concentration during the bud and mature-flower stages of growth. The levels drop rapidly when leaves dry. Herbicides bleach leaves and cause a reduction in the concentration of miserotoxin. Tests with fertilizer on range plants showed that use of urea (nitrogen at 200 kg/ha)

increased the level of miserotoxin during the second year of fertilizer use on a clearcut site. Use of urea (nitrogen at 100 kg/ha) on grassland sites did not affect miserotoxin levels (Cheeke and Schull 1985; Majak and Wikeem 1986).

Toxic parts:

leaves
stems

References:

Cheeke, P. R., Shull, L. R. 1985. Natural toxicants in feeds and poisonous plants. AVI Publishing Company, Inc., Westport, Conn., USA. 492 pp.

Quinton, D. A., Majak, W., Hall, J. W. 1989. The effect of cattle grazing on the growth and miserotoxin content of Columbia milkvetch. *J. Range Manage.*, 42: 368-371.

Notes on Toxic plant chemicals:

The glycoside (3-nitro-1-propyl-beta-D-glucopyranoside), called miserotoxin, is the poisonous principle in timber milk-vetch. Other toxic chemicals have been found including the following:

3-nitro-1-propyl-beta-D-gentiobioside (called gentitoxin)
3-nitropropyl-beta-D-allolactoside.

Miserotoxin is rapidly hydrolysed by rumen organisms. The acute toxic effect is related to methemoglobinemia, where hemoglobin is oxidized by nitrite (Cheeke and Schull 1985, Majak et al. 1988).

Miserotoxin is not converted to NPA (3-nitro-1-propionic acid) in the digestive tract of nonruminants. Cattle and sheep can be intoxicated by feeding the chemical NPOH (3-nitro-1-propanal) at 20-60 mg/kg of body weight. NPOH is lethal at 30-35 mg/kg in cattle when fed intravenously:

LD-50 » 77 mg/kg for oral acute toxicity in rats
LD-50 » 25 mg/kg for chronic toxicity in rats fed twice daily for several days.

The acute and chronic syndromes were caused experimentally in rats, pigs, chicks, pigeons, rabbits, and mice (Majak and Pass 1989).

Toxic plant chemicals:

miserotoxin

3-nitropropanol

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[breathing, labored](#)

[collapse](#)

[cyanosis](#)

[death](#)

[emphysema](#)

[incoordination](#)

[liver, congestion of](#)

[muscle, weakness of](#)

[weakness](#)

Notes on poisoning:

Cattle that have ingested timber milk-vetch can suffer from acute syndrome, in which a rapid onset with death occurs a few hours to a day after ingestion. Chronically affected animals have liver damage, emphysema, Wallerian degeneration of the spinal cord and peripheral nerves, and focal hemorrhages in the brain. Lactating animals are most susceptible to the toxin (Majak and Pass 1989).

References:

James, L. F., Hartley, W. J., Van Kampen, K. R. 1981. Syndromes of *Astragalus* poisoning in livestock. J. Am. Vet. Med. Assoc., 178: 146-150.

Majak, W., Pass, M. A. 1989. Aliphatic nitrocompounds. Pages 143-159 in Cheeke, P. R., ed. Toxicants of plant origin. Vol. II Glycosides. CRC Press, Inc., Boca Raton, Fla., USA. 277 pp.

Honey bees

General symptoms of poisoning:

[death](#)

[incoordination](#)

[weakness](#)

Notes on poisoning:

Honey bees were poisoned after ingesting the nectar of timber milk-vetch. Sickness and death occur with 0.1-0.8% daily mortality rate of the hive population. In experiments, 2.5% miserotoxin in a 50% sugar solution killed 100% of bees within 48 h. Poisoned bees were unable to fly, and dead bees were usually seen with the wings extended and the proboscis protruding (Majak et al. 1980).

References:

Majak, W., Neufeld, R., Corner, J. 1980. Toxicity of *Astragalus*

miser v. *serotinus* to the honeybee. J. Apic. Res., 19: 196-199.

Majak, W., Pass, M. A. 1989. Aliphatic nitrocompounds. Pages 143-159 in Cheeke, P. R., ed. Toxicants of plant origin. Vol. II Glycosides. CRC Press, Inc., Boca Raton, Fla., USA. 277 pp.

Horses

Sheep

General symptoms of poisoning:

[breathing, labored](#)

[cyanosis](#)

[death](#)

[incoordination](#)

Notes on poisoning:

Sheep often collapse and die from acute miserotoxin poisoning after exhibiting few clinical signs. In sheep the respiratory signs of chronic poisoning are more prominent than the nervous system signs. The animals lose weight and develop respiratory distress, hind limb paresis, nasal discharge, and a roaring sound. Lactating sheep are more susceptible to intoxication than nonlactating ones (Majak and Pass 1989).

Notes on poisoning: *Avena sativa*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Oats (*Avena sativa*) can cause nitrate toxicity in livestock. Cattle are more prone to toxicity, but swine and turkeys have been poisoned on oat stubble. Grass tetany also occurs during periods of lush growth when ruminants suffer from a mineral imbalance.

Notes on poisoning: *Barbarea vulgaris*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Yellow rocket (*Barbarea vulgaris*) is a naturalized plant found across much of Canada. This plant poisoned a horse in one unusual case in which the animal ate large quantities of the plant from a wagon that was hauling the weed from a field (Hansen 1930). The symptoms suggested glucosinolate poisoning, as in *Brassica* spp.

Notes on poisoning: *Bassia hyssopifolia*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Five-hooked bassia (*Bassia hyssopifolia*) is a naturalized herb found in southern parts of western Canada. The plant is suspected of poisoning livestock. James et al. (1976) report experimental poisoning of sheep after they were fed macerated above-ground parts of the plant.

References:

James, L. F., Williams, M. C., Bleak, A. T. 1976. Toxicity of *Bassia hyssopifolia* to sheep. *J. Range Manage.*, 29: 284-285.

Nomenclature:

Scientific Name: *Bassia hyssopifolia* (Pall.) Ktze.

Vernacular name(s): five-hooked bassia

Scientific family name: *Chenopodiaceae*

Vernacular family name: goosefoot

Sheep

General symptoms of poisoning:

[coma](#)

[death](#)

[gait, unsteady](#)

[incoordination](#)

[tetany](#)

[weakness](#)

Notes on poisoning:

In experimental feeding of sheep, five-hooked bassia caused symptoms similar to poisoning by [Kochia scoparia](#). In addition to the symptoms listed, hemorrhaging on the rumen surface and enlarged kidneys occurred. Calcium concentrations in the serum of five sheep dropped from an average of 10.9 mg/mL to 3.6 mg/mL. Signs of photosensitization were also noted in some of the sheep (James et al. 1976).

Canadian Biodiversity Information Facility

Notes on poisoning: *Brassaia actinophylla*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Australian umbrella tree (*Brassaia actinophylla*) is an ornamental shrub grown indoors in Canada. This plant caused toxic symptoms in a dog after it ingested the leaves. Experimental work on rats caused death after they ingested 3.2 g of leaf tissue over 7 days. Symptoms in the rats included extramedullary hematopoiesis in the spleen, with black tarry gastrointestinal content caused by blood (Quam et al. 1985).

References:

Mitchell, J. C. 1981. Allergic contact dermatitis from *Hedera helix* and *Brassaia actinophylla* (Araliaceae). *Contact Dermatitis*, 7: 158-159.

Notes on poisoning: *Brassica campestris*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Bird rape (*Brassica campestris*) includes the vegetables turnip and chinese cabbage. These plants can accumulate toxic quantities of SMCO, which poisoned several types of livestock after they ingested sufficient quantities (Benevenga et al. 1985). Please see the expanded notes on poisoning by this chemical under kale (*Brassica oleracea*) and the effects on various livestock animals.

Cattle

General symptoms of poisoning:

[abortion](#)

[death](#)

[dehydration](#)

[gait, staggering](#)

Notes on poisoning:

In one case in Saskatchewan, a herd of cattle gained access to waste mustard seed. Six cows died and two were ill. Symptoms included depression, staggering, and reluctance to move. Several cows aborted, but most showed clinical signs of sickness. Postmortem findings revealed profuse edema of the forestomachs and abomasum. A 2-3 cm layer of clear, yellowish, gelatinous fluid was present under the serosa of the rumen, reticulum, and omasum. Allylisoithiocyanate at a rate of 1000 mg/100 mL was liberated from the seeds. A rate of 250 mg/100 mL is regarded as acutely toxic to cattle (Kernaleguen et al. 1989).

Notes on poisoning: *Brassica napus*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Rapeseed (*Brassica napus*) meal is used as an additive to livestock feed, but toxicity occurs from glucosinolates and erucic acid, which form in the seeds. Canadian breeders have developed new cultivars called canola, which are low in these compounds (Cheeke and Schull 1985). See discussions under [Brassica oleracea](#) for more information on poisoning by *Brassica* species.

Notes on poisoning: *Brassica oleracea*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Brassica oleracea includes common cultivated crops such as kale, broccoli, Brussels sprouts, and cabbage. All these vegetables are capable of forming toxic quantities of SMCO, a chemical that can cause hemolytic anemia in livestock. These plants also contain glucosinolates, which can cause goiter. In general, these widely used vegetables are safe for human consumption. Cases of livestock poisoning occur when they are used almost exclusively as fodder for animals (Kingsbury 1964, Smith 1980, Cheeke and Schull 1985, Benevenga et al. 1989). Glucosinolates contained in kale, cabbage, and broccoli (*Brassica oleracea*) can cause goiter in humans. These plants cause goiter in less than 5% of cases in humans. The chemicals cause a reduction in performance of young livestock, especially swine and poultry (Fenwick et al. 1989). It is important to note that the frequency of toxicity has dropped dramatically since a few decades ago. Researchers have changed the quantity of toxic compounds in the entire *Brassica* spp., creating new cultivars with lower quantities of these chemicals. The threat of poisoning from some of the plants has diminished or virtually disappeared in some cultivars. For example, the Canadian development of rapeseed into the so-called "double-zero" cultivars (low in glucosinolates and in erucic acid) has allowed rapeseed meal to be used for livestock at much higher levels without reducing performance (Cheeke and Schull 1985).

Image or illustration

Brassica oleracea:

Images: images.google.com

Notes on Poisonous plant parts:

SMCO is most abundant in young leaves and growing points. Brussels sprouts can have high amounts of the chemical, as can the flowering parts of the plants. The most drastic hemolytic anemia occurs when these plants form exclusive fodder for livestock (Smith 1980).

Toxic parts:

all parts
flowers
leaves

References:

Smith, R. H. 1980. Kale poisoning: the brassica anemia factor. Vet. Rec., 107: 12-15.

Notes on Toxic plant chemicals:

Glucosinolates are chemicals that can inhibit the function of the thyroid gland. Various components of the chemicals can be detrimental to both humans and livestock. Goitrin inhibits thyroid function. Thiocyanates and isothiocyanates inhibit iodine uptake by the thyroid gland. Nitriles can be formed from glucosinolates and these chemicals are toxic, affecting the liver and kidneys (Cheeke and Schull 1985). SMCO (S-methyl-L-cysteine sulfoxide) is an alpha-amino acid that causes hemolytic anemia in livestock. This chemical is restricted to various members of the family Cruciferae in the genera *Brassica* and *Raphanus* as well as the family Liliaceae in the genus *Allium* (onions). Additional notes on this chemical can be found under members of these genera. The concentration of SMCO

in kale plants may double as the plants mature. The quantity of SMCO is increased with the addition of nitrogen to high-sulfate soils. SMCO can be greatly reduced in low-sulfate soils. The variation of SMCO varies greatly amongst different varieties of plants in the genus *Brassica*, suggesting that concentrations of SMCO may be heritable (Benevenga et al. 1989).

Lampe, K. F., McCann, M. A. 1985. AMA Handbook of poisonous and injurious plants. American Medical Assoc. Chicago, Ill., USA. 432 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cats

Dogs

Humans

General symptoms of poisoning:

[mouth, irritation of](#)

Notes on poisoning:

Ingesting material containing calcium oxalate raphide crystals causes irritation of the soft mouth parts and perhaps the throat of humans and animals. Swelling of tissues causes pain and a burning sensation that slowly subsides. Cool liquids or analgesics may be indicated. The insoluble oxalates do not cause systemic poisoning (Lampe and McCann 1985).

Notes on poisoning: *Calla palustris*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Wild calla (*Calla palustris*) is a native plant that grows in swamps and marshes through much of Canada. Calcium oxalates occur, which can cause severe irritation of the mouth and throat. No cases of livestock poisoning are found in the literature, but the potential for poisoning is present. Humans are also at risk from this plant (Kingsbury 1964, Lampe and McCann 1985).

References:

Lampe, K. F., McCann, M. A. 1985. AMA Handbook of poisonous and injurious plants. American Medical Assoc. Chicago, Ill., USA. 432 pp.

Notes on poisoning: *Cannabis sativa*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Accidental ingestion of marijuana (*Cannabis sativa*) by pets is an occasional problem. Family pets or young children may accidentally ingest the plant, which may be stored in plastic bags. A dog ingested hashish brownies and then exhibited various symptoms such as hyperactivity, vomiting, somnolence, staggering, and glazed eyes. In another case, in Edmonton, a pet ferret ingested the plant and became comatose after experiencing sneezing bouts and ataxia. Although no fatalities of humans have been reported, the effects on a young child accidentally ingesting marijuana are bound to be very disturbing to the parents (Jones 1978, Smith 1988).

References:

- Jones, D. L. 1978. A case of canine cannabis ingestion. N. Z. Vet. J., 26: 135-136.

Notes on poisoning: *Caulophyllum* *thalictroides*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Blue cohosh (*Caulophyllum thalictroides*) is a native plant found in rich woods in eastern Canada. The plant contains chemicals that can cause cell damage. Experiments show that handling powdered root can cause irritation of mucous membranes, with possible dermatitis. No case histories of poisoning were found in the literature, but the plant has poisoning potential. Children should not be allowed to eat the attractive blue fruits of this plant (Muenscher 1975, Lampe and McCann 1985). No references were found of poisoning of livestock.

References:

Lampe, K. F., McCann, M. A. 1985. AMA Handbook of poisonous and injurious plants. American Medical Assoc. Chicago, Ill., USA. 432 pp.

Image or illustration

Caulophyllum thalictroides:

Images: images.google.com

Notes on Poisonous plant parts:

The berries and roots contain chemicals that are cytotoxic, causing cell damage. The plant is extremely bitter and is not usually ingested by livestock. (Muenscher 1975, Lampe and McCann 1985).

Toxic parts:

mature fruit
roots

References:

Lampe, K. F., McCann, M. A. 1985. AMA Handbook of poisonous and injurious plants. American Medical Assoc. Chicago, Ill., USA. 432 pp.

Muenschler, W. C. 1975. Poisonous plants of the United States. Revised. Collier Books, New York, N.Y., USA. 277 pp.

Notes on Toxic plant chemicals:

An alkaloid and saponins occur in this plant. The chemicals are cytotoxic, damaging animal cells. The plant is reported to have orally active oxytocic substances, which cause uterine contractions (Fergusen and Edwards 1954, Lampe and McCann 1985).

Toxic plant chemicals:

N-methylcytisine

Notes on poisoning: *Centaurea repens*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Russian knapweed (*Centaurea repens*) and yellow star-thistle (*Centaurea solstitialis*) are both naturalized in western Canada. Both plants cause chewing disease in horses. The problem is restricted to horses. Prolonged consumption of the plants is required to produce the symptoms. Russian knapweed is more toxic than yellow star-thistle (Cheeke and Schull 1985, Panter 1990):

- intake of 1.8-2.5 kg/100 kg of body weight per day of Russian knapweed causes toxicity after ingesting 59-71% of its body weight of the plant material in about 30 days;

- intake of 2.3-2.6 kg/100 kg of body weight per day of yellow star-thistle causes toxicity after ingesting 86-200% of its body weight of the plant material in about 54 days.

There are no known treatments for horses once the symptoms appear.

Notes on Poisonous plant parts:

Horses must ingest fresh aboveground plant material for prolonged periods to reach a threshold level of unknown toxicity and then the symptoms appear abruptly. Chewing disease in horses has occurred in parts of the western United States. In California the peak times of disease onset are June-July and October-November (Cordy 1978).

Canadian Biodiversity Information Facility

Notes on poisoning: *Ceratocephalus* *testiculatus*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Bur buttercup (*Ceratocephalus testiculatus*) is an introduced herb that so far is known only from around Kamloops, British Columbia. This plant is found in several western states bordering Canada, where it is rapidly spreading. The plant has also been found on South Bass Island in Ohio on Lake Erie. This plant contains ranunculin, as do some species of the genus *Ranunculus* (buttercup). This chemical changes into a toxic chemical when the plant is crushed. Sheep have been poisoned and have died in the western United States after ingesting aboveground plant material; this plant is considered highly toxic. About 500 g of green plant can kill a 45-kg sheep. This plant grows in dry sandy areas, such as sage slopes and in livestock pens, and has recently been found as a weed in grain and alfalfa fields (Olsen et al. 1983, Cusick 1989).

References:

plant juices

References:

Cusick, A. W. 1989. Bur buttercup (*Ceratocephalus testiculatus*: Ranunculaceae): a poisonous plant newly established in Ohio.

Mich. Bot., 28: 33-35.

Notes on Toxic plant chemicals:

Crushing the plant releases an enzyme that changes ranunculin, a glycoside, to protoanemonin, a highly irritant, yellow, volatile oil. This chemical is unstable and changes to nontoxic anemonin or volatilizes upon drying, leaving nontoxic plant material. The median LD-50 was 10.9 g/kg for sheep fed aboveground plant parts in the flower to early-seed stage. A sheep fed 7 g/kg of body weight might develop transient anorectic effects. Intake of 13.9 g/kg or greater would usually be lethal (Olsen et al. 1983).

Toxic plant chemicals:

ranunculin

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Sheep

General symptoms of poisoning:

[anorexia](#)
[breathing, labored](#)
[death](#)
[diarrhea](#)
[dyspnea](#)
[recumbency](#)

[weakness](#)

Notes on poisoning:

In Utah 150 of 800 sheep that ingested bur buttercup died. Symptoms took less than 24 h and included watery diarrhea, recumbency, weakness, and death. Experimental feeding showed more complete signs, such as tachycardia, dyspnea, anorexia, and occasional fever. Post-mortem findings revealed edema of the peritoneal surface to the ruminoreticulum, subendocardial hemorrhages in the left ventricle, and congestion of the heart, kidneys, liver and lungs. Severity was directly related to the dosage. Death results apparently as a failure of the cardiovascular system, with massive fluid shifts (Olsen et al. 1983).

Canadian Biodiversity Information Facility

Notes on poisoning: *Chelidonium majus*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Greater celandine (*Chelidonium majus*) is a perennial naturalized herb found in parts of eastern Canada. This plant is suspected in the death of a four-year old boy (Koopman 1937). There are records of skin irritation and soreness after the latex is applied to the skin, a practice that was followed in Europe to help minor skin injuries (Cooper and Johnson 1984). Cattle were poisoned and died in Britain after ingesting the ripe fruit of this plant (Reeks 1903); 500 g of the plant can cause toxic effects in horses or cattle (Frohne and Pfander 1983).

Image or illustration

Chelidonium majus:

Images: images.google.com

Notes on Poisonous plant parts:

The entire plant is considered poisonous. The plant contains bright yellow latex that turns reddish after exposure to air. The

plant is considered unpalatable because of its acrid taste and pungent, fetid smell (Frohne and Pfander 1983, Cooper and Johnson 1984).

Toxic parts:

latex

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Frohne, D., Pfander, H. J. 1983. A colour atlas of poisonous plants. Wolfe Publishing Ltd., London, England. 291 pp.

Notes on Toxic plant chemicals:

Chelidonine is the major alkaloid found in greater celandine. At least 20 other alkaloids have been found in the plant. The concentration of these alkaloids varies in various plant organs, depending on the stage of growth (Frohne and Pfander 1983).

Toxic plant chemicals:

chelidonine

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[convulsions](#)

[death](#)

[drowsiness](#)

[gait, staggering](#)
[salivation](#)

Notes on poisoning:

One case of cattle poisoning is attributed to this plant. The cattle became drowsy, had a staggering gait, salivated, and some cows died. Calves that suckled the poisoned cows were unaffected. Postmortem examination revealed gastrointestinal irritation (Reeks 1903).

References:

Reeks, H. C. 1903. Poisoning of cattle by common celandine. J. Comp. Pathol. Ther., 16: 367-371.

Humans

General symptoms of poisoning:

[coma](#)
[death](#)
[diarrhea](#)
[drowsiness](#)
[headache](#)

Notes on poisoning:

The case of a 4-year-old boy who sickened and died is cited in the literature. Postmortem examination showed severe irritation of the large intestine. The cause of death was suspected to be greater celandine (Koopman 1937).

References:

Koopman, H. 1937. A fatal case of celandine poisoning. Sammlung von Vergiftungsfallen, 8: 93-98.

Notes on poisoning: *Chenopodium album*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Lamb's-quarters (*Chenopodium album*) is a naturalized annual herb found in disturbed soils across Canada. This plant can cause sickness and death in livestock if large quantities are ingested. The plants can accumulate both nitrates and soluble oxalates. Cattle and sheep have been poisoned. Humans who consume large quantities of the plant and are subsequently exposed to sunlight suffer photosensitization (Whitehead and Moxon 1952, Cooper and Johnson 1984).

Canadian Biodiversity Information Facility

Notes on poisoning: *Chrysanthemum indicum*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Chrysanthemum (*Chrysanthemum indicum*) and cultivated hybrids (*C. X morifolium* Ramat.) are perennial ornamentals grown indoors and outdoors. Some humans develop contact dermatitis after extended exposure to garden chrysanthemums. This is an occupational hazard of florists, nursery workers, and gardeners. (Rook and Mitchell 1979, Frohne and Pfander 1983).

Toxic parts:

leaves

References:

Frohne, D., Pfander, H. J. 1983. A colour atlas of poisonous plants. Wolfe Publishing Ltd., London, England. 291 pp.

Notes on Toxic plant chemicals:

Arteglasin A is a sesquiterpene lactone of the quaianolide type and is one of the active allergens of garden chrysanthemums. A cross-link can form between this chemical and sulfhydryl groups of body proteins so that complete antigens are produced. Repeated exposure can cause the allergic reaction. Humans who are sensitive to one member of the Compositae family can become sensitive to other members of the plant family, such as yarrow (*Achillea millefolium*) or wild chamomile (*Matricaria chamomilla*) (Mitchell

and Rook 1979; Frohne and Pfander 1983).

Notes on poisoning: *Chrysothamnus* *nauseosus*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Stinking rabbitbrush (*Chrysothamnus nauseosus*) is a native shrub found on rangeland in western Canada. This plant has been reported to be toxic to livestock, and some feeding experiments have supported this conclusion. However, the plant is so unpalatable that quantities sufficient to cause toxicity are not likely to be ingested (Sampson and Malmsten 1935, Kingsbury 1964, Fuller and McClintock 1986).

Notes on poisoning: *Cicuta douglasii*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Western water-hemlock (*Cicuta douglasii*) is a native perennial plant found in wet soils in British Columbia. This plant is poisonous to all types of livestock and to humans. Many cases of poisoning have occurred in cattle, sheep, and horses. Pigs seem more resistant to the toxins, but they have still been poisoned. Humans have also been poisoned by this plant. Children are especially susceptible because ingestion of only one bite of the rootstock is sufficient to cause death. The onset of symptoms is so rapid that treatment may not be successful (Starrveld and Hope 1975, James and Ralphs 1986). See additional information in the general notes under [Cicuta maculata](#).

Image or illustration

Cicuta douglasii:

Images: images.google.com

Notes on Poisonous plant parts:

The toxins are concentrated in the chambered rootstock but also occur in the leaves and stems as well (James and Ralphs 1986).

Toxic parts:

leaves
 roots
 young shoots

References:

James, L. F., Ralphs, M. H. 1986. Water hemlock. *Utah. Sci.*, 47(2): 67-69.

Notes on Toxic plant chemicals:

Cicutoxin is a highly unsaturated alcohol that is very toxic. The following dosages have been found:

Lethal dose (fresh green plant material)	Animal
0.1 kg	sheep
0.4 kg	cattle
0.3 kg	horse

Pigs appear to be more resistant to poisoning than other livestock. Adult humans can be poisoned and can die with only two or three bites of the rootstock (Starrveld and Hope 1975, James and Ralphs 1986).

Canadian Biodiversity Information Facility

Notes on poisoning: *Cicuta maculata*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Spotted water-hemlock (*Cicuta maculata*) is a native perennial herb found in wet soils and marshes across most of Canada and is considered the most violently toxic plant in North America. Humans and all classes of livestock are susceptible to poisoning and death after ingesting plant material. The onset of symptoms is often so sudden and traumatic that treatments are not always successful. The symptoms are similar in all cases of poisoning: salivation, muscular spasms, violent convulsions, coma, and death from asphyxiation. Death can occur within 15 minutes to 2-3 h after a lethal dose (Starrveld and Hope 1976, Panter et al. 1988).

Image or illustration

Cicuta maculata:

Images: images.google.com

Notes on Poisonous plant parts:

The toxin is concentrated in the rootstock in the spring. Later during the growing season, the roots contain less toxin, and the leaves and stems contain sufficient chemical to cause lethal poisoning (Starreveld and Hope 1975).

Toxic parts:

all parts
roots

References:

Pammel, L. H. 1928. Cowbane (wild parsnip). N. Am. Vet., 9: 25-26.

Skidmore, L. V. 1933. Water hemlock (*Cicuta maculata* L.) poisoning in swine. Vet. J., 89: 76-80.

Smith, R. A., Lewis, D. 1987. *Cicuta* toxicosis in cattle: case history and simplified analytical method. Vet. Hum. Toxicol., 29(3): 240-241.

Starreveld, E., Hope, C. E. 1975. Cicutoxin poisoning (water hemlock). Neurology, 25: 730-734.

Notes on Toxic plant chemicals:

The chemical cicutoxin, (trans)heptadeca-8:10:12-triene-4:6-diene- 1:4-diol, is a highly unsaturated higher alcohol. Cicutol is also present. Bohlman (pers. comm.) in Mulligan and Munro (1981) found the following concentrations of these chemicals in *Cicuta* rootstocks:

<i>Cicuta maculata</i> var. <i>maculata</i>	1.01 mg/g active ingredients
<i>Cicuta douglasii</i>	0.75 mg/g
<i>Cicuta virosa</i>	0.07 mg/g
<i>Cicuta bulbifera</i>	0.01 mg/g

The first two *Cicuta* spp. are considered the most violently toxic plants in North America. *Cicuta virosa* is less likely to cause poisoning because of its reduced concentration of toxic compounds. *Cicuta bulbifera* contains too little toxin to be considered a threat.

Toxic plant chemicals:

cicutol

cicutoxin

[pupils, pinpoint](#)

[reflex excitability](#)

[salivation](#)

[teeth grinding](#)

[unconsciousness](#)

[voiding, involuntary](#)

[vomiting](#)

Notes on poisoning:

Symptoms of poisoning by the genus *Cicuta* include dizziness, salivation, clenching and grinding of teeth, violent convulsions, cyanosis, coma, and death from asphyxiation. In one case, a fisherman took two bites from the roots and then felt dizzy and fell unconscious within 30 min. The patient endured pain and convulsions for some time. Recommended treatment includes administration of oxygen, anesthesia to control gross wild movements, and intravenous sodium bicarbonate to correct metabolic acidosis. At least 83 cases of human poisoning by water-hemlock have been reported since 1900, of which 21 were fatal. The rootstocks are generally distasteful, but ingesting of only one bite causes symptoms in humans (Starrveld and Hope 1976). These notes apply to all water-hemlock species (*Cicuta*) listed in this information system.

Sheep

General symptoms of poisoning:

[breathing, labored](#)
[death](#)
[recumbency](#)

Notes on poisoning:

Ewes weighing 70 kg were experimentally poisoned with fresh rootstock. The ewe given 100 g showed few symptoms; 200 g of plant material caused extensive symptoms including seizures, recumbency, and labored breathing. Recovery occurred after several days. Gavage with 450 g of the rootstock caused death in 90 min (Panter et al. 1988).

Canadian Biodiversity Information Facility

Notes on poisoning: *Cicuta virosa*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Northern water-hemlock (*Cicuta virosa*) is a native perennial herb found in wet soils across northern Canada. It contains lower quantities of the toxic chemicals that cause poisoning in humans and livestock. However, Frohne and Pfander (1983) mention a case of human poisoning in Europe after ingestion of some rootstock of this plant. Livestock can also be poisoned if enough of the plants are ingested. Instances of poisoning in Canada should be fewer for northern water-hemlock because the concentration of chemicals is lower and the plant has essentially a boreal distribution outside of major livestock-growing areas. See additional information under [Cicuta maculata](#)

Notes on poisoning: *Clivia miniata*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Kaffir lily (*Clivia miniata*) is an indoor ornamental plant grown for its flowers. The plant contains small amounts of the alkaloid lycorine. Large quantities must be ingested to cause symptoms of toxicity. Children and family pets can be poisoned (Frohne and Pfander 1983, Lampe and McCann 1985).

Canadian Biodiversity Information Facility

Notes on poisoning: *Codiaeum variegatum*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Croton (*Codiaeum variegatum*) is a common houseplant. Chewing the bark and roots is said to cause burning of the mouth. Some young leaves are used in the East Indies as a vegetable, but cases of irritation have been reported. The latex has caused eczema in some gardeners (Morton 1962, Frohne and Pfander 1983).

Canadian Biodiversity Information Facility

Notes on poisoning: *Colchicum autumnale*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Autumn crocus (*Colchicum autumnale*) is an outdoor ornamental grown for its autumn flowers. The plant is poisonous to all animals and to humans. Livestock have been poisoned in Europe and Asia, where the plants are native. Poisoning has been reported in cattle, goats horses, sheep, and swine, as well as in humans and dogs. The toxic chemical colchicine can be excreted through the milk of lactating animals, thereby poisoning young animals and humans. Cattle and, to a lesser extent, goats and sheep can develop complete resistance to colchicine (Cooper and Johnson 1984). This plant is found only in garden cultivation or maybe as a houseplant in Canada. Children and family pets are therefore most at risk from ingesting autumn crocus.

Images: images.google.com

Toxic parts:

all parts

References:

Lampe, K. F., McCann, M. A. 1985. AMA Handbook of poisonous and injurious plants. American Medical Assoc. Chicago, Ill., USA. 432 pp.

Notes on Toxic plant chemicals:

Colchicine is more toxic than colchiceine. These chemicals withstand drying, storage, and boiling without losing their toxic qualities. Colchicine affects the central nervous system, paralyzing nerve endings and blocking neuromuscular connections.

All parts of the plant are poisonous:

- 0.03-0.06% colchicine in the corm (bulb)
- 0.02-0.04% colchicine in the seeds

Ingesting fresh leaves in the following quantities results in death (Cooper and Johnson 1984):

8-16 g/kg of body weight	cattle
6.4 g/kg body weight	lambs (2-3 months old)
12 g/kg body weight	guinea pigs (adult)

Toxic plant chemicals:

colchiceine
colchicine

Canadian Biodiversity Information Facility

Notes on poisoning: *Conium maculatum*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Poison-hemlock (*Conium maculatum*) is a naturalized herb found in parts of southern Canada. The plant grows on dry to moist soils. Cattle, goats, horses, swine, and sheep as well as rabbits, poultry, deer, and humans have been poisoned after ingesting poison-hemlock. Animal species vary in their susceptibility to acute toxicity (Keeler et al. 1980):

cows	3.3 mg/kg body weight	1.5-2 h
ewes	44 mg/kg body weight	1.5-2 h
mares	15.5 mg/kg body weight	30-40 min

Poison-hemlock causes toxicity and death in animals after it is ingested. It also causes teratogenic effects called crooked calf disease in young pigs and cattle, caused by the chemical coniine (Keeler 1974, Panter et al. 1985).

Image or illustration

Conium maculatum:

Images: images.google.com

Notes on Poisonous plant parts:

All parts of poison-hemlock contain some level of the alkaloids, except for the sap in young plants. The most toxic chemical, gamma-coniceine is abundant in leaves flowers and less common

in the fruits, where it is quickly converted to coniine and N-methylconiine (Cromwell 1956).

Toxic parts:

flowers
leaves
mature fruit
roots
seeds
stems
young shoots

Widmer, W. R. 1984. Poison hemlock toxicosis in swine. *Vet. Med. Small Anim. Clin.*, 79: 405-408.

Notes on Toxic plant chemicals:

gamma-Coniceine is the precursor of the other alkaloids in

poison- hemlock. This chemical is a partly unsaturated piperidine alkaloid. The other chemicals, including coniine and N-methylconiine, are saturated. During the first year of growth, gamma-coniceine is the predominant chemical. During the second year of growth, the content of both coniine and N-methylconiine increase, especially in the leaves and fruits, with a decrease in the first chemical. gamma-Coniceine is considered seven or eight times more toxic than coniine, with N-methylconiine even less toxic (Cromwell 1956, Fairbairn and Suwal 1961, Panter and Keeler 1989).

The following LD50 toxicities in mice have been reported (Bowman and Snaghvi 1963):

gamma-coniceine	death time
2.6 mg/kg (intravenous)	30 sec
12.0 mg/kg (subcutaneous)	12 min
12.0 mg/kg (oral)	8 min

coniine	death time
19.0 mg/kg (intravenous)	30 sec
80 mg/kg (subcutaneous)	15 min
100 mg/kg (oral)	10 min

N-methylconiine	death time
27.5 mg/kg (intravenous)	30 sec
150.5 mg/kg (subcutaneous)	16 min
204.5 mg/kg (oral)	12 min

Toxic plant chemicals:

coniine
gamma-coniceine
N-methylconiine

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[arthrogryposis](#)

[breathing, rapid](#)

[carpal joint, flexure](#)

[depression](#)

[diarrhea](#)

[elbow joint, flexure](#)

[gait, unsteady](#)

[incoordination](#)

[limbs, lateral rotation](#)

[muscle spasms](#)

[salivation](#)

[scoliosis](#)

[teeth grinding](#)

[torticollis](#)

[trembling](#)

[urine, coffee-colored](#)

[vomiting](#)

Notes on poisoning:

General signs of poisoning in all types of livestock include apathy, salivation, frequent regurgitation, teeth grinding, and reduced milk production. For a lethal dose, cattle require coniine at a rate of about 16 mg/kg of body weight (Keeler et al. 1980).

Penny, R. H. 1953. Hemlock poisoning in cattle. Vet. Rec., 42: 669-670.

Horses

General symptoms of poisoning:

[collapse](#)

[trembling](#)

[unconsciousness](#)

Notes on poisoning:

Horses exhibit symptoms similar to other types of livestock that have ingested poison-hemlock. Trembling and paralysis are common symptoms.

References:

MacDonald, H. 1937. Hemlock poisoning in horses. Vet. Rec., 49: 1211-1212.

