Dining on the Wilds

- Takes you inside the classroom for an interesting graphic slide presentation which gives you a close-up look at the identification of many wild edible plants, herbs and mushrooms of North America.
- Come along on live field trips. Observe and enjoy plants in their natural habitat. Learn how to use these natural, nutritive items.
- Taste the fun of a cooking class where unique recipes are demonstrated. You are in for a truly mouth watering treat.
- Watch the fun as students bring family and friends to a gourmet buffet where everyone brings home made dishes containing at least one wild ingredient.
- Listen to student comments as to why they enrolled in the class and why some have come back repeatedly.

[Others say](#)

I have thoroughly enjoyed Dining on the Wilds. The tapes have been a great help. They are very informative. ...

Sincerely,
Susie Teague
[Cedar Creek Nature Studies](#)

- This video set is a unique, fun and educational experience that your whole family will enjoy viewing over and over again.

Survival Tip

A C O R N S

California black oak
Quercus kelloggii

Warning

Unprocessed acorns usually have toxic quantities of tannin and may shutdown the digestive track. Proper leaching removes the tannin making them a major wild food item.

The most common steps in leaching are

- shelling the nuts
- removing the inner skin
- grinding the nuts
- cold water leaching allows the acorn meal to thicken when cooked

Hot water leaching is faster and more common with "modern" experimenters but does not thicken or act as a binder (like eggs or gluten) when cooked.

California black oak acorns usually are harvested in October to December

A Method of Cold Water Leaching

Shell the acorns in your favorite way. Some suggestions step on them with hard shoes until you hear a pop sound. Drive over them. Use a nut cracker (dried acorns are more brittle). Crack with a hammer or rock. Soak them in water until they split open (about 2 weeks to a month).

Place about a cup of shelled nuts in a 1 quart blender and fill it with water. Jog the blender for 5 to 15 seconds at a time to knock off the skins. Stop the blender and skim the skins from the surface when there are enough to skim. Repeat the jogging and skimming until no more skins float to the surface.

Grind the nuts in the blender to a fine meal. The water will turn milky white. Pour the nuts and water into a large container with a fine cloth strainer (or 5 gal nylon paint strainer) through a sieve. The part staying in the sieve needs to be ground again. The meal that stays in the cloth strainer needs more leaching. The very fine sediment that goes through the cloth thickens when it is cooked. When all the nuts are ground and pass through the sieve, move the cloth strainer and meal to another container of cold water and agitate the meal more fine sediment will cloud the water. After letting it set for about 10 min. remove the meal from the water and pour the water into the first container of murky water. Fill the second container with water again and put the meal into the fresh cold or warm water. The water may need to be change again.

Let the first container of murky water settle for 2 hours to overnight and change the water but keeping the sediment. This water changing may need to be done more than once. When the leaching water is poured off test for tannin by cooking equal amounts of meal and taste for tannin (bitter after taste and/or dry feel to the mouth). Cooking brings out the tannin taste. If there is no tannin taste pour the sediment into the strainer with the rest of the leached meal and let it drain. The acorns are now leached

A c o r n B r o w n i e s

2 cups drained but wet cold water leached acorn flower
 1 cup chopped walnuts
 1 cup fruit juice concentrate or honey
 1/2 cup water with
 1 teaspoon baking soda

mix water and baking soda first then mix with other ingredients. Bake in a greased pan at 350F for 45 min. Cool and serve

White man's wiwish

(wiwish is a Cahuilla name for acorn mush)

1 cup of drained but wet cold water leached acorn flower
 1 cup water (some acorns need more some less)
 1/4 to 1/2 teasp. Salt (to taste)

1/4 cup sweetener honey or fruit juice concentrate (optional)

Mix ingredients together and bring to a boil, or until wewish thickens.

Because some search engines penalize for "over use of words"
"nuts" has been used in place of a c o r n s .

Dining on the Wilds a six session video course.

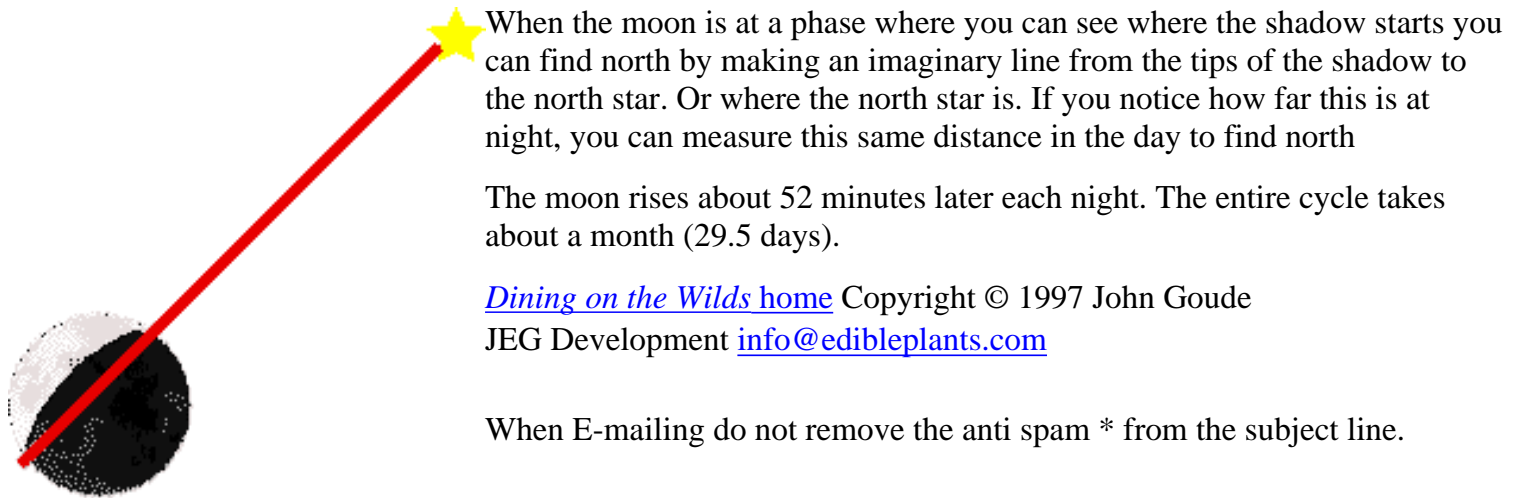

North by the moon

How would you find north?

The moon is a compass or more accurately a pointer to the north star. So if you can see the moon you should be able to find north. There are two ways to do this.

On a fairly full moon you can see a crescent of shadows. The finger in the crescent points to the north.

When the moon is at a phase where you can see where the shadow starts you can find north by making an imaginary line from the tips of the shadow to the north star. Or where the north star is. If you notice how far this is at night, you can measure this same distance in the day to find north

The moon rises about 52 minutes later each night. The entire cycle takes about a month (29.5 days).

Wild Edible Plant Nutrition (per 100 grams)

Name	Calories	Protein	Fat	Calcium	Phosphorus	Iron	Sodium	Potassium	Vitamin A	Thiamin	Riboflavin	Niacin	Vitamin C
	(grams)	(mg)	(mg)	(mg)	(mg)	(mg)	(mg)	(mg)	(I.U.)	(mg)	(mg)	(mg)	(mg)

Warning: Some of these plants have toxic parts or are toxic until prepared properly. (Cherry pits contain cyanide.) Before you eat any wild plant make sure of its identity and that it has been prepared properly. Some people may have bad reactions to some plants (allergies etc.). This list has some that I have not seen in any wild edible plant book yet. The cardinal edibility rule is "KNOW BEFORE YOU EAT". However do not be afraid of wild edible plants, because it is a fascinating study, but please be wise and careful.

A * by a plant name means there is not agreement, among people who study wild edible plants, on the edibility of this plant.

- [Wilderness Survival class March - April 2004](#)
- [Wild edible plant classes April. - May. 2004](#)
- [Maps](#)
- [Agave festival April](#) is sponsored by some friends of mine.
- [E-mail](#) for custom survival and edible plant classes. (When E-mailing do not remove the anti spam * from the subject line.)

I have done special classes and lectures for

schools, homeschool groups, church outings, search and rescue, sheriff's posse, garden clubs, Pathfinder and scout groups, summer camps, outdoor schools, etc.

Wild Edible Plants Class

Class Content:

- Over 200 California Wild Edible Plants
- Identification
- Edible Parts
- Habitat
- Season
- Nutritive value
- Food preparation in field and kitchen

(In addition: edibility rules, basics for eating wild plants safely, primitive cookery, mushrooms, poisonous plants, herbal usage of the wild edibles, and much more.)

Class includes:

- Lectures
- Demonstrations
- "Wild" banquet
- Slides
- Food Sampling
- Certificate of Achievement
- Displays
- two Field trips
- Wild food cookery demonstrations

Instructors:

Miriam Kramer

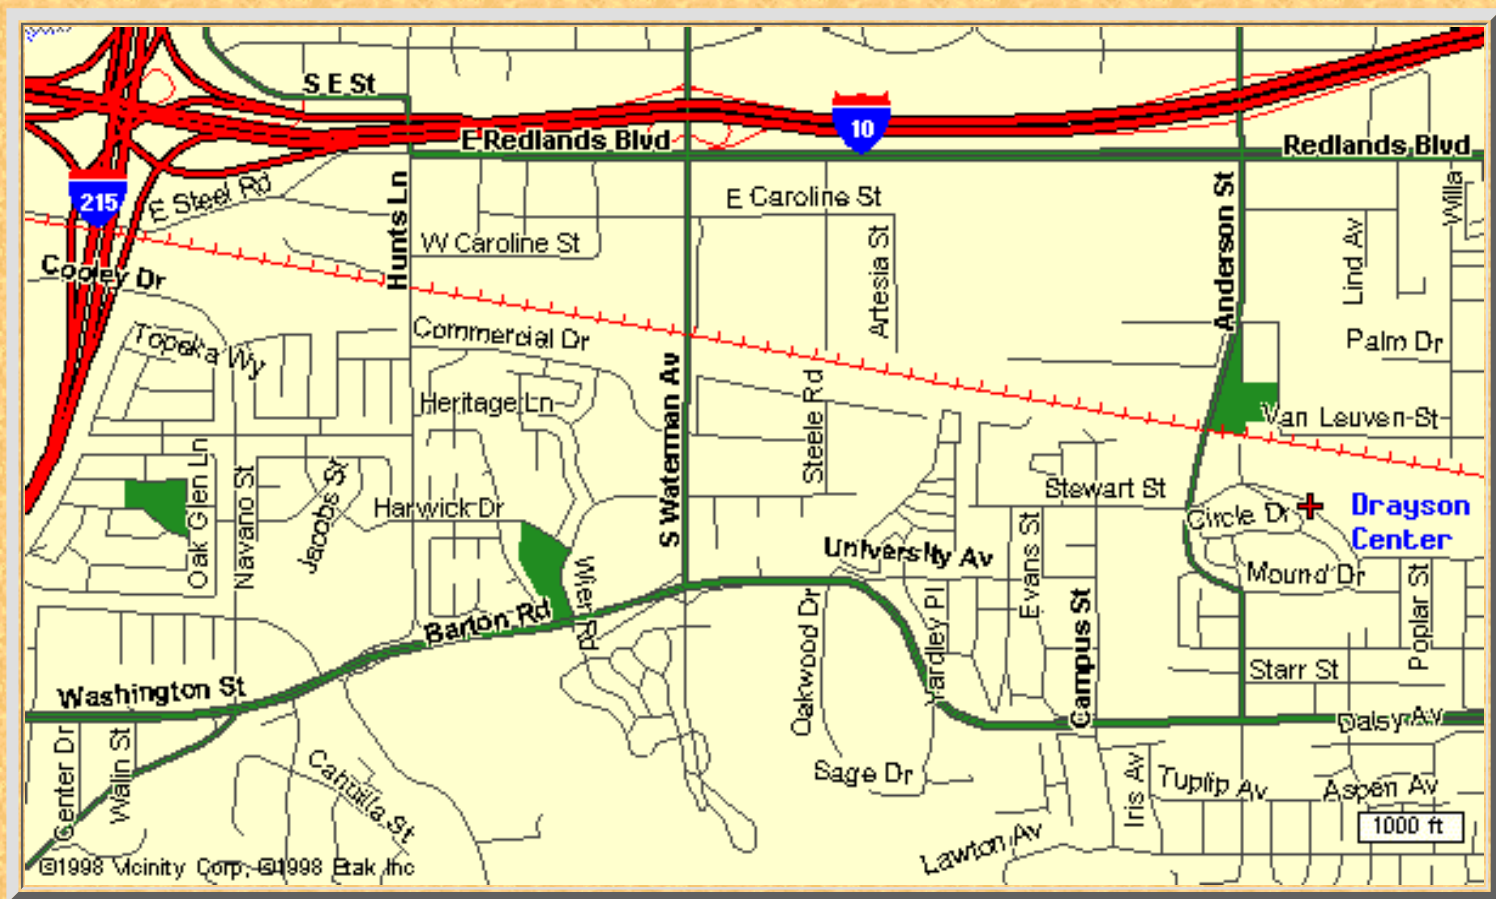

is author of Wild Plants to Eat correspondence course, co-author of Wild Plants to Eat Workbook and slide set, and is featured on the six-hour "Dining on the Wilds" video set. She was associate director of the former International Wilderness Club, and has extensive classroom and field experience teaching about edible wild plants in 30 states, Canada, and Peru. She was listed in Who's Who in American Women and similar publications.

John Goude

has studied edible wild plants for 35 years in 16 states, has taught wild edible plants in four states, is a U. S. Forest Service volunteer interpretive specialist, has taught at Rabbitstick rendezvous of Society of Primitive

Technology, President of Forage Ahead, a wild edible plant enthusiasts club, has cataloged and cross indexed over 500 North American wild edible plants, was president of Riverside California Chapter of International Wilderness Club, produced the six-hour "Dining on the Wilds" video set.

The following assistants and guest speakers add the fine touches to the Loma Linda class to make it an exciting learning experience **Doug Vonkrieglstein, Evie Roach, and Duke Petersen** and others. .

LOMA LINDA CLASS INFORMATION, CALL: [E-mail](#)

When E-mailing do not remove the anti spam * from the subject line.

Date and Time: April 12 - May 17 (2 Sunday field trips) Monday, 6:30 to 8:30 PM.

Place: Loma Linda University Drayson Center, 25040 Stewart Street

Cost: \$89 (includes textbook, handouts. food samples, etc.)

DIRECTIONS: Drayson Center is on Stewart St. about 2 blocks east of Anderson, (south of I-10) in Loma Linda

Wilderness Survival Class

Date: March 1 - April 5, 2004

Time: Monday evenings, 6:30 to 8:30 + (plus 2 Sunday field trips)

Place: Loma Linda University Drayson Center

Cost: \$65 includes materials

Class Content:

- Survival concepts
- Planning
- Leadership skills
- Navigation
- Signaling
- Weather
- Shelter building
- Fire building
- Water purification
- Primitive skills
- and more

Instructor:

John Goude has been a Pathfinder leader for more than 30 years. He has taught wilderness survival at Camp Cedar Falls, Rabbitstick, Winter Count Rendezvous and SAR City (a major desert search and rescue training program). He is a certified Hug-a-Tree and Survive teacher. Most of all he has lived through real survival situations and brought those with him back safely.

Nature Bound Pocket Field Guide

by Ron Dawson

This is a large pocket size book (335 pages) on wilderness skills, survival and first aid (80 pages) with most of the book about wild edible plants(176 pages) and poisonous plants(76 pages). Each plant has a full page (4.5" X 5") description of the plant and uses etc. and a full page color photograph of the plant.

This book covers 80 edible and 34 poisonous plants. There are general preparation directions but no recipes.

ISBN 0-8163-1072-6

Wild Plant Cookbook

Bill and Bev Beatty shared this work with Bill doing most of the writing and Bev the illustrations. It is a very attractive book, written with philosophical insight and combining nutrition, economy, good tasting recipes, and fun. This book is a perfect resource for those interested in good health and food self-sufficiency, who want to know the vitamins and minerals our bodies need and which wild plants contain them. 174 pages

Common Edible and Useful Plants of the West

by Muriel Sweet

Covers more than 100 plants in 64 pages. Each plant has a good line drawing. There are no recipes.

Some plants in this book are not covered in other books that I have found to be edible. Many books do not fully cover the often edible cambium layer of plants.

ISBN 0-87961-046-8

A Field Guide to Edible Wild Plants of Eastern and Central North America

Peterson Field Guide 23
by Lee Allen Peterson

Descriptions and illustrations of more than 370 edible wild plants found in eastern and central North America, plus 37 poisonous look-alikes

Over 400 drawings and 78 color photographs show precisely how to recognize each species

14 habitats are described in full detail, with plants in each habitat listed by season for easy collecting

Preparation directions for 22 different food uses, including cereals, jams and jellies, teas, and many others

In my opinion this is the best for the east. It is the book I used extensively when I lived in Michigan and Ohio, and studied plants in surrounding states. This book has use symbols in the margin that indicate the use of the plant.

ISBN 0-395-31870-X
\$18.00

Wild Edible Plants of Western North America

A husband and wife team with Donald Kirk author and Janice Kirk illustrator. Nearly 2000 species of wild edible plants found in the western United States and in southwestern Canada and northwestern Mexico are covered in 343 pages. Various methods of preparing wild foods and careful warnings to avoid poisonous plants are given.

This book is the most complete book for western North America (west of the rockies). Its weakness is that the line drawings sometimes try to cover more than one species in one drawing thus making it hard to identify the plant with certainty. There are no recipes. Overall this is the best for the west.

ISBN 87961-036-0,

Oaks of North America

Howard Miller and Samuel Lamb had forestry careers, but were partial to the oaks. Their book has three major parts: history and uses of oaks, oaks of the East, and oaks of the West. Very helpful in identification are the keys for each section of oaks. The authors often trekked hither and yon in search of each species to photograph the oak and its leaf, acorn, and bark. Accompanying each is an informative chapter of description, details of identification, growth habitat, and excellent range maps. They mention ways each species is useful and unique from the other oaks. 328 pages.

ISBN 87961-137-5
\$12.95.

Berry Picker

In the old days of Scandinavia the bear was a very respected animal and was closely watched. The people noticed how the bear picked berries and made a device like a bears paw to gather their berries too. Over the years the materials have changed but the principle remains unchanged.

This berry picker can pick some kinds of berries 2 to 10 times as fast as normal hand picking. I have found it to be good for blue berries, rose hips, choke cherries, hawthorn berries, kinnikinnick

Botanical name spelling dictionary

The plants of North America are numerous and have unusual spellings by the common English vocabulary standards. Often one only reads the name making it harder to remember how it is spelled. Being a creative speller anyway I decided to make this list of plant names so that my spelling checker will stop bugging me about them.

This list is only for North America. It was not intended to have plant names from other places. However it would have parts of names from other places

To use this list your spelling checker will need to:

- Be able to have 4 custom dictionaries open at a time.
- Custom dictionary size of up to 107 kb In this case about 10,000 words
- Accept word lists in its custom dictionary

The following files are made from this zip file.

readme.txt	installation instructions, etc.	2 kb
famssp.dic	family, sub species names, etc.	44 kb
genera.dic	genera names	69 kb
speic1.dic	species names a-l	107 kb
speic2.dic	species names m-z	97 kb

[E-mail for a trial](#) the zip file 103 kb (\$5 if you keep it)

Please indicate if you can not have attached files in your return e-mail. If you do not have unZIP software let me know.

Bible spelling dictionary

The Bible has many words not found in most computer spelling dictionaries. Being a creative speller anyway I decided to make this list of Biblical words so that my spelling checker will stop bugging me about them.

This list is mainly for KJV, NKJV, NIV, ASV versions. It includes many of the common book abbreviations too.

To use this list your spelling checker will need to:

- Be able to have at least one custom dictionary open.
- Custom dictionary size of up to 57 kb In this case over 6,000 words
- Accept word lists in its custom dictionary

The following files are made from this zip file.

readme.txt	installation instructions, etc.	2 kb
bible.dic	List of Bible words	57 kb

[E-mail for a trial](#) the zip file 21 kb (\$5 if you keep it)

Please add "NO ATTACH" to the subject line if you can not have attached files in your return e-mail.

Please add "NO ZIP" to the subject line if you can not unzip files.

The auto responder will e-mail the file back to you immediately if you can have attached files and zipped files.

(proposed) Internet Pathfinder honor

1. Define the following terms in the context of the Internet: URL, TCP/IP, HTML, homepage, site, hit (on a page), E-mail, browser, search engine, directory, bookmark, surfing, animation, GIF, JPEG, background, Internet Phones, FTP, HTTP, Newsgroups, gopher?.
2. Write a page, without the aid of a HTML editor, using these commands properly
<HTML>
<HEAD>
<TITLE>
<BODY>

<A HREF...>
3. What are frames, tables, and lists. Explain the differences between them. What are META statements used for? There are many text formatting commands. Describe how to use some of them. (H1-6, B, STRONG, I, EM, P, BR, HR)
4. Develop a personal homepage about yourself and your interests containing a graphic file and a link to another file.
5. Participate in making or updating a homepage for your Pathfinder club, church, or school.
6. Do research on the Internet on a topic of interest to you using Search Engines and links and give a report (oral or written) on what you found. Or visit 25 Internet sites of which 5 would be church related. Give a report on the sites telling what you like or don't like about each site. Rate them on design (organization, use of graphics, overall visual appeal, ease of use etc.) and content,
7. What are some dangers on the Internet? How can you avoid them? Discuss some ways that can help protect you from those dangers.
8. For at least a month use E-mail to exchange messages with a pathfinder in another country.

SKILL LEVEL 2

(proposed) Advanced Internet Pathfinder honor

1. Write a web site, without the aid of a HTML editor, of at least 3 pages in HTML using these commands properly <HTML>
<HEAD>
<TITLE>
<BODY>
 using GIF and JPEG files

<A HREF...> for internal links, links to other files in your site and links to files in other sites.
The site should include frames, tables, ordered lists and unordered lists.

Use text formatting commands such as. (H1-6, B, STRONG, I, EM, P, BR, HR)

<META ...>

2. Install and setup, for use with an Internet service provider, a browser and E-mail program on a computer.
3. Give a brief history of the Internet.
4. Make an animated GIF image and one using a transparent color.
What can be done to make GIF files load from the web faster.
When is it better to use:
 - a. JPEG image files
 - b. GIF image files?
5. Use FTP and news groups

SKILL LEVEL 3

[Pathfinders homepage](#)

[E-mail John Goude](#)

When E-mailing do not remove the anti spam * from the subject line.

Proposed modifications

Edible Wild Plant Honor

1. Identify in the wild 15 edible wild plants.
2. Identify in the wild or from pictures
 - 5 trees and
 - 5 shrubs which are edible.
3. Identify, prepare and eat
 - 3 kinds of wild berries or fruits,
 - 3 salad plants or seeds
 - 3 potherbs,
 - 2 tubers (or roots)
4. From two of the plants below, demonstrate at least one way how to prepare and eat that plant, and explain how you can prepare the other parts.
 - 5 parts of the cattail for food (root preparation required)
 - 4 parts of milkweed
 - 4 parts of daylily
 - 3 parts of yucca
 - 3 stages of a mesquite, or screwbean
 - acorns for food,
 - thresh and winnow seeds from plants such as lambs' quarters, amaranth, dock, or grass;
 - other major wild edible plants in your area if none of the above are available
5. Tell a Bible or church history story that involves poisonous or wild edible plants or where such knowledge would have been useful (2 Kings 4:38-41). Or find a Bible object lesson in a wild edible plant.
6. The roots of what 2 water plants were dried and ground into meal by the Indians? Or name 2 wild plants used as staple food items by the indigenous people of your area and tell how they stored and prepared them.

7. What is the cardinal edibility rule?

What is the general edibility rule for berries? List an exception.

[black and blue, red, and white]

What is the general edibility rule for plants with milky sap? List an exception.

8. Identify 3 poisonous plants in your area that no part can be made edible. Tell how you would recognize water hemlock (*Cicuta* sp.) and poison hemlock (*Conium* sp.)? Tell why mushrooms so very dangerous to eat?

Please give your [feed back](#) on this honor (roughly equivalent to a BSA merit badge). Could it be taught in your area to 10 to 15 year olds?

When E-mailing do not remove the anti spam * from the subject line.

Some have suggested that an advanced honor be made moving the threshing and poisonous plants to an advanced honor

[\[Why Change\]](#)

[\[Answers\]](#)

[Home](#)

Copyright © 1996, 2001 John Goude

JEG Development

Why change the Edible Wild Plant Honor

- The current honor teaches Pathfinders to do **high risk** activities. In the book Poisonous Plants of California the statement is made that,

"Of all poisonous plants in California, toxic mushrooms cause the most serious illnesses and nearly all the fatalities to humans."

Some mushrooms in the United States are so toxic that people have **died** from the mushroom toxin transferred by a knife to edible plants. Do you really want to teach your Pathfinder's to engage in the high risk activity of wild mushroom eating? I do not want to be responsible for getting someone into something that could kill them or put them in the hospital and have liver damage to live with for the rest of their life.

- The current honor was written with only the eastern states in mind. Many of the required plants do not grow wild in the west.
 - It is strange to beg a stranger to allow a edible wild plant class to dig up their prized bed of day lilies. They often reply, "These gorgeous flowers are not wild! Go get some real wild plants." Even in the east day lilies are not native they only grow where they have been introduced.
 - There are many areas that milkweed does not grow at all. But yet the honor **requires** it to be eaten.

This honor was originally written by someone I have great respect for, but he had studied wild edible plants mainly in the east when he wrote it. Is it time to update this honor to be safe and less regional ? How would the proposed changes effect those teaching it in the far north of Alaska and Canada? I would like some feedback from there.

JEG Development 

Edible Wild Plant Honor Answers

4. From two of the plants below, demonstrate at least one way how to prepare and eat that plant, and explain how you can prepare the other parts.

- 5 parts of the cattail for food (root preparation required), root, shoot, cattail, pollen, rhizome
- 4 parts of milkweed, (all parts are poisonous until cooked) young leaves, buds, flowers, young pods
- 4 parts of daylily, tubers, shoots, buds, flowers
- 3 parts of yucca, flower stalk, flower, seed pod
- 3 stages of a mesquite, flower, green pods, mature pods
- [acorns for food](#)
- lambs' quarters, amaranth, dock, or grass; thresh, winnow the seeds, tender leaves and stems can be eaten raw or cooked.
- or other major wild edible plants in your area if none of the above are available

5. Tell a Bible or Church history story that involves poisonous or edible wild plants or where such knowledge would have been useful. Or find a Bible object lesson in a wild edible plant.

Gen. 13:18 (ASV) And Abram moved his tent, and came and dwelt by the oaks of Mamre, which are in Hebron, and built there an altar unto Jehovah.

Gen. 14:12-13 (ASV) And they took Lot, Abram's brother's son, who dwelt in Sodom, and his goods, and departed. 13 And there came one that had escaped, and told Abram the Hebrew. Now he dwelt by the oaks of Mamre, the Amorite, brother of Eshcol, and brother of Aner. And these were confederate with Abram.

Gen. 18:1 (ASV) And Jehovah appeared unto him by the oaks of Mamre, as he sat in the tent door in the heat of the day.

(Do you think Abram ate the acorns? There is archaeological evidence that they were eaten back then.)

II Kings 4:38-41 (NIV) Elisha returned to Gilgal and there was a famine in that region. While the company of the prophets was meeting with him, he said to his servant, "Put on the large pot and cook some stew for these men."

39 One of them went out into the fields to gather herbs and found a wild vine. He

gathered some of its gourds and filled the fold of his cloak. When he returned, he cut them up into the pot of stew, though no one knew what they were. 40 The stew was poured out for the men, but as they began to eat it, they cried out, "O man of God, there is death in the pot!" And they could not eat it. 41 Elisha said, "Get some flour." He put it into the pot and said, "Serve it to the people to eat." And there was nothing harmful in the pot.

Matt 3:4(NIV) John's clothes were made of camel's hair, and he had a leather belt around his waist. His food was locusts and wild honey. (Locusts are carob or a similar bean pod.)

Lichens are an edible plant that is a blend of two plants depending on each other. So Jesus is a blend of divine and human.

Luke 1:35 (NIV) The angel answered, "The Holy Spirit will come upon you, and the power of the Most High will overshadow you. So the holy one to be born will be called the Son of God.

John 1:1-5 (NIV) In the beginning was the Word, and the Word was with God, and the Word was God. 2 He was with God in the beginning. 3 Through him all things were made; without him nothing was made that has been made. 4 In him was life, and that life was the light of men. 5 The light shines in the darkness, but the darkness has not understood it.

John 1:9-14 (NIV) The true light that gives light to every man was coming into the world. 10 He was in the world, and though the world was made through him, the world did not recognize him. 11 He came to that which was his own, but his own did not receive him. 12 Yet to all who received him, to those who believed in his name, he gave the right to become children of God-- 13 (JEG) children born not of natural descent, nor of their human decision or someone else's will, but born of God. 14 The Word became flesh and made his dwelling among us. We have seen his glory, the glory of the One and Only, who came from the Father, full of grace and truth.

Most acorns are very BITTER and need to be washed of their bitterness before they are useful. So we must be washed of our bitterness of sin to be useful to God.

Ps 51:2-3 (NIV) Wash away all my iniquity and cleanse me from my sin. 3 For I know my transgressions, and my sin is always before me.

Ps 51:6-7 (NIV) Surely you desire truth in the inner parts; you teach me wisdom in the inmost place. 7 Cleanse me with hyssop, and I will be clean; wash me, and I will be whiter than snow.

Ps 51:10-13 (NIV) Create in me a pure heart, O God, and renew a steadfast spirit within me. 11 Do not cast me from your presence or take your Holy Spirit from me 12 Restore to me the joy of your salvation and grant me a willing spirit, to sustain me. 13 Then I will teach transgressors your ways, and sinners will turn back to you.

Titus 3:4-7 (NIV) But when the kindness and love of God our Savior appeared, 5 he

saved us, not because of righteous things we had done, but because of his mercy. He saved us through the washing of rebirth and renewal by the Holy Spirit, 6 whom he poured out on us generously through Jesus Christ our Savior, 7 so that, having been justified by his grace, we might become heirs having the hope of eternal life.

Cleavers stick to your clothes. That is how God wants us to stick to Him and to the good.

Rom 12:9 (ASV) Let love be without hypocrisy. Abhor that which is evil; cleave to that which is good.

Deut 10:20 (KJV) Thou shalt fear the LORD thy God; him shalt thou serve, and to him shalt thou cleave, and swear by his name.

(NIV) Fear the LORD your God and serve him. Hold fast to him and take your oaths in his name.

Deut 30:20 (KJV) That thou mayest love the LORD thy God, and that thou mayest obey his voice, and that thou mayest cleave unto him: for he is thy life, and the length of thy days: . . .

(NIV) and that you may love the LORD your God, listen to his voice, and hold fast to him. For the LORD is your life, and he will give you many years in the land . . .

Josh 23:8 (KJV) But cleave unto the LORD your God, as ye have done unto this day.

(NIV) But you are to hold fast to the LORD your God, as you have until now.

Acts 11:23 (KJV) Who, when he came, and had seen the grace of God, was glad, and exhorted them all, that with purpose of heart they would cleave unto the Lord.

(NIV) When he arrived and saw the evidence of the grace of God, he was glad and encouraged them all to remain true to the Lord with all their hearts.

See also Josh 22:5 , Deut 11:22 , Deut 13:4 (KJV)

Tumbleweed God blows the wicked like wind blows tumbleweed.

Ps 83:13 (NIV) Make them like tumbleweed, O my God, like chaff before the wind.

Isa 17:13 (NIV) Although the peoples roar like the roar of surging waters, when he rebukes them they flee far away, driven before the wind like chaff on the hills, like tumbleweed before a gale.

This is a start but God has given you many more think up some yourself.

6. The roots of what 2 water plants were dried and ground into meal by the Indians? Or name 2 wild plants used as staple food items by the indigenous people of your area and tell how they stored and prepared them.

Cattail, arrowhead, bulrush

7. What is the cardinal edibility rule?

Positively identify every plant that you eat and know it is edible and how to prepare it.

What is the general edibility rule for berries?. [black and blue, red, and white]

90% of black or blue berries, half of red berries, 10% of white berries are edible.
For berries the rule is

Black and blue are good for you.
Red use your head.
White don't bite.

Andrew Manthe

List an exception Raw poke berries (seeds) and nightshade berries and black and poisonous,

Western snow berries are white and edible but if they are not ripe they are bitter and give you a sore throat.

Symphoricarpos mollis poisonous Eastern snow berries will make you vomit.

Symphoricarpos albus

What is the general edibility rule for plants with milky sap?

Plants with a milky sap are usually not edible.

List an exception. Milk weed (cooked), dandelion, salsify, wild lettuce, figs, lettuce, mulberry, etc.

8. Identify 3 poisonous plants in your area that no part can be made edible.

Tell how you would recognize water hemlock and poison hemlock?

Water and poison hemlock are in the carrot family both usually have purple spots.

Water hemlock has veins running to the notch of the leaves and has hollow roots that often contain a yellow liquid.

Tell why mushrooms so very dangerous to eat?

Some people with PhDs in mycology (mushroom study) have been killed by mistakenly eating poisonous mushrooms. Other people have died after eating food cut with a knife that had not been washed after it cut poisonous mushrooms. The Bible never mentions them as a food acceptable for people.

Experience nature as God intended. Taste it !
Click here to learn about wild plants you can eat and enjoy.
Dining on the Wilds a six session video course.

Survival Tip

A C O R N S

California black oak
Quercus kelloggii

Warning

Unprocessed acorns usually have toxic quantities of tannin and may shutdown the digestive track. Proper leaching removes the tannin making them a major wild food item.

The most common steps in leaching are

- shelling the nuts
- removing the inner skin
- grinding the nuts
- cold water leaching allows the acorn meal to thicken when cooked

Hot water leaching is faster and more common with "modern" experimenters but does not thicken or act as a binder (like eggs or gluten) when cooked.

California black oak acorns usually are harvested in October to December

A Method of Cold Water Leaching

Shell the acorns in your favorite way. Some suggestions step on them with hard shoes until you hear a pop sound. Drive over them. Use a nut cracker (dried acorns are more brittle). Crack with a hammer or rock. Soak them in water until they split open (about 2 weeks to a month).

Place about a cup of shelled nuts in a 1 quart blender and fill it with water. Jog the blender for 5 to 15 seconds at a time to knock off the skins. Stop the blender and skim the skins from the surface when there are enough to skim. Repeat the jogging and skimming until no more skins float to the surface.

Grind the nuts in the blender to a fine meal. The water will turn milky white. Pour the nuts and water into a large container with a fine cloth strainer (or 5 gal nylon paint strainer) through a sieve. The part staying in the sieve needs to be ground again. The meal that stays in the cloth strainer needs more leaching. The very fine sediment that goes through the cloth thickens when it is cooked. When all the nuts are ground and pass through the sieve, move the cloth strainer and meal to another container of cold water and agitate the meal more fine sediment will cloud the water. After letting it set for about 10 min. remove the meal from the water and pour the water into the first container of murky water. Fill the second container with water again and put the meal into the fresh cold or warm water. The water may need to be change again.

Let the first container of murky water settle for 2 hours to overnight and change the water but keeping the sediment. This water changing may need to be done more than once. When the leaching water is poured off test for tannin by cooking equal amounts of meal and taste for tannin (bitter after taste and/or dry feel to the mouth). Cooking brings out the tannin taste. If there is no tannin taste pour the sediment into the strainer with the rest of the leached meal and let it drain. The acorns are now leached

A c o r n B r o w n i e s

2 cups drained but wet cold water leached acorn flower
 1 cup chopped walnuts
 1 cup fruit juice concentrate or honey
 1/2 cup water with
 1 teaspoon baking soda

mix water and baking soda first then mix with other ingredients. Bake in a greased pan at 350F for 45 min. Cool and serve

White man's wewish

(wewish is a Cahuilla name for acorn mush)

1 cup of drained but wet cold water leached acorn flower
 1 cup water (some acorns need more some less)
 1/4 to 1/2 teasp. Salt (to taste)

1/4 cup sweetener honey or fruit juice concentrate (optional)

Mix ingredients together and bring to a boil, or until wewish thickens.

Because some search engines penalize for "over use of words"
"nuts" has been used in place of a c o r n s .

Dining on the Wilds

Learning Nature through Wild Edible Plants and Ethnobotany

This set of pages will give you . . .

1. [WHY?](#) learn wild edible plants
2. [DESCRIPTION](#) of the video course
3. [Table of contents](#)
4. [WHO](#) made it?
5. [OTHERS](#) say
6. [Cover](#) (25KB)
7. How to [ORDER](#)

Dining on the Wilds

- Takes you inside the classroom for an interesting graphic slide presentation which gives you a close-up look at the identification of many wild edible plants, herbs and mushrooms of North America.
- Come along on live field trips. Observe and enjoy plants in their natural habitat. Learn how to use these natural, nutritive items.
- Taste the fun of a cooking class where unique recipes are demonstrated. You are in for a truly mouth watering treat.
- Watch the fun as students bring family and friends to a gourmet buffet where everyone brings home made dishes containing at least one wild ingredient.
- Listen to student comments as to why they enrolled in the class and why some have come back repeatedly.
- This video set is a unique, fun and educational

[Others say](#)

I have thoroughly enjoyed Dining on the Wilds. The tapes have been a great help. They are very informative. ...

Sincerely,
Susie Teague
[Cedar Creek Nature Studies](#)

experience that your whole family will enjoy viewing over and over again.

Winter Count

February 10-16, 2002 and
February 16-22, 2003

Rabbitstick

September 15 -21, 2002
and
September 14-20, 2003

Come and celebrate our **Rabbitstick!** Join other potters, knappers, archers, atlatlers, felters, trackers, foragers, drummers, basket makers, hide-scrappers, tanners, storytellers, fire dancers, and many, many other primitive technologists and enthusiasts for 7 days of classes and fun on the historic Henry's Fork of the Snake River.

Named after a simple tool used extensively by western natives and, in a modified version, by aborigines all over the world, the rabbitstick leads the world as one of man's earliest and longest lasting tools. As each ancient hunter would pass his knowledge and insights on to the younger generations, so to have people come to our gatherings to share their lessons and insights with other instructors and students. Come and experience the tradition! **in Rexburg, Idaho**

**September 15 -21, 2002 and
September 14-20, 2003**

Cost \$245 now thru Sept. 1 \$50 more after Sept. 1

Winter Count is a similar conference but is a dry camp (no river) about 50 miles from Phoenix Arizona off Maricopa Rd.

**February 10-16, 2002 and
February 9-15, 2003**

Cost \$245 Late registration or gate \$50 more

No Drugs, Alcohol, or Pets

Fee covers Camping, 2 meals per day, and basic instruction.

Fee does not include project material fees that may range from free to \$100.

Mountain misery

Chamaebatia foliolosa

Mountain misery was used by the Indians of the Sierras as a medicine for various diseases like flues, colds, coughs, etc.

Take one leaf cluster of 4 or 5 leaves and steep it in a cup of hot water for 15-20 min. at the first symptoms of an illness. Somehow drink the tea. Some have found it useful as aroma therapy.

The first time I tried this plant, I had just come back from a rendezvous and many people had an illness that started as a fever and weakness progressing to a cough and laryngitis. I noticed one day that I was coming down with the symptoms that others had started with and been sick for more than a week. At the rendezvous I had been trading Mountain misery and had some left. So I made a cup of tea and drank it just before I went to bed. That night I woke up feeling very hot. In the morning the fever had left and I never did get the rest of the symptoms that the others had gotten.

I have tried this remedy several times since then, and usually it works but two times it apparently did nothing for me. It seems

to work better on respiratory system flues better than on digestive system flues. It has not worked on colds (a respiratory infection without much fever or generalized aches).

The common name "Mountain misery" was given to this low growing plant because its resinous leaves leave sticky resin on every thing they touch. Some people think the resin has an unpleasant medicine odor.

If you would like to try this ancient but potent Indian herbal remedy on your misery send \$5 to: Please make checks and money orders payable to JEG Development.

Flip Flop Winch

Mors Kochanski taught me this one and gave his blessing to put it on the web. It is his modification of a Finnish windless

In these pictures the logs have been shortened. In real life they should be as big as you can work with. The lever is practical up to about 8 ft. or 2.5m long. The longer the winch log the more stable this device is but too long makes it so stable you can not turn or flip it

winch.
Continue flipping the winch pole and winding with the lever pole until you have winched your load to where you want it.

- If you are winching alone tie 2 keeper loops of cord around the lever and the rope so that you can flip. If you have a helper one of you flip and the other winch.
- Remember the winch is going to move toward the anchor at half the rate that the load does.

The COURTS have ruled Adventure Pass is discretionary (not mandatory)

The court was ambiguous as to whether the rest of the recreation fee demonstration program being discretionary.

Let's whet your kids' appetite for spectator sports in the national forest. [Click here](#) to see what [smokeybear.com](#) coloring book wants your kids to think are good forest activities.

US Forest Service Adventure Pass

The US Forest Service in Southern California tells volunteers

You gave, NOW GIVE MORE!

They falsely announce to the world that volunteers are exempt from the [Adventure Pass](#) and then tell them they must buy a pass if they use the forest when off duty. Many volunteers are just scraping by financially such as students, under employed, etc., and would have to borrow the money for a pass, but the

bureaucrats can not see that problem because they sit behind a desk and draw a full time government pay check. All they can see is the potential income from adventure pass sales to volunteers and every one else. It is another example of BIG Government greed and a slap in the face of people who freely give their time and personal resources to maintain the National Forest and try to make it a nice place for everyone to visit. Perhaps being that this is just one of many test programs, they are testing volunteers to see how much they will take before it hurts the rate of volunteering. If volunteer programs fall flat where they pull this trick then they will know this particular program will not work.

Did you know that many projects are done mainly by volunteer labor but the signs are set to make one believe that the labor is paid for by adventure pass money.

Services that have been performed for decades now have signs on them claiming the service is paid for by adventure pass money. For example: there is a trash dumpster at Therman Flats Picnic area that has been there since the early 1970's that got an Adventure Pass Funding sign. (That sign has been removed to prove this page untrue.)

One of the Forest Service web pages claims "The number of repeat violators of the Adventure Pass

program is very low. Of 47,000 Notices of Non-compliance issued during the past year, about 30 individuals, or 0.07% are considered repeat offenders. These individuals have three or more Notices of Non-compliance and have made no attempt to remedy the situation through payment of fees." However they refuse to ticket me in my area because they know I will not pay. In other words if they think you will not pay they will not ticket. This makes compliance appear to be higher than it really is. I have seen a FS person giving out tickets and pass my vehicle (He had heard me tell someone about the discretionary nature of the pass and commented about it to them). I got no ticket and therefore no statistic either. I know other people that do not get tickets anymore either. It seems that they have a list of do not ticket vehicles.

Most of the money collected goes to collections and enforcement. 20% goes to the treasury. Each year the treasury gets 4% more of the take. So is the second year the treasury gets 28%. That leaves about 12% of the fees to go to projects. The next year only about 8% will go to projects. This is a very bad deal for the Forest Service and us tax payers. Now Congress has cut from the FS budget the amount they collected from the demonstration fee. So they are no further ahead than if there never was a fee. They can make it appear that they have more money and can give "new" services because they cut back on waste somewhere else.

Since Congress has been cutting VERY DEEPLY into the Forest Service Budget especially since 1994 the Forest Service has been strapped for funds to the point of greatly increasing the danger of disastrous fires. They are caught in the middle on this one. Is the answer to increase the cost of volunteering?

Democrats George Miller (CA) and Earl Blumenauer (OR) are leading the charge to divert more of your taxes from the Forest Service and charging you to go on your land. Another sneaky way to increase taxes so that BIG government can get BIGGER to control you more.

Should you have to pay to inspect how your trustee is caring for your land?

Do you take care of your National Forest as if you were going to invite guests over?

- It is my opinion that they would do better to charge market value or at least charge actual costs for mining claims, grazing, and wood cutting and logging permits instead of almost giving these away. (Oh yes, these funds go into a black hole and never return to this Forest or any National Forest.) These fees are set by congress and the agency has no say in how much they will charge. Perhaps a better way would be to have a minimum fee set by congress and give the agency the option to charge as much more as their costs require.
- We need to get congress to reinstate the Forest Service share in the budget so that they can hire people instead of giving these people welfare and not letting them work. Congress should mandate that **all** use and entrance fees stay in the government service that generated the fee.
- I think that if a volunteer gives 10 to 20 hours or more of non court ordered civil service volunteer time the Forest Service should then grant that volunteer an unrestricted (usable during off time) administrative pass or an adventure pass good for one year. Some other worthy volunteers are search and rescue, sheriff citizen patrol, fire fighters etc. Many of these volunteers have to buy most of their own equipment and training. Is it fair to expect them to give more than they already are giving?

The president of a local search and rescue organization (All volunteers) informs me that they have to pay the fee while training or searching for someone in the National Forest. The Forest Service

tells me through my congressman that they do not. Who do you believe?

Other search and rescue volunteers have told me "I'm with the Sheriff's Search and Rescue team and am also irked at having to pay to hike in my call-out area. On searches and trainings we're not supposed to have to have an Adventure Pass for the forest service to waive tickets. But, we have to call them ahead and let them know so they won't do it (like they own the forest???)

"However, a lot of us like to do personal trail familiarization hikes in our call-out area and adjoining call-out areas. For those we have to have the almighty Pass."

Do you want search and rescue to be familiar with the area when your child is lost?

Most of time I have gone in to get an administrative pass to prepare for a program or class field trip, it has taken 30 to 40+ minutes to get the pass even though I called ahead. I still had to arrange to go in to the office during office hours. (April 1999 was a very fast one it only took about 5 minutes in the office.)

What can you do about it? Write e-mail to the Forest Service and your congressman is a good start. You can print out and display [protest art](#). The Forest Service claims to Congress that we the people enjoy paying these new TAXES. Have you told your congress representative the level of your GREAT joy in paying for this tax diversion?

(I do not necessarily agree with the opinions of any link.)

If you think that I am all wet in my protest in this experimental Adventure Pass issue, drop me [John Goude](#) a line. When E-mailing do not remove the anti spam * from the subject line.

I have gladly served with the Forest Service as a Volunteer Interpretive Specialist for 5 summers mainly leading nature walks for the general public and have given school programs during the rest of the year. This means that at times I need to go into the National Forest when not giving a program to prepare. Technically I am not on duty and need a pass. Very often things I use in a program happen when I am in the National Forest not planning a program. As experienced outdoors people know, one can not plan most of these types of encounters with nature. In my thinking they make or break an interpretive presentation.

For example: One time I was backpacking on the Sugarloaf mountain in the San Bernardino mountains. During the evening we were watching the stars and a very bright meteor went streaking across the sky. It suddenly exploded and filled the moon less dark night sky with bright light! Can such a story add to a star watch when there are meteors streaking across the sky? Can

you plan such an encounter with nature?

In the ceremony on 10/26/97 where they acknowledged the other volunteers including many of the ones planning on not being present, the Forest Service decided to single me out and refused to publicly acknowledge any of my volunteer time, of about 100 hours. After the ceremony I was told it was because of my non public protest of volunteers having to buy Adventure Passes. Up to that time I had kept my protest to be within the organization. I have now gone public with this page because of this move on their part.

As the bumper sticker a fellow volunteer gave me says:

Can't see the forest for the fees

Granlund's position confirmed on Nat'l Forest Adventure Pass

from The Valley Messenger, November 1998, Vol. 25, No. 11 (used by permission)

Assemblyman Brett Granlund (R – Yucaipa), announced that he has received a legal opinion from the California Legislative Counsel that confirmed his position that California residents do not have to have a National Forest Adventure Pass to park on the state highways right-of-ways within a national forest.

Granlund's 65th Assembly District, including Big Bear City, Running Springs, Angelus Oaks and other communities in and around the San Bernardino National Forest, has received hundreds of telephone calls and a petition that contained more than 8,000 signatures from residents and visitors complaining about the new unfair taxation.

The National Adventure Pass program requires a \$5 daily, or \$30 annual, pass for any vehicle that is parked along the roadway to display the pass in their vehicle.

Granlund said the opinion stated: "The Forest Service of the United States Department of Agriculture may not issue a citation for a violation of the fee provisions of the federal Recreational Fee Demonstration Program for a vehicle that is parked on the right-of-way of a portion of State Highway Route 38 within certain National Forests without displaying a National Forest Adventure Pass, unless there are additional facts indicating that a recreational use of the forest has occurred."

The opinion gave an example that persons driving on State Highway 38 from Big Bear City en route to the City of Redlands could have their vehicles break down on the state highway right-of-way within the forest and leave the vehicles in order to search for assistance.

Another example Counsel Gregory cited was a person who might become drowsy while driving through the forest, park his or her vehicle by the side of the highway and go for a walk in order to stir himself or herself awake, all without leaving the highway right-of-way.

During this year's Legislative session, Granlund authored a resolution that requested that the U.S. Congress rescind the Forest Service's authority to sell passes and issue \$100 citations to violators of the program.

Assembly Joint Resolution (AJR) 77 encourages the president and the Congress of the United States to enact the Forest Tax Relief Act, authored by Representative Mary Bono. AJR 77. was unanimously passed by the state Assembly and Senate and approved by the governor.

The opinion said that, at a minimum, any citation would need to include additional facts indicating that a recreational use of the forest has occurred, such as: a statement that the alleged violator was observed walking into the forest after having parked the vehicle.

Granlund said that the opinion cited a similar case addressed by a federal court, (*U.S. vs. Maris*) where the court held that merely driving through a national forest was not a recreational use.

Granlund said this opinion was valid on any state road through all national forest land and

Highway 38 was only used as an example. He also said that it is the job of the Forest Service to prove that a recreational use happened. To the best of his knowledge, the U.S. Forest Service and the State of California have never signed any agreement on this issue.

"This fee program," said Granlund, "is a recreational pass and not a vehicle pass. It is the obligation of the Forest Service to give citations to people not vehicles."

[Adventure Pass](#)

Legislative Counsel of California

Highways: San Bernardino National Forest - #16919

Dear Mr. Granlund:

QUESTION

May the Forest Service of the United States Department of Agriculture issue a citation for a violation of the fee provisions of the federal Recreational Fee Demonstration Program for a vehicle that is parked on the right-of-way of a portion of State Highway Route 38 within the San Bernardino National Forest without displaying a National Forest Adventure Pass?

OPINION

The Forest Service of the United States Department of Agriculture may not issue a citation for a violation of the fee provisions of the federal Recreational Fee Demonstration Program for a vehicle that is parked on the right-of-way of a portion of State Highway Route 38 within the San Bernardino National Forest without displaying a National Forest Adventure Pass, unless there are additional facts indicating that a recreational use of the forest has occurred.

ANALYSIS

Section 315 of Title III of the Omnibus Consolidated Rescissions and Appropriations Act of 1996 (P.L. 104-134; hereafter Section 315) requires the United States Secretary of Agriculture (hereafter the secretary), acting through the Forest Service of the United States Department of Agriculture (hereafter the Forest Service), to implement, until September 30, 1999, a Recreational Fee Demonstration Program (hereafter the demonstration program) on selected federal lands to demonstrate the feasibility of user-generated cost recovery for the operation and maintenance of recreational areas on those lands (Sec. 315(a) and (f)). Under the demonstration program, the secretary is required to charge and collect fees for admission to, or for the use of, the selected outdoor recreation sites (Sec. 315(b)(1)) and to establish those fees based upon a variety of cost recovery and fair market valuation methods (Sec. 315(b)(2)). The fees are imposed in lieu of fees charged under any other provision of law (Sec. 315(d)(2)). Eighty percent of the amount collected under the demonstration program is required to be used for activities at the site from which the funds are collected and 20 percent is required to be used by the agency that administers the site (Sec. 313(c)(1)(A) and (3), and (c)(2)(A) and (B)).

The secretary is authorized to assess a fine of not more than \$100 for any violation of the demonstration program's fee provisions (Sec. 315(b)(5)). Section 261.15 of Title 36 of the Code of Federal Regulations (hereafter Section 261.15) makes it a crime, punishable by a fine of not more than \$100, to fail to pay any fee established for admission or entrance to, or use of, any national forest site, facility, equipment, or service furnished by the United States. Thus, failure to pay a fee imposed under the demonstration program is prosecutable as a violation of Section 251.15.

The Forest Service has informed us that in the San Bernardino National Forest (hereafter the forest), among other national forests in southern California, it has implemented the demonstration program as the Southern California fee Demonstration Project (hereafter the project). Under the project, fees are collected through the issuance of a "National Forest Adventure Pass" (hereafter the pass). According to the official literature of the Forest Service describing the project, the pass is issued as a daily pass for \$5 or an annual pass for \$30, and is required to be displayed on a vehicle only when the vehicle is parked within the forest for recreational purposes. The Forest Service enforces the fee provisions of the project by posting a citation on vehicles found not displaying the pass in violation of the project's fee provisions.

The citation issued to enforce the project's fee provisions provides for identification of the issuing officer, the alleged violator (hereafter the person), and the person's vehicle, describes the offense, and provides a space for the officer to describe the location of the vehicle. The offense is described in a "Description" section with two sentences that read: "This vehicle is not displaying a valid National Forest Adventure Pass as required by the Southern California Fee Demonstration Project. This Project is authorized by Section 315 of Public Law 104-134." A set of instructions provided on the citation inform the person that he or she has 14 days to correct the violation and that failure to correct may result in a fine of not more than \$100. According to the instructions, the person may correct the violation by re returning the notice to the project headquarters in San Bernardino with (1) a daily pass, (2) certain evidence of possession of an annual pass, (3) the purchase price of a daily pass, or (4) an explanation supporting the contention that the citation was issued in error.

An issue that arises at this point is whether a citation may be imposed for failure to display a pass, in view of the fact that both Section 315 and Section 261.15 authorize punishment for failure to pay certain fees, but not expressly for failure to redisplay a pass. In that regard, it has been held that the power of an administrative agency to administer a congressionally created and funded program necessarily requires the formulation of policy and the making of rules to fill any gap left, implicitly or explicitly, by Congress (*Morton v. Ruiz* (1974) 39 L.Ed.2d 270, 292). If a court determines that Congress has not directly addressed the pre issue question at issue, or that the statute is silent or ambiguous with respect to the specific issue, the question for the court is whether the agency's answer is based on a permissible construction of the statute (*Chevron U.S.A. v. Natural Res. Def. Council* (1984) 81 L.Ect.2d 694, 703).

Nothing in either Section 315 or Section 261.15 prescribes the method for enforcing the fee provisions of the demonstration program. Thus, applying the holdings set forth above, our view is that any reasonable method of enforcing the fee provisions that is consistent with the purposes of the demonstration program would be authorized. Because the literature distributed by the Forest Service advises purchasers of the pass that the pass is to be displayed on the purchaser's vehicle, we think that it is reasonable for the Forest Service to deem the failure to display the pass when parked within the forest for recreational purposes to be rebuttable evidence that the pass was not purchased and that, consequently, the fee was not paid. Accordingly, we conclude that the Forest Service's decision to enforce the fee provisions of the project by requiring the purchase and display of a pass is reasonable and, there ore, authorized.

However, citing a vehicle for a violation of the project's fee provisions when the vehicle is parked on the right-of-way of State Highway Route 38 raises the question of whether probable cause exists for that issuance. There is no provision of federal law that sets forth the standard of probable

cause for issuing the citations in question. However, the procedure and practice for the conduct of proceedings involving petty offenses, such as a violation of the project's fee provisions, (*1) is governed by Rule 58 of the Federal Rules of Criminal Procedure (Fed. Rules Cr. Proc., Rule 58, 18 U.S.C.A.; hereafter Rule 58). Under that procedure, a trial is authorized to proceed on an indictment, information, or complaint, in the case of a misdemeanor, or on a citation or violation notice in the case of a petty offense (Rule 58(b)(1)). Thus, at the initial stage of federal criminal procedure for petty offenses, a citation serves the same function as a complaint; that is, it provides support for the decision to continue prosecuting the alleged offense (see *Jaben v. U.S.* (1965) 14 L.Ed.2d 345, 353). Therefore, we think that the standards established for probable cause to issue a complaint are applicable to citations.

The United States Supreme Court has stated that a complaint must provide the affiant's answer to the magistrate's hypothetical question, "What makes you think that the defendant committed the offense charged?" (Ibid.). The complaint is required to present enough information to enable a judgment that the charges are not capricious and are sufficiently supported to justify bringing into play the further steps of the criminal process (Ibid.). At a minimum, the complaint is required to follow the statutory language describing the offense charged and relate the essential facts constituting that offense (*Bytes v. U.S.* (9th Cir. 1964) 327 F.2d 825, 835).

The offense in question is utilizing the recreational facilities of the forest without having paid the recreational use fee. The essential elements of the offense are that (1) a vehicle has been parked (2) within the forest (3) for a recreational purpose (4) without displaying a pass.

When a vehicle is found parked without a pass on, for example, a forest road, a campground, or a trailhead parking lot, the third element listed above is supported by the reasonable inference that the purpose for parking the vehicle at that location was to use the recreational facilities of the forest.

However, in the case of parking within the forest on the right-of-way of State Highway Route 38, which is a major artery through the area, that presumption is much less supportable because there are many possible alternative explanations for having parked at that location. A person driving on State Highway Route 38 from Big Bear City en route to the City of Redlands, for example, with no intention of using the recreational facilities of the forest, could have his or her vehicle break down on the state

highway right-of-way within the forest and have to leave the vehicle in order to search for assistance. As another example, a person might become drowsy while driving through the forest, park his or her vehicle by the side of the highway, and go for a walk in order to stir himself or herself awake, all without ever leaving the highway right-of-way.

Therefore, it is our view that probable cause to issue a citation is not present on the basis that the vehicle is parked within the forest on the right-of-way of State Highway Route 38, because the circumstance above does not support the element of the offense requiring recreational use of the forest. We think that, at a minimum, the citation would need to include additional facts indicating that a recreational use of the forest has occurred, such as, for example, a statement that the alleged violator was observed walking into the forest after having parked the vehicle.

A similar question was addressed by a federal district court in a recent case, where the court held that merely driving through a national forest area on a public highway was not a recreational use of that area and was, therefore, not subject to the exaction of the demonstration program's user fee (U.S. v. Maris (D.Or. 1997) 987 F.Supp. 865, 868).

In the Maris case, the defendants entered the Oregon Dunes National Recreation Area of the Siuslaw National Forest by driving on South Jetty Road, a public highway, en route to accessing public coastal lands (Ed., at p. 866). There was no evidence that the defendants used the forest in any way other than driving on South Jetty Road to get through the forest to their destination (ibid.). The defendants were charged with violating Section 261.15 by failing to pay, upon entering the national forest, the user fees imposed under the demonstration program (Ibid.).

The district court construed the language of Section 315 as granting authority that is limited to recreational use fees and may not be extended to include imposing tolls for the use of public highways that run through forest lands (Id., at p. 867). The court also found that, in any case, imposition of those tolls would be prohibited under former Section 932 of Title 43 of the United States Code (hereafter Section 932) on South Jetty Road because that route was established prior to October 21, 1976 (Id., at pp. 867-868). Section 932, which remains in effect for those rights-of-way existing prior to October 21, 1976, granted the right-of-way for the construction of highways over public land not reserved for public use and thus prohibits tolls on those preexisting rights-of-way (Ibid.).

The facts in the question presented here are similar to those present in the Maris case, that is, State Highway Route 38 is a public highway and the activity in question is parking on that highway at a location that is within the forest, an apparently nonrecreational use of the forest that is similar to the one at issue in the Maris case. We think that a court faced with those facts, and nothing more, would find that parking on a public highway on a location that is within a national forest is not itself a recreational use for which a fee is authorized under Section 315

Accordingly, it is our opinion that the Forest Service of the United States Department of Agriculture may not issue a citation for a violation of the fee provisions of the federal Recreational Fee Demonstration Program for a vehicle that is parked on the right-of-way of a portion of State Highway Rout 38 within the San Bernardino National Forest without displaying a National Forest Adventure Pass, unless there are additional facts indicating that a recreational use of the forest has occurred.

Very truly yours,
Abel Munoz
Deputy Legislative Counsel

(*1) A "petty offense" is defined as, among other things, an infraction for which the maximum fine is not greater than \$5,000 (18 U.S.C.A. Secs. 19 and 3571(b)(6) and (7)). Because a violation of the project's fee provisions is punishable by a fine o not more than \$100 (Sec. 315(b)(5); see also 36 C.F.R. 261.15), we conclude that it is a "petty offense" under the Federal Rules of Criminal Procedure.

WHY STUDY WILD EDIBLE PLANTS

1. SURVIVAL

If you were lost in the wilderness for a long time would you survive? With the current enthusiasm for backpacking and wilderness living, there is an increased probability of people getting lost. If you were lost in the wilderness would you starve? People have starved to death while tramping on hundreds of wild edible plants. This could happen to anyone if they had no knowledge of what to eat in the wilds. Don't let this happen to you!

2. DISASTER

If you were cut off by a natural disaster or civil unrest from getting food from the market, would you go hungry? During war many people have survived from lack of their normal food because they knew about wild edible plants. I know a German lady who ate many dandelions during World War II, and the Finnish used cambium of trees to stretch their flour supply.

3. BACKPACKING and WILDERNESS OUTINGS

One way to cut down weight on that backpack trip is to depend on wild edibles for a portion of your food. After days of dehydrated food--a fresh wild salad is a real treat! Do you really like **MREs** (meals ready to eat) anyway? I find that looking for plant friends as I walk along keeps my mind active and makes the walk even more enjoyable. While you are out there exploring, why not explore with your taste buds too. (note: some wilderness areas and parks have strict restrictions on picking any plant. Check with the proper people before picking plants.)

4. ECONOMY

With supermarket prices so high, wild edible plants can be a great budget stretcher, and who doesn't like something **free**.

5. NUTRITION

Wild edible plants are so rich in vitamins and minerals that they have been called a tonic rather than a food. Some of these plants are richer sources of nutrients than domestic plants.

6. ECOLOGY

You will become more aware of ecology which is discovering how the life cycle of plants relates to the life

cycles of other plants and animals. Hopefully, you will also become a conservationist and perhaps even a gardener.

7. HISTORY

You will have more appreciation for the Native American's old ways and want to help keep some of these ways alive through the study of ethnobotany.

8. MEDICINAL

With herbal medicine gaining in popularity it is beneficial to learn not only the edible properties of a plant but also its medicinal value. You might also find yourself in a situation where no doctor is available. Not only is your health benefited but also your pocketbook!

9. VARIETY

So if you are tired of eating the same foods week after week wild edible plants can add a pleasant change to your menu. You will have fun discovering a greater depth of food flavors as you eat more and more wild edible plants.

10. GOURMET

Wild edible plants can be made into exotic gourmet dishes. If you want to do something different have a "wild" party and invite your neighbors in. They will be amazed at how delicious your wild edibles can be.

11. HOBBY

Studying wild edible plants is a very fascinating hobby. With 300,000 plants in the world and 120,000 considered edible you won't run out of something to do for a long time. You will become attuned to the wild plants that are edible and will look upon them as friends.

12. SPIRITUAL

Nature study is an excellent way to learn about the Creator and is very restful to the soul who will take the time to listen to Him through the things He made.

Dining on the Wilds

Learning Nature through Wild Edible Plants and Ethnobotany

This set of pages will give you . . .

1. [WHY?](#) learn wild edible plants
2. [DESCRIPTION](#) of the video course
3. [Table of contents](#)
4. [WHO](#) made it?
5. [OTHERS](#) say
6. [Cover](#) (25KB)
7. How to [ORDER](#)

Dining on the Wilds

- Takes you inside the classroom for an interesting graphic slide presentation which gives you a close-up look at the identification of many wild edible plants, herbs and mushrooms of North America.
- Come along on live field trips. Observe and enjoy plants in their natural habitat. Learn how to use these natural, nutritive items.
- Taste the fun of a cooking class where unique recipes are demonstrated. You are in for a truly mouth watering treat.
- Watch the fun as students bring family and friends to a gourmet buffet where everyone brings home made dishes containing at least one wild ingredient.
- Listen to student comments as to why they enrolled in the class and why some have come back repeatedly.
- This video set is a unique, fun and educational experience that your whole family will enjoy viewing over and over again.

[Others say](#)

I have thoroughly enjoyed Dining on the Wilds. The tapes have been a great help. They are very informative. ...

Sincerely,
Susie Teague

Edible Wild Plants of the Yard

WARNING: A plant on the list just means that it is discussed on the video. This does not mean that it is edible. Some plants in an edible list are toxic until prepared correctly or have toxic parts. **KNOW before you eat !**

Dandelion

Plantain
Narrow leaf plantain
Clover
Grass
Wild oats
Foxtail barley
Curly dock
Sour dock
Dock
Sheep sorrel
Lady's thumb
Lambsquarters
Strawberry blite
Orach

Amaranth

Domestic Amaranth
Wild lettuce
Prickly wild lettuce
Sow thistle

Chickweed

Mustard
Winter cress
Wild radish
Shepherd's purse
Peppergrass
Mallow

Purslane

Filaree
Russian thistle

Taraxacum officinale

Plantago major
Plantago lanceolata
Trifolium, Medicago species

Avena fatua
Setaria SPP
Rumex crispus
Rumex
Rumex
Rumex acetosella
Polygonum SPP
Chenopodium album
Chenopodium capitatum
Atriplex patula

Amaranthus

Amaranthus
Lactuca tatarica
Lactuca serriola
Sonchus asper

Stellaria media

Brassica rapa
Barbarea
Raphanus sativus
Capsella bursa-pastoris
Lepidium virginicum
Malva neglecta

Portulaca oleracea

Erodium cicutarium
Salsola iberica, Kali tenuifolia

Herbs

WARNING: A plant on the list just means that it is discussed on the video. This does not mean that it is edible. Some plants in an edible list are toxic until prepared correctly or have toxic parts. **KNOW before you eat !**

Yarrow	<i>Achillea millefolium</i>
Chamomile	<i>Matricaria chamomilla</i>
Purple cone	<i>Agustifolia purpurea</i>
Gill over the ground .	<i>Glecoma hederacea</i>
Mullein	<i>Verbascum thapsus</i>
Yerba santa	<i>Eriodictyon californicum</i>
Eucalyptus	<i>Eucalyptus SPP</i>
Horsetail	<i>Equisetum SPP</i>
Oregon grape	<i>Mahonia (Berberis)</i>
Yerba Buena	<i>Satureja douglasii</i>
Bearberry	<i>Arctostaphylos uva-ursi, rubra, alpin</i>
Ginkgo biloba	<i>Ginkgo biloba</i>
Mugwort	<i>Artemisia</i>
Mountain misery	Chamaebatia foliolosa

Remember, YOU are a caretaker of these plants.

Edible Wild Plants of the Roadside and Meadows

WARNING: A plant on the list just means that it is discussed on the video. This does not mean that it is edible. Some plants in an edible list are toxic until prepared correctly or have toxic parts. **KNOW before you eat !**

Cleavers	<i>Galium aparine</i>
Stinging nettle	<i>Urtica gracilis</i>
Watercress	<i>Nasturtium officinale</i>
Brooklime	<i>Veronica americana SPP</i>

Monkey flower	Mimulus guttatus
Chicory	Cichorium intybus
Salsify	Tragopogon SPP
Queen Anne's lace	Daucus carota
Fireweed	Eqilobium angustifolium, latifolium
Evening primrose	Primula SPP
Thistle	Cirsium SPP (31)
Milk thistle	Silbum marianum
Wild onions	Allium
Burdock	Arctium minus, lappa
Milkweed	Asclepias
Jerusalem artichoke	Helianthus tuberosus
Day lily	Hemerocallis aurantiaca
Vetch	Vicia SPP
Chia	Salvia columbariae
California Bay	Umbellularia californica
Sage (black/blue)	Salvia mellifera
Horehound	Marrubium vulgare
Hottentot Fig	Mesembryanthemum edule
Ice plant	Capobrotus edule
Tarweed	Madia glomerata, sativa
Sunflower	Helianthus annuus
Wild aster/Oxeye daisy	Aster ledophyllus
Goldenrod	Solidago missouriensis
Pineappleweed	Matricaria matricarioides
Chamomile	Anthemis SPP
Mullein	Verbascum thapsus
Asparagus	Sagittaria SPP, Asparagus officinalis

Remember, YOU are a caretaker of these plants.

[\[Return\]](#)

Edible Wild Plants of the Northwest

WARNING: A plant on the list just means that it is discussed on the video. This does not mean that it is edible. Some plants in an edible list are toxic until prepared correctly or have toxic parts. **KNOW before you eat !**

Avalanche lily	Erythronium grandiflorum ssp.
Yellow bells	Fritillaria pubica
Bear grass	Xerophyllum tenax
Strawberry blite	Chenopodium capitatum
Skunk cabbage	Lysichiton americanum
Devil's club	Echinopanax horridum or(Oploanax h)
Clitonia	Clintonia borealis
Twist stalk	Streptopus SPP
Buffaloberry	Shepherdia SPP
Bunch berry	Cornus canadensis
Mountain ash	Sorbus SPP (Pyrus)
Salal	Gaultheria shallon
Bearberry	Arctostaphylos uva-ursi,rubra,alpin
Licorice	Glycyrrhia lepidota

Remember, YOU are a caretaker of these plants.

Edible Wild Plants of the Woodlands

WARNING: A plant on the list just means that it is discussed on the video. This does not mean that it is edible. Some plants in an edible list are toxic until prepared correctly or have toxic parts. **KNOW before you eat !**

Violet	Viola purpurea, pedunculata SPP
woodsorrel	Oxalis SPP
Bracken fern	Pteridium aquilinum
Wild ginger	Asarum SPP
Miner's lettuce	Claytonia perfoliata (Montia)
Lomatium	Lomatium SPP

Brodiaea	Brodiaea pulchella	
Mariposa lily/fairy lantern/star tulip	Calochortus nuttallii,gunnisonii	
Lily	Lilium Pardalinum	
Solomon's seal	Polygonatum SPP	
False Solomon's seal	Smilacina SPP	
Trillium	Trillium ovatum SPP (4)	
Shooting stars	Dodecatheon hendersonii	
Alum root	Heuchera SPP (28)	
Waterleaf	Hydrophyllum occidentale	
Indian paintbrush	Castilleja	
Horsetail	Equisetum SPP	
Spearmint	Mentha spicata	
Peppermint	Mentha piperita	
Pennyroyal	Hedeoma pulegioides	
Coyote mint	Monardella villosa	
Henbit	Lamium amplexicaule	
Field mint	Mentha	
Rose	Rosa californica, arkansana	
Redbud	Cercis occidentalis	
Sumac	Rhus hirta, typhina,glabra,copallina	
Squawbush	Rhus trilobata	
Lemonade berry	Rhus integrifolia	
Sugarbush	Rhus ovata	
Manzanita	Arctostaphylos	
Wild strawberry	Fragaria virginiana	
Raspberry	Rubus Leucodermis	
Thimbleberry	Rubus parviflorus	
Blackberry	Rubus	
Blueberry	Vaccinium occidentale	
Serviceberry	Amelanchier SPP (24)	
Toyon	Heteromeles arbutifolia	
Currant	Ribes SPP	
Gooseberry	Ribes roezlii, velutinum	
Mulberry	Morus SPP	
Western snowberry.	Symphoricarpos occidentalis SPP	The eastern species causes vomiting (Symphoricarpos albus)

Barberry	<i>Crataegus berberifolia</i>
Oregon Grape	<i>Mahonia (Berberis)</i>
Grape	<i>Vitis californica</i> , SPP
Elderberry	<i>Sambucus melanocarpa</i> , <i>mexicana</i>
Hawthorne	<i>Crataegus</i> SPP
Hackberry	<i>Celtis douglasii</i> , <i>pallida</i>
Pin Cherry	<i>Prunus pensylvanica</i>
Sour Cherry	<i>Prunus cerasus</i>
Holly leaf Cherry	<i>Prunus ilicifolia</i>
Chokecherry	<i>Prunus virginiana</i>
Indian plum	<i>Oemleria cerasiformis</i>
Cascara/coffeeberry	<i>Rhamnus californica</i> , <i>purshiana</i>
Deer bush	<i>Ceanothus</i>
Aspen	<i>Populus</i> SPP
Willow	<i>Salix</i> SPP
Maple	<i>Acer</i> SPP
Butternut	<i>Juglans cinerea</i>
Hazel nut	<i>Corylus cornuta</i> , <i>americana</i>
Chinquapin	<i>Castanopsis</i> <i>chrysophylla</i> , <i>sempervire</i>
	<i>Chrysolepis sempervirens</i>
Digger pine	<i>Pinus sabiniana</i>
Sugar pine	<i>Pinus lambertiana</i>
Pinyon pine	<i>Pinus</i> <i>monophylla</i> , <i>quadrifolia</i> , <i>edulis</i>
White oak	<i>Quercus alba</i>
Black oak	Quercus kelloggii
Live oak	<i>Quercus chrysolepis</i>

Remember, YOU are a caretaker of these plants.

Edible Wild Plants of the Desert

WARNING: A plant on the list just means that it is discussed on the video. This does not mean that it is edible. Some plants in an edible list are toxic until prepared correctly or have toxic parts. **KNOW before you eat !**

Prickly pear	Opuntia SPP
Cholla	Opuntia SPP
Barrel cactus	Ferocactus acanthodes, Echinocactus
Organ pipe/ apple/ saguaro cactus	Lemaireocereus thurberi(organ)/Cereus giganteus (Sagaro)
Ocotillo	Fouquieria splendens
Joshua tree	Yucca brevifolia
Yucca;	Yucca SPP
Nolina	Nolina bigelovii, microcarpa
Agave	Agave SPP (10)
Juniper	Juniperus SPP
Jojoba	Simmondsia chinensis
Desert willow	Chilopsis linearis
Palo verde	Cercidium floridum
Honey mesquite	Prosopis glandulosa
Screwbean mesquite	Prosopis pubescens
Ironwood	Olneya tesota
Catclaw/Acacia	Acacia SPP
Desert apricot	Prunus fremontii
Fan palm	Washingtonia filifera
Date palm	Phoenix SPP
Ephedra	Ephedra SPP
Cresote bush	Larrea divaricata
Bladder pod	Isomeris ardorea
Chuparosa	Beloperone californica
Apricot Mallow	Sphaeralcea ambigua
Wild parsley	
Tansy mustard	Descurainia pinnata
Tumbling mustard	Thelypodopsis SPP
Prince's plume	Stanleya elata, pinnata
Desert candle	Caulanthus crassicaulis
Black sage	Salvia mellifera
White sage	Salvia apiana
Blue sage	Salvia
Desert lavender	Hyptis emoryi
Indian paintbrush	Castilleja
Pincushion	Coryphanta vivipara

Blazing star	<i>Liatris punctata</i>
Desert lily	<i>Hesperocallis undulata</i>
Coyote gourd	<i>Cucumrbita foetidissima</i>
Desert sunflower	
Buckwheat	<i>Eriogonum fasciculatum</i>
Desert trumpet	<i>Eriogonum inflatum</i>
Wild rhubarb	<i>Rumex hymenosepalus</i>

Remember, YOU are a caretaker of these plants.

Edible Wild Mushrooms

In *Poisonous Plants of California* the statement is made that "Of all poisonous plants in California, toxic mushrooms cause the most serious illnesses and nearly all the fatalities to humans. Those who gather and eat mushrooms should use every precaution to ensure that their mushrooms are correctly identified and known to be edible."

There is no simple test for recognizing toxic mushrooms. Do not listen to old wives tales such as

whether a piece of silver turns black when cooked with a mushroom. Examine very carefully and when in doubt don't. There is an old folk saying that goes like this: "There are old mushroom hunters, and there are bold mushroom hunters--but there are no old, bold mushroom hunters.

WARNING: A plant on the list just means that it is discussed on the video. This does not mean that it is edible. Some plants in an edible list are toxic until prepared correctly or have toxic parts. **KNOW before you eat !**

Dining on the Wilds a six session video course.

Survival Tip

Dandelion

Taraxacum officinale

Dandelions, now one of the most despised of plants, were first brought to America by the Pilgrims because they had heard that there was not enough food here to feed Europeans. The British colony James Town nearly starved to death because "gentlemen" do not do farm work. Word of this disaster got back to the Pilgrims so they decided to bring European food and medicinal plants that grow well there. Sure enough dandelions grow well everywhere in America too.

Why did they choose the dandelion? Even though it has milky sap there is no part of this plant that is toxic (unless it has been poisoned with things like weed killer) (Many plants that have milky sap are toxic.) One can eat:

- Roots
- Crown (where the leaves connect to the root)

- Leaves
- Flower buds
- Flowers

I have never known anyone who liked to eat the fluffy seed balls.

The leaves are somewhat bitter if picked at the wrong time of the year or the growing conditions are not right. They are best if picked in the cool seasons or if they grow in the shade. They make a nutritious addition to a salad. The salad will taste much better if there are non bitter greens in it too.

The roots are good cooked like carrots. Some peoples favorite way to eat them is to parch and grind them to use instead of coffee. The bitters are thought to make it to be good for liver, gallbladder, spleen and kidney ailments. Because of it's high iron content it is a good blood builder.

Some say the sap will remove warts.

Perhaps that is why the ancient languages called this plant the disorder (tarax) remedy (ac) to make our modern botanical name Taraxacum.

Dining on the Wilds video course has much more information about Dandelions.

Survival Tip

Amaranth

Amaranth an annual grows up to about 6 ft [by the royal measure of king George III], (2meters) [for everyone else] with course alternating oval pointed leaves. Often the tap root has a reddish color. From the base of the leave stems grow the seed spikes. The tiny black seeds are surrounded by sharp bristly bracts which need to be removed before eating See the threshing / winnowing demonstration on video 1 of [Dining on the Wilds](#) .

Amaranth or Lamb's Quarters Seed Bread

3 1/2 cup flour (some ww good)
1/2 cup amaranth or lamb's quarters seed (put in blender or grinder to make fine flour)
3 T honey or sugar
1 1/4 t salt
1 package quick rise yeast
3/4 cup milk, substitute or water
1/4 cup water
2 T oil or margarine

Combine 3 1/2 cups flour and salt in large bowl, set aside. Combine milk, 1/4 cup water and oil in sauce pan. Bring milk mixture to 125-130 F degrees over low heat. Cool to lukewarm. Add sugar and yeast. Stir in lambs quarters flour and other dry ingredients adding to wet ingredients slowly, mixing in enough remaining 1 cup flour to make soft dough. On lightly floured surface knead 4 minutes. Let rise 1 hour in covered

bowl in a warm place. Push down and knead. Make loaves or rolls. Let rise until double in bulk and bake at 325o for 30-45 minutes.

--Ed Hackie, Dining on the Wilds Manual

In the spring and early summer cook the greens as you would spinach. Or eat them in a salad.

amaranth seed heads

Survival Tip

Chickweed

Stellaria media

Is an annual herb with slender stems that are up to about a foot long. It has smooth stems with 1 row of tiny hairs growing in a row on one side of the stem that switches sides at each pair of opposite (oval with a point at the end) leaves. The flowers are small and white with 5 petals that are so deeply notched that they look like 10 petals. The flowers open mainly on sunny days. Chickweed likes to grow in moist shady soil in the cool/cold seasons of the year. The sap is not milky. Some people think it looks similar to the toxic sandwort.

Chickweed has a very mild taste but can be quite stringy; so cut the stems in short lengths and enjoy a fresh wild salad rich in iron and Vitamin C. It can also be cooked or used to make a chickweed bread

2 cups of chopped chickweed leaves and stems.
¼ cup minced onion
2 tablespoons oil
2 tablespoons honey or fruit juice concentrate
1 teaspoon salt
3 cups wheat flour
¾ cup warm water
1 packet yeast

Sauté onion and chickweed until tender (not brown). Dissolve honey and yeast into the warm water and then the salt. Mix the yeast mixture with the sautéed chickweed and onions and slowly add the flour until the dough no longer sticks to your fingers. Form into a ball and let it rise to twice its volume. Shape into loaves and let rise again. Bake at 375F for 40-45 minutes.

Chickweed has been used to treat bronchitis, coughs, colds, hoarseness., it has been used as a diuretic for kidney and bladder problems. Many herbalists use chickweed to help in weight control because they claim it

dissolves fat deposits and fatty tumors.

Externally, it is used in the form of a poultice or ointment and applied to boils, ulcers and abscesses. The fresh juice has also been used to dissolve warts and other skin growths.

Survival Tip

P u r s l a n e P o r t u l a c a o l e r a c e a

Portulaca oleracea is a smooth low growing succulent plant with reddish stems and underside of leaves, alternate leaves. It has small yellow flowers which produce many sand size black seeds. It often grows in gardens and fields as a weed. Make sure that the purslane is well washed of dirt and grit (usually best to wash it in a bowl of water). (Careful often this plant is the target of the herbicide in some agricultural operations.)

One thing that makes this plant special is that the fat it does have contains omega-3 fatty acids, which some research indicates is useful in preventing heart attacks. Have you been scorning the plant that could keep your heart? It has also been used to treat arthritis and inflammation.

"I have made a satisfactory dinner off a dish of Purslane which I gathered and boiled. Yet men have come to such a pass that they frequently starve, not from want of necessaries, but for want of luxuries." - Henry David Thoreau

P U R S L A N E R A T A T O U I L L E

2 cups chopped purslane
1/2 cup chopped onion
1/2 bell pepper
2 cups canned or fresh tomatoes
1-4 oz can of sliced mushrooms
Salt to taste
Sprinkle of garlic powder

Soy sauce (optional)

Cook purslane, onion and pepper until tender. Add remaining ingredients and simmer a few minutes. Rice can be added to the mixture if desired and cooked for 20-40 minutes.

Replace the lettuce in any salad with fresh raw p u r s l a n e!

Survival Tip

Violets

Viola papilionacea

Violet leaves are an excellent source for vitamins A and C. Some have 8,200 IU vitamin A and 210 mg vitamin C per 100 grams.

I like them best in salads or used like lettuce in sandwiches. The leaves and flowers make a salad beautiful and much more nutritious.

If you must cook them, you can use them like okra to thicken soup. Or add them to omelets. Or try some old colonial favorites, candy them by dipping them in beaten egg white and then into powdered sugar. Then set them out to dry. Violet vinegar was made by soaking violet flowers in vinegar.

Crushed violets have been used as poultices for boils, swellings and many skin diseases.

The mountain violet *Viola purpurea* is also called "johnny-jump-up" has a yellow front and purple back is edible.

Pansies a botanically similar plant are also edible, if they have not been poisoned with pesticides.

Warning

Violet roots and some yellow violets are emetic. (cause vomiting) African violets are mildly toxic. Violets with deeply cut leaves, such as the Birdfoot violet *Viola pedata*, look very much like the toxic Larkspur *Delphinium* or Monkshood *Aconitum*. The flowers are quite different so wait for the flowers to come out before eating violets with deeply cut leaves.

Some violets are rare or endangered so make sure that the violets you eat are abundant.

Survival Tip

Miners Lettuce

Claytonia perfoliata

Former name: Montia perfoliata

C. parviflora

C. exigua

C. rubra

Is an annual herb with slender stems and bracts that usually completely surround the stem forming a disk. It is in the same family as purslane (see a later plant of the month) and in the same genus as the many spring beauties. Not all miners lettuce is green. I have seen it in a purplish or brownish green. It ranges from Alaska to Mexico, California to South Dakota, and is also found in New Hampshire.

Miners lettuce is named after the California gold rush miners who ate it to get their vitamin C to fight scurvy. Imagine how thankful the miners were when this plant came up in the spring. The winter has just past and they all have red bleeding gums and loose teeth. Many of them have sores that will not heal. Rejoicing that spring has come, feasting on a salad of miners lettuce that cures them of those miseries brought on by scurvy. If they had only known about pine needles and straw berry leaves they would have had plenty of vitamin C.

Miner's lettuce at its best

later in bloom and going to seed

Enlarged flower

seeds are about 2mm across.

Survival Tip

Toyon

Christmas berry

California holly

(Heteromeles arbutifolia)

Toyon berries become ripe in late November or early December are native to most of California. They can ripen as early as September and can remain on the bush until April. The berries are mealy and are almost tasteless. They taste similar to a cheap very starchy cherry pie or an over ripe mealy dry apple. They are something to eat that does not taste bad in the winter though. They are in the same class as their family member delicious apples not very good and not very objectionable. I have tried making a jam from these berries but it was not what I would call a great success. It might have been better if mixed with a strong tasting fruit like cranberries.

These bushes gave Hollywood its name because they grow abundantly on the dry hills behind Hollywood California. In my opinion Toyon is a much better bush to put in the median strip of freeways than the deadly toxic, air poisoning, introduced Oleander that Caltrans seems to love so much. (Some people are so sensitive to Oleander that they can not live near it and remain healthy.) Toyon is an evergreen that makes a nice edible "child safe" decoration. (Some toxic Christmas decorative plants Holly, Mistletoe, Poinsettia) [Please do not send e-mail saying Poinsettia is

not toxic. Poinsettia causes vomiting]

Notice the small barbs on the leaves. The whitish pith of the berries. This small leaf and berry are at about X 2 magnification.

Survival Tip

Honey? Mesquite

Prosopis glandulosa

The first time I gathered and tried to eat Honey? Mesquite was not good tasting. It was nauseatingly sour! Then I found out that some trees (bushes) are that way. So that is why even the horses didn't eat the beans before I got to them! I had gotten them from a horse farm. Since then I have eaten and enjoyed the pleasantly sour Honey Mesquite in a number of ways.

To some Indian tribes they were such an important food item they named the months by the stage of the mesquite. They would eat the buds, flowers and pods. The bean pods ripen between July and September. The seeds themselves are VERY hard, so the pod is the part eaten.

One of the biggest destroyers of mesquite is the Beef industry, because ranchers want the water to grow grasses for the cattle. So they destroy these nutrition laden bushes. (This industry has driven many other plants to near extinction usually because of lack of knowledge.)

Mesquite Carrot Soup

Serves Two to Three

by Jolene Allred

2 tablespoons butter 1 cup mesquite broth
3 cups sliced carrots
½ cup chopped onion 1 cup whole milk
1 large clove garlic, minced Fresh ground white pepper
½ cup water

In a large saucepan with a lid, melt the butter. Quickly sauté the carrot, onion, and garlic. Add the water, cover the pan, and simmer until tender. Puree carrots in blender or food processor. Return to saucepan. Add mesquite broth and milk. Season with fresh ground white pepper. Heat. Recipe is easily doubled.

Basic Mesquite Broth

(Wet Method)

This sweet, caramel-like broth is the basis for many delicious recipes.

4 cups broken mesquite pods 8 cups water

Place the broken mesquite pods in a large pot, cover with the 8 cups of water, cover, and boil for one hour. Cool. Wring and tear the pods in the broth, stirring and mashing the sweet pith into the liquid. Or put one cup of the pods and just a little of the broth into a food processor fitted with a steel blade and whirl until the pods are shredded. Repeat until all pods are shredded. Return the material to the broth and stir. The object is to get as much of the pulp into the broth as possible. Drain off the liquid and discard the fiber. Simmer the liquid uncovered until reduced to 3 cups.

Survival Tip

Cattail

Typha agustifolia

Cattails are one of the most versatile and wide spread wild edible plants that there are. They grow in desert water holes, mountain ponds, roadside ditches, northern swamps. The two main species that grow in America are *Typha latifolia* and *T. agustifolia*. I have scanned the less common *T. agustifolia* because I can get reasonable amounts of it on my scanner. The *T. latifolia* is much larger (3 to 5 meters tall [10 to 15 feet]) I understand that a species even grows in Australia. Let us explore some of the parts of this incredible plant.

At the very top is the stamenate or pollen part of the cattail. It is good eating. Further down there is a distinct break and the undeveloped seed or fluff part. The lower part is good before it turns any brown. After any part of it turns brown it is tough and fibrous. You can cook both parts as you would cook corn on the cob. Some say it tastes like the cob. When they are at this stage, some people call them kittens tails.

To collect some pollen, cover the cattail with a large plastic bag and beating the pollen out of the stamenate. After beating the pollen out, you can cut the cattail because the lower part is good for cooking yet. Often they break while beating them. A little of the pollen can be added to other flour to make bright yellow bread or pancakes. This pollen is high in protein like most pollens.

The shoots of the cattail. can be yanked and eaten raw or cooked. If you eat them raw, I recommend that you sterilize them with Clorox or other pathogen killer.

Look at the cross section of a root. See the starch laden central core to the root. The outside layer is entirely fiber. To get the starch from the fibrous core; first by peeling off the outside

layer and cutting away bruised parts where mud and sand have gotten into the root. Then tease the fibers apart so they release the starch by pounding them in a mortar or by crushing and teasing them in a bowl of water. The water becomes ropy and slippery. Let the starch settle out and pour off the water and dry the starch and you have nutritious flour. When living off the land I have just cooked the root cores and chewed the starch out of them.

Poison Ivy / Oak Treatment

Toxicodendron (Rhus)

They have finally separated poison oak/ivy/sumac into their own genus.

1. Take Manzanita *Arctostaphylos sp.* branches, leaves, flowers, berries and all, pack them tightly into a kettle
2. Cover them with water and simmer for about an hour.
3. Let the solution cool and remove the plant parts.
4. Sponge the solution onto the *Rhus* rash. In a few hours the itching should have gone away.
5. Apply the solution 2 or 3 times a day until the rash is gone. For me it takes 3 to 5 days and without treatment it takes 3 to 5 weeks). It is important to get the rash as soon as it starts. Once it does more damage the longer it takes to heal.

An Emergency Room MD (took the class Dining on the Wilds is based on) went to a survival school. Someone there got Poison ivy on both sides of the body. The victim wanted to treat it herbaly so He pulled out his Manzanita and the victim treated one side with the Manzanita solution and the other side with Jewelweed. The Manzanita side healed faster than the Jewelweed side.

Several Indian tribes used the Manzanita or uva-ursi leaves to treat poison oak.

A survival teacher friend of mine says oak bark works in the above method too. He claims that it is the tannin that does the trick. Well good tanning to you if you get poison ivy / oak. There is some evidence that Uva ursi *Arctostaphylos uva-ursi* works well too.

BTW deer and goats like to eat poison ivy / oak. Therefore deer hunters must value the Poison ivy /oak?

Larry D. Olsen, Author "*Outdoor Survival Skills*"

"*Dining on the Wilds*" is a program designed to teach. I have reviewed the material and find it to be extensive, informative and a pleasurable experience. The teachers seem to know what they're talking about.

If you really want to learn about edible wild plants "*Dining on the Wilds*" will not only get you started but will lead you to excellence in identification, harvesting and preparation of literally hundreds of edible and useful plants in the wilds.

Signed,
Larry D. Olsen, Author "*Outdoor Survival Skills*"

A Homeschooler

"It's amazing! Even our 4 and 6 year old children are learning faster than some adults by watching *Dining on the Wilds* video set. Our homeschooler age 12 wants to make your course part of his schooling. I'm confident our children could survive, if they had to, by dining on the wilds!"

Mel and Becky in Florida

Hi John:

Are you the same John Goude that produced the *Dining on the Wilds* video set? I recently purchased them and find them a good resource.

Best Regards,

Bo Gullledge

University of South Florida

Arthur Schwartz, host of "**Arthur Schwartz With Food Talk**" and "**Sunday Food Talk**" on WOR radio in New York

"Dining on the Wilds", It's an impressive presentation.

author of "**Cooking in a Small Kitchen**", "**What to Cook When You Think There's Nothing in the House**" , and "**Soup Suppers**"

Natural Health magazine 7-8/96

"... the incredibly informative guide covers everything from foraging desert treats to identifying poisonous plants."

Shooting Industry 10/96

"'Dining on the Wilds' teaches hunters to live off the land and to supplement their wild game meals with wild edible plants."... "'Dining on the Wilds' could also be useful in a survival situation where the only food available is what nature provides."

Soldier of Fortune magazine.

DINING ON THE WILDS

As a practicing roadside ruminant, it is easy to spot writers who have read a couple "survival" handbooks from those who routinely graze nature's veggie patch. Aside from the green things stuck in their teeth, we mean.

Although we make light of it, knowing what you can eat in the wild and what will kill you is serious business. It's not something you want to learn by trial and error when the time comes. It's a skill best learned beforehand, from someone who knows.

The *Dining on the Wilds* video series of six tapes, complete with a syllabus and *Wild Plants to Eat* workbook, is the best thing we've seen come down the pike that isn't actual field experience.

Presented by folks with excellent been-there-done-that credentials, the video series is lucid, entertaining and sound education. It covers the full subject: wild edibles of the yard, roadside and meadow, seacoast, wetlands, desert, mountains, mushrooms, poisonous plants, herbs; plus specific treatment of the Northwest and Eastern and Central regions and demonstrations of such arts as threshing and handling acorns, yucca, cattail, prickly pear and domestic flowers - more than 300 in all.

We're admitted tool freaks, but when it comes to wilderness survival, knowledge is more important than tools: Knowledge will never break, sink or be left at camp. And keeping your belly full is the

most important consideration.

[\[Dining on the Wilds \(frame\)\]](#) . [\[Dining on the Wilds \(no frame\) \]](#)

Dining on the Wilds

Miriam Kramer

Miriam Kramer's edible wild plant ventures began in 1966 in Paducah, Kentucky. Miriam's late husband, Jack Darnall, had been invited by their church to teach a wilderness survival seminar. Since Miriam had taken Botany courses and had a big interest in wild flowers she was asked to teach the edible wild plant portion.

After that first wilderness camp the news spread like wildfire and soon they were getting calls to conduct camps all over the U.S. For a number of years they used vacation time to teach the camps, but finally had to devote full time to the project, and conducted camps and seminars all over the U.S. and a few foreign countries. Miriam has taught edible wild plants in 27 states as well as Peru and other faraway places.

Besides conducting week long camps and weekend seminars they developed the International Wilderness Club, made a 16 mm movie Prepare for the Storm, published the Surviving Journal and later the Come Out publication. Together they wrote the Wilderness Survival Manual and the Wild Plants to Eat Workbook, and Miriam wrote the Dining on the Wilds Reference Manual. They also produced the popular Wild Plants to Eat slide as well as the Mushrooms to Eat slide set. Miriam has also written 8 correspondence courses on edible wild plants, survival, herbs and natural remedies.

Besides being featured in newspaper articles, Miriam has had several articles published in journals, and has been listed in "Who's Who in American Women" and several similar publications.

Early on Miriam decided there was a need to share the knowledge of the experts so with \$25.00 she started a mail order book business, Outdoor Eduquip, which has been stated to have the most complete inventory of books, visuals, and videos on edible wild plants, herbs, backpacking, mountaineering, survival and country living available.

Miriam currently is the head teacher of a wild edible plant class for Loma Linda University. The class has become very popular not only with the locals but with individuals coming from outlying areas as far away as 100 miles. The class appeals to a large spectrum of people (ages 5-85) from notable doctors to old ladies with walkers, and has had sessions of up to 65 in attendance.

Dining on the Wilds

John showing a friend how to eat Dudleya

- Occupation:
Computer consultant

- Education:
BS Computer Science

- height 5' 11"
- Single
- Left handed

- Other interests include:
4 X 4, Pathfinders (a church scouting type group), crafts, camping, hiking, cross country skiing, inventing things, ham radio KE6VUB, whistling

-
- When I was 6 my Mother fixing Lambs Quarters to eat and about had to use force to get me to eat "those weeds". We also ate Giant puff ball mushrooms, Black walnuts, butter nuts, hickory nuts, and mulberries etc. from our farm in Michigan.

When I was 9 we moved to Africa as missionaries. I remember her telling the grounds people to mow a lawn. They replied "Oh no, madam, that is food!" We ended up eating that food, "African spinach" (amaranth), and other foods that grew "wild".

When I was 12 we toured Europe. I remember eating stinging nettles and wild berries in Finland and Sweden. The stinging nettle was another contest of the wills because I had been reintroduced to them by the touch method.

In high school I joined the Outdoor Life book club and got every book they had on wilderness survival. I had no mentor to help me learn the plants, so I didn't get very far in learning them then. I also learned from biology class that biologist didn't know what they were talking about. In some areas I knew more than the teacher just by keeping my eyes open and looking around.

In college I took a course called Wilderness Camping and Survival, became friends with Harry Hails, who taught the edible plant portion and went all around the Southern California with him looking for edible plants. One time we went on a camp out that Miriam Darnall

was leading.

- I have studied and/or taught* wild edible plants for 31 years in several states, California*, Michigan*, Ohio*, Arizona*, Nevada, Colorado*, Utah, Idaho*, Kentucky, Wisconsin, Oregon*, Washington, New Mexico*, Colorado*, Arkansas*, Ontario*, New York, Massachusetts*, Pennsylvania, North Carolina, Missouri, Illinois (Indiana, Minnesota, West Virginia, Nebraska to a lesser extent).
- I have taught at
 - outdoor schools
 - summer camps
 - church outings
 - U. S. Forest Service interpretive Specialist volunteer 5 years
 - Rabbitstick and Winter count rendezvous of Society for Primitive Technology a group dedicated to keeping the knowledge of primitive skills alive.
- I have been co-teaching it at Loma Linda University with Miriam Darnall-Kraimer for 10 years.

Online Directory for the 108th Congress

[¿Quiere ponerse en contacto con miembros del Congreso en Español?](#)

Contacting the Congress is a very up-to-date database of congressional contact information for the 108th Congress. As of April 6, 2004 there are 524 email addresses (of which 443 are Web-based email homepages), and 539 WWW homepages known for the 540 members of the 108th Congress. More traditional ground mail addresses are available for all Congressmembers.

Find your members of Congress by clicking on your state on the map to the right or filling out the following form:

- **Address Search:** Enter your address to determine who represents you in Congress.
- **ZIP Code Search:** Don't feel comfortable submitting your address? Enter just your 5 or 9 digit ZIP code!
- **State Search:** Select just your state to list your state's Congressional delegation.
- **City Search:** Enter a city and state (*without* a ZIP code) to identify the members of Congress representing that city.

Wild Food Adventures

Provides expertise in wild edible plants through workshops, expeditions, teaching events, presentations, outdoor guiding, and outfitting anywhere in North America. Technical advising, curriculum development, and custom research services are also available. Emphasis is on the past, present, and future uses of wild edible plants and other foragables. We also offer publications: the Wild Food Adventurer newsletter, a national publication on wild foods. The Wild Food Primer, a guide to studying wild foods. And a bookstore complete with reviews of the best books available.

Our Mission

Is to help people connect with the Earth, Earth culture, human history, and the future through the study of edible plants in

Areas of Expertise

Edible wild plants and other foragables of North America. Wild foods of Native Americans. The role wild foods play in recreational and unplanned survival. Wild Gourmet Garden Vegetables. Plant identification. Poisonous plants. Sea vegetables. Processing wild foods. Nutrition of wild foods. Research in these areas is continually being conducted.

Help us Communicate with You

If you want regular updates on wild food events, books and publications, E-mail us leaving your name, mailing address, and phone number. If you'd like, also tell us why you are interested in wild edible plants.

natural settings. People who genuinely make these connections will live more sustainable lifestyles and be better caretakers of the environment.

Our mission is also to partner with and assist original North Americans in their efforts to restore and revitalize traditional foodways. Foodways involve the identification, collection, transportation, processing, storage, retrieval, and use of traditional wild foods. We strive to honor and preserve the wild food knowledge, experiences, and wisdom of original North Americans.

Edible Wild Plants and other Foragables Defined

Edible wild plants are wild plants with one or more parts that can be used for food if gathered at the appropriate stage of growth, and properly prepared. Foragables are natural objects that cannot run off when you approach. They may include edible plant and animal life.

Workshops and Rendezvous involve trips to a variety of habitats. We visit city streets, parks, forests, mountains, coastal habitats, farms, lakes, swamps and more. Some times we look, sometimes we process foods, sometimes we snack, and sometimes we feast. We always have fun with wild foods!

Wild Edible Plant Keyword Descriptors:

Botany, ethnobotany, Native American Indian ethnobotany, wild edible plants, wild food plants, poisonous plants, adventure education, experiential education, wilderness education, outdoor education, primitive living skills, primitive technology, prehistoric Earth skills, outdoor survival skills, wilderness survival, edible cuisine, raw food, living food, wild cuisine, wild gourmet garden vegetables, volunteer vegetables, sustainability, sustainable living, voluntary simplicity, simple living, wildcrafting, special forest products, permaculture, and deep ecology.

THE PURPOSE of [this hands-on program](#) is to learn about the environment and get back in touch with nature. By [studying foraging and nature](#), we enjoy our renewable resources and reaffirm our commitment to preserving and rebuilding our ecological riches.

Here are all the resources you need to learn about foraging...

Check out the [tour calendar](#) to attend field walks and other events throughout the northeast.

Get information about [travel directions, meeting places and times](#).

Find out [how to sign up and what to bring](#).

Learn about the many common, renewable, edible and medicinal [wild plants](#) growing in your neighborhood.

Find out how you may safely identify, collect, and use our delicious, healthful [wild mushrooms](#).

Enjoy my tasty, innovative vegetarian [wild plant recipes](#) and [mushroom recipes](#).

Arrange a private tour or presentation for a [school](#), [birthday party](#), [camp](#), [scout troop](#), [garden club](#), or [library](#), or to discover what's growing on your property.

My [resumé](#) provides extensive background information.

Letters of recommendation from [teachers](#) and [kids](#) add another perspective on my background and work.

The [press clippings](#) page supplies entertaining and informative coverage by diverse journalists.

Don't miss the hilarious press and media coverage of [my arrest](#) by undercover NYC park rangers, for eating a [dandelion](#) in Central Park!

Watch [TV clips](#) of my best current and archival appearances on local, national, and international news and talk shows, plus my [public access show](#).

Listen to [radio clips](#) from news and talk show appearances, plus archives of my popular NY environmental listener-sponsored radio series.

You'll also enjoy reading excerpts and [reviews](#) from my critically acclaimed [books](#), which you may [purchase](#), autographed (along with [other](#) foraging items):

[*1. Identifying and Harvesting Edible and Medicinal Plants in Wild \(and Not-So-Wild\) Places*](#)

[2. Shoots and Greens
of Early Spring in
Northeastern North America](#)

[3. The Wild Vegetarian
Cookbook](#)

[4. Stalking
the Wild Dandelion](#)

[Watch excerpts](#) of both my videos series--*Foraging with the "Wildman,"* [on sale now,](#) and *The Wild Vegetarian Kitchen* , [on sale](#) soon.

If you're romantically inclined, you'll love the articles about my 2001 wild [wedding](#) to Leslie-Anne Skolnik.

Like original, off-beat,
all-natural music, unusual
instrumentation, or jazz?
Then the [Brillophone](#) page is
for you!

Enjoy chess? Then check out
some of the best [tournament
games](#) from my
pre-"Wildman" days.

Finally, discover the best
related sites on the web, on
my [GreenLinks](#) page.

Happy Foraging!

[A Taste Of Nature;](#)

Edible Plants of the Southwest and How to Prepare Them. © 1994

Kahanah Farnsworth, author.

[Introduction to the book](#)

[FREE recipe for edible native plants.](#)

[Orach Quiche á la Greek!](#)

(Be prepared to give your email address)

Edible wild plants are free food. You will be glad to know which wild plants are edible if you spend long days camping, backpacking, walking on hunting expeditions, or fishing trips. Learn how to harvest wild plants while trapping, foraging or roughing it. Edible flowers and edible roots can be eaten during survival exercises, mountain climbing, rock climbing or even river rafting! Edible plants are useful to many people who engage in activities such as filming on location, photography, reconnoitering, doing surveys and many other outdoor activities! Edible parts of plants include flowers, roots, tubers, leaves, fruit, nuts, shoots and even the occasional stem or branch. [*This website editor has even eaten wild plants while dieting.*]

This book tells you how to identify edible plants and provides gourmet recipes for native plants! The author has illustrated the book with drawings for every plant. The illustrations are clear and simple, making it easier to identify each plant. This book makes a wonderful gift for the person who has everything- a birthday, holiday, or "anything" gift to make someone feel special.

The information on these pages is provided as a free service in the hopes that you will purchase the fine book "A Taste of Nature" by Kahanah Farnsworth.

Personal Information

We've lived on these five acres in central Kentucky for thirty years with our daughters, Abby and Molly. Abby and Molly have now graduated from the University of Kentucky. We built our home out of stone found on this property using a modified slip form method described in Helen and Scott Nearing's [The Good Life](#).  We're very happy with the outcome. Incidentally, this book is an essential addition to your library if you plan for or dream of a more self-sufficient future. We've also watched in amazement as a bare piece of cow pasture has transformed into a veritable Eden through our benign neglect.

We grow pawpaws, persimmons, elderberries and Mayapples for our own enjoyment. We are interested, however, in developing a pawpaw orchard and selling both fruits and trees. We've made some wonderfully delicious pawpaw custards, ice creams and pies. We've also made an elderberry wine that is reminiscent of Miers 44--only better. Please share your experiences and recipes with us. Thanks

[Top of the page](#)

There's lots more Pawpaw information on the Web, and here are three particularly good links:

or
Feel free to drop us a
line, [Jeannie and Berry](#)

Growing Pawpaws

I have claimed in the past that it was a bad idea to buy bare rooted Pawpaw trees from a nursery. I'd like to amend that advice. I just attended the Pawpaw field day at Kentucky State University in Frankfort KY (10/21/99), and had the pleasure of meeting Annie Black and Diana Lalani of Hidden Springs Nursery in Cookeville TN. You can feel safe ordering bare rooted pawpaws from them, as they are very knowledgeable, and take great care in digging their trees. Contact them at Hidden Springs Nursery, 170 Hidden Springs Lane, Cookeville, TN 38501. Another nursery that knows its pawpaws is One Green World, 28696 S. Cramer Rd., Molalla, OR 97038-8576. Ask for their catalog. Once you get your pawpaw, you'll need to protect it from the sun for a year or two. Build a little lattice shelter; use the translucent plastic protectors sold by some nurseries; or, prop a cedar or

pine on the south side of your new tree to protect it from intense sunlight. I buy the cheapest three-legged tomato cages, and place them over the young trees. I then put a white kitchen garbage bag over the cage and poke some holes in the top to keep too much heat from building up. The tree will do well in full sun after that second year.

Do you have some seed from a pawpaw you really enjoyed? Clean it well and place in moist sphagnum peatmoss in a baggy in your refrigerator over the winter. Never let the seed dry out. By late February or early March, the seed will have been stratified long enough to sprout. The best pot to start your seed in is a 12" length of 4" plastic sewer pipe. The plastic base of a 2 liter soft drink bottle makes an excellent bottom for this pot. Fill the pot with growing medium or top soil and plant the seed about an inch deep. The reason you need this tall skinny pot is because when the seed sprouts it sends down a ten inch tap root before you ever see anything. The seed itself should stay in the soil while the first leaves emerge. These aren't cotyledons, but true leaves. Usually, when the seed itself emerges from the top of the soil, it means your pot wasn't deep enough, and the tap root pushed the seed out of the soil. Don't expect to see anything for quite a while. Keep the soil moist, and don't give up until almost September. The seed will sprout sooner in a greenhouse, but always requires the four months or more of stratification.

You found a patch that produces really fine fruit and you want to dig a small sprout for transplanting? Most pawpaw patches consist of a parent tree and many root suckers. Digging these root suckers is usually unsuccessful because there isn't much of a tap root. Best wait for the fruit and plant the seeds. Another unusual characteristic of the pawpaw is that it should be transplanted when it is not completely dormant. This is because in the dormant state, the root is also dormant (unlike most deciduous trees). If it's wounded at all during the transplant, rot or disease will set in and the tree will die.

Pawpaws aren't real easy to grow, but they're well worth the trouble both as an ornamental and fruit tree.

There is a person who sells Pawpaw pulp...

And his name is Chris Chmiel. Chris, called "Dr. Pawpaw" around Albany, OH, is extremely knowledgeable about all aspects of pawpaw culture and use. Here's what he says about his pawpaw pulp product: "I am selling the 1 pound bags for \$4.50. The 2 pound bags are \$8.00. I am also willing to ship small quantities, because I have a better shipping system. I am also willing to ship fresh fruit boxes of the pawpaws for \$5.00 a pound, which is 4 to 6 fruit. Contact [Dr. Pawpaw](#), with your questions and orders. If you want

the fresh fruit, you'd better contact him in August or September.

With the success of "My Wild Friends"(out of print), Blanche has now released "More My Wild Friends" AND "My Favorite Plants".

My Favorite Plants

NEW! "old" book revived Because several people have expressed their wish to own the now out of print "*My Wild Friends*", I decided to excerpt the "best of the best" from that book into a "new" one, "*My Favorite Plants*". I extracted essays and recipes on the plants I use the most.

If you missed the first book, here's a chance to get valuable information on plants such as nettle, chickweed, cattails etc.

Don't buy this book if you already have "*My Wild Friends*"; aside from a few new drawings and recipes, it's basically the same book. But if you don't own "*My Wild Friends*", this just might be the perfect solution.

Cost: \$17 (+.85 MA tax) + \$5 shipping.

132 pps. 6"x9";

A perfect companion to "*More My Wild Friends*".

My Wild Friends is now out of print - see My Favorite Plants instead.

My Wild Friends

Free Food From Field and Forest

Written and illustrated by

Blanche Cybele Derby

Have you ever eaten black locust flowers, cattail buds, or stinging nettle leaves? These are just some of the common "weeds" discussed in this book that are free, plentiful, and easy to prepare.

Using wild plants as food has become more popular, as people realize how tasty and nutritious they are. While this book is a culinary adventure of exploring New England's fields and forests for unusual foods, web visitors from around the world will

recognize "weeds" that may well have originated from their backyards.

My Wild Friends includes:

- the author's personal stories and observations about her favorite plants
- over 100 beautiful illustrations
- over 50 recipes
- information on plant habitats, best parts to use, and best times to harvest
- extensive bibliography
- 264 pages; 6"x9"
- comb binding so book lays flat

What people are saying about "*My Wild Friends*"

Review by **Shannon Younger**

"The other day a wondrous treat arrived in my mail box; a book titled **My Wild Friends** by list member **Blanche Derby**. I have to say, I was charmed and enchanted almost instantly by this tome. The illustrations are all done by Blanche and harkens back to the days of the turn of the last century when children's and young adult's books were complimented with artwork by the likes of Arthur Rackam or Howard Pyle. My son, who is speech delayed, babbled on incessantly about the pictures, wanting to know more about the scenes and the plants. The prints are creative, intuitive and very imaginative. They draw the reader into the book. I caution you to look at each illustration with care though, because you will find additional allusions to the plants hidden in the picture, some are very subtle and some not so subtle. Leave's and flower's motifs are repeated in the design work. You will find references to several cultures in the artwork as well. The work is very delightful and whimsical, and as you can see I am very enthusiastic about the entire book.

The text is useful and reads easily, and is a down right pleasure too! Blanche makes a point to tell the reader that this is not a field guide. Ohhh Dear Blanche to my mind it is so much more though. Through Blanche's stories and pages I have learned more about Ben Charles Harris, a wild edible plant author and guru from decades past. I had only known of him from books in the library and now he is a real, 3-dimensional personality come to life.

There are many plants covered in the book. Organized by chapter per plant or grouping of plants in the case of edible flowers. With each chapter the reader is introduced to the plant with a jewel of an essay, and I do mean jewel here, pun intended. Blanche shows you many facets of each special plant friend. She weaves a story and sometimes she includes a special bit of lore or legend, as well as giving the reader insights into why she finds this plant to be special. My personal favorite character in the book is the "Orchard Cat" who made the Apple Orchard part of his territory. These chapters are sneaky, before you realize it, you have learned or reviewed much information in a painless and enjoyable manner. She does cover several plants that one does not often find in foraging books, along with the favorites. Best of all the reader will see these plant friends in a very different light (more intimate view) after having read the book.

Blanche also gives tips on harvesting and preparing each plant for eating. I have tried several of her recipes already with things available at the grocery store (we have about 6 inches of snow on the ground at the moment). The recipes are simple, easy to prepare and very tasty. My children were able to help with the preparation and it became a family project, making this book a good resource for homeschooling. The Cranberry (Apple) Bread was a big hit here! This was probably the easiest Cranberry bread recipe I have ever made, and I am one of those people who wait all year long for cranberry season when these fruits are available fresh in the market. Each chapter has at least one recipe and often there will be other ideas on preparation written into the text. Also included with each chapter is a run down on basic information. This page appears at the very beginning of the chapters and lists: Scientific Name, Family, Also Known As, Habitat, Parts Used, Season, and any Cautions. Blanche has

included a very useful bibliography in "My Wild Friends." Here I emphasize the word useful, because she gives a paragraph description of what each book listed is about and what you can expect to find in the book information wise. She obviously spent a goodly amount of time crafting this section of the book as well. It was nice to receive a book with a penned and personal note in the front cover, making the book all that more special. Blanche, bravo and a resounding "two thumbs up." Thank you for hours of reading pleasure, learning and good eats. ..." Review by **Shannon Younger**, writing on the "[Wild Forager](#)" list forum

More My Wild Friends

Free Food From Field and Forest

Written and illustrated by

Blanche Cybele Derby

Do You Know.

- what weed is a main ingredient in the national dish of Colombia?
- what plant is an important part of an anti-cancer formula?
- which flowers to use in a salad?
- how to find spices for free?
- that the oil from this plant is effective against PMS?

This supplement to My Wild Friends introduces a whole new group of common plants with uncommon stories to tell. More My Wild Friends combines fascinating facts and recipes with information on plants that are plentiful and available. They have much to offer and this book tells how they can be used to enrich our lives. Inside this book you will find:

- the author's personal stories and observations about plants
- over 40 detailed black and white illustrations
- over 30 recipes
- information on plant habitats, best parts to use, and best times to harvest
- annotated bibliography

114pps., 6"x 9" \$12.(+MA tax .60) + \$5. Shipping

excerpt from "I'm a Crusader for This Invader" chapter:

The Division of Fisheries and Wildlife recently published A Guide to Invasive Plants in Massachusetts, a booklet that features 17 of the most problematic imported plants that threaten to usurp the territories of native plants and animals. Each plant is illustrated with a beautiful color photo and description. Many of these are well-known intruders like bittersweet but lesser-known culprits are also showcased. One of these is Autumn Olive (*Elaeagnus umbellata*), an Asian shrub that was introduced into this country in 1830. After being here for over 160 years, why is this plant now on the state's "hit list? ...

recipe from "Its Food! It's Medicine! It's Sheep Sorrel" chapter:

Sorrel Soup

2 cups uncooked sheep sorrel/wood sorrel leaves; (wood sorrel flowers are o.k.)

1/2 cup sautéed onions
Dash of pepper/nutmeg
3 cups vegetable or chicken broth
2 medium potatoes (optional)

Mix ingredients in saucepan and simmer until potatoes are soft.
This serves 3; the recipe can be doubled.

Edible Wild Plants: Upcoming Events

WALKS/TALKS IN '04

--Join me in exploring the weeds around us! This list will be added to as the spring progresses. Check it periodically. All events are in MA +free unless otherwise noted. For more info e-mail:qs2t@hotmail.com

- Coming soon!! Watch for excerpts from my video *Edible Plants: Wild and Tame* on Easthampton, (and maybe Northampton + Amherst) cable TV.
- Thurs April 22: (Earth Day) Slide show, Goldthread Herbal Pharmacy, 267 Pleasant St Northampton; 6:30pm
- Sun May 16: Show 'n tell Pioneer Valley Pond and Koi Club 94 Gillette Av. Spfld (not open to public)
- Sat May 22: Walk @ Great Falls Discovery Center, Avenue A, Turner's Falls; 9:30am-11:30 pm; \$12 (snack included)
- Sun May 23: Walk @ Fannie Stebbins Refuge, Bark Haul RD, Longmeadow ; 3:30-5:00 followed by a potluck in Suffield CT.
- (tentative date) Sat June 5 (raindate Sun June 6): Walk the Blueberry Patch, 1672 Main Rd W. Granville; 1-3
- Sun June 13: Walk @ Spirit in Nature, Westhampton; 1-3
- Sat Sept 11: Walk @ Spirit in Nature, Westhampton; 1-3

Artist and author **Blanche Cybele Derby** has supplemented her diet with wild plants for over thirty years. She has lectured and led many wild weed walks, and writes about many edibles for her local newspaper. An enthusiastic practitioner of what she preaches, she hopes that this book will inspire others to become more involved in the natural world. [Click here to contact her](#)

Edible and Medicinal Plants of Southern Illinois

"Nature's pharmacy" or "nature's fruit market" may be the best way to explain it. Long before there were modern medical centers or supermarkets, the inhabitants of Southern Illinois survived by "living off the land." The forests, wetlands, and grasslands of Southern Illinois are a rich source for edible and medicinal plants. Imagine getting a fever or an infection and not having a doctor to call or an emergency room nearby. The early inhabitants had to be creative to prevent starvation or survive disease.

Many early inhabitants did not survive disease, but occasionally some remedy would work to ease suffering and would then be considered a "medicine." Even after there were doctors, many of the "medicines" used were derived directly from plant products. The doctor would often take extracts from plants with a mortar and pestle to prepare powders, ointments, or pills. Many plants are still used today, in some form, to eliminate suffering.

The following rules **MUST** be observed when collecting and eating wild plants:

- Study with an expert or take the plant to an expert for proper identification.
- After positive identification of an edible plant, taste only a small amount. This will prevent allergic reactions to previously unused plant products.
- The purpose of the information in the plant reports is not to recommend

or endorse herbal medication, self diagnosis or self medication. If you are ill, seek the advice of a physician. The information is provided as historic reference and not scientific fact.

- Practice conservation. Never collect more plants than you intend to use and never pick endangered or threatened plant species.
- Avoid harvesting plants from polluted ground. Roadsides or areas along railroad tracks are often polluted with herbicides or tainted with chemicals such as lead or benzene. Be careful!!
- Wash and cook all plants carefully.

The plants listed below have parts that are edible or may be medicinal. The list will be updated regularly. Click on the plants that are underlined to read more information about their uses.