Humans

General symptoms of poisoning:

[coma](#)

[convulsions](#)

[death by asphyxiation](#)

[dizziness](#)

[headache](#)

[incoordination](#)

[pupil dilation](#)

[thirsty](#)

[vomiting](#)

Notes on poisoning:

Poison-hemlock has been ingested on purpose and accidentally. Socrates was executed in 399 B.C. by an extract of this plant. Humans have accidentally ingested it, mistaking it for carrot or parsnip. The symptoms are similar to those in other animals. Coldness is often felt in the extremities. There is rapid onset of irritation of mucous membranes of the mouth and throat, accompanied by salivation and nausea. Severe poisoning may cause coma and death by respiratory failure. Treatment includes administering activated charcoal after emesis ceases. Treatment is otherwise symptomatic. Despite the severity of poisoning mortality is low (Cooper and Johnson 1984, Lampe and McCann 1985).

Notes on poisoning: *Convallaria majalis*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Lily-of-the-valley (*Convallaria majalis*) is a perennial outdoor ornamental herb. The plant contains cardiac glycosides as well as saponins. There are some references in the literature that mention poisoning and death in humans after accidental ingestion of the berries and leaves, and even by drinking the water that the plants were kept in. Frohne and Pfander (1983) suggest that serious cases are unlikely to occur because the glycosides are poorly absorbed. They cast doubt on the report of poisoning by ingesting water that lily-of-the-valley was standing in because experiments with animals did not substantiate these reports. However, in spite of these reservations, some cases of human poisoning are mentioned in the literature, and so these plants should be considered potentially poisonous. Because of the cardiac glycosides and saponins found in this plant, animals that have access to the plant material may be poisoned. Certainly, ingesting large quantities of lily-of-the-valley can cause problems to family pets such as cats and dogs.

Canadian Biodiversity Information Facility

Notes on poisoning: *Cyclamen persicum*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Cyclamen persicum is a houseplant that has a toxic saponin, cyclamin, in the tuberous rhizomes. The rhizome is bitter and found underground, so that children or family pets are unlikely to be exposed to the toxins. There is no information on the amounts of saponins, if any, in cyclamen foliage (Spoerke et al. 1987).

References:

Spoerke, D. G., Spoerke, S. E., Hall, A., Rumack, B. H. 1987. Toxicity of *Cyclamen persicum* (Mill). *Vet. Hum. Toxicol.*, 29: 250-251.

Nomenclature:

Scientific Name: *Cyclamen persicum* Mill.

Vernacular name(s): cyclamen

Scientific family name: *Primulaceae*

Vernacular family name: primrose

Image or illustration

Cyclamen persicum:

Images: images.google.com

Notes on Poisonous plant parts:

The tuberous rhizomes contain the chemical cyclamin. However, these rhizomes are in the soil and have an acrid taste, so that ingestion by children is not likely (Spoerke et al. 1987). Cyclamin is a triterpenoid saponin, which is an irritant that can cause nausea and even paralysis upon absorption. The chemical is not volatile, but it is water soluble and can occur as small white crystals or an amorphous, lusterless mass (Spoerke et al. 1987).

Toxic parts:

rhizome

tubers

Canadian Biodiversity Information Facility

Notes on poisoning: *Cynoglossum officinale*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Hound's-tongue (*Cynoglossum officinale*) is a naturalized biennial plant found across southern Canada. The plant contains pyrrolizidine alkaloids, which have caused poisoning and death in horses and cattle. The plant causes disorders of the central nervous system and can cause hepatic failure in horses (Knight et al. 1984).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Image or illustration

Cynoglossum officinale:

Images: images.google.com

Notes on Poisonous plant parts:

The concentration of the various alkaloids is highest in the rosette stage, i.e., when the leaves are all attached to the root crown and a stem has not grown yet (Knight et al. 1984).

Toxic parts:

leaves

References:

Knight, A. P., Kimberling, C. V., Stermitz, F. R., Roby, M. R. 1984. *Cynoglossum officinale* (hound's-tongue) - a cause of pyrrolizidine alkaloid poisoning in horses. J. Am. Vet. Med. Assoc., 185: 647-650.

Notes on Toxic plant chemicals:

The following LD-50 toxicities have been determined in male rats:

heliosupine	60 mg/kg
echinatine	350 mg/kg

The amount of pyrrolizidine alkaloid content in the plant has been reported to be 0.6-2.1% of dry matter (Cheeke and Schull 1985).

Toxic plant chemicals:

echinatine
heliosupine

Canadian Biodiversity Information Facility

Notes on poisoning: *Daphne mezereum*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

February daphne (*Daphne mezereum*) is an ornamental shrub that grows across southern Canada. This shrub and other *Daphne* species are poisonous to humans and animals. The plants contain irritant chemicals that cause pain, burning, and tingling sensations on exposed skin. These sensations are intensified on mucous membranes in the mouth, throat, and stomach after ingesting the fruits. More serious symptoms also occur in humans, including kidney damage, which may lead to death. With the exception of February daphne, the other *Daphne* species and cultivars are found only as ornamental plants in the more southerly and temperate parts of Canada. February daphne is naturalized in several eastern provinces. Horses and swine have been poisoned and have died after ingesting daphne leaves or berries, although poisoning of animals is a rare occurrence. Family pets can be poisoned if they have access to the plants. Several references give additional information (Frohne and Pfander 1983, Cooper and Johnson 1984, Lampe and McCann 1985, Fuller and McClintock 1986).

Image or illustration

Daphne mezereum:

Images: images.google.com

Notes on Poisonous plant parts:

All the *Daphne* species in this information system have the same toxic chemical found in all parts of the plant. The only part of the plants without mezerein is the fruit pulp. It is the broken seeds that are responsible for symptoms when fruit is chewed. Ingesting one or two of the bitter berries can cause severe poisoning in children. Twelve berries can be fatal to an adult human (Frohne and Pfander 1983, Fuller and McClintock 1986).

Toxic parts:

all parts
bark
flowers
mature fruit
seeds

References:

Frohne, D., Pfander, H. J. 1983. A colour atlas of poisonous plants. Wolfe Publishing Ltd., London, England. 291 pp.

Fuller, T. C., McClintock, E. 1986. Poisonous plants of California. Univ. California Press, Berkeley, Calif., USA. 432 pp.

Notes on Toxic plant chemicals:

Daphnetoxin and mezerein are diterpene alcohols with a daphnane skeleton. Mezerein has cocarcinogenic activity as does the chemically related phorbol esters found in many toxic members of the spurge family (Euphorbiaceae). In mice, daphnetoxin was determined to have an LD-50 of 275 micro g/kg and the mouse ear inflammation unit is 0.2 micro g of mezerein per ear (Frohne and Pfander 1983). The bark of these daphne plants contains a coumarin glycoside that has the aglycone dihydroxycoumarin (Fuller and McClintock 1986).

Toxic plant chemicals:

daphnetoxin
dihydroxycoumarin
mezerin

References:

Fuller, T. C., McClintock, E. 1986. Poisonous plants of California. Univ. California Press, Berkeley, Calif., USA. 432 pp.

Lampe, K. F., McCann, M. A. 1985. AMA Handbook of poisonous and injurious plants. American Medical Assoc. Chicago, Ill., USA. 432 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Dogs

Horses

General symptoms of poisoning:

[abdominal pains](#)

[death](#)

[vomiting](#)

Notes on poisoning:

Horses have been poisoned by the leaves and berries of the *Daphne* species. Abdominal pains, breathing problems, and death occurred. Post-mortem symptoms included inflammation, swelling, and blood-stained contents of the gastrointestinal tract. Experimental feeding produced similar symptoms but did not result in death. Only 100-150 g of the plants, which are bitter, were eaten (Cooper and Johnson 1984).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Humans

General symptoms of poisoning:

[abdominal pains](#)

[breathing, labored](#)

[convulsions](#)

[death](#)

[diarrhea](#)

[dysphagia](#)

[gait, staggering](#)

[hoarseness](#)

[kidney failure](#)

[mouth, irritation of](#)

[muscle twitching](#)

[prostration](#)

[temperature, elevated](#)

[thirsty](#)

[vomiting](#)

Notes on poisoning:

Human poisoning by the *Daphne* species can include minor irritation of the mouth region including pain, burning, and tingling. If the plant material is also chewed and ingested, more severe symptoms occur, including bloody diarrhea, abdominal pains, vomiting, and convulsions. In severe cases, prostration, hallucinations, shedding of the lining of the oral and mucous membranes, and renal damage can occur. In one case, a child was killed in Nova Scotia after ingesting berries (Fyles 1920). Ingestion may lead to muscular twitching and somnolence, which persists for days. Few cases of poisoning actually occur, but the consequences of ingestion can be serious (Frohne and Pfander 1983, Cooper and Johnson 1984, Lampe and McCann 1985, Fuller and McClintock 1985).

Notes on poisoning: *Datura innoxia*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Angel's trumpet (*Datura innoxia*) contains toxic alkaloids that have caused poisoning and death in humans and other animals. Most of the literature concerns poisoning by jimsonweed (*Datura stramonium*), but angel's trumpet should be considered poisonous as well. This plant is occasionally grown as an outdoor ornamental herb because of its spectacular tubular flowers. See additional information under general notes of [Datura stramonium](#).

Notes on poisoning: *Datura stramonium*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Jimsonweed (*Datura stramonium*) is a naturalized annual herb found across most of southern Canada. This plant contains toxic tropane alkaloids, which have caused poisoning and death in humans and other animals. Jimsonweed is named for a case of human poisoning in Jamestown, Va., when soldiers were poisoned by eating the plant in a salad and then suffered delirium and hallucinations. The seeds and leaves are deliberately used to induce intoxication. Children are attracted by the large flowers and become poisoned after sucking the nectar from the base of flowers or ingesting the seeds. Occurrences of human poisoning are more frequent than livestock poisoning in recent literature reports. Animals of all types can be poisoned. The literature mentions poisoning of cattle, goats, horses, poultry, sheep, and swine. Because of the plant's strong odor and unpleasant taste, animals consume it only when other food is not available. The seeds are sometimes milled with other seeds and have caused problems (Cooper and Johnson 1984, Cheeke and Schull 1985, Lampe and McCann 1985).

Notes on Toxic plant chemicals:

Several tropane alkaloids including hyoscyamine, hyoscine (also called scopolamine), and traces of atropine are found in the plant. The total alkaloid content in the plant varies from 0.25 to 0.7%. The alkaloids are found even in the nectar and can contaminate honey (Cooper and Johnson 1984, Cheeke and Schull 1985).

Toxic plant chemicals:

atropine
hyoscine(scopolamine)
hyoscyamine

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[anorexia](#)

[bloat](#)

[muzzle, dry](#)

[pupils, pinpoint](#)

[tenesmus](#)

Notes on poisoning:

Symptoms in cattle include incoordination, restlessness, and increased respiration rate. Nelson et al. (1982) conducted feeding experiments on heifers that were fed a normal diet with varying amounts of jimsonweed seeds added. The seeds contained 0.26% atropine and 0.55% hyoscyne. Death of cattle seemed unlikely because rumen atony and anorexia limited intake of the feed to below lethal levels. The toxic dosage is about 2.9 mg of atropine and 0.5 mg of hyoscyne per kilogram of body weight, which is about 107 seeds per kilogram of body weight.

Chickens

General symptoms of poisoning:

[weight gain, reduced](#)

References:

Cheeke, P. R., Shull, L. R. 1985. Natural toxicants in feeds and poisonous plants. AVI Publishing Company, Inc., Westport, Conn., USA. 492 pp.

Goats

General symptoms of poisoning:

[breathing, rapid](#)

[death](#)

[drowsiness](#)

[incoordination](#)

[recumbency](#)

[reflex excitability](#)

[trembling](#)

[water intake, reduced](#)

Notes on poisoning:

Goats have been poisoned by consuming jimsonweed. Experimental feeding of fresh leaves and fruit caused locomotion disturbances, tremors, drowsiness, and recumbency. Postmortem findings showed lung congestion, hemorrhagic and fatty liver, and heart dilation with hemorrhaging. The renal cortex was pale yellow and the medulla hemorrhagic. The cells of many renal tubes had also degenerated (El Dirdiri et al. 1981).

References:

El Dirdiri, N. I., Wasfi, I. A., Adam, S. E., Edds, G. T. 1981. Toxicity of *Datura stramonium* to sheep and goats. *Vet. Hum. Toxicol.*, 23: 241-246.

Horses

General symptoms of poisoning:

[anorexia](#)

[breathing, rapid](#)

[diarrhea](#)

[heart rate, elevated](#)

[pupil dilation](#)

[thirsty](#)

References:

Cheeke, P. R., Shull, L. R. 1985. Natural toxicants in feeds and poisonous plants. AVI Publishing Company, Inc., Westport, Conn., USA. 492 pp.

Humans

General symptoms of poisoning:

[agitation](#)

[babinski reflex](#)

[choreiform movement](#)

[confusion](#)

[convulsions](#)

[death](#)

[dizziness](#)

[drowsiness](#)

[faintness](#)

[gait, unsteady](#)

[hallucination](#)

[heart rate, elevated](#)

[inebriation](#)

[memory loss](#)

[mouth dry](#)

[nausea](#)

[pupil dilation](#)

[reflex excitability](#)

[skin, dry](#)

[skin, flushed](#)

[speech, slurred](#)

[temperature, elevated](#)

[thirsty](#)

[unconsciousness](#)

[urination, absent](#)

[vision, impaired](#)

Notes on poisoning:

Symptoms of *Datura* species poisoning include dry mouth, mydriasis, dry and warm skin, sometimes with reddening of the face and neck. Hallucinations are common, along with blurred vision, random movements, nausea, delirium, and sometimes coma and death. Tachycardia and elevated temperatures occur. Treatment with physostigmine is recommended at 0.5 mg for children and 2 mg for adults (Moore 1976, Cooper and Johnson 1984, Lampe and McCann 1985).

Sheep

General symptoms of poisoning:

[ataxia](#)

[breathing, rapid](#)

[collapse](#)

[dyspnea](#)

[gait, unsteady](#)
[incoordination](#)
[recumbency](#)
[reflex excitability](#)
[trembling](#)
[water intake, reduced](#)

Notes on poisoning:

Jimsonweed poisoning in sheep causes symptoms such as locomotion disturbances, rapid respiration, inability to stand and death. Sheep that were experimentally fed fresh leaves and fruits became ill and died (El Dirdiri et al. 1981). Postmortem examination showed lung congestion, a dilated heart, and hemorrhagic, fatty liver. The renal cortex was pale yellow and the medulla was hemorrhagic. Sheep that received 10 g/kg/day died within 38 days.

References:

El Dirdiri, N. I., Wasfi, I. A., Adam, S. E., Edds, G. T. 1981. Toxicity of *Datura stramonium* to sheep and goats. *Vet. Hum. Toxicol.*, 23: 241-246.

Swine

General symptoms of poisoning:

[depression](#)
[gait, rigid](#)
[incoordination](#)
[lethargy](#)
[pupil dilation](#)

Notes on poisoning:

Swine exhibit symptoms of incoordination, stiff gait, pupil dilation, and drowsiness. Earlier reports had suggested that jimsonweed ingested by pregnant sows might cause arthrogryposis in newborn pigs, but Keeler (1981) determined that this was not the case after feeding experiments. Other studies have found that pigs tolerated, with little effect, and alkaloid intake of 2.2 mg/kg of body weight from seeds containing 0.2-0.6% alkaloid content. Because of the unpalatability of jimsonweed seeds, the feed is rejected and therefore lethal quantities are not likely to be ingested (Cheeke and Schull 1985).

Canadian Biodiversity Information Facility

Notes on poisoning: *Delphinium glaucum*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Tall larkspur (*Delphinium glaucum*) is a native herb found in central and western Canada. The plant is poisonous to cattle and can be poisonous to horses and sheep when ingested in higher amounts. In an experiment with *Delphinium barbei* (not found in Canada), six times as much plant material (per kilogram of body weight) was needed to poison sheep than to poison cattle. Why cattle are sensitive to larkspur poisoning is not understood. The alkaloid methyllycaconitine causes curare-like effects on the skeletal muscles and can cause motor paralysis, followed by death from asphyxiation (Nation et al. 1982, Cheeke and Schull 1985, Olsen and Manners 1989).

Image or illustration

Delphinium glaucum:

Images: images.google.com

Notes on Poisonous plant parts:

All parts of larkspur plants contain alkaloids. Cattle have been poisoned after browsing on the aboveground plant material. Sheep and horses have been experimentally poisoned by various larkspur species, but they are much more tolerant of the toxic alkaloids (Olsen and Manners 1989).

Toxic parts:

all parts
leaves
seeds

References:

Looman, J. 1984. The biological flora of Canada. 5. *Delphinium glaucum* Watson, tall larkspur. Can. Field-Nat., 98: 345-361.

Olsen, J. D., Manners, G. D. 1989. Toxicology of diterpenoid alkaloids in rangeland larkspur (*Delphinium* spp.). Pages 291-326 in Cheeke, P. R., ed. Toxicants of plant origin. Vol. I. Alkaloids. CRC Press, Inc., Boca Raton, Fla., USA. 335 pp.

Notes on Toxic plant chemicals:

Methyllycaconitine, a diterpene alkaloid, is considered to be the most toxic of the alkaloids occurring in larkspurs that are likely to be grazed by cattle on rangelands. Many other alkaloids occur in larkspurs, but they are much less toxic than methyllycaconitine. The LD-50 of this chemical on mice is 3.2 mg/kg administered intravenously. It has a pronounced curare-like effect on skeletal muscle (Olsen and Manners 1989).

Toxic plant chemicals:

methyllycaconitine

Notes on poisoning: *Descurainia pinnata*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Green tansy mustard (*Descurainia pinnata*) is a native herb found in fields and rangelands across central and western Canada.

Poisoning has occurred in cases where animals have fed almost exclusively on the plants over long periods. Cattle, goats, and horses have been poisoned (Kingsbury 1964, Staley 1976).

References:

Kingsbury, J. M. 1964. Poisonous plants of the United States and Canada. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.

Cattle

General symptoms of poisoning:

[blindness](#)

[death](#)

[weight loss](#)

Notes on poisoning:

Symptoms in cattle start with partial or complete blindness, followed by an inability to use the tongue or throat, leading to an inability to eat. Death occurs if treatment is not applied to recover the ability to eat and see. Treatment has included administering 9-14 L of water twice daily to improve digestion. More recent treatment involves intravenous injections of ethanol diluted in Ringers solution (Staley 1976).

Canadian Biodiversity Information Facility

Notes on poisoning: *Dicentra cucullaria*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Dutchman's-breeches (*Dicentra cucullaria*) is a native herb found in the rich woodlands of eastern Canada. The plant has been shown to cause poisoning when fed to cattle under experimental conditions. The underground tubers caused more severe symptoms. When plant tubers were fed at 2 kg/100 kg of animal weight, various symptoms occurred, including trembling and convulsions (Black et al. 1923). Poisoning may occur during the spring, when the ground is soft and the tubers might be dug up.

References:

Notes on poisoning: *Dictamnus albus*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Gas plant (*Dictamnus albus*) has caused phytophotodermatitis in humans. In one case in Ottawa, a gardener suffered recurring skin eruptions for several summers. The original diagnosis was poison-ivy, but subsequent testing proved that the gas plant was causing the skin reactions. The plant juices are absorbed by the skin and, in the presence of long-wave ultraviolet light, cell damage occurs. Once this cause is recognized, careful avoidance of contact with the gas plant prevents further problems (Henderson and DesGroseilliers 1984). This is an uncommon and colorful plant found in Canadian herbaceous borders.

References:

Henderson, J. A., DesGroseilliers, J.-P. 1984. Gas plant (*Dictamnus albus*) phytophotodermatitis simulating poison ivy. Can. Med. Assoc. J., 130: 889-891.

Nomenclature:

Scientific Name: *Dictamnus albus* L.

Vernacular name(s): gas plant

Scientific family name: *Rutaceae*

Vernacular family name: rue

Dictamnus albus:

Images: images.google.com

Notes on Poisonous plant parts:

Exposure to the plant juices is required, which occurs when weeding around the plant or cutting the flowers (Henderson and DesGroseilliers 1984).

Toxic parts:

plant juices

References:

Cheeke, P. R., Shull, L. R. 1985. Natural toxicants in feeds and

poisonous plants. AVI Publishing Company, Inc., Westport, Conn., USA. 492 pp.

Henderson, J. A., DesGroseilliers, J.-P. 1984. Gas plant (*Dictamnus albus*) phytophotodermatitis simulating poison ivy. Can. Med. Assoc. J., 130: 889-891.

Notes on Toxic plant chemicals:

Furocoumarins, which are derived from psoralen, are found in several of the plants that cause phytophotodermatitis. These compounds are primary photodynamic agents that absorb long-wave ultraviolet light at the surface of the skin and then cause cell damage (Henderson and DesGroseilliers 1984, Cheeke and Schull 1985).

Toxic plant chemicals:

furocoumarin

General poisoning notes:

Giant dumbcane (*Dieffenbachia amoena*) is an indoor ornamental plant. Experimental work on rodents proved the toxicity of leaf and stem tissue from giant dumbcane. Death occurred after administration of 3.0 g of plant extract in 10.0 mL of liquid per 100 g of body weight (Der Marderosian et al. 1976).

Notes on poisoning: *Dieffenbachia maculata*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Spotted dumbcane (*Dieffenbachia maculata*) is an indoor ornamental. Experimental work with leaf and stem material caused death in mice and rats (Der Marderosian et al. 1976). Toxic symptoms have also occurred in humans and house pets. Chewing produces painful irritation of the mouth and throat. Symptoms may take several days to disappear. The insoluble oxalates do not cause systemic poisoning in humans (Lampe and McCann 1985).

References:

Der Marderosian, A. H., Giller, F. B., Roia, F. C. 1976. Phytochemical and toxicological screening of household ornamental plants potentially toxic to humans. 1. J. Toxicol. Environ. Health, 1: 939-953.

Notes on poisoning: *Dieffenbachia seguine*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Mother-in-law plant (*Dieffenbachia seguine*) is an ornamental. Chewing dumbcanes (*Dieffenbachia* spp.) leaves or stems causes immediate pain and swelling in the mouth and throat. In severe cases, speech may become unintelligible, hence the name dumbcane. In the past these plants were used as a means of human torture. Family pets have also been poisoned after chewing on dumbcane plant material. The effects are almost instantaneous, before the plant material is actually ingested. The plant juices can also cause inflammation and contact dermatitis in some individuals (Arditti and Rodriguez 1982, Lampe and McCann 1985). Mrvos et al. (1990) determined that in many cases where people had contact with broken leaves of dumbcane plants, symptoms occurred within 5 min and were short and of minor consequence. The researchers concluded that concerns regarding oral complications may be exaggerated.

Notes on Toxic plant chemicals:

Dieffenbachia spp. contain calcium oxalate crystals, which are found in special cells called idioblasts; these cells have nozzle-like apertures at either end. The small needle-like crystals are small (0.2 mm long) and are forcibly extruded when the tissue is ruptured, as when chewed. This release of crystals from plant tissue can continue for several minutes. The initial sensation upon ingesting dumbcane tissue is one of pain (Dore 1963, Cheeke and Schull 1985). Proteolytic enzymes have also been found in dumbcanes and may account for some of the toxic effects (Walter and Khanna 1963, Arditti and Rodriguez 1982).

Toxic plant chemicals:

oxalate
proteolytic enzymes

Hanna, G. 1986. Plant poisoning in canines and felines. *Vet. Hum. Toxicol.*, 28: 38-40.

Dogs

Humans

General symptoms of poisoning:

[aphonia](#)
[breathing, labored](#)
[diarrhea](#)
[mouth, irritation of](#)
[salivation](#)
[vomiting](#)

Notes on poisoning:

Chewing dumbcane plants causes immediate intense pain and irritation of the lips, tongue, and mouth. There is edematous swelling of the oral mucosa. Bullae may form. Speech capability is often reduced or lost, a condition that can last for several days. The pain and irritation can also persist, and the edema can leave superficial necrosis. Excessive salivation is common. Treatment requires use of cool liquids; analgesics may be indicated (Arditti and Rodriguez 1982, Lampe and McCann 1985). Cut stem sections are particularly dangerous for nursery workers because of the possibility of getting plant juices into the eyes. Inflammation accompanied by intense pain, watering, and gross swelling can occur. Visual acuity may be reduced (Arditti and Rodriguez 1982).

Canadian Biodiversity Information Facility

Notes on poisoning: *Digitalis purpurea*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Foxglove (*Digitalis purpurea*) is an attractive biennial plant that is cultivated in Canada and is naturalized in several provinces. Upon ingestion, this plant can cause toxic reactions that lead to severe sickness and death in animals and in humans. Several important pharmaceutical drugs such as digitalis and digoxin are derived from this plant. The chemicals increase the force of contraction of the heart muscle and are therefore used in cases of heart congestion. Foxglove (*Digitalis purpurea*) is a naturalized herb found in eastern Canada and British Columbia. It is also a common outdoor ornamental. All classes of livestock are susceptible to poisoning by foxglove. However, because of the unpalatable nature of the plant, poisoning is infrequent, although when it does occur it is often severe and dramatic, frequently resulting in death. Human poisoning occurs rarely. However, poisoning was reported in the children who ate the flowers or drank water from vases. Accidentally including foxglove leaves in tea has led to poisoning and death. Cardiac glycosides are commonly described drugs that have a low margin of safety. Slight overdoses of prescribed medicine can cause symptoms of toxicity (Cooper and Johnson 1984, Cheeke and Schull 1985, Joubert 1989).

Image or illustration

Digitalis purpurea:

Images: images.google.com

Notes on Poisonous plant parts:

The entire plant contains toxic compounds. The leaves and seeds are used to produce digoxin and other cardenolides for pharmaceutical use. The chemicals do not lose their toxicity by drying, storage, boiling or incorporation in hay. The plants are unpalatable and are seldom eaten by animals (Cooper and Johnson 1984, Joubert 1989).

Toxic parts:

all parts
flowers
leaves
seeds
stems

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Notes on Toxic plant chemicals:

Digitoxin is one of several cardiac glycosides found in foxglove and is considered the most toxic of these chemicals. The toxins are split by hydrolysis into a sugar and an aglycone (nonsugar compound). The aglycones have a direct effect on the muscles to the heart (Joubert 1989).

Toxic plant chemicals:

digitoxin

Cattle

General symptoms of poisoning:

[death](#)

[dyspnea](#)

[lungs, congestion of](#)

Notes on poisoning:

Dairy cattle have become poisoned after ingesting foxglove. Postmortem examination showed consolidation of the apical lobes of both lungs, with marked emphysema and bullae formation in the diaphragmatic lobes. Duodenal and jejunal mucosa were extremely congested and hemorrhagic. Some cattle recovered after treatment, whereas others took several days. One cow died 2 days after ingesting foxglove (Thomas et

al. 1987).

References:

Thomas, D. L., Quick, M. P., Morgan, R. P. 1987. Suspected foxglove (*Digitalis purpurea*) poisoning in a dairy cow. Vet. Rec., 120: 300-301.

Dogs

Goats

Horses

Humans

General symptoms of poisoning:

[abdominal pains](#)

[diarrhea](#)

[nausea](#)

Notes on poisoning:

Digitalis poisoning toxicity has a variable latent period depending on the quantity ingested. Gross disturbances in heartbeat and pulse are common. Most cases of human poisoning result from slight overdoses of prescribed drugs that contain digoxin or other related chemicals. Smith et al. (1982) describe the symptoms of digoxin and digitoxin toxicity, including nausea and severe vomiting. Many people develop hyperkalemia. Advanced cardiac rhythm disturbances are common, along with tachycardia and ventricular fibrillation. Treating patients with purified Fab fragments of digoxin-specific antibodies produces an initial favorable response and should lead to safe, effective reversal of life-threatening digitalis intoxication. Accidental ingestion of foxglove has occurred when the leaves were used in tea or when flowers were ingested (Cooper and Johnson 1984).

References:

Lampe, K. F., McCann, M. A. 1985. AMA Handbook of poisonous and injurious plants. American Medical Assoc. Chicago, Ill., USA. 432 pp.

Poultry

Sheep

Swine

General symptoms of poisoning:

[abdominal pains](#)

[convulsions](#)

[death](#)

[diarrhea](#)

Notes on poisoning:

General symptoms of foxglove poisoning for all types of animals include diarrhea, abdominal pain, irregular pulse, tremors, and convulsions. In severe cases, death occurs. Postmortem examination of pigs showed gastrointestinal inflammation, punctiform necrosis of the border of the spleen, and fatty degeneration of some nerve fibers in the heart. The presence of digitoxin in the body tissues confirms foxglove poisoning in animals (Cooper and Johnson 1984, Joubert 1989).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Turkeys

General symptoms of poisoning:

[appetite, loss of](#)

[convulsions](#)

[death](#)

[drowsiness](#)

[pupil dilation](#)

Notes on poisoning:

Several turkeys died after ingesting foxglove leaves. Several turkeys slowly recovered. The crops were surgically removed from affected birds, a procedure which speeded up recovery time (Parker 1951).

References:

Parker, W. H. 1951. Foxglove (*Digitalis purpurea*) poisoning in turkeys. Vet. Rec., 63: 416.

Notes on poisoning: *Dirca palustris*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Leatherwood (*Dirca palustris*) is a native shrub found in parts of eastern Canada in woodlands. This shrub contains unknown poisonous chemicals that are most potent in the bark. Chewing the bark can cause severe burning in the mouth and can produce a nauseating taste; dermatitis can occur, especially during flowering and fruiting time (Fyles 1920, Lampe and McCann 1985).

Canadian Biodiversity Information Facility

Notes on poisoning: *Echium vulgare*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Blueweed (*Echium vulgare*) is a naturalized biennial herb found in fields and waste places across Canada. The bristly hairs on this plant cause skin irritation. There is no mention of whether the irritation is purely mechanical or whether it is caused by chemicals in the hairs on the leaves and stems. This plant may also contain pyrrolizidine alkaloids including heliosupine (Cheeke 1989, Cooper and Johnson 1984). Poisoning by this plant has not been reported. Purple bugloss (*Echium lycopsis* L. = *Echium plantagineum* L.) has been collected in Canada on a couple of occasions, but it does not persist. This species does contain several pyrrolizidine alkaloids, including echimidine, echiumine, and heliotrine. The plant has caused death of horses and liver damage of sheep in Australia (Cooper and Johnson 1984, Cheeke 1989). Lampe and McCann (1985) discuss toxicity of both species to humans after ingestion of herbal teas containing *Echium* spp. Chronic consumption can cause veno-occlusive disease of the liver (Budd-Chiari syndrome), with hepatic vein thrombosis leading to cirrhosis. Purple bugloss (*Echium lycopsis*), which is discussed above, contains chemicals that can cause this type of problem. However, it does not appear to persist in Canada. There is no information in the literature on blueweed causing such poisoning, but it may contain pyrrolizidine alkaloids (Cheeke 1989). Caution is obviously warranted. Teas containing either of these plants should not be used by humans.

Canadian Biodiversity Information Facility

Notes on poisoning: *Equisetum arvense*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Field horsetail (*Equisetum arvense*) is a native plant growing across Canada. This plant contains thiaminase which causes thiamine deficiency in horses. Ruminants are not generally affected by problems of thiamine deficiency because it is made in the rumen. However, some cattle were reported to have symptoms. In Canada, horses have been poisoned by ingesting field horsetail (Henderson et al. 1952, Cheeke and Schull 1985).

Image or illustration

Equisetum arvense:

Images: images.google.com

Notes on Poisonous plant parts:

The horsetails have separate fertile and sterile fronds. Field horsetail has a fertile frond that is flesh-colored and appears before the green sterile frond.

Toxic parts:

leaves
stems

References:

Cheeke, P. R., Shull, L. R. 1985. Natural toxicants in feeds and poisonous plants. AVI Publishing Company, Inc., Westport, Conn., USA. 492 pp.

Notes on Toxic plant chemicals:

Thiaminase is an enzyme that splits thiamine, a B vitamin, making it inactive. Thiamine is involved in decarboxylation reactions in animal bodies. Deficiency of thiamine leads to accumulation of pyruvate in the blood, with a resulting impairment in energy metabolism and cellular shortage of ATP. Hay that contains horsetail at a level of 20% or more may produce symptoms of thiamine deficiency in horses in 2-5 weeks (Cheeke and Schull 1985).

Toxic plant chemicals:

thiaminase

Notes on poisoning: *Equisetum palustre*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Marsh horsetail (*Equisetum palustre*) is a native horsetail growing across Canada. This plant has poisoned cattle and, rarely, sheep. In addition to thiaminase, it contains an alkaloid, that causes the toxicity (Kingsbury 1964, Cooper and Johnson 1984).

Image or illustration

Equisetum palustre:

Images: images.google.com

Notes on Poisonous plant parts:

Marsh horsetail has separate fertile and sterile stems. Unlike field horsetail, both types of fronds are greenish, with the added fruiting sporangia body on top of the fertile frond.

Toxic parts:

leaves
stems

References:

Frohne, D., Pfander, H. J. 1983. A colour atlas of poisonous plants. Wolfe Publishing Ltd., London, England. 291 pp.

Notes on Toxic plant chemicals:

Palustrine, an alkaloid, has been found in marsh horsetail. This alkaloid may contribute to the poisoning of cattle by this plant. Thiaminase activity is usually not a problem in ruminants because thiamine is produced in the rumen. Therefore, the presence of alkaloids is suspected to cause the toxic responses. The alkaloid content varies greatly (96-302 mg/100 g of dry weight). Frosted plant material quickly loses most of its alkaloid content, whereas air-dried marsh horsetail can keep its alkaloid content for years (Frohne and Pfander 1983).

Toxic plant chemicals:

palustrine
thiaminase

Notes on poisoning: *Erysimum cheiranthoides*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Wormseed mustard (*Erysimum cheiranthoides*) is a naturalized herb found across Canada in fields and waste places. It contains large quantities of glucosinolates, which release allyliso thiocyanate upon hydrolysis. Cattle and swine were poisoned in Canada when feeds were contaminated with sufficient quantities of seed from wormseed mustard plants (Kingsbury 1964, Palechek 1986).

Notes on poisoning: *Euonymus atropurpureus*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Burningbush (*Euonymus atropurpureus*) is an ornamental shrub that grows across southern Canada. Several reviews have noted that this plant is poisonous, but documented cases appear to refer to the closely related European spindle tree (*Euonymus europaeus*). See additional information under general notes on the European spindle tree. Children who ingest the seeds should be attended to. Children and horses have been poisoned by ingesting the European spindle tree. Symptoms of poisoning of children and horses are discussed under that plant as well.

Notes on poisoning: *Euonymus europaeus*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

European spindle tree (*Euonymus europaeus*) is an ornamental shrub that can grow in the warmer parts of Canada. The shrub has poisoned children as well as goats, horses, and sheep. Children are attracted to the mature fleshy orange fruits, which contain seeds with cardiac glycosides and alkaloids. Children have become quite ill. Fatal poisoning has occurred in two horses after they ingested shoots of this plant (Frohne and Pfander 1983, Cooper and Johnson 1984, Lampe and McCann 1985).

Image or illustration

Euonymus europaeus:

Images: images.google.com

Notes on Poisonous plant parts:

The conspicuous fruiting structures of the European spindle tree entice children to eat them. The seeds contain toxins that have caused poisoning of children (Frohne and Pfander 1983).

Toxic parts:

bark

leaves

seeds

References:

Frohne, D., Pfander, H. J. 1983. A colour atlas of poisonous plants. Wolfe Publishing Ltd., London, England. 291 pp.

Notes on Toxic plant chemicals:

Several cardiac glycosides have been found in the seeds, including evomonoside, whose aglycone is digitoxigenin. Alkaloids also make up about 0.1% of the seeds, including evonine. The toxicity of the alkaloidal fraction has not been studied. Cardiac glycosides are also found in the leaves and bark (the alkaloid content is too low to be of any consequence) (Frohne and Pfander 1983, Lampe and McCann 1985).

Toxic plant chemicals:

evomonoside

evonine

References:

Frohne, D., Pfander, H. J. 1983. A colour atlas of poisonous plants. Wolfe Publishing Ltd., London, England. 291 pp.

Canadian Biodiversity Information Facility

Notes on poisoning: *Eupatorium rugosum*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

White snakeroot (*Eupatorium rugosum*) is a native herb that grows in rich soils in eastern Canada. This plant has caused illness and death of humans and several types of livestock. Large losses of human life occurred in the 19th century from the mysterious milk sickness. Mortality ranged from 10 to 25%, and the population of entire villages left a location because they could not find the cause of the disease. It was later discovered that cattle had ingested white snakeroot and that a toxin was subsequently passed through the milk to humans and was toxic. With modern collection and combination techniques, milk sickness from commercial milk sources is no longer a problem. However, the resurgence of small-scale farming and home milk production may result in occasional cases of milk sickness (Kingsbury 1964, Stotts 1984, Cheeke and Schull 1985, Beier and Norman 1990).

Several types of herbivorous livestock have also been poisoned by ingesting white snakeroot, resulting in a disease called trembles. Cattle, goats, horses, sheep, and swine have shown toxic reactions. Suckling animals can develop milk sickness as well. Trembles was more of a problem in the past, before the increased use of herbicides and prepared feeds. Poisoning was also more frequent when animals were allowed to range through bushlots. The amount of white snakeroot that must be ingested before death is variable, ranging from 1 to 20%. Symptoms can occur within a few days or up to 3 weeks later. Daily intake rates of 0.5-1.5% of body weight generally leads to the onset of symptoms. Drying the plant material does not completely remove the danger to animals (Doyle and Walkley 1949, Kingsbury 1964, Cheeke and Schull 1985, Beier and Norman 1990).

Additional care must be taken with milk from cattle or goats that may have ingested white snakeroot. Many articles state that a lactating animal does not always show symptoms. However, milk from that animal can still cause milk sickness. Calves, humans,

and cats have been poisoned in such cases. Dogs given the milk are also be at risk. Experimental work has shown that trembles can occur in rabbits and guinea pigs. White snakeroot grows in rich moist open woods and along water courses. Animals should not be allowed to graze this plant.

Notes on Toxic plant chemicals:

Tremetol is a secondary aromatic alcohol with a sterol and ketone fraction. One of these ketones, tremetone, has been tested on chickens, with negative results, but was toxic to goldfish in experimental studies. In Iowa the concentration of tremetol was found to be highest during the summer (Kaufmann 1982).

Notes on poisoning: *Euphorbia cyparissias*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Cypress spurge (*Euphorbia cyparissias*) is a naturalized herb found across southern Canada. Ingesting the plant has caused loss of cattle in New York State. This plant is usually avoided by livestock but is ingested if incorporated with hay. The plant is abundant in some locations in southern Ontario. Some humans are sensitive to the irritant latex and may develop inflammation.

Notes on poisoning: *Euphorbia helioscopia*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Sun spurge (*Euphorbia helioscopia*) is a naturalized herb occasionally found in southern Canada. The latex contains a strong irritant that causes burning and swelling in animals that ingest it. Sheep were poisoned and a human child died after ingesting the plant. This plant can cause irritation to livestock that ingestion it.

[coma](#)

[death](#)

[diarrhea](#)

[lungs, congestion of](#)

[mouth, irritation of](#)

[salivation](#)

[vomiting](#)

Notes on poisoning:

In Britain, sheep that had ingested sun spurge experienced severe swelling and inflammation of the mouth, diarrhea, and salivation. The animals recovered fully when moved to new pasture that did not contain this plant (Cooper and Johnson 1984). One of two children died after sucking the juice of sun spurge. Symptoms included burning of the mouth, esophagus, and stomach, salivation, vomiting, narrowing of the pupils, and lung edema. One child went into a coma before death (Cooper and Johnson 1984).

Notes on poisoning: *Euphorbia lactea*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Candelabra-cactus (*Euphorbia lactea*) is an indoor ornamental plant. The latex (juice) of the plant contains an intense irritant that causes problems when the latex comes in contact with mucous membranes and eyes. Severe eye problems have also been experimentally produced in dogs. Ingestion should be avoided by children and family pets.

Humans

General symptoms of poisoning:

[keratoconjunctivitis](#)

Notes on poisoning:

The milky sap of candelabra-cactus contains an irritant that can cause intense burning and keratoconjunctivitis if a drop gets into the eyes. In one case, a man felt intense pain in his eye followed by mild conjunctival hyperemia and punctate staining of the cornea. Within 24 h the patient had copious mucous discharge, marked conjunctival edema, swollen lids, and severe pain in the eye. A few days later the eye began to heal, with complete recovery after a couple of weeks. Experiments on dogs resulted in similar symptoms, with eventual clearing of the eyes (Crowder and Sexton 1964).

Notes on poisoning: *Euphorbia lathyris*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Caper spurge (*Euphorbia lathyris*) is an outdoor ornamental that has become naturalized in British Columbia. This plant contains an irritant toxin in the latex. Humans have been poisoned after ingesting the seed capsules, which resemble capers, a different plant. Goats apparently eat this plant without experiencing great problems, but the toxin can accumulate and can be passed through the milk (Fuller and McClintock 1986).

Canadian Biodiversity Information Facility

Notes on poisoning: *Euphorbia pulcherrima*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Poinsettia (*Euphorbia pulcherrima*) is a popular Christmas plant grown for its red leafy bracts. It has been listed as a known toxic plant that has caused a loss of human life. The case cited in all literature is based on the death of a child in Hawaii who ingested a leaf of poinsettia. The author of that report said that the incident was based on hearsay (Stone and Collins 1971). Various studies have not found any of the toxic diterpenes that occur in the latex of other spurges (*Euphorbia* spp.). Extensive studies on rats that were fed "extraordinarily" high doses of poinsettia showed no mortality, no symptoms of toxicity, and no changes in normal behaviour (Stone and Collins 1971). Klug et al. (1990) reviewed 353 calls to poison control centres and found that nausea and vomiting were cited in 0.02% of the cases with rash and sneezing cited in 0.0028%. An older dog that ingested poinsettia reportedly experienced protracted vomiting, followed by renal failure, coma, and death. This is the only case in the literature of death to an animal. Case histories show that some humans develop a sensitivity to the latex, resulting in dermatitis. Short exposures to poinsettia in a few cases have led to bouts of vomiting, but no substantiated cases of death can be found in the literature. Poinsettia should no longer be regarded as a severely toxic plant.

Notes on poisoning: *Euphorbia tirucalli*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Penciltree (*Euphorbia tirucalli*) is an attractive indoor ornamental tree. The plant contains caustic and irritant chemicals in the latex which cause reactions with the skin, mucous membranes, and the eyes. Severe burning and inflammation result after the latex comes into contact with the skin. Ingestion causes burning and irritation of the mouth and stomach, accompanied by pain and perhaps diarrhea. Apparently, injudicious medicinal use of the latex of this plant has caused fatalities in East Africa (Fuller and McClintock 1986). Family pets should not be allowed to ingest the plant.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Humans

General symptoms of poisoning:

[blindness, temporary
keratoconjunctivitis](#)

Notes on poisoning:

Pencil tree latex causes keratoconjunctivitis if it gets into the eyes. The symptoms include immediate burning pain of the eyeball and eyelids, tearing, and photophobia. These symptoms are followed by 8-12 h of chemosis of the lids and conjunctiva, with blurred vision and increased pain. Erosion of the corneal epithelium, decreased visual acuity, and corneal edema occur (Crowder and Sexton 1964).

Notes on poisoning: *Fagopyrum esculentum*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Buckwheat (*Fagopyrum esculentum*) is cultivated in Canada as a crop for fodder and for the production of buckwheat honey.

Ingesting entire plants, dried or fresh, has caused photosensitization in animals with exposed or light-colored skin including cattle, goats, sheep, swine, and turkeys. Exposure to the sun is necessary. This plant is considered to be a primary photosensitizer, although jaundice has occurred concurrently, which indicates secondary involvement of the liver (Cooper and Johnson 1984, Cheeke and Schull 1985). Buckwheat has been found to be an effective replacement for wheat or barley in rations for swine (Anderson and Bowland 1981). Closely related tartary buckwheat (*Fagopyrum tataricum* L.) is also a satisfactory grain replacement in ruminant animals (Nicholson et al. 1976).

Humans can be sensitized to dust from buckwheat flour after long exposure. Asthma is the usual response, although rare individuals may manifest food allergy reactions after ingesting food products containing buckwheat flour. Photosensitization has not occurred in humans (Blumstein 1936).

Notes on poisoning: *Galanthus nivalis*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Snowdrop (*Galanthus nivalis*) is an outdoor ornamental spring flower. This plant contains the alkaloid lycorine, which can cause poisoning. Some individuals were poisoned after ingesting the bulbs as emergency food in Holland during World War II. Large amounts of bulbs need to be ingested to produce toxic reactions (Lampe and McCann 1985, Fuller and McClintock 1986).

Canadian Biodiversity Information Facility

Notes on poisoning: *Ginkgo biloba*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Ginkgo (*Ginkgo biloba*) is an ornamental tree growing in the warmer parts of Canada. This plant is of botanical interest because it is the sole survivor of the order Ginkgoales, with fossil evidence tracing back over 200 million years. The tree now survives only in cultivation. The trees are planted for their beautifully shaped leaves, which turn an attractive yellow in autumn. Usually only male trees are planted because the fleshy pulp on the fruits develop an obnoxious smell resembling rancid butter when the pulp is deteriorating on the ground. The interior kernel of the fruit is considered a delicacy by people of Chinese, Japanese, and southeast Asian descent. Contact dermatitis occurs in sensitive individuals when they remove the fleshy pulp from the seeds in the autumn. Children who handle the attractive yellow fruits may develop dermatitis. The pulp is also used as a folk medicine in China and Japan. The crude extract contains a toxin that causes convulsions and death if used in excess. This type of poisoning is unlikely unless the extract (gin-nan) is available in Canada.

Image or illustration

Ginkgo biloba:

Images: images.google.com

Notes on Poisonous plant parts:

The endosperm (the food storage tissues) of the seeds contains a chemical that can cause convulsions and death in humans if taken

in excessive quantities. The Chinese and Japanese use a crude extract of ginkgo seed, called gin-nan, as an antitussive and expectorant in folk medicine. Excessive use of this extract has caused gin-nan food poisoning in China and Japan. Some deaths have occurred. Ginkgo seeds can be obtained in specialized food stores, and ginkgo trees grow and bear fruit at least in some areas of the country, such as Ottawa. The seeds are often picked by Chinese and Japanese for food consumption. The seed coat and the fruit pulp of ginkgo can cause allergic contact dermatitis. This most often happens when the fruit pulp is removed to get at the seed, which is considered a delicacy in Chinese and Japanese cooking (Nakamura 1985).

Toxic parts:

mature fruit
seeds

References:

Lepoittevin, J.-P., Benezra, C., Asakawa, Y. 1989. Allergic contact dermatitis to *Ginkgo biloba* L.: relationship with urushiol. Arch. Dermatol. Res., 281: 227-230.

Tomb, R. R., Foussereau, J., Sell, Y. 1988. Mini-epidemic of contact dermatitis from ginkgo tree fruit (*Ginkgo biloba* L.). Contact Dermatitis, 19: 281-283.

Wada, K., Ishigaki, S., Ueda, K., Take, Y., Sasaki, K., Sakata, M., Haga, M. 1988. Studies on the constitution of edible and medicinal plants. 1. Isolation and identification of 4-O-methylpyridoxine, toxic principle from the seed of *Ginkgo biloba* L. Chem. Pharm. Bull. (Tokyo), 36: 1779-1782.

Notes on Toxic plant chemicals:

4-O-Methylpyridoxine is a chemical that has an antivitamin B6 activity. This chemical is found in the endosperm (the food storage tissue) of the seeds. The chemical causes convulsions in guinea pigs at oral doses of 11 mg/kg. 4-O-Methylpyridoxine also inhibits the formation of 4-aminobutyric acid from glutamate, which might induce seizures (Wada et al. 1988). Ginkgolic acids 1 are aromatic compounds found in the pulpy exterior of the fruit of ginkgo. These chemicals cause allergic contact dermatitis. Lepoittevin et al. (1989) determined that despite the close structure between ginkgolic acids 1 and the components of urushiol 4 (the allergen of poison-ivy), the hypothesis that the acids transform into catechol 4 in vivo (as with poison-ivy) cannot be supported. Cross-reactivity between ginkgo and urushiol did not occur when tested on guinea pigs.

Toxic plant chemicals:

ginkgolic acids 1
4-O-methylpyridoxine

Notes on poisoning: *Glechoma hederacea*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Ground-ivy (*Glechoma hederacea*) is a creeping ground cover that can grow abundantly in uncultivated damp or shaded ground around houses and garden areas. This plant contains an irritant oil that is toxic to horses if they ingest large quantities of the fresh or dried plant. In one case in Canada the death of horses was reported (Fyles 1920, Fuller and McClintock 1986).

General symptoms of poisoning:

[cyanosis](#)

[dyspnea](#)

[lungs, congestion of](#)

[pupil dilation](#)

[salivation](#)

[sweating](#)

Notes on poisoning:

In Prince Edward Island two horses ingested large quantities of ground-ivy in November when the ivy provided an abundance of green foliage. The horses panted continually and died within a week. One horse would lie down and the other horse would not. In Europe, horses have been reported to ingest large amounts of fresh or dried ground-ivy, with subsequent poisoning. Apparently, cattle and sheep were not poisoned after they ingested the plant (Fyles 1920).

Notes on poisoning: *Gloriosa superba*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Glory lily (*Gloriosa superba*) is a rarely grown indoor ornamental vine best suited to greenhouses. Ingesting the tubers causes severe poisoning in humans. The plant contains two alkaloids, including colchicine, which cause severe gastroenteritis, vomiting, and possible unconsciousness. Severe hair loss is a consistent symptom of colchicine poisoning. Complete recovery is slow (Gooneratne 1966, Angunawela and Fernando 1971, Lampe and McCann 1985).

References:

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Humans

General symptoms of poisoning:

[alopecia](#)
[dehydration](#)
[diarrhea](#)
[hemoglobinuria](#)
[unconsciousness](#)
[vomiting](#)
[weakness](#)

Notes on poisoning:

Ingesting the tubers causes severe vomiting, abdominal pain, severe and bloody diarrhea, vaginal bleeding, weakness, and retention of urine and waste. Swelling of the lower or upper limbs may occur. Partial to complete hair loss occurs, sometimes on all parts of the body. Recover is slow, because colchicine is slowly

secreted from the system. Treatment includes fluid retention, monitoring of renal function and blood pressure, and treatment for diarrhea (Gooneratne 1966, Angunawela and Fernando 1971, Lampe and McCann 1985).

References:

Angunawela, R. M., Fernando, H. A. 1971. Acute ascending polyneuropathy and dermatitis following poisoning by tubers of *Gloriosa superba*. Ceylon Med. J., 16: 233-235.

Canadian Biodiversity Information Facility

Notes on poisoning: *Glyceria grandis*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Tall manna grass (*Glyceria grandis*) is a native and naturalized grass found across Canada. This plant has caused sickness and death in a herd of cattle in British Columbia. The poisoning took place early in the season, suggesting that the amount of cyanogenic potential decreases in the plant later in the season (Puls et al. 1978).

References:

Puls, R., Newschwander, F. P., Greenway, J. A. 1978. Cyanide poisoning from *Glyceria grandis* S. Wats. ex Gray (tall mannagrass) in a British Columbia beef herd. Can. Vet. J., 19: 264-265.

Nomenclature:

Scientific Name: *Glyceria grandis* S. Wats.

Vernacular name(s): tall manna grass

Scientific family name: *Gramineae*

Vernacular family name: grass

Go to ITIS^{*ca} for more taxonomic information on: [Glyceria grandis](#)

Canadian Biodiversity Information Facility

Notes on poisoning: *Gutierrezia sarothrae*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Broom snakeweed (*Gutierrezia sarothrae*) is a native perennial found in western rangelands. This plant has caused acute toxicity and abortion in cattle, which has also been experimentally induced in goats and sheep. The plant is more toxic during the early stages of growth and if it grows on poor, sandy soils. Major losses of cattle through acute toxicity and abortion have occurred in the southern United States, in Texas, and in New Mexico (Kingsbury 1964, Molyneux et al. 1980).

References:

Kingsbury, J. M. 1964. Poisonous plants of the United States and Canada. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.

Image or illustration

Gutierrezia sarothrae:

Images: images.google.com

Notes on Poisonous plant parts:

As little as 9 kg of fresh broom snakeweed has produced abortion in cattle within 7 days. Death has been experimentally produced in cattle, sheep, and goats by feeding fresh plants equivalent to 10-20% of body weight for 3 days to 2 weeks (Kingsbury 1964).

Toxic parts:

leaves
stems

References:

Kingsbury, J. M. 1964. Poisonous plants of the United States and Canada. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.

Molyneux, R. J., Stevens, K. L., James, L. F. 1980. Chemistry of toxic range plants. Volatile constituents of broomweed (*Gutierrezia sarothrae*). J. Agric. Food Chem., 28: 1332-1333.

Notes on Toxic plant chemicals:

The essential oil contains monoterpenes, such as alpha-pinene and geraniol, and sesquiterpenes, such as gamma-humulene. However, Molyneux et al. (1980) do not believe that these chemicals contribute to the abortifacient nature of broom snakeweed. Saponins are believed to be the cause of the toxicity to animals and may also be implicated in the abortifacient fraction (Cheeke and Schull 1985).

Toxic plant chemicals:

alpha-pinene
gamma-humulene

References:

Molyneux, R. J., Stevens, K. L., James, L. F. 1980. Chemistry of toxic range plants. Volatile constituents of broomweed (*Gutierrezia sarothrae*). J. Agric. Food Chem., 28: 1332-1333.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[abortion](#)

[anorexia](#)

[appetite, loss of](#)

[constipation](#)

[death](#)

[diarrhea](#)

[muzzle, crusty](#)

[urination, frequent](#)

Notes on poisoning:

Acute toxicity includes symptoms of listlessness, anorexia, rough coat, diarrhea or constipation, vaginal discharge, and hematuria. Cattle produce a nasal discharge, and the muzzle becomes crusty. Lesions include those of gastroenteritis and degeneration of the kidneys and liver. Severe toxic nephritis with necrosis occurs in serious cases. The spleen may be congested and the uterus, edematous. Abortion is a major result of poisoning. Premature calves are weak or are dead at birth with retained placenta. The pregnant cow may experience swelling of the vulva and early udder development (Kingsbury 1964, Molyneux et al. 1980, Ralphs 1985).

References:

Kingsbury, J. M. 1964. Poisonous plants of the United States and Canada. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.

Goats

General symptoms of poisoning:

[abortion](#)

[death](#)

References:

Kingsbury, J. M. 1964. Poisonous plants of the United States and Canada. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.

Sheep

General symptoms of poisoning:

[abortion](#)

[anorexia](#)

[constipation](#)

[death](#)

[diarrhea](#)

[icterus](#)

[weakness](#)

Notes on poisoning:

Symptoms of broom snakeweed poisoning in sheep are similar to those in cattle and include anorexia, rough coat, diarrhea or constipation, vaginal discharge, and hematuria. Sheep display minor icterus. Lesions include those of gastroenteritis and degeneration of the liver and kidneys. Toxic nephritis is found in severe cases. Abortion also occurs, but less frequently than in cattle (Kingsbury 1964).

Image or illustration

Gymnocladus dioica:

Images: images.google.com

Notes on Poisonous plant parts:

The seeds contain a low concentration of the alkaloid cytisine, and chewing one or two seeds would not be enough to produce toxic results. This tree is an ornamental that survives and produces seeds in the warmer parts of the country; it grows successfully in Ottawa. In feeding experiments the foliage has proved to be toxic to sheep and the seeds to cattle (Reynard and Norton 1942, Lampe and McCann 1985).

Notes on poisoning: *Hedera helix*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

English ivy (*Hedera helix*) is an indoor and outdoor ornamental vine. This plant contains saponins, which have caused poisoning in cattle, dogs, sheep, and humans. Two chemicals in the sap can also cause severe contact dermatitis in sensitive humans. Cases of poisoning are found in older European literature; the plant grows naturally in Europe. Cattle that ingested large quantities of the vines were ill for a few days. Humans who ingested the berries have shown symptoms, including coma. Dermatitis is rare but can be severe. Weeping lesions and blisters respond slowly to treatment (Cooper and Johnson 1984, Massmanian et al. 1980). Family pets should not be allowed to eat English ivy leaves.

Image or illustration

Hedera helix:

Images: images.google.com

Notes on Poisonous plant parts:

The sap contained in the leaves and stems of English ivy can cause dermatitis and irritation in sensitive humans. The dermatitis usually occurs after pruning the plant (Massmanian et al. 1988). The leaves and fruit contain saponins that hydrolyze into toxic hederin compounds. These toxins have caused poisoning in animals and humans (Cooper and Johnson 1984).

Toxic parts:

leaves
mature fruit
plant juices

References:

Boyle, J., Harman, R. M. 1985. Contact dermatitis to *Hedera helix* (common ivy). *Contact Dermatitis*, 12: 111-112.

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Massmanian, A., Valcuende Caverro, F., Ramirez Bosca, A., Castells Rodellas, A. 1988. Contact dermatitis from variegated ivy (*Hedera helix* subsp. *canariensis* Willd.). *Contact Dermatitis*, 18: 247-248.

Notes on Toxic plant chemicals:

English ivy contains hederasaponins, which undergo partial hydrolysis to form toxic substances (micro-hederin and beta-hederin). These toxins can cause poisoning in humans and other animals if ingested in sufficient quantities. English ivy also contains allergenic and irritant chemicals, falcarinol and didehydrofalcarinol, which cause intense burning and dermatitis in sensitive humans (Cooper and Johnson 1984; Massmanian et al. 1988).

Toxic plant chemicals:

didehydrofalcarinol
falcarinol
hederasaponins

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Massmanian, A., Valcuende Caverro, F., Ramirez Bosca, A., Castells Rodellas, A. 1988. Contact dermatitis from variegated ivy (*Hedera helix* subsp. *canariensis* Willd.). Contact Dermatitis, 18: 247-248.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

Dogs

General symptoms of poisoning:

[agitation](#)

[diarrhea](#)

[muscle spasms](#)

[paralysis](#)

[vomiting](#)

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Humans

General symptoms of poisoning:

[blisters, weeping](#)

[breathing, labored](#)

[coma](#)

[convulsions](#)

[diarrhea](#)

[erythema](#)

[muscle spasms](#)

[paralysis](#)

[vomiting](#)

Notes on poisoning:

Cattle that ingested large quantities of English ivy vine became ill and excitable, started staggering, and bellowed loudly. The odor of crushed ivy leaves was on the breath and in the milk. Recovery was quick and complete in three days (Cooper and Johnson 1984). English ivy berries are often listed as being poisonous to children, and cases of English ivy poisoning are listed in older European literature. Symptoms of ingestion included laboured breathing, coma, convulsions, and excitation (Cooper and Johnson 1984). Frohne and Pfander (1983) state that the ripe berries are dry and taste bitter. Large quantities are unlikely to be consumed by children.

Notes on poisoning: *Helenium autumnale*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Sneezeweed (*Helenium autumnale*) is a native herb found in parts of central and western Canada. This plant causes illness and occasional death in cattle and horses. It has been proved to be experimentally toxic to dogs but it is very unlikely that dogs would voluntarily ingest it. The plant is well-named because it is highly irritating to the nose, eyes, and stomach (Kingsbury 1964, Cheeke and Schull 1985, Fuller and McClintock 1986, Herz 1988).

References:

Canadian Biodiversity Information Facility

Notes on poisoning: *Helianthus annuus*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Sunflower (*Helianthus annuus*) causes allergic contact dermatitis in sensitive individuals after contact with the sesquiterpene lactones contained in fragile, multicellular, capitate glandular hairs (Hausen and Spring 1989). Cattle have been poisoned in Europe after ingesting plants that did not have mature seeds. This is a result of nitrate toxicity, which has caused sickness and death (Cooper and Johnson 1984).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Hausen, B. M., Spring, O. 1989. Sunflower allergy. On the constituents of the trichomes of *Helianthus annuus* L. (Compositae). Contact Dermatitis, 20: 326-334.

Nomenclature:

Scientific Name: *Helianthus annuus* L.

Vernacular name(s): sunflower

Scientific family name: *Compositae*

Vernacular family name: composite

Helianthus annuus:

Images: images.google.com

Toxic parts:

hairs

References:

Hausen, B. M., Spring, O. 1989. Sunflower allergy. On the constituents of the trichomes of *Helianthus annuus* L. (Compositae). Contact Dermatitis, 20: 326-334.

Notes on Toxic plant chemicals:

Sunflower contains several sesquiterpene lactones, including the most active chemical, 1-O-methyl-4,5-dihydroxyniveusin A, in the hemiketal form. The complete mixture of sesquiterpene lactones

contributes to the allergic response in humans. These chemicals are found in the capitata glands on sunflower leaves (Hausen and Spring 1989). Sunflowers can also accumulate toxic amounts of nitrates, which have poisoned cattle in Europe (Cooper and Johnson 1984).

Toxic plant chemicals:

-dihydroniveusin A
nitrate

Notes on poisoning:

Heliotropium

curassavicum

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Spatulate-leaved heliotrope (*Heliotropium curassavicum*) is a native herb found in southern parts of western Canada. This plant contains pyrrolizidine alkaloids. It and other members of the genus (*Heliotropium species*) are used in herbal teas and have been used in several parts of the world for medicinal reasons. Over consumption of such teas may cause veno-occlusive disease of the liver (Budd-Chiari syndrome), with hepatic vein thrombosis (Lampe and McCann 1985, Huxtable 1989).

References:

Huxtable, R. J. 1989. Human health implications of pyrrolizidine alkaloids and herbs containing them. Pages 41-86 in Cheeke, P. R., ed. Toxicants of plant origin. Vol. I. Alkaloids. CRC Press, Inc., Boca Raton, Fla., USA. 335 pp.

Lampe, K. F., McCann, M. A. 1985. AMA Handbook of poisonous and injurious plants. American Medical Assoc. Chicago, Ill., USA. 432 pp.

Nomenclature:

Scientific Name: *Heliotropium curassavicum* L.

Notes on poisoning: *Heracleum* *mantegazzianum*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Giant hogweed (*Heracleum mantegazzianum*) is naturalized in south central Ontario. It has caused photosensitization in children after exposure to the plant followed by sunlight (Morton 1975). This plant has also been introduced into New York State, where children have also contracted dermatitis from it (Gunby 1980).

References:

Notes on poisoning: *Hyacinthoides nonscripta*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

English bluebell (*Endymion non-scriptus*) is an ornamental bulb plant that is grown outdoors and forced indoors for its early spring flowers. This species was formerly included under the genus *Scilla*. The plant contains glycosides, which are chemically similar to the cardiac glycoside digitalis. Cattle, a horse, and humans were poisoned after ingesting this plant. Children or family pets should be prevented from chewing the plants (Cooper and Johnson 1984).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Nomenclature:

Scientific Name: *Hyacinthoides nonscripta* (L.) Garcke

Vernacular name(s): English bluebell

Scientific family name: *Liliaceae*

Vernacular family name: lily

Go to ITIS^{*ca} for more taxonomic information on: [Hyacinthoides nonscripta](#)

Cattle

General symptoms of poisoning:

[breathing, shallow](#)

[heart rate, slow](#)

[lethargy](#)

[temperature, depressed](#)

Notes on poisoning:

A group of cows and calves in Britain grazed on English bluebells and a few days later became dull and lethargic, chewed intermittently, and produced hard, dry feces. Temperature and respiration were decreased and heart beat became erratic. Lactating cows became dry. Recovery was slow when the cows were removed from the plants and given extra feed (Cooper and Johnson 1984).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Horses

General symptoms of poisoning:

[abdominal pains](#)

[diarrhea](#)

[skin, cold and moist
temperature, depressed
urination, absent
vomiting](#)

Notes on poisoning:

A horse that ate several bulbs of English bluebell became ill within 6 h. Symptoms included initial choking, abdominal pain, slow pulse, low temperature, and cold, clammy skin. Within 10 h the animal produced dark-colored diarrhea with blood and ceased urinating. The horse recovered slowly, passing blood-stained urine for several days (Cooper and Johnson 1984).

Canadian Biodiversity Information Facility

Notes on poisoning: *Hydrangea macrophylla*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Hydrangea (Hydrangea macrophylla) is an outdoor ornamental that is grown in the warmer parts of Canada. This plant has poisoned humans after they ingested the flower buds. Sensitive individuals can develop dermatitis after exposure to hydrangea. Older case reports of poisoning of horses and cattle appear in the literature, but no recent reports are available (Apted 1973, Bruynzeel 1986, Fuller and McClintock 1986).

References:

Apted, J. H. 1973. Phytodermatitis from hydrangeas. Arch. Dermatol., 108: 427.

Hydrangea macrophylla:

Images: images.google.com

Toxic parts:

flower buds
leaves

References:

Der Marderosian, A. H., Giller, F. B., Roia, F. C. 1976. Phytochemical and toxicological screening of household ornamental plants potentially toxic to humans. 1. J. Toxicol.

Environ. Health, 1: 939-953.

Notes on Toxic plant chemicals:

Hydragin, a cyanogenetic glycoside, is presumed to be responsible for toxicity because it can release hydrocyanic acid upon hydrolysis. Der Marderosian and Roia (1976) administered 3 g of plant extract intraperitoneally, in 10 mL of liquid suspension per 100 g of body weight. All rats died when given extracts from hydrangea flowers and leaves. No mice died when orally fed 100 mg of flower material per 35 g body weight.

Toxic plant chemicals:

hydragin

Notes on poisoning: *Hymenoxys richardsonii*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Colorado rubberweed (*Hymenoxys richardsonii*) is a native herb found in the southern prairies. This plant has caused poisoning and death in sheep, goats, and occasionally cattle. Sheep and goats consume this plant when there is little else to eat. Poisoning is therefore most frequent in spring and late autumn, when other forage is reduced. Cattle are poisoned less frequently because they find the plant unpalatable (Cheeke and Schull 1985).

Notes on Toxic plant chemicals:

Hymenovin (hymenoxon) is a sesquiterpene lactone that contains an alpha-methylene-gamma-lactone moiety. This moiety inhibits the enzymatic capability of adenylate cyclase by alkylation of its thiol group. The inhibition can disrupt the cellular transmission of external signals to the internal regulatory proteins. Mercaptans, such as cysteine, may be used in treatment by partly detoxifying the moiety before it can damage cellular enzymes (Elissalde and Ivie 1987). The oral LD-50 of hymenovin (hymenoxon) is 2.9-8.5 g/kg in sheep (Cheeke and Schull 1985).

Toxic plant chemicals:

hymenovin

Canadian Biodiversity Information Facility

Notes on poisoning: *Hyoscyamus niger*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Black henbane (*Hyoscyamus niger*) is a naturalized herb found across parts of southern Canada. This plant contains several alkaloids, and it has caused rare poisoning in humans, cattle, poultry, and swine. Human poisoning has been accidental or purposeful because of its reported medicinal or hallucinogenic properties. Black henbane has been used medicinally since ancient times to help with a variety of health problems and as a preventative. Its hallucinogenic effects have led people to eat the seed or chew the flowers, often with detrimental results. Ingestion causes anticholinergic syndrome with stimulatory and hallucinatory effects (Hocking 1947, Spoerke et al. 1987). Cattle have been poisoned in Europe after ingesting black henbane that was included in forage. The alkaloid content is retained upon drying, and ingestion is said to taint the milk of cows. Poultry have died after ingesting the seeds, and pigs have died after eating the roots (Cooper and Johnson 1984, Spoerke et al. 1987).

Image or illustration

Hyoscyamus niger:

Images: images.google.com

Notes on Poisonous plant parts:

All parts of the plant contain alkaloids in varying quantities (see the additional notes under chemicals). Ingestion of four flowers has caused some symptoms in humans (Frohne and Pfander 1983, Spoerke et al. 1987).

Toxic parts:

all parts
flowers
leaves
roots
seeds

References:

Frohne, D., Pfander, H. J. 1983. A colour atlas of poisonous plants. Wolfe Publishing Ltd., London, England. 291 pp.

Notes on Toxic plant chemicals:

Hyoscyamine, hyoscyne, and atropine can all be found in black henbane. The alkaloid content has been measured at 0.08% (roots), 0.17% (leaves), and 0.3% (seeds). The major affect of hyoscyamine is depression of the central nervous system (Frohne and Pfander 1983; Cooper and Johnson 1984).

Toxic plant chemicals:

atropine
hyoscyne(scopolamine)
hyoscyamine

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[bloat](#)

[breathing, labored](#)

[convulsions](#)

[cyanosis](#)

[heart rate, elevated](#)

[incoordination](#)

[pupil dilation](#)

[restlessness](#)

Notes on poisoning:

Symptoms of ingestion include restlessness, excitation, convulsions, pupil dilation, difficulty in breathing, increased heart rate, and bloat. Postmortem examination showed degeneration of heart muscle and cyanosis of mucous membranes (Cooper and Johnson 1984).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Humans

General symptoms of poisoning:

[coma](#)

[confusion](#)

[death](#)

[hallucination](#)

[mouth dry](#)

[nausea](#)

[pupil dilation](#)

[skin, flushed](#)

[vomiting](#)

Notes on poisoning:

Symptoms of poisoning include thirst, dry mouth, dilated pupils,

warm and flushed skin, and hallucinations. Purposeless movements, such as picking at the air, have been observed. Heart rate is elevated. These are the symptoms that occur after the roots are ingested. Ingesting the flowers has caused agitation, restlessness, dry skin, and pupil dilation (Spoerke et al. 1987).

Notes on poisoning: *Hypericum perforatum*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

St. John's-wort (*Hypericum perforatum*) is a naturalized herb found in eastern Canada and British Columbia. The plant contains hypericin, which is a primary photosensitizing chemical. Ingestion has caused skin problems in cattle, horses, rabbits, sheep, and swine. The skin problems occur on white or light-colored skin; dark skin is not affected. Severe symptoms such as convulsions, staggering, and coma have occurred in some animals. Loss of wool quality occurs in sheep, and the meat of affected animals is of poor quality. This plant is widespread in Canada. The reaction is more severe if fresh plants are eaten, but dried plants can also cause photosensitization, even though 80% of the hypericin is lost (Araya and Ford 1981, Cooper and Johnson 1984, Crompton et al. 1988).