UCMP Glossary: Botany

| [Phylogenetics](#) | [Geology](#) | [Biochemistry](#) | [Cell biology](#) |
[Ecology](#) | [Life history](#) | [Zoology](#) | **Botany** | [Paleogeography](#) |

adventitious roots -- A root that grows from somewhere other than the primary root, for example, roots that arise from stems or leaves.

alternation of generations -- Life cycle in which **haploid** and **diploid** generations alternate with each other.

anemophily -- Seed plants which are pollinated by wind are said to be anemophilous.

angiosperm -- n. A group of plants that produce seeds enclosed within an ovary, which may mature into a fruit; [flowering plants](#).

anther -- The pollen producing tip of a **stamen**; part of a flower. [More info?](#)

antheridium -- The organ on a [gametophyte](#) plant which produces the sperm cells.

anthophyte -- A flowering plant, or any of its closest relatives, such as the Bennettitales, Gnetales, or Pentoxylales.

apical meristem -- Group of cells at the growing tip of a branch or root. It divides cells to create new tissues.

archegonium -- The organ on a [gametophyte](#) plant which produces the egg cell, and nurtures the young [sporophyte](#).

axil -- The angle formed between a leaf stalk and the stem to which it is attached. In flowering plants, buds develop in the axils of leaves.

bipinnate -- Describing a pinnate leaf in which the leaflets themselves are further subdivided in a pinnate fashion.

bisporangiate -- When a flower or cone produces both **megaspores** and **microspores**, it is said to be bisporangiate. Most flowers are bisporangiate.

blade -- Any broad and flattened region of a plant or alga, which allows for increased photosynthetic surface area.

bract -- Any reduced leaf-like structure associated with a cone or flower.

bryophyte -- Plants in which the **gametophyte** generation is the larger, persistent phase; they generally lack conducting tissues. Bryophytes include the Hepaticophyta (liverworts), [Anthocerotophyta](#) (hornworts), and Bryophyta (mosses).

carpel -- A unit of the **pistil**; it is evolutionarily a modified leaf.

cataphyll -- In [cycads](#), a scale-like modified leaf which protects the developing true leaves.

columella -- A small column of tissue which runs up through the center of a spore capsule. It is present in [hornworts](#), mosses, and some rhyniophytes.

compound leaves -- n. Leaves with two or more leaflets attached to a single leaf stem.

cotyledon -- n. The "seed leaves" produced by the embryo of a seed plant that serve to absorb nutrients packaged in the seed, until the seedling is able to produce its first true leaves and begin photosynthesis; the number of cotyledons is a key feature for the identification of the [two major groups of flowering plants](#).

elater -- A cell or part of a cell which assists in dispersing spores. The elaters change shape as they lose or acquire water, and they will then push against surrounding spores.

embryophyte -- Synonym for the [Plantae](#), as here defined. It includes all green photosynthetic organisms which begin the development of the sporophyte generation within the [archegonium](#).

enations -- Flaps of tissue such as those found on psilophytes.

endodermis -- Literally "inner skin", this is a layer of cells which surrounds the central core of vascular tissue, and which helps to regulate the flow of water and dissolved substances.

entomophily -- Seed plants which are pollinated by [insects](#) are said to be entomophilous.

epiphyte -- A [plant](#) which grows upon another plant. The epiphyte does not "eat" the plant on which it grows, but merely uses the plant for structural support, or as a way to get off the ground and into the canopy environment.

eustele -- When a plant's vascular tissue develops in discrete bundles, it is said to have a eustele. See also protostele and siphonostele.

fiber -- Elongated and thickened cell found in xylem tissue. It strengthens and supports the surrounding cells.

flower -- Collection of reproductive structures found in flowering plants. [More info?](#)

fruit -- In [flowering plants](#), the structure which encloses the seeds. True fruits develop from the ovary wall, such as bananas and tomatoes, though not all fruits are edible, such as the dry pods of milkweed or the winged fruits of the maple.

grain -- (1) The texture of wood, produced by the kinds of **xylem** cells present. (2) The **fruit** of a member of the [grasses](#).

guard cells -- Pair of cells which surround a **stomate** and regulate its size by altering their shape.

gymnosperm -- n. A plant that produces seeds, which are not enclosed; includes any [seed plant](#) that does not produce flowers.

gynostemium -- The central reproductive stalk of an [orchid](#), which consists of a **stamen** and **pistil** fused together.

habit -- The general growth pattern of a plant. A plant's habit may be described as creeping, trees, shrubs, vines, etc.

herb -- Generally any plant which does not produce wood, and is therefore not as large as a tree or shrub, is considered to be an herb.

heterosporangiate -- Producing two different kinds of **sporangia**, specifically microsporangia and megasporangia. Compare with **heterosporous**.

heterosporous -- Producing two different sizes or kinds of spores. These may come from the same or different sporangia, and may produce similar or different gametophytes. Contrast with **homosporous**, and compare with **heterosporangiate**.

holdfast -- Anchoring base of an alga.

homosporous -- Producing only one size or kind of spore. Contrast with **heterosporous**.

hypha -- n. Threadlike filaments that form the mycelium (body) of a fungus;
hyphae- pl.

inflorescence -- A cluster of flowers.

internode -- The region of a stem between two **nodes**, when there is no branching of the vascular tissue.

lamina -- Any broad and flattened region of a plant or alga, which allows for increased photosynthetic surface area.

leaf -- An organ found in most vascular plants; it consists of a flat **lamina** (blade) and a **petiole** (stalk). Many flowering plants have additionally a pair of small **stipules** near the base of the petiole.

leaf trace -- The strand of vascular tissue which connects the leaf veins to the central vascular system of the stem.

leaflet -- In a compound leaf, the individual blades are called leaflets.

magnoliid -- Any member of the basal assemblage of [flowering plants](#).

mannoxylic -- Wood in which there is a great deal of **parenchyma** tissue among the xylem is called mannoxylic. [Cycads](#) and **pteridosperms** have mannoxylic wood. Contrast with [pycnoxylic](#).

megaspore -- In plants which are **heterosporous**, the larger kind of spore is called a megaspore; it usually germinates into a female (egg-producing) **gametophyte**. Contrast with **microspore**.

meristem -- Group of undifferentiated cells from which new tissues are produced. Most plants have **apical meristems** which give rise to the primary tissues of plants, and some have **secondary meristems** which add wood or bark.

merophytes -- Group of cells which have all been produced from the same initial cell. Leaves and stems in particular are often built from specific patterns of merophytes.

microphyll -- A kind of leaf, specifically one which has a single, unbranched vein in it. Microphylls are only found in the [lycophytes](#).

microspore -- In plants which are **heterosporous**, the smaller kind of spore is called a microspore; it usually germinates into a male (sperm-producing) **gametophyte**. Contrast with **megaspore**.

mycorrhizae -- Symbiotic association between a [fungus](#) and the roots or rhizoids of a [plant](#). [More info?](#)

node -- The region of a stem between two **internodes**, where there is branching of the vascular tissue into leaves or other appendages.

ovary -- In [flowering plants](#), the part of the flower which encloses the **ovules**. When the ovary matures, it becomes the **fruit**.

ovule -- In [seed plants](#), the structure which gives rise to the seed.

paleoherb -- Any member of a group of basal [flowering herbs](#) which may be the closest relatives of the [monocots](#). They include the water lilies, Piperales, and Aristolochiales.

parenchyma -- A generalized cell or tissue in a plant. These cells may manufacture or store food, and can often divide or differentiate into other kinds of cells.

perennial -- A plant which continues to grow after it has reproduced, usually meaning that it lives for several years.

perianth -- The **sepals** and **petals** of a flower are together called the perianth; literally "around the anthers". [More info?](#)

peristome -- A set of cells or cell parts which surround the opening of a moss sporangium. In many mosses, they are sensitive to humidity, and will alter their shape to aid in spore dispersal.

petal -- One of the outer appendages of a flower, located between the outer **sepals** and the **stamens**. Petals often display bright colors that serve to attract pollinators.
[More info?](#)

phloem -- Nutrient-conducting tissue of vascular plants.

phragmoplast -- The cell plate formed during cell division.

phytomelanin -- a papery "sooty" black layer over the seed of plants in the [Asparagales](#), which includes agaves, aloes, onions and hyacinths. It is an important character for defining the group.

pinnately compound -- Leaves which are divided up like a feather are said to be pinnately compound.

pistil -- The central set of organs in a flower; it is composed of one or more **carpels**.
[More info?](#)

pith -- To severely damage the brain of a frog, also any central region of **parenchyma** tissue within a plant stem.

pits -- Thin regions of the cell wall in xylem conducting cells. Their structure is an important characteristic for recognizing different kinds of wood.

plasmodesmata -- Cytoplasmic connections between neighboring cells in plant tissues.

platyspermic -- Having seeds which are flattened and disc-like. Contrast with **radiospermic**.

plicate -- Folded like a paper fan, as in the leaves of palms, cyclanthoids, and some orchids.

pollen -- The **microspore** of [seed plants](#).

pollen tube -- In [seed plants](#), the extension of the male gametophyte as it emerges from the pollen grain in search of the female gametophyte.

pollination -- Process of transferring the pollen from its place of production to the place where the egg cell is produced. This may be accomplished by the use of wind, water, [insects](#), [birds](#), [bats](#), or other means. Pollination is usually followed by **fertilization**, in which sperm are released from the pollen grain to unite with the egg cell.

pollinia -- A mass of fused pollen produced by many [orchids](#).

protostele -- When a plant's vascular tissue develops in a solid central bundle, it is said to have a protostele. See also siphonostele and eustele.

pseudoelaters -- Moisture-sensitive cells produced in the sporangium of [hornworts](#).

pteridophyte -- Plant in which the **sporophyte** generation is the larger phase and in which the **gametophyte** lives an existence independent of its parent sporophyte. Pteridophytes are almost all vascular plants, and include the [lycophytes](#), [trimerophytes](#), [sphenophytes](#), and ferns.

pteridosperm -- An extinct group of [seed plants](#) which bore fern-like leaves.

pycnoxylic -- Wood in which there is little or no **parenchyma** tissue among the xylem is called pycnoxylic. Conifers and [flowering plants](#) have pycnoxylic wood. Contrast with [mannoxylic](#).

radicle -- The end of a plant embryo which gives rise to the first root.

radiospermic -- Having seeds which are round or ovoid. Contrast with **platyspermic**.

reticulate -- Interconnecting, like a network.

rhizoid -- n. A cellular outgrowth of a plant that usually aids in anchoring to the surface and increasing surface area to acquire water or nutrients; found in mosses, liverworts, and hornworts.

rhizome -- n. A horizontal underground stem, such as found in many ferns, where only the leaves may stick up into the air; sphenophytes (horsetails and their relatives) spread via rhizomes, but also produce erect stems.

root -- Usually the below ground portion of a plant. Contrast with **shoot**.

rosette -- A series of **whorls** of leaves or leaf-like structure produced at the base of the stem, just above the ground.

secondary growth -- Growth in a plant which does not occur at the tips of the stems or roots. Secondary growth produces wood and bark in [seed plants](#).

sepal -- The outermost structures of a flower. [More info?](#)

shoot -- Usually, the above ground portion of a plant, bearing the leaves. Contrast with **root**.

siphonostele -- When a plant's vascular tissue develops as a central cylinder, it is said to have a siphonostele. See also protostele and eustele.

spermatophyte -- A [seed plant](#).

sporangiophore -- A stalk to which sporangia are attached.

sporangium -- A chamber inside of which spores are produced through [meiosis](#).

sporophyll -- Any leaf which bears sporangia is called a sporophyll.

stamen -- Part of a flower, the tip of which produces pollen and is called the **anther**. [More info?](#)

stigma -- The sticky tip of a **pistil**. Or, the dense region of pigments found in many photosynthetic protists which is sensitive to light, and thus functions somewhat like a miniature eye. [More info?](#)

stipe -- A scientific term for "stalk".

stipules -- Paired appendages found at the base of the leaves of many [flowering plants](#).

stomata -- Openings in the epidermis of a stem or leaf of a plant which permit gas exchange with the air. In general, all plants except liverworts have stomata in their sporophyte stage.

streptophytes -- The [clade](#) consisting of the [plants](#) plus their closest relatives, the [charophytes](#).

strobilus -- A tightly clustered group of **sporophylls** arranged on a central stalk; commonly termed a "cone" or "flower".

style -- The narrow stalk of the **pistil**, located above the ovary but below the **stigma**.

synangium -- A cluster of sporangia which have become fused in development.

tepals -- When the **sepals** and **petals** of a flower are indistinguishable, they are referred to as tepals. Tepals are common in many groups of [monocots](#). [More info?](#)

thalloid -- Plants which have no roots, stems, or leaves are called thalloid, such as liverworts and [hornworts](#).

tracheophyte -- Any member of the clade of plants possessing **vascular tissue**; a vascular plant.

tree -- Any tall plant, including many conifers and [flowering plants](#), as well as extinct lycophytes and sphenophytes.

tuber -- An underground stem which has been modified for storage of nutrients, such as a potato.

turgor pressure -- Force exerted outward on a cell wall by the water contained in the cell. This force gives the plant rigidity, and may help to keep it erect. [More info?](#)

vegetative growth -- Growth of a plant by division of cells, without sexual reproduction.

venation -- The arrangement and pattern of veins in a leaf.

whorl -- An arrangement of appendages, such as branches or leaves, such that all are equally spaced around the stem at the same point, much like the spokes of a wheel or the ribs of an umbrella.

wood -- A **secondary** tissue found in [seed plants](#) which consists largely of xylem tissue.

xylem -- Water-conducting tissue of vascular plants.

- [General Notes](#)

Scientific name

Quercus kelloggii Newb.

Common names

Black, California black oak

Height

60 to 90 feet

Mature Tree DBH (Diam. at Breast Ht.)

1 to 4 feet

Longevity

100-200 yrs., occasionally up to 500 yrs.

Sprouting

Excellent sprouter

Acorn

Matures second year; 1-1/2 in. long; thin cup over half the nut

Foliage

Deciduous; 5 in. long; 5-7 lobed; spiny leaf tips; dark yellow-green above and pale yellow-green below

Shade Tolerance

Intermediate tolerance as seedling and intolerant as tree matures

Fire Tolerance

Very sensitive to cambium being killed in hot fires

Elevation

200 to 6000 feet

Associates

Most common with tanoak, madrone, mixed conifer forest species; also with coast live oak, interior live oak, and blue oak

Sites

More common on forest sites; found on moister hardwood rangelands; well-drained soils

General Notes

Protected by Forest Practice Act on timberlands; commercial properties for finished lumber

CELEBRATING ANOTHER SPRING...

Our annual spring "Grass Issue" catalog features a cover picture taken at the San Jacinto Monument near Houston. Why? This year, Native American Seed will be working together with the Texas Department of Parks and Wildlife to restore the health and vitality of the unspoiled prairie immediately surrounding this historic place. The rest of the story is told in the pages of the catalog, so if you're not already on our mailing list be sure to send us an [email](#) with your name and address.

Spring is the time to plant native grasses, whether you want to convert your lawn from high-maintenance, water-guzzling exotics to low-maintenance, environmentally friendly natives - or to begin restoring many acres of abused or overgrazed land. We've got all the materials and expertise you need, either right here on the website or just at the other end of a phone call.

Featured This Month

Our [Plant in Spring or Fall Mix](#) is a special blend of 14 perennials including not just the colorful Gayfeather shown here, but some of the most beautiful wildflowers that grow in our region - Standing Cypress, Pink Evening Primrose, Scarlet Sage, Foxglove and Butterfly Weed, to name just a few. Many of these beautiful species can also be used in cut-flower arrangements. Plant them this year and be patient as they develop strong roots in the soil, and enjoy their beauty as they flower for years and years to come.

▶ [Continue...](#)

Special Grass Mixes

If you're planning to establish native grasses in your lawn or on your acreage, spring is the time. Check out the [Planting Tips](#) in our Gardener's Corner for an overview of what's involved. Check the Grass Mixes and Native Grasses categories in the SHOP pages. And as always, you can give us a call if you need help deciding what's best for your combination of soils, temperatures and rainfall. **Pictured Here:** Our [Native Coastal Prairie Mix](#) comes from a conservation harvest we conducted on a sandy Gulf Coast Prairie. If you have acreage near the Gulf that you want to restore, it could be exactly the right mix for you.

[About Calflora](#)

[Why Registration?](#)

[Why a Fee?](#)

Welcome to Calflora, the on-line gateway to information about

wild plants in California. The pioneering Calflora database facilitates access to a wide array of information concerning California native plants via simple, easy-to-use search pages. Calflora serves the needs and interests of an expanding user community, bringing together professionals, scientists, educators, students and amateurs alike.

Calflora strives to constantly improve. To serve its users better, Calflora requires them to register. If you have not yet registered, click on the [Register as a User or Guest](#) link below. If you have already registered, click the [continue to Calflora](#) link below to login.

- [Register as a User or Guest](#)
- [I'm registered already, continue to Calflora](#)

Behind the scenes... we're making big changes in the Calflora database structure so it will be easier to make updates and add new data. We're doing our best to keep the online system running smoothly through this transition, but please let us know right away if you find bugs: calflora@calflora.org

BOULDER OUTDOOR SURVIVAL SCHOOL

"BOSS teaches that in a world of dizzying technological change, less can indeed be more" - USA Today

Welcome to BOSS

On behalf of all of the instructors and staff here at BOSS, let me say "welcome" to our school and to our website. For over 35 years, people have come to BOSS to learn a field-based, hands-on curriculum of wilderness survival skills. Whether you want the physical challenge of our world-famous **Field Courses**, the intense instruction of our **Skills Courses**, or the adventurous journeys of our **Explorer Courses**, we are excited to give you the attention, personalized instruction, and quality you've come to expect from BOSS.

What Others Say...

"A step beyond Outward Bound... We recommend BOSS."

- *Men's Health Magazine*

" * * * * (top rating) ...the place to go to gain primitive survival skills."

- *The Ultimate Adventure Sourcebook*

"...the BOSS program is in a league of its own..."

-Shape Magazine

"BOSS is consistently head above the others as the most rewarding survival school."

-Fielding's The World's Most Dangerous Places

"After roughing it with the BOSS, you'll be ready for just about anything...."

- Men's Fitness Magazine

[Click here to read more from the media...](#)

"Congratulations, BOSS! You exceeded my expectations! The course was challenging, inspiring, and educational. Your instructors are top notch, the trip was well planned, and the scenery incredible."

- D. Williams, 7-Day Field Course alum

"The mosquito bites and the scratches are gone. The beard had been shaved, a few pounds have reappeared, but the feelings I experienced are still growing and getting stronger...I can't wait to return!"

- R. Baumann, 7-Day Field Course alum

"I've taken other outdoor and survival courses, but the BOSS courses were the best. The instructors were excellent and really cared about each participant."

- S. O'Conner, Survival Skills I, 7-Day Field Course, Desert Navigator and Mountain Navigator alumna

"The course was a life experience that was the hardest thing I have ever done. It was an experience for my spirit like very few things in our modern world – it taught me basic lessons of life and nature. I can't wait to do more courses with BOSS."

- J. Garey-Sage, 28-Day Field Course, Survival Skills I, Mountain Navigator and Desert Navigator alum

Lost in the Woods The 9 Rules for Survival

SARBC

Search and Rescue Society of British Columbia

Lost in the Woods - The 9 Rules for Survival

by Gary O'Brien, SARBC

PREPARE YOURSELF and YOUR CHILD

Child survival needs adult assistance. You can help children learn what to do if they get lost in the woods, by discussing and practicing the "Rules for Survival".

Nobody ever expects to get lost, but it happens. Hopefully, this information will insure a safe return of your child should this misfortune ever occur.

The Rules are presented in a way which children can understand.

A definition of Survival:

Staying WARM and DRY, while waiting to be found.

1. **Stay Together, DO NOT Separate - if with a friend or pet.**

The reason for this rule is body heat. Cuddling up to a large dog or friend will help keep you warm. If with a dog, do not let it run loose, it can help you more by staying close and providing heat and companionship.

2. **Stay in one place or area. DO NOT WANDER!**

This is the MOST important rule of them all. If you wander - We Can not Find You. One reason is that people looking for you move very slowly while searching for clues. If you are out front running along, we won't be able to catch up. Another reason for not wandering is the possibility of falling and hurting yourself while travelling. Being lost and hurt could be tragic.

3. Keep Warm.

This rule means to keep warm with the clothes you are wearing. NEVER take any clothes off. Cover up all the exposed skin you can. If you are wearing a sweater or jacket, do it up. Watch out for your shoe laces. Branches have a tricky way of undoing them. The most important part of your clothing is a hat or something that covers your head. Over 70% of all your body heat escapes through your head.

4. Find a Cozy Waiting Place, Not a Hiding Place.

A cozy waiting place means, a warm place out of the wind and rain but not a place where searchers can not see you. Under a large tree is a good place.

5. Put Out Something Bright.

Put out something bright or make something to tell people searching for you where you are. Make a flag using what you have, but **Do Not Take Off Any Clothes** to do so. Some suggestions are white paper, money, hair ribbons, a strip from an orange garbage bag, etc. Spell the word "HELP" or "SOS" on the ground using rocks and sticks or make a large arrow with them, pointing to where you are. Do anything to attract attention!

6. Look Bigger For Searchers.

If possible, your waiting place should be near an open space. When you hear someone coming, move to the middle of the clearing and call. **Do Not Run** in the direction of the noise. If it is an aircraft you heard, lie down so the pilot has a bigger target to look at. Then wave with both your arms and legs, like making an angel in the snow. Stand up immediately after the aircraft has passed, as the ground can be very cold.

7. Do Not Lie on the Bare Ground.

The only exception to this rule is the one above. Laying on the cold ground for a very short period of time, attracting attention, is OK. Being in direct contact with the ground for any length of time is dangerous. The cold ground can rob precious body heat from you. Build a mattress using available materials such as branches, moss, leaves, etc. This mattress should be as thick as the mattress you sleep on at home! After the mattress is completed, gather the same amount or more, of the same material and use it for the blankets. This is called a survival bed.

8. Do Not Eat Anything you are not sure of.

Do Not eat any berries, mushrooms or anything else unless you are 100% sure what they are. Being hungry is not too bad of a feeling compared with being violently sick. And remember, there won't be anyone there to look after you. You can go without food for a long time, but you cannot go without water.

9. **Stay Away from Large Rivers and Lakes.**

You must have drinking water to survive, but be careful where you get it from. Do Not go near any large bodies of water. Instead, drink from a water supply that is smaller than you are, so you can not fall in. Another source of water can be found on leaves in the form of dew.

Hug-A-Tree National Headquarters

Last Updated 9/23/98

HUG-A-TREE and SURVIVE is a non-profit organization that was started in San Diego, California after a search for a nine-year-old boy who died in the local mountains. A group of the searchers put together an assembly program designed to tell a simple story that will teach young children very basic principles for staying safe in the wilderness. The story captures their interest and is easily remembered.

[History of Hug-A-Tree](#)

Hoods Woods

Become a REAL Survivor!

Hoods Woods Has been offering the best survival information on the Internet since 1992 when Ron grabbed the Survival.com domain name. The domain wasn't just a name either, it described both a lifestyle and what Ron has been teaching and studying since the 1960's. A lot of dirt has been slept in and a lot of time went into bringing you the material on this site. We hope you'll enjoy it!

Ron and Karen Hood have filled this site with gobs of useful [FREE Wilderness Adventure information](#) and resources. Our goal is to make this important information available to everyone. One of our greatest pleasures are the [hundreds of "Thank You" messages](#) we get from our video students, readers and visitors. We know that as you read the information on these pages you will have questions and perhaps would like to share information. That is the purpose of our forum. We invite you to join the [Hoodlums group](#). You will discover a family of great folks willing to share and learn and teach.

The Forum is FREE!

Welcome to SimplySurvival.com

For over 20 years, Greg Davenport has conducted Leadership Reaction Courses and Wilderness Survival Education programs. Greg's finely honed unique approach to back country travel and survival sets the standard for teaching modern and primitive survival skills while advancing an individuals survival and improvising mind.

[To learn more about Greg's approach to survival click here.](#)

Simply Survival is the creation of [Greg Davenport](#) and is based on his many years of teaching Global Survival and wilderness experience.

Simply Survival News

Nathan Jones, who represents Hydration Technologies (HTI), recently demonstrated a new water filter that is sure to revolutionize the water industry. The emergency water filtration system converts any water source (no matter how filled with dirt or biological pathogens) into pure drinkable water. It requires no pumping, doesn't clog, and uses a re-hydration formula that supplies much needed electrolytes and nutrients to the consumer. In the photograph below, Nathan demonstrates the XPack water filtration system using an extremely muddy water source. For more information on this product, go to [Hydration Technologies web site](#)

We have an extensive photo gallery that covers our various courses and programs.

Rick Arnold, an old friend and member of the Survival Incorporated team, stopped by during a recent trip to Washington State. Rick recently retired from the USAF SERE team and took a position with Survival Inc's military sales team. He has some great ideas and I am sure we will see great things from him in the future. For more information go to the [Survival Incorporated's web site](#).

"The more you know,
the less you need."

Welcome to the Aboriginal Living Skills School, LLC

Arizona has been our home since 1987. With more than 18 years of southwestern experience, ALSS is northern Arizona's oldest and best known wilderness survival and primitive living skills school. While large enough to accommodate virtually all of your training needs, we are a small school and consciously choose to remain so as this allows us to maintain the highest level of quality possible. At ALSS, our focus remains on getting better, not bigger.

Due to Arizona's incredible terrain variation, we teach courses as wide-ranging as desert survival and winter camping, ensuring flexibility to meet your needs. Our field courses are held in the field, not just outside, allowing you to explore and harvest natural materials directly from a wilderness environment for optimal realism and enjoyment. Time tested programs are continually updated with new and exciting skills while limited enrollment ensures you personalized instruction, maximum adventure and fun!

At ALSS, we remain dedicated to sharing with you some of the most honest, well rounded self-reliance and preparedness training available. In short, feel free to look over our [training advantages](#), and peruse my [instructor profile](#) and [media achievements](#). If you have questions regarding the ALSS experience, please don't hesitate to contact me.

Primitively Yours,

Cooylunsin

What the Hunter/Gatherers Ate

Also see the www.PaleoFood.com Recipe Collection and the www.Foraging.com Page

Index to Sections Below

- [Sites by Individuals](#)
- [Educational Institutions](#)
- [Media Reports](#)
- [Associations/Organizations](#)
- [Foraging and Ethnobotany](#) <-- now on its own page.
- [Commercial Sites](#)
- [Books](#)
- [Food Vendors](#)
- [Dehydrators](#)
- [Food Science](#)
- [Mailing Lists/Archives/Forums](#)

Sites by Individuals

- [Introduction to the Paleolithic Diet](#) is Ben Balzer's page. He is a family physician in Australia. Probably the clearest introduction on the web.
- Second Opinions is a site by Barry Groves, PhD. It includes many articles exposing dietary and medical misinformation. A selection of them: [The Naïve Vegetarian](#) is a long article covering various diets with a focus on pointing out the fallacies of vegetarianism. [The Cholesterol Myth](#) points out there is no evidence that eating cholesterol is bad. [Does Animal Fat Really Cause Cancer?](#) points out that an examination of a couple of studies that came out in July 2003 does not support the claims that media is making for them. [Polyunsaturated Oils and Cancer](#) argues that polyunsaturated oils increase cancer risk. [William Banting: The Father of the Low-Carbohydrate Diet](#) is a history of the first low carb diet, which was also paleo.
- [Paleolithic Nutrition: Your Future Is In Your Dietary Past](#) is an article Jack Challem wrote for Nutrition Science News: April 1997.
- [An Interview with Ward Nicholson](#) now has three parts on the web. Good overview of man's diet over the past 65 million years. Long but highly recommended reading. First published in Chet Day's "Health & Beyond" newsletter. Now part of a very comprehensive [Beyond](#)

[Vegetarianism](#) site. Every argument that your vegetarian friends use to avoid meat for health reasons is debunked here.

- Tamir Katz's [Paleolithic Diet Information](#) page has been put up by a medical student at SUNY Stony Brook. He has a knack of clearly and directly explaining things. Excellent for friends and relatives of paleo eaters who are wondering why you eat weirdly.
- [Neanderthin \(Paleo\) eating](#) is Vad's page where he tries to sum up, super concentrated, what this whole thing is about. Includes menus, weight loss, and more.
- In [On the Benefits of Ancient Diets](#) Staffan Lindeberg discusses how the Western diet causes health problems. Also an overview of his Kitava study. Staffan now has a home page [Utbildningarom prevention](#), though initially only in Swedish.
- [Living Longer, yes! But living well?](#) by Dr. Anthony G. Payne is a general article that also gets into a paleo diet.
- A diet high in phytic acid, which can be found in whole grains (it's in the bran) and beans like soy, is very detrimental for mineral absorption. Phytic acid strongly binds to minerals like calcium, iron, zinc and magnesium to form insoluble salts, phytates, which precipitate from the body. Staffan Lindeberg has written a [summary on phytic acid](#).
- Two common foods clearly are Neolithic and avoiding them is key to a paleo diet. Here are link pages for avoiding them: [Gluten-Free Page](#) and [No-Milk Page](#).
- There are some disorders that can be controlled somewhat by using a paleo diet. Here are link pages on three of them: [Autism](#) and [Multiple Sclerosis](#) and [Rheumatoid Arthritis](#).
- JoAnn Betten of the PaleoFood mailing list and I have collected many recipes at [www.PaleoFood.com](#). All have no grains, no gluten, no dairy, no beans/legumes, no refined sugar, or other Neolithic foods.
- Ashton Embry has an essay [Paleolithic Nutrition and Multiple Sclerosis](#) and another [Paleolithic Nutrition](#). He's the leading proponent on the Net for using dietary intervention to control MS.
- [The Evolution of Human Nutrition](#) by Barry Bogin is interesting reading which covers themes like homo erectus and up to date findings, and the relation to nutrition.
- In William Calvin's [The Ascent of Mind, Chapter 8](#) he discusses why he thinks that the Acheulian hand-ax (the oldest of the fancy stone tools of Homo erectus) was really a "killer frisbee." He argues that natural selection for throwing accuracy, which requires brain machinery, is the evolutionary scenario for bootstrapping higher intellectual functions. There are many more articles about evolution and human development throughout William's [extensive site](#).
- [Pemmican: Recipes, Stories and Stores](#) is a link page with more on this than you've seen before.
- Lynne Olver at the Morris County Library has assembled [The food timeline](#), which gives you the history of Neolithic foods. Includes paleo foods, like animal domestication and when some foods were first noted in the literature.
- [Eating](#) is an essay by Todd Moody.

- [The Meat, Leaves and Berries Page](#) is a "paleo" like diet put up by Dan John. But dairy products are allowed. Couldn't tell much, as many pages came up blank with ActiveX turned off.
- [Dental Microwear Web Site](#) is on the study of the microscopic scratches and pits that form on a tooth's surface as the result of its use. See the page on references. Some are evidences of past diet.
- Mary G. Enig, Ph.D., an expert of international renown in the field of lipid chemistry, has a [Trans Fat InfoWeb Page](#). A simple introduction to trans fatty acids. [Trans Fatty Acid Fact Sheet](#) is a short page listing the negative highlights of this food.
- [Factors that Inhibit Calcium Absorption](#) is an article pointing out the non-paleo things we do, mostly food related, that are negative for calcium absorption.
- [The Cholesterol Myths](#) by Uffe Ravnskov, M.D., Ph.D. argues that too much animal fat being dangerous is a myth. This is a collection of essays, complete with the critical references.
- [The Cholesterol Myth](#) is an article by Thomas J. Moore from his book, Heart Failure. Argues that diet has hardly any effect on your cholesterol level; the drugs that can lower it often have serious or fatal side effects; and there is no evidence at all that lowering your cholesterol level will lengthen your life.
- Dr. Joseph Mercola has an extensive web site on alternatives to traditional medicine. A hodge podge of different things. On his [Low Grain Guide To Health](#) he has a few that are relevant to paleo eating. At bottom take link to his Sugar Index Page. Also see [The Health Benefits of Grassfed Animal Products](#). Also see [Low Grain and Carbohydrate Diets Treat Hypoglycemia, Heart Disease, Diabetes Cancer and Nearly ALL Chronic Illness](#). Also see: [Caveman Cuisine](#) by Sally Fallon and Mary G. Enig, PhD.
- There is ample evidence that [grain consumption is behind many cancers](#). Here is a quick analysis of the connection.
- Jack Challem has written [Alpha-Lipoic acid: Quite Possibly the "Universal" Antioxidant](#) and meat is the best source.
- [paleofood.de](#) is a site all in German, but [PaleoFood.Info](#) is their English version. Here is Loren Cordain's [Food Pyramid](#).
- [To Crack a Coconut](#) tells how this is done in Thailand, without fancy tools, then gets into pressing milk, and some recipes.
- [Cooking Clan of the Cave Bear Style!](#) is a student experiment in boiling water in a skin pot over a fire (or not...)
- Aris Stathakis has a page [How To Make Real South African Biltong](#) - a traditional South African dried meat.
- Brett Saks, B.S., D.C. has a page [The Adverse Effects of Wheat and Other Grains](#). Based on his clinical experiences.
- Chet Day sent a copy of the article by Robert Crayhon ([Interview with Loren Cordain](#)) to

the Rea Centre in London, a place claiming to be proponents of a paleo diet. You can check out their counterpoint at [Hunter Gatherer Paradigm Examined in New Light](#). It argues that our ancestors were not big meat eaters. Argues that since men are the scientists that hunting has been exaggerated out of proportion, and that gathering was the primary source of food. Chet Day also asked some questions and created [The Rea Center Interview: Paleo Nutrition, Veganism, and More](#). Incredibly wordy with little content.

- Philip Thrift has a page on [Principles of Paleofitness](#). He follows NeanderThin and works out daily before eating.
- [Blindness, Mad Cow Disease and Canola Oil](#) by John Thomas points out the negatives of canola oil.
- The [Venison Processing FAQ](#) covers everything from choosing your target to recipes.
- [The Paleolithic Diet](#) is Bob Hodgen's story of his experiences on NeanderThin. Includes short explanation.
- Krispin Sullivan has written [The Lectin Report](#). A good place to start to learn about these toxic proteins in Neolithic foods.
- [Aquatic Ape Theory](#) is a site covering all links on the subject. (The theory argues that humans evolved along the water's edge, but such evidence is now covered by the oceans.)
- Buried in the middle of [The Revised Metabolic Oncolytic Regimen for Effecting Lysis in Solid Tumors](#) one can find their diet recommendations for tumor control. It has a paleo diet orientation. Protein is 35%, preferably Omega 3 rich. Carbohydrates (also 35%) are only vegetables and fruit, no beans, bread, potatoes, or any grain. Then dietary and supplemental forms of fat should provide 20-30% of (daily) calories.
- [WWW.PALEODIET.NU](#) is a site in Swedish put up by Niclas Larsson. He has plans to grow the site.
- Aletheia Price has [Edible Insects](#). Very comprehensive. Read the "About the Author."
- [Weird & Different Recipes](#) is a page by Bert Christensen that includes several insect recipes and other foods that a Paleolithic dieter may have eaten.
- Zachary Huang has put up his [Bug-Eating Page](#). Mostly pictures of people eating giant silkworms and mealworms. Also see his other links.
- [Vad är Paleodiet?](#) is a site in Swedish put up by Hans Kylberg.

[\[Ctrl-Home for Top, or Click Here\]](#)

Educational Institutions

- [The Paleo Diet](#) is Loren Cordain's site. It promotes his book and also includes, for free download, PDF files of all of his scientific articles on Paleo Diet.
- [Diet and Heart Disease. It is not what you think](#) is a online course by Stephen Byrnes covering the Lipid Hypothesis.
- [Cooking up quite a story: Ape, human theory causes evolutionary indigestion](#) is an article by

- William J. Cromie discussing the controversy over how long humans have been cooking.
- Buried in a tutorial at The Institute For Ice Age Studies we find a section on Strategies for Survival. Hunting and gathering start at [Scheduling and Mobility](#).
 - [Plant-animal subsistence ratios and macronutrient energy estimations in worldwide hunter-gatherer diets](#).
 - [Origins and Evolution of Human Diet](#) is an academic web site devoted to discussion of evolution and the human diet. Especially don't miss the articles on the conferences link! And in them especially see the [Boyd Eaton one!](#)
 - [Hunters and Gatherers Anthropology](#) is a course taught by Raymond Hames at U. of Nebraska. Includes lecture notes on the book [The Foraging Spectrum](#) which outlines the important research issues, theory, and problems in hunter-gatherer research. His site has many other sub-pages that shouldn't be missed.
 - [How to Carve an Elephant](#) is a chapter in Making Silent Stones Speak: Human Evolution and the Dawn of Technology by Kathy D. Schick and Nicholas Toth (1993). A cute writeup on some archaeologists that showed that a dead elephant can be carved up using the simple tools that were available 1.5 - 1.9 million years ago.
 - [Prehistoric Diet and Nutrition](#) is a class at Indiana U. taught by Jeanne Sept, Professor of Anthropology.
 - [Plant-animal subsistence ratios and macronutrient energy estimations in worldwide hunter-gatherer diets](#), by Cordain et. al. is an abstract of an analysis showing that whenever and wherever it was ecologically possible, hunter-gatherers consumed high amounts (45-65% of energy) of animal food.
 - [The Changing Nature of Inuit Nutrition and Dietary Patterns](#) by James H. Boschma III goes into detail on the dietary patterns of the Inuit.
 - Cabrillo College's Anthropology Department has [Monte Verde A Pre Clovis Site](#), which among other things, discusses the foods these early Native Americans ate.
 - [From the Neolithic Revolution to Gluten Intolerance: Benefits and Problems Associated with the Cultivation of Wheat](#), by Luigi Greco, Department of Pediatrics, U. of Naples. A history of gluten intolerance and why it is so common.
 - [Investigation of the Role of Wild Plant Foods in Pre-Agrarian Europe](#) is a project currently being undertaken by Sarah Mason at the University College London.
 - [Plains Archaic people](#) discusses the hunter-gatherers of the American plains. These PaleoIndians big-game hunters exploited a narrow-spectrum, focal resource base (one, maybe two animal species depending on location - e.g., reindeer in north; limited range of small game; few if any plants). Long and technical.
 - [Underwater storage techniques preserved meat for early hunters](#) demonstrates how PaleoIndians living in the Great Lakes region at the end of the last Ice Age preserved meat from large animal kills by storing it underwater.
 - [Flints and Stones: Real Life in Prehistory](#) is an exhibition at the Museum of Antiquities on the world of the late stone age hunter gatherers in Britain. Only three pages are food related:

- [The hunter gatherer way of life](#) is heavy on the tools used in Britain. [Tasks and activities around the home fire](#) has some on food processing. [Could you survive today as a hunter gatherer?](#) has pictures of collectable foods and you select whether it is edible or not. In three parts: fungi, foliage, and nuts & berries. More than half of the options are poisonous.
- [Health Issues and Trans Fat](#) by Mary G. Enig discusses how it was claimed in 1958 that these were culprits in heart disease, but the edible oil industry quickly squelched this information.
 - [Do dietary lectins cause disease?](#) is an editorial in the British Medical Journal which suggests that lectins, which are high in cereals, potatoes, and beans, may be behind some autoimmune diseases.
 - [You Are What You Eat: New Theories About Rheumatoid Arthritis](#) is a newsreport about an article in the British Journal of Nutrition. The authors argue that their theory implicating diet needs more research.
 - [The Southern Greek Palaeolithic, Mesolithic, and Neolithic Sequence at Franchthi](#) is a cave where the deposits revealed what the occupants ate over the years.
 - [Stone Age Habitats](#) hasn't much to do with food, but there is mention of cooking hearths, and a couple nice graphs. But for some reason the time lines are flipped.
 - Fattening cattle with corn changes the lipid balance and is clearly not the natural diet for a grass eating cow. In [Simple change in cattle diets could cut E. coli infection](#) researchers have found that when cattle were fed hay or grass for just five days before slaughter, much less E. Coli cells were present in the animal's feces and virtually all surviving E. coli bacteria were not acid-resistant and were killed by human stomach acid.
 - A [Hunter-Gatherer Bibliography](#) compiled by students of James W. Helmer Department of Archaeology, U. of Calgary. 112K.
 - J. Ned Woodall, Department of Anthropology, Wake Forest U., teaches a course on Problems with the Past: Controversial Topics in the Cultural and Physical Evolution of Humans. Here is the [reading list](#).
 - ['First farmers' with no taste for grain](#) is an article by Mike Richards on the use of meat in ancient British Isles diets. The suggestion is that the Brits were depending primarily on meat for their nutrition up to around 2000 B.C.
 - ['Man the Hunter' returns at Boxgrove](#). Mark Roberts, the Director of the Boxgrove Project, provides evidence that the hominids of the Lower Palaeolithic period did hunt their meat.
 - [In sorrow shalt thou eat all thy days](#) Peter Rowley-Conwy, Archaeology at the University of Durham, argues that many hunter-gatherers never wanted to farm.
 - [No carefree life for Mesolithic people](#). Hunter-gatherers worked much harder for their living than has previously been thought, writes Rob Young.
 - Neanderthal bone chemistry provides food for thought. Using bone-chemistry analyses, a team determined the Neandertals must have feasted on meat. [Neanderthal diet at Vindija and Neanderthal predation: The evidence from stable isotopes](#) is the full text of the article.
 - Kristin D. Sobolik is Assistant Professor of Anthropology and Quaternary Studies at U. of

Maine. She has a [home page](#) listing her publications, many of which are on prehistoric diets.

- [Blueberries May Restore Some Memory, Coordination and Balance Lost with Age](#) is a study from Tufts U. which found that blueberries make rats feel young again.
- [Human Skeletons and Society in Prehistoric Italy](#) basically shows how various ills increased in the Neolithic age. The best parts are the graphs showing the disorders they found and how they increased as the food become more away from a Paleolithic diet. This is the link to [infectious disease and childhood stress](#).
- [Loren Cordain, Ph.D.](#) has his interests, awards, publications, etc. listed on a web page.
- An abstract: [Reducing the serum cholesterol level with a diet high in animal fat.](#) by Newbold HL.
- Hunter/gatherers often eat grubs. Entomologists at the [University of Iowa](#) have created some recipes based on insects, and insects can be bought via internet.
- [The Food Insects Newsletter](#) site includes selected on-line articles from back issues. Probably more paleo than most people can handle.
- [Bugfood!](#) is by the U. of Kentucky Department of Entomology. Discusses insects as food and insect snacks from around the world.
- [Nutritional Value of Various Insects per 100 grams](#) is part of the Iowa State Entomology site. Also see recipes and where to buy.

[\[Ctrl-Home for Top, or Click Here\]](#)

Media Reports

- [New road reveals Stone Age site](#) which may provide evidence of fire in the British Isles back between 250,000 and 300,000 years ago.
- [High-cholesterol diet 'doesn't increase stroke risk'](#) reports on a study of 43,000 middle-aged men. While it finds no correlation with stokes and fatty foods, they did not look for a correlation with anything else.
- [Meat eating is an old human habit](#) reports on an analysis of our ancestor's teeth that shows we became meat eaters 2.5 million years ago.
- Vilhjalmur Stefansson spent many years as an Eskimo among Eskimos. After a year experiment eating only meat at Bellevue Hospital, he wrote about his experiment and his years as an Eskimo in [Adventures in Diet](#), a three part series Harper's Monthly Magazine, November 1935 - January 1936.
- In [Chips means zits](#) Loren Cordain blames today's refined foods, such as bread, rice and cakes, for the pimples suffered by 95% of westernized teenagers.
- [Neanderthals' strong-arm tactics revealed](#) discusses whether they threw spears or just used them to stab animals.
- [Food for Thought, Dietary change was a driving force in human evolution](#) is an article in Scientific American that discusses our evolution in the context of diet.

- [In prehistoric cave, scientists use computers as their guide](#) lists off the diet of some middle Paleolithic era cave dwellers in Northern Israel.
- [Animal Protein Consumption Associated With Bone Density in Elderly Women](#). This isn't really new. Herta Spencer back in the 80's showed that meat helped if an adequate amount of calcium was consumed. Studies showing that protein was bad used isolated, fractionated amino acids from milk or eggs.
- In [Bread blamed for short sight](#) Jennie Brand Miller links the dramatic increase in myopia in developed countries on childhood over-consumption of bread.
- [Meat Eating More Healthy in Prehistoric Times](#) discusses the healthier fats in wild meat. Loren Cordain's team compared the muscle, brain, bone marrow and fat of wild animals with those of cattle.
- [The Caveman Diet](#) by Jeanie Davis is an MSN article touting the benefits of grass fed bison.
- [Cave men diets offer insights to today's health problems, study shows](#). But, you have to eat wild meat, which has a healthier ratio of omega-6 to omega-3 fatty acids.
- [High 'Good' Cholesterol Level Lowers Stroke Risk](#) is a news report highlighting that high HDL is the only indicator of lower stroke risk. However, it fails to mention that a low-carb diet is the only diet that increases HDL.
- [Neanderthals Were As Smart As Us](#) reports on new research that reveals that Neanderthals were not dumb, but had the technical and intellectual skills to put them on an equal basis with modern humans.
- [Seafood Gave Modern Humans Edge](#) reports that by studying the chemicals that remained in the bones of the earliest modern humans, scientists discovered that their diet, included fish and fowl as well as large mammals. The Neanderthals, on the other hand, only ate large mammals, which became extinct. Also see [Fishy clue to rise of humans](#).
- [Agriculture Is Bad for You](#) is a Time Europe article pointing out that some dieticians recommend we change our eating habits to resemble those of our ancestors. A pro-Paleo article!
- [Coconut oil promises to be anti-viral agent](#) reports on trials that have confirmed that coconut oil has an anti-viral effect that reduces the viral level in HIV-AIDS patients to undetectable levels.
- [The Soft Science of Dietary Fat](#) is a summary of an article in Science Magazine reporting that mainstream nutritional science has demonized dietary fat, yet 50 years and hundreds of millions of dollars of research have failed to prove that eating a low-fat diet will help you live longer. In fact, there are good reasons to believe high-carbohydrate diets may be even worse than high-fat diets. Here is the [original article](#).
- [Fatty Fish Protects Hearts of All Ages](#) reports that those who consumed fatty fish even just once a week lowered their risk of a fatal heart attack by 44% compared to the risk among those who did not opt for the fish.
- [Homocysteine A Possible Risk Factor For Alzheimer's](#) discusses an association between Alzheimer's disease and moderately-elevated blood levels of the amino acid, homocysteine.

Homocysteine levels can be reduced by consumption of foods with folic acid and vitamin B12, i.e. greens and meat.

- [Diabetics Improve Health With Very High-Fat, Low Carb Diet](#) discusses a successful study.
- [Early Humans Had Woodworking Technology](#) reports on finding evidence that humans produced wood tools, possibly spears, 1.5 million years ago. This is a million years earlier than previously believed.
- [Early Humans Ate Termites](#) reports that ancient hominids had a taste for termites.
- Harvard Magazine on [Paleolithic Fast Food](#). By excavating a cave they found that animals that move slower were eaten in the past and in later years ones that move faster were eaten.
- [The discovery of fire](#) speculates that man controlled fire 1.6 million years ago. Circumstantial evidence also suggests that they were cooking their food.
- [Insulin-Like Compound Predicts Stroke Risk](#) states that insulin resistance (which is usually caused by excessive carb intake, meaning that caused by normal intake of grains and sugar) is a predictor (i.e. indicates increase risk) of strokes.
- [Go back to stone-age diet, says health professor](#) is an interview with Loren Cordain.
- [New Human Ancestor?](#) Two and a half million years ago a humanlike creature in what is now Ethiopia raised a stone and smashed it down on an antelope bone to get at the marrow and fat inside. This is the earliest known evidence of a stone tool used to butcher an animal.
- [New Species Of Human Ancestor](#). A more detailed version than the ABC News one. They also ate catfish and horse. Note the bit about "high fat meat"!
- [Fossil find may be 'missing link'](#). A third page on 2.5 million year old fossil find in Ethiopia.
- [Olive oil 'reduces cancer risk'](#) claims that using olive oil in cooking may prevent the development of bowel cancer.
- Scientific American has an interesting article about the ill effects of sugar and aging at: [AGE Breakers - Rupturing the body's sugar-protein bonds might turn back the clock](#). Typically, the drug companies are trying to develop a drug to fight off the symptoms rather than treating the cause of the problems with a proper diet.
- [A taste for meat](#) argues that our ancestors three million years ago ate a lot of small mammals that could be caught without tools. Published in [Science Magazine](#) (which requires a subscription).
- [The Caveman Diet](#) is the CBS story on 48 hours where they featured Ray Audette and the paleo diet. Focuses on weight loss.
- [Modern Stone Age food](#) is an article based on an interview with Boyd Eaton that appeared in the USA Weekend insert magazine.
- In [What the Hominid Ate](#) by analyzing carbon atoms in tooth enamel researchers challenge the widely held belief that these 3 million year ago homnoids ate little more than fruits and leaves.
- The Electronic Telegraph had a 12-Aug-97 article ["Barbecues are a thing of the past"](#). Some archaeologists from Liverpool University working in the Suffolk forest found what they

believe may be a hearth that is 400,000 years old. [Free registration required]

- [Revealing Anciet Family Ties](#) is a chart of our human lineage. It is included as it has arrows at the 2.5 million year mark showing when stone tools and meat eating were introduced. See also: [article introduction](#) and [main text](#).
- [Great Debate Builds the Rationale for Eating Meat](#) is the story of how Dan Murphy debated the PETA and the arguments he used. (You will need to scroll down a bit).
- [Eating Like a Caveman](#) is a page written by Kathleen Doheny. She gives an overview of the paleo diet, then tells of her experience of trying it for a day. Includes this quote by Loren Cordain "If it's a fad, it's the oldest fad going."

Associations/Organizations

- [The International Network of Cholesterol Skeptics](#) has a [Discussion about the cavemen's diet](#). Has comments from many researchers, some familiar from elsewhere on this page. No comments from Lorain Cordain, but much discussion and disagreement with him.
- [The Weston A. Price Foundation](#) was set up by Sally Fallon and Mary Enig. Like the Price-Pottenger Nutritional Foundation, with which they were previously affiliated, it is not completely paleo in its recommendations. But lots of good articles nonetheless. See [The Oiling of America](#). Also see [Guts and Greast: The Diet of Native Americans](#). And what they think of Loreen Cordain's [The Paleo Diet](#). And many other articles.
- A small subset of the people eating only raw foods are eating animal foods (RAF). And some of them have put up a resource page for [Raw Paleolithic Diets](#).
- [Protein-Rich Diets May Reduce Heart Disease Risk](#) is a report on a prospective cohort study showing higher protein intake is associated with reduced risk of heart disease among women. Though this report is filled with politically correct commentary which was not part of the study as published.
- [Food](#) is part of the Vegan Straight-Edge site. The page is almost a resource page for paleodiet, with the sole exception of the comments about meat and protein requirements. It's quite interesting. Other pages at the site include: [The origins of agriculture - a biological perspective and a new hypothesis](#) in which Greg Wadley & Angus Martin argue that the shift to cultivation and animal domestication was due to the "comfort" derived from the opioid peptides from gluten. And John Coleman's [Opioids In Common Food Products-Addictive Peptides In Meat, Dairy and Grains](#). (There isn't any evidence presented that this is an issue with meat, but it is a vegan site!)
- [Paleolithic diet](#) is a definition found in the Gale Encyclopedia of Alternative Medicine.
- Nutrition Australia has a Q&A page on: [I have read somewhere recently about a 'Paleolithic diet'. What exactly is the 'Paleolithic diet'?](#) Written as an introduction.
- A hunting rights group has put up [Eating Meat is Natural](#), written by Jim Powlesland. It appears to be a summary from "The Paleolithic Prescription: A Program of Diet & Exercise

and a Design for Living".

- [Diet and the evolution of the earliest human ancestors](#) is a study of jaw size and shape, tooth size, shape, and wear patterns, which give clues as to what the earliest human ancestors ate two to four million years ago.
- [Fatty Fish Cuts Risk Of Death From Heart Attack In Elderly](#) is another study showing the benefits of omega-3 fatty acids consumption.
- [Concerns Regarding Soybeans](#) by Mary Enig and Sally Fallon discusses the negatives with soy consumption. Abstracted from Health Freedom News, September 1995.
- [Soy Online Service](#) is a New Zealand site dedicated to "uncovering the truth about soy".
- [Tragedy and Hype](#) is a very comprehensive article on soy that appeared in Nexus Magazine. Shows how the soy industry manipulated things to turn their toxic food into a health food.
- [Should we be Scared of Soy?](#) covers the various health negatives of soy consumption.
- [Ray Peat's Newsletter](#) has a web site with some sample articles. There are two articles of interest to Paleodieters: "The Benefits of Coconut Oil" and "Toxicity of Unsaturated Oils". When you click on them then select open. A Ray Peat coconut oil article also appears Dr. Mercola's site: [The Benefits of Coconut Oil](#).
- [Coconut: In Support of Good Health in the 21st Century](#) by Mary Enig is an address she gave to a Cocotech meeting. Long and gets into coconut oil's competition. Many references at the end.
- [Review and Atlas of Paleovegetation](#). Preliminary land ecosystem maps of the world since the Last Glacial Maximum (18,000 14C years ago).
- American Scientist had an article on [Chimpanzee Hunting Behavior and Human Evolution](#) by Craig B. Stanford in the May-June 1995 issue. It discusses British primatologist Jane Goodall's observations.
- [Paleolithic Diet: How our bodies want to be treated](#). is a page from The Healing Crow, an organization dedicated to bringing the aspects of mind, body, and spirit into our health.
- The [Price-Pottenger Nutrition Foundation](#) promotes some Paleolithic nutrition concepts, though they recommend dairy, a non-paleo food. Many good articles worth reading there.
- [Why I Am Not a Vegetarian](#) by Dr. William T. Jarvis makes comments about the "ideological" commitment to a diet that are at least as interesting as the comments about diet itself.
- [Trans Fat Spells Double Trouble for Arteries](#) points out that the popular trans fat is unhealthy and not disclosed on food labels.
- [Desert Locust Recipes](#) from the Food and Agriculture Organization.
- [Croque-insectes](#) is all in French. The site is on insects, and cooking them is part of the site.

[\[Ctrl-Home for Top, or Click Here\]](#)

[Foraging and Ethnobotany](#) <-- now on its own page.

Commercial Sites

- [Was Agriculture a Good Idea, or an Act of Desperation?](#) by Norm Kidder is an interesting essay on evidence that hunter-gatherers sometimes became so good at getting food that they settled down to form permanent communities. From the [Primitive Ways](#) site.
- [The Caveman's Banquet](#) is Atkins' take on the paleo diet.
- [A Diet Solution Based on Evolution](#) points out that most of the calories consumed today are from foods that did not exist in the past, but then the article ends up with the politically correct twist that saturated fats are bad. Mostly is a book report on Loren Cordain's The Paleo Diet.
- [The Paleolithic Diet and Its Modern Implications](#) is an interview with Loren Cordain, PhD done by Robert Crayhon, MS. The same article also appears here: [The Paleolithic Diet and Its Modern Implications](#).
- [The Myths of Vegetarianism](#) by Stephen Byrnes goes through many of the arguments that vegetarians use and explains why they are myths. A must read for all vegetarians.
- [The Lectin Report](#) explains the background on lectins and their connection to health problems.
- [The Homocysteine Revolution](#) is an interview with Dr. Kilmer McCully. High homocysteine levels have been connected with heart disease. Folic acid (highest in leafy green vegetables) and B12 (abundant in animal proteins) help keep homocysteine levels under control.
- In an interview with Mary G. Enig, Ph.D. She expresses clearly her well qualified opinion that saturated fats are NOT the problem they are reputed to be. Over two pages: Health Risks from Processed Foods and Trans Fats [Part 1](#) + [Parts 2 + 3](#).
- [Insulin and It's Metabolic Effects](#) by Ron Rosedale MD deals with insulin as the "master switch" for a large number of disease processes. Argues that low insulin is key for long lifespan. Overly long.
- Elson M. Haas, M.D. has written a nice summary of [Types of Diets](#). Has sections on the Paleolithic and 14 other diets. Put up by Healthy Net.
- Dr Stoll's [Sugar and Immunity](#) is an article on the Leukocytic Index which shows the devastating effect of refined carbohydrates on immunity.
- [The Skinny on Fat](#) is an overview of the different types of fat and their uses in the body by Dr. Michael G. Kurilla, M.D.
- Jonathan Bowden, M.A. has a two part non-technical introduction to [The Paleolithic Diet](#).
- [Why Americans Are So Fat](#) by William Faloon blames a deficiency of conjugated linoleic acid (CLA) for why we have become fat. CLA is found in beef and milk fat, both of which are decreasing in our diets. In addition CLA is much lower in grain fed cows than in grass fed ones.

- [Just Game Recipes](#) has just what it says. Not all are paleo, but lots of good ideas for cooking game.
- [The Australian Native Food Industry](#) gets into Australia's unique edible plants and animals that could form the basis for a substantial and sustainable industry.
- [Eskimo Ice-cream](#) discusses food in the Inuit culture and includes some recipes.

[\[Ctrl-Home for Top, or Click Here\]](#)

Books

Note that prices at amazon.com are no longer the cheapest. Books can be purchase elsewhere for less. The place I use is [Books-a-Million](#), which is cheap when using their discount card. Now the best advice is to shop around and not to automatically buy from amazon.com. One suggestion for price comparison is BookFinder4U. Except it doesn't reflect free shipping deals. May even be helpful in finding out-of-print books.

- [The Paleo Diet: Lose Weight and Get Healthy by Eating the Food You Were Designed to Eat](#) is Loren Cordain's book. His [publisher's page](#).
- [NeanderThin: Eat Like a Caveman to Achieve a Lean, Strong, Healthy Body](#) by Ray Audette is based on the ideas of paleolithic nutrition. The diet contains natural, unprocessed carbohydrates and can be followed as a low-carb, moderate or high carb diet, depending upon whether and how much fruit is used. The expanded hard cover edition can be found at [Amazon.com](#). Also see Amazon.com for many [reviews on the out-of-print edition](#). A [paperback edition](#) is now out.
- [Life Without Bread: How a Low-Carbohydrate Diet Can Save Your Life](#) by Christian B. Allan, Wolfgang Lutz. It is based on Dr. Lutz's work with thousands of patients in Austria. It deals with the health issues connected to high carb consumption. It is basically an English version and update of Dr. Lutz's 1967 book with the same title: *Leben ohne Brot*. He recommends eating only 72 grams of carbohydrates, and an unlimited amount of fat. And provides evidence as to why this is the healthiest diet. Read the review at Amazon.com by Todd Moody.
- Protein Power by Eades and Eades was a best seller for over a year. Now they have published [The Protein Power Lifeplan: A New Comprehensive Blueprint for Optimal Health](#). It uses many paleo arguments for their diet recommendations. All easy to understand. And also a [Paperback Edition](#).
- [Meat-Eating and Human Evolution \(Human Evolution Series\)](#) is a \$70 book that address the questions surrounding when, how, and why early humans began to eat meat. See and read the sample pages.
- [Evolutionary Aspects of Nutrition and Health - Diet, Exercise, Genetics and Chronic Disease](#) is a compilation of articles showing how humanity's genetic makeup has been directly influenced by nutritional selective pressures and how our present day diet may be discordant with our stone age genome. The book is rather expensive, but the description on

the page is worth reading. One section is now entirely online! See [Cereal Grains: Humanity's Double-Edged Sword](#) by Loren Cordain.

- The book [The Cholesterol Myths](#) by Uffe Ravnskov, MD, PhD, is a much expanded version of [his web site](#). See [reviews at amazon.com](#).
- [Lights Out: Sleep, Sugar, and Survival](#) recommends a very paleo-like diet, and they also make a good argument for electric lighting as a major contributor to modern health problems. It's written in a very magazinish, overblown style, but the reasoning is overall sound.
- [Starch Madness: Paleolithic Nutrition for Today](#) by Richard L. Heinrich. Has a foreword by Barry Sears of Zone fame. For Publishers Weekly and author's review see [Amazon.com](#).
- [Diet Prevents Polio](#) by Dr Sandler is a web site on a 50 year old book where he argues that low blood sugar, due to a high carb diet, makes one susceptible to polio, and other viruses and disease. He did research showing that a meat based diet, very low carb, keeps blood sugar stable.
- [Survival of the Fittest](#) is a "Darwinian Diet and Exercise Program" by Del Thiessen providing nutritional and activity strategies. Notes our "Stone-Age" relatives were free of the most common diseases of civilization. No reviews yet at [Amazon.com](#).
- [Nutrition and Evolution](#) by Michael Crawford and David Marsh explains how diet may have shaped evolution. Heavy reading. See reviews at Amazon.com. Now unfortunately out-of-print
- [The Carnitine Miracle](#) by Robert Crayhon, M.S. The nutrient carnitine is abundant in red meat. According to Crayhon carnitine helps balance blood lipids and blood sugar levels, maximizes energy levels, increases endurance, eliminates discomfort in ketosis, promotes burning of fat and building of muscle and increases overall well-being. See reviews at [Amazon.com](#).
- Dr. Weston Price's book [Nutrition & Physical Degeneration](#). puts to rest a lot of myths about diet, dental, physical, and emotional health, and presents the strongest case for a super-nutritious Native (or Paleo) Diet. His book outlines the conditions/causes for exceptional health. A classic that was first published in 1938.
- Diana Schwarzbein is another M.D. that has come to realize that low carb is what works. See reviews at [The Schwarzbein Principle](#). The book is based on her work with insulin-resistant patients with Type II diabetes. She concludes that low-fat diets cause heart attacks, eating fat makes you lose body fat, and it's important to eat high-cholesterol foods every day.
- From September to December, 1997, Robert McFerran posted draft chapters of his book, [Arthritis - Searching for the Truth - Searching for the Cure](#), to the Ask Dr Stoll Bulletin Board. Includes his view of human history and its relationship to dietary needs.
- [Nourishing Traditions: The Cookbook that Challenges Politically Correct Nutrition and the Diet Dictocrat](#) by Mary G. Enig, Ph.D. and Sally Fallon. The premise is the culinary traditions of our ancestors, and the food choices and preparation techniques of healthy nonindustrialized peoples, should serve as the model for contemporary eating habits.

However, they push whole grains and dairy, which aren't Paleolithic.

- Arthur De Vany Ph.D. is writing a book called [Evolutionary Fitness](#) on "What Evolution Teaches Us About How to Live and Stay Healthy".
- [The Stone Age Diet](#) was written by Walter L. Voegtlin back in 1975. It is out-of-print. However we have put up his [Functional and Structural Comparison of Man's Digestive Tract with that of a Dog and Sheep](#).
- [The Cambridge World History of Food](#) encapsulates much of what is known of food and nutrition throughout the span of human life on earth. Selected chapters are online.
- Excerpts from [Dismantling a Myth: The Role of Fat and Carbohydrates in our Diet](#) by Wolfgang Lutz MD. Covers various digestive disorders. See newer English edition above.
- Peter D'Adamo's serotype diet book [Eat Right 4 Your Type](#) is in sympathy with the paleo diet approach, at least if you are Type O.
- Online books on the Hunza people: [The Wheel of Health](#) by G.T. Wrench, M.D. [High Road to Hunza](#) by Barbara Mons. [The Healthy Hunzas](#) by J.I. Rodale.
- [Ishmael](#) is the website of Daniel Quinn, who has written several popular books. He believes that humans are just one of the species on earth and shouldn't keep increasing their agricultural food supply, which just leads to increased population at the expense of other species.
- Ian Tattersall has written [Becoming Human: Evolution and Human Uniqueness](#). In [Chapter One](#) at the beginning there is a discussion of the diet about 40 kyr ago.
- Barry Sears, Ph.D., has a couple books on his Zone Diet. Somewhat paleo in its orientation. [Zone Home](#) is one of the sites on the diet.
- Charles Hunt has written [Charles Hunt's Diet Evolution](#). It is not truly a paleo diet, but more of a low-carb diet. Its subtitle is "Eat Fat and Get Fit". The author is PR oriented and studied up on the web and then wrote the book. Now out-of-print.
- [We Want to Live](#) is a book by Aajonus Vonderplanitz. His basic philosophy is that (a) food is to be eaten in a live, raw condition; and (b) a diet rich in raw fats and raw meats from natural sources is essential to health. [From the Planets](#) is a book review by Ralph W. Moss, and at [Amazon.com](#) there are reader reviews. The [Live-Food Mailing List](#) discusses the concepts of this book.
- [Man Eating Bugs: The Art and Science of Eating Insects](#) by Peter Menzel, Faith D'Aluisio gets laudatory reviews at amazon.com.

[\[Ctrl-Home for Top, or Click Here\]](#)

Food Vendors

- [3-Corner Field Farm](#), on the border of NY and Vermont, sells grass-fed lamb.
- [Alaskan Harvest](#) sells only fresh ocean caught fish, as well as range fed reindeer and muskox.

- [American Grass Fed Beef](#) sells beef meat, jerky, sticks, and bacon from Missouri. (Their bratwurst and summer sausage are not paleo.)
- [Arctic Wild Harvest Company](#) in Canada has several unique foods harvested from their arctic wilderness.
- [Arizona Nut House](#) has a variety of [Nutcrackers](#) for sale.
- [BisonCentral.com](#) has lots of info on bison, plus a [long list of places selling bison](#).
- [Callie's Organics](#) is a home and office delivery business with a variety of organic and specialty produce, and other organic foods. Warehouse is in the Bronx.
- [Conservation Beef](#) is a group of ranchers selling grass-fed meat from Montana.
- [Cranberry Lane](#) has coconut oil, palm oil, and the hard to find red palm oil. Scroll down.
- [Crowfield Farm](#) sells bison meat. No mail order. Delivery from Rochester east to Lyons.
- [D'Artagnan](#) has organic game and poultry, and wild mushrooms. Expensive.
- [Diamond Organics](#) ships certified organic greens, fruits, mushrooms and sprouts throughout the US.
- [eatwild.com](#) has a page on Why Grassfed is Best! Contains a comprehensive list of suppliers of grassfed meat in all 50 states plus Canada. Also, the "New Research" section is a good database of citations on the benefits of grassfarming. And a book is for sale.
- [Fallow Hollow Deer Farm](#) sells online naturally raised, grass fed meat, poultry and eggs.
- [Falster Farm](#) in San Antonio, TX raises miniature Hereford cows, and sells pasture raised poultry and eggs. Poultry are raised to order.
- [Farm To Table](#) connects you to New York State farmers. Put in your location and it tells you where farmer's markets are.
- [Fox Fire Farms](#) in Colorado sells natural lamb, a true free range product raised on pasture.
- [Frank's Organics](#) delivers to parts of Australia. Included are fresh fruit, vegetables, eggs, meat, and dried fruit and nuts.
- [Frieda's](#) sells specialty produce and markets over 500 items including exotic fruit, specialty vegetables, dried fruits and nuts, mushrooms, squash, and a wide variety of Asian and Latin foods.
- [Game Sales International](#) is a direct importer of wild game meats, game birds, and specialty foods.
- [Garden Spots Distributors](#), in PA, has some organic dried fruit. Nuts don't appear to be organic. Apparently they carry organic produce, poultry and beef, but none of these appear at the web site.
- [GourmetStore.com](#) specializes in gourmet items, especially unusual and hard-to-locate dried items. See a variety of chile powders, and roasted chestnut and hazelnut flours.
- [Grassland Beef](#) sells grass fed beef. Raised and shipped from Missouri.
- [GreatBeef.com](#) is a network of independent family farmers and ranchers. Use the site to locate producers in your area.

- The [Gunthorp Farm](#) raises pigs that have been pastured. They are in Indiana.
- [Hay Creek Stock Farm](#) sells beef, pork, and lamb. Located in Minnesota.
- [Heartland Farms](#) in Pakenham, Ontario sells grass-fed beef and other grass-fed farm products. Local sales only.
- [Hills Foods Ltd](#) sells organic meats, game meats, and specialty poultry; including guaranteed wild (no grains) animal such as wild Arctic Caribou, alligator and muskox. They also have some non-meat wild associated specialty items.
- Homestead Products has a page on [Grain Mills](#). While they don't get into nuts, the Country Living Mill is a burr grinder and suitable for them.
- [Hunt's Black Walnut Cracker](#) is for those with a walnut tree in their back yard. This is a serious device.
- [Jaffe Brothers](#) in California features an extensive line of organically grown and untreated dried fruits, nuts, dates, seeds, and other select products.
- [Jamaican Gold](#) is a premium hand made coconut oil. See story of how it is made.
- [K.C's Game Meat Market](#) in Coldwater, Ontario raises elk, buffalo and deer on grass and a small amount of grain.
- [Lasater Grasslands Beef®](#) sells truly free range beef.
- [Living and Raw Foods Resources](#) list many resources for organically grown food.
- [Living Tree Community](#) sells Organic Raw Almond Butter, organic nuts, and organic dried fruit. Also has recipes section.
- [Lucy's Kitchen Shop](#) sells almond flour.
- [Maine Coast Sea Vegetables Inc.](#) offer four organically certified varieties: alaria, dulse, kelp, and laver.
- [MacFarlane Pheasant Farm](#) sells pheasant and a whole line of game meats.
- [McRoberts Game Farm](#) offers a variety of exotic meats, such as llamas, elk, yak and yak-crosses, white buffalo, Pere David Deer, miniature donkeys, and bactrian camels.
- [McRoberts Gourmet Foods](#) has Yak Jerky by mail order, in addition to other yak products.
- [Meadow Raised Meats](#) is an association of farmers in NY State that ship beef, chicken, pork, veal, lamb, goat, and venison.
- [Mt. Banahaw Tropical Herbs](#) in the Philippines offers unrefined Virgin Coconut Oil.
- [Mount Royal USA](#) bills themselves as "The Venison and Game Meat Connection." All farms feature farm-raised game using controlled diets that are free of steroids, growth hormones and antibiotics.
- [Mountain America Jerky](#) sells fresh made-to-order gourmet game meat jerky. No preservatives - No MSG - No growth promoters or steroids.
- [The Natural Food Hub](#) is a directory of many food vendors. They have a hunter/gatherer attitude towards food. See information on natural foods. Also a nice collection of edible wild plant and animal links. A site to spend time at.

- [Nature's First Law Online Superstore](#) has organic sun dried fruit. See sun-ripened, raw, organic olives and mangoes.
- [New West Foods](#) has buffalo, ostrich, and wild game. Formerly Denver Buffalo Company. Whether bison is grass or grain fed is not known.
- [North Hollow Farm](#) in Vermont sells naturally grown beef and pork. Some corn is fed to them.
- [Northstar Bison](#) in Wisconsin sells totally grassfed "buffalo." Can order on the web for next Monday shipping.
- Nuts4U sells [coconut flour](#), and other nut flours.
- [Omega Nutrition](#) sells coconut butter and some nut oils.
- Organic Kitchen, the organic foods resource for the web, maintains a long list of [organic food vendors](#).
- [Organics Direct](#) in London UK has an extensive organic delivery service offering fruit and vegetables.
- [Outlands Natural New Zealand Meat](#) Products. Beef comes from cattle raised from birth to bite, outside on ranches with evergreen pastures. Can be bought in Whole Foods stores.
- [Overseas Game Meat Export](#) is an outfit in Australia that supplies Australian game meat from the Outback to health food stores.
- [Peaceful Pastures](#) sells by mail all the common farm meats. Site does not say that the diets are not supplemented by some grain. E-mail asking this question was not answered.
- [Pinyon Pinenuts](#) are collected in the wild by George & Penny Frazier. Site also has some pinenut information.
- [Polarica](#), with a retail store in San Francisco, sells exotic meats and other gourmet foods.
- [Promofood International](#) sells rendered goose fat and some other oils.
- Coconut oil and palm oil are good for frying and are considered Paleolithic. Palm oil is best for deep fat frying. [Rainbow Meadow](#) sells them on the web.
- [Really Raw Honey](#) is totally unprocessed so it still contains pollen, propolis, honeycomb and live enzymes.
- [Rehoboth Ranch](#) in Texas sells grass fed beef and lamb over the web.
- [Rougie Rendered Goose Fat](#) is tasty and recommended for cooking, as olive oil breaks down at a relatively low temperature.
- [Sandhills Red Angus](#) raises grass fed beef in Nebraska. While they sell cuts, they focus on selling whole, half, quarter, and eighths of a beef.
- [Seattle's Finest Exotic Meats](#) has all natural farm raised exotic meats from around the world.
- [Smoky Hill Bison Co.](#) in Kansas sells many different cuts and boxes of bison meat. Grass fed.
- [Southern Game Meat](#) sells a brand of kangaroo meat internationally.

- [Special Foods!](#) has lots of unusual flours. Some are paleo! Check out: malanga, yam, lotus, water chestnut, and artichoke.
- [Starr Organic](#) in Florida sells mail order citrus, mangoes, avocados, bananas, limes, and lemons. Prices at site may not be current.
- [SunOrganic Farm](#) has dried fruit, nuts, nut butters, and other foods.
- [Texas Bison Company](#) sells grassfed bison meat.
- [Texas GrassFed Beef Company](#) is a marketing alliance for cattlemen who raise beef on grass. They sell beef by the cut in addition to bulk purchases. They also have lamb, goat, pork and poultry. All products come from critters eating grass or legumes and some browse. NO GRAIN!
- [The Little Canadian Meat Company](#) sells beef raised without growth hormone implants, digestive stimulants or antibiotics. Animals are grassfed and forage on certified organic pastures. Available on the Ontario area.
- [Three Fork Creek Ostrich Ranch](#) sells meat over the web.
- [Urban Organic](#) delivers organic produce to the NY Metropolitan area.
- The [Valley Livestock Marketing Cooperative](#) supplies grass fed beef, pork, lamb, veal and chickens from Hudson Valley farmers. They will ship by mail, or you can pick it up.
- [VERMONTBEEF.COM](#) sells pure Vermont pasture finished beef.
- Paleolithic eaters avoid grains, but they do eat nuts and seeds. These can be ground into flour for baking. Research finds that there are three types of grinders, but only one suitable for oily foods, the burr grinder. Walton Feed has a good description of the types at [Which Grinder is Best For You?](#)
- [Waterfall Hollow Farm](#) sells pasture-finished beef raised on certified-organic pasture. Now also selling pasture-raised chicken.
- [White Egret Farm](#) is a family farm in Texas raising drug, and pesticide free goats, beef, pork, turkeys, chicken, and guinea fowl. Ships direct to consumers.
- [Whole Foods Market](#) carries pasture fed meats, and many other organic foods. Web ordering and stores around the US under different names.
- [Y.S. Organic Bee Farms](#) has totally pure, unprocessed, unfiltered, raw bee products.

[\[Ctrl-Home for Top, or Click Here\]](#)

Dehydrators

- [The Dry Store](#) has the American Harvest [GardenMaster Dehydrator](#). This is one of the two leading choice for serious dehydrating. Can run with 30 trays.
- The [Excalibur Dehydrator Website](#) includes a pitch for dehydrating foods and showcases their dehydrators with square trays that slide in like a drawer, and not stacked like the round ones. This is the other leading choice.

- [Excalibur Dehydrator](#) has quite a bit of information on dehydrating, including its history, along with a sales pitch to buy their high-end dehydrators.
- Living Foods sells the Excalibur line. See [View all Dehydrators](#).
- The [L'EQUIP Model 528 Food Dehydrator](#) is a rectangular model that can have up to 20 trays. Has computer-controlled dehydrator sensor.
- Has [Dehydrators](#) made from the finest birch plywood. Plus they have a book for sale.
- [The Harvest Saver](#) is a compact, small volume drying system. They also have [A Basic Look at Dehydration](#) which covers the technical aspects of dehydration from a commercial point-of-view.

[\[Ctrl-Home for Top, or Click Here\]](#)

Food Science

- Wild Side of the Menu is a three part site on wild game: [Care and Cookery](#) and [Field to Freezer](#) and [Preservation of Game Meats](#).
- The National Food Safety Database lost its funding and it seems that only pieces now remain. The [Food and Nutrition Publications](#) page has a couple of links to Fruit Freezing and Home Drying in the General section. The wild game info is gone.
- [Drying and Curing Food](#) points to articles from the Michigan State University Extension, the Florida Cooperative Extension Service, and other sources.
- [USDA Nutrient Database for Standard Reference](#) can be searched for all common foods.
- The [California Rare Fruit Growers](#) has information on hundreds of different fruits.

Mailing Lists/Archives/Forums

- The PaleoDIET mailing list is a RESEARCH oriented list. To get a subscription questionnaire send a message to listserv@maelstrom.stjohns.edu with SUB PALEODIET yourfirstname yourlastname in the body. Actual subscriptions are processed by the list owner. Searchable [archives of the mailing list](#) are available.
- The PaleoFOOD mailing list is a SUPPORT list for people trying to follow a Paleolithic diet in today's age. The FAQ for the list is [NeanderThin](#). See first link in the Book section. To subscribe send SUB PALEOFOOD yourfirstname yourlastname in a message body to listserv@maelstrom.stjohns.edu. Searchable [archives of the mailing list](#) are available. Also see [Other Archives](#).
- The PaleoRECIPE mailing list is a RECIPE list is a companion list to the PaleoFOOD list. To subscribe send SUB PALEORECIPE yourfirstname yourlastname in a message body to listserv@maelstrom.stjohns.edu. Searchable [archives of the mailing list](#) are available.
- [CaveManFood](#) is a Yahoo group on how to eat like our CaveMan ancestors. Light activity.

- There is now a newsgroup called alt.support.diet.paleolithic that is independent of the mailing lists. It is not very active.
- A mailing list now exists on Evolutionary Fitness. To subscribe send SUB EVOLUTIONARY-FITNESS yourfirstname yourlastname in a message body to listserv@maelstrom.stjohns.edu. Searchable [archives of the mailing list](#).
- [PADIET-L](#) is an e-mail based discussion forum for topics relating to the origins and evolution of human diet. Little activity. See [list archives](#).
- [AV-Skeptics - Aajonus Vonderplanitz Skeptics](#) provides a democratic forum for people to deflate the exaggerated promises, fraudulent claims, junk science, invented evidence, and humorous exploits of raw meat gadfly Aajonus Vonderplanitz.
- [Live-Food Mailing List](#) for persons interested in learning about and experimenting with the use of raw animal foods, and specifically, in the work Aajonus Vonderplanitz. It is recommended that members of the list be familiar with Aajonus Vonderplanitz and his book, "We Want to Live."
- [EatBugs](#) is a Yahoo group on insect appreciation and eating them for lunch! Very light activity.

[COMPLETE INDEX TO THIS WEBSITE](#)

"Why practice the skills of ancient man? Each time we breathe in the smoke of a fire created by rubbing one stick against another, we breathe in the air of the dawn of all time. Each time we crack two stones together, we rejoin the brotherhood of man and a past that unites us all. Learning is ever on the increase, yet all we learn swirls together as it joins into and affects time forever. What we do with that which we have learned can bless or curse future generations. Everything our hands do imprints upon time forever. There are those in the past who knew this...perhaps, it is time we took the hand of time gone by to learn what we have forgotten."

---Benjamin Pressley

Welcome to the Windsong Primitives website! If you're interested in primitive, survival or wilderness living skills this is the place to be! Check here frequently for articles on skills, stories from ancient cultures, links to other great resources and much more. Also, for what has been updated recently, visit our [What's New at WINDSONG PRIMITIVES web page](#). There is information below on who I am, some of the magazines I write for and how to get in touch with me to inquire about classes I teach, resources I have available and more. A link to my catalog of books is below. Click [here](#) to acquire information on how to acquire my complete, illustrated catalog of books, primitive hunting weaponry and primitive items. You can also learn how to receive our text-only version of our catalog via e-mail. If you have a suggestion or comment about this website or a question about any subject relating to primitive, survival or wilderness living skills feel free to [E-Mail](#) me. Have fun visiting and I hope I can be of service to you or your group.

[Original Stories, Thoughts and Poems By Benjamin Pressley](#)

ABOUT BENJAMIN PRESSLEY AND WINDSONG PRIMITIVES:

Benjamin Pressley practices and teaches the skills of the past; primitive, survival and wilderness living skills practiced for generations by Native Americans and aboriginal peoples all over the world.

"If you go back into anyone's past far enough, no matter where your ancestry lies, your ancestors practiced these skills. So, in a sense, it is the past that unites us all.

"These skills are of interest and use to many people for many different reasons. Some are interested in how ancient peoples lived from day to day. Outdoors enthusiasts are interested because these skills are also skills that would apply if thrust into a survival situation with loss of modern gear. All find that learning and practicing these skills give them an appreciation and enhances their enjoyment for what nature and the outdoors has to offer." (Benjamin Pressley)

Benjamin Pressley has taught all ages in classes he now teaches through his school, WINDSONG PRIMITIVES. Formerly he taught many classes through the organization he and a friend (Robert Likas) founded, called TRIBE. TRIBE was a great success with a staff of people like Kim (his wife), Robert Likas and Mike & Susan Jaiy Geno (Now of [Ancient Whispers](#)). TRIBE was a successful network, school and a resource that brought together people practicing primitive skills all over the

U.S., with membership in Guam, Canada and New Guinea. **TRIBE** published a quarterly newsletter that contained articles, news, events, resources and information for anyone interested in the skills of the past. Benjamin Pressley was the Editor and Director. **TRIBE** has since had to disband. He has taught and continues to teach at schools, civic organizations, Scouts, Y-Indian Guides, Royal Rangers, YMCA, museums and historical sites. He has written and self published 13 books on various primitive, survival and wilderness living skills. He is also a writer for magazines, such as: *Backwoodsman*, [Wilderness Way](#) and *American Survival Guide*. Benjamin has been Staff Editor for *Backwoodsman* magazine and the Southeastern U.S. Field Editor for *Wilderness Way* magazine. He has played roles in instructional video curriculum and educational television movies depicting life in our country between 1750-1790.

[Back To What's On This Website](#) // [Back To Top](#)

WHAT WINDSONG PRIMITIVES HAS TO OFFER:

Benjamin Pressley is able to bring years of experience to your school, club, civic organization or group. He is also available for personal instruction. Benjamin is able to offer demonstrations, lectures, hands-on instructional classes and workshops of any length, whatever you have in mind. He is able to offer instruction and presentation of primitive, wilderness living, survival, early American (Historic, i.e. After Columbus), Native American (Historic and Prehistoric) and aboriginal skills and crafts. Below you will find a list of some of the many things he is able to offer. He will be glad to work with you to plan a program to suit your special needs. WINDSONG PRIMITIVES can connect you with just about any program of instruction or presentation you have in mind. At this website you will also find endorsements, a biography and information about Benjamin Pressley and WINDSONG PRIMITIVES. Other references are available on request. Feel free to give us a call with any questions you may have. Complete Media Package available on request that includes, endorsements, references, fee schedule, as well as programs and classes available. Feel free to discuss any special needs you may have in the area of skills presentation or financially.

CATALOG INFORMATION: Order WINDSONG PRIMITIVES' complete catalog of books, primitive hunting weaponry and primitive items! *To get your WINDSONG PRIMITIVES' catalog, send \$3.00 (Refunded as a credit on first order). International please add \$4.00, Canada please add \$2.00. U.S. funds only. See [Contact Information](#) for address to mail to.*

Also available: WINDSONG PRIMITIVES' VIRTUAL CATALOG. A complete, text-only version of WINDSONG PRIMITIVES' catalog mentioned above. This catalog is free of charge. Just type: WINDSONG PRIMITIVES' VIRTUAL CATALOG in the subject of your e-mail and it will be e-mailed to you in a reply as an attachment (239K). Also feel free to drop us a note in the message section of your e-mail, if you wish. To request your virtual catalog now, just click here to [e-mail us](#).

Aborigine: The earliest inhabitants of a continent or region.

Herbal Medicine Discussion Groups

(Browse through all groups and join the groups that suit you!)

● **aboutherbs**

Description

An interactive mailing list, talk about herbs, cooking with herbs,herbal crafts, medicinal uses of herbs, recent studies on herbs,gardening tips, feel free to share and ask questions. Exchange information on how to keep the planet clean and green, this is a friendly peaceful list. We also discuss spiritual issues and connecting with nature issues also.

Subscription Instructions

To subscribe, go to the About Herbs discussion group web page (<http://groups.yahoo.com/group/aboutherbs>) and click on "Join This Group."

Additional Information

● **Bach Flower Remedies**

Description

Bach Flower Remedies (aka Bach Flower Essences) are 38 flower and plant based remedies that treat negative emotions.

Subscription Instructions

To subscribe, go to the Bach Flower Remedies discussion group web page (<http://groups.yahoo.com/group/talkbach>) and click on "Join This Group."

Additional Information

● **CherokeeHealth**

Description

The focus of this place is to help the whole person through prayer, suggested herbal remedies, and preventative care.

Subscription Instructions

To subscribe, go to the Cherokee Health discussion group web page (<http://groups.yahoo.com/group/CherokeeHealth>) and click on "Join This Group."

Additional Information

● **ChineseHerbalAcademy**

Description

A discussion group for licensed professionals and matriculated students in the field of Chinese herbal medicine, as well as postgraduates from related disciplines, such as pharmacology or Chinese philosophy.

Subscription Instructions

To subscribe, go to the Chinese Herbal Academy discussion group web page (<http://groups.yahoo.com/group/chineseherbacademy/>) and click on "Join This Group."

Additional Information

● **Culinary Herbalist**

Description

This is the list for the gardening and use of culinary herbs

Subscription Instructions

To subscribe, send email to HERB-L-request@orednet.org with the following in the body of the message:

subscribe

Additional Information

None

● **HERB**

Description

A mailing list for the general public and practitioners to discuss all aspects of Medicinal Herbalism. Active list. Unmoderated.

Subscription Instructions

To subscribe, fill out the subscription form at the following web page address:

<http://lists.ibiblio.org/mailman/listinfo/herb>

Additional Information

None.

● **Herbal Remedies**

Description

This List is for those who are interested in HEALING using "Nutrition", "Herbal Remedies", & "All Natural" methods including Laughter. It is a forum whereby people with any kind of physical problem can get their questions answered, and thereby take full responsibility for their own health using Naturopathic methods.

Subscription Instructions

To subscribe, go to the Herbal Remedies discussion group web page (http://groups.yahoo.com/group/Herbal_Remedies) and click on "Join This Group."

Additional Information

● **Herb Students**

Description

A list will attempt to assist students of traditional Chinese herbal medicine in the studying and understanding of this very large topic.

Subscription Instructions

To subscribe, go to the Acupuncture Guild discussion group web page (<http://www.pairlist.net/mailman/listinfo/herb-students>) and fill out the subscription form.

Additional Information

● **herbal-discussion**

Description

This list is for the discussion and or just information of natural remedies, recipes using herbs for health and just for pleasure.

Subscription Instructions

To subscribe, go to the herbal-discussion discussion group web page (<http://groups.yahoo.com/group/a-herbal-discussion>) and click on "Join This Group."

Additional Information

● **herbal-healing**

Description

This list is for discussion of any form of herbal healing. How you use herbs and the healing properties of the herbs.

Subscription Instructions

To subscribe, go to the herbal-healing discussion group web page (<http://groups.yahoo.com/group/1herbal-healing>) and click on "Join This Group."

Additional Information

● **herb-witches**

Description

This list is intended to be a forum to discuss herbs and their magickal and medicinal qualities and uses. Especially how they relate and intertwine. Discussion of any other properties of herbs is also welcome.

Subscription Instructions

To subscribe, go to the herb-witches discussion group web page (<http://groups.yahoo.com/group/herb-witches>) and click on "Join This Group."

Additional Information

● **herb_kitchen**

Description

A list for all lovers of herbs. We exchange recipes for cooking with herbs, and all kinds of things you can do with herbs, including house, bath, beauty, health, decoration, oils, vinegars, potporri, soaps, gifts, and tips on buying, preserving and growing herbs.

Subscription Instructions

To subscribe, go to the Herb Kitchen discussion group web page (http://groups.yahoo.com/group/herb_kitchen) and click on "Join This Group."

Additional Information

● **Homemade Medicinal Herbs**

Description

Sharing information/ideas, etc. about herbs, natural health, well being, and anything you feel is related to making our world a better place.

Subscription Instructions

To subscribe, go to the Homemade Medicinal Herbs discussion group web page (http://groups.yahoo.com/group/Homemade_Medicinal_Herbs) and click on "Join This Group."

Additional Information

● **Kombucha Mailing List**

Description

A mailing list for the general public to discuss the Kombucha medicinal "mushroom"

Subscription Instructions

To subscribe, send email to kombucha-subscribe@topica.com with the following in the BODY of the message:

subscribe

Additional Information

[Kombucha Mailing List Web Page.](#)

● **Medicinal Herbs**

Description

This list is for the discussion of medicinal herbs.

Subscription Instructions

To subscribe, go to the Philippine Herbs discussion group web page (<http://groups.yahoo.com/group/medicinal-herbs/>) and click on "Join This Group."

Additional Information

● philippineherbs

Description

The purpose of this group is to discuss everything related to Philippine herbs. Many indigenous herbs here in the Philippines are now becoming mainstream in herbal health, such as papaya, banaba, lagundi, etc. Many herbs are also popular ingredients in natural soaps and other personal care products.

Subscription Instructions

To subscribe, go to the Philippine Herbs discussion group web page (<http://groups.yahoo.com/group/philippineherbs>) and click on "Join This Group."

Additional Information

● Phytopharmacognosy

Description

A mailing list restricted to healthcare practitioner, academics, and industrialists with expertise in medicinal plants.

Subscription Instructions

To subscribe, send email to mailbase@mailbase.ac.uk with the following in the body of the message:

Join Phytopharmacognosy [your_name]

where "[your_name]" is your first and last name.

Additional Information

Archives and further information can be found on the [Phytopharmacognosy Web Page](#).

● UK Herbalist

Description

Discussion group is only for professional practitioners of Herbal Medicine in Europe.

Subscription Instructions

To subscribe, send your resume to: gcwhite@ntlworld.com.

Additional Information

● **Wise Woman Herbal**

Description

Wise Woman Ways are those used by grandmothers and farmers wives, by Native American women and desert midwives. They are the natural ways... the feminine ways of healing. The list owner is a fourth generation Wise Woman who also specializes in herbal pregnancy care.

Subscription Instructions

To subscribe, go to the Wise Woman Herbal discussion group web page (<http://groups.yahoo.com/group/WiseWomanHerbal>) and click on "Join This Group."

Our Purpose

The California School of Traditional Hispanic Herbalism officially opened its doors in January of 1998, to teach and preserve the healing traditions of the Hispanic curanderos and curanderas (folk healers) of California. Many of these classes had been informally taught for two years prior to the creation of the school.

Although primarily offering classes in herbalism, the school also stresses an understanding of curanderismo, the healing techniques and philosophies of Native-Hispanic California. The cross-cultural influences of European and Asian herbs, as well as the use of native plants made California curanderismo a unique and potent healing medium. These practices also include the use of intuitive diagnosis skills, psychoactive plants, ritual and magic.

Instructors and Important People

Charles (Chuck) Garcia

The director and primary instructor of the school, is a third generation curandero, having learned much of his skills from his mother, Martha Garcia (who passed in 2001 at 84 years) who learned them from her father, Desidro

Navarro. Charles has treated and healed family, friends, and colleagues for almost two decades before going public with his herbal practice. He continues to treat physical, emotional, and spiritual illnesses in the Hispanic and Anglo communities of Northern California.

He has lectured on Hispanic Herbalism for the University of California Berkeley Joint Medical Program, the UC Berkeley Urban Botany Program, California State University at San Marcos, the Oakland office of the American Red Cross, the San Francisco Community Healthcare Consortium, On Lok Healthcare Services of San Francisco, the San Francisco office of AmeriCorp, the Sonoma County Herb Festival, and most recently at the 2003 meeting of the Wilderness Medical Society at the University of California, San Francisco and UC Davis. Chuck wrote a weekly column for a newspaper in South Texas, and has contributed a chapter on herbal first aid to the textbook Wilderness Emergency Care, by Steve Donelan. He was also a consultant for **America's Most Wanted** on the topic of Hispanic witchcraft.

Chuck attended classes at the **Pacific School of Herbalism** where he still maintains a close association with the director, Adam Seller. He recommends Adam's classes for those who desire to learn a strong western based medium of herbal healing.

On his off time, Chuck enjoys writing poetry and camping in the Sierra while searching for medicinal plants.

Linda Garcia

Linda is Charles' wife of 25 years. A technical publications director, writer and editor, and Red Cross Instructor, she is also the Computer Maven of the school while their daughter, Jennifer, has attended the University of Alaska, Fairbanks. Linda created a power point slide presentation for Charles, and often accompanies him on his lectures. For several years both she and her daughter have attempted to make Charles computer literate.

Jennifer Garcia

A 2003 graduate of the University of Alaska Fairbanks, in theatre arts, Jennifer has kept her dorm mates and drama crew physically and mentally healthy with numerous herbs and tinctures sent by her father to the Great White North. She has also developed syrups and tinctures on her own using local Alaskan plants. A somewhat mysterious figure in a long flowing wool cape, Jennifer has a sharp eye for diagnosis. She is currently editing a documentary on her father's wildcrafting adventures while working in local community theatre.

Clara S.

Clara is a published author and aficionado of Mexican and Texas Hispanic cultures. She is also Charles' official apprentice. Clara is currently learning curanderismo and developing her own clientele.

Sumitra R.

A transplant from the Pacific Northwest, Sumitra currently owns and runs a shop with her partner, providing shamanic herbs, artifacts, tools, reference materials, and supplies to shamanic practitioners of all faiths. She is Charles' newest apprentice.

Ruth McConnel

An old family friend and long time student, Ruth is the official dye mistress of the school. A long time participant of Renaissance Faire, Ruth has a background in the use of natural dyes as used during the Elizabethan era, as well as the use of California Native plant dyes. She is a former volunteer for the US Park Service at Point Reyes National Seashore.

Schedule

In-House Classes for Summer 2004

Traditional Hispanic Herbalism **Thursday evenings, June 17th**

7:30 to 9:30

An easy five week informational course focusing on popular folklore cures, teas, infusions, decoctions, poultices, wines, vinegars, concepts of illness, the hierarchy of Hispanic lay healers, and more. Students should be prepared to taste teas, tinctures, wines, vinegars, and some healing foods. If possible, a weekend herb walk will be planned. This class is a pre-requisite for the Hispanic Materia Medica class but can be taken concurrently. It is not a pre-requisite for the Advanced Traditional Hispanic Herbalism and Magic, but is recommended.
\$170.

The Hispanic Materia Medica **To be offered in the Fall**

A five to six week course, depending on the number of herbs covered. As requested by many former students, the Hispanic Materia Medica is an extensive list of Native, European and some Asian plants as used by Hispanic folkhealers. Their uses in specific ailments, health maintenance and spiritual healing will be discussed. Traditional Hispanic Herbalism and Magic or Advanced Traditional Hispanic Herbalism and Magic is a prerequisite for this course. Students with a background in herbalism make take this course with the permission of the instructor.
\$170.

Advanced Traditional Hispanic Herbalism and Ritual **Monday evenings, June 21st**

An eight week course with a more hands-on approach. Students cover many of the same herbs discussed in Traditional Hispanic Herbalism, but will make their own tinctures, salves, liniments, poultices, and plasters. Emphasis is placed on combinations of herbs used for specific ailments such as pneumonia, asthma, COPD, gynecological issues, mental distress, HIV, addiction, and tumors. This class will also cover cross-cultural herbal influences, basic magical protections, cleansings, and spells.
\$225.

Beginning Case Studies **Monday evenings, May 10th**

7:30 to 9:30

An intensive five week course open to students who have taken or are taking Traditional Hispanic Herbalism, Advanced Traditional Hispanic Herbalism and Ritual, or Materia Medica, or with the approval of the instructor. Three to four actual cases will be introduced to students, covering physical, emotional, spiritual, and chronic ailments. Students will develop treatments for each case, consult with each other, and discuss support treatments. Case studies may include HIV, cancer, diabetes, emotional trauma, physical injury, gender issues, and geriatric concerns. Four student minimum is required for this course.
\$175

Payment Policy

At least two-thirds of the course fee is expected at the first class meeting. This is unfortunate, but too many students have failed to meet their financial obligations. Complete payment is expected before the final class date. **Please make all checks payable to Charles R. Garcia.**

Note: A \$20 per class discount is available to any graduate of the Red Cross Wilderness First Responder class or any student of the Tracker School.

INTENSIVES

These are focused treatments of particular aspects in Hispanic healing. They will be offered throughout the year depending on weather and student interest. Private Intensives can be scheduled by groups and organizations.

Herb Walk and Lecture

A pleasant walk in Samuel P. Taylor State Park in Marin County. Local herbs and edible plants will be identified and discussed. Historical native uses will be covered. Bring lunch and water bottle. Note that poor weather may result in the postponement of any outdoor class. \$10 per person.

TBA

Curanderismo: Hispanic Mysticism, Magic and Ritual

A popular topic in the advanced course, this intensive will explore in depth the use of ritual, psychoactive plants, protection against spells, dreamwalking, witchcraft, Catholic and Native cultural influences, and the dangers inherent in this aspect of curanderismo. Not for the faint of heart or those skeptical of the existence of evil. Four person minimum.

TBA

\$25.00

HIV and Cancer Support

An intensive solely devoted to HIV and cancer support techniques. Topics include herbal support, diet, sexual issues, and depression. Also the use of ritual to improve the emotional and mental state of clients. Four person minimum. This class is dedicated to the memory of Ann Larricq, student, friend, and healer.

Sunday morning, July 11th, 10:30a.m. to 1:30 ?

\$30.00

Traditional California Healing Plants and Medicine Making

A day of history and fun covering the use of many California healing and edible plants from various regions of the state as used by Hispanics, natives, Anglos, and Chinese healers. Some remedies will be made by students. Five person minimum.

TBA

\$45.00

Supportive Bronchial Care Intensive

Chronic Obstructive Pulmonary Disease, SARS, asthma, bronchitis, pneumonia, AIDS related TB: All these conditions are increasing. Traditional herbal uses can help support the effectiveness of regular medical care and ease various bronchial discomfort. The use of herbs, steams, food, and lifestyle will be discussed.

Saturday May 29th 10:30 a.m. to 2:00 p.m. \$30 Four person minimum.

Intensive on Herbs and Survival

This course, originally created for earthquake and disaster training, will cover medicinal herbs available from sidewalks, lawns, parks, and other urban settings. May cover some edible plants. Some first aid techniques will be demonstrated. Will be held at Samuel P. Taylor State Park in Marin County, where students will identify healing plants and use them in emergency scenarios. Bring a lunch. This class is recommended for students or associates of the Tracker School, Red Cross Wilderness Emergency Response, or the Wilderness Medical Society. Note that poor weather may result in the postponement of any outdoor class.

Saturday July 10th 10:30 am to 2:30 (?) p.m. \$50 Five person minimum.

Intuitive Diagnosis and Tracking I

A one day class held outdoors at a nearby regional park. A picnic lunch should be brought. This class covers deductive and intuitive abilities used by native healers. Techniques in tracking as used by Tom Brown jr. of the Tracker School, will be used to increase observational skills. Mental exercises in visualization, empathy and imagination will be taught. Psychoactive plants and dream walking will be but not emphasized.. Approval of the instructor is necessary for this class. Note that poor weather may result in the postponement of any outdoor class. Bring lunch. Three person minimum.

Sunday July 18th 10:30 to ?

\$75

Class Settings

We understand that evening classes are difficult for working adults, so we have taken steps to relieve the stress by teaching small classes **at my home in Richmond** in an informal, but informative, manner. Light refreshments are usually served.

Outdoor classes are taught at nearby Wildcat Canyon Park or in nearby Marin County at Samuel P. Taylor State Park.

On-Line Classes

Due to numerous requests for a correspondence course, The California School of Traditional Hispanic Herbalism has offered on-line classes since April, 1998. Lectures are sent to students weekly via e-mail. Questions and comments are expected within four days for inclusion in the following lecture. Failure to respond to two classes in a row will result in the student being dropped from the course. There are no refunds if a student is dropped. Classes are offered continually through the year.

Currently offered classes are:

Traditional Hispanic Herbalism and Magic

Seven classes. History of California Hispanic herbalism. The hierarchy of lay healers. Poultices, teas, decoctions, wines, vinegars, folklore, ritual, magic, poisons as used in healing, cultural concepts of illness, treatment of serious ailments. Photo attachments of some herbs may be sent with the lecture.

\$75

Hispanic Materia Medica

Five classes. A comprehensive list of native and European herbs, and their use in specific ailments. Some photos may be attached to lessons.

\$75

Hispanic Ritual and Magic

Three classes. In depth lectures covering history, ritual, witchcraft, the use of psychoactive plants and the dangers to client and healer. Not for the faint of heart or those inclined to serious skepticism of the supernatural.

\$60.00

Payment Policy for On-line Classes

Full payment is expected before the first lecture is sent. This is unfortunate, but many on-line students have not met their financial obligations. Complete payment is expected before the end of the course. **Please make all checks payable to Charles R. Garcia.**

Future Courses

Late Summer/Fall 2004

Intensive On Herbal Sweats, Steam Therapies, and Poultices

Of growing interest to many students, this class will address the use of sweating; its practicality and dangers in dealing with a number of health issues. It will also cover the neglected use of herbal steams and poultices.

Anticipated cost: \$45. Four student minimum.

Street Herbalism

A course only for those who will attempt to treat the homeless. Anticipated to take three weeks. Topics to be covered...safety, bladder infections, skin conditions, bronchial conditions, drug and alcohol issues, sidewalk herbs, mental illness, police interaction, self defense. Approval of the instructor is required for this course.

Intensive on Long-Term Survival Herbalism

Survivalism and survivalists are terms often misinterpreted by the public in general. Many social and religious communities of the 1800's would have been branded survivalists in this day and age. This course focuses on the growth of herbs, use, storage, and application of herbal remedies by those who are attempting a simpler and low profile life-style for whatever the reason. Anticipated cost. \$35. Five student minimum.

Outdoor Survival for the Outdoor Challenged (and Herb Lecture) I

Is the idea of sleeping outdoors terrifying to you? Can't get a propane stove to work, let alone cook on it? Is your idea of camping staying at the local Motel 6? This is the class for you. Taught by Linda Garcia (with a complimentary herb lecture by Chuck), this is a full day and overnight class at a local state park. For a variety of reasons, a surprisingly large number of urban men and women cannot enjoy 24 hours in the outdoors . Deal with your doubts and fears! Linda has trained and led numerous city-bred children, and no few adults, to enjoy the beauty of nature through easy hikes, star gazing, and warm night fires. Weekends and 3 day holidays only. Anticipated cost: \$50 per person, plus camping fee for the park.

TBA Summer 2004

Supportive Bronchial Care Intensive

Chronic Obstructive Pulmonary Disease, SARS, asthma, bronchitis, pneumonia, AIDS related TB: All these conditions are increasing. Traditional herbal uses can help support the effectiveness of regular medical care and ease

various bronchial discomfort. The use of herbs, steams, food, and lifestyle will be discussed. **TBA Summer.**
Anticipated cost: \$30 Four person minimum.

Special Classes

Special classes and lectures on various topics of Hispanic herbalism can be arranged for groups of five persons or more. Please contact the school directly for details. A special class was recently arranged by the El Toro Creek Garden Club of San Luis Obispo County on the history and use of native and introduced herbs to California. In 2002 a lecture was given to the Native American Students Association of UC Berkeley on the history of California curanderismo.

A Word on Certification

Many herbal schools give certificates of completion or certification documents. In California this means literally nothing, as the state does not recognize herbalism unless practiced in conjunction with Traditional Chinese Medicine. Students who complete several courses at this school receive a small leather medicine pouch in recognition of their efforts. Several former students have continued their education at other institutions, some are practicing healers, two are doctors, most use what they have learned to help family and friends.

Frequently Asked Questions (FAQ)

Over the years the same questions have arisen concerning classes, information on Curanderismo, and research information. To save time, the most common questions and my answers are listed below.

1. Can you send me a catalog of classes, costs, and class dates?

No, I cannot. All the information concerning both current classes and online classes is on this website. This includes scheduled topics, dates, costs, and payment policy. Please print these pages for your convenience and future reference. The California School of Traditional Hispanic Herbalism keeps costs low by NOT printing brochures and catalogs.

2. Why are classes so expensive?

They are not. They are some of the most reasonably priced classes in the United States.

3. Can you put me in touch with other curanderos and curanderas in my area?

I am sorry, but curanderos and curanderas do not usually network. I suggest you start with a local Hispanic herb store, often called a yerberito or botanica for local references.

4. I am doing a research paper on curanderismo. Can you tell me what you know or where I can find information on the topic?

I can tell you what I know if you are willing to take the time and be trained or sign up for my classes as I have not yet written the definitive book on the topic. For an overview of the subject, I suggest you read:

- Infusions of Healing by Joie Davidow
- Mexican-American Folklore by John O. West
- Witchcraft Along the Rio Grande by Marc Simmons
- Curanderismo: Mexican-American Folkhealing, 2nd edition, by Robert T. Trotter (though I disagree with the methodology he uses in his studies)
- Homegrown Healing: Traditional Home Remedies from Mexico, by Annette Sandoval

You can also peruse the extensive database at Baylor University School of Nursing for excellent information concerning Hispanic folk medicine.

<http://www.rice.edu/projects/HispanicHealth/Courses/mod7/mod7.html>

5. Are you available for lectures?

Yes, I am, though I am no longer willing to drive several hundred miles on my own nickel to do it. Pay for plane fare to and from, a hotel if it's outside of California, and a cup of coffee, and I would be more than happy to lecture your class or organization.

6. Will you do health consultations over the phone or on-line?

No. It's unethical to diagnose a patient without actually seeing him or her and getting complete background information--physical, emotional, and spiritual.

THE ***MOORE FOUNDATION*** **And Academy** **Leaders in Homeschooling**

Hand in hand with homeschooling parents providing individualized curriculum, educational materials, and unit studies for Homeschool along with aid in learning disabilities, and gifted education.

"We invite everyone to search our site for an exciting adventure in learning. Our bookstore contains valuable Christian resources with character building values to help families in nurturing their children in the admonition of the Lord."

While taking into consideration the readiness and interests of the child, our educational counselors work closely with each parent to prepare a personalized curriculum for their student. Our goal is to nurture the seeds of uniqueness within each child. Moore Academy students mature in wisdom and personal growth through a program unlike any other. We are proud to present to the world, students who can think for themselves and be leaders for God.

Saskatchewan Canada has one of the world's great wilderness canoe areas. Half of the province is covered by forest and one-eighth is water. The Precambrian shield in northern Saskatchewan provides the setting for an adventurer's paradise.

The information presented on these pages will help you appreciate this land and enable you to come in person to enjoy it. Just remember that for thousands of years people have used these portage trails, these campsites and these waterways, and we hope that future generations may also be able to enjoy them.

Read online from the current issue:

[The poor man's ceramic knife sharpener](#)

By Rick Brannan

There are few things more frustrating and dangerous than working with a dull knife. In my quest for a sharp knife, I have purchased many different styles of knife sharpeners. From whetstones to oilstones, fixed-angle sharpeners to diamond dust-impregnated steels, I have used them all and have spent hundreds of dollars in the process. Which is why knife sharpening has become big business. Some sharpeners cost more than the knives.

But of all the sharpeners I have used over the years, I have had the best results with the ceramic sharpeners.

[The tenuous hold of honesty in modern America](#)

By John Silveira

I went to high school in Derry, New Hampshire. Pinkerton Academy. Its most famous alumnus is the late Alan B. Shepard, one of the original seven American astronauts, first to ride in the Mercury space capsule, and the only one of those seven to walk on the moon. I was a senior at Pinkerton the day Shepard took his suborbital flight. The press was there, too, looking for a story. I don't think they knew what they'd find.

Hardyville, USA

[Heading for Hardyville Gulch](#)

by Claire Wolfe

So I'm driving out of town when I see the strangest thing. There's Nat's old Dodge pickup parked at the side of the road. He's roped his battered shooting bench in the bed. And there sits Nat himself with his spotting scope nearby, his deer rifle at the ready, and a six-pack of Moose Drool beer. He's peering over the rifle down the long, empty stretch of road that leads to Hardyville.

Naturally, I have to stop and find out what the heck is going on.

BHM Web Site Exclusive

[Brood X](#) by Rev. J.D. Hooker

Though I was still in my early thirties at the time, I clearly remember fishing during the last big 17-year hatch. At that time I'd simply gather up a large quantity of already dead locusts from where they'd fallen around the tree trunks and, after threading a locust on to a relatively large #1-size hook attached to a tapered leader, I'd flip-cast the bug into a shaded area right up near the bank. If I didn't get a strike within the first few seconds, I'd give my rod a little twitch causing the bug to move only a couple of inches. This nearly always triggered an actual attack by a frenziedly feeding fish.

BHM Web Site Exclusive

[Getting Logs](#) by Dorothy Ainsworth

Attention: Would-be loggers. There have been changes in policy at the United States Forest Service and the Bureau of Land Management. I have just found out that the procedure to obtain logs through the USFS or BLM has changed drastically because of the NEPA (National Environmental Protection Agency). You can no longer go into a ranger station like I did and simply get a permit to cut your own logs in a given area. Now you have to go through a "process".

BHM Web Site Exclusive

Ayoob on Firearms

[Firearms handling refresher Part III: Rifles](#) by Massad Ayoob

Always remember that training is a good investment in anything serious. Your local fish and wildlife department, or your local gun shop, can probably steer you to certified instructors. So can the National Rifle Association, at their toll-free number 1-877-NRA-2000. Jeff Cooper's Gunsite has an excellent course they call "General Rifle," and Clint Smith's Thunder Ranch still offers the course that made "Urban Rifle" a byword in training. Another good source is the Firearms Academy of Seattle where the pictures that accompany this article were taken. I particularly recommend the rifle classes FAS offers taught by Georges Rahbani. The graduates rave about the program.

[Succulent venison stew](#)

From Our [Seventh Year Anthology](#)

Here are some cucumber pickles to make at home By Olivia Miller

Preserving produce by "pickling" is one of the oldest and most delightful ways to save your summer harvest for your winter table. The word "pickle" applies to any food preserved in brine and/ or vinegar, with or without bacterial fermentation, and with or without the addition of spices and sugar.

[Read this article](#)

From Our [Eleventh Year Anthology CD](#)

Build this sturdy large-capacity food dehydrator By Charles Sanders

Drying of food as a means of preservation has been around for a long time. Populations in suitably dry climates all around the globe have dried meat, fish, fruit, and vegetables in times of plenty as a way to provide for the leaner months of the year. My grandmother used to tell us of when she was a child, helping to spread apple slices on the top of a tin-shed roof for drying. An aunt once described stringing fresh young bean pods on a long heavy thread and hanging them to dry, coming up with what they called leather-britches beans. Obviously, these were simple and imperfect food drying systems, but they do show ways in which food can be dried at home.

Featured Writer

[Determined woman builds distinctive vertical log studio](#)

By Dorothy Ainsworth

For a novice, there's no thrill like the tactile kinetic experience of driving a 16-penny nail home in three blows, then burying its head with two extra whacks for no reason. There was evidence of beginner's overkill everywhere. Electrical cord repairs looked like snakes that had swallowed gophers. A job wasn't finished until all the nails were gone. There were no gimmicks or shortcuts in the learning process. I sweated and strained and scarred. But the satisfaction of sawing a clean square cut with a hand saw rivaled sewing a fine seam or baking a perfect loaf of bread, and eventually the results became just as predictable.

ROPE WORKS ©1999

Lashing

Lashings are used to join poles or spars when building pioneering structures. These structures can be functional, such as tables, bridges, and towers or decorative such as gateways. The only limit as to the type of structure is the imagination of the builder.

Correctly tied lashings in pioneering structures are essential for safety. When young people see an interesting structure they charge up and over with no thought as to the soundness of the structure. This places the responsibility for a safe structure directly on the builder.

The following topics about lashing are covered in :

ROPE WORKS

Square Lashing
Diagonal Lashing
Tripod Lashing With Racking Turns
Tripod Lashing With Plain Turns
Shear Lashing With Racking Turns
Shear Lashing With Plain Turns
Shear Lashing Quick

About HVO

"Two mighty agencies in collision. Two antagonist and gigantic forces in contact, and producing effects on a scale inconceivably grand!"

"The atmosphere in all directions was filled with ashes, spray, gases... while the burning lava, as it fell into the water, was shivered into millions of minute particles, and, being thrown back into the air, fell in showers of sand on all the surrounding country. The coast was extended into the sea... and a pretty sand-beach and a new cape was formed."

T. Coan, minister in Hawai'i, 1841

Explosions and collapsing land endanger people

Such vivid descriptions and scenes of lava entering the sea along Kilauea's shoreline draw millions of people to Hawai'i who are hoping to witness for themselves growth of new land and experience the remarkable interaction of lava and water. Beautiful and stunning, the explosive interaction can be dangerous to visitors who venture too close to a lava entry point. Also, the new land created by lava entering the sea is unstable. Large areas regularly collapse into the sea, usually triggering a series of stronger explosions and sending a wave of scalding seawater onshore. Such explosions have hurled hot rocks and lava fragments more than 100 m (330 ft) inland!

Unfortunately, the entry of lava into the ocean is difficult to observe from a distance because it's often obscured by an energetic and acidic steam plume or by an abrupt cliff above the entry point. This often invites visitors to jeopardize their safety by walking right up to and over the point where lava enters the ocean. Activity that may appear stable and non-threatening can actually change without warning, leaving no time for escape.

Photograph by T.N Mattox on September 23, 1993.

Lava entering the ocean is often hidden beneath a steam plume, which may draw unwary visitors too close to the entry point for safety.

Why are lava entries so dangerous?

New land created by lava entering the sea looks like a stable platform that extends a few tens to hundreds of meters into the ocean. We refer to this new land as a lava delta. But what can't be seen is the loose pile of unconsolidated lava fragments underneath that supports the new land. This pile of material can easily slide away when the growing delta advances over a steep submarine slope. Areas the size of several football fields can collapse into the ocean with little or no warning.

People standing on a growing lava delta during a collapse event can be swept into the sea, splashed with scalding water, and hit by flying rock debris. Visitors to an active lava delta at Kilauea Volcano are advised not to venture onto the new land. Entry points can only be viewed safely from behind the former sea cliff and shoreline.

Hazardous activity near active lava deltas

Yes, it's true... Reeko's done it again.... His latest experimentation has left the lab in ruins... This time the government radiation team has indicated that the damage is far too great to repair and suggested a move to another location (in fact, they suggested a remote location such as Siberia...).

Reeko and the crew set out on a mission to find a lab that was bigger, better, and faster than before. And now we proudly present to you our new home, featuring more experiments, more interactive games, and less sugar than the previous version. Step right this way and discover for yourself how fun (and wacky) science can be...

[Visit our new home here - http://www.spartechsoftware.com/reeko](http://www.spartechsoftware.com/reeko)

Reeko's Mad Scientist Lab

Welcome

Is this Reeko? Reeko? You feeling OK buddy?

Welcome to **Reeko's Mad Scientist Lab**. Your source of free science experiments for parents, teachers, and children of all ages. Kick off your shoes. Pull up a chair. Make yourself comfortable. Oh yeah, did we mention that protective goggles *are* required...

Got a question or comment about our science lab? [Email Reeko](#) and let him know what's on your mind!

Welcome!

Welcome to Reeko's Mad Scientist Lab! Your source of science and chemistry experiments for parents, teachers, kids, and children of all ages.

As you'll soon find out - nothing is ordinary around here. Be curious, explore (place your cursor over objects and click everywhere), and above all - HAVE FUN!

Principles of Floatation (easy)

Ever wonder why a really heavy boat floats while a small rock sinks like a... uhhh, rock? Have you noticed that while in the pool, if you stretch out flat you will float but if you curl up in a ball you will sink? Grab your lab coats and head for the kitchen sink - [our first science experiment](#) demonstrates those puzzling floatation principles.

Slip sliding away... (advanced)

How would you like to have your very own hovercraft. You know - the futuristic vehicle that travels on air hovering inches above the ground. We'll grab your coats and head for the door. In this lab exercise we're fixing to [create a real, working hovercraft](#) ... OK, so it's only big enough for a mouse but then again, you don't have a *driver's license* so what'd you expect?

Got a question or comment about one of the experiments? Have you found a really cool experiment that you'd like to share with the rest of the world? Or, do you just want

What if I were to tell you that I could make water flow uphill? Now wait, don't leave yet - this is serious. This lab experiment will show you that [what goes up doesn't always have to come back down](#).

[Chemical reaction in action](#) (easy)

A chemical reaction is a process where one type of substance is chemically converted to another substance. That fizzling toilet bowl cleaner is a chemical reaction. The fire in your fireplace is another type of chemical reaction. The *smoke* that comes out of Dad's ears when you break one of his favorite golf clubs is a result of a chemical reaction. OK, so maybe Reeko's stretching it a little with that explanation. [This experiment](#) demonstrates a chemical reaction that's fairly common all around us (and we don't have to go anywhere near Dad's golf clubs).

[Look Ma' - no hands](#) (intermediate)

Remember the old soda-in-the-straw trick. You know, the one where you put a straw into a glass of soda and then cover the end of the straw with your finger. When you remove the straw from the glass the water stays inside until you remove your finger. [In this little scientist experiment](#) we apply this same principal to learn about something called *pressure*.

[Look out! It's gonna blow!](#) (advanced)

Here's a popular experiment that's been around for years and has left many kitchens in ruin (just kidding of course). In the volcano experiment we [build a real working volcano](#) that actually mimics the properties of the real thing.

[Things aren't always as they appear](#) (easy)

Dazzle your friends. Impress your buddies. Confuse your Dad. Here we [create an optical illusion](#) with a very basic scientific explanation.

to yak? Drop us a line!

More Info

Looking for more experiments? Check your local library (in the kid's or science sections) for great science books. Need some suggestions? Try these.

 [The Kid's Science Book](#)
(Robert Hirschfeld & Nancy White)

 [My First Science Book](#)
(Angela Wilkes)

 [The Science Book](#) (Sara Stein)

 [Science for Every Kid](#)
(Janice VanCleave)

What? There's not a library next door and don't feel like walking 10 miles through the sleet and snow (barefoot of course). Check out [Reeko's Book Reviews](#) and order online directly from Amazon.

And don't forget to tell them that Reeko sent ya'.

Try some of these other really cool science sites and don't forget to tell them that Reeko sent ya'! (note: to avoid being turned away, you may not want to mention Reeko's name until you're *finished* exploring these sites).

 [Franklin Institute Science Museum](#)

 [The Mineral Gallery](#)

 [WorldTime Interactive Atlas](#)

 [Space Shuttle](#)

And if these still don't quench that insatiable curiosity then check out [Reeko's Extensive Science Link List](#).

Look out below! (intermediate)

Let's say I'm standing on top of a tall building hanging over the edge carefully balancing a bowling ball in one hand and a tennis ball in the other. You're on the ground under me looking up (and probably covering your head). Hmmm, something is not quite right here and [some scientific experimentation](#) is definitely called for...

Now that you're good and warmed up with plenty of momentum... (advanced)

Now we get to learn about a little principle called momentum (the speed or force of something that is moving). Sometimes interesting things happen when a totally motionless object gets in the way of a moving one. To demonstrate - the next time dad finds out you've been in his toolbox again and he's coming at you with that crazed look on his face. Rather than running, flinching, or ducking in terror try freezing like a statue and see how it freaks him out. Or better yet, [try this experiment](#) and see for yourself.

Pop Quiz !!!

Did you work your way through all of the experiments? Did you find all of the hidden tips and science facts? Take our [Pop Quiz](#) and find out how 'science savvy' you are. And we promise, no matter how you score - we won't send Mom or Dad a report card.

What? You're still here?

That wasn't enough cranial stimulation for one session? You need more experiments?!?! OK... You asked for it - [through this door](#) you can enter the top secret, select little scientists only section of Reeko's Mad Scientist Lab (Section F).

Do Cats have belly buttons? NEW!

Hey Reeko! I tried the experiment and it *didn't* work! Now what am I supposed to do ?!?!? Follow these [Five tried-and-true rules](#) for guaranteeing a experiment will produce the results you are looking for.

Don't forget to [Email Reeko](#) with your questions, comments, and/or suggestions. And check out [what others have said about us](#) (edited of course).

What is quicksand anyway? How come I can see through glass? Do LifeSavers really spark when you chew them? Chimp, the lab monkey, is back and available to answer all those [weird science questions](#) that have been driving us crazy...

Did you find a hidden Pot of Gold?

Reeko has been receiving rave reviews on the new [Pot of Gold contest](#) so he tore himself away from his latest genetic experimentation and sprinkled more pots of gold around the lab! Join us on our search for the hidden Pots of Gold and get your name added to the [Pot of Gold Hall of Fame](#) page!

Mystery Puzzle of the Month!

The results of Reeko's latest science escapades left him with a little free time on his hands. So while the government radiation teams worked on the lab cleanup, Reeko settled down to work on his newest online game for the kids. The result - the [Mystery Puzzle of the Month game](#). Get ready to roam this site gathering the clues needed to solve this month's puzzle...

MOLECULAR MACHINES:

Experimental Support for the Design Inference

Michael J. Behe

A Series of Eyes

How do we see? In the 19th century the anatomy of the eye was known in great detail and the sophisticated mechanisms it employs to deliver an accurate picture of the outside world astounded everyone who was familiar with them. Scientists of the 19th century correctly observed that if a person were so unfortunate as to be missing one of the eye's many integrated features, such as the lens, or iris, or ocular muscles, the inevitable result would be a severe loss of vision or outright blindness. Thus it was concluded that the eye could only function if it were nearly intact.

As Charles Darwin was considering possible objections to his theory of evolution by natural selection in *The Origin of Species* he discussed the problem of the eye in a section of the book appropriately entitled "Organs of Extreme Perfection and Complication." He realized that if in one generation an organ of the complexity of the eye suddenly appeared, the event would be tantamount to a miracle. Somehow, for Darwinian evolution to be believable, the difficulty that the public had in envisioning the gradual formation of complex organs had to be removed.

Darwin succeeded brilliantly, not by actually describing a real pathway that evolution might have used in constructing the eye, but rather by pointing to a variety of animals that were known to have eyes of various constructions, ranging from a simple light sensitive spot to the complex vertebrate camera eye, and suggesting that the evolution of the human eye might have involved similar organs as intermediates.

But the question remains, how do we see? Although Darwin was able to persuade much of the world that a modern eye could be produced gradually from a much simpler structure, he did not even attempt to explain how the simple light sensitive spot that was his starting point actually worked. When discussing the eye Darwin dismissed the question of its ultimate mechanism (1):

How a nerve comes to be sensitive to light hardly concerns us more than how life itself originated.

He had an excellent reason for declining to answer the question: 19th century science had

not progressed to the point where the matter could even be approached. The question of how the eye works--that is, what happens when a photon of light first impinges on the retina--simply could not be answered at that time. As a matter of fact, no question about the underlying mechanism of life could be answered at that time. How do animal muscles cause movement? How does photosynthesis work? How is energy extracted from food? How does the body fight infection? Nobody knew.

Calvinism

Now, it appears to be a characteristic of the human mind that when it is unconstrained by knowledge of the mechanisms of a process, then it seems easy to imagine simple steps leading from non-function to function. A happy example of this is seen in the popular comic strip Calvin and Hobbes. Little boy Calvin is always having adventures in the company of his tiger Hobbes by jumping in a box and traveling back in time, or grabbing a toy ray gun and "transmogrifying" himself into various animal shapes, or again using a box as a duplicator and making copies of himself to deal with worldly powers such as his mom and his teachers. A small child such as Calvin finds it easy to imagine that a box just might be able to fly like an airplane (or something), because Calvin does not know how airplanes work.

A good example from the biological world of complex changes appearing to be simple is the belief in spontaneous generation. One of the chief proponents of the theory of spontaneous generation during the middle of the 19th century was Ernst Haeckel, a great admirer of Darwin and an eager popularizer of Darwin's theory. From the limited view of cells that 19th century microscopes provided, Haeckel believed that a cell was a "simple little lump of albuminous combination of carbon," (2) not much different from a piece of microscopic Jello. Thus it seemed to Haeckel that such simple life could easily be produced from inanimate material. In 1859, the year of the publication of *The Origin of Species*, an exploratory vessel, H.M.S. Cyclops, dredged up some curious looking mud from the sea bottom. Eventually Haeckel came to observe the mud and thought that it closely resembled some cells he had seen under a microscope. Excitedly he brought this to the attention of Thomas Henry Huxley, Darwin's great friend and defender. Huxley, too, became convinced that it was *Urschleim* (that is, protoplasm), the progenitor of life itself, and Huxley named the mud *Bathybius Haeckelii* after the eminent proponent of abiogenesis.

The mud failed to grow. In later years, with the development of new biochemical techniques and improved microscopes, the complexity of the cell was revealed. The "simple lumps" were shown to contain thousands of different types of organic molecules, proteins, and nucleic acids, many discrete subcellular structures, specialized compartments for specialized processes, and an extremely complicated architecture. Looking back from the perspective of our time, the episode of *Bathybius Haeckelii* seems silly or downright embarrassing, but it shouldn't. Haeckel and Huxley were behaving naturally, like Calvin: since they were unaware of the complexity of cells, they found it easy to believe that cells could originate from simple mud.

Throughout history there have been many other examples, similar to that of Haeckel, Huxley and the cell, where a key piece of a particular scientific puzzle was beyond the understanding of the age. In science there is even a whimsical term for a machine or structure or

process that does something, but the actual mechanism by which it accomplishes its task is unknown: it is called a 'black box.' In Darwin's time all of biology was a black box: not only the cell, or the eye, or digestion, or immunity, but every biological structure and function because, ultimately, no one could explain how biological processes occurred.

Ernst Mayr, the prominent biologist, historian, and guiding force behind the neo-Darwinian synthesis, has pointed out that (3):

Any scientific revolution has to accept all sorts of black boxes, for if one had to wait until all black boxes are opened, one would never have any conceptual advances.

That is true. But in earlier days when black boxes were finally opened science, and sometimes the whole world, appeared to change. Biology has progressed tremendously due to the model that Darwin put forth. But the black boxes Darwin accepted are now being opened, and our view of the world is again being shaken.

Proteins

In order to understand the molecular basis of life it is necessary to understand how things called "proteins" work. Although most people think of protein" as something you eat, one of the major food groups, when they reside in the body of an uneaten animal or plant proteins serve a different purpose. Proteins are the machinery of living tissue that builds the structures and carries out the chemical reactions necessary for life. For example, the first of many steps necessary for the conversion of sugar to biologically-usable forms of energy is carried out by a protein called hexokinase. Skin is made in large measure of a protein called collagen. When light impinges on your retina it interacts first with a protein called rhodopsin. As can be seen even by this limited number of examples proteins carry out amazingly diverse functions. However, in general a given protein can perform only one or a few functions: rhodopsin cannot form skin and collagen cannot interact usefully with light. Therefore a typical cell contains thousands and thousands of different types of proteins to perform the many tasks necessary for life, much like a carpenter's workshop might contain many different kinds of tools for various carpentry work.

What do these versatile tools look like? The basic structure of proteins is quite simple: they are formed by hooking together in a chain discrete subunits called amino acids. Although the protein chain can consist of anywhere from about 50 to about 1,000 amino acid links, each position can only contain one of twenty different amino acids. In this way they are much like words: words can come in various lengths but they are made up from a discrete set of 26 letters. Now, a protein in a cell does not float around like a floppy chain; rather, it folds up into a very precise structure which can be quite different for different types of proteins. When all is said and done two different amino sequences--two different proteins--can be folded to structures as specific as and different from each other as a three-eighths inch wrench and a jigsaw. And like the household tools, if the shape of the proteins is significantly warped then they fail to do their jobs.

The Eyesight of Man

In general, biological processes on the molecular level are performed by networks of proteins, each member of which carries out a particular task in a chain.