References:

- Araya, O. S., Ford, E. J. 1981. An investigation of the type of photosensitization caused by the ingestion of St John's wort (*Hypericum perforatum*) by calves. *J. Comp. Pathol.*, 91: 135-141.

Notes on Toxic plant chemicals:

Hypericin, a fluorescent pigment, is regarded as a derivative of naphthodianthrone. The pigment is contained in small black dots that are just visible to the naked eye on leaves and petals. The chemical is a primary photosensitizer because the photodynamic action occurs in the skin (Araya and Ford 1981).

Notes on poisoning: *Ilex aquifolium*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

English holly (*Ilex aquifolium*) has been implicated in cases where children have eaten the berries. Kingsbury (1969) noted that the often-quoted fatal dosage of 20-30 berries comes from European literature before 1889 and that this quantity has not been confirmed. Modern references show that symptoms are usually confined to vomiting and diarrhea (Cooper and Johnson 1984, Lampe and McCann 1985). This holly is used as an outdoor ornamental, and the glossy green leaves and red berries may be sold as Christmas decorations.

Canadian Biodiversity Information Facility

Notes on poisoning: *Ipomoea tricolor*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Hallucinations are the predominant effect after ingesting morning glory seeds. Ingesting 200-300 seeds produces an effect equivalent to 300 micro g of LSD. Vivid visual and tactile hallucinations, as well as increased awareness of colors have been described. Symptoms include facial flushing, nausea, mydriasis, diarrhea, and hypotension (Spoerke and Smolinske 1990).

Ipomoea tricolor has a long history of use as a human hallucinogen in southern Mexico, where the seeds were used in the preparation of a drink (Fuller and McClintock 1986). A single undocumented case of poisoning of a pet cat (after ingestion of seeds) has come to our attention. The cat showed erratic behavior and "looked like a lunatic". There was no apparent permanent damage afterwards. Several cultivars of *Ipomoea tricolor* are available in Canadian garden catalogs for home gardeners and, with few exceptions, no mention is made of any potential toxic affects from ingesting the seeds of these plants. Sample cultivars are "Heavenly Blue", "Pearly Gates", and "Scarlet O'Hara". The total alkaloid content is shown to vary, depending on the cultivar grown. It is advisable to remove and destroy the fruiting parts as they develop to avoid ingestion by children or pets.

Image or illustration

Ipomoea tricolor:

Images: images.google.com

Notes on Poisonous plant parts:

The embryo of the seeds, and not the shell, contains the toxic chemicals. Ingesting 200-300 seeds can cause problems in adult

humans (Spoerke and Smolinske 1990).

Toxic parts:

seeds

References:

Spoerke, D. G., Smolinske, S. C. 1990. Toxicity of houseplants. CRC Press, Inc., Boca Raton, Fla., USA. 335 pp.

Notes on Toxic plant chemicals:

The seed embryos contain several indole alkaloids that have hallucinogenic activity. These include d-lysergic acid amide (0.035%), d-isolysergic acid amide (0.005%), and elymoclavine (0.005%). The total alkaloid content varies with different plant cultivars. For instance, the cultivar "Pearly Gates" had 0.041%, whereas "Scarlet O'Hara" had 0.002% total alkaloids (Spoerke and Smolinske 1990).

Toxic plant chemicals:

d-isolysergic acid amide

d-lysergic acid amide

elymoclavine

References:

Spoerke, D. G., Smolinske, S. C. 1990. Toxicity of houseplants. CRC Press, Inc., Boca Raton, Fla., USA. 335 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cats

General symptoms of poisoning:

[pupil dilation](#)

Notes on poisoning:

In an undocumented case, a pet cat was attracted to the fruiting capsule of a morning glory vine growing on an apartment balcony. The dry fruiting capsule contained seeds that rattled in the wind. The cat ate an unknown quantity of seeds and later was

noted to run around chasing nothing. It meowed a lot and its eyes did not appear to focus on anything. The owner remarked that the cat "looked like a lunatic". There were no apparent lasting symptoms.

Fuller, T. C., McClintock, E. 1986. Poisonous plants of California. Univ. California Press, Berkeley, Calif., USA. 432 pp.

Humans

General symptoms of poisoning:

[blood pressure, low](#)

[diarrhea](#)

[hallucination](#)

[nausea](#)

[pupil dilation](#)

Notes on poisoning:

In one reported case of deliberate ingestion of 250 seeds of morning glory, a 20-year-old women developed inappropriate responses and weeping. The pupils were dilated, the face flushed, and hyper- active reflexes were noted. After 5 h, anxiety, and increased awareness of colors was recorded, but without hallucinations. Diarrhea was noted after 9 h. Hypotension occurred intermittently. After 2 days most of the symptoms had disappeared, with the exception of dilated pupils and increased deep tendon reflexes (Spoerke and Smolinske 1990).

Notes on poisoning: *Iris pseudacorus*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Yellow iris (*Iris pseudacorus*) is a naturalized plant found in wet areas in parts of southern Canada. This plant has poisoned cattle and swine and may cause similar symptoms in humans if the rhizomes are ingested. The plant juices can cause dermatitis in sensitive humans. In British Columbia cattle were poisoned by a cultivated blue-flowered *Iris* species. The symptoms of that poisoning are described under this species (Bruce 1920, Cooper and Johnson 1984).

References:

Bruce, E. A. 1920. Iris poisoning of calves. J. Am. Vet. Med. Assoc., 56: 72-74.

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Nomenclature:

Scientific Name: *Iris pseudacorus* L.

Vernacular name(s): yellow iris

Scientific family name: *Iridaceae*

Vernacular family name: iris

Image or illustration

Iris pseudacorus:

Images: images.google.com

Notes on Poisonous plant parts:

Ingesting the rhizome causes poisoning in animals, and the plant juices cause dermatitis in sensitive individuals (Cooper and Johnson 1984).

Toxic parts:

plant juices
rhizome

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Notes on Toxic plant chemicals:

The toxin in Iris species has not been confirmed, but a glycoside, iridin (or irisin), has been implicated (Cooper and Johnson 1984).

Toxic plant chemicals:

iridin

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[abdominal pains](#)

[blistering](#)

[death](#)

[diarrhea](#)

[mouth, irritation of](#)

[recumbency](#)

[salivation](#)

Notes on poisoning:

Ingesting yellow flag rhizome has apparently caused diarrhea and bloody feces in cattle in Europe. The toxin can survive drying because yellow flag in hay causes diarrhea (Cooper and Johnson

1984).

In a case in British Columbia, cattle ingested rhizomes from an unidentified blue-flowered cultivated *Iris* species. Three calves showed symptoms and died within 4 days. Initial symptoms included recumbency and excessive salivation. The glands of the head and throat became hard and enlarged. Raised sores appeared on the lips and muzzle, becoming yellowish scabs that irritated animals. Acute abdominal pain occurred, and bloody feces were passed. Death followed. Postmortem findings showed irritation of the lower stomachs and intestines. The kidneys, liver, and spleen were very dark-colored. Unfortunately, the identity of this iris was never determined (Bruce 1920). Livestock should be denied access to any *Iris* species that grow in the wild or in gardens, because ingestion may cause poisoning.

Notes on poisoning: *Iris versicolor*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Blue flag (*Iris versicolor*) is a native herb found in eastern and central Canada. This plant has been mentioned as causing poisoning in humans and animals, but case reports have not been found. The plant juice can cause dermatitis in sensitive individuals. Other iris species have also been implicated in poisoning of animals and in causing dermatitis in humans (see additional information under [Iris pseudacorus](#)). Because of the potential for poisoning, care should be taken to prevent access by livestock to blue flag, which grows in moist soils near rivers, lakes, and marshes (Fyles 1920, Cooper and Johnson 1984).

Canadian Biodiversity Information Facility

Notes on poisoning: *Juglans nigra*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Black walnut (*Juglans nigra*) is native to southwestern Ontario and has been planted as a cultivated tree. The shavings of wood from this tree have caused laminitis in horses in the United States. Black walnut shavings are less likely to be used as bedding in Canada because the tree is not common here. However, if bedding is obtained from a hardwood mill or furniture manufacturing plant, sufficient black black walnut shavings may be present to cause problems. Reforestation of black walnut has been attempted in southern Ontario by leaving nuts for squirrels to gather in the autumn. The squirrel bury them for the winter, allowing many black walnut trees to germinate by this method. Pollen of black walnut has been implicated in causing laminitis in horses (MacDaniels 1983, Minnick et al. 1987).

References:

Image or illustration

Juglans nigra:

Images: images.google.com

Notes on Poisonous plant parts:

Wood shavings of black walnut have caused symptoms in horses. The chemical juglone has not been found in appreciable amounts in the wood. Other chemicals are probably involved in causing symptoms in horses from wood shavings (Minnick et al. 1987).

Toxic parts:

bark
mature fruit
wood

References:

Minnick, P. D., Brown, C. M., Braselton, W. E., Meerdink, G. L., Slanker, M. R. 1987. The induction of equine laminitis with an aqueous extract of the heartwood of black walnut (*Juglans nigra*). Vet. Hum. Toxicol., 29: 230-233.

Notes on Toxic plant chemicals:

Juglone, a naphthoquinone, has been found in the bark, nuts, and roots of black walnut. Pure juglone is less potent than a crude extract of the plant in inducing toxic effects. Additional compounds seem to be involved in causing more severe cases. Two ponies given 1 g of pure juglone orally developed mild laminitis that disappeared within 24 h (Minnick et al. 1987).

Toxic plant chemicals:

juglone

References:

Canadian Biodiversity Information Facility

Notes on poisoning:

Kalanchoe

daigremontiana

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Devil's-backbone (*Kalanchoe daigremontiana*) is an indoor ornamental plant. This plant contains a cardiac glycoside that has caused experimental toxicity and death in chicks and mice. It has caused illness in pets, such as rabbits and mice. Dogs and cats are also at risk from ingesting plant material. The plants should be kept away from children, as well. Devil's-backbone produces plantlets along the leaf margins, which fall off and become new plants. These plantlets can be found in profusion around the pot in which an adult devil's-backbone is growing. Children and family pets have easy access to these plantlets. Several other species of *Kalanchoe* may be found growing as houseplants in Canada. Tests have shown that some of them may also contain toxic bufadienolide compounds. These compounds were only recently discovered (Williams and Smith 1985, Joubert 1989), and so caution should be exercised with all species. Some members of the genus *Kalanchoe* have caused poisoning of sheep and cattle in South Africa and Australia, where they are native or naturalized (Cheeke and Schull 1985, Williams and Smith 1985).

Image or illustration

Kalanchoe daigremontiana:

Images: images.google.com

Notes on Poisonous plant parts:

Williams and Smith (1984) found that the leaves contained more toxin than the stems.

Toxic parts:

leaves

stems

References:

Joubert, J. P. 1989. Cardiac glycosides. Pages 61-97 in Cheeke, P. R., ed. Toxicants of plant origin. Vol. II. Glycosides. CRC Press, Inc., Boca Raton, Fla., USA. 277 pp.

Wagner, H., Fischer, M., Lotter, H. 1985. Isolation and structure determination of daigremontianin, a novel bufadienolide from *Kalanchoe daigremontiana*. *Planta Med.*, 33: 169-171.

Williams, M. C., Smith, M. C. 1984. Toxicity of *Kalanchoe* spp. to chicks. *Am. J. Vet. Res.*, 45: 543-546.

Notes on Toxic plant chemicals:

Daigremontianin is a bufadienolide. Bufadienolides are cardiac glycosides that are similar to cardenolides, differing only in the structure of the C-17 substituent on the D ring. This chemical has been found to be toxic in experiments on mice (Wagner et al. 1985).

Toxic plant chemicals:

daigremontianin

References:

Wagner, H., Fischer, M., Lotter, H. 1985. Isolation and structure determination of daigremontianin, a novel bufadienolide from *Kalanchoe daigremontiana*. *Planta Med.*, 33: 169-171.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cats

General symptoms of poisoning:

[breathing, labored](#)

[convulsions](#)

[paralysis](#)

References:

Fuller, T. C., McClintock, E. 1986. Poisonous plants of California. Univ. California Press, Berkeley, Calif., USA. 432 pp.

Chickens

General symptoms of poisoning:

[breathing, labored](#)

[convulsions](#)

[death](#)

[depression](#)

[incoordination](#)

[muscle twitching](#)

[paralysis](#)

[trembling](#)

Notes on poisoning:

Experimental feeding of leaf extracts to chicks caused depression, closed eyes, ruffled and drooping feathers, twitching of the neck and head, and often spiralling of the head over the back. In severe cases, convulsions, paralysis, neck and limb tremors, and death occurred. A dosage of 8 mg/g of body weight caused mild symptoms; dosages between 12-20 mg/g of body weight caused some deaths. Stem extracts produced less severe symptoms and no deaths, even when fed at the equivalent of 20 mg/g of body weight (Williams and Smith 1984).

Fuller, T. C., McClintock, E. 1986. Poisonous plants of California. Univ. California Press, Berkeley, Calif., USA. 432 pp.

Williams, M. C., Smith, M. C. 1984. Toxicity of *Kalanchoe* spp.

to chicks. Am. J. Vet. Res., 45: 543-546.

Rabbits

General symptoms of poisoning:

[breathing, rapid](#)

[opisthotonos](#)

[paralysis](#)

Notes on poisoning:

A pet rabbit ate three-quarters of a leaf and became depressed and torpid; it subsequently experienced rapid breathing and teeth grinding. It fell down when attempting to walk. Paralysis followed. An injection of atropine was administered, and the rabbit recovered fully within 9 h (Williams and Smith 1984).

Notes on poisoning: *Kalmia angustifolia*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Sheep-laurel (*Kalmia angustifolia*) is a native shrub found in eastern Canada in boggy areas. This plant contains a toxin that has poisoned cattle, goats, and sheep as well as humans. Poisoning rarely happens in the wild. Other animals have been poisoned by sheep-laurel, including zebras at a zoo, as well as horses. Meat of chickens that had ingested sheep-laurel may be toxic to other animals. The nectar contains the toxin that results in toxic honey (Marsh 1930, Kingsbury 1964, Verlangieri 1976, Lampe and McCann 1985).

Image or illustration

Kalmia angustifolia:

Images: images.google.com

Notes on Poisonous plant parts:

The entire plant is poisonous, including the nectar and honey made from it (Pritchard 1956, Kingsbury 1964).

Toxic parts:

all parts
flowers
leaves
mature fruit
stems

References:

Pritchard, W. R. 1956. Laurel (*Kalmia angustifolia*) poisoning of sheep. N. Am. Vet., 37: 461-462.

Verlangieri, A. J., Gawlikowski, J. N., Shapiro, R. 1976. Acute toxicity of *Kalmia angustifolia*, (sheep laurel) extracts in the rat. Vet. Toxicol., 18: 122-124.

Notes on Toxic plant chemicals:

Andromedotoxin and resins derived from diterpenes are the toxic compounds found in all the toxic species of the heath plant family. The toxin is found even in the nectar of flowers (Fuller and McClintock 1986). Experimental poisoning of rats using leaf extracts resulted in an average LD-50 (female) of 8.2 g of green leaves per kilogram body weight. The leaves were toxic only in the spring. Leaves of plants growing in wet areas were more toxic than those growing in dry areas (Verlangieri et al. 1976).

Toxic plant chemicals:

andromedotoxins

Chemical diagram(s) are courtesy of [Ruth McDiarmid](#), Biochemistry Technician, Kamloops Range Station, Agriculture and Agri-Food Canada,

Kamploops, British Columbia, Canada.

Verlangieri, A. J., Gawlikowski, J. N., Shapiro, R. 1976. Acute toxicity of *Kalmia angustifolia*, (sheep laurel) extracts in the rat. *Vet. Toxicol.*, 18: 122-124.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[breathing, shallow](#)

[diarrhea](#)

[gait, staggering](#)

[incoordination](#)

[recumbency](#)

[salivation](#)

[vomiting](#)

Notes on poisoning:

Experimental poisoning of cattle showed symptoms, including soft feces, salivation, vomiting, diarrhea, and incoordination. Consuming green leaves equivalent to 0.2% of an animal's body weight was determined to cause toxic signs in cattle (Marsh 1930). A few cattle in the field were poisoned after ingesting sheep-laurel (Kingsbury 1964).

Notes on poisoning: *Kalmia polifolia*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Bog-laurel (*Kalmia polifolia*) is a native shrub found across Canada in boggy areas. The plant has caused experimental poisoning in cattle, goats, and sheep, with sheep being most susceptible. Suspected poisoning of cattle and sheep in the west have been reported. Bog-laurel is less toxic than sheep-laurel (*Kalmia angustifolia*). Only the western variety of bog-laurel (*Kalmia polifolia* var. *microphylla*) has been tested for toxicity. However, the plant should be considered potentially toxic through its entire range in Canada (Clawson 1933, Kingsbury 1964, Lampe and McCann 1985).

Notes on poisoning: *Kochia scoparia*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Kochia (Kochia scoparia) is both naturalized and cultivated as an outdoor ornamental in various parts of Canada. Ingestion has caused poisoning in cattle, horses, and sheep. Hepatogenous photosensitivity and liver damage often occur together, along with the outward signs of photosensitization. In addition, polioencephalomalacia, toxic hepatitis, and nephrosis can occur. *Kochia* has been examined as a forage crop because it is very drought-tolerant. Toxicity varies from one year to the next. Increased rainfall has raised the oxalate content of the plants. Oxalates are at least partly responsible for the complicated toxic affects of *kochia* ingestion (Galitzer and Oehme 1978, Dickie and Berryman 1979, Thilsted et al. 1989).

Notes on Toxic plant chemicals:

Kochia has been found to contain total oxalates of up to 11.4% and maximum soluble oxalates of 4.7%. This level of soluble oxalates is sufficient to cause some of the signs of toxicity seen in poisoning. In addition, saponins and alkaloids have been described that may contribute to the complex symptoms of *kochia* ingestion (Dickie et al. 1989, Thilsted et al. 1989).

Toxic plant chemicals:

oxalate

Notes on poisoning: *Laburnum anagyroides*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Golden-chain (*Laburnum anagyroides*) is an outdoor ornamental that survives only in southwestern Ontario and coastal British Columbia. This plant contains cytisine, an alkaloid, which has caused poisoning and death in cattle, dogs, horses, swine, and humans after twigs, fruit pods, and seeds were ingested. Most of the cases of poisoning are found in European literature. Children and family pets should be prevented from ingesting the pods or seeds (Cooper and Johnson 1984, Lampe and McCann 1985, Fuller and McClintock 1986).

Image or illustration

Laburnum anagyroides:

Images: images.google.com

Notes on Poisonous plant parts:

All parts of the plant contain the alkaloid cytisine, but the bark and seeds have the highest amount of the chemical. The leaves become less toxic as the fruit pods develop, which become more toxic (Cooper and Johnson 1984).

Toxic parts:

all parts
bark
leaves
seeds

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Toxic plant chemicals:

cytisine

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[death](#)
[gait, unsteady](#)
[muscle spasms](#)
[recumbency](#)

Notes on poisoning:

Ingesting twigs and pods of golden-chain have produced toxic symptoms including stiff, unsteady gait, violent tremors, recumbency, and death. Milk yield has been reduced, and large yellow clots were found in the milk (Cooper and Johnson 1984).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Dogs

General symptoms of poisoning:

[convulsions](#)

[death](#)

Notes on poisoning:

Dogs that were poisoned experienced convulsions and died after chewing golden-chain sticks (Cooper and Johnson 1984).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Horses

General symptoms of poisoning:

[abdominal pains](#)

[coma](#)

[death](#)

[incoordination](#)

[muscle spasms](#)

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Humans

General symptoms of poisoning:

[abdominal pains](#)

[confusion](#)

[death](#)

[dizziness](#)

[drowsiness](#)

[headache](#)

[mouth, irritation of](#)

[nausea](#)

[temperature, elevated](#)

[vomiting](#)

Notes on poisoning:

Most cases of human poisoning occur when children eat the pods or seeds by mistake. Symptoms develop rapidly within half an hour because cytisine is rapidly absorbed through mucous membranes of the mouth, stomach, and intestine. Nausea, vomiting, pupil dilation, weakness, breathing difficulty, dizziness, and muscular incoordination can result. Ingesting large quantities can be fatal. In one case, a man ingested 23 pods of golden-chain and died. Toxicological analysis showed that 35-50 mg of cytisine had been absorbed (Cooper and Johnson 1984, Fuller and McClintock 1986).

Notes on poisoning: *Lactuca scariola*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Prickly lettuce (*Lactuca scariola*) is a naturalized herb found across parts of southern Canada. In the western United States, cattle developed pulmonary emphysema after ingesting the plant. The injury appears to be associated with a deficiency, because the toxicity develops after the cattle have fed on dry rangelands. When they are subsequently moved to lush, autumn pasture, some cattle feed ravenously on the prickly lettuce regrowth and, in a few days, the symptoms may develop (Beath et al. 1953).

References:

Beath, O. A., Gilbert, C. S., Eppson, H. F., Rosenfeld, I. 1953. Poisonous plants and livestock poisoning. Wyo. Agric. Exp. Stn. Bull., 324. 94 pp.

Nomenclature:

Scientific Name: *Lactuca scariola* L.

Vernacular name(s): prickly lettuce

Canadian Biodiversity Information Facility

Notes on poisoning: *Lantana camara*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Yellow sage (*Lantana camara*) is occasionally sold as a houseplant and may also be planted outdoors in the summer in Canada. Children who ingested green berries became ill and died. In warmer parts of the world (e.g., Florida, Australia), the plant grows outside and becomes weedy. Livestock have been poisoned after ingesting the entire plants. Importantly, livestock that ingest berries exhibit symptoms that are different from those of children who ingest the berries. Livestock do not normally encounter this plant in Canada, but the symptoms of poisoning are included under cattle. Sheep and goats have also been poisoned. Care should be taken to keep children as well as family pets away from this plant (Wolfson and Solomons 1964, McLennan and Amos 1989, Spoerke and Smolinske 1990). Cats and dogs that have access to yellow sage indoors can become poisoned if they ingest the immature berries of foliage of this plant. No records were found in the literature of toxicity in pets from yellow sage ingestion.

Image or illustration

Lantana camara:

Images: images.google.com

Notes on Poisonous plant parts:

Ingesting the leaves has caused poisoning in livestock in areas

where the plant can survive outdoors, such as Florida and Australia. Young children who ingested the green berries became ill and died (Wolfson and Solomons 1964, McLennan and Amos 1989).

Toxic parts:

immature fruit
leaves

References:

McLennan, M. W., Amos, M. L. 1989. Treatment of lantana poisoning in cattle. Aust. Vet. J., 66: 93-94.

Sharma, O. P., Dawra, R. K., Makkar, H. P. 1989. Toxicity of isolated lantana (*Lantana camara* L.) constituents to male and female guinea pigs. Vet. Hum. Toxicol., 31: 10-13.

Notes on Toxic plant chemicals:

Lantadene A and lantadene B, which are pentacyclic triterpenes, have been suspected as the toxic constituents of yellow sage leaves. However, there are conflicting findings on the chemical toxins and their toxic affects on animals. Sharma et al. (1989) found that crystal polymorphism in the triterpenoids changes the toxicity (polyhedral crystals are toxic to guinea pigs and rod-shaped crystals are not). In addition, the toxic component of the berries has not been defined. The plant also contains a fish poison, lancamarone, that is present in the greatest concentration in the summer. The effects of this chemical on mammals have not been studied (Spoerke and Smolinske 1990).

Toxic plant chemicals:

lantadene A & B

[death](#)

[diarrhea](#)

[lethargy](#)

[liver, congestion of](#)

[pupil dilation](#)

[pupils, pinpoint](#)

[unconsciousness](#)

[vomiting](#)

[weakness](#)

Notes on poisoning:

Ingesting the green berries of yellow sage produces the following symptoms: vomiting, diarrhea, weakness, lethargy, cyanosis, slow labored breathing, dilated pupils, ataxia, coma, and depressed deep tendon reflexes. Postmortem findings showed congestion of the lungs and kidneys. The small intestines were dilated. These symptoms all occurred after an unknown quantity of the immature green berries was ingested. The rough texture of the leaves and stems discourages children from ingesting them. Humans have therefore not shown the photosensitivity and liver problems that occur when livestock ingest entire plants. Lavage

should be done quickly to reduce or prevent symptoms. Several authors have reported that the ripe berries are nontoxic to humans (Wolfson and Solomons 1964, Spoerke and Smolinske 1990).

Canadian Biodiversity Information Facility

Notes on poisoning: *Laportea canadensis*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Canada nettle (*Laportea canadensis*) is found in moist woods and along streams. This plant has stinging hairs on the leaves and stem that readily penetrate thin-skinned areas on humans. The tips of the hairs break off, allowing the contained liquid to penetrate the body. Intense localized itching results. Applying water to the surface of the affected area can increase the sensation; this problem may persist for several weeks. In Australia, other members of the genus *Laportea* have caused severe reactions in humans, and a death was reported in New Guinea after severe exposure. Livestock have responded frantically to contact with these plants in Australia. Canada nettle can cause reactions in animals upon exposure in Canada. Avoid this plant if possible (MacFarlane 1963, Mitchell and Rook 1979).

References:

MacFarlane, W. V. 1963. The stinging properties of *Laportea*. *Econ. Bot.*, 17: 303-311.

Nomenclature:

Scientific Name: *Laportea canadensis* (L.) Gaud.

Vernacular name(s): Canada nettle

Scientific family name: *Urticaceae*

Vernacular family name: nettle

Go to ITIS*^{ca} for more taxonomic information on: [Laportea canadensis](#)

Image or illustration

Laportea canadensis:

Images: images.google.com

Notes on Poisonous plant parts:

Canada nettle is covered with stinging hairs on the leaves and stem. The tips of the hairs are readily fractured on contact with

skin, allowing the internal liquid to be injected into the local body area. The hairs are sharply pointed, allowing ready penetration of thinner skinned portions of the body (MacFarlane 1963).

Toxic parts:

hairs

References:

MacFarlane, W. V. 1963. The stinging properties of *Laportea*. Econ. Bot., 17: 303-311.

Notes on Toxic plant chemicals:

The active ingredient in the stinging hairs is not known. The chemicals acetylcholine, histamine, and 5-hydroxytryptamine, which cause the stinging of hairs from the closely related American stinging nettle (*Urtica dioica*), are not the primary toxic chemicals in Canada nettle. Some studies on native Australian *Laportea* species have shown that no detectable loss of activity occurs after 46 years in a dry state. Immersion in boiling water for 10 min does not deactivate the chemical. In fact, the pain is intensified in humans if the affected area is exposed to water, a reaction that may last for many weeks (MacFarlane 1963).

Toxic plant chemicals:

unknown chemical

References:

MacFarlane, W. V. 1963. The stinging properties of *Laportea*. Econ. Bot., 17: 303-311.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Humans

General symptoms of poisoning:

[erythema](#)

[itchiness](#)

[pain](#)

[skin, flushed](#)

Notes on poisoning:

Canada nettle hairs induce localized pain and discomfort as well as erythema, reddening, and localized sweating. The pain may persist for weeks. Canada nettle differs from American stinging nettle (*Urtica dioica*) in that the intense pain can persist for weeks or months (MacFarlane 1963, Mitchell and Rook 1979).

Notes on poisoning: *Lathyrus odoratus*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Sweet pea (*Lathyrus odoratus*) is a summer annual commonly cultivated because of its beautiful fragrant flowers. The pods and seeds contain BAPN (beta-aminopropionitrile), which causes osteolathyrism, a syndrome characterized by skeletal deformities and aortic rupture. This chemical was first extracted from sweet pea plants and has since been found in some other members of the genus *Lathyrus*. Horses are more susceptible to this syndrome than other livestock. Most of the information on osteolathyrism is based on experimental work. This problem has not occurred in humans; instead, see neurolathyrins under grass pea ([Lathyrus sativus](#)). In Canada, ingesting enough sweet pea to cause osteolathyrism is not likely (Selye 1957, Cheeke and Schull 1985).

Roy, D. N., Spencer, P. S. 1989. Lathyrogens. Pages 169-201 in Cheeke, P. R., ed. Toxicants of plant origin. Vol. III. Proteins and amino acids. CRC Press, Inc., Boca Raton, Fla., USA. 271 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Horses

General symptoms of poisoning:

[aneurysm](#)

[gait, rigid](#)

[scoliosis](#)

Notes on poisoning:

Literature reports of osteolathyrism show that horses are particularly susceptible. Symptoms include skeletal deformity, such as long bone curvature, kyphosis, scoliosis, osteoporosis, and poor development of connective tissue. Aortic rupture also occurs. These effects are due to defective synthesis of collagen and elastin tissue caused by BAPN (Cheeke and Schull 1985).

References:

Cheeke, P. R., Shull, L. R. 1985. Natural toxicants in feeds and poisonous plants. AVI Publishing Company, Inc., Westport, Conn., USA. 492 pp.

Rodents

General symptoms of poisoning:

[abortion](#)

[aneurysm](#)

[bones, fragile](#)

Notes on poisoning:

Experimental feeding of sweet pea seeds to rats has caused symptoms of osteolathyrism, including the production of fragile bones, muscle atrophy, fatty bone marrow, hernias, thin skin, and scoliosis (Selye 1957, Cheeke and Schull 1985).

References:

Selye, H. 1957. Lathyrism. Rev. Can. Biol., 16: 1-82.

Turkeys

General symptoms of poisoning:

[aneurysm](#)

Notes on poisoning:

Experimental feeding of the toxic chemical beta-aminopropionitrile (BAPN) caused aortic dissecting aneurysms in turkey poults. Mortality was quite high as a result. See additional information under general notes of [Lathyrus sativus](#) (Lalich et al. 1957, Simpson and Cardeilhac 1983).

Notes on poisoning: *Lathyrus sativus*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Grass pea (*Lathyrus sativa*) has been used as a food and forage crop in Europe and Asia, where ingesting the seeds for 3-6 months can cause neurolathyrism, a syndrome characterized by muscular rigidity, weakness, and paralysis of the leg muscles. In severe cases, victims may be reduced to crawling. Young men between 20 and 30 years old are primarily affected. Livestock may also develop paralysis if they ingest grass pea for a long time. Neurolathyrism still occurs in India, where grass pea is used as flour (Cooper and Johnson 1984, Roy and Spencer 1989). Poisoning from grass pea is unlikely in Canada. However, some other *Lathyrus* species that occur in Canada may also contain BOAA.

Notes on Toxic plant chemicals:

BOAA (beta-N-oxalylamino-L-alanine) is generally regarded as the cause of neurolathyrism, although the exact nomenclature is still under study. The concentration of BOAA in the seed varies from 0.1 to 2.5%. This variation may help explain the conflicting reports of toxicity (Roy and Spencer 1989).

Notes on poisoning: *Ligustrum vulgare*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Common privet (*Ligustrum vulgare*) is an ornamental shrub that is often planted as a hedge, and therefore the flowers and berries are trimmed. In older European literature, ingesting the berries has been noted to cause sickness in children. In more recent cases of ingestion by children, symptoms included only vomiting and diarrhea, after up to 12 berries were eaten (Frohne and Pfander 1983). Reynard and Norton (1942) cite the case of sheep that died after ingesting the trimmings from a hedge of a related privet (*Ligustrum ovalifolium*).

Canadian Biodiversity Information Facility

Notes on poisoning: *Linaria vulgaris*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Yellow toadflax (*Linaria vulgaris*) is an introduced herb that is widely naturalized across Canada. This plant contains several compounds, including glucosides and the cyanogenic glucoside prunasin. The plant is regarded as toxic to livestock in Europe. Cattle generally avoid grazing stands of this plant, but there is more potential for poisoning when the animals are provided with hay that has a high content of yellow toadflax. No definitive records of poisoning are found in the literature. Other members of the genus are found in Canada as well, including the introduced Dalmatian toadflax (*Linaria dalmatica*). For safety's sake, hay should not be fed to livestock if it contains a high content of these plants.

Notes on poisoning: *Lobelia inflata*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Indian-tobacco (*Lobelia inflata*) is a herb native to Canada. In the past, aboriginal people smoked its dried leaves. This plant and related *Lobelia* species were used as medicinal plants. Overdoses led to cases of poisoning, which resulted in fatalities. No modern cases of poisoning are found in the literature. The dried leaves of *Lobelia* may be found in health food stores as a herbal medicine (Lampe and McCann 1985).

Canadian Biodiversity Information Facility

Notes on poisoning: *Lonicera xylosteum*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Fly honeysuckle (*Lonicera xylosteum*) is cultivated in southwestern Quebec and southern Ontario. This ornamental shrub has been implicated in cases of poisoning of children in Europe. Recent literature indicates that cases of poisoning are rare, and the symptoms are considered mild. Experimental poisoning of rabbits has caused mild symptoms. Injecting fruit extracts at high doses has caused sickness and death in mice. Ingesting a large number of berries (ca. 30) may cause abdominal pain and vomiting in children (Frohne and Pfander 1983). Additional species of cultivated honeysuckle have also been implicated in cases of human poisoning. Woodbine (*Lonicera periclymenum*) may be poisonous. This climbing honeysuckle is occasionally planted. See the general notes under Tartarian honeysuckle, ([Lonicera tatarica](#)).

Image or illustration

Lonicera xylosteum:

Images: images.google.com

Notes on Poisonous plant parts:

The berries have been implicated in cases of toxicity in Europe. In North America no cases of poisoning occurred after children ingested the berries (Lampe and McCann 1985).

Toxic parts:

mature fruit

References:

Frohne, D., Pfander, H. J. 1983. A colour atlas of poisonous plants. Wolfe Publishing Ltd., London, England. 291 pp.

Notes on Toxic plant chemicals:

The toxin is unknown, but saponins are thought to be responsible for the cases of poisoning. Traces of alkaloids were also found (Frohne and Pfander 1983).

Toxic plant chemicals:

unknown chemical

References:

Frohne, D., Pfander, H. J. 1983. A colour atlas of poisonous plants. Wolfe Publishing Ltd., London, England. 291 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Humans

General symptoms of poisoning:

[abdominal pains](#)

[diarrhea](#)

[vomiting](#)

Notes on poisoning:

Symptoms of ingestion include abdominal pain, diarrhea, and vomiting. More severe symptoms have been listed in early European literature, but severe toxicity has not been conclusively documented (Frohne and Pfander 1983).

References:

Frohne, D., Pfander, H. J. 1983. A colour atlas of poisonous plants. Wolfe Publishing Ltd., London, England. 291 pp.

Rabbits

General symptoms of poisoning:

[diarrhea](#)

Notes on poisoning:

Experimental feeding of berries (dry weight at 25 g/kg of body weight) to rabbits caused diarrhea and lack of movement within 24 h Frohne and Pfander 1983).

References:

Frohne, D., Pfander, H. J. 1983. A colour atlas of poisonous plants. Wolfe Publishing Ltd., London, England. 291 pp.

Rodents

General symptoms of poisoning:

[death](#)

[drowsiness](#)

Notes on poisoning:

Mice experimentally injected with berry extract (dry weight at 20-40 g/kg of body weight) experienced brief excitation, followed by drowsiness, abdominal spasms, and equilibrium and respiratory problems. Death sometimes followed in 10 min to several hours. A connection was made between saponin content and toxicity (Frohne and Pfander 1983).

Image or illustration

Lupinus argenteus:

Images: images.google.com

Notes on Poisonous plant parts:

The concentration of anagryne decreases in the leaves once the seeds begin to form, and then is greatest in the seeds. Total alkaloid content is greatest in the seeds. See notes under silky lupine (*Lupinus sericeus*) for additional information.

Toxic parts:

leaves
seeds

References:

Keeler, R. F. 1989. Quinolizidine alkaloids in range and grain lupins. Pages 133-167 in Cheeke, P. R., ed. Toxicants of plant origin. Vol. I. Alkaloids. CRC Press, Inc., Boca Raton, Fla., USA. 335 pp.

Notes on Toxic plant chemicals:

Two alkaloids, lupanine and sparteine, (both quinolizidine alkaloids), are probably involved in causing poisoning in sheep (Keeler 1989). This species also has been found to contain 3.34 g/kg of anagryne, exceeding the minimum level of 1.44 g/kg needed to cause crooked calf disease (Davis 1982, Davis and Stout 1986).

Toxic plant chemicals:

anagryne

lupanine

Notes on poisoning: *Lupinus burkei*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Burkes" lupine (*Lupinus burkei*) is a native herb found in southern British Columbia. Chemical analysis of aboveground plant material has shown that this species can occasionally contain enough of the chemical anagyrene to cause teratogenic effects in calves if the plant is ingested maternally between day 40 and day 70 of gestation. The literature does not include cases of poisoning or teratogenic problems caused by this plant. See additional notes under silky lupine ([Lupinus sericeus](#)).

References:

Davis, A. M., Stout, D. M. 1986. Anagyrene in western American lupines. J. Range Manage., 39: 29-30.

Canadian Biodiversity Information Facility

Notes on poisoning: *Lupinus polyphyllus*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Large-leaved lupine (*Lupinus polyphyllus*) is a native of British Columbia and has been introduced in eastern Canada. This species has been used in developing many of the cultivars of lupines grown in gardens. Davis and Stout (1986) measured quantities of anagryne that exceeded the minimum necessary to cause crooked calf disease (teratogenic deformities) in calves. The literature does not include any documented cases. Care should be taken to prevent pregnant cattle from feeding on this lupine from day 40 to day 70 of gestation. See additional notes under silky lupine (*Lupinus sericeus*).

Notes on poisoning: *Lupinus sericeus*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Silky lupine (*Lupinus sericeus*) is a native herb of western Canada. This lupine has caused poisoning and death in cattle, goats, horses, and sheep. Sheep eat the plants more readily than do other animals and are therefore more commonly poisoned. Cattle also suffer from crooked calf disease, a teratogenic syndrome caused by maternal ingestion of certain lupines between day 40 and day 70 of gestation. The calves can suffer from arthrogryposis, scoliosis, and other deformities. Humans are also at risk from lupine toxins. In one case in California, a child was born with limb deformities. The family raised milk goats that had also given birth to kids with deformed limbs, and a dog gave birth to deformed pups. All had ingested the goat's milk during pregnancy. Anagryne in a local lupine species was believed to cause the problem. Tests showed that lactating goats that ingest lupine seeds pass anagryne in the milk. Edible lupine seeds are being marketed in health food stores. In Edmonton (Smith 1987), a woman suffered mild dizziness and incoordination after ingesting the seeds. She did not follow specific instructions to soak and boil the seeds in several changes of water, which is necessary to remove the toxins.

Image or illustration

Lupinus sericeus:

Images: images.google.com

Notes on Poisonous plant parts:

The teratogenic alkaloid anagryne is highest in the seeds, pods, and young leaves. The quinolizidine alkaloids implicated in lupine poisoning and death are found mostly in the seeds and pods. Large quantities of the plant material must be ingested in a short time. The alkaloids remain after drying, so that hay containing sufficient quantities of lupine can be toxic (Kingsbury 1964, Keeler 1989).

Toxic parts:

leaves
mature fruit
seeds
stems

References:

Davis, A. M., Stout, D. M. 1986. Anagryne in western American lupines. *J. Range Manage.*, 39: 29-30.

Keeler, R. F. 1989. Quinolizidine alkaloids in range and grain lupins. Pages 133-167 in Cheeke, P. R., ed. *Toxicants of plant origin*. Vol. I. Alkaloids. CRC Press, Inc., Boca Raton, Fla., USA. 335 pp.

Kingsbury, J. M. 1964. *Poisonous plants of the United States and Canada*. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.

Notes on Toxic plant chemicals:

Silky lupine contains two major quinolizidine alkaloids, lupanine and sparteine. These alkaloids and their derivatives cause poisoning and death in livestock. This species also contains a teratogenic chemical, anagryne, which causes birth deformities in calves after maternal ingestion of the plants between day 40 and day 70. Amounts of up to 6.84 g/kg have been measured, which exceeds the minimum of 1.44 g/kg required to cause crooked calf disease (Davis and Stout 1986, Keeler 1989). The LD-50 of lupanine by oral ingestion in rats is 1464 mg/kg. This alkaloid is rapidly cleared from the body (Pettersen et al. 1987).

Toxic plant chemicals:

anagryne
lupanine

sparteine

Horses

General symptoms of poisoning:

[breathing, labored](#)

[convulsions](#)

[trembling](#)

Notes on poisoning:

Horses do not ingest lupines as readily as do sheep. Toxic symptoms therefore seldom appear in horses. Symptoms are similar to those seen in sheep (Kingsbury 1964).

References:

Kingsbury, J. M. 1964. Poisonous plants of the United States and

Humans

General symptoms of poisoning:

[dizziness](#)

[incoordination](#)

Notes on poisoning:

Smith (1987) reports the case of a woman who complained of dizziness and incoordination after ingesting edible lupine seeds purchased in Edmonton. The women had not followed the cooking instructions, which required soaking and boiling the seeds in several changes of water. The toxic alkaloids are removed through several stages of cooking; the process must be continued until no bitterness is left. In lupine seeds a lethal dose of lupanine has been determined to be about 100 mg/kg. If not properly cooked, 10 g of seeds may liberate more than 100 mg of lupanine. Keeler (1989) discusses a possible link between ingesting goat's milk and the occurrence of birth deformities in a baby. The goats may have been eating a lupine species that contained the teratogenic chemical anagryne, which was passed through the woman when she drank goat's milk during pregnancy.

References:

Keeler, R. F. 1989. Quinolizidine alkaloids in range and grain lupins. Pages 133-167 in Cheeke, P. R., ed. Toxicants of plant origin. Vol. I. Alkaloids. CRC Press, Inc., Boca Raton, Fla., USA. 335 pp.

Sheep

General symptoms of poisoning:

[breathing, labored](#)

[coma](#)

[convulsions](#)

[death by asphyxiation](#)

[depression](#)

[dyspnea](#)

Notes on poisoning:

Symptoms of lupine ingestion in sheep include labored breathing, depression, coma (often with snoring), and death from asphyxiation. Tremors and convulsions may occur. The animal may butt other sheep or stand leaning against an object. Teeth

grinding and frothing have been observed. Sheep consume lupine more readily than do other livestock and are therefore the major species susceptible to lupine toxicity. Ingesting seeds equal to 0.25-0.5% of body weight can cause poisoning (Keeler 1964).

Canadian Biodiversity Information Facility

Notes on poisoning: *Mangifera indica*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Mango (*Mangifera indica*) is a tropical fruit that is seasonally available in Canadian food stores. The skin of the fruit and the petiole, by which the fruit is attached to the stem, contain oleoresins. These chemicals are cross-reactive to the catechols contained in poison-ivy plants and in other members of *Rhus* species that cause dermatitis. Humans who are sensitized and develop dermatitis from these plants should be cautious about touching the skin of mangoes. The shells of cashews (*Anacardium occidentale*) are also cross-reactive with catechols of *Rhus* species. However, cashews shells are removed before the nuts are sold in Canada (Kingsbury 1964, Geller 1989).

Notes on poisoning: *Medicago sativa*

[Introduction](#)[Interactive](#)[All poisonous plants by
Botanical name](#)[All poisonous plants by
Common name](#)[Important WWW Poisonous
Plants sites](#)

General poisoning notes:

Alfalfa (*Medicago sativa*) is an important forage and silage crop in Canada. However, under some circumstances, alfalfa can cause a variety of different toxic problems. Ingesting rapidly growing alfalfa at the vegetative to mid-bud stage can cause bloat in cattle and sheep (Hall and Majak 1989). Alfalfa has also caused photosensitization in cattle with white skin (MacDonald 1954). Alfalfa contains phytoestrogens which cause infertility in animals, including cattle and sheep. These compounds are also contained in some alfalfa pills that are found in health food stores, and these may cause problems in some cases (Cheeke and Schull 1985). Alfalfa also contains saponins that can interfere with the growth of poultry and thus reduce egg-laying (Fuller and McClintock 1986, Oakenfull and Sidhu 1989). Low saponin cultivars have been developed.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[bloat](#)
[infertility](#)

Notes on poisoning:

Cattle are especially susceptible to bloat after ingesting rapidly growing alfalfa in the vegetative to mid-bud stage of growth. The formation of stable foam bubbles is recognized as being affected by the concentration of cytoplasmic proteins, which is in turn affected by rumen pH, and the colloidal suspension of chloroplast particles from the plant; the stability is controlled by ion concentration (Hall and Majak 1989). Alfalfa also contains phytoestrogens, which have caused infertility problems in dairy cattle because of cystic ovaries and irregular estrous cycles. Precocious development of mammary glands also occurs, as well as genital

formation in heifers. The coumestan chemicals suppress estrous and inhibit ovulation (Cheeke and Schull 1985, Adams 1989).

[infertility](#)

Notes on poisoning:

Alfalfa tablets are available in health food stores as a dietary supplement for humans. The benefits of the tablets are not clear. Measurements of the phytoestrogen content of some commercial brands have ranged from 20 to 190 ppm. This level of intake, in conjunction with other sources of estrogen (such as birth control pills and estrogen replacement therapy), may be potentially harmful (Cheeke and Schull 1985).

Notes on poisoning: *Melilotus alba*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

White sweet-clover (*Melilotus alba*) is a cultivated and naturalized plant that occurs as a weed across most of Canada. This plant contains a glycoside with a coumarin fraction. When sweet-clover is harvested for feed, the succulent stems usually mold before drying. The molds metabolize the glycoside into dicoumarol, which interrupts vitamin K activation of prothrombin, necessary in blood clotting. Levels of dicoumarol at more than 10 ppm are suspected of possible poisoning. Dicoumarol levels are usually higher in small and round bales than in stacks. Cattle, horses, and sheep have been poisoned. However, cattle are almost exclusively poisoned by sweet-clover (Blakely 1985, Cheeke and Schull 1985).

Melilotus alba:

Images: images.google.com

Notes on Poisonous plant parts:

Moldy sweet-clover is produced through insufficient drying of bales and silage. Dicoumarol production by molds is not likely to occur if animals ingest living plants.

Toxic parts:

leaves
stems

References:

Cheeke, P. R., Shull, L. R. 1985. Natural toxicants in feeds and poisonous plants. AVI Publishing Company, Inc., Westport, Conn., USA. 492 pp.

Notes on Toxic plant chemicals:

A glycoside, melilotoside, contains an ether and coumarin. The coumarin is metabolized by various molds (e.g., *Penicillium* spp.) into dicoumarol. Dicoumarol inhibits vitamin K, which causes hemorrhaging. Sweet-clover has a succulent stem, which makes molding common after cutting. Round bales have been found to have significantly higher dicoumarol (mean of 22.9 +/- 3.10 mg/kg) than stacks of silage (means 1.8 of +/- 6.3 and 0.6 +/- 2.1 mg/kg). The outer parts of round bales had a higher concentration of dicoumarol (Benson et al. 1981, Cheeke and Schull 1985).

Toxic plant chemicals:

dicoumarol

melilotoside

Chemical diagram(s) are courtesy of [Ruth McDiarmid](#), Biochemistry Technician, Kamloops Range Station, Agriculture and Agri-Food Canada, Kamloops, British Columbia, Canada.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[abortion](#)

[anemia](#)

[heart rate, elevated](#)

[hemorrhage](#)

Notes on poisoning:

Symptoms of moldy sweet-clover poisoning may appear without any obvious cause. Trauma and surgery are often followed by severe hemorrhage and death. Hemorrhage may result after uncomplicated parturition. Newborn calves may die during the first few days of life if their dams have been fed on toxic feed. In Saskatchewan 286 animals from 56 herds were affected in 1983. The mortality rate was

12.1%. Aborted fetuses and calves less than 2 weeks old were affected most often. Poisoning usually occurred between January to April. Sweet-clover fed as bales was more of a problem than when fed as silage (Radostits et al. 1980, Blakely 1985). Treatment using vitamin K1 was effective at dosages of 1.1-3.3 mg/kg of body weight after poisoning by sweet-clover containing dicoumarol at a minimum of 90 ppm. Vitamin K3 was ineffective as treatment (Alstad et al. 1985).

References:

Alstad, A. D., Casper, H. H., Johnson, L. J. 1985. Vitamin K treatment of sweet clover poisoning in calves. J. Am. Vet. Med. Assoc., 187: 729-731.

Radostits, O. M., Searcy, G. P., Mitchall, K. G. 1980. Moldy sweetclover poisoning in cattle. Can. Vet. J., 21: 155-158.

Horses

General symptoms of poisoning:

[anemia](#)

[hemorrhage](#)

Notes on poisoning:

In one case in Saskatchewan, a Percheron mare was anemic and was hemorrhaging from the left nostril at 60 drops per min. Mucous membranes were blanched. Subcutaneous edema extended from the intermandibular space to the pectoral region. The animal was treated with an injection of 4.2 g of menadione sodium bisulphate and with 4 L of whole blood preserved in acid citrate dextrose solution. Complete recovery resulted. The mare had been fed weathered sweet-clover hay free-choice with access to pasture (McDonald 1980).

Canadian Biodiversity Information Facility

Notes on poisoning: *Menziesia ferruginea*

[Introduction](#)[Interactive](#)[All poisonous plants by
Botanical name](#)[All poisonous plants by
Common name](#)[Important WWW Poisonous
Plants sites](#)

General poisoning notes:

Western minniebush (*Menziesia ferruginea*) is a native shrub found in western Canada. This plant has occasionally been implicated in cases of sheep poisoning. Feeding experiments have shown that it does cause poisoning in sheep. It is considered less toxic than some other members of the heath family, such as *Kalmia* spp. and *Rhododendron* spp. (Marsh 1914, Kingsbury 1964).

References:

Kingsbury, J. M. 1964. Poisonous plants of the United States and Canada. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Humans

General symptoms of poisoning:

[aphonia](#)

[blistering](#)

[hoarseness](#)

[mouth, irritation of](#)

[urticaria](#)

Notes on poisoning:

Chewing the leaf causes severe pain and irritation, along with blistering and edema of mouth tissue. Hoarseness and loss of voice can also occur. The insoluble oxalates do not cause systemic poisoning in humans (Lampe and McCann 1985). Ingesting the ripened fruit can cause rapidly developing urticaria (hives) in sensitive individuals (Mitchell and Rook 1979). The ripe fruit is edible but is not normally produced indoors in Canada.

Notes on poisoning: *Narcissus poeticus*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Narcissus (*Narcissus poeticus*) is an ornamental bulb that is planted outdoors as a perennial and is occasionally used indoors as a winter forced flower. This plant contains allergens in the aboveground plant parts, which cause dermatitis in sensitive humans. Ingesting the bulbs can cause poisoning in humans and has also poisoned some cattle. Family pets could be at risk if they ingest quantities of this plant. Serious cases of poisoning are rare. Humans have been poisoned only when the bulbs were mistaken for onions (Mitchell and Rook 1979, Litovitz and Fahey 1982, Cooper and Johnson 1984). See notes under daffodil ([Narcissus pseudonarcissus](#)) for more information.

Toxic plant chemicals:

lycorine

References:

Lampe, K. F., McCann, M. A. 1985. AMA Handbook of poisonous and injurious plants. American Medical Assoc. Chicago, Ill., USA. 432 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[convulsions](#)

[drowsiness](#)

[gastroenteritis](#)

Notes on poisoning:

During World War II, cattle were fed daffodil bulbs because of scarce feed. They developed seizures, sedation, hypotension, and gastrointestinal and hepatic degeneration. Animal poisoning is more

severe than human poisoning because humans develop rapid emesis (Litovitz and Fahey 1982, Cooper and Johnson 1984).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Litovitz, T. L., Fahey, B. A. 1982. Please don't eat the daffodils. N. Eng. J. Med., 306: 547.

Humans

General symptoms of poisoning:

[abdominal pains](#)

[conjunctivitis](#)

[diarrhea](#)

[dizziness](#)

[dyspnea](#)

[eczema](#)

[erythema](#)

[hoarseness](#)

[itchiness](#)

[nausea](#)

[vomiting](#)

Notes on poisoning:

Ingesting daffodil bulbs produces the following symptoms: abdominal pains, vomiting, nausea, lightheadedness, shivering, and sometimes diarrhea. Because emesis is rapid, more severe symptoms do not usually occur. Ingesting bulbs is rare (Litovitz and Fahey 1982, Lampe and McCann 1985).

References:

Canadian Biodiversity Information Facility

Notes on poisoning: *Nerium oleander*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Oleander (*Nerium oleander*) is an ornamental indoor shrub found in Canadian homes and offices. This plant is quite toxic if the leaves or stems are ingested. Humans have died after eating meat that was skewered with oleander stems. Ingesting a single leaf may be toxic to a person. The dry leaves remain toxic. Cattle, horses, and sheep have been poisoned experimentally (Wilson 1909, Kingsbury 1964). Livestock are not likely to have access to oleander in Canada. Children and family pets should be prevented from ingesting green or dry leaves, chewing stems, or sucking the nectar from flowers.

all parts
flowers
leaves
stems
young shoots

References:

Fuller, T. C., McClintock, E. 1986. Poisonous plants of California. Univ. California Press, Berkeley, Calif., USA. 432 pp.

Notes on Toxic plant chemicals:

Oleandrin, a cardiac glycoside, is found throughout the plant, including the nectar of the flowers. Smoke from burning twigs is said to be toxic (Fuller and McClintock 1986).

Toxic plant chemicals:

oleandrin

References:

Fuller, T. C., McClintock, E. 1986. Poisonous plants of California. Univ. California Press, Berkeley, Calif., USA. 432 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[breathing, rapid](#)

[death](#)

[heart rate, elevated](#)

[mouth, irritation of](#)

[pupil dilation](#)

Notes on poisoning:

Experimental poisoning of cattle has shown symptoms that include elevated breathing and heart rate. If a large dose is given, the heart action becomes so low that a pulse is almost undetectable. Green leaves at a rate of as little as 0.005% of a cow's body weight can cause death (Wilson 1909, Kingsbury 1964).

References:

Kingsbury, J. M. 1964. Poisonous plants of the United States and Canada. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.

Wilson, F. W. 1909. Oleander poisoning of livestock. Univ. Ariz. Agric. Exp. Stn. Bull., 59. 383-397 pp.

Horses

General symptoms of poisoning:

[breathing, rapid](#)

[death](#)

[mouth, irritation of](#)

[pupil dilation](#)

Notes on poisoning:

Experimental poisoning of horses with fresh oleander leaves resulted in toxic symptoms, including elevated breathing and pulse, greenish feces, some abdominal pain, cold extremities, and a swollen and irritated mouth and tongue. A dose of green leaves equal to 0.005% of a horse's body weight is sufficient to kill a horse (Wilson 1909, Kingsbury 1964).

References:

Kingsbury, J. M. 1964. Poisonous plants of the United States and Canada. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.

Wilson, F. W. 1909. Oleander poisoning of livestock. Univ. Ariz. Agric. Exp. Stn. Bull., 59. 383-397 pp.

Humans

General symptoms of poisoning:

[abdominal pains](#)

[coma](#)

[death](#)

[diarrhea](#)

[dizziness](#)

[drowsiness](#)

[dyspnea](#)

[mouth, irritation of](#)

[nausea](#)

Notes on poisoning:

Humans have been poisoned from using the twigs of oleander to skewer meat or roast frankfurters. Ingesting a single green or dry leaf may cause poisoning. Symptoms include dizziness, abdominal pain, vomiting, unconsciousness, bloody stools, and light and rapid pulse. Death has occurred in some cases. Symptoms occur several hours after ingesting a toxic dose (Wilson 1909, Kingsbury 1964).

References:

Kingsbury, J. M. 1964. Poisonous plants of the United States and Canada. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.

Wilson, F. W. 1909. Oleander poisoning of livestock. Univ. Ariz. Agric. Exp. Stn. Bull., 59. 383-397 pp.

Sheep

General symptoms of poisoning:

[breathing, rapid](#)

[death](#)

[mouth, irritation of](#)

Notes on poisoning:

Experimental feeding of green oleander leaves has caused elevated breathing, partial unconsciousness, sore mouth and nostrils, discolored mucous membranes, and death (dose: 0.015% body weight of green leaves). Cold extremities and gastroenteritis also occur (Wilson 1909, Kingsbury 1964).

References:

Kingsbury, J. M. 1964. Poisonous plants of the United States and Canada. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.

Canadian Biodiversity Information Facility

Notes on poisoning: *Nicotiana tabacum*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Tobacco (*Nicotiana tabacum*) is cultivated in some areas of Canada as a commercial crop for the tobacco industry.

Teratogenic problems have occurred in the United States when pregnant swine were allowed to forage on tobacco stalks. The sows showed no toxic signs. Pregnant swine should be denied access to tobacco plants. Rare cases of human dermatitis from contact with tobacco leaves have been reported (Bush and Crowe 1989, Gonçalves et al. 1990).

References:

Bush, L. P., Crowe, M. W. 1989. *Nicotiana* alkaloids. Pages 87-107 in Cheeke, P. R., ed. Toxicants of plant origin. Vol. I. Alkaloids. CRC Press, Inc., Boca Raton, Fla., USA. 335 pp.

Crowe, M. W., Swerczek, T. W. 1974. Congenital arthrogryposis in offspring of sows fed tobacco (*Nicotiana tabacum*). *Am. J. Vet. Res.*, 35: 1071-1073.

Image or illustration

Nicotiana tabacum:

Images: images.google.com

Notes on Poisonous plant parts:

The left-over stalks of tobacco plants that remain in the field have caused teratogenic problems. Problems are related to high-yield tobacco crops where heavy fertilization produces yields of dry leaf that exceed 1300 kg/0.40 ha. Experimental feeding of

aqueous filtrate of the leaves and juice of tobacco stalks has also caused teratogenic problems in swine (Crowe and Swerczek 1974).

Toxic parts:

leaves
stems

References:

Crowe, M. W., Swerczek, T. W. 1974. Congenital arthrogryposis in offspring of sows fed tobacco (*Nicotiana tabacum*). Am. J. Vet. Res., 35: 1071-1073.

Notes on Toxic plant chemicals:

Pyridine alkaloids such as anabasine, anatabine, and perhaps anabasine, are responsible for teratogenic problems in swine. Anabasine is the major alkaloid of related *Nicotiana glauca*, in the southern United States, and it has caused teratogenic problems in calves, sheep, and swine. However, anabasine is found in much smaller quantities in tobacco. Anatabine and perhaps anabaseine are therefore believed to be involved in the teratogenic effects on swine (Bush and Crowe 1989).

Toxic plant chemicals:

anabasine
anatabine

References:

Bush, L. P., Crowe, M. W. 1989. *Nicotiana* alkaloids. Pages 87-107 in Cheeke, P. R., ed. Toxicants of plant origin. Vol. I. Alkaloids. CRC Press, Inc., Boca Raton, Fla., USA. 335 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Humans

General symptoms of poisoning:

[eczema](#)

Notes on poisoning: *Onoclea sensibilis*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Sensitive fern (*Onoclea sensibilis*) is a native plant that is found through eastern Canada into Manitoba. The plant, often abundant in low, wet areas, has been implicated in the poisoning and death of horses in field cases. Only one set of experimental poisonings has been undertaken, but the resulting symptoms were similar when horses were fed hay containing sensitive fern (Waller et al. 1944).

References:

Waller, E. F., Prince, F. S., Hodgson, A. R., Colovos, N. F. 1944. Sensitive-fern poisoning of horses. Univ. N. H. Agric. Stn. Tech. Bull., 83. 7 pp.

Nomenclature:

Scientific Name: *Onoclea sensibilis* L.

Vernacular name(s): sensitive fern

Scientific family name: *Polypodiaceae*

Vernacular family name: ffern

Go to ITIS^{*ca} for more taxonomic information on: [Onoclea sensibilis](#)

Image or illustration

Onoclea sensibilis:

Images: images.google.com

Notes on Poisonous plant parts:

When the fronds (aboveground leaves) are included in hay, they produce toxic symptoms in horses. The fertile fronds (spore-bearing stalks) are also included in hay. A literature search did not reveal any reports on the toxin, nor was the plant organ that contains the toxin identified.

Toxic parts:

leaves

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Horses

General symptoms of poisoning:

[brain, congestion of](#)

[colic](#)

[death](#)

[falling down](#)

[gait, unsteady](#)

[icterus](#)

[incoordination](#)

Notes on poisoning:

Ingesting hay containing sensitive fern produces the following symptoms: difficulty in eating, falling down, walking as if blind, rubbing against objects, and death. Postmortem examination showed extreme icterus, swollen liver, paralysis of the alimentary tract, and brain edema. Old horses are more affected than younger ones. Horses that are worked and are fed a grain supplement, in addition to hay that includes the fern, are not affected. Recovery may occur if the horses are given good hay and grain before serious nervous symptoms develop (Waller et al. 1944).

Notes on poisoning: *Ornithogalum umbellatum*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Star-of-Bethlehem (*Ornithogalum umbellatum*), an outdoor ornamental flower, contains glycosides similar to digitalis. In some countries children have been poisoned after ingesting the flowers or bulbs. Ingesting two bulbs by an adult caused shortness of breath. The bulbs contain the highest quantity of these toxins. Cattle in South Africa (the native region for star-of-Bethlehem) have been poisoned, resulting in permanent blindness and death after ingestion. Children and family pets should be prevented from ingesting material from this plant (Cooper and Johnson 1984, Lampe and McCann 1985, Spoerke and Smolinske 1990).

Notes on poisoning: *Oxytropis lambertii*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Purple locoweed (*Oxytropis lambertii*) is found in the southern parts of Manitoba and Saskatchewan. This species can cause locoism, a chronic disease that results after long-term grazing. The plant contains swainsonine, an alkaloid, which results in cellular dysfunction through a long biological process. Affected animals show nervous system impairment, with symptoms such as dullness and excitement, as well as immune system impairment. Abortion and congenital birth deformities may occur. Animals affected include cattle, horses, and sheep. Animals may become habituated to locoweed. Death can result (James 1983, Cheeke and Schull 1985).

Canadian Biodiversity Information Facility

Notes on poisoning: *Oxytropis sericea*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Locoweed (*Oxytropis sericea*) is a native herb in western Canada. This plant has caused a number of problems in cattle, horses, and sheep. Swainsonine, an indolizidine alkaloid, inhibits alpha-mannosidase in animal bodies, which can lead to disruption of cellular function. Locoism is a chronic disease that causes depression, incoordination, and nervousness under stress. Death can result. The cellular problems occur most readily in tissues of the nervous system. Pregnant animals often abort or give birth to young with congenital deformities. Congestive right heart disease occurs at high altitudes (above 2190 m) in cattle. Right ventricular hypertrophy and dilation, subcutaneous edema, and pulmonary hypertension are significant symptoms (James 1983, Cheeke and Schull 1985, James et al. 1986, Panter et al. 1988).

Ralphs, M. H., James, L. F., Nielsen, D. B., Panter, K. E. 1984. Management practices reduce cattle loss to locoweed on high mountain range. Rangelands, 6: 175-177.

Ralphs, M. H., James, L. F., Pfister, J. A. 1986. Utilization of white locoweed (*Oxytropis sericea* Nutt.) by range cattle. J. Range Manage., 39: 344-347.

Notes on Toxic plant chemicals:

Swainsonine, an indolizidine alkaloid, inhibits alpha-mannosidase in the animal's body. Inhibition results in the accumulation of oligosaccharides in cells because glycosidases remove their respective sugars until a mannose residue is reached. Hydrolysis of the carbohydrate then stops. Eventually disruption of cellular function results. The effect of swainsonine on alpha-mannosidase is reversible when locoweed is no longer consumed. However, advanced clinical signs are irreversible because axon degeneration occurs. The central nervous system is most sensitive to mannose accumulation (Cheeke and Schull 1985).

Toxic plant chemicals:

slaframine

swainsonine

Notes on poisoning: *Papaver nudicaule*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Iceland poppy (*Papaver nudicaule*) is an ornamental outdoor plant that occasionally escapes from cultivation. The plant contains alkaloids that may cause problems in animals that ingest it. Horses, cattle, and sheep were poisoned when discarded plants were given to livestock (Cooper and Johnson 1984).

Notes on poisoning: *Papaver orientale*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Oriental poppy (*Papaver orientale*) is a perennial ornamental herb that is commonly planted in flower beds. This plant contains some alkaloidal chemicals that may be physiologically active in animals, but no cases of poisoning have occurred under natural conditions. During fall and spring clean-up, all old flower heads and pods should be picked up so that they are not left for animals to eat (Kingsbury 1964).

Canadian Biodiversity Information Facility

Notes on poisoning: *Papaver somniferum*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Opium poppy (*Papaver somniferum*) is an ornamental flower that can still be found around some older homes. The plant persists by setting seed each year. This plant is the source of pharmacological and recreational drugs, as well as the poppy seeds that are used for oil and as a condiment on bagels, cakes, and other foods. Cattle have been poisoned in Europe after ingesting either stalks with pods that were being discarded or seed residue left over from oil extraction. Humans are either poisoned or addicted by various contained and derived chemicals found in the opium poppy (Frohne and Pfander 1983, Cooper and Johnson 1984). It is important to note that poppy seeds sold in stores are harmless, as the toxins have been destroyed by heat (Fuller and McClintock 1986).

Notes on poisoning: Parthenocissus quinquefolia

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Virginia creeper (*Parthenocissus quinquefolia*) is a native climbing vine found in eastern Canada. It is also used as an ornamental climber on trellises and building walls. Children who ingested berries and leaves have reportedly been poisoned and have died. Some authors view these reports as circumstantial. However, this plant should be considered as potentially toxic if ingested (Warren 1912, Kingsbury 1964, Fuller and McClintock 1986).

References:

- Fuller, T. C., McClintock, E. 1986. Poisonous plants of California. Univ. California Press, Berkeley, Calif., USA. 432 pp.
- Kingsbury, J. M. 1964. Poisonous plants of the United States and Canada. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.
- Warren, L. E. 1912. A note on the poisonous properties of *Parthenocissus quinquefolia*. Merck's Rep., 21: 123.

Nomenclature:

Scientific Name: *Parthenocissus quinquefolia* (L.) Planch.

Vernacular name(s): Virginia creeper

Scientific family name: *Vitaceae*

Vernacular family name: grape

Go to ITIS*^{ca} for more taxonomic information on: [Parthenocissus quinquefolia](#)

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Humans

General symptoms of poisoning:

[death](#)

[tenesmus](#)

[vomiting](#)

Notes on poisoning:

Cases have been reported of illness and death resulting after berries of Virginia creeper were ingested. In another case, two children became ill after swallowing the juice from chewed leaves. Symptoms included vomiting, purging, and tenesmus. The children collapsed and were in stupor for 2 h. A dozen ripe berries were fed to a guinea pig, which died within 36 h (Warren 1912). Modern reports view these cases as circumstantial. The amounts of oxalate contained in the plant is usually not significant (Kingsbury 1964, Fuller and McClintock 1986).

Canadian Biodiversity Information Facility

Notes on poisoning: *Pastinaca sativa*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Parsnip (*Pastinaca sativa*) is a cultivated and a naturalized herb in much of Canada. The plant juices can cause photodermatitis in some individuals after exposure to sunlight. Exposure to leaves, stems, and peeling roots can cause the problem. The edible roots contain enough furocoumarins to be physiologically active in some cases. These toxins are mutagenic (even in the dark) inducing melanization in human skin. Photodermatitis from this plant is often confused with poison-ivy dermatitis (Mitchell and Rook 1979, Ivie et al. 1981).

References:

Ivie, G. W., Holt, D. L., Ivey, M. C. 1981. Natural toxicants in human foods: psoralens in raw and cooked parsnip root. *Science* (Wash D. C.), 213: 909-910.

Mitchell, J. C., Rook, A. 1979. *Botanical dermatology*. Greenglass Ltd, Vancouver, B.C., Canada. 787 pp.

Nomenclature:

Scientific Name: *Pastinaca sativa* L.

Vernacular name(s): wild parsnip

Scientific family name: *Umbelliferae*

Vernacular family name: parsley

Go to ITIS^{*ca} for more taxonomic information on: [Pastinaca sativa](#)

Image or illustration

Pastinaca sativa:

Images: images.google.com

Notes on Poisonous plant parts:

Exposure to the plant juices in the leaves, stems, or roots can result in dermatitis caused by phototoxic furocoumarins. Wetness of the skin accentuates the results. Ingesting large quantities of parsnip root may expose people to sufficient quantities of psoralens to have physiological effects. Parsnips produce much higher concentrations of these toxins in response to disease infection (Mitchell and Rook 1979, Ivie et al. 1981).

Toxic parts:

plant juices

roots

References:

Ivie, G. W., Holt, D. L., Ivey, M. C. 1981. Natural toxicants in human foods: psoralens in raw and cooked parsnip root. *Science* (Wash D. C.), 213: 909-910.

Mitchell, J. C., Rook, A. 1979. *Botanical dermatology*. Greenglass Ltd, Vancouver, B.C., Canada. 787 pp.

Notes on Toxic plant chemicals:

Three furocoumarins (psoralen, xanthotoxin, bergapten) are found in parsnip roots. These chemicals are phototoxic, mutagenic, and photo-carcinogenic. The cumulative concentration is about 40 ppm. Consumption of 0.1 kg of parsnip could expose a person to 4-5 mg of psoralens, a level that may cause some physiological effects. These chemicals are potent photosensitizers and are highly mutagenic in long-wavelength ultraviolet light (Ivie et al. 1981).

Notes on poisoning: *Persea americana*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Avocado (*Persea americana*) is a common exotic fruit. The seeds are often planted to produce foliage plants in households. In California, Guatemalan cultivars have caused toxic affects in cattle, goats, rabbits, canaries, and fish. Family pets should be prevented from ingesting the leaves. The seeds have caused toxicity and death in canaries and have experimentally poisoned mice. Leaves should not be allowed to fall accidentally into fish tanks (Hurt 1943, Fuller and McClintock 1986).