Let us return to the question, how do we see? Although to Darwin the primary event of vision was a black box, through the efforts of many biochemists an answer to the question of sight is at hand. (4) When light strikes the retina a photon is absorbed by an organic molecule called 11-*cis*-retinal, causing it to rearrange within picoseconds to *trans*-retinal. The change in shape of retinal forces a corresponding change in shape of the protein, rhodopsin, to which it is tightly bound. As a consequence of the protein's metamorphosis, the behavior of the protein changes in a very specific way. The altered protein can now interact with another protein called transducin. Before associating with rhodopsin, transducin is tightly bound to a small organic molecule called GDP, but when it binds to rhodopsin the GDP dissociates itself from transducin and a molecule called GTP, which is closely related to, but critically different from, GDP, binds to transducin.

The exchange of GTP for GDP in the transducinrhodopsin complex alters its behavior. GTP-transducinrhodopsin binds to a protein called phosphodiesterase, located in the inner membrane of the cell. When bound by rhodopsin and its entourage, the phosphodiesterase acquires the ability to chemically cleave a molecule called cGMP. Initially there are a lot of cGMP molecules in the cell, but the action of the phosphodiesterase lowers the concentration of cGMP. Activating the phosphodiesterase can be likened to pulling the plug in a bathtub, lowering the level of water.

A second membrane protein which binds cGMP, called an ion channel, can be thought of as a special gateway regulating the number of sodium ions in the cell. The ion channel normally allows sodium ions to flow into the cell, while a separate protein actively pumps them out again. The dual action of the ion channel and pump proteins keeps the level of sodium ions in the cell within a narrow range. When the concentration of cGMP is reduced from its normal value through cleavage by the phosphodiesterase, many channels close, resulting in a reduced cellular concentration of positively charged sodium ions. This causes an imbalance of charges across the cell membrane which, finally, causes a current to be transmitted down the optic nerve to the brain: the result, when interpreted by the brain, is vision.

If the biochemistry of vision were limited to the reactions listed above, the cell would quickly deplete its supply of 11-*cis*-retinal and cGMP while also becoming depleted of sodium ions. Thus a system is required to limit the signal that is generated and restore the cell to its original state; there are several mechanisms which do this. Normally, in the dark, the ion channel, in addition to sodium ions, also allows calcium ions to enter the cell; calcium is pumped back out by a different protein in order to maintain a constant intracellular calcium concentration. However, when cGMP levels fall, shutting down the ion channel and decreasing the sodium ion concentration, calcium ion concentration is also decreased. The phosphodiesterase enzyme, which destroys cGMP, is greatly slowed down at lower calcium concentration. Additionally, a protein called guanylate cyclase begins to resynthesize cGMP when calcium levels start to fall.

Meanwhile, while all of this is going on, metarhodopsin II is chemically modified by an enzyme called rhodopsin kinase, which places a phosphate group on its substrate. The modified rhodopsin is then bound by a protein dubbed arrestin, which prevents the rhodopsin from further activating transducin. Thus the cell contains mechanisms to limit the amplified signal started by a single photon.

Trans-retinal eventually falls off of the rhodopsin molecule and must be reconverted to 11-*cis*-retinal and again bound by opsin to regenerate rhodopsin for another visual cycle. To accomplish this *trans*-retinal is first chemically modified by an enzyme to transretinol, a form containing two more hydrogen atoms. A second enzyme then isomerizes the molecule to 11-*cis*-retinol. Finally, a third enzyme removes the previously added hydrogen atoms to form 11-*cis*-retinal, and the cycle is complete.

To Explain Life

Although many details of the biochemistry of vision have not been cited here, the overview just given is meant to demonstrate that, ultimately, *this is* what it means to 'explain' vision. This is the level of explanation that Biological science eventually must aim for. In order to say that some function is understood, every relevant step in the process must be elucidated. The relevant steps in biological processes occur ultimately at the molecular level, so a satisfactory explanation of a biological phenomenon such as sight, or digestion, or immunity, must include a molecular explanation. It is no longer sufficient, now that the black box of vision has been opened, for an 'evolutionary explanation' of that power to invoke only the anatomical structures of whole eyes, as Darwin did in the 19th century and as most popularizers of evolution continue to do today. Anatomy is, quite simply, irrelevant. So is the fossil record. It does not matter whether or not the fossil record is consistent with evolutionary theory, any more than it mattered in physics that Newton's theory was consistent with everyday experience. The fossil record has nothing to tell us about, say, whether or how the interactions of 11-*cis*-retinal with rhodopsin, transducin, and phosphodiesterase could have developed step-by-step. Neither do the patterns of biogeography matter, or of population genetics, or the explanations that evolutionary theory has given for rudimentary organs or species abundance.

"How a nerve comes to be sensitive to light hardly concerns us more than how life itself originated," said Darwin in the 19th century. But both phenomena have attracted the interest of modern biochemistry. The story of the slow paralysis of research on life's origin is quite interesting, but space precludes its retelling here. Suffice it to say that at present the field of origin-of-life studies has dissolved into a cacophony of conflicting models, each unconvincing, seriously incomplete, and incompatible with competing models. In private even most evolutionary biologists will admit that science has no explanation for the beginning of life. (5)

The purpose of this paper is to show that the same problems which beset origin-of-life research also bedevil efforts to show how virtually any complex biochemical system came about. Biochemistry has revealed a molecular world which stoutly resists explanation by the same theory that has long been applied at the level of the whole organism. Neither of Darwin's black boxes--the

origin of life or the origin of vision or other complex biochemical systems--has been accounted for by his theory.

Irreducible Complexity

In *The Origin of Species* Darwin stated (6):

If it could be demonstrated that any complex organ existed which could not possibly have been formed by numerous, successive, slight modifications, my theory would absolutely break down.

A system which meets Darwin's criterion is one which exhibits *irreducible complexity*. By irreducible complexity I mean a single system which is composed of several interacting parts that contribute to the basic function, and where the removal of any one of the parts causes the system to effectively cease functioning. An irreducibly complex system cannot be produced gradually by slight, successive modifications of a precursor system, since any precursor to an irreducibly complex system is by definition nonfunctional. Since natural selection requires a function to select, an irreducibly complex biological system, if there is such a thing, would have to arise as an integrated unit for natural selection to have anything to act on. It is almost universally conceded that such a sudden event would be irreconcilable with the gradualism Darwin envisioned. At this point, however, 'irreducibly complex' is just a term, whose power resides mostly in its definition. We must now ask if any real thing is in fact irreducibly complex, and, if so, then are any irreducibly complex things also biological systems.

Consider the humble mousetrap (Figure 1). The mousetraps that my family uses in our home to deal with unwelcome rodents consist of a number of parts. There are: (1) a flat wooden platform to act as a base; (2) a metal hammer, which does the actual job of crushing the little mouse; (3) a wire spring with extended ends to press against the platform and the hammer when the trap is charged; (4) a sensitive catch which releases when slight pressure is applied; and (5) a metal bar which holds the hammer back when the trap is charged and connects to the catch. There are also assorted staples and screws to hold the system together.

Figure 1. A household mousetrap. The working parts of the trap are labeled. If any of the parts are missing the trap does not function.

If any one of the components of the mousetrap (the base, hammer, spring, catch, or holding bar) is removed, then the trap does not function. In other words, the simple little mousetrap has no ability to trap a mouse until several separate parts are all assembled.

Because the mousetrap is necessarily composed of several parts, it is irreducibly complex. Thus, irreducibly complex systems exist.

Molecular Machines

Now, are any biochemical systems irreducibly complex? Yes, it turns out that many are.

Earlier we discussed proteins. In many biological structures proteins are simply components of larger molecular machines. Like the picture tube, wires, metal bolts and screws that comprise a television set, many proteins are part of structures that only function when virtually all of the components have been assembled. A good example of this is a cilium. (7) Cilia are hairlike organelles on the surfaces of many animal and lower plant cells that serve to move fluid over the cell's surface or to "row" single cells through a fluid. In humans, for example, epithelial cells lining the respiratory tract each have about 200 cilia that beat in synchrony to sweep mucus towards the throat for elimination. A cilium consists of a membrane-coated bundle of fibers called an axoneme. An axoneme contains a ring of 9 double microtubules surrounding two central single microtubules. Each outer doublet consists of a ring of 13 filaments (subfiber A) fused to an assembly of 10 filaments (subfiber B). The filaments of the microtubules are composed of two proteins called alpha and beta tubulin. The 11 microtubules forming an axoneme are held together by three types of connectors: subfibers A are joined to the central microtubules by radial spokes; adjacent outer doublets are joined by linkers that consist of a highly elastic protein called nexin; and the central microtubules are joined by a connecting bridge. Finally, every subfiber A bears two arms, an inner arm and an outer arm, both containing the protein dynein.

But how does a cilium work? Experiments have indicated that ciliary motion results from the chemically-powered "walking" of the dynein arms on one microtubule up the neighboring subfiber B of a second microtubule so that the two microtubules slide past each other (Figure 2). However, the protein cross-links between microtubules in an intact cilium prevent neighboring microtubules from sliding past each other by more than a short distance. These cross-links, therefore, convert the dynein-induced sliding motion to a bending motion of the entire axoneme.

Figure 2. Schematic drawing of part of a cilium. The power stroke of the motor protein, dynein, attached to one microtubule, against subfiber B of a neighboring microtubule causes the fibers to slide past each other. The flexible linker protein, nexin, converts the sliding motion to a bending motion.

Now, let us sit back, review the workings of the cilium, and consider what it implies. Cilia are composed of at least a half dozen proteins: alpha-tubulin, beta-tubulin, dynein, nexin, spoke protein, and a central bridge protein. These combine to perform one task, ciliary motion, and all of these proteins must be present for the cilium to function. If the tubulins are absent, then there are no filaments to slide; if the dynein is missing, then the cilium remains rigid and motionless; if nexin or the other connecting proteins are missing, then the axoneme falls apart when the filaments slide.

What we see in the cilium, then, is not just profound complexity, but also irreducible complexity on the molecular scale. Recall that by "irreducible complexity" we mean an apparatus that requires several distinct components for the whole to work. My mousetrap **must** have a base, hammer, spring, catch, and holding bar, all working together, in order to function. Similarly, the cilium, as it is constituted, **must** have the sliding filaments, connecting proteins, and motor proteins for function to occur. In the absence of any one of those components, the apparatus is

useless.

The components of cilia are single molecules. This means that there are no more black boxes to invoke; the complexity of the cilium is final, fundamental. And just as scientists, when they began to learn the complexities of the cell, realized how silly it was to think that life arose spontaneously in a single step or a few steps from ocean mud, so too we now realize that the complex cilium can not be reached in a single step or a few steps. But since the complexity of the cilium is irreducible, then it can not have functional precursors. Since the irreducibly complex cilium can not have functional precursors it can not be produced by natural selection, which requires a continuum of function to work. Natural selection is powerless when there is no function to select. We can go further and say that, if the cilium can not be produced by natural selection, then the cilium was designed.

The Study of "Molecular Evolution"

Other examples of irreducible complexity abound, including aspects of protein transport, blood clotting, closed circular DNA, electron transport, the bacterial flagellum, telomeres, photosynthesis, transcription regulation, and much more. Examples of irreducible complexity can be found on virtually every page of a biochemistry textbook. But if these things cannot be explained by Darwinian evolution, how has the scientific community regarded these phenomena of the past forty years? A good place to look for an answer to that question is in the *Journal of Molecular Evolution*. *JME* is a journal that was begun specifically to deal with the topic of how evolution occurs on the molecular level. It has high scientific standards, and is edited by prominent figures in the field. In a recent issue of *JME* there were published eleven articles; of these, all eleven were concerned simply with the analysis of protein or DNA sequences. None of the papers discussed detailed models for intermediates in the development of complex biomolecular structures. In the past ten years *JME* has published 886 papers. Of these, 95 discussed the chemical synthesis of molecules thought to be necessary for the origin of life, 44 proposed mathematical models to improve sequence analysis, 20 concerned the evolutionary implications of current structures, and 719 were analyses of protein or polynucleotide sequences. There were zero papers discussing detailed models for intermediates in the development of complex biomolecular structures. This is not a peculiarity of *JME*. No papers are to be found that discuss detailed models for intermediates in the development of complex biomolecular structures in the *Proceedings of the National Academy of Science*, *Nature*, *Science*, the *Journal of Molecular Biology* or, to my knowledge, any journal whatsoever.

Sequence comparisons overwhelmingly dominate the literature of molecular evolution. But sequence comparisons simply can't account for the development of complex biochemical systems any more than Darwin's comparison of simple and complex eyes told him how vision worked. Thus in this area science is mute. This means that when we infer that complex biochemical systems were designed, we are contradicting no experimental result, we are in conflict with no theoretical study. No experiments needs to be questioned, but the interpretation of all experiments must now be reexamined, just as the results of experiments that were consistent with a Newtonian view of the universe had to be reinterpreted when the waveparticle duality of matter was discerned.

Conclusion

It is often said that science must avoid any conclusions which smack of the supernatural. But this seems to me to be both bad logic and bad science. Science is not a game in which arbitrary rules are used to decide what explanations are to be permitted. Rather, it is an effort to make true statements about physical reality. It was only about sixty years ago that the expansion of the universe was first observed. This fact immediately suggested a singular event--that at some time in the distant past the universe began expanding from an extremely small size. To many people this inference was loaded with overtones of a supernatural event--the creation, the beginning of the universe. The prominent physicist A.S. Eddington probably spoke for many physicists in voicing his disgust with such a notion (8):

Philosophically, the notion of an abrupt beginning to the present order of Nature is repugnant to me, as I think it must be to most; and even those who would welcome a proof of the intervention of a Creator will probably consider that a single winding-up at some remote epoch is not really the kind of relation between God and his world that brings satisfaction to the mind.

Nonetheless, the Big Bang hypothesis was embraced by physics and over the years has proven to be a very fruitful paradigm. The point here is that physics followed the data where it seemed to lead, even though some thought the model gave aid and comfort to religion. In the present day, as biochemistry multiplies examples of fantastically complex molecular systems, systems which discourage even an attempt to explain how they may have arisen, we should take a lesson from physics. The conclusion of design flows naturally from the data; we should not shrink from it; we should embrace it and build on it.

In concluding, it is important to realize that we are not inferring design from what we do not know, but from what we do know. We are not inferring design to account for a black box, but to account for an open box. A man from a primitive culture who sees an automobile might guess that it was powered by the wind or by an antelope hidden under the car, but when he opens up the hood and sees the engine he immediately realizes that it was designed. In the same way biochemistry has opened up the cell to examine what makes it run and we see that it, too, was designed.

It was a shock to people of the nineteenth century when they discovered, from observations science had made, that many features of the biological world could be ascribed to the elegant principle of natural selection. It is a shock to us in the twentieth century to discover, from observations science has made, that the fundamental mechanisms of life cannot be ascribed to natural selection, and therefore were designed. But we must deal with our shock as best we can and go on. The theory of undirected evolution is already dead, but the work of science continues.

This paper was originally presented in the Summer of 1994 at the meeting of the C.S. Lewis Society, Cambridge University.

Mike Behe received a Bachelor of Science degree in Chemistry from Drexel University in 1974 and the Ph.D. in Biochemistry from the University of Pennsylvania in 1978.

After doing postdoctoral work at the National institutes of Health he became assistant professor of Chemistry at the City University of New York/Queens College.

In 1985 he moved to Lehigh University in Bethlehem, PA, where he is currently Associate Professor in the Department of Biological Sciences.

Mike is married to the former Celeste LaTassa. They are members of St. Theresa Parish in Hellertown, PA, where they are raising their six children: Grace, age 10; Benedict, 9; Clare, 7; Leo, 5; Rose, 3; and Vincent, 1.

Look for Dr. Behe's new book published by the Free Press, *Darwin's Black Box: The Biochemical Challenge to Evolution*.

Chaparral and Fire

The California chaparral is a plant community composed of small shrubs and bushes that are adapted to fire. You can see the chaparral in the coastal mountains around San Diego, Los Angeles, Santa Barbara, San Luis Obispo, San Jose and other locations in the Coast Ranges, and also in the foothills of the Sierra Nevada and Klamath Mountains. The chaparral consists of tall bushes and small trees with dark green leaves. Most of the plants are less than ten feet high. When we say that plants are adapted to fire, we mean that the plants actually need fire as part of their lives, and that the plant species could die out if fire didn't occur. Sounds a little strange, doesn't it? Why would plants have anything to do with fire?

A couple of sprigs of chaparral plants are shown below. These are of **Manzanita** (or 'little apple' in Spanish because of the appearance of the fruit, which is not a true apple), **California Lilac** (Ceanothus) which has beautiful blue, white, or lilac blossoms in the early Spring, **Chamise** which has tiny white masses of flowers on the ends of its branches of tiny green leaves, and **Toyon** (or Christmas Holly, named because of the red berries that grow on the small tree around Christmas time---it is the Holly in Hollywood).

These plants usually have really stiff, tough little leaves...they are usually quite shiny and look like they have a waxy covering. The leaves actually do have a waxy covering, which seals in the water inside the leaf during the hot summer months. The wax causes the leaves to burn really hot in a fire, like little candles.

Such waxy-leaf plants are called sclerophyls, and have sclerophyllous properties. Try saying sclerophyllous three times and then wipe the spit off the screen!

Chaparral is found where the summers are long and hot, and where it might not rain for half a year or more. The hillsides are covered by stiff bushes that grow very close together, and you can't really walk through them without getting scratched up. As the bushes get older and older, more and more dead wood and leaves accumulate, until the chaparral can contain as much dead wood as living wood. So now we have little waxy leaves and a dried out woodpile to think about when we start talking about fires.

Fire can start in the chaparral because of lightning, or because of careless smokers. The vegetation will usually be dense enough to allow a really big fire after it is about 10 years old, and often very old chaparral (40 years old or older) will have so much dead wood that flames will be taller than houses and can reach right across streets.

Once fires start they can move across the hillsides very quickly. There is lots of heat given off. One fire in 1994 produced the heat of five atom bombs in a single hour. You sure didn't want to get in the way of that wildfire!

The waxy leaves and the dead wood cause a hot fire, and when it is over there is not very much left to see. Just a few burned stumps and sticks, piles of ash, and nothing apparently left alive. It is pretty depressing to look at.

So why was this good for the plants? How can dying in a fire help a plant? The answer lies in the seeds of some of the plants, and in the special nature of the blackened stumps of some of the others.

Now just imagine what it would be like to be a little seedling trying to grow under all of the big plants if they were still there. Down on the ground it would be too shaded for light to reach the new little leaves, and the big plants would gobble up all of the water. The little seedling would probably die, and there would be no room for it anyway.

After the fire there is space to grow, and there is water to drink and beautiful sunlight for energy. You might guess that all of the seeds would have burned up in the fire, but you would be wrong. In fact, the seeds may have been in the soil for years, just waiting for the fire. These seeds have a special outer coat that doesn't allow water to come in and cause the seed to sprout.

The fire causes the outer coat to break up. The cause is either the heat from the fire, or chemicals from the smoke... maybe both.

The rain can then get into the seed, and up it sprouts into a world of wonderful light. It is kind of like the parent plant knowing it is getting old and woody, and deciding to get out of the way to make room for the kids.

The waxy covering on the parent's leaves often has another purpose, and that is to burn with great heat. This might seem a little weird, but it is to make that the less fire-protected seeds of other plants are killed, as they might have taken away water and sunlight from the plant's own seedlings.

Some species of chaparral can sprout from their stumps. These bushes keep a lot of energy in their roots, and after the top of the plant burns off, they simply sprout new leaves and branches. In this way, some plants may survive many fires, and could be hundreds of years old. Below we see a so-called "stump-sprouter" on the left, and a "seeder" on the right.

And so the plant species continue, and soon the hillside looks like it did before. The new sprouts and seedlings are really tasty for wildlife, and so life quickly returns. And the plants grow, get old, there is a fire, the plants grow, get old, there is another fire.....and on....and on....

Giardia lamblia

CDC/MMWR

NIH/PubMed

Agricola

1. Name of the Organism:
Giardia lamblia

Giardia lamblia (intestinalis) is a single celled animal, i.e., a protozoa, that moves with the aid of five flagella. In Europe, it is sometimes referred to as *Lamblia intestinalis*.

2. Nature of Acute Disease:

[Giardiasis](#) is the most frequent cause of non-bacterial diarrhea in North America.

3. Nature of Disease:

[CDC Case Definition](#)

[What is a "Case Definition"?](#)

[Overview of Public Health Surveillance](#)

Organisms that appear identical to those that cause human illness have been isolated from domestic animals (dogs and cats) and wild animals (beavers and bears). A related but morphologically distinct organism infects rodents, although rodents may be infected with human isolates in the laboratory. Human giardiasis may involve diarrhea within 1 week of ingestion of the cyst, which is the environmental survival form and infective stage of the organism.

Normally illness lasts for 1 to 2 weeks, but there are cases of chronic infections lasting months to years. Chronic cases, both those with defined immune deficiencies and those without, are difficult to treat.

The disease mechanism is unknown, with some investigators reporting that the organism produces a toxin while others are unable to confirm its existence. The organism has been demonstrated inside host cells in the duodenum, but most investigators think this is such an infrequent occurrence that it is not responsible for disease symptoms. Mechanical obstruction of the absorptive surface of the intestine has been proposed as a possible pathogenic mechanism, as has a synergistic relationship with some of the intestinal flora.

Giardia can be excysted, cultured and encysted in vitro; new

isolates have bacterial, fungal, and viral symbionts. Classically the disease was diagnosed by demonstration of the organism in stained fecal smears.

Several strains of *G. lamblia* have been isolated and described through analysis of their proteins and DNA; type of strain, however, is not consistently associated with disease severity. Different individuals show various degrees of symptoms when infected with the same strain, and the symptoms of an individual may vary during the course of the disease.

Infectious Dose - Ingestion of one or more cysts may cause disease, as contrasted to most bacterial illnesses where hundreds to thousands of organisms must be consumed to produce illness.

4. Diagnosis of Human Illness:

Giardia lamblia is frequently diagnosed by visualizing the organism, either the trophozoite (active reproducing form) or the cyst (the resting stage that is resistant to adverse environmental conditions) in stained preparations or unstained wet mounts with the aid of a microscope. A commercial fluorescent antibody kit is available to stain the organism. Organisms may be concentrated by sedimentation or flotation; however, these procedures reduce the number of recognizable organisms in the sample. An [enzyme linked immunosorbant assay](#) (ELISA) that detects excretory secretory products of the organism is also available. So far, the increased sensitivity of indirect serological detection has not been consistently demonstrated.

5. Associated Foods:

Giardiasis is most frequently associated with the consumption of contaminated water. Five outbreaks have been traced to food contamination by infected or infested food handlers, and the possibility of infections from contaminated vegetables that are eaten raw cannot be excluded. Cool moist conditions favor the survival of the organism.

6. Relative Frequency of Disease:

Giardiasis is more prevalent in children than in adults, possibly because many individuals seem to have a lasting immunity after infection. This organism is implicated in 25% of the cases of gastrointestinal disease and may be present asymptotically. The overall incidence of infection in the United States is estimated at 2% of the population. This disease afflicts many homosexual men, both HIV-positive and HIV-negative individuals. This is presumed to be due to sexual transmission. The disease is also common in child day care centers, especially those in which diapering is done.

7. Course of Disease and Complications:

About 40% of those who are diagnosed with giardiasis demonstrate disaccharide intolerance during detectable infection and up to 6 months after the infection can no longer be detected. Lactose (i.e., milk sugar) intolerance is most frequently observed. Some individuals (less than 4%) remain symptomatic more than 2 weeks; chronic infections lead to a malabsorption syndrome and severe weight loss. Chronic cases of giardiasis in immunodeficient and normal individuals are frequently refractile to drug treatment. Flagyl is normally quite effective in terminating infections. In some immune deficient individuals, giardiasis may contribute to a shortening of the life span.

8. Target Populations:

Giardiasis occurs throughout the population, although the prevalence is higher in children than adults. Chronic symptomatic giardiasis is more common in adults than children.

9. Food Analysis:

Food is analyzed by thorough surface cleaning of the suspected food and sedimentation of the organisms from the cleaning water. Feeding to specific pathogen-free animals has been used to detect the organism in large outbreaks associated with municipal water systems. The precise sensitivity of these methods has not been determined, so that negative results are questionable. Seven days may be required to detect an experimental infection.

10. Selected Outbreaks:

Literature references can be found at the links below.

Major outbreaks are associated with contaminated water systems that do not use sand filtration or have a defect in the filtration system.

[MMWR 38\(23\):1989](#)

In April 1988, the Albuquerque Environmental Health Department and the New Mexico Health and Environment Department investigated reports of giardiasis among members of a church youth group in Albuquerque. The first two members to be affected had onset of diarrhea on March 3 and 4, respectively; stool specimens from both were positive for *Giardia lamblia* cysts. These two persons had only church youth group activities in common.

[MMWR 32\(50\):1983](#)

On August 8, 1983, the Utah Department of Health was notified by the Tooele County Health Department (TCHD) of an outbreak of diarrheal illness in Tooele, Utah, possibly associated with a contaminated public water supply that resulted from flooding during Utah's spring thaw.

[Morbidity and Mortality Weekly Reports](#)

For more information on recent outbreaks see the CDC.

Frequently Asked Questions about *Giardiasis*.

FSIS Parasites and Foodborne Illness [Resource page](#)

Giardia duodenalis, cause of giardiasis (GEE-are-DYE-uh-sis), is a one-celled, microscopic parasite that can live in the intestines of animals and people. It is found in every region throughout the world and has become recognized as one of the most common causes of waterborne (and occasionally foodborne) illness.

12. Molecular Structural Data:

None currently available.

13. FDA Regulations or Activity:[Bacteriological Analytical Manual.](#)

Current recovery methods are published in this FDA methodology reference. The FDA continues to actively develop and improve methods of recovering parasitic protozoa and helminth eggs from foods.

[MC 2000 DRUG CASE](#)

"Rescuers have an important role in the first aid medical treatment of victims"

World Congress on Drowning

Hypothermia treatment starts in the field by rewarming (stabilizing) victims with equipment supplying warm humidified air or oxygen and warm IV-fluids to minimize core-temperature afterdrop.

The growing popularity of outdoor recreation, has resulted in greater demand for an effective on-site method of treating hypothermia.

Other than for mild cases, the most effective and safest treatment for all levels of hypothermia is the addition of heat to the body core, rather than via the periphery.

Research on hypothermia conducted at the University of Victoria (Victoria, B.C., Canada) developed the survival behaviors such as the [HELP - and the - HUDDLE](#) - survival positions, now promoted world wide, the cold water [immersion survival - time table](#) and the Uvic Thermo-float jacket.

Two team members (Robert Douwens and Dr. John Hayward) also developed and patented the hypothermia treatment technology [RES-Q-AIR system](#).

What is the major injury rescue specialists face?

"Without a doubt hypothermia," says Bob Ayres, Canadian Coast Guard Rescue Specialist Coordinator, . . . "Due to the cold waters on our coast we have adapted specialized equipment, including inhalation rewarming units known as

the [RES-Q-AIR](#) to stabilize and begin warming in the field."

Info: (323) 377-3523 Vendors: (323) 428-1666

Please note - dates, times, etc are outside of my control. A powwow can be cancelled for nearly any reason, including weather. Information numbers are included and should be used for more information. E-mailing me about vender applications, complaints, directions, etc will likely be ignored. I do not run these events, I only list them. I will be at the events that have OCB Will Be There listed on them, and possibly other events as well. Feel free to stop by and thank me if you'd like.

- Gary

 2200 Sunset AVE.

Farmington New Mexico

Gourd Sessions 11:00am & 6:00pm Grand Entries 12:00pm & 7:00pm Head Staff TBA

shy_sal2004@yahoo.com

Info: (505)324-0352 ext 1449

Events should be submitted no less than six weeks before they begin, and submissions should include a vender application as well.

Submissions sent in may or may not be posted on this calendar depending upon my time, my mood, the odd quirks in the server and for just about any other reason under the sun.

If you wish to yell at me for not having an event listed, a problem with an event listing, etc., the fee is \$75 per hour, three hours minimum, payable in advance.

Los Angeles, CA

AMERICAN INDIAN ARTISTS MENTOR PROGRAM: Making Storytellers
with Barbara Moranda, Laguna Pueblo

Join us in a fun-filled weekend created to celebrate National American Indian
Heritage Month. The 2003 Intertribal Marketplace offers our guests one of the
most unique events in Southern California. Over 100 nationally recognized
American Indian and Canadian First Nation's artists will sell and display their

work. Spend time with Featured Artist, Jimmy "Ca Win" Calabaza. Enjoy live music, dance, storytelling, gourmet food, and artist demonstrations while the children create their own works of art in the Children's Craft Village. Parking is available along Marmion Way or take the new Gold Line and exit at the Southwest Museum stop.

Admission: \$8.00 for adults; \$6.00 for seniors and students; children 6 and under are free. Show your Gold Line stub and receive \$1.00 off your paid admission.

Native Voices at the Autry Theatre Festival: Standing Up Stories by Julie
Pearson-Little Thunder (Creek)

Los Angeles, California.

Directed by Marie Clements (Metis) 8:00 p.m. This family play explores how
Indian women extend their families by taking other women to be their adopted
relatives. The usually informal process of intertribal adoption is a lifelong
commitment to be there for the adopted relative, sharing the duties as well the
privileges of a family member. The stories include a young professional woman's
relationship with her adoptive Yuchi grandmother, a Cheyenne woman who
rescues her adopted niece from an abusive relationship, and a Cherokee language
class, the night after 9/11. Wells Fargo Theatre Autry Museum of Western
Heritage 4700 Western Heritage Way Los Angeles, CA 90027 (323) 667-2000
These staged readings are free in the Autry Museum's Wells Fargo Theatre.
Reservations are strongly recommended. To RSVP, please call 323.667.2000 ext.

354. Native Voices at the Autry is devoted to developing new works for the stage by Native Americans and is made possible in part by grants from Wells Fargo, the City of Los Angeles Cultural Affairs Department, the Los Angeles County Arts Commission, the National Endowment for the Arts, JPMorganChase, and the Sidney Stern Memorial Trust.

THE AMERICAN WEST

A CELEBRATION OF THE HUMAN SPIRIT...

*We are all Pioneers . . .
... Pathfinders on the Trails of Old and New Frontiers . . .*

A Presentation of the History and Development of the American West!

Western Gift Ideas

Within these pages you will find the History and Development of the American West, from the Frontier and Pioneer days of the Wild West, to today's Modern West.

Featuring: Westward Expansion, Western Trails, America's Freedom Documents, Cowboys, Indians, Native Americans, Pioneers, Trappers, Scouts, Gunslingers (*the whole dang blang shootin' match is heah, bucko!*), Outlaws, Gunbattles, Ghost Towns,

Gold & Silver Mining, Saloons, Dodge City, Tombstone, O.K. Corral, Virginia City, Doc Holliday, Kit Carson, Wyatt Earp, Wild Bill Hickok, Davy Crocket, Daniel Boone, Billy the Kid, Jesse James, Buffalo Bill, Sitting Bull, Roy Rogers, Western Theme Parks, Museums and Exhibitions, the Prairie, Buffalo, Horses, Rodeos, Stage Coaches, Frontier Railroads, River Steam Boats, and anything of interest or of significance west of the Mississippi River. We carry a lot of links to other major high quality western-type web sites.

Search AmericanWest for a topic.

A special segment of this site is devoted to the [Modern West](#) with emphasis on the Information Society, including . . .

THE NEXT FRONTIER - The Wonders of the Universe!

...Definition of The West:
....These are the 22 Western States
.... that form the American West
....(west of the Mississippi River).

AmericanWest [AWARDS](#).

Our [Banner Exchange](#) page.

[Stories](#) by AW's Visitors.

[Reviews and Comments](#) from visitors to the site.

Upcoming Events

● [American Westward Expansion](#)

Includes maps of the Lewis & Clark Expedition, the Santa Fe Trail, the Oregon Trail, the Mormon Pioneer Trail, the Pony Express Route, the Overland Trail and Key Dates of Expansion. A story on frontier transportation explains the important role of the transcontinental railroad and the railroad companies.

● [Native American Tribes and Nations](#) Native Americans' "CENTER OF THE UNIVERSE", your one-stop source for in-depth and extensive information on Native Americans, covering the past, the present and the future. There are also stories on famous Indian Chiefs and many 19th century pictures. Many Home Pages for Native American Nations, Organizations, Institutions and Individuals. Many information sources are from the Government and there are possibilities to contact Representatives directly via email.

● [European Emigration](#)

As an example of European mass emigration to America propelling the expansion westward during the 19th century, the Swedish case is rather typical. Explained are the reasons for leaving the *old country* and what the Swedes could expect to find in the *new country*. There is also a story of Bengt Lindeblad's (the originator of this site) own emigration experiences about 100 years later. Many pictures and many links to other information sources.

● [Gunslingers and Outlaws](#)

From Doc Holliday, Wild Bill Hickok, and Jesse James to Butch Cassidy and the Sundance Kid. Some famous Gunbattles.

...THE WHOLE DANG BLANG SHOOTIN' MATCH IS HEAH, BUCKO!

● [Pioneer Towns, Forts and Other Places](#)

The Alamo. Pioneer towns such as Tombstone, Virginia City and Carson City, and Dodge City are featured as well as ghost towns Like Bodie, CA and Jerome AZ. Plenty on the Black Hills and Deadwood, South Dakota, too.

● [Western Pioneers, Frontiersmen, Mountain Men and Fur Traders](#)

Buffalo Bill, Davy Crockett, Daniel Boone, James Bowie, Kit Carson and other well-known Westerners.

● [Women of the West Museum](#)

● [Women of the West](#) and life on the Plains.

● [Susan LaFlesche Picotte](#) and life on the Plains.

A new section (suggestions are encouraged!): Science in the 19th century

● [The Progress of Medicine in the 1800's](#)

● [Nikola Tesla](#)

● [Thomas Edison in Menlo Park](#)

● [Medicine in the Civil War](#)

● [Scientific Medicine](#)

● [Florence Nightingale](#)

● [Smithsonian - Power Machinery](#)

● [American Archaeology](#)

● [Cowboys](#)

Here you can round-up all the information you'll ever need about Cowboys.

● [CowboyPoetry.com](#) Here at CowboyPoetry.com we have the internet's largest collection of Cowboy Poetry. Among other honors, we've been recognized as a "hot site" by USA Today, a "preferred site" by Read the West, and featured as the "Best of the West" site at The Wyoming Companion. Our site gets updated with new poetry twice monthly, and each update is accompanied by an email newsletter to our many visitors.

● [Cowboy Poetry](#)

● [Western Music](#)

Images From The Old West

● [Searchable database](#) of images, U. of Nebraska Press

● [WESTERN FILMS](#)

● Rattlesnake Jack's [Old West Clip Art Parlour](#) and Emporium.

● [Selected Images](#) From the National Archives.

● [The National Park Service](#)

Our collected heritage, including archeology, historic places, structures, landscapes and museums. An excellent way to get involved in our heritage !!

● [Wells Fargo Museum](#)

Wells Fargo Bank has a web-site with much material on the Old West. Let's start at their Museum.

● [Buffalo - and other animals](#)

Buffalos once roamed from Canada to Mexico and all over the American plains in very large numbers. Buffalos were also the center of life for the plains tribes of Native Americans, providing them with food, shelter, clothing and spiritual inspiration.

● [Research Areas](#)

A tremendous amount of historical information about the American West.

● [Contribution from Schools to the American West](#)

Schools and students studying the History and Development of the American West are welcome to contribute stories and graphics to this section through their web-site (we will link up to it free of charge, in return we hope you will establish a link to our site providing that the same high standard is applied to the contributed material). See our first contributions. We are also adding links that could be useful to teachers and students.

● [America's Freedom Documents](#)

The migration westward was driven by the pursuit of happiness, liberty, freedom and justice. Here is a fantastic link to the very documents that "We the People" had agreed upon to help facilitate our goals.

● [The American Revolution](#)

This site contains a complete American history, from the colonial period until modern times, including westward expansion.

● [Academy of Achievement](#)

Brings you face to face with the extraordinary individuals who have shaped the twentieth century. It is an amazing collection, not of mere artifacts, but of people and ideas that fill you with inspiration, encouragement, and the will to achieve.

● [The Modern West](#)

- Libraries
- New Exciting Aquariums
- The World's Largest Mall
Over 800 stores and services, as large as 48 city blocks and a hotel in the mall.

THE JEFF DAVIS SHOW

Austin, Texas

Hello -- my name is Jeff Davis, I have been involved in the freedom movement since 1990. We at The Jeff Davis Show have made a commitment to restore America back to a land of real freedom - not the illusion of freedom spoon fed by the power Elite. It is a big job, never in history have so many resources been pitted against a people yearning to be free. Many do not realize the fact- they are not free. This is our battleground. We are battling a system of mind control, which can only be defeated by the truth. This is our mission at The Jeff Davis Show. We refuse to stop, in fact over the next year we will be bringing incredible truth information to the people, that cannot be disputed.

We also believe that freedom can be restored. Remember Rome and Babylon both fell. We ask that you give up on your Establishment rag paper and send the savings to us. Just \$10.00 a month, goes a long way when you are spreading truth. Purchase our television show video's- they are good and non- copyrighted. If you have a business or know someone who does, you can advertise with us ! The folks who help our efforts- we will work hard for them. My personal Guarantee !! Our enemies spend vast resources - attempting to keep people dumbed-down and diverted. However, when the truth about the establishment lies are revealed, it doesn't take much for eyes to be opened. I know this first hand- ten years ago, I was your average brainwashed sheep.

I do this not for fame or fortune -- only for freedom, if not for me, then for our children and grandchildren. Thank you for your prayers and support.

God Bless us all !!

You can send donations to:

" The Jeff Davis Show"

PO Box 200357

Austin, Texas 78720

Thank you for visiting and your interest in our efforts

POWERFUL INFORMATION !!

"The Jeff Davis Show" has for many years provided high quality and very informative Television programs

Below are some of the best!!!

1. "The Destruction of America"

The world famous 90-minute presentation by host Jeff Davis. A powerful explanation of the various mechanisms employed by the globalists, including diversions, distractions, the Hegelian dialectic, and psychological warfare. This documentary puts all the pieces of the puzzle together. Who the rulers are, what are their goals, origins and a list of various control factions. Comments from viewers have included "a

Masterpiece of information." A MUST SEE for all people of the world !!

\$20.00

Also available on audio cassette -- \$ 7.00

2. "Justice for the Davidians"

A 2-hour interview with Waco survivors Katherine Matteson, Clive and Edna Doyle. A powerful indictment of the de facto government's Multi Jurisdictional Task Forces. Includes exclusive footage, compiled from independent sources.

\$20.00

3. "Richard McLaren and Richard Keyes interview"

Possibly the last live interviews with these Republic of Texas members from their respective jails. Very interesting: much different information than the establishment media released. A truthful presentation by forgotten P.O.W's.

\$20.00

Special Offer: Any two videos for \$35.00 or all three for \$50.00 Please allow 2-3 weeks for delivery.

In addition to these videos, we will be making cassette tapes and other information available by request.

NEW!! Books by Author Texe Marrs, founder of Living Truth Ministries

1. "Circle of Intrigue"

Cloaked in mystery and shrouded in secrecy, ten ruthless men comprise the "Inner Circle" of the Illuminati conspiracy. This book reveals the shocking truth about their plans for global conquest.

\$15.00

2. "Project Lucid"

The nightmarish reality of the 666 Universal Human Control System.

Using massively powerful computer databases linked to surveillance mechanisms, the "Mark of the Beast" system which the slave masters intend to become a reality looms in the distance unless stopped. A powerful wake-up call for the information age.

\$15.00

3. "Big Sister is Watching You"

What do you really know about Hillary Clinton and The White House Feminists who now propagate the U.S. Government? The

real truth is revealed in this shocking book.

\$12.00

*New !! Book --- Common Sense --An Introduction to the
New World Order*

Written by former Austin, Texas city Council member George
Humphrey

\$ 5.00

RESTOP® (REST-STOP)

You know the feeling. You've got to go, but there are no restroom facilities around. You don't want to use the great outdoors and face possible embarrassment, and the last thing you want is to be forced to use an unclean or unsafe facility. What option do you have?

RESTOP gives you two options when you are on the go and without restroom facilities.

RESTOP 1 is designed for liquid waste while **RESTOP 2** handles both liquids and solids. Both contain our exclusive blend of polymers and enzymes to instantly gel liquid and break down solid waste. RESTOP's patented design prevents leakage and fully contains waste, even if the bag is dropped! What's more, both products can be disposed of in any trash receptacle—no special dumping requirements, harsh chemicals, or hassle like other portable toilets!

Why use RESTOP?

- RESTOP is completely **portable**. A four pack of RESTOP 1 can be easily carried in a purse, backpack, or glove compartment, ready when you need it. And it's lightweight!
- RESTOP is completely **spill proof**. Liquid waste is turned into a odorless gel instantly on contact. And RESTOP's patented one-way valve prevents leakage, even if the bag is turned upside down!
- RESTOP is **sanitary**. Since RESTOP is designed for a single use, there's no chance of disease or smell like a public restroom.
- RESTOP is **disposable**. Unlike bottles or other containers, all RESTOP products can be disposed of legally in any normal trash container. And RESTOP's unique enzyme formula breaks down waste into

environmentally-friendly components.

What kinds of people use RESTOP products?

[Aviators](#)

[Boaters](#)

[Anglers](#)

[Campers](#)

[Hunters](#)

[In the Car](#)

[Family Activities](#)

[Potty Training](#)

[Truckers](#)

Anyone who can't get to a restroom can use RESTOP products! Pilots, boaters, campers, hikers, hunters and families all love RESTOP because it can go anywhere, stored until you need it. Keep a supply in the car to avoid the problem of finding a restroom when you need it. Perfect for those who care about the environment and who don't want to pollute with human waste. Click on the icon to find out how people use RESTOP.

Contact us today, and never be far from a RESTOP!

The Survival Foods And Gardening Section

SAVING MONEY WITH A THERMOS BOTTLE

By Kurt Saxon

Many subscribers write that they will eventually buy all my books but they can't afford them at this time. Many are students on limited allowances. Some are on Social Security or pensions. Others are on Welfare, as I was after an injury, when I got \$86.00 per month in 1969. I paid \$50.00 for rent and had only \$36.00 left for food and incidentals. Even so, I ate better than before. Prices were indeed lower then but, surprisingly, the costs of the more basic foods have hardly changed.

For instance, 60 pounds of hard red winter wheat, the highest in protein, minerals and vitamins, averages \$8.00 (240 breakfasts at 4 cents each). Brown rice, also higher in nutrition than white, costs \$14.00 for 25 pounds. Also 200 servings since rice swells twice as large as wheat. These are bought in bulk at any feed and seed store.

Wheat and rice are the staple foods of billions and, if prepared my way, will fill you up, give you boundless energy; and cost nothing, if you consider that the saving in gas or electricity will offset their purchase prices.

I do not mean that wheat and rice, plain, is what I am asking you to live on. When is the last time you have eaten a potato plain? I am simply suggesting you process all your food in inexpensive, energy-saving ways and eat better than you ever have for less than \$10.00 per week. Then you can not only afford all my books but many other things you have wanted but had to do without because most of your food budget goes to pay others to do what you should learn to do for yourself.

The thermos and the dehydrator are first steps in eating better for so much less. As a Survivalist, you will have to understand food

preparation or you might as well eat, drink and be merry in the short time you have left.

A great factor which makes this practical and easy to understand is that since it is by a man, it is basic, gut-level and moron-simple. You won't even need to open a cookbook.

First the thermos. There are three kinds but only one is practical. Forget the cheap, plastic ones lined with Styrofoam. These might cook oatmeal and white rice but do not have the heat holding power you need. Silvered glass thermoses are fine, but a bump will break them. Also, since you are going to do actual cooking and will use a fork to remove the contents, they will not hold up.

The only practical cooking thermos is the Aladdin Stanley. It is lined with stainless steel, is well insulated and will keep steaming hot for up to 24 hours and holds a quart. It is also unbreakable, with a lifetime warranty. It costs \$22.00 at Wal-Mart or can be ordered through any sporting goods store. It would save you its price in a few days. If you have a family, get two or three.

Most foods cook at 180 degrees or more. We are used to boiling, which is 212 degrees, and foods do cook faster, the higher the temperature. But if time is not important, cooking at a lower temperature is even better as most vitamins are not broken down. Thus, if you cook at a minimum heat, you save nutrition.

A great factor in thermos cooking is the saving in the cost of energy. Whereas it would take about two hours to cook whole-grain wheat or nearly an hour to cook brown rice. Thermos cookery takes only five minutes to cook anything. So it is indeed possible to save as much in energy as you spend on the food. You can imagine the convenience of thermos cookery in camping, which would save on wood, weight of food carried, and no food odors to alert bears or enemies.

Thermos cookery is also an advantage to anyone living where he is not allowed to cook. There are no cooking odors to tip off the landlord.

First, you need the thermos. Then you need a heat source. If you are in a

non-cooking room, buy a cheap, one burner hot plate from your local Wal-Mart, Target, Sears etc. You will need a one quart saucepan. You will also need a special funnel to quickly pour the pan's contents into the thermos, plus a spoon or fork to help the last of the food into the funnel.

To make the funnel, cut off the bottom four inches from a gallon plastic milk container. If you do not buy milk or cannot find an empty container, go to your nearest laundromat. You will find in the trash receptacle, an empty gallon bleach bottle. Use that the same as the milk container but wash it until there is no more bleach odor.

The first step in thermos cookery is to fill the thermos with water up to the point reached by the stopper. Empty the water into the saucepan and make a scratch or other indelible mark at the water's surface inside the saucepan. This will allow you to put just enough water in the saucepan, as too much will leave food out and too little will give you less cooking water.

Just to test how the cooker works, start with four ounces of wheat. You do not need to buy 60 pounds. You can buy two pounds from your health food store for about \$.80 This would give you eight meals at 10 cents each.

In the evening, put four ounces in your saucepan, plus a half-teaspoon of salt to prevent flatness, even if you intend to sweeten it. Fill to the mark with water. (If you have hot water, let the tap run until it is hottest. Tests have shown that less energy is used in using hot tap water than in boiling from cold.) Bring the contents to a rolling boil, stirring all the while. This will take from three to five minutes.

Then quickly, but carefully, swirl and pour the contents into the funnel and help any lagging matter from the pan to the funnel and into the thermos. Cap firmly but not tightly, shake and lay the thermos on its side, to keep the contents even.

Next morning open the thermos and pour its contents into the saucepan. With four ounces of dry wheat, you will now have at least 3/4 pound of cooked wheat and about a pint of vitamin and mineral enriched water. It has a pleasant taste. Drink it.

You can now put milk and sweetener on it or margarine, salt and pepper, etc. If you can eat the whole $\frac{3}{4}$ of a pound, you will be surprised at how energetic you feel for the next several hours. An added bonus is its high fiber content.

Having tried the four ounce portion, you might next use eight ounces. This will absorb most of the water. It is unlikely that you could eat a pound and a half of cooked whole grain wheat. You can either divide it and eat the other half for supper or if you are a family man, make it the family breakfast food to replace the expensive brand.

If you have children, get them into the act by fantasizing they are Rangers on a jungle patrol.

For lunch, prepare a few ounces of hamburger or other meat chopped finely, plus chopped potatoes and other vegetables the night before. After breakfast, put these and the right amount of water in the saucepan and prepare as usual. At lunchtime you will have a quart of really delicious stew. Since nothing leaves the thermos in cooking, as contrasted to the flavor leaving stew cooking on the stove, you can understand the better tasting, higher vitamin content of thermos stew.

Lunch and possibly supper should not cost you more than 25 cents if you study the article on the dehydrator. Jerky and dried vegetable stew is good and costs little.

The brown rice dishes could also be either a main course or desert. Brown rice has a much greater swelling factor than wheat so four ounces of rice will pretty much fill the thermos. You can put vegetables and meat in it to cook or try a favorite of mine. It is four ounces of brown rice, 9 cents; one ounce of powdered milk, 10 cents in a large box; two ounces of raisins, 22 cents; one teaspoon of salt; some cinnamon and four saccharine tablets. Cook overnight. This is 46 cents for 1 $\frac{1}{2}$ pounds of desert.

With some experimenting, you can become an expert in thermos cookery. If you are single and live alone, you could, conceivably, eat nothing except what you cooked in a thermos. But if you are married,

and especially if you have children, don't push it. Even with the economy of this system, it's not worth alienating your family. If your wife doesn't like it, challenge her to make the food tastier and think up some thermos recipes. You might also tell her the advantages of thermos cookery.

For one thing, she would spend much less time in the kitchen. What with the expected brownouts, she could do all the cooking in five, ten, fifteen minutes, depending on how many thermos bottles she used. Another important factor is that, especially during the heat waves, the home would not suffer the added heat from the kitchen. This would also cut down on the air conditioning costs.

A tip you may not have known is that the pilot light in a gas stove not only raises the temperature in the kitchen but also accounts for a fourth of all the gas burned in the stove. Matches are much cheaper. Turn the pilot light off.

Be sure to get SURVIVOR Vol. 1 for a full course on inexpensive but tasty and nourishing food, plus sprouting for green vegetables, soy milk, tofu, etc.

Internet *Pizazz*TM Promotion Team

From San Diego to Seattle, this professional team of marketers, programmers, designers, and artists create business successes online. Internet Pizazz uses the Internet as a powerful tool for market research and promotion. They understand what your business needs. When you are ready to start a promotion campaign, Internet Pizazz will use their extensive knowledge to make the computers of the world serve your business!

Websites are like any other address or phone number, they *must be promoted* if you want customer response.

The group that gives *Pizazz*TM to Internet presentations are eclectic and diverse. Independent contractors are free to choose which projects they will devote themselves to. They like what they do; they believe in the products and services of their clients. Combining experience and creativity with honest enthusiasm is one key to tremendous success. We'd like to have the opportunity to consider the needs of your company. Please email or call us.

-

Ads On-line

Ads On-line is an electronic publication in the San Diego area. The business is an information computer bulletin board serving the 619 and 760 area codes of southern California.

Archetype

Empowers your printed word!
Evaluation, editing, design, typesetting, laserprinting.

HMC

HMC consultants have been in the San Diego/Orange County areas of California since the early 1980s. The personnel have been involved in the computer industry since the early 1960s. HMC has extensive background in hardware design, software design and implementation, and overall system integration. Some industries which have benefitted from the expertise of HMC are clinical/pathology laboratories, retail point-of-sale, manufacturing and distribution companies, and small business organizations.

The primary strength of HMC is complete service to the client, including recommendations, installation, training, programming, and support services.

Infotainment Computers

Infotainment Computers specializes in *Information and Entertainment* computer systems. The owner is an engineer with years of high-tech design experience. Their philosophy of selling is based upon doing what is best for the customer. The service is so good that some word-of-mouth referrals are still coming in *years* after the original customer made a purchase.

Pacific Coast Software

Pacific Coast software is a major web provider. We urge you to [see their site for yourself](#). The cutting edge technology running on their servers defines the state-of-the-art for Internet commerce systems.

Prevision Associates

Prevision Associates has decades of graphic design experience. Corporate design and gallery art have been used and shown world wide since the 1960s.

Individuals by first name

Julio- Market researcher and programmer.

Robert- Future projects research.

Roger- Marketing consultant.

Here's Roger's resume'

BSEE degree in electronic engineering.

16 years in the business of specifying and developing computer systems.

Senior marketing specialist.

Professional affiliations:

- **Chairman of American National Standards Institute (ANSI) X3A1-Optical Character Recognition and Bar Code Print Quality.**
- **Member of American Production and Inventory Control Society (APICS)-San Diego chapter.**

Engineering experience:

System/project engineering on industrial process control systems, mini-computer systems. A senior project quality assurance engineer working with highly specialized industrial computer systems and shared processor data entry computer systems.

Developed marketing and sales training aids.

Made numerous national presentations and seminars for VAR/Distributors.

Worked with end-users and VAR/Distributors.

Extensive experience in barcode and automatic identification systems area.

Developed systems for industrial, retail, government and hospital environments.

Developed programs for beta site testing.

A Taste of Nature; Edible Plants of the Southwest and How to Prepare Them.

© 1994 Kahanah Farnsworth

- Contents of these web pages:
- [Introduction to the book](#) This page.
- [Plant illustration, \(image\)](#). This page.
- [Ordering information](#). This page.
- [FREE recipe will be sent to you by email, find out how to get it!](#) Another page.
- [Return to The Official Edible Plants Home Page](#) Home page.

Introduction-

"This handbook is designed to be user friendly. All of the edible plants were selected for their availability, easy recognition, and usefulness. They are common throughout the Southwest and similar plant communities elsewhere. Endangered edible plants and edible plants which might be mistaken for poisonous plants are not included. Recognizing the different plants and knowing their uses adds a new dimension to our enjoyment of nature. It increases our appreciation of the great diversity of plants and the uniqueness of each one. The beauty and usefulness of plants helps to enrich our lives.

When you go foraging, please remember that we are gatherers and not destroyers. It is usually necessary to harvest only a small part of a plant in order to use it. Most plants will continue to grow and produce if they are left in the ground and only some of the leaves or a portion of the stems are removed. If there are only one or two plants growing in a location, please pass them by and give them a chance to propagate. It is also important to know if your edible plant is growing in a healthy environment where there are no chemical sprays, polluted water, or car fumes.

All of the recipes in this book have been eaten and enjoyed by people of all ages. If you have a favorite recipe, but can't locate a specific plant, it is often possible to substitute a comparable plant in its place."

This is what Orach looks like, if you click on the image you will move to the FREE Orach Quiche á la Greek! recipe page. Please be prepared to give your email address. To find out how to properly identify Orach and find it in the wild, you would do best to buy the book and study it. In fact, the book makes a great addition to your daypack while hiking or camping! With the knowlege in this book you may never have to pay for salad again. You don't have to ever be bored by Iceberg lettuce again, these plants will put variety in your diet and enhance your gourmet cooking abilities.

How to order this information-packed book:

\$10.00 (US dollars) for the book.

\$2.00 (US dollars) for shipping and handling.

Orach (*Atriplex patula*)

Features: Orach grows near water or in moist locations, and is one of our favorite wild plants. It can appear almost vine-like with its slender, fragile 1' - 2.5' long stems. Sometimes it grows upright, other times it almost sprawls along the ground. Its dark green leaves are halbert-shaped and grow opposite each other along stems and branches. Orach leaves resemble spinach both in appearance and flavor. Smaller pairs of leaves spring up on short stems at the juncture of the larger leaves and the stem. Its green flowers are small and inconspicuous.

Facts: Orach is rich in iron, and extremely nutritious. Because it is a member of the Saltbush family, it is also slightly salty, and was a welcome addition to the diet of many Native Americans.

Foods:

Raw: Orach is delicious eaten raw as a snack or in sandwiches and salads, but when it grows near water of unknown purity it should be well-washed before eating.

Cooked: Orach can be steamed, boiled, stir-fried, or added to omelets. It cooks quickly and should not be over-cooked because it greatly reduces in volume. Always taste your dish first before adding salt.

PAWPAW RECIPES

There aren't a lot of recipes for the pawpaw out there- at least that I've found. Euell Gibbon's book [Stalking the Wild Asparagus](#)  has some pawpaw recipes, and is still the best source for native plant info, lore and recipes. Another excellent cookbook that contains pawpaw recipes is Mark F. Sohn's [Mountain Country Cooking](#).  If you've found or developed a kitchen tested recipe, we'd sure appreciate hearing about it. You will certainly get credit for your contribution on our page or in a planned pawpaw cookbook. Here are some recipes. Enjoy!

Pawpaw Recipes

- [Pawpaw Ice Cream Pie](#)
- [Pawpaw Chiffon Pie](#)
- [Pawpaw Bread](#)
- [Pawpaw Cookies](#)
- [Pawpaw Smoothie](#)
- [Breakfast Drink](#)
- [Pawpaw Cake I](#)

- [Pawpaw Cake II](#)

Pawpaw Ice Cream Pie

- 2 cups strained pawpaw pulp
- 1 cup brown sugar
- 1 quart vanilla ice cream - softened
- 1 nine-inch graham cracker crust

Stir the brown sugar into the pulp until it is completely dissolved. Now fold this mixture into the softened ice cream. Pour this concoction into the graham cracker crust and place in freezer. Remove from freezer about 30 minutes before serving.

[Top of the page](#)

Pawpaw Chiffon Pie (borrowed from Euell Gibbons' Stalking the Wild Asparagus Quoted from pg 162 of the book: In a saucepan, mix together 1/2 cup of brown sugar, 1 envelope unflavored gelatin and 1/2 teaspoon of salt. Stir into this 2/3 cup of milk and 3 slightly beaten egg yolks. Cook and stir the mixture until it comes to a boil. Remove from the fire and stir in 1 full cup of strained pawpaw pulp. Chill until it mounds slightly when spooned. This will take 20 to 30 minutes in the refrigerator. Shortly before the mixture is sufficiently set, beat the 3 egg whites until they form soft peaks, then gradually add 1/4 cup of sugar, beating until stiff peaks form. Fold the partly set pawpaw mixture thoroughly into the egg whites. Pour into a 9-inch graham cracker crust...and chill until firm.

[Top of the page](#)

Pawpaw Bread

- 2 Cups sifted all-purpose flour

- 1 teaspoon soda
- 1/2 teaspoon salt
- 1/2 cup butter
- 1 cup sugar
- 2 eggs
- 1 cup pawpaw pulp
- 1/3 cup milk
- 1 teaspoon lemon juice
- 1/2 cup chopped nuts (1/3 at least, should be black walnuts)

Preheat oven to 350 degrees. Sift flour with soda and salt. Cream butter. Gradually add sugar, creaming well after each addition. Stir eggs and pawpaw pulp; blend thoroughly. Combine milk and lemon juice and add dry ingredients to pawpaw pulp alternately with liquids beginning and ending with dry ingredients. Stir in nuts.

[Top of the page](#)

Pawpaw Cookies

- 1 1/2 cups mashed pawpaw pulp
- 2 cups flour
- 1 teaspoon soda
- 1 teaspoon salt
- 1/2 cup butter
- 1 cup sugar
- 2 eggs

- 1 teaspoon grated lemon rind
- 1 cup chopped black walnuts

Preheat oven to 350 degrees. Press ripe pawpaws through food mill to obtain pulp. Sift together flour, soda, and salt. Cream butter and sugar; beat in eggs. Add lemon rind, flour mixture and pawpaw pulp. Fold in black walnuts. Drop on greased cookie sheet and bake for 15 minutes.

[Top of the page](#)

Pawpaw Smoothie (from Luisa Robles, graduate student at the University of Maryland and pawpaw fan:

- 1/2 cup pawpaw pulp
- 1 cup yogurt
- 2 teaspoons cinnamon
- 1 pinch nutmeg
- 5 drops lemon juice

Blend everything together until smooth

[Top of the page](#)

Pawpaw Breakfast Drink, also from Luisa. She adapted this from a drink she knew in Mexico by substituting pawpaw pulp for bananas: Prepare one can of frozen OJ in regular way. In a blender, mix about 1/2 cup orange juice with 2 cups pawpaw pulp. Blend briefly. Add the rest of the orange juice and mix well. "It makes a great breakfast when you are in a hurry, or a great snack between meals!"

Pawpaw Cake

- 2 1/4 cups cake flour (sift before measuring)
- 1/2 tsp baking powder

- **3/4 tsp baking soda**
- **1/2 tsp salt**
- **1/2 cup butter**
- **1 1/2 cups sugar**
- **2 eggs**
- **1 cup mashed pawpaw**
- **1 tsp vanilla**
- **1/4 cup yogurt or buttermilk**

Sift together flour, baking powder, baking soda and salt. Cream butter and sugar. Beat eggs into creamed butter-sugar mixture one at a time. Add vanilla and buttermilk or yogurt to pawpaw. Add the flour mixture to the butter mixture in 3 parts, alternating with the banana mixture. Stir the batter after each addition until smooth. Bake in greased pans in preheated 350 degree oven about 1/2 hour. When cool, sprinkle with powdered sugar.

[Top of the page](#)

Pawpaw Cake II from the Sept 27, 1995 *Frankfort State Journal*

- **1/4 C shortening**
- **1 C sugar**
- **1 1/4 C sifted all purpose flour**
- **1 tsp baking powder**
- **1 C mashed pawpaw pulp**
- **1 beaten egg**
- **1 tsp baking soda**

- **1 tsp vanilla**

Cream 1/4 cup shortening with 1 cup sugar. Add 1 well beaten egg and 1 cup mashed pawpaw. Sift together flour, baking powder and baking soda. Stir into the creamed mixture. Add vanilla and pour into an 8 inch square pan or two round layer cake pans. Bake at 375 degrees for 50 minutes. When cool, frost with cream cheese thinned with milk or any simple white frosting. Decorate with pawpaw slices.

Persimmon Cookbook

This is a sampling of some of the persimmon recipes we've run across, and we're providing them here by popular demand. Over the last several months, the response to our homepage about Pawpaws, Persimmons, Elderberries, etc has been somewhat overwhelming. While we emphasized Pawpaws and recipes thereof, there has been strong interest in Persimmon recipes. Still, the best single source for native plant info, lore and recipes is Euell Gibbon's

[Stalking the Wild Asparagus](#).  If you don't own it you should. Another excellent cookbook containing persimmon recipes is Mark F. Sohn's

[Mountain Country Cooking](#).  Finally, there are a couple of persimmon recipe books that are only available from small independent publishers.

They are "Persimmon Recipes" by Dymple Green, available for \$4 from Dymple's Delight, Rt 4, Box 53, Mitchell, IN 47446 and, "Old Fashioned Persimmon Recipes", available for around \$4 from [Bear Wallow Books](#), 7172 North Keystone Ave., Suite A, Indianapolis, IN 46240. So anyway, here goes. Hope you find something here you really like.

Persimmon Recipes

[Patrick Persimmon Pudding](#)

[Marguerite Hager's Persimmon Pudding](#)

[Persimmon Cake](#)

[Persimmon Pie](#)

[Persimmon Cookies](#)

[Persimmon Whip](#)

[Persimmon Cream Pie](#)

[Heavenly Persimmon Ice Cream Pie](#)

[Brown County Persimmon Fudge](#)

[Persimmon Jam](#)

The following four recipes work best with the Asian type persimmon:

[Persimmon Marmalade](#)

[Jellied Persimmon Salad](#)

[Persimmon-Almond Loaf with Orange Glaze](#)

[Persimmon Bread](#)

Fitzpatrick Persimmon Pudding

- 2 cups persimmon pulp
- 1 1/2 cups sugar
- 2 eggs, beaten
- 1 cup buttermilk
- 1 tsp baking soda
- 1 cup evaporated milk (canned)
- 2 cups flour
- 2 tsp baking powder
- 1/2 tsp cinnamon
- Pinch salt
- 1 tsp vanilla
- 1/4 cup cooking oil

Combine pulp, sugar and eggs. Stir baking soda into buttermilk. Add both milks to batter, then add the dry ingredients. Last add the vanilla and oil. Transfer batter to an oiled 9-by-13-inch baking dish or pan and bake in a preheated 325-degree oven one hour. This pudding will rise high and, when cool, fall some. It breaks away from the pan.

[Top of the page](#)

Persimmon Cake

- 2 cups persimmon pulp
- 1/2 teaspoon baking soda
- 1 cup milk
- 1/2 teaspoon salt

- 2 cups flour
- 1 tsp cinnamon
- 2 eggs
- 1/2 cup melted butter

Steam the persimmons just enough to loosen the seeds, but not enough to dissolve the skins. Run them through a food mill to take out seeds and skins. Measure 2 cups. Put pulp in the large bowl of mixer and mix the soda with it. Sift or stir together remaining dry ingredients. Add dry ingredients, milk, eggs and butter to the persimmon pulp and beat five minutes at medium speed. Turn batter into two greased and floured 8-inch layer cake pans and bake in a pre-heated 350-degree oven 60 to 70 minutes or until cake tests done. The cake will be a little chewy in the center, but absolutely delicious; turn out of pans and cool layers thoroughly before frosting.

Persimmon-Caramel Frosting

- 1 cup butter or margarine
- 2 cups brown sugar
- 1/2 cup persimmon pulp
- 1/2 tsp cinnamon
- 1/2 tsp nutmeg
- About 5 cups sifted confectioners' sugar
- 1 cup chopped nuts garnish (optional)

Melt butter in saucepan, Add brown sugar, and bring to boil. Add pulp and spices;boil again, stirring constantly. Remove from heat, and add enough confectioners' sugar to make desired consistency for spreading. Beat several minutes, and frost cake. If desired, press chopped nuts into sides of icing while still soft.

[Top of the page](#)

Persimmon Pie

- 1 egg
- 1 cup milk
- 1/2 cup sugar
- 1/8 tsp salt
- 1 Tbs cornstarch
- Cinnamon to taste
- 2 cups persimmon pulp
- 1 unbaked 9-inch pie shell

Combine egg, milk, sugar, salt, cornstarch, cinnamon and pulp. Pour mixture into pie shell and bake in a preheated 450-degree oven 10 minutes. Reduce heat to 350 degrees and bake 50 to 60

minutes longer. Serve with whipped cream.

[Top of the page](#)

Persimmon Cookies

- 1 cup persimmon pulp
- 1 cup nuts
- 1 cup raisins
- 1 cup sugar
- 1/2 cup shortening
- 1 tsp soda, dissolved in pulp
- 2 1/4 cup flour
- 1/2 tsp cinnamon
- 1/2 tsp ground cloves
- 1/2 tsp nutmeg
- 1 egg

Cream shortening and sugar. Add egg, soda and persimmon pulp. Add dry ingredients, nuts and raisins. Drop with teaspoon on greased cookie sheet. Bake for 10 minutes in 350-375 oven. Makes approx. 90 cookies.

[Top of the page](#)

Persimmon Whip

- 1/2 cup persimmon pulp
- 2 env unflavored gelatin
- 1 1/2 Tbs honey
- 2 tsp Lemon Juice
- 1 1/2 cup persimmon pulp
- 1/2 tsp salt
- 2 eggs whites, beaten stiff

Put 1/2 cup persimmon pulp into the top of a double boiler. Sprinkle gelatin over it and let it soak for 5 minutes. Heat over boiling water; stir until gelatin is dissolved. Remove from heat. Add honey, lemon juice, remaining persimmon pulp and salt. Pour into a bowl and cool. Refrigerate until almost set. Fold in stiffly beaten egg whites. Pour into serving dish and refrigerate several hours until it is set. Yields 6 servings.

[Top of the page](#)

Persimmon Cream Pie

Beat 2 eggs with 1/2 tsp cinnamon, 1/2 cup sugar and 1/4 tsp salt. Add 2 cups milk or cream, 1 cup persimmon pulp, 2 tablespoons melted butter and 1 teaspoon lemon juice. Pour into unbaked pie shell. Bake in very hot oven (450) 10 minutes, reduce temperature to 350 and bake 30 minutes longer. Let cool before slicing.

This recipe is from the Northwoods Nursery catalog (27635 S Oglesby Rd, Canby OR 97013).

[Top of the page](#)

Heavenly Persimmon Ice Cream Pie

- 1 pint vanilla ice cream, softened
- 2 cups persimmon pulp
- 1 1/2 cups sugar
- 1/2 tsp salt
- 1 tsp cinnamon
- 1/2 tsp ginger
- 1 tsp vanilla
- 1 1/2 cups Cool Whip
- 1/2 cup slivered almonds
- Spread ice cream in graham cracker pie shell and chill in freezer. Combine pulp with the 1 1/2 cups sugar, salt, spices and vanilla. Fold in 1 cup Cool Whip. Pour mixture over ice cream in pie shell. Cover with foil and freeze 4 hours. Remove from freezer and garnish with remaining 1/2 cup of Cool Whip and almonds..

[Top of the page](#)

Brown County Persimmon Fudge

- 1 cup persimmon pulp
- 6 cups sugar
- 2 1/2 cups milk
- 1/2 cup light corn syrup
- 1/2 cup butter (or margarine)

Combine pulp, sugar, milk and syrup in large sauce pan. Cook slowly 1 1/2 to 2 hrs until mixture reaches soft ball stage or (230 degrees F) Cool to lukewarm. Stir often. Add butter. Beat well. When mixture begins to thicken, stir in 1 cup chopped nuts. Spread in buttered 8 1/2 x 13 inch pan.

[Top of the page](#)

Persimmon Jam (From the Ortho Canning Book - 1982 and sent to us by M. Schoewe)

- 4# (about 10 very large) persimmons (these are obviously Oriental Persimmons)
- 4 c sugar

Cut persimmons in half & scrape out the pulp. Put pulp through a food mill to puree. Measure out 4 c. pulp. Put pulp & sugar into a pot & stir well until thick - about 30 minutes. Keep below boiling point or the jam will become bitter

Ladle jam into jars & seal with melted paraffin or process. The jam will thicken after it cooks.

[Top of the page](#)

Persimmon Marmalade

- 1 quart peeled persimmons
- 1 c water
- Juice of 1 lemon
- Sugar

Combine persimmons and water. Boil to a thick pulp, add juice of lemon and cup of sugar to each quart of pulp. Boil 10 minutes longer. Pour into sterilized jars and seal.

[Top of the page](#)

Marguerite Hager's Persimmon Pudding

This new recipe was sent in by R. Dennis Hager from Maryland. It looks great.

- 2 cups persimmon pulp
- 2 cups milk
- 1 tsp vanilla
- 1 1/2 cups sugar
- 2 1/2 cups self-rising flour
- 2 eggs
- 1 cup melted butter

Blend ingredients well, adding butter last. Pour in greased 9 x 12 pan and bake at 350 F for 1 hour.

Dennis says, "This pudding is very rich. It keeps well and the flavor continues to develop. It is best when 2-3 days old. The crust has a great flavor. The next time I make it, I'm going to try

smaller pans, so there will be more crust!"

[Top of the page](#)

Jellied Persimmon Salad

- 1 small package orange gelatin
- 1 cup hot water
- 2 cups persimmon pulp
- 1 Tbs lemon juice
- 1/2 cup finely chopped celery

Dissolve gelatin in hot water. Add persimmon pulp and lemon juice. Cool, then fold in celery. Pour into oiled ring mold or individual molds and chill

[Top of the page](#)

Persimmon-Almond Loaf with Orange Glaze This recipe and the next one for Persimmon Loaf were sent to us by Andi in California (Thanks Andi) "Fragrant and fruity, this persimmon loaf is my variation on an old-fashioned date tea bread. With its sweet and nutty flavors, it is a favorite of both children and adults for brunch or for lunch with chicken salad. Orange Glaze makes a perfect topping for this quick bread.."

- 2 cups unbleached all-purpose flour
- 1 1/2 tsp baking soda
- 1 tsp baking powder
- 1 tsp ground cinnamon
- 1/2 tsp salt
- 1/4 tsp freshly ground nutmeg
- 2 large ripe persimmons (about 1 pound)
- 8 Tbs (1 stick) unsalted butter, at room temperature
- 1/2 C sugar
- 1 large egg
- 1/4 C sour cream
- 2 tsp almond extract
- 1 C dried apricots or peaches, chopped
- 1/2 C toasted sliced almonds

First, adjust an oven rack to the middle shelf and preheat the oven to 350 degrees. Lightly butter an 8 1/2 x 4 1/2 x 2 1/2 inch loaf pan. Second, sift together the flour, baking soda, baking powder, cinnamon, salt, and nutmeg into a mixing bowl. Set aside. Next, peel the

persimmon and scoop the flesh into a medium-size mixing bowl. Mash with a fork. Set aside. Now, using an electric mixer, beat the butter and sugar at medium high speed until light and fluffy. Add the egg and beat until thoroughly combined. Add the persimmon pulp, sour cream, and almond extract. Blend at low speed to combine the ingredients. The mixture will look curdled. Add the sifted flour mixture, 1/2 cup at a time, and beat at low speed until the batter is smooth, stopping occasionally to scrape down the sides of the work bowl with a spatula. Fold in the chopped apricots and toasted almonds. The batter will be very dense and sticky. Scrape the batter into the prepared loaf pan. Bake until a toothpick inserted in the center of the loaf comes out clean, about one hour. Cool the bread in the pan on a rack for about 20 minutes before unmolding. Unmold and spread with Orange Glaze.

Orange Glace

- 2 tsp cornstarch
- 1/2 C fresh orange juice
- 1/2 C thawed frozen orange juice concentrate
- 1 1/2 Tbs unsalted butter
- 2 Tbs confectioners' sugar
- 1/2 tsp almond extract

[Top of the page](#)

Persimmon Bread

- 1 C persimmon pulp
- 1/2 C chopped persimmon
- 1/2 C butter
- 1 C sugar
- 2 beaten eggs
- 1 3/4 C flour
- 1 tsp baking soda
- 1 tsp baking powder
- 1/2 tsp salt
- 1/2 C nuts

Mix together butter, sugar and eggs. Sift together dry ingredients except baking soda, which you add to persimmon pulp. Add persimmon pulp. Fold in dry ingredients. Add chopped persimmon and nuts. Pour into buttered 8 x 11 inch pan and bake 45 minutes at 325 degrees, or until toothpick inserted in middle of loaf comes out clean. Andi says this is very good.

Elderberry Recipes

Though Jeannie and I don't claim to be experts on the elderberry and its uses, we have enjoyed the fruit for many years. Over the past several weeks there have been many email requests for recipes as people have discovered the ripening berries. Well this list is far from exhaustive, but it's a start. Hope you find something you can use.

- [Elderberry Jelly](#)
- [Elderberry Jam](#)
- [Elderberry Pie](#)
- [Gleckler's Elderberry Pie](#)
- [Elderberry Wine](#)
- [Julie's Wine #1](#)
- [Julie's Wine #2](#)
- [Elderberry Ice Cream](#)
- [Elderberry Ice Cream Easy Method](#)

Sure-Jell Elderberry Jelly

6 quarts or 3 lbs elderberries

2 lemons

Remove stems and crush. Place in saucepan. Bring to boil slowly until juice starts to flow. Reduce heat; cover and simmer 15 minutes. Place 3 layers of damp cheesecloth or jelly bag in large bowl. Pour prepared fruit into cheesecloth. Tie cheesecloth closed, hang and let drip into bowl until dripping stops. Press gently. Measure juice. If necessary, add up to 1/2 cup water for exact measure. Ingredients are now:

3 C juice

1/4 C fresh lemon juice

4 1/2 C sugar

Stir Sure-Jell into juice and add lemon juice. Bring mixture to full rolling boil. Add sugar quickly. Return to full boil and boil exactly one minute, stirring constantly. Immediately fill jars and seal.

[Top of the page](#)

Elderberry Jam from the *Ball Blue Book*

2 quarts crushed elderberries

6 C sugar

1/4 C vinegar

Combine berries, sugar and vinegar. Bring slowly to boiling, stirring occasionally until sugar dissolves. Cook rapidly until thick. As mixture thickens, stir frequently to prevent sticking. Pour, boiling hot, into sterilized jars. Adjust caps. Yield: about 3 pints.

[Top of the page](#)

Elderberry Pie

1 recipe Plain Pastry or frozen pie crust

2 1/2 C stemmed elderberries

1/2 C sugar

1/8 t salt

2 T flour

3 T lemon juice

Line a piepan with pastry. Fill with elderberries. Mix sugar, salt and flour; sprinkle over berries. Add lemon juice. Cover with top crust. Bake in very hot oven (450 degrees) 10 minutes, reduce temperature to moderate (350 degrees) and bake 30 minutes longer. This recipe is from the 1950 *Culinary Arts Institute Encyclopedic Cookbook*.

[Top of the page](#)

Gleckler's Elderberry Pie

This recipe was sent in by Marianne Gleckler of Metamora, Ohio. It's her husband's grandmother's recipe, and "it's very good."

3 C elderberries

3/4 C white sugar

1/4 C brown sugar

1 T vinegar

1/4 t salt

4 T corn starch or tapioca pudding mix (I use pudding mix)

Pat with butter

Makes a 9 inch 2 crust pie

[Top of the page](#)

Elderberry Wine

This wine is very much like a cream sherry. These are the ingredients for 1 gal wine.

3 1/2 lbs. elderberries

3 lbs. sugar

7 pints water

Sherry or all-purpose wine yeast

Nutrient

Crush the fruit in a plastic pail and add one quart of boiled water that has cooled. Mix well.

Crush one Campden tablet and dissolve the powder in about 1/2 C warm water and mix with fruit pulp. Leave the mixture in a cool place for 24 hours, stirring twice during that time. Strain through fine muslin or other similar material and squeeze gently but not too hard. Discard fruit pulp.

Boil 1 lb of sugar in 2 quarts water for 1 minute and allow to cool. Mix this with the juice and return the lot to the plastic pail. Add yeast and ferment for 10 days.

Pour off the top wine into a gallon jar, leaving as much of the deposit behind as possible. Boil another 1 lb of sugar in 1 C water for 1 minute and when cool add to rest. Plug the neck of the jar with cotton or install a fermentation lock and ferment in a warm place for 14 days.

After this, boil the last 1 lb of sugar in the remaining cup of water for one minute; cool, add to rest. Refit lock or cotton and leave in warm place until all fermentation has ceased.

Rack into sterilized wine bottles and cork. Try to wait at least six months to drink.

Elderberry Ice Cream from John Kennett (100657.2473@compuserv.com)

"First pick your elderberries. The easiest way is to snip off whole bunches, and then strip the individual berries off using the prongs of a fork at your leisure. I picked about half a carrier bag of bunches, which came out to a big saucepan of berries.

Put the berries into a saucepan with a little water, a sprinkling of sugar and the juice of half a lemon. Go steady on the sugar, you can always add more later if you need to.

With a lid on the saucepan, gently simmer for about 45 minutes, or until the berries have gone very soft. Leave to cool, and then push the berries through a sieve, discarding the pips that remain. This will leave a rich elderberry syrup. Taste it, and add more sugar if required. As a guide I had about a pint of syrup at the end.

Whip half a pint of double cream until it stands in peaks, and in a separate bowl whisk two eggwhites until they are stiff enough to tip the bowl upside down. This can be quite a feat with a hand whisk!

Fold the cream, eggwhites and elderberry syrup together gently, until the whole mixture is a uniform lurid purple. Pour into a suitable freezer container - I used a pyrex glass bowl. Then stick it into your freezer."

**Elderberry Ice Cream from Natalie with a quick method for freezing.
(nat88keys@yahoo.com)**

1 small bath towel

1 gallon-sized zipper seal bag

2 sandwich-sized zipper seal bags

1 1/2 cups rock salt

25-30 ice cubes

Desired amount of milk, half and half, or cream

Desired amount of sugar

Elderberry syrup (from recipe above)

"Mix milk, half and half, or cream with desired amount of sugar and syrup. (I find that the best ice cream comes from half and half topped with a LITTLE BIT of whole milk. Skim milk turns out runny with small

ice chunks, and both light and heavy whipping cream don't freeze well, and become more of a 'mush') A tall cup or medium bowl and a spoon works well.

Once well-blended, pour into sandwich-sized bag, and seal. Place this bag inside the other sandwich-sized bag, and seal.

Place ice cubes and rock salt into gallon-sized bag. The ice cubes should occupy about 1/3 of the bag. Place sandwich bags inside bag containing rock salt and ice, and seal. Wrap in towel and shake vigorously for 4-5 minutes. (You may want to take turns with a friend. My arms sometimes get tired from all the shakin'.)

When ice cream has thickened, remove sandwich bags, and scoop (or pour) into bowls. Double bagging the ice cream keeps rock salt from falling into the bag and getting the ice cream salty. Yuck!" Natalie goes on to say you can try other flavors with this method. Thanks Natalie.

store.**From Publishers Weekly**

Reich's is indeed a "worthy" addition to the gardening reference shelf, packed with information not readily found elsewhere. The author, a contributor to Horticulture and The New York Times, writes gracefully and knowledgeably about more than 20 fruit species easily grown in North America's temperate climate. Gardeners tired of the same old apples and pears will relish the prospect of growing such exotic fruits as the maypop, a cold-hardy passionfruit, the enticingly fragrant clove currant and the diminutive but intensely flavorful alpine strawberry. Part of what makes these fruits worthy of attention is that they are surprisingly easy to grow; they require far less spraying and pruning than their more commonly cultivated cousins, and--best of all for Northern gardeners--they demand some degree of winter cold. Reich provides detailed information, leavened with anecdotes and quotes from sources ancient and modern, on each fruit's cultivation, propagation, harvest and use, plus a list of cultivars. Appendixes cover botanical nomenclature, how to plant, propagate and care for the fruits and, last but not least, where to purchase them. Illustrations not seen by PW.

Copyright 1991 Reed Business Information, Inc. --*This text refers to an out of print or unavailable edition of this title.*

From Library Journal

This delightful book describes 19 fruits including maypops, pawpaws, medlars, jujubes, and Asian pears. Fruits were selected for being at home in a temperate climate, tasting good to eat out of hand, requiring minimal upkeep, and possessing ornamental beauty. For each, the compact, authoritative, and interesting text offers history, description, propagation, harvest, uses, and cultivars. A precise vocabulary--"frugiverous, frass, bletting"--sparkles in a clearly written text that is never overly... 8 of 8 people found the following review helpful:

★★★★★ A taste teaser! I want to get these plants!,
September 11, 2000Reviewer: OTMAR E VARELA P from New Orleans, Louisiana
USA

This book is, first of all, a wonderful read. It is full of historical notes, very interesting to this nonbotanist, and is fully researched. Advances have been made since it was written, and perhaps some of the suppliers given in the back are no longer with us; but a good web search will remedy that. It describes the flavors, scents, and appearance of the fruits in succulent detail. Since I have read it, I have been buying and trying to get friends to buy the various fruits listed. It is torture not being able to go out and buy jujubes, gumis, hardy kiwi, pawpaws, and all the rest of the children of Pomona that are here delineated. A wonderful book, full of charming oddities and wit.

Pawpaw Program

[Kentucky State University](#) has the only full-time pawpaw [*Asimina triloba* (L.) Dunal] research program in the world as part of the [KSU Land Grant Program](#).

Pawpaw research efforts are directed at improving seed and clonal propagation methods, developing orchard management recommendations, conducting regional variety trials, understanding fruit ripening processes, developing fruit storage techniques, and germplasm collection and characterization of genetic diversity. KSU also is the home of the [PawPaw Foundation](#), a nonprofit organization dedicated to the research and development of pawpaw as a new fruit crop.

The USDA National Clonal Repository for *Asimina* spp.

Since 1994, Kentucky State University has served as the USDA National Clonal Germplasm Repository (NCGR), or gene bank, for *Asimina* spp. (pawpaw), as a satellite site of the [NCGR repository](#) at Corvallis, OR. There are over 1,700 accessions (trees) from 17 states that are planted on 8 acres at the KSU farm. We are attempting to evaluate the genetic diversity contained in wild pawpaw populations across its native range so that unique material can be added to the [KYSU repository](#) collection; this potentially rich source of useful genetic traits will be used in breeding efforts.

Pawpaws: A Paw for You and a Paw for Me

The Autumn birding hike of October 10th was not very productive in terms of birds. However, during the course of the hike, several of the participants got their first introduction to the Pawpaw, *Asimina triloba*. The name of this plant is sometimes spelled Papaw - and in that form is often confused with another fruit that sometimes goes by that name, the Papaya, *Carica papaya*. (The latter is in a totally different family than our Pawpaw, and can only grow in tropical areas.)

Our Pawpaw, which grows as far north as New York and southern Ontario, out west as far as Nebraska and Texas, and south to Florida, is known by several other names including the American Custard Apple, the West Virginia Banana, and the Indiana Banana. There are about seven other members of the genus *Asimina*, all growing in the southeastern U.S.

The Pawpaw made some headlines in 1992 when it was reported that a Purdue University researcher had isolated a powerful anti-cancer drug, as well as a safe natural pesticide from the Pawpaw tree. The substances are said to be primarily found in the twigs and small branches. The researcher, [Jerry McLaughlin](#), revealed that it was because of some childhood experiences with eating the fruit that he had a feeling that there was something biologically active in the plant.

In the book, Sturtevant's [Edible Plants of the World](#), one finds the Pawpaw fruit called "...a natural custard, too luscious for the relish of most people. The fruit is nutritious and a great resource to the savages." Millspaugh, in [American Medicinal Plants](#), describes the fruit as "soft, sweet and insipid, having a taste somewhat between that of the May-apple and the banana, tending to the former." The Peterson Field Guide mentions that the seeds, along with being an emetic, have narcotic properties.

As late as the early 1900's, fishermen in the Ohio valley were using strips of the inner bark for stringing fish. They likely learned this use from the Indians, who used these bark strips to make fabric and nets. It is also thought that the Indians may have been responsible for extending the range of the Pawpaw far beyond its natural growing area.

Closer to home, a West Virginian and DC resident, [Neal Peterson](#), has been conducting a Pawpaw research study for the past eight years at the [Western Maryland Research and Education Center](#) near Keedysville. He has 600 trees planted on the Center's property and has been evaluating the fruit from the individual trees with an aim to choose the ten "best" trees in his orchard in order to begin producing the most tasty Pawpaws

possible. Peterson hopes to bring Pawpaws to the mass market.

Note: October, 1997: I found a listing for Paw Paws on the [NCSU Poisonous Plants of North Carolina Page](#). Apparently some individuals cannot eat them without severe stomach and intestinal pain.

Note: Pawpaw Flower picture by [Will Cook](#)

Note: Another green fruit that can be found in some places along the canal - this one in late fall - is the [Osage Orange](#). These fruits are about the size of baseballs and look like brains.... Some aver that they keep spiders away. There are a lot of these trees in the Antietam Campground area of the C and O Canal. (Mile 70 or so)

NEW! Free E-Postcards of Gourds! Choose from one of several original art gourds from this site and send it to a friend or loved one as a free e-postcard with your own personal message! There are Halloween, winter, and holiday cards available now, and more to come soon! (Also, in response to a few requests, this flag postage stamp design is available as a pin or magnet. See bottom of this page.)

About my gourd art

Gourds grow on vines and harden over winter to a hard, wood-like texture. They have been used by cultures all over the world for many purposes, including water-carriers and rattles. They are also a popular medium for many kinds of artists, including American Indian, American folk, and modern.

My art gourds range in size from tiny to huge. They are grown on my parents' farm in rural central Kentucky, and I clean them, burn my designs into them with a woodburner, paint them, mostly with watercolors so the natural textures can show through, and coat them with an acrylic varnish to protect the art.

My mother began our family gourd art tradition, and got me started doing mostly Cherokee and rural designs. I began selling them at craft fairs, and started my website in 1996, to share my gourds and information with visitors and sell some unique pieces in the process.

My Cherokee gourds often incorporate traditional designs, symbols, or motifs. Most also have some writing on them in the Tsalagi language (using Sequoyia's Syllabary), whether it is simply "Tsalagi" or a longer message. Several tell traditional stories and myths in pictures and words, like "[Grandmother Spider and the Sun](#)". Many are more personal, mixing traditional designs or motifs with other kinds of images. One example of this is "[People of Today](#)", which illustrates a quote by Chief Wilma Mankiller.

I do many other kinds of designs as well, including nature, rural scenes, green man, seasonal, butterfly, ducks and loons, horses, cats, cardinals, and other animals, celestial (sun and/or moon), grape and vine, chili peppers,

harvest/autumn leaves, wind zephyrs, flowers, and American Indian designs other than Cherokee. I can also handle a lot of different requests. I've even done custom pieces from pictures of people's houses, pets, even family members, so feel free to [email me](#).

I also make lots of items out of gourds, including baskets, birdhouses, ornaments, wall hangings, pins, magnets, and hair barrettes. If you wish to make an order, simply choose the motif you want and the kind of gourd item. You can give me more specific requests in the comments section of the order form, whether you choose to pay with a credit card using my secure PayPal feature, or pay by check or money order using the print and mail form.

Please take a look around and enjoy your visit. I will always try to be adding more gourds and pictures. If you would like to see some examples of my work, head on to the [Design Gallery](#) page. And [let me know](#) if I can help you with something.

Many people have asked me about crafting gourds themselves. Please see the gourd info page for some general information. Here are two books that you may also find helpful:

Also check out my parents' site on pawpaws, persimmons, elderberries, and other native plants

The flag stamp design is available as a pin for \$15 and a magnet for \$10

Editorial Reviews

From Library Journal

Sohn's unusual book offers a guided tour to the food of Appalachia, from Maryland to Georgia. It is not, as he points out, Southern cooking but a separate though related cuisine from the "deep valleys, small farms, and rugged people" of this mountain chain. Corn and

 [Stalking the Wild Asparagus](#) by Euell Gibbons, John McPhee

 [The Good Life](#) by Scott Nearing (Author), Helen Nearing (Author)

 [Uncommon Fruits Worthy of Attention: A Gardener's Guide](#) by Lee Reich, Vicki Herzfeld Alein

▶ [See more in the Page You Made](#)

Featured Item:

[The Maple Sugar Book](#) by Helen Nearing, et al

potatoes, nuts and beans, pork, tomatoes, and apples are all staples, with sorghum used for sweetening. Recipes include Corn Sticks and Slick Dumplings, Bacon-Potato Soup, and Sorghum Pie. But this is not just a cookbook, for there are stories and anecdotes, lengthy discussions of recipe origins, history and lore, and more. A book that will be as much fun to browse through as to cook from, this is recommended for most collections.

Copyright 1997 Reed Business Information, Inc.

From [Booklist](#)

Although it contains recipes for old-fashioned fried chicken, cream gravy, apple turnovers, and cornbread, this is not your usual country cookbook. It is a sampling of the culinary heritage of nine Appalachian states that celebrates the homegrown fruits of mountain soil and the labors of mountain cooks of the 1930s, 1940s, and 1950s. Sohn's love for Appalachian cookery comes across clearly in the chatty text, which includes plenty of intriguing general background and cooking tips. Each of the... ▶ [read more](#)

★★★★☆ Mediocre presentations..., May 10, 2004

Reviewer: hillbillyman from Big Stone Gap, VA

Who care about healthy alternative? I defeats the purpose of the nature of these dishes.

The author uses the word "we" way too much- it is clear that he is not of the hills like us-- I am sorry but living in the area doesn't automatically entitle you to adopt our way of life as your own, and profit from it.

We have done well over the years by keeping to ourselves... That is what makes our region unique.

Was this review helpful to you?

★★★★☆ This book is a rip-off, February 4, 2004

Reviewer: Billy Turnbull from Pikeville, KY USA

This book that highlights many recipes of the mountains is basically a contrived presentation that steals most of the recipes from the traditional people of the Appalachian mountains by someone who is a native of Oregon. Very bland recipes and very bland presentations. Avoid at all costs.

2000

Reviewer: [tomorrows_heirlooms \(see more about me\)](#) from Fallbrook, CA USA

I love cook books. I am a reader and veritable connoisseur of cookbooks. But, to be honest, if one is to really cook out of a cookbook, would author(s) henceforth please chose to have their works spiral-bound; maybe even with coated pages? This removes their book off the 'coffee table' (HardBack editions??) and brings it into the kitchen, where a cookbook belongs. Thank you for listening. Now I have to get back to my PawPaw Pie.

Was this review helpful to you?

★★★★★ GRANDMOTHER'S SECRETS REVEALED!, January 7, 2000

Reviewer: A reader from Beech Bluff, TN United States

I purchased this book from in a Memphis bookstore last year and was thrilled with it. It has all the traditional recipes - some of which I had long since forgotten - from my childhood in the Tennessee hills. All the recipes which I have tried so far have resulted in dishes that were like a taste of the past. I highly recommend this book to any displaced Southern mountaineer longing for a taste of home. You won't regret it!

Poisonous Plants Informational Database

Search on the following fields:

Scientific Name:

Common Name:

Primary Poisons:

**Species Most Often
Affected:**

This database of photos was started by Animal Science faculty and staff at Cornell University as a public service. Some of the information has been put together by students in the Animal Science 625 course. Please let us know if you find any errors or misidentifications and we will get them corrected as soon as possible.

The images are copyrighted. They can be used in teaching, downloaded, and copied, provided it is in an educational setting and proper attribution is provided. Alteration of images in any form is restricted.

IMPORTANT: This database of poisonous plants is correct to the best of our knowledge. However, just because a plant is NOT listed does not mean that it is NOT poisonous to a certain species. A good rule of thumb: if you have any doubt about a plant, assume it is poisonous!

Medicinal Plants for Livestock

Beneficial OR Toxic?

This series of web pages will attempt to answer some basic questions about the safety and efficacy of some medicinal plants. More plants will be added as information is available. Please read the introduction before reading about the plants.

Website Contents

 - [Other Resources](#) and the references for this web site

Introduction to Medicinal Plants for Livestock

The idea of using medicinal plants to treat livestock is not new. Many of the active ingredients in chemically manufactured drugs were originally derived from plant compounds (e.g., the pyrethroids). Also, in many developing countries, medicinal plants are still being used on a regular basis. (The use of plants and traditional methods for treating animals is called [ethnoveterinary medicine](#).) There is a renewed interest, especially in developed countries, in using plants to treat livestock, pets, and humans. Why?

- Many people believe that plants are less toxic and safer than manufactured drugs.
- Many people believe that plants are more natural than manufactured drugs.
- Medicinal plants can be made at home and are less expensive than manufactured drugs.
- In developing countries, medicinal plants often are more accessible than manufactured drugs.

The big questions are: Are medicinal plants effective for livestock? Are they really safe? Of the hundreds of plants used in ethnopharmacology, very few have been researched for their efficacy and toxicity. In the U.S., medicinal plants for humans are registered with the [Food and Drug Administration](#). Medicinal plants for livestock currently are not sold on a wide scale in the U.S.

Based on the [U.S. Department of Agriculture](#) regulations, medicinal plants for livestock must meet the same stringent requirements as other animal drugs if they are to be registered and approved for use in food producing animals.

Just because medicinal plants for livestock have not been registered, does not mean they are not accessible. How can you know or decide if a medicinal plant is safe or toxic for your livestock? Click on the [plants list](#) to learn about what is known and not known about a few plants used in ethnoveterinary medicine.

When reading about the plants please remember that:

- There is incomplete toxicity information on most of these plants;
- There is incomplete efficacy information on most of these plants; and
- The toxic dose and potentially effective dose could be very close.

PLANTS TOXIC TO ANIMALS

About this database:

This database was created in order to assist the University of Illinois veterinary students in identifying common plants that are toxic to animals. This database brings together information available in library books, plants grown in the [Poisonous Plant Garden](#), mounted specimens of plants, and the reference notes for a toxicology course (VB320) which is taught during the fall semester each year.

Although the VB320 notes address toxic plants found in all regions of the U.S., only the species most commonly found in the midwestern states are covered in this database. Common house plants are also included as opportunities arise. All of the [books employed](#) were found in the University of Illinois Library system. In particular, the booklet, Illinois plants poisonous to livestock by L.R. Tehon, C. C. Morrill, and Robert Graham provided the basis for the database structure as well as additional text information for food animals. This database will be revised or updated as time and resources permit. Photographs, unless noted otherwise, are originals taken in the Poisonous Plant Garden for this project.

The plant lists represent the entries which we hope to complete sometime in the future. Plant entries can be selected from either the [common name list](#) or the [scientific name list](#) of plants. A description of the [database structure](#) and the entries is also available.

The initial funding for this project was received from the University of Illinois Educational Technology Board and the University of Illinois Library Research and Publications Committee. Additional funding was received from Dr. Florence Dunbar.

Many thanks are due to Dr. Val Beasley for the use of his reference notes, to Zhenguo Zhang and Mary Shultz, Graduate Assistants for the project, and to Bryan McGoldrick, veterinary student and 1995-96 Curator of the Poisonous Plant Garden.

Comments and suggestions are appreciated. Please address them to [Mitsuko Williams](#), University of Illinois, Veterinary Medicine Library.

Phytochemical and Ethnobotanical Databases

High-Low Chemical query

This query displays either a **HI-LOW** or just a list of plants containing a particular chemical.

Enter the chemical name in the box below (e.g. tyrosine) or select the Chemical link to choose from the list of chemicals in the database.

[Chemical:](#) (required)

View only the top 40 plants with quantitative data.

Check to include plants *without* quantitative data.

FDA Poisonous Plant Database

DISCLAIMER

The information in this database is intended only for scientific exchange. It has not been approved by the United States Food and Drug Administration for publication nor does it have any official status. The information is continually increasing and being modified; it is neither error-free nor comprehensive. Information herein is in the public domain. Any copyrighted or privately owned material inadvertently included will be removed as soon as possible.

For information or concerns about the toxicity of plants, contact the local Poison Control Center in your area. A directory of these is available from [The American Association of Poison Control Centers](#).
(<http://www.aapcc.org/>)

For a poisoning emergency, call 1-800-222-1222. If the victim has collapsed or is not breathing, call 911.

Search the FDA Poisonous Plant Database

Enter a term or exact phrase (e.g. a plant name). All records containing that text will be displayed. Use of common terms such as 'poison' or 'plant' will generate a large number of "hits"

Enter search term:

(search is not case-sensitive)

This database contains references to the scientific literature describing studies of the toxic properties and effects of plants and plant parts. Records are displayed in List Format as the following example indicates:

-
46. **AUTHOR(S):** Yeong, M. L.; Wakefield, S. J.; Ford, H. C.
TITLE: "Hepatocyte membrane injury and bleb formation following low dose **comfrey** toxicity in rats."

CITATION: 1993 Intnatl J Exp Pathol, 74 (2), 211-217

FDA #: F24387 || **GRIN:** 36020

FAMILY: *Boraginaceae* || **LATIN NAME:** ---

COMMON NAME: **comfrey** || **STANDARD NAME:** Symphytum officinale L.

Notes:

- This searchable database replaces the static pages of bibliographic information and the vascular plant list previously available.
 - Fields are Author(s), Title, Citation, FDA Document #, GRIN Reference, Family, Latin Name, Common Name, Standard Name.
 - The database contains approximately 49,600 records.
 - Common search terms such as 'poison' or 'plant' can generate a large number of "hits".
 - If the number of records found by the search is more than 600, you will be asked to provide a more restrictive search term.
 - --- indicates there is no entry in the database.
 - An entry form for a new search is included at the bottom of each output page.

Scientific Name: *Coronilla varia*

Common Name: Crown Vetch

Species Most Often Affected: horse

Poisonous Parts:

Primary Poisons:

Questions pertaining to *Coronilla varia*:

[Is Crown Vetch safe to feed to horses?](#)

[Can crown vetch be harmful to horses?](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Prunus spp.*

Common Name: Wild Cherries, Black Cherry, Bitter Cherry, Choke Cherry, Pin Cherry

Species Most Often Affected: horses, cattle, moose, sheep, swine, goats

Poisonous Parts: seeds, leaves

Primary Poisons: amygdalin, prunasin

[Scroll down for more images.](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Daphne spp.*

Common Name: Daphne

Species Most Often Affected: cats, dogs, humans

Poisonous Parts: berries, all

Primary Poisons: mezereinic acid anhydride

[Scroll down for more images.](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Amanita spp.*

Common Name: Monkey Agaric, Panther Cap, Death Cap, and Death Angel Mushrooms

Species Most all

Often Affected:

Poisonous Parts: cap?

Primary Poisons: toxalbumin

Questions pertaining to *Amanita spp.*:

[Is Death Parasol the same as Death Cap?](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Zigadenus spp.*

Common Name: Death Camas

Species Most Often Affected: all

Poisonous Parts: all, bulbs, leaves, flowers, pollen

Primary Poisons: zygacine

[Scroll down for more images.](#)

Questions pertaining to *Zigadenus* spp.:
[Does this situation seem reasonable?](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *A. verna*

Common Name: Destroying Angels

Species Most Often Affected: all

Poisonous Parts: cap?

Primary Poisons: ibotenic acid and muscimol

[Scroll down for more images.](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Delphinium spp.*

Common Name: Delphiniums and Larkspurs

Species Most Often Affected: cattle, humans, goats

Poisonous Parts: all

Primary Poisons: alkaloids delphinine, ajacine, and others

[Scroll down for more images.](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Rumex spp.*

Common Name: Dock

Species Most Often Affected: cattle, sheep

Poisonous Parts: leaves

Primary Poisons: soluble oxalates

[Scroll down for more images.](#)

Questions pertaining to *Rumex spp.*:

[Need macro and microscopic identification of *Atropa belladonna*.](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Apocynum spp.*

Common Name: Dogbane

Species Most Often Affected: horses, cattle, humans, sheep, cats, dogs, goats

Poisonous Parts: rhizome

Primary Poisons: apocynamarin

[Scroll down for more images.](#)

Questions pertaining to *Apocynum* spp.:

[What type of poison is present in oleander?](#)

[Is *Plumeria rubra* poisonous to cats?](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Leucothoe axillaris* and *Leucothoe davisiae*

Common Name: Drooping Leucothoe and Sierra Laurel

Species Most Often Affected: goats, sheep
Poisonous Parts: leaves, nectar
Primary Poisons: andromedotoxin

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Sambucus canadensis*

Common Name: Elderberry

Species Most Often Affected: cattle, humans, goats

Poisonous Parts: leaves, twigs, roots, unripe fruits

Primary Poisons: sambunigrin

[Scroll down for more images.](#)

Questions pertaining to *Sambucus canadensis*:

[Are elderberries poisonous to humans?](#)

[Are *Sambucus canadensis* and *Sambucus nigra* similar?](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Claviceps spp.*

Common Name: Ergot

Species Most Often Affected: all

Poisonous Parts: fungus

Primary Poisons: indole alkaloid

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *A. muscaria*

Common Name: Fly Agaric

Species Most Often Affected: all

Poisonous Parts: cap?

Primary Poisons: ibotenic acid and muscimol

[Scroll down for more images.](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Amsinckia intermedia*

Common Name: Fiddleneck

Species Most Often Affected: horses, swine, cattle

Poisonous Parts: seeds

Primary Poisons: intermedine, lycopsamine

[Scroll down for more images.](#)

Questions pertaining to *Amsinckia intermedia*:

[Which poisonous plants are in the Bay area of California?](#)

[Can the cold weather kill off Fiddleneck?](#)

[I need some information on Fiddleneck...](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Linum usitatissimum*

Common Name: Flax

Species Most Often Affected: cattle, sheep

Poisonous Parts: all

Primary Poisons: cyanogenic glycoside

[Scroll down for more images.](#)

Questions pertaining to *Linum usitatissimum*:

[Can flax seeds be poisonous to horses?](#)

[Could you give me some information about the toxicity of these plants?](#)

[Are these plants really poisonous?](#)

[Are these wildflowers toxic?](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Digitalis purpurea*

Common Name: Foxglove

Species Most Often Affected: cats, cattle, dogs, goats, horses, humans
Poisonous Parts: flowers, leaves, seeds
Primary Poisons: cardiac or steroid glycosides
Link to web page(s): plants/digitalis.html

[Scroll down for more images.](#)

Questions pertaining to *Digitalis purpurea*:

[Could *Laurentia longiflora* be responsible for my fish dying?](#)

[Do you have any information on *Laurentia longiflora*?](#)

[What type of poison is present in oleander?](#)

[Is *Plumeria rubra* poisonous to cats?](#)

[Could you answer some questions for my book?](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Laburnum anagyroides*

Common Name: Golden Chain or Laburnum

Species Most Often Affected: cattle, dogs, horses, humans, swine
Poisonous Parts: pods, seeds, all
Primary Poisons: cytisine

[Scroll down for more images.](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Lobelia spp.*

Common Name: Great Lobelia, Cardinal Flower, and Indian Tobacco

Species Most Often Affected: humans, goats

Poisonous Parts: all

Primary Poisons: lobelamine, lobeline

[Scroll down for more images.](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Senecio spp.*

Common Name: Senecio, Groundsels, and Ragworts

Species Most Often Affected: horse, cattle, goats, sheep, human

Poisonous Parts: leaves

Primary Poisons: jacobine, seneciphylline

[Scroll down for more images.](#)

Questions pertaining to *Senecio spp.*:

[Which poisonous plants are in the Bay area of California?](#)

[Does Ragwort exist in the US or Canada?](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Halogeton glomeratus*

Common Name: Halogeton

Species Most Often Affected: sheep, cattle

Poisonous Parts: leaves, stems

Primary Poisons: soluble oxalates

[Scroll down for more images.](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Tetradymia spp.*

Common Name: Horsebrush

Species Most Often Affected: sheep, cattle

Poisonous Parts: leaves

Primary Poisons:

[Scroll down for more images.](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Equisetum arvense* and other spp.

Common Name: Horsetail

Species Most Often Affected: horse
Poisonous Parts:
Primary Poisons:

[Scroll down for more images.](#)

Questions pertaining to *Equisetum arvense* and other spp.:
[How can I get rid of this horsetail \(equisetum arvense\)?](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Iris spp.*

Common Name: Irises

Species Most Often Affected: cattle, humans, swine

Poisonous Parts: rhizomes and rootstocks

Primary Poisons: irisin, iridin, or irisine

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

List of Scientific and Common Name Equivalents

- 1 *Abrus precatorius* - Rosary Pea
- 2 *Aconitum spp.* - Monkshood, Aconite, or Wolfsbane
- 3 *Actaea spp.* - Baneberry, Dolls Eyes, White Cohosh, Snakeberry
- 4 *Aesculus spp.* - Horse Chestnut, Buckeye
- 5 *Agrostemma githago* - Corn Cockle
- 6 *Aleurites fordii* - Tung Oil Tree
- 7 *Allium spp.* - Commercial Onions, Wild Onions, Swamp Onions, and Chives
- 8 *Amanita spp.* - Monkey Agaric, Panther Cap, Death Cap, and Death Angel Mushrooms
- 9 *A. muscaria* - Fly Agaric
- 10 *A. pantherina* - Panther
- 11 *A. verna* - Destroying Angels
- 12 *Amaranthus spp.* - Pigweed
- 13 *Amsinckia intermedia* - Fiddleneck
- 14 *Apocynum spp.* - Dogbane
- 15 *Argemone mexicana* - Prickly Poppy or Mexican Poppy
- 16 *Arisaema spp.* - Jack in the Pulpit
- 17 *Asclepias spp.* - Milkweed
- 18 *Astragalus and Oxytropis spp.* - Locoweed
- 19 *Atropa belladonna* - Belladonna or Deadly Nightshade
- 20 *Brassica spp.* - Rape, Cabbage, Turnips, Broccoli, Mustard
- 21 *Caltha palustris* - Marsh Marigold or Cowslip
- 22 *Cannabis sativa* - Marijuana
- 23 *Centaurea solstitialis* - Yellow Star Thistle
- 24 *Chelidonium majus* - Celandine
- 25 *Chenopodium album* - Lamb's Quarters
- 26 *Cicuta spp.* - Water Hemlock or Cowbane
- 27 *Claviceps spp.* - Ergot
- 28 *Conium maculatum* - Poison Hemlock
- 29 *Coronilla varia* - Crown Vetch
- 30 *Convallaria majalis* - Lily of the Valley
- 31 *Daphne spp.* - Daphne
- 32 *Datura spp.* - Jimsonweed, Downy Thornapple, Devil's Trumpet, Angel's Trumpet
- 33 *Delphinium spp.* - Delphiniums and Larkspurs
- 34 *Dicentra spp.* - Bleeding Heart, Squirrel Corn, Dutchman's Breeches
- 35 *Digitalis purpurea* - Foxglove
- 36 *Equisetum arvense and other spp.* - Horsetail
- 37 *Eupatorium rugosum* - White Snakeroot

- 38 *Euphorbia spp.* - Poinsettia, Spurges, Snow on the Mountain
- 39 *Fagopyrum esculentum* - Buckwheat
- 40 *Festuca arundinacea* - Tall Fescue
- 41 *Gelsemium sempervirens* - Jessamine
- 42 *Glechoma spp.* - Ground Ivy, Creeping Charlie, and Gill over the Ground
- 43 *Halogeton glomeratus* - Halogeton
- 44 *Helleborus niger* - Christmas Rose
- 45 *Hyoscyamus niger* - Henbane
- 46 *Hypericum perforatum* - St. Johns Wort, Klamath Weed
- 47 *Iris spp.* - Irises
- 48 *Laburnum anagyroides* - Golden Chain or Laburnum
- 49 *Lantana camara* - Lantana, Red Sage, Yellow Sage, or West Indian Lantana
- 50 *Lathyrus spp.* - Sweet Pea, Tangier Pea, Everlasting Pea, Caley Pea and Singletary Pea
- 51 *Leucothoe axillaris and Leucothoe davisiae* - Drooping Leucothoe and Sierra Laurel
- 52 *Linum usitatissimum* - Flax
- 53 *Lobelia spp.* - Great Lobelia, Cardinal Flower, and Indian Tobacco
- 54 *Lotus corniculatus* - Birdsfoot Trefoil
- 55 *Lupinus spp.* - Lupine
- 56 *Medicago sativa* - Alfalfa or Lucerne
- 57 *Metilotus alba and Melilotus officinalis* - White and Yellow Sweetclover
- 58 *Menispermum canadense* - Moonseed
- 59 *Nerium oleander* - Oleander
- 60 *Nicotiana spp.* - Tobacco and Tree Tobacco
- 61 *Onoclea sensibilis* - Sensitive Fern
- 62 *Ornithogalum umbellatum* - Star of Bethlehem
- 63 *Papaver spp.* - Various Poppies including Opium Poppy
- 64 *Phytolacca americana* - Pokeweed
- 65 *Pieris japonica and other spp.* - Japanese Pieris, Mountain Fetterbrush
- 66 *Pinus ponderosa* - Ponderosa Pine
- 67 *Podophyllum peltatum* - Mayapple and Mandrake
- 68 *Prunus spp.* - Wild Cherries, Black Cherry, Bitter Cherry, Choke Cherry, Pin Cherry
- 69 *Pteridium aquilinum* - Bracken Fern
- 70 *Quercus spp.* - Oak Trees
- 71 *Ranunculus spp.* - Buttercups or Crowfoot
- 72 *Rheum rhaponticum* - Rhubarb
- 73 *Ricinus communis* - Castor Bean
- 74 *Robinia pseudoacacia* - Black Locust
- 75 *Rumex spp.* - Dock

- 76 *Sambucus canadensis* - Elderberry
- 77 *Sanquinaria canadensis* - Bloodroot
- 78 *Saponaria spp.* - Bouncing Bet and Cow Cockle
- 79 *Senecio spp.* - Senecio, Groundsels, and Ragworts
- 80 *Solanum spp.* - Common Nightshade, Black Nightshade, Horse Nettle, Buffalo Bur, Potato
- 81 *Sorghum spp.* - Sorghum or Milo, Sudan Grass, and Johnson Grass
- 82 *Symplocarpus foetidus* - Eastern Skunk Cabbage
- 83 *Taxus cuspidata* - Yew
- 84 *Tetradymia spp.* - Horsebrush
- 85 *Toxicodendron diversiloba* - Poison oak
- 86 *Toxicodendron radicans* - Poison ivy
- 87 *Toxicodendron vernix* - Poison Sumac
- 88 *Trifolium spp.* - Alsike Clover, Red Clover, White Clover
- 89 *Triglochin maritima* - Arrowgrass
- 90 *Urtica spp.* - Stinging Nettle
- 91 *Vicia spp.* - Common Vetch, Hairy Vetch, Narrow leaved Vetch, Purple Vetch and Broad Beans
- 92 *Veratrum californicum* - Corn Lily, False Hellbore
- 93 *Wisteria spp.* - Wisteria
- 94 *Xanthium strumarium* - Cocklebur
- 95 *Zigadenus spp.* - Death Camas
- 96 *Acer rubrum* - Red maple, Swamp maple, Soft maple
- 97 *Acer saccharum* - Sugar maple, Rock maple, Hard maple
- 98 *Acer saccharinum* - Silver maple, Soft maple, White maple

Scientific Name: *Arisaema spp.*

Common Name: Jack in the Pulpit

Species Most Often Affected: humans
Poisonous Parts: all
Primary Poisons: oxalate

Questions pertaining to *Arisaema spp.*:

[Could you help me find some information on plants poisonous to dogs?](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Pieris japonica* and other spp.

Common Name: Japanese Pieris, Mountain Fetterbrush

Species Most

Often Affected:

Poisonous Parts: leaves, nectar

Primary Poisons: andromedotoxin

[Scroll down for more images.](#)

Questions pertaining to *Pieris japonica* and other spp.:

[Are Pieris Japonica plants poisonous to dogs?](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Gelsemium sempervirens*

Common Name: Jessamine

Species Most Often Affected: horses, goats
Poisonous Parts: all
Primary Poisons: gelsemine

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Sorghum spp.*

Common Name: Sorghum or Milo, Sudan Grass, and Johnson Grass

Species Most Often Affected: horses, cattle, goats
Poisonous Parts: leaves, stems
Primary Poisons: dhurrin, nitrate

[Scroll down for more images.](#)

Questions pertaining to *Sorghum spp.*:

[Is there a way to manage sorghum sudan grass to eliminate its poisonous effects?](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Hypericum perforatum*

Common Name: St. Johns Wort, Klamath Weed

Species Most Often Affected: horses, sheep, goats

Poisonous Parts: all

Primary Poisons: hypericum

[Scroll down for more images.](#)

Questions pertaining to *Hypericum perforatum*:
[Are these plants really poisonous?](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Chenopodium album*

Common Name: Lamb's Quarters

Species Most Often Affected: cattle, horses, humans, sheep, swine

Poisonous Parts: all

Primary Poisons: nitrates

[Scroll down for more images.](#)

- DTWA000I: Net.Data detected an internal error [IBM][CLI Driver][DB2/6000] SQL0007N The character "%" following "SE('%Lamb's Quarters" is not valid. SQLSTATE=42601.

Scientific Name: *Lantana camara*

Common Name: Lantana, Red Sage, Yellow Sage, or West Indian Lantana

Species Most Often Affected: cattle, dogs, goats, cats, humans, sheep
Poisonous Parts: unripe, green berries
Primary Poisons: triterpenes

Questions pertaining to *Lantana camara*:

[Need more information on these plants...](#)

[Could you tell me if these landscaping plants are poisonous horses?](#)

[How dangerous are lantana berries?](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Convallaria majalis*

Common Name: Lily of the Valley

Species Most Often Affected: cats, dogs, humans, goats

Poisonous Parts: all

Primary Poisons: cardiac glycosides and saponins

[Scroll down for more images.](#)

Questions pertaining to *Convallaria majalis*:

[Could *Laurentia longiflora* be responsible for my fish dying?](#)

[Do you have any information on *Laurentia longiflora*?](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Astragalus* and *Oxytropis* spp.

Common Name: Locoweed

Species Most Often Affected: horse, sheep, cattle

Poisonous Parts: flowers, leaves, stems

Primary Poisons: selenium, nitro compounds, swainsonine

[Scroll down for more images.](#)

Questions pertaining to *Astragalus* and *Oxytropis* spp.:
[Could you send me some information about swainsonine?](#)

This image is copyrighted. It may be used in teaching, printed, downloaded, or copied, provided it is in an educational setting and proper attribution is provided. Alteration of this image in any form is restricted.

Scientific Name: *Lupinus spp.*

Common Name: Lupine

Species Most

cattle, goats

Often Affected:

Poisonous Parts: seeds

Primary Poisons: lupinine, anagrine, sparteine, and hydroxylupanine

Link to web page(s): plants/lupine.html

ALKALOIDS

Alkaloids are compounds containing nitrogen in a heterocyclic ring that are common to about 15 to 20% of all vascular plants. They are synthesized by plants from amino acids.

Piperidine Nucleus

Pyridine Nucleus

Indole Nucleus

Indolizidine Nucleus

Tropane Nucleus

Quinolizidine Nucleus

Nuclei of several different types of alkaloids

The amino acids are decarboxylated to amines and then react with amine oxides to form aldehydes. Mannich-type condensation of the aldehyde and amine groups creates their characteristic heterocyclic ring.

Alkaloids are subclassified on the basis of the chemical type of their nitrogen containing ring. Alkaloids are formed as metabolic by-products. However, their characteristic bitter taste and accompanying toxicity generally help to repel insects and herbivores.

Complicated ecological interrelationships have developed between several insects and alkaloids. For example, the consumption of specific pyrrolizidine alkaloids is necessary for some danoid butterflies to synthesize their pheromones.

INDOLE ALKALOIDS

Indole alkaloids are derived from the amino acid tryptophan as can easily be discerned by comparing their nitrogen containing nucleus to the chemical structure of tryptophan.

Comparison of

Nucleus of an Indole Alkaloid

Tryptophan

Important classes of indole alkaloids include:

- the ergot alkaloids (ergotamine, ergocristine, etc.),
- [the fescue alkaloids](#) (ergovaline, ergosine, ergonine, lysergic acid amide),
- 3-methylindole (produced by rumen fermentation of tryptophan), and
- [the beta-carbolines](#).

MIND BENDING BETA-CARBOLINES

This is intended to provide information on a class of indole alkaloids called [beta-carbolines](#) which are compounds that comprise the tricyclic pyrido (3,4) indol ring system with alkyl C1 constituents.

This group of indole alkaloids are of widespread distribution being found in [23 angiosperm plant families](#), 3 fungi genera, and in a variety of animal tissues[\[1\]](#). In addition, [beta-carbolines](#) can be found in tobacco smoke [\[2\]](#), marijuana smoke [\[3\]](#), and in charred food stuffs [\[4\]](#).

The [beta-carbolines](#) do not represent a significant poisoning hazard to livestock due to their very low concentrations. None-the-less, these toxicants are interesting from a chemical perspective in terms of structure-activity relationships. Some of their more interesting aspects are as follows:

- [ETHNOBOTANY: AYAHUASCA](#)
- [NEUROPHARMACOLOGY: BETA-CARBOLINES, SEROTONIN AND BRAIN CHEMISTRY](#)
- [BETA-CARBOLINE CONTAINING PLANTS](#)
- [REFERENCES](#)

 - [References](#)
-

Introduction

Piperidine alkaloids are identified by their saturated heterocyclic ring, i.e., [piperidine nucleus](#). The best known piperidine alkaloid poisons are those of poison hemlock, *Conium maculatum*. Socrates is reputed to have been killed with a poison hemlock extract. There are at least [5 naturally occurring conium alkaloids](#).

Symptoms of Poisoning

Conium alkaloids

acutely affect the nervous system. Livestock progress from:

- nervousness -->
- trembling -->
- incoordination -->
- dilated pupils -->
- weak heartbeat -->

- cold extremities -->
 - coma -->
 - to death by respiratory failure.
 - **Conium Alkaloids are teratogenic agents.**
-

Livestock most affected

- [Swine](#) (1g of *C. maculatum* seed/kg lw given orally) - Lethal
- [Cattle](#) (3.3 mg coniine/kg lw given orally) - Severe toxic signs
- [Horses](#) (15.5 mg coniine/kg lw given orally) - Severe toxic signs
- [Sheep](#) (44 mg coniine/kg lw given orally) - Moderate toxic signs

Swine

Fresh plant is enthusiastically consumed by pigs in feed trials. Third eyelid expands over entire eye about 15 minutes after poisoning causing temporary blindness. Weakness, trembling, and lethargy are observed. Both seeds and foliage are teratogenic in swine causing cleft palates in piglets exposed at 30 to 45 days gestation, and arthrorypsis, scoliosis, hydrocephalus, and severe contraction of fetlock joints in piglets exposed at 43 to 61 days gestation.

Cattle

Cattle are about ten times more vulnerable than sheep apparently because of differences in liver metabolism. An injectable dose of 16 mg coniine/kg live weight is lethal in cows. Field trials have induced crooked calf disease in the offspring of cows fed poison hemlock or dosed with conium alkaloids, implicating poison hemlock as a likely cause of deformed calves on ranges with no lupine herbage present.

Horses

Although horses are readily poisoned by poison hemlock, field trials thus far have not been able to induce teratogenic responses in pregnant mares poisoned with conium alkaloids, indicating that the horse fetus may be resistant to these toxins.

Sheep

Signs of poisoning in sheep are restlessness, followed by tremors and ataxia. The lethal dose for sheep is @ 240 mg coniine/kg live weight. Their resistance to poisoning when compared to cattle is attributed to species differences in liver metabolism. Research

indicates that poison hemlock is not teratogenic in sheep.

Prevention of livestock poisoning

Swine paddocks should be monitored for poison hemlock because swine will readily eat it. Poison hemlock is not highly palatable to cattle, horses, and sheep and rarely will they eat a toxic amount of it if more palatable vegetation is available on the range. Because conium alkaloids are teratogenic to cattle, care should be taken that cows in the first 3 mo of pregnancy not be grazed on sparse pastures with an appreciable population of poison hemlock. The seeds contain the highest concentration of toxicants. Therefore, feed grain can potentially be contaminated with poison hemlock. Although, herbicides and routine cultivation severely reduce the amount of poison hemlock in grain fields, seed contamination is still a potential danger in unsprayed or newly established grain fields.

[\[Return to list of toxicants\]](#)

Introduction

Polycyclic diterpene alkaloids have a complicated diterpene [nucleus](#). They are found in plants in the *Delphinium* spp. (Larkspurs) and in the *Aconitium* spp. (monkshood). Larkspurs kill more cattle in the United States yearly than all other poisonous plants combined.

Larkspurs (*Delphinium* spp.)

Description and distribution

Larkspurs are the primary source of plant poisoning of cattle on the western ranges of the United States. Larkspurs are grouped by their height. Low larkspurs, for example, *D. andersonii* and (em) *D. menziesii*, have a growing habit of <3 ft and are generally found at lower elevations. They are one of the first plants to emerge in the spring, even when there is still snow cover, and hence, appear inviting to cattle hungry for green vegetation. Early spring is when poisonings due to low larkspurs are most likely to occur. Tall larkspurs ((em)*D. barbeyi*, *D. occidentale*, *D. glaucum*, *D. Trollifolium*, etc.) are 3 to 6 ft tall and grow at high elevations in deep soils with plentiful moisture. They can be found

in alpine meadows or under dense tree cover in aspen and pine forests and are very palatable to cattle. Calves tend to congregate under tree cover while the mature herd is out grazing. Because of their small size, calves are particularly susceptible to poisoning from the larkspur patches found in the woods.

Where poisons are found in plant

Larkspurs alkaloids are concentrated in the growing tips and new leaf growth of the plant. Therefore, larkspurs tend to be most poisonous in early spring, gradually drop in toxicity throughout the growing season, and severely decrease in toxicity following flowering. (Become essentially benign?)

Symptoms of poisoning

The alkaloids in Larkspurs, for example, methyllycaconitine, appear to act as powerful neuromuscular blocking agents. Symptoms of poisoning are rarely observed out on the range because animals progress to death so rapidly. The first sign of trouble may be a bloated corpse. In field trials, symptoms include restlessness, nausea, abdominal pain, muscle weakness and involuntary twitching, stiff gait, straddled stance with hind legs braced apart --> collapse --> death by respiratory paralysis. Cattle are about 4 times as susceptible to Larkspur poisoning as sheep and are killed by as little as 17g of green foliage per kg liveweight.

Prevention of poisoning

Sheep and goats have been used to try to cut down on the larkspur population of rangelands. Sheep have not been that successful because they tend to graze larkspur later in the spring than cattle and generally do not feed on the growing points. Death due to larkspur poisoning has been reported in sheep. Goats have been used to more success (? , check). Spot spraying larkspur with herbicides and then reseeding to grasses also helps reduce larkspur populations.