Notes on poisoning: *Phacelia campanularia*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

California bluebell (*Phacelia campanularia*) has been found near Fort Saskatchewan, Alta., where it was probably introduced. This plant causes dermatitis that is similar to poison-ivy dermatitis. The plants in Alberta have caused at least one case of dermatitis (Hardwick, personal communication). If these plants expand their range, more people may develop dermatitis (Munz 1965, Mitchell and Rook 1979).

Notes on poisoning: *Phalaris arundinacea*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Reed canarygrass (*Phalaris arundinacea*) is cultivated and has also escaped across much of southern Canada. The plant grows well in poorly drained soils subject to prolonged flooding. The plant has caused animal performance lower than the nutritional composition of the plant suggests. Sheep in New Zealand exhibited Phalaris staggers, which includes distress, convulsions, and death. No cases of this have been reported in North America (Majak et al. 1979, Cheeke and Schull 1985).

Notes on Toxic plant chemicals:

Several indole alkaloids are found in reed canarygrass, including hordenine, gramine and 5-methoxy-N-methyltryptamine. Other indole alkaloids were also found. In the interior of British Columbia the concentration of the latter two was found to increase towards the end of the growing season. Differences were also found in various cultivars. Cultural practices and environmental factors such as moisture stress may also increase the amount of alkaloids (Majak et al. 1979, Corcuera 1989).

Notes on poisoning: *Philodendron scandens*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Heart-leaved philodendron (*Philodendron scandens*) is an ornamental. Chewing the leaves of philodendrons results in painful burning and swelling of the mouth parts because of the oxalates. Contact dermatitis also occurs (Lampe and McCann 1985). A recent survey showed that even though 67% of 188 cases involved philodendrons, only one case developed minor symptoms (Mrvos et al. 1990). McIntire et al. (1990) describe the death of an infant after it had ingested a philodendron. The child had ulceration of lips and tongue as well as esophageal erosion. Death was caused by cardiac arrest secondary to vagotonia resulting from esophageal erosions. Family pets can also exhibit signs of toxicity if they chew on leaves of philodendrons. Hanna (1986) lists several symptoms attributable to ingestion of these plants by pets. However, Sellers et al. (1977) conducted laboratory feeding studies on cats and concluded that signs of acute toxicity were not found upon necropsy, even when large quantities of leaves were ingested. Experimental work on mice and rats showed that death occurred when the rodents were given extracts from leaves and stems (Der Marderosian et al. 1976).

Notes on poisoning: *Phoradendron flavescens*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

American mistletoe (*Phoradendron flavescens*) is the familiar mistletoe of Christmas. Ingesting a large number of the berries or tea made from the berries has led to poisoning and death in humans. Mistletoe, used as decorations at Christmas, should be kept out of the reach of children and family pets (Kingsbury 1964, Fuller and McClintock 1986).

Phoradendron flavescens:

Images: images.google.com

Toxic parts:

all parts
leaves
mature fruit

References:

Fuller, T. C., McClintock, E. 1986. Poisonous plants of California. Univ. California Press, Berkeley, Calif., USA. 432 pp.

Notes on Toxic plant chemicals:

American mistletoe contains two amines, beta-phenylethylamine and tyramine, as well as a lectin, phoratoxin. These chemicals are probably responsible for toxic reactions after ingestion (Fuller

and McClintock 1986).

Toxic plant chemicals:

beta-phenylethylamine

phoratoxin

tryamine

References:

Fuller, T. C., McClintock, E. 1986. Poisonous plants of California. Univ. California Press, Berkeley, Calif., USA. 432 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Humans

General symptoms of poisoning:

[cardiac arrest](#)

[death](#)

[gastroenteritis](#)

Notes on poisoning:

Ingesting a few berries causes abdominal pain and diarrhea. Tea made from the berries caused death about 10 h after symptoms of acute gastroenteritis, followed by cardiovascular collapse. Plant material has slowed the heartbeat in a way similar to digitalis (Kingsbury 1964, Fuller and McClintock 1986).

Notes on poisoning: *Phytolacca americana*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Pokeweed (*Phytolacca americana*) is a native herb found in the southwestern parts of Ontario and Quebec. The young shoots are used as poke salad and the leaves as a folk medicine or tea. In both cases, the plant material should be boiled at least twice to get rid of the toxin, according to literature reports. Failure to do so has caused poisoning in humans. Ingesting a few berries does not cause problems, but larger quantities, if uncooked, can be toxic to humans. Cattle, horses, sheep, and particularly swine, have been poisoned by ingesting pokeweed plant material. The berries have poisoned young turkeys experimentally (Patterson 1929, Barnett 1975, Callahan et al. 1981, Cooper and Johnson 1984).

Image or illustration

Phytolacca americana:

Images: images.google.com

Notes on Poisonous plant parts:

Leaves, young shoots, and roots are poisonous. The berries are considered relatively nontoxic to humans, although toxicity to animals and humans has been reported. Barnett (1974) describes experimental poisoning and death in turkey poults.

Toxic parts:

all parts
leaves
mature fruit
roots
stems
young shoots

References:

- Barnett, B. D. 1975. Toxicity of pokeberries (fruit of *Phytolacca americana* Large) for turkey poults. *Poult. Sci.*, 54: 1215-1217.

- Stein, Z. L. 1979. Pokeweed-induced gastroenteritis. *Am. J. Hosp. Pharm.*, 36: 1303.

Notes on Toxic plant chemicals:

Phytolaccatoxin, a triterpene saponin, has been implicated in pokeweed toxicity. The toxin is water-soluble, which has led to the common assumption that boiling the plant material twice will get rid of toxicity. Such treatment is usually sufficient to remove the toxin (Lampe and McCann 1985).

Toxic plant chemicals:

phytolaccatoxin

phytolaccigenin

[diarrhea](#)

[gastroenteritis](#)

[salivation](#)

[vomiting](#)

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Humans

General symptoms of poisoning:

[abdominal pains](#)

[blood pressure, low](#)

[breathing, rapid](#)

[confusion](#)

[diarrhea](#)

[dizziness](#)

[gastroenteritis](#)
[headache](#)
[heart rate, elevated](#)
[nausea](#)
[salivation](#)
[stomach cramps](#)
[stool, bloody](#)
[sweating](#)
[thirsty](#)
[trembling](#)
[unconsciousness](#)
[urinary incontinence](#)
[vomiting](#)
[weakness](#)

Notes on poisoning:

Symptoms of toxicity include sweating, bloody diarrhea, abdominal pains, weakness, incontinence, vomiting, salivation, unconsciousness, tremors, and blurred vision. Ingesting the leaves or young shoots causes toxicity. Sometimes tea made from the leaves can cause poisoning. Symptomatic treatment and replacement of fluids are recommended (Callahan et al. 1981, Jaeckle and Freemon 1981).

References:

Callahan, R., Piccola, F., Gensheimer, K., Parkin, W. E., Prusakowski, J., Scheiber, G., Henry, S. 1981. Epidemiologic notes and reports. Plant poisonings - New Jersey. U.S. Dep. Health Hum. M. M. W. R., 30: 65-67.

Lewis, W. H., Smith, P. R. 1979. Poke root herbal tea poisoning. J. Am. Med. Assoc., 242: 2759-2760.

Stein, Z. L. 1979. Pokeweed-induced gastroenteritis. Am. J. Hosp. Pharm., 36: 1303.

Sheep

General symptoms of poisoning:

[diarrhea](#)
[drowsiness](#)
[gastroenteritis](#)

[vomiting](#)

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Swine

General symptoms of poisoning:

[death](#)

[gait, unsteady](#)

[gastroenteritis](#)

[liver, congestion of](#)

[muscle twitching](#)

[paralysis, posterior](#)

Notes on poisoning:

Swine are most frequently poisoned by pokeweed. Symptoms include staggering, vomiting, posterior paralysis, tremors, and death. Post-mortem findings show swollen, dark liver and severe hemorrhagic gastritis (Patterson 1929).

References:

Patterson, F. D. 1929. Pokeweed causes heavy losses in swine herd. Vet. Med. Small Anim. Clin., 24: 114.

Turkeys

General symptoms of poisoning:

[ascites](#)

[gall bladder, enlarged](#)

[hock, swollen](#)

[weight gain, reduced](#)

Notes on poisoning:

Experimental feeding of mashed berries to turkey poults caused weight-gain reduction, ascites, and swollen hocks, causing unsteadiness. Enlarged gall bladder filled with brown fluid was common in dead birds. Wild birds ingest the berries and spread seeds; no toxic cases have been mentioned. Chickens are not poisoned by the berries (Barnett 1975, Cooper and Johnson 1984).

Notes on poisoning: *Pinus ponderosa*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Ponderosa pine (*Pinus ponderosa*) is a native tree in British Columbia. Pregnant cows that ingest the needles abort within 2 days to 2 weeks. Calves near full term may be born in good condition. Cows in the third trimester are affected; the problem usually occurs during winter and spring, when forage is scarce. Cows may retain the placenta. If medical attention is not given, a high degree of fatality can occur. Annual losses in the entire western United States have been estimated at 4.5 million dollars. This problem has also occurred in British Columbia (MacDonald 1952, Stevenson et al. 1972, Gartner et al. 1988, Lacey et al. 1988).

Notes on Toxic plant chemicals:

Although no chemical has been proved to cause toxicity and abortion in cattle, several toxic compounds have been suspected, including diterpene resin acids. Additional factors such as stage of gestation when ingestion occurs, environmental stress, and condition of the cow compound the problem. Inducting experimental abortion has not been consistent (Gartner et al. 1988).

Canadian Biodiversity Information Facility

Notes on poisoning: *Podophyllum peltatum*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

May-apple (*Podophyllum peltatum*) is a native herb of moist woods in parts of southeastern Canada. May-apple extracts have been used in folk medicine and pharmaceuticals. Misuse has caused toxic reactions and even fatalities. Workers in the extraction process have developed dermatitis. Ingesting the ripe fruit may, at worst, cause catharsis. Cattle, sheep, and swine have been poisoned after ingesting may-apple vegetation (McIntosh 1928, Rosenstein et al. 1976).

References:

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[agitation](#)

[lacrimation, severe](#)

[pupil dilation](#)

[salivation](#)

Notes on poisoning:

A cow in Ontario experienced toxic symptoms after ingesting may-apple. The symptoms included salivation, moaning, excitation, swollen eyes and muzzle, lacrimation, pupil dilation, and congestion of all visible mucous membranes (McIntosh 1928).

References:

McIntosh, R. A. 1928. May apple poisoning in a cow. Ont. Vet. Coll. Rep., 29: 18-20.

Humans

General symptoms of poisoning:

[catharsis](#)

[coma](#)

[confusion](#)

[conjunctivitis](#)

[death](#)

[erythema](#)

[gastroenteritis](#)

[vomiting](#)

Notes on poisoning:

In humans most cases of poisoning from May-apple have resulted from the use or handling of the pharmaceutical extracts from the plant. Because of its irritant qualities, may-apple has been used topically to remove papilloma and warts. It has also been used as an abortifacient, as shown experimentally with mice and rabbits. The use of these extracts as a laxative in pregnancy has been discouraged. The extracts have been shown to have an antimitotic capacity. In a case of suicide, a man ingested a bottle containing 10-11 g of podophyllum extract. Initially he experienced few symptoms, but after 10 h the patient became confused and comatose; respiration was assisted and the man died after 39 h (Rosenstein et al. 1976, Cassidy et al. 1982).

Notes on poisoning: *Primula obconica*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Primula (*Primula obconica*) is an ornamental herb that may be grown indoors or outdoors. Sensitized humans develop dermatitis from exposure to the allergen contained in hairs on leaves and other plant parts. Pollen also can cause dermatitis. Some other species of the genus *Primula* can cause dermatitis as well (Mitchell and Rook 1979).

References:

Fernandez De Corr,s, L., Leanizbarrutia, I., Munoz, D., Bernaola, G., Fernandez, E. 1987. Contact dermatitis from a neighbour's primula. *Contact Dermatitis*, 16: 234-235.

Mitchell, J. C., Rook, A. 1979. *Botanical dermatology*. Greenglass Ltd, Vancouver, B.C., Canada. 787 pp.

Spoerke, D. G., Smolinske, S. C. 1990. *Toxicity of houseplants*. CRC Press, Inc., Boca Raton, Fla., USA. 335 pp.

Nomenclature:

Scientific Name: *Primula obconica* Hance.

Vernacular name(s): primula

Scientific family name: *Primulaceae*

Vernacular family name: primrose

References:

Agriculture Quebec. 1975. *Noms des maladies des plantes du Canada/ Names of plant diseases in Canada*. , Quebec City, Que., Canada. 288 pp.

Image or illustration

Primula obconica:

Images: images.google.com

Notes on Poisonous plant parts:

Minute glandular hairs accumulate the allergen, which is exuded in tiny drops. The hairs are most common on the leaves but are also found on other plant parts. The pollen grains can also cause dermatitis (Mitchell and Rook 1979).

Toxic parts:

flowers
hairs
leaves

References:

Mitchell, J. C., Rook, A. 1979. Botanical dermatology. Greenglass Ltd, Vancouver, B.C., Canada. 787 pp.

Notes on Toxic plant chemicals:

Primin, a quinone, is the allergen in primula. This chemical is found in minute (0.05-0.3 mm long) glandular hairs. The concentrated allergen accumulates as irregular resinous drops on the hairs. Highly sensitive people may react to 20 micro gm of the allergen. The allergen content of primula is highest between April and August, when grown outdoors (Mitchell and Rook 1979).

Toxic plant chemicals:

primin

References:

Mitchell, J. C., Rook, A. 1979. Botanical dermatology. Greenglass Ltd, Vancouver, B.C., Canada. 787 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Notes on poisoning: *Prunus pensylvanica*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Pin cherry (*Prunus pensylvanica*) is a native tree found throughout most of Canada. The leaves have an average N rate of 91 mg/100 g, with as much as 143 mg/100 g recorded. These levels are potentially lethal to livestock if ingested. M. Pitcher (personal communication) notes that captive moose in Newfoundland and Alberta nature parks and zoos regurgitate a gray, chalky, paste-like substance when fed pin cherry browse mixed with their normal browse, white birch (*Betula papyrifera*). Livestock that ingest pin cherry plant material can be poisoned (Kingsbury 1964).

Canadian Biodiversity Information Facility

Notes on poisoning: *Prunus serotina*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Black cherry (*Prunus serotina*) is a native tree found in eastern Canada. It is occasionally cultivated as an ornamental. The plant contains chemicals that can release hydrogen cyanide in animals. All types of animals can be poisoned by ingesting leaves and twigs. There have been claims of children dying after ingesting an excessive number of seeds, found in the berries. Cyanide poisoning interferes with respiration and blood circulation; death is often swift (Kingsbury 1964, Cheeke 1983, Cheeke and Schull 1985).

Image or illustration

Prunus serotina:

Images: images.google.com

Notes on Poisonous plant parts:

The leaves of black cherry contain on average of 212 mg hydrocyanic acid (HCN) per 100 g of fresh leaves. A lethal dose of HCN for humans is between 0.5 and 0.35 mg/kg of body weight. The lethal dose of HCN for cattle and sheep is about 2.0 mg/kg of body weight (Kingsbury 1964).

Toxic parts:

leaves

seeds

twigs

References:

Kingsbury, J. M. 1964. Poisonous plants of the United States and Canada. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.

Notes on Toxic plant chemicals:

Two cyanogenic glycosides are found in black cherry. Amygdalin and prunasin are found in the leaves, twigs, and seeds (Cheeke and Schull 1985). Hydrogen cyanide is formed when the glycosides are hydrolyzed by plant enzymes after damage or by rumen organisms. Majak et al. (1990) found that cyanide production is most rapid in cattle that had been starved for a day. High rates of cyanide production were obtained in the rumen after the animal ingested fresh alfalfa and cubed alfalfa hay.

Toxic plant chemicals:

amygdalin

prunasin

Chemical diagram(s) are courtesy of [Ruth McDiarmid](#), Biochemistry Technician, Kamloops Range Station, Agriculture and Agri-Food Canada, Kamloops, British Columbia, Canada.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[breathing, labored](#)

[death by asphyxiation](#)

[gait, staggering](#)

[muscle spasms](#)

[pupil dilation](#)

Notes on poisoning:

Symptoms of cyanide poisoning are common to all animals. Symptoms may be minimal, with difficult breathing followed by death. Other signs of toxicity may include a short period of stimulation followed by slow pulse, dilated pupils, spasms, staggering, loss of consciousness, and death, which results from asphyxiation. Postmortem findings include bright red blood and congestion of internal organs (Kingsbury 1964, Scimeca and Oehme 1985).

Notes on poisoning: *Prunus virginiana*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Chokecherry (*Prunus virginiana*) is a native shrub or small tree found through most of Canada. Children have been poisoned and have died after ingesting large quantities of berries, which contain the seeds. All types of livestock can be poisoned by ingesting the plant material. Cattle and sheep have been poisoned by red chokecherry (Pardee 1847, Kingsbury 1964). Related species, including peach (*Prunus persica*) and apricot (*Prunus armeniaca*), have pits with enough toxin to cause poisoning and death in humans and animals.

Image or illustration

Prunus virginiana:

Images: images.google.com

Notes on Poisonous plant parts:

At all stages of growth, leaves of red chokecherry contained quantities of prunasin that were well above the minimum 1.4% level required for acute poisoning. Twigs also contained levels of prunasin at or above the level required to cause acute poisoning. Twigs developed more toxin during dry years. The prunasin level of buds and flowers was above the minimum level as well (Majak et al. 1981).

Toxic parts:

leaves
seeds
twigs

References:

Majak, W., McDiarmid, R. E., Hall, J. W. 1981. The cyanide potential of Saskatoon serviceberry (*Amelanchier alnifolia*) and chokecherry (*Prunus virginiana*). *Can. J. Anim. Sci.*, 61: 681-686.

Notes on Toxic plant chemicals:

Two cyanogenetic glycosides, amygdalin and prunasin, are found in red chokecherry plant material. Levels of HCN at 143-243 mg have been found in 100 g of leaves. The higher amounts apply to wilted leaves. A lethal dose in cattle occurs after ingesting fresh leaves equivalent to about 0.25% of body weight (Kingsbury 1964, Cheek and Schull 1985).

Toxic plant chemicals:

amygdalin

prunasin

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[agitation](#)

[coma](#)

[convulsions](#)

[death by asphyxiation](#)

[dyspnea](#)

[gait, staggering](#)

Notes on poisoning:

Experimental work on cattle showed that fresh leaves consumed at a rate equivalent to 0.25% of an animal's body weight constitute a lethal dose. Symptoms listed above are applicable to all types of animals. Postmortem findings usually show bright red blood and congested internal organs (Kingsbury 1964, Scimeca and Oehme

1985).

Humans

General symptoms of poisoning:

[abdominal pains](#)

[babinski reflex](#)

[coma](#)

[convulsions](#)

[cyanosis](#)

[death by asphyxiation](#)

[vomiting](#)

Notes on poisoning:

Ingesting large quantities of red chokecherry fruits, without removing the seeds, has caused illness and death in children. The onset of symptoms is usually sudden and includes abdominal pain, vomiting, convulsions, inability to speak, labored breathing, coma, and death from asphyxiation. The blood is initially bright red because cell respiration is interrupted (Pardee 1847, Kingsbury 1964).

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Bracken (*Pteridium aquilinum*) is a native fern that grows across most of Canada. This fern has caused sickness and loss of cattle in Canada and in other countries. Cattle, sheep, and wild animals have also been poisoned after ingesting bracken. Bracken contains several chemicals that cause problems. Thiaminase results in vitamin B1 deficiency in nonruminants such as horses and swine. Ptaquiloside, a carcinogen-mutagen, causes acute and chronic symptoms of illness in ruminants. The spores may contain carcinogens that can cause problems to animals and humans. The young fronds of bracken are ingested as human food, especially in Japan. They contain significant quantities of the carcinogen (Cheeke and Schull 1985, Fenwick 1988, Hirono 1989).

Image or illustration

Pteridium aquilinum:

Images: images.google.com

Notes on Poisonous plant parts:

All parts of bracken contain toxic chemicals. Ingesting fresh or dry fronds (leaves) or underground rhizomes has caused toxic signs and death in ruminants and nonruminants. After ingesting the young fronds, animals were found to be affected by carcinogenic compounds that the young fronds contain; these compounds may also cause problems in humans. The spores appear to be the most carcinogenic part of bracken and may cause problems in livestock. Humans who work outdoors in areas where bracken grows abundantly could also be at risk from the spores (Milne and Fenwick 1988, Milne 1988, Hirono 1989).

Toxic parts:

all parts
leaves
rhizome
spores
young shoots

References:

Fenwick, G. R. 1988. Bracken (*Pteridium aquilinum*) - toxic effects and toxic constituents. J. Sci. Food Agric., 46: 147-173.

Notes on Toxic plant chemicals:

A group of chemical compounds have been implicated in the various toxic properties of bracken. Thiaminase, an enzyme that decomposes vitamin B1, has caused toxic problems, particularly in nonruminants, which cannot synthesize their own vitamin B1. Ptaquiloside and aquilide A possess an unusual, planar, illudane norsesquiterpene skeleton. Under alkaline conditions these chemicals yield pterodin B, a proximate carcinogen-mutagen. Pterodin B has been implicated as a cause of the cancers noted after bracken ingestion, and ptaquiloside has been implicated as a contributor to the toxic signs in ruminant animals (Cheeke and Schull 1988, Fenwick 1988). Bracken also contains prunasin, a cyanogenic glycoside, which appears to be a deterrent to herbivory (Tewe and Iyayi 1989).

Toxic plant chemicals:

aquilide A
prunasin

ptaquiloside

thiaminase

Cattle

General symptoms of poisoning:

[anemia](#)

[bone marrow damage](#)

[cancer and tumors](#)

[death](#)

[hemorrhage](#)

Notes on poisoning:

Consuming significant quantities of bracken fronds can cause bracken poisoning, which results in bone marrow damage. Only small foci of erythropoietic cells and some megakaryocytes remain. Hemorrhaging occurs, with blood in the feces and bleeding from the nose, vagina, and membranes around the mouth and eyes. Postmortem examination shows hemorrhaging in the stomach, intestines, lungs, and heart (Cheeke and Schull 1985, Fenwick 1988, Hirono 1989).

Kelleway, R. A., Geovjian, L. 1978. Acute bracken fern poisoning in a 14-month-old horse. Vet. Med. Small Anim. Clin., 73: 295-296.

Humans

General symptoms of poisoning:

[cancer and tumors](#)

Notes on poisoning:

The young fronds of bracken have been used as a food source, particularly in Japan. Ptaquiloside, a carcinogenic compound, has been found in bracken. The toxin is especially abundant in the young fronds. If the fronds are not processed in any way, tumor incidence in rats is 78%. After the fronds are processed with boiling water or are boiled with wood ash, sodium bicarbonate, or

salt, the incidence of cancer is reduced to 4-25%. Mammary cancer and ileal and urinary bladder tumors were observed. Cattle develop urinary papilloma. The carcinogen can be transferred by milk. The high incidence of stomach cancer in Japan may be partly due to the consumption of bracken (Cheeke and Schull 1985, Hirono 1989).

References:

Cheeke, P. R., Shull, L. R. 1985. Natural toxicants in feeds and poisonous plants. AVI Publishing Company, Inc., Westport, Conn., USA. 492 pp.

Milne, R. 1988. Heathlands of England harbour cancer spores. New Sci., 118: 23.

Sheep

General symptoms of poisoning:

[blindness](#)

Notes on poisoning:

Sheep in the British Isles have developed a condition called bright blindness. The sheep develop degeneration of the neuroepithelium of the retina, with low counts of blood platelets and white blood cells. This problem has been linked to the consumption of bracken. Cattle with similar symptoms have been reported (Fenwick 1989).

References:

Cheeke, P. R., Shull, L. R. 1985. Natural toxicants in feeds and poisonous plants. AVI Publishing Company, Inc., Westport, Conn., USA. 492 pp.

Swine

General symptoms of poisoning:

[appetite, loss of](#)
[death](#)

Notes on poisoning:

Reports of acute bracken poisoning in swine are infrequent, perhaps because of few symptoms. The symptoms are similar to

heart failure. Experimental feeding of dry, powdered rhizomes produced loss of appetite after 8 weeks, followed by rapid deterioration and death 2 weeks later. Postmortem findings revealed damage to the heart. Ingestion by pregnant sows resulted in some death of the piglets after birth (Fenwick 1988).

Notes on poisoning: Quercus alba

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

White oak (*Quercus alba*) is a native tree found in southern Quebec and Ontario. Ingesting the leaves and acorns has caused some toxic problems in cattle. The concentration of toxic phenolics is less than in red or black oak (*Q. rubra* or *Q. velutina*). Symptoms are similar for all three species of oak. In severe cases, renal failure usually results in death (Sandusky et al. 1977, Cockrill and Beasley 1979).

Notes on poisoning: *Quercus rubra*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Red oak (*Quercus rubra*) is a native tree found in eastern Canada. This plant contains toxic tannins that have caused poisoning and death in cattle and horses. Sheep may have also been poisoned by this oak. Poisoning can lead to depression, anorexia, loss of condition, and kidney damage. Kidney failure usually results in death (Duncan 1961, Cockerill and Beasley 1979).

Image or illustration

Quercus rubra:

Images: images.google.com

Notes on Poisonous plant parts:

The leaves and acorns are toxic. The immature acorns contain more toxin than the mature acorns (Cockrill and Beasley 1979).

Toxic parts:

acorns
immature fruit
leaves

References:

Cockrill, J. M., Beasley, J. N. 1979. Renal damage to cattle during acorn poisoning. *Vet. Med. Small Anim. Clin.*, 74: 82, 84-85.

Notes on Toxic plant chemicals:

The toxic agents are polyhydroxyphenolic compounds (tannins) including gallic acid, pyrogallol, and tannic acid. The concentration of these compounds is higher in immature, green acorns than in mature ones. The following quantities of phenolics were found in acorns (Basden and Dalvi 1987):

Oak species	Total phenolics (% of total weight)
Quercus alba (white oak)	1.09 (0.41-2.54)
Quercus rubra (red oak)	3.72
Quercus velutina (black oak)	4.51 (3.29-6.13)

Black oak and red oak contain a greater total average of phenolics in the acorns does than white oak.

Toxic plant chemicals:

gallic acid
pyrogallol
tannic acid

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[anorexia](#)

[constipation](#)

[depression](#)

[kidney failure](#)

[teeth grinding](#)

Notes on poisoning:

Cattle that ingest a small number of acorns may show some loss of condition. However, they often develop a preference for eating the acorns. Toxic amounts cause depression, anorexia, constipation, the passing of small fecal balls covered in mucous and blood, teeth grinding, and submandibular edema. Death is usually caused by kidney failure. Postmortem findings reveal a large number of acorns in the rumen, gastroenteritis in the caudal portion of the digestive tract, and small, shrunken kidneys with diminished reserve capacity. If renal stress occurs, the reserve function of the kidney may be exceeded. Perirenal edema and hemorrhagic enteritis were the prominent lesions. Multifocal necrosis of the proximal convoluted tubules of the kidney is characteristic (Sandusky et al. 1977, Cockrill and Beasley 1979).

Cockrill, J. M., Beasley, J. N. 1979. Renal damage to cattle during acorn poisoning. *Vet. Med. Small Anim. Clin.*, 74: 82, 84-85.

Horses

General symptoms of poisoning:

[abdominal pains](#)

[anorexia](#)

[colic](#)

[constipation](#)

[depression](#)

[diarrhea](#)

[hematuria](#)

[icterus](#)

Notes on poisoning:

Horses that ingested leaves of red oak developed symptoms of depression, anorexia, abdominal pain, constipation, slight icterus, hematuria, edema, and weakness. The symptoms occurred 6-9 days after ingestion. Blood transfusions were thought to speed recovery (Duncan 1961).

Canadian Biodiversity Information Facility

Notes on poisoning: *Quercus velutina*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Black oak (*Quercus velutina*) is a native tree found only in southern Ontario. The acorns contain significant quantities of toxic phenolics. This plant caused sickness and death in cattle after they ingested acorns on autumn pastures. The occurrence of poisoning from black oak in southern Ontario is minimal because of its restricted distribution (Sandusky et al. 1977, Basden and Dalvi 1987).

Canadian Biodiversity Information Facility

Notes on poisoning: *Ranunculus bulbosus*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Bulbous buttercup (*Ranunculus bulbosus*) is a naturalized herb found in a few Canadian provinces. In the past, the juice of this plant was used by beggars in Europe to cause skin lesions, thus eliciting compassion. The volatile chemical protoanemonin is an irritant. Ingesting this plant has poisoned cattle, swine, and humans. The recent literature includes few cases of poisoning (Kingsbury 1964, Cooper and Johnson 1984).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Kingsbury, J. M. 1964. Poisonous plants of the United States and Canada. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.

Nomenclature:

Scientific Name: *Ranunculus bulbosus* L.

Vernacular name(s): bulbous buttercup

Scientific family name: *Ranunculaceae*

Vernacular family name: crowfoot

Go to ITIS*^{ca} for more taxonomic information on: [Ranunculus bulbosus](#)

Toxic parts:

plant juices

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Notes on Toxic plant chemicals:

Ranunculin, a glycoside, occurs in the juice of the buttercups. Upon maceration, a plant enzyme is released that converts ranunculin to protoanemonin. This chemical, a yellow volatile oil, is unstable and either polymerizes to nontoxic anemonin or is volatilized. Air-dried plants, as those found in hay, are nontoxic. Protoanemonin is an irritant that can cause blisters and other problems when ingested (Cooper and Johnson 1984).

Toxic plant chemicals:

ranunculin

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[breathing, labored](#)

[gait, unsteady](#)

[nasal discharge](#)

[salivation](#)

Notes on poisoning:

In one case in Britain, a cow salivated, coughed, and discharged mucous from the nostrils after ingesting buttercup plants. The animal swayed in the hindquarters with an uneasy movement of

the legs. A period of noisy breathing preceded recovery (Cooper and Johnson 1984).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Humans

General symptoms of poisoning:

[abdominal pains](#)

[diarrhea](#)

[mouth, irritation of](#)

Notes on poisoning:

Ingesting the bulbous bases of this buttercup has caused a few cases of illness. An acrid taste and burning of the mouth and throat precludes ingesting large quantities. Other symptoms may include diarrhea and abdominal pain (Cooper and Johnson 1984).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Swine

Canadian Biodiversity Information Facility

Notes on poisoning: *Ranunculus sceleratus*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Celery-leaved buttercup (*Ranunculus sceleratus*) is a native herb found across most of Canada. This plant contains a toxic irritant that produces protoanemonin upon mastication. All types of livestock can become ill upon ingestion, but cattle are most commonly affected. Horses and goats have also been poisoned (Cooper and Johnson 1984, Fuller and McClintock 1986).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Fuller, T. C., McClintock, E. 1986. Poisonous plants of California. Univ. California Press, Berkeley, Calif., USA. 432 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[abdominal pains](#)

[blindness](#)

[constipation](#)

[diarrhea](#)
[gait, unsteady](#)
[mouth, irritation of](#)
[salivation](#)

Notes on poisoning:

Ingesting the celery-leaved buttercup causes salivation, abdominal pain, and inflammation of the mouth. In more serious cases, severe ulceration of the mouth and of the digestive and urinary systems occurs. The animal excretes dark-colored diarrhea and urine. Unsteady gait occurs in the hind legs, and vision can be impaired or lost. Convulsion precedes death, although fatalities are rare. Animals should not be allowed to graze pastures for at least 2 weeks after spraying with 2,4-D because the plants may be grazed selectively by animals (Cooper and Johnson 1984).

Notes on poisoning: *Rhamnus cathartica*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

European buckthorn (*Rhamnus cathartica*) is a small naturalized shrub that is found throughout much of eastern Canada and in the Prairie Provinces. The shrub has spines on the branches and trunks. These shrubs commonly grow along fence rows and roadsides and in old fields. In some areas, they are a common undergrowth shrub in woodlands. The bark and fruits contain chemicals that have a strong purgative action that can affect humans. Severe poisoning is rare (Cooper and Johnson 1984, Lampe and McCann 1986).

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Humans

General symptoms of poisoning:

[abdominal pains](#)

[diarrhea](#)

[gastroenteritis](#)

[hemorrhage](#)

[muscle spasms](#)

[vomiting](#)

Notes on poisoning:

European buckthorn is usually ingested by children, who eat the black berries or chew the twigs. Under normal circumstances, the symptoms are usually mild and are limited to transient abdominal pain, vomiting, and diarrhea. Ingesting 20 berries or more can have more serious consequences such as gastrointestinal symptoms, fluid depletion, kidney damage, muscular convulsions, and hemorrhage. Serious cases may result in difficult breathing and collapse. Treatment includes inducing vomiting, if it has not already occurred, and fluid replacement (Cooper and Johnson 1984, Fuller and McClintock 1985).

Notes on poisoning: *Rhamnus frangula*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Alder buckthorn (*Rhamnus frangula*) is a naturalized shrub or small tree that is found in parts of eastern Canada and the Prairie Provinces. This plant is found along fencerows and roadsides and in lightly shaded woodlands. Several purgative chemicals, including emodin, occur in the bark and in the purple-black fruits. This plant causes usually mild symptoms if ingested by children. There is one record of fatal poisoning of a cow (Cooper and Johnson 1984, Fuller and McClintock 1985).

Canadian Biodiversity Information Facility

Notes on poisoning: *Rheum rhaponticum*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Rhubarb (*Rheum rhaponticum*) is a perennial cultivated plant that persists around old farm sites. The plant contains oxalate crystals, which have been reported to cause poisoning when large quantities of raw or cooked leaves are ingested. Anthraquinones (glycosides) have been implicated more recently in the poisoning. The stalks are widely used as preserves and are also eaten raw, without problems. The toxic content is much lower in the stalks. Humans have been poisoned after ingesting the leaves. Human poisoning was a particular problem in World War I, when the leaves were recommended as a food source in Britain. Some animals, including goats and swine, have also been poisoned by ingesting the leaves. Children should be taught to eat only the rhubarb stalks, preferably under supervision (Robb 1919; Cooper and Johnson 1984).

Image or illustration

Rheum rhaponticum:

Images: images.google.com

Notes on Poisonous plant parts:

Rhubarb leaves contain the highest amounts of oxalates and perhaps anthraquinones, which may be partly responsible for toxicity. The stalks also contain some low levels of oxalates, but this is not a problem (Cooper and Johnson 1984).

Toxic parts:

leaves

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Notes on Toxic plant chemicals:

Oxalates are contained in all parts of rhubarb plants, especially in the green leaves. There is some evidence that anthraquinone glycosides are also present and may be partly responsible (Cooper and Johnson 1984).

Toxic plant chemicals:

anthraquinones

oxalate

Chemical diagram(s) are courtesy of [Ruth McDiarmid](#), Biochemistry Technician, Kamloops Range Station, Agriculture and Agri-Food Canada, Kamloops, British Columbia, Canada.