PYRIDINE ALKALOIDS

Index

- [Introduction](#)
 - [Tobacco Family \(*Nicotianasp.*\)](#)
 - [Distribution](#)
 - [Description](#)
 - [Symptoms of poisoning](#)
-

Introduction

Pyridine alkaloids are similar to piperidine alkaloids except that their heterocyclic ringed, nitrogen containing nucleus is unsaturated. Two toxic alkaloids will be discussed here. The pyridine alkaloid, [nicotine](#), and the piperidine-pyridine alkaloid, [anabesine](#). Both of these are found in plants in the *Nicotiana* spp. which includes cultivated, wild, and tree tobacco.

Symptoms of Poisoning

Nicotine

- acutely affects the nervous system by blocking autonomic ganglia and neuromuscular junctions. Livestock progress from:

- excitement -->
- shaking and twitching -->
- rapid breathing -->
- staggering -->
- weakness and prostration -->
- coma -->
- descending paralysis of the central nervous system -->
- to death by respiratory failure.

Anabesine

- Research indicates that anabesine is a teratogenic agent but nicotine is not.

Poisoning due to consumption of tobacco leaves and stalks has been documented in cattle, horses, sheep, and swine as well as dogs and even humans (after consuming the leaves as boiled greens). Nicotine was a popular old time wormer and insecticide that occasionally poisoned livestock as well as its intended target. Swine will readily eat the soft pith of tobacco stalks and extreme care must be taken to keep them from gleaming tobacco fields or discarded stalks. Deformed offspring due to ingestion of the anabasine alkaloid in tobacco have been documented in cattle, sheep, and swine. These deformities are clinically the same as those caused by maternal consumption of lupine or poison hemlock (carpal flexure, cleft palates, arthrogryposis of the forelimbs and curvature of the spine). Wild and cultivated tobaccos contain some anabasine. However, @ 99% of the total alkaloid content of tree tobacco is anabasine.

Pyrrolizidine Alkaloids

Most alkaloids are amino acid derivatives, and have no certain role in plant metabolism except for serving to repel insects and herbivore predators due to their bitter taste. Pyrrolizidine alkaloids are very common in plants used in livestock feeds and in rangeland weeds such as tansy ragwort, *Senecio jacobea*, and *Heliotropium spp.* and *Crotalaria spp.* Pyrrolizidine alkaloids contain nitrogen in a heterocyclic ring forming a definite structure called the pyrrolizidine nucleus. It appears that the pyrrolizidine alkaloids themselves are not toxic, rather, some of their metabolites, primarily their "pyrrolic" derivatives are highly toxic. Toxic alcohols can also be produced as secondary metabolites. The common PAs, Heliotrine and lasiocarpine, are partially reduced to the non-toxic 1-methylene and 7-hydroxy-1 methyl derivatives in the rumen. However, these can be activated by oxidases in the animal's liver to pyrrolic derivatives and thus have pathological effects in the heart, liver, kidney and respiratory system. The basis for alkaloid regulation and its effects in the ruminal ecosystem are not yet fully understood, but is a well-known fact that its degradation is directly proportional to its concentration in the rumen. Heliotrine degrading bacteria have been isolated and identified in the rumen. Although these bacteria appear to get very little useful energy from the cleavage of heliotrine, this characteristic may well improve their ability to successfully compete in the rumen of an animal exposed to this type of alkaloid.

This series of web pages was created by Manuel Hernandez, an undergraduate student at Cornell University for the AS625 class. All comments and suggestions are welcome.

STEROID ALKALOIDS

Steroid alkaloids have a fairly complex nitrogen containing nucleus. Two important classes of steroid alkaloids are

- **the *Solanum* type** - one example is [solanidine](#). This steroid alkaloid is the nucleus (i.e. aglycone) for two important glycoalkaloids, [solanine and chaconine](#), found in potatoes. Other plants in the *Solanum* family including various nightshades, Jerusalem cherries, and tomatoes also contain solanum-type glycoalkaloids. Glycoalkaloids are glycosides of alkaloids.
- **the *Veratrum* type**. There are more than 50 *Veratrum* alkaloids including [veratramine](#), [cyclopamine](#), [cycloposine](#), [jervine](#), and [muldamine](#) occurring in plants of the *Veratrum* spp. The *Zigadenus* spp., death camas, also produces several veratrum-type of steroid alkaloids including [zygacine](#).

Solanum-type Alkaloids

- [Introduction](#)
- [Where poisons are found](#)
- [Symptoms of poisoning](#)

Introduction

Solanum-type alkaloids are found in plants in the form of glycosides of alkaloids. Glycosides are ethers that join a noncarbohydrate moiety, the aglycone, by an ester bond to a carbohydrate moiety. In solanum-type glycoalkaloids, the aglycone is a steroid alkaloid. Solanine and chaconine cause poisoning in potatoes. They have the same aglycone, solanidine, but the structure of their carbohydrate sidechains is different. Tomatine is a glycoalkaloid found in tomatoes. Its aglycone is tomatidine.

Where poisons are found

Production of solanum-type glycoalkaloids is favored by the same conditions that promote the development of chlorophyll. Therefore, the concentration of these glycoalkaloids is highest in potato sprouts and green potato skins, and tomato vines and green tomatoes. Care should be taken to prevent the exposure of potatoes to sunlight. These alkaloids are not destroyed by cooking or drying at high temperatures. New potato varieties can not be introduced unless they contain less than 20 mg glycoalkaloids/100 g.

The glycoalkaloids are more poisonous than the steroid alkaloid aglycones. Humans and all classes of livestock are susceptible to poisoning by solanum-type glycoalkaloids. Luckily,

- glycoalkaloids are poorly absorbed by the gastrointestinal tract of mammals,
- an appreciable amount of solanum-type glycoalkaloids is hydrolyzed in the gut of

mammals to the less toxic aglycones,

- these metabolites are rapidly excreted in the urine and feces of mammals. Because exposure to these poisons is generally by ingestion, it takes a relatively large amount of them to cause death.

Symptoms of poisoning

In potatoes, solanum-type glycoalkaloids cause:

- a bitter taste above 14mg/100g, and
- a burning sensation to mouth and throat above 20mg/100g.

Solanum-type glycoalkaloids are:

- gastrointestinal tract irritants -->
 - inflamed intestinal mucosa, ulceration, hemorrhage, stomach pains, constipation or diarrhea
- cholinesterase inhibitors and thus affect the nervous system-->
 - apathy, drowsiness, salivation, labored breathing, trembling -->
 - ataxia, muscle weakness, convulsions, involuntary urination -->
 - paralysis, loss of consciousness, coma, death due to respiratory paralysis

Nitrate

Forage plants and water are common sources of high levels of nitrates. Some of the causes of abnormal accumulation of nitrates in plants are: nitrogen fertilization, drought conditions and some herbicidal treatments. Nitrate accumulation also largely depends on the type of plant. Some of the most common grasses that accumulate nitrate are sudan grass, oats, rape, wheat, barley, and corn. Although in the rumen nitrate is readily reduced to nitrite and then to ammonia, the consumption of plant materials with high levels of nitrate will lead to an acute intoxication. This process is closely related to increased concentrations of nitrite in the rumen which leads to the production of methaemoglobin, a substance that interferes with the ability of blood cells to carry oxygen when concentrations reach 30-40% of total hemoglobin concentrations. Some of the clinical signs of nitrate intoxication are abdominal pain, labored breathing, and cyanotic mucous membranes. Increased dietary nitrate, however, induces a change in the bacterial population that leads to an increased tolerance to high nitrate concentrations in the diet. Nitrate reduction in the rumen competes with other essential metabolic reactions such as methanogenesis, end-product formation, and microbial protein synthesis, and its toxicity reduces growth, causes Vitamin A deficiency, abortion, infertility, and goiter.

Oxalate Degradation

Only a few plants contain sufficient amounts of sodium and potassium oxalate to be considered toxic. Moreover, ruminants that consume these plants develop increasing amounts of tolerance to oxalate. An oxalate degrading anaerobe microorganism has been isolated from pure culture of rumen bacteria. This organism, *Oxalobacter formigenes*, uses oxalate as a sole energy source and produces carbon dioxide and formate as end products. This ability is extremely rare among anaerobic bacteria and therefore this organism occupies an unique niche in the rumen's microflora. The ability of the ruminant to adapt and tolerate high oxalate diets directly depends on the selection of oxalate-degrading microorganisms.

GLYCOSIDES

Glycosides are ethers that consist of a carbohydrate moiety joined by an ester bond to a noncarbohydrate moiety (referred to as the aglycone). The structure and/or properties of their aglycone is used to group and identify them. For example, isoflavones are glycosides with a flavone aglycone, and cardiac glycosides are steroid glycosides that act as powerful stimulators of the heart.

CALCINOGENIC GLYCOSIDES

INDEX

- [Introduction](#)
 - [How poisoning occurs](#)
 - [Symptoms of poisoning](#)
 - [References](#)
-

INTRODUCTION

Certain plants contain glycosides of the active metabolite of vitamin D. The metabolite is called [1,25-dihydroxycholecalciferol](#) or more simply 1,25-OHD3. Consumption of glycosides of 1,25-OHD3 by grazing animals leads to a vitamin D toxicity which causes the deposition of excessive calcium in the soft tissues (calcinosis). Of the three rangeland plants, *Cestrum diurnum*, *Solanum malacoxylon*, and *Trisetum flavescens*, known to contain these glycosides only *Cestrum diurnum* is found in the U.S. primarily in Florida.

HOW POISONING OCCURS

Vitamin D functions to regulate calcium and phosphorus absorption. Its metabolite, 1,25-OHD3, controls the synthesis and functions of calcium-binding proteins in the intestinal mucosa transporting calcium after digestion from the intestines to the blood stream. Animals synthesize their own 1,25-OHD3 through a feedback system in which low (high) serum calcium levels trigger increased (decreased) parathyroid hormone secretion which in turn triggers the production of more (less) 1,25-OHD3 leading to increased (decreased) absorption of calcium into the blood. This feedback system is disrupted by the consumption of external sources of 1,25-OHD3 which are not sensitive to already existing serum calcium levels. This excess 1,25-OHD3 causes elevated serum calcium levels leading to a condition known as calcinosis in which the extra calcium is deposited on the animal's soft tissues.

SYMPTOMS OF POISONING

A kilogram of dried *Cestrum diurnum* leaves yields approximately 3×10^3 IU D3. If *Cestrum diurnum* makes up 15 to 30% of the animal's diet, this may be sufficient to cause calcinosis. Symptoms in animals grazing toxic levels of *Cestrum diurnum* are

- progressive weight loss,

- lameness and stiffness,
- arched backs,
- hypercalcemia,
- hyperphosphatemia, and
- calcification of the tendons, ligaments, lungs, diaphragm, kidney, and cardiovascular system.

CARBOXYATRACTYLOSIDE

INDEX

- [Introduction](#)
 - [Cocklebur \(*Xanthium* spp.\)](#)
 - [How poisoning occurs](#)
 - [Symptoms of poisoning](#)
 - [References](#)
-

INTRODUCTION

Cockleburs are a herbaceous annual found in the U.S. along the shores of streams and ponds and in low-lying areas of farm fields. In its seedling stage it contains a hyperglycemic glycoside named carboxyatractyloside that can be deadly to livestock.

Cocklebur (*Xanthium* spp.)

Cockleburs tend to grow in areas that are waterlogged much of the year, but dry during the summer. They have a fruit capsule containing two seeds. Only one seed germinates the first year. Germination is delayed in the second seed until the following year. Cocklebur seedlings are high in carboxyatractyloside until the emergence of their first true leaves after which toxicity is lost. Carboxyatractyloside is a plant growth inhibitor. It has been hypothesized that carboxyatractyloside functions in a germinating cocklebur seed to keep the other seed in the fruit capsule dormant the same year.

HOW POISONING OCCURS

[Carboxyatractyloside](#) causes hypoglycemia in animals that consume it probably because it causes uncoupling of oxidative phosphorylation. Experimentally, phenylbutazone (BUTE) has been shown to reduce its toxicity by inducing synthesis of a non-cytochrome P450-dependent detoxification enzyme.

SYMPTOMS OF POISONING

Rooting pigs are very susceptible to poisoning from cocklebur seedlings. Symptoms include

- depression, unwillingness to move, hunched backs-->
- nausea, vomiting-->
- weakness, prostration, dyspnea, opisthotonus-->
- the animal collapses and makes paddling motions-->
- convulsions-->coma-->death.

Prior to death, animal becomes severely hypoglycemic with blood glucose levels dropping to 16mg/100ml. Increased vascular permeability leads to gross lesions of the gall bladder and peritoneal cavity and to liver necrosis.

Cardiac Glycosides

- Cardiac glycosides are divided into two main types:
 - * **Bufadienolides** are C₂₄ steroids,

- The primary cardiac glycoside present in [Helleborus](#) is the bufadienole, hellebrin.
- Hellebrigenin, the aglycone of hellebrin is more potent than the glycoside itself.

* **Cardenolides** (most prevalent) are C₂₃ steroids.

- Cardenolides have a hormonal nature as substances. Their effects are on the heart and kidney.
- Strong, bitter and disagreeable taste.
- Cardiotoxic = affect contractions of the heart muscle.
- Break down in fermentation by enzymatic action.
- Treatment: atropine and activated charcoal, lidocaine for *H. viridis*

- Assumed mechanism of action: inhibition of the Na⁺, K⁺-ATPase resulting in increased intracellular sodium and subsequent intracellular calcium leading to enhanced muscle contraction in cardiac tissue.

Cardenolides are classified according to the chemical composition of their aglycones as **lanataglycosides A, B, C, D and E**. Only [*Digitalis lanata*](#), the woolly foxglove contains all five forms. The entire foxglove plant is toxic. Symptoms of poisoning include dizziness, vomiting, irregular heart beat, and delirium or hallucinations.

Digitonin is probably the best known derivative of the Digitalis cardenolides. It is a drug derived from *D. purpurea*. It is used in modern medicine to increase the force of the systolic contractions and prolong duration of the diastolic phase in congestive heart failure. Digitalis drugs lower venous pressure in hypersensitive heart ailments, elevate blood pressure in a weak heart act as a diuretic, and reduce edema. However, the therapeutic dose is dangerously close to the lethal dose.

- Some plants containing cardiac glycosides:

[*Christmas rose Helleborus niger*](#), [*foxglove Digitalis purpurea*](#), lily of the valley ([*Convallaria majalis*](#)) and white water lily ([*Nymphaea alba*](#)).

[\[Return to list of toxicants\]](#)

Introduction

This section will discuss toxicants that are derived from coumarin compounds in plants. For example, the glucoside melilotoside found in sweet clover (*Melilotus alba* and *M.officinalis*) is an ether of glucose bonded with an ester bond to coumarin. It yields the toxicant dicoumarol when exposed to specific molds. Furocoumarins are toxic compounds that consist of a coumarin nucleus bonded to a furan ring. Several plants contain the psoralens that are generally the precursors of furocoumarins.

[\[return to list of toxicants\]](#)

DICOUMAROL

Dicoumarol - HOW POISONING OCCURS

Plant enzymes in sweet clover [partition the aglycone coumarin from melilotoside](#). When sweet clover is put up as hay it is easy for it to be contaminated with molds because of its succulent stems. This is particularly likely when conditions are wet at cutting or curing or when foliage is lush. Molds such as *Penicillium nigricans* , *P.jensi* , and the *Aspergillus* metabolize the coumarin into dicoumarol. Dicoumarol

is similar in [structure](#) to vitamin K. When consumed by livestock it inhibits vitamin K production. Vitamin K is necessary in the body to activate prothrombin. When tissue is damaged, thromboplastin is released and converts prothronin to thrombin. Thrombin alters the solubility of fibrinogen in blood and causes it to clot and seal the tissue damage. Dicoumarol prevents [this process](#). [Warfarin](#) is a synthetic toxicant derived from coumarol. It is used in rat, gopher, and ground squirrel poisons and also acts as a vitamin K inhibitor to block the blood clotting process and provoke hemorrhaging. It is toxic to livestock that may accidentally consume it in its pelleted form and to dogs that consume poisoned squirrels, etc.

Dicoumarin - PLANTS INVOLVED

Sweet clover (*Melilotus alba* and *M. officinalis* is grown as a green manure and hay crop in the northern U.S. and in Canada. Its coumarin content gives it a distinctive sweet odor similar to vanilla. Its use as hay was widespread in the 1920s. A series of wet summers led to an epidemic of "bleeding disease" in cattle. Use of the forage is less common now and low- melilotoside varieties are available. Sweet vernal grass (*Anthoxanthum odoratum* is a coumarin-containing forage in England that also causes "bleeding disease". Hay with >10 ppm dicoumarol should be viewed with caution.

SYMPTOMS OF POISONING

Bleeding disease "only in cattle?"

- mild cases - extended blood-clotting time that can lead to hemorrhaging when livestock are castrated or dehorned.
- severe cases - internal and/or external hemorrhaging cause pale mucous membranes, subcutaneous swellings of pooled blood, weakness, and death.
- treatment - injections of vitamin K, whole blood transfusion.

[\[Index\]](#)[\[Introduction\]](#)[\[Dicoumarols\]](#)[\[Furocoumarins\]](#) [\[Return to list of toxicants\]](#)

Furocoumarins

Furocoumarins - HOW POISONING OCCURS

Furocoumarins are primary photodynamic agents. They absorb long-wave ultra-violet radiation upon exposure of the skin of the affected animal to sunlight and become photoactive. They then cause cell damage by inhibiting DNA synthesis by binding pyrimidine bases and nucleic acids.

PLANTS INVOLVED

Bishop's weed (*Ammi majus*), spring parsley (*Cymopterus watsonii*), and dutchman's breeches (*Thamnosma texana* and *T. montana*) are weeds found in different rangeland regions of the U.S. Livestock consume them as forage or as seed contamination in grain. They contain several psoralens including xanthotoxin and bergapten that break down readily to form furocoumarins. Furocoumarins are also produced by some plants, for example, celery and parsnips, in response to fungal infestation.

SYMPTOMS OF POISONING

- severe blistering and peeling particularly of light-skinned parts of the animal
 - clouding of the cornea and eye lesions -->severe cases - blindness
 - blistering and erythema of the udder of lactating females, e.g. ewes and cows, -->severe cases - starvation of their offspring when dams refuse to nurse
 - "celery dermatitis" - blistering of arms of farm workers handling celery when the celery is diseased with pink rot (*Sclerotinia sclerotiorum*) and produces xanthotoxin and trisoralen.

GLUCOSINOLATES (GOITROGENIC GLYCOSIDES)

Index

- [Introduction](#)
- [How poisoning occurs](#)
- [Plants involved](#)
- [Symptoms of poisoning](#)
- [Prevention of poisoning](#)
- [Benefits of glucosinolates](#)

[\[Return to list of toxicants\]](#)

Introduction

[Glucosinolates](#) are thioethers. They generally consist of a sugar entity, b-D-thioglucose, with an ester bond to an organic aglycone that is an alkyl group yielding isothiocyanate, nitrile, thiocyanate or a similar compound upon hydrolysis. These compounds often contribute a bitter, "hot" taste to condiments (mustard, horseradish) and may exhibit goitrogenic or antithyroid activity. [\[return to list of toxicants\]](#)

How poisoning occurs

Glucosinolates are hydrolyzed by either the enzyme glucosinolase or thioglucosidase into glucose, HSO₄⁻, and one of the following aglycone derivatives: isothiocyanates, thiocyanates, nitriles, or related compounds such as oxazolidine-2-thiones. The enzymes for hydrolysis are produced by plants and by rumen organisms. They react with the glucosinolates when plant tissue is crushed, for example by mastication, or when the plant is consumed into the rumen of a ruminant animal.

- **Isothiocyanates** - are irritating to mucous membranes and not readily consumed in sufficient quantities to be toxic. However, if they are consumed as glucosinolates and then hydrolyzed to isothiocyanates in the gut, they can have powerful antithyroid effects and interfere with the synthesis of necessary thyroid hormones.
- **Oxazolidine-2- thiones** - are closely related to isothiocyanates. One way they are produced is by the conversion of the glucosinolate progoitrin in rapeseed meal to

goitrin which in turn is hydrolyzed to these compounds. Oxazolidine-2-thiones depress growth and increase the incidence of goiters. They inhibit thyroid function by blocking the incorporation of iodine into thyroxine precursors and by suppressing thyroxine secretion from the thyroid.

- **Nitriles** - depress growth, cause liver and kidney lesions, and in severe cases --> liver necrosis, bile duct hyperplasia, and megalocytosis of tubular epithelium in the kidney.
 - **Thiocyanates** - inhibit iodine uptake by the thyroid --> leading to reduced iodination of tyrosine --> resulting in decreased production of the important thyroid hormone thyroxine.
-

Plants involved

Some common plants that contain glucosinolates include

- *Amoracia lapathifolia*, Horseradish
 - *Brassica campestris*, Turnips, yellow-hulled rape
 - *Brassica chinensis*, Pak-choi
 - *Brassica napus*, Rutabaga, brown-hulled rape
 - *Brassica nigra*, Black mustard
 - *Brassica oleracea*, Cabbage, brusselsprouts, brocolli, cauliflower, kale, kohlrabi
 - *Crambe abyssinica*, Crambe
 - *Limnanthes alba*, Meadowfoam
 - *Nasturtium officinalis*, Watercress
 - *Raphanus sativus*, Radish
 - *Thiaspi arvense*, Stinkweed
-

Symptoms of poisoning

Glucosinolates are found in several **oil meals** that have been used traditionally in the northern states, Canada, and Europe as protein supplements for livestock. Some examples include crambe, mustard, and meadowfoam meal, and most importantly, rapeseed meal. Rapeseed meal contains several glucosinolates and produces not only oxazolidine-2-thiones but also isothiocyanates, nitriles and thiocyanates.

Poultry and **swine** and other nonruminants can tolerate 5-10% rapeseed meal in their diets. **Symptoms of poisoning in poultry** may include depressed growth, goiters, perosis, poor egg production, off-flavored eggs, enlarged thyroid in chick embryos, and liver damage. **Symptoms of poisoning in swine** include growth depression, goiters, and

enlarged livers.

Although rumen enzymes break down glucosinolate aglucones to their toxic derivatives, other rumen enzymes are able to metabolize these toxicants into less toxic compounds. Hence, ruminants can generally tolerate diets of 10% rapeseed meal. More than this can cause antithyroid symptoms.

Glucosinolates and their derivatives can be transferred through milk and placenta to the young of female animals.

Prevention of poisoning

Addition of extra iodine to diets can help to counteract the antithyroid effects of thiocyanates but not of oxazolidine-2-thiones.

Canadian plant breeders have developed low-glucosinolate cultivars of rapeseed. These cultivars are referred to as canola rather than rapeseed. Meal from them can be used in high enough quantities to provide all the protein supplementation demanded in livestock diets that require high levels of protein.

Benefits of glucosinolates

Glucosinolates are responsible for the unique taste of many of the condiments that make our foods more interesting to taste.

Research indicates that glucosinolates and their derivatives may have potential in fighting human cancers. Inclusion of *Brassica* vegetables appear to help protect against rectal and colon cancer. These vegetables aid in the detoxification of carcinogens such as aflatoxins and polybromobiphenyl. They enhance the activity of several hepatic enzymes used in detoxification processes. Benzyl isothiocyanate and thiocyanate have been shown in the lab to inhibit tumor development in animals exposed to carcinogens. Indole-3-carbinol, a product of glucosinolates, is a compound with promise in anticancer research.

PHYTOESTROGENS (COUMESTANS AND ISOFLAVONES)

INDEX

- [Introduction](#)
 - [Clovers \(*Trifolium* spp.\)](#)
 - Alfalfa (*Medicago sativa*)
 - [How poisoning occurs](#)
 - [Symptoms of poisoning](#)
-

INTRODUCTION

Phytoestrogens are plant estrogens. When consumed by livestock they exhibit estrogenic activity and may hamper reproductive performance. Clovers such as subterranean clover (*Trifolium subterranean*) and red clover (*Trifolium pratense*) generally contain isoflavones. Alfalfa (*Medicago sativa*) contains coumestans.

Subterranean Clover and Red Clover (*Trifolium subterranean*)

Subterranean Clover

Subterranean clover is a winter annual grown in the northwest regions of the U.S. as a winter and spring pasture crop. It pushes its seeds down into the ground upon maturity and thus reseeds itself. Its seeds can remain dormant for many years making it difficult to eradicate once established in a pasture.

Red Clover

HOW POISONING OCCURS

Certain water soluble glucosides in plants bear a close resemblance to estradiol and are known as plant estrogens ([click here to see the similarities](#)). Clovers synthesize isoflavones such as biochanin A, daidzein, formononetin, and genistein from phenylalanine, while alfalfa synthesizes coumestans from cinnamic acid. Although formononetin has about half, one third, and one quarter the estrogenic activity of biochanin A, daidzein, and genistein, respectively, negative estrogenic effects on sheep

appear to be directly correlated to the formononetin content of the clover forage. This is because [rumen microorganisms degrade genistein and biochanin A to p-ethylphenol and phenolic acids](#), thus destroying their estrogenic effects. However, rumen microorganisms demethylate formononetin to daidzein, and then together with any daidzein directly consumed from the clover, these minor [phytoestrogens are metabolized to equol](#) which is a much more potent form of estrogen. Absorbed equol is rapidly excreted in the urine of cattle, but not in sheep. Thus sheep are much more susceptible to the estrogenic effects of isoflavones. Isoflavones alter the responsiveness of the animal tissue to endogenous estrogen. High serum levels of phytoestrogens may also inhibit the release of gonadotropic hormones from the pituitary gland and fill receptor sites in the cervix and uterus meant for endogenous estrogens.

SYMPTOMS OF POISONING

The cervix of a ewe exposed to high formononetin clover cultivars undergoes morphological changes. The cervical folds fuse together so that the cervical tissue resembles uterine tissue. During breeding season, the cervix and vagina fail to respond to endogenous estrogen stimulation and temporary infertility results because of reduced ability of the sperm to penetrate the oviduct. This is because the cervical mucus does not undergo its normal changes or "priming" to aid sperm longevity in the cervix. After 24 hours, the amount of viable sperm present in the cervix is only about 5% of that found in a healthy cervix. Ovulation generally occurs following standing heat so this reduced longevity of sperm can have serious consequences on conception rates. The condition may become permanent if the ewe remains on these forages for prolonged periods of time.

Cattle that are exposed to alfalfa cultivars with high contents of coumestans may experience cystic ovaries and irregular heat cycles. Dairy heifers may exhibit precocious mammary and genital development.

Ranunculosides or Ranoculins

- Ranunculosides or ranoculins as they are also called are volatile lactones. They are glycosides which upon hydrolysis split up into ranunculine and glucose. Ranunculine is then converted into an unsaturated lactone: protoanemonine

Picture . Protoanemonin formation

- Protoanemonine is a very unstable compound. Upon drying it reacts into anemonine which further converts into anemonic acid by itself. Ranunculine, protoanemonine and anemonine have medicinal properties, anemonic acid does not. Protoanemonine is toxic, its derivatives are not.
- The sap of any plant of the family *Ranunculaceae* has a burning taste and may cause reddening of skin followed by swelling and even blistering. If swallowed in large quantities, stomach irritation may follow and further develop into stomach colic and extreme gastro-enteritis and diarrhea mixed with blood. For treatment large quantities of mucilage is required.
- Ranunculosides are chemically similar to coumarins (both are lactones) but are less stable as they are not phenolic substances.
- Anyone collecting or handling plants of the family *Ranunculaceae* with bare hands should be careful not to holding them for long as the sap irritates the skin and can cause blisters.

- Some plants containing ranunculoides:

Christmas rose (*Helleborus niger*), marsh marigold (*Calatha palustris*), clematis (*Clematis recta*), wood anemone (*Anemone nemorosa*), hepatica (*Hepatica nobilis*), field buttercup (*Ranunculus acris*), globe flower (*Trollius europaeus*,) and pasque flower (*Pulsatilla vulgaris*)

SAPONINS

INDEX

- [Introduction](#)
 - [Plants involved](#)
 - [Symptoms of poisoning](#)
 - [Bloat?](#)
 - [Cholesterol absorption?](#)
-

INTRODUCTION

Saponins are glycosides with a distinctive foaming characteristic. They are found in many plants, but get their name from the soapwort plant (*Saponaria*), the root of which was used historically as a soap (Latin *sapo* ---> soap). They consist of a polycyclic aglycone that is either a choline steroid or triterpenoid attached via C3 and an ether bond to a sugar side chain. The aglycone is referred to as the sapogenin and steroid saponins are called saraponins. The ability of a saponin to foam is caused by the combination of the nonpolar sapogenin and the water soluble side chain. Saponins are bitter and reduce the palatability of livestock feeds. However if they have a triterpenoid aglycone they may instead have a licorice taste as glucuronic acid replaces sugar in triterpenoids. Some saponins reduce the feed intake and growth rate of nonruminant animals while others are not very harmful. For example, the saponins found in oats and spinach increase and accelerate the body's ability to absorb calcium and silicon, thus assisting in digestion. Certain pasture weeds contain substantial quantities of dangerous saponins and result in life threatening toxicities for certain animal species.

Plants Involved

Saponins are generally not a problem in tropical forage legumes. However, they are common in several temperate forage legumes. The use of alfalfa, (*Medicago sativa*, in supplemental protein meals for swine and poultry is limited by its saponin content. Although alfalfa contains several saponins (medicagenic acid, soyasapogenol A, soyasapogenol B, lucernic acid), medicagenic acid appears to be the one responsible for its antinutritional effects. Saponin content in alfalfa foliage is low in spring and fall and high in midsummer. Low-saponin cultivars of alfalfa have been developed. The seeds and foliage of chickpeas (*Cicer arietinum*), soybeans (), and common beans () also contain saponins. Several rangeland weeds in the US including corn cockle (*Agrostemma githago*, soapwort (*Saponaria officinalis*), cow cockle (*Saponaria vaccaria*), and

broomweed (*Gutierrezia sarothrae*) cause serious toxicity problems for grazing livestock because of their saponins. Alfombrilla (*Drymaria arenaroides*) is a weed in northern Mexico containing @3% saponins that is responsible for cattle losses in Mexico and has potential for spread to the southwest U.S. Yucca contains sarsaponins and is occasionally grazed by cattle. However, research indicates that sarsaponins might actually be beneficial to rumen digestion. Other plants containing saponins include Christmas Rose (*Helleborus niger*), Horse Chestnut trees (*Aesculus hippocastanum*), Asparagus fern (*Asparagus officinalis*), and Daisies (*Bellis perennis*)

[\[Index\]](#) [\[Introduction\]](#) [\[Plants involved\]](#) [\[Symptoms of poisoning\]](#) [\[Bloat?\]](#) [\[Cholesterol absorption?\]](#)

Symptoms of Poisoning

Alfalfa poisoning in poultry and swine:

- irritated mucous membranes of the mouth and digestive tract -->
- reduced feed intake,
- low dietary protein quality (supplemental methionine will counteract this).
- the above factors lead to--> decreased performance and growth rate.
- increased excretion of cholesterol.

Corn cockle, soapwort, cow cockle, and broomweed poisoning

- listlessness
- anorexia
- weight loss
- rough hair coat
- gastroenteritis and diarrhea
- in the case of broomweed, possibly abortion.

Alfombrilla

- same symptoms as above plants, but progressing rapidly to -->
- arched back -->
- coma -->
- death

As well as irritating the membranes of the respiratory and digestive tract, the aglycones in certain saponins increase the permeability of the membranes of red blood cells. In severe cases, the membranes are destroyed and their hemoglobin escapes into the bloodstream. This hemolytic effect varies considerably between different plant species.

[\[Index\]](#) [\[Introduction\]](#) [\[Plants involved\]](#) [\[Symptoms of poisoning\]](#) [\[Bloat?\]](#) [\[Cholesterol absorption?\]](#) [\[References\]](#) [\[Return to list of toxicants\]](#)

Bloat

Historically, saponins have been blamed for the incidence of bloat in ruminants consuming fresh alfalfa. Bloat occurs in animals grazing temperate legumes that contain saponins but not in livestock grazing tropical legumes or temperate legumes like birdsfoot trefoil that do not contain saponins. However, low-saponin cultivars of alfalfa can cause bloat. Current research blames bloat on cytoplasmic protein fractions that are also present in the plants..

Cholesterol absorption?

Humans generally do not suffer severe poisoning from saponins. Our cholesterol inactivates them so that only our mucus membranes are affected. Because of this, saponins have been used in sneezing powders, emetics, and cough syrups to facilitate expectoration. Most saponins are also diuretic. In humans, this effect disappears within a week following the neutralizing action of cholesterol.

Alfalfa saponins may have potential in human health issues because they reduce serum cholesterol by preventing its reabsorption after it has been excreted in the bile. It is hypothesized that the saponins either bind with bile salts or cause the bile salts to bind to the polysaccharides in dietary fiber. Either way the bile salts are unavailable to bind with cholesterol. Unfortunately, the feeding of alfalfa saponins to hens has not resulted in low cholesterol eggs!

VICINE AND COVICINE

INDEX

- [Introduction](#)
 - [How poisoning occurs](#)
 - [Symptoms of poisoning in humans](#)
 - [Effects on chickens](#)
 - [Effects of fava silage](#)
-

INTRODUCTION

Fava beans, *Vicia faba*, are a common human food in the Mediterranean regions of Europe. Their potential as a protein supplement for livestock is being explored in the U.S. and Canada. However, fava beans contain the glycosides [vicine](#) and covicine. These glycosides hamper the development of fava beans as a worldwide food and feed crop because they cause a disease called favism in people who have an inherited absence of the enzyme glucose-6-phosphate dehydrogenase (G6PD) in their red blood cells.

HOW POISONING OCCURS

More than 100 million people worldwide are genetically deficient in G6PD. People whose red blood cells are deficient in G6PD appear to be more resistant to the detrimental effects of malaria. Thus, this genetic condition is rarely found in populations with little historical exposure to malaria, but instead is concentrated in populations where malaria is prevalent. Susceptible people are exposed to favism either by inhaling the pollen of fava bean flowers or by eating the beans. In people who lack G6PD, [divicine](#), the aglycone of vicine, and [isouramil](#), the aglycone of covicine, cause acute hemolytic either by direct action on the red cell membranes or by producing hydrogen peroxide which in turn breaks down red cell membranes. The enzyme G6PD functions to maintain plentiful supplies of reduced glutathione. Oxidants such as divicine, isouramil, and hydrogen peroxide are normally reduced and rendered inactive by exposure to reduced glutathione. However, vulnerable individuals produce insufficient GSH to block the destruction of red cell membranes by these oxidants. The incidence of this genetic deficiency is as high as 50% in some populations. Prior to the advent of highly effective blood transfusion technology, mortality rates of 6 to 8% were reported in G6PD deficient children exposed to fava beans.

[\[Index\]](#) [\[Introduction\]](#) [\[How poisoning occurs\]](#) [\[Symptoms in humans\]](#) [\[Effects on chickens\]](#)[\[Effects of fava silage\]](#)

SYMPTOMS OF POISONING IN HUMANS

Symptoms appear shortly after inhaling pollen but not until about 5 to 24 hours after eating the beans. They include

- headaches, dizziness, nausea, yawning -->
 - vomiting, abdominal pain, and fever -->
 - at this point, symptoms either spontaneously subside, or -->
 - acute hemolytic anemia occurs.
-

EFFECTS ON CHICKENS

Fava beans have detrimental effects on the the metabolism of chickens because of their content of tannins, protease inhibitors, and lectins as well as vicine and convicine. These factors result in lower growth rate and feed efficiency, and enlarged livers and pancreas in chicks, and in poorer feed efficiency in laying hens. Dietary vicine has been shown to cause reduced fertility and hatchability of eggs, decreased egg and yolk weights, fewer eggs, increased plasma lipid and peroxide levels, and heavier livers with increased lipid peroxide levels and decreased glutathione levels in layers.

[\[Index\]](#) [\[Introduction\]](#) [\[How poisoning occurs\]](#) [\[Symptoms in humans\]](#) [\[Effects on chickens\]](#)[\[Effects of fava silage\]](#)

EFFECTS OF FAVA BEAN SILAGE

In contrast to the disappointing results of fava beans on chickens, fava bean silage has compared favorably with oat, corn, and field pea silage when fed to ruminants.

Selenium and Livestock

Metabolism, Toxicity, and Deficiency

[Background & Metabolism](#) [Distribution/Occurrence](#) [Feed Analyses](#) [Toxicity](#) [Deficiency](#) [Cattle](#) [Sheep](#) [Swine](#) [Horses](#) [Poultry](#)
[Sites](#) [References](#)

(This web page is a collection/summary of the works of several authors, referenced at the bottom of the page.)

BACKGROUND & METABOLISM

Selenium was discovered as an essential nutrient in 1957, though it was not discovered what role it played in the body until 1973. The discovery of Se in glutathione peroxidase was the key to understanding its importance in nutrition and health. Glutathione peroxidase, or GSH-Px, is essential for protecting cellular membranes from being destroyed.

Compounds called free radicals are highly reactive molecules, and if left unchecked will destroy cellular membranes. Vitamin E and GSH-Px are two molecules that help prevent this damage. Vitamin E prevents the dangerous molecules (peroxides) from being formed, but even with adequate vitamin E, some peroxides evade destruction. GSH-Px destroys the peroxides before they have a chance to cause membrane damage. GSH-Px concentration and activity is directly related to the selenium status of the animal. Selenium and vitamin E are both antioxidants because they both protect the membranes from oxidative damage. Due to this shared duty, there is a relationship between the compounds, in which one can substitute for the other in a very small way. For instance, more Se is needed when an animal's vitamin E concentrations are low. The sparing effect is an extension of this idea of substitution. Selenium spares vitamin E by:

1. preserving pancreas integrity for normal fat digestion, thus normal vitamin E absorption
2. reducing the amount of vitamin E needed to maintain lipid membranes via GSH-Px
3. aiding in the retention of vitamin E in the blood

Vitamin E spares Se by:

1. maintaining body Se in an active form and prevents loss from the body
2. preventing destruction of membrane lipids from within the membrane, which inhibits the production of hydroperoxides and decreases the amount of GSH-Px needed

Selenium has also been recently found in another enzyme, 5'-deiodinase. 5'-deiodinase is an enzyme that catalyzes the reaction of the inactive form of thyroxine to the active form. Thyroxine is a very important hormone from the thyroid that helps in regulating body temperature, metabolism, reproduction, circulation, and muscle function. It is known that Se protects the body from heavy metals such as cadmium, mercury, and silver by forming unreactive complexes with them. There are theories that Se may be involved in many other functions in the body, such as-

- a selenoprotein in sperm
- in RNA
- role in prostaglandin synthesis
- role in essential fatty acid metabolism
- required for normal immune response

Elemental selenium (Se (0)) can be reacted upon in several ways: it can be reduced to a Se(-2), called selenide, or it can be oxidized to a (+4) state, selenite, or a (+6) state,

selenate. Selenium is very similar to sulfur in its chemical properties; it is therefore, not surprising that the main form of organic Se in the body is as selenomethionine and selenocystine. Methionine and cystine are sulfur-containing amino acids, the Se can replace the sulfur because of its chemical similarities to sulfur.

There is not a lot of information on the absorption and pathway of Se from the gastrointestinal tract. It is known that it is absorbed mostly from the upper small intestine; there is no absorption from the stomach, rumen, or abomasum. The amount absorbed depends on the chemical form in which it is ingested. There does not seem to be any feedback loop to reduce the amount of Se absorbed; it has been shown, in rats, that 95% of dietary Se was absorbed regardless if fed deficient or toxic amounts. Absorbed Se travels in the plasma on a protein to its destination tissue. Tissue concentrations vary, the kidneys retain a large amount of Se, along with cardiac and skeletal muscle, and the liver. It is deposited more readily when it is in an organic form. Selenium is readily transferable through the placenta, the mammary barrier, and from hen to egg, so the animal's status will affect offspring and milk concentrations. The primary routes of excretion are through the urine and the feces, exhalation of Se only occurs in cases of toxicity. It has been found that the microorganisms in the rumen may convert Se into insoluble compounds, causing the ruminant animal to absorb less than its monogastric counterpart. It has also been suggested that more Se is absorbed when administered with a high-protein diet, the reasons have not been confirmed.

[Go back to top of page](#)

DISTRIBUTION/OCCURRENCE

Distribution of selenium is variable throughout the United States. Most of the Eastern and Northwestern areas of the country have low selenium in the soil and in the plants, while in the Midwest, there are adequate amounts of selenium in the forages. For a more detailed map:[Map of Selenium Status in US](#). There are several plant species that accumulate selenium in toxic amounts, and can cause problems in animals which consume them. The most prevalent of these species is the *Astragalus* genus, which are the locoweeds and milk vetches. For more information on *Astragalus*:

- [Canadian Poisonous Plant Page on *Astragalus bisulcatus*](#)
- [Astragalus Toxicity](#)
- [Astragalus \(pictures and description\)](#)

There are several other species of plants that are characterized as Se accumulators, such as *Zylorhiza*, woody aster and *Oonopsis*, goldenweed. All of these plants are more prevalent in the western United States. Highly seleniferous plants are not readily eaten by most animals due to their bitter taste and strong odor, but will be consumed when other forage is sparse.

FEED ANALYSES

FEED	Se CONTENT (mg/kg)	FEED	Se CONTENT (mg/kg)
Alfalfa	0.32 - 0.37	Barley grain	0.11 - 0.22
Brewer's Grain	0.70	Corn (distiller's grain)	0.48
Corn (gluten meal)	1.11	Corn (grain)	0.08
Cottonseed	10.0	Fish meal	1.4 - 2.4
Flax seed	0.9	Oats (grain)	0.26
Oats (hay)	0.17	Oats (silage)	0.01
Rape seed	1.05	Sorghum silage	0.21
Soybean seed	0.11	Sunflower meal	2.13
Wheat (soft, winter grain)	0.05	Wheat (hard, winter grain)	0.45
Whey (dehydr.)	0.06	Yeast	0.98 - 1.08

This data was taken from the NRC Nutrient Requirements for the different species.

There is only one mineral supplement that contains selenium, and that is selenite.

[Go back to top of page](#)

The toxicity and deficiency sections are general information and contain diseases that affect most species; for species specific diseases, see that species' section.

TOXICITY

Selenium toxicity is a serious threat to livestock in the western United States. There is more data on the toxicity of Se in cattle and sheep, but selenosis affects all livestock. There are two general types of toxicity, acute and chronic.

ACUTE TOXICITY

Acute poisoning is caused by the consumption, usually in a single feeding, of a sufficient quantity of highly seleniferous plants, which produce severe symptoms. Usually, death occurs within a few hours. Cattle and sheep are the most likely species to be affected, but also horses, goats, and swine. Studies have shown that possibly as little as 3 mg/kg body weight is the minimum lethal dose in cattle, for horses it may be 3.3 mg/kg BW, and for swine, 1.2 mg/kg BW caused death in 5 days. Symptoms include: abnormal movement, dark watery diarrhea, elevated temperature, weak and rapid pulse, labored respiration, bloating and abdominal pain, mucous membranes are pale and blue, and pupils are dilated. There is no known treatment to reverse the effects of the poisoning, and oftentimes the animal dies before a diagnosis can be made.

CHRONIC TOXICITY

There are two different types of chronic poisoning dependent on the chemical form of the ingested selenium. "Blind staggers" occurs when animals ingest water-soluble selenium compounds naturally found in accumulator plants. Toxicity from eating plants or grain with protein-bound, insoluble selenium is called "alkali disease."

Blind staggers normally occurs in cattle and sheep feeding on seleniferous plants. Symptoms manifest in three stages:

1. wandering, stumbling over objects, anorexia, visual impairment
2. increase in the severity of the first stage, front legs seem unable to support animal
3. blindness, paralysis of tongue and swallowing mechanism, rapid and labored respiration, salivation, and low temperature

The animal will die within a few hours from the onset of the third stage. The action of the toxicity has been documented to delay between stages. The first and second stages may be unnoticeable, and then weeks later, the animal may show signs of the third stage and die. In sheep, it is more difficult to diagnose because the stages are not as well defined as in cattle. Toxic amounts of Se can also cause birth defects in offspring from dams fed

such levels.

Alkali disease is more chronic than blind staggers, often taking years to manifest itself. It is caused by feeding on plants and grain that have protein-bound, insoluble selenium. This disease can affect all livestock, but it is detected mostly in cattle and horses. General

symptoms include: lack of vitality, anemia, emaciation, stiffness of joints, lameness, rough coat, loss of long hair, and hoof sloughing and deformities. Hoof deformities are a classic sign of selenium and can cause lameness and severe pain for the animal; food and water must be provided to the animal, for it may be hesitant to walk.

PREVENTION

The most effective way of preventing selenosis is to remove the animals from the seleniferous area. Treating the soil with sulfates, thus changing the S:Se ratio, can sometimes depress Se uptake by accumulator plants. Results from studies have shown that feeding a higher protein diet may reduce the toxicity of Se; animals fed the same amount of toxic selenium but fed a higher protein diet lived for a few more days than those animals fed a low protein diet. Dilution of high Se feeds with low Se feeds in a mixed ration will help to prevent toxicity. Recognition of seleniferous plants, proper land management, and grazing control are all necessary to completely prevent selenosis.

[Go back to top of page](#)

DEFICIENCY

Deficiency of Se is much more common in the eastern United States where the soil content of Se is low. There are many different diseases that affect the different species, all of which will be addressed in the species sections. There is one disease that is consistent in all livestock species, and that is Nutritional Muscular Dystrophy, or White Muscle Disease (WMD). Nutritional muscular dystrophy is caused by the deficiency of Se and/or vitamin E and S-containing amino acids. The disease is characterized by degeneration of the skeletal muscles, causing stiff gaits, and other problems.

PREVENTION

The most effective way of preventing Se deficiency is to supplement concentrates fed to animals with commercially available supplements to a level of about 0.1-0.3 mg/kg Se. Sodium selenite is the most common commercial supplement; calcium selenite is also

useful, and is less hazardous than sodium selenite. For animals that also eat forage, it would be possible to supplement low Se diets with high Se plants and grains. There are also Se-supplemented salt licks available, and may be the most viable option to farmers. Fertilizer containing Se has not been shown to significantly increase the Se content of the plants from that soil. In areas of known Se deficiency, it is often practice to give calves and second trimester pregnant cows intramuscular injections of Se and vitamin E to prevent disease.

[Go back to top of page](#)

CATTLE

The nutrient requirement for Se for dairy cattle has been set at 0.3 mg/kg, while the requirement for beef cattle is 0.2 mg/kg. Requirements are higher when legumes are fed, S intake is high, vitamin E intake is low, and when diets contain heavy metals. Diets with high amounts of unsaturated fatty acids will increase the requirement for Se. Effects of Se deficiency in cattle include, white muscle disease, retained placenta, unthriftiness, cystic ovarian disease, and anemia.

[Go back to top of page](#)

SHEEP

The nutrient requirement for Se for sheep is 0.10 - 0.20 mg/kg. Sheep share some of the same diseases that cattle get. There is high incidence of white muscle disease in lambs, and there are two types of WMD that affect lambs. The first is congenital WMD, where lambs are wither stillborn, or die within a few days, after physical exertion. The second type is delayed WMD, and can occur from 1-4 months after birth. These lambs walk with

an unsteady gait and arched back. Ewes also suffer from infertility and embryonic loss when Se deficient. There is also a general unthriftiness, i.e., growth depression, decrease in food consumption, and decrease in wool production.

[Go back to top of page](#)

SWINE

The nutrient requirement for Se for swine is 0.10 - 0.30 mg/kg. Pigs may show a variety of diseases in relation to Se deficiency. Hepatic dietetica is the degeneration of the liver, which can manifest itself acutely in rapidly growing pigs as liver failure, or more sub-acutely as jaundice, edema, and/or cardiomyopathy. Mulberry heart disease occurs in growing pigs that develop severe cardiomyopathy, often coupled with hemorrhages of the cardiac tissue. Similar to the other species, pigs can also develop nutritional muscular dystrophy. Spermatogenesis decreases when Se intake is extremely low. Pigs are also more susceptible to swine dysentery when selenium deficient.

[Go back to top of page](#)

HORSES

The nutrient requirement for horses is 0.10 mg/kg. Nutritional muscular dystrophy is the known disease that affects horses with Se deficiency. Similar to sheep, there are three different patterns of NMD that can occur. The first is acute, with death occurring within 24 hours. The foal's tongue may be paralyzed, making in unable to suckle. The second case is more common and is induced by exercise. Older foals are more susceptible to this form; they show an unsteady gait and general muscle weakness, rapid heart rate with arrhythmia, and labored breathing. After a few days, it is difficult to make them stand and they salivate excessively. Mortality from this condition is only about 30-45%. The third condition affects mostly older animals, and is the result of chronic Se deficiency. Affected animals show anorexia, emaciation, generalized muscle weakness, rapid heart rate, and diarrhea.

[Go back to top of page](#)

POULTRY

The nutrient requirement for poultry varies with the status of the animal. For young chicks, < 6 weeks, the requirement is 0.15 mg/kg; for the others, the requirement is 0.10 mg/kg. Several conditions affect poultry due to Se deficiency. One is exudative diathesis, which is the accumulation of fluid throughout the body, particularly in the abdomen and feet. This is caused by increased permeability of the capillaries and leakage of fluid from the capillaries. Chicks with this condition are also anemic and are protein deficient. It occurs about 2-4 weeks after hatching and is easily diagnosed due to the edema and the blue-green tint to the skin after progressing to the hemorrhagic stage. Poultry are also affected by nutritional muscular dystrophy. They also suffer from pancreatic atrophy, which has been found to be caused solely by Se deficiency. Atrophy of the pancreas results in a reduction in the amounts of lipase, trypsinogen, and chymotrypsin--all

enzymes that aid in digestion of food. Therefore, this leads to extremely reduced growth and feathering. Egg production decreases when hens are Se deficient; there is no evidence that suggests an effect on male reproduction.

Lead Poisoning

This page provides information on lead poisoning in humans as well as domestic animal populations. Sections include [sources](#) of lead in houses and barns, [environmental contamination](#) and some of its' causes, toxic levels in [children](#) and [animals](#), [symptoms](#) of toxicity and [links](#) to related sites of information.

With the relatively recent restrictions on the use of lead based paints, one of the largest sources of lead poisoning has been greatly reduced. These paints are still present in houses, garages, barns, on fences and furniture. The prevalence of lead in the world around us is still a significant health hazard, especially to certain "at risk" portions of human and animal populations. Although adults are susceptible to lead poisoning, children and newborns are most susceptible because of lower tolerance levels and the tendency to introduce foreign objects into the body.

Sources In the Home

- Lead-Based Paint-Present on many surfaces in homes not recently rebuilt or remodeled
- Lead Pipes-More common in older homes
- Lead Solder -On pipes and water heaters
- Enameled or Ceramic Pots and Dishware-Improper glazing can leech lead into foods
- Paper Wrappings-Holiday paper and party decorations (10g/kg)
- Food Packages-Polythene plastic bags, flour bags(20mg/kg),cardboard boxes with dyes (50mg/kg)
- Candy Packaging-Candy bar wrappers(7g/kg), Colored sports trading cards packaged with gum(88mg/kg)

Although lead paint chips are still the most common source of acute lead poisoning, candy wrappers and food packaging are of particular concern because they are in direct contact with immediately consumed items. It is important to keep these items from being consumed, chewed or licked.

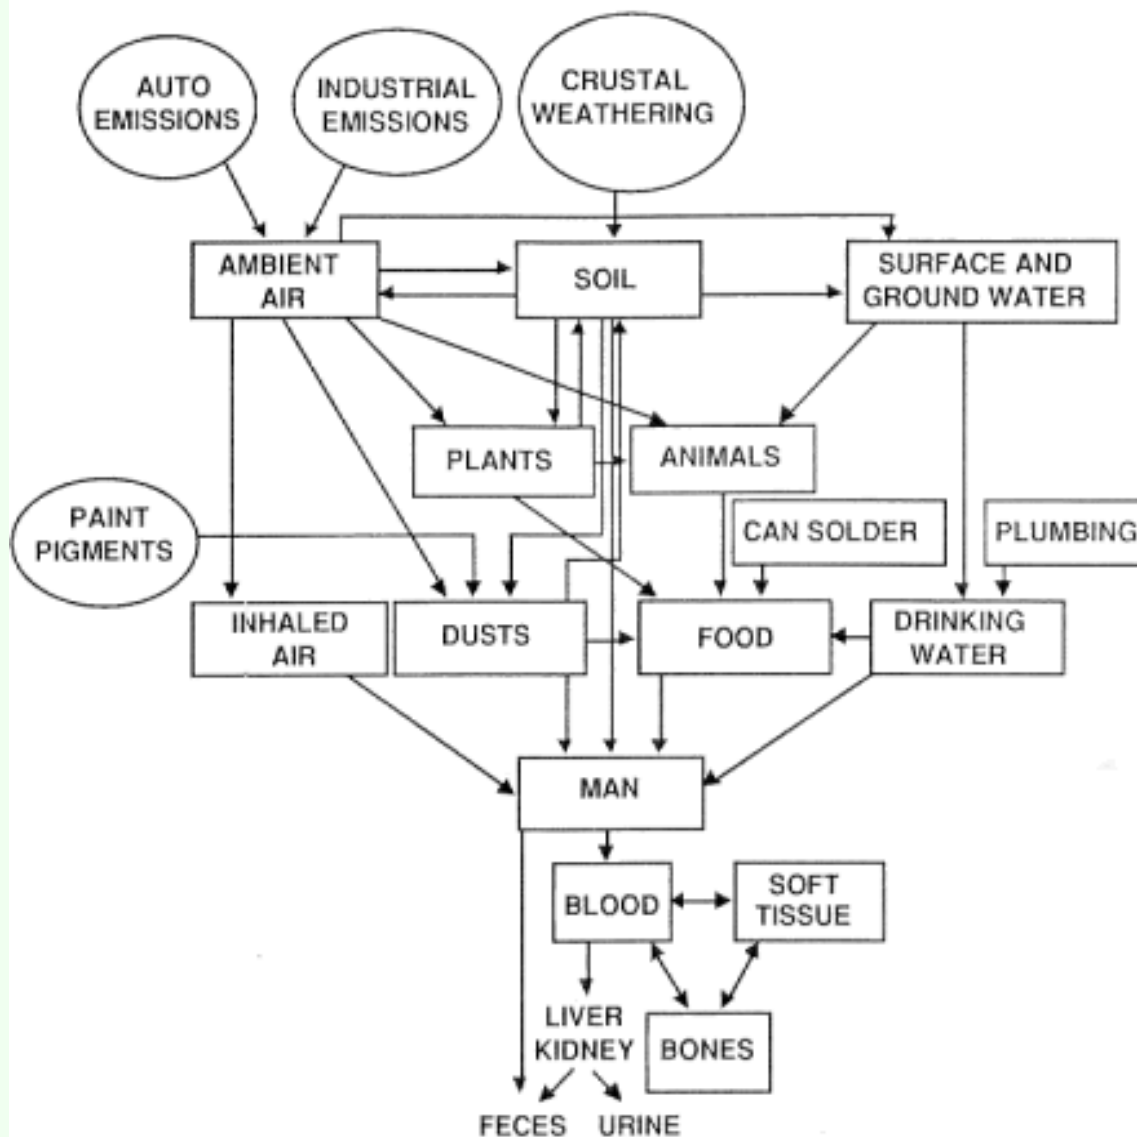

Figure 1 Pathways of lead from the environment to man, and body disposition of lead (EPA, 1986).

Environmental Contamination

- Mining-All types of mining industries, especially strip mining can cause lead and other minerals to leech into ground water, soil and even into the air as dust particles.
- Steel Industry-Any company that produces steel or uses steel in production can contribute to the bioaccumulation of lead in soil, water and air.
- Crop Enhancers-Many crop yields are increased with the use of fertilizers, fungicides and herbicides that contain appreciable amounts of lead (e.g. lead arsenate)
- Automobiles-Lead is added to some gasoline as an anti-knock agent and lead is emitted in motor vehicle exhaust.
- Batteries-Improper disposal of batteries from automobiles, electric vehicles and emergency lighting systems>
- Rogue Metal-Parts of Farm Machinery, Mining Machinery, Food Processing

Equipment or other metal objects that can break and leave pieces or shavings where they may leech into food or the environment.

Toxic Levels In Children

The blood concentrations and classes of poisoning are adapted from CDC literature "Preventing Lead Poisoning in Young Children" published in October 1991.

Class	Blood lead concentration (µg/dl)	Comment
I	= or < 9	A child in Class I is not considered to be lead- poisoned
IIA	10-14	Many children (or a large proportion of children) with blood lead levels in this range should trigger community-wide childhood lead poisoning prevention activities. Children in this range may need to be screened more frequently.
IIB	15-19	A child in Class IIB should receive nutritional and educational interventions and more frequent screening. If the blood lead levels persist in this range, environmental investigation and intervention should be done.
III	20-44	A child in Class III should receive environmental evaluation and remediation and a medical evaluation. Such a child may need pharmacologic treatment of lead poisoning.
IV	45-69	A child in Class IV will need both medical and environmental interventions, including chelation therapy.
V	= or > 70	A child in Class V lead poisoning is a medical emergency . Medical and environmental management must begin immediately

<

Toxic Levels In Animals

- Cattle-Intakes of greater than 6 mg/kg body weight can lead to chronic poisoning and intakes greater than 10 mg/kg BW may cause acute lead poisoning.
- Sheep-Generally occurs only in lambs and symptoms of poisoning appear at intakes

greater than 4.5 mg/kg BW.

- Pigs, Goats and Rabbits-More resistant than sheep or cows. Very minor signs of poisoning occur at intakes of 60 mg/kg BW. This is equal to blood concentrations of 130 micrograms per dl.
- Horses-Respiratory "roaring" occurs at intakes of 6.4 mg/kg BW. Signs of anemia occur at intakes of 7.4 mg/kg.
- Birds-Poultry can withstand dietary intakes of 100 mg/kg feed with no symptoms. Levels of 500 mg/kg induced serious poisoning.
- Dogs and Cats-Nervous symptoms of poisoning appear at intakes of 5 mg/kg BW/day.

Symptoms of Toxicity

- The general symptoms of lead poisoning are universal although more information is available on poisoning in humans. The first symptoms of lead toxicity are very general and nonspecific. These include nausea, sluggishness, vomiting, painful gastrointestinal irritation, diarrhea, loss of appetite, colic, weakness and dehydration. These symptoms are common to many disorders and can often lead to inaccurate diagnosis.
- Some symptoms more specific to human poisoning include discoloration of the lips and skin attributed mild secondary anemia, a lead line on the gums, developmental disorders, sterility and abortion. There have also been some preliminary reports indicating that chronic lead poisoning can also lead to chronic nephritis and premature development of arteriosclerosis.
- More severe cases of poisoning can produce symptoms including convulsions, "wrist drop" or external limb paralysis, coma and ultimately death.

Iron Toxicity, What You Don't Know

The toxicity of iron is governed by absorption. The more you take in the more you are at risk. The iron is absorbed in the ferrous state by cells of the intestinal mucous . Gastric and intestinal secretions can reduce ferric ions (the unusable form of the iron) to the ferrous (absorbable) state. Ferrous iron reacts with hydrogen peroxide (H₂O₂) to form OH, in the reaction: $Fe(II) + H_2O_2 \rightarrow OH \cdot + OH^- + Fe(III)$ Under normal conditions, the free radicals formed are controlled and removed by antioxidants, but if you have an over abundance of iron in your body, the free radicals will not be removed fast enough and there will be a build up.

Factors that influence iron toxicity are:

- Copper Level
- Phosphorus Level
- Vitamin E level

Factors that enhance iron absorption are:

- Valine and Histidine
- Ascorbic Acids, with or without Vitamin E
- Succinate
- Pyruvic Acid
- Citric Acid

Ferritin is a unique iron storage protein containing 24 storage proteins. When excess dietary iron is absorbed, the body produces more ferritin. Ferritin is greatly abundant in the heart and liver, therefore there is a large amount in these organs, and iron rushes to these organs for storage. The body can only produce so much of these proteins, however, so excess iron builds up in these organs and causes tissue destruction. Iron Overload is characterized by increased levels of ferritin (the iron storage protein), haemosiderin (another storage protein), and iron catalyzed lipid peroxidation.

There are many reasons why certain people absorb more iron than others:

1. Not everyone takes in the same amount of iron.
2. When alcohol and food are consumed together, the alcohol facilitate the absorption of iron.
3. Many people develop alcoholic cirrhosis (disease of the liver), and, hence , lose their ability to control iron uptake.
4. Dietary patterns such as drinking orange juice with a meal, increases iron absorption.

Diseases that Can Cause Iron Toxicity

Iron toxicity is not always due to an increase in dietary iron. There are many diseases that can lead to a problem in iron absorption and in turn iron toxicity. With acute iron poisoning, much of the damage to the gastrointestinal tract and liver may be a result of a high localized iron concentration and free radical production, leading to hepatotoxicity via lipid peroxidation and the destruction of the hepatic mitochondria. Therefore, the patient needs rapid removal of iron from the gut to prevent tissue damage.

The iron accumulating disease is **Hemochromatosis**. This is an iron storage disease the results from the inability of the intestine to keep out unneeded iron. Instead, iron accumulates in the liver causing siderosis (the accumulation of storage iron in tissues) and damage to the storage organs. A normal man will usually absorb 1 mg of iron/day, but with this disease, he will absorb 3mg/day. This is a very common problem, 1 out of every 15 people have a form of this disease.

There are two types of this disease:

1. Heredity or Primary Hemochromatosis
2. Acquired or Secondary Hemochromatosis

Hereditary Hemochromatosis is a hereditary disease where the intestines lack the normal ability to keep out the available but unneeded dietary iron. Patients suffering from this disease take in the iron, but have problems excreting it. The excess is therefore placed into storage. It has been shown numerous times, that with an increased uptake from the diet of 1-3 mg of iron, more than required, per day, in a period of 40-50 years, 20-40g of iron will be accumulated in the body. This accumulation especially occurs in the liver and heart, and will eventually lead to necroses and cardiopathy. This condition can be spotted at an early stage by determination of serum ferritin concentration and liver biopsy. This condition can be treated and cured if caught before the tissue damage begins.

Acquired Hemochromatosis is an intestinal abnormality occurring with acquired diseases.

Some of the diseases this may happen with are:

Anemia and Ineffective Erythropoiesis

These diseases may result when a patient receives blood transfusions, but receives them for too long and the iron begins to build up.

Liver Disease

if a patient has a liver disease, he will not be able to control the iron uptake from the liver and the iron will begin to accumulate.

High Intake of Iron

Many times people are diagnosed with anemia, but the confidence rating in this diagnosis is only 95%. Therefore, many people are given supplements that they do not need and the iron in their body increases.

Problems Resulting From Iron Toxicity

There are many problems that may result from iron toxicity, these include: anorexia, oliguria, diarrhea, hypothermia, diphasic shock, metabolic acidosis, and death. In addition to these, the patient may experience vascular congestion of the gastrointestinal tract, liver, kidneys, heart, brain, spleen, adrenals, and thymus.

As a result of iron storage disease, the liver becomes cirrhotic. Hepatoma, the primary cancer of the liver, has become the most common cause of death among patients with hemochromatosis. Also, when siderosis becomes severe in young people, myocardial disease is a common cause of death.

Impotence may occur in young men, and amenorrhea may occur in young women. Both of these sexual related problems are due to iron loading in the anterior pituitary.

Children are at Risk as Well

The lethal dose of iron for a 2 year old child is 3 g, and 1 g leads to severe poisoning. Accidental iron poisoning occurs in children consuming 10-50 iron tablets in the form of ferrous sulfate, over a period of a few hours. The ingested iron enters the stomach where the pH is low. The ferrous sulfate will remain in a soluble form, leading to irritation of the gastric mucosa. When the ferrous sulfate leaves the stomach, the pH is changed again by the pancreatic bicarbonate in the duodenum. This leads to the formation of insoluble iron complexes, causing further mucosal damage.

There was a study conducted from 1983-1990, reported in **Pediatrics**. This study reported that 53 children younger than 6 died as a direct result of unintentional ingestion. Iron supplements caused the death of 16 of these children. Iron supplements, causing 30.2% of fatalities, are the single most frequent cause of pediatric pharmaceutical unintentional fatalities.

The reason for this high percentage involves many factors, including:

- The ready availability of prenatal vitamins and iron supplements in homes with young children.
- The similar appearance of iron supplements to candy.
- The unrestricted over the counter marketing of high strength iron.

These problems could be eliminated by increasing parental education, repackaging and reformulating iron supplements, and making the warning labels more clear.

For more information on your child's risk of iron toxicity, see [Child Safety](#).

Treatment for Iron Toxicity

The following are treatments for iron toxicity:

- **Removal of the patient's blood, one unit at a time.** This is the cheapest, safest,

and most efficient way to reduce siderosis.

- **Dietary restriction.** This not an efficient way to cure the problem, but patients with iron storage disease should avoid heavily iron enriched foods, vitamins supplemented with iron, and therapeutic iron.
- **Chelating agents.** Deferoxamine is the best and least dangerous. It is expensive and administered by painful intramuscular injections. These result in the excretion of 5-15mg of iron. This is very dangerous, however, because the dose and route of administration are limited by the hypotensive effect of the drug. Deferoxamine has an LD50 of 250mg/kg body weight. This drug can only be used for a certain amount of time, not only because of it's toxicity, but also because it results in the removal of other mineral such as copper and zinc.

General Characteristics of Mycotoxins

Definition

"myco" ----> "fungus"

"toxin" ----> "poison" (Cheeke and Shull, 1985)

Mycotoxins are toxic, secondary metabolites of low molecular weight produced by naturally occurring fungi. (Chu, 1992)

Mycotoxins are neither infectious nor contagious, but can occur on a herd-wide basis. (Wren, 1994)

[\[Index\]](#) [\[Definition\]](#) [\[Mycotoxin Family\]](#) [\[Analysis of Mycotoxins\]](#) [\[Sampling\]](#) [\[Testing Kits\]](#) [\[Preventing Mycotoxin Contamination\]](#) [\[References\]](#)

Common Members of the Mycotoxin Family

- Aflatoxins
- Trichothecenes
- Zearalenone

- Fumonisin
 - Ochratoxins
 - Slaframine
-

Analytical Techniques for Mycotoxins

The "**General Referee on Mycotoxins**" gives a good overview of analytical techniques. It is published in the "**Annual Report on Mycotoxins**", which appears annually in the February/March issue of the Journal of the Association of Official Analytical Chemists. (Chu, 1992)

Because of the diversity of chemical structures and physicochemical properties of mycotoxins, approaches for their analysis vary considerably. The analysis is further complicated by the typically uneven distribution of mycotoxins in samples and by sample matrix interference. (Chu, 1992)

Troubleshooting Mycotoxin Problems in Livestock

Sampling Skills

Mycotoxin contamination of foods and feeds is usually heterogeneous. Therefore, precautions must be taken in sampling to obtain a reliable quantitative estimate of the concentration of a mycotoxin in a given lot. (Wood, 1992)

- Samples must be representative of entire lot
- Obtain samples from multiple locations
- Use of a grain or forage sampling probe is recommended
- Obtain samples from a moving grain stream
- Take samples at various unloading sites
- 10 pounds minimum
- mix thoroughly
- subsampling
- send 2 to 5 pounds for analysis
- freezing or air-tighted packing if necessary (especially for high moisture samples)

(Ideas listed were adapted from Dr. Larry Thompson's lecture and from Wren, 1994)

 - Minicolumn
-

Suggestions to Prevent Mycotoxin Contamination of Feed Stuffs

- Control the environmental factors that influence fungal growth: (Diekman and Green, 1992)
 - Moisture content of grain (<14%)
 - Relative humidity (<70%)
 - Temperature (-2.2 Centigrade)
 - Oxygen availability (<0.5%)
- Control the physical condition of the grain: (Adapted from Dr. Thompson's lecture)
 - Minimize grain damage during harvest
 - Screen grain to reduce broken kernels
- Clean storage system regularly (Wren, 1994)
- Use mold inhibitors and anti-caking additives (Diekman and Green, 1992)
- Ammoniation - to reduce aflatoxin concentrations (Diekman and Green, 1992)
- Floating separation - *Fusarium*-infected kernels are lighter than sound kernels (Diekman and Green, 1992)
- Wash, wet or dry milling and heating process (roasting, boiling, baking and frying) (Wood, 1992)
- Addition of 0.5% hydrated sodium calcium aluminosilicate in formulated feed (Diekman and Green, 1992)
- Animal aspects: (Adapted from Dr. Thompson's lecture)
 - Reduce the stress to animals
 - Increase plane of nutrition

(Comment)

Not all molds (or fungi) are toxic. Part of the deleterious impact of mycotoxins on ruminants may be caused by the indirect effect of reduced nutrition from the infected grains or forages. (Adapted from Dr. Thompson's lecture)

Abstract

Aflatoxins are toxic metabolites produced by certain fungi in/on foods and feeds . They are probably the best known and most intensively researched mycotoxins in the world. Aflatoxins have been associated with various diseases , such as [aflatoxicosis](#) , in livestock , domestic animals and humans throughout the world . The occurrence of aflatoxins is influenced by certain environmental factors ; hence the extent of contamination will vary with geographic location , agricultural and agronomic practices, and the susceptibility of commodities to fungal invasion during preharvest , storage, and/or processing periods . Aflatoxins have received greater attention than any other mycotoxins because of their demonstrated potent [carcinogenic effect](#) in susceptible laboratory animals and their acute toxicological effects in humans . As it is realized that absolute safety is never achieved , many countries have attempted to limit exposure to aflatoxins by imposing [regulatory limits](#) on commodities intended for use as food and feed

.

[Home Page](#)

Introduction

In the 1960 more than 100,000 young turkeys on poultry farms in England died in the course of a few months from an apparently new disease that was termed "**Turkey X disease**". It was soon found that the difficulty was not limited to turkeys. Ducklings and young pheasants were also affected and heavy mortality was experienced.

A careful survey of the early outbreaks showed that they were all associated with feeds, namely Brazilian peanut meal. An intensive investigation of the suspect peanut meal was undertaken and it was quickly found that this peanut meal was highly toxic to poultry and ducklings with symptoms typical of Turkey X disease.

Speculations made during 1960 regarding the nature of the toxin suggested that it might be of fungal origin. In fact, the toxin-producing fungus was identified as [Aspergillus flavus](#) (1961) and the toxin was given the name **Aflatoxin** by virtue of its origin (A.flavis--> Afla).

This discovery has led to a growing awareness of the potential hazards of these substances as contaminants of food and feed causing illness and even death in humans and other mammals. Studies that are summarized in the following sections revealed that aflatoxins are produced primarily by some strains of **A. Flavus** and by most, if not all, strains of **A. parasiticus**, plus related species, **A. nomius** and **A. niger**. Moreover, these studies also revealed that there are four major aflatoxins: [B1](#), [B2](#), [G1](#), [G2](#) plus two additional metabolic products, [M1](#) and M2, that are of significance as direct contaminants of foods and feeds. The aflatoxins M1 and M2 were first isolated from milk of lactating animals fed aflatoxin preparations; hence, the M designation. Whereas the B designation of aflatoxins B1 and B2 resulted from the exhibition of blue fluorescence under UV-light, while the G designation refers to the yellow-green fluorescence of the relevant structures under UV-light. These toxins have closely similar structures and form a unique group of highly oxygenated, naturally occurring heterocyclic compounds. Their molecular formulas as established from elementary analyses and mass spectrometric determinations are:

- B1 : C₁₇ H₁₂ O₆
- B2 : C₁₇ H₁₄ O₆
- G1 : C₁₇ H₁₂ O₇
- G2 : C₁₇ H₁₄ O₇

Aflatoxins B2 and G2 were established as the dihydroxy derivatives of B1 and G1, respectively. Whereas, aflatoxin M1 is 4-hydroxy aflatoxin B1 and aflatoxin M2 is 4-dihydroxy aflatoxin B2.

Occurrence

In Raw Agricultural Products :

Aflatoxins often occur in [crops](#) in the field prior to harvest . Postharvest contamination can occur if crop drying is delayed and during storage of the crop if water is allowed to exceed critical values for the mold growth . Insect or rodent infestations facilitate mold invasion of some stored commodities.

Aflatoxins are detected occasionally in milk, cheese, corn, peanuts, cottonseed, nuts, almonds, figs, spices, and a variety of other foods and feeds . Milk, eggs, and meat products are sometimes contaminated because of the animal consumption of aflatoxin-contaminated feed . However, the commodities with the highest risk of aflatoxin contamination are corn, peanuts, and cottonseed.

In Processed Foods :

[Corn](#) is probably the commodity of greatest worldwide concern , because it is grown in climates that are likely to have perennial contamination with aflatoxins and corn is the staple food of many countries . However, procedures used in the processing of corn help to reduce contamination of the resulting food product . This is because although aflatoxins are stable to moderately stable in most food processes , they are unstable in processes such as those used in making tortillas that employ alkaline conditions or oxidizing steps . Aflatoxin-contaminated corn and cottonseed meal in dairy rations have resulted in aflatoxin M1 contaminated milk and milk products , including non-fat dry milk , cheese , and yogurt .

Factors Favorizing Aflatoxin Production

Fungal growth and aflatoxin contamination are the consequence of interactions among the fungus, the host and the environment . The appropriate combination of these factors determine the infestation and colonization of the substrate , and the type and amount of aflatoxin produced . However , a suitable substrate is required for fungal growth and subsequent toxin production , although the precise factor(s) that initiates toxin formation is not well understood . Water stress , high-temperature stress , and insect damage of the host plant are major determining factors in mold infestation and toxin production . Similarly , specific crop growth stages, poor fertility , high crop densities, and weed competition have been associated with increased mold growth and toxin production. Aflatoxin formation is also affected by associated growth of other molds or microbes . For example, preharvest aflatoxin contamination of peanuts and corn is favored by high temperatures, prolonged drought conditions, and high insect activity; while postharvest production of aflatoxins on corn and peanuts is favored by warm temperatures and high humidity.

[Return to Cornell Toxic Agents List](#)

Aflatoxicosis and Animal Health

[Aflatoxicosis](#) is primarily a hepatic disease . The susceptibility of individual animals to aflatoxins varies considerably depending on species, age, sex, and nutrition . In fact, aflatoxins cause liver damage, decreased milk and egg production, recurrent infection as a result of immunity suppression (eg. salmonellosis), in addition to embryo toxicity in animals consuming low dietary concentrations. While the young of a species are most susceptible, all ages are affected but in different degrees for different species. Clinical signs of aflatoxicosis in animals include gastrointestinal dysfunction, reduced reproductivity, reduced feed utilization and efficiency , anemia, and jaundice. Nursing animals may be affected as a result of the conversion of aflatoxin B1 to the metabolite aflatoxin M1 excreted in milk of dairy cattle.

The induction of cancer by aflatoxins has been extensively studied. Aflatoxin B1, aflatoxin M1, and aflatoxin G1 have been shown to cause various types of cancer in different animal species. However, only aflatoxin B1 is considered by the **International Agency for Research on Cancer (IARC)** as having produced sufficient evidence of [carcinogenicity](#) in experimental animals to be identified as a carcinogen.

Aflatoxins and Human Health

Humans are exposed to aflatoxins by consuming foods contaminated with products of fungal growth . Such exposure is difficult to avoid because fungal growth in foods is not easy to prevent . Even though heavily contaminated food supplies are not permitted in the market place in developed countries, concern still remains for the possible adverse effects resulting from long-term exposure to low levels of aflatoxins in the food supply . Evidence of acute aflatoxicosis in humans has been reported from many parts of the world , namely the Third World Countries, like Taiwan, Ouganda, India, and many others . The syndrome is characterized by vomiting, abdominal pain, pulmonary edema, convulsions, coma, and death with cerebral edema and fatty involvment of the liver , kidneys , and heart.

Conditions increasing the likelihood of acute aflatoxicosis in humans include limited availability of food, environmental conditions that favor fungal development in crops and commodities, and lack of regulatory systems for aflatoxin monitoring and control. Because aflatoxins, especially aflatoxin B1, are potent carcinogens in some animals, there is interest in the effects of long-term exposure to low levels of these important mycotoxins on humans . **In 1988, the IARC placed aflatoxin B1 on the list of human carcinogens.** This is supported by a number of epidemiological studies done in Asia and Africa that have demonstrated a **positive association between dietary aflatoxins and Liver Cell Cancer (LCC)** . Additionally , the expression of aflatoxin-related diseases in humans may be influenced by factors such as age, sex, nutritional status, and/or concurrent exposure to other causative agents such as viral hepatitis (HBV) or parasite infestation.

Recent Methods of Analysis for Aflatoxins in Foods and Feeds

Sampling and Sample Preparation :

Sampling and sample preparation remain a considerable source of error in the analytical identification of aflatoxins. Thus, systematic approaches to sampling, sample preparation, and analysis are absolutely necessary to determine aflatoxins at the parts-per-billion level . In this regard, specific plans have been developed and tested rigorously for some commodities such as corn, peanuts, and tree nuts; sampling plans for some other commodities have been modeled after them. A common feature of all sampling plans is that the entire primary sample must be ground and mixed so that the analytical test portion has the same concentration of toxin as the original sample.

Solid-Phase Extraction :

All analytical procedures include three steps: extraction, purification, and determination. The most significant recent improvement in the purification step is the use of solid-phase extraction.

Test extracts are cleaned up before instrumental analysis(thin layer or liquid chromatography) to remove coextracted materials that often interfere with the determination of target analytes.

Thin-Layer Chromatography :

Thin layer chromatography (TLC) , also known as flat bed chromatography or planar chromatography is one of the most widely used separation techniques in aflatoxin analysis. Since 1990, it has been considered the AOAC official method and the method of choice to identify and quantitate aflatoxins at levels as low as 1 ng/g. The TLC method is also used to verify findings by newer, more rapid techniques .

Liquid Chromatography :

Liquid chromatography (LC) is similar to TLC in many respects, including analyte application, stationary phase, and mobile phase. Liquid chromatography and TLC complement each other. For an analyst to use TLC for preliminary work to optimize LC separation conditions is not unusual.

Liquid chromatography methods for the determination of aflatoxins in foods include normal-phase LC (NPLC), reversed-phase LC (RPLC) with pre- or before-column derivatization (BCD), RPLC followed by postcolumn derivatization (PCD), and RPLC with electrochemical detection.

Immunochemical Methods :

Thin layer chromatography and LC methods for determining aflatoxins in food are laborious and time consuming . Often, these techniques require knowledge and experience of chromatographic techniques to solve separation and interference problems. Through advances in biotechnology, highly specific antibody-based tests are now commercially available that can identify and measure aflatoxins in food in less than 10 minutes. These tests are based on the affinities of the monoclonal or polyclonal antibodies for aflatoxins. The three types of immunochemical methods are radioimmunoassay (RIA), enzyme-linked immunosorbent assay (ELISA), and immunoaffinity column assay (ICA).

Confirmation of Identities of the Aflatoxins :

Although analytical methods might consist of different extraction, clean-up, and quantitation steps, the results of the analyses by such methods should be similar when the methods are applied properly. Since the reliability of the quantitative data is not in question, the problem still to be solved is the confirmation of identity of the aflatoxins. The confirmation techniques used involve either chemical derivatization or mass spectrometry (MS).

Safety Issues in Handling Moldy Grains and Aflatoxins :

Safety is a key issue for scientists working in the aflatoxin area. Steps must be taken to minimize exposure to the toxins as well as to the producing microorganisms, **Aspergillus flavus** and **Aspergillus parasiticus**. A safety program should be established that meets the requirements of the Laboratory Standard of the Occupational Safety and Health Administration (1990) and the guidelines of the National Institutes of Health (1981) covering use of chemical carcinogens .

Monitoring Techniques for Assessing Human Exposure to Aflatoxins

In the last few years, new technologies have been developed that more accurately monitor individual exposures to aflatoxins. Particular attention has been paid to the analysis of aflatoxin DNA adducts and albumin adducts as surrogates for genotoxicity in people. Autrup et al.(1983) pioneered the use of synchronous fluorescence spectroscopy for the measurement of aflatoxin DNA adducts in urine. Urine samples collected after exposure to aflatoxins were found to contain 2,3-dihydroxy-2-(N7-guanyl)-3-hydroxyaflatoxin B1, trivially known as **AFB-Gual**. Wild et al.(1986) used highly sensitive immunoassays to quantitate aflatoxins in human body fluids. An enzyme linked immunosorbent assay (ELISA) was used to quantitate aflatoxin B1 over the range of 0.01 ng/ml to 10 ng/ml, and was validated in human urine samples. Using this method, aflatoxin-DNA adduct excretion into urine was found to be positively correlated with dietary intake, and the major aflatoxin B1-DNA adduct excreted in urine was shown to be an appropriate dosimeter for monitoring aflatoxin dietary exposure.

[Return to Cornell Toxic Agents List](#)

Control and Management of Aflatoxins

A- Regulatory Control :

Aflatoxins are considered unavoidable contaminants of food and feed, even where good manufacturing practices have been followed. The FDA has established specific guidelines on acceptable levels of aflatoxins in human food and animal feed by establishing action levels that allow for the removal of violative lots from commerce. [The action level](#) for human food is 20 ppb total aflatoxins, with the exception of milk which has an action level of 0.5 ppb for aflatoxin M1. The action level for most feeds is also 20 ppb. However, it is very difficult to accurately estimate aflatoxins concentration in a large quantity of material because of the variability associated with testing procedures; hence, the true aflatoxin concentration in a lot cannot be determined with 100% certainty.

B- Detoxification Strategies :

Because aflatoxin contamination is unavoidable, numerous strategies for their detoxification have been proposed. These include physical methods of separation, thermal inactivation, irradiation, solvent extraction, adsorption from solution, microbial inactivation, and fermentation. Chemical methods of detoxification are also practiced as a major strategy for effective detoxification :

- **Structural Degradation Following Chemical Treatment :**

A diverse group of chemicals has been tested for the ability to degrade and inactivate aflatoxins. A number of these chemicals can react to destroy (or degrade) aflatoxins effectively but most are impractical or potentially unsafe because of the formation of toxic residues or the perturbation of nutrient content and the organoleptic properties of the product. Two chemical approaches to the detoxification of aflatoxins that have received considerable attention are ammoniation and reaction with sodium bisulfite.

Many studies provide evidence that chemical treatment via ammoniation may provide an effective method to detoxify aflatoxin-contaminated corn and other commodities. The mechanism for this action appears to involve hydrolysis of the lactone ring and chemical conversion of the parent compound aflatoxin B1 to numerous products that exhibit greatly decreased toxicity.

On the other hand, sodium bisulfite has been shown to react with aflatoxins (B1, G1, and M1) under various conditions of temperature, concentration, and time to form water-soluble products.

- **Modification of Toxicity by Dietary Chemicals :**

The toxicity of mycotoxins may be strongly influenced by dietary chemicals that alter the normal responses of mammalian systems to these substances. A variable array of chemical factors, including nutritional components (e.g. dietary protein and fat, vitamins, and trace elements), food and feed additives (e.g. antibiotics and preservatives), as well as other chemical factors may interact with the effects of aflatoxins in animals.

- **Alteration of Bioavailability by Aflatoxin chemisorbents :**

A new approach to the detoxification of aflatoxins is the addition of inorganic sorbent materials, known as **chemisorbents**, such as hydrated sodium calcium aluminosilicate (HSCAS) to the diet of animals. HSCAS possesses the ability to tightly bind and immobilize aflatoxins in the gastrointestinal tract of animals, resulting in a major reduction in aflatoxin bioavailability.

[\[Top of Page\]](#) [\[Abstract\]](#) [\[Introduction\]](#) [\[Occurrence\]](#) [\[Factors favorizing aflatoxin production\]](#) [\[Aflatoxicosis and animal health\]](#) [\[Aflatoxins and human health\]](#) [\[Methods of analysis for aflatoxins\]](#) [\[Assessing human exposure to aflatoxins\]](#) [\[Control and management of aflatoxins\]](#) [\[Economic impact of aflatoxins\]](#) [\[References\]](#)

[Return to Cornell Toxic Agents List](#)

Economic Impact of Aflatoxins

[The economic impact](#) of aflatoxins derive directly from crop and livestock losses as well as indirectly from the cost of regulatory programs designed to reduce risks to animal and human health. The Food and Agriculture Organization (FAO) estimates that 25% of the world's food crops are affected by mycotoxins, of which the most notorious are aflatoxins. Aflatoxin losses to livestock and poultry producers from aflatoxin-contaminated feeds include death and the more subtle effects of immune system suppression, reduced growth rates, and losses in feed efficiency. Other adverse economic effects of aflatoxins include lower yields for food and fiber crops .

In addition, the ability of aflatoxins to cause cancer and related diseases in humans given their seemingly unavoidable occurrence in foods and feeds make the prevention and detoxification of these mycotoxins one of the most challenging toxicology issues of present time.

Trichothecenes

Trichothecenes are produced by several common molds including species in the genera *Acremonium* (*Cephalosporium*), *Cylindrocarpon*, *Dendrodochium*, *Myrothecium*, *Trichoderma*, *Trichothecium*, and most numerous in *Fusarium*. Trichothecenes are composed of a tetracyclic sesquiterpene skeleton containing a six-membered oxane ring, a stable epoxide group in positions 12 and 13 and a 9,10 olefinic bond. They have been classified into four groups. *Fusarium* spp. contain several well known trichothecenes including two highly toxic members of group A, diacetoxyscirpenol (DAS) and T-2 toxin, and toxins in group B including deoxynivalenol (DON) and nivalenol. DON is the most common but least toxic of these. Trichothecenes are strong inhibitors of protein synthesis in mammalian cells. However, DON received its common name, vomitoxin, from the vomiting that generally accompanies trichothecene poisoning. (D'Mello, et.al., 1991)

DON resulted in feed refusal in swine. In lambs, consumption of a wheat diet containing DON at 15.6 mg/kg of BW for 28 d did not alter feed consumption, weight gain, or feed efficiency. Oral administration of DON showed that it was rapidly passed essentially unchanged (95%) and excreted primarily in urine. Incubation of DON with ruminal microorganisms in vitro for 48 h resulted in partial conversion to deepoxy DON. These results indicate that the impact of DON on ruminants is lower than initially suspected. DON caused no organ damages to animals. Extremely low amounts of DON (<4ng/ml) were transmitted to milk after a single oral dose of 920 mg to a dairy cow. (Diekman and Green, 1992)

The FDA issued an "advisory" to federal and state officials recommending a level of concern for DON of 2 micrograms of DON/ gm for wheat entering the milling process, 1 microgram/ gm in finished wheat products for human consumption, and 4 microgram/ gm for wheat and wheat milling by-products used in animal feed. (Wood, 1992)

Zearalenone

Mycotoxins produced by *Fusarium* spp. are of two general types: 1) the nonestrogenic trichothecenes, including DON, nivalenol, T-2 toxin, and diacetoxyscripenol, and 2) the mycoestrogens, including Zearalenone (ZEN) and zearalenol. Zearalenone and zearalenol are both estrogenic resorcylic acid lactone compounds produced by the fungi *Fusarium* spp. (Diekman and Green, 1992)

Despite their structural dissimilarity to the steroidal estrogens, ZEN and several of its derivatives possess **estrogenic activity**. ZEN undergoes a folding such that hydroxyl or potential hydroxyl groups become appropriately orientated to facilitate binding to tissue receptors that normally bind estrogens. Similar binding affinities for ZEN have been determined for the estrogen receptor in sheep and calf uterus. (Diekman and Green, 1992)

Poultry show little reaction to ZEN ingestion. However, **swine** are strongly affected with symptoms in prepubertal gilts including enlarged mammae, swelling of uterus and vulva, and atrophy of the ovaries. In severe cases, prolapse of the vulva and rectum may occur. Boars exhibit enlarged mammae and atrophied testes. (Flannigan, 1991)

Although **cattle** are not as sensitive to ZEN as swine, a few experiments have been done to determine whether ZEN affects performance of cattle. Infertility, reduced milk production, and hyperestrogenism in cows have been reported in association with ZEN. Hay containing 14 ppm of ZEN caused infertility in cattle. Holstein cows that consumed 25 to 200 ppm of ZEN for 42 consecutive days exhibited swollen and hyperemic external genitalia but had estrous cycles of normal lengths and normal ovulations. Enlarged mammary glands that exhibited secretory activity were reported in prepubertal heifers that consumed moldy corn with ZEN. Dairy cattle fed a ration that contained 385 to 1925 ppb of ZEN for 7 weeks had normal milk production. No ZEN residues were found in milk, urine, serum or tissues. Corn that contained 500 ppb of ZEN had no effect on milk or butterfat production. (Diekman and Green, 1992)

Virgin dairy heifers fed 250mg of purified ZEN for three estrous cycles had an average conception rate of 62%, compared with 87% in control heifers. Nonlactating, nonpregnant dairy cows given 500 mg of ZEN daily for two estrous cycles had normal serum concentration of progesterone, normal mating behavior, and normal genital tracts. (Diekman and Green, 1992)

In vivo studies have revealed that ZEN is rapidly metabolized in animals and humans and eliminated mainly as water-soluble glucuronides. Free and conjugated forms of ZEN have been found in the milk of lactating cows under experimental conditions. That high oral doses of the toxin are required to elicit such a response indicates that consumption of

contaminated feed by dairy cows would not result in a health hazard to humans.(Wood, 1992)

Tannins: fascinating but sometimes dangerous molecules

Welcome to the Tannin home page. We offer a variety of information on tannins including, but not limited to, their biosynthesis, chemical structures, toxicology, positive effects, chemical analysis....

Tannins are naturally occurring **plant polyphenols**. Their main characteristic is that they **bind and precipitate proteins**. They can have a large influence on the nutritive value of many foods eaten by humans and feedstuff eaten by animals. Tannins are common in fruits (grapes, persimmon, blueberry...), in tea, in chocolate, in legume forages (trefoil..), in legume trees (*Acacia* spp., *Sesbania* spp., ...), in grasses (sorghum, corn ...).

Tannins contribute to many aspects of our daily lives. They are responsible for the **astrigent taste we experience when we partake of** wine or unripe fruits, and for the enchanting colors seen in flowers and in autumn leaves.

For more information on tannins explore the following topics:

THIAMINASES

Thiaminases are enzymes found in a few plants and the raw flesh and viscera of certain fish and shellfish. When ingested these enzymes split thiamin (Vitamin B1), an important compound in energy metabolism, and render it inactive. The following pages detail how thiaminases work metabolically, where they are found, and the effect their ingestion can have on livestock and humans.

An Overview of Thiamin Metabolism

This is thiamin:

This is what thiamin does:

The active form of thiamin - thiamin pyrophosphate (TPP) works as a coenzyme in the following important reactions:

1. The conversion of pyruvate to acetyl-CoA catalyzed by pyruvate dehydrogenase.
2. The conversion of alpha-ketoglutarate to succinyl-CoA in the TCA cycle catalyzed by alpha-ketoglutarate dehydrogenase.
3. The conversion of branched-chain alpha-keto acids to acyl-CoA's catalyzed by branched-chain alpha-ketoacid dehydrogenase.
4. The transfer of a 2C fragment from alpha-keto sugars to aldose acceptors in the pentose-phosphate shunt catalyzed by transketolase.

It should be obvious from the above that thiamin is an essential component of energy metabolism. Without sufficient thiamin, animals have impaired pyruvate utilization, causing increased plasma pyruvate levels and a shortage of cellular ATP. Thiamin deficient animals also have below normal transketolase activity, and therefore a good test of thiamin status is to test the amount of erythrocyte transketolase activity an animal exhibits. Because thiamin is so essential to energy utilization, general signs of thiamin deficiency include weight loss, impaired feed utilization, and weakness. More deficiency signs are detailed in the pages under Signs/Symptoms of Thiamin Deficiency.

Some thiamin is also used to form thiamin triphosphate which is thought to have a function in brain cell viability, though its exact role is still unclear.

Natural sources of thiamin include yeasts, meats (especially pork liver), and whole cereal grains. Unfortunately, processing of grains greatly reduces their thiamin content. Thiamin is absorbed through the intestinal wall by both passive diffusion and active, carrier-mediated transport depending on the concentration present. Active transport is highest in the jejunum and ileum, therefore lower gut fermentors that are not coprophagous absorb little of the thiamin produced by intestinal microflora. Ruminants generally have their thiamin needs met by the thiamin production of the rumen microflora. Once absorbed, thiamin is transported in the

serum chiefly bound to albumin.

Thiaminases - Definition and Mechanism of Action

Thiaminases are enzymes that cleave the thiamin molecule and render it biologically inactive. Generally there are two types of thiaminases:

- **Type I** - the most common form, this type is found in fish, shellfish, ferns and some bacteria. It acts by displacing the pyrimidine methylene group with a nitrogenous base or SH-compound to eliminate the thiazole ring.
- **Type II** - found in certain bacteria, this type acts through the hydrolytic cleavage of the methylene-thiazole-N bond to yield pyrimidine and thiamin moieties.

Both types of thiabinase require a cosubstrate - usually an amine or sulfhydryl-containing compound such as proline or cysteine. Once the thiamin molecule is cleaved by a thiabinase the body is incapable of restoring it. Thus, the ingestion of significant amounts of thiabinases can induce thiamin deficiency even though there may be a sufficient amount of thiamin in the diet.

Thiabinases are denatured by heat, therefore subjecting any of the sources of thiabinases to cooking or other heat treatment will render the thiabinases inactive.

[Back to Index](#)

Signs of thiamin deficiency in non-ruminants.

Because they are unable to fully utilize the energy in their diet, thiamin-deficient non-ruminants will exhibit severe anorexia which will, of course, be accompanied by weight loss and weakness. Such animals will also typically show neurological disfunction to a greater or lesser degree including ataxia and convulsions. Some species, especially birds, will exhibit opisthotonus - a retraction of the head sometimes referred to as "star-gazing". Thiamin deficiency will also cause cardiac disfunction in some species. Symptoms of this include cardiac enlargement and a slowed heart rate. Further heart failure can lead to severe cases of edema.

The following photo shows cardiac enlargement in a pig. On the left is the heart of a normal pig, the heart on the right is of a thiamin-deficient pig.

In humans thiamin deficiency leads to a disease termed "beri-beri". Symptoms of beri-beri are basically the same as thiamin deficiency in other non-ruminants - anorexia, cardiac enlargement, and muscular weakness leading to ataxia. However, the disease has been divided into the following two forms:

- **Dry beri-beri** - usually without cardiac involvement, this form of the disease is typified by atrophy of the legs and peripheral neuritis. It occurs mainly in adults.
- **Wet beri-beri** - the primary sign of this form of the disease is cardiac enlargement and edema.

[Back to Index](#)

Signs/Symptoms of thiamin deficiency in ruminants

Thiamin deficiency in ruminants manifests itself as polioencephalomalacia. Signs of polioencephalomalacia include disorientation and wandering, blindness and opisthotonus or retraction of the head. The brain of infected animals becomes inflamed and edematous. Ruminants will also show symptoms as seen in other animals - anorexia, poor feed utilization and weakness.

Normally ruminants are fairly resistant to thiamin deficiency since rumen microbes provide the animal with sufficient amounts of thiamin. However, the ingestion of thiabinases will lead to polioencephalomalacia. Additionally, young growing ruminants, especially cattle and sheep, fed high-grain diets are especially susceptible. Diets high in grains can encourage the growth of certain thiaminase-producing bacteria in the rumen. These bacteria, including *Clostridium sporogenes* and a few species of *Bascillus* can produce enough thiabinases to induce thiamin deficiency.

A sheep with polioencephalomalacia:

[Back to Index](#)

Bracken Fern (*Pteridium aquilinum*)

Bracken fern is widespread in humid temperate areas including the North American West Coast, Europe, Japan, Australia, and New Zealand. The highest thiaminase activity is in the rhizomes, but all areas of the plant contain some thiaminase and show seasonal variability as follows:

The most common instances of bracken poisoning in livestock occur during one of the following scenarios:

1. In the spring - when bracken fern is one of the first plants to emerge and therefore potentially a major component of the pasture.
2. In animals kept on very lush pastures that may select bracken fern for its fiber content.
3. Bracken fern contamination in hay.
4. In fields where plowing has exposed the rhizomes.
5. Bracken fern used as bedding.

Non-ruminants consuming significant amounts of bracken fern in their diet will

exhibit signs of thiamin deficiency. Horses fed hay with greater than twenty percent bracken fern will begin to be symptomatic within a month.

[Back to Index](#)

Horsetails (*Equisetum arvense*)

Horsetails are widespread in moist areas of the United States and Canada and contain significant thiamin activity. The most common instance of thiaminase poisoning resulting from horsetails is the contamination of hay with horsetails. A horse consuming hay containing twenty percent or more of horsetail plants will show signs of thiamin deficiency in two to five weeks

[Back to Index](#)

Other sources

Nardoo (*Marsilea drummondii*)

Nardoo is an Australian fern that can contain thiaminase activity up to one hundred times that of bracken fern. Nardoo will often grow in areas that have recently flooded, and is responsible for a large number of cases of thiamin deficiency and death in sheep in Australia and New Zealand.

Fish and Shellfish

Thiaminases are present in the viscera of certain raw fishes and shellfishes, especially carp. Humans, even sushi lovers, rarely eat enough raw fish in their diet to constitute a problem. However, thiaminase induced thiamin deficiency has been seen in mink and foxes fed large amounts of raw fish in their diet. Termed Chastek's paralysis, after the fox farmer who first documented the disease, thiamin deficiency in these animals follows the same path as outlined above.

Rock Fern (*Cheilanthes sieberi*)

Another Australian fern, found mainly on the coast, rock fern also has a high level of thiaminase activity.

Kochia (*Kochia scoparia*)

Kochia, also termed summer cypress and fireweed grows mainly in desert regions of the south-western United States. Ruminants grazing on kochia have developed polyencephalomalacia, however it is unclear whether this effect is due to the presence of a thiaminase or a hepatotoxin which interferes with thiamin utilization. Infected animals also exhibit liver necrosis, which suggests a hepatotoxin as the main factor in kochia poisoning. If a thiaminase exists, it is probably not a dominant factor.

Bacteria

As stated in the page on thiamin deficiency in ruminants, it is known that certain species of bacteria are capable of producing thiaminases. *Clostridium sporogenes* and a few species of *Bacillus* are thought to be the main culprits. If these species dominate in the rumen environment, thiamin

deficiency can result. Feeding high grain diets favors the growth of these species, and young ruminants, age two to seven months, are at greatest risk.

[Back to Index](#)

Treatment of Thiaminase Poisoning

Animals suffering from thiamin deficiency due to the ingestion of thiabinases generally respond very well to treatment if caught early. Intra-muscular of injections of thiamin, and removing the source of the thiaminase from the animal's diet, are usually sufficient to bring around full recovery. Doses of 100-500 mg of thiamin for sheep and 200-500 mg for calves, depending on body weight are sufficient.

[Back to Index](#)

The story of Australian explorers, or why you should cook your ferns.

Okay, so legend has it, and so does Moorehead's book *Cooper's Creek* (1963), that a couple of Australian explorers, Robert Burke and William Wills, died in 1861 from thiaminase poisoning. They were wandering around the Australian continent, doing what explorers do, and their supply of pork which was their main source of thiamin ran out. So what did these guys start feasting on? Nardoo, of course. Now, if they had watched the Aborigines they would have known that one does not eat nardoo without cooking it first. But, being typical explorers, and thus thinking that they were smarter than the indigenous people that had lived on the continent for thousands of years, Burke and Wills ate their nardoo raw. They began complaining in their journals of increasing weakness and starvation, but "not so much from absolute want of food" because, Wills wrote, "I have a good appetite and relish the nardoo much but it seems to give us no nutriment." What they were suffering from then, was thiamin deficiency. Coupling a low-thiamin diet with a large intake of thiabinases from the nardoo, Burke and Wills developed beri-beri. They complained not only of weakness, but of edema too, and sensitivity to cold. They died.

The moral of the story? Cook your ferns before you eat them, and maybe throw a little pork in your diet too.

PLANT LECTINS

- [INTRODUCTION](#)
- [LECTINS IN FOODS](#)
- [FUNCTIONS OF LECTINS](#)
- [LECTINS STRUCTURE](#)
- [LECTINS IN PLANT TISSUES](#)
- TOXICITY OF LECTINS
- [DETOXIFICATION](#)
- [LECTINS AND CANCER](#)

INTRODUCTION

The high toxicity of castor beans was recognized during the last century when the extract was found to agglutinate a suspension of erythrocytes of different animal species. Since then, lectins were studied and extracted from plants, including fungus and lichens, as well as in animals.

Lectins are glycoproteins of 60,000-100,000 MW that are known for their ability to agglutinate (clump) erythrocytes in vitro. There are over 400,000 estimated binding sites for kidney bean agglutinin on the surface of each erythrocytes. Lectins are found in most types of beans, including soybeans. Reduced growth, diarrhea, and interference with nutrient absorption are caused by this class of toxicants. Different lectins have different levels of toxicity, though not all lectins are toxic, though no all are toxins. The bright

scarlet seeds of precatory bean

Abrus precatorius contain the highly toxic glycoprotein, abrin. Less toxic lectins can be fatal if ingested in high amounts. Some of such lectins is concanavalin A from *Concanavalia ensiformis* (jack bean). Others may exhibit no hemagglutinating activity as in the case of ricin from castor bean and yet it is one of the most toxic substances.

The terms phytohemagglutinins, phytagglutinins, and lectins are used interchangeably. Lectins-containing plants have been found in many botanical groups including mono- and dicotyledons, molds and lichens, but most frequently they have been detected in Leguminoseae and Euphorbiaceae. They may exist in various tissues of the same plant and have different cellular localizations and molecular properties.

Lectins interaction with certain carbohydrate is very specific. This interaction is as specific as the enzyme-substrate, or antigen-antibody interactions. Lectins may bind with free sugar or with sugar residues of polysaccharides, glycoproteins, or glycolipids which can be free or bound (as in cell membranes). The term lectin refers to the specificity of the reaction (legere = to choose).

One of the major interest in this class of glycoproteins is the therapeutic use against HIV-1. Jacalin, a plant lectin, is found to completely block human immunodeficiency virus type 1 in vitro infection of lymphoid cells. This activity of the jacalin is attributed to its ability to specifically induce the proliferation of CD4+ T lymphocytes in human.

TABLE 1. Lectin activity in 88 food items

Source of the agglutinating activity in the food; part of various countries	Food item	Agglutinin	Comments
Legumes (20)	Lupinus albus (white)	Concanavalin	Purified (2); agglutinates bovine erythrocytes and human cells

1. Lectin activity was determined by the method of [1]. 2. Purified lectins were used for the agglutination of human erythrocytes and bovine erythrocytes. 3. Lectin activity was determined by the method of [1]. 4. Purified lectins were used for the agglutination of human erythrocytes and bovine erythrocytes. 5. Lectin activity was determined by the method of [1]. 6. Purified lectins were used for the agglutination of human erythrocytes and bovine erythrocytes. 7. Lectin activity was determined by the method of [1]. 8. Purified lectins were used for the agglutination of human erythrocytes and bovine erythrocytes. 9. Lectin activity was determined by the method of [1]. 10. Purified lectins were used for the agglutination of human erythrocytes and bovine erythrocytes.

LECTINS IN FOODS

The ability to agglutinate human erythrocytes or representatives of human indigenous microflora was detected in 29 of 88 food items. Many foods contained substantial amounts of agglutinating activity, and lectins extracts could be diluted several folds and still produce agglutination. Great variation was observed in agglutination activity in the same food item purchased from different stores or from the same store on different days. Sometimes a food that possessed substantial activity on one day was found to have little or even no activity on other day.

cells and are then internalized into the root hair to form nitrogen-fixing nodules. The symbiosis is specific in that certain species of *Rhizobium* can only associate with a particular species of legume. Such observations were made from the studies that were done on soybean *Rhizobium japonicum* and the clover *Rhizobium trifolii*. Other functions of lectins in plants may include:

- Enzymes (but unknown substrate)
- Storage of proteins
- Defense mechanism
- Cell wall extension
- Mitogenic stimulation
- Transport of carbohydrates
- Packaging and/or mobilization of storage materials

LECTINS STRUCTURE

One major property of lectins is their specific saccharide- binding sites. Some lectins are composed of subunits with different binding sites. These include the lectin from the red kidney bean, *Phaseolus vulgaris*. It is composed of two different subunits combined into five different forms of noncovalently bound tetramers. Since subunits have very different specificities for cell surface receptors, each combination is considered to have a different function. The specificity of the binding sites of the lectins suggest that there are endogenous saccharide receptors in the tissues from which they are derived or on other cells or glycoconjugates with which the lectin is specialized to interact.

Metal Binding Sites

Biological activity of the lectins may be attributed to the metal ions which are the essential part of the native structure of most leguminous lectins. The most studied and fully sequenced lectin is concanavalin A. The metal binding sites of the concanavalin A are situated in the amino terminal part of the polypeptide chain. In this lectin, each subunit has aspartic 10 and 19, asparagine 14, histidine 24, serine 34, glutamic acid 8, and tyrosine 12 that are involved in the binding to one calcium and one magnesium ion.

Lectins of soybean, peas, faba bean, lentils, and sainfoin have amino acids that are involved in metal binding, which are conserved. The exception is of the tyrosine residue at position 12 of concanavalin A which is replaced with by phenylalanine in the other legume lectins.

Hydrophobic Sites

The stability of the native structure of most lectins is thought to be caused by the hydrophobic interactions. Such hydrophobic sites, forming cavities in the lectins structure, may play an important biological role. The hydrophobic binding sites of auxins, or

cytokinin and adenine, for instance, by concanavalin A may enhance the functions of lectins on the plant life cycle.

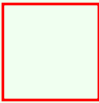

Glycosylation Sites

Despite the generalization that most lectins are considered glycoproteins, concanavalin A, lentils lectin, and wheatgerm agglutinin contain no covalently attached carbohydrates. However, non-glycoprotein lectins are believed to be synthesized as glycosylated precursors. This is supported by the following observation:

- 1) pro-concanavalin A is an inactive glycoprotein from which the glycosidic side chain is removed during post-translational processing.
- 2) Non-glycoprotein wheatgerm agglutinin molecules are produced by removing a carboxyl terminal glycopeptide from the glycosylated precursor during post-translational processing.

All glycoprotein lectins contain a peptide sequence: asparagine- X-threonine/serine, which is characteristic of glycosylation sites. These sequences are different in the non-glycoprotein lectins. Also, peptide sequences, which in one glycoprotein lectin contain the glycosidic side-chains, are not necessarily conserved in another glycoprotein lectin. This may suggest that the biological activity of the lectins may not be determined by carbohydrate part of their structure.

Carbohydrate Binding Sites

Lectins differ markedly in their  sugar-binding specificity. A sequence participating in carbohydrate-binding site of concanavalin A, for instance, are poorly conserved in other lectins.

Three Dimensional Structure

The three dimensional structures of lectins can be used to show the structural similarities and homologies of legume lectins. When the secondary structure of Viciae lectins, for instance, is compared with those

concanavalin A, an identical or homologous B- turn structures are found in these lectins. Hydrophobic profiles of two chains and single-chain lectins are superimposed, and concanavalin A has three domains that appear in some two-chain lectins of Viciaeae.

The two-chain and single-chain legume lectins exhibit high homology in the primary sequences and three-dimensional structures. Therefore evolution seems to have imposed only slight modification in the genetic coding for these lectins. This fact suggests the possibility of using lectins as an acceptable phylogenetic markers.

LECTINS IN PLANT TISSUES

Lectins in soybean plant are different from those in seeds. *Dolichos biflorus*'s lectins were studied in both the leaves and seeds. Lectins found to be produced with low level and constant for the period between 2-8 weeks after germination, then increased several folds in the next ten weeks. At this time extracts of stems and leaves contain several nanograms of lectin- like material per microgram of nitrogen, whereas mature seeds have about 1000 ng lectin per microgram. It is notable that in developing seeds the amount of lectin rises very abruptly. It is undetectable during the first 26 days after flowering but reaching a maximal level by day 28. Lectins from the stems and leaves do not agglutinate erythrocytes that could be agglutinated by seeds lectins. Stems and leaves

lectin is a dimer of a molecular weight of 68,000, in contrast to the tetrameric seed lectin with a molecular weight of 110,000.

TOXICITY OF LECTINS

Pathological lesions occur in animals injected with kidney beans extracts. Various tissues suffer from parenchymatous, fatty degeneration, and edema. In the liver local necrosis and fatty changes can be observed. Hemorrhages are observed in the stomach, the intestinal wall, and other organs. Distentions of capillary vessels may present in the Kidney and myocard with numerous thrombi. Morphological changes in rats fed navy beans include: increased weight of kidney and heart, pancreatic acinar atrophy, and fatty metamorphosis of the liver. Such changes may be attributed to the low availability of essential amino acids and low food intake of the animals consuming the raw bean diet. For example, rats fed raw kidney beans develop multiple histological lesions. Also, lectins from red kidney beans are found to induce small intestinal epithelial growth, crypt cell hyperplasia and DNA synthesis. Small amounts of isolated black bean agglutinin show low food absorption and nitrogen retention in rate.

The absorption of glucose from a ligated intestinal loop in anesthetized rats, previously fed a bean diet or given the black bean agglutinin by stomach tube, was much decreased. Raw kidney beans were found to interfere with vitamin E utilization in chicks. The hypoglycemia observed in rats fed a bean diet may indicate a reduced intestinal absorption of glucose.

Diet rich in raw soybean has a goitrogenic effect. This is indicated by the fact that fecal loss of thyroxine from the gut is higher in animals fed raw soybeans than in the controls. Raw soybean meals reduces fat and fatty acids absorption (not soybean trypsin inhibitor) in young chicks. Such meals also depresses the utilization of vitamin D in turkey. These effects are not found when the meals include heated soybean.

Ricin, abrin, crotin, and related toxins, produce similar macroscopic and microscopic pathological lesions. The intensive inflammation with destruction of epithelial cells, edema, hyperemia, and hemorrhages in the lymphatic tissues are very common. Several signs of toxicity may include: fatty degeneration and necrosis in the liver, degenerative lesions of the myocard, and extension and presence of blood clots of capillaries of all organs. At the site of lectin application, local hemorrhages are frequently observed.

In vitro, plant lectins effect lymphocyte mitogenesis, aggregate immunoglobulin induce histamine release from basophils and mast cells. When raw ground garden beans are supplemented with essential nutrients diet, weight lose and death to rats may occur within 1-2 weeks, due to the toxicity of the lectins in the beans. Raw navy beans have been found toxic for Japanese quail but not toxic for germ-feed birds. However, several cases of human intoxication were reported due to ingestion of raw or partially cooked beans.

Effect on the Gastrointestinal Tract

When given orally to experimental animals, lectins interact with the mucosa of the gastrointestinal tract causing acute gastrointestinal symptoms, failure to thrive and even death. When administered parenterally, they can alter host resistance to infection or to tumor challenge. They even can be highly allergenic under certain conditions. In vitro and in vivo tests show that intestinal cell damage are caused by bean lectins. In this regard, intestinal invertase is strongly inhibited by bean lectin as well as the absorption of vitamin B. One of the possible explanation of the toxicity of the lectins, which are resistance to gastric and intestinal digestion, is the binding to the cell lining of the intestinal walls, causing lesions and interference with nutrients absorption.

Effects on Cell Membrane

The reaction between the agglutinin and the cell membrane is believed to result in an alteration of the cell function thus producing the toxic effect. Only those cells bearing the specific receptor groups for the respective lectin would be effected. For instance, significant changes in membrane properties are induced by binding of lectins to liver cells of diabetic rats. The changes may influence such cellular properties as aggregation and deformability of erythrocytes, permeability, electrical resistance, and binding properties of mitogen, hormone, and lipoprotein receptors. The binding of concanavalin A and ricin, for instance, can be reduced by 20-25% as a result of a membrane reduction of glycoprotein carbohydrates content.

Ricin Toxicity

After intravenous injection of ricin, both the intestinal tissue and the intestinal juice of rabbits became highly toxic, indicating its concentrating in this tissue and its secretion into the intestinal lumen, but it can not be found in urine. Ricin may be appear in the milk of lactating guinea pigs which had been injected after the birth of the litters (suckling young became markedly resistance against subsequent injections of the toxin).

Magnesium blood level decreases after injection of ricin in cats. Quantitative analysis of plasma, liver, and urine, of rats acutely poisoned with ricin, along with the observation of the reduced respiratory quotient of the liver, can be used to conclude that: the toxic action of ricin may be explained by an interference with some metabolic process in the liver, possibly the Krebs cycle. Also, a rise of the blood values of urea, glucose, bilirubin, transaminases, and lactic dehydrogenase in rats fed ricin could be observed. However, detection of albumin and hematuria could lead to the conclusion that a hepatonephritis with hepatic cytolysis may be an early manifestation of ricin intoxication. A lag period between the injection of a lethal amount of ricin and death is not less than 12 hours. Ricin is many times more toxic when injected than when given orally.

DETOXIFICATION

The destruction of ricin toxicity by heat has long been recognized (1889 by Stillmark). The presence of more than one toxic principle which differ in heat resistance in castor beans must be taken into account when working with products derived from these seeds.

Although the castor bean allergen is more resistance to boiling than ricin, it can be inactivated by autoclaving. For its safe use as fertilizer and for animal feeding, detoxification of castor pomace is essential. Steam heating significantly reduces the toxicity of pomace to become harmless for sheep, rabbits, and rats, when the beans is about 10% of their diet. When used before heating castor bean, calcium hydroxide may aid in achieving complete destruction of the ricin and the allergen.

However, animals can be immunized successfully when injected with heated ricin solution in order to resist the toxicity of castor bean cake. Mice can also be protected against the fatal action of ricin if injected with blood serum from immunized goats (when given not later than 6 hours after the ricin injection).

Autoclaving is proved very helpful in enhancing the nutritive value of legumes, an effect that is probably related to the destruction of toxic hemagglutinins and other growth inhibiting factors. For complete elimination of the toxicity of kidney bean and field bean, preliminary soaking prior to autoclaving is required. In addition, autoclaving for 5 minutes is sufficient to eliminate the toxicity of finely ground navy bean meal.

However, dry heating has been found to be less effective. Thirty minutes of dry heating had little effect on hemagglutinating activity of certain varieties of *V. vulgaris*, and activity was still detectable after 18 hours of heating. Whereas, heating of the soaked beans or autoclaving was fully effective.

Moreover, formaldehyde has been recognized to reduce the agglutinating and toxic actions of ricin and agglutinating activity of bean lectin, but phenol was inactive in this respect. Potato lectin was more rapidly destroyed by phenol than by formaldehyde.

Adsorption of lectins on erythrocytes or stroma that are brought into solution is observed after heating to 56 degree C. The agglutinating and the toxic activity from a bean lectin solution disappear when it is treated with stroma. For both ricin and kidney bean agglutinin, no agglutination of erythrocytes occurs at low pH, and adsorbed lectins are observed to dissociate from the erythrocytes.

LECTINS AND CANCER

lectins present on the surface of tumor cells are targeted for therapeutic purposes. It has been found that treatment with anti- lectin antibodies can suppress growth of tumor cells in agarose, and inhibit lung colonization in vivo. Lectins have the potential use in cancer treatment strategies due to the fact that lectins present on the surface of tumor cells are capable of binding exogenous carbohydrate-containing molecules and internalize them by endocytosis.

For example, wheat germ lectin (WGA) is found to induce lectin- dependent macrophage-mediated cytotoxicity against human bladder cancer (T-24) cells. Alveolar macrophage (AM) are phagocytes, mainly present in the pulmonary alveoli, are important in the antitumor defense mechanism of the lung because they can bind to the target cell- but are unable to induce cytolysis. However, studies have revealed that human AM tumorcidal activity can be induce by wheat germ lectins. Another finding is that the sensitivities of six human tumor cell lines depend on the number of receptor sites exist on the surface of WGA. Although the effector mechanism is still unknown, the binding of AM with tumor cells initiated by WGA may increase sensitivity to the cytotoxicity mediated by human AM.

In addition, WGA is found to enhance the cell killing ability of murine peritoneal macrphages. In vivo studies show that WGA has an inhibitory effect on the growth of murine tumors. The tumoricidal activity of human blood monocytes can be induced by the WGA. As a result, the monocytes are able to become cytotoxic to four different human tumor cell lines: T-24 bladder carcinoma, A-375 melanoma, ACHN renal carcinoma, and U373MG glioblastoma. Murine systems also show similar response. However, concanavalin A, PHA, PWM and SBA are unable to produce tumoricidal monocytes.

RICIN TOXIN FROM CASTOR BEAN PLANT

Ricinus communis

Ricin is one of the most poisonous naturally occurring substances known.

Introduction

The seeds from the castor bean plant, *Ricinus communis*, are poisonous to people, animals and insects. One of the main toxic proteins is "**ricin**", named by Stillmark in 1888 when he tested the beans' extract on red blood cells and saw them agglutinate. Now we know that the agglutination was due to another toxin that was also present, called RCA (Ricinus communis agglutinin). **Ricin is a potent cytotoxin but a weak hemagglutinin, whereas RCA is a weak cytotoxin and a powerful hemagglutinin.**

Poisoning by **ingestion** of the castor bean is due to **ricin**, not RCA, because RCA does not penetrate the intestinal wall, and does not affect red blood cells unless given intravenously. If RCA is injected into the blood, it will cause the red blood cells to agglutinate and burst by hemolysis.

Perhaps just one milligram of ricin can kill an adult.

The symptoms of human poisoning begin within a few hours of ingestion.

The symptoms are:

- abdominal pain
- vomiting
- diarrhea, sometimes bloody.

Within several days there is:

- severe dehydration,
- a decrease in urine,
- and a decrease in blood pressure.

If death has not occurred in 3-5 days, the victim usually recovers. It is advisable to keep children away

from the castor bean plant or necklaces made with its seeds. In fact don't even have them in or around a house with small children. If they ingest the leaves or swallow the seeds, they may get poisoned. The highly toxic seeds beaded into necklaces, cause skin irritation at the contact point.

If the seed is swallowed without chewing, and there is no damage to the seed coat, it will most likely pass harmlessly through the digestive tract. However, if it is chewed or broken and then swallowed, the ricin toxin will be absorbed by the intestines.

It is said that just one seed can kill a child. Children are more sensitive than adults to fluid loss due to vomiting and diarrhea, and can quickly become severely dehydrated and die.

Castor bean plants in a garden should not be allowed to flower and seed.

Mechanism of Toxic Action

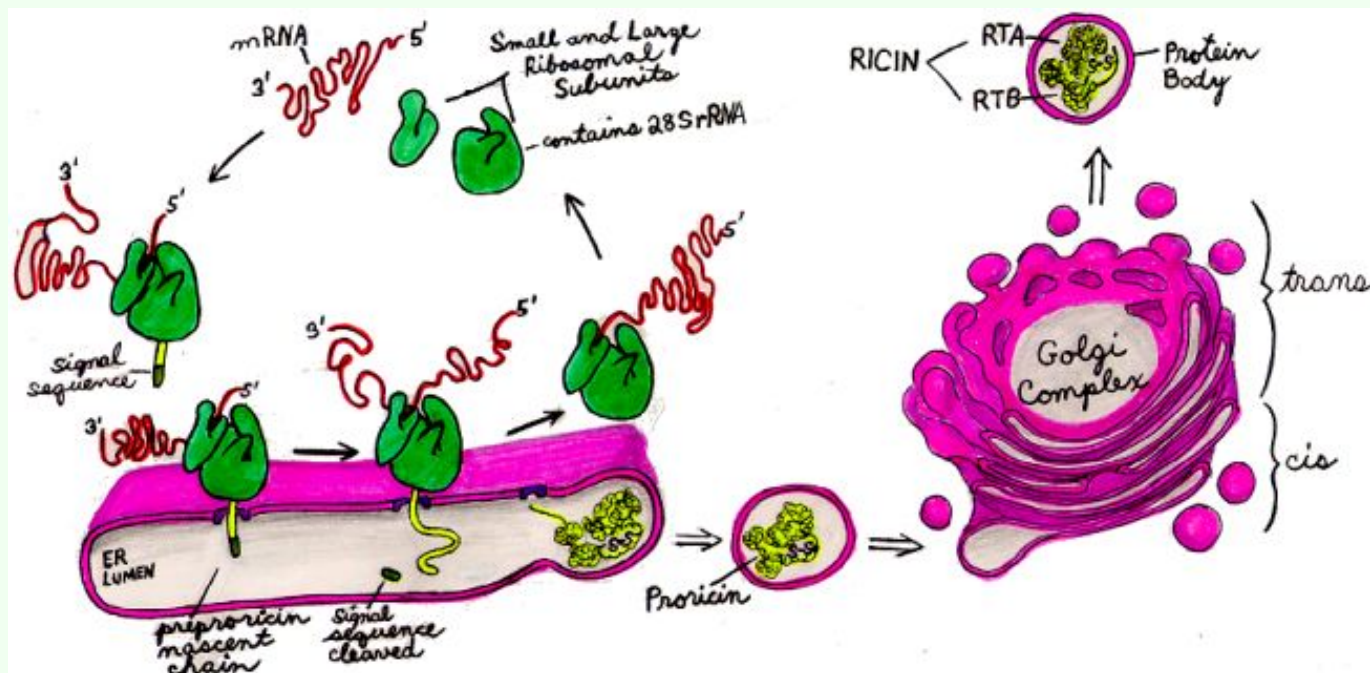

Many **cytotoxic proteins** from a variety of plants have been identified, and they are related to ricin both in structure and function. They **inhibit protein synthesis** by specifically and irreversibly inactivating **eukaryotic ribosomes**.

These "**ribosome-inactivating proteins**" (RIPs) are typically N-glycosylated, 30 kDa monomers (**Type 1 RIPs**). However, in order to bind to the cell surface galactosides and enter the cytosol to reach ribosomes, they require a second monomer, a galactose-binding, 30 kDa lectin. The monomers are joined by a disulfide bridge to form the toxic heterodimers (**Type 2 RIPs**).

Some plants, such as **wheat** and **barley**, have only **Type 1 RIPs**, and are **not poisonous**, while others, such as the **castor bean plant seed**, contain the **Type 2 RIPs** that are among the **most potent cytotoxins in nature**. 5% of the *Ricinus* seed consists of ricin and RCA (*Ricinus communis* agglutinin).

Ricin is a heterodimeric type 2 RIP. This ribosome-inactivating enzyme (32 kDa), also known as the A chain, is linked by a disulfide bond to the galactose/N-acetylgalactosamine-binding lectin (34 kDa), also called the B chain.

Ricin Biosynthesis

Ricin and RCA are synthesized in the endosperm cells of maturing seeds, and are stored in an organelle called the "protein body", a vacuolar compartment. When the mature seed germinates, the toxins are destroyed by hydrolysis within a few days.

Ricin begins synthesis as a **prepolypeptide** that contains both **A and B chains**. The **signal sequence** of the N₃-terminus targets the nascent chain to the **endoplasmic reticulum (ER)** and is then cleaved off. As the **proricin** polypeptide elongates it is N-glycosylated within the lumen of the ER. Protein disulfide isomerases catalyze **disulfide bond formation** as the proricin molecule folds itself. Proricin undergoes further oligosaccharide modifications within the **Golgi complex** and then is transported within vesicles to the **protein bodies**.

Ricin is not catalytically active until it is proteolytically cleaved by an endopeptidase within the protein bodies. This **splits** the polypeptide into the A chain and the B chain **still linked by a single disulfide bond**. Since ricin is inactive until then, the plant avoids poisoning its own ribosomes in case some proricin accidentally passes into the cytosol during synthesis and transport.

Ricin Enzymatic Action

The **ricin A** portion of the heterodimer is the enzyme that binds and **depurinates** a specific adenine of the **28S rRNA**. The adenine ring of the ribosome becomes sandwiched between two tyrosine rings in the **catalytic cleft** of the enzyme and is hydrolyzed by the enzyme's N-glycosidase action. The target adenine is a specific RNA sequence that contains the unusual tetranucleotide loop, **GAGA**. Ricin is more active against animal than plant ribosomes, and intact bacterial ribosomes are generally not susceptible.

Ricin Structure

This figure from Lord et al, depicts a 3-dimensional ribbon drawing of ricin, modeled from X-ray crystallography data. **The upper right half, the dotted ribbon, is the A chain, and the lower left half, the solid ribbon, is the B chain.**

The **A chain (or RTA)** is a 267-amino acid globular protein. It has 8 alpha helices and 8 beta sheets. The substrate binding site is the cleft marked by the substrate adenine ring.

The **B chain (or RTB)** is a 262-amino acid protein that is shaped like a barbell. It has a binding site for galactose at each end, (depicted by lactose rings). These two sites allow hydrogen bonding to specific membrane sugars (galactose and N-acetyl galactosamine). A disulfide bridge (-S-S-) joins RTA with RTB (far-right, center). The spheres are trapped water molecules.

[Return to Cornell poison plant home page](#)

[Return to Toxic Agents List](#)

Ricin Uptake

The RTB portion of ricin binds to both glycoproteins and glycolipids at cell surfaces that terminate with galactose. It has two binding sites for galactose, and 106 to 108 ricin molecules may bind per cell. **However, just a single ricin molecule that enters the cytosol can inactivate over 1,500 ribosomes per minute and kill the cell.**

As shown in the diagram, the pathway for internalization of ricin involves:

1. endocytosis by coated pits and vesicles or,
2. endocytosis by smooth pits and vesicles. The vesicles fuse with an endosome.
3. Many ricin molecules are returned to the cell surface by exocytosis, or
4. the vesicles may fuse to lysosomes where the ricin would be destroyed.
5. If the ricin-containing vesicles fuse to the Trans Golgi Network, (TGN), there's still a chance they may
6. return to the cell surface.
7. Toxic action will occur when RTA, aided by RTB, penetrates the TGN membrane and is liberated into the cytosol.

Once inside the cytosol, the RTA catalyzes the depurination of the ribosomes, halting protein synthesis.

Therapeutic Applications of Immunotoxins

Ricin can be targeted to specific cells, such as **cancer cells**, by conjugating the RTA subunit to antibodies or growth factors that preferentially bind the unwanted cells. These immunotoxins have worked very well for *in vitro* applications, e.g. **bone marrow transplants**. Although they have not worked very well in many *in vivo* situations, progress in this area of research shows promise for the future.

IN VITRO APPLICATIONS

In **bone marrow transplant** procedures, **RTA-immunotoxins** have been used **successfully** to destroy T lymphocytes in bone marrow taken from histocompatible **donors**. This reduces rejection of the donor bone marrow, a problem called "graft-vs-host disease" (GVHD). In steroid-resistant, acute GVHD situations, RTA-immunotoxins helped alleviate the condition. Also, in **autologous bone marrow transplantation**, a sample of the patients **own bone marrow** is treated with anti-T cell immunotoxins to destroy malignant T-cells in **T cell leukemias** and **lymphomas**.

IN VIVO APPLICATIONS

"For the in vivo treatment of solid tumors, considerable problems can arise due to poor access of the immunotoxin (IT) to the tumor mass; lack of IT specificity, tumor cell heterogeneity, antigen shedding, breakdown or rapid clearance of the IT, and dose-limiting side effects". (Lord et al.). One common problem encountered in patients treated with ricin-immunotoxins is the "vascular leak syndrome", in which fluids leak from blood vessels leading to hypoalbuminemia, weight gain and pulmonary edema. "Research efforts to expand and develop immunotoxins and therapies for clinical use in **cancer and AIDS** are continuing with strategies utilizing recombinant DNA technology (Lord et al.).

Toxigenic Ablation

TOXIGENES

"Toxigenes are DNA fusions in which DNA encoding a potent toxin, e.g. RTA, is placed under the transcriptional control of a tissue- or developmental stage-specific promoter and/or enhancer. When expressed intracellularly, the toxigene product causes cell death. The introduction and expression of a toxigene in transgenic animals or plants may lead to **cell type-specific ablation**, which can be used to

- study developmental cell lineages or to
- generate animal models of degenerative diseases." (Lord et al.)

SUICIDE TRANSPORT

Diagram shows injection of ricin into vagal nerve and subsequent destruction of neurons (dashed neurons destroyed, solid neurons unaffected).

Neuroscientists can selectively destroy neurons by injecting ricin into nerves. Retrograde axonal transport mechanisms bring the toxin to the neuronal cell bodies where the ribosomes are localized.

Ultrastructural analysis reveals that ricin first causes the dispersion of polyribosomes, and then the rough endoplasmic reticulum disorganizes into smooth vesicles. The cell bodies (perikaryon) swell, the nuclei degenerate and the entire neuron disintegrates.

Since ricin is a N-acetyl galactosamine-binding lectin, it can be used with different lectins that have different

specificities to map **neuronal patterns of glycosylation**. When suicide transport is observed after injection of the toxin, it confirms the presence of **N-acetyl galactosamine** residues on the neuronal cell surface. Strategies in suicide transport work very well in studies of **adult** peripheral sensory and motor neurons because they are sensitive to ricin.

Neurons in the central nervous system of adults are resistant to ablation by ricin, whereas young developing brains are sensitive, suggesting that brain development involves changes in glycosylation of CNS neurons. The galactose terminal residues may be either clipped or masked by addition of sialic acids residues.

In suicide transport experiments, often some ricin **leaks out of the nerve**, causing systemic poisoning of the animal. This problem can be avoided by simultaneously administering a **ricin antiserum**.

The value of using suicide transport strategies is summarized (from Wiley and Oeltmann):

- anatomical mapping of neurons
- modeling of motor neuron degenerative diseases
- studying consequences of peripheral nerve damage and repair mechanisms
- mapping cellular neurotransmitter receptors
- disease-related applications including
 - eradication of latent herpes simplex virus in trigeminal sensory neurons
 - production and analysis of glial fibrillary bundles
 - treatment of equine neuromas

Polypeptide Toxins in Amanita Mushrooms:

All of the toxins found in the *Amanita* spp. mentioned in this poisonous plants list are peptides. The distribution of the peptides varies in the different parts of the mushroom, with the cap being the most deadly part. The amatoxins, phallotoxins, and virotoxins are found in [A. bisporigera](#), [A. ocreata](#), [A. phalloides](#), [A. phalloides var. alba](#), [A. suballiacea](#), [A. tenuifolia](#), [A. virosa](#), and some other [mushrooms](#). The phallolysins are a recently discovered group of toxins as yet only seen in [A. phalloides](#). Ibotenic acid is found in [A. cothurnata](#), [A. muscaria var. formosa](#), [A. muscaria var. muscaria](#), and [A. pantherina](#).

1. [Amatoxins](#)
2. [Phallotoxins](#)
3. [Virotoxins](#)
4. [Phallolysins](#)
5. [Ibotenic acid/Muscimol](#)

[Return to the Toxic Agents List](#)

Back to the [INDEX](#)

1. Amatoxins

There are nine amatoxins:

- alpha-Amanitin
- beta-Amanitin
- gamma-Amanitin
- epsilon-Amanitin
- Amanin
- Amanin amide - only found in [A. virosa](#)
- Amanullin
- Amanullinic acid
- Proamanullin

Amatoxins are solely responsible for fatal human poisonings. They are bicyclic octapeptides which are much more potent than any of the other toxins. The amatoxins are taken up by the liver where they begin to cause damage. They are then secreted by the bile into the blood where they are taken up by the liver again, causing a cycle of damage and excretion. In the liver, amatoxins inhibit

RNA-polymerase II. The liver is slowly destroyed and is unable to repair itself due to the inactivation of the RNA-polymerase. Thus, the liver slowly dissolves with no hope of repair.

Back to the [TOP](#) of the page

2. Phallotoxins

There are seven naturally occurring phallotoxins:

- Phalloin
- Phalloidin
- Phallisin
- Prophalloin
- Phallacin
- Phallacidin
- Phallisacin

The phallotoxins are all derived from the same seven amino acid cyclic peptide backbone. There are two groups of phallotoxins, neutral and acidic. The neutral phallotoxins contain D-threonine, while the acidic ones contain beta-hydroxy-succinic acid.

Phallotoxins destroy liver cells by disturbing the equilibrium of G-actin with F-actin, causing it to shift entirely to F-actin. This leads to numerous exvaginations on the liver cell's membrane which render the cell susceptible to deformity by low-pressure gradients, even those of the portal vein in vivo. This is followed by loss of potassium ions and cytoplasmic enzymes which leads to depletion of ATP and glycogen causing the final downfall of the liver.

Back to the [TOP](#) of the page

3. Virotaxins

There are six virotaxins:

- Viroidin
- Desoxoviroidin
- Ala1-viroidin
- Ala1-desoxoviroidin
- Viroisin

- Desoxoviroisin

Although they have the same [toxicological](#) effects as and appear to be derived from the phallotoxins, the virotoxins are monocyclic heptapeptides, not bicyclic peptides.

Back to the [TOP](#) of the page

4. Phallolysins There are three phallolysins that are hemolytically active proteins, but, as previously stated, they are heat and acid labile and do not pose a threat to humans.

Back to the [TOP](#) of the page

5. Ibotenic acid/Muscimol Ibotenic acid is an Excitatory Amino Acid (EAA) and muscimol is its derivative. These toxins act by mimicking the natural transmitters glutamic acid and aspartic acid on neurons in the central nervous system with specialized receptors for amino acids. These toxins may also cause selective death of neurons sensitive to EAAs.

SMCO

Several Brassica species contain considerable levels of S-methyl-L-cysteine sulphoxide (SMCO), an amino acid which is degraded in the rumen to dimethyl disulphide and is thought to be the primary cause of haemolytic anemia.

This series of web pages was created by an undergraduate student at Cornell University for the AS625 class. All comments and suggestions are welcome.

Tryptophan

Increased intake of L-tryptophan from lush pastures and its subsequent microbial degradation in the rumen is associated with pulmonary oedema and emphysema. Tryptophan is degraded in the rumen to the toxic metabolite 3-methylindole in a two-step degradation process. The rates of tryptophan degradation, however, depends on both availability of the substrate and dietary intake. There appears to be a greater tryptophan rate of conversion in ruminants fed on forage diets than those fed concentrate diets. Sudden dietary changes from a sparse feed to a lush, succulent pasture might cause acute bovine pulmonary emphysema, a respiratory disease of cattle. There is no effective treatment for this condition, and prevention by avoiding sudden dietary changes to lush pastures seems to be the only alternative.

Mimosine

Mimosine is a non-protein amino acid found in leaves, pods and seeds of tropical legumes of the genus *Leucaena*. Mimosine is degraded in the rumen to 3-hydroxy-4(1H)-pyridone (3,4DHP), a goitrogen. *Leucaena* consumption in ruminants may cause poor growth, alopecia, swollen and raw coronets above the hooves, lameness, mouth and esophageal lesions, depressed serum thyrosine levels, and goiter. Susceptibility of ruminants to intoxication, however, greatly depends on specific microbial populations. Further transfer of ruminant fluids from a resistant animal to a susceptible one results in a complete elimination of the toxic effects of Mimosine. This appears to be a possible solution to the toxicity of *leucaena* in ruminant animals.

This series of web pages was created by an undergraduate student at Cornell University for the AS625 class. All comments and suggestions are welcome.

Sesquiterpene Lactones and their toxicity to livestock

Cattle, sheep and horses

The objective of this web page is to describe the different classes of naturally-occurring sesquiterpene lactones. Because sesquiterpene lactones are responsible for the toxicity of several livestock poisons it is useful to focus on their effects on mammals such as cattle, sheep and horses that are most commonly exposed to sesquiterpene lactone poisoning.

[\[General description\]](#) [\[Representative Structure\]](#) [\[Distribution\]](#) [\[Biological activity\]](#)
[\[Poisons\]](#)

GENERAL DESCRIPTION

Sesquiterpene lactones constitute a large and diverse group of [biologically active](#) plant chemicals that have been identified in several plant families. However, the greatest numbers are found in the [Compositae](#) family with over 3000 reported different structures.

Sesquiterpene lactones (SQL) are a class of naturally occurring plant terpenoids that are formed from "head-total condensation of three isoprene units and subsequent cyclization and oxidative transformation to produce a cis or trans-fused lactone. Sesquiterpene lactones are [characteristic constituents](#) of Compositae. These secondary compounds are primarily classified on the basis of their carbocyclic skeletons into germanocranolides, guaianalides, eudesmalides, pseudoguaianolides and xanthanolides. The suffix "olide"

refers to the lactone function and is based on costunolide, a germanacranolide which is related to the ten-membered carbocyclic sesquiterpene, germacrone.

An individual plant species generally produces one skeletal type of SQL concentrated primarily in the leaves and flower heads. The percentage of SQL per dry weight may vary from 0.01% to 8%. Losses of livestock intoxicated by plants containing SQL are well known. In fact, they have been shown to exhibit a wide range of biological activities.

DISTRIBUTION OF DIFFERENT STRUCTURAL CLASSES OF SESQUITERPENE LACTONES IN THE COMPOSITAE

Tribes (No. of genera)	No. of genera with sesquiterpene lactones	Type of lactones present
Eupatorieae (50)	4	Germacranolides Elemanolides Guaianolides Ambrosanolides Seco-Ambrosanolides

Vernonieae (50)	4	Germacranolides Elemanolides Guaianolides
Astereae (100)	1	Germacranolides Guaianolides Elemanolides
Inuleae (100)	5	Guaianolides Xanthanolides Ambrosanolides Helenanolides Seco-Eudesmanolides Seco-Ambrosanolides Germacranolides
Heliantheae (250)	24	Elemanolides Guaianolides Eudesmanolides Xanthanolides Ambrosanolides Helenanolides Seco-Eudesmanolides Seco-Ambrosanolides Seco-Helenanolides
Senecioneae (50)	4	Germacranolides Xanthanolides Eremophilanolides Helenanolides Bakkenolides
Anthemideae (50)	10	Germacranolides Elemanolides Guaianolides Helenanolides Cadinanolides Chrymoranolides
Arcototeae-Calenduleae (50)	1	Guaianolides

Cynareae (50)	8	Germacranolides Elemnolides Guaianolides Eudesmanolides
Mutisieae (55)	1	Eudesmanolides
Lactuceae (75)	7	Germanocranolides Eudesmanolides Guaianolides

[\[General description\]](#) [\[Representative Structure\]](#) [\[Distribution\]](#) [\[Biological activity\]](#)
[\[Poisons\]](#)

BIOLOGICAL ACTIVITY

The sesquiterpene lactones are highly irritating to the nose, eyes, and gastrointestinal tract. **Sheep** and **goats** are the main livestock species affected, primarily because the plants are unpalatable and rarely consumed in toxic quantities by **cattle** and **horses**. Sneezeweed poisoning is often referred to as "spewing sickness" because of the characteristic vomiting seen. Affected **sheep** may have a green stain around the mouth and stand with upturned heads attempting to retain the regurgitated plant material. Vomited material is often inhaled into the lungs, causing either death from inhalation pneumonia or permanent lung damage accompanied by chronic coughing. Primary lesions are gastrointestinal tract irritation, congestion of the liver and kidney, and pulmonary damage.

Since many sesquiterpene lactones are also **antimicrobial agents**, it is possible that they also exert their action by altering the microbial composition of rumen and thus affecting its vital metabolic function. Hence, rumen dysfunction may contribute to the toxicity caused by sesquiterpene lactones in livestock. They are also **neurotoxic**; a SQL, repin, has been implicated in causing a syndrome similar to Parkinson's disease in **horses**.

Livestock poisoning from foraging on bitter tasting plants of the family of Compositae is well documented. Besides its deleterious effects on domestic animals, it is well reported that many Compositae plants containing sesquiterpene lactones are also toxic to wild animals.

The toxicity of sesquiterpene lactones is due to [binding](#) of the exocyclic methylene group with tissue constituents, such as sulphhydryl groups and other nucleophilic components.

Scientific Name	Common Name(s)	Species Most Often Affected	Parts Poisonous	Primary Poison(s)
Abrus precatorius	Rosary Pea	all	seeds	abrin
Aconitum spp.	Monkshood, Aconite, or Wolfsbane	humans, cattle, goats	leaves, roots, all	aconitine
Aesculus spp.	Horse Chestnut, Buckeye	humans, cattle, goats	fruit	Unknown, possibly saporins, narcotic alkaloids, or glycosides.
Agrostemma githago	Corn Cockle	poultry, cattle, humans, goats	seeds	githagin
Amanita spp.	Monkey Agaric, Panther Cap, Death Cap, and Death Angel Mushrooms	all	cap?	toxalbumin
A. muscaria	Fly Agaric	all	cap?	ibotenic acid and muscimol
A. pantherina	Panther	all	cap?	ibotenic acid and muscimol
A. verna	Destroying Angels	all	cap?	ibotenic acid and muscimol
Apocynum spp.	Dogbane	horses, cattle, humans, sheep, cats, dogs, goats	rhizome	apocynamarin
Arisaema spp.	Jack in the Pulpit	humans	all	oxalate
Atropa belladonna	Belladonna or Deadly Nightshade	humans, goats	all	atropine and scopolamine

Brassica spp.	Rape, Cabbage, Turnips, Broccoli, Mustard	cattle, humans, swine, sheep, goats, poultry	roots, seeds	glucosinolates, brassica, anemia factor
Chelidonium majus	Celandine	cattle, humans	roots	isoquinoline alkoids
Chenopodium album	Lamb's Quarters	cattle, horses, humans, sheep, swine	all	nitrates
Cicuta spp.	Water Hemlock or Cowbane	all	roots, all	cicutoxin
Claviceps spp.	Ergot	all	fungus	indole alkaloid
Conium maculatum	Poison Hemlock	all	all	coniine
Convallaria majalis	Lily of the Valley	cats, dogs, humans, goats	all	cardiac glycosides and saponins
Daphne spp.	Daphne	cats, dogs, humans	berries, all	mezereinic acid anhydride
Datura spp.	Jimsonweed, Downy Thornapple, Devil's Trumpet, Angel's Trumpet	cattle, humans, horses, goats	flowers, leaves, seeds	atropine, scopolamine, and hyoscyamine
Delphinium spp.	Delphiniums and Larkspurs	cattle, humans, goats	all	alkaloids delphinine, ajacine, and others
Dicentra spp.	Bleeding Heart, Squirrel Corn, Dutchman's Breeches	cats, cattle, humans	all	isoquinolone alkaloids
Digitalis purpurea	Foxglove	cats, cattle, dogs, goats, horses, humans	flowers, leaves, seeds	cardiac or steroid glycosides
Eupatorium rugosum	White Snakeroot	cattle, dogs, goats, horses, humans, rabbits, sheep	all	tremetone

Euphorbia spp.	Poinsettia, Spurges, Snow on the Mountain	cattle, horses, humans, sheep	leaves, stems and sap	phorbol esters
Helleborus niger	Christmas Rose	humans	all	protoanemonin
Hyoscyamus niger	Henbane	humans	seeds	atropine, scopolamine, and hyoscyamine.
Iris spp.	Irises	cattle, humans, swine	rhizomes and rootstocks	irisin, iridin, or irisine
Laburnum anagyroides	Golden Chain or Laburnum	cattle, dogs, horses, humans, swine	Pods, seeds, all	cytisine
Lantana camara	Lantana, Red Sage, Yellow Sage, or West Indian Lantana	cattle, dogs, goats, cats, humans, sheep	unripe, green berries	triterpenes
Lathyrus spp.	Sweet Pea, Tangier Pea, Everlasting Pea, Caley Pea and Singletary Pea	horses, rodents, turkeys, sheep, humans	seeds	DABA, ODAP, amine, phenol, glycoside
Lobelia spp.	Great Lobelia, Cardinal Flower, and Indian Tobacco	humans, goats	all	lobelamine, lobeline
Medicago sativa	Alfalfa or Lucerne	cattle, chickens, humans, sheep	all	canavanine, saponins
Menispermum canadense	Moonseed	humans, goats	all	dauricine
Nerium oleander	Oleander	horses, cattle, sheep, dogs, humans, goats	all, leaves, stems	nerioside, oleandroside, saponins, cardiac glycosides
Nicotiana spp.	Tobacco and Tree Tobacco	humans, swine	leaves	nicotine, pyridine
Ornithogalum umbellatum	Star of Bethlehem	humans	bulbs, flowers, all	convallatoxin, convallaside

Papaver spp.	Various Poppies including Opium Poppy	cattle, humans	all	codine, morphine, protopine
Phytolacca americana	Pokeweed	cattle, sheep, humans, turkeys, swine, horses	all	phytolaccatoxin, phytolaccigenin
Podophyllum peltatum	Mayapple and Mandrake	cattle, humans, swine	all	alpha- and beta- peltatin, podophylloresin
Pteridium aquilinum	Bracken Fern	horse, cattle, sheep, humans, swine	all	prunasin, ptaquiloside, thiaminase
Rheum raphonticum	Rhubarb	goats, humans, swine, horses	leaves	anthraquinones, oxalate
Ricinus communis	Castor Bean	all	seeds	ricin, albumin
Robinia pseudoacacia	Black Locust	horses, cattle, humans, poultry, sheep, goats	bark, leaves, seeds	robin, phasin
Sambucus canadensis	Elderberry	cattle, humans, goats	leaves, twigs, roots, unripe fruits	sambunigrin
Senecio spp.	Senecio, Groundsels, and Ragworts	horse, cattle, goats, sheep, human	leaves	jacobine, seneciphylline
Solanum spp.	Common Nightshade, Black Nightshade, Horse Nettle, Buffalo Bur, Potato	cattle, humans, rodents, sheep, horses, goats	leaves, immature fruit	soladulcidine, solanine
Symplocarpus foetidus	Eastern Skunk Cabbage	human	all	oxalate
Taxus cuspidata	Yew	all	leaves, seeds, twigs	taxine
Toxicodendron diversiloba	Poison oak	humans		

Toxicodendron radicans	Poison ivy	humans		
Toxicodendron vernix	Poison Sumac	humans		
Urtica spp.	Stinging Nettle	dogs, humans	hairs	acetylcholine, histamine, 5-hydroxytryptamine
Vicia spp.	Common Vetch, Hairy Vetch, Narrow leaved Vetch, Purple Vetch and Broad Beans	chickens, horses, humans	seeds	beta-cyano-L-alanine
Wisteria spp.	Wisteria	humans	all, flowers, seeds, leaves	wistarine
Xanthium strumarium	Cocklebur	cattle, humans, rodents, swine	seedlings, seeds	carboxyatractyloside
Zigadenus spp.	Death Camas	all	all, bulbs, leaves, flowers, pollen	zygacine

Poisonous Plants Informational Database

Plants of concern to ruminants...

Toxins that Affect the Ruminant

The ruminal microorganisms metabolize most of the naturally occurring toxins present in feeds to metabolites which do not pose a threat to the animal's health and thus are considered the first line of defence against natural toxicity. However, some compounds are metabolized to toxic metabolites in the rumen or inhibit the production of other essential compounds thereby causing distress in the animal. Diverse examples of naturally occurring toxins and the biochemical mechanisms by which they are detoxified in the rumen are going to be considered.

Ruminants acquire tolerance to increased concentrations of toxic materials in feeds. Increased tolerance to toxins can be related to a change in the microbial population in the rumen. Some of the toxins present in feeds that affect the performance of the ruminant animal include [oxalates](#), [nitrates](#), [pirrolizidine alkaloids](#), [mimosine](#), [phyto-oestrogens](#), [tryptophan](#), [SMCO](#), [phenolic monomers](#), and [mycotoxins](#).

Halogeton glomeratus	Halogeton	sheep, cattle	leaves, stems	soluble oxalates
Iris spp.	Irises	cattle, humans, swine	rhizomes and rootstocks	irisin, iridin, or irisine

Laburnum anagyroides	Golden Chain or Laburnum	cattle, dogs, horses, humans, swine	Pods, seeds, all	cytisine
Lantana camara	Lantana, Red Sage, Yellow Sage, or West Indian Lantana	cattle, dogs, goats, cats, humans, sheep	unripe, green berries	triterpenes
Linum usitatissimum	Flax	cattle, sheep	all	cyanogenic glycoside
Lotus corniculatus	Birdsfoot Trefoil	cattle, sheep		CN tannini
Lupinus spp.	Lupine	cattle, goats	seeds	lupinine, anagyrine, sparteine, and hydroxylupanine
Medicago sativa	Alfalfa or Lucerne	cattle, chickens, humans, sheep	all	canavanine, saponins
Melilotus alba and Melilotus officinalis	White and Yellow Sweetclover	horses, cattle, sheep	stem	dicoumarol
Nerium oleander	Oleander	horses, cattle, sheep, dogs, humans, goats	all, leaves, stems	nerioside, oleandroside, saponins, cardiac glycosides
Papaver spp.	Various Poppies including Opium Poppy	cattle, humans	all	codine, morphine, protopine
Phytolacca americana	Pokeweed	cattle, sheep, humans, turkeys, swine, horses	all	phytolaccatoxin, phytolaccigenin
Pinus ponderosa	Ponderosa Pine	cattle	needles, young shoots	unknown
Podophyllum peltatum	Mayapple and Mandrake	cattle, humans, swine	all	alpha- and beta- peltatin, podophylloresin
Prunus spp.	Wild Cherries, Black Cherry, Bitter Cherry, Choke Cherry, Pin Cherry	horses, cattle, moose, sheep, swine, goats	seeds, leaves	amygdalin, prunasin
Pteridium aquilinum	Bracken Fern	horse, cattle, sheep, humans, swine	all	prunasin, ptaquiloside, thiaminase
Quercus spp.	Oak Trees	horse, cattle	acorns, young leaves	gallotannins, quercitrin, and quercetin
Ranunculus spp.	Buttercups or Crowfoot	cattle, goats, horses	all	protoanemonin

Ricinus communis	Castor Bean	all	seeds	ricin, albumin
Robinia pseudoacacia	Black Locust	horses, cattle, humans, poultry, sheep, goats	bark, leaves, seeds	robin, phasin
Rumex spp.	Dock	cattle, sheep	leaves	soluble oxalates
Sambucus canadensis	Elderberry	cattle, humans, goats	leaves, twigs, roots, unripe fruits	sambunigrin
Senecio spp.	Senecio, Groundsels, and Ragworts	horse, cattle, goats, sheep, human	leaves	jacobine, seneciphylline
Solanum spp.	Common Nightshade, Black Nightshade, Horse Nettle, Buffalo Bur, Potato	cattle, humans, rodents, sheep, horses, goats	leaves, immature fruit	soladulcidine, solanine
Sorghum spp.	Sorghum or Milo, Sudan Grass, and Johnson Grass	horses, cattle, goats	leaves, stems	dhurrin, nitrate
Taxus cuspidata	Yew	all	leaves, seeds, twigs	taxine
Tetradymia spp.	Horsebrush	sheep, cattle	leaves	
Trifolium spp.	Alsike Clover, Red Clover, White Clover	horse, cattle	all, leaves	nitrate
Triglochin maritima	Arrowgrass	cattle, sheep	all, leaves, flowers	taxiphillin, triglochinin
Xanthium strumarium	Cocklebur	cattle, humans, rodents, swine	seedlings, seeds	carboxyatractyloside
Zigadenus spp.	Death Camas	all	all, bulbs, leaves, flowers, pollen	zygacine

Plants of concern to goat owners...

Toxic Plants and the Common Caprine

Unlike the public's vision of a goat, the cast iron-stomached beast that can eat everything from a tin can to plastic wrapping, there are many things that can kill a goat. Some poison plants are ingested by accident, while browsing, but a major reason for the toxic poisoning of goats comes as a result of starvation.

As with all nutritional toxicology, it is the size of the dose, and the poison present in the plant that will determine whether the animal lives or dies. This web page is devoted to the caprine species, and to many of the plants out there that can kill them. It gives a fairly comprehensive list of plants commonly found in areas with goats, but it is not complete.

[List of toxicants in plants poisonous to goats](#)

This list comes from an old Dairy Goat Management book that I had kicking around at home, and may be incomplete. For a more comprehensive, and more scientific list, consult Mary Smith, and David Sherman's *Goat Medicine*.

This series of web pages was created by Kevin Kirchofer, an undergraduate student at Cornell University for the AS625 class. All comments and suggestions are welcome.

WARNING: These web pages are only meant to be informative. Neither Cornell University nor the author of this site endorse or recommend the use of these plants.

Natural History

Green iguanas (*Iguana iguana*) are large semi-arboreal to arboreal lizards of the primarily

New World Americas. They are almost an exclusively herbivorous reptile. Earlier beliefs were that the juveniles were insectivores, and then gradually grew into herbivorous adults. However recent studies on stomach content in wild iguanas have revealed that this is not the case. Iguanas are born herbivores and do not go through an ontogenetic shift from insectivore to herbivore. The digestive system is therefore designed to digest plant materials

and not, as some recommend, to digest meat in any amount. The green iguana has evolved an elaborate hindgut, housing a microbial fermentation system that allows it to utilize fiber as effectively as mammalian ruminants. The adult iguanas spend most of their time in the upper parts of the trees, while the juveniles are either on the ground or in the lower parts of the trees and bushes. Due to the iguana's habitat, its wild diet consists of a variety of leaves, small fruits and flowers - and this variety should be provided in captivity as well. It may sound easy to provide a

varied diet for the captive iguana, however the diet must also be a nutritiously balanced and healthy diet and this is why the iguana owner needs to learn some basic guidelines for making a proper Iguana-salad.

Photo by Chris Estep

Feeding Ethics

Iguanas don't recognize what we are trying to feed them as being proper food. They are attracted by certain shapes and colors, and may, like humans, get 'hooked' on junk foods, foods that either lack nutritional value or that are downright harmful to them, or foods that they are simply used to getting. This is a particular problem with pre-owned iguanas, iguanas being fed less than ideal diets, and those who have come from pet stores where they have been fed the generally inappropriate feed usually fed to them. One needs to learn how to deal with this syndrome, how to be patient, not give in, and eventually be rewarded with your iguana eating what it should!

Dietary Adjustment

There is no simple answer as to what is the best diet for iguanas. Green iguanas are hardy and extremely adaptable and will fare on a wide variety of different diets as long as they all meet a certain basic criteria. When keeping an iguana as a pet, one of the best ways to adjust the diet is to look at the veterinary problems with the associated with the diet at different stages in an iguana's life.

- In juvenile and immature animals primarily during the first two years but also up to the ages of 4-5 years, one of the most common problems associated with diet that veterinarians encounter is metabolic bone disease, caused by a lack of usable calcium. Green iguanas grow at a truly remarkable rate from hatchlings to sexual maturity,

approximately a 100 fold increase in weight in 3 years. This implies very rapid growth of all body structures including the skeletal system which will require large amounts of usable calcium.

- A diet higher in protein content will allow an iguana to maximize it's potential growth during the first two years. There is evidence from observations of juveniles both in the wild and in captivity, that given the opportunity, they will seek a higher protein diet such as insects and possibly carrion.
- Once sexual maturity is reached (2-3 years), growth slows down somewhat but continues at a fair rate for another year or two. In females during breeding, extra demands are placed for the production of eggs and for calcification of egg shells.
- At 4-5 years of age, the growth rate tapers drastically and the diet should be adjusted accordingly. One of the more common problems in older iguanas that are brought to veterinarians is visceral gout caused by the deposition of uric acid in the kidneys and other internal organs. This is a result of a diet too high in protein, particularly organ meat products. Another common problem usually seen in male iguanas upon autopsy is metastatic calcification, the deposition of calcium in the internal organs. Both of these conditions are fatal and can be prevented through proper diet.

From The Green Iguana Manual by Philippe de Vosjoli

Recommended Diet and Feeding Schedule:

For juveniles up to 2½ years of age:

Feeding Schedule: Daily. Twice daily or continuous availability for hatchlings.

Diet: 85-90% plant matter

10-15% animal protein sources and/or commercial pet diet

Vitamin/Mineral Supplementation: One small pinch of vitamin/mineral supplement per animal,

no more than once a day.

For iguanas 2½ years and up:

Feeding Schedule: Every 1-2 days

Diet: 95% plant matter

5% animal protein sources and/or commercial pet diet

Vitamin/Mineral Supplementation: One full pinch per 2 lbs twice a week or 1/8th of a teaspoon per 3-4 lbs of body weight per week.

Note: For mature females, increase calcium supplementation and protein sources (up to 15%) starting in late December and through egg-laying.

Edible and Toxic Foliage

Before you go about preparing a salad for your iguana, one of the first things the you as an owner of an iguana needs to learn is to distinguish between "good" and "bad" food. The "good" foods are those food items that can be fed on a daily basis, ones listed in the [Basic Iguana Diet](#). If you plan to have the iguana free roaming in the house it is a necessary to find out what plants can be placed in the home. Only those that are non toxic should present. Please refer to [Melissa Kaplan's Edible Plants](#) page to determine which house plants are safe to have accessible to the iguana.

There are also those plants which should either be avoided or only be used occasionally (ones every other week). Some of these include: spinach, romaine lettuce, onions, beets, beet greens, celery stalk, Swiss-chard, carrots, bananas, grapes, lettuce, kale, Chinese cabbage, broccoli, turnips, cauliflower and brussels sprouts. However there are some plants that are to be avoided all together. These plants are not edible and may have severe toxic consequences for the animal. Rhubarb is extremely toxic because of the formation of [calcium oxalate](#) crystals. For a complete list of plants toxic to iguanas and their pathways of toxicity, please refer to [Melissa Kaplan's Harmful Plants](#) complete listing. However, if you would like to view the plants for visual identification you can see the plants at the Cornell University pages of [Poisonous Plants](#). If your reptile does ingest something it should not have, watch it carefully for signs of distress. Signs will usually include respiratory changes (i.e. rate of breathing increases or decreases, breaths become shallower or deeper, breathing becomes labored or difficult), increased salivation, dry heaves, vomiting, lethargy, increased activity, rubbing mouth on ground or other surfaces, scratching at face or mouth, diarrhea or other alteration of feces. Don't wait to see if the signs will abate - call (or have someone call) your regular reptile vet or emergency reptile vet (have these numbers and locations on hand before you need them) and let them know what the animal ate, what the signs are, and that you are on your way. The [National Animal Poison Control Center](#) may also be able to offer you pertinent information, but in a potential emergency where time is of the essence, you should get your reptile to a vet who can administer an antidote and supportive therapy as quickly as possible.

A Well Balanced Diet

Calcium Rich Vegetables, where the Ca : P > 2 - 35% or more of the diet.

- Collards, mustard greens, alfalfa chow or pellets, dandelions, bok choy, swiss chard
- Beet greens, escarole, green beans, turnips
- *Note:* Kale and bok choy in small amounts only.

Other Vegetables: A variety weekly - 35% or more of diet.

- Romaine lettuce, frozen mixed vegetables (thawed), shredded squashes, zucchini, sweet potatoes
- Bell Peppers, various sprouts, grated carrots, okra, cooked sweet potatoes
- *Note:* Broccoli, cauliflower, brussel sprouts and other members of the cabbage family should be fed in small amounts because they may cause thyroid problems when fed

frequently in large quantities.

Grain/Fiber sources: Optional - up to 20% of diet.

- **Mixed grain bread and natural bran cereal**

Fruits: Offer a variety weekly - No more than 15% of diet.

- **Calcium Rich: Fresh or dried figs, papaya, raspberries**
- **Other: Melons, apples, plums, peaches, strawberries, tomatoes, bananas, grapes, kiwi**

Animal Protein sources: Up to 15% for hatchlings and sub adults. No more than 5% of adult diet.

- **Insects: Crickets, meal worms, king meal worms**
- **Meats: Cooked chicken, small pre killed mice**
- **Commercial pet diet: Soaked high quality dog or monkey chow**
- **Other: Hard boiled eggs**

- ***Note on primate diets: If it weren't for the high D₃ content, these diets could probably make up a substantial percentage of an iguana diet but the high D₃ content in combination with calcium will cause metastatic calcification in mature iguanas. Thus they should be used in moderation.***

We receive a large volume of mail about feeding iguanas meat. A large vocal group of iguana fans oppose this despite the fact that iguanas can and do eat meat in the wild and in captivity. As stated above, animal protein should be NO MORE THAN 5%. Please do not email us further about this.

Photo by Chris Estep

Basic Iguana Diet and Preparation

Greens (30-40% of volume)

Romaine Kale Leaf Lettuce Collards Spinach Escarole Mustard Greens Parsley, etc.

Handling: All greens thoroughly rinsed and chopped or diced. Hatchlings or juveniles need finely chopped food to aid digestion. Gut Fauna in young iguanas can be overwhelmed by the large pieces of food.

Bulk Vegetables (30-40% of volume)

**Frozen mixed vegetables (carrots, corn, peas, limas) Green beans Zucchini Cabbage Peas
Avocado Broccoli Yams**

Handling: All vegetables should be fresh or frozen: thawed and served room temperature or slightly warm, chopped.

Fruit (10-30% of volume)

Banana Melon (Honey dew, Cantaloupe, etc.) Kiwi Grapes Papaya Mango Strawberries
Cherries Blueberries Peaches

Handling: All fruit washed and chopped into small pieces designed to be bite-sized for various size iguanas. Bananas served with skin.

Protein (1-5% of volume)

Cooked chicken

Dog or Monkey chow

Handling: Chicken meat chopped. Process food soaked.
Iguana Diet Chart by Robert Ehrig of the International Iguana Society

Nutritional Disorders in Green Iguanas

Deficiency/ Metabolic Bone Disease

Causes:

Calcium deficiency is the lack of physiologically available calcium. Simply supplementing the diet with calcium will not assure that the calcium will be absorbed through the lining of the intestine and become usable. For the effective absorption of calcium through the intestinal lining an adequate amount of vitamin D₃ and the proper calcium/phosphorus ratio is required. It is recommended that in iguanas that minerals be provided in the ratio of 1 part D₃ to 2 parts calcium to 1 part phosphorus. These can be added in the form of vitamin supplements such as Rep-Cal[®] and TerraFauna Vitalife[®] using the proper dosage.

Secondary Causes:

Calcium deficiency can also be caused by the excessive feeding of oxalic acid. When ingested, oxalic acid has a high affinity for blood calcium. This causes a reduction of calcium levels as well as the formation of a potentially lethal, insoluble substance Calcium Oxalate. Refer to Melissa Kaplan's chart on the oxalate to calcium ratio of selected iguana foods to determine a suitable diet for your pet. Acute cases of ingestion of high levels of oxalic acid is potentially lethal. The deposition of the crystals in the kidneys will cause blockage, necrosis, and ultimately death. One plant to avoid at all costs is Rhubarb. The high content of oxalic acid in the rhubarb leaves are toxic will kill even the largest of the

iguanas. 

Symptoms:

The symptoms of metabolic bone disease will vary depending on a number of factors, such as the age of the animal and duration of the disease. In juveniles, symptoms can include a soft lower jaw and deformities of the back and legs. In larger animals, osteoporosis and fibrous osteodystrophy may occur. These are characterized by the

swollen, smooth appearance of the hind limbs and swollen lower jaw. Animals with fibrous osteodystrophy are often initially perceived as rotund, fat animals until they manifest abnormal behaviors, usually the result broken limbs and bones now too weak to support the weight of the animal. Fibrous dystrophy results in swollen limbs due to the deposition of scar tissue around the ever-weakening and thinning bones to make up for the structural weakness.

Gout

Causes:

Visceral gout is a disease caused by the accumulation of urate crystals and characterized by the presence of particular lesions called "tophi". In captive herbivorous reptiles, the primary cause is excessive animal protein in the diet. It is a common cause of death in older iguanas fed a primarily high meat or canned dog food diet. The feeding of meats high in purines have been closely associated with high urate levels in herbivorous reptiles. A secondary cause is the lack of water which is needed to by the iguana to flush out uric acid derivatives. Once present, visceral gout is usually fatal.

Mineralization of Internal Organs/Metastatic Calcification

Causes:

Once an iguana matures and growth rate tapers, excessive calcium in the diet will be readily absorbed into the blood stream with high levels of vitamin D₃ and can accumulate in various internal organs. Over time this will eventually kill the animal. Care must be given to not over supplement the diet of adult iguanas. It is recommended that 100-200 IU/ of D₃ per kilogram (2.2 lb) be fed per week. The moral is that too much of a good thing is not always better.

Poisonous Plants Informational Database

Adaptations to Toxicity

We live in a world that surrounds us with poison. Plants, looking to their own best interests, produce an incredible array of toxic concoctions. Human industry has presented us with harmful compounds previously unknown in nature, like DDT and PCB's. Even essential nutrients, like salt and vitamins, can be toxic if given at the right dose. As Paracelsus the physician once said, "All substances are poisons, there is none which is not a poison." And yet, toxic as our environment is, some animals have come up with astounding adaptations that allow them to find their niche amongst these deadly plants. Come meet these incredible survivors:

Melinis minutiflora

Index

- [Introduction and Common Names](#)
- [Chemical Compounds and Toxicity](#)
- [Uses and Efficacy](#)

Introduction

Melinis minutiflora Beauv. (listed under the Family Gramineae or Poaceae) also is referred to as *Panicum minutiflora* and *P. melinus*. It is a seed propagated tropical grass (C4) that grows to height of approximately 3 ft. It originated in Africa, though it can now be found in much of South and Central America, the Caribbean, and parts of India. *M. minutiflora* is considered a nuisance weed in many parts of the world including Hawaii, Brazil, Venezuela, and Colombia (Duke, 1983). Hawaii is currently tracking its spread on the islands.

Most of the research with this grass has focused on its nutritional value as a pasture grass. It can be an easy to establish pasture grass. However, it also can outgrow all other grasses and weeds in a pasture and form monotypic stands. Like many tropical grasses, it does not make good hay or silage (although it is used for hay and silage in some tropical countries). *M. minutiflora* can be overgrazed and damaged from repeated mowings (e.g., for making hay).

To learn more about the genus *Melinis* please refer to [L. Watson and M.J. Dallwitz's web site](#). [James A Duke's Handbook of Energy Crops](#) (1983, unpublished) provides nutrition information, as well as, chemical, medicinal, and ecology information. [The University of Hawaii's web site](#) has several pictures available of *M. minutiflora*. Common names for *Melinis minutiflora* include:

- Herbe molasses
- Molasses grass (U.S.)
- Puakatau
- Stinkgrass (U.S.)
- Yeragua (Colombia)
- Yerba agua (Dominican Republic)
- Yerba melao (Puerto Rico)

[Return to Index](#)

Chemical Compounds and Toxicity

Little is known about the chemical composition and toxicity of *M. minutiflora*. Preliminary chemical analyses at Cornell University indicate the presence of phenolics in the roots. The

volatile oil (from the glanular hairs) contains fatty acids, esters, and probably phenolics (Duke, 1983). The leaves contain calcium oxalate crystals (Lersten, 1983).

No toxicity studies could be found. Since little is known about the chemical composition (beyond nutritionally important compounds), it is difficult to assess the toxicity of the plant when used for medicinal purposes. Some phenolics are poisonous, while others are known to have antioxidant and anticancer properties.

Oxalates (including calcium oxalates) have caused adverse effects in livestock and can decrease the availability of calcium in a plant. For example, some of the calcium in alfalfa is in the oxalate form and unavailable to ruminants. Ruminants tend to be more tolerant of oxalates than non-ruminants (e.g., horses), because rumen microbes degrade the oxalate. Therefore, if ruminants are slowly exposed to a diet high in oxalates (over an approximately 4 day period), the population of oxalate degrading microbes in the rumen increases sufficiently to prevent oxalate poisoning. Given that *M. minutiflora* is used as a pasture plant and that most treatments with it are for external parasites, one might assume that the level of oxalates will not cause adverse effects. However, oxalate levels can vary with the growing season, so one should be cautious when using any oral treatments with the grass, especially with non-ruminants (Cheeke, 1998). Studies need to be conducted to determine the types of phenolics and other bioactive compounds in *M. minutiflora*, in order to better assess its potential toxicity, identify the active compounds, and determine variation in the compounds at different growth stages.

[Return to Index](#)

Uses and Efficacy

In the Dominican Republic, the roots of *M. minutiflora* are used for internal parasite infections in animals. The roots are washed, ground, mixed with water, and given as an oral treatment. The anti-parasitic properties of *M. minutiflora* are currently being studied at Cornell University. Preliminary tests have been conducted with *Haemonchus contortus*. These tests indicate that crude ethanol extracts of the grass decrease the viability of *H. contortus* eggs. Further studies on the effect on third stage larvae are underway.

M. minutiflora is insecticidal, arachnicidal, and an insect repellent. In Tanganyika, the leaves are rubbed on livestock to repel insects. Studies conducted by Mwangi, et al. (1995) and Hernandez, et al. (1990), demonstrate that the grass repels ticks (*Rhipicephalus appendiculatus* and *Boophilus microplus*). Studies also have shown that *M. minutiflora*, when inter-cropped with maize, repelled cereal stemborer females from oviposting on the maize (Khan, et al. 1997).

Petiveria alliacea

Index

- [Introduction and Common Names](#)
- [Chemical Compounds and Nutritional Value](#)
- [Toxicity](#)
- [Uses and Efficacy](#)

Introduction

Petiveria alliacea (Family Phytolaccaceae), commonly known as anamu, is a herbaceous perennial. *P. alliacea* can be found growing in tropical areas of Central and South American, the Caribbean, and Africa. The leaves and roots of the plant have a strong odor. An excellent source of information on this plant is presented on the [Raintree Nutrition](#) web site. The Raintree site includes ethnobotanical data, references, and abstracts. Some of the common names for *Petiveria alliacea* include:

- Anamu (Dominican Republic)
- Apacin (Guatemala)
- Feuilles Ave
- Herbe Aux Poules
- Mucura (Peru)
- Petivere A Odeur Ail

A more complete list of common names can be found on the Raintree site.

Chemical Compounds and Nutritional Value

P. alliacea contains several biologically active compounds. The quantity of compounds varies in the plant parts. Primary compounds in the essential oil of the roots include: benzaldehyde, dibenzyl disulfide, dibenzyl trisulfide, and cis- and trans-stilbene. Some of the compounds in *P. alliacea* are listed below.

- benzaldehyde -- root
- benzoic acid -- root
- benzyl-2-hydroxyethyl-trisulfide -- leaf
- coumarin -- root
- isoarborinol
- isoarborinol acetate
- isoarborinol cinnamate

- isothiocyanates -- seed
- polyphenols -- leaf
- senfol -- leaf
- tannins -- leaf
- trithiolaniacine -- root

[Return to Index](#)

Toxicity

Few data on the toxicity of *P. alliacea* could be found in the literature. In one study with mice, oral doses did not cause toxicity. However, methanol extracts of the plant do cause uterus contractions, which can lead to abortion - one of its uses in traditional human medicine. Also, extracts have been shown to inhibit mitosis.

Caution should be taken if *P. alliacea* is fed to animals on a regular basis. The plant can accumulate nitrates and has caused nitrate poisoning in cattle. Also, in studies where cattle were fed *P. alliacea* regularly (3g/kg bodyweight/day), the cattle suffered several adverse reactions.

Uses and Efficacy

In the Dominican Republic, the roots of *Petiveria alliacea* are used in treatments for internal parasites in livestock and as an insect repellent. No studies on the anti-parasitic properties of *P. alliacea* in livestock could be found in the literature. However, when *P. alliacea* root was applied to soil, populations of *Meloidogyne incognita* were decreased compared to controls. Also, hexane extracts of the plant showed some activity against the blood protozoa *Trypanosoma cruzi* *in vitro*. Studies have shown that crude ethanol extracts exhibit some repellent activity against *Boophilus microplus* (tick species). Dibenzyltrisulfide, one of the compounds in the roots of *P. alliacea*, is insecticidal (*Cylas formicarius elegantulus* and *Hypothenemus hampei*) and acaricidal (*Boophilus microplus*).

In other studies, extracts of *P. alliaceae*: provided some protection against *Listeria monocytogenes* infections in mice, inhibited inflammation in induced paw oedema in mice, and reduced blood platelet aggregation *in vitro*.

P. alliacea has been used to treat the following ailments in humans:

- Abortifacient -- La, Trinidad, and Venezuela
- Ache (head, tooth) - Dominican Republic, Haiti, and Mexico
- Antiseptic -- Haiti
- Aphrodisiac
- Bite (snake)
- Cold -- Haiti, Mexico
- Counterirritant -- Trinidad
- Cystitis -- Trinidad

- Decoagulant -- Trinidad
- Depurative -- Haiti, La, Mexico, Trinidad, and Venezuela
- Diuretic - Brazil, Haiti, La, and Mexico
- Emmenagogue -- Dominican Republic, Guatemala, La, and Mexico
- Expectorant -- Haiti, La, and Mexico
- Fever -- Haiti, Mexico
- Flu - Dominican Republic and Trinidad
- Head cold -- Trinidad
- Hysteria - La and Mexico
- Inflammation - Dominican Republic
- Insecticide -- Dominican Republic
- Nerve -- La and Mexico>
- Paralysis -- Mexico
- Parturition
- Pertussis
- Piscicide
- Poison (Arrow) -- Brazil
- Rabies -- Mexico
- Repellant (Bat) - Panama (Choco)
- Repellant (Insect) - Dominican Republic, Haiti, and Mexico
- Rheumatism -- Mexico
- Rootcanal -- Venezuela
- Sedative - Brazil and Haiti

Portulaca oleracea

Index

- [Introduction and Common Names](#)
- [Chemical Compounds and Nutritional Value](#)
- [Toxicity](#)
- [Uses and Efficacy](#)

Introduction

Portulaca oleracea (Family Portulacaceae), commonly known as purslane in the U.S., is an herbaceous weed. The origin of purslane is uncertain. It can be found growing wild and/or cultivated in much of the world. It existed in the New World before the arrival of Columbus, and was found in Europe by the late 16th century. It can be found growing in almost any unshaded area, including flower beds, corn fields, and waste places. Purslane can be found growing in cold climate areas (e.g., Canada) as well as warm areas (e.g., the Caribbean). It has been used in salads and as a medicinal plant (for people) for hundreds of years. To see pictures of purslane, please go to [the University of Hawaii's web site](#) or [Virginia Tech's web site](#). Common names for *Portulaca oleracea* include:

- Akulikuli-kula
- Ancharupa
- Beldroega
- Berbin
- Coupe-Pied
- Coupier
- Farfena (Central Oman)
- Gelang pasir
- Golasiman (Philippines)
- Krokot
- Ma Ch'Ih Hsien
- Ngalug (Philippines)
- Parpinah
- Perpine
- Pig weed
- Porcelana

- Pourpier Commun, Pourpier
- Purslane (U.S.)
- Pusley (U.S.)
- Rigla (Egypt)
- Semizotu
- Stilchi (Garo in India)
- Suberi-Hiyu
- Verdolaga (Dominican Republic)
- Vertolaga (Peruvian Amazon)

[Return to Index](#)

Chemical Compounds and Nutritional Value

P. oleracea contains many biologically active compounds and is a source of many nutrients. Some of the biologically active (and, in some case, potentially toxic compounds) include free oxalic acids, alkaloids, omega-3 fatty acids, coumarins, flavonoids, cardiac glycosides, and anthraquinone glycosides. It has high contents of Omega-3 fatty acids and protein (compared to other vegetables) (Ezekwe, et al. 1999). The quantity of these compounds in *P. oleracea* varies with the growing conditions (e.g., planting date, soil quality, fertilization) and the age of the plant. Some of the compounds in *Portulaca oleracea* are listed below. For a more complete list, go to [Dr.](#)

[Duke's Phytochemical Database](#).

- alanine -- plant and herb (570-13,400 ppm)
- alkaloids -- leaf (300 ppm)
- caffeic acid -- plant
- calcium oxalate -- herb
- catechol -- plant
- beta-cyanin -- herb
- digalactosyldiacylglycerol -- herb
- docosahexaenoic acid -- herb
- dopa -- plant
- eicosapentaenoic acid -- herb (10 ppm)
- HCN -- plant
- histidine -- herb (220-5,170 ppm)
- l-noradrenalin -- plant (2,500 ppm)
- linoleic acid -- herb (704-18,245 ppm) and seed (67,686 ppm)
- linolenic acid - herb (3,221-64,315 ppm) and seed (17,226 ppm)
- alpha-linolenic acid -- herb (4,000-80,000 ppm)
- lysine -- herb (650-13,200 ppm)
- methionine -- herb (90-2,814 ppm)

- norepinephrine -- plant
- oleic acid -- herb (16-2,160 ppm) and seed (49,935 ppm)
- omega-3's -- plant (30,000 ppm)
- oxalates -- shoot
- oxalic acid -- plant (1,679-16,790 ppm)
- phytin-p -- plant (4-40 ppm)
- saponin -- plant
- sinapic acid -- plant
- beta-sitosterol -- seed
- tannin -- plant
- threonine -- herb (470-9,400 ppm)
- tryptophan -- herb (160-3,400 ppm)
- valine -- herb (660-13,200 ppm)

[Return to Index](#)

Toxicity

No data on the toxicity of *P. oleracea* could be found in the literature. However, the plant does contain cardiac glycosides and oxalic acids, which can be toxic.

Uses and Efficacy

In the Dominican Republic, all parts of *Portulaca oleracea* are used in treatments for internal parasites. The plant always is mixed with other plants (e.g., *Chenopodium ambrosioides*). No in vitro or in vivo efficacy tests with the plant or extracts of the plant against common internal parasites could be found in the literature. In de Bairacli-Levy (1991), *P. oleracea* is listed as a treatment for parasites, a blood-cleanser, and to refresh the digestive system. The plant is to be fed fresh (after it has seeded) ad lib. While efficacy tests have not been conducted for these specific livestock uses, *Portulaca oleracea* has been extensively studied for other forms of bioactivity. In vitro and in vivo tests have been conducted with *P. oleracea* to determine, for example, its anti-inflammatory, analgesic, and anti-fungal activity. *P. oleracea* has been used to treat the following ailments in humans:

- Alexiteric -- China
- Alterative -- Turkey
- Anthrax -- China
- Antidote
- Antiphlogistic -- China
- Aperient -- Java
- Ardor -- Turkey
- Astringent - India and Sudan

- Bactericide -- China
- Bite (Bug, snake) - China and the Philippines
- Bladder -- India
- Bleorrhagia -- China
- Boil -- China
- Burn
- Cardiotonic -- Haiti
- Cold -- China
- Colic -- China
- Demulcent -- Sudan
- Dermatitis -- China
- Detergent -- India
- Diuretic -- China, Haiti, India, Sudan and Turkey
- Diarrhea and dysentery - China and the Philippines
- Dyspepsia -- China and Haiti
- Dysuria
- Ear ache
- Eczema -- China
- Edema -- China
- Emollient -- China, Dominican Republic and Turkey
- Empacho -- Trinidad
- Enteritis -- China
- Erysipelas -- China
- Fever -- China
- Fungicide
- Genital -- China
- Gonorrhoea
- Heat - India and the Philippines
- Hematuria
- Hemostat -- Haiti
- Hemoptysis
- Hemorrhage
- Herpes -- China
- Hyperglycemia
- Hypotension -- Trinidad
- Inflammation
- Insomnia -- Haiti

- Intestine -- China
- Kidney - Haiti and India
- Leucorrhea -- China
- Liver
- Lung -- India
- Mouth
- Nausea -- China
- Opacity -- China
- Ophthalmia -- Malaya
- Palpitation -- Trinidad
- Pile -- China
- Poison -- Australia
- Poultice -- China
- Pruritis -- China
- Scald
- Scurvy -- China, Haiti, India and Turkey
- Sedative -- Turkey
- Soporific -- Haiti
- Sore -- China
- Spleen
- Swelling -- China
- Thirst -- China
- Tonic -- China
- Toothhache
- Tumor -- Brazil, China, Colombia and Gabon
- Urogenital -- China, Kurdistan and Spain
- Vermifuge -- China, Dominican Republic, Iraq, Java, Trinidad and Venezuela
- Viricide
- Vulnerary -- India
- Wart -- Japan, Mexico and Peru
- Wound - China

Treating Livestock with Medicinal Plants: Beneficial or Toxic?

Other Resources on Medicinal Plants and Ethnoveterinary Medicine

Ethnoveterinary medicine is a growing area of research. More and more scientists, veterinary practitioners, field workers in developing countries, and livestock owners are becoming interested in medicinal plants. A simplistic definition for ethnoveterinary medicine is: local or indigenous knowledge and methods for caring for, healing, and managing livestock. This includes social practices and ways in which livestock are incorporated into farming systems.

There are lots of resources on medicinal plants. Here are just a few that I find interesting.

Fescue Toxicosis in Horses

Equine fescue toxicosis is caused when pregnant mares eat [tall fescue](#) that is infected with an endophyte fungus, *Acremonium coenophialum*. Both the [mare](#) and the [foal](#) can be affected when the mare eats endophyte-infected fescue.

A pasture seeded with fescue may look appetizing to a horse (and its owner!), but don't judge a book by its cover!

All is not lost if your broodmare eats endophyte-infested fescue. [Treatment](#) is available, although [prevention](#) is the best protection.

[\[Fescue Toxicosis\]](#)[\[The Plant\]](#)[\[Fescue Pasture Mgmt & Eradication\]](#)[\[The Endophyte\]](#)[\[The Alkaloids\]](#)[\[Toxicosis in Mares\]](#)[\[Toxicosis in Foals\]](#)[\[Treatment\]](#)[\[Other Sources of Info\]](#)
[\[Return to list of toxicants\]](#)

[Click here for more info on the plant itself](#)

Acremonium coenophialum

The endophyte, *Acremonium coenophialum*, grows symbiotically with tall fescue. It is similar to the ergot fungus although *A. coenophialum* is evolutionarily derived from *Epicloe typhina*. This fungus is the reason for some of the advantages of fescue, such as

insect resistance. However, it is also the cause of the toxicity. The endophyte produces the toxic alkaloid substances (there is also some alkaloid production by the fescue itself). The major alkaloid produced is the indole alkaloid, ergovaline.

The endophyte grows between the plant cells. It is most proliferative in the spring, and closely associates with the growing flower and seed head. It is through contamination of the seed that infection of fescue is spread. Plant to plant or field to field transmission of the endophyte is very limited.

[\[Return to list of toxicants\]](#)

Fescue Alkaloids and Toxic Effects

Tall fescue produces the two diazaphenanthrene alkaloids, perlolidone and perloline. Under lab conditions, administering perloline to sheep has caused mild photosensitivity, increased pulse and respiration rates, loss of muscle control, convulsions, and comas. **However, perloline and perlolidone do not appear to be responsible for the fescue toxicities observed under field conditions.**

Rather, alkaloids produced by the endophyte appear to be the culprits.

Acremonium coenophialum produces both loline and ergopeptine classes of alkaloids. The lolines are saturated pyrrolizidine alkaloids with mild vasoconstrictive properties. They may possibly contribute to the hyperthermia (elevated body temperatures) and fescue foot (gangrene of the animal's extremities, often the rear hooves or tail tip) observed in cattle and sheep poisoned by fescue. However, the ergopeptine class of alkaloids produced by *Acremonium coenophialum* were shown in the mid-1970s to be the primary causative agents of fescue toxicity.

Ergopeptines are indole alkaloids that help chemically defend the fescue plants from insect pests and also have a positive influence on plant hormones and/or growth regulators. Unfortunately, they interfere with prolactin secretion, body temperature regulation, and feed intake of livestock grazing the infected fescue. Additionally, these alkaloids can constrict blood vessels, and reduce blood flow to the extremities.

The primary ergopeptine in fescue is

- ergovaline.

Others include

- ergosine
- ergonine, and
- lysergic acid amine (structurally similar to LSD)

[\[Fescue Toxicosis\]](#)[\[The Plant\]](#)[\[Fescue Pasture Mgnt & Eradication\]](#)[\[The Endophyte\]](#)[\[The Alkaloids\]](#)[\[Toxicosis in Mares\]](#)[\[Toxicosis in Foals\]](#)[\[Treatment\]](#)[\[Other Sources of Info\]](#)
[\[Return to list of toxicants\]](#)

Fescue Toxicosis: Effects on Broodmares

Unlike other livestock, the signs of fescue toxicity in horses are almost exclusively related to poor reproduction. Mares that consume large amounts of endophyte-infested tall fescue can suffer from a number of reproductive problems. These can include

- prolonged gestation
- abortion
- premature separation of the chorion
- dystocia
- thickened placenta
- retained placenta
- aglactia (suppression of lactation, i.e. no milk)

Additionally, mares who graze endophyte-infested fescue pastures in early pregnancy may have delayed pregnancy rates or early embryonic death.

Prolonged Gestation

The normal gestation length in horses is approximately 11 months. However, mares that graze on endophyte-infested fescue can have pregnancies that last up to 13 months or more. This is a problem because the fetus continues to grow during the extra time which can result in dystocia (difficult birth). The foals born after prolonged gestation may appear to be immature despite their extra fetal development.

The characteristics of a foal born after prolonged gestation include a large frame size and poorly developed muscles. Also, some foals may have overgrown hooves, while others may have premature and irregular eruption of baby teeth. These foals can also exhibit hyperthyroidism, resulting in poor suckling reflex, incoordination, and low body temperature.

[\[Fescue Toxicosis\]](#)[\[The Plant\]](#)[\[Fescue Pasture Mgnt & Eradication\]](#)[\[The Endophyte\]](#)[\[The Alkaloids\]](#)[\[Toxicosis in Mares\]](#)[\[Toxicosis in Foals\]](#)[\[Treatment\]](#)[\[Other Sources of Info\]](#)
[\[Return to list of toxicants\]](#)

Fescue Toxicosis: Effects on Foals

The newborn foal can suffer greatly from the effects of fescue toxicosis. The range of fetal deaths in the last third of pregnancy for herds affected by fescue toxicity varies from 0 to 100%.

Generalized symptoms associated with foals born to mares grazing on endophyte-infected fescue include

- [prolonged gestation](#)
- dystocia
- abnormal foal maturation
- weakness
- starvation (due to dam's agalactia)

Poor Immunity in Foals

Many foals born to mares pastured on endophyte-infected fescue have reduced immunity, which makes them highly susceptible to infections. Normally, foals receive antibodies from the mare in the form of colostrum, consumed almost immediately after birth. However, mares affected with fescue toxicosis are often agalactic, and so their production of milk is limited or nonexistent. Thus, the newborn foal is not able to consume enough colostrum to have an adequate transfer of antibodies from the mother to the foal. The foal is at risk to contract a number of illnesses and infections.

If a mare does not supply an adequate amount of milk or colostrum to the newborn foal, the foal should be given colostrum from a donor mare, or colostrum that is stored in a colostrum bank. If neither of these options is available, the foal should be given colostrum from another species of animal, followed by intravenous antibodies and a diet of supplemental milk. Cow or goat milk is often used, although additional sugar (in the form of dextrose) is added to more closely resemble the mare's milk.

[\[Fescue Toxicosis\]](#)[\[The Plant\]](#)[\[Fescue Pasture Mgmt & Eradication\]](#)[\[The Endophyte\]](#)[\[The Alkaloids\]](#)[\[Toxicosis in Mares\]](#)[\[Toxicosis in Foals\]](#)[\[Treatment\]](#)[\[Other Sources of Info\]](#)
[\[Return to list of toxicants\]](#)

Treatment of Fescue Toxicity

The best form of treating fescue toxicosis in horses is [prevention](#). However, this is not always possible. Nonpregnant horses can safely graze on endophyte-infected fescue pastures, as can broodmares during the second trimester of pregnancy. If a pregnant horse *must* graze on endophyte-infected fescue, there are pharmaceuticals available to

help reduce the adverse effects.

Some of the available drugs include

- domperidone (which prevents ergovaline from inhibiting prolactin release and, hence, prevents agalactia).
 - [More on obtaining this drug](#)
- perhenazine
- reserpine

AYAHUASCA: VISIONARY VINE OF THE AMAZON

Banisteriopsis caapi (Malpighiaceae)

Ayahuasca, caapi, kahpi, mihi, dapa, and yage are all terms used in reference to the hallucinogenic drink made from the bark of the neotropical lowland rainforest lianas, *Banisteriopsis caapi* and *B. inebrians*. The drink was originally used by the indigenous people of the upper Amazon and Orinoco rivers and is prepared by boiling the bark in water. The hallucinogens present belong to the [beta-carboline](#) class of alkaloids and the major psychoactive ingredients are harmaline, and to a lesser extent, harmine and tetrahydro harmine. In addition to the hallucinogenic effects of the [beta-carbolines](#), *Psychotria viridis* or *Diplopterys cabrerana*, are often added. Both these plants contain dimethyl tryptamine (DMT) and it seems that the effects of DMT are strongly potentiated by the mono amine oxidase inhibiting [beta-carbolines](#).

Current research on the pharmacological effects of [beta-carbolines](#) and ayahuasca are being undertaken by research groups at the University of California at Los Angeles as part of the [Hoasca Project](#)

There is also a growing body of evidence that points to the use of isoquinoline and tryptamine-related alkaloids such as the [beta-carbolines](#) as a strategy for the control of intestinal helminths and other microbes by forest dwelling people. It is readily accepted that hallucinogen use by the indigenous people of tropical America has a long history and is an integral part of their culture. In addition, during native ceremonies, repeated references are made to the cleansing and purifying properties of these drugs. Because

these compounds are not only hallucinogens, but powerful emetics with antimicrobial and antihelminthic properties, [5-6] it is suspected that the use of ayahuasca is more than vision seeking--it is actually chemotherapy. The mode of this antihelminthic action is believed to be related to the similarity in structure of [serotonin](#) to the [beta-carboline alkaloids](#). It is possible that these indole alkaloids are antagonists of serotonin in intestinal worm metabolism but little comparative data on the effects of naturally occurring psychoactive drugs on parasitic worms is available. Work in this area is currently underway.

NEUROPHARMACOLOGY of BETA-CARBOLINE ALKALOIDS

[Beta-carbolines](#) are a class of indole alkaloids which are structurally similar and biosynthetically derived from the amino acid L-tryptophan. [Tryptophan derivatives](#) are very important in Central Nervous System (CNS) function and include the neurotransmitter, [serotonin](#), the Pineal metabolite, [melatonin](#), the potent hallucinogen, dimethyl tryptamine (DMT); and the mono amine oxidase inhibitors (MAOI), the [beta-carbolines](#).

A clue as to the [beta-carboline's](#) mode of action can be seen by examining their relationship to [serotonin](#). It seems that ingestion of [beta-carbolines](#) raises serotonin levels and this increase is a result of the inhibited action of mono amine oxidase (MAO). Normally, MAO degrades the neurotransmitters [serotonin](#), dopamine, and epinephrine. Therefore, inhibition of this enzyme seriously affects brain chemistry.

MAO inhibitors fall into two classes: Irreversible and reversible MAOIs. In addition they can inhibit either or both of the two types of the MAO enzyme, MAO-A and MAO-B which are associated with serotonergic and dopaminergic neurons respectively [8]. Irreversible MAOIs (e.g. the hydrazides iproniazid and phenelzine) bind permanently to the enzyme and cause MAO inhibition lasting 1-2 weeks after ingestion. They are used clinically to treat depression. Reversible MAOIs, such as moclobemide, which is used as an antidepressant, and the [beta-carbolines](#) harmine and harmaline, are effective for a much shorter time, usually less than twenty-four hours. There are significant dangers in using MAO inhibitors. Most MAOIs potentiate the cardiovascular effects of tyramine and other monoamines found in foods. There are therefore several foods that should be avoided when on MAOIs. Ingestion of aged cheese, beer, wine, pickled herring, chicken liver, yeast, large amounts of coffee, citrus fruits, canned figs, broad beans, chocolate or cream while MAO is inhibited can cause a hypertensive crisis including a dangerous rise in blood pressure. Effects of amphetamines, general anaesthetics, sedatives, anti-histamines, alcohol, potent analgesics and anticholinergic and antidepressant agents are prolonged and intensified. Overdosage of MAOIs by themselves is also possible with effects including hyperreflexia and convulsions[8].

Another result of ingesting [beta-carbolines](#) or other MAOIs at high doses is the occurrence of vivid visual hallucinations. It is not understood whether this hallucinatory effect is related directly to the inhibition of MAO, but due to the structural similarity to [serotonin](#), it is possible that [beta-carbolines](#) are acting as [serotonin](#) antagonists in much the same way LSD does. The current theory implicates LSD temporarily binding to the

[serotonin](#) receptor. Upon the release of LSD an over abundance of [serotonin](#) is present in the CNS and affects perception. It is notable, however, that the hallucinations experienced from ingestion of [beta-carbolines](#) differ from those experienced with LSD.

MIND BENDING BETA-CARBOLINES

BETA-CARBOLINE CONTAINING PLANTS

Images property of www.nepenthes.com

The [beta-carbolines](#) are distributed among [23 angiosperm plant families](#). The most commonly used trivial nomenclature of the [beta-carboline alkaloids](#) is based on the root "harm" from *Peganum harmala* the plant that was first known to contain these compounds.

Peganum harmala (Zygophyllaceae) is a weed and wasteland species native to the deserts of India whose range stretches through the Gobi desert into the former Soviet Union. The [mature *Peganum harmala*](#) or the Syrian rue is a common livestock poison in the former Soviet rangelands but specific information concerning the extent of its damage are difficult to locate. The content of [beta-carbolines](#) in the Syrian rue range from 2% to 4%.

- [mature *Peganum harmala*](#)
- [Peganum harmala habitat](#)
- [Peganum harmala drawing](#)

[Passiflora incarnata](#) (Passifloraceae) or the Maypop passion flower is a common ornamental in the United States. This species and other varieties have been used as model systems to investigate the effects [beta-carboline alkaloids](#) have on insect feeding patterns [7]. The amount of [beta-carbolines](#) in this species range from 0.5 -1.0%.

- [Mature *Passiflora incarnata*](#)
- [Passiflora incarnata seedling](#)

[Banisteriopsis caapi](#) (Malpighiaceae) is a liana native to the new world tropics where it is the principle ingredient in the hallucinogenic beverage [ayahuasca](#). This plant and the beverage have received attention lately by several members of the scientific community involved with the [Hoasca Project](#) and more underground information can be found by referencing the King of Brews. The [beta-carboline](#) content in [Banisteriopsis caapi](#) ranges from 1.0 - 2.0%.

- [Banisteriopsis caapi](#)

Conium maculatum (Poison Hemlock)

Index

- [Distribution](#)
 - [Description](#)
 - [How to Distinguish From Other Plants](#)
 - [Toxic ingredient: Piperidine Alkaloids](#)
-

Distribution

Poison hemlock is native to Europe. However, it is now widely distributed across the United States, especially in the Northern states. It is common along roadsides, hiking trails, ditches and field borders.

Description

Poison Hemlock can grow to be about 6 to 10 ft. tall. It has leaves and white flowerheads resembling those of parsnips, carrots, and water hemlock. It has a fleshy, white taproot, a main stem with characteristic light red spots and a disagreeable smell. All plant parts are poisonous. However, the seeds contain the highest concentration of poison. The conium alkaloids are volatile and can even cause toxic reactions when inhaled.

mottling on the stems

note the characteristic red

How to distinguish from other plants

Water hemlock does not have the same main taproot and stem. Instead, water hemlock has a branching, tuberous root stalk similar to that of a dahlia plant. The lower part of the stem of water hemlock is divided into chambers which contain its toxicant. Poison Hemlock is also commonly confused with wild carrot, cow parsnip, etc. Human deaths have occurred from harvesting and consuming the roots as wild carrots or parsnips. The stems should always be checked for red mottling. However, this characteristic is not always readily apparant.

More information describing this plant can be found under its [listing](#) in the Canadian Poisonous Plants Information System, courtesy of Derek B. Munro.

The saturated heterocyclic ring of a piperidine nucleus

Nicotiana spp. (Tobacco and Tree Tobacco)

Distribution and description

Domestic tobacco (*N. tabacum*) is widely cultivated throughout the southeast United States. Wild tobaccos (*N. attenuata* and *N. trigonophylla*) are upright, leafy evergreen plants found in sandy, arid regions of the western US. Tree tobacco (*N. glauca*) is similar in appearance but can grow to be a small tree and is found at low elevations of Arizona and California.

Tobacco has large, simple, alternate, bright green, often sticky, leaves. Its stems are often sticky and hairy.

Tobacco flowers are organized in panicles. They have a tubular shape with 5 fused petals that flare at the mouth into 5 distinct lobes. They are fragrant and range in color from white to a very light pink, purple, or yellow.

More information describing them is available under the listing for [Nicotiana tabacum](http://www.ansci.cornell.edu/plants/tobacco.html),

The Toxicology of the *Astragalus* genus

[Click here for full size pictures of *Astragalus*](#)

To those of you with slow connections: these are a BIG color images ~120kb each

Members of the genus *Astragalus* are known by a number of different names. Those most widely used are **locoweed** and **milkvetch**. There are over 2000 species in this genus that are known currently, of which many are known to carry various toxins. (Williams, 1984) They can be found in North and South America, Asia, Europe, Northern Africa and Australia. There are nearly 400 species in North America whose range extends over most of most of the continent. (Ralphs, 1992) They are predominantly in the [central plains and grassland regions of the United States](#) where they are the most common of the Leguminosiae. Due to their range and toxicity, livestock poisoning by locoweed is the most widespread toxic plant problem in the western U.S., (Ralphs, James, Nielsen, Baker, Molyneux, 1988) costing millions of dollars both in livestock loss and in cost of plant control (Williams, 1984) Despite the unpleasant effects of *Astragalus* poisoning, animals often become habituated to eating, fueling their further intoxication by the plant. (Ralphs, Panter, James, 1990)

Astragali poison in three main ways:

- With the indolizidine alkaloid [swainsonine](#) as in the case of *A. lentiginosus* and *A. lusitanicus*
- With the nitropropanol bearing glycoside [miserotoxin](#) as in the case of *A. miser*

AND

- With toxic levels of [selenium metabolites](#) (Se) as in the case of *A. bisulcatus*

In this series of web pages I'd like to present a compilation of some of the toxicological information available on *Astragalus*. This will include a description of the specific toxicants named above, their modes of action, the physiological effects and the common symptoms of poisoning by [swainsonine](#), [miserotoxin](#) and [Se excess](#), as well as some [general effects of *Astragalus* intoxication](#). Also in these pages will be [some means to identify *Astragalus*](#), (whenever I could find them) and [that researchers have explored to control poisoning by these plants](#).

Astragalus and *Oxytropis* spp. (Locoweed and Milkvetch families)

The plant

Astragalus and *Oxytropis* are leguminous perennials found in large concentrations in western North America. Many species of *Astragalus* are not poisonous and are good rangeland forage plants. However, within the same species, concentrations of toxicants can vary widely from plant to plant so all locoweeds and milk vetches should be approached with caution and assumed potentially dangerous to livestock. Their leaves are alternate and pinnately compound. Flowers are leguminous and the fruit is a legume pod with kidney shaped seeds. The pod is often conspicuously enlarged causing the seeds to rattle in it when ripe, hence the common names, rattlebox and rattleweed, that are often assigned to it. The keel petal of *Oxytropis* tends to be long and pointed whereas that of *Astragalus* tends to be blunter.

Note that these two closely related genera also carry many of the same toxins. (James, Hartley, Panter, Nielsen)

Lead is a highly toxic metal that was used for many years in products found in and around our homes. Lead may cause a range of health effects, from behavioral problems and learning disabilities, to seizures and death. Children 6 years old and under are most at risk, because their bodies are growing quickly.

Research suggests that the primary sources of lead exposure for most children are:

- deteriorating lead-based paint,
- lead contaminated dust, and
- lead contaminated residential soil.

EPA is playing a major role in addressing these residential lead hazards. In 1978, there were nearly three to four million children with elevated blood lead levels in the United States. In the 1990s, that number had dropped to 434,000 kids, and it continues to decline. While we still have a significant challenge, EPA is very proud of how federal, state, and private sector partners have coordinated efforts with the public to better protect our children.

Since the 1980's, EPA and its federal partners have phased out lead in gasoline, reduced lead in drinking water, reduced lead in industrial air pollution, and banned or limited lead used in consumer products, including residential paint. States and municipalities have set up programs to identify and treat lead poisoned children and to rehabilitate deteriorated housing. Parents, too, have greatly helped to reduce lead exposures to their children by cleaning and maintaining homes, having their children's blood lead levels checked, and promoting proper nutrition. The Agency's Lead Awareness Program continues to work to protect human health and the environment against the dangers of lead by developing regulations, conducting research, and designing educational outreach efforts and materials.

Buddleja americana

Index

- [Introduction and Description](#)
- [Common Names](#)
- [Chemical Compounds and Toxicity](#)
- [Uses and Efficacy](#)

Introduction and Description

Buddleja americana is a member of the family Loganiaceae and is native to Central America. The plant grows to a height of 3 meters. The leaves are oval (20cm) with white hairs on the edges. The flowers are very small and greenish-yellow. The plant has a strong odor.

Common Names

- Hoja blanca -- Honduras
- Salvia -- Honduras, El Salvador
- Zayolizcan

Chemical Compounds

Very little information regarding the types and quantity of chemical compounds in *Buddleja americana* could be found. Also, little toxic information could be found. The only information located stated that the plant contains saponic glycosides, alkaloids, tannins, sterols, and triterpenes, and that ethanol extracts are poisonous to fish. Since information on exact compounds could not be located, the following discussion is about general properties of these types of compounds.

Saponic glycosides occur in many temperate legume forages and are one of the causes of bloat in ruminants. They are bitter compounds and can decrease feed palatability and feed intake. While some saponins can decrease growth in swine and poultry, others have beneficial effects and are used as feed additives.

Alkaloids, in general, are bitter and toxic. However, many alkaloids have medicinal properties. Triterpenes are biochemically complex. Many terpenes have medicinal properties, though many also are toxic. Without better phytochemical information about this plant it is neither possible to determine if it contains compounds that may be medicinal nor ones that could be toxic.

[Return to Index](#)

Uses and Efficacy

As with the chemical composition and toxicity information, few data are available regarding the efficacy of *Buddleja americana*. Farmers in Honduras indicated that it was used to relieve stomach pain caused primarily by parasites. It normally is combined with plants that are supposed to kill the parasites. However, the only information regarding its efficacy was about its ability to control bacteria. Ethanol extractions were shown to inhibit *Escherichia coli* but not *Staphylococcus aureus*.

Some Uses in Humans:

- Headache -- Colombia
- Analgesic -- Mexico
- Burn -- Mexico
- Diuretic -- Mexico and El Salvador
- Cirrhosis -- Mexico
- Hepatitis -- Mexico
- Hypnotic -- Mexico
- Pain (stomach) -- Honduras
- Parasites -- Honduras
- Rheumatism -- Mexico and El Salvador
- Sore -- Mexico
- Tetanus -- Mexico
- Tumor -- Mexico
- Wound -- Honduras and Mexico

Carica papaya

Index

- [Introduction and Common Names](#)
- [Chemical Compounds](#)
- [Toxicity](#)
- [Uses and Efficacy](#)

Introduction

Carica papaya (Family Caricaceae) originated in Central America. It is an interesting tree in that the male and female parts exist in different trees. The fruits, leaves, and latex are used medicinally. Papain, a major compound in the fruit and latex has been used in brewing and wine making and the textile and tanning industries. Common names for papaya trees include:

- Betik petik
- Chich Put
- Fan Kua
- Gandul
- Katela gantung
- Kates
- Kavunagaci
- Kepaya
- Kuntaia
- Lechoso
- Lohong Si Phle
- Mapaza
- Mu Kua
- Papailler
- Papaw and pawpaw tree
- Papaya
- Papaye
- Papayer
- Pepol
- Tinti

- Wan Shou Kuo

[Return to Index](#)

Chemical Compounds

Carica papaya contains many biologically active compounds. Two important compounds are chymopapain and papain, which are supposed to aid in digestion. Papain also is used to treat arthritis. The level of the compounds vary in the fruit, latex, leaves, and roots. In addition, plant parts from male and female trees differ in the quantity of the compounds. For example, phenolic compounds tend to be higher male trees than female trees. The quantity of fresh papaya latex and dry latex (crude papain) also vary with the sex of the tree and the age of the tree. Female and hermaphrodite trees yield more crude papain than male trees and older fruit yields more than younger fruit. However, the activity of the papain is higher in the extracts from the younger fruit than the older fruit. Cultivars also vary in the quantity of the compounds. For example, the primary and secondary volatile compounds in the fruit of one cultivar studied were linalool and trans-linalool oxide, respectively. In another cultivar, the primary and secondary volatile compounds were cis-linalool oxide and linalool, respectively.

The following list of compounds found in parts of *Carica papaya* is not comprehensive. The quantity of the compounds are estimates based on several sources (listed in the references). For more information please refer to the references and the [USDA Phytochemical and Ethnobotanical Databases](#).

- alkaloids -- 1,300-4,000 ppm in leaves
- butanoic acid -- as much as 1.2mg/kg in fruit pulp
- methyl butanoate -- as much as 18% of the volatile components in the fruit
- carpaine -- leaves (1,000-1,500 ppm), bark, roots, and seeds
- dehydrocarpaines -- 1,000 ppm in leaves
- pseudocarpaine -- 100 ppm in leaves
- chymopapain-a and b -- latex and exudate
- flavonols -- 0-2,000 ppm in leaves
- benzylglucosinolate -- found in all parts of the plant, but highest in young leaves
- linalool -- as much as 94% of the volatile components in the fruit
- cis- and trans-linalool oxide -- fruit
- alpha-linolenic acid -- 250-2,238 ppm in fruit
- nicotine
- papain -- fruit and 53,000 ppm in latex and exudate
- alpha-phellandrene -- fruit
- tannins -- 5,000-6,000 ppm in leaves
- alpha-terpinene -- fruit
- gamma-terpinene -- fruit
- 4-terpineol -- fruit

- terpinolene -- fruit
- methyl-thiocyanate and benzyl-isothiocyanate

[Return to Index](#)

Toxicity

With the exception of infertility, the literature reviewed did not indicate any adverse reactions from the consumption of *Carica papaya* fruit, latex, or extracts. However, the leaves and roots of *Carica papaya* contain cyanogenic glucosides which form cyanide. The leaves also contain tannins. Both of these compounds, at high concentrations, can cause adverse reactions. Also, inhaling papaya powder (high in the enzymes papain and chymopapain, can induce allergies.

In trials with rats, daily oral doses of benzene and alcohol extracts (20mg/kg body weight (BW) for 30 days) did not effect body or reproductive organ weights or adversely effect liver or kidney function. However, aqueous extracts (1mg/kg BW for 7 or 15 days) and benzene extracts given orally to female rats caused infertility and irregular oestrous cycles. Male rats given ethanol seed extracts orally (10 or 50 mg/day for 30, 60, or 90 days) or intramuscularly (0.1 or 1.0 mg/day for 15 or 30 days) had decreased sperm motility. The oral doses also decreased testis mass and sperm count. Studies with aqueous seed extracts also decreased fertility in male rats. The fertility of the male and female rats returned to normal within 60 days after the treatments were discontinued.

In addition to decreasing infertility, papain might cause abortions shortly after conception. The papain apparently dissolves a protein(s) responsible for adhering the newly fertilized egg to the wall of the uterus.

[Return to Index](#)

Uses and Efficacy

The efficacy of treatments with *Carica papaya* is dependent on the quantity of the different compounds in the preparation. The quantity of the compounds, as previously indicated, differ in the fruit, latex, leaves, and roots and vary with the extraction method, age of the plant part, and the cultivar and sex of the tree.

The application of papaya latex that is probably of most interest to livestock producers is as an anthelmintic (dewormer). Satrija et al. (1994) tested the efficacy of papaya latex (at doses of 2, 4, and 8 g/kg BW) against *Ascaris suum* in 16 pigs. The eggs per gram (epg) on days 0, 1, 5, and 7 were determined using a modified McMaster technique and the adult worms were collected and sexed at necropsy on day 7. The 4- and 8-g/kg BW treatments significantly decreased the epg produced (by 99%) and the number of adult worms by 80 and 100%, respectively. The study conducted by Satrija et al. supports the results of other studies which indicate that papaya latex is effective against *Ascaridia galli* in chickens. One adverse effect of the treatment was transient diarrhea in the 8-g/kg BW group on day 1 of the study. In another study, water extracts of papaya seeds decreased *Ascaridia galli* infections in chicks by 41.7% (compared to piperazine hexahydrate which decreased infections by 99%).

In traditional veterinary medicine, papaya seeds also are used as dewormers. In Indonesia and the Philippines, air-dried seeds are ground and mixed with water - 3 g of seeds/kg bodyweight. The

animals are given the seed/water mixture once a day for 6 days. In Indonesia, papaya leaves are used as feed for animals after parturition - 2 leaves boiled in water fed every 2 days for 1 week. It also has been reported that papaya leaf extract is used as a prophylaxis against malaria, though no studies on this use could be found in the literature.

Results from studies on biological activities of *Carica papaya* parts, extracts, and isolated compounds are briefly summarized below:

- Antimicrobial
 - Latex (with a minimum protein concentration of 138 microliters/ml) and root extracts inhibited *Candida albicans*. However, aqueous extracts were not active.
 - Extracts of pulp and seeds showed bacteriostatic properties when tested against *Staphylococcus aureus*, *Escherichia coli*, *Salmonella typhi*, *Bacillus subtilis*, and other bacteria *in vitro*. However, in another study, aqueous extracts (type of extract and plant part not indicated) were not active against *Staphylococcus aureus* and *Escherichia coli* *in vitro*.
 - Alpha-D-mannosidase and N-acetyl-beta-D-glucosaminidase (isolated from latex) acted synergistically to inhibit yeast growth.
- Parasitic
 - Powdered air-dried seeds given orally to 4 dogs (60mg/kg BW for 30 days) decreased *Dirofilaria immitis* infections.
 - Papaya latex fed (at a rate of 2, 4, 6, or 8g/kg BW) to mice with experimental infections of *Heligmosomoides polygyrus* decreased infections rates by 55.5-84.5% compared to non-treated control mice.
 - Seeds at concentrations of less than 100 micrograms/ml exhibited activity against *Entamoeba histolytica* *in vitro*.
 - Benzylisothiocyanate (isolated from papaya) at concentrations of 100-300 micromoles inhibits the energy metabolism and affected the motor activity of *Ascaridia galli* *in vitro*
- Sedative and muscle relaxer -- studies with rats indicate that alcohol extracts (at a dose of 5 mg/kg BW intraperitoneally or greater) relaxed central muscles. The extracts (at a dose of 10 mg/kg BW intraperitoneally or greater) also had sedative properties.
- Purgative -- in one study with rats, aqueous extracts increased the number of wet feces and the movement of intestinal contents.

Papaya has been used to treat the following ailments in humans:

- Abortifacient -- Java, Panama, Sri Lanka, and Turkey
- Amebicide -- Japan
- Arthritis and rheumatism -- Haiti and Java
- Asthma and respiration -- Mauritius, Mexico, and Philippines
- Bactericide -- India
- Cancer -- Australia and Mexico
- Cardiotonic -- Turkey

- Colic -- Malaya
- Constipation and laxative -- Honduras, Panama, and Trinidad

Cecropia spp.

Index

- [Introduction and Description](#)
- [Common Names](#)
- [Chemical Compounds](#)
- [Toxicity](#)
- [Uses and Efficacy](#)

Introduction and Description

Cecropia spp. belong to the family Cecropiaceae (previously included in the family Moraceae) and are native to tropical America. The trees are reported to have a milky caustic latex, and many of them are attractive to ants. *C. peltata*, the species for which the most information was easily accessible, grows to a height of 20-25m. The bark is gray and red and has rings. The "umbrellas" can be 1m in diameter and the leaves which make up the umbrella can be 30-40cm in diameter. The branches are hollow.

Common Names

Cecropia spp.

- Trumpet Tree
- Trumpet Wood
- Snake Wood
- Yagrumo
- Yagrumo Hembra
- Llagrumo Hembra
- Bois Canot
- Guarumo
- Guarima
- Guarumbo
- Trompeta

C. peltata

- Bois Canon
- Bois Trompette
- Grayumbe

- Grayumbo
- Guarumo -- Honduras
- Trompette
- Trompettier
- Trumpet Tree
- Yagruma
- Yagrumo

Chemical Compounds

No information on chemical compounds in *Cecropia* spp. could be found.

Toxicity

The only toxicity information available indicates that *Cecropia* spp. may cause itching and skin rashes. These reactions are caused by the leaves and by the ants residing in the trees.

Uses and Efficacy

Cecropia peltata is used by some Honduran farmers to aid animals during birthing. It is given during labor to speed up the birthing process and after labor so that the placenta is quickly expelled. No information on the preparation or doses was available.

The only study that could be located regarding its medicinal properties indicated that leaf extracts had anticonorrheal activity.

Some Uses in Humans: *Cecropia* spp.

- Asthma -- Mexico
- Astringent -- Venezuela
- Cardiac -- Venezuela
- Dysentery -- Mexico
- Liver -- Mexico
- Masticatory -- Colombia
- Tonic -- Venezuela
- Ulcer -- Mexico
- Venereal -- Mexico
- Warts -- Mexico
- Wounds -- Mexico

C. peltata

- Asthma -- Haiti and Mexico

- Astringent -- Haiti
- Cardi tonic -- Haiti, Mexico, and Uruguay
- Caustic -- Mexico
- Chorea -- Mexico
- Cough and bronchitis -- Haiti and Trinidad
- Diabetes -- Mexico
- Diarrhea and dysentery -- Haiti
- Diuretic -- Mexico and Uruguay
- Dropsy -- Mexico
- Fever -- Trinidad
- Flu -- Trinidad
- Gonorrhoea -- Haiti
- Hepatitis -- Mexico
- Herpes -- Haiti
- Liver
- Nerve -- Mexico
- Obesity -- Mexico
- Poison -- Mexico
- Snake bites and scorpions -- Trinidad
- Warts, calluses, and corns -- Brazil, Cuba, Dominican Republic, French Guinea, Jamaica, Martinique, and Mexico
- Wounds -- Haiti

Chenopodium ambrosioides

Index

- [Introduction](#)
- [Description](#)
- [Common Names](#)
- [Chemical Compounds](#)
- [Toxicity](#)
- [Uses and Efficacy](#)

Introduction

Chenopodium ambrosioides (Family Chenopodiaceas) originated in Central America, though it has been distributed to much of the world. It has been used as an anthelmintic (medicine for controlling internal parasites) for many years. In the early 1900s it was one of the major anthelmintics used to treat ascarids and hookworms in humans, cats, dogs, horses, and pigs. Usually, oil of chenopodium was used. It was sometimes referred to as Baltimore Oil, because of the large production facility in Baltimore that specialized in extracting the oil from the plant. Chenopodium was replaced with other, more effective and less toxic anthelmintics in the 1940s.

Chenopodium is still used to treat worm infections in humans in many countries. In Honduras, as well as other Latin American countries, the whole plant or the leaves are ground and added to water. This mixture is then consumed. In a few areas in Latin America, the plant also is used to treat worm infections in livestock. [Return to Index](#)

Description

Chenopodium ambrosioides is an herb that grows to a height of 40cm. The leaves are oval (up to 4cm long and 1cm wide) and toothed. The flowers are small and green, and the seeds are very small and green when fresh and black when dry. The plant has a very strong odor. Seeds can be purchased through seed catalogues. [Return to Index](#)

Common Names

- American Wormseed -- U.S.
- Apazote, Epazote, Ipazote -- Latin America
- Paico -- Peru
- Wurmsaamen Gansefuss -- Germany
- L'anserine vermifuge -- France

- Erva de Santa Maria -- Brazil

[Return to Index](#)

Chemical Compounds

There are many compounds in *Chenopodium*. The compound considered to be the active ingredient is ascaridole, a monoterpene. The major components of oil of chenopodium are: ascaridole (60-80%), isoascaridole, p-cymene, limonene, and x-terpinene. The level of the different compounds varies depending on the part of the plant, age of the plant, and whether it is dried or fresh plant material.

The quantity of ascaridole (or other compounds) in chenopodium can be determined using gas chromatography and mass spectrometry (GC/MS). The major compounds in chenopodium can be extracted with methanol or hexanes and then sent through the GC/MS.

Some of the Compounds in *Chenopodium ambrosioides* (for a more complete list see [USDA Phytochemical and Ethnobotanical Databases](#)):

- Alpha-pinene -- plant 440-4800 ppm
- Ascaridole -- leaves 185-18000 ppm
- D-camphor -- plant
- Essential oil -- fruit 1830-25000 ppm, leaves 2000-3000 ppm
- L-pinocarvone -- plant 1040-11400 ppm
- Limonene -- plant
- P-cymene -- leaves 365-4400 ppm
- P-cymol -- plant 730-8000 ppm
- Saponins -- roots 25000 ppm
- Terpinene -- plant
- Terpinyl-acetate -- plant 75 ppm
- Terpinyl-salicylate -- plant 75 ppm

[Return to Index](#)

Toxicity

Oil made from *Chenopodium ambrosioides* is very toxic. However, little is known about the toxicity of fresh and dried plant material, how the oil and plant are metabolized, and why toxic reactions occur. The reaction that animals have to chenopodium seem to vary. For example, one goat can show signs of mild toxicity, while another goat, from the same herd, may not show any adverse effects. Therefore, using this treatment can be risky. Signs of toxicity include: salivation, increased heart rate and respiration, changes in blood chemistry, decreased rumen motility, decreased contractions in the intestines, and convulsions. Oil of chenopodium can cause skin reactions, and it is dangerous to inhale.

Oil of chenopodium has caused death or adverse reactions at doses of:

- Goats -- 0.2ml/kg body weight (BW)
- Sheep -- 0.1ml/kg BW
- Cats -- 0.2ml/kg BW
- Dogs -- 0.2ml/kg BW (vomiting)
- Rabbits -- 0.5ml

The dose that causes adverse effects is very close to the dose that is supposed to be efficacious. Therefore, extreme caution should be used when treating an animal with this plant or the oil made from the plant. Other than treating the symptoms, there is no known cure to an overdose from this plant and the oil. [Return to Index](#)

Uses and Efficacy

Oil of Chenopodium and paste from fresh plant are primarily used to treat internal parasites in humans and non-ruminant animals. However, good data on efficacy is not available. Trials done in the early 1900s usually did not have control animals to which the treated animals could be compared.

In vitro studies with oil of chenopodium and chenopodium extracts have shown that it inhibits egg development of parasites and inhibits maturation of larva. However, these results have not been confirmed in in vivo studies.

Current research is being done on the potential of using chenopodium to treat ruminants at Cornell University. Results of the completed trials show that oil of chenopodium does decrease fecal egg counts. However, the decrease is not very large and does not compare to the control that can be achieved with other anthelmintics. Also, the effective dose does cause some adverse reactions in the animals. Oil of chenopodium has been shown (in vitro) to decrease egg hatching of *Haemonchus contortus*, a common parasite of small ruminants. Further research is needed to determine the efficacy, dose, and practical applications for oil and fresh plant material of *Chenopodium ambrosioides*.

When oil of chenopodium was in common use, it was administered via gel capsules and followed up with castor or linseed oil. Often, the person or animal taking the drug fasted first.

Recommended doses were:

- Dogs -- 0.03-0.1ml/kg BW followed by 30ml castor oil, fast for 24h before treatment
- Horses -- 16-18 ml and 1L of linseed oil, fast for 36h before treatment
- Swine -- 0.5-1ml/11.5kg BW, followed by 60ml castor oil
- Cats -- 0.03-0.05ml/kg BW, followed by 30ml castor oil
- Chickens -- 0.3ml in 3ml castor oil

Doses being tested are:

- Goats -- 0.2ml/kg BW
- Sheep -- 0.1ml/kg BW

Doses with fresh plant material are harder to determine, since the quantity of compounds in the plants varies so much. The only information on fresh plant doses are for humans. One book recommends two cups of a plant/water mixture (8 leaves with water) per day for adults and 3-4

tablespoons of the mixture per day for children over five. The book warns against giving the treatment to children under 5 and pregnant women.

Some Other Uses (in humans):

- Amebicide -- Trinidad
- Analgesic -- China
- Anemia -- Colombia
- Arthritis -- China
- Asthma -- Dominican Republic, Panama, Trinidad, and Turkey
- Bite(Bug) -- China
- Dysentery -- Panama and Trinidad
- Fungicide -- Trinidad
- Narcotic -- U.S.
- Nerves -- Mexico, Turkey, and U.S.
- Stimulant -- Trinidad and Turkey
- Stomach (ache) and/or colic -- Brazil, Chile, China, Dominican Republic, Haiti, Honduras, Mexico, Turkey, and Venezuela
- Vermifuge -- Bahamas, Brazil, China, Dominican Republic, Guatemala, Haiti, Mexico, Panama, Spain, Trinidad, Turkey, U.S., and Venezuela

Eucalyptus spp.

Index

- [Introduction](#)
- [Common Names](#)
- [Chemical Compounds](#)
- [Toxicity](#)
- [Uses and Efficacy](#)

Introduction

Eucalyptus spp. (Family Myrtaceae) originated in Australia. It now grows in almost all tropical and subtropical areas and is cultivated in many other climates. Much research has been conducted on the medicinal properties of *Eucalyptus spp.* Of the different species, *E. globulus* has been the most widely studied. Eucalyptus is used to treat many human ailments and some livestock ailments. Eucalyptus extracts, oils, or fresh leaves are used in steam inhalation treatments, consumed in teas, or used in bathing.

While *Eucalyptus* trees are well known for their medicinal properties and their strong fragrance, they are best known as the feed source for koala. The koala only eat a few species of *Eucalyptus*. However, there are over 500 species of the tree.

[Return to Index](#)

Common Names

- Blue Gum tree
- Eucalipto
- Eucalypt
- Eucalyptus
- Fever tree
- Lemon Eucalyptus
- Okaliptus
- Silver-leaf Ironbark

[Return to Index](#)

Chemical Compounds

There are many compounds in *Eucalyptus spp.*. While the same compounds exist in many of the species, some compounds can be found in only one or a few species. Within species the quantity of essential oil and the specific compounds in the essential oil and extracts of dry and fresh leaves, buds, mature fruit, and bark vary with the origin of the tree and the age of the leaves. The following discussion and list of *Eucalyptus spp.* and the compounds in them is not comprehensive. The quantity of the compounds in the oils and plant parts are estimates based on several sources (listed in the references). For more information please refer to the references and the [USDA Phytochemical and Ethnobotanical Databases](#).

E. globulus is one of the more important species of Eucalyptus. The essential oil in the leaves is commonly used for medicinal purposes. The quantity of essential oil ranges from less than 1.5 to over 3.5%. On average, between 70 and 95% of the oil is 1,8-cineole (eucalyptol). However, some studies have shown the oil to contain as little as 4% 1,8-cineole. The essential oil from the fruit, buds, and branches contain from 15-57% 1,8-cineole. Activities contributed to this compound include: anesthetic, antibronchitic, antidiarrheal, antilaryngitic, antipharyngitic, antiseptic, antitussive, CNS-stimulant, choleric, counterirritant, dentifrice, expectorant, fungicide, hepatotonic, herbicide, hypotensive, pesticide, and sedative. Other major components in the oil are:

- aromadendrene -- 8-23% in fruit, bud, and branch oils and 50-350 ppm in the leaves
- camphene -- traces in leaf oil
- cryptone -- 0-18% in leaf oil
- p-cymene -- <1-27% in leaf oil
- d-limonene -- traces in leaf oil
- alpha-phellandrene -- traces in leaf oil
- alpha-pinene -- <1-18% in leaf oil
- beta-pinene -- traces in leaf oil
- spathulenol -- <1-17% in leaf oil
- gamma-terpinene -- traces in leaf oil
- alpha-thujene -- 0-12% in fruit, bud, and branch oils

Other important compounds found in the leaves, buds, branches, and bark include:

- antioxidants (from bark) -- eriodictyol, naringenin, quercetin, rhamnagin, rhamnetin, taxifolin
- citriodorol
- cuminaldehyde -- 25-135 ppm in the leaves
- epiglobulol -- one study indicated 28,000 ppm in leaves
- euglobins -- These compounds are believed to have anti-tumor promoting activity.
- d-linalool -- leaves
- pinocarvone -- leaves
- rutin -- leaves
- tannins -- as much as 11% have been found in dry powdered leaves. Several activities have

been attributed to tannins including antidysenteric, antimutagenic, antinephritic, antioxidant, antiviral, bactericide, cancer-preventive, hepatoprotective, pesticide, psychotropic, and viricide properties.

- gamma-terpinene -- leaves
- terpineol -- leaves

E. citriodora essential oil contains mainly citronellol (approximately 58%), which is best known for its aromatic properties. Other compounds in the plant include:

- aromadendrene
- citronellal -- 50-18,020 ppm in the leaves
- citronellic acid -- 1% in leaf oil
- citronellol -- 7.6% in leaf oil and 230-4,000 ppm in the leaves
- citronellyl acetate -- 24% in leaf oil and 20-130 ppm in the leaves
- p-cymene -- 10-180 ppm in the leaves
- limonene -- 20-1,420 ppm in the leaves
- linalool -- 15-180 ppm in the leaves
- alpha-pinene -- 5-380 ppm in the leaves
- tannin
- terpinene -- 1-180 ppm in the leaves
- terpinolene -- 5-160 ppm in the leaves
- ursolic acid

E. camaldulensis essential oil (from the leaves) ranges from less than 1 to over 2%. The quantity of 1,8-cineole in the oil ranges from 15-78%. Other compounds in the leaves include:

- betulinic acid
- eucalyptic and eucalyptolic acid
- oleanolic acid
- ursolic acid

Other *Eucalyptus spp.* of note and some of the compounds in them include:

- *E. amplifolia*, *E. blakelyi*, *E. grandis*, and *E. tereticornis* contain euglobals.
- *E. cladocalyx* contains traces of cyanogenic glycosides.
- *E. cornea* leaves contain up to 25% tannins.
- *E. dives* oil contains 33% piperitone.
- *E. dunnii* oil contains 48-58% 1,8-cineole, 5-7% globulol, 10-16.5% alpha-pinene, and 3-8% alpha-terpineol.
- *E. macarthurrii* oil contains 50% geranyl acetate.
- *E. macrocarpa* contains macrocarpal A, believed to be antibacterial.
- *E. macarorrhyncha* contains 12-20% rutin.
- *E. maidenii* and *E. smithii* oils contain 70-85% 1,8-cineole.

- *E. viminalis* oil contains high quantities of phellandrene (an inhalation irritant) and traces of cyanogenic glycosides.

[Return to Index](#)

Toxicity

Eucalyptus spp. contain high levels of phenolics and terpenoids which can be toxic. Animals such as the koala which eat *Eucalyptus* have developed methods for detoxifying the compounds in the liver. In addition, they have bacteria that degrade tannin-protein complexes. Most animals do not have this ability.

Several adverse reactions have been attributed to the use of or contact with *Eucalyptus* oils, extracts, and fresh and processed plant material. Some of the specific compounds that can be toxic or cause adverse reactions include: 1,8-cineole, cyanogenic glycosides, rutin, and tannins. Most studies on adverse reactions have been conducted with rodents and most documented cases of adverse reactions focus on humans. Less information is available on livestock.

Overdoses of the oil in humans cause gastro-intestinal burning, abdominal pain, vomiting, and convulsions, depress respiration and the central nervous system, and may lead to comas and death. The data on deaths caused by consumption of eucalyptus oil in humans are not consistent -- death has occurred after consumption of as little as 4-5 ml, while other people have become ill and recovered after consuming 120-220 ml of the oil. Based on rodent studies, the oral LD50 (the orally consumed dose that is lethal to 50% of the animals) for eucalyptus oil is very high -- 4.44g/kg body weight(BW) for rats and 3.32g/kg BW for mice. The LD50 is lower when only 1,8-cineole is used -- 2.48g/kg BW for rats. The dermal LD50 for rabbits is greater than 5g/kg BW.

Eucalyptus oil is not believed to be teratogenic or contaminate milk. However, some studies have indicated that citronellal and phellandrene, which can be found in some *Eucalyptus spp.*, are weak mutagenics and carcinogenics, respectively.

It is very difficult to determine the potential for adverse reactions with the use of Eucalyptus treatments. This is because, as previously stated, the type and quantity of compounds depends on the species (which often is not indicated on the label of purchased preparations), the age of the leaves, the method used for drying leaves, buds, and bark, and the preparation methods of essential oils and extracts. In addition, many studies on adverse reactions do not indicate the species or preparation method used, complicating the situation. While *Eucalyptus spp.* can cause adverse reactions, the U.S. Food and Drug Administration has approved the use of eucalyptus oil and 1,8-cineole (eucalyptol) for human food use. The Council of Europe also has approved the use of the oil as a human food additive (at a level of 15 ppm). In France, infusions of *E. globulus* leaves can be registered as products for the treatment human benign bronchial disorders without toxicological studies. However, some toxicological studies are required for the registration of powdered leaf formulas.

While not related to the use of *Eucalyptus* in treatments, I find it interesting that growing certain species of *Eucalyptus* can cause its own problems. In Australia sawfly larvae, which contain poisonous polypeptides, often gather in mounds beneath *E. melanophloia*. When cattle consume

the larvae, they become uncoordinated, tremble, and can suffer permanent liver damage.

Uses and Efficacy

As with toxicity, the efficacy of eucalyptus oils and extracts is most likely dependent on their chemical composition. In general, oils from *Eucalyptus spp.* have antimicrobial properties. Two studies which tested the oils from several species showed that *E. citriodora* had the most antimicrobial activity. There was no relationship between 1,8-cineole content and antimicrobial activity. Other studies have demonstrated that the oil and leaf extracts of *Eucalyptus spp.* have antifungal and repellent activity.

The applications that are probably of most interest to livestock producers are as a mastitis preventative and treatment, as a treatment for endometritis, and as an anthelmintic (dewormer). An herbal gel called AV/AMP/14 (produced by Dabur Ayurved Ltd. and contains *Cedrus deodara*, *Curcuma longa*, *Glycyrrhiza glabra*, and *Eucalyptus globulus*) was used to treat and prevent subclinical mastitis in crossbred cows. Twice daily topical applications to the udder significantly reduced somatic cell counts (Pavneesh et al. 1996 and Joshi et al. 1996).

In a study on bovine endometritis, cows with endometritis were given, via an intrauterine infusion, 100 mls of a 10% solution of a tincture (alcohol and water mixtures) of *Eucalyptus globulus*. The eucalyptus tincture was compared to tinctures of *Allium sativum* (garlic, believed to have antimicrobial activity) and *Gnaphalium conoideum* (a plant that has no antimicrobial properties). The parameters measured in the study included the number of infusions given (which were repeated every 48 h until there was a change in the endometritis) and the days to first visible oestrus, days open, and number of services before conception. All of these time periods are believed to be longer when there are infections in the reproductive tract. The eucalyptus and garlic tinctures significantly reduced the days to first visible oestrus and the days open, although fewer garlic treatments were needed. There were no significant differences between the three treatments in the number of services required for conception. The study did not include any approved, commercially available treatments for endometritis (Esparza-Borges and Ortiz-Marquez 1996).

Fresh leaves, leaf-extracts, and growth regulators and their intermediaries (which are endoperoxides) of *Eucalyptus grandis* were tested for their anthelmintic properties by Bennet-Jenkins and Bryant (1996). Leaves were fed to 5 goats with experimental infections of *Haemonchus contortus* (the barberpole worm) (and natural infections of *Ostertagia*) for seven days (two days with lucerne/oaten chaff and five days as the sole source of feed). At necropsy, the number of adult *H. contortus* in the *E. grandis*-fed goats was 91% lower than the number in 4 control goats. There was no significant difference in the number of *Ostertagia*. Isolated *E. grandis* compounds (and synthetic congeners) were effective *in vitro* and *in vivo* (in mice and sheep) -- but practical formulation and administration methods for these compounds have not been identified.

Another application that may be of interest to livestock producers is as a treatment for ectoparasites and non-specific skin infections. Two experimental herbal mixtures (AV/EPP/14 and AV/AAGD/14 produced by Dabur Ayurved Limited in India), which contain *Eucalyptus globulus* oil along with several other plant oils, have been tested on dogs to treat ectoparasites, fungal skin infections, and non-specific skin infections. While the mixtures appear to be effective, no

comparative treatments were used in the studies. Also, it is unknown which plant oils in the mixtures contain the most active ingredients -- that is, the eucalyptus oil may not have been the effective ingredient in the herbal mixture (Agrawal 1997 and Bhilegaonkar and Maske 1997).

Many *in vitro* and a few *in vivo* tests have been conducted with extracts and oils of different *Eucalyptus* species. Following is a summary of some of the specific activities identified for *Eucalyptus* spp.:

- Eucalyptus oil (species not specified)
 - antibacterial -- concentrations ranging from 0.16 to >20 microliters/ml inhibited 22 bacterial strains *in vitro*.
 - antifungal -- concentrations ranging from 0.25 to 10 microliters/ml inhibited 11 fungi *in vitro*.
 - repellent activity -- effective in repelling *Pediculus humanus* (human body louse), with citronellal being the active compound.
- Isolated compounds from *Eucalyptus* spp.
 - ursolic acid -- exhibited anticholestatic activity and protected against hepatotoxicity (induced by paracetamol and galactosamine) in rats.
 - euglobals -- were shown to have antitumor properties.
- *E. camaldulensis* -- ethanol extracts showed activity against bacteria and fungi.
- *E. globulus*
 - antimicrobial -- essential oil has limited activity against *Paenibacillus* larvae, the causal agent of American foulbrood disease and methanol extracts of leaves at concentrations of 10mg/ml or less inhibited *Staphylococcus aureus*, *Escherichia coli*, *Pseudomonas aeruginosa*, and *Candida albicans* *in vitro*.
 - antispasmodic -- water/alcohol extracts of leaves decreased smooth muscle contractions *in vitro*.
 - antifungal -- the oil is believed to have limited antifungal activity, although water extracts were not effective against the fungi *Epidermophyton floccosum*, *Microsporium canis*, and *Trichophyton mentagrophytes*.
- *E. macarthurii* and *E. riwagum* -- mixed results were obtained when the essential oils were tested for antibacterial and antifungal activity *in vitro*.
- *E. citriodora*
 - antiinflammatory -- alcohol extracts of the leaves given to mice at concentrations of 100, 300, and 1,000 mg/kg BW inhibited induced paw oedema in mice by 12, 22, and 49%, respectively.
 - antibacterial and antifungal activity -- essential oil inhibited *Bacillus megaterium*, *Staphylococcus aureus*, *Escherichia coli*, *Candida albicans*, *Aspergillus niger*, and *Zygorrhynchus* spp. *in vitro* and inhibited ringworm causing fungi.

Listed below are some uses of *E. globulus* in humans:

- Anodyne -- China
- Antimalaria -- Honduras

- Antiseptic -- China, Honduras, and Turkey
- Arthritis -- China
- Asthma
- Astringent -- Turkey
- Bronchitis -- Mexico and U.S.
- Burn -- China
- Cancer -- Australia (Aborigine), China, Spain, and U.S.
- Catarrh -- Mexico, Turkey, and U.S.
- Cold -- Honduras and Mexico
- Cough -- Honduras
- Deodorant -- Turkey
- Diabetes -- Mexico
- Diaphoretic
- Diphtheria
- Dysentery -- China
- Expectorant -- Honduras
- Fever -- China, Honduras, and Turkey
- Flu -- Mexico
- Gingivitis -- U.S.
- Hemostat -- Turkey
- Inflammation
- Inhalant
- Insect repellent -- Honduras and Venezuela
- Laryngitis -- Mexico
- Malaria -- Spain and Venezuela
- Miasma -- Venezuela
- Purgative
- Respiratory
- Skin diseases (ringworm) -- Guatemala
- Sores, wounds -- China
- Spasms -- Honduras and Turkey
- Stimulant -- Turkey
- Suppurative
- Throat
- Tuberculosis -- China
- Vermifuge

- Tumors (Breast)

- [Uses and Efficacy](#)

Introduction and Description

Gelsemium sempervirens belongs to the family Loganiaceae. It grows in the piedmont and coastal areas of the southeastern U.S. It is an early flowering climbing vine. The flowers are yellow, funnel shaped, and have a strong odor. The roots and rhizome of yellow jessamine were historically used to treat migraine headaches and types of neuralgia.

Common Names

- Carolina Jessamine -- U.S.
- Gelber Jasmin -- Germany
- Jasmin sauvage -- France
- Sariyasemin
- Yellow Jessamine

[Return to Index](#)

Chemical Compounds

Gelsemium sempervirens contains ergot type alkaloids. Following is a list of some of the compounds in the root of the plant. Potential activities of some of the compounds are listed as well as the quantities of the compounds in parts per million. For further information regarding the compounds in the plant refer to [USDA Phytochemical and Ethnobotanical Databases](#).

- 9-Hydroxysemperoside
- Brasoside
- Emodin-monomethylether
- Fabiatin
- Gelsedine -- activity CNS depressant
- Gelsemicine -- CNS depressant, convulsant, hypotensive, and respirapalytic

- Gelsemide
- Gelsemide-7-glucoside
- Gelsemidine -- CNS depressant
- Gelsemine -- analgesic, CNS depressant, CNS stimulant, cardiodepressant, and hypotensive
- Gelseminine
- Gelsemiol
- Gelsemiol-1-glucoside
- Gelsemiol-3-glucoside
- Gelsevirine -- CNS depressant
- Ipuranol
- n-Pentatriacontane
- Scopoletin -- allelochemic, analgesic, antiasthmatic, antiedemic, antifeedant, antiinflammatory, antileukotrienogenic, antiseptic, antitumor, CNS stimulant, cancer preventive, hypoglycemic, hypotensive, myorelaxant, pesticide, phytoalexin, spasmolytic, and uterosedative
- Sempervirine
- Tannin -- antidiarrheic, antidysenteric, antimutagenic, antinephritic, antioxidant, antiradicular, antiviral, bactericide, cancer-preventive, hepatoprotective, pesticide, psychotropic, and viricide

[Return to Index](#)

Toxicity

All parts of *G. sempervirens* are toxic, including the flower and nectar. The primary toxic compounds are gelsemine and gelseminine, which act as motor nerve depressants. Symptoms of toxicity in humans include difficulty in use of voluntary muscles, muscle rigidity and weakness, dizziness, loss of speech, dry mouth, visual disturbances, trembling of extremities, profuse sweating, respiratory depression, and convulsions. In Germany, human therapeutic use of the rhizome is not permitted, because it is not believed that efficacy has been adequately documented and serious risks are known. In some Australian states, the use of *G. sempervirens* is restricted and subject to poison control. The therapeutic dose in humans and the toxic dose are very close. No data could be found regarding livestock toxicity. However, many ergot alkaloids are known to be toxic to livestock.

Uses and Efficacy

It has been claimed that *G. sempervirens* can be used to treat several types of ailments. However, there is little substantial proof. There are some testimonials regarding its effectiveness in treating various ailments in cats (e.g., fever with shivering, muscle weakness, and vertigo). The doses used were: 30cc BID for 2 days and 3 doses of 30cc 12 hrs apart.

Some Uses in Humans:

- Analgesic -- Mexico
- Anodyne -- Mexico, Turkey, and U.S.
- Asthma -- Mexico
- Cephalgia -- Mexico
- CNS-depressant -- U.S.
- Cough -- U.S.
- Dermatologic aid -- U.S.
- Depressant
- Dysmenorrhea -- Mexico
- Fever -- Turkey and U.S.
- Gonorrhoea -- Mexico
- Hypertension-- Mexico
- Malaria -- Mexico and Turkey
- Migraine
- Neuralgia -- Europe
- Parturition -- U.S.
- Pertussis -- Mexico
- Pleurisy -- U.S.
- Poison, homicide -- Mexico, Turkey, and U.S.
- Polio
- Rheumatism -- Mexico
- Sedative, nerves, hysteria -- Mexico and Turkey
- Shortwindedness -- U.S.
- Spasm -- Mexico and Turkey
- Stomach ache -- U.S.
- Tonic -- Turkey

Gliricidia sepium

Index

- [Introduction and Description](#)
- [Common Names](#)
- [Chemical Compounds](#)
- [Toxicity](#)
- [Uses and Efficacy](#)

Introduction and Description

Gliricidia sepium is a leguminous tree and belongs to the family Fabaceae. *Gliricidia*, which originated in Central America, is used in many tropical and sub-tropical countries as live fencing. That is, it is planted along the side of fields, and the trunks are used as fence posts. During the dry season, when much of the forage is gone, the tree limbs are cut and the foliage is offered to livestock.

Gliricidia trees are a medium size, with composite leaves. The flowers are reddish and on the end of branches without leaves. The fruit is a pod about 10-15 cm. Typically, it can be found growing in acid soils with low to medium fertility.

Common Names

Usually *Gliricidia sepium* is just called *gliricidia*. There are only a few local names for the tree.

- Cacao de nance, cacahnanance -- Honduras
- Kakawate -- Philippines
- Mata Raton
- Madre Cacao -- Guatemala
- Madriado -- Honduras

[Return to Index](#)

Chemical Compounds

There are many compounds in *Gliricidia sepium*. The ones most researched are the tannins. In one study, *Gliricidia* was found to contain 40.7g of condensed tannins/kg dry matter. Tannins bind to protein and can make plants with high levels have an astringent dry mouth taste. The exact quantity of tannins varies with the location of the tree. The active medicinal compounds may be the tannins or other compounds such as afrormosin, medicarpin, or some isoflavins. Most of the research with *gliricidia* and its compounds have focused on nutritive quality. However, some

studies have focused on the ability of the plant and/or roots to decrease soil nematode populations, and control insects or fungi.

Some of the Compounds in *Gliricidia sepium*(for a more complete list see [USDA Phytochemical and Ethnobotanical Databases:](#)

- Afrormosin (an isoflavan) -- reported to be an antitumor promoting agent
- Formononetin (an isoflavan)
- Gliricidin-6a -- wood
- Gliricidol-9A -- wood
- Medicarpin (a pterocarpan) -- reported to be antifungal
- 7,4'-dihydroxy-3'-Methoxyisoflavin
- 2'-O-Methylsepiol -- plant
- Tannin -- reported to have potential antidiarrheic, antidysenteric, antimutagenic, antinephritic, antioxidant, antiradicular, antiviral, bactericide, cancer-preventive, hepatoprotective, pesticide, psychotropic, and viricide activities
- 7,3',4'-Trihydroxyflavanone -- plant

[Return to Index](#)

Toxicity

No published studies could be found regarding the toxicity of using gliricidia to repel insects. However, many animals cannot tolerate the consumption of large quantities of gliricidia. The tannins bind proteins and decrease the nutritive value of the plant. Some animals, such as goats, can consume larger quantities of plants with tannins than other animals such as cattle and sheep. Goats, unlike cattle and sheep, have a salivary protein binding factor that binds to the tannins.

[Return to Index](#)

Uses and Efficacy

Gliricidia is used by farmers in some Latin American countries to repel insects. The leaves are ground up and combined with water. The animal is then bathed with the resulting paste. According to some of the farmers, if this is repeated every 7-14 days, the number of torsalo (tropical warble fly) infections is decreased. No published studies could be found to substantiate this claim. However, when interviewing farmers and checking goats in Honduras, I found that the goats who the farmers claimed to have bathed with gliricidia had only 2-3 torsalos, while others had 10 or more. Also, one study did indicate that the heartwood of gliricidia contains compounds that attract and are toxic to certain insects (e.g., southern army worm, cabbage looper, yellow woolly bear, and *Glyptotermes dilatatus*, a termite).

In the Philippines, gliricidia is washed and pounded to extract the juice from the leaves. It is then applied to the area affected by external parasites once to twice a day for one week. In Guatemala, the bark and leaves of gliricidia are used to treat human skin diseases.

Research has been conducted on both the antifungal and antimicrobial properties of gliricidia extracts. In a brine shrimp toxicity test, a general screening method indicative of cytotoxicity and pesticidal activity, the LC50 was 454ug.ml (CI 328-608). , medicarpin, one of the compounds in the leaves and heartwood of gliricidia, is supposed to be antifungal. In an antifungal study, gliricidia extracts inhibited the germination of *Drechslera oryzae* only 6%. However, in another study, 50ug of stem chloroform extracts inhibited the growth of *Cladosporium cucumerinum* and slightly inhibited the growth of *Candida albicans*. In contrast, in another study, the antimicrobial properties of extracts from the bark of gliricidia were tested. It was effective against bacteria causing dermatitis. However, it was not effective against enterobacteria or *Candida albicans*. The discrepancy in the effectiveness against *Candida albicans* could be because of the quantity of plant extract used or the types of extracts used. In another study, leaf extracts were found to be effective against the dermatophytes *Microsporum canis*, *Trichophyton mentagrophytes* var *algodonosa*, and *T. rubrum*. It was not effective against *Epidermophyton floccosum*, *M. gypseum* or *T. mentagrophytes* var *granulare*.

In another study, gliricidia was found to inhibit the growth of various strains of *Neisseria gonorrhoea* in *in vitro* tests. Tinctures made from the leaves were used for these tests.

Some Uses in Humans:

- Headache
- Briuse
- Burn -- Panama
- Cold, cough -- Curacao
- Debility
- Expectorant -- Curacao
- Fatigue
- Fever -- Panama
- Gangrene -- Guatemala
- Gonorrhoea -- Guatemala
- Insecticide
- Insect repellent -- Curacao, Guatemala, and Honduras
- Itch, skin, sores -- Curacao, Guatemala, Honduras, and Panama
- Poison (Humans and animals) -- Panama and Venezuela
- Rodenticide (rats) -- Guatemala, Honduras, Panama, El Salvador, Venezuela
- Shade tree (for other crops) -- Sri Lanka
- Sedative -- Curacao
- Tumor -- Guatemala
- Ulcer -- Guatemala

Hyptis verticillata

Index

- [Introduction and Description](#)
- [Common Names](#)
- [Chemical Compounds](#)
- [Toxicity](#)
- [Uses and Efficacy](#)

Introduction and Description

Hyptis verticillata belongs to the family Lamiaceae and originated in Central America. It grows to a height of approximately 2 meters. The leaves are oval and the flowers are white.

[Return to Index](#)

Common Names

- Herbe Au Diable
- Herbe Bourrique
- Hierba Martina -- Mexico
- Malcasada Grande
- Maman-Houanne
- Mamanhouane
- Mastuerzo
- Quitadolor -- Honduras
- Wild mint
- Verbena -- Honduras and El Salvador

[Return to Index](#)

Chemical Compounds

Little research has been done on the compounds in *Hyptis verticillata*. Some research on the lignin composition has been done. Cadina-4,10(15)-diene-3-one is believed to be an active compound. (For more information regarding the compounds see [USDA Phytochemical and Ethnobotanical Databases](#).)