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Goats

General symptoms of poisoning:

[diarrhea](#)
[mouth, frothing of](#)
[vomiting](#)

Notes on poisoning:

A goat that ate rhubarb leaves stood with outspread legs, an open mouth, and protruding eyes. The animal was crying and produced sour green vomit and profuse diarrhea (Cooper and Johnson 1984).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Humans

General symptoms of poisoning:

[abdominal pains](#)
[abortion](#)
[convulsions](#)
[death](#)
[drowsiness](#)
[muscle twitching](#)
[nausea](#)
[vomiting](#)

Notes on poisoning:

Ingesting rhubarb leaves has caused many fatalities, especially during World War II, when the leaves were recommended as food for a short time. In one fatal case, oxalic acid was ingested at a rate of only 1.3 g/kg, whereas five or six times this amount normally constitutes a fatal dose. More recent evidence indicates that anthraquinone glycosides may be involved. Symptoms include abdominal pain, nausea, vomiting, weakness, and drowsiness. Blood clotting is reduced. A woman in early pregnancy aborted before she died. Two children ingested 20-100 g of leaves and stalks. They vomited and developed jaundice, with some kidney and liver damage. Analysis for

oxalate crystals in the urine may help diagnosis (Robb 1919, Cooper and Johnson 1984).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Robb, H. F. 1919. Death from rhubarb leaves due to oxalic acid poisoning. J. Am. Med. Assoc., 73: 627-628.

Spoerke, D. G., Smolinske, S. C. 1990. Toxicity of houseplants. CRC Press, Inc., Boca Raton, Fla., USA. 335 pp.

Swine

General symptoms of poisoning:

[convulsions](#)

[death](#)

[gait, staggering](#)

[mouth, frothing of](#)

Notes on poisoning:

Swine that ingested rhubarb plants exhibited the following symptoms: foaming at the mouth, staggering, and convulsions, followed by death. Postmortem examination revealed severe inflammation of the stomach and intestines (Cooper and Johnson 1984).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Cattle

General symptoms of poisoning:

[anorexia](#)

[death](#)

[nasal discharge](#)

[salivation](#)

[vomiting](#)

[weakness](#)

Notes on poisoning:

Cattle are not poisoned as often as sheep because of the bitter taste of the leaves. Symptoms of ingestion may include initial anorexia, salivation, and dullness. Vomiting may be accompanied by bloat. Abdominal pain and nasal discharge occur. In severe cases, death may result (Kingsbury 1964).

References:

Kingsbury, J. M. 1964. Poisonous plants of the United States and Canada. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.

Sheep

General symptoms of poisoning:

[convulsions](#)

[death](#)

[nasal discharge](#)

[paralysis](#)

[salivation](#)

Notes on poisoning:

The palatability of the leaves is low. However, ingesting the leaves causes symptoms, including salivation, nasal discharge, convulsions, paralysis of the limbs, and weakness. In severe cases, death can occur after a period of coma (Looman et al. 1983).

References:

Kingsbury, J. M. 1964. Poisonous plants of the United States and Canada. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.

Notes on poisoning:

Rhododendron

macrophyllum

[Introduction](#)[Interactive](#)[All poisonous plants by](#)[Botanical name](#)[All poisonous plants by](#)[Common name](#)[Important WWW Poisonous](#)[Plants sites](#)

General poisoning notes:

California rose-bay (*Rhododendron macrophyllum*) is a native shrub found in southwestern British Columbia. This plant has poisoned goats and sheep. Azaleas are now considered part of the genus *Rhododendron*. Animals and humans have been poisoned after ingesting the foliage, nectar, or honey made from these plants. Klein-Schwartz and Litovitz (1985) found that humans who ingested plant parts of *Rhododendron* plants exhibited few symptoms of poisoning. Of 152 cases, only nine developed any symptoms and only one resulted in vomiting and transient hypertension. The authors concluded that ingesting moderate amounts of azalea material posed little danger to humans. Azaleas are often used as houseplants. Children and family pets should be prevented from ingesting these plants. Livestock have been poisoned by ingesting foliage of azaleas and rhododendrons. Sheep are most commonly affected in North America. Death has occurred in some cases (Casteel and Wagstaff 1989). Poisoning usually occurs when animals gain access to clippings or when little other forage is available, as in the winter. Rhododendrons retain their leaves over the winter. Goats and cattle have been poisoned as well. Andromedotoxins (grayanotoxins) are the toxins involved.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Goats

General symptoms of poisoning:

[ataxia](#)

[colic](#)

[convulsions](#)

[death](#)

[opisthotonos](#)

[recumbency, lateral](#)

[vomiting](#)

[weakness](#)

Notes on poisoning:

In one case, several young and adult goats gained access to clippings of California rose-bay; most were poisoned, and some young goats died. Symptoms included initial lateral recumbency and a tonic-clonic convulsive episode starting 6 h after ingestion. Vomiting, ataxia, and weakness occurred. Vomiting continued over 2 days. Intense colic was observed. Lactating goats dried up. Some animals remained recumbent for a couple of days (Casteel and Wagstaff 1989).

References:

Casteel, S., Wagstaff, J. 1989. *Rhododendron macrophyllum* poisoning in a group of goats and sheep. *Vet. Hum. Toxicol.*, 31: 176-177.

Humans

General symptoms of poisoning:

[mouth, irritation of](#)

[vomiting](#)

Notes on poisoning:

Klein-Schwartz and Litovitz (1985) found that only minimal symptoms were exhibited, such as vomiting, after ingesting species of the genus *Rhododendron*. Lampe and McCann (1985) note that ingesting significant quantities of leaves can cause more severe symptoms such as burning of the mouth, salivation, vomiting, diarrhea, headache, and dimness of vision. Such occurrences are unlikely because of the bitterness of the leaves. Reports occur regarding the toxicity of honey made from azaleas and rhododendrons. This honey is bitter and is unlikely to be ingested in large quantities.

References:

Klein-Schwartz, W., Litovitz, T. 1985. Azalea toxicity: an overrated

problem?.Clin. Toxicol., 23: 91-101.

Sheep

General symptoms of poisoning:

[ataxia](#)

[colic](#)

[depression](#)

[recumbency](#)

[vomiting](#)

[weakness](#)

Notes on poisoning:

Ingesting clippings of California rose-bay caused illness in sheep. Symptoms included severe vomiting, ataxia, and weakness. Vomiting continued over a few days. The animals walked a short distance and then fell down. Some animals remained recumbent for many hours. Colic was observed (Casteel and Wagstaff 1989).

Canadian Biodiversity Information Facility

Notes on poisoning: *Rhus radicans*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Poison ivy (*Rhus radicans*; synonym *Toxicodendron radicans*) is a native shrub or vine found throughout southern Canada. Three recognized varieties are found in various parts of the country (Mulligan and Junkins 1977). Urushiol is the allergenic agent found in most parts of the plant. Damage to plant tissues causes the nonvolatile chemicals to be exposed. Humans are often sensitized, with symptoms ranging from mild itchiness and redness to severe oozing lesions with fever. Poison ivy is probably responsible for more cases of plant dermatitis in Canada than any other plant. Urushiol can contaminate clothes, tools, and the fur of domestic animals. Humans can subsequently develop dermatitis from contact. Humans do not contract the dermatitis on first contact, but most people are sensitized the first time (Mulligan 1990, Schwartz and Downham 1981, Gayer and Burnett 1988). For more information please see the bulletin "[Poison Ivy, Western Poison Oak, Poison Sumac](#)"

Notes on Toxic plant chemicals:

Urushiol, a group of alkylcatechols, is found in the sap of poison-ivy plants. The allergic reaction has been traditionally thought to involve initial oxidation by which a protein-reactive

quinone is formed. Recent work indicates that redox cycling in the skin, following penetration of the allergenic alkybenzenes, initially depletes local levels of endogenous-reducing equivalents such as NADH and glutathione. Further cycling results in the uncontrolled generation of radical species that exhibit protein reactivity. The urushiol is not volatile and can contaminate clothing, tools, and domestic animals. Under dry conditions, the chemical can remain harmful for long periods (Mulligan 1990, Schmidt et al. 1990).

Toxic plant chemicals:

urushiol oil
3-pentadecyl catechol

Notes on poisoning: *Rhus vernix*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Poison sumac (*Rhus vernix*; synonymy *Toxicodendron vernix*) is a native shrub or vine found in southern Quebec and southern Ontario. The sap of this plant contains the allergen urushiol. The chemical is released when plant tissue is damaged. Humans are highly sensitive to allergic reaction, although at least one exposure is needed for sensitization. Mild to severe dermatitis can result from exposure to poison sumac (Mulligan 1990, Gayer and Burnett 1988). For more information please see the bulletin "[Poison Ivy, Western Poison Oak, Poison Sumac](#)"

Image or illustration

Rhus vernix:

Images: images.google.com

Notes on Poisonous plant parts:

Most parts of poison sumac contain the allergen except the pollen, anthers, xylem, and epidermis. Damage to plant parts releases the sap that contains the allergen (Mulligan 1990). The allergen occurs in the plant sap, which is found in all plant parts except the pollen, anthers, xylem, and epidermis. If the stems are damaged they can release the allergen, even in the winter. The

roots are also dangerous (Mulligan 1990).

Toxic parts:

all parts
leaves
mature fruit
plant juices
roots
stems

Notes on poisoning: *Ricinus communis*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Castor bean (*Ricinus communis*) is an ornamental herbaceous shrub that is occasionally planted indoors or outdoors as a rapidly growing annual ornamental. The seeds (and to a much lesser extent the leaves) contain ricin, a protein, which is highly toxic in small quantities. Humans as well as cattle, dogs, goats, horses, poultry, rabbits, sheep, and swine have been poisoned after ingesting the seeds. The seed coat must be damaged to allow water to penetrate the seed interior, thus releasing the water-soluble toxin ricin. Most reported cases of animal poisoning have occurred overseas where the seed is used as food and, if improperly treated, has caused illness and death. Humans who ingested the seeds became ill and died. The toxin has been used for of suicide and assassination. Two to four chewed seeds can cause death in children (Cooper and Johnson 1984, Griffiths et al. 1987).

DO NOT ALLOW THESE PLANTS TO SET SEEDS!!

Ricinus communis:

Images: images.google.com

Notes on Poisonous plant parts:

The ricin content is highest in the seeds, although a small fraction of the toxin is contained in the leaves. Swallowing a seed without chewing prevents the release of the toxin because of the hard seed coat. However, chewing the seed allows release of the water-soluble chemical, and poisoning can occur (Cooper and Johnson 1984).

Toxic parts:

seeds

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Notes on Toxic plant chemicals:

Ricin, a simple protein (a toxalbumin), is one of the most potent naturally occurring substances. Ricin is soluble in water and is therefore not present in extracted oil. Another protein, called ricinus agglutinin (or ricin), causes hemagglutinating activity, coagulation of the red blood cells. Toxicity from this protein disappears after heat treatment, usually as steam. After the oil is extracted, the remaining pomace is used in some countries as animal feed, if properly treated with heat and water. There is wide variation in sensitivity to the toxin in different species. A lethal dose by injection may be as small as two-millionths of body weight.

Experimental oral lethal doses are as follows:

horses	0.1 g/ kg
cattle, foals, rabbits, sheep, swine	1-2 g/kg
goats	5.5 g/kg

Because ricin is a protein, antibodies can be produced by

immunization, which allows animals to withstand up to 800 times a normal lethal dose. Ricin has been used by secret intelligence services as an assassination weapon. In one case, the Bulgarian secret police used a 1.53 mm metal pellet containing a reservoir for a few hundred millionths of a gram of ricin to kill a Bulgarian broadcaster. The pellet was injected by use of an umbrella, and the man died within 4 days (Cooper and Johnson 1984, Griffiths et al. 1987).

Toxic plant chemicals:

ricin

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[abortion](#)

[breathing, shallow](#)

[death](#)

[diarrhea](#)

[weakness](#)

Notes on poisoning:

Cattle have been poisoned overseas after ingesting improperly treated castor bean products such as cattle cakes. Symptoms include severe diarrhea with blood and mucous in the feces, abortions, a drastic reduction in milk yield, and death of newborn calves. Weakness, feeble pulse, shortness of breath, and swollen joints have also occurred. Temperature was subnormal, with the pulse fast and weak. The lethal dose was estimated at 250 g of husks. Postmortem findings showed hemorrhaging in the heart,

degeneration of the kidneys and liver, and intense inflammation and erosion of the intestinal membranes. Symptoms are similar for other types of animals (Cooper and Johnson 1984).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Chickens

General symptoms of poisoning:

[death](#)

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Horses

General symptoms of poisoning:

[abdominal pains](#)

[sweating](#)

[temperature, elevated](#)

Notes on poisoning:

The accidental addition of castor beans into grain given to horses caused sweating, a rocking gait, rapid pulse, muscle spasms, elevated temperature, and abdominal pains. The early symptoms may be confused with respiratory infection (Cooper and Johnson 1984).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Humans

General symptoms of poisoning:

[abdominal pains](#)

[death](#)

[diarrhea](#)

[fever](#)

[nausea](#)

[vomiting](#)

Notes on poisoning:

Two to four chewed seeds may be enough to cause death in children. Symptoms of poisoning include abdominal pains, diarrhea, vomiting, nausea, drowsiness, dehydration, incoordination, and hematuria. In cases of acute toxicity, symptoms appear after several hours to a few days, although they can occur quickly. Griffiths et al. (1987) found that ricin causes apoptotic changes: cytoplasmic shrinkage, nuclear condensation, and breakdown of cells into membrane-bound fragments. Large-scale disruption in lymphoid tissues occurs. Death has been accidental or purposeful (Malizia et al. 1977, Griffiths et al. 1987). Castor bean contains an unknown potent respiratory allergen. Repeated exposure increases sensitivity (Cooper and Johnson 1984).

Poultry

General symptoms of poisoning:

[diarrhea](#)

[feathers, ruffled](#)

Notes on poisoning:

In one case of accidental poisoning, poultry deteriorated rapidly, showing ruffled feathers, drooping wings, and grayish combs and wattles. Their crops were impacted for days, egg laying ceased,

and molting started. Several birds died (Cooper and Johnson 1984).

Notes on poisoning: *Robinia pseudoacacia*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Black locust (*Robinia pseudoacacia*) is a naturalized shrub or tree that is planted as an ornamental in warmer parts of Canada. The seeds, bark, and leaves contain toxic proteins that have caused sickness and death in cattle, horses, poultry, sheep, and humans. The plant should be considered toxic to all animals if ingested. Children were poisoned (with rare reports of fatalities) after chewing on plant material, especially the bark. This tree can be found around older farms and houses and is also planted along fencerows. Children should be taught not to ingest any parts of the plant. If older trees are cut down in areas where livestock have access, make sure that the animals do not ingest any sprout (sucker) growth that may emerge from the stump (Hansen 1924, Kingsbury 1964, Cooper and Johnson 1984).

seeds

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Notes on Toxic plant chemicals:

Robin (or robinin) and phasin, which are toxic proteins called toxalbumins, are present in black locust. A glycoprotein that agglutinates red blood cells has been extracted from the plant. It is not clear if this is robin or another substance. Experimental feeding to horses has shown the following toxicities:

=> aqueous extract of bark about 0.1% of body weight caused symptoms

=> powdered bark about 0.04% of body weight caused symptoms

The poisonous principle appears to be about one-tenth as toxic to cattle (Kingsbury 1964, Cooper and Johnson 1984).

Toxic plant chemicals:

phasin
robin(in)

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[anorexia](#)

[death](#)

[dyspnea](#)

[nausea](#)

[paralysis, posterior](#)

[weakness](#)

Notes on poisoning:

Cattle that ingested the sprouts and leaves of black locust were poisoned. Experiments show that cattle are 10 times less sensitive to the toxin than horses. Symptoms include anorexia, weakness, posterior paralysis, nausea, coldness of the extremities, and dilation of the pupils. Death occurs in severe cases (Hansen 1924, Kingsbury 1964).

References:

Kingsbury, J. M. 1964. Poisonous plants of the United States and Canada. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.

Horses

General symptoms of poisoning:

[anorexia](#)

[death](#)

[nausea](#)

[paralysis, posterior](#)

[pupil dilation](#)

[weakness](#)

Notes on poisoning:

Horses that ingested black locust leaves, sprouts, and bark were poisoned and died. Symptoms are similar to those of cattle and include anorexia, weakness, posterior paralysis, nausea, coldness of the extremities, and pupil dilation. Symptoms of colic also occur. In severe cases, death occurs. Postmortem findings showed mucous inflammation of the gastrointestinal tract and occasional severe gastroenteritis. In some cases a yellowish pigmentation of the membranes occurred (Hansen 1924, Kingsbury 1964).

References:

Kingsbury, J. M. 1964. Poisonous plants of the United States and Canada. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.

Humans

General symptoms of poisoning:

[death](#)

[nausea](#)

[pupil dilation](#)

[vomiting](#)

Notes on poisoning:

Humans, usually children, were poisoned after ingesting the bark of black locust. Symptoms include pupil dilation, feeble pulse, severe vomiting, and a death-like palor. The extremities may become cold. Intestinal inflammation, hemorrhaging of the lymphatic tissues, and possible liver damage often occur. Fatalities are rare. The chances of poisoning are rare. Children should not be allowed to ingest plant material from this tree (Hansen 1924, Kingsbury 1964).

Canadian Biodiversity Information Facility

Notes on poisoning: *Rudbeckia laciniata*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Cut-leaved coneflower (*Rudbeckia laciniata*) is native to some parts of Canada and is naturalized in others. A double-flowered form is also used as an ornamental in flower beds and is usually called golden glow. Early circumstantial evidence of poisoning of horses, sheep, and swine can be found. Experiments on sheep and swine have shown that some symptoms of toxicity can occur, although animals generally refuse to eat the unpalatable plants. Animal poisoning by this plant should be considered unlikely (Kingsbury 1964).

Notes on poisoning: *Rumex acetosa*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Garden-sorrel (*Rumex acetosa*) is a naturalized herb found across southern Canada. It is occasionally cultivated as a garden green. Ingesting large quantities of the plant caused toxicity in sheep and cattle in other countries. Humans should restrict their intake of the leaves of this plant because they contain oxalate crystals (Cooper and Johnson 1984).

stems

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Notes on Toxic plant chemicals:

Oxalates are considered the primary toxin. However, under certain circumstances, nitrates may accumulate to toxic levels. In recorded cases of poisoning, the symptoms were consistent with those of oxalate poisoning (Cooper and Johnson 1984).

Toxic plant chemicals:

oxalate

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[kidney failure](#)

Notes on poisoning:

Reports of poisoning in cattle are inconsistent. Lactating cows that ingested large quantities of garden-sorrel showed symptoms similar to those of milk fever. Treatment with calcium had transient effects because of subsequent kidney failure (Cooper and Johnson 1984).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Sheep

General symptoms of poisoning:

[coma](#)

[death](#)

[incoordination](#)

[mouth, frothing of](#)

[pupil dilation](#)

[recumbency](#)

Notes on poisoning:

Ingesting large amounts of garden-sorrel caused toxicity in sheep in Britain. Symptoms included incoordination, falling, then inability to rise, dilation of the pupils, coma, and death (in five sheep). In lactating ewes, the initial signs resembled milk fever, but favorable response to calcium injection was transient because of kidney failure. No cases of poisoning from this plant have been reported in North America (Kingsbury 1964, Cooper and Johnson 1984).

leaves
stems

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Notes on Toxic plant chemicals:

Oxalate crystals are found in sheep sorrel. Under certain circumstances, nitrates can accumulate in sufficient quantity to cause poisoning. If large enough quantities of oxalates are absorbed by ruminants, they combine with blood calcium, forming calcium oxalate and causing calcium deficiency. The crystal can accumulate in the kidneys and brain causing renal failure and nervous disorders (Cooper and Johnson 1984).

Toxic plant chemicals:

oxalate

Canadian Biodiversity Information Facility

Notes on poisoning: *Sambucus canadensis*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

American elder (*Sambucus canadensis*) is a native shrub found in the moist soils of swamps and along rivers and lakes in eastern Canada. This plant contains cyanogenic glycosides and a cathartic chemical. The plant has poisoned cattle and perhaps sheep. Children were poisoned after using the hollow stems for whistles. Ingesting uncooked berries may cause nausea (Kingsbury 1964, Muenscher 1978). Red-berried elder (*Sambucus pubens*) is a native shrub found from Newfoundland to Manitoba. There are unsubstantiated reports that this species may also have toxic potential. Children should not be allowed to chew the stems or berries.

Notes on poisoning: *Sambucus nigra*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

European elder (*Sambucus nigra*) is an outdoor ornamental introduced from Europe. Several cultivars may be available in Canada. This shrub contains cyanogenic glycosides. Swine have been poisoned in Europe, and circumstantial reports of poisoning of cattle and turkeys have been noted. Berries eaten raw can cause nausea and vomiting in humans (Cooper and Johnson 1984). Children should not be allowed to ingest the berries.

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Canadian Biodiversity Information Facility

Notes on poisoning: *Sarcobatus vermiculatus*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Greasewood (*Sarcobatus vermiculatus*) is a native shrub found in western Canada from southwestern Saskatchewan to southeastern British Columbia. In the western United States, sheep that ingested this plant became ill and died. Oxalates are present in all parts of the plant but are concentrated in the leaves. This plant is regarded as valuable forage. Toxicity can be avoided with good animal management (Kingsbury 1964, Cheeke and Schull 1985).

References:

Cheeke, P. R., Shull, L. R. 1985. Natural toxicants in feeds and poisonous plants. AVI Publishing Company, Inc., Westport, Conn., USA. 492 pp.

Image or illustration

Sarcobatus vermiculatus:

Images: images.google.com

Toxic parts:

leaves

References:

Kingsbury, J. M. 1964. Poisonous plants of the United States and Canada. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.

Notes on Toxic plant chemicals:

Oxalates are found in greasewood. On a dry-weight basis the total content was measured at between 10 and 22%, mostly as soluble salts. The oxalate content is greatest in the leaves, the amount increasing with maturity. Ingesting plant material equal to 1.5-5.0% of an animal's body weight can cause toxicity in sheep (Kingsbury 1964).

Toxic plant chemicals:

oxalate

Kingsbury, J. M. 1964. Poisonous plants of the United States and Canada. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Sheep

General symptoms of poisoning:

[coma](#)

[death](#)

[depression](#)

[prostration](#)

[weakness](#)

Notes on poisoning:

In the western United States, 1000 sheep were lost at a single time. Symptoms occur within 3-5 h of ingesting a toxic quantity of greasewood plant. Symptoms may occur abruptly after animals have been watered. Toxic signs include depression, weakness, prostration, coma, and death. Respiration and heart action grow progressively weaker, and death occurs in 12-20 h. Hypocalcemia is caused by the formation of calcium oxalate in the system. Microscopic lesions occur in the kidney tubules (Kingsbury 1964, Scimeca and Oehme 1985).

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Siberian scilla (*Scilla siberica*) is a hardy perennial bulb planted outdoors, and sometimes forced indoors, for its beautiful early spring flowers. The entire plant contains cardiac glycosides, which can potentially cause poisoning if ingested. No cases of poisoning have been documented. This is not a good plant to have around children or pets, which have a habit of chewing leaves. Other *Scilla* species may be available in Canada and may also contain toxins. *Scilla* species may also cause skin irritation in sensitive individuals (Lampe and McCann 1985, Spoerke and Smolinske 1990).

Notes on poisoning: *Senecio integerrimus*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Entire-leaved groundsel (*Senecio integerrimus*) is a native herb found through parts of western Canada in the prairies, parklands, and parts of the Rocky Mountains. This plant has caused experimentally chronic poisoning of cattle and horses. Ingesting the plant material over long periods causes irreversible liver damage in animals. This plant grows when other forage is abundant so that it is not a toxic threat unless forage is scarce or the plant is abundant in an area to be cut for hay (Clawson 1933).

References:

Clawson, A. B. 1933. The American groundsels species of *Senecio* as stock poisoning plants. Vet. Med. Small Anim. Clin., 28: 105-110.

Nomenclature:

Scientific Name: *Senecio integerrimus* Nutt.

Vernacular name(s): entire-leaved groundsel

Scientific family name: *Compositae*

Vernacular family name: composite

Go to ITIS^{*ca} for more taxonomic information on: [Senecio integerrimus](#)

Image or illustration

Senecio integerrimus:

Images: images.google.com

Notes on Poisonous plant parts:

Ingesting the aboveground parts caused poisoning of cattle and horses in experiments. Two cows died after ingesting 92.3 and 135% of their body weight in green plants. A horse fed plants equal to 156% of its body weight (in 81 days) died. A horse fed 76% of its body weight (in 79 days) suffered liver damage. Sheep fed 4.5 kg of green plant material for 28 days showed no symptoms. Liver damage results from ingesting this plant material but takes a long time to develop (Clawson 1933).

Toxic parts:

all parts
flowers
leaves
stems

References:

Clawson, A. B. 1933. The American groundsels species of *Senecio* as stock poisoning plants. *Vet. Med. Small Anim. Clin.*, 28: 105-110.

Kingsbury, J. M. 1964. *Poisonous plants of the United States and Canada*. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.

Notes on Toxic plant chemicals:

Pyrrolizidine alkaloids are found in other toxic members of the genus *Senecio* and are probably the chemicals responsible for cases of poisoning found in experiments.

Toxic plant chemicals:

unknown chemical

Clawson, A. B. 1933. The American groundsels species of *Senecio* as stock poisoning plants. *Vet. Med. Small Anim. Clin.*, 28: 105-110.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[death](#)
[depression](#)
[icterus](#)
[liver, cirrhosis of](#)
[restlessness](#)
[weakness](#)
[weight loss](#)

Notes on poisoning:

Experimental ingestion of plant material caused poisoning and death in cattle. Symptoms are similar to poisoning by other members of the genus *Senecio*, with liver damage causing many of the symptoms. Signs included depression, a peculiar sweet odor from the skin, yellowish discoloration of mucous membranes, itchiness, edema, serum oozing from the skin, and liver damage (Clawson 1933).

References:

Clawson, A. B. 1933. The American groundsels species of *Senecio* as stock poisoning plants. Vet. Med. Small Anim. Clin., 28: 105-110.

Horses

General symptoms of poisoning:

[confusion](#)

[death](#)

[depression](#)

[icterus](#)

[restlessness](#)

[weakness](#)

[weight loss](#)

Notes on poisoning:

Ingesting plant material caused a yellowish discoloration of mucous membranes, a sweet odor from the skin, depression, weakness, restless walking and, after 1 or 2 days, insensibility to objects and pushing against obstacles, urine discoloration, and death. All horses that showed definite symptoms died. Liver damage was apparent upon postmortem examination (Clawson 1933).

Notes on poisoning: *Senecio jacobaea*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Tansy ragwort (*Senecio jacobaea*) is a naturalized herb that is found in fields in eastern Canada and British Columbia. This plant contains pyrrolizidine alkaloids which primarily cause irreversible liver cirrhosis in animals that ingest them. This plant has poisoned cattle and horses, and possibly goats. In the late 19th century and early 20th century, the mysterious Pictou cattle disease in Nova Scotia resulted in heavy losses of cattle. Tansy ragwort ingestion was recognized as causing the problem. In the 1960s cattle losses in Oregon valued at several million dollars were attributed to tansy ragwort ingestion. This plant should be eradicated from forage and crops (Cheeke and Schull 1985, Huxtable 1989). Animals and humans may be poisoned if they drink the milk of animals that have ingested this plant (Molyneux and James 1990, Bain 1990).

Image or illustration

Senecio jacobaea:

Images: images.google.com

Notes on Poisonous plant parts:

All parts of the plant contain toxic pyrrolizidine alkaloids. The flowers contain the highest concentration of the toxins. The concentration in the leaves increases to a maximum just before flower maturity (Johnson and Molyneux 1986).

Toxic parts:

all parts
flowers
leaves
stems

References:

Johnson, A. E., Molyneux, R. J. 1986. The pyrrolizidine alkaloid free base and N-oxide content of toxic range plants. J. Toxicol. Toxin Rev., 5: 256.

Pethick, W. H. 1921. Pictou cattle disease. Can. Vet. Rec., 2: 13-16.

Notes on Toxic plant chemicals:

Pyrrolizidine alkaloids such as jacobine and seneciphylline are found in tansy ragwort. The content of these alkaloids has been measured at a mean of 0.31% (Cheeke and Schull 1985, Johnson and Molyneux 1986).

Toxic plant chemicals:

jacobine
seneciphylline

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[abdominal edema](#)

[agitation](#)

[anorexia](#)

[diarrhea](#)

[jaundice](#)

[liver, cirrhosis of](#)

[nervousness](#)

Notes on poisoning:

So-called Pictou disease was identified in Pictou county, N. S., in cattle and horses; it also occurred in Prince Edward Island. For 20 years, the Canadian government ordered affected herds to be slaughtered before feeding trials confirmed, in 1906, that ingestion of tansy ragwort was responsible. The pyrrolizidine alkaloids cause irreversible liver cirrhosis, with pronounced fibrosis and biliary hyperplasia. Other symptoms include a peculiar bleached color of the hair, nervousness, incoordination, coma, and death. A rapid loss of milk production occurs in lactating cattle, and the milk may taste bitter with an unpleasant odor. Postmortem findings showed liver cirrhosis, often an enlarged gall bladder, abdominal edema, and edema in the mucosa and submucosa of the stomach and intestine (Pethick 1921, Cheeke and Schull 1985, Scimeca and Oehme 1985).

In a case in Oregon, a 3-week-old calf died. Post-mortem findings

showed signs of liver cirrhosis; tansy ragwort poisoning was diagnosed. The dam did not show any signs of tansy ragwort poisoning. Milk from goats was also shown to pass the pyrrolizidine alkaloid (Pearson 1977).

Pethick, W. H. 1921. Pictou cattle disease. *Can. Vet. Rec.*, 2: 13-16.

Goats

General symptoms of poisoning:

[abdominal edema](#)

[liver, cirrhosis of](#)

Notes on poisoning:

Goats are not usually poisoned, but if they are fed tansy ragwort they produce mutagenic milk. The pyrrolizidine alkaloids are found in the milk (Huxtable 1989).

References:

Cheeke, P. R., Shull, L. R. 1985. Natural toxicants in feeds and poisonous plants. AVI Publishing Company, Inc., Westport, Conn., USA. 492 pp.

Horses

General symptoms of poisoning:

[abdominal edema](#)

[coma](#)

[death](#)

[depression](#)

[dyspnea](#)

[gait, staggering](#)

[incoordination](#)
[jaundice](#)
[liver, cirrhosis of](#)
[skin, peeling of](#)
[weight loss](#)

References:

Cheeke, P. R., Shull, L. R. 1985. Natural toxicants in feeds and poisonous plants. AVI Publishing Company, Inc., Westport, Conn., USA. 492 pp.

Pearson, E. G. 1991. Liver failure attributable to pyrrolizidine alkaloid toxicosis and associated with inspiratory dyspnea in ponies: three cases (1982-1988). J. Am. Vet. Med. Assoc., 198: 1651-1654.

Humans

General symptoms of poisoning:

[liver, cirrhosis of](#)

Notes on poisoning:

Pyrrolizidine alkaloids from tansy ragwort were found in honey produced in Oregon and Washington states. The honey is off-color and bitter and is usually not sold. The amount of toxin is so low that acute symptoms of poisoning are unlikely. However, because the effects are cumulative, long term ingestion of this honey cannot be considered safe. There are no records of toxicity from ingesting honey (Fuller and McClintock 1986).

Canadian Biodiversity Information Facility

Notes on poisoning: *Senecio vulgaris*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Common groundsel (*Senecio vulgaris*) is a naturalized herb found across much of Canada in fields and waste places. This plant contains pyrrolizidine alkaloids, which cause irreversible liver damage after chronic exposure. Cattle and horses have died after ingesting common groundsel. Humans use this plant in teas and herbal remedies in some parts of the world. Death occurred after some species of the genus *Senecio* were ingested. Humans should not ingest foods that contain any plant material from this genus. In a case of prenatal exposure, a mother ingested tea containing an estimated 0.343 mg of senecionine, resulting in fatal veno-occlusive disease in a newborn infant (Huxtable 1989, Spoerke and Smolinske 1990).

Image or illustration

Senecio vulgaris:

Images: images.google.com

Notes on Poisonous plant parts:

The highest concentration of pyrrolizidine alkaloids is found in the flowers and the lowest in the roots. The amount of toxin increases in the leaves, reaching a maximum just before flower maturity (Johnson and Molyneux 1986).

Toxic parts:

all parts
flowers
leaves

References:

Johnson, A. E., Molyneux, R. J. 1986. The pyrrolizidine alkaloid free base and N-oxide content of toxic range plants. J. Toxicol. Toxin Rev., 5: 256.

Notes on Toxic plant chemicals:

Senecionine, a pyrrolizidine alkaloid, is found in common groundsel. A total of less than 1% alkaloids was measured (Johnson and Molyneux 1986, Huxtable 1989).

Toxic plant chemicals:

senecionine

Chemical diagram(s) are courtesy of [Ruth McDiarmid](#), Biochemistry Technician, Kamloops Range Station, Agriculture and Agri-Food Canada, Kamloops, British Columbia, Canada.

References:

Huxtable, R. J. 1989. Human health implications of pyrrolizidine alkaloids and herbs containing them. Pages 41-86 in Cheeke, P. R., ed. Toxicants of plant origin. Vol. I. Alkaloids. CRC Press, Inc., Boca Raton, Fla., USA. 335 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[blindness](#)

[death](#)

[incoordination](#)

[liver, cirrhosis of](#)

[prostration](#)

Notes on poisoning:

Cattle were poisoned after ingesting common groundsel. In some cases, calves 3-8 months old died, whereas older cows showed no clinical signs. Calves from cows eating contaminated hay during pregnancy died the following autumn. The same effects were obtained experimentally from the offspring of rats fed the toxins during pregnancy. Other symptoms include nervousness, incoordination, pushing against objects, walking in circles, and blindness with glazed eyes (Fuller and McClintock 1986).

References:

Fuller, T. C., McClintock, E. 1986. Poisonous plants of California. Univ. California Press, Berkeley, Calif., USA. 432 pp.

Horses

General symptoms of poisoning:

[anorexia](#)

[ataxia](#)

[death](#)

[depression](#)

[diarrhea](#)

[hemoglobinuria](#)

[liver, cirrhosis of](#)

Notes on poisoning:

Ingesting common groundsel leads to sickness and death. Early symptoms include anorexia and listlessness. Animal owners do not usually notice problems until liver damage occurs. Experimental tests show that routine measurement of food intake and weekly body weight can alert owners to pyrrolizidine poisoning early enough so that liver damage can be reduced. Measuring the serum bile acid is the best way to predict animal survival. Liver damage was induced in horses after they ingested an average of 233 +/- 9.2 mg of pyrrolizidine alkaloid per kilogram of body weight. Other symptoms include ataxia, head pressing, and stall walking. Megalocytic hepatopathy develops. Liver damage is often severe before obvious clinical signs develop (Lessard et al. 1986, Mendel et al. 1988).

Humans

General symptoms of poisoning:

[liver, cirrhosis of](#)

Notes on poisoning:

Common groundsel is used in herbal medicine and teas around the world. Humans should not ingest any foods, teas, or remedies that contain any plant material from the genus *Senecio*. Chronic poisoning occurs, resulting in veno-occlusive disease in children and Budd-Chiari syndrome (more commonly) in adults (Huxtable 1989).