Some of the Compounds in *Hyptis verticillata*

- Cadina-4,10(15)-diene-3-one
- Dehydropodophyllotoxin -- cytotoxic
- 4'-Demethyldesoxypodophyllotoxin -- cytotoxic
- Epipodorhizol
- Hyptinin
- Maslinic acid
- 5'-Methoxydehydropodophyllotoxin -- cytotoxic
- Oleanolic acid
- B-Peltatin -- plant (antimiotic)
- Podorhizol
- Rosmarinic acid -- antibacterial
- Sideritoflavone -- antibacterial
- Ursolic acid

[Return to Index](#)

Toxicity

No published studies on the toxicity of *Hyptis verticillata* could be found. However, it is believed that lignans have phytoestrogen activity. Also, phenolic compounds formed after oxidative reactions of phenolic precursors such as rosmarinic acid can effect endocrine function.

Uses and Efficacy

Hyptis verticillata is used by some farmers in Honduras to treat infections after castration. No studies have been conducted to prove its efficacy regarding this use. However, some compounds have been shown to be antimiotic and inhibit *Candida albicans*. On TLC plates, rosmarinic acid at levels of 5ug, 7.5ug, and 5ug were found to inhibit *Bacillus subtilis*, *Micrococcus luteus*, and *Escherichia coli*, respectively. Effectiveness against these bacteria could explain the antiseptic properties of infusions prepared from the plant.

Research has been conducted on *Hyptis verticillata* acaricidal and insecticidal activities. Cadina-4,10(15)-diene-3-one, isolated from *Hyptis verticillata*, has been shown to have chemosterilant activity against the cattle tick and be toxic against the sweet potato pest *Ipomoea* spp. The compound did not kill adult ticks, but did decrease oviposition and egg hatching.

Other laboratory studies have shown that sideritoflavone is antiphlogistic, and several compounds in *Hyptis verticillata* are cytotoxic, antiviral, and antidiarrhoic. None of the compounds, however, have been tested in animals.

Some Uses in Humans:

- Aches (head, back, stomach) -- Dominican Republic, Honduras, Mexico, and El Salvador
- Colds -- Africa and the Caribbean

- Dyspepsia
- Itch
- Pectoral -- Haiti
- Rheumatism -- Mexico
- Sedative -- Haiti and El Salvador
- Skin infections -- Mexico and other Central American countries
- Spasm -- Dominican Republic
- Stings
- Tooth pain -- Honduras

Ocimum basilicum, *O. americanum*, and *O. micranthum*

Index

- [Introduction and Description](#)
- [Common Names](#)
- [Chemical Compounds](#)
- [Toxicity](#)
- [Uses and Efficacy](#)

Introduction and Description

Ocimum basilicum (common basil), *O. americanum*, and *O. micranthum* are members of the family Lamiaceae. These plants, as well as oils from them, have received lots of attention for their potential medicinal properties. Of these plants, *O. basilicum* is the most widely used. It is used in cosmetics, liqueurs, medicines, and perfumes.

Most *Ocimum* spp. can be grown and found throughout the world. However, they are not native to all areas. For example, *O. micranthum* originated in Central America. It grows to a height of approximately 50cm. The leaves are oval and slightly toothed, and the flowers are white or purple. *O. basilicum* looks very similar, but grows a bit taller (50-80cm).

[Return to Index](#)

Common Names

- Albahaca -- (*O. micranthum* in Honduras and Salvador), (*O. basilicum* in Guatemala)
- Balanoi -- (*O. basilicum* in the Philippines)
- Chahchabram
- Chiu Ts'Eng T'A
- Dama-Kasseh -- *Ocimum* spp. in Ethiopia
- Feslegen
- Hung que -- (*O. basilicum* in Vietnam)
- I Tzu Ts'Ao
- Lo Le
- Mreas preou -- (*O. basilicum* in Cambodia)
- Msubasha -- (*O. Suave*) Tanzania
- Ofgahng -- *Ocimum* spp. in Ethiopia

- Raihan Al Malik, Raihana, and Rainan
- Saint Josephwort
- Selaseh, Selasih, Selaseh hitam, and Selaseh jantan
- Sweet basil -- U.S.
- Taibedle -- Ocimum spp. in Ethiopia

[Return to Index](#)

Chemical Compounds

There are many compounds in *Ocimum* spp. The dried leaves of *O. basilicum* contain 0.20-1% essential oil. The major compounds in the oil are linalool and methylchaviol. The exact amounts, however, vary considerably. For example, in some studies camphene has been found in *O. americanum* and not in *O. basilicum*. Conversely, cineole has been found in *O. basilicum* and not in *O. americanum*. Also, differences in the potassium to calcium ratio in the culture media can change the quantity of the major constituents in the essential oil.

Some of the Compounds in *Ocimum basilicum*(for a more complete list see [USDA Phytochemical and Ethnobotanical Databases](#).):

- Caffeic acid -- Leaf 19,000 ppm
- 1,8-Cineole -- plant 776 ppm, essential oil 1.6-8%
- p-Coumaric acid -- Leaf 760 ppm
- p-Cymene -- plant 1-16 ppm, essential oil <0.1%
- Limonene -- plant 2-934 ppm, essential oil <1.0%
- Linalool -- plant 30-300 ppm, essential oil 1.1-65.4%
- Methylchaviol -- plant 238-8,780 ppm, essential oil 13.5-87.2%
- Methyl cinnamate -- plant 1-2,800 ppm, essential oil 0-11.2%
- Myrcene -- leaf 2-80 ppm, essential oil 0.1-2%
- alpha-Pinene -- plant 2-180 ppm, essential oil 0.2-0.4% (all essential oil compositions are based on relative abundance)
- B-Pinene -- plant 3-160 ppm, essential oil <1.0%
- Quercetin
- Rutin -- leaf
- Safrole -- plant 60-400 ppm
- alpha-Terpinene -- essential oil 0.03-0.2%
- Tryptophan -- leaf 2,210 ppm

[Return to Index](#)

Toxicity

There is little available literature on the toxicity of *Ocimum* spp. However, *O. basilicum*, the species that appears to be used the most medicinally and the one for which the most analysis has been done, contains several potentially dangerous compounds. Some of these compounds are: safrole, rutin, caffeic acid, tryptophan, and quercetin.

Acute bovine pulmonary emphysema (ABPE), a respiratory disease in cattle, is caused by absorbed metabolites of tryptophan. Usually, ABPE occurs in cattle over 2-3yrs of age that are suddenly moved onto lush pasture. Tryptophan is toxic at a dose of 0.25-0.35g/kg body weight (BW). Whether or not a dose of *Ocimum* spp. could cause ABPE is not known.

P-coumaric acid and caffeic acid (phenolic acids) can inhibit digestion of plant cell walls in ruminants, because of their antimicrobial activity. When these phenolic acids are metabolized by rumen microbes, benzoic acid, 3-phenyl-propionic acid (PPA), and cinnamic acid may be formed. When these compounds are detoxified, hippuric acid is formed. PPA can decrease metabolic efficiency. Detoxifying the compounds costs the animal nitrogen, which also can decrease productivity.

Quercetin (a flavanoid) may be a cocarcinogen in bracken fern (*Pteridium aquilinum*). It has been suggested that it may interact with Bovine papilloma virus type 4, leading to malignant epithelial papillomas in the upper alimentary tract. Adverse effects from quercetin in *Ocimum* spp., when used to treat animals, is not known.

Safrole, which was used to flavor sodas, was banned as a food additive in the U.S. It has been shown to cause cancer in rats. Oil of *Ocimum* also contains d-limonene, which has anticarcinogenic properties.

[Return to Index](#)

Uses and Efficacy

Both the essential oil, leaves, seeds, flowers, and roots of *Ocimum* spp. are used as medicines. The essential oil has been shown in vitro to have antibacterial activity against *Staphylococcus aureus*, *Salmonella enteritidis* and *Escherichia coli*, antiseptic activity against *Proteus vulgaris*, *Bacillus subtilis*, and *Salmonella paratyph*, and antifungal activity against *Candida albicans*, *Penicillium notatum*, and *Microsporeum gyseum*.

Oils from some *Ocimum* spp. have been shown to repel insects and have larvicidal activity against houseflies, blue bottle flies, and mosquitoes. The effective concentration of the oil to kill 90% of the larva ranged from 113-283 ppm. Camphor, d-limonene, myrcene, and thymol are some of the compounds in the oil that may provide the repellent properties. Eugenol and methylchavicol may be responsible for the larvicidal activity.

Little published information can be found about the use of oil from *Ocimum* and fresh plant materials in the treatment of animals. Therefore, efficacious doses are not known. However, *O. basilicum* has been used as an expectorant in animals. Also, *O. micranthum* has been combined with *Chenopodium ambrosioides* to treat stomach pain and colic in animals. It also has been used

as a paste to massage the udder of livestock.

Some Uses in Humans:

- Alcoholism -- India
- Aphrodisiac -- India, Philippines
- Bites (dog, bug, snake) -- China
- Circulation -- China
- Collapse, convulsion, and delirium -- India
- Croup -- Iraq
- Depression -- Greece
- Diarrhea -- Honduras, Iraq, Kurdistan, Philippines
- Diuretic -- Sudan, Turkey
- Ear ache, deafness -- India, Panama, Philippines, Salvador
- Fever -- Honduras, India, Mexico
- Fungicide -- Philippines
- Halitosis
- Headache -- Honduras, India, Panama, Salvador
- Infection, inflammation -- China, Philippines
- Kidney -- China, India, Turkey
- Labor, parturition -- China, India
- Medicine -- Samoa
- Regular menstrual flow -- Honduras, Philippines, Salvador
- Nerves -- Honduras, Salvador
- Repellent -- Tanzania
- Spasm -- China, Haiti, India, Spain, Turkey
- Stimulant -- Philippines, Sudan, Turkey
- Stomach (carminative, pain, cancer, diaphragm tumors, colic) -- Algeria, Cambodia, China, Europe,
- Haiti, Laos, Philippines, Salvador, Turkey, Venezuela, Vietnam
- Throat and toothache
- Wart -- Greece

Rheum palmatum and *Rheum rhabarbarum*

Index

- [Introduction and Description](#)
- [Common Names](#)
- [Chemical Compounds](#)
- [Toxicity](#)
- [Uses and Efficacy](#)

Introduction and Description

Rheum palmatum is commonly known as Chinese rhubarb, and *Rheum rhabarbarum* (also known as *R. rhaponticum*) is commonly referred to as wild rhubarb in the U.S. Both plants belong to the family Polygonaceae. Rhubarb has very broad leaves and elongated, often reddish, petioles (leaf stalks).

The petioles of rhubarb are edible, though the leaf blades are very toxic. The roots and rhizomes of *R. palmatum* and the roots of *R. rhabarbarum* are used in medicinal treatments. *R. palmatum* is considered a stronger medicinal than *R. rhabarbarum*. The most common medicinal use of these plants is as a laxative in humans.

Common Names

R. palmatum

- Chinese rhubarb
- Da huang
- Rawend
- Rhubarb
- Rhabarber -- Germany
-

R. rhabarbarum

- Garden rhubarb
- Papaz ravendi
- Rapontik -- Germany
- Rhapontic -- France
- Wild rhubarb

[Return to Index](#)

Chemical Compounds

The roots of *Rheum* spp. contain anthranoid derivatives (approx. 3-4%). The predominant type of anthranoid derivatives are rhein, emodin, aloe-emodin, chrysophanol and physcion. *R. rhabarbarum*, unlike *R. palmatum*, contains rhaponticin, which has estrogen-like actions. The detection of rhaponticin is used to determine if *R. palmatum* has been mixed with *R. rhabarbarum* in supposedly pure medicinal mixtures.

Following is a list of compounds in *R. palmatum* and *R. rhabarbarum*. The compounds are divided by plant and the parts of the plant. Potential activities of some of the compounds are listed as well as the quantities of the compounds in parts per million. Rhubarb roots contain several minerals, though only a few are listed below. For further information regarding the compounds in the plant refer to [USDA Phytochemical and Ethnobotanical Databases](#).

Rheum palmatum Root

- 3,5,4'-Trihydroxystilbene-4'-o-beta-d-glucopyranoside
- 4-(p-Hydroxyphenyl)-2-butanone-beta-d-glucoside
- Aloe-emodin -- antiherpetic, antileukemic, antiseptic, antitubercular, antitumor, antiviral, bactericide, cathartic, cytotoxic, genotoxic, pesticide, purgative, termitifuge, and viricide
- Chrysophanol -- 690-3,190, antiseptic, bactericide, candidicide, cathartic, hemostat, pesticide, and purgative
- Cinnamic acid -- anesthetic, antiinflammatory, bactericide, cancer-preventive, choleric, fungicide, herbicide, laxative, pesticide, and vermifuge
- d-Catechol
- Emodin -- antiaggregant, antifeedant, antiinflammatory, antimutagenic, antiseptic, antitumor (breast), antiulcer, antiviral, cathartic, cytotoxic, gonadotropic, immunosuppressive, pesticide, purgative, spasmolytic, styptic, vasoelaxant, viricide
- Gallic acid -- anticarcinomic, antifibrinolytic, antioxidant, antiseptic, antiviral, astringent, bacteristatic, cancer-preventive, carcinogenic, hemostat, nephrotoxic, pesticide, styptic, and xanthine-oxidase-inhibitor
- Hyperin -- antiinflammatory, antioxidant, antitussive, antiviral, capillarifortificant, capillarigenic, diuretic, hepatoprotective, hypotensive, pesticide, and viricide
- Physcion -- antiseptic, cathartic, pesticide, and purgative
- Physcion-8-o-beta-d-gentiobioside
- Physcion-diglucoside
- Quercitrin -- aldose-reductase-inhibitor, antiarrhythmnic, anticataract, antifeedant, antifu, antihemorrhagic, antiinflammatory, antiviral, CNS depressant, cancer preventive, cardiogenic, choleric, detoxicant, diuretic, dye, hepatogenic, hypotensive, paralytic, pesticide, spasmolytic, vasopressor, and viricide
- Rhein -- anticarcinomic, antiseptic, antitumor, antiviral, bactericide, candidicide, cathartic, cytotoxic, pesticide, proteinase-inhibitor, purgative, and viricide
- Rheinoides -- 12,900

- Rheosmin
- Sennoside-a -- 2,000-8,740, purgative
- Sennoside-b -- purgative
- Tannins -- 50,000-100,000, antidiarrheic, antidysenteric, antimutagenic, antinephritic, antioxidant, antiradicular, antiviral, bactericide, cancer-preventive, hepatoprotective, pesticide, psychotropic, and viricide
- Tetrarin

Rhizomes

- Iron -- 100-180
- Magnesium -- 1,980-2,560
- Manganese
- Potassium -- 6,330-21,600

Rheum rhabarbarum Root

- (+)-Catechin and (+)-Catechin-5-o-glucoside
- (-)-Epicatechin and (-)-Epicatechin-3-o-gallate
- 1,2,6-tri-o-Galloyl-glucose and 1,6-di-o-Galloyl-glucose
- 1-o-Galloyl-glycerol
- 2-o-Cinnamoylglucogallin
- 3,5,4'-Trihydroxystilbene-4'-o-(6''-o-galloyl)-glucoside
- 3,5,4'-Trihydroxystilbene-4'-o-glucoside
- 4-(p-Hydroxyphenyl)butanone-o-glucoside
- 6-Hydroxymusizin-8-o-glucoside
- 6-o-Galloyl-glucose
- Aloe-emodin-8-o-glucoside
- Anhydrorhapontigenin
- Emodin -- for activity refer to *R. palmatum* root
- Emodin-8-o-glucoside
- Emodin methyl ether
- Chrysarone
- Chrysarone methyl ether
- Chrysophanic acid
- Chrysophanin
- Chrysophanol -- for activity refer to *R. palmatum* root
- Chrysophanol-1-o-glucoside and chrysophanol-8-o-glucoside
- Chrysopontin, chrysorhapontin, and desoxyrhaponticin
- Ferulic acid

- Fallic acid -- for activity refer to *R. palmatum* root
- Gallic acid-3-o-(6'-o-galloyl)-glucoside and gallic acid-4-o-(6'-o-galloyl)-glucoside
- Glucochrysarone
- Glycogallin
- Isoemodin
- Isolindleyin
- Isorhapontigenin
- Lindleyin -- analgesic, antiarthritic, and antiinflammatory
- Methyl chrysophanic acid
- p-Coumaric-acid
- Physcion -- for activity refer to *R. palmatum* root
- Physcion-8-o-glucoside
- Procyanidin-b1,3'-o-gallate
- Rhapontic acid
- Rhaponticin -- estrogenic, 14,200
- Rhapontigenin
- Rhein -- for activity refer to *R. palmatum* root
- Rheinosides -- 12,900
- Sennoside-a and sennoside-b -- for activity refer to *R. palmatum* root
- Sinapic acid -- cancer preventive
- Torachryson-8-o-glucoside

Petiole

- alpha-Tocopherol -- 2-48
- Arsenic -- 0.01
- Cadmium
- Caffeic acid
- Calcium -- 600-18,462
- Fumaric acid
- Gallic acid -- 53
- Oxalic acid -- 4,400-13,360
- Protocatechuic-acid
- Quercetin-3-glucoside
- Quercetin-3-rhamnoside
- Quercetin-3-rutinoside
- Rubidium
- Sinapic acid

- Vanillic acid

Leaf

- alpha-Tocopherol -- 1,197-1,238
- Anthraquinone-glycosides
- Anthrones -- 10,000-15,000
- Calcium oxalate
- Cyanidin-3-glucoside
- Cyanidin-3-rutinoside
- Dihydroxyglutamic acid
- Isoquercitrin
- Oxalic acid -- 3,000-11,000
- Rutin -- 6,000

[Return to Index](#)

Toxicity

The leaf blades of *R. rhabarbarum* are very toxic. They contain high levels of oxalic acid which can interact with blood calcium. Precipitation of calcium oxalate in the renal tubules can lead to renal failure. Symptoms of oxalate poisoning in humans include: nausea, vomiting, abdominal pain, anuria, and hemorrhages. In ruminants, oxalic acid can be degraded by rumen bacteria. The tolerance of ruminants to oxalate can be increased by gradually increasing the amount of oxalate in the diet. In general, however, oxalate is considered toxic to ruminants.

The active compounds (those that provide the laxative effect) in these plants also can cause side effects. Chronic consumption of anthranoid derivatives can turn urine a yellow or red color. Chronic use may also cause liver damage. During normal (non-chronic) use, anthranoid derivative laxatives cause increased losses of body water and electrolytes. Potassium loss may be responsible for symptoms such as a decrease in muscle activity and cardiac arrhythmia.

Many anthranoid derivatives have been shown in *in vitro* tests to be mutagenic. Positive results of mutagenicity have been obtained with chrysophanol, aloe-emodin, emodin, and chrysarobin in *Salmonella*/microsome assays. Tests with rhein were negative. There is some indication that chronic use of anthranoid derivative laxatives could be carcinogenic.

[Return to Index](#)

Uses and Efficacy

While *Rheum* spp. have definite laxative properties when used to treat human ailments, no scientific studies could be found proving its effectiveness in the treatment of livestock. In livestock, it is used as a treatment for diarrhea, chronic constipation, gastritis, anemia, nervousness, and lack of appetite. According to one source, the dose for livestock should be very small (1-2 roots, finely sliced). Also, some medicinal plant sources for humans and livestock

recommend purchasing the powdered root versus trying to grow the plant and prepare the treatment at home.

Some Uses in Humans: *R. palmatum*

- Astringent -- China and U.S.
- Constipation -- China and U.S.
- Stomach (cancer) -- China and Japan
- Tonic -- China
- Tumor

R. rhabarbarum

- Laxative -- France and Turkey
- Astringent -- Turkey
- Depurative -- Turkey
- Stomachic -- Turkey
- Tonic -- Turkey

Symphytum officinale -- Comfrey

Index

- [Introduction and Description](#)
- [Common Names](#)
- [Chemical Compounds](#)
- [Toxicity](#)
- [Uses and Efficacy](#)

Introduction and Description

Symphytum officinale, more commonly known as comfrey, belongs to the family Boraginaceae. Comfrey is a common wild plant in parts of the U.S. and is cultivated in much of the world. It is a perennial herb with deep roots. Comfrey has large, rough, prickly leaves and pinkish or creamy bell-like flowers. When it is not flowering, it is often confused with foxglove (*Digitalis spp.*). Comfrey is commonly used to make tea. It also has been promoted in the past as a forage crop.

There seems to be a great deal of difference in opinion regarding the medicinal use of comfrey. In some sources used for this web page, the medicinal use of comfrey is highly criticized. In fact, it has been banned from sale in some countries such as Canada. However, in another source used for this web page, comfrey was promoted as a great medicinal plant and people were advised to ignore the findings of scientists.

Common Names

- Borraja
- Bourrache
- Buyuk Karakafesotu
- Comfrey
- Consoude
- Consuelda
- Hirehari-So
- Liane Chique

[Return to Index](#)

Chemical Compounds

Comfrey contains at least eight pyrrolizidine alkaloids (PA). The amount of PAs in roots ranges from 0.3-0.4%. The content in leaves usually is lower. (For more information regarding the compounds in comfrey refer to [USDA Phytochemical and Ethnobotanical Databases](#)).

Some of the compounds in Comfrey are:

- Acetyllycopsamine (PA) -- roots and leaves
- Allantoin -- leaf 13,000ppm, root 6,000-8,000 ppm
- Caffeic acid -- root
- Echimidine (PA) -- roots and leaves
- Heliosupine (PA) -- roots and leaves
- Intermedine (PA) -- roots and leaves
- Lasiocarpine (PA) -- roots and leaves
- Lycopsamine (PA) -- roots and leaves
- Mucilage -- roots
- Rosmarinic acid -- leaf 5,000 ppm
- Symphytine (PA) -- roots and leaves
- Tannic acids -- roots

[Return to Index](#)

Toxicity

There are several dangers associated with the use of comfrey. One of the biggest problems is that people accidentally collect foxglove instead of comfrey. Foxglove is deadly. Among other things, it can cause irregular heart beats and convulsions.

Another problem with comfrey is that it contains at least eight pyrrolizidine alkaloids (PA). While the level of PAs in fresh plant may not be very high, ready-to-use preparation often have high levels (e.g., 270-2900 mg/kg). PAs are hepatoxins and can cause irreversible liver damage. One of the problems is that the effects of the alkaloids can be cumulative. Therefore, damage to the liver may not be associated to the alkaloids in comfrey. Sometimes toxicity signs will not be present until an animal is stressed by something that requires greater liver function (e.g., lactation). Also, the leaves and roots of comfrey have been shown to be carcinogenic. PAs from comfrey given to rats caused mortality. Liver pathology was characteristic of PA toxicosis. When rats were fed dietary levels of 0.5% roots and 8% leaves, they formed hepatomas.

There are species differences in susceptibility to PAs. Horses and cattle are most commonly poisoned by PAs, while sheep are much more resistant. Goats are more susceptible than sheep, and pigs are more susceptible than cattle and horses. Common clinical signs from PA toxicity include: jaundiced skin (from impaired liver function); rough unkempt appearance; diarrhea; prolapsed rectum; edema of tissues of the digestive tract; dullness; photosensitization; and abnormal behaviour. Horses may have neurological signs such as "head pressing." Poisoned cattle may have

a bloated appearance. Further information on PAs and species differences is presented in Cheeke 1998.

[Return to Index](#)

Uses and Efficacy

Comfrey has been promoted and used as a medicinal plant for years. However, no published studies could be found to support the medicinal claims.

In the Philippines, the leaves are made into a decoction and used as a drench for swine to treat fevers. One half to one cup of the decoction is given to the swine 3 times a day for 2-3 days. It also is recommended as a treatment for dogs after hip dysplasia. The dose is one tablespoon of minced leaves or three comfrey tablets twice a day, five days a week until the problem is gone. Some other oral uses of comfrey in dogs include treating rickets, arthritis, and rheumatism. For livestock, it is recommended as a treatment for internal hemorrhaging, ulcers, arthritis, broken bones, and rheumatism. Preparation consists of boiling one pound of comfrey in 1.5 quarts of water for one hour. Ground-ivy and Spanish liquorice can be added. A half pint drench is given to the animal three times/day. Molasses is supposed to be added to the mixture when the treatment is for ulcers. The dose for treating broken bones in livestock is two handfuls of well bruised roots/day.

Comfrey leaves and roots also are used topically to treat wounds, arthritis, sprains, and broken bones. In these applications, allantoin is believed to be the effective compound. Absorption of PAs through the skin, based on tests with rats, is 20-50 times lower than when orally administered, thus decreasing the toxic risks.

Some Uses in Humans:

- Arthritis
- Astringent -- Europe and Turkey
- Bone injuries
- Cancer -- U.S.
- Circulation -- China
- Diarrhea -- Haiti
- Expectorant -- Turkey
- Hemostat-- Turkey
- Inflammation, sores and swelling-- China, Europe and Spain
- Pectoral -- Haiti
- Sedative -- Turkey
- Stimulant -- Turkey
- Wounds

UCMP Glossary: Phylogenetics

| [Phylogenetics](#) | [Geology](#) | [Biochemistry](#) | [Cell biology](#) |
[Ecology](#) | [Life history](#) | [Zoology](#) | [Botany](#) | [Paleogeography](#) |

adaptation -- Change in an organism resulting from natural selection; a structure which is the result of such selection.

anagenesis -- Evolutionary change along an unbranching lineage; change without speciation.

ancestor -- Any organism, population, or species from which some other organism, population, or species is descended by reproduction.

basal group -- The earliest diverging group within a clade; for instance, to hypothesize that [sponges](#) are basal [animals](#) is to suggest that the lineage(s) leading to sponges diverged from the lineage that gave rise to all other animals.

character -- Heritable trait possessed by an organism; characters are usually described in terms of their states, for example: "hair present" vs. "hair absent," where "hair" is the character, and "present" and "absent" are its states.

clade -- A monophyletic taxon; a group of organisms which includes the most recent common ancestor of all of its members and all of the descendants of that most recent common ancestor. From the Greek word "klados", meaning branch or twig.

cladogenesis -- The development of a new clade; the splitting of a single lineage into two distinct lineages; speciation.

cladogram -- A diagram, resulting from a cladistic analysis, which depicts a hypothetical branching sequence of lineages leading to the taxa under consideration. The points of branching within a cladogram are called nodes. All taxa occur at the endpoints of the cladogram.

convergence -- Similarities which have arisen independently in two or more organisms that are not closely related. Contrast with homology.

crown group -- All the taxa descended from a major cladogenesis event, recognized by possessing the clade's synapomorphy. See: stem group.

derived -- Describes a character state that is present in one or more subclades, but not all, of a clade under consideration. A derived character state is inferred to be a modified version of the primitive condition of that character, and to have arisen later in the evolution of the clade. For example, "presence of hair" is a primitive character state for all mammals, whereas the "hairlessness" of whales is a derived state for one subclade within the Mammalia.

diversity -- Term used to describe numbers of taxa, or variation in morphology.

endosymbiosis -- When one organism takes up permanent residence within another, such that the two become a single functional organism. Mitochondria and plastids are believed to have resulted from endosymbiosis.

evolution -- Darwin's definition: descent with modification. The term has been variously used and abused since Darwin to include everything from the origin of man to the origin of life.

evolutionary tree -- A diagram which depicts the hypothetical phylogeny of the taxa under consideration. The points at which lineages split represent ancestor taxa to the descendant taxa appearing at the terminal points of the cladogram.

extinction -- When all the members of a clade or taxon die, the group is said to be extinct.

gradualism -- A model of evolution that assumes slow, steady rates of change. Charles Darwin's original concept of evolution by natural selection assumed gradualism. Contrast with punctuated equilibrium.

hierarchy -- A series in which each element is categorized into successive ranks or grades with each level subordinate to the one above.

homology -- Two structures are considered homologous when they are inherited from a common ancestor which possessed the structure. This may be difficult to determine when the structure has been modified through descent.

hypothesis -- A concept or idea that can be falsified by various scientific methods.

ingroup -- In a cladistic analysis, the set of taxa which are hypothesized to be more closely related to each other than any are to the outgroup.

lineage -- Any continuous line of descent; any series of organisms connected by reproduction by parent of offspring.

monophyletic -- Term applied to a group of organisms which includes the most recent common ancestor of all of its members and all of the descendants of that most recent common ancestor. A monophyletic group is called a clade. [More?](#)

outgroup -- In a cladistic analysis, any taxon used to help resolve the polarity of characters, and which is hypothesized to be less closely related to each of the taxa under consideration than any are to each other.

paraphyletic -- Term applied to a group of organisms which includes the most recent common ancestor of all of its members, but not all of the descendants of that most recent common ancestor. [More?](#)

parsimony -- Refers to a rule used to choose among possible cladograms, which states that the cladogram implying the least number of changes in character states is the best.

phylogenetics -- Field of biology that deals with the relationships between organisms. It includes the discovery of these relationships, and the study of the causes behind this pattern. [More?](#)

phylogeny -- The evolutionary relationships among organisms; the patterns of lineage branching produced by the true evolutionary history of the organisms being considered.

plesiomorphy -- A primitive character state for the taxa under consideration.

polarity of characters -- The states of characters used in a cladistic analysis, either original or derived. Original characters are those acquired by an ancestor deeper in the phylogeny than the most recent common ancestor of the taxa under consideration. Derived characters are those acquired by the most recent common ancestor of the taxa under consideration.

polyphyletic -- Term applied to a group of organisms which does not include the most recent common ancestor of those organisms; the ancestor does not possess the character shared by members of the group. [More?](#)

primitive -- Describes a character state that is present in the common ancestor of a clade. A primitive character state is inferred to be the original condition of that character within the clade under consideration. For example, "presence of hair" is a primitive character state for all mammals, whereas the "hairlessness" of whales is a derived state for one subclade within the Mammalia.

pseudoextinction -- The apparent disappearance of a taxon. In cases of pseudoextinction, this disappearance is not due to the death of all members, but the evolution of novel features in one or more lineages, so that the new clades are not recognized as belonging to the paraphyletic ancestral group, whose members have ceased to exist. The Dinosauria, if defined so as to exclude the birds, is an example of a group that has undergone pseudoextinction.

punctuated equilibrium -- A model of evolution in which change occurs in relatively rapid bursts, followed by longer periods of stasis.

radiation -- Event of rapid cladogenesis, believed to occur under conditions where a new feature permits a lineage to move into a new niche or new habitat, and is then called an adaptive radiation.

rank -- In traditional taxonomy, taxa are ranked according to their level of inclusiveness. Thus a **genus** contains one or more **species**, a **family** includes one or more genera, and so on.

relatedness -- Two clades are more closely related when they share a more recent common ancestor between them than they do with any other clade.

reticulation -- Joining of separate lineages on a phylogenetic tree, generally through hybridization or through lateral gene transfer. Fairly common in certain land plant clades; reticulation is thought to be rare among metazoans.

selection -- Process which favors one feature of organisms in a population over another feature found in the population. This occurs through differential reproduction—those with the favored feature produce more offspring than those with the other feature, such that they become a greater percentage of the population in the next generation.

sister group -- The two clades resulting from the splitting of a single lineage.

stasis -- A period of little or no discernible change in a lineage.

stem group -- All the taxa in a clade preceding a major cladogenesis event. They are often difficult to recognize because they may not possess synapomorphies found in the crown group.

synapomorphy -- A character which is derived, and because it is shared by the taxa under consideration, is used to infer common ancestry.

systematics -- Field of biology that deals with the diversity of life. Systematics is usually divided into the two areas of [phylogenetics](#) and [taxonomy](#).

taxon -- n. Any named group of organisms, not necessarily a clade; a taxon may be designated by a Latin name or by a letter, number, or any other symbol; **taxa-** pl.

taxonomy -- The science of naming and classifying organisms.

vicariance -- Speciation which occurs as a result of the separation and subsequent isolation of portions of an original population.

Last updated:2004-04-20

UCMP Glossary: Geology

| [Phylogenetics](#) | **Geology** | [Biochemistry](#) | [Cell biology](#) |
[Ecology](#) | [Life history](#) | [Zoology](#) | [Botany](#) | [Paleogeography](#) |

abyssal plain -- The ocean floor offshore from the [continental margin](#), usually very flat with a slight slope.

accrete -- v. To add terranes (small land masses or pieces of crust) to another, usually larger, land mass.

alkaline -- Term pertaining to a highly basic, as opposed to acidic, substance. For example, hydroxide or carbonate of sodium or potassium.

allochthonous -- Refers to something formed elsewhere than its present location. Antonym of [autochthonous](#).

amber -- Fossilization where the organism is entrapped in resin and preserved whole.

andesite -- [Igneous volcanic](#) rock, less [mafic](#) than [basalt](#), but more mafic than [dacite](#); rough volcanic equivalent of [diorite](#).

anticline -- A fold of rock layers that is convex upwards. Antonym of [syncline](#).

archipelago -- n. A group of islands; an expanse of water with scattered islands.

asphalt -- A dark bituminous substance found in natural beds. Residue from petroleum distillation.

autochthonous -- Refers to something formed in its present location. Antonym of [allochthonous](#).

Banded Iron Formation -- n. Rock consisting of alternating light and dark layers of iron-rich chert (the dark layers have more iron minerals) formed from 3.8 to 1.7 billion years ago.

basalt -- Highly [mafic igneous volcanic](#) rock, typically fine-grained and dark in color; rough volcanic equivalent of [gabbro](#).

basement rock -- n. The oldest rocks in a given area; a complex of metamorphic and igneous rocks that underlies the sedimentary deposits. Usually Precambrian or Paleozoic in age.

basin -- n. Any large depression in which sediments are deposited.

Basin and Range Province -- n. One of the most extensive systems of fault-bounded mountains separated by sediment-filled valleys, extending across Idaho, Oregon, Nevada, Utah, Arizona, New Mexico, California, and northern Mexico.

bedrock -- n. The general term referring to the rock underlying other unconsolidated material, i.e. soil.

biostratigraphy -- n. The study of rock layers (e.g., distribution, environment of deposition, age) based on their fossils; **biostratigraphic**- adj.

biostratinomy -- The study of what happens between the death of an organism and burial. Part of [taphonomy](#).

bioturbation -- n. The disturbance of sediment by organisms, e.g. burrows, trails, or complete mixing.

blueschist -- [Metamorphic](#) rock formed under great pressures, but not so great temperatures.

calcareous -- adj. Term used to describe a structure, secreted by an organism, that consists of or contains calcium carbonate (CaCO_3), e.g., the shell of a bivalve.

caldera -- n. A large circular volcanic depression, often originating due to collapse.

carbon film -- Thin layer of carbon remains of past life found in [sedimentary rocks](#).

carbonate -- n. (adj.) A mineral composed mainly of calcium (Ca) and carbonate (CO₃) ions, may also include magnesium (Mg), iron (Fe) and others; n. rock or sediments derived from debris of organic materials composed mainly of calcium and carbonate (e.g., shells, corals, etc.) or from the inorganic precipitation of calcium (and other ions) and carbonate from solution (seawater). For example, [limestone](#) or [dolomite](#). **carbonate platform** – n. A broad (100s of meters), flat, shallow submarine expanse of carbonate rock, more common in the early-middle Paleozoic. **carbonate bank** – n. A narrow (10s of meters), fairly flat, shallow, submarine plateau of carbonate rock, more common from the middle-late Paleozoic to the present, e.g., the Bahama Banks.

casts -- Fossils formed when water containing minerals leaks into a mold. The minerals harden to form a copy of the original structure or organism.

chalk -- A soft compact calcite, CaCO₃, with varying amounts of silica, quartz, feldspar, or other mineral impurities, generally gray-white or yellow-white and derived chiefly from fossil seashells.

chert -- Hard, dense [sedimentary rock](#), composed of interlocking quartz crystals and possibly amorphous silica (opal). The origin of the silica is normally biological, from [diatoms](#), [radiolaria](#) or [sponge spicules](#). Synonymous with flint.

clast -- n. An individual grain or constituent of a rock; **clastic**- adj. Describes a rock or sediment composed mainly of fragments of preexisting rocks or minerals that have been transported some distance from their place of origin, e.g., sandstone, shale.

compactions -- Fossils that have undergone some degree of flattening of their three-dimensional structure.

compression -- [Fossil](#) formed when an organism is flattened (compressed) and a thin film of organic material from its body is left in the rock.

concretion -- n. A hard, rounded mass, commonly of silica, calcite, dolomite, iron oxide, pyrite, or gypsum, that formed within a rock from the precipitation of these minerals around a nucleus, such as a leaf, bone, shell, or fossil, and ranging in diameter from centimeters to meters.

conglomerate -- A coarse-grained [sedimentary rock](#), with **clasts** larger than 2 mm.

continental crust -- The Earth's [crust](#) that includes both the continents and the **continental shelves**.

continental margin -- n. The ocean floor from the shore of continents to the [abyssal plain](#).

continental rise -- n. Part of the **continental margin**; the ocean floor from the **continental slope** to the [abyssal plain](#). The continental rise generally has a gentle slope and smooth topography.

continental shelf -- n. The part of the continental margin from the coastal shore to the continental slope; usually extending to a depth of about 200 meters and with a very slight slope, roughly 0.1 degrees; includes continental and oceanic sediments down to the ocean floor.

continental slope -- n. Part of the **continental margin**; the ocean floor from the **continental shelf** to the **continental rise** or [oceanic trench](#). Usually to a depth of about 200 meters. The continental slope typically has a relatively steep grade, from 3 to 6 degrees.

copal -- Brittle aromatic yellow to red resins of recent or fossil origin, obtained from tropical trees.

coprolites -- Fossilized feces.

core -- That portion of the interior of the Earth that lies beneath the [mantle](#), and goes all of the way to the center. The Earth's core is very dense, rich in iron and the source of the magnetic field.

craton -- n. A part of the Earth's crust that has attained stability and has been little deformed for a long period of time, refers only to continents; **cratonic**- adj.

cross-bedding -- (n) The arrangement of sedimentary beds tilted at different angles to each other, indicating that the beds were deposited by flowing wind or water.

crust -- n. The outermost layer of the Earth, varying in thickness from about 10 kilometers (6 miles) below the oceans, to 65 kilometers (about 40 miles) below the continents; represents less than 1 percent of the Earth's volume.

dacite -- [Igneous volcanic](#) rock, less [mafic](#) than [andesite](#), typically fine-grained and light in color; rough volcanic equivalent of [granodiorite](#).

delta -- n. A low, nearly flat accumulation of sediment deposited at the mouth of a river or stream, commonly triangular or fan-shaped; **deltaic**– adj.

deposition -- Any accumulation of material, by mechanical settling from water or air, chemical precipitation, evaporation from solution, etc.

diagenesis -- All of the changes that occur to a fossil (or more generally any [sediment](#)) after initial burial; includes changes that result from chemical, physical as well as biological processes. The study of diagenesis is part of [taphonomy](#).

diatomite -- Diatomite, or diatomaceous earth, is a siliceous sedimentary rock formed from the accumulations of [diatoms](#) or other nanoplankton.

diorite -- [Igneous plutonic](#) rock, less [mafic](#) than [gabbro](#), but more mafic than [granite](#) and granodiorite; rough plutonic equivalent of [andesite](#).

dip -- The angle that a bedding plane or [fault](#) makes with the horizontal when measured perpendicular to the [strike](#) of the bedding plane or fault.

dolomite -- A [carbonate sedimentary rock](#) composed of more than 50 percent of the mineral calcium-magnesium carbonate ($\text{CaMg}(\text{CO}_3)_2$).

drill core -- n. A column of material (e.g., mud, ice, rock) removed from the earth by drilling. Often used as a tool for exploration of natural resources.

drumlin -- n. Elongated mound of glacial sediment deposited parallel to ice flow.

epicenter -- Point on the Earth's surface directly above the [focus](#) of an earthquake.

erosion -- n. The processes by which materials of the Earth's [crust](#) are worn away, loosened, or dissolved while being transported from their place of origin.

erratic -- n. A large, isolated boulder left behind by a glacier.

escarpment -- n. A steep or vertical cliff, either above or below sea level.

esker -- n. A ridge of glacial sediment deposited by a stream flowing in and under a melting glacier.

estuary -- n. An area where fresh water comes into contact with seawater, usually in a partly enclosed coastal body of water; a mix of fresh and salt water where the current of a stream meets the tides; **estuarine**– adj.

evaporite -- n. a deposit of salt minerals (e.g., halite, gypsum, anhydrite) left behind by the evaporation of seawater, usually forms within a restricted basin.

extrusive -- [Igneous](#). Antonym of [intrusive](#).

fault -- n. (v.) A fracture, or large crack, in the Earth's crust where one side moves up/down/sideways relative to the other; **fault block**- n. pieces of crust that have slipped into or alongside a fault; **fault zone**- n. an area with multiple faults.

felsic -- Term used to describe the amount of light-colored feldspar and silica minerals in an [igneous](#) rock. Complement of [mafic](#).

focus -- The initial point within the Earth that ruptures in an earthquake, directly below the [epicenter](#).

fold -- Bent rock [strata](#).

fossil -- Any evidence of past life, including remains, traces, imprints as well as life history artifacts. Examples of artifacts include fossilized bird's nests, bee hives, etc.

fossil record -- All of the fossils that have existed throughout life's history, whether they have been found or not.

fossiliferous -- adj. Rich in fossils.

freezing -- To preserve an organism without any significant alteration to its chemical composition by subjecting it to freezing temperatures.

gabbro -- Highly [mafic igneous plutonic](#) rock, typically dark in color; rough plutonic equivalent of [basalt](#).

Gastroliths -- Fossilized gizzard stones, usually only applicable in the fossil study of reptiles

geologic maps -- Maps that show the types and ages of rock of an area. These maps are used by paleontologists to find areas that are likely to contain fossils they are interested in.

glass -- A non-crystalline rock that results from very rapid cooling of magma.

granite -- Highly [felsic igneous plutonic](#) rock, typically light in color; rough plutonic equivalent of [rhyolite](#). Granite is actually quite rare in the U.S.; often the term is applied to any quartz-bearing plutonic rock.

granodiorite -- [Igneous plutonic](#) rock, less [felsic](#) than granite, typically light in color; rough plutonic equivalent of [dacite](#).

graywacke -- [Sandstone](#) composed of poorly sorted angular [clasts](#).

hydrothermal vent -- n. A place on the seafloor, generally associated with spreading centers, where warm to super-hot, mineral-rich water is released; may support a diverse community of organisms.

hypersaline -- adj. Extremely salty, having much more salt than normal seawater.

Ichnology -- The study of trace fossils.

igneous rock -- Any rock solidified from molten or partly molten material.

impressions -- Prints or marks made when an organism's body has been compressed (flattened). Impressions are different from compressions because no thin organic material is left behind.

interbedded -- adj. Describes beds (layers) of rock lying between or alternating with beds of a different kind of rock.

intrusion -- n. Magma (and the rock it forms) that has pushed into pre-existing rock; **intrusive**- adj.; [plutonic](#)- syn. [extrusive](#)- ant.

island arc -- n. A curved chain of islands that rise from the sea floor, usually near a continent. The convex side usually faces the open ocean, while the concave side usually faces the continent, e.g., the Aleutian Islands in Alaska; **volcanic arc**- syn.

isotope -- One of two or more variations of the same chemical element, differing in the number of neutrons not the number of protons.

kame -- n. A short, steep-sided knoll of glacial sediment.

karst -- n. A type of topography formed by dissolution of rocks like limestone and gypsum that is characterized by sinkholes, caves, and subterranean passages.

kettle lakes -- n. Lakes formed as water fills a hole formerly occupied by a block of stranded ice.

lava -- Any molten material that is [extrusive](#) or [volcanic](#), or the rock that forms from a molten extrusive.

limestone -- A [carbonate sedimentary rock](#) composed of more than 50 percent of the mineral calcium carbonate (CaCO₃).

limy -- adj. Describes sediments, soils, or rocks that contain a significant amount of lime (calcium oxide, CaO).

loess -- n. A widespread, loose deposit consisting mainly of silt; most loess deposits formed during the Pleistocene as an accumulation of wind-blown dust carried from deserts, alluvial plains, or glacial deposits.

lowland -- n. (adj.) Large area of relatively low relief, usually applied to coastal regions that do not rise high above sea level. *upland, highland* – ant.

mafic -- Term used to describe the amount of dark-colored iron and magnesium minerals in an [igneous](#) rock. Complement of [felsic](#).

magma -- n. Molten rock generated within the Earth; forms intrusive (solidifies below the surface) and extrusive (solidifies above the surface) igneous rocks.

mantle -- That portion of the interior of the Earth that lies between the [crust](#) and the [core](#).

marine terrace -- n. A platform of marine deposits (typically sand, silt, gravel) sloping gently seaward. Such a platform may be exposed along the coast, forming cliffs, due to uplift and/or the lowering of sea level, e.g., Marine terraces of coastal Southern California.

marl -- n. A loose, crumbly deposit consisting of clay and calcium carbonate and formed in marine or freshwater conditions.

melange -- A body of rocks consisting of large blocks (mappable size) of different rocks jumbled together with little continuity of contacts.

metamorphic rock -- Any rock derived from other rocks by chemical, mineralogical and structural changes resulting from pressure, temperature or shearing stress.

metamorphism -- n. The process of altering the chemical or mineralogical composition of a rock through different amounts of heat and pressure below the surface of the Earth; **metamorphose**- v.

microfossil -- n. A very small fossil, best studied with the aid of a microscope, e.g. foraminifera, radiolarians, and small vertebrate fossils such as teeth. *macrofossil*-ant.

mid-oceanic ridges -- Elongated rises on the ocean floor where [basalt](#) periodically erupts, forming new oceanic crust; similar to continental [rift zones](#).

mineralization -- The process of replacing any organism's original material with a mineral.

molds -- Fossils formed when the sediment surrounding a buried organism hardens. When the organism decays, its impression is left in the rock and can be seen if the rock is broken open.

moraine -- n. A mound or ridge of sediment deposited by a glacier; **lateral moraine**- n. deposited to the side of a glacier; **terminal moraine**- n. deposited to the front of a glacier; **ground moraine**- n. deposited on the land surface.

oceanic crust -- n. The Earth's [crust](#) which is formed at [mid-oceanic ridges](#), typically 5 to 10 kilometers thick with a density of 3.0 grams per centimeter cubed.

oceanic trench -- Deep steep-sided depression in the ocean floor caused by the [subduction](#) of [oceanic crust](#) beneath either other oceanic crust or [continental crust](#).

orogeny -- n. The tectonic processes of folding, faulting, and uplifting of the earth's crust that result in the formation of mountains.

outcrop -- Any place where [bedrock](#) is visible on the surface of the Earth.

paleosol -- Soil horizon from the geologic past.

peat -- n. A deposit of partly decayed plant remains in a very wet environment; marsh or swamp deposit of plant remains containing more than 50 percent carbon.

permineralization -- Fossilization process that occurs when minerals, carried by ground water, enter and harden in the pores of an organism's structures.

Phanerozoic -- n. The geologic eon that includes the interval of time from approximately 543 million years ago to the present, comprising the Paleozoic, Mesozoic, and Cenozoic eras.

pillow lava -- [Lava](#) extruded beneath water characterised by [pillow-type shapes](#).

plate -- n. Rigid parts of the Earth's [crust](#) and part of the Earth's upper [mantle](#) that move and adjoin each other along zones of seismic activity. The theory that the crust and part of the mantle are divided into plates that interact with each other causing seismic and tectonic activity is called **plate tectonics**.

pluton -- n. Any body of igneous rock that solidified below the earth's surface.

plutonic -- Applies to igneous rocks formed beneath the surface of the Earth; typically with large crystals due to the slowness of cooling. Synonym of [intrusive](#). Antonym of [volcanic](#).

radio-carbon dating -- Method for determining the age of an organic substance by measuring the amount of the carbon [isotope](#), carbon-14, remaining in the substance; useful for determining ages in the range of 500 to 70,000 years.

rebound -- v. To spring back after a weight has been removed.

red bed -- n. Sedimentary layers composed primarily of sandstone, siltstone, and shale, that are predominantly red in color due to the presence of iron oxides; often used in reference to the Permian or Triassic sediments of the western U.S.

reef -- n. A large ridge or mound-like structure within a body of water that is built by calcareous organisms such as corals, red algae, and bivalves; **barrier reef**- n. A reef growing offshore from a land mass and separated by a lagoon or estuary, e.g, the Great Barrier Reef of Australia; **patch reef**- n. A discontinuous reef growing in small areas, separated by bare areas of sand or debris, often part of a larger reef complex.

replacement -- Fossilization process that occurs when an organism is completely decomposed and replaced by mineral.

rhyolite -- Highly [felsic igneous volcanic](#) rock, typically light in color; rough volcanic equivalent of [granite](#).

rift -- n. A long, narrow crack in the entire thickness of the Earth's crust, which is bounded by normal [faults](#) on either side and forms as the crust is pulled apart; v. To split the Earth's crust; **rift zone**- n. The area on continents where a trough bounded by normal faults is forming; the site of crustal extension, similar to that which occurs at [mid-oceanic ridges](#); **rift basin** or **rift valley**- n. The long, and fairly wide trough that has formed as a section of the Earth's crust has dropped down along faults, e.g., African Rift Valley in East Africa.

rock cycle -- The process through which one type of rock (igneous, sedimentary, or metamorphic) is converted into another.

salt lick -- n. A natural or artificial deposit of exposed salt that animals lick for nutrients.

sandstone -- [Sedimentary rock](#) composed of sand-sized [clasts](#).

sea-floor spreading -- n. The process of adding to the Earth's crust at mid-ocean ridges as magma wells up and forces previously formed crust apart.

sediment -- Any solid material that has settled out of a state of suspension in liquid.

sedimentary rock -- Any rock resulting from the consolidation of [sediment](#).

siderite -- Also called ironstone, that is a concretion of iron carbonate. Common in the [Mazon Creek](#) fossil beds.

silicification -- Process whereby silica replaces the original material of a substance. For example, silicified wood.

sill -- n. A sheet-like igneous intrusion that parallels the plane of the surrounding rock.

sinkhole -- n. A natural depression in the surface of the land caused by the collapse of the roof of a cavern or subterranean passage, generally occurring in limestone regions.

soil -- Unconsolidated materials above [bedrock](#).

stratigraphy -- n. The study of rock layers, especially their distribution, environment of deposition, and age; **stratigraphic**, adj.

stratum -- A layer of [sedimentary rock](#); plural is **strata**.

strike -- The direction or trend of a bedding plane or [fault](#), as it intersects the horizontal.

subduction -- n. A geologic process in which one edge of one crustal [plate](#) is forced below the edge of another; **subduct**– v.; **subduction zone**- n. A long narrow area in which subduction is taking place, e.g. the Peru-Chile trench, where the Pacific Plate is being subducted under the South American Plate.

subsidence -- n. The sudden sinking or gradual downward settling of the Earth's surface with little or no horizontal motion.

syncline -- A fold of rock layers that is convex downwards. Antonym of [anticline](#).

taphonomy -- The study of what happens to a [fossil](#), from the time of its initial creation (e.g. the death of an organism or the imprint left by the movement of an organism) and the time that the fossil is discovered by a paleontologist. For example, shells or bones can be moved by running water, and later be [compressed](#) by overlying [sediment](#). Taphonomy is often broken into two parts, [biostratinomy](#) and the study of [diagenesis](#).

tectonic -- adj. Describing the forces that cause the movements and deformation of Earth's crust on a large scale, also describes the resulting structures or features from these forces.

terrane -- n. A general term used to refer to a piece of the crust that is usually smaller than a continent but larger than an island; **exotic terrane**- n. terrane that has an unknown origin or a different origin than its surrounding rocks.

topography -- n. The relief features of the Earth's surface, above and below sea level; the set of landforms in a region.

trace fossil -- Evidence left by organisms, such as burrows, imprints, coprolites, or footprints. Trace fossils are not preserved parts of the organism.

tuff -- n. A general term for consolidated rocks made of material ejected from volcanic explosions.

turbidite -- n. The sediments or rocks that formed as a result of a turbidity flow.

turbidity current -- n. A bottom fast-flowing current that moves down a slope, depositing suspended sediments over the floor of a body of water

turbidity flow -- n. A flow of dense, muddy water moving down a slope due to a turbidity current

unconformity -- Any interruption of the continuity of a [depositional](#) sequence.

undifferentiated -- adj. Unable to distinguish between. Undifferentiated rocks: rocks for which it is not possible to specify finer age divisions.

upland -- n. (adj.) An area that is higher relative to the surrounding areas, but not mountainous; **highland**– syn.; *lowland*– ant.

uplift -- n. (v.) The process or result of raising a portion of the Earth's crust through different tectonic mechanisms.

volcanic -- adj. Describes the action or process of magma and gases rising to the crust and being extruded onto the surface and into the atmosphere; also applies to the resulting igneous rocks that cool on the surface of the Earth, including beneath water, which typically have small crystals due to the rapidity of cooling.

volcanically - adv. **extrusive** - syn. [plutonic](#) - ant.

volcanism -- n. The process by which magma and associated gases rise to the Earth's crust and are extruded, or expelled, onto the surface and into the atmosphere.

weathering -- n. The physical, chemical, and biological processes by which rock is broken down into smaller pieces.

UCMP Glossary: Biochemistry

| [Phylogenetics](#) | [Geology](#) | **Biochemistry** | [Cell biology](#) |
[Ecology](#) | [Life history](#) | [Zoology](#) | [Botany](#) | [Paleogeography](#) |

alginate -- component of the cell walls of many [rhodophytes](#) and [kelps](#). Alginates have an affinity for water, and so help to slow desiccation when the algae are exposed to the air; they are commercially important in the production of paper, toothpaste, beer, and frozen foods.

amino acid -- unit molecule from which proteins are constructed by polymerization.

ATP -- "adenosine triphosphate". A relatively stable, high energy molecule used to fuel chemical reactions within cells.

biochemistry -- the study of those molecules used and manufactured by living things.

bioluminescence -- the production of light by a chemical reaction within an organism. The process occurs in many bacteria and protists, as well as certain animals and fungi.

brevitoxin -- neurotoxin produced by the [dinoflagellate](#) *Ptychodiscus brevis*.

calcite -- A common crystalline form of natural calcium carbonate, CaCO₃, that is the basic constituent of limestone, marble, and chalk. Also called calcspar.

calcium carbonate -- a "salt" used by many marine invertebrates, such as corals and [echinoderms](#), and by protists, such as [coccolithophorids](#), to construct their exoskeletons.

carbohydrates -- class of biochemical compounds which includes sugars, starch, chitin, and steroids.

cellulose -- carbohydrate polymer of the simple sugar glucose. It is found in the cell walls of [plants](#) and [green algae](#), as well as dinoflagellates. Cellulose is the most abundant compound on earth that is manufactured by living things.

chitin -- n. A carbohydrate polymer found in the cell walls of [fungi](#) and in the exoskeletons of [arthropods](#), which provides strength for support and protection; **chitinous**- adj.

chlorophyll -- n. The green-colored pigment that absorbs light during photosynthesis, often found in plants, algae, and some bacteria; it includes a porphyrin ring, and often has a long hydrophobic tail. [More info?](#)

collagen -- long proteins whose structure is wound into a triple helix. The resulting fibers have a high tensile strength. Collagen is a primary component of mammalian hair.

dinosteranes/dinosteroids -- chemicals found in [dinoflagellates](#), which have been useful in documenting their existence early in the fossil record.

DNA -- "deoxyribonucleic acid". The nucleic acid which carries the genetic code of an organism. It is the primary component of chromosomes. [MORE?](#)

enzyme -- complex protein which helps to speed biochemical reactions. Enzymes are important in the construction and degradation of other molecules.

flagellin -- protein which is the primary component of [prokaryotic](#) flagella.

fucoxanthin -- yellowish-brown pigment found in some members of the [Chromista](#), including kelps and diatoms.

glucose -- simple sugar, and the primary product of photosynthesis. It is polymerized to make cellulose and chitin.

glycoprotein -- a membrane-bound protein which has attached branching carbohydrates. These may function in cell-cell recognition, such as in human blood groups and immune system response, as well as in resisting compression of cells.

hemoglobin -- protein complex found in the blood of most [chordates](#) and the roots of certain legumes. It binds oxygen molecules, and in chordates serves as the means by which the oxygen is supplied to the cells of the body.

histones -- [proteins](#) attached to the DNA of eukaryotes which allows it to be packaged into chromosomes.

hydrophilic -- "water loving". Hydrophilic compounds dissolve easily in water, and are usually polar.

hydrophobic -- "water fearing". Hydrophobic compounds do not dissolve easily in water, and are usually non-polar. Oils and other long hydrocarbons are hydrophobic.

integrin -- adhesive protein of the extracellular matrix in [animals](#).

ion -- an atom or small molecule which carries a positive or negative charge.

laminarin -- a beta-glucan polysaccharide produced by many [chromists](#) through photosynthesis.

lipids -- a class of biochemical compounds which includes fats, oils, and waxes.

luciferase -- enzyme which activates luciferin to produce bioluminescence.

luciferin -- compound whose activated form emits light.

neurotoxin -- poison which interferes with nerve function, usually by affecting the flow of ions through the cell membrane.

nucleic acid -- class of biochemical compounds which includes DNA and RNA. They are among the largest molecules known. [MORE?](#)

nucleotide -- unit from which nucleic acids are constructed by polymerization. It contains a sugar, a phosphate group, and an organic base. ATP is a nucleotide.

peptidoglycan -- carbohydrate polymer cross-linked by proteins. It is found in the cell wall of Gram positive [bacteria](#), where it stains with the dye crystal-violet.

peridinin -- carotenoid pigment found in dinoflagellates.

phosphate -- an ion consisting of a phosphorus atom and four oxygen atoms. Among other things, it is used in the construction of nucleic acids.

photosynthesis -- biochemical process in which light energy is absorbed by chlorophyll, and is used to fuel the building of sugar molecules.

phycocyanin -- blue, water-soluble pigment found in the [cyanobacteria](#) and the [red algae](#).

phycoerythrin -- red, water-soluble pigment found in the cyanobacteria and red algae.

pigment -- any colorful compound, used by living things to absorb or block sunlight, and in sexual displays. [More info?](#)

polymer -- a large molecule constructed from many smaller identical units. These include proteins, nucleic acids, and starches.

protein -- class of biochemical compounds constructed from amino acids. Proteins may be structural, such as those that make up hair and cartilage, or they may be reactive, such as the enzymes.

proteinaceous -- describes any structure which is composed of protein.

proteoglycan --

rbcL -- a gene which is located in the chloroplast of photosynthetic organisms. It codes for the large subunit of the protein rubisco, and its sequence has been useful in plant phylogenies.

RNA -- "ribonucleic acid". The nucleic acid which carries the DNA message into parts of the cell where it is interpreted and used. The 18S ribosomal RNA sequence has been used in many groups of organisms to reconstruct phylogeny.

rubisco -- protein which fixes carbon in photosynthetic organisms. It binds molecules of carbon dioxide to a five-carbon molecule. Rubisco is the most common protein on earth.

saxitoxin -- neurotoxin found in a variety of dinoflagellates. If ingested, it may cause respiratory failure and cardiac arrest.

silica -- amorphous silicon dioxide (glass). It is a structural component in many organisms, such as [diatoms](#) and [horsetails](#).

spongin -- proteinaceous compound of which the spicules in [Demospongiae](#) are composed.

starch -- a complex polymer of glucose, used by plants and green algae to store surplus sugar for later use.

sugar -- any of several small carbohydrates, such as glucose, which are "sweet" to the taste.

Last updated:2004-04-20

UCMP Glossary: Cell **biology**

| [Phylogenetics](#) | [Geology](#) | [Biochemistry](#) | **Cell biology** |
[Ecology](#) | [Life history](#) | [Zoology](#) | [Botany](#) | [Paleogeography](#) |

amoeboid -- Having no definite shape to the cell, able to change shape.

amphiesma -- The outer covering of a [dinoflagellate](#), consisting of several membrane layers.

aperture -- Small opening, for example the opening in the test of a foram.

bacteriophage -- [Virus](#) which infects and destroys a bacterial host. Some phages, however, will incorporate their DNA into that of their host, and remain dormant for an extended period. For this reason, they have become essential tools of genetic engineers.

capsid -- The protein "shell" of a free virus particle.

cell -- Fundamental structural unit of all life. The cell consists primarily of an outer plasma membrane, which separates it from the environment; the genetic material (DNA), which encodes heritable information for the maintenance of life; and the cytoplasm, a heterogeneous assemblage of ions, molecules, and fluid.

cell cycle -- Complete sequence of steps which must be performed by a cell in order to replicate itself, as seen from [mitotic](#) event to mitotic event. Most of the cycle consists of a growth period in which the cell takes on mass and replicates its DNA. Arrest of the cell cycle is an important feature in the reproduction of many organisms, including humans.

cell membrane -- The outer membrane of a cell, which separates it from the environment. Also called a plasma membrane or plasmalemma.

cell wall -- Rigid structure deposited outside the cell membrane. [Plants](#) are known for their cell walls of [cellulose](#), as are the green algae and certain protists, while [fungi](#) have cell walls of [chitin](#).

chloroplast -- A chlorophyll-containing plastid found in algal and green plant cells.

chromosome -- Linear piece of eukaryotic DNA, often bound by specialized proteins known as histones.

coenocytic -- Condition in which an organism consists of filamentous cells with large central vacuoles, and whose nuclei are not partitioned into separate compartments. The result is a long tube containing many nuclei, with all the cytoplasm at the periphery.

colonial -- Condition in which many unicellular organisms live together in a somewhat coordinated group. Unlike true multicellular organisms, the individual cells retain their separate identities, and usually, their own membranes and cell walls.

contractile vacuole -- In many protists, a specialized vacuole with associated channels designed to collect excess water in the cell. Microtubules periodically contract to force this excess water out of the cell, regulating the cell's osmotic balance.

cytoplasm -- All the contents of a cell, including the plasma membrane, but not including the nucleus.

cytoskeleton -- Integrated system of molecules within eukaryotic cells which provides them with shape, internal spatial organization, motility, and may assist in communication with other cells and the environment. Red blood cells, for instance, would be spherical instead of flat if it were not for their cytoskeleton.

dikaryotic -- Having two different and distinct nuclei per cell; found in the [fungi](#). A dikaryotic individual is called a dikaryon.

diploid -- Having two different sets of chromosomes in the same nucleus of each cell. Most metazoans and plants are diploid. Compare with [haploid](#).

double membrane -- In mitochondria and plastids, there is a two-layered membrane which surrounds the organelle. This is believed to be the result of endosymbiosis, with the outer membrane coming from the eukaryotic cell, and the inner membrane belonging to the original prokaryote which was "swallowed".

endoplasmic reticulum -- (ER) network of membranes in eukaryotic cells which helps in control of protein synthesis and cellular organization.

eukaryote -- n. An organism whose cells have cytoskeletons for support and their DNA contained in a nucleus, separated from the other contents of the cell; e.g., protists, plants, animals, and fungi; **eukaryotic**- adj.

extracellular matrix -- (ECM) Region outside of [metazoan](#) cells which includes compounds attached to the plasma membrane, as well as dissolved substances attracted to the surface charge of the cells. The ECM functions both to keep animal cells adhered together, and well as buffering them from their environment.

eyespot -- Light-sensitive organelle found in many groups of protists, and in some metazoans.

filament -- Long chain of proteins, such as found in hair, muscle, or in flagella.

fission -- Division of single-celled organisms, especially prokaryotes, in which mitosis does not occur. Also used to refer to mitosis in certain unicellular fungi.

flagellum -- n. Hair-like structure attached to a cell, used for locomotion in many protists and prokaryotes. The prokaryotic flagellum differs from the eukaryotic flagellum in that the prokaryotic flagellum is a solid unit composed primarily of the protein flagellin, while the eukaryotic flagellum is composed of several protein strands bound by a membrane, and does not contain flagellin. The eukaryotic flagellum is sometimes referred to as an undulipodium.

frustule -- The mineral "skeleton" of a [diatom](#) or other unicellular organism.

Golgi apparatus -- Eukaryotic organelle which package cell products, such as enzymes and hormones, and coordinate their transport to the outside of the cell.

haploid -- Having a single set of chromosomes in the nucleus of each cell. Mosses, and many protists and fungi, are haploid, as are some insects, bryophytes, and the gametes of all organisms. Contrast with [diploid](#).

haptonema -- Peg-like structure unique to the [Prymnesiophyta](#); its function is not known.

lorica -- A vase-shaped or cup-shaped outer covering. Found in many protists, including some flagellates, ciliates, [chrysophytes](#), and [choanoflagellates](#), as well as in some animal cells.

lysosome -- Eukaryotic organelle which carries digestive enzymes. The lysosome fuses with a vacuolar membrane containing ingested particles, which are then acted upon by the enzymes.

mastigoneme -- Small hair-like filaments found on the "hairy" flagellum of the [Chromista](#).

membrane -- Semi-fluid structure which bounds all cells, and partitions the interior of eukaryotic cells. It consists primarily of two lipid layers, with proteins "dissolved" in the lipids.

mesokaryotic -- Nuclear condition unique to the [dinoflagellates](#) in which the chromosomes remain permanently condensed.

microtubules -- Type of filament in eukaryotic cells composed of units of the protein tubulin. Among other functions, it is the primary structural component of the eukaryotic flagellum.

microvilli -- Thin fingerlike protrusions from the surface of a cell, often used to increase absorptive capacity or to trap food particles. The "collar" of [choanoflagellates](#) is actually composed of closely spaced microvilli.

mitochondrion -- Complex organelle found in most eukaryotes; believed to be descended from free-living bacteria that established a symbiotic relationship with a primitive eukaryote. Mitochondria are the site of most of the energy production in most eukaryotes; they require oxygen to function. See: **double membrane**.

mitosis -- The process of nuclear division in eukaryotes. It is one step in cytokinesis, or cellular division. [MORE ?](#).

MTOC -- (microtubule organizing center) MTOCs are bundles of protein tubes which may be found at the base of a [eukaryotic](#) flagellum. In animals, they also function in creating the arrays of microtubules that pull the chromosomes apart during mitosis.

multicellular -- Any organism which is composed of many cells is termed multicellular.

nanometer -- n. A unit of measure; one millionth (10^{-9}) of a meter.

nuclear membrane -- The double membrane which surrounds the eukaryotic nucleus. It has many pores in its surface which regulate the flow of large compounds into and out of the nucleus.

nucleoid -- Region in prokaryotes where the DNA is concentrated. Unlike a nucleus, it is not bound by a membrane.

nucleus -- Membrane-bound organelle which contains the DNA in the form of chromosomes. It is the site of DNA replication, and the site of RNA synthesis.

organelle -- n. A membrane-bound structure in a eukaryotic cell that partitions the cell into regions which carry out different cellular functions, e.g., mitochondria, endoplasmic reticulum, lysosomes.

plasma membrane -- Outer membrane of a cell, sometimes called the cell membrane. The term plasma membrane is used more frequently when discussing prokaryotes.

plasmid -- Circular loop of DNA in prokaryotes. Eukaryotic DNA is organized into chromosomes.

plastid -- Any of several pigmented cytoplasmic organelles found in plant cells and other organisms, having various physiological functions, such as the synthesis and storage of food.

prokaryotic -- Literally "before the nucleus", the term applies to all [bacteria](#) and [archaea](#). Prokaryotic cells have no internal membranes or cytoskeleton. Their DNA is circular, not linear.

protoplasm -- All the contents of a cell, including the nucleus. (see: cytoplasm)

pseudopodia -- Fingerlike extensions from an amoeboid cell; literally "false feet".

repeat sequences -- The length of a nucleotide sequence that is repeated in a tandem cluster.

reticulopodia -- Long thread-like pseudopodia that branch apart and rejoin, forming a fine network. They are characteristic of [forams](#).

ribosome -- (ribosomal RNA)

syncytic -- see [Hexactinellida](#)

test -- n. A hard shell produced by some unicellular protists; may be made of calcium carbonate, silica, or sand grains.

theca -- General term for any stiff outer covering of a unicellular protist, and usually made up of interlocking plates. [dinoflagellates](#) and [diatoms](#) are examples of protists with thecae.

transduction -- [Viral](#) transfer of DNA to new host.

trichocyst -- Organelle in [ciliates](#) and [dinoflagellates](#) which releases long filamentous proteins when the cell is disturbed. Used as a defense against would-be predators.

ultrastructure -- The detailed structure of a specimen, such as a **cell**, **tissue**, or **organ**, that can be observed only by electron microscopy. Also called fine structure.

undulipodium -- Another term for a eukaryotic flagellum.

vacuole -- Membrane-bound fluid-filled space within a cell. In most plant cells, there is a single large vacuole filling most of the cell's volume. Some bacterial cells contain gas vacuoles.

Last updated:2004-04-20

UCMP Glossary: Ecology

| [Phylogenetics](#) | [Geology](#) | [Biochemistry](#) | [Cell biology](#) |
Ecology | [Life history](#) | [Zoology](#) | [Botany](#) | [Paleogeography](#) |

absorption -- The taking in of water and dissolved minerals and nutrients across cell membranes. Contrast with [ingestion](#).

aerobic -- Pertaining to the presence of free oxygen. Aerobic organisms require oxygen for their life processes.

anaerobic -- Pertaining to the absence of free oxygen. Anaerobic organisms do not require oxygen for their life processes, in fact oxygen is toxic to many of them. Most anaerobic organisms are [bacteria](#) or [archaeans](#).

autotroph -- Any organism that is able to manufacture its own food. Most [plants](#) are autotrophs, as are many [protists](#) and [bacteria](#). Contrast with [consumer](#). Autotrophs may be **photoautotrophic**, using light energy to manufacture food, or **chemoautotrophic**, using chemical energy.

benthic -- Organisms that live on the bottom of the ocean are called benthic organisms. They are not free-floating like pelagic organisms are.

biological/biotic factors -- Living factors such as decomposers, scavengers and predators.

biomes -- The world's major communities, classified according to the predominant vegetation and characterized by adaptations of organisms to that particular environment. [MORE?](#)

boreal -- adj. Describes the northern biotic area that is dominated by tundra, taiga, and coniferous forests.

canopy -- Layer of vegetation elevated above the ground, usually of tree branches and epiphytes. In tropical forests, the canopy may be more than 100 feet above the ground.

carnivore -- Literally, an organism that eats meat. Most carnivores are [animals](#), but a few fungi, plants, and protists are as well.

consumer -- Any organism which must consume other organisms (living or dead) to satisfy its energy needs. Contrast with [autotroph](#).

cyst -- n. A small, capsule-like sac that encloses an organism in its resting or larval stage, e.g., a resting spore of an alga.

decomposer -- An organism that breaks down the tissue and/or structures of dead organisms.

decomposition -- The breakdown of dead organic material by detritivores or saprophytes.

dessication -- Mummification.

detritus -- Accumulated organic debris from dead organisms, often an important source of nutrients in a food web.

detritivore -- Any organism which obtains most of its nutrients from the detritus in an ecosystem.

disease -- Organisms suffer from disease when their normal function is impaired by some genetic disorder, or more often from the activity of a parasite or other organism living within them. Many diseases are caused by [viruses](#), [bacteria](#), or [fungi](#).

ecosystem -- All the organisms in a particular region and the environment in which they live. The elements of an ecosystem interact with each other in some way, and so depend on each other either directly or indirectly.

environment -- The place in which an organism lives, and the circumstances under which it lives. Environment includes measures like moisture and temperature, as much as it refers to the actual physical place where an organism is found.

food chain/food web -- All the interactions of predator and prey, included along with the exchange of nutrients into and out of the soil. These interactions connect the various members of an ecosystem, and describe how energy passes from one organism to another.

frugivore -- Animal which primarily eats fruit. Many [bats](#) and [birds](#) are frugivores.

generalist -- Organism which can survive under a wide variety of conditions, and does not specialize to live under any particular set of circumstances.

grassland -- Region in which the climate is dry for long periods of the summer, and freezes in the winter. Grasslands are characterized by [grasses](#) and other erect herbs, usually without trees or shrubs. Grasslands occur in the dry temperate interiors of continents, and first appeared in the [Miocene](#).

Groundwater -- Water found underground as a result of rainfall, ice and snow melt, submerged rivers, lakes, and springs. This water often carries minerals. These minerals can accumulate in the remains of buried organisms and eventually cause fossilization.

habitat -- The place and conditions in which an organism lives.

halophile -- Organism which lives in areas of high salt concentration. These organisms must have special adaptations to permit them to survive under these conditions.

herbivore -- Literally, an organism that eats [plants](#) or other autotrophic organisms. The term is used primarily to describe animals.

host -- Organism which serves as the habitat for a parasite, or possibly for a symbiont. A host may provide nutrition to the parasite or symbiont, or simply a place in which to live.

ingestion -- The intake of water or food particles by "swallowing" them, taking them into the body cavity or into a vacuole. Contrast with [absorption](#).

inorganic -- Not containing carbon. Not from living things. Ex., minerals, water, oxygen, etc.

intertidal -- The coastal zone measuring from the lowest to the highest tide mark. The intertidal zone is subject to alternating periods of flooding and drying.

kelp forest -- Marine ecosystem dominated by large [kelps](#). These forests are restricted to cold and temperate waters, and are most common along the western coasts of continents. Kelp forests first appeared in the [Miocene](#).

limnology -- The study of river system ecology and life.

litter -- Leaf litter, or forest litter, is the detritus of fallen leaves and bark which accumulate in forests.

macroscopic -- Objects or organisms that are large enough to be seen with the naked eye.

marine -- Refers to the ocean.

microscopic -- Objects or organisms that are too small to be seen with the naked eye.

monsoonal -- adj. Describes a climate pattern with a wind system that changes direction with the seasons; this pattern is dominant over the Arabian Sea and Southeast Asia.

morphology -- n. The form and structure of anything, usually applied to the shapes, parts, and arrangement of features in living and fossil organisms.

niche -- n. The portion of the environment which a species occupies, defined in terms of the conditions under which an organism can survive, and may be affected by the presence of other competing organisms.

nitrogen fixation -- The conversion of gaseous nitrogen into a form usable by plants. Ususally by [bacteria](#).

nocturnal -- Active only at night.

nutrient -- Any element or simple compound necessary for the health and survival of an organism. This includes air and water, as well as food.

nutrient cycling -- All the processes by which nutrients are transferred from one organism to another. For instance, the carbon cycle includes uptake of carbon dioxide by plants, ingestion by animals, and respiration and decay of the animal.

omnivore -- Literally, an organism that will eat anything. Refers to animals who do not restrict their diet to just plants or other animals.

organic -- adj. Pertaining to compounds containing carbon. Also refers to living things or the materials made by living things. *inorganic*– ant.

parasite -- n. An organism that lives on or within a host (another organism); it obtains nutrients from the host without benefiting or killing (although it may damage) the host; **parasitic**- adj.; **parasitism**- n. a type of symbiotic relationship in which one organism benefits and the other does not.

pathogenic -- Organism which causes a disease within another organism.

pelagic -- Pelagic organisms swim through the ocean, and may rise to the surface, or sink to the bottom. They are not confined to live on the bottom as benthic organisms do.

periphyton -- Dense strands of algal growth that cover the water surface between the emergent aquatic plants. [Spirogyra](#) is commonly responsible for this growth.

photic zone -- Region of the ocean through which light penetrates; and the place where photosynthetic marine organisms live.

phytoplankton -- Tiny, free-floating, photosynthetic organisms in aquatic systems. They include [diatoms](#), [desmids](#), and [dinoflagellates](#).

plankton -- n. Very small, free-floating organisms of the ocean or other aquatic systems, including phytoplankton, which produce their own nutrients through photosynthesis, or zooplankton, which get their nutrients from organisms.

pollinator -- Animal which carries pollen from one [seed plant](#) to another, unwittingly aiding the plant in its reproduction. Common pollinators include [insects](#), especially bees, butterflies, and moths, [birds](#), and [bats](#).

predator -- Organism which hunts and eats other organisms. This includes both carnivores, which eat animals, and herbivores, which eat plants.

prey -- Organism hunted and eaten by a predator.

producer -- Any organism which brings energy into an ecosystem from inorganic sources. Most [plants](#) and many protists are producers.

rain shadow -- n. The dry region on the leeward side of a mountain range, where rainfall is noticeably less than on the windward side. For example, the White Mountains in east central California are in the rain shadow of the Sierra Nevada.

riparian -- Having to do with the edges of streams or rivers.

salinity -- A measure of the salt concentration of water. Higher salinity means more dissolved salts.

saprophyte -- Organism which feeds on dead and decaying organisms, allowing the nutrients to be recycled into the ecosystem. [Fungi](#) and [bacteria](#) are two groups with many important saprophytes.

scavenger -- An organism that feeds upon dead and dying organisms.

seaweed -- Any large photosynthetic [protist](#), including [rhodophytes](#) and [kelps](#). Seaweeds are not true [plants](#), but like plants they can make their own food. [More info?](#)

specialist -- Organism which has adopted a lifestyle specific to a particular set of conditions. Contrast with [generalist](#).

substrate -- "Supporting surface" on which an organism grows. The substrate may simply provide structural support, or may provide water and nutrients. A substrate may be inorganic, such as rock or soil, or it may be organic, such as wood.

symbiosis -- n. A relationship between two organisms that live in intimate contact with each other; includes mutualism (both organisms benefit, they rely on each other for survival), parasitism (one organism benefits at its host's expense) and commensalism (one partner benefits and the other is neither benefitted nor harmed); **symbiotic**- adj.

temperate -- Region in which the climate undergoes seasonal change in temperature and moisture. Temperate regions of the earth lie primarily between 30 and 60 degrees latitude in both hemispheres.

terrestrial -- Living on land, as opposed to marine or aquatic.

tropical -- Region in which the climate undergoes little seasonal change in either temperature or rainfall. Tropical regions of the earth lie primarily between 30 degrees north and south of the equator.

upwelling -- The raising of benthic nutrients to the surface waters. This occurs in regions where the flow of water brings currents of differing temperatures together, and increases productivity of the ecosystem.

zooplankton -- Tiny, free-floating organisms in aquatic systems. Unlike [phytoplankton](#), zooplankton cannot produce their own food, and so are consumers.

UCMP Glossary: Life history

| [Phylogenetics](#) | [Geology](#) | [Biochemistry](#) | [Cell biology](#) |
[Ecology](#) | **Life history** | [Zoology](#) | [Botany](#) | [Paleogeography](#) |

adult -- The mature stage of an organism, usually recognized by the organism's attaining the ability to reproduce.

asexual reproduction -- A type of reproduction involving only one parent that usually produces genetically identical offspring. Asexual reproduction occurs without **meiosis** or **syngamy**, and may happen through budding, by the division of a single cell, or the breakup of an entire organism into two or more parts.

clone -- An identical copy of an organism. Most plants, fungi, algae, and many other organisms naturally reproduce by making clones of themselves as a form of **asexual reproduction**.

development -- The process by which a multicellular organism is produced from a single cell.

diploid life cycle -- Occurs when the only multicellular stage in an organism's life cycle is [diploid](#).

dispersal -- The scattering of organisms of a species, often following a major reproductive event. Spores and larvae are commonly dispersed into the environment. Pollen or gametes may also be dispersed, but in this case the intent is to target another individual so that reproduction may occur. Organisms may disperse as spores, seeds, eggs, larvae, or adults.

dormancy -- A period of suspended growth and metabolic activity. Many plants, seeds, spores, and some invertebrates become dormant during unfavorable conditions.

egg -- (1) A large gamete without flagellae that is fertilized by a sperm cell. An egg cell is also called an ovum. (2) A complex multicellular structure in which an animal embryo develops.

embryo -- Once a **zygote** begins to undergo cellular divisions, it becomes an embryo.

female -- In organisms with separate sexes, the one which produces eggs.

fertilization -- The process by which an egg is made capable of generating offspring. It is often synonymous with [syngamy](#).

gamete -- Reproductive cells which fuse to form a **zygote**. Gametes are **haploid**, and may be differentiated into egg and sperm.

gametophyte -- The haploid stage in the life cycle of an organism undergoing alternations of generations. The gametophyte is multicellular and mitotically produces gametes. In plants, the gametophyte nourishes the zygote and young [sporophyte](#).

germination -- The process by which a seedling emerges and develops from a seed, or by which a sporeling emerges and develops from a spore.

haploid life cycle -- Occurs when the only multicellular stage in an organism's life cycle is [haploid](#).

haploid-diploid life cycle -- Occurs when a multicellular [diploid](#) phase, or **sporophyte**, alternates with a multicellular [haploid](#) phase, or **gametophyte**. Only [plants](#) and certain algae possess this kind of life cycle, which is also called "alternation of generations".

karyogamy -- A process of fusion of the nuclei of two cells; the second step in **syngamy**.

larva -- Among invertebrates, an immature stage in the life cycle which usually is much smaller than, and morphologically different from, the adult. In insects with **metamorphosis**, the larva must become a **pupa** before reaching adulthood.

male -- In organisms with separate sexes, the one which produces sperm.

meiosis -- A two-stage type of cell division in sexually reproducing organisms. In meiosis, a diploid cell divides to produce four haploid cells, each with half the original chromosome content. For this reason, meiosis is often called a "reduction division". In organisms with a diploid life cycles, the products of meiosis are usually called **gametes**. In organisms with an alternation of generations, the products of meiosis are called spores.

metamorphosis -- n. A process of developmental change whereby a larva reaches adulthood only after a drastic change in morphology; occurs in most amphibians and insects, for some insects, this change may include another stage (pupa) before the adult stage; **metamorphose**- v.

motile -- Able to move oneself about, capable of self-locomotion.

nymph -- In aquatic insects, the larval stage.

plasmogamy -- A process of fusion of the cytoplasm of two cells; the first step in **syngamy**.

pupa -- In metamorphosing insects, a stage between the **larva** and adult during which the organism undergoes major developmental changes.

reproduction -- The manufacture of offspring as part of an organism's life cycle. This is not the same as **dispersal**. Reproduction may be sexual, involving the fusion of gametes, or asexual.

sedentary -- Living in a fixed location, as with most plants, tunicates, sponges, etc. Contrast with [motile](#).

seed -- A structure produced by [seed plants](#) which encapsulates the embryo. The seed often provides nourishment during germination, but may lie dormant for many years first.

sexual reproduction -- A type of reproduction in which two parents give rise to offspring that have unique combinations of genes inherited through the gametes of the two parents. Sexual reproduction involves **meiosis** and **syngamy**.

spore -- n. A single cell that is dispersed as a reproductive unit, or that encapsulates a cell during unfavorable environmental conditions; in organisms with an alternation of generations; the products of meiosis are spores.

sporophyte -- The diploid stage in the life cycle of an organism undergoing an alternation of generations. The sporophyte is multicellular and develops from a zygote. The mature sporophyte meiotically produces haploid spores that later generate the [gametophyte](#) generation.

syngamy -- The process of union of two gametes; sometimes called fertilization. It encompasses both **plasmogamy** and **karyogamy**.

zygote -- The product of gamete fusion. In organisms with a haploid life cycle, the zygote immediately undergoes **meiosis**, but in organisms with a multicellular diploid stage, the zygote is merely the first stage in the diploid portion of the life cycle.

UCMP Glossary: Zoology

| [Phylogenetics](#) | [Geology](#) | [Biochemistry](#) | [Cell biology](#) |
[Ecology](#) | [Life history](#) | **Zoology** | [Botany](#) | [Paleogeography](#) |

abdomen -- Region of the body furthest from the mouth. In [insects](#), the third body region behind the head and thorax.

ambulacra -- Row of tube feet of an [echinoderm](#).

amniotic egg -- n. An egg that can be laid on land due to the presence of a fluid-filled amniotic sac (**amnion**) that cushions and protects the developing embryo; **amniote**- n. Any of a group of land-dwelling vertebrates that have an amnion during embryonic development, including reptiles, birds, and mammals.

anapsid -- n. A vertebrate distinguished by a skull with no openings in the side behind the eyes, e.g. turtles.

anus -- End of the digestive tract, or gut, through which waste products of digestion are excreted, as distinct from the mouth.

bipedal -- adj. Describes an animal that walks on two legs.

biramous -- [Arthropod](#) appendages that are biramous have two branches, an outer branch and an inner branch. These branches may have separate functions; in [crustaceans](#), for instance, the inner branch of a leg is used for walking, while the outer branch may be paddle-shaped or feathery and often functions as a gill. Contrast with **uniramous**.

blood -- Fluid which circulates throughout the body of an animal, distributing nutrients, and often oxygen as well.

book lung -- A set of soft overlapping flaps, covered up by a plate on the abdomen, through which oxygen is taken up and carbon dioxide given off. Characteristic of many terrestrial [arachnids](#) such as scorpions and spiders.

brain -- Collection of nerve cells usually located at the anterior end of an animal, when present at all. The nerves coordinate information gathered by sense organs, locomotion, and most internal body activities.

cephalon -- In [trilobites](#), the head shield bearing the eyes, antennae, and mouth.
[More info?](#)

chaetae -- Stiff bristles characteristic of [annelids](#).

chela -- The claw of an [arthropod](#).

chelicera -- The first pair of appendages of a **chelicerate** arthropod. Originally a short clawed appendage, the chelicerae of many arachnids are highly modified for feeding; in [spiders](#), for instance, they are modified into poisonous fangs.

chordate -- n. An animal with a notochord (a cartilaginous rod that extends the length of the body), dorsal hollow nerve cord (a fluid-filled tube that runs the length of the body), gill slits or pouches, and a tail at some stage in its life cycle.

clitellum -- In [annelids](#), a swelling of the body towards the head of the animal, where the gonads are located. Both oligochaetes and leeches have a clitellum.

cnidocyst -- The "stinging cell" of a [cnidarian](#).

coelom -- Fluid-filled cavity within the body of an animal; usually refers to a cavity lined with specialized tissue **peritoneum** in which the gut is suspended. The structure and development of the coelom is an important character for recognizing major groups of animals.

compound eye -- Found in many but not all [arthropods](#), a compound eye is composed of a large number of small, closely packed simple eyes (**ommatidia**), each with its own lens and nerve receptors.

cuticle -- 1) In animals, a multilayered, extracellular, external body covering, usually composed of fibrous molecules such as chitin or collagen, and sometimes strengthened by the deposition of minerals such as calcium carbonate. 2) A waxy layer which seals the outer surface of land plants, helping to retain moisture.

diapsid -- n. A vertebrate distinguished by a skull with two pairs of openings in the side behind the eyes, e.g., lizards, snakes, crocodiles, dinosaurs, and pterosaurs.

ectoderm -- The outer basic layer of tissue in those animals with true tissues. In vertebrates, for instance, the embryonic ectoderm differentiates into the skin and also the nervous system.

endoderm -- The innermost basic layer of tissue in those animals with true tissues. Forms the gut and its derivatives: in vertebrates, these include the liver, trachea, and lungs.

epidermis -- The outermost layer of cells or skin. This tissue often contains specialized cells for defense, gas exchange, or secretion.

epithelium -- Layer of cells which lines a body cavity; cells may be ciliated or unciliated, and may be **squamous** (flat, scale-shaped), **cuboidal** (cube-shaped), or **columnar** (column-shaped). Your stomach and cheeks are lined with epithelium.

esophagus -- That portion of the gut which connects the pharynx to the stomach.

exoskeleton -- n. An external, often hard, covering or integument that provides support and protection to the body.

gastrodermis -- In [cnidarians](#), the endodermis which lines the gut cavity. The term is often used instead of endodermis since cnidarians only have two tissue layers instead of three.

genus -- n. A category in the classification of plants and animals between species and family; **genera**- pl.

gill -- In aquatic animals, highly [vascularized](#) tissues with large surface area; these are extended out of the body and into the surrounding water for gas exchange.

gill arches -- Stiffenings which support the flesh between the gill slits of [chordates](#). In most vertebrates, the first gill arches have been modified to form the [jaw](#), and in tetrapods, the inner ear bones.

gill slit -- A slitlike or porelike opening connecting the pharynx of a [chordate](#) with the outside of the body. Gill slits may contain the gills and be used for gas exchange, as in most fish, but may also be used for filter-feeding, or may be highly modified in land-dwelling vertebrates.

gnathobase -- The expanded and hardened base of the appendage of many arthropods, notably [trilobites](#), [crustaceans](#), and marine [cheliceramorphs](#). Used to macerate food items before ingestion.

gut (enteron) -- Body cavity formed between the mouth and anus in which food is digested and nutrients absorbed; it consists of the [mouth](#), [pharynx](#), [esophagus](#), [stomach](#), [intestine](#), and [anus](#), though some animals do not have all these regions.

head -- That part of the body at the "front" end, where the brain, mouth, and most sensory organs are located.

heart -- Muscular pump which circulates the blood.

intestine -- The portion of the digestive tract between the stomach and anus; it is the region where most of the nutrients are absorbed.

jaw -- Often loosely applied to any movable, toothed structures at or near the mouth of an animal, such as the [scolecodonts](#) of [annelids](#). In [vertebrates](#), the jaw is derived from the first **gill arch**.

jointed -- When stiff body parts are connected by a soft flexible region, the body is said to be jointed.

librigenae -- The "free cheeks"; separate, detachable portions of the trilobite cephalon. [More info?](#)

lophophore -- Complex ring of hollow tentacles used as a feeding organ. The tentacles are covered by cilia, which generate a current to bring food particles into the mouth. The structure is only found in the [brachiopods](#), [phoronids](#), and [bryozoans](#). [More info?](#)

marsupial -- n. (adj.) A mammal whose young are born while still embryos, and must crawl into its mother's external pouch (called the **marsupium**) to finish development.

mesoderm -- In animals with three tissue layers (i.e. all except [sponges](#) and [cnidarians](#)), the middle layer of tissue, between the **ectoderm** and the **endoderm**. In vertebrates, for instance, the mesoderm forms the skeleton, muscles, heart, spleen, and many other internal organs.

mesogloea -- Jellylike material between the outer ectoderm and the inner endoderm of [cnidarians](#). May be very thin or may form a thick layer (as in many jellyfish).

mouth -- Front opening of the digestive tract, into which food is taken for digestion. In [flatworms](#), the mouth is the only opening into the digestive cavity, and is located on the "belly" of the worm.

mucus -- Sticky secretion used variously for locomotion, lubrication, or protection from foreign particles.

muscle -- Bundle of contractile cells which allow animals to move. Muscles must act against a [skeleton](#) to effect movement.

myotome -- Segment of the body formed by a region of muscle. The myotomes are an important feature for recognizing early [chordates](#).

nematocyst -- Older name for a [cnidocyst](#).

nerve -- A bundle of **neurons**, or nerve cells. More properly, it is a bundle of axons.

nerve cord -- Primary bundle of nerves in chordates, which connects the brain to the major muscles and organs of the body.

neuron -- A specialized cell that can react to stimuli and transmit impulses. A neuron consists of a **body** which contains the nucleus; **dendrites**, which are short branches off the body that receive incoming impulses; and a long **axon** which carries impulses away from the body and to the next neuron.

notochord -- Characteristic of [chordates](#), the notochord is a stiff rod of tissue along the back of the body. In vertebrates, the backbone is deposited around the notochord and nerve cord.

organ -- Collection of tissues which performs a particular function or set of functions in an animal or plant's body. The heart, brain, and skin are three organs found in most animals. The leaf, stem, and root are three organs found in most plants. Organs are composed of **tissues**, and may be organized into larger **organ systems**.

organ system -- Collection of organs which have related roles in an organism's functioning. The nervous system, vascular system, and muscle system are all organ systems.

osculum -- The main opening through which filtered water is discharged. Found in [sponges](#).

papilla(e) -- Cellular outgrowths. These look like little bumps or fingers on the surface of cells.

parapodia -- A sort of "false foot" formed by extension of the body cavity. Polychaetes and some insect larvae have parapodia in addition to their legs, and these provide extra help in locomotion.

pedipalps -- The second pair of appendages of [cheliceromorphs](#). In many arachnids, such as spiders, the pedipalps are enlarged in the male and used for copulation.

pharyngeal slits -- Characteristic of [chordates](#), pharyngeal slits are openings through which water is taken into the pharynx, or throat. In primitive chordates the pharyngeal slits are used to strain water and filter out food particles; in fishes they are modified for respiration. Most terrestrial vertebrates have pharyngeal slits only in the embryonic stage.

pharynx -- Cavity in the digestive tract just past the mouth itself. May be muscularized for sucking or swallowing in various animals.

phylum -- n. A category in the hierarchy of animal classification between class and kingdom; **phyla**- pl.

placenta -- n. In mammals, a tissue formed within the uterus through which nutrients are passed from the mother to the embryo (and later the fetus) and its wastes are removed; **placental**- n. (adj.) A mammal whose young form a placenta as they develop in the mother's uterus.

pleurae -- In trilobites and other arthropods, pleurae are elongated flat outgrowths from each body segment, that overlies and protect the appendages.

pore -- Any opening into or through a tissue or body structure.

proboscis -- Elongated organ, usually associated with the mouth. The proboscis is an important feeding appendage in [echiurans](#).

pygidium -- In trilobites, the posterior division of the body, formed by fusion of the **telson** with one or more posterior **pleurae**.

segmentation -- In many animals, the body is divided into repeated subunits called **segments**, such as those in centipedes, [insects](#), and [annelids](#). Segmentation is the state of having or developing a body plan in this way.

septum -- Partition which divides up a larger region into smaller ones, such as in the central body cavity of some anthozoa.

siphon -- Opening in [molluscs](#) or in [urochordates](#) which draws water into the body cavity. In many molluscs, the siphon may be used to expel water forcibly, providing a means of propulsion.

skeleton -- Support structure in animals, against which the force of muscles acts. Vertebrates have a skeleton of [bone](#) or cartilage; arthropods have one made of [chitin](#); while many other invertebrates use a **hydrostatic** skeleton, which is merely an incompressible fluid-filled region of their body.

spicule -- Crystalline or mineral deposits found in sponges, sea cucumbers, or urochordates. They are structural components in many [sponges](#), and may serve a protective function in other organisms.

spiracle -- In insects and some other terrestrial arthropods, a small opening through which air is taken into the **tracheae**. Insects have several spiracles, arranged along the sides of the abdomen.

spongocoel -- Central body cavity of sponges. [More Info?](#)

synapsid -- n. A vertebrate distinguished by a skull with one pair of openings in the side behind the eyes, e.g., mammals and their close relatives.

telson -- The last segment of the abdomen in many arthropods. May be flat and paddlelike, buttonlike, or long and spiny, as in the [horseshoe crabs](#).

tentacles -- Appendages which are flexible, because they have no rigid skeleton. Cnidarians and molluscs are two kinds of organisms which may have tentacles.

tetrapod -- n. A vertebrae that has (or whose close relatives have) four limbs with digits, not fins.

thorax -- In insects, the second body region, between the head and abdomen. It is the region where the legs and wings are attached.

tissue -- A group of cells with a specific function in the body of an organism. Lung tissue, vascular tissues, and muscle tissue are all kinds of tissues found in some animals. Tissues are usually composed of nearly identical cells, and are often organized into larger units called **organs**.

tracheae -- Internal tubes through which air is taken for respiration. Vertebrates with lungs have a single trachea carrying air to the lungs, while insects and some other land-living arthropods have a complex network of tracheae carrying air from the **spiracles** to all parts of the body.

tube feet -- Extensions of the water-vascular system of [echinoderms](#), protruding from the body and often ending in suckers. May be used for locomotion and/or for maintaining a tight grip on prey or on the bottom.

tubercle -- Any small rounded protrusion. In pycnogonids and some cheliceramorph arthropods, the central eyes are carried on a tubercle.

uniramious -- Among [arthropods](#), uniramous refers to appendages that have only one branch. Insects, centipedes and millipedes, and their relatives are uniramous arthropods; land-living chelicerates such as scorpions, spiders, and mites are also uniramous but probably descended from ancestors with biramous appendages. Contrast with **biramous**.

vascular -- Refers to a network of tubes which distribute nutrients and remove wastes from the tissues of the body. Large multicellular animals must rely on a vascular system to keep their cells nourished and alive.

vertebra -- A component of the **vertebral column**, or backbone, found in [vertebrates](#).

zooxanthellae -- Symbiotic [dinoflagellates](#) in the genus *Symbiodinium* that live in the tissues of a number of marine invertebrates and protists, notably in many foraminiferans, cnidarians, and some mollusks.

Last updated:2004-04-20

UCMP Glossary: Paleogeography

| [Phylogenetics](#) | [Geology](#) | [Biochemistry](#) | [Cell biology](#) |
[Ecology](#) | [Life history](#) | [Zoology](#) | [Botany](#) | **Paleogeography** |

Avalonia -- n. A separate plate in the Early Paleozoic consisting of much of Northern Europe, Newfoundland, Nova Scotia, and some coastal parts of New England.

Baltica -- n. A separate continental plate of the Early Paleozoic composed of the United Kingdom, Scandinavia, European Russia and Central Europe; named for the Baltic Sea.

Bering Land Bridge -- n. The vast tundra plain that was exposed between Asia and North America during the Last Glacial Maximum, about 21,000 years ago; it served as a migration route for people, animals, and plants. Also known as **Beringia**.

Cathaysian terranes -- n. A set of small landmasses that developed in tropical to subtropical latitudes on the eastern side of Pangea during the Permian and Triassic, includes modern North China (Sino-Korea), South China (Yangtze), Eastern Qiangtang, Tarim, and Indochina.

Cimmerian terranes -- n. An archipelago of small landmasses that developed in tropical and subtropical latitudes on the eastern side of Pangea during the Triassic, blocks that comprised it include modern Turkey, Iran, Afghanistan, Tibet, and Malaysia; also called **Cimmeria**.

Congo craton -- n. A separate continental plate that rifted from the supercontinent Rodinia in the Late Precambrian; contained a large part of north-central Africa.

Cretaceous Western Interior Seaway -- n. The epicontinental sea that formed as marine waters from the north spread over North America from around 130 to 70 million years ago (Ma), at its peak in the Middle Cretaceous (~ 90 Ma) it extended from present-day Utah to the Appalachians and from the Arctic to the Gulf of Mexico; also referred to as the **Western Interior Seaway**

Euramerica -- n. A supercontinent that existed in the Late Silurian through Devonian, formed by the collision of Baltica, Laurentia, and Avalonia; included modern North America, Greenland, Scandinavia, and Europe; also called the “Old Red Continent” for the red color of its oxidized deposits.

Gondwana -- n. A supercontinent that existed from Cambrian to Jurassic time, mainly composed of South America, Africa, Madagascar, India, Antarctica, and Australia.

Iapetus Ocean -- n. A relatively small ocean that existed between the continents of Laurentia, Baltica, and Avalonia from the Late Precambrian to the Devonian.

Laurasia -- n. A supercontinent that existed from the Jurassic to Early Tertiary after splitting from Pangea; composed of Laurentia, Baltica, Avalonia, (modern North America, Scandinavia, Greenland, Western and Central Europe); eventually fragmented into Eurasia and North America in the Tertiary with the opening of the North Atlantic Ocean.

Laurentia -- n. A separate continental plate that existed from the Late Precambrian to Silurian, consisting of the major part of North America, northwest Ireland, Scotland, Greenland, and pieces of Norway and Russia.

Paleo-Tethys Ocean -- n. A large ocean that originated between eastern Gondwana, Siberia, Kazakhstan, and Baltica in the Ordovician and finally closed in the Jurassic; replaced by the Tethys Ocean as eastern Pangea was assembled.

Pangea -- n. A supercontinent that existed from the the end of the Permian to the Jurassic, assembled from large continents like Euramerica, Gondwana, and Siberia, as well as smaller landmasses like the Cathaysian and Cimmerian terranes; Greek for “all lands.”

Pannotia -- n. A supercontinent that existed in the Late Precambrian and gave rise to the continents of Gondwana, Laurentia, Siberia, and Baltica in the Cambrian.

Panthalassic Ocean -- n. A vast ocean that existed from the Late Precambrian to the Jurassic, circling the globe and connecting to smaller oceans that developed throughout the Phanerozoic; also known as the **Panthalassa**.

Rodinia -- n. A supercontinent that existed during the Late Precambrian before the supercontinent Pannotia; the oldest supercontinent for which we have a good record; Russian for "homeland."

Siberia -- n. A separate continental plate that existed from the Latest Precambrian to the Carboniferous, composed of a large part of central Russia, namely Siberia.

Tethys Ocean -- n. A small ocean that existed from the Triassic to the Jurassic; as Pangea was split into Gondwana and Laurasia in the Jurassic, an arm developed westward called the **Tethys Seaway** or **Tethys Sea**.

Introduction to the Anthophyta

the flowering plants

If you have ever stopped to smell the roses, then you are familiar with the largest group of [plants](#), the Anthophyta. The distinctive feature of this group is the **flower**, a cluster of highly-specialized leaves which participate in reproduction. Not all flowers are as conspicuous as the *Magnolia* blossom in the picture above; oaks, ivy, and [grasses](#) also produce flowers, but because they are not as showy we often do not notice them.

The flowering plants are important in many ways above and beyond their aesthetic appeal in flower arrangements. Not a day goes by in which our lives are not affected by flowering plants. Nearly all of our food comes from flowering plants; grains, beans, nuts, fruits, vegetables, herbs and spices almost all come from plants with flowers, as do tea, coffee, chocolate, wine, beer, tequila, and cola. Much of our clothing comes from them as well -- cotton and linen are made from "fibers" of flowering plants, as are rope and burlap, and many commercial dyes are extracted from other flowering plants. We also owe them credit for a large number of our drugs, including over-the-counter medicines such as aspirin, prescribed drugs such as digitalis and atropine, and controlled drugs such as opium, cocaine, marijuana, and tobacco.

Click on the buttons below to find out more about the Anthophyta.

You can navigate deeper into the Anthophyte groups by selecting Systematics!

You can find more information about floristics, collections, and images of flowering plants by looking through our [Listings of Remote Catalogs](#).

For images covering much of angiosperm diversity, try the flowering plant image collection at the [University of Wisconsin](#).

Image of *Magnolia* blossom by Brian R. Speer

Anthophyta: More on Morphology

Angiosperms produce their reproductive organs within a flower.

Like other seed plants, angiosperms are **heterosporangiate**, producing pollen and ovules in different organs. Unlike most seed plants, however, the pollen and ovule-bearing organs are usually produced together in a **bisporangiate strobilus** called a **flower**.

In the center of a typical flower are the **carpels**, modified leaves which enclose the ovules. These are often fused to form a single **pistil** in the center of the flower. Surrounding the carpels are several narrow stalks topped by pollen sacs; these pollen-bearing stalks are called **stamens**. Around these reproductive organs is the **perianth**, usually consisting of an outer whorl of **sepals** and an inner whorl of **petals**. In monocots and "primitive" dicots, the sepals and petals may be indistinguishable, as in the lily shown at right. In this case the perianth parts are called **tepals**.

The first flowering plants had numerous floral parts spiralled around a central axis, much like the flowers of *Magnolia*. In most angiosperms, however, the floral parts are relatively few, and are arranged in a **whorl**, in which a set of parts are all attached around the central axis at the same level, instead of being attached in a staggered spiral. The parts of these earliest flowers were likely very large and radially arranged; they were not fused to each other, as is common in many groups today.

In many angiosperms, the flowers are arranged in clusters called **inflorescences**. The flowers may be attached along a tall stalk, arranged in broad open clusters, or pressed tightly together so that

the cluster looks like a single flower.

Angiosperm means "vessel seed".

Angiosperms differ from other [seed plants](#) in that they enclose their ovules (and seeds) within a carpel. The carpel is a modified leaf bearing the ovules, but the carpel is folded onto itself, wrapping the ovules inside. The "vessel" which the carpel forms gives the angiosperms their name.

Although the carpels are hypothesized to give extra protection to the developing ovules and seeds, there is a problem with encasing the ovules -- how to get the pollen to the ovule so that it can deliver the sperm? In angiosperms, the pollen tube does not simply grow through an opening in the tissue surrounding the ovule, but it must penetrate and grow *through* the tissue.

This feature of angiosperms allows for sexual selection and pollen competition in ways that are not possible in other seed plants. The carpel tissue can "screen" arriving pollen, and selectively prevent growth of certain genotypes. In some flowers, this increases outbreeding, as the plant prevents its own pollen from germinating.

A fruit is a matured ovary.

Once the pollen has fertilized the egg cell contained within the ovule, the ovule develops into a seed, and the ovary of the enclosing carpel begins to enlarge and ripen, forming the **fruit**. This is the botanical definition of a fruit, and is not the same as the popular usage of "fruit". For example, a botanist considers acorns, tomatoes, green beans, and coconuts to be fruits. The individual grains of wheat and rice are also fruits by this definition. By contrast, strawberries are NOT fruits; the individual hard bits on the outside of the strawberry are the matured ovaries, and are properly considered fruits, while the fleshy red portion is actually stem tissue stimulated to growth by the maturing fruits.

It should also be pointed out that ALL flowering plants produce fruits, and that not all fruits are edible. The fruit of the potato plant is quite poisonous, and should not be eaten. Cotton bolls are dry fruits from which we harvest cotton fibers.

You can read about the morphological differences between [monocots and dicots](#) on our server.

California State University has an online interactive [Fruit Key](#) with illustrations.

UCMP Glossary: G

| [A](#) | [B](#) | [C](#) | [D](#) | [E](#) | [F](#) | **G** | [H](#) | [I](#) | [J](#) | [K](#) | [L](#) | [M](#) | [N](#) | [O](#) | [P](#) | [Q](#) | [R](#) |
[S](#) | [T](#) | [U](#) | [V](#) | [W](#) | [X](#) | [Y](#) | [Z](#) |

gabbro -- Highly [mafic igneous plutonic](#) rock, typically dark in color; rough plutonic equivalent of [basalt](#).

gamete -- Reproductive cells which fuse to form a **zygote**. Gametes are **haploid**, and may be differentiated into egg and sperm.

gametophyte -- The haploid stage in the life cycle of an organism undergoing alternations of generations. The gametophyte is multicellular and mitotically produces gametes. In plants, the gametophyte nourishes the zygote and young [sporophyte](#).

gastrodermis -- In [cnidarians](#), the endodermis which lines the gut cavity. The term is often used instead of endodermis since cnidarians only have two tissue layers instead of three.

Gastroliths -- Fossilized gizzard stones, usually only applicable in the fossil study of reptiles

generalist -- Organism which can survive under a wide variety of conditions, and does not specialize to live under any particular set of circumstances.

genus -- n. A category in the classification of plants and animals between species and family; **genera**- pl.

geologic maps -- Maps that show the types and ages of rock of an area. These maps are used by paleontologists to find areas that are likely to contain fossils they are interested in.

germination -- The process by which a seedling emerges and develops from a seed, or by which a sporeling emerges and develops from a spore.

gill -- In aquatic animals, highly [vascularized](#) tissues with large surface area; these are extended out of the body and into the surrounding water for gas exchange.

gill arches -- Stiffenings which support the flesh between the gill slits of [chordates](#). In most vertebrates, the first gill arches have been modified to form the [jaw](#), and in tetrapods, the inner ear bones.

gill slit -- A slitlike or porelike opening connecting the pharynx of a [chordate](#) with the outside of the body. Gill slits may contain the gills and be used for gas exchange, as in most fish, but may also be used for filter-feeding, or may be highly modified in land-dwelling vertebrates.

glass -- A non-crystalline rock that results from very rapid cooling of magma.

glucose -- simple sugar, and the primary product of photosynthesis. It is polymerized to make cellulose and chitin.

glycoprotein -- a membrane-bound protein which has attached branching carbohydrates. These may function in cell-cell recognition, such as in human blood groups and immune system response, as well as in resisting compression of cells.

gnathobase -- The expanded and hardened base of the appendage of many arthropods, notably [trilobites](#), [crustaceans](#), and marine [cheliceramorphs](#). Used to macerate food items before ingestion.

Golgi apparatus -- Eukaryotic organelle which package cell products, such as enzymes and hormones, and coordinate their transport to the outside of the cell.

Gondwana -- n. A supercontinent that existed from Cambrian to Jurassic time, mainly composed of South America, Africa, Madagascar, India, Antarctica, and Australia.

gradualism -- A model of evolution that assumes slow, steady rates of change. Charles Darwin's original concept of evolution by natural selection assumed gradualism. Contrast with punctuated equilibrium.

grain -- (1) The texture of wood, produced by the kinds of **xylem** cells present. (2) The **fruit** of a member of the [grasses](#).

granite -- Highly [felsic igneous plutonic](#) rock, typically light in color; rough plutonic equivalent of [rhyolite](#). Granite is actually quite rare in the U.S.; often the term is applied to any quartz-bearing plutonic rock.

granodiorite -- [Igneous plutonic](#) rock, less [felsic](#) than granite, typically light in color; rough plutonic equivalent of [dacite](#).

grassland -- Region in which the climate is dry for long periods of the summer, and freezes in the winter. Grasslands are characterized by [grasses](#) and other erect herbs, usually without trees or shrubs. Grasslands occur in the dry temperate interiors of continents, and first appeared in the [Miocene](#).

graywacke -- [Sandstone](#) composed of poorly sorted angular [clasts](#).

Groundwater -- Water found underground as a result of rainfall, ice and snow melt, submerged rivers, lakes, and springs. This water often carries minerals. These minerals can accumulate in the remains of buried organisms and eventually cause fossilization.

guard cells -- Pair of cells which surround a **stomate** and regulate its size by altering their shape.

gut (enteron) -- Body cavity formed between the mouth and anus in which food is digested and nutrients absorbed; it consists of the [mouth](#), [pharynx](#), [esophagus](#), [stomach](#), [intestine](#), and [anus](#), though some animals do not have all these regions.

gymnosperm -- n. A plant that produces seeds, which are not enclosed; includes any [seed plant](#) that does not produce flowers.

gynostemium -- The central reproductive stalk of an [orchid](#), which consists of a **stamen** and **pistil** fused together.

UCMP Glossary: S

| [A](#) | [B](#) | [C](#) | [D](#) | [E](#) | [F](#) | [G](#) | [H](#) | [I](#) | [J](#) | [K](#) | [L](#) | [M](#) | [N](#) | [O](#) | [P](#) | [Q](#) | [R](#) |
 S | [T](#) | [U](#) | [V](#) | [W](#) | [X](#) | [Y](#) | [Z](#) |

salinity -- A measure of the salt concentration of water. Higher salinity means more dissolved salts.

salt lick -- n. A natural or artificial deposit of exposed salt that animals lick for nutrients.

sandstone -- [Sedimentary rock](#) composed of sand-sized [clasts](#).

saprophyte -- Organism which feeds on dead and decaying organisms, allowing the nutrients to be recycled into the ecosystem. [Fungi](#) and [bacteria](#) are two groups with many important saprophytes.

saxitoxin -- neurotoxin found in a variety of dinoflagellates. If ingested, it may cause respiratory failure and cardiac arrest.

scavenger -- An organism that feeds upon dead and dying organisms.

sea-floor spreading -- n. The process of adding to the Earth's crust at mid-ocean ridges as magma wells up and forces previously formed crust apart.

seaweed -- Any large photosynthetic [protist](#), including [rhodophytes](#) and [kelps](#). Seaweeds are not true [plants](#), but like plants they can make their own food. [More info?](#)

secondary growth -- Growth in a plant which does not occur at the tips of the stems or roots. Secondary growth produces wood and bark in [seed plants](#).

sedentary -- Living in a fixed location, as with most plants, tunicates, sponges, etc. Contrast with [motile](#).

sediment -- Any solid material that has settled out of a state of suspension in liquid.

sedimentary rock -- Any rock resulting from the consolidation of [sediment](#).

seed -- A structure produced by [seed plants](#) which encapsulates the embryo. The seed often provides nourishment during germination, but may lie dormant for many years first.

segmentation -- In many animals, the body is divided into repeated subunits called **segments**, such as those in centipedes, [insects](#), and [annelids](#). Segmentation is the state of having or developing a body plan in this way.

selection -- Process which favors one feature of organisms in a population over another feature found in the population. This occurs through differential reproduction—those with the favored feature produce more offspring than those with the other feature, such that they become a greater percentage of the population in the next generation.

sepal -- The outermost structures of a flower. [More info?](#)

septum -- Partition which divides up a larger region into smaller ones, such as in the central body cavity of some anthozoa.

sexual reproduction -- A type of reproduction in which two parents give rise to offspring that have unique combinations of genes inherited through the gametes of the two parents. Sexual reproduction involves **meiosis** and **syngamy**.

shoot -- Usually, the above ground portion of a plant, bearing the leaves. Contrast with **root**.

Siberia -- n. A separate continental plate that existed from the Latest Precambrian to the Carboniferous, composed of a large part of central Russia, namely Siberia.

siderite -- Also called ironstone, that is a concretion of iron carbonate. Common in the [Mazon Creek](#) fossil beds.

silica -- amorphous silicon dioxide (glass). It is a structural component in many organisms, such as [diatoms](#) and [horsetails](#).

silicification -- Process whereby silica replaces the original material of a substance. For example, silicified wood.

sill -- n. A sheet-like igneous intrusion that parallels the plane of the surrounding rock.

sinkhole -- n. A natural depression in the surface of the land caused by the collapse of the roof of a cavern or subterranean passage, generally occurring in limestone regions.

siphon -- Opening in [molluscs](#) or in [urochordates](#) which draws water into the body cavity. In many molluscs, the siphon may be used to expel water forcibly, providing a means of propulsion.

siphonostele -- When a plant's vascular tissue develops as a central cylinder, it is said to have a siphonostele. See also protostele and eustele.

sister group -- The two clades resulting from the splitting of a single lineage.

skeleton -- Support structure in animals, against which the force of muscles acts. Vertebrates have a skeleton of [bone](#) or cartilage; arthropods have one made of [chitin](#); while many other invertebrates use a **hydrostatic** skeleton, which is merely an incompressible fluid-filled region of their body.

soil -- Unconsolidated materials above [bedrock](#).

specialist -- Organism which has adopted a lifestyle specific to a particular set of conditions. Contrast with [generalist](#).

spermatophyte -- A [seed plant](#).

spicule -- Crystalline or mineral deposits found in sponges, sea cucumbers, or urochordates. They are structural components in many [sponges](#), and may serve a protective function in other organisms.

spiracle -- In insects and some other terrestrial arthropods, a small opening through which air is taken into the **tracheae**. Insects have several spiracles, arranged along the sides of the abdomen.

spongin -- proteinaceous compound of which the spicules in [Demospongiae](#) are composed.

spongocoel -- Central body cavity of sponges. [More Info?](#)

sporangiophore -- A stalk to which sporangia are attached.

sporangium -- A chamber inside of which spores are produced through [meiosis](#).

spore -- n. A single cell that is dispersed as a reproductive unit, or that encapsulates a cell during unfavorable environmental conditions; in organisms with an alternation of generations; the products of meiosis are spores.

sporophyll -- Any leaf which bears sporangia is called a sporophyll.

sporophyte -- The diploid stage in the life cycle of an organism undergoing an alternation of generations. The sporophyte is multicellular and develops from a zygote. The mature sporophyte meiotically produces haploid spores that later generate the [gametophyte](#) generation.

stamen -- Part of a flower, the tip of which produces pollen and is called the **anther**. [More info?](#)

starch -- a complex polymer of glucose, used by plants and green algae to store surplus sugar for later use.

stasis -- A period of little or no discernible change in a lineage.

stem group -- All the taxa in a clade preceding a major cladogenesis event. They are often difficult to recognize because they may not possess synapomorphies found in the crown group.

stigma -- The sticky tip of a **pistil**. Or, the dense region of pigments found in many photosynthetic protists which is sensitive to light, and thus functions somewhat like a miniature eye. [More info?](#)

stipe -- A scientific term for "stalk".

stipules -- Paired appendages found at the base of the leaves of many [flowering plants](#).

stomata -- Openings in the epidermis of a stem or leaf of a plant which permit gas exchange with the air. In general, all plants except liverworts have stomata in their sporophyte stage.

stratigraphy -- n. The study of rock layers, especially their distribution, environment of deposition, and age; **stratigraphic**, adj.

stratum -- A layer of [sedimentary rock](#); plural is **strata**.

streptophytes -- The [clade](#) consisting of the [plants](#) plus their closest relatives, the [charophytes](#).

strike -- The direction or trend of a bedding plane or [fault](#), as it intersects the horizontal.

strobilus -- A tightly clustered group of **sporophylls** arranged on a central stalk; commonly termed a "cone" or "flower".

style -- The narrow stalk of the **pistil**, located above the ovary but below the **stigma**.

subduction -- n. A geologic process in which one edge of one crustal [plate](#) is forced below the edge of another; **subduct**– v.; **subduction zone**- n. A long narrow area in which subduction is taking place, e.g. the Peru-Chile trench, where the Pacific Plate is being subducted under the South American Plate.

subsidence -- n. The sudden sinking or gradual downward settling of the Earth's surface with little or no horizontal motion.

substrate -- "Supporting surface" on which an organism grows. The substrate may simply provide structural support, or may provide water and nutrients. A substrate may be inorganic, such as rock or soil, or it may be organic, such as wood.

sugar -- any of several small carbohydrates, such as glucose, which are "sweet" to the taste.

symbiosis -- n. A relationship between two organisms that live in intimate contact with each other; includes mutualism (both organisms benefit, they rely on each other for survival), parasitism (one organism benefits at its host's expense) and commensalism (one partner benefits and the other is neither benefitted nor harmed); **symbiotic**- adj.

synangium -- A cluster of sporangia which have become fused in development.

synapomorphy -- A character which is derived, and because it is shared by the taxa under consideration, is used to infer common ancestry.

synapsid -- n. A vertebrate distinguished by a skull with one pair of openings in the side behind the eyes, e.g., mammals and their close relatives.

syncline -- A fold of rock layers that is convex downwards. Antonym of [anticline](#).

syncytic -- see [Hexactinellida](#)

syngamy -- The process of union of two gametes; sometimes called fertilization. It encompasses both **plasmogamy** and **karyogamy**.

systematics -- Field of biology that deals with the diversity of life. Systematics is usually divided into the two areas of [phylogenetics](#) and [taxonomy](#).

Last updated:2004-04-20

Introduction to the Anthocerotophyta

The hornworts

Most people are unaware of hornworts, though they are a quite common and widespread group of [plants](#) which may be found in tropical forests, along streamsides, and in disturbed fields around the world. Most species are small and unassuming greasy blue-green patches, but some tropical species can cover large areas of soil or the sides of trees. Because of their unique morphology, there have been many questions about relationships and origin of the Anthocerotophyta.

Hornworts are a very unusual group of plants.

The group's common name "hornwort" refers to the tall narrow **sporophytes** which are embedded in the top of the plant. As in other bryophytes, the sporophyte remains attached to its parent **gametophyte** throughout its life, but unlike these other plants, the sporophyte continues to grow throughout its life; this happens as a group of cells at the base of the horn divide repeatedly. This continuous growth from a **near-basal meristem** is unique among plants to hornworts.

As the sporophyte grows longer, it splits into two halves lengthwise, releasing the spores as they mature. Along with the spores are cells called **pseudoelaters**, which change shape as they dry out and thereby assist in scattering the spores.

When a spore germinates, it produces a flat **thalloid** plant with a greasy blue-green color and odd morphology. The best way to recognize a hornwort, and especially to tell it apart from a liverwort or fern gametophyte, is to look at the plant under a low-power microscope; hornworts will generally have a single large **chloroplast** per cell. This is an especially useful character for sterile material, but you must look at *fresh* material, since hornworts tend to dry up and fall apart if not kept moist, and will quickly rot if immersed.

Hornworts are a problematic group for evolutionary biologists.

The oldest hornwort fossils are spores from the late [Cretaceous](#) (Maastrichtian), which have been compared to the spores of the living genus *Phaeoceros*. A somewhat older fossil, *Notothylicites filiformis*, has been described as a hornwort from the Santonian (Late Cretaceous) of Czechoslovakia, but the identification of the fossil as a hornwort is not entirely certain -- the fossil preserves the whole plant, but in rather poor detail, and might be better interpreted as a liverwort. Most hornwort fossils are [Miocene](#) spores found in Europe and assigned to the Anthocerotaceae.

Such a late date for oldest fossils of hornworts is curious, considering that most cladistic analyses of living plants suggests that the group originated early in the history of land plants, probably before the [Devonian](#), and should be one of the oldest lineages of plants. The presence of a **columella**, or small column of tissue, running up through the center of the capsule is reminiscent of [mosses](#) and of "**rhyniophytes**", such as *Horneophyton*, and further supports the idea of an early divergence. The delicate hornworts may not have been easily preserved, which might explain the absence of a Paleozoic record. However, it seems puzzling that their spores, which would be much more likely to be preserved, are not encountered either.

Above, you can see pictures of the hornwort *Phaeoceros*. On the left is a plant with young sporophytes beginning to elongate from the top of the gametophyte. On the right is a plant with older sporophytes, which have split open and begun to release spores. Click on either picture to see

an enlarged version.

There are usually two or three families recognized in the Anthocerotophyta, as listed below. Because of the uncertain relationships of fossil hornworts, only living taxa are included in the list here.

NOTOTHYLALES

Notothyladaceae -- *Notothylas*

ANTHOCEROTALES

Anthocerotaceae -- 3 to 6 genera, including *Anthoceros* and *Phaeoceros*

Dendroceroaceae -- *Dendroceros* and *Megaceros*

For additional information about [hornwort classification](#), visit the [Tree of Life](#). You can also view hornwort images at the [University of Wisconsin](#), the source of the images used here (by permission).

Or for additional information about bryophytes in general, try the homepage of the [American Bryological and Lichenological Society](#).

Introduction to the Cycads

Legacy of the Mesozoic

Cycads are an ancient group of [seed plants](#) with a crown of large compound leaves and a stout trunk. They are a minor component of the flora in tropical and subtropical regions today, but during the [Jurassic Period](#), they were a common sight in many parts of the world. For this reason, the Jurassic is often referred to as the "Age of Cycads".

Today only a handful of cycads still exist, and many are facing possible extinction in the wild (such as *Microcycas* in western Cuba). However, because of their large attractive leaves, many cycads have found a home in public and private gardens around the world. The above photograph shows a group of "Sago Palms", *Cycas revoluta*, growing outside the Hertz music building on the U.C. Berkeley campus. Though cycads are often known by this name, they are not closely related to the palms.

Click on the buttons below to find out more about the Cycads.

For oodles of cycad information and links, visit [The Cycad Pages](#) at the [Royal Botanic Gardens](#) in Sydney, Australia. Or read the [Virtual Cycad Encyclopedia](#) by the Palm and Cycad Societies of Florida.

Information on living cycads of Mexico, mostly in Spanish, is available from [Q'Taxa](#) at the University of California - Riverside. There are several nice cycad images on [Andy Boze's](#) page on [cycads](#), with many quality pictures of cycad cones and seeds. See cycads when you visit [Carnavon National Park](#) in Queensland, Australia or the [Fairchild Tropical Garden](#), long respected for having the largest collection of cycads in the US, and one of the largest such collections in the world.

You might also scan the [International Palm Society](#) listings of palm and cycad affiliated societies.

-

The history behind the classes.