Canadian Biodiversity Information Facility

Notes on poisoning: *Solanum dulcamara*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Climbing nightshade (*Solanum dulcamara*) is a naturalized woody vine that is found along fencerows, among shrubbery, and at wood edges across most of southern Canada. The plant, especially in its green immature fruits, contains steroidal alkaloids, which have caused poisoning in cattle and sheep. Humans may have been poisoned after ingesting immature berries. Recent experiments show that the mature red berries contain only a small amount of toxin and have little chance of harming children (Alexander et al. 1948, Cooper and Johnson 1984, Hornfeldt and Collins 1989).

Image or illustration

Solanum dulcamara:

Images: images.google.com

Notes on Poisonous plant parts:

The immature green berries of climbing nightshade have been shown to be toxic to hamsters and mice. Mature red berries did not cause symptoms in mice. Doses were administered (8 mg/kg by orogastric needle) and symptoms occurred within 5-24 h when green berries were given. Ripened berries of climbing nightshade do not appear to present a hazard to children (Baker et al. 1989, Hornfeldt and Collins 1989).

Toxic parts:

immature fruit
leaves

References:

Baker, D. C., Keeler, R. F., Gaffield, W. 1989. Pathology in hamsters administered *Solanum* plant species that contain steroidal alkaloids. *Toxicon*, 27: 1331-1337.

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Hornfeldt, C. S., Collins, J. E. 1989. Determination of the toxicity of nightshade berries, *Solanum dulcamara*. *Vet. Hum. Toxicol.*, 31: 363.

Notes on Toxic plant chemicals:

Immature green berries of climbing nightshade contain parent steroidal alkaloid aglycones: 50% solasodine and 50% of another aglycone thought to be soladulcidine. The total alkaloid concentration has been found to be 0.030% of dry matter in the green berries. Water gavage of dry green fruit suspension caused some deaths when given at the rate of 1.4-2.0 g per hamster (avg. wt. 190 g) (Baker et al. 1989).

Toxic plant chemicals:

soladulcidine
solanine

solasodine

Chemical diagram(s) are courtesy of [Ruth McDiarmid](#), Biochemistry Technician, Kamloops Range Station, Agriculture and Agri-Food Canada, Kamloops, British Columbia, Canada.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[incoordination](#)

[muscle spasms](#)

[nervousness](#)

[regurgitation](#)

[salivation](#)

[temperature, depressed](#)

[vomiting](#)

Notes on poisoning:

Cattle that ingested the plant in Britain exhibited symptoms of nervousness, rapid pulse, incoordination, and edema to the front part of the body. The flesh of a slaughtered animal smelled strongly of the plant (Cooper and Johnson 1984).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Humans

General symptoms of poisoning:

[abdominal pains](#)

[breathing, labored](#)

[death](#)

[dyspnea](#)

[gastroenteritis](#)

[lethargy](#)

[thirsty](#)

[vomiting](#)

Notes on poisoning:

A child who probably ingested the berries of climbing nightshade died 2 days after exhibiting symptoms of vomiting, weakness, thirst, abdominal pain, dyspnea, and cyanosis. Postmortem examination showed acute inflammation of the mucosa of the stomach and intestines. An alkaloid (7 mg) characteristic of solanine was found in the liver. The evidence is not conclusive, but the child was eating blackberries in an area full of climbing nightshade berries (Alexander et al. 1948).

References:

Alexander, R. F., Forbes, G. B., Hawkins, E. S. 1948. A fatal case of solanine poisoning. Br. Med. J., 2: 518.

Hornfeldt, C. S., Collins, J. E. 1990. Toxicity of nightshade berries (*Solanum dulcamara*) in mice. Clin. Toxicol., 28: 185-192.

Rodents

General symptoms of poisoning:

[breathing, labored](#)

[craniofacial problems](#)

[death](#)

Notes on poisoning:

Tests with mice show that ingesting green (unripe) berries can cause gastroenteritis lesions, labored breathing, and lethargy. Villous atrophy of the small intestine also occurred. The red (ripe) berries did not cause any problems (Hornfeldt and Collins 1990). Tests with unripe berries on

pregnant hamsters induced congenital craniofacial malformations in fetuses in 16% of cases. Dosages administered were high, resulting in the death of some dams. Severe gastrointestinal necrosis caused the deaths. Fetuses showed encephalocele with occasional cleft palate and harelip. Another member of the genus (*Solanum sarrachoides* Sendt.; hairy nightshade) also caused a few problems in fetuses, but the numbers were not statistically significant (Keeler et al. 1990).

References:

Hornfeldt, C. S., Collins, J. E. 1990. Toxicity of nightshade berries (*Solanum dulcamara*) in mice. *Clin. Toxicol.*, 28: 185-192.

Keeler, R. F., Baker, D. C., Gaffield, W. 1990. Spirosolane-containing *Solanum* species and induction of congenital craniofacial malformations. *Toxicon*, 28: 873-884.

Sheep

General symptoms of poisoning:

[death](#)

[diarrhea](#)

[falling down](#)

[gait, staggering](#)

[pupil dilation](#)

[temperature, elevated](#)

Notes on poisoning:

In one case in Britain, sheep ingested climbing nightshade plant material and developed rapid respiration, feeble pulse, elevated temperature, dilated pupils, and green diarrhea, then death. Postmortem findings showed dark, tarry blood, contracted ventricles, and plant material in the stomach (Cooper and Johnson 1984).

Canadian Biodiversity Information Facility

Notes on poisoning: *Solanum nigrum*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Black nightshade (*Solanum nigrum*) is a naturalized herb found scattered across southern Canada in waste places. This plant can be easily confused with eastern black nightshade, a native herb, which is more commonly found in its range in eastern Canada (see taxonomy and distributions in Ogg et al. 1981, Bassett and Munro 1985). Black nightshade contains toxic glycoalkaloids in the plant. The highest concentration is in the green immature berries. All kinds of animals can be poisoned after ingesting nightshade including cattle, sheep, poultry, and swine. Children have been poisoned and have died after ingesting unripe berries. The ripe berries cause reduced symptoms of mild abdominal pains, vomiting, and diarrhea (Cooper and Johnson 1984, Lampe and McCann 1985). Some Canadian garden catalogs sell seed for garden huckleberry (*Solanum melanocerasum* All.; also previously known as *Solanum nigrum* L. var. *guineense* L.). This plant has edible black fruits that can be cooked for use in pies, jams, and preserves. The plant may persist from seed for more than a year in gardens in warmer parts of Canada. There is no evidence that the ripe fruits are toxic. Other species of nightshade occur in Canada, and some may contain small amounts of toxins. Eastern black nightshade (*Solanum ptycanthum* Dun ex DC.) may contain small amounts of toxin in the green berries. Berries of hairy nightshade (*Solanum sarrachoides* Sendt.) have been tested as a teratogen in hamsters but the results were not statistically significant (Keeler et al. 1990).

Image or illustration

Solanum nigrum:

Images: images.google.com

Notes on Poisonous plant parts:

All parts of the plant contain alkaloids, especially the green immature berries. The concentration increases in the leaves until plant maturity. The ripe black berries contain little alkaloidal content and can sometimes be eaten with no harmful effects (Cooper and Johnson 1984).

Toxic parts:

all parts
immature fruit
leaves

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Notes on Toxic plant chemicals:

Toxic glycoalkaloids, including solanine, solasodine, and chaconine are found in black nightshade, especially in the green immature berries. Nitrates can also accumulate in the plant material (Cooper and Johnson 1984).

Toxic plant chemicals:

chaconine

[diarrhea](#)
[incoordination](#)
[muzzle, dry](#)
[pupil dilation](#)
[temperature, depressed](#)

Notes on poisoning:

Symptoms of poisoning are similar to those for swine. Cattle can also develop edema from the lower jaw to the front of the legs (Cooper and Johnson 1984).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Humans

General symptoms of poisoning:

[abdominal pains](#)
[death](#)
[diarrhea](#)
[dizziness](#)
[temperature, elevated](#)
[unconsciousness](#)
[vomiting](#)

Notes on poisoning:

Humans have been poisoned and have died (rarely) after ingesting usually green immature berries. Ripe, black berries have little toxin in them, although abdominal pains and vomiting could occur. Symptoms usually occur only after a latent period of several hours and may persist for several days. Symptoms resemble those of bacterial gastroenteritis and include headache, speech impairment, and unconsciousness (Cooper and Johnson 1984, Lampe and McCann 1985).

Canadian Biodiversity Information Facility

Notes on poisoning: *Solanum pseudocapsicum*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Jerusalem-cherry (*Solanum pseudocapsicum*) is an indoor ornamental grown for its colorful berries. This plant contains an alkaloid, solanocapsine, that is related to solanine. Experiments have shown that the chemical can cause death, although it is unlikely because oral absorption of the toxin is minimal. Experiments with cats and rats have shown that oral ingesting leaves and berries has not caused severe symptoms. By extrapolation, children or family pets that ingest moderate amounts of leaf or berry material may experience mild gastroenteritis and vomiting (Der Marderosian et al. 1976, Spoerke and Smolinske 1990).

References:

- Der Marderosian, A. H., Giller, F. B., Roia, F. C. 1976. Phytochemical and toxicological screening of household ornamental plants potentially toxic to humans. 1. J. Toxicol. Environ. Health, 1: 939-953.
- Spoerke, D. G., Smolinske, S. C. 1990. Toxicity of houseplants. CRC Press, Inc., Boca Raton, Fla., USA. 335 pp.

Nomenclature:

Scientific Name: *Solanum pseudocapsicum* L.

Vernacular name(s): Jerusalem-cherry

Scientific family name: *Solanaceae*

Vernacular family name: nightshade

Go to ITIS^{*ca} for more taxonomic information on: [Solanum pseudocapsicum](#)

Image or illustration

Solanum pseudocapsicum:

Images: images.google.com

Notes on Poisonous plant parts:

In experiments, extracts of the unripe and ripe berries have caused deaths in rats; the doses were very high and were given intraperitoneally. However, rats that ingested leaves did not die. Humans who ingest berries probably experience only mild gastrointestinal effects (Spoerke and Smolinske 1990).

Toxic parts:

immature fruit
leaves
mature fruit

References:

Der Marderosian, A. H., Giller, F. B., Roia, F. C. 1976. Phytochemical and toxicological screening of household ornamental plants potentially toxic to humans. 1. *J. Toxicol. Environ. Health*, 1: 939-953.

Spoerke, D. G., Smolinske, S. C. 1990. Toxicity of houseplants. CRC Press, Inc., Boca Raton, Fla., USA. 335 pp.

Notes on Toxic plant chemicals:

Solanocapsine is an alkaloid that is structurally similar to solanine. It has a similar steroidal skeleton with an additional nitrogen group, but it is not a glycoside. Slowing of frog hearts has been shown with concentrations as low as 1:8 million. Oral absorption is minimal in animals. Rats experimentally injected with extracts from berries of Jerusalem-cherry (intraperitoneally, 3 g/100 g of body weight) resulted in the following fatalities:

- ripe fruit => 3 out of 5 rats killed
- unripe fruit => 4 out of 5 rats killed

These results indicate that death is possible, although the dosages given were very high (Der Marderosian et al. 1976, Spoerke and Smolinske 1990).

Toxic plant chemicals:

solanocapsine

References:

Spoerke, D. G., Smolinske, S. C. 1990. Toxicity of houseplants. CRC Press, Inc., Boca Raton, Fla., USA. 335 pp.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cats

General symptoms of poisoning:

[heart rate, slow](#)

Notes on poisoning:

Oral administration of pure solanocapsine has produced only slow heart rate and vomiting. Injection resulted in seizures and death. Oral ingestion of berries or leaves would likely produce only mild gastroenteritis and vomiting (Spoerke and Smolinske 1990).

References:

Der Marderosian, A. H., Giller, F. B., Roia, F. C. 1976. Phytochemical and toxicological screening of household ornamental plants potentially toxic to humans. 1. J. Toxicol. Environ. Health, 1: 939-953.

Spoerke, D. G., Smolinske, S. C. 1990. Toxicity of houseplants. CRC Press, Inc., Boca Raton, Fla., USA. 335 pp.

Humans

General symptoms of poisoning:

[abdominal pains](#)

[gastroenteritis](#)

[vomiting](#)

Notes on poisoning:

Experiments on animals suggest that children who ingest leaf or berry material might suffer only mild gastroenteritis or vomiting. Nevertheless, children should be taught to avoid eating these plants (Spoerke and Smolinske 1990).

Notes on poisoning: *Solanum tuberosum*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Potato (*Solanum tuberosum*) is a common introduced garden plant cultivated for its edible tubers. The entire plant contains toxic glycoalkaloids but usually in harmless quantities in the edible tubers. However, in the presence of light, the tubers photosynthesize and coincidentally increase the amount of toxins. The skin, eyes, and sprouts of the tubers can develop toxic amounts. Even the flesh of the tuber can develop toxic quantities of the glycoalkaloids. Cattle, sheep, and swine as well as humans were poisoned and died after ingesting parts of potato plant. Other animals were also been poisoned experimentally. A dog became comatose after ingesting green potato tubers. The aboveground plant portion can also be toxic. The berries produced by the plant can contain 10-20 times more glycoalkaloids than the tubers (Cooper and Johnson 1984). The glycoalkaloids solanine and chaconine are not destroyed by normal cooking. Alkaloidal levels above 20 mg/100 g are considered unsafe for human consumption. Some cultivars have naturally high concentrations of alkaloids and have been rejected for use. Care should be taken to store potatoes in light-proof paper bags. If any green-colored potatoes are found, they should be discarded. Potato peelings and sprouts destined for a compost heap should be buried and kept from dogs or other animals. Sharma and Salunkhe (1989) provide an excellent review of potatoes and toxins and their effects on animals.

Solanum tuberosum:

Images: images.google.com

Notes on Poisonous plant parts:

Potato tubers can develop toxic levels of glycoalkaloids if they are exposed to sunlight. The development of the toxins coincides with the production of chlorophyll in the presence of light. The toxins are highest in the skin, eyes, and sprouts. In a test on rats fed 10% sprouts from early pregnancy, 55% of litters died because of failure to lactate. Potato cultivars, such as "Lenape" have been developed with natural toxic levels of alkaloids in the tubers; these cultivars have not been released for use. The leaves, stems, and berries of potato also contain toxic substances. The concentration of alkaloids in the berries may be 10-20 times that of the tubers (Butterworth and Pelling 1980, Cooper and Johnson 1984, Cheeke and Schull 1985, Salunkhe 1989).

Toxic parts:

immature fruit
leaves
stems
tubers

Butterworth, K. R., Pelling, D. 1980. Are potato 'apples' toxic? J. Pharm. Pharmacol., 32: 79 P.

Cheeke, P. R., Shull, L. R. 1985. Natural toxicants in feeds and poisonous plants. AVI Publishing Company, Inc., Westport, Conn., USA. 492 pp.

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Notes on Toxic plant chemicals:

Two glycoalkaloids, alpha-solanine and alpha-chaconine, are the major alkaloids in potatoes. The major effects are gastrointestinal tract irritation and nervous system impairment. Exposing the potato tubers to light may increase the concentration of glycoalkaloids to 0.05% in the tuber instead of the usual 0.008%. Potatoes are now screened for toxin levels, which must be below 20 mg/100 g. Levels above 14 mg/100 g are bitter. One variety developed in the 1960s, "Lenape", had levels over 30 mg/100 g and

was rejected. Berries of potatoes have also been tested and an LD-50 of 677 g/kg was found in mice. It has been estimated that ingesting 400 g of potato berries would be required to induce symptoms in humans (Butterworth and Pelling 1980, Filadelfi 1982; Cooper and Johnson 1984, Sharma and Salunkhe 1989).

Toxic plant chemicals:

chaconine

solanine

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[anemia](#)

[anorexia](#)

[convulsions](#)

[death](#)

[diarrhea](#)

[restlessness](#)

Notes on poisoning:

Cattle were poisoning after they were given access to green, decayed, or sprouting potatoes. In Europe, feeding large quantities of stored potatoes to young cattle over long periods is recognised as causing severe anemia (Cooper and Johnson 1984).

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Dogs

General symptoms of poisoning:

[breathing, labored](#)

[coma](#)

[pupil dilation](#)

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Humans

General symptoms of poisoning:

[abdominal pains](#)

[confusion](#)

[death](#)
[drowsiness](#)
[gastroenteritis](#)
[hallucination](#)
[headache](#)
[trembling](#)
[vomiting](#)

Notes on poisoning:

Ingesting potatoes with green flesh, skin, or tubers causes sickness and, in some cases, human fatalities. Symptoms of ingestion include those common to gastrointestinal problems and nervous disorders. Clinical signs include headache, vomiting, diarrhea and abdominal pain. Neurological symptoms include apathy, restlessness, drowsiness, stupor, confusion, hallucinations, dizziness, trembling, and visual impairment. In severe cases, fatalities occur. Certain birth defects are believed to result from ingesting potatoes infected with potato blight (*Phytophthora infestans*). However, no definitive proof has been found yet (McMillan and Thompson 1979, Sharma and Salunkhe 1989).

References:

McMillan, M., Thompson, J. C. 1979. An outbreak of suspected solanine poisoning in schoolboys: examination of criteria of solanine poisoning. *Q. J. Med.*, 48: 227-243.

Rodents

General symptoms of poisoning:

[craniofacial problems](#)
[gastroenteritis](#)

Notes on poisoning:

Pregnant hamsters were gavaged with potato sprout material. Some dams died as a result of experimentally ingesting sprout material. Fetal craniofacial malformations occurred in 24% of cases (Keeler et al. 1990).

References:

Keeler, R. F., Baker, D. C., Gaffield, W. 1990. Spirosolane-containing *Solanum* species and induction of congenital craniofacial malformations. *Toxicol.* 28: 873-884.

Sheep

General symptoms of poisoning:

[death](#)

[incoordination](#)

[weakness](#)

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Swine

General symptoms of poisoning:

[anorexia](#)

[coma](#)

[convulsions](#)

[diarrhea](#)

[incoordination](#)

[pupil dilation](#)

[restlessness](#)

[salivation](#)

[vomiting](#)

[weakness](#)

Notes on poisoning:

In Europe, swine that ingested potatoes were poisoned and subsequently died. Some animals died suddenly, whereas others showed signs of incoordination, convulsions, and appeared dazed. Additional symptoms included anorexia, excess salivation, vomiting, diarrhea or constipation, and circulatory failure. Some cases required amputation, resulting from necrosis of the feet (Cooper and Johnson 1984).

Notes on poisoning: *Solidago mollis*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Velvety goldenrod (*Solidago mollis*) is a native herb found in the southern prairie provinces. This plant was fed experimentally to sheep, killing them. The corrosive resins have caused weight loss in calves, sheep, and small laboratory animals. The toxin has not been determined. In the United States, some other goldenrods (*Solidago* spp.) were shown to be poisonous. The presence of a fungal rust on the plants was implicated in the poisoning (Beath et al. 1953, Kingsbury 1964).

References:

Canadian Biodiversity Information Facility

Notes on poisoning: *Sorghum bicolor*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Sorghum (*Sorghum bicolor*) is a cultivated plant grown as ensilage, as poultry feed, or sometimes as broomcorn, for its long, flexible, high-quality broom fibers. Sorghum can contain a cyanogenic glycoside that can produce HCN during times of stress or if damaged by frost or mastication. Modern sorghums have been developed for their low HCN potential and are normally safe. Sorghum can also accumulate toxic levels of nitrates. Cattle and rarely horses have been poisoned (Kingsbury 1964, Gray et al. 1968, Clay et al. 1976).

References:

Image or illustration

Sorghum bicolor:

Images: images.google.com

Notes on Poisonous plant parts:

Damaged leaves and stems can release HCN. Since HCN is volatile, silage made from this plant is generally safe (Cheeke and Schull 1985).

Toxic parts:

leaves
stems

References:

Cheeke, P. R., Shull, L. R. 1985. Natural toxicants in feeds and poisonous plants. AVI Publishing Company, Inc., Westport, Conn., USA. 492 pp.

Notes on Toxic plant chemicals:

In the presence of plant enzymes released by damage, a cyanogenic glycoside, dhurrin, produces hydrocyanic acid (HCN) in the animal's system. Levels of cyanide at 250 mg/100 g of plant tissue have been measured after damage. A lethal dose of cyanide is 0.5-3 mg/kg of body weight. Some sorghum plants have been measured with levels 10 times a lethal of HCN (Cheeke and Schull 1985).

Toxic plant chemicals:

dhurrin

nitrate

Chemical diagram(s) are courtesy of [Ruth McDiarmid](#),

Biochemistry Technician, Kamloops Range Station, Agriculture and Agri-Food Canada, Kamloops, British Columbia, Canada.

Kingsbury, J. M. 1964. Poisonous plants of the United States and Canada. Prentice-Hall Inc., Englewood Cliffs, N.J., USA. 626 pp.

Horses

General symptoms of poisoning:

[abortion](#)

[incoordination](#)

[urinary incontinence](#)

Notes on poisoning:

In the United States sublethal doses of HCN caused degeneration of the lumbar and sacral segments of the spinal cord in horses after they ingested sorghum. Large quantities of sediment occur in the urine. If forced to move, affected horses sway from side to side and dribble urine, a condition known as sorghum cystitis ataxia. Other symptoms include an extremely enlarged bladder and patchy encephalomalacia with axonal degeneration. Damage is permanent. When fed sorghums during early pregnancy, mares have aborted. The causal toxin has not been determined yet (Fuller and McClintock 1986, Morgan et al. 1990).

Notes on poisoning: *Sorghum halepense*

[Introduction](#)[Interactive](#)[All poisonous plants by
Botanical name](#)[All poisonous plants by
Common name](#)[Important WWW Poisonous
Plants sites](#)

General poisoning notes:

Johnson grass (*Sorghum halepense*) is a naturalized herb found as a weed in only a few counties of southwestern Ontario. This plant can produce toxic quantities of HCN if it is damaged through frost, mastication, or water stress. Johnson grass can also accumulate toxic amounts of nitrate under certain circumstances. Cattle and a horse were poisoned after ingesting Johnson grass. Plants are spread from rhizomes but susceptibility to severe frost has limited the plants to a few counties in southwestern Ontario. The grass is found in fields and field edges. Toxicity is not likely, but ingesting large quantities of Johnson grass can cause problems (Gray et al. 1968, Clay et al. 1976, Warwick and Black 1983).

References:

Sharma, R. P., Salunkhe, D. K. 1989. *Solanum* glycoalkaloids. Pages 179-236 in Cheeke, P. R., ed. *Toxicants of plant origin. Vol. I. Alkaloids.* CRC Press, Inc., Boca Raton, Fla., USA. 335 pp.

Notes on Toxic plant chemicals:

A cyanogenic glycoside, dhurrin, is found in Johnson grass. After the plant has been damaged by mastication, plant enzymes convert the glycoside to other chemicals, including HCN. Cyanide, which is lethal, is released into the animal's system. Nitrates can accumulate under some circumstances. Nitrate poisoning has occurred in cattle (Gray et al. 1968, Clay et al. 1976).

Toxic plant chemicals:

chaconine

dhurrin

nitrate

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[abortion](#)

[breathing, rapid](#)

[death](#)

[death by asphyxiation](#)

[gait, staggering](#)

[methemoglobinemia](#)

[mouth, frothing of](#)

Notes on poisoning:

Johnson grass can accumulate toxic levels of nitrates, which leads to methemoglobinemia. In severe cases, death can occur 4-6 h after ingestion. Three to five days after acute poisoning, surviving pregnant animals may abort (Clay et al. 1976). Dhurrin, a cyanogenic glycoside, is found in plant material. When the plant is damaged by frost, mastication, or water stress, HCN can be released and cyanide can enter the animal's system. Symptoms are the result of cytotoxic hypoxia, leading in severe cases to death from asphyxiation. Other symptoms include increased respiration, irregular pulse, frothing at the mouth, and staggering (Gray et al. 1968, Fuller and McClintock 1986).

References:

Canadian Biodiversity Information Facility

Notes on poisoning: *Sorghum sudanense*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Sudan grass (*Sorghum sudanense*) is a cultivated forage that is planted as a late-season emergency forage crop and is either pastured or cut for green feed. Some naturalized plants are occasionally found in waste places. Sudan grass can have an HCN potential after damage to the plant. It can also accumulate toxic quantities of nitrates. These problems can be avoided by proper management. Cattle are the main livestock animals that have been poisoned. In one case in California, sheep became photosensitive after ingesting Sudan grass pasture for several days. The photodynamic pigment was not determined (Gray et al. 1968, Clay et al. 1976, Fuller and McClintock 1986).

Notes on Toxic plant chemicals:

Sudan grass contains a cyanogenic glycoside, dhurrin, that can release HCN after plant damage such as frost, mastication, and water stress and allows plant enzymes to alter the glycoside. If enough HCN is released into the animal's system, cyanide leads to cytotoxic hypoxia, which can result in death by asphyxiation. Nitrates can also accumulate to toxic levels in Sudan grass. A case of photosensitization occurred in sheep. A photodynamic pigment may be contained in Sudan grass (Gray et al. 1968, Clay et al. 1976, Fuller and McClintock 1986).

Toxic plant chemicals:

dhurrin

nitrate

Notes on poisoning: *Suckleya suckleyana*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Poison suckleya (*Suckleya suckleyana*) is a native herb found in the southern Saskatchewan and southern Alberta. This plant has caused losses of cattle and possibly sheep in the western United States. The plant is not normally ingested, but in times of scarce forage, it may be eaten in sufficient amounts to cause death. It contains an unknown cyanogenic glycoside that upon ingestion of sufficient quantity can release cyanide in the animal system, resulting in cytotoxic hypoxia. Experiments with cattle, sheep, laboratory rabbits, and guinea pigs have shown the cyanogenic potential of poison suckleya. This plant is not usually ingested by animals and is not common in the southern prairies. However, poisoning can occur (Thorp and Deem 1938, Berry and Gonzales 1986).

References:

Thorp, F., Deem, A. W. 1938. *Suckleya suckleyana*, a poisonous plant. J. Am. Vet. Med. Assoc., 47: 192-197.

Nomenclature:

Scientific Name: *Suckleya suckleyana* (Torr.) Rydb.

Vernacular name(s): poison suckleya

Scientific family name: *Chenopodiaceae*

Vernacular family name: goosefoot

Suckleya suckleyana:

Images: images.google.com

Toxic parts:

leaves

stems

References:

Berry, T. J., Gonzales, P. 1986. Do your cattle-owning clients know about this poisonous range plant? Vet. Med., 81:

1055-1056.

Notes on Toxic plant chemicals:

An unknown cyanogenic glycoside is found in poison suckleya. Upon ingestion, cyanide is released in the animal's system. The cyanide potential of this plant was measured at 0.01-0.24%. After fasting, sheep showed transitory symptoms, with forced feedings of large amounts of the plant containing 0.011% cyanide potential. Plant material measured at 0.0364% cyanide potential is lethal to cattle, guinea pigs, and sheep (Thorp and Deem 1938).

Toxic plant chemicals:

unknown chemical

References:

Berry, T. J., Gonzales, P. 1986. Do your cattle-owning clients know about this poisonous range plant? *Vet. Med.*, 81: 1055-1056.

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Cattle

General symptoms of poisoning:

[breathing, labored](#)

[cyanosis](#)

[death by asphyxiation](#)

[gait, staggering](#)

[muscle twitching](#)

Notes on poisoning:

Ingesting abundant plant material causes cyanide to be released into cattle. Symptoms include glassy eyes, muscular twitching, dribbling urine, staggering, cyanosis, fast and weak heart, labored breathing, spasms, and death by asphyxiation. Postmortem findings showed black-colored blood, congestion of the mucous membrane on the folds of the abomasum and initial part of the duodenum, and a distended bladder. Treatment includes

intravenous sodium nitrate and sodium thiosulfate, with a laxative to remove plant material from the rumen (Thorpe and Deem 1938, Berry and Gonzales 1986).

References:

Thorp, F., Deem, A. W. 1938. *Suckleya suckleyana*, a poisonous plant. J. Am. Vet. Med. Assoc., 47: 192-197.

Sheep

General symptoms of poisoning:

[collapse](#)

[death by asphyxiation](#)

[dyspnea](#)

[heart rate, slow](#)

[salivation](#)

Notes on poisoning:

On the rangelands of the western United States, sheep were believed to have died as a result of ingesting poison suckleya. Sheep were experimentally poisoned after they were force-fed plant material. Sickness and death resulted. Symptoms were similar to those of cattle that died from cytotoxic hypoxia (Thorpe and Deem 1938).

References:

Thorp, F., Deem, A. W. 1938. *Suckleya suckleyana*, a poisonous plant. J. Am. Vet. Med. Assoc., 47: 192-197.

Notes on poisoning: *Symphoricarpos albus*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Thin-leaved snowberry (*Symphoricarpos albus*) is a native shrub found throughout much of Canada in woods and open slopes. The plant is also used as an ornamental shrub in many areas. The white berries contain the isoquinoline alkaloid chelidonine, as well as other alkaloids. Ingesting the berries causes mild symptoms of vomiting, dizziness, and slight sedation in children. The risk of severe poisoning does not appear great because of vomiting that occurs after ingestion. Children should be discouraged from eating the attractive white fruit (Lewis 1979, Lampe and McCann 1985).

Notes on poisoning: *Symphytum asperum*

[Introduction](#)

[Interactive](#)

[All poisonous plants by Botanical name](#)

[All poisonous plants by Common name](#)

[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Prickly comfrey (*Symphytum asperum*) is a naturalized herb found in parts of southern Canada. The plant contains pyrrolizidine alkaloids, which can cause veno-occlusive symptoms leading to liver cirrhosis. The plant can also accumulate toxic amounts of nitrates. Animals do not normally eat the plant because of the bristly hairs on the leaves. However, swine given the plant as green fodder showed signs of nitrate poisoning. Long-term use of the plant as food could lead to liver dysfunction (Cooper and Huxtable 1984, Huxtable 1989).

Huxtable, R. J. 1989. Human health implications of pyrrolizidine alkaloids and herbs containing them. Pages 41-86 in Cheeke, P. R., ed. Toxicants of plant origin. Vol. I. Alkaloids. CRC Press, Inc., Boca Raton, Fla., USA. 335 pp.

Notes on Toxic plant chemicals:

This plant contains pyrrolizidine alkaloids such as echimidine. These alkaloids cause veno-occlusive symptoms in animals. Total alkaloid content (as a percentage of dry weight) for fresh leaves is about 0.01% and for dry leaves, about 0.059%. Many members of the genus contain much higher concentrations of alkaloids in the roots (Huxtable 1989).

Toxic plant chemicals:

echimidine
nitrate

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Swine

General symptoms of poisoning:

[breathing, labored](#)
[cyanosis](#)

[methemoglobinemia](#)

Notes on poisoning:

Prickly comfrey is not normally ingested by animals because of the bristly hairs on the leaves. This plant can accumulate nitrates. In Britain, swine were poisoned when given prickly comfrey as green fodder. Symptoms were typical for nitrate poisoning, including apathy, labored breathing, cyanosis, and methemoglobinemia (Cooper and Johnson 1984).

Notes on poisoning: *Symphytum officinale*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Common comfrey (*Symphytum officinale*) is an introduced and naturalized herb found on damp roadsides and waste places in many parts of Canada. This plant contains several pyrrolizidine alkaloids, which cause veno-occlusive symptoms, liver cirrhosis, and death. Humans have been affected after ingesting herbal teas and medicines. Rats have developed hepatocellular tumors after ingesting the alkaloid symphytine, found in common comfrey. Canadian health officials have sought to ban sale of some comfrey products. Animals normally do not ingest the plant because of the bristly hairs. Topical herbal preparations are not considered toxic because the alkaloids do not reach the liver (Steuart 1987, Huxtable 1989, Ridker and McDermott 1989). Russian comfrey (*Symphytum X uplandicum* Nym. [synonymy: *Symphytum peregrinum* Ledeb.]) has been grown in Canada in Lethbridge, Alta., and Vancouver Island, as a trial forage crop for livestock, but it was not found to be suitable. This plant may be available from some nursery seed suppliers. Russian comfrey also contains pyrrolizidine alkaloids and should not be taken internally as a herb remedy.

Images: images.google.com

Notes on Poisonous plant parts:

The roots have greater concentrations of pyrrolizidine alkaloids than the leaves. Animals do not commonly ingest the plants because of the bristly leaves (Cooper and Johnson 1984, Huxtable 1989).

Toxic parts:

all parts
leaves
roots

References:

Cooper, M. R., Johnson, A. W. 1984. Poisonous plants in Britain and their effects on animals and man. Her Majesty's Stationery Office, London, England. 305 pp.

Huxtable, R. J. 1989. Human health implications of pyrrolizidine alkaloids and herbs containing them. Pages 41-86 in Cheeke, P. R., ed. Toxicants of plant origin. Vol. I. Alkaloids. CRC Press, Inc., Boca Raton, Fla., USA. 335 pp.

Notes on Toxic plant chemicals:

Common comfrey contains several pyrrolizidine alkaloids, including echimidine, heliosupine, lycopsamine, and symphytine. Alkaloids were found in the plant totalling 0.07% dry weight in roots and 0.062% in dry leaves, and 0.006% in fresh leaves. Two alkaloids found in common comfrey were shown to cause liver and bladder tumors in rats; the roots have more toxins than leaves. Some commercial products of roots and leaves sold as herbal teas and medicinal preparations have a total alkaloidal concentration of 270 mg/kg (leaves) and 2900 mg/kg (roots). Ingesting a cup of tea made from the roots may contain 8.5 mg of alkaloid, which is 26 mg per cup if the gelatinous residue is consumed. [Huxtable 1989].

Toxic plant chemicals:

echimidine

heliosupine
lycopsamine

Animals/Human Poisoning:

Note: When an animal is listed without additional information, the literature (as of 1993) contained no detailed explanation.

Humans

General symptoms of poisoning:

[ascites](#)
[liver, cirrhosis of](#)

Notes on poisoning:

Ingesting pyrrolizidine alkaloids for several months leads to veno-occlusive problems and severe portal hypertension, which can lead to cirrhosis of the liver and death. Symptoms include ascites, edema, and reduced urinary output. Children are more susceptible than adults. In two cases, one woman was estimated to consume at least 85 mg of pyrrolizidine alkaloids from a herbal leaf preparation over 6 months; another woman consumed 512 mg over 6 months (comfrey-pepsin preparation) (Huxtable 1990). Ridker and McDermott (1989) note that pulmonary endothelial hyperplasia can also occur from direct exposure to these alkaloids. Rats have developed hepatocellular tumors because of the alkaloid symphytine.

Canadian Biodiversity Information Facility

Notes on poisoning: *Symplocarpus foetidus*

[Introduction](#)[Interactive](#)[All poisonous plants by Botanical name](#)[All poisonous plants by Common name](#)[Important WWW Poisonous Plants sites](#)

General poisoning notes:

Skunk cabbage (*Symplocarpus foetidus*) is a robust native herb found in wet marshy areas in parts of eastern Canada. Ingesting the plant can cause intense pain and irritation in the mouth area after chewing the roots or leaves (Lampe and McCann 1985). No case reports of such irritation were found in the literature for humans or livestock.