Traditionally, the [flowering plants](#) have been divided into two major groups, or **classes**,: the Dicots (Magnoliopsida) and the [Monocots](#) (Liliopsida). Many people take this separation into two classes for granted, because it is "plainly obvious", but botanists have not always recognized these as the two fundamental groups of angiosperms. Although Theophrastus (circa 370 BC) is credited with first recognizing differences between the two groups, classification of plants was based upon overall growth form -- trees, herbs, vines -- until the 1600s.

In 1682, [John Ray](#) published his *Methodus Plantarum Nova*, in which Dicotyledones and Monocotyledones were first given formal taxonomic standing. This system was popularized by the French botanist Antoine Laurent de Jussieu in his *Genera Plantarum* of 1789, a work which improved upon, and gradually replaced, the system of plant classification devised by [Linnaeus](#).

The fuzzy distinction between the classes.

Even after the general acceptance of Monocots and Dicots as the primary groups of flowering plants, botanists did not always agree upon the placement of families into one or the other class. Even in this century some plants called [paleoherbs](#) have left problems for taxonomy of angiosperms. These plants have a mix of characters which do not occur together in most other flowering plants. For instance, the [Nymphaeales](#), or water lilies, have reticulate venation in their leaves, and what may be a single cotyledon in the embryo. It is not clear whether it is a single lobed cotyledon, or two which have been fused. The water lilies also have a vascular arrangement in their stem similar to that of monocots.

There are also monocots which possess characters more typical of dicots. The [Dioscoreales](#) and Smilacaceae have broad reticulate-veined leaves; the Alismataceae have acropetal leaf development; and *Potamogeton* is one of several monocots to have floral parts in multiples of

four.

This "fuzziness" in the definitions of Monocotyledonae and Dicotyledonae is not simply the result of poor botany. Rather, it is a real phenomenon resulting from the shared ancestry of the two groups. It is now believed that some of the dicots are more closely related to monocots than to the other dicots, and that the angiosperms do not all fit neatly into two clades. In other words, the dicots include a basal **paraphyletic** group from which the monocots evolved. [Click here](#) for a cladogram which illustrates our current understanding of basal angiosperm relations.

The characters which distinguish the classes.

Despite the problems in recognizing basal angiosperm taxa, the standard distinctions between dicots and monocots are still quite useful. It must be pointed out, however, that there are many exceptions to these characters in both groups, and that *no single character* in the list below will infallibly identify a flowering plant as a monocot or dicot.

The table summarizes the major morphological differences between monocots and dicots; each character is discussed in more detail below. For more information, refer to the page on [monocot morphology](#).

MONOCOTS	DICOTS
Embryo with single cotyledon	Embryo with two cotyledons
Pollen with single furrow or pore	Pollen with three furrows or pores
Flower parts in multiples of three	Flower parts in multiples of four or five
Major leaf veins parallel	Major leaf veins reticulated
Stem vascular bundles scattered	Stem vascular bundles in a ring
Roots are adventitious	Roots develop from radicle
Secondary growth absent	Secondary growth often present

- **Number of cotyledons** -- The number of cotyledons found in the embryo is the actual basis for distinguishing the two classes of angiosperms, and is the source of the names Monocotyledonae ("one cotyledon") and Dicotyledonae ("two cotyledons"). The **cotyledons** are the "seed leaves" produced by the embryo. They serve to absorb nutrients packaged in the seed, until the seedling is able to produce its first true leaves and begin photosynthesis.
- **Pollen structure** -- The first angiosperms had pollen with a single furrow or pore through the outer layer (**monosulcate**). This feature is retained in the monocots, but most dicots are descended from a plant which developed three furrows or pores in its pollen (**triporate**).
- **Number of flower parts** -- If you count the number of petals, stamens, or other floral parts, you will find that monocot flowers tend to have a number of parts that is divisible by three, usually three or six. Dicot flowers on the other hand, tend to have parts in multiples of four or five (four, five, ten, etc.). This character is not always reliable, however, and is not easy to use in some

flowers with reduced or numerous parts.

- **Leaf veins** -- In monocots, there are usually a number of major leaf veins which run parallel the length of the leaf; in dicots, there are usually numerous auxillary veins which reticulate between the major ones. As with the number of floral parts, this character is not always reliable, as there are many monocots with reticulate venation, notably the aroids and Dioscoreales.
 - **Stem vascular arrangement** -- Vascular tissue occurs in long strands called **vascular bundles**. These bundles are arranged within the stem of dicots to form a cylinder, appearing as a ring of spots when you cut across the stem. In monocots, these bundles appear scattered through the stem, with more of the bundles located toward the stem periphery than in the center. This arrangement is unique to monocots and some of their closest relatives among the dicots.
 - **Root development** -- In most dicots (and in most seed plants) the root develops from the lower end of the embryo, from a region known as the **radicle**. The radicle gives rise to an **apical meristem** which continues to produce root tissue for much of the plant's life. By contrast, the radicle aborts in monocots, and new roots arise **adventitiously** from nodes in the stem. These roots may be called prop roots when they are clustered near the bottom of the stem.
 - **Secondary growth** -- Most seed plants increase their diameter through secondary growth, producing wood and bark. Monocots (and some dicots) have lost this ability, and so do not produce wood. Some monocots can produce a substitute however, as in the palms and agaves.
-

Common questions about the classes.

Having taught in introductory botany for more than five years, I have fielded many questions from students, and present below some of the more common questions and misconceptions. Thanks go to my students for taking an active role in their own education, and asking these questions

Q: Are pine trees monocots or dicots?

A: Pines are **conifers**, and are neither monocots nor dicots. Only flowering plants are considered to be members of these two classes. This question is similar to asking whether a chicken is a monocot or a dicot; it is neither.

Q: Do all dicots produce flowers?

A: Yes, sort of. All dicots and monocots are flowering plants, and so are descended from flower-producing plants. However, the flowers are not always large and showy the way we expect flowers to be. Oaks, maples, and sycamore are all dicot trees, but they do not produce obvious flowers. Grasses and cattails are monocots whose flowers are often overlooked because they do not have sepals or petals.

There are also some flowering plants which flower only rarely. Duckweeds are tiny flowering plants which reproduce and spread primarily by **vegetative growth**; they grow by cellular division, and the resulting cluster will then break apart.

Q: If monocots don't have wood, then what supports palm trees?

A: Palms rely on overlapping leaf bases, thickened enlarged cells, and prop roots to stay up. This strategy is also used by cycads and tree ferns. We hope to have a special exhibit soon expanding

on the architecture of trees which will explain this in more detail.

Introduction to the Plantae

The green kingdom

The Plantae includes all land plants: mosses, [ferns](#), conifers, [flowering plants](#), and so on—an amazing range of diverse forms. With more than 250,000 species, they are second in size only to the [arthropoda](#).

Plants have been around for a very long time. The plants first appeared in the [Ordovician](#), but did not begin to resemble modern plants until the Late Silurian. By the close of the [Devonian](#), about 360 million years ago, there were a wide variety of shapes and sizes of plants around, including tiny creeping plants and tall forest trees.

The most striking, and important, feature of plants is their green color, the result of a pigment called [chlorophyll](#). Plants use chlorophyll to capture light energy, which fuels the manufacture of food—sugar, starch, and other carbohydrates. Without these food sources, most life on earth would be impossible. There would still be mushrooms and algae, but there would be no fruits, vegetables, grains, or any animals (which ultimately rely on plants for their food too!)

Another important contribution of plants is their shaping of the environment. Think of a place without plants. The only such places on earth are the arctic wastelands, really arid deserts, and the deep ocean. Everywhere else, from the tundra to the rainforest to the desert, is populated by plants. In fact, when we think of a particular landscape, it is the plants which first come to mind. Try to picture a forest without trees, or a prairie without grasses. It is the plants which produce and maintain the terrestrial environment as we know it.

Click on the buttons below to find out more about the Plant Kingdom.

You can navigate deeper into the Plantae groups by selecting Systematics!

We have an extensive list of [Botanical Collections Catalogs](#) on the Internet, including links to gardens, museums, floras, and image collections.

Visit also the following sites for additional information on paleobotany, plant systematics, and evolution:

- [Illinois State Museum: Plants of Mazon Creek](#)
- [UCMP Virtual Paleobotany Laboratory](#)

UCMP Glossary: A

| [A](#) | [B](#) | [C](#) | [D](#) | [E](#) | [F](#) | [G](#) | [H](#) | [I](#) | [J](#) | [K](#) | [L](#) | [M](#) | [N](#) | [O](#) | [P](#) | [Q](#) | [R](#) |
[S](#) | [T](#) | [U](#) | [V](#) | [W](#) | [X](#) | [Y](#) | [Z](#) |

abdomen -- Region of the body furthest from the mouth. In [insects](#), the third body region behind the head and thorax.

absorption -- The taking in of water and dissolved minerals and nutrients across cell membranes. Contrast with [ingestion](#).

abyssal plain -- The ocean floor offshore from the [continental margin](#), usually very flat with a slight slope.

accrete -- v. To add terranes (small land masses or pieces of crust) to another, usually larger, land mass.

adaptation -- Change in an organism resulting from natural selection; a structure which is the result of such selection.

adult -- The mature stage of an organism, usually recognized by the organism's attaining the ability to reproduce.

adventitious roots -- A root that grows from somewhere other than the primary root, for example, roots that arise from stems or leaves.

aerobic -- Pertaining to the presence of free oxygen. Aerobic organisms require oxygen for their life processes.

alginate -- component of the cell walls of many [rhodophytes](#) and [kelps](#). Alginates have an affinity for water, and so help to slow desiccation when the algae are exposed to the air; they are commercially important in the production of paper, toothpaste, beer, and frozen foods.

alkaline -- Term pertaining to a highly basic, as opposed to acidic, substance. For example, hydroxide or carbonate of sodium or potassium.

allochthonous -- Refers to something formed elsewhere than its present location. Antonym of [autochthonous](#).

alternation of generations -- Life cycle in which **haploid** and **diploid** generations alternate with each other.

amber -- Fossilization where the organism is entrapped in resin and preserved whole.

ambulacra -- Row of tube feet of an [echinoderm](#).

amino acid -- unit molecule from which proteins are constructed by polymerization.

amniotic egg -- n. An egg that can be laid on land due to the presence of a fluid-filled amniotic sac (**amnion**) that cushions and protects the developing embryo; **amniote**- n. Any of a group of land-dwelling vertebrates that have an amnion during embryonic development, including reptiles, birds, and mammals.

amoeboid -- Having no definite shape to the cell, able to change shape.

amphiesma -- The outer covering of a [dinoflagellate](#), consisting of several membrane layers.

anaerobic -- Pertaining to the absence of free oxygen. Anaerobic organisms do not require oxygen for their life processes, in fact oxygen is toxic to many of them. Most anaerobic organisms are [bacteria](#) or [archaeans](#).

anagenesis -- Evolutionary change along an unbranching lineage; change without speciation.

anapsid -- n. A vertebrate distinguished by a skull with no openings in the side behind the eyes, e.g. turtles.

ancestor -- Any organism, population, or species from which some other organism, population, or species is descended by reproduction.

andesite -- [Igneous volcanic](#) rock, less [mafic](#) than [basalt](#), but more mafic than [dacite](#); rough volcanic equivalent of [diorite](#).

anemophily -- Seed plants which are pollinated by wind are said to be anemophilous.

angiosperm -- n. A group of plants that produce seeds enclosed within an ovary, which may mature into a fruit; [flowering plants](#).

anther -- The pollen producing tip of a **stamen**; part of a flower. [More info?](#)

antheridium -- The organ on a [gametophyte](#) plant which produces the sperm cells.

anthophyte -- A flowering plant, or any of its closest relatives, such as the Bennettitales, Gnetales, or Pentoxylales.

anticline -- A fold of rock layers that is convex upwards. Antonym of [syncline](#).

anus -- End of the digestive tract, or gut, through which waste products of digestion are excreted, as distinct from the mouth.

aperture -- Small opening, for example the opening in the test of a foram.

apical meristem -- Group of cells at the growing tip of a branch or root. It divides cells to create new tissues.

archegonium -- The organ on a [gametophyte](#) plant which produces the egg cell, and nurtures the young [sporophyte](#).

archipelago -- n. A group of islands; an expanse of water with scattered islands.

asexual reproduction -- A type of reproduction involving only one parent that usually produces genetically identical offspring. Asexual reproduction occurs without **meiosis** or **syngamy**, and may happen through budding, by the division of a single cell, or the breakup of an entire organism into two or more parts.

asphalt -- A dark bituminous substance found in natural beds. Residue from petroleum distillation.

ATP -- "adenosine triphosphate". A relatively stable, high energy molecule used to fuel chemical reactions within cells.

autochthonous -- Refers to something formed in its present location. Antonym of [allochthonous](#).

autotroph -- Any organism that is able to manufacture its own food. Most [plants](#) are autotrophs, as are many [protists](#) and [bacteria](#). Contrast with [consumer](#). Autotrophs may be **photoautotrophic**, using light energy to manufacture food, or **chemoautotrophic**, using chemical energy.

Avalonia -- n. A separate plate in the Early Paleozoic consisting of much of Northern Europe, Newfoundland, Nova Scotia, and some coastal parts of New England.

axil -- The angle formed between a leaf stalk and the stem to which it is attached. In flowering plants, buds develop in the axils of leaves.

Introduction to the Uniramia

Beetles and millipedes and flies and centipedes and....

The largest major group of [arthropods](#) is a clade that includes insects, millipedes, centipedes, and their relatives. This group, the Uniramia, was formerly defined to include the [Onychophora](#), which are now considered a separate clade. It is restricted here to include only "true" arthropods with exoskeletons and jointed appendages.

Uniramians have strictly **uniramous** appendages; that is, their legs have only one branch. Most are terrestrial, but some are aquatic for part or all of their life cycles. They make up by far the most common and diverse major clade of arthropods, and in fact make up over three-fourths of all known animal species on the planet -- and probably an even greater proportion of the total number of species, known and unknown. As the paleontologist J. Kukulová-Peck once put it: To a first approximation, every animal is an insect. Think about that the next time you call Orkin Pest Control.

Click on the buttons below to learn more about the Uniramia.

There is an immense amount of entomological information on the WWW. Click [here](#) for a list of

servers pertaining to insects and other uniramians, courtesy of the Department of Entomology at Colorado State University. Or click [here](#) for recipes.

Glumiflorae

Grasses, sedges, rushes, and cattails

The Glumiflorae are the grasses, sedges, rushes, and cattails, and are easily recognized by their “grassy” appearance. Though you might not guess it by looking at them, they are [flowering plants](#), producing numerous tiny flowers without showy petals.

The Glumiflorae is one of the largest and most familiar groups of plants. They are arguably the single-most important group of organisms on the planet today, providing us with corn, rice, wheat, and barley—the four highest grossing crops, as well as sugar cane. Their ecological importance in maintaining soil stability and providing turf has made them a common sight in yards and lawns around the world.

Click on the buttons below to learn more about the Glumiflorae.

For more information about the Glumiflorae, try the [Texas A&M listings for the Commelinidae](#)
[Glumiflorae pictures](#) at Wisconsin (includes Commelinaceae too).

Introduction to the Spermatophytes

The seed plants

The **spermatophytes**, which means "seed plants", are some of the most important organisms on Earth. Life on land as we know it is shaped largely by the activities of seed plants. Soils, forests, and food are three of the most apparent products of this group.

Seed-producing plants are probably the most familiar [plants](#) to most people, unlike mosses, liverworts, horsetails, and most other seedless plants which are overlooked because of their size or inconspicuous appearance. Many seedplants are large or showy. Conifers are seed plants; they include pines, firs, yew, redwood, and many other large trees. The other major group of seed-plants are the [flowering plants](#), including plants whose flowers are showy, but also many plants with reduced flowers, such as the oaks, grasses, and palms.

Click on the buttons below to find out more about the Spermatophytes.

You can navigate deeper into the Spermatophyte groups by selecting Systematics!

authors

Orchidales

Orchids and their kin

The Orchidales include the orchids and three smaller families. Together, they are one of the largest groups of [plants](#), although they are not of particular ecological or economic importance. *Vanilla* is cultivated for the strong flavor of its fruits; the little black specks in vanilla ice cream are actually the seeds from the orchid. Many kinds of orchids are cultivated and bred for their delicate and often bizarre flowers. The orchid pictured at right above is *Phalaenopsis McLellans*, a commonly cultivated genus. On the left is *Epipactis gigantea*, a native California orchid.

Unlike their closest relatives, most orchids have only a single large stamen attached to the pistil to form the **gynostemium**, visible in the center of an orchid flower. The flowers are bilaterally symmetrical, a necessity for reliable pollination by [bees](#). Many tropical species of orchid will rely on a single species of euglossine bee to pollinate them, and the bee will visit only that particular species of orchid which its kind pollinates. Because of this, the orchid must ensure that its pollen is properly delivered. This is most often achieved by gluing the whole supply of pollen to the visiting bee in a mass called the **pollinia**. When the bee visits another orchid of the same species, thousands of pollen grains are delivered, allowing the plant to mature thousands of tiny dust-like seeds.

The first orchids were large terrestrial plants, but like bromeliads, orchids took to the trees, where they have diversified to become the largest family of flowering plants. They are able to survive in the treetops in part because many species form **mycorrhizal** associations with [fungi](#). The fungi increase the area over which the orchid can acquire nutrients and water, while the orchid provides food to the fungus which it makes by photosynthesis.

Because orchids are primarily tropical epiphytes and small herbs, they do not have a fossil record. However, like palms and some members of the Iridales, they have **plicate** (corrugated) leaves, and these leaf forms are among the earliest known fossil [monocots](#).

The Orchidales may be divided into the following families:

Burmanniaceae

Thismiaceae

Corsiaceae

Orchidaceae - the orchids

Apostasioideae - *Apostasia* and *Neuwiedia*

Cypripedoideae - lady's slippers (4 genera)

Orchidoideae - most orchids (750 genera)

The first three families are sometimes put into another order, the **Burmnniales**, but are still considered the closest relatives of the Orchidaceae, so this separation is largely a matter of opinion. The Orchidales have traditionally been considered the "pinnacle" of monocot evolution, and so are listed last in many floras. This view does not reflect any biologically meaningful information, and so has been abandoned.

For more information about the Orchidales, try [Steve Saunders' exhaustive WWW orchid resource list](#), the [Orchidales Resources List](#) at Texas A&M, or the DELTA descriptions for the [Burmanniaceae](#), [Corsiaceae](#), and the [Orchidaceae](#)

Extensive horticultural information is available from [The Orchid House](#) in Ontario, Canada.

Paleo-Tethys Ocean -- n. A large ocean that originated between eastern Gondwana, Siberia, Kazakhstan, and Baltica in the Ordovician and finally closed in the Jurassic; replaced by the Tethys Ocean as eastern Pangea was assembled.

paleoherb -- Any member of a group of basal [flowering herbs](#) which may be the closest relatives of the [monocots](#). They include the water lilies, Piperales, and Aristolochiales.

paleosol -- Soil horizon from the geologic past.

Pangea -- n. A supercontinent that existed from the the end of the Permian to the Jurassic, assembled from large continents like Euramerica, Gondwana, and Siberia, as well as smaller landmasses like the Cathaysian and Cimmerian terranes; Greek for "all lands."

Pannotia -- n. A supercontinent that existed in the Late Precambrian and gave rise to the continents of Gondwana, Laurentia, Siberia, and Baltica in the Cambrian.

Panthalassic Ocean -- n. A vast ocean that existed from the Late Precambrian to the Jurassic, circling the globe and connecting to smaller oceans that developed throughout the Phanerozoic; also known as the **Panthalassa**.

papilla(e) -- Cellular outgrowths. These look like little bumps or fingers on the surface of cells.

paraphyletic -- Term applied to a group of organisms which includes the most recent common ancestor of all of its members, but not all of the descendants of that most recent common ancestor. [More?](#)

parapodia -- A sort of "false foot" formed by extension of the body cavity. Polychaetes and some insect larvae have parapodia in addition to their legs, and these provide extra help in locomotion.

parasite -- n. An organism that lives on or within a host (another organism); it obtains nutrients from the host without benefiting or killing (although it may damage) the host; **parasitic**- adj.; **parasitism**- n. a type of symbiotic relationship in which one organism benefits and the other does not.

parenchyma -- A generalized cell or tissue in a plant. These cells may manufacture or store food, and can often divide or differentiate into other kinds of cells.

parsimony -- Refers to a rule used to choose among possible cladograms, which states that the cladogram implying the least number of changes in character states is the best.

pathogenic -- Organism which causes a disease within another organism.

peat -- n. A deposit of partly decayed plant remains in a very wet environment; marsh or swamp deposit of plant remains containing more than 50 percent carbon.

pedipalps -- The second pair of appendages of [cheliceromorphs](#). In many arachnids, such as spiders, the pedipalps are enlarged in the male and used for copulation.

pelagic -- Pelagic organisms swim through the ocean, and may rise to the surface, or sink to the bottom. They are not confined to live on the bottom as benthic organisms do.

peptidoglycan -- carbohydrate polymer cross-linked by proteins. It is found in the cell wall of Gram positive [bacteria](#), where it stains with the dye crystal-violet.

perennial -- A plant which continues to grow after it has reproduced, usually meaning that it lives for several years.

perianth -- The **sepals** and **petals** of a flower are together called the perianth; literally "around the anthers". [More info?](#)

peridinin -- carotenoid pigment found in dinoflagellates.

periphyton -- Dense strands of algal growth that cover the water surface between the emergent aquatic plants. [Spirogyra](#) is commonly responsible for this growth.

peristome -- A set of cells or cell parts which surround the opening of a moss sporangium. In many mosses, they are sensitive to humidity, and will alter their shape to aid in spore dispersal.

permineralization -- Fossilization process that occurs when minerals, carried by ground water, enter and harden in the pores of an organism's structures.

petal -- One of the outer appendages of a flower, located between the outer **sepals** and the **stamens**. Petals often display bright colors that serve to attract pollinators. [More info?](#)

Phanerozoic -- n. The geologic eon that includes the interval of time from approximately 543 million years ago to the present, comprising the Paleozoic, Mesozoic, and Cenozoic eras.

pharyngeal slits -- Characteristic of [chordates](#), pharyngeal slits are openings through which water is taken into the pharynx, or throat. In primitive chordates the pharyngeal slits are used to strain water and filter out food particles; in fishes they are modified for respiration. Most terrestrial vertebrates have pharyngeal slits only in the embryonic stage.

pharynx -- Cavity in the digestive tract just past the mouth itself. May be muscularized for sucking or swallowing in various animals.

phloem -- Nutrient-conducting tissue of vascular plants.

phosphate -- an ion consisting of a phosphorus atom and four oxygen atoms. Among other things, it is used in the construction of nucleic acids.

photic zone -- Region of the ocean through which light penetrates; and the place where photosynthetic marine organisms live.

photosynthesis -- biochemical process in which light energy is absorbed by chlorophyll, and is used to fuel the building of sugar molecules.

phragmoplast -- The cell plate formed during cell division.

phycocyanin -- blue, water-soluble pigment found in the [cyanobacteria](#) and the [red algae](#).

phycoerythrin -- red, water-soluble pigment found in the cyanobacteria and red algae.

phylogenetics -- Field of biology that deals with the relationships between organisms. It includes the discovery of these relationships, and the study of the causes behind this pattern. [More?](#)

phylogeny -- The evolutionary relationships among organisms; the patterns of lineage branching produced by the true evolutionary history of the organisms being considered.

phylum -- n. A category in the hierarchy of animal classification between class and kingdom; **phyla**- pl.

phytomelanin -- a papery "sooty" black layer over the seed of plants in the [Asparagales](#), which includes agaves, aloes, onions and hyacinths. It is an important character for defining the group.

phytoplankton -- Tiny, free-floating, photosynthetic organisms in aquatic systems. They include [diatoms](#), [desmids](#), and [dinoflagellates](#).

pigment -- any colorful compound, used by living things to absorb or block sunlight, and in sexual displays. [More info?](#)

pillow lava -- [Lava](#) extruded beneath water characterised by [pillow-type shapes](#).

pinnately compound -- Leaves which are divided up like a feather are said to be pinnately compound.

pistil -- The central set of organs in a flower; it is composed of one or more **carpels**. [More info?](#)

pith -- To severely damage the brain of a frog, also any central region of **parenchyma** tissue within a plant stem.

pits -- Thin regions of the cell wall in xylem conducting cells. Their structure is an important characteristic for recognizing different kinds of wood.

placenta -- n. In mammals, a tissue formed within the uterus through which nutrients are passed from the mother to the embryo (and later the fetus) and its wastes are removed; **placental**- n. (adj.) A mammal whose young form a placenta as they develop in the mother's uterus.

plankton -- n. Very small, free-floating organisms of the ocean or other aquatic systems, including phytoplankton, which produce their own nutrients through photosynthesis, or zooplankton, which get their nutrients from organisms.

plasma membrane -- Outer membrane of a cell, sometimes called the cell membrane. The term plasma membrane is used more frequently when discussing prokaryotes.

plasmid -- Circular loop of DNA in prokaryotes. Eukaryotic DNA is organized into chromosomes.

plasmodesmata -- Cytoplasmic connections between neighboring cells in plant tissues.

plasmogamy -- A process of fusion of the cytoplasm of two cells; the first step in **syngamy**.

plastid -- Any of several pigmented cytoplasmic organelles found in plant cells and other organisms, having various physiological functions, such as the synthesis and storage of food.

plate -- n. Rigid parts of the Earth's [crust](#) and part of the Earth's upper [mantle](#) that move and adjoin each other along zones of seismic activity. The theory that the crust and part of the mantle are divided into plates that interact with each other causing seismic and tectonic activity is called **plate tectonics**.

platyspermic -- Having seeds which are flattened and disc-like. Contrast with **radiospermic**.

plesiomorphy -- A primitive character state for the taxa under consideration.

pleurae -- In trilobites and other arthropods, pleurae are elongated flat outgrowths from each body segment, that overlie and protect the appendages.

plicate -- Folded like a paper fan, as in the leaves of palms, cyclanthoids, and some orchids.

pluton -- n. Any body of igneous rock that solidified below the earth's surface.

plutonic -- Applies to igneous rocks formed beneath the surface of the Earth; typically with large crystals due to the slowness of cooling. Synonym of [intrusive](#). Antonym of [volcanic](#).

polarity of characters -- The states of characters used in a cladistic analysis, either original or derived. Original characters are those acquired by an ancestor deeper in the phylogeny than the most recent common ancestor of the taxa under consideration. Derived characters are those acquired by the most recent common ancestor of the taxa under consideration.

pollen -- The **microspore** of [seed plants](#).

pollen tube -- In [seed plants](#), the extension of the male gametophyte as it emerges from the pollen grain in search of the female gametophyte.

pollination -- Process of transferring the pollen from its place of production to the place where the egg cell is produced. This may be accomplished by the use of wind, water, [insects](#), [birds](#), [bats](#), or other means. Pollination is usually followed by **fertilization**, in which sperm are released from the pollen grain to unite with the egg cell.

pollinator -- Animal which carries pollen from one [seed plant](#) to another, unwittingly aiding the plant in its reproduction. Common pollinators include [insects](#), especially bees, butterflies, and moths, [birds](#), and [bats](#).

pollinia -- A mass of fused pollen produced by many [orchids](#).

polymer -- a large molecule constructed from many smaller identical units. These include proteins, nucleic acids, and starches.

polyphyletic -- Term applied to a group of organisms which does not include the most recent common ancestor of those organisms; the ancestor does not possess the character shared by members of the group. [More?](#)

pore -- Any opening into or through a tissue or body structure.

predator -- Organism which hunts and eats other organisms. This includes both carnivores, which eat animals, and herbivores, which eat plants.

prey -- Organism hunted and eaten by a predator.

primitive -- Describes a character state that is present in the common ancestor of a clade. A primitive character state is inferred to be the original condition of that character within the clade under consideration. For example, "presence of hair" is a primitive character state for all mammals, whereas the "hairlessness" of whales is a derived state for one subclade within the Mammalia.

proboscis -- Elongated organ, usually associated with the mouth. The proboscis is an important feeding appendage in [echiurans](#).

producer -- Any organism which brings energy into an ecosystem from inorganic sources. Most [plants](#) and many protists are producers.

prokaryotic -- Literally "before the nucleus", the term applies to all [bacteria](#) and [archaea](#). Prokaryotic cells have no internal membranes or cytoskeleton. Their DNA is circular, not linear.

protein -- class of biochemical compounds constructed from amino acids. Proteins may be structural, such as those that make up hair and cartilage, or they may be reactive, such as the enzymes.

proteinaceous -- describes any structure which is composed of protein.

proteoglycan --

protoplasm -- All the contents of a cell, including the nucleus. (see: cytoplasm)

protostele -- When a plant's vascular tissue develops in a solid central bundle, it is said to have a protostele. See also siphonostele and eustele.

pseudoelaters -- Moisture-sensitive cells produced in the sporangium of [hornworts](#).

pseudoextinction -- The apparent disappearance of a taxon. In cases of pseudoextinction, this disappearance is not due to the death of all members, but the evolution of novel features in one or more lineages, so that the new clades are not recognized as belonging to the paraphyletic ancestral group, whose members have ceased to exist. The Dinosauria, if defined so as to exclude the birds, is an example of a group that has undergone pseudoextinction.

pseudopodia -- Fingerlike extensions from an amoeboid cell; literally "false feet".

pteridophyte -- Plant in which the **sporophyte** generation is the larger phase and in which the **gametophyte** lives an existence independent of its parent sporophyte. Pteridophytes are almost all vascular plants, and include the [lycophytes](#), [trimerophytes](#), [sphenophytes](#), and ferns.

pteridosperm -- An extinct group of [seed plants](#) which bore fern-like leaves.

punctuated equilibrium -- A model of evolution in which change occurs in relatively rapid bursts, followed by longer periods of stasis.

pupa -- In metamorphosing insects, a stage between the **larva** and adult during which the organism undergoes major developmental changes.

pycnoxylic -- Wood in which there is little or no **parenchyma** tissue among the xylem is called pycnoxylic. Conifers and [flowering plants](#) have pycnoxylic wood. Contrast with [mannoxylic](#).

pygidium -- In trilobites, the posterior division of the body, formed by fusion of the **telson** with one or more posterior **pleurae**.

Introduction to the Lycophyta

Club mosses and Scale trees

The lycophytes are a small and inconspicuous group of [plants](#) today, but in the Carboniferous some lycophytes were forest-forming trees more than 35 meters tall. Lycophytes are the oldest extant group of vascular plants, and dominated major habitats for 40 million years.

The club mosses (Lycopodiales) are usually evergreen, and have been used as Christmas decorations, though their flammable spores and increasing rarity has made this illegal in some states. Other lycophytes, such as *Selaginella*, may form extensive carpets in the understory of wet tropical forests.

The most significant feature of lycophytes are **microphylls**, a kind of leaf which has arisen and evolved independently from the leaves of other vascular plants. The microphyll has only a single unbranched strand of vascular tissue, or **vein**, whereas **megaphylls**, found in other plants with leaves, have multiple veins, usually branching one or more times within the leaf.

Click on the buttons below to learn more about the Lycophyta.

The University of Wisconsin offers images of lycophytes used in their [General Botany](#) courses.

Or peruse Dr. John Clayton's article on [New Zealand native plants](#) for use in aquaria, including *Isoetes*.

authors

Introduction to the Fungi

Of athlete's foot, champignons, and beer. . .

The Kingdom Fungi includes some of the most important organisms, both in terms of their ecological and economic roles. By breaking down dead organic material, they continue the cycle of nutrients through ecosystems. In addition, most vascular [plants](#) could not grow without the symbiotic fungi, or **mycorrhizae**, that inhabit their roots and supply essential nutrients. Other fungi provide numerous drugs (such as penicillin and other antibiotics), foods like mushrooms, truffles and morels, and the bubbles in bread, champagne, and beer.

Fungi also cause a number of plant and animal diseases: in humans, ringworm, athlete's foot, and several more serious diseases are caused by fungi. Because fungi are more chemically and genetically similar to animals than other organisms, this makes fungal diseases very difficult to treat. Plant diseases caused by fungi include rusts, smuts, and leaf, root, and stem rots, and may cause severe damage to crops. However, a number of fungi, in particular the yeasts, are important "model organisms" for studying problems in genetics and molecular biology.

Click on the buttons below to learn more about the Fungi.

For more about fungus:

Try the [Fun Facts About Fungi](#) page at the University of Michigan or visit [Mykoweb](#), an on-line mushroom museum with many nice photos and links. For those with some biological training, try the excellent home page for the [Introductory Mycology](#) course taught by Joseph Spatafora.

We don't have a large exhibit on fungi. Until we do, may we suggest that you try the [images of fungi](#) offered by Tom Volk through the University of Wisconsin-La Crosse. Or consult the extensive listings of the [WWW Virtual Library of Mycology](#) to access links to on-line mycological information. The [WWW Virtual Library Yeast Page](#) provides links to sources of information on yeasts, in particular to sources dealing with genetics and molecular biology.

We also maintain a list of on-line [Mycological and Lichenological Collection Catalogs](#) which you can search for more information.

Fungi: Life History and Ecology

*This photograph taken using the UCMF
[Environmental Scanning Electron Microscope](#)*

Fungi exist primarily as filamentous dikaryotic organisms.

As part of their life cycle, fungi produce spores. In this electron micrograph of a mushroom gill, the four spores produced by meiosis (seen in the center of this picture) are carried on a clublike **sporangium** (visible to the left and right). From these spores, haploid **hyphae** grow and ramify, and may give rise to asexual sporangia, special hyphae which produce spores without meiosis.

The sexual phase is begun when haploid hyphae from two different fungal organisms meet and fuse. When this occurs, the cytoplasm from the two cells fuses, but the nuclei remain separate and distinct. The single hypha produced by fusion typically has two nuclei per "cell", and is known as a **dikaryon**, meaning "two nuclei". The dikaryon may live and grow for years, and some are thought to be many centuries old. Eventually, the dikaryon forms sexual sporangia in which the nuclei fuse into one, which then undergoes meiosis to form haploid spores, and the cycle is repeated.

Some fungi, especially the [chytrids](#) and zygomycetes, have a life cycle more like that found in many [protists](#). The organism is haploid, and has no diploid phase, except for the sexual sporangium. A number of fungi have lost the capacity for sexual reproduction, and reproduce by asexual spores or by vegetative growth only. These fungi are referred to as Fungi Imperfecti, and

include, among other members, the athlete's foot and the fungus in bleu cheese. Other fungi, such as the yeasts, primarily reproduce through asexual **fission**, or by **fragmentation** -- breaking apart, with each of the pieces growing into a new organism.

Fungi are heterotrophic.

Fungi are not able to ingest their food like animals do, nor can they manufacture their own food the way plants do. Instead, fungi feed by **absorption** of nutrients from the environment around them. They accomplish this by growing through and within the **substrate** on which they are feeding. Numerous hyphae network through the wood, cheese, soil, or flesh from which they are growing. The hyphae secrete digestive enzymes which break down the substrate, making it easier for the fungus to absorb the nutrients which the substrate contains.

This filamentous growth means that the fungus is in intimate contact with its surroundings; it has a very large surface area compared to its volume. While this makes diffusion of nutrients into the hyphae easier, it also makes the fungus susceptible to dessication and ion imbalance. But usually this is not a problem, since the fungus is growing within a moist substrate.

Most fungi are **saprophytes**, feeding on dead or decaying material. This helps to remove leaf litter and other debris that would otherwise accumulate on the ground. Nutrients absorbed by the fungus then become available for other organisms which may eat fungi. A very few fungi actively capture prey, such as *Arthrotrrys* which snares nematodes on which it feeds. Many fungi are **parastitic**, feeding on living organisms without killing them. Ergot, corn smut, Dutch elm disease, and ringworm are all diseases caused by parasitic fungi.

Mycorrhizae are a symbiotic relationship between fungi and plants.

Most [plants](#) rely on a symbiotic fungus to aid them in acquiring water and nutrients from the soil. The specialized roots which the plants grow and the fungus which inhabits them are together known as **mycorrhizae**, or "fungal roots". The fungus, with its large surface area, is able to soak up water and nutrients over a large area and provide them to the plant. In return, the plant provides energy-rich sugars manufactured through photosynthesis. Examples of mycorrhizal fungi include truffles and *Auricularia*, the mushroom which flavors sweet-and-sour soup.

In some cases, such as the vanilla [orchid](#) and many other orchids, the young plant cannot establish itself at all without the aid of its fungal partner. In liverworts, mosses, [lycophytes](#), ferns, conifers, and [flowering plants](#), fungi form a symbiotic relationship with the plant. Because mycorrhizal associations are found in so many plants, it is thought that they may have been an essential element in the transition of plants onto the land.

More information on one ecologically and economically important group of fungi, the Uredinales or rust fungi, is available through the [Arthur Herbarium](#) at [Purdue University](#).

Introduction to the Liliopsida

The Monocots

The Monocotyledonae comprise one-quarter of all [flowering plant](#) species. They include some of the largest and most familiar groups of plants, including lilies, [orchids](#), [agaves](#), palms, and [grasses](#). Though often described as having a stereotype morphology, the monocots are actually quite diverse, ranging from tiny duckweeds to large palms and climbing vines.

Economically, monocots are perhaps the most important organisms on earth. Our four most important foods -- corn, rice, wheat, and barley -- all come from monocots. Bamboo and palms are a primary source of building materials and fibers in many tropical countries. Sugar cane, pineapples, dates, bananas, and many of our familiar tropical fruits also come from monocots.

Click on the buttons below to learn more about the Monocots.

Photo of pampas grass by Brian R. Speer; all others courtesy the [Jepson Herbarium](#), and used with permission.

Asparagales

The Asparagales include nearly 5000 species of agaves, aloes, onions, day-lilies and related plants. As such, they are one of the most structurally diverse groups of [monocots](#), ranging from small herbs to flowering Agaves that may reach more than ten meters in height. They provide us with asparagus, onion, and garlic, as well as many garden plants, such as daffodils. Agave was of particular importance to the Aztecs, supplying fibers for instruments and paper, as well as the drink now called tequila.

The picture above shows some of the structural and taxonomic diversity in the Asparagales. The plants shown are (clockwise, from upper left): *Aloe saponaria* growing in La Jolla, California; *Amaryllis*, a common ornamental; *Dracaena draco*, a sizeable tree on the Canary Islands; *Triteilia*, a relative of the onion; and *Maianthemum dilatatum*, an understory herb growing in northern California. All pictures courtesy of the Jepson Herbarium.

Most members of the Asparagales produce a tight cluster of leaves at the base of the plant or on top of a squat trunk; from the top of this, a long stalk develops bearing the flowers. A few members, such as Asparagus and Solomon's seal have leaves attached along the stem.

A permineralized fossil plant called *Protoyucca* is known from the [Miocene](#) of northwestern Nevada. Its vascular structure and secondary growth are not unlike those found in the Joshua tree (*Yucca brevifolia*).

The Asparagales have been lumped into the [Liliales](#) since the beginning of this century, though they share no synapomorphies with that group. They have recently been removed again, and are now distinguished (mostly) by the presence of a layer of **phytomelanin** around their seeds. This appears as a papery "sooty" black layer over the seed.

For more information about the Asparagales, try the DELTA descriptions for the [Agavaceae](#), [Alliaceae](#), [Amaryllidaceae](#), [Anthericaceae](#), [Aphyllanthaceae](#), [Asparagaceae](#), [Asphodelaceae](#), [Asteliaceae](#), [Blandfordiaceae](#), [Calectasiaceae](#), [Convallariaceae](#), [Cynastraceae](#), [Dasypogonaceae](#), [Doryanthaceae](#), [Dracaenaceae](#), [Eriospermaceae](#), [Hanguanaceae](#), [Hemerocallidaceae](#), [Herreriaceae](#), [Hostaceae](#), [Hyacinthaceae](#), [Hypoxidaceae](#), [Ixoliriaceae](#), [Luzuriagaceae](#), [Nolinaceae](#), [Philesiaceae](#), [Phormiaceae](#), [Ruscaceae](#), [Tecophilaeaceae](#), [Velloziaceae](#), and the [Xanthorrhoeaceae](#)

Learn about the [relationships of Agavaceae](#) and other closely allied families. You can view images of [Agavaceae](#) at Texas A&M Botany. They also have images of the [Amaryllidaceae and Hemerocallidaceae](#) listed under the Liliaceae. View images of [Malagasy Dracaenaceae](#) at the Missouri Botanical Garden

Introduction to the Aves

The Birds

The vertebrate class Aves includes the birds, an extremely distinctive and successful clade, with an estimated 9000 species worldwide, including the snowy owl pictured here. Although descended from the [dinosaurs](#), birds have evolved remarkable specializations for flight: a unique "one-way" breathing system, light yet strong hollow bones, a skeleton in which many bones are fused or lost, powerful flight muscles, and -- most importantly -- feathers.

Click on the buttons below to learn more about birds.

You can navigate deeper into the birds by selecting "Systematics"!

UCMP Special Exhibit: [Vertebrate Flight](#)

Visit our series of pages on the wonder of flight in vertebrates, including a discussion of [avian flight](#).

Interested in birds? There are several good ornithology sites on the Web. Check out the [California State University BioWeb](#) listing of ornithological sites, or the list of [Electronic Resources on Ornithology](#). All of these have extensive lists of links to Web sites. [Birding on the Web](#) is also an excellent site.

We also maintain our own list of [On-line Ornithology Collections and Resources](#).

For a remarkable set of images of birds in flight, check out [How Birds Fly](#). Serious avian aficionados will be interested in the great multivolume reference book, [The Birds of North America](#).

Chiroptera

Night fliers

Small and furry, bats are the only [mammals](#) to have achieved powered flight. Their arms are spindly, with membranes stretched between the fingers on each hand. This arrangement makes their wings quite different from those of [birds](#) and [pterosaurs](#), and in fact the bats have evolved flight quite independently.

Most bats also differ from other flying animals in their reliance on hearing for navigation. While birds have large eyes and keen sight, many bats have a poor sense of vision, and must rely on hearing sonar echos to find their way around. This might make bats easy prey for strong fliers with keen sight, but they get around this problem because they are **nocturnal**, coming out at night, or by living in tropical forests, where the light is dim and the obstacles are many.

Despite their resemblance to [rodents](#), bats are not closely related to mice at all. Though their exact placement is still uncertain, there is recent evidence that they may be more closely related to the [primates](#). Whatever their relationships, bats are among the most successful groups of mammals: there are nearly 1,000 species of bats around the world, making up about one quarter of all mammal species.

Click on the buttons below to learn more about the Chiroptera.

Want to learn more about flight? What do a pterosaur, a bat, and a bird have in common? How do we know they evolved flight independently? Find out for yourself!

To learn much more about bats -- from their scientific names to how to keep them out of your belfry -- visit the informative Website maintained by [Bat Conservation International](#). Hear an archived radio broadcast about bats, read fascinating background information, or follow bat-related links from the [Watershed Radio](#) Website. Or try this [bat conservation and information page](#) (maintained in Germany) for links to many more on-line sources of bat information.

Introduction to the Trimerophytes

A number of fossil vascular [plants](#) of the [Devonian](#) are superficially similar to the "rhyniophytes" but show some features not found in the rhyniophytes. These plants are grouped together in the Trimerophytophyta, the "trimerophytes." This group is almost certainly **paraphyletic**; that is, it does not include all the descendants of a common ancestor. Nonetheless, trimerophytes are of great evolutionary interest, because they include fossils that are close to the common ancestry of prominent plant taxa, such as ferns, [progymnosperms](#), and [sphenophytes](#). The trimerophytes appear to form a sort of basal group close to the ancestry of these major taxa.

Like the rhyniophytes, trimerophytes lacked leaves and roots; most of the plant body consisted of branching stems that were photosynthetic throughout their length. Vascular tissue was present, forming a solid central bundle in the center of the stem, or **protostele**. However, whereas rhyniophytes branched **dichotomously** -- stems always branched into two equal branches -- trimerophytes branched **pseudomonopodially**, which is a way of saying that branching was unequal, forming a main stem, or axis, with several smaller lateral branches. You can see this pattern of branching in the picture of *Psilophyton forbesii*, at right. Lateral branches typically branched dichotomously, and were often shortened to form bushy "webs" of small, closely spaced branches. Some trimerophytes also bore **enations** -- small flaps of tissue lacking vascularization, and therefore not true leaves -- on the main stems, giving them a superficially "thorny" appearance.

Like the rhyniophytes, but unlike the superficially similar [zosterophylls](#) from the same time period, trimerophytes bore sporangia at the tips of branches. The spindle-shaped sporangia produced only one type of spore: trimerophytes were thus **homosporous**. Spores released from the sporangia would have germinated into **gametophytes**, but no fossil trimerophytes gametophytes have been identified, and we do not know whether trimerophytes, like their later relatives the ferns, sphenopsids, and seed plants, had small, inconspicuous gametophytes.

Trimerophytes varied in size from a few centimeters to nearly a meter tall; large trimerophytes were among the largest plants of the Early Devonian. One of the meter-high trimerophytes, *Pertica quadrifaria*, has attained some post-extinction fame as the state fossil of Maine. Another species in this genus is pictured below.

Introduction to the Sphenophyta

Yesterday's trees, today's horsetails

Three hundred million years ago, a walk through a lowland forest or swamp, or along a riverbank or floodplain, would have revealed a great variety of trees, even though the familiar conifers and [flowering plants](#) of today were not present. Prominent among the trees of the time, and also common in the shrubbery, were plants in the Sphenophyta, distinguished by their straight stems with branches or leaves arranged in regular whorls. Some [Paleozoic](#) sphenophytes grew up to thirty meters tall (nearly 100 feet).

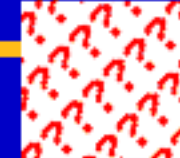

Today, the sphenophytes consist of only one genus, *Equisetum*, with about thirty living species known worldwide. A few species, like the tropical Mexican species pictured above, may reach ten feet in height, but most living species are small, weedy plants -- remnants of former glory. *Equisetum* are known as horsetails, foxtails, or scouring rushes -- this last name is derived from the fact that *Equisetum* stores granules of silica within its cells, making it an effective tool for scrubbing pots and polishing wood. These plants are sometimes pestiferous weeds, and are somewhat toxic to livestock, but they also have medicinal value: *Equisetum* was used in traditional native American and Ukrainian medicine to stop bleeding, and recent research has shown that *Equisetum* is also effective as a diuretic.

Click on the buttons below to find out more about the Sphenophyta.

[Images of living sphenophytes](#) are available from the [University of Wisconsin](#).

UCMP Glossary: M

| [A](#) | [B](#) | [C](#) | [D](#) | [E](#) | [F](#) | [G](#) | [H](#) | [I](#) | [J](#) | [K](#) | [L](#) | **M** | [N](#) | [O](#) | [P](#) | [Q](#) | [R](#) |
[S](#) | [T](#) | [U](#) | [V](#) | [W](#) | [X](#) | [Y](#) | [Z](#) |

macroscopic -- Objects or organisms that are large enough to be seen with the naked eye.

mafic -- Term used to describe the amount of dark-colored iron and magnesium minerals in an [igneous](#) rock. Complement of [felsic](#).

magma -- n. Molten rock generated within the Earth; forms intrusive (solidifies below the surface) and extrusive (solidifies above the surface) igneous rocks.

magnoliid -- Any member of the basal assemblage of [flowering plants](#).

male -- In organisms with separate sexes, the one which produces sperm.

mannoxylic -- Wood in which there is a great deal of **parenchyma** tissue among the xylem is called mannoxylic. [Cycads](#) and **pteridosperms** have mannoxylic wood. Contrast with [pycnoxylic](#).

mantle -- That portion of the interior of the Earth that lies between the [crust](#) and the [core](#).

marine -- Refers to the ocean.

marine terrace -- n. A platform of marine deposits (typically sand, silt, gravel) sloping gently seaward. Such a platform may be exposed along the coast, forming cliffs, due to uplift and/or the lowering of sea level, e.g., Marine terraces of coastal Southern California.

marl -- n. A loose, crumbly deposit consisting of clay and calcium carbonate and formed in marine or freshwater conditions.

marsupial -- n. (adj.) A mammal whose young are born while still embryos, and must crawl into its mother's external pouch (called the **marsupium**) to finish development.

mastigoneme -- Small hair-like filaments found on the "hairy" flagellum of the [Chromista](#).

megaspore -- In plants which are **heterosporous**, the larger kind of spore is called a megaspore; it usually germinates into a female (egg-producing) **gametophyte**. Contrast with **microspore**.

meiosis -- A two-stage type of cell division in sexually reproducing organisms. In meiosis, a diploid cell divides to produce four haploid cells, each with half the original chromosome content. For this reason, meiosis is often called a "reduction division". In organisms with a diploid life cycles, the products of meiosis are usually called **gametes**. In organisms with an alternation of generations, the products of meiosis are called spores.

melange -- A body of rocks consisting of large blocks (mappable size) of different rocks jumbled together with little continuity of contacts.

membrane -- Semi-fluid structure which bounds all cells, and partitions the interior of eukaryotic cells. It consists primarily of two lipid layers, with proteins "dissolved" in the lipids.

meristem -- Group of undifferentiated cells from which new tissues are produced. Most plants have **apical meristems** which give rise to the primary tissues of plants, and some have **secondary meristems** which add wood or bark.

merophytes -- Group of cells which have all been produced from the same initial cell. Leaves and stems in particular are often built from specific patterns of merophytes.

mesoderm -- In animals with three tissue layers (i.e. all except [sponges](#) and [cnidarians](#)), the middle layer of tissue, between the **ectoderm** and the **endoderm**. In vertebrates, for instance, the mesoderm forms the skeleton, muscles, heart, spleen, and many other internal organs.

mesogloea -- Jellylike material between the outer ectoderm and the inner endoderm of [cnidarians](#). May be very thin or may form a thick layer (as in many jellyfish).

mesokaryotic -- Nuclear condition unique to the [dinoflagellates](#) in which the chromosomes remain permanently condensed.

metamorphic rock -- Any rock derived from other rocks by chemical, mineralogical and structural changes resulting from pressure, temperature or shearing stress.

metamorphism -- n. The process of altering the chemical or mineralogical composition of a rock through different amounts of heat and pressure below the surface of the Earth; **metamorphose**- v.

metamorphosis -- n. A process of developmental change whereby a larva reaches adulthood only after a drastic change in morphology; occurs in most amphibians and insects, for some insects, this change may include another stage (pupa) before the adult stage; **metamorphose**- v.

microfossil -- n. A very small fossil, best studied with the aid of a microscope, e.g. foraminifera, radiolarians, and small vertebrate fossils such as teeth. *macrofossil*-ant.

microphyll -- A kind of leaf, specifically one which has a single, unbranched vein in it. Microphylls are only found in the [lycophytes](#).

microscopic -- Objects or organisms that are too small to be seen with the naked eye.

microspore -- In plants which are **heterosporous**, the smaller kind of spore is called a microspore; it usually germinates into a male (sperm-producing) **gametophyte**. Contrast with **megaspore**.

microtubules -- Type of filament in eukaryotic cells composed of units of the protein tubulin. Among other functions, it is the primary structural component of the eukaryotic flagellum.

microvilli -- Thin fingerlike protrusions from the surface of a cell, often used to increase absorptive capacity or to trap food particles. The "collar" of [choanoflagellates](#) is actually composed of closely spaced microvilli.

mid-oceanic ridges -- Elongated rises on the ocean floor where [basalt](#) periodically erupts, forming new oceanic crust; similar to continental [rift zones](#).

mineralization -- The process of replacing any organism's original material with a mineral.

mitochondrion -- Complex organelle found in most eukaryotes; believed to be descended from free-living bacteria that established a symbiotic relationship with a primitive eukaryote. Mitochondria are the site of most of the energy production in most eukaryotes; they require oxygen to function. See: **double membrane**.

mitosis -- The process of nuclear division in eukaryotes. It is one step in cytokinesis, or cellular division. [MORE ?](#).

molds -- Fossils formed when the sediment surrounding a buried organism hardens. When the organism decays, its impression is left in the rock and can be seen if the rock is broken open.

monophyletic -- Term applied to a group of organisms which includes the most recent common ancestor of all of its members and all of the descendants of that most recent common ancestor. A monophyletic group is called a clade. [More?](#)

monsoonal -- adj. Describes a climate pattern with a wind system that changes direction with the seasons; this pattern is dominant over the Arabian Sea and Southeast Asia.

moraine -- n. A mound or ridge of sediment deposited by a glacier; **lateral moraine**- n. deposited to the side of a glacier; **terminal moraine**- n. deposited to the front of a glacier; **ground moraine**- n. deposited on the land surface.

morphology -- n. The form and structure of anything, usually applied to the shapes, parts, and arrangement of features in living and fossil organisms.

motile -- Able to move oneself about, capable of self-locomotion.

mouth -- Front opening of the digestive tract, into which food is taken for digestion. In [flatworms](#), the mouth is the only opening into the digestive cavity, and is located on the "belly" of the worm.

MTOC -- (microtubule organizing center) MTOCs are bundles of protein tubes which may be found at the base of a [eukaryotic](#) flagellum. In animals, they also function in creating the arrays of microtubules that pull the chromosomes apart during mitosis.

mucus -- Sticky secretion used variously for locomotion, lubrication, or protection from foreign particles.

multicellular -- Any organism which is composed of many cells is termed multicellular.

muscle -- Bundle of contractile cells which allow animals to move. Muscles must act against a [skeleton](#) to effect movement.

mycorrhizae -- Symbiotic association between a [fungus](#) and the roots or rhizoids of a [plant](#). [More info?](#)

myotome -- Segment of the body formed by a region of muscle. The myotomes are an important feature for recognizing early [chordates](#).

[S](#) | [T](#) | [U](#) | [V](#) | [W](#) | [X](#) | [Y](#) | [Z](#) |

calcareous -- adj. Term used to describe a structure, secreted by an organism, that consists of or contains calcium carbonate (CaCO_3), e.g., the shell of a bivalve.

calcite -- A common crystalline form of natural calcium carbonate, CaCO_3 , that is the basic constituent of limestone, marble, and chalk. Also called calcspar.

calcium carbonate -- a "salt" used by many marine invertebrates, such as corals and [echinoderms](#), and by protists, such as [coccolithophorids](#), to construct their exoskeletons.

caldera -- n. A large circular volcanic depression, often originating due to collapse.

canopy -- Layer of vegetation elevated above the ground, usually of tree branches and epiphytes. In tropical forests, the canopy may be more than 100 feet above the ground.

capsid -- The protein "shell" of a free virus particle.

carbohydrates -- class of biochemical compounds which includes sugars, starch, chitin, and steroids.

carbon film -- Thin layer of carbon remains of past life found in [sedimentary rocks](#).

carbonate -- n. (adj.) A mineral composed mainly of calcium (Ca) and carbonate (CO_3) ions, may also include magnesium (Mg), iron (Fe) and others; n. rock or sediments derived from debris of organic materials composed mainly of calcium and carbonate (e.g., shells, corals, etc.) or from the inorganic precipitation of calcium (and other ions) and carbonate from solution (seawater). For example, [limestone](#) or [dolomite](#). **carbonate platform** – n. A broad (100s of meters), flat, shallow submarine expanse of carbonate rock, more common in the early-middle Paleozoic. **carbonate bank** – n. A narrow (10s of meters), fairly flat, shallow, submarine plateau of carbonate rock, more common from the middle-late Paleozoic to the present, e.g., the Bahama Banks.

carnivore -- Literally, an organism that eats meat. Most carnivores are [animals](#), but a few fungi, plants, and protists are as well.

carpel -- A unit of the **pistil**; it is evolutionarily a modified leaf.

casts -- Fossils formed when water containing minerals leaks into a mold. The minerals harden to form a copy of the original structure or organism.

cataphyll -- In [cycads](#), a scale-like modified leaf which protects the developing true leaves.

Cathaysian terranes -- n. A set of small landmasses that developed in tropical to subtropical latitudes on the eastern side of Pangea during the Permian and Triassic, includes modern North China (Sino-Korea), South China (Yangtze), Eastern Qiangtang, Tarim, and Indochina.

cell -- Fundamental structural unit of all life. The cell consists primarily of an outer plasma membrane, which separates it from the environment; the genetic material (DNA), which encodes heritable information for the maintenance of life; and the cytoplasm, a heterogeneous assemblage of ions, molecules, and fluid.

cell cycle -- Complete sequence of steps which must be performed by a cell in order to replicate itself, as seen from [mitotic](#) event to mitotic event. Most of the cycle consists of a growth period in which the cell takes on mass and replicates its DNA. Arrest of the cell cycle is an important feature in the reproduction of many organisms, including humans.

cell membrane -- The outer membrane of a cell, which separates it from the environment. Also called a plasma membrane or plasmalemma.

cell wall -- Rigid structure deposited outside the cell membrane. [Plants](#) are known for their cell walls of [cellulose](#), as are the green algae and certain protists, while [fungi](#) have cell walls of [chitin](#).

cellulose -- carbohydrate polymer of the simple sugar glucose. It is found in the cell walls of [plants](#) and [green algae](#), as well as dinoflagellates. Cellulose is the most abundant compound on earth that is manufactured by living things.

cephalon -- In [trilobites](#), the head shield bearing the eyes, antennae, and mouth.
[More info?](#)

chaetae -- Stiff bristles characteristic of [annelids](#).

chalk -- A soft compact calcite, CaCO₃, with varying amounts of silica, quartz, feldspar, or other mineral impurities, generally gray-white or yellow-white and derived chiefly from fossil seashells.

character -- Heritable trait possessed by an organism; characters are usually described in terms of their states, for example: "hair present" vs. "hair absent," where "hair" is the character, and "present" and "absent" are its states.

chela -- The claw of an [arthropod](#).

chelicera -- The first pair of appendages of a **chelicerate** arthropod. Originally a short clawed appendage, the chelicerae of many arachnids are highly modified for feeding; in [spiders](#), for instance, they are modified into poisonous fangs.

chert -- Hard, dense [sedimentary rock](#), composed of interlocking quartz crystals and possibly amorphous silica (opal). The origin of the silica is normally biological, from [diatoms](#), [radiolaria](#) or [sponge spicules](#). Synonymous with flint.

chitin -- n. A carbohydrate polymer found in the cell walls of [fungi](#) and in the exoskeletons of [arthropods](#), which provides strength for support and protection;
chitinous- adj.

chlorophyll -- n. The green-colored pigment that absorbs light during photosynthesis, often found in plants, algae, and some bacteria; it includes a porphyrin ring, and often has a long hydrophobic tail. [More info?](#)

chloroplast -- A chlorophyll-containing plastid found in algal and green plant cells.

chordate -- n. An animal with a notochord (a cartilaginous rod that extends the length of the body), dorsal hollow nerve cord (a fluid-filled tube that runs the length of the body), gill slits or pouches, and a tail at some stage in its life cycle.

chromosome -- Linear piece of eukaryotic DNA, often bound by specialized proteins known as histones.

Cimmerian terranes -- n. An archipelago of small landmasses that developed in tropical and subtropical latitudes on the eastern side of Pangea during the Triassic, blocks that comprised it include modern Turkey, Iran, Afghanistan, Tibet, and Malaysia; also called **Cimmeria**.

clade -- A monophyletic taxon; a group of organisms which includes the most recent common ancestor of all of its members and all of the descendants of that most recent common ancestor. From the Greek word "klados", meaning branch or twig.

cladogenesis -- The development of a new clade; the splitting of a single lineage into two distinct lineages; speciation.

cladogram -- A diagram, resulting from a cladistic analysis, which depicts a hypothetical branching sequence of lineages leading to the taxa under consideration. The points of branching within a cladogram are called nodes. All taxa occur at the endpoints of the cladogram.

clast -- n. An individual grain or constituent of a rock; **clastic**- adj. Describes a rock or sediment composed mainly of fragments of preexisting rocks or minerals that have been transported some distance from their place of origin, e.g., sandstone, shale.

clitellum -- In [annelids](#), a swelling of the body towards the head of the animal, where the gonads are located. Both oligochaetes and leeches have a clitellum.

clone -- An identical copy of an organism. Most plants, fungi, algae, and many other organisms naturally reproduce by making clones of themselves as a form of **asexual reproduction**.

cnidocyst -- The "stinging cell" of a [cnidarian](#).

coelom -- Fluid-filled cavity within the body of an animal; usually refers to a cavity lined with specialized tissue **peritoneum** in which the gut is suspended. The structure and development of the coelom is an important character for recognizing major groups of animals.

coenocytic -- Condition in which an organism consists of filamentous cells with large central vacuoles, and whose nuclei are not partitioned into separate compartments. The result is a long tube containing many nuclei, with all the cytoplasm at the periphery.

collagen -- long proteins whose structure is wound into a triple helix. The resulting fibers have a high tensile strength. Collagen is a primary component of mammalian hair.

colonial -- Condition in which many unicellular organisms live together in a somewhat coordinated group. Unlike true multicellular organisms, the individual cells retain their separate identities, and usually, their own membranes and cell walls.

columella -- A small column of tissue which runs up through the center of a spore capsule. It is present in [hornworts](#), mosses, and some rhyniophytes.

compactions -- Fossils that have undergone some degree of flattening of their three-dimensional structure.

compound eye -- Found in many but not all [arthropods](#), a compound eye is composed of a large number of small, closely packed simple eyes (**ommatidia**), each with its own lens and nerve receptors.

compound leaves -- n. Leaves with two or more leaflets attached to a single leaf stem.

compression -- [Fossil](#) formed when an organism is flattened (compressed) and a thin film of organic material from its body is left in the rock.

concretion -- n. A hard, rounded mass, commonly of silica, calcite, dolomite, iron oxide, pyrite, or gypsum, that formed within a rock from the precipitation of these minerals around a nucleus, such as a leaf, bone, shell, or fossil, and ranging in diameter from centimeters to meters.

conglomerate -- A coarse-grained [sedimentary rock](#), with **clasts** larger than 2 mm.

Congo craton -- n. A separate continental plate that rifted from the supercontinent Rodinia in the Late Precambrian; contained a large part of north-central Africa.

consumer -- Any organism which must consume other organisms (living or dead) to satisfy its energy needs. Contrast with [autotroph](#).

continental crust -- The Earth's [crust](#) that includes both the continents and the **continental shelves**.

continental margin -- n. The ocean floor from the shore of continents to the [abyssal plain](#).

continental rise -- n. Part of the **continental margin**; the ocean floor from the **continental slope** to the [abyssal plain](#). The continental rise generally has a gentle slope and smooth topography.

continental shelf -- n. The part of the continental margin from the coastal shore to the continental slope; usually extending to a depth of about 200 meters and with a very slight slope, roughly 0.1 degrees; includes continental and oceanic sediments down to the ocean floor.

continental slope -- n. Part of the **continental margin**; the ocean floor from the **continental shelf** to the **continental rise** or [oceanic trench](#). Usually to a depth of about 200 meters. The continental slope typically has a relatively steep grade, from 3 to 6 degrees.

contractile vacuole -- In many protists, a specialized vacuole with associated channels designed to collect excess water in the cell. Microtubules periodically contract to force this excess water out of the cell, regulating the cell's osmotic balance.

convergence -- Similarities which have arisen independently in two or more organisms that are not closely related. Contrast with homology.

copal -- Brittle aromatic yellow to red resins of recent or fossil origin, obtained from tropical trees.

coprolites -- Fossilized feces.

core -- That portion of the interior of the Earth that lies beneath the [mantle](#), and goes all of the way to the center. The Earth's core is very dense, rich in iron and the source of the magnetic field.

cotyledon -- n. The "seed leaves" produced by the embryo of a seed plant that serve to absorb nutrients packaged in the seed, until the seedling is able to produce its first true leaves and begin photosynthesis; the number of cotyledons is a key feature for the identification of the [two major groups of flowering plants](#).

craton -- n. A part of the Earth's crust that has attained stability and has been little deformed for a long period of time, refers only to continents; **cratonic**- adj.

Cretaceous Western Interior Seaway -- n. The epicontinental sea that formed as marine waters from the north spread over North America from around 130 to 70 million years ago (Ma), at its peak in the Middle Cretaceous (~ 90 Ma) it extended from present-day Utah to the Appalachians and from the Arctic to the Gulf of Mexico; also referred to as the **Western Interior Seaway**

cross-bedding -- (n) The arrangement of sedimentary beds tilted at different angles to each other, indicating that the beds were deposited by flowing wind or water.

crown group -- All the taxa descended from a major cladogenesis event, recognized by possessing the clade's synapomorphy. See: stem group.

crust -- n. The outermost layer of the Earth, varying in thickness from about 10 kilometers (6 miles) below the oceans, to 65 kilometers (about 40 miles) below the continents; represents less than 1 percent of the Earth's volume.

cuticle -- 1) In animals, a multilayered, extracellular, external body covering, usually composed of fibrous molecules such as chitin or collagen, and sometimes strengthened by the deposition of minerals such as calcium carbonate. 2) A waxy layer which seals the outer surface of land plants, helping to retain moisture.

cyst -- n. A small, capsule-like sac that encloses an organism in its resting or larval stage, e.g., a resting spore of an alga.

cytoplasm -- All the contents of a cell, including the plasma membrane, but not including the nucleus.

cytoskeleton -- Integrated system of molecules within eukaryotic cells which provides them with shape, internal spatial organization, motility, and may assist in communication with other cells and the environment. Red blood cells, for instance, would be spherical instead of flat if it were not for their cytoskeleton.

"Green Algae": Systematics, Part 2

The Charophytes

Charophytes are well known to students of biology. Spirogyra, stoneworts, and desmids are all members of this fresh-water group of "[green algae](#)". The charophytes have gained even more attention recently because they are now known to be the most closely related group of organisms to the Plantae. The charophytes are in fact **paraphyletic** with respect to the Plantae -- some members of the group are more closely related to the plants than to the other charophytes, though there is still considerable debate as to the exact relationships among the various members.

Unlike the other green algae, the charophytes share with plants the **phragmoplast** method of cell division, and the asymmetric arrangement of their sperm flagella. This latter character is only observable in the Charales and Coleochaetales, since members of the remaining orders do not produce flagellated gametes as part of their life cycle.

Visit the [Tree of Life](#) for more information about the relationships of the [charophytes](#) to each other, and to the plants.

Plantae: More on Morphology

[CLICK HERE FOR A TABLE](#) comparing the gametophytes and sporophytes of the major extant divisions. The table is **linked** to each of the divisions pictured.

Plant cells have a cell wall, large central vacuole, and plasmodesmata.

Like other eukaryotes, plants have a nucleus, plasma membrane, mitochondria, and other organelles, but plant cells differ from animal, fungal, and protist cells in a number of important ways. The most obvious difference is the presence of a **cell wall** which surrounds each cell. It is composed primarily of **cellulose**, a complex carbohydrate made from glucose. Cellulose provides structural support while remaining flexible; flower petals, for instance, are flexible but will snap if folded too far.

When plant cells divide, they must form a new cell wall between them, and this is accomplished by the formation of a **phragmoplast**, a system of microtubules oriented *along* the axis of cell division which helps to guide the deposition of cellulose. This is also an important difference from the "green algae", which produce a **phycoplast** during mitosis, in which the microtubules lie *perpendicular* to the axis of division. Only plants and [charophytes](#) divide their cells with the aid of a phragmoplast.

Neighboring cells in plants are connected across their cell walls by extensions of the cells through pores called **plasmodesmata**. A plasmodesma allows cells to transfer nutrients, water, and some other diffusible materials without having to pass them across membranes or other barriers. They are also important for understanding how diseases spread through the tissues of a plant.

At maturity, most plant cells are filled with a single large **vacuole**, such that the nucleus, plastids, and other organelles are all close to the cell membrane. This can be seen in the picture at right. At the far right is the nearly transparent nucleus, and clusters of plastids can be seen toward the bottom and left. Those plastids which appear to be in the "middle" of the cell are actually at the

periphery; remember that there is a cell wall toward you, and a wall on the far side of the cell, with the vacuole filling most of the space in between.

The vacuole is a membrane-bound bag of fluid, containing ions, stored nutrients, and waste materials. The storage of waste materials is a very important function of the vacuole, since plants cannot excrete their wastes the way [animals](#) do. The vacuole also assists the cell in maintaining **turgor pressure**. The high concentration of materials in the vacuole causes water to diffuse into the cell, increasing its volume. Because of the cell wall, however, the amount of space into which the cell can expand is limited. The cell thus exerts outward pressure on its cell wall, and when all cells are maintaining this pressure, the plant gains rigidity. You can notice this by comparing crisp fresh celery with celery that has sat around and grown limp. The old celery has lost fluids, and is no longer rigid.

Plastids manufacture food through photosynthesis.

Plastids are perhaps the most important feature of plants, that is, from the perspective of animals that live on land. The plastid is an organelle which contains [chlorophyll](#). The chlorophyll captures the energy of light, and makes it accessible to the plant for **photosynthesis**. This provides the energy plants use to manufacture sugars, which are then used as a fuel source for continued growth. The sugars are often linked together for easy storage into a complex carbohydrate called **starch**. Without these sugars and starch, life on land as we know it would be impossible, for there would be practically no food -- no grains, no fruits, no vegetables. Another useful by-product of photosynthesis is oxygen, though plants are not the most important producers of this gas. Most of our oxygen comes from [phytoplankton](#) in the earth's oceans.

Lost in the Woods

The Child Survival section

This *Child Survival* program is presented to students, cubs, guides, parents and interest groups across North America. It is not a "Hug a Tree" program. It goes into more detail and adds more Rules for Survival. The presentation is about one hour and thirty minutes. The maximum group size is about one hundred and twenty (or whatever the instructor can handle). The film, "*Lost in the Woods*" by Barry Casson, is shown as part of the presentation. Experiments taken from the book, "*Lost in the Woods*" by Colleen Politano, are done during each session.

The Instructor package is available from SARBC. Please see below for a link.

[Discussing Feelings](#)

[Child's survival Kit](#)

[The 9 Rules for survival](#)

[Instructor Kit](#)

From Ken Hill

[Children's Woodsproofing](#)

The Lost in the Woods program is available three ways:

- Requesting an Instructor (Victoria Area)
- Purchasing the Video and Instructors Kit
- Borrowing the video and Instructors Kit (BC Only)

To request an Instructor please use this [form](#). Instructors provided by SARBC are available in the Greater Victoria Area.

To purchase the Video and Instructors Kit, please use this [form](#). We now accept credit cards, or you may order by sending a cheque to SARBC.

To borrow the video and Instructors Kit, please use this [form](#). Kits are available on a first come, first serve basis and presently are limited in quantity.

Lost in the Woods - Child Survival K-7 Discussing Feelings

SARBC

Search and Rescue Society of British Columbia

Discussing Feelings

by Gary O'Brien, SARBC

Because children have fears, which can be more intense than those of an adult, they are discussed by the instructor during the Child Survival lecture. The following words are addressed to the students, and elaborated.

Talking about FEELINGS, and knowing how to deal with them, is very important.

Nobody likes being scared or frightened.

Help yourself keep calm by singing, whistling or even telling yourself jokes or stories. Do anything it takes to make yourself feel better. Try using your imagination to pretend you are somewhere else that you really enjoy.

You usually do not have to worry about wild animals. They do not like to be near people. If they hear or smell you, they will usually run away.

A good rule is Answer a Noise with a Noise. If you hear a noise in the woods, make a noise back. If it is an animal it will run away, if it is a searcher then you will be found.

The fear of dark can be easily overcome by memorizing your surroundings during daylight so that you can see with your memory when it gets dark. Nothing changes just because it gets dark. Try practicing in your bedroom.

There is no punishment for being lost and yet children have been known to hide or run away from searchers in fear of punishment. Children should not have any fear of returning home. Mom and Dad, or whoever is looking after you are going to be very happy to see you again. There will be NO punishment.

There are Friendly strangers who will help you when needed. Some of these are police officers, fire fighters, ambulance personnel and Search and Rescue teams. Generally, these Friendly strangers always work in groups.

Lost in the Woods - Child Survival Kit

SARBC

Search and Rescue Society of British Columbia

Lost in the Woods - Child Survival Kit

by Gary O'Brien, SARBC

During the presentation of this Child Survival lecture, the instructor would show the students each item and how it is made. For instance the reflector is tin foil pasted to cardboard (no sharp edges), and, the right and safe way to tear a face hole in the bright orange garbage bag is demonstrated.

Make an Emergency Survival Kit (and practice using it):

1. A Zip Lock sandwich bag for the container (also used as a cup for drinking water)
2. A snack of high energy trail mix (contained in its own zip lock bag)
3. A whistle used for calling for help (three short blasts)
4. A signal flag approximately 10cm by 100cm (cut from orange plastic garbage bag)
5. A reflector for sending signals (use soft, flexible material)
6. A large, bright color garbage bag used as poncho (pre-tear slit for face opening - Do not "cut" hole)

Lost in the Woods Instructor Kit

SARBC

Search and Rescue Society of British Columbia

Lost in the Woods - Instructor Kit

by Gary O'Brien, SARBC

The Lost in the Woods Child Survival presentation Instructor kit includes:

1. Video - Lost in the Woods, 24 minutes, by Barry Casson
2. Video - Lost in the Woods Instructor teaching a group of students, 1 hour 20 minutes
This video is to give an Instructor some ideas about presenting the material.
3. Book - Lost in the Woods by Colleen Politano
4. Handout - Illustrated 9 Rules, suitable for copying
5. Handout - Canadian EPC pamphlet, substitute FEMA pamphlet to suit
6. Certificate - Sample, change and copy to suit
7. Overview of the presentation for Instructors

Note: Every child should receive the illustrated 9 Rules handout, the others are optional.

Children's Woodsproofing

SARBC

Search and Rescue Society of British Columbia

Children's Woodsproofing

Copyright © 1996
Kenneth A. Hill, PhD
Training Officer (External)
Waverley Ground Search and Rescue
Nova Scotia, Canada
October, 1987

Objectives

The Woodsproofing concept arose primarily out of concern for the survival of children who become lost, particularly those who defeat the efforts of search teams through mobility, and fail to take the simplest precautions against hypothermia.

Through the program, members of the Woodsproofing Committee of Waverley Ground Search and Rescue hope,

1. to provide a large number of children, especially younger children, with basic information about how they should react if they become lost;
2. to provide parents and other adults with information about prevention; and,
3. through exposure and interaction with children, encouraging their trust in members of ground search teams, who would no longer be regarded as "strangers".

Disclaimer

The term "woodsproofing" is a misnomer, as it suggests there is some assurance that children will actually use the information they receive from the program, and that the information, even if it is used, is guaranteed to save them in all possible situations.

We can make no such guarantees.

We employ the term as a convenience, for communicating to the public (who are already familiar with the term "streetproofing"), and because of its conventional usage to denote similar programs elsewhere.

The program we provide is aimed at teaching several basic principles to children (and their parents) that will help ground search teams find the most children in the shortest amount of time and with the least amount of discomfort to the lost child. Nevertheless, suggestions for a more accurate label are welcome.

Methods

Overview.

As presently constituted, the Woodsproofing program is aimed primarily at boys and girls between five and ten years of age, and their parents.

Though the specifics of individual sessions may vary, the overall structure of the program is the same:

1. children and their parents are shown the film entitled "Lost in the Woods" (see Appendix),
2. parents and other adults are separated from the children, and the two groups are spoken to by team members who specialize in these respective tasks, and
3. the groups are subsequently reunited for some less formal activity, such as a demonstration by the team's dog handler, followed by informal interaction between team members and the audience.

Parent participation.

Involvement of the parents in the Woodsproofing session is considered important for two reasons:

1. it is felt that the concept of prevention would be more fruitfully discussed with the parents than their children, and
2. the ability of the child to use woodsproofing skills may depend on how they believe the parent will respond to their being lost.

Regarding the latter point, a child who expects his parents to be angry may be reluctant to remain put and wait for searchers to find him; rather, he may fearfully thrash through the woods in the hope of finding his way out as soon as possible.

Consequently, during the woodsproofing session, parents are asked to clearly communicate the message to their child that they will not react punitively should the child become lost.

In addition, participation by the parents in the child's woodsproofing should enhance the child's involvement in the session and the perceived significance of the lessons being taught.

Preparation.

Some preparation is necessary before the session is to begin.

First, there should be one WGSR person in charge, who is responsible for scheduling the event, recruiting sufficient WGSR people to attend the session, bringing the film, projector, extra reel, extension cord, screen, and books, and generally overseeing the events of the session.

A minimum of two WGSR people are required to present a woodsproofing session, so long as the size of the group of children is small (about 15 or fewer). One person will address the children, the other will speak to the adults.

However, the session will be more successful if additional team members are also present, preferably dressed in orange coveralls, backpacks, and gear (e.g., radios). The sight of WGSR people in full search attire tends to facilitate interaction between team members and the audience, and provides the child with an opportunity to see what a searcher looks like, should they ever become lost.

Introduction and film presentation.

When ready to begin the session, the team member in charge should stand before the group and introduce him/herself to the audience. In a sentence or two, he or she will briefly describe the scheduled events, i.e., that a film will be presented, and that afterwards we would like to speak with the children and adults separately, because we have different things to talk to them about.

At that point, the children are asked to come to the front of the room and sit on the floor before the screen. No child over five should be allowed to stay back with his or her parent, if it can be avoided.

The film tends to build feelings of tension and parental concern; parents who are observed watching the film with their children typically spend considerable time consoling the child nonverbally, such as holding and patting.

We want to delay the release of this parental concern in order to maximize the parent's motivation to cooperate with our suggestions about prevention (described below).

Post-film discussion: the children.

The children should be addressed by someone who feels comfortable with an audience of this age range and is able to establish rapport.

The speaker should either crouch or sit on a chair with the children huddled on the floor around him.

The children's attention should be captured and maintained as much as possible, without becoming heavyhanded or "bossy."

One useful approach is to insist (in a friendly way) that the children raise their hands when they want to answer a question ("just like in school").

This also provides the advantage of calling on the more reticent, shyer children for their input as well (even the ones who don't raise their hands), before answers can be blurted out by the more gregarious children.

The speaker can begin the session by introducing himself and any other WGSR people there.

The objective for this part of the discussion is to ensure, through repetition, that the children remember four basic points made in the film:

1. to stay in an open place,
2. to stay warm by buttoning up your coat,
3. to cover your head, and
4. to build a survival bed of leaves and tree boughs.

Additional points about not eating strange berries or hugging a tree are optional and up to the discretion of the speaker; however, it should be noted that the more one tries to teach the younger children under these circumstances the less they will remember.

After making the statement about raising hands, the speaker can ask the children, "What happened to Calvin?" (the boy in the film).

After the children answer (usually emphatically) that Calvin "got lost," the speaker can ask how this happened.

The children typically respond with the fact that he was following a deer.

You can elaborate this with something like, "That's right! He was following a deer and not paying attention to where he was going." (Always reward the children's responses; there are no "wrong" answers.)

It is best to emphasize throughout the discussion that Calvin reacted intelligently to his predicament. He did "all the right things," because he was a "smart kid" (a comment one searcher actually makes in the film).

This will highlight the fact that he is someone to emulate and to learn from.

The speaker can ask, "What was the first 'right thing' that Calvin did, once he realized he was lost?"

The correct answer is that he stayed in an open place, rather than continuing to try to find his way out of the woods.

The second 'right thing' is that he buttoned up his jacket to stay warm; the third is that he covered his head with his hood; and the fourth is that he built a survival bed to provide further protection from the elements.

Calvin was scared, but he kept cool; he remembered all the things to do that he had been told about.

Repetition is necessary if the children are going to remember the four points under conditions of high stress and anxiety - that is, should they become lost themselves.

Each time an additional "right thing" is introduced, previous points should be repeated. Use the same wording each time, and get the children to recite along with you as you go through the list of "right things."

Pretend you can't remember them yourself, children will enjoy the game of reminding you what all the right things are.

Repeat the list until you're sure they'll remember it, then go through it once again. It's better to err on the side of overkill.

At this point, you can change the focus of the discussion from the film to the children themselves.

Ask if any of them have ever been lost. Some hands may go up rather tentatively, and you might hear some tall tales about being lost in the woods under harrowing conditions much worse than Calvin's.

Frequently, though, no one raises their hand.

Now ask if anyone has ever been lost in the shopping centre or the supermarket and you'll get a more positive response.

Then ask those children what they did when they got lost. Almost always, they will answer that they told "someone who works there."

Repeat this phrasing to the children. The point you want to get across is that, when you are lost, some strangers are safe to approach for help.

One hurdle for a successful Woodsproofing session is to overcome the typical warning not to speak to strangers, and certainly not to follow them anywhere.

The point of using the shopping centre example, which many children are familiar with, is that you can get around this hurdle by using an exception that the children are already aware of, rather than trying to introduce a new exception.

Thus, when a child is lost in the woods, search and rescue people are safe (despite the fact they are strangers) because "they work there" (in the woods, looking for lost people).

A third and final objective for the discussion with the children is to talk about how their parents will react if they should indeed happen to get lost in the woods.

Begin this discussion by asking the question, "How do you think your Mom and Dad will feel if you become lost, and you're late for supper?"

Many children have difficulty answering this question, because the phrase "late for supper" suggests parental anger and punishment. Some will answer that their parents would be "sad," and you should reward these answers enthusiastically.

Elaborate on this with phrases like "terribly worried," or "scared to death," emphasizing that anger would be the farthest thing from the parent's mind.

Finally, add the statement that, "When (not 'if') you're found, your Mom and Dad would be very happy to see you, and probably give you a big hug."

Among children's worst fears is abandonment by the parents, the withdrawal of love and concern.

For example, a not uncommon worry is that the parents will have moved away while the child is attending school, and not a few children have emitted, at one time or another, an internal sigh of relief to find the family car still parked in the driveway.

When a child is lost in the woods, this fear can be magnified to the dimensions of terror, making a panic reaction all the more likely.

You can confront this fear directly by asking the question, "If you got lost, would your parents wait a few days for you to come home, or what?"

You'll receive some nervous laughter, because even young children realize that this fear is irrational.

Emphasize that, in fact, parents will know that their child is lost, that they will be very worried about them, and that they will send someone to look for them right away. That "someone," of course, is us.

Post-film discussion: the parents.

The objective for the discussion with the children's parents is prevention. There are two general areas to be addressed.

One area refers to practical steps that parents can take to prevent their child from wandering off in the woods and getting lost, and the second has to do with the child's attitude.

Regarding the practical steps, suggest to the parents that they purchase some brightly colored forestry tape ("flagging"), available at many sporting goods stores and other retail outlets (e.g., Canadian Tire).

When the family goes camping, the parent can use the tape to mark off a clearly visible perimeter, beyond which the child is instructed not to travel without an adult.

Families who live near wooded areas can engage in a similar activity around their homes. As the child grows and becomes increasingly familiar with the area inside the tape, the perimeter can be extended.

A related activity, which should be recommended, is that the parent take the child for a walk (it could be the same time as the perimeter is being set up) and engage the child in building a survival bed.

The child should be allowed to pick the "best spot" (an open space), and to gather sufficient boughs and leaves to make the bed (advise the parents not to chop down any branches, as the child will not have this advantage should he ever need to make a survival bed).

The parent can pretend to "tuck" the child into his new bed. This will likely be an enjoyable activity and will help ensure that the child will remember this important step should they ever become lost.

This is a skills-oriented approach to prevention. An alternative approach, one which is found in many families who live near wooded areas, is a policy of avoidance.

That is, children are instructed (usually quite ominously) not to go into the woods at all.

This policy is comparable to telling children who live by the sea not to go near the water, for fear of drowning, rather than teaching them to swim.

Children who are kept out of the forest, through parental fears of their becoming lost, are being deprived of an educational experience and an esthetically pleasing place to play.

What is worse, they are totally unprepared, both emotionally and practically, in the event that they should wander into the woods anyway, despite parental admonitions.

No parent realistically expects their child to mind them 100% of the time. However, parents whose children have received woodsproofing, and who live near wooded areas, should be less apprehensive about the consequences of their child straying beyond the perimeter.

Other ways that parents can prepare their children for the woods include always ensuring that the child has adequate protection from hypothermia. The point should be made that hypothermia kills many more people in fair but wet weather than in cold weather.

There are many types of compact windbreakers and plastic sheets that fit into pouches; these can easily be slipped into a pocket or a backpack. The low-budget version is a large, orange garbage bag, which provides an instant portable tent (the child can poke a hole to see out).

Children should also be provided with a whistle, hanging from a lanyard around the neck, with instructions to blow three times if they need help (and only then).

Children can also be provided with high-calorie foods, such as dried fruit or candy, a provision which few children will object to carrying.

Unfortunately, many children will likely consume these "emergency" supplies at their first opportunity.

As important as these skills and provisions are to the child's survival, the most important thing a parent can do is to facilitate in their child the appropriate attitude toward being lost.

Recall that, coincidentally with the parental discussion, the children are being told that their parents will not be angry at them if they become lost and will not punish them when they're found.

We would be irresponsible to assume that this will always be true, and to let it go at that. A major objective of the parental discussion is to ensure that the parents understand that, if they need someone to blame, it is the parents' fault if the child gets lost - not the child's.

Consequently, they should make sure that they communicate to their children the very points that we make to the children during the woodsproofing session:

1. that they will not be angry at them if they become lost, and
2. that they will send people to look for them right away.

Children who are persuaded of these statements are better prepared emotionally to control their panic and to follow the basic survival steps, especially regarding staying in one place.

In fact, parents should be instructed to communicate this message immediately upon rejoining their children after the discussion. Almost all parents will gladly comply with this request.

Problems to avoid.

Actually, if you remember to bring all the equipment, have sufficient manpower to run the session, and have good directions about how to find the location, there will be few problems of any consequence. However, one area that is sometimes problematic is dealing with a group of kids (usually boys) who have gotten out of control.

The first rule is never to allow yourself (or any other WGSR person) to be put in charge of controlling the children (either intentionally or by default). That is, always make sure there is at least

one leader around who will stay in the vicinity of the children and will take the initiative in controlling them if they get out of hand.

Thus, when the parents and children separate, one or two of the group leaders could be asked to stay in the room with the children. It's a good idea to mention this request to the group leader before the session begins.

On the other hand, if you find that unruly behaviour is a frequent problem during the children's sessions, you might wonder whether the sessions are lasting too long, or even if your presentation of the discussion might be the problem.

Talking to young children, especially involving them in an extended conversation, is harder than it looks; you may be losing their interest after the first few minutes of the discussion. Try watching someone who seems to be good at it, then have them watch you leading a discussion, with the goal of making some constructive criticism.

Summary

The following is an outline of the central points discussed in this paper:

I. Discussion With the Children:

1. Stay in an open place.
2. Button up your coat to stay warm.
3. Cover your head.
4. Make a survival bed of leaves and tree boughs.
5. "Mess up your yard" (leave clues for searchers).

Additional points:

6. Searchers are "safe" strangers.
7. Your parents will worry about you and send searchers right away.
8. When you're found your parents won't punish you.

II. Discussion With the Parents:

1. Parents are responsible for prevention - don't blame the child.
2. Establish perimeters around camp sites and homes near wooded areas.
3. Practice making a survival bed with your child.
4. Make sure your child understands that you won't be angry if they become lost.

Appendix: Materials

VHS Video or Book

"Lost in the Woods" [SARBC](#), P.O. Box 187, Victoria, BC, V8W 2M6

Book

Colleen Politano (author), LOST IN THE WOODS: CHILD SURVIVAL, Porthole Press, Ltd., 2082 Neptune Road, Sidney, BC V8L 3X9

Addendum: 1996

The "Woodsproofing for Children" program was developed in the fall of 1986 by the Waverley team in response to the death of 9-year-old Andy Warburton.

Since that time more than 50,000 children (really!) in Nova Scotia have received woodsproofing as described herein.

There is at least one documented case where a woodsproofed child had benefitted from this training, and several known cases where woodsproofed children had been found by family or neighbors in their "hasty searches" before calling the police.

We used to have to search for at least one or two children every year, sometimes more. Since the woodsproofing program began, 10 years ago, we've had only one search for a lost child in the targeted age group (knocking on wood).

Remember: "The best search is the one you don't have to conduct."

Kenneth Hill, Search Director, Waverley Ground Search and Rescue khill@husky1.stmarys.ca

Quick Reference Math

SARBC

Search and Rescue Society of British Columbia

Keep in mind that SARBC assumes no responsibility for the use or mis-use of information provided here.

Math and Info Pocket Card templates in Acrobat PDF format

[Basic Formulae, Proportional POA, Height of Object](#) (PDF document - 12k)

[Team Leader info, Terrain Analysis, Acronyms, BC layout](#) (PDF document - 14k)

[Numerical Influence of Clue, O'Connor, Probability Zones, Scenario Analysis](#) (PDF document - 17k)

[Speed Tables](#) (PDF document - 9k)

[Influence of Clue - full page](#) (PDF document - 10k)

[O'Connor Method - full page](#) (PDF document - 5k)

The following formulae are included in the Pocket Card templates above.

Consideration of the maximization of the ROW POA - through the utilization of resources and area segment coverage (single/multiple - same/different resources)

ROW POA[updated] = ROW POA[current] / (1-OPOS)

The ROW POA as calculated by shifted POA should be the same as this result.

OVERALL POS

OPOS = (POD 1)*(POA1) + (POD2)*(POA2) + (PODn)*(POAn)

Relative Increase

For what-if use of resources

RI = 100(ROW POA[updated] - ROW POA[current] / ROW POA[current])

Proportional POA

Some people feel more confident using values which are proportional (or relational) to each other. They don't want to worry about whether or not they add up to 100%. Also see next page for the O'Connor method (letters).

To use proportional initial POA's, don't worry about whether the values add up to 100%.

Example:		Converted to %
Segment 1	- 29	21%
Segment 1	- 35	25%
Segment 1	- 40	28%
Segment 1	- 18	13%
Segment 1	- 13	9%
ROW	- 5	4%
TOTAL	- 140	100%(rounded)

Potential Clue Influence Levels for Search Segments

- A - Clue strongly suggests subject is in segment
- B -
- C - Clue suggests subject is in segment
- D -
- E - Clue suggests nothing about subject in/not in segment
- F -
- G - Clue suggests subject is not in segment
- H -
- I - Clue strongly suggests subject is not in segment

Clue Authenticity Ratings

- Clue is Very Likely Authentic
- Clue is Likely Authentic
- Clue is Even: As Likely Authentic as Not
- Clue is Likely Not Authentic
- Clue is Very Likely Not Authentic

Numerical Influence of Clue

Potential Influence Level
Authenticity Rating

	A	B	C	D	E	F	G	H	I
Very Likely Auth	100.0	70.7	50.0	35.4	25.0	17.7	12.5	8.8	6.3
Likely Auth	100.0	77.1	59.5	45.9	35.4	27.3	21.0	16.21	2.5
Even: Auth/Not Auth	100.0	84.1	70.7	59.5	50.0	42.0	35.4	29.7	25.0
Likely Not Auth	100.0	91.7	84.1	77.1	70.7	64.8	59.5	54.5	50.0
Very Likely Not Auth	100.	100.	100.	100.	100.	100.	100.	100.	100.

This allows us to reflect the Influence of a clue to POA's, and change them accordingly.

To apply the values above to the current POA distribution, use the following formula.

$$D = S1[\text{old}] * IOC[1] + S2[\text{old}] * IOC[2] + S3[\text{old}] * IOC[3] + \dots + Sn[\text{old}] * IOC[n]$$

(S=area segment POA)

$$S1[\text{new}] = (S1[\text{old}] * IOC[1] / D * 100$$

$$S2[\text{new}] = (S2[\text{old}] * IOC[2] / D * 100$$

$$S3[\text{new}] = (S3[\text{old}] * IOC[3] / D * 100$$

$$\dots$$

$$Sn[\text{new}] = (Sn[\text{old}] * IOC[n] / D * 100$$

To reverse the effect of a bad clue, apply the complement of the bad clue to the current POA distribution to undo its effects.

To use the O'Connor method (letters) instead of the Mattson Method (percentages):

- A - Very Likely
- B -
- C - Likely
- D -

- E - Even Chance
- F -
- G - Unlikely
- H -
- I - Very Unlikely

O'Connor Method - Relative value to determine initial POA's

	VERY LIKELY		-	<-	->	-	VERY UNLIKELY		
	A	B	C	D	E	F	G	H	I
If lowest letter used is:									
A	1								
B	2	1							
C	3	2	1						
D	4	3	2	1					
E	5	4	3	2	1				
F	6	5	4	3	2	1			
G	7	6	5	4	3	2	1		
H	8	7	6	5	4	3	2	1	
I	9	8	7	6	5	4	3	2	1

As an example, If you evaluated area segments and they ranged from Very Likely to Unlikely (A - G), then, going down the side to "G", use the numbers under the top row.

If there were 4 area segments, and they were evaluated as:

- Segment 1 - G
- Segment 2 - A
- Segment 3 - C
- Segment 4 - D

Then:

- The total will be 17 (7+1+5+4) or (G+A+C+D)
- The person's POA for Segment 1 is 7/17
- The person's POA for Segment 2 is 1/17
- The person's POA for Segment 3 is 5/17
- The person's POA for Segment 4 is 4/17

Which now have to be converted to percentages:

Seg 1 - 41% Seg 2 - 6% Seg 3 - 29% Seg 4 - 24% = 100% (rounded)

Area - with variable searcher spacing (meters/feet) and searcher speed (Km or Mi per hour)

(Sq Km)

$$\text{AREA} = (\# \text{ searchers} \times \text{hours} \times \text{speed} \times \text{spacing}) / \# \text{ sweeps} \times 1000$$

(Sq Mi)

$$\text{AREA} = (\# \text{ searchers} \times \text{hours} \times \text{speed} \times \text{spacing}) / \# \text{ sweeps} \times 5280$$

Scenario Analysis
(Conditional Probabilities)

Segment	Initial POA		Weighted POA		Planning POA
	Area A	Area B	Area A(p=.70)	Area B(p=.30)	
1	.30	.10	.70 x .30=.210	.30 x .10=.030	.210+.030=.240
2	.25	.05	.70 x .25=.175	.30 x .05=.015	.175+.015=.190
3	.20	.05	.70 x .20=.140	.30 x .05=.015	.140+.015=.155
4	.10	.30	.70 x .10=.070	.30 x .30=.090	.070+.090=.160
5	.05	.25	.70 x .05=.035	.30 x .25=.075	.035+.075=.110
6	.05	.20	.70 x .05=.035	.30 x .20=.060	.035+.060=.095

ROW	.05	.05	.70 x .05=.035	.30 x .05=.015	.035+.015=.050
	(p = probability that scenario is valid)				
	Area A (Seg 1-3)		Area B (Seg 4-6)		

Scenario Analysis is the consideration of alternate search scenarios. It is common for an overhead team to consider all the segments in a search area and assign POA's. Each planner is assuming his/her scenario and assigning POA's accordingly - accounting for a divergence between planners for each segment. Indeed, five people may allocate their POA according to five different scenarios, that is, making entirely different assumptions about the lost person's behaviour. As a result, the averaged, or Mattson POA's may be less than optimal for planning purposes.

Scenario analysis involves having the Plans Chief present a number of explicit scenarios to those assigning POA's to the segments. They are asked to estimate the probability of each scenario (as decimal). Planners then assign POA's to all of the segments for each of the scenarios.

For example:

If there are two scenarios, planners would estimate POA for each segment twice.

Once a planner has assigned POA to every segment for every scenario, each POA is weighted by multiplying it by the probability of the scenario to which it applies.

The weighted POA for each segment are then summed across scenarios, yielding one set of POA for a given planner.

These planning POA can then be averaged with the POA from other planners in the usual manner, yielding a set of consensus or Mattson POA with which to plan the search.

The table above represents hypothetical POA for one planner.

The planner has assigned a probability of .70 for Area A and .30 for Area B. His un-weighted POA assignments appear in the 2nd and 3rd columns. In the 2nd column, for example, these POA estimates are made under the assumption that the Area A scenario is valid, while POA appearing in the 3rd column pertain to the Area B scenario.

	50%Z	.7dn	3.1dn
	75%Z	.8up	4.0dn
	93%	3.0up	6.0dn

- Tend to concentrate on game, not navigation.
- Tend to overextend into dark and push beyond physical abilities.
- Often try to take short cuts.
- Tendency to follow game to dense underbrush or deep snows, deadfall areas, boulder fields, etc. with little regard for exhaustion or navigation.
- Often only prepared for the day.
- Unprepared for extremely foul weather-heavy storms/improved hunting.
- When weather turns colder most take shelter.

REASON LOST: Disoriented, misjudge time/distance, accidental or intentional separation

DETECTABILITY

83% in good weather * Communicative
 66% in bad weather * Mobile
 Detectability enhanced due to bright clothing

17% wear dark clothing

TRAVEL AIDS

39% used natural drainages
(paths, trails usually not available)

- Generally 15-35 yrs old.
- 85% good physical condition.
- Most are in good mental condition.
- 33% have much experience, most have limited experience.
- 80% properly equipped & clothed, 50% no survival training (East US).
- 40% adequate equip/clothing, 40-50% questionable, 20% inadequate for Colorado.
- Cause - human error caused by subject.
- Weather a factor in 18%, darkness in 33%.
- Many wander about and go cross-country (in the west).
- Civilization and landmarks not attractors.
- 66% found within 2 mi from PLS.
- Calif. 87% found within 5 mi.
- Colo. 78% found within 5 mi.
- East US 97% found within 4 mi.
- 90% not moving for more than 24 hrs.
- Calif. and Colo. 45% moved at night. East US 80% moved at night.
- 25-60% found by SAR using attraction, confinement, hasty and heli-search.
- 25-45% found themselves.

BEHAVIOUR CHARACTERISTICS OF HIKERS

		MI	
MEDIAN		2.5dn	
25% UP			
20% SAME			
55% DOWN			
Hilly	25%Z	2.0dn	3.0dn
	50%Z	.6dn	3.6dn
	75%Z	.4up	6.1dn
	83%Z	4.0up	6.0dn

- Generally relies on trails with set destination.
- Trails create problems if overgrown, snow covered, poor junctions, slide over trail, trail not maintained, poorly defined junctions.
- Mismatched abilities:one may get tired, fall behind and eventually get disoriented/lost.
- Take other trails or short cuts - cutting switchbacks-leading to disorientation or going down wrong hill or drainage.
- Poor or no map or compass.
- Very dependent on trails and travel aids for navigation.

REASON LOST: 40% Disoriented
20% accidental & intentional
separation, poor supervision
25-30% misjudge time/distance

DETECTABILITY

75% in good weather
67% in bad weather

TRAVEL AIDS

75% used paths, trail or drainage

- Largely under 30 yrs old. 33% are 10-15 yrs old.
- Good physical and mental condition.
- Not necessarily experienced, less than 20% with much experience, most with little experience.
- 40% adequately equipped/clothed, 30% questionable, 30% not.
- Cause - human error caused by subject, weather, darkness.
- 82-90% found within 5 mi of PLS.
- 67% found within 2 mi of PLS.
- 92% moving less than 24 hrs.
- 30-40% travelled at night.
- 40% found by hasty team.
- 17% confinement/attraction instrumental.
- 5% found by dogs.
- 3% found by line searchers.

Those who travelled more than 10 mi, also descended several thousand feet, and followed trails, as opposed to going cross-country.

[Top of Page](#)

BEHAVIOUR CHARACTERISTICS OF Hiker-Climbers

CLIMBERS:

- Range from "Hill walkers" to "Scramblers" to "Rock climbers" to "Ice climbing" to "Alpine Mountaineering".
- Best climbing ages are "30-35" not uncommon "14-60".
- Climb for the pure joy of climbing.
- They do not need to have a great deal of physical strength nor superior co-ordination.
- Avalanches are the major cause of fatalities.
- Falling is the major cause of injuries.
- Stranded by weather or rock fall (landslide).
- Well equipped and self-sufficient.
- Tend to stay on or near routes.
- ** Check for scuff marks near cliff.

Many climbing accidents never get reported because of pride.

1959 to 1982

No. of accidents	Canada - 365	B.C. - 158
No. involved	Canada - 733	B.C. - 312
No. injured	Canada - 283	B.C. - ?

	90%	1.0up	3.0dn

- May be affected by senility or Alzheimer's; mentally retarded, or a form of psychosis.
- Sometimes oriented to the past.
- Behaviour characteristics very similar to that of children.
- Easily attracted by things.
- Active ones will overexert themselves.
- If active and lucid, likely to overextend self rapidly.
- High hypothermia risk - lower normal temperatures.
- Many have suboptimal nutrition, are less able to generate heat from reserve calories, and are poorly clothed.

*** 44% travelled more than 4 mi (Calif.), 84% (East US) less than 2 mi.

DETECTABILITY * Often deaf or hard of hearing
59% in good weather
10% in bad weather
(Difficulty in locating subjects, most found in prone position regardless of weather condition)

TRAVEL AIDS
47% used travel aids - (hunters used path or game trail).
Those lost in bush areas seldom used any type of trail.
Frequently found under brush, or in densely treed areas.

[Top of Page](#)

BEHAVIOUR CHARACTERISTICS OF FISHERMEN

- Usually well oriented.
- Reason accident related, usually boat - swept of feet,
● boat overturned or went over waterfall, falls over cliff.
- Often recovery mission.

DETECTABILITY

TRAVEL AIDS

[Top of Page](#)

BEHAVIOUR CHARACTERISTICS OF MENTALLY RETARDED

	MI
Flat median	1.2
Hilly median	1.6
33% up	
8% same	
58% down	

- Act and react similar to kids 6-12.
- Usually does not respond to name called.
- Remain in same area for days.
- Usually hidden from view - fright, hiding from elements.
- No physical impairments but will not help themselves.
- Easily attracted by sights and sounds.
- May set off to explore without any sense of direction or how to return.

DETECTABILITY

(kids 6-12)
65% in good weather
10% in bad weather
(due to bad weather crawl under logs, heavy branches)

TRAVEL AIDS

67% used travel aids - (used paths, game trails, streams or drainages).
33% were found in brushy areas.

[Top of Page](#)

BEHAVIOUR CHARACTERISTICS OF DESPONDENTS

FLAT TERRAIN	
MEDIAN	.8 MI
RANGE	.06-2.1 MI
50% Z	.4-1.0 MI

- Often seeking solitude.
- Usually found within sight and sound of civilization.
- All maintain they weren't lost - merely getting away to think.
- Felt intruded upon.
- Some avoided being found.
- (US) Found near prominent locations ex. scenic lake/hill, lookout.
- (US) Tend not to go into underbrush.
- (US) Most tend to go upward to distinctive locations.
- (CAN) Tend to settle down in first secluded spot, often next to a tree.
- (CAN) Attracted to secluded, open spaces, surrounded by trees, some distance away from trails. Don't travel far.

DETECTABILITY

Not responsive to searchers - feel it is an intrusion upon their solitude.

TRAVEL AIDS

Usually stay in one place.

[Top of Page](#)

BEHAVIOUR CHARACTERISTICS OF MISC. CATEGORY

		MI	
Median	Flat	1.6	
	Hilly	1.6dn	
Hilly	25%Z	.6dn	1.6dn
	50%Z	0	3.0dn
	75%Z	1.4up	3.1dn
	84%	2.5up	3.2dn
66% went down			

- Pinecone, berry, mushroom pickers; rock hounds; photographers.
- Poor survival risk.
- Go in good weather, no extra clothing.
- Generally unprepared (physically, clothing).
- Complete disorientation.
- Attempts to find their way usually gets them further into trouble - because of disorientation.
- Intentions are usually to stay in one location.
- Dosen't know the area.
- Little or no food, water or survival gear.

REASON LOST: disoriented, poor supervision, intentional separation

DETECTABILITY

75% in good weather

50% in bad weather

(will retreat if weather foul) * high % are communicative.

TRAVEL AIDS

50% used paths, trail or drainage

- More cases for young [<8 yrs old] and older [>60 yrs old].
- Generally good physical condition.
- 65-70% in good mental condition.
- 40-50% adequately equipped.
- 45-55% properly clothed, 30% questionable, 15% not.
- Cause - human error, caused by subject.
- Greater likelihood to wander about or go cross-country.
- 69% found within 2 mi of PLS.
- 90% found within 5 mi of PLS.
- 33% found within 1/2 mi of PLS.
- 90% not moving more that 24 hrs.
- 30-50% move at night.
- Found by variety of techniques.

[Top of Page](#)

BEHAVIOUR CHARACTERISTICS OF SKIERS

- Generally under 35 yrs old.
- Almost all are in good physical and mental condition.
- 33% have much experience, significant number with some experience.
- Generally well equipped and clothed.
- 60% have survival training.
- Cause - Human error caused by subject - 33% weather, 20% darkness.
- 54% found within 2 mi. from PLS.
- 82-85% found within 5 mi.
- 83% are not moving more than 24 hrs.
- 30-45% move at night.
- 50% found by hasty search, visual tracking. 50% by themselves.

REASON LOST:

Disoriented, misjudge time/distance

30% accidental & intentional separation.

20% poor or no map.

DETECTABILITY

* 50% Mobile * Almost all are communicative

TRAVEL AIDS

Used path or trail or drainages.

25% attracted by civilization.

Probability of Location (POL)

SARBC

Search and Rescue Society of British Columbia

Probability of Location (POL)

[Mike Doyle](#)

Have you ever wanted to mark the spot on a map, showing the location of a missing person? For a few of the lost person [categories](#), this is possible to a point. You may end up with more than one "X" on the map. But at least you can send teams to check the "X"s out, instead of just sending searchers to the traditional high POA area segments.

Some of the information relating to predicting the location of a missing person would be found in [Behaviour Characteristics](#), [Speed Tables](#), [Missing Person Statistics](#), [Questionnaire](#) items (age, carrying, plans, psych profile, terrain profile, medical profile, weather profile, etc.), witnesses, friends, family, co-workers, etc.

More information can be found in publications from [NASAR](#)

Really good [Interviewing](#) skills are important. Without information, it is difficult to run an effective search. Planning is guesswork at best.

The area of search planning that has received the least amount of attention, is [Time Line Analysis](#). **NEW!** Without a contiguous time line, planning becomes dependent upon guesswork again. Analysing a Time line is of paramount importance for predicting lost person behaviour and location.

It is all very well to go out with the high tech gadgets, and the high tech search patterns, but why not go to the "X"s first?

How do you predict where the "X"s are? Start with the above, know your missing person, law of opposites, and, time line. Is that it? No, much more discussion is needed.

I'm going to say that the stats mentioned here are reasonably old, and haven't been updated with the new stuff.

To kick off "X" marks the spot (POL), why not look at a specific category.

Starting with "Despondent", it is my *personal* experience that one can very quickly come up with a few likely spots - one of which the subject will be at.

I'm sure you have knowledge of other categories, where the subjects have fit a set of behaviour characteristics. If so, you know where the next one is likely to be. Is there a category where POL cannot be used effectively?

If anyone has any thoughts on the matter they wish to share, please leave a post in the [Probability of Location Discussion area](#).

Review

There are two types of sensors in the eye: rods and cones.

Cones function well in brightly lit surroundings, perceive colour and much detail.

Rods are far more sensitive than cones, giving night vision with the pupils wide open. Rods do not distinguish colours or see fine detail.

Both rods and cones respond to a wide range of colours, but rods are very insensitive to red light.

Rods respond to various colours, but give a sensation only of black, grey or white.

Rods and cones are distributed non-uniformly across the retina.

Cones are only in the center. While in the periphery, the rods dominate.

Thus, the best visual acuity in good illumination is obtained for that part of the image focused on the center (fovea). The eye is most sensitive in conditions of weak illumination to images focused off-center (on the periphery of the retina).

Rods are de-sensitized by light (very quickly). It takes 20-30 minutes to re-sensitize (or dark adapt).

If light is needed, yet it is important to keep eyes dark-adapted, then use a red filter on the light. Rods are not sensitive to red light.

Night Observation Procedures

- look for shapes, shadows, contrast and movement
- since the center of the pupil is insensitive, all looking should be toward a side
- Eyes should be kept in motion - to keep the rods at their peak of sensitivity
- don't stare directly at a sighted object
- to avoid eye fatigue, every few minutes the observer should close their eyes for a few seconds to allow them to rest

Remember:

- allow eyes to become dark-adapted
 - colours are not discernable
 - details cannot be seen
 - use red light only
-

Using Binoculars at night

One measure of the effectiveness of binoculars for night use is *exit pupil*. This is the diameter of the bundle of light rays exiting toward the eye from the eye-piece of the binoculars.

This number is found by dividing the objective lens diameter by the power (7x35 = 5mm exit pupil, or, 7x50 = 7mm exit pupil). The pupil of the eye is about 7mm when fully dialated. If the exit pupil is less than 7mm, then the eye isn't fully used.

(For day use, a small exit pupil is satisfactory, since the eye pupil is only about 2mm in diameter. However, the large exit pupil is advantageous because of ease of centering the eye behind the eye-piece.)

Use

Binoculars should be held aimed straight forward and the eyes turned off-center - to avoid using the insensitive center of the retina. This requires practice, but is very effective.

Elementary School Preplan

Search Action Plan for Elementary Schools Prepared by:

Loreen Keefe and Michael Doyle
Search and Rescue Society of British Columbia (SARBC)
March 1988 Updated July 1995

In cooperation with:

Wishart School Principal, staff and parents
Wishart Safe Arrival program volunteers
Colwood Detachment R.C.M.P., Community Policing Branch

Example Elementary School Search Action Plan

INTRODUCTION

There was a case of two missing six year old girls. They disappeared after being dropped off at their Elementary school. They were missing for about an hour. During that time, it became clear that there really was no plan for such an event. The Safe Arrival program volunteers know their program, and know of a child's absence within moments of roll call. But what to do after notification?

SARBC volunteered to draft a plan, which would address what to do next.

The Plan, which follows, is the result of several consultations with school staff, Principal, Safe Arrival program volunteers and the RCMP.

Please note that Sections D-E are School specific.

PREAMBLE

"Safe Arrival Program"

At the beginning of each school year, children are sent home with the "Safe Arrival" Form. Parents are asked to list the following phone numbers:

- home, both parent's business numbers, and three alternate numbers (neighbors, relatives and friends). This information is then put on a rollex card file at the school.
- If a child is to be absent from school, a "Contact Parent" is to be notified.
- Each morning, a volunteer from the Safe Arrival program phones the designated "Contact Parent" and gets a list of all the children who will be absent that day.
- Teachers take "roll-call" at school.
- Absentees are checked with the "Contact Parent's list".
- If a child is absent and not on the list, then the following occurs:
 - Parent(s)/Guardian notified.
If unable to contact the parent/guardian, check back with the teacher to see if the child has arrived in the interim. Siblings are questioned regarding the whereabouts of missing child.
 - If at this point the child is still missing, the "Safe Arrival" volunteer notifies the

Principal of the school.

NOTE : The above procedure is based on the assumption that the child is registered in the "Safe Arrival" program.

NOTE : In the school records, it is noted who is the child's court appointed guardian and any stipulations.

SECTION A GUIDELINES and INSTRUCTIONS

ITEM 1

Safe Arrival program personnel will advise the Principal (Search Coordinator), and will contact parents of the missing child. They will advise parents that their child has not arrived at school. If the child is not at home and parents are unaware of their child's whereabouts, instruct the parents they are responsible for the following:

- Attempt to locate their child by contacting the homes of their child's friends, and check with family and neighbors.
- Check the route the child normally takes to school and areas the child frequents.
- If there is no adult at the child's home, make arrangements for someone to be there, or parents should return home, in case child returns and/or additional information is needed.

Parents must be given a fixed time to locate the child, minimum 20 min - maximum 30 min, with the understanding that the school will be contacting the RCMP after 30 minutes. Advise the parents that if they are unable to locate their child within thirty minutes, they are to contact both their local RCMP Detachment and the school.

*** Obtain description of child's clothing***

ALSO SEE PARENT/GUARDIAN RESPONSIBILITIES

ITEM 2

Missing child's siblings and classmates are to be questioned regarding the following:

- Known intentions of the missing child (identify child's friends).
- Possible sightings of the missing child.
- Areas the missing child frequents/plays.

ITEM 3

Search Coordinator will establish a Search Headquarters - a quiet room with access to telephone, tables, paper, pens, etc.

Search Coordinator is to complete "Missing Child Information Form". (For information: school records, teacher and child's parents)

- Include child's picture on the form as well.
- Photocopy several copies for searchers.

Search Coordinator will stay at search headquarters.

ITEM 4

Search Coordinator will dispatch search teams and document all information and decisions.

Search Coordinator is responsible for the following briefings:

School Staff : Notify that child is missing, description of child and subsequent procedures.

Staff Search Teams :

- Description of missing child -see "Missing Child Information Form".
- Search Procedures :

NOTE: The Search Coordinator will, in advance, assign personnel by function, to search each Zone.

- Building Search - Thorough search of all rooms, including small spaces that a child could hide in. (ie.cupboards, etc.)
- Outbuildings and Grounds Search - Thorough, systematic search for child and possible

articles that the child may have dropped. Periodically, call out the child's name and listen for at least ten seconds for a response.

- In the event of clues or items found, note precisely where found. Bring back to Search HQ.
- Give searchers deadlines to return to Search HQ.
- In the event that the child is found and there is suspicion of foul play, send someone for help, don't disturb the area and administer First-Aid as necessary. (See Section F for more info.)

NOTE: School staff (Searchers), do not leave the school grounds, only "call and listen" from the perimeters. The Search Coordinator will also document the following:

- Child's home address on the map.
- Areas searched and any observations.
- General public sightings (Witness reports).
- Any applicable information for the search effort.

The Search Coordinator will, if the child is not found within 30 minutes, notify the RCMP, and have copies of the following documents:

- Missing Child Information Form - completed.
- Log or list of what has been done so far.
- Map with the school and the child's house identified on it.
- List of areas the child would frequent.

SECTION A PARENT/GUARDIAN RESPONSIBILITIES

The news of a missing child sends a chill through any caring person, especially the Parents or Guardians. Sometimes, what to do first or next seems to be confusing, as thoughts of what could have happened, race through our minds. There are some things which can be done, now.

If a child is found to be missing from school, then the child's Parents/Guardians are notified by the school.

Once notified that their child is missing from school, Parents/Guardians should be prepared to help the search effort by doing the following:

- Arrange to leave work if it becomes necessary.
- Attempt to locate their child by contacting the homes of their child's friends, and check with family and neighbors.
- Check the route the child normally takes to school and areas the child frequents.
- If there is no adult at the child's home, make arrangements for someone to be there, or Parents/Guardians should return home, in case child returns and/or additional information is needed.

Parents/Guardians are RESPONSIBLE for the duties outlined by numbers 2, 3 and 4 above.

Parents/Guardians have a fixed time to locate their child, minimum 20 min - 30 min maximum, with the understanding that the school will be contacting the RCMP within 30 minutes.

If the Parents/Guardians are unable to locate their child within 30 minutes, they are to contact both their local RCMP Detachment and the school.

Give Description of child's clothing to School Search Coordinator.

If the Parents/Guardians feel they must go to the school, they should understand that they come under the direction and control of the Search Coordinator.

SECTION C MISSING CHILD INFORMATION FORM (PLEASE PRINT)

Date: _____ Time (reported missing): _____
Name: _____ Nickname: _____
Password: _____
Parent/Guardian Name: _____
Address: _____ Phone #: _____
LAST KNOWN LOCATION: _____

SECTION D
AREAS CHILDREN FREQUENT - SCHOOL SPECIFIC
EXAMPLE ONLY

This would show a map of the area with the following information numbered on the map.

Grade One

- (1) Yards and houses of friends
- (2) Streets near both their own home and friends

Grade Two

School yards of the following schools:

- (3) Wishart
- (4) Dunsmuir
- (5) Sangster
- (2) Friend's homes
- (6) Ocean View Park

Grade Four

- (7) Gravel Pit
- (8) Webb Place - underdeveloped area

Grade Five and Six

- (9) Metchosin Road - near firehall
- (4) Dunsmuir School Ground
- (10) "Forest Area" - off Wishart Road, going towards Metchosin Road
- (11) Reservoir - Latoria Road
- (12) New Town Houses - Mary Anne Crescent
- (12) Play Ground - Mary Anne Crescent
- (7) Gravel Pit
- (13) Winthrop Path - Near Bunker Road

Grade Five

- (3) Fields behind school

Grade Six

- (9, 10) Around Church
- (15) Forest Behind School
- (7) Gravel Pit
- (14) By Johnny's Store
- (3) Path Between Portables

Grade Six and Seven

- (3) Forest beyond School Field

- (6) Ocean View Park
- (9,10) Church Parking Lot
- (10) End of Wishart Place

NOTE : The above areas are located on Colwood Street Maps. (You would see accompanying Map for locations of bracketed items.)

ENTER CHILD'S HOME ADDRESS: _____

SECTION E SCHOOL LAYOUT

This section would show the school layout, as well as, all rooms by floor.

SECTION F PRESERVATION OF EVIDENCE

Compiled from lectures given by RCMP and District Coroner. This information is to be given to Field Team Leaders only in certain situations (this is a very sensitive topic).

In the case of suspected foul play, or death of the missing person:

- Safeguard the scene by sealing off the entire area. Allow only people actually engaged in the investigation into the area. Record the names of all people who came into contact with the scene area. If relieved of this duty by Police officer in charge, note his/her name, and time.
 - a. Note any vehicles in the immediate area and record their licence plate numbers.
 - b. Note any people in the area not involved with the search, and write down a general description of each person.
- The first member on the scene, or the Team Leader if immediately available, will be responsible for completing a file including: names of all persons present; all relevant times; the condition of the scene; the condition, description, and location of the victim; type of day; description of the area; a rough sketch of the scene also noting any peculiar or unusual items or pieces of evidence (signs of struggle, weapons, bloodstains, etc.).
- Try to hold all witnesses, if any, and limit conversation between them. Treat suspects as witnesses, try and hold as a witness.
- In the case of violent or sexual crime, record the FIRST statements of the victim, and who the victim made them to.
- First-aid and evacuation, if necessary, must be the prime concern. However, try to protect the scene as much as possible. Use only the people necessary, the rest of the team must be excluded from the area.
- One person should approach the scene to determine the course of action. The rest of the team should stay back.
- All team members who had any part of 1,2,3,4 or 5 above should record their observations and should be prepared to attend a Coroner's inquest if one is called.

This concludes the Search Action Plan.

SEARCH AND RESCUE: RCMP ROLE

[back](#)

In Canada, except within federally owned National Parks, the overall responsibility for land and inland water search and rescue (SAR) rests with the provinces, territories and municipalities. Typically this responsibility is delegated to the police force of jurisdiction.

The police force of jurisdiction in all provinces except Ontario and Quebec; in both territories, and in various municipalities is the Royal Canadian Mounted Police (RCMP). In these areas, police services, including SAR, is performed pursuant to formal police services agreements.

The RCMP recently completed an extensive review of its search and rescue policy and training requirements. The review resulted in a revitalized search and rescue program which will enable the RCMP to provide SAR services in a more effective and cost efficient manner.

In order to achieve these objectives the RCMP is placing special emphasis on:

- Response;
- Interdepartmental Cooperation;
- Prevention, and
- Volunteers.

New initiatives in these areas will create and maintain a solid framework for search and rescue in the areas where the RCMP has a contractual responsibility.

RESPONSE

In the area of response, new RCMP policy will clearly outline the roles and responsibilities of RCMP personnel within a province, territory or municipality.

RCMP SAR Coordinators ensure that regional issues, including policy, training and resources are promptly addressed. Each province or territory served by the

RCMP has a SAR coordinator.

Detachment Commanders ensure that complaints of lost or overdue persons are promptly investigated and a "Lost/Missing Person Report" is compiled. When warranted, a SAR trained RCMP Search Commander is appointed and a search is initiated.

RCMP Search Commanders assume overall on-site authority for the organization and management of the actual search and ensure the search is well organized and managed according to proven management procedures. The assistance of a SAR trained volunteer civilian Search Manager and SAR trained volunteers may be requested.

Initial SAR responses may involve one or more of the following: Police Service Dog Team; trained volunteer SAR civilian dog team; Trained volunteer "Hasty Team" (in some areas RCMP Hasty Teams are used); RCMP helicopter equipped with Forward Looking Infrared (FLIR); trained volunteer "specialist" teams, e.g. avalanche, white water, ice rescue, etc.; trained volunteer SAR divers (although most areas use RCMP Dive Teams); trained human trackers and other SAR trained persons.

Subsequent or more concentrated searches may involve the use of SAR trained volunteer teams; (who conduct open or closed grid searches); the Civil Air Search and Rescue Association (CASARA), or other provincial agencies with SAR capabilities; or in the case of inland water searches, the [Canadian Coast Guard Auxiliary](#) (CCGA).

Training

Under recently released new SAR policy, the minimum training requirement for RCMP Search Commanders will be a "basic SAR" and "SAR management" course.

As a standard for training, the RCMP has formally recognized "basic", "advanced" and "management" SAR courses produced by, or based on the principles of, the United States based Emergency Response Institute (ERI), and the U.S. National Association for Search and Rescue (NASAR).

Canadian courses which meet these standards include, but are not limited to, the Provincial Emergency Program (PEP), in the province of British Columbia, and the Emergency Measures Organization (EMO), in the Yukon.

The RCMP has also initiated action to introduce sessions on SAR at the recruit training level, as well as on Detachment Commander training courses.

These training initiatives will ensure a standard and uniform level of SAR training is provided throughout the RCMP.

Equipment

A variety of RCMP-owned equipment may be utilized in SAR operations. Equipment is generally referred to as "multi-tasked", which means that the equipment used by the RCMP to conduct a wide variety of police services,

- [Home](#)
- [About the RCMP](#)
- [Priorities](#)
- [Programs and Services](#)
- [Operations](#)
- [Strategic Direction](#)
- [Corporate Management and Comptrollership](#)
- [National Police Services](#)
- [Technology](#)
- [Newsroom](#)
- [Careers / Recruiting](#)

including SAR; and "primary SAR" which means the primary purposes for acquiring this equipment was to perform a SAR function.

Multi-tasked equipment owned and operated by the RCMP includes 404 inshore water transport; 8 patrol vessels (8 m or more in length), 26 fixed wing aircraft and 9 helicopters, five of which are equipped with FLIR. The FLIR equipped helicopters are stationed at Vancouver, British Columbia; Edmonton, Alberta; Fredericton, New Brunswick; Gander, Newfoundland and Whitehorse, Yukon. All multi-tasked helicopters are equipped with mounts to accommodate FLIR.

Primary SAR equipment owned and controlled by the RCMP includes: 1 - 7.3 m Zodiac Hurricane 730-0B located in Iqaluit, NWT; 1 - 8.2 m Boston Whaler located in Yellowknife, NWT; 8 - Zodiac markIII Grand Raid Inflatables located at strategic locations in Newfoundland; 1 - 8.2 m welded aluminum cuddy cabin boat located at Agassiz; and 1 - 9.1 m aluminum cuddy cabin located in Hay River, NWT. In some instances, primary SAR equipment is operated by SAR trained civilian volunteers, pursuant to formal written agreements.

Interdepartmental Cooperation

RCMP divisions are identified by a single alphabetic prefix, i.e. British Columbia is "E" Division. An RCMP division generally identified equates to a province or territory ([see map](#)). As the province or territory has overall responsibility for SAR, requirements may vary by region.

RCMP Divisions either have, or will be developing, formal written agreements or Memorandums of Understanding (MOUs) within each provincial or territory served by the RCMP, as well as with other applicable federal departments. These MOUs will clarify the respective roles of each agency.

The agreements will clarify, within the confines of the province, the roles of the Civilian Air Search & Rescue Association, (CASARA); the Canadian Marine Rescue Association (CMRA); Canadian Parks Service; Departments of Forestry and Natural Resources, as well as Workers Compensation Coverage for volunteers and other government and non-governmental agencies with an interest in SAR and provincial expectations or standards for SAR volunteers.

On a national level the RCMP at "HQ" Ottawa works very closely with the National Search and Rescue Secretariat (NSS). The role of the NSS is to enhance the provision of effective, efficient and economical SAR service in Canada by facilitating the development of the National Search and Rescue Plan (NSP). The NSP is a unique undertaking by federal and participating provincial, municipal and private SAR organizations with the objective of saving lives by enhancing SAR prevention and the provision, throughout Canada's accepted areas of responsibility, of effective and affordable SAR services.

RCMP "HQ" is also an active participant on the Interdepartmental Committee on Search and Rescue (ICSAR) which includes representatives from DND, CCG, Parks Canada, Fisheries and Oceans, and Environment Canada.

Prevention

It is often said that if the general public were properly trained through extensive "preventive" programs, there would be few requirements in Canada for either "searches" or "rescues".

Although individuals are primarily responsible for their own safety, the RCMP has recently undertaken a number of new prevention initiatives. These initiatives are being directed at three target groups: school children ages 5-12; special interest groups, and the general public.

School children are taught how to survive in the woods when lost. Videos are used to instill SAR awareness to special interest groups. Videos include two 1995 presentations developed by the RCMP in "K" Division (Alberta). Prevention brochures are disseminated to the general public during police week and during other special occasions. Brochures include one entitled "Prepared for the Woods", which is produced by Emergency Preparedness Canada.

Volunteers

Properly trained civilian volunteers are, at the very least, equally as effective as highly trained paid professionals, and in many instances are more readily available.

While the RCMP Search Commander maintains authority for the organization and management of the search, national RCMP policy promotes, whenever feasible, the organization and use of this valuable resource. The exact level and extent of civilian involvement in SAR generally varies by province, according to provincial guidelines, standards, Workers Compensation and local RCMP requirements.

Provincial standards and certification are invaluable in pre-determining the qualifications of volunteers. This is especially true in the case of volunteer SAR dog teams as the Search Commander has a obligation to ensure both the handler and the dog will recognize clues; will not destroy evidence; will not injure the lost person, and will not become lost or injured themselves.

To the extent possible, potential volunteer search managers will be encouraged to attend RCMP-sponsored search management courses, together with potential RCMP SAR Commanders. Furthermore, it is RCMP policy that when feasible, the RCMP will also assist in the training of volunteers.

The RCMP is committed to the principles of community based policing and SAR is an excellent example of the high level of partnership and commitment between the police and the community.

Conclusion

Recent developments have brought a new level of SAR importance and accountability in the RCMP and a greater reliance on the development and use of trained volunteers. Through improved response, prevention and inter-departmental cooperation, it is hoped that many search emergencies can be avoided and that many lives will be saved.

The RCMP has undertaken numerous efforts to enhance the general effectiveness of its national SAR program. This has involved an examination of, and in some cases, a complete overhaul of our force's responsibilities, levels of service, standards, training, allocation of resources, and types of resources.

No amount of police resources and equipment will ever replace the vital knowledge and commitment of the citizen within the community. The role of invaluable volunteers in SAR can only be expected to grow in the future.

INTRODUCTION

These guidelines have been developed for use by prehospital , clinic and hospital personnel dealing with cold problems in Alaska. They are meant to be guidelines, not absolute rules, governing the treatment of hypothermia and cold water near drowning.

Field personnel, from first responders through paramedics, may not want to carry the full set of guidelines with them. It may be more practical simply to carry the portion pertinent to their level of training, and to be generally familiar with the content for their level.

The full set of guidelines probably would be best utilized in hospital radio rooms, where calls come in from prehospital personnel with various levels of training.

To illustrate:

If a call comes in to Dillingham hospital from Naknek about a hypothermic patient, the hospital personnel need to ask the level of training of the prehospital personnel. If the caller is an EMT-II, for example, the hospital personnel can then turn to Hypothermia-EMT-II and direct the EMT in appropriate treatment.

Readers should note that these protocols are primarily designed to be used in EMS education and as a reference for the treatment of cold injuries and for use in assisting in the development of local standing orders. In the absence of standing orders, they may be used to guide the treatment of cold injuries until communication with a physician is established.

These guidelines are **not** intended to serve as a comprehensive teaching document on cold related illnesses and injuries. Consequently, those teaching the treatment of cold injuries must be prepared to elaborate on pathophysiology and treatment.

[Back to the Table of Contents](#)

HYPOTHERMIA: GENERAL POINTS

A.

The evaluation and treatment of hypothermia whether wet or dry, on land or water, are similar. Specific differences are covered in the following pages.

B.

In the cold patient, a rectal temperature is one of the vital signs. In terms of the ABC's, think:

A - Airway B - Breathing C - Circulation D - Degrees

C.

In the cold patient, body core temperature becomes an important sign. While obtaining a body core temperature is

important and useful for assessing and treating hypothermia, there is tremendous variability in individual physiologic responses at specific temperatures and a low reading thermometer may not always be available. Therefore, these guidelines are not solely based on the patient's measured temperature.

D.

Assessment of temperature:

1. The simplest assessment of a patient's body temperature may be performed by placing an ungloved hand against the skin of the patient's back or chest. If the skin feels warm, hypothermia is unlikely. This method, however, does not provide a reliable estimate of the patient's core temperature.
2. Axillary and oral measurements are poor measures of core temperature. Rectal temperatures more closely approximate the core temperature and are a practical method for use in the field. It is acknowledged that other methods of estimating the core temperature exist. Use of techniques other than rectal measurements should be evaluated for their accuracy and practicality in the field. The decision to use a methodology other than rectal temperatures should be made in consultation with the service's physician medical director.
3. Patients with cold skin should have a rectal temperature taken with a low reading thermometer. Household thermometers are useless in this setting. Low reading rectal thermometers should be capable of measuring temperatures as low as 70°F.
4. CAUTION: Electronic thermometers may not be accurate if they are left in the cold.

E:

The hypothermic patient should be assessed carefully for coexisting injuries and illnesses. The signs and symptoms of hypothermia may be mimicked by alcohol, diabetes, altitude sickness, overdose and other conditions. As a result, a thorough assessment of the patient is imperative. Associated significant illness or injury may exacerbate hypothermia. Splinting should be performed, when indicated, with caution to prevent additional injuries to frostbitten tissues.

F.

Ensure that items, oxygen, and fluids (both oral and IV) coming into contact with the patient, are warmed.

G.

Since cold skin is easily injured, avoid direct application of hot objects or excessive pressure (e.g. uninsulated hot water bottles, tourniquets).

H.

As in any resuscitation, a positive attitude is important. The hypothermic patient may appear to be beyond help because of skin color, pupil dilation, and depressed vital signs. However, patients suffering from severe hypothermia have been resuscitated. Therefore, be cautious about assuming the patient cannot be resuscitated. It is also wise to be cautious about what you say during the resuscitation. Seemingly unconscious patients frequently remember what is said and done.

I.

Severe cold injuries are encountered relatively infrequently. Consequently, it is necessary that you preplan the management of these conditions and that you are familiar with the appropriate equipment.

J.

The inside of the ambulance and any rooms where hypothermia patients are treated should be warm enough to prevent further heat loss, ideally above 80° F (26.7° C).

K.

CPR has no significant effect on survival of the hypothermic patient in the following situations, and, in accordance with state law and local standing orders, CPR should not be initiated when:

1. Cold water submersion patients who have been under the water for more than 1 hour.
2. Hypothermia patients with a core temperature of less than 60° F (15.5° C).
3. Obvious fatal injuries, e.g. decapitation.
4. Frozen patients, e.g. ice formation in the airway.
5. The chest wall is so stiff that compression is impossible.
6. Rescuers are exhausted or at danger.

L.

Recent legislation (1994 HB 39) has empowered EMTs, paramedics and physicians-assistants to declare death in the field following 30 minutes of properly performed advanced life support, even when the patient is hypothermic. It is recommended in these cases, however, that resuscitations be continued for at least 60 minutes and be combined with the rewarming techniques found in these guidelines before being terminated. Please note that this legislation does not authorize Emergency Trauma Technicians and the general public to pronounce a patient dead.

M.

The patient with severe hypothermia must be handled very gently. The cold heart is very prone to cardiac arrest. Even cautious movement of the patient may induce cardiac arrest.

N.

The indications for the pneumatic anti-shock garments are the same as for normothermic patients. The use of the PASG is controversial and they should be used in accordance with established local protocols.

O.

The pulse should be checked for up to 45 seconds when assessing a hypothermic patient or a patient who has been removed from cold water.

[Back to the Table of Contents](#)

HYPOTHERMIA: GENERAL PUBLIC

A.

Assessment of Patient

1. **Severe Hypothermia:** If the patient is cold and has any of the following signs or symptoms, he is considered to

have severe hypothermia:

- a. Temperature of 90° F (32.2° C) or less.
- b. Depressed vital signs, such as a slow pulse and/or slow respiration.
- c. Altered level of consciousness, including slurred speech, staggering gait, decreased mental skills, or the lack of response to verbal or painful stimuli.
- d. No shivering in spite of being very cold. (Note: This sign is potentially unreliable and may be altered by alcohol intoxication.)

2. **Mild Hypothermia:** If the patient is cold and does not have any of these signs or symptoms, he is considered to have mild hypothermia.

B.

Basic Treatment for Hypothermia

1. Prevent further heat loss. Insulate from the ground, protect from the wind, eliminate evaporative heat loss by removing wet clothing or by covering the patient with a vapor barrier (such as a plastic garbage bag), cover the head and neck and move the patient to a warm environment. Consider covering patient's mouth and nose with a light fabric to reduce heat loss through respirations.
2. Activate the emergency medical services system to provide transport to a medical facility.
3. Do not give alcohol.

C.

Treatment for Mild Hypothermia

1. Treat the patient as outlined in Section B.
2. If there is no way to get to a medical facility, rewarm the patient gradually by:
 - a. Placing patient in as warm an environment as possible.
 - b. Increasing heat production through exercise and calorie/fluid replacement. This method of adding heat is particularly important when emergency care is not readily available as in remote or prolonged transport environment.
 - c. Rewarming passively through the application of insulated heat packs to high heat transfer/loss areas such as the head, neck, underarms, sides of the chest wall, and groin, and heavy insulation to prevent further heat loss.
 - d. Considering warm showers and warm bath if the patient is alert.
 - e. Placing patient in a sleeping bag and providing contact with a warm body. The patient should **not** be placed a sleeping bag with another individual who is hypothermic. This method should be considered a last resort since it may endanger the rescuer and is less efficient than other methods.
3. Encourage the patient to drink warm fluids as soon as he, or she, is capable of swallowing and protecting his or her airway.

D.

Treatment for Severe Hypothermia with Signs of Life (e.g. Pulse and Respirations Present)

1. Treat the patient as outlined in sections B and C above with the following exceptions:
 - a. Do **not** put severely hypothermic patients in a shower or bath.
 - b. Do **not** give a patient oral fluids unless he or she is capable of swallowing and protecting his or her airway.
2. Treat patients who are hypothermic very gently (do not rub or manipulate extremities).

E.

Treatment for Severe Hypothermia with No Life Signs

1. Treat as above.
2. If no pulse (after checking for up to 45 seconds) and no respirations and no contraindications as listed in section K, start CPR.
3. Use mouth-to-mask breathing.
4. Reassess the patient's physical status periodically.
5. Transfer to a medical facility as soon as possible.

[Back to the Table of Contents](#)

HYPOTHERMIA: FIRST RESPONDER/EMERGENCY MEDICAL TECHNICIAN I

A.

Assessment of Patient

1. **Severe Hypothermia:** If the patient is cold and has any of the following signs or symptoms, he is considered to have severe hypothermia:
 - a. Temperature of 90° F (32.2° C) or less.
 - b. Depressed vital signs, such as a slow pulse and/or slow respiration.
 - c. Altered level of consciousness, including slurred speech, staggering gait, decreased mental skills, or the lack of response to verbal or painful stimuli.
 - d. No shivering in spite of being very cold. (Note: This sign is potentially unreliable and may be altered by alcohol intoxication.)
2. **Mild Hypothermia:** If the patient is cold and does not have any of these signs or symptoms, he is considered to have mild hypothermia.

B.

Basic Treatment for Hypothermia

1. Prevent further heat loss. Insulate from the ground, protect from the wind, eliminate evaporative heat loss by removing wet clothing or by covering the patient with a vapor barrier (such as a plastic garbage bag), cover the head and neck and move the patient to a warm environment. Consider covering patient's mouth and nose with a light fabric to reduce heat loss through respirations.
2. Treat and transport to a medical facility.
3. Do not give alcohol.
4. When administered, oxygen should be heated to 105° - 108° F (40.5° - 42.2° C), measured at the mouth, and humidified, if possible.
5. Splinting should be performed, when indicated, with caution to prevent additional injuries to frostbitten tissues.

C.

Treatment for Mild Hypothermia

1. Treat the patient as outlined in Section B.
2. If there is no way to get to a medical facility, rewarm the patient gradually by:
 - a. Placing patient in as warm an environment as possible.
 - b. Increasing heat production through exercise and calorie/fluid replacement. This method of adding heat is particularly important when emergency care is not readily available as in remote or prolonged transport environment.
 - c. Rewarming passively through the application of insulated heat packs to high heat transfer/loss areas such as the head, neck, underarms, sides of the chest wall, and groin, and heavy insulation to prevent further heat loss.
 - d. Considering warm showers and warm bath if the patient is alert.
 - e. Placing patient in a sleeping bag and providing contact with a warm body.
The patient should **not** be placed a sleeping bag with another individual who is hypothermic. This method, however, should be considered a last resort, however, since it may endanger the rescuer and is less efficient than other methods.
3. Encourage the patient to drink warm fluids as soon as he, or she, is capable of swallowing and protecting his or her airway.

D.

Treatment for Severe Hypothermia with Signs of Life. (i.e. Pulse and Respirations Present):

1. Obtain a core temperature (rectal).
2. Treat the patient as outlined in sections B and C above with the following exceptions:
 - a. Do **not** put severely hypothermic patients in a shower or bath.
 - b. Do **not** give a patient oral fluids unless he or she is capable of swallowing and protecting his or her airway.
3. Treat patients who are hypothermic very gently (do not rub or manipulate extremities).

4. Transport patient to a medical facility as soon as possible.
5. Reassess the patient's physical status periodically.

E.

Treatment for Severe Hypothermia with No Life Signs:

1. Treat as above.
2. If no pulse (after checking for up to 45 seconds) and no respirations and no contraindications as listed in section K, start CPR.
3. Use mouth-to-mask breathing.
4. Advanced airway devices: The indications and contraindications for advanced airway devices are the same in both the hypothermic and the warm patient. However, hypothermic patients may be more difficult to intubate, precipitation of ventricular fibrillation may be a danger, and intubation should only be attempted under optimum conditions by skilled personnel only if the airway is inadequate.
5. If the rescuers are authorized to use an automated external defibrillator and the device states that shocks are indicated, one set of three stacked shocks should be delivered. If the core temperature of the patient cannot be determined or is above 86° F, treat the patient as if normothermic. If the patient's core temperature is below 86° F, discontinue use of the AED after the initial three shocks.
6. If resuscitation has been provided in conjunction with rewarming techniques for more than 60 minutes without the return of spontaneous pulse or respiration, contact the base physician for recommendations. If contact with a physician is not possible, Emergency Medical Technicians may consider terminating the resuscitation in accordance with HB 39 and local protocols.

HYPOTHERMIA: EMERGENCY MEDICAL TECHNICIAN II

A.

Assessment of Patient

1. **Severe Hypothermia:** If the patient is cold and has *any* of the following signs or symptoms, he is considered to have severe hypothermia:
 - a. Temperature of 90° F (32.2° C) or less.
 - b. Depressed vital signs, such as a slow pulse and/or slow respiration.
 - b. Alternate level of consciousness, including slurred speech, staggering gait, decreased mental skills, or the lack of response to verbal or painful stimuli.
 - d. No shivering in spite of being very cold. (Note: This sign is potentially unreliable and may be altered by alcohol intoxication.)

2. **Mild Hypothermia:** If the patient is cold and does not have any of these signs or symptoms, he is considered to have mild hypothermia.

B.

Basic Treatment for Hypothermia

1. Prevent further heat loss. Insulate from the ground, protect from the wind, eliminate evaporative heat loss by removing wet clothing or by covering the patient with a vapor barrier (such as a plastic garbage bag), cover the head and neck and move the patient to a warm environment. Consider covering patient's mouth and nose with a light fabric to reduce heat loss through respirations.
2. Treat and transport to a medical facility.
3. Do not give alcohol.
4. When administered, oxygen should be heated to 105° - 108° F (40.5° - 42.2° C), measured at the mouth, and humidified, if possible.
5. Splinting should be performed, when indicated, with caution to prevent additional injuries to frostbitten tissues.
6. Do not give coffee or alcohol.
7. I.V. Therapy
 - a. Indications for I.V.'s are the same for mildly hypothermic patients as they are for normothermic patients.
 - b. Most hypothermic patients are dehydrated and may require aggressive fluid resuscitation.
 - c. Do not delay transport, communications, or other therapy by taking a long time to start an I.V. I.V.'s are difficult to start in cold patients.
 - d. The recommended fluid for rehydration is a balanced salt solution, such as normal saline or ringer's lactate.
 - e. I.V.'s should be heated to 104° - 108° F (40° - 42° C), when possible.
8. Medications:
 - a. Indications for medications are the same for mildly hypothermic patients as they are for normothermic patients.
 - b. Medications are inefficient and poorly metabolized in the hypothermic patient. In addition, due to delayed metabolism, medications given in normal therapeutic doses to severely hypothermic patients can result in toxicity when the patient is rewarmed.
 - c. As with any person with altered consciousness, Narcan and 50% dextrose should be considered when there is a reasonable suspicion that their use is warranted.
 - d. Sodium bicarbonate is not to be used unless specifically ordered by a physician.

C.

Treatment for Mild Hypothermia

1. Treat the patient as outlined in Section B.

2. If there is no way to get to a medical facility, rewarm the patient gradually by:
 - a. Placing patient in as warm an environment as possible.
 - b. Increasing heat production through exercise and calorie/fluid replacement. This method of adding heat is particularly important when emergency care is not readily available as in remote or prolonged transport environment.
 - c. Rewarming passively through the application of insulated heat packs to high heat transfer/loss areas such as the head, neck, underarms, sides of the chest wall, and groin, and heavy insulation to prevent further heat loss.
 - d. Considering warm showers and warm bath if the patient is alert.
 - e. Placing patient in a sleeping bag and providing contact with a warm body. The patient should **not** be placed a sleeping bag with another individual who is hypothermic. This method, however, should be considered a last resort, however, since it may endanger the rescuer and is less efficient than other methods.
3. Encourage the patient to drink warm fluids as soon as he, or she, is capable of swallowing and protecting his or her airway.

D.

Treatment for Severe Hypothermia with Signs of Life (e.g. Pulse and Respirations Present):

1. Obtain a core temperature (rectal).
2. Treat the patient as outlined in sections B and C above with the following exceptions:
 - a. Do **not** put severely hypothermic patients in a shower or bath.
 - b. Do **not** give a patient oral fluids unless he or she is capable of swallowing and protecting his or her airway.
3. Treat patients who are hypothermic very gently (do not rub or manipulate extremities).
4. Administer 10 cc/kilogram of a balanced salt solution as a bolus followed by 5 cc/kg/hr as a continuous infusion.
5. Transport patient to a medical facility as soon as possible.
6. Reassess the patient's physical status periodically.

E.

Treatment for Severe Hypothermia with No Life Signs:

1. Treat as above.
2. If no pulse (after checking for up to 45 seconds) and no respirations and no contraindications as listed in section K on page 2, start CPR.
3. Use mouth-to-mask breathing.
4. Advanced airway devices: The indications and contraindications for advanced airway devices are the same in both the hypothermic and the warm patient. However, hypothermic patients may be more difficult to intubate, precipitation of ventricular fibrillation may be a danger, and intubation should only be attempted under optimum conditions by skilled personnel only if the airway is inadequate.

5. If the rescuers are authorized to use an automated external defibrillator and the device states that shocks are indicated, one set of three stacked shocks should be delivered. If the core temperature of the patient cannot be determined or is above 86° F, treat the patient as if normothermic. If the patient's core temperature is below 86° F, discontinue use of the AED after the initial three shocks.
6. If resuscitation has been provided in conjunction with rewarming techniques for more than 60 minutes without the return of spontaneous pulse or respiration, contact the base physician for recommendations. If contact with a physician is not possible, Emergency Medical Technicians may consider terminating the resuscitation in accordance with HB 39 and local protocols.

HYPOTHERMIA: EMERGENCY MEDICAL TECHNICIAN III/PARAMEDIC

A.

Assessment of Patient

1. **Severe Hypothermia:** If the patient is cold and has *any* of the following signs or symptoms, he is considered to have severe hypothermia:
 - Temperature of 90° F (32.2° C) or less.
 - Depressed vital signs, such as a slow pulse and/or slow respiration.
 - Altered level of consciousness, including slurred speech, staggering gait, decreased mental skills, or the lack of response to verbal or painful stimuli.
 - No shivering in spite of being very cold. (Note: This sign is potentially unreliable and may be altered by alcohol intoxication.)
2. **Mild Hypothermia:** If the patient is cold and does not have any of these signs or symptoms, he is considered to have mild hypothermia.

B.

Basic Treatment for Hypothermia

1. Prevent further heat loss. Insulate from the ground, protect from the wind, eliminate evaporative heat loss by removing wet clothing or by covering the patient with a vapor barrier (such as a plastic garbage bag), cover the head and neck and move the patient to a warm environment. Consider covering patient's mouth and nose with a light fabric to reduce heat loss through respirations.
2. Treat and transport to a medical facility.
3. Do not give alcohol.
4. When administered, oxygen should be heated to 105° - 108° F (40.5° - 42.2° C), measured at the mouth, and humidified, if possible.

5. Splinting should be performed, when indicated, with caution to prevent additional injuries to frostbitten tissues.

6. 6. I.V. Therapy

- Indications for I.V.'s are the same for mildly hypothermic patients as they are for normothermic patients.
- Most hypothermic patients are dehydrated and may require aggressive fluid resuscitation.
- Do not delay transport, communications, or other therapy by taking a long time to start an I.V. I.V.'s are difficult to start in cold patients.
- The recommended fluid for rehydration is a balanced salt solution, such as normal saline or ringer's lactate.
- I.V.'s should be heated to 104° - 108° F (40° - 42° C), when possible.

7. Medications:

- a. Indications for medications are the same for mildly hypothermic patients as they are for normothermic patients.
- b. Medications are inefficient and poorly metabolized in the hypothermic patient. In addition, due to delayed metabolism, medications given in normal therapeutic doses to severely hypothermic patients can result in toxicity when the patient is rewarmed.
- As with any person with altered consciousness, Narcan and 50% dextrose should be considered when there is a reasonable suspicion that their use is warranted.
- Sodium bicarbonate is not to be used unless specifically ordered by a physician.

C.

Treatment for Mild Hypothermia

1. Treat the patient as outlined in Section B.
2. If there is no way to get to a medical facility, rewarm the patient gradually by:
 - Placing patient in as warm an environment as possible.
 - Increasing heat production through exercise and calorie/fluid replacement. This method of adding heat is particularly important when emergency care is not readily available as in remote or prolonged transport environment.
 - Rewarming passively through the application of insulated heat packs to high heat transfer/loss areas such as the head, neck, underarms, sides of the chest wall, and groin, and heavy insulation to prevent further heat loss.
 - Considering warm showers and warm bath if the patient is alert.
 - Placing patient in a sleeping bag and providing contact with a warm body. The patient should **not** be placed a sleeping bag with another individual who is hypothermic. This method, however, should be considered a last resort, however, since it may endanger the rescuer and is less efficient than other methods.
3. Encourage the patient to drink warm fluids as soon as he, or she, is capable of swallowing and protecting his or her airway.

D.

Treatment for Severe Hypothermia with Signs of Life (i.e. Pulse and Respiration Present):

1. Obtain a core temperature (rectal).
2. Treat the patient as outlined in sections B and C above with the following exceptions:
 - Do **not** put severely hypothermic patients in a shower or bath.
 - Do **not** give a patient oral fluids unless he or she is capable of swallowing and protecting his or her airway.
3. Treat patients who are hypothermic very gently (do not rub or manipulate extremities).
4. Administer 10 cc/kilogram of a balanced salt solution as a bolus followed by 5 cc/kg/hr as a continuous infusion.
5. Transport patient to a medical facility as soon as possible.
6. Reassess the patient's physical status periodically.

E.

Treatment for Severe Hypothermia with No Life Signs (CPR Required)

1. Treat as above.
2. If no pulse (after checking for up to 45 seconds) and no respirations and no contraindications as listed in section K on page 2, start CPR.
3. Use mouth-to-mask breathing.
4. Advanced airway devices: The indications and contraindications for advanced airway devices are the same in both the hypothermic and the warm patient. However, hypothermic patients may be more difficult to intubate, precipitation of ventricular fibrillation may be a danger, and intubation should only be attempted under optimum conditions by skilled personnel only if the airway is inadequate.
5. Guidelines have not been established for the use of advanced cardiac life support procedures in the hypothermic patient. One series of defibrillation attempts if the patient is in ventricular fibrillation (200 ws, 300 ws, 360 ws, OR 200 ws, 200 ws, 360 ws) is reasonable followed by a bolus of bretylium/lidocaine. If successful the patient should be transported immediately to the nearest medical facility. If unsuccessful and the patient's core temperature is below 86° F, the patient should immediately be transported to the nearest medical facility without further attempts at defibrillation. If the temperature is above 86° F, continue with resuscitation as if the patient was normothermic. Additional treatment should be determined by the medical director.
Note: Shivering can mimic ventricular fibrillation.
6. If the cardiac rhythm is asystole, as assessed in two different leads, do not attempt defibrillation. Additional ACLS medications should be used with caution in accordance with physician signed standing orders and as stated in B--7 of this section.
7. If resuscitation has been provided in conjunction with rewarming techniques for more than 60 minutes without the return of spontaneous pulse or respiration, contact the base physician for recommendations. If contact with a physician is not possible, Emergency Medical Technicians may consider terminating the resuscitation in accordance with HB 39 and local protocols.

[Back to the Table of Contents](#)

HYPOTHERMIA: SMALL/BUSH CLINIC

A.

The extent of the evaluation and treatment in small/bush clinics is defined by the training of the personnel and the available equipment as outlined in the foregoing guidelines.

B.

For transfer to a higher medical facility, the patient must be stabilized in the clinic rather than transferred as an unstable patient. If the patient is requiring CPR or is otherwise with unstable vital signs, then the necessary equipment and trained personnel-if not already at the clinic-should be sent to the clinic in order to stabilize the patient for transfer to a higher medical facility.

C.

Once the rewarming process has started in the clinic, it should be continued until transfer is possible and appropriate or the patient recovers.

[Back to the Table of Contents](#)

HYPOTHERMIA: HOSPITAL

A.

General Points

1. Treat to the level of your ability as your hospital equipment, staff, and skills dictate.
2. All patients should be stabilized before any transport to another facility. The patient should be kept in the sending hospital until the patient is stable or accepted by the receiving hospital.

B.

Evaluation

1. Initial attention to the ABCs and CPR as needed.
2. Vital signs, including rectal temperature.
3. Brief history.
4. Brief physical exam:
 - a. Feel for skin temperature.
 - b. Level of consciousness and neurological examination.

- c. Cadiopulmonary exam.
 - d. Associated trauma.
 - e. Weight.
5. Suggested laboratory and x-ray evaluation, depending on available staffing and equipment:
- a. Chest x-ray.
 - b. 12 lead electrocardiogram.
 - c. Urine: urinalysis, sodium and osmolality.
 - d. Blood: CBC, BUN, creatinine, electrolytes, sugar, platelets, PTT, prothrombin time, liver function tests, amylase.
 - e. Arterial blood gases.

C.

Monitoring and Treatment

1. Basic treatment is the same as that indicated for prehospital personnel in these guidelines.
2. Physiologic monitoring. Pulse oximetry or transcutaneous oxygen monitoring may be unreliable due to peripheral vasoconstriction. Consider topical methyl salicylate as a skin vasodilator. All patients should be on a cardiac monitor.
3. Administer 10 cc/kilogram of a crystalloid solution (5% dextrose in normal saline) as a bolus followed by 5 cc/kg/hr as a continuous infusion. Large amounts of fluid may be necessary for complete fluid resuscitation. A CVP line may help to determine fluid status. I.V.'s should be heated to 104° - 108° F (40° - 42° C), when possible.
4. Urinary bladder catheter, preferably with a thermistor.
5. Nasogastric tube or orogastric tube, if the patient is unconscious and intubated.
6. Endotracheal/Nasotracheal tube is indicated in the unconscious patient after careful neck evaluation.
7. Ventilate with moist air or oxygen heated to 105° - 108° F (40.5° - 42.2° C), measured at the mouth, and humidified, if possible.
8. Continue monitoring until stable and warm.

D.

Adding Heat

1. The recommended possibilities include:

EXTERNAL METHODS	INTERNAL METHODS
Gradual Spontaneous Rewarming	Warm Steam Inhalation/Ventilation (105° - 108° F) = (40.5° - 42.2° C)
Warming Blankets	Peritoneal Lavage (105° - 110° F) = (40.5° - 43.3° C)

Tub Bath (Up to 100° F (37.7°C))	Extracorporeal Circulation
	Warm Gastric/Bladder Lavage (105° - 110° F) = (40.5° - 43.3° C)
	Warm IV's (104° - 108° F) = (40° - 42° C)
	Chest Lavage via Chest Tubes

2. Regardless of the method chosen for adding heat, the patient must be under total physiologic control and the temperatures of devices, fluids, and gasses used for rewarming should be monitored.
3. Tub bath is one of the most rapid rewarming methods and requires *immediate* laboratory results and extremely close physiological monitoring.
4. For Severe Hypothermia without Signs of Life: Warm the core as rapidly as possible, using one or more of the internal methods, preferably cardiopulmonary bypass, if available.
5. For Severe Hypothermia with Life Signs: Use the rewarming method available in the facility which is most familiar to you.

E.

Most Common Problems

1. Arrhythmias:
 - a. Arrhythmias other than ventricular fibrillation will usually convert spontaneously with rewarming. If treatment is not working, continue rewarming.
 - b. In ventricular fibrillation with a core temperature of less than 85° F, consider one attempt at defibrillation (200 ws, 300 ws, 360 ws OR 200 ws, 200 ws, 360 ws) and intravenous bretylium/lidocaine.
2. Dehydration: Monitor and treat accordingly.
3. Hyperkalemia: Monitor and treat accordingly. (Do not infuse potassium in I.V.'s until serum potassium is obtained.)
4. Hyperglycemia and hypoglycemia: Monitor and treat accordingly.
5. Arterial Blood Gasses: Monitor and treat accordingly.

F.

Transferring Patients to Tertiary Care Facilities

1. The general indications to transfer the patient from a smaller hospital to a tertiary care facility are:
 - a. Lack of nursing and support staff.
 - b. Lack of equipment to properly provide for a critically ill patient.

2. Specifically, the patient should be transferred if there is:
 - a. no capability for continuous arterial blood gas monitoring;
 - b. profound neurological depression;
 - c. associated significant trauma; or
 - d. associated significant frostbite.
3. The patient should not be transferred until he or she has been accepted by the receiving medical facility and has been stabilized as much as possible to ensure safe transport.

[Back to the Table of Contents](#)

COLD WATER NEAR DROWNING: GENERAL POINTS

- A.
For the purposes of this document, cold water is defined as being less than 70° F (21.1° C).
- B.
Anyone submerged long enough to be unconscious should be transported to the hospital, *even if they he or she has regained consciousness*.
- C.
If the person has been under water for **LESS** than one hour, full resuscitative efforts should employed. If the person has been under water for **MORE** than one hour, resuscitation efforts are usually unsuccessful.
- D.
Recent legislation (1994 HB 39) has empowered EMTs, paramedics and physicians-assistants to declare death in the field following 30 minutes of properly performed advanced life support, even when the patient is hypothermic. It is recommended in these cases, however, that resuscitations be continued for at least 60 minutes and be combined with the rewarming techniques found in these guidelines before being terminated. Please note that this legislation does not authorize Emergency Trauma Technicians and the general public to pronounce a patient dead.
- E.
If it is not known how long the person has been under water, you should consider him/her to have been under water less than one hour.
- F.
There is no difference between fresh and salt water near drowning regarding outcome or treatment.
- G.
If it does not delay rescue, maintain the patient's body in a horizontal position while removing him/her from the water.
- H.

These principles apply to *any* near drowning, not just those in cold water. The difference between warm and cold water is that in submersions greater than 6 minutes, the chance for survival in warm water is much less than in cold water. The colder the water, the better the chance for survival.

I.

Because hypothermia is rarely profound (below 85° F (29.4° C) in cold water near drowning, the hypothermia aspect of the problem is less critical than the pulmonary or coagulation aspects. Thus, rewarming is done very cautiously and gradually, without the need for invasive techniques such as peritoneal lavage or AV shunts.

J.

Many near drowning patients die of a particular type of disseminated intravascular coagulation, not from their pulmonary problems.

K.

Persons surviving an immersion episode should be transported to the nearest medical facility for further evaluation. Accumulation of fluid in the lungs (noncardiogenic pulmonary edema) may develop 6 - 24 hours after submersion.

[Back to the Table of Contents](#)

COLD WATER NEAR DROWNING: GENERAL PUBLIC

Evaluation and Treatment

1. The Heimlich Maneuver should be used only when a foreign body airway obstruction is suspected.
2. CPR *must* be started immediately when the patient is determined to be pulseless, pulse check of up to 45 seconds.
3. Assess carefully for associated injuries.
4. Follow the General Public section on hypothermia for additional therapy as needed.

[Back to the Table of Contents](#)

COLD WATER NEAR DROWNING: FIRST RESPONDER/EMERGENCY MEDICAL TECHNICIAN I

Evaluation and Treatment

1. The Heimlich Maneuver should be used only when a foreign body airway obstruction is suspected.
2. CPR *must* be started immediately when the patient is determined to be pulseless after a pulse check of up to 45 seconds.
3. Assess carefully for associated injuries.

4. Follow the Emergency Medical Technician I section on Hypothermia for additional therapy as needed.

[Back to the Table of Contents](#)

COLD WATER NEAR DROWNING: EMERGENCY MEDICAL TECHNICIAN II

Evaluation and Treatment

1. The Heimlich Maneuver should be used only when a foreign body airway obstruction is suspected.
2. CPR *must* be started immediately when the patient is determined to be pulseless after a pulse check of up to 45 seconds.
3. Assess carefully for associated injuries.
4. Follow the Emergency Medical Technician II section on Hypothermia for additional therapy as needed, with the following exceptions.
 - a. If the main problem is not severe hypothermia, medication should be used as in the normothermic patient.
 - b. Because hypovolemia is generally not a problem in cold water near drownings, a balanced salt solution should be infused at a 'to keep open' rate.

[Back to the Table of Contents](#)

COLD WATER NEAR DROWNING: EMERGENCY MEDICAL TECHNICIAN III

Evaluation and Treatment

1. The Heimlich Maneuver should be used only when a foreign body airway obstruction is suspected.
2. CPR *must* be started immediately when the patient is determined to be pulseless after a pulse check of up to 45 seconds.
3. Assess carefully for associated injuries.
4. Follow the Emergency Medical Technician III/Paramedic section on Hypothermia on page 19 (including the 45 second pulse check) for additional therapy as needed, with the following exceptions.
 - a. If the main problem is not severe hypothermia, medication should be used as in the normothermic patient.
 - b. Because hypovolemia is generally not a problem in cold water near drownings, a balanced salt solution should be infused at a 'to keep open' rate.

[Back to the Table of Contents](#)

COLD WATER NEAR DROWNING: PARAMEDIC

Evaluation and Treatment

1. The Heimlich Maneuver should be used only when a foreign body airway obstruction is suspected.
2. CPR *must* be started immediately when the patient is determined to be pulseless after a pulse check of up to 45 seconds.
3. Assess carefully for associated injuries.
4. Follow the Emergency Medical Technician-III/Paramedic section on Hypothermia on page 19 (including the 45 second pulse check) for additional therapy as needed, with the following exceptions.
 - a. If the main problem is not severe hypothermia, medication should be used as in the normothermic patient.
 - b. Because hypovolemia is generally not a problem in cold water near drownings, a balanced salt solution should be infused at a 'to keep open' rate.

[Back to the Table of Contents](#)

COLD WATER NEAR DROWNING: SMALL/BUSH CLINIC

Evaluation and Treatment

1. The extent of the evaluation and treatment in small/bush clinics is defined by the training of the personnel and the available equipment as outlined in the foregoing guidelines.
2. It is very important to clear the airway with any of the standard maneuvers, but no specific maneuvers are mandatory to expel water from the lungs. Do not do the Heimlich maneuver on these patients unless there is evidence of a solid foreign body airway obstruction.
3. CPR *must* be started immediately when the patient is determined to be pulseless after a pulse check of up to 45 seconds.
4. Assess carefully for associated injuries.
5. Follow the Small/Bush Clinic Section on Hypothermia for additional therapy as needed, with the following exceptions.
 - a. If the main problem is not severe hypothermia, medication should be used as in the normothermic patient.
 - b. Because hypovolemia is generally not a problem in cold water near drownings, a balanced salt solution should be infused at a 'to keep open' rate.

[Back to the Table of Contents](#)

COLD WATER NEAR DROWNING: HOSPITAL

A.

Evaluation

The evaluation of the cold water near drowning patient is generally the same as indicated in the Hospital section of the hypothermia guidelines except for the laboratory evaluation, which in near drowning should be, in order:

1. Arterial blood gases.
2. Chest x-ray.
3. 12 lead electrocardiogram.
4. Electrolytes, BUN, CBC.
5. Scan the serum for pinkness (indicating hemolysis).
6. Institute cardiorespiratory monitoring.
7. I.V. therapy D5W at keep open levels. (In children, 1/4 - 1/2 maintenance rate.)

B.

Therapy

1. Attention to the ABC's, with respiratory support, intubation, etc., as needed.
2. Rewarming. Active rewarming methods (warm air inhalation, external heat sources, etc.) should be used as indicated by rectal temperature.

Once circulation has been established, do only passive rewarming (light sheets or light blankets; room temperature). Note that these patients often become hyperthermic.

3. Aspiration pneumonitis and pulmonary edema may be treated with appropriate diuretics, and mechanical ventilation and oxygenation.
4. Profound neurological depression: Consider aggressive cerebral resuscitation, as per Conn3, with intraventricular pressure monitoring, diuretics, and barbiturates.
5. Hemolysis - Treat as with any patient with hemolysis.
6. Disseminated Intravascular Coagulation - Treat as with any patient with DIC.
7. Renal insufficiency - Treat as with any patient with renal insufficiency.
8. Cardiopulmonary bypass is an appropriate therapy when the patient has resistant hypoxemia and cannot be rewarmed.

C.

Transferring the Near Drowning Patient to a Tertiary Care Facility

1. First the patient should be stabilized at the nearest hospital with intubation as necessary, and ventilation.

2. The general indications to transfer the patient from a small hospital to a tertiary care facility are:
 - a. Lack of nursing and support staff.
 - b. Lack of equipment to properly provide ongoing care for a critically ill patient.
3. Specifically, the patient should be transferred if there is:
 - a. no capability for arterial oxygen monitoring..
 - b. deterioration of pulmonary status.
 - c. renal insufficiency.
 - d. hemolysis.
 - e. profound neurological depression.
 - f. significant associated trauma.

[Back to the Table of Contents](#)

FROSTBITE: INTRODUCTION

Frostbite is the freezing of tissue and may involve only superficial tissues or may extend to the bone. The onset and severity of frostbite may be affected by air temperature, wind speed, duration of exposure, amount of exposed area, and predisposing conditions such as:

- poor or inadequate insulation from the cold or wind;
- impaired circulation from tight clothing or shoes;
- fatigue;
- altitude;
- immersion;
- injuries;
- circulatory disease;
- poor nutrition;
- dehydration;
- hypothermia;
- alcohol or drug use; and
- tobacco products.

A discussion of the pathophysiology of frostbite is beyond the scope of this document. Simply put, damage to the frostbitten tissues is caused by crystallization of water within the tissues, typically between the cells, as well as changes in electrolyte

concentration within the cells.

Frostbite is frequently seen in Alaska, although, in most circumstances, the frostbite is superficial and treated by the patient at home. Occasionally, it is severe enough to warrant transport to a medical facility for evaluation and treatment. Seldom will it be necessary for emergency medical personnel to perform in-field rewarming for deep frostbite. It may, however, be necessary to treat patients with superficial frostbite who have sustained other injuries, (e.g. a motor vehicle crash patient who has been exposed to sub-zero temperatures while awaiting the arrival of rescue and medical personnel).

These guidelines are designed to assist prehospital emergency medical personnel in assessing and treating frostbite. In-hospital treatment is beyond the scope of this section and readers are encouraged to refer to "Cold Injury: A Collection of Papers by William J. Mills, M.D. and Colleagues," which appeared in the January/February/March 1993 issue of *Alaska Medicine*, the official journal of the Alaska State Medical Association and the American Society for Circumpolar Health.

[Back to the Table of Contents](#)

FROSTBITE: GENERAL POINTS

Hypothermia and other life threatening conditions may be present in the patient with frostbite and must be evaluated and treated immediately.

When caring for a patient in extremely cold temperatures, take great care to prevent hypothermia, tissues from becoming frostbitten, and already frostbitten tissues from becoming worse.

If transporting a patient with frostbite which will not be rewarmed in the field, the medical provider should protect the frostbitten parts from additional injury and temperature changes.

Superficial frostbite affects the dermis and shallow subcutaneous layers of the skin and is recognized by white or gray colored patches. The affected skin feels firm, but not hard. The skin initially turns red and, once frostbitten, is not painful. No tissue loss will occur when treated properly.

Deep frostbite affects the dermal and subdermal layers and may involve an entire digit or body part. The skin feels hard and cold and the affected tissue is white or gray. A pulse cannot be felt in the deeply frostbitten tissue and skin will not rebound when pressed.

Large blisters on the frostbitten area indicate that deep frostbite has partially thawed.

Treatment of deep frostbite is usually extremely painful and best accomplished in a medical facility. If you can get the patient to a medical facility within a reasonable amount of time, or do not have the capability to rewarm the tissues properly or cannot prevent refreezing, you should transport the patient rather than attempt to rewarm the tissue in the field. Advice should be sought from a physician by radio or telephone before electing to rewarm frostbitten tissue in the field, whenever possible.

In most circumstances, the risks posed by improper rewarming or refreezing outweigh the risks of delaying treatment

for deep frostbite.

Tissue which is thawed and then refrozen almost always dies. Consequently, the decision to thaw the frostbitten tissue in the field commits the provider to a course of action which may involve pain control, maintaining warm water baths at a constant temperature, and protecting the tissue from further injury during rewarming and eventual transport. If rewarmed in the field, frostbitten extremities cannot be used for ambulation.

It is reasonable to consider rewarming the frostbitten tissue in a controlled manner if uncontrolled, spontaneous, rewarming is likely to occur during prolonged evacuation or transport.

Make plans for transporting the patient as early as circumstances allow. In some circumstances, when frostbite is not severe and is not complicated by other injuries, and there are resources available to monitor the patient's progress, a physician should be consulted. He or she may decide the patient should not be transported. This should be clearly understood and carefully documented by the prehospital provider.

Do not:

- rub the frozen part;
- allow the patient to have alcohol or tobacco;
- apply ice or snow;
- attempt to thaw the frostbitten part in cold water;
- attempt to thaw the frostbitten part with high temperatures such as those generated by stoves, exhaust, etc.; and
- break blisters which may form.

Frostbitten tissues should be handled extremely gently before, during, and after rewarming.

[Back to the Table of Contents](#)

FROSTBITE: EVALUATION AND TREATMENT

Anticipate, assess and treat the patient for hypothermia, if present.

Assess the frostbitten area carefully since the loss of sensation may cause the patient to be unaware of soft tissue injuries in that area.

Obtain a complete set of vital signs and the patient's temperature.

Obtain a patient history, including the date of the patient's last tetanus immunization.

If there is frostbite distal to a fracture, attempt to splint the fracture in a manner which does not compromise distal circulation.

Determine whether rewarming the frostbitten tissue can be accomplished in a medical facility. If it can, transport the patient

while protecting the tissue from further injury from cold or impacts.

If the decision is made to rewarm frostbitten tissue in the field, you should prepare a warm water bath (approximately 100° - 106° F) in a container large enough to accommodate the frostbitten tissues without them touching the sides or bottom of the container.

Advanced life support personnel should administer morphine or other analgesics in accordance with physician signed standing orders or on-line medical control if the frostbitten area is extensive and the medical providers are authorized to do so.

A source of additional warm water must be available.

Shock due to frostbite is very uncommon. However, medical personnel should always be alert for shock and begin treatment at the earliest sign it is developing. If the frostbite patient develops shock, personnel should perform a thorough examination for additional injuries.

Remove jewelry and clothing, if present, from the affected area.

If possible, consult a physician regarding the administration of oral analgesics, such as acetaminophen, ibuprofen or aspirin.

Water should be maintained at approximately 100° - 106° F and gently circulated around the frostbitten tissue until the distal tip of the frostbitten part becomes flushed.

Pain after rewarming usually indicates that tissue has been successfully rewarmed.

After re-warming, let the frostbitten tissues dry in the warm air. Do **not** towel dry.

After thawing, tissues that were deeply frostbitten may develop blisters or appear cyanotic. Blisters should not be broken and must be protected from injury.

Pad between affected digits and bandage affected tissues loosely with a soft, sterile dressing.

Rewarmed extremities should be kept at a level above the heart, if possible.

Protect the rewarmed area from refreezing and other trauma during transport. A frame around the frostbitten area should be constructed to prevent blankets from pressing directly on the injured area.

Do not allow an individual who has frostbitten feet except when the life of the patient or rescuer is in danger. Once frostbitten feet are rewarmed, the patient becomes nonambulatory.

1. Community Health Aides should use the protocols for their level of EMS certification. CHAs who are not certified as EMTs should use the EMT-I protocols for cold injuries.
2. Drug therapy should be moderated because in the cold patient medications are both inefficient and poorly metabolized.
3. "Cerebral Salvage in Near Drowning following Neurological Classification by Triage," A. W. Conn, Canadian Anesthesia Society Journal, Volume 27, No. 3, May, 1980

Henriette's Herbal Homepage

Herbal medicine and culinary herbs:
one of the oldest and largest herbal information sites on the net.

Welcome. On this site you'll find

- The [culinary herb FAQ](#) and the [medicinal herb FAQ](#)
- [Classic herbal works](#) - *added more 03May04* - including major ones like
 - [King's American Dispensatory](#)
 - [Felter's Eclectic Materia Medica](#)
 - [Ellingwood's American Materia Medica](#)as well as minor ones, and links to classic herbal works elsewhere
- 4668 [Botanical plant photos](#), and a couple hundred less botanical photos
- [Herbal forum archives](#)
- [Best of the Herbal Forums](#) - (BoHF) - *added more 04May04*
- [Links I like](#)
- [Plant names](#) - *updated 23Apr04*
- [Herbal FTP files](#) on [ibiblio.org](#), mirrored on [sunsite.sut.ac.jp](#)
- [Henriettes örtsidor](#): my Swedish pages
- [Henrietten yrttisivuja](#): my Finnish pages
- Neat stuff like [Herbal articles](#)
- [Site history, plus short author bio](#)
- [Site statistics](#): size of the site, and some usage statistics - *updated 08May04*
- [Best of RHOD](#), which is completely unrelated to herbs

Last updated 08May04 - Have a comment? [Tell me](#). Or try [YIM](#)

Please [sign my guestbook](#) - I love to see new things there.

The Medicinal HerbFAQ

1 Introduction

Hi all,

This is the (umpth + n) edition of the FAQ / Resource list. (I've lost track).

Feel free to send additions, corrections and comments.

hetta.spamcop.net (no blanks)

1.1 Contributors

FAQ Keeper: Henriette Kress, hetta.spamcop.net (no blanks)

1.2 Wishlist

Actually there isn't much important stuff missing anymore. The following topics are currently up for grabs:

Wanted for chapter 2 (Single herbs):

- Ginkgo

Wanted for chapter 3 (Herbs for specific things):

- Herbs for flu

Wanted in addition:

- Anything else you see posted every so often, but that I haven't included in the FAQ or on the wishlist.

If you wish to contribute send me a short note; I'll keep track of who promised to do what, and if you can't find the time to put something together in two months your topic will be up for grabs again.

Your contribution can be as long as you wish to make it; but it should be GOOD (like all the entries in this FAQ - thanks, folks).

Also, if you really know what you are talking about I'd like to hear your comments on any entry in this FAQ.

(Strange - all I ever get is 'Good Show. Keep it up.', but no-one ever tells me if they found any errors.)

-

So you want to to to a herb school? There's lots. Which are the good ones? Which will give you value for your money and which will hand you fancy gold-plated diplomas instead of the knowledge you went there for? Which are the ones where you'll have to arrive with a chastity belt firmly locked in order to avoid the teachers' amorous advances? Where will you learn all about goats and rather less about herbs?

The best way to find out juicy bits like that is to attend a herbal conference or two, and *_gossip_*. I can recommend the Southwest conference for that myself, as I've been to that one (watch me listen to horror stories with my chin on my collarbone...), but I expect others will be equally enlightening.

Note, the herb school I attended gave excellent value for the money; the diploma is factual and not that fancy; I didn't learn squat about goats; and I didn't have to fend off any of the teachers, either. All this before I attended even one conference... lucky me, eh?

There is no really comprehensive up-to-date list of herbal schools anywhere. I've put some schools into my list; there are other lists elsewhere. Here's a few:

- The Natural Healers site lists a few (American) herb schools - sort them by specialty and/or location: <http://www.naturalhealers.com>
- The American Herbalists guild has put parts of their (US) Herbal Education Directory online: http://www.americanherbalistsguild.com/school_search.htm - the \$12 version of the

same includes descriptions etc., at least according to their site:

<http://www.americanherbalistsguild.com>

- The American Herb Association also has compiled a list of (US) schools: <http://www.ahaerb.com> - theirs costs \$3.50.
- Herbnet also lists schools: http://www.herbnet.com/university_p1.htm

Whichever school you choose, do read the accreditation notes on this page - otherwise you might end up taking a correspondence course at Clayton.

(Why do I dislike Clayton? A real ND degree means that you can get a license to legally practise as an ND a few states in the US. The real thing also took about four years of hands-on training. In comparison, Clayton's mail order ND degree isn't worth the paper it's printed on. As long as Clayton hands out ND degrees without having the real ND degree backing they're a diploma mill in my eyes - and I have a *real* dislike for diploma mills. Let them call it something else, something with no real significance (which is what correspondence school diplomas *should* be), and I'll withdraw all my objections to their operations. Until then, pffshaw.)

7.1 Some hands-on schools I know of in the US

ND degrees:

These schools give you -real- ND degrees, with the possibility to get a ND license in one of the licensing states. There are also fake ND schools - read about those here: [7.6, Accreditation](#).

- Southwest College of Naturopathic Medicine & Health Sciences. Tempe, Arizona. <http://www.scnm.edu/>
- Bastyr University. Kenmore, WA. <http://www.bastyr.edu/>
- University of Bridgeport, College of Naturopathic Medicine. Bridgeport, CT. <http://www.bridgeport.edu/naturopathy/>
- National College of Naturopathic Medicine. Portland, OR. <http://www.ncnm.edu/> (Needs flash, which I abhor.)

Other herbal hands-on schools:

Full-time:

- Southwest School of Botanical Medicine, Michael Moore. Bisbee, Arizona. <http://www.swsbm.com/>
- The Rocky Mountain Herbal Institute, Hot Springs, MT. Mainly Chinese herbology. <http://www.rmhiherbal.org>
- California School of Herbal Studies, Forestville, CA. <http://www.cshs.com/>
- The North American College of Botanical Medicine (formerly the National College of Phytotherapy), Albuquerque, NM. <http://www.swcp.com/botanicalmedicine>
- Desert Woman Botanicals, Monica Rude, Gila, NM. Several 3-month apprenticeships in

medicinal herb growing, harvesting, drying, marketing, shipping, use in products. Enthusiastic, hard working workers interested in herb growing should apply.

<http://www.desertwoman.net/>

- NorthEast School of Botanical Medicine, 7Song. Ithaca, NY. A six-month, three days a week school: <http://www.ph.utexas.edu/~wolfe/NSBM/NSBMcur.html>

Part-time:

- Howie Brounstein, Columbines and Wizardry Herbs, Inc., Eugene, Oregon. A wildcrafting class. <http://www.teleport.com/~howieb/howie.html>
- Pacific School of Herbal Medicine, Adam Seller. Oakland, California. Classes range from a couple of hours (for beginners) through 650 hours (to become a professional herbalist). Adam also has clinical case studies for the practising herbalist. <http://www.pshm.org>
- Christopher Hobbs, Williams, OR. 8 month apprenticeship program, one weekend a month. <http://www.christopherhobbs.com>
- Herbal Therapeutics, David Winston. Broadway, NJ. A two-year school with classes one evening a week. <http://www.herbaltherapeutics.net>
- Rosemary Gladstar, Vermont. 12 month apprenticeship program, one weekend a month. <http://www.sagemountain.com>
- Althea Northage-Orr, Chicago, IL. Evening classes. <http://www.chicagocollegeofhealingarts.com>

I don't know if these are full- or part time:

- Susun Weed has intensives and correspondence courses: <http://www.susunweed.com>

7.2 Some hands-on schools in Canada

ND degree:

This school gives you a -real- ND degree, with the possibility to get a ND license in one of the licensing states. There are also fake ND schools - read about those here: [7.6, Accreditation](#)

- The Canadian College of Naturopathic Medicine, Toronto, Ontario. <http://www.ccnm.edu>

Other herbal hands-on schools:

- Dominion Herbal College, Burnaby, B.C. <http://www.dominionherbal.com>
 - Mohawk College of Applied Arts & Technology, Hamilton, Ontario. This is phytotherapy, not herbalism, but then I'm a snob. <http://www.mohawkc.on.ca/dept/cehs/phytotherapy.html>
 - Wild Rose College of Natural Healing, Terry Willard. Calgary, Alberta. <http://www.wrc.net/>
-

7.3 Some correspondence courses I know of in the US

It's rather difficult to judge these from their ads. I've added "good" to those which I've only heard good things about.

- Rosemary Gladstar has a correspondence course. <http://www.sagemountain.com>
"good"
 - The Australasian College of Herbal Studies. <http://www.herbed.com>
"good"
 - David Hoffmann, Therapeutic Herbalism. If you would like more information, his address is:
2068 Ludwig Avenue, Santa Rosa, CA 95407. 707/544-7210. Stuck in the stoneage, eh, David, with no URL yet? I'll drop this one in my next update, because addresses and phone numbers change, and I can't check them from here.
 - Christopher Hobbs Home study course. <http://www.christopherhobbs.com>
 - Jeanne Rose has a correspondence course. <http://www.jeannerose.net>
 - The School of Natural Healing, founded by Dr. John R. Christopher. They have an Herbalist course and a Master Herbalist course, among others. <http://schoolofnaturalhealing.com>
 - The East-West Herb Course, Michael Tierra. This is TCM, not western herbalism. <http://www.planetherbs.com>
-

7.4 Some schools and correspondence courses elsewhere

- The School of Natural Health Sciences, London, UK. <http://www.learnbymail.com/courses/herbalism.htm>
- The Waikato Centre for Herbal Medicine is in New Zealand. Graduates are able to become full Professional Members of the NZ Association of Medical Herbalists. The course is 4 year, three years at college (one day a week) and the 4th year is working alongside a Registered Medical Herbalist in Clinical Training. There is also a correspondence programme. <http://www.herbalcentre.co.nz>
- The International College of Herbal Medicine, in New Zealand. <http://www.HerbCollege.com>

The UK Herb Society has a Herbs educational resources page with more UK schools: <http://www.herbsociety.org.uk/education.htm>

The NIMH (the National Institute of Medical Herbalists, UK) also lists some schools; unfortunately, their list is rather out of date: <http://www.nimh.org.uk>

7.5 About correspondence schools, and licensing of herbalists

From: tim.thorne.thorne.com (Tim Birdsall, ND)

I have absolutely no quarrel with distance learning. However there is a substantive difference between getting an MBA by home study and getting a health care degree! How can you learn physical diagnosis without someone standing over your shoulder saying "No, the spleen is here." or "Yes, this person's liver feels enlarged." To the best of my knowledge, no other health care profession has any legitimate degrees offered exclusively via home study.

7.6 Accreditation of ND schools and ND licensing in the US

From: Paul Bergner <bergner.concentric.net>

Subject: Clayton School

Someone recently posted that the Clayton School had obtained "accreditation". By what body, may I ask? Is it something recognized by the Department of Education, or is it some form of gratuitous self-accreditation? The test of legitimacy is whether students are eligible for government student loans.

From Henriette:

Clayton's "ND" degree won't get you a ND license in the states where ND licensing is possible. If you want a real ND degree you need to attend one of the real ND schools mentioned above.

The accrediting agency for naturopathic schools is the Council on Naturopathic Medical Education (CNME), Eugene OR. <http://www.cnme.org>

The CNME is accredited by the US Department of Education and is the only recognized licensing agency for naturopathic medical schools in the US.

States in which you can get licensed as an ND:

If you're an ND who has graduated from one of the eligible ND schools you can get licensed in these states:

Alaska, Arizona, Connecticut, Hawaii, New Hampshire, Montana, Oregon, Vermont, Washington, Utah,

after passing the Naturopathic Physicians Licensing Exam (NPLEx).

There are additional recognized ND licenses in Florida. No new licenses are being granted there, however.

British Columbia and Ontario currently license NDs who pass licensing exams and who have graduated from any of the legitimate naturopathic medical schools with an ND.

Other resources:

Federation of Naturopathic Medical Licensing Boards, Inc., 5002 W Glendale Ave, Ste 101, Glendale, AZ 85301, USA, phone 602-937-4756.

American Association of Naturopathic Physicians (AANP), Seattle, WA.

The Medicinal HerbFAQ

2.1 Valeriana

Also see [3.5, Herbs to make you sleep](#).

> [Valeriana - uses? pros? cons? safety? dosage?](#)

From Todd Caldecott (toddius.netidea.com):

Valerian is an excellent herb to use, in combination with other herbs, or used alone. The active constituents are the volatile oil (isovalerianic/enic acid) and valepotriates. Valerian depresses the central nervous system, similar to GABA (which occurs naturally in the brain and inhibits nerve impulse transmission.) There are no cons to taking valerian other than if you use it other than in a capsule it can smell up your house as a tea. Or if you have cats they may rub up and down your leg (they like it, similar to catnip) while you are drinking you tea, causing you to stumble and fall, spilling hot liquid all over yourself. For Valerian to be effective you must take it in sufficient quantities to work e.g. 1-2 tsp. of the tincture (alcohol extract) before bed, or 6-10 capsules of the dried plant. Onset is typically 1 hour. You may awaken a little muddleheaded, which is quickly relieved as soon as you move about. For a daily dose, 5 ml (1 tsp.) of the tincture 3 times a day between meals is the standard dose.

About 20% of the population respond to Valerian as a stimulant, so if you take it and have insomnia or buzzed out, try hops, chamomile, passionflower, skullcap or *Avena*, which are all excellent herbs to relieve stress, anxiety and insomnia.

2.1.1 Valium is not derived from Valerian

>Valerian is the parent of Valium isn't it?

From Michael Moore (hrbmoore.rt66.com):

There is absolutely NO connection between Valerian and Valium...believe me...just an accident of circumstance...*Valeriana* is a classic Roman Latin reference...Valium is an invented trade name...a copycat name from a pharmaceutical manufacturer to aid in making a conscious or unconscious connection with "Librium", a successful tranq whose market Valium was originally aimed at.

Valerian HAS had some anecdotal use for ADD...the only problem is that extended use of enough Valerian to have value has ALSO brought about emotional lability in some folks. Using herbs as drug substitutes has value, but with Valerian having SO many different physiologic effects (depressant for CNS, stimulant to gastric, pulmonary and cardiovascular functions) it is a botanical that is best used within a constitutional framework...i.e. evaluating the PERSON metabolically to find out if the profile of effects from Valerian is complementary or antagonistic.

From Colette Gardiner coletteg.efn.org:

Re the name Valium and its relation to the name Librium. For some weird reason I actually remember reading an article in the newspaper on the new drug Valium. There was a quote from the inventor basically saying he had been trying to invent something similar to Librium only better. He went on for a paragraph or so about comparing the various sensations and effects, and concluded that yes Valium was "nicer".

The Medicinal HerbFAQ

2.2 Yohimbe

From [_urban shaman_](#), reached over [Carras.aol.com](#):

If people wanted to obtain a legal hyperalert sexually aroused state, they might find some yohimbe (*Corynanthe yohimbe*, *Pausinystalia yohimbe*) and brew it up by simmering a quart of water with 1 gm of ascorbic acid to 5 gm yohimbe until there's only 50% of the original water volume left. Add a lot of sugar afterward. Mixes synergistically with sassafras and Pau d'arco if you're adventurous and would like to cure your ills and get a hard-on at the same time. However, most people who have tried yohimbe have been disappointed. They didn't know you need to brew it 20 to 30 minutes at approx. 200x with an organic acid to release the alkaloid components.

The active alkaloid, yohimbine bitartrate, is the component of the only allopathic medicines known to cause erection in impotent males and approaches the concept of an aphrodisiac. Yohimbine bitartrate particularly affects nerves and changes blood flow regulators in the genital area. The medical texts never mention that it does the same thing to women, showing a typical disregard for female erection.

In the best case scenario this decoction will cause many users to get a melting spinal sensation and extreme epidermal sensitivity with high interpersonal perception and melding. It can be extremely sexually arousing...or at least all the signs and signals are there...

And the worst case scenario for yohimbe? - well, you have to remember ethnographic reports documenting cases of some African tribes drinking it in copious quantities in pre-raid rituals to suppress fear and jack up physical aggressiveness. After getting to the point where they were bouncing up and down so much they looked like a mosh pit full of spears, they'd run 10 miles over to the next village and kill off most of the neighboring tribe, stopping only to rape the dogs, cattle, women, children, surviving males, dead bodies, water jugs and tree holes before running back home. I'm not sure this is something we need downtown on Friday night.

Yohimbe Caution: it will keep both partners up all night. In the male of the species this becomes really inconvenient and irritating as after a few hours an erection becomes more of a liability than an asset - especially as this aspect continues long past the point - as long as 8 hours - where you'd like to go to sleep and there's this turgid log attached to you that won't go away and is just beginning to ache.

Note on the Caution: A warm bath can help with the log-on problem, as can gentle massage. However this should be avoided for at least four hours after ingestion because of the effect of raised body temperature on metabolism of the alkaloid - i.e., heat could intensify the stimulant effects.

Females are not exempt from this - it has the same effect on them, although it is easier to sleep on.

A possible downside of this erectile effect in high doses is the danger of blood vessel damage and gangrene in the penis resulting from the localized poor circulation condition known as penile erection.

More from _urban shaman_ on the subject:

There are a number of caveats re yohimbe - it shouldn't be taken with MAO inhibitors or by persons with high blood pressure, diabetes, glaucoma, or a history of mental disturbance, especially including bipolar disorder.

A good dose prepared using methods as I described can have profound psychological effects - enough so that 'set' and 'setting' can become issues if the concentration/quantity is sufficient. This condition can easily be entered into by simply acquiring relatively recently gathered/dried/imported specimens of the herb and using enough of it. Botanicals are very wiggly in the potency dept. - a primary breakdown in the process occurs when practitioners have never seen a 'good' specimen of the herb in question. There are no low cost analytical methods for determining the active compound density of herbal materials gathered in the wild. It totally depends on recognition by experts - and sometimes even the best of them may have to compromise, as there just may not be any high quality material to be had.

Still more from _urban shaman_ on the subject:

The "approved" alkaloid is yohimbine hydrochloride. Herbal Yohimbe extracts are sold by a number of health food companies including I believe Michaels and Herb Pharm. Yohimbe bark and powder may be available from "...of the Jungle" in Sebastopol CA. Please remember, if you're considering making extracts - Yohimbe is strongly synergized by alcohol. It is also easily extracted in alcohol/water - but the alcohol should be evaporated off after extraction unless you're looking for a real wow-wow effect. There could be high blood pressure complications from ingesting strong concentrations of Yohimbe. Dayton Laboratories sells the prescription preparation Dayto Himbin in tablet and liquid form. The tablets contain about 5.5 mg hydrochloride. The liquid contains phenylalanine as well and should be used with caution. Total daily doses run on average between 20-30 mg of the hydrochloride.

The medical action is to increase penile blood inflow and decrease penile blood outflow. The action is cited as having an erectile function without increase in libido. I have not taken the hydrochloride so don't speak from direct experience.

Although the caveats state that Yohimbine exerts no cardiac stimulation, it is later noted that Yohimbine is an unpredictable CNS stimulant and may cause elevated blood pressure and cardiac rates.

From this information I hazard we are to take it that in the same manner that yohimbine causes erections without raising libido, it also causes cardiac rate increase without stimulating the heart? (I love the guys who write this hype - they're so wise)

Buried deep in the caveats for the Dayto Himbin product is language saying you should not give this to people with a history of mental instability, and that it causes recipients to express a range of curious behaviors at doses lower than those required to cause erection - among which are tremors, irritation, dizziness, flushing (note that niacin causes a body flush at sites almost identical to those of a sexual flush).

Horse breeders administer large doses of niacin to both parties of a horse breeding "to get them in the mood". I would not suggest, however, that taking niacin along with yohimbe would have a parallel effect. If you don't know what a "sexual flush" is - take 200 mg of niacin and stand naked in front of a 3 panel mirror and watch your face, neck, "loins", and chest.

From Henriette:

If you have problems keeping it up, or are too dry, you might want to start with these:

- reduce your stress
- sleep enough and regularly
- change your contraceptive pills (if applicable)
- check your medication(s) for side effects (there's often surprises in the fine print)
- eat your vitamins
- if your partner's idea of foreplay is "Brace yerself, Sheila!" then you might benefit from some helpful books, imaginative games, or even from some softporn magazines.

If all that is OK, there are some herbs which remedy imbalances or work as aphrodisiacs, that aren't as quirky as yohimbe:

Try muira puama (*Ptychopetalum*), cotton root bark (*Gossypium*), or damiana (*Turnera*).

A nice wine will relax both partners - after you've tried and had problems there's psychological barriers, too, so you do need to relax. A romantic circumstance usually helps, too.

2.2.1 Yohimbe is a MAO inhibitor, yohimbine isn't

From Michael Moore:

The alkaloid yohimbine is NOT an MAO inhibitor. The herb yohimbe IS.

The whole plant is potentially so evil and insidious BECAUSE it's complex chemistry contains both adrenergics AND cholinergics...with effects that substantially mimic both sympathetic adrenergic, sympathetic cholinergic AND parasympathetic neuroreceptors all at the same time. It contains both yohimbine alkaloid groups (stimulating and hypertensive) and several potent

reserpinoid (Rauwolfia) alkaloids (tranquilizing and hypotensive) ...a warlock's brew.

Consistent use will, because of it's wildly opposite effects, find and widen metabolic chinks in almost ANYBODY.

The Medicinal HerbFAQ

2.3 Absinthe FAQ pointer

If you really are serious about absinthe go get the FAQ from http://www.erowid.org/chemicals/absinthe/absinthe_faq.shtml

I put this on top of the absinthe entry of this FAQ long ago: "Be warned - thujone IS dangerous, no matter what that FAQ says."

This sparked some debate, which follows.

But first, the La Fee Verte folks have made a very good absinthe FAQ: <http://www.feeverte.net/faq.html> - they also debunk the thujone danger.

2.3.1 More on Absinthe

Dale Kemery wrote

>I've been puzzled by absinthe for a long time. My recent reading has only intensified my curiosity. Is/was absinthe a true psychedelic beverage? Or what were/are its effects? For a long time I relied on the traditional reports about absinthe turning the brain to mush.

>However, considering the hysterical disinformation campaign of Howard Anslinger aimed against marijuana, I've become very suspicious of any official strictures. What *is* the story about wormwood/absinthe?

>Where can I learn more?

From christopher.gn.apc.org (Christopher Hedley):

This is from R.F.Weiss, Herbal Medicine. Weiss was an MD who taught herbal medicine in medical schools in Germany, so I suppose he counts as fairly impartial and reliable:

"The plant contains 0.25-0.5% of a volatile oil the main constituent of which is thujone as well as bitters. The bitter action predominates. Wormwood is a typical aromatic bitter. The volatile oil is remarkably effective against worms. It is however toxic, whilst the bitter principle is largely non-toxic. Absinthe is made with wormwood oil, but in Germany its manufacture has been banned since 1923. The usual wormwood preparations contain so little of the oil that there is no risk of toxic effect. In some Mediterranean countries, where absinthe is consumed in large quantities, the seriously damaging effects on the central nervous system which have given the plant its bad name may develop and even lead to seizures. This shows that wormwood also has central stimulant properties that are no doubt of benefit in the small quantities normally used.

Wormwood herb, for tea, 1 teaspoon to a glass of boiling water, leave to infuse for 10 minutes.

Wormwood tincture. 10-20-30 drops three times daily in water."

Comment; so the story is the same one as coffee, i.e. abuse/overuse of a perfectly good and useful herb.

Wormwood is *Artemisia absinthium*, it is used a lot in aperitif wines and spirits in Europe, but only in small amounts or it dominates the taste.

It is mostly used for intestinal parasites, 'weak digestion', liver and gall bladder troubles and as an emmenagogue. I always recommend it as a prophylactic for folk traveling to hot countries, 15 drops of tincture three times daily usually does the trick. The American spp of *Artemisia*, incl. sagebrush and mugwort, have pretty much the same properties.

- No *Artemisias* should be taken during pregnancy.

I trust this is useful info. Christopher Hedley

From Howie Brounstein <howieb.teleport.com>:

>>Be warned - thujone IS dangerous, no matter what that FAQ says.

The reason this line is attached to the Absinthe Pointer is because the Absinthe FAQ is slanted.

Most sources say that long term use of Absinthe is dangerous and debilitating. I was under the impression that many people became addicted to it and suffered mental and physical deterioration, thus it became outlawed. I would stress that this is long term use. Wormwood, *Artemisia absinthium* is pretty nasty stuff, you would have to drink a lot of tea to feel its narcotic like effects, but by then you'd be retching from its foul taste. Of course, you could try to hide the flavor with other stuff ... thus Absinthe.

Personally, I don't like it, don't feel its worth the havoc on your body for the effect. I like the smell of it, and would keep it around for that. The Absinthe FAQ, however, takes the point that it may be harmless, that the debility was caused by alcohol addiction, or Absinthe impurities, and a marihuana - like political scare tactics. I am not sure what to make of it, but the warning does remain that thujone is dangerous when taken in large enough quantities, and that the Absinthe of history did hurt a generation of people no matter what the specifics.

>If thujone is so dangerous, what are we to make of it as the primary constituent of *Artemisia*? Are we endangering ourselves whenever we inhale it?

Firstly, the chemistries of *Artemisia absinthium* and Mugwort, *Artemisia vulgaris* or *douglasiana* are different. Some of the contraindications are different; the uses are different; their histories are different. Also, it may be a bit premature to say that one chemical, thujone, is THE active ingredient in either. That would be a bit too reductionist for my tastes. We can't even assume that because a plant contains some small amount of a poison, that the plant is poisonous, or we'd have to give up onions, spinach, mustard. The difference between food and poison is often dosage; the difference between poison and medicine is dosage. So let's focus on thujone. A brief list of plants containing thujone includes:

Salvia officinalis L. - Sage (Leaf)
Salvia triloba L. - Greek Sage (Plant)
Artemisia dracuncululus L. - Tarragon (Shoot)
Mentha x rotundifolia (L.) HUDSON - Applemint (Leaf)
Pycnanthemum tenuifolium SCHRAD. - Slenderleaf Mountain Mint (Shoot)
Mentha pulegium L. - European Pennyroyal (Plant)
Thymus orospedanus H. del VILLAR - Orosped Thyme (Plant)
Achillea millefolium L. - Yarrow (Plant)
Capsicum frutescens L. - Cayenne (Fruit)
Carum carvi L. - Caraway (Fruit)
Glycyrrhiza glabra L. - Licorice (Root)
Juniperus sabina L. - Sabine (Plant)
Matricaria recutita L. - Annual Chamomile (Plant)
Mentha arvensis L. - Cornmint (Plant)
Sassafras albidum (NUTT.) NEES - Sassafras (Root)
Satureja hortensis L. - Summer Savory (Plant)

This list, and others like it is available free from the Phytochemical databases - <http://www.ars-grin.gov/duke/> .

So as you can see, many plants that are very safe (in normal dosages) contain this chemical. So smell your Mugwort, drink Mugwort tea, smoke it, smear the juice all over your body on a vision-dream quest, just don't extract pure thujone from it and snort it.

>Someone on another list suggested smoking *Artemisia* because there's a strong connection with marijuana --both affect the same (or similar) receptors in the brain, and are apparently similar botanically (I don't know what that means technically). Additionally, a book called *Absinthe, History in a Bottle* by Barnaby Conrad III mentions thujone-enol's structural similarity to THC.

Smoking *Artemisia*? Hmm, for me Mugwort is a flavor, used in small amounts as not to be too overwhelming. Kind of mentholly. Or perhaps for it's dreaming effects. But once again folks are implying a generalization: This one constituent (or group of constituents) is shaped like THC, and perhaps affects the same receptor sites as THC, so it must make you feel like you smoked THC. Oops, flawed logic again. Just because the shape of two molecules are similar doesn't mean that they have similar biological effects.

They might, but its not guaranteed. My take on this: Ingesting Mugwort, or any *Artemisia* I've tasted, does not make you feel like you've ingested Marihuana.

So enjoy the smells, drown your concerns, and a happy, aromatic holiday season to all you netters out there.

Howie Brounstein

From Dale Kemery, DalePK.aol.com, to above:

I thought you might be interested in more complete information about absinthe, wormwood and thujone, after our recent exchange on the subject. I've come across a comprehensive summary about it in Jonathan Ott's superb "Pharmactheon." (Although using his name with any glowing adjective is redundant because everything I've seen of his is so complete, exhaustive and thoroughly researched and studied.)

"Absinthe was prepared by distilling alcohol over mashed leaves of wormwood, and other common ingredients were *Angelica* root, *Acorus calamus* rhizome (which may contain the psychoactive asarones; ...), cinnamon, fennel seed, star anise (both of which contain anethole, another potentially psychoactive compound...) and other plants. The characteristic and much-desired green color of the liqueur, which was supposed to whiten when mixed with water, was sometimes artificially enhanced by addition of indigo and other plants, or toxic metal salts like copper sulfate and antimony chloride...

He chronicles the history of the banning of absinthe and a recent renewal of interest in absinthe, then says:

"It is commonly assumed that the thujones were the neurotoxic principles of absinthe, although alcohol also is a potent neurotoxin (absinthe contained from 68-85% alcohol) and significant quantities of copper and antimony salts used as adulterants (particularly in cheap imitation absinthe for the poorer classes) may have been present and responsible for the neurotoxicity...While large doses of injected thujones are unquestionably toxic, modern toxicological studies of thujones, in the quantities present in absinthe, without the copper and antimony adulterants, are needed before concluding that the neurotoxicity associated with absinthism was a consequence of thujone content. I suspect the copper and antimony salts, as well as the unusually high alcohol content had more to do with absinthe toxicity than the thujone content. Non-thujone essential oils commonly present in absinthe have also been shown to have convulsant properties and are probably neurotoxic."

The obvious inference is that thujone is unlikely the culprit in "absinthism." And even though he acknowledges the toxicity of "large doses of injected thujones," the operative words are "large"

and "injected." It may be assumed (without any evidence to support this statement) that swallowing thujone in some form (tea, for example) would subject it to the chemical rigors of digestion, a pathway that is much different from intravenous or even intramuscular injection. Whether the same can be said for, say, smoking a thujone-containing plant is another matter since inhalation effectuates a much more direct transfer into the blood without the intervention of hydrochloric acid, pepsin and other digestive enzymes.

From christopher.gn.apc.org (Christopher Hedley):

A note.. Sage (*Salvia officinalis*) essential oil is 30% thujone and good sage has up to 2.5% essential oil. Wormwood contains 1% essential oil, I don't have a figure on the % of thujone but if we assume it to be less than half then it is possible to consume more thujone in Sage tea than in Wormwood tea and no one has suggested that long term use of sage is toxic.

Distilling alcohol over Wormwood would extract mostly the volatile oil. Weiss says that the pure volatile oil was also used in the making of absinthe - this is still an ingrained habit in food and drink manufacture and one that should be condemned. Flavouring with volatile oils is NOT the same as flavouring with plants.

Thujone has been given bad press but I still don't think that consuming large amounts of volatile oil for long periods has anything to recommend it. Also the thujone has strong stimulating effects, noticeable when smoking wormwood - which as Howie says is nothing like smoking Mugwort. Presumably absinthe had the same degree of stimulation and thus people were encouraged to drink more and abuse it.

The comparison between thujone and THC is an interesting example of just how far theory can lead people astray. Always try for yourself I say.

From Howie Brounstein <howieb.teleport.com>:

> Also the thujone has strong stimulating effects, noticeable when smoking wormwood- which as Howie says is nothing like smoking Mugwort. Presumably absinthe had the same degree of stimulation and thus people were encouraged to drink more and abuse it.

Hmmm. Did I say that. Oh yes, so I did. It is hard to put into words. Mugwort can be used like Wormwood for worms, warming, female reproductive system effects, and it has similar contra-indications. Yet wormwood has something else, a more overtly drugged feeling it produces that I have never experienced with other *Artemisias*. I don't know what chemical is responsible for it, it may be thujone unrelated, for all I know. But I know the feeling.

From: "Rob Miedema" <8rm1.qlink.queensu.ca>

Thujone does not in fact act like THC at all. That belief was founded on the observation that they have similar chemical structures, but was proven incorrect (Hold et al., 2000). Actually, it seems that thujone exerts its effects on GABA-A receptors in the brain. This is the same receptor that alcohol acts on, but the two chemicals have opposite effects. Therefore the balance between thujone and ethanol in the absinthe is critical. Thujone, or rather it's active metabolites

(7-hydroxy-alpha-thujone, alpha-thujone), and other products in wormwood that steep into absinthe (e.g. camphor) are actually convulsants. They inhibit the brains inhibitory system causing overexcitation. Death in animals as large as cats and rabbits results from moderate doses and there are documented cases of death in humans (Burkhard et al., 1999). One person's statement that oral ingestion is not injection so it is probably fine is false, the thujone actually needs to be metabolized by the liver to break it down into its active components.

If you still want to try it here's one how-to, and a vivid description of the experience:

>Making Absinthe is extremely easy, as long as you don't require the full alcoholic content. Just take Pernod, pour off about an ounce and cram wormwood herb in the top. Let it set for a week or two. That's it. Pernod is Absinthe without the wormwood and about half the alcohol.

From ix.io.com (Lupo LeBoucher):

This is unlikely to absorb much thujone; for a really horrible and ridiculously potent absinthe, buy a fifth of 100 proof vodka, pour it over an ounce of wormwood, and a quarter ounce of anise seeds, and let it steep for a month or two. After straining the liquid, the resulting decoction will be a horrible looking liquid with approximately the color and psychoactivity of 1970s gasoline, though gasoline tastes better (long story).

To ingest (one cannot drink it), pour over a lump of sugar into a strong mixture of water & lemon juice, hold nose, and swallow before you taste the bitter horror. Be sure to do this in the vicinity of a sink with running water; one may need to wash the awful stuff down or provide your absinthe with a convenient place to rest should it decide to come up for a breather.

Effects reportedly include, audio-visual hallucinations similar to the opiates, with a bit o nitrous; numb mucus membranes; dizziness, nausea, picking up the ugliest member of the opposite sex one has ever encountered and vomiting green bile over oneself while asleep (experts disagree whether or not the latter was an effect of the previous, rather than an effect of the thujone - ask Heysoos, I didn't do it).

The above recipe was taken from a book called "The Magical and Ritual Uses of Herbs" (by Richard Allen Miller) which described Absinthe as "an excellent after-dinner liqueur" which makes one wonder what types of dinners Mr. Miller has at his place.

From ix.io.com (Lupo LeBoucher):

>Anise has no effect; the active ingredients in absinthe are just wormwood and alcohol.

The anise went in the mix in a misguided attempt to kill some of the bitter flavor (since it was what the standard recipes used). All I succeeded in doing was killing some of the wormwood "flavor" *retch* upon burping.

>The plain wormwood probably could be swallowed as a tea followed by the booze as a chaser.

The plain infusion used to be prescribed as a "tonic".

I don't know if it would have the same effect; the essential oils in the wormwood, which contain the active ingredients, are not likely to be water soluble.

From stygianv.shadow.net (Coyote Osborne):

> Anise has no effect; the active ingredients in absinthe are just wormwood and alcohol.

Ah, but anise does have an important effect here. It keeps the wormwood/absinthe from irritating your stomach so much. I would recommend fennel and perhaps peppermint or basil for this also.

> The plain wormwood probably could be swallowed as a tea followed by the booze as a chaser. The plain infusion used to be pre-scribed as a "tonic".

Actually, most of the things in wormwood are damaged or destroyed if added to hot water. Warming it gently (like brandy) works, but not making an infusion with water that is boiling. I suspect that a good rule of thumb is that if it is hot enough to destroy alcohol, it is also hot enough to make the wormwood lose it's efficacy.

>From reading that book or other, somehow I got the idea to make absinthe by mixing a whole ounce of wormwood in a half fifth of whiskey and forgetting about it for a few months. That shit is impossibly bitter. It's one of the most bitter herbal substances you know.

Yes. Not even the worms like it. :)

It does have some interesting properties, though, and prepared properly can even taste... well I won't say nice... but it will taste such a way that it is desirable.

Acquired taste perhaps? Good for the sensually indulgent? Weird?

From Stuart Cullen <stuartcullen@hotmail.com>

Just a little extra info from an experienced Absinthe drinker. I have drunk three different types of absinthe (two Portugese [50% and 58% alcohol by volume] and One Czech [55% by volume]) on innumerable occasions -- usually 4+ European shots a night.

In Portugal, to get its most extreme effect I was told to add sugar to the shot, light the absinthe, blow it out, drink it through a straw, cup my hand over the glass and inhale as much of the fumes as I could. I am sure this would be potent with any alcoholic drink. I have drunk stronger vodka [63% by volume] yet it has never had the effect of absinthe.

I have experienced one 'hallucination' -- I was once positively sure that a girl was dancing beside me for several minutes when there was no-one there. I have experienced numerous total blackouts from its usage. I am not an expert on herbs or a student of any related subject but absinth/e is a drug NOT an alcoholic drink (believe me).

An endnote from Henriette:

I'm told the "absinthe" recipes given above are completely off the wall. I'll believe that, because nobody in their right mind would ever call tincture, tea or even leaf of wormwood straight off the plant palatable.

Some say that wormwood has a nice "floral" scent. Yech, says I, because to me that "floral scent" is a thoroughly nauseating smell, which carries over into the taste if ingested. Urgh.

Wormwood is intensely bitter. Couple that bitterness with the revolting taste and you're set for something fit to give to your worst enemies, but not fit to serve at table.

On that note, I made about half a liter of wormwood tincture (1:5 45 %) years ago. Anybody over 18 (can't have kids getting drunk on this stuff) who drinks 1/2 dl (2 ounces) of that tincture in front of me (outdoors, please, with convenient bushes nearby) can have the whole bottle -- if they still want it after ingesting their half deciliter.

The Medicinal HerbFAQ

2.4 St. John's Wort (*Hypericum*) (SJW)

[photosensitivity](#) - [maoi](#) - [standardized extracts](#)

Also see <http://www.hypericum.com>.

2.4.1 St. John's Wort (*Hypericum*) and photosensitivity

Here's the question (on the herblist (see [8.1.1](#) below) in November 1994):

>As to *Hypericum perforatum* (St. John's Wort) causing photosensitivity in humans, I have been unable to find a single study that verifies this in vivo. Lots of research on the effects of hypericin on cattle and insects, but humans? This may be an example of assumptive jumping from mammalian lab results to humans. Anyone know a study that indicates photosensitivity in humans due to *Hypericum*?

The discussion can be found here:

<http://www.ibiblio.org/herbmed/archives/Best/1994/sjw-photosens.html>

Two years after above was included in the FAQ:

In recent discussions on a high-quality herbal mailing list the conclusion was that yes, some very few people can have problems with photosensitivity and *Hypericum*; that it might manifest a tad more often with topical application of oil on skin which is exposed to sunlight; but that actually, in very sensitive people, it might be enough to just take sensible amounts of tincture internally for photosensitivity to appear (even without synergy with meds).

2.4.2 St. John's Wort (*Hypericum*) and MAO inhibition

>>St John's Wort does in fact work like an MAO inhibitor and likewise causes the same dangerous side-effects.

>That's the wrong term. They're not "side effects"; they're food or drug interactions. But if SJW is an MAO-inhibitor then they're certainly "dangerous".

From smisch.tiac.net (Samson):

Yes, they would be if SJW really were a MAOI. But it's not. That was a theory that was floating around for a while without much support, and it has since been disproven.

See eg.

- Thiede HM; Walper A: Inhibition of MAO and COMT by *Hypericum* extracts and hypericin. J Geriatr Psychiatry Neurol, 7 Suppl 1:1994 Oct, S54-6
- Bladt S; Wagner H: Inhibition of MAO by fractions and constituents of *Hypericum* extract. J Geriatr Psychiatry Neurol, 7 Suppl 1:1994 Oct, S57-9

"Using pure hypericin as well as in all ex vivo experiments, no relevant inhibiting effects could be shown. From the results it can be concluded that the clinically proven anti-depressive effect of *Hypericum* extract cannot be explained in terms of MAO inhibition."

Hypericin does show some MAO-inhibition in vitro at very high concentrations. At regular human doses, though, virtually nil.

2.4.3 About standardized hypericin content in St. John's Wort (*Hypericum*)

On alt.folklore.herbs in Oct 97:

>(somebody) wrote:

>>I gathered my own SJW when it was flowering, (snip)

(somebody else) replied:

>You don't know how strong a dose you are receiving in your homemade tincture. St. John's Wort

keeps the serotonin in your brain from breaking down so rapidly. This is called a selective serotonin re-uptake inhibitor (SSRI) and the level of serotonin in your brain goes up. This may be good for people who have low levels of serotonin such as depressives but it is not good for people with normal serotonin levels. I would stick to the companies who standardize their dose for 0.3% hypericin and only take the recommended dose.

Then jmt... (J. Mark Taylor) stepped in and replied to the recommendation to "stick to the companies who standardize their dose for 0.3% hypericin":

... I would ignore this advice. We don't buy carrots by beta-carotene content and we don't buy potatoes by carbohydrate ratings. Although nutraceutical interests may soon begin marketing things that way, they only take away from the fundamental nature of wholistic health.

Comment from Henriette:

This 'standardization' is just yet another marketing trick to me. Get suppliers you trust, know your tinctures, and don't fall for scams, not even 'scientifically proven' ones.

Pure hypericin -has- been shown to produce side effects in almost all laboratory tests, while side effects with the whole plant extract (*Hypericum* tincture, made solely with *Hypericum* flowering tops and alcohol) are exceedingly rare.

However, after the herb made it big in the US (in 1996? 1997 ?), tens of thousands of people have been taking it, daily, in larger or smaller quantities (they don't always remember or even know that more is not always better); as tinctures, "standardized extracts", capsules, and you-name-its. If -you- experience side effects, you're just one of the unhappy few "exceedingly rare" cases. If that's the case use your common sense and stop taking it.

The Medicinal HerbFAQ

2.5 Ginseng

There are a number of plants called ginseng; a websearch (I don't recommend it, you'll get from 16000 to 90000 pages to wade through) will turn up a lot of different plants, not always correctly named:

- Ginseng, Asian (*Panax ginseng*)
 - also including Korean Red Ginseng, which is processed, making the root red and giving it a bit differing properties from the unprocessed yellowish-white ginseng root
- Ginseng, American (*Panax quinquefolius*)

- Ginseng, "Siberian" (*Eleutherococcus senticosus*) - better to call this Eleuthero, as it isn't a true ginseng.

- Ginseng, "Brazilian" (*Pfaffia paniculata*) - better to call this Suma, as it isn't a true ginseng.
- Ginseng, "Indian" (*Withania somnifera*) - better called Ashwagandha, as it isn't a true ginseng

While not all of these are ginsengs, they are all adaptogens. Adaptogens help you with your general stress response. The definition of an adaptogen is that it lets mice swim for longer in their bucket of water before they drown; it will also give you more stamina.

Further adaptogens are for example:

- Reishi mushroom (*Ganoderma lucidum*)
- Gotu kola (*Centella asiatica*)
- Rose root, gold root (*Rhodiola rosea* or *Sedum roseum*)

- Maral root (*Leuzea rhaponticum* or *L. carthamoides*, or *Rhaponticum carthamoides*), a Russian plant - you use the root and/or seeds.

This is only a partial list. In any list of adaptogens you will find at least one plant that isn't found in any other adaptogen list.

A couple of good webpages on ginsengs and adaptogens can be found here:

- <http://www.healthy.net/search/content/art/articles603.htm>
- <http://www.healthy.net/search/content/art/articles628.htm>

There are some practical considerations:

On the herblist Aug. 1994:

>Could someone be kind enough to summarize the possible adverse effects of ginseng? I've been taking a popular brand for a month now and am generally happy with the effect on a chronic sinus problem and energy levels, but beginning to feel kind of strung out ... I am drinking caffeine and wonder if this could be a problem. Also need to know about possible adverse interactions with prescription drugs such as blood pressure medications.

From Jonathan Treasure <jonno.teleport.com>:

Woah...."Ginseng Abuse Syndrome" is even recognised by the AMA. You do not mention what kind of Ginseng or how much. I will defer to the TCM people on this list to give wither you from the Chinese view but ... surely you're not really doing coffee and ginseng? Oh dear oh dear ... tut tut.

1. It is nonsensical to take caffeine and ginseng together regularly. You will stress your adrenals (*get strung out*) and possibly raise your *stress threshold* to a danger point.

2. Ginseng should be used with extreme caution in hypertensive situations especially if under medication.
3. Sinusitis? Not the *usual* prescription. Pass.
4. Toxic signs - not uniformly predictable but can include hypertension, euphoria, nervousness, skin eruptions, morning diarrhea.
5. Contraindications - nervous anxiety, nervous tension, hypertension, disturbed menstruation, stimulant or rec. drug abuse, good vitality in younger persons.

Most recommend taking as a tonic for a period then alternating without e.g. 3 weeks on 2 weeks off.

> the Peterson guide I have on edible wild plants recommends wild American ginseng as a trail nibble...

If you did happen to find a Wild American ginseng, you should leave it right where it is! Shame on Peterson. The plant is rare, and probably endangered throughout its range.

Paul Iannone

On alt.folklore.herbs June 1995:

> I've heard the ads for ginseng pills - are they worth the money? If so, are all brands the same?

You definitely want to buy from a reputable company. According to Professor Wang at the University of Alberta, researchers found that many prepackaged ginseng products had a major shortcoming designed to fool the consumer. You guessed it ... no ginseng.

Elizabeth Toews

The UP side of poison ivy

Rarely mentioned but soon enough found out, ginseng and poison ivy are childhood sweethearts: they grow up in the same neck of the woods. If you go digging ginseng in the Cumberlands of Tennessee, you will get poison ivy -- all over your fingers. With common roots in the forest loam, the one looks out for the other.

But if that's not sufficient protection, the 'sang has yet another look-out in the plant kingdom: Virginia creeper. A master of disguise, ginseng sets up housekeeping in the thick of creeper beds. Takes a covite to tell them apart; the untutored need not apply.

Cumberland ginseng endangered? Don't think so. Most of the knowledgeable diggers have sense enough to harvest after the seeds have matured, and don't have to be told to replant from what they've dug. If there's to be "more where that came from" (talking car payments), they know they have to replant. It's city slickers, out for a test drive of their bean boots, we got to look out for. For their advancement, thank we heavens, there is poison ivy.

Alex Standefer (astandef.seraph1.sewanee.edu)

> I had read somewhere that women should not take ginseng on a regular basis (I'm cutting back from six capsules to two per day), but was told by a friend that Siberian ginseng is suitable for women to take.

Ginseng shouldn't be used as a stimulant, but where needed it can be taken for comparatively long periods by children, women, old people, anyone.

I have many female clients who take ginseng on a regular basis, in formulas appropriate to their health pattern.

As a general rule Chinese herbalists don't use ginseng by itself.

--Paul Iannone

The Medicinal HerbFAQ

2.6 Stevia Leaf - Too Good To Be Legal?

by Rob McCaleb, Herb Research Foundation

For hundreds of years, people in Paraguay and Brazil have used a sweet leaf to sweeten bitter herbal teas including mate. For nearly 20 years, Japanese consumers by the millions have used extracts of the same plant as a safe, natural, non-caloric sweetener. The plant is stevia, formally known as *Stevia rebaudiana*, and today it is under wholesale attack by the U.S. Food and Drug Administration.

Stevia is a fairly unassuming perennial shrub of the aster family (Asteraceae), native to the northern regions of South America. It has now been grown commercially in Brazil, Paraguay, Uruguay, Central America, the United States, Israel, Thailand and China. The leaves contain several chemicals called glycosides, which taste sweet, but do not provide calories. The major glycoside is called stevioside, and is one of the major sweeteners in use in Japan and Korea. Stevia and its extracts have captured over 40% of the Japanese market. Major multinational food companies like Coca Cola and Beatrice foods, convinced of its safety, use stevia extracts to sweeten foods for sale in Japan, Brazil, and other countries where it is approved. Europeans first learned of stevia when the Spanish Conquistadors of the Sixteenth Century sent word to Spain that the natives of South America had used the plant to sweeten herbal tea since "ancient times".

The saga of American interest in stevia began around the turn of the Twentieth Century when researchers in Brazil started hearing about "a plant with leaves so sweet that a part of one would sweeten a whole gourd full of mate." The plant had been described in 1899 by Dr. M. S. Bertoni. In 1921 the American Trade Commissioner to Paraguay commented in a letter "Although known to science for thirty years and used by the Indians for a much longer period nothing has been done commercially with the plant. This has been due to a lack of interest on the part of capital and to the difficulty of cultivation."

Dr. Bertoni wrote some of the earliest articles on the plant in 1905 and 1918. In the latter article he notes:

"The principal importance of Ka he'e (stevia) is due to the possibility of substituting it for saccharine. It presents these great advantages over saccharine:

1. It is not toxic but, on the contrary, it is healthful, as shown by long experience and according

to the studies of Dr. Rebaudi.

2. It is a sweetening agent of great power.
3. It can be employed directly in its natural state, (pulverized leaves).
4. It is much cheaper than saccharine."

Unfortunately, this last point may have been the undoing of stevia. Noncaloric sweeteners are a big business in the U.S., as are caloric sweeteners like sugar and the sugar-alcohols, sorbitol, mannitol and xylitol. It is small wonder that the powerful sweetener interests here, do not want the natural, inexpensive, and non-patentable stevia approved in the U.S.

In the 1970s, the Japanese government approved the plant, and food manufacturers began using stevia extracts to sweeten everything from sweet soy sauce and pickles to diet Coke. Researchers found the extract interesting, resulting in dozens of well-designed studies of its safety, chemistry and stability for use in different food products.

Various writers have praised the taste of the extracts, which has much less of the bitter aftertaste prevalent in most noncaloric sweeteners. In addition to Japan, other governments have approved stevia and stevioside, including those of Brazil, China and South Korea, among others. Unfortunately, the US was destined to be a different story. Stevia has been safely used in this country for over ten years, but a few years ago, the trouble began.

FDA ATTACK ON STEVIA

Around 1987, FDA inspectors began visiting herb companies who were selling stevia, telling them to stop using it because it is an "unapproved food additive". By mid 1990 several companies had been visited. In one case FDA's inspector reportedly told a company president they were trying to get people to stop using stevia "because Nutra Sweet complained to FDA." The Herb Research Foundation(HRF), which has extensive scientific files on stevia, became concerned and filed a Freedom of Information Act request with FDA for information about contacts between Nutra Sweet and FDA about stevia. It took over a year to get any information from the FDA, but the identity of the company who prompted the FDA action was masked by the agency.

In May, 1991 FDA acted by imposing an import alert on stevia to prevent it from being imported into the US. They also began formally warning companies to stop using the "illegal" herb. By the beginning of 1991, the American Herbal Products Association (AHPA) was working to defend stevia. At their general meeting at Natural Products Expo West, members of the industry pledged most of the needed funds to support work to convince FDA of the safety of stevia. AHPA contracted HRF to produce a professional review of the stevia literature. The review was conducted by Doug Kinghorn, Ph.D., one of the world's leading authorities on stevia and other natural non-nutritive sweeteners. Dr. Kinghorn's report was peer-reviewed by several other plant safety experts and concluded that historical and current common use of stevia, and the scientific evidence all support the safety of this plant for use in foods. Based on this report, and other evidence, AHPA filed a petition with FDA in late October asking FDA's "acquiescence and concurrence" that stevia leaf is exempt from food additive regulations and can be used in foods.

FDA, apparently attempting to regulate this herb as they would a new food additive, contends that there is inadequate evidence to approve stevia. However, because of its use in Japan, there is much

more scientific evidence of stevia's safety than for most foods and additives. The extent of evidence FDA is demanding for the approval of stevia, far exceeds that which has been required to approve even new synthetic food chemicals like aspartame (Nutra Sweet).

AHPA's petition points out that FDA's food additive laws were meant to protect consumers from synthetic chemicals added to food. FDA is trying, in the case of stevia to claim that stevia is the same as a chemical food additive. But as the AHPA petition points out, Congress did not intend food additive legislation to regulate natural constituents of food itself. In fact, Congressman Delaney said in 1956, "There is hardly a food sold in the market today which has not had some chemicals used on or in it at some stage in its production, processing, packaging, transportation or storage." He stressed that his proposed bill was to assure the safety of "new chemicals that are being used in our daily food supply," and when asked if the regulations would apply to whole foods, he replied "No, to food chemicals only." AHPA contends that stevia is a food, which is already recognized as safe because of its long history of food use. Foods which have a long history of safe use are exempted by law from the extensive laboratory tests required of new food chemicals. The AHPA petition, however, supports the safe use of stevia with both the historical record, and references to the numerous toxicology studies conducted during the approval process in Japan, and studies by interested researchers in other countries.

To date, the FDA still refuses to allow stevia to be sold in the U.S. but the recently-enacted Dietary Supplement Health and Education Act of 1994 may prevent the FDA from treating stevia and other natural herbs as "food additives."

rmccaleb.herbs.org -- [also herbal.netcom.com]

2.6.1 Changed legal status of Stevia Leaf

> [Where do you get your stevia? No one here in RI will sell it.](#)

From: Mark D. Gold (mgold.holisticmed.com):

You should suggest to your local natural food stores and herb stores in RI that the legal status of stevia has changed recently. While importation of stevia was banned to protect Monsanto's NutraSweet sales and the future sales of other artificial sweeteners a few years ago, stevia can now be sold as a "dietary supplement." I have a copy of the FDA's new "Import Alert" on my Web page (or I can email it to you). Stevia products can and have been sold over the last few years as skin treatment products. Therefore, your local natural foods store should be able to get stevia skin treatment products and supplements from their distributor (or they should find a distributor who does sell it).

Stevia still cannot be legally sold as a "sweetener" by itself or in another product. This will help protect companies such as Monsanto (selling a dangerous artificial sweetener - aspartame) from having to compete against a safe, natural sweetener on a large-scale basis. But at least individuals can now use stevia as a supplement.

I have a list of stevia resources on my web page which you can use and give to your local natural

foods store. Hope this helps.

The Medicinal HerbFAQ

2.7 Poison Ivy / Oak / Sumac

[recognize it](#) - [avoid the rash](#) - [why the rash?](#) - [what helps](#) - [Jewelweed, *Impatiens*](#) - [get rid of poison ivy](#)

We're lucky in Finland in that we don't have any of these problem plants. But since it's asked every week in season it has to be in the FAQ, so what's in here is mostly pulled from rec.gardens archives 1992 - 1994, or from alt.folklore.herbs archives 1993 -, or taken off bionet.plants June 1995. If you wrote some text I've included here but you aren't mentioned please email - I'll be happy to mention you in the next posting.

2.7.1 How to recognize PI/PS/PO

From Kay Klier (klier.fern.com):

POISON IVY (*Toxicodendron radicans* = *Rhus radicans* = *Rhus toxicodendron*)

Found in a wide range of habitats, but in the midwest often seen in disturbed woods, roadsides, and flood plains. Most widespread of PI, PS, and PO.

Small, slightly woody plant, or shrubby, or vining. LEAVES ALTERNATE (= 1 leaf per node), TRIFOLIATE (= 3 leaflets), with pedicel (leafstalk) and the CENTRAL LEAFLET WITH PETIOLULE (= leaflet stalk). The lateral two leaflets are not distinctly stalked. Leaflets are a variety of shapes, but generally ovate or obovate (roughly apple-leaf shaped). Leaflets may be smooth-edged (entire), irregularly toothed, or shallowly lobed. Leaves of one variant look like small oak-leaves (but look again!).

Leaves apple-green and shiny in the spring, deep green and often dusty in the summer, turning a glorious reddish orange in the fall. Flowers tiny, whitish, in clusters; fruits white berries in late summer or fall.

Closest look-alike: Box-elder seedlings (*Acer negundo*), which has OPPOSITE, trifoliolate leaves; the lateral two leaflets are often slightly stalked. Older box-elders generally have 5 leaflets per leaf.

POISON SUMAC (*Toxicodendron vernix* = *Rhus vernix*)

Shrub, to perhaps 15-20 ft tall, often branched from the base. LEAVES ALTERNATE WITH 7-13 LEAFLETS, lateral leaflets without a petiolule (leaflet stalk), TERMINAL LEAFLET WITH A STALK. MIDRIB OF THE LEAF WITHOUT A PAIR OF WINGS OF TISSUE THAT RUN BETWEEN LEAFLET PAIRS. More small, whitish berries in a long cluster. Usually in wetlands, Maine to Minnesota, south to Texas and Florida.

Closest look-alikes: Staghorn sumac, *Rhus typhina*, which has clusters of fuzzy, red fruits and toothed leaflets, and likes dry soils; Smooth sumac, *Rhus glabra*, with bright red fruits and slightly toothed leaves; much drier soil than PS.

POISON OAK (*Toxicodendron diversiloba* = *Rhus diversiloba*).

Reputedly the worst of the bunch. Erect shrub, usually about 3-6 ft tall (to 12 ft!), bushy, with ALTERNATE LEAVES OF THREE LEAFLETS, the LEAFLETS generally lobed slightly or as much as an oak leaf; CENTRAL LEAFLET STALKED. Leaves generally bright, shiny green above, paler below. Fruits are small whitish berries. Common on the west coast, esp. low places, thickets and wooded slopes. Occasionally a 5-leafleted form is found.

Steve Hix (fiddler.concertina.Eng.Sun.COM), in response to above:

>POISON OAK description...

If it were only that simple! In addition to that form, you can find poison oak growing as a vine (very like wild grape, but with smooth bark) up to six inches in diameter disappearing up into the tree tops near streams, or in thickets that look a *lot* like blackberry without spines, or sometimes as collections of leafless single branches (later the leaves appear, shiny and red, changing to oily green, and so on).

Fortunately, it doesn't seem to grow much above 5000' elevation.

2.7.2 How to avoid the rash

Difficult if you live near PO/PI/PS...

... the best way not to get the rash is to learn to recognize the plant(s) and avoid it (them) after that.

But:

- You can even get a dose if a bunch of the leaves get dumped into a stream or pond ... the oil ends up floating on the surface of the water.
- Dogs / cats / horses can get it on their coats and you'll get it from them when you pet them

barehanded.

- If you burn these plants and inhale the smoke you'll get a bad case of internal PI.

2.7.3 Why does it give you a rash? / Spreading the oil about

From Ron Rushing (f_rushingrg.ccsvox.sfasu.edu):

The irritant in poison ivy, poison sumac, and poison oak is urushiol. The rash you get is an allergic reaction. Everything I say below about poison ivy should also apply to poison oak and sumac. If you brush up against a healthy undamaged plant, you won't usually get urushiol on you. You usually have to come in contact with a damaged leaf. Almost all plants have damaged leaves - either from insects, weather, or from your stepping on them.

The oil is easily transferred from one place to another. For example, I got some on my shoelaces once, and I kept getting poison ivy on my hands for a couple of months. Once it is on your hands, it can, and will, end up anywhere on your body.

The rash from poison ivy can take up to 72 hours to appear after exposure, and is often spread on the body by taking showers while the oils are still on the skin.

Once you get the oil on clothing, it can sit for months and still cause a rash upon contact with your skin. For example, lets say you get some poison ivy oil on your boots, then put the boots away for the winter. Next spring you get out the boots and go for a walk - but not in the woods. A few days later, voila - your hands are breaking out from putting on your boots and tying the laces. As long as you've washed the original oil off your skin, the exudate from the blisters should not re-infect your skin. It's just exudate, and does not contain urushiol.

From krrbert.uiuc.edu (K. R. Robertson):

Washing with strong soap merely removes excess poison from the skin, but will not remove any which has already reacted, because the poison is believed to form a complex with skin proteins and therefore is not removable short of removing the skin! Even so, it is difficult to wash off this insoluble poison completely.

Eating a leaf of poison-ivy may have disastrous results. One may surpass the normal level of immunity by the first bite; in this case one is in for an internal case of poison-ivy, occasionally known to be fatal.

The mechanism of sensitivity is not thoroughly understood. It does not behave like protein sensitivities such as hay fever. It is a hypersensitivity of the delayed type, whose mechanism is related to that of organ transplant rejection.

(Originally prepared by William T. Gillis, 1973, Revised by Kenneth R. Robertson, 1993, Illinois Natural History)

Poison Ivy, oak, sumac: Clothes contamination

From: Gerry Creager <n5jxs.tamu.edu>

One thing a lot of folks don't seem to understand, especially now that a lot of laundry detergents are available for cold water use, is that HOT water is a good element for elimination of the oily residue that causes the allergic reaction. I noted several anecdotal comments about reinnoculation that could have been prevented if the contaminated clothes were washed in hot water (not warm, not warm/cold, HOT!) and alone so as to avoid cross contamination to other clothing. I've had good result with this in our family as well as in the folks I have advised with the problem. Me? I'm one of those who so far has not manifested an allergy despite a lot fo time in the woods!

From ab282.detroit.freenet.org (Robert Gault):

The active ingredient in poison ivy and other plants in the same family is 3-n-Pentadecylcatechol, common name urushiol, which is a chemical in the phenol family.

Dermatitis (skin inflammation and blistering) is spread by the act of scratching which redistributes the urushiol over the body. While the normal treatment for poison ivy does not include the suggestion below, a reasonable approach would be to convert the urushiol into a water soluble material. Phenols are acids so washing with a weak base like diluted house hold ammonia or a paste of baking soda should do the trick.

From Kay Klier (klier.fern.com):

People who react to any of the species of PI/PO/PS will undoubtedly react to the others; further, they may cross-react with mango (*Mangifera indica*), cashew (*Anacardium occidentale*), and Chinese or Japanese Lacquer (*Rhus verniciflua*). (the cellulose-based spray paint that is called lacquer is not involved in this... just "real" lacquer, like carved lacquer boxes, etc.). Generally speaking, it's not a good idea to sit under any member of the Anacardiaceae in the rain... they all tend to have a leaf toxin that falls on innocent bystanders below.

Most people are NOT sensitive to PI/PO/PS at birth, but become sensitized through repeated exposures. Some people are apparently immune throughout their lives, but I really don't know how to test that claim... ;-)

There is a barrier cream and a cleanup wash called Technu commonly used by those who are sensitized to PI/PO/PS. Works quite well.

2.7.4 What helps

First a word of caution:

The recommendations listed here are without medical foundation and, if actually used, are at the sole risk of the reader.

- **Jewelweed**, *Impatiens pallida*, *I. capensis*, *I. biflora*, or similar species. AKA Touch-me-not, silverweed.

The plant produces both cleitogamous (self-fertilized), and chasmogamous (cross-fertilized) flowers. Mature seed pods will build tension as they dry, and can "shoot" seeds 5 feet away when activated by a slight disturbance.

- **Jewelweed, fresh:** crush some leaves and a bit of the stem and rub the resulting juice on the rashy area. Repeat frequently.
- **Jewelweed decoction:** take one part Jewelweed (or stronger as needed), and twenty parts water. Boil water in non-metallic container, add jewelweed, boil for fifteen minutes, strain and store in jar in fridge or freeze as ice cubes. Apply frequently.
- **Jewelweed juice:**
From YE71.MUSIC.FERRIS.EDU (Robert King):
 - Gather the entire plant, leaves, stems, and all; the plant is very succulent and juicy... I have never had a need to add extra water, but if you do, use distilled. Don't be greedy, either trim tops & outer branches, or selectively take entire plants from the center of a crowded stand. One large (4-foot) plant should be adequate for the largest rash on one person. Plants will lose turgor and wilt quickly after cutting, this is OK, just makes it easier to emulsify.
 - Liquefy the plants in a blender at the highest speed possible. Then extract the juice by filtering thru cloth, common strainer, or fruit press... a little pulp in the mix won't hurt, this will settle out after a couple hours, anyway. Use immediately, or refrigerate... this stuff spoils rapidly at room temperature..!!
 - Apply the juice to the infected area with a common paint brush... I've found 1 to 2" size works best. Blow-dry the area as you apply it with a hair dryer on low heat... after several coats of 'paint,' an orange-colored "skin" will develop. This "skin" will protect uninfected areas against the poison ivy allergen.
 - Repeat this procedure as needed, especially first thing in the morning, and before bedtime. Be sure to use common sense in keeping any fluid that happens to come from blisters away from unprotected areas... yourself AND others. Keeping the infected area as dry as possible will hasten the healing; continue application until no more blisters are present... usually about 3 days.
 - Ironically, jewelweed favors growing in areas of similar habitat as poison ivy, therefore it can often be found nearby, preferring moist ground, near water, or often, even in shallow water. It grows rapidly in ideal environs, but usually doesn't reach significant size until mid-summer; therefore, it might pay to keep a bit frozen in the fridge from the previous year for early-season use. The

extract tends to spoil rapidly, even at cooler temperatures, so I wouldn't recommend keeping it for much more than a week without freezing... the fresh solution works best, anyway.

- **Catnip:** rub fresh catnip leaves on the affected area.
- **Mugwort** (Jilara [jane.swdc.stratus.com])
Pick two large handfuls of fresh mugwort (*Artemisia vulgaris*) and let infuse in 1 cup alcohol for overnight. Apply to affected area with a clean sponge/washcloth/q-tips/whatever every four hours. Dries it up quickly.
Robert Gault reminded me that mugwort is a strong allergen (have I told you they keep track of mugwort pollen in the air over here?). To quote Robert Gault: 'Can you imagine the result if the poison ivy sufferer is also allergic to Mugwort?!' Ouch - yes, I can.
- **Aloe vera** (Jilara [jane.swdc.stratus.com])
Take a large leaf from the aloe vera plant you keep on your windowsill for burns. (If you don't have one, get one!) (NOTE: "aloe vera gel" sold commercially does NOT work!) Slice lengthwise to expose the juicy interior of the leaf. (This will give you an upper and lower leaf, with a juicy side to each.) Trim off leaf edges. Apply directly to affected area, juicy side against the sores. Bandage in place. Apply a new leaf every day until healed. This works phenomenally well, but you have to put up with bulky slabs of aloe vera leaf against the area. Which would you rather have: oozing sores or a succulent slab of leaf? Thought so. ;-) I can't laude this one enough! It works faster than any other remedy! And relieves the dreadful *itching*, too!
- **Gumweed Plant** (*Grindelia*)
Native Americans used the resin from the gumweed plant to treat poison ivy.
- **Baking Soda**
I swear by baking soda paste for poison oak. It not only soaks up the oozing mess, it completely stops the itching throughout the day.
- **Mixed alcohol liniment**
Take sweetfern, jewelweed, witch hazel, rubbing alcohol... Zip it all up in a blender until it's green and mashed, let it sit for two weeks (ouch! I know...not for THIS outbreak, sorry), strain it and voila, a marvy liniment.
- **Poison Ivy leaf**
From: bear.helium.Gas.UUG.Arizona.EDU (Soaring Bear), May 1994:
Actually, this is just the time of the year to build up your immunity by nipping off a very tiny piece of poison ivy leaf (size of a head of a pin) and put in a capsule and swallow. Do 1-2 times a week. Stop if you start breaking out.
Caution from krrobert.uiuc.edu (K. R. Robertson):
Eating a leaf of poison ivy may have disastrous results. One may surpass his normal level of immunity by the first bite; in this case he is in for an internal case of poison-ivy, occasionally known to be fatal.
- **Salt** (from bss8n.galen.med.virginia.edu)
For the little initial blisters, I rub salt and burst them and leave the salt on to dry. They're history. Also salt worked on the moist areas of my face and under my nose where lye soap lather couldn't stay dried out long enough to dry out the rash. Works well on large surface rashes in case the blister stage grew untreated (but it didn't work on the "mini-mountain"

reaction to p.i. that my mom got). MOST essential, leave the salt on to dry, adding more salt moistened with water to help create a paste that will stick as it dries, thus drying out that nasty, annoying p.i. The worse the spread, the longer the duration of salt/soap treatment alternated 12 hours to 1) dry out the present fresh redness, and 2) dry out *new* fresh red. Yep, you guessed it... the salt falls off everywhere. That's one reason I used the lye soap during bed hours. The other reason was that neither treatment, in a prolonged battle (1 1/2 wks) stayed effective by itself, i.e. continuous dry-out, but alternating them did it. I've wondered why?

- **Lye soap** (bss8n.galen.med.virginia.edu)
 - initially from a pioneer reenactment lady. The older/yellower the bar got, the less effective it seemed. Now, I've found it at the grungiest grocery store in town, a soap called Oxygen. Wet the bar and lather it up on the rash into a paste and let dry. Easier than the salt but since discovering salt, I tend to believe salt is more effective for me, at least with my initial tiny blisters, which is all I ever have to deal with now.

2.7.5 Jewelweed, *Impatiens*

From Elizabeth Perdomo, ElizPer.aol.com:

Jewelweed is a plant I wouldn't be without here in the South, any time of the year! It works so remarkably well for Poison Ivy, Oak and Sumac, and for Fungal Infections, as well (try it on athlete's feet!). People are always getting inspired to rake up leaves in the middle of winter, and get into the roots or old leaves, producing the nasty itch. However, since the plant only grows in mid-late summer, this is what I do to keep a supply around...

Harvesting: Jewelweed is an annual, which means it flowers, produces seeds and then dies all in one year. Thus, I try to harvest Jewelweed well before flowering time, so it has a chance to regroup, flower and seed before frosts. To do so, I cut off (with knife or pruner) the top 1/3 of some of the plants, leaving many untouched. I don't pull or pinch the tops, as this often dislodges or pulls up the plant. If you take more than about the top 1/3, the plant may not have enough time to sprout side shoots and go to seed, thus diminishing future supply for you, others & the earth...

Preparing: Jewelweed is one of those plants which just doesn't dry well. It's too fleshy and juicy, and loses its good qualities when dried. I make a strong infusion, by adding LOTS of the plant to a pot (non-aluminium) of boiling water. Then, I cover the pot, and allow it to simmer for at least 30 minutes. After simmering, covered, I put it into a blender or food processor and blend. Then, I

cover the mixture again and allow it to cool to room temp. After cooling, I strain the mixture through a stainless steel strainer and/or cheesecloth. Then, if needed right away, I label and store part of the mixture in a jar in the refrigerator. The remainder, I freeze in ice cube trays. After frozen, pop the cubes into a zip lock bag and LABEL WELL with herb name/date before returning to freezer. Then, I have a winter's supply. The cubes also feel really good on especially sensitive areas, like on the face, between fingers, under arms and in private parts... I also use the fresh Jewelweed and make it into a tincture by filling a jar with the plant, and then covering it with 100 proof vodka. If you are going to use it exclusively for EXTERNAL use, it could be "tinctured" in rubbing alcohol.

Administering: Whether fresh, infused, tinctured or in ice cube form, apply Frequently!!! Cotton balls work well to apply the infusion or tincture. Yes, the tincture burns some, so I dampen the cotton ball 1st with water, then add the tincture. The alcohol also helps to dry out the ooze... If someone has a really bad, "systemic" case (not just a few bumps on their ankles or hands), I recommend that folks take the (vodka) tincture INTERNALLY, about 1/2 dropper 2-4 x Daily, in liquid, But for only 2-3 Days! (I don't recommend using this orally if pregnant or nursing.) It seems that the oral use in conjunction with frequent, liberal external use, can really turn a bad case of poison ivy around fast! Also, for "oozy" spots, cosmetic grade (French) clay can be sprinkled on as often as desired to help dry the spots out. Sometimes, I mix the clay with powdered oatmeal, and apply the mixture to absorb and sooth.

Elizabeth Perdomo

From: Peter Gail <PETERGAIL.AOL.COM>

Re: the post about jewelweed tincture: Be extremely careful in applying an alcohol extract of jewelweed on anybody. Over the past 8 years Steven Foster has reported one and I have observed 3 extremely severe skin reactions from such applications, in each case landing the person in hospital. Euell Gibbons also referred to the possiblity of allergic reactions to jewelweed tinctures.

Comment from Henriette: the frozen cubes don't have these risks.

2.7.6 How to get rid of poison ivy in your yard

Suggestions from rec.gardens/alt.folklore.herbs:

1. Planting catnip should get rid of poison ivy.
2. Goats. They are very effective, but in the end will be a bigger bother than the poison ivy. (Be suspicious if someone offers you free goats!)
3. Poison ivy again: buy the super concentrated form of Round-Up and dilute to 3 times the recommended strength. (Well, hot damn! It killed off nearly every piece of PI in one application and only a few (about a dozen) plants returned a year later.)
4. Pull it, but protect yourself (big plastic bag, disposable suit...) Immediately wash all clothes you used two-three times. Do not touch the plastic bag / disposable suit from the outside. Do

not touch your clothes / boots / whatever from the outside before washing.

The Medicinal HerbFAQ

2.8 Echinacea

[uses](#) - [poaching](#)

2.8.1 Using Echinacea

(also see King's dispensatory, here: <http://www.ibiblio.org/herbmed/eclectic/kings/echinacea.html>)

From Todd Caldecott (toddius.netidea.com):

In my training with NA's I learned that *Echinacea* (blood purifier and antibiotic) can be used as long as two weeks. The German research branch of their equivalent of FDA (called Kommission E) Drs. Wagoner and Bauer demonstrated this fact. Their studies also showed that tinctured extract of this plant could be chemically potent or not depending on how it was grown, harvested and extracted. In their studies, the extracts available on the commercial market were far less potent than their own prepared version. So their conclusion was 2 weeks on then off for a week, then one could use it for another two weeks at diminished activity. Also the plant varieties of *Echinacea angustifolia*, *E. purpurea* and to a lesser extent *E. pallida* all had medicinal chemical activity. The whole plant is medicinal but needs to be at least 3 years old before you should harvest.

There is no evidence to suggest that *Echinacea* cannot be used longer than 2 weeks. In the original study (and please be patient I'm doing this from memory) *Echinacea* was found to be increasingly effective for 5 days, after which the study ceased. This paper, originally written in German, was mistranslated, leading one to believe that *Echinacea's* effects plateaued after five days. *Echinacea* is being used by several professionals long term. Typically though, it is used as a surface immune tonic, useful in chronically immunodepressed patients who suffer from chronic colds etc. (although its use in AIDS is still a matter of some controversy). For most of us who take it seasonally for colds etc. it is most effective when taken in combination with other herbs i.e. garlic,

Baptisia, Thymus, Astragalus etc.

2.8.2 Echinacea - poaching and extinction

Thread on the phytopharmacognosy list:

> Over 90% of all *Echinacea* material in the U.S. and Europe comes from cultivated species. There is very little wild harvested ech. on the market. The claim that the use of ech. preparations contributes to the extinction of this plant species is nonsense. Such claims may apply to other medicinal plants but not to the easy to cultivate Ech. spp..

From P. Mick Richardson <richards.mobot.org>, to above:

Disappearance of the plant in the wild may be nonsense to you but it is reality to those of us who live in areas where the plant is native. Several points. The plant is easy to grow in cultivation but if you have no land on which to grow it you can get ready cash by collecting it in the wild. Even if 90% comes from cultivated sources, the remaining 10% is still a massive amount in relation to the ever decreasing number of plants in the wild, especially when consumption rises each year and the 10% translates into an ever increasing number of plants to be sought.

After receiving your message, I sought out a local person who collects seeds of *Echinacea* from wild plants in Missouri for cultivation of the plant. He confirmed my suspicions that the plant is becoming non-existent in many parts of Missouri as local populations are exterminated. So the nonsense is in fact reality to the people who see the plants. I suggest greater cultivation of the plant would decrease the demand for wild-harvested material. After all, no-one would be killing rhinos and elephants for sale if there was not a market for them. Let's stop before *Echinacea* becomes a great auk or a passenger pigeon example for textbooks. Sorry to ramble on, but extinction is for ever and it would be shameful for herbalists to contribute to it.

... and more in the same thread:

From: P. Mick Richardson <richards.mobot.org>:

It is illegal to collect *Echinacea* unless it is on your own property in Missouri. However, if someone offers cash for echinacea plants, then the demand will be met by poaching. Although on a lesser scale, it is no different to the situation with rhino horn and elephant ivory. If there is a cash

market, people will provide the product. I could give descriptions of the nationalities of the buyers but this is probably unnecessary. The plants end up in Europe, presumably the site of greatest demand.

Hopefully, there will soon be enough *Echinacea* in cultivation that the price will fall and this may remove the demand for wild-collected plants. Until then, if you encourage the use of *Echinacea*, you endanger the plants growing wild in Missouri. Admittedly *Echinacea* is being poached on a lesser scale than *Panax* or *Hydrastis*, but it is still disappearing. Let's aim for complete domestication. It works for *Ginkgo*, which is a cultivated cash crop in the U.S.A. now.

The Medicinal HerbFAQ

2.9 Feverfew and migraine

by Eugenia Provence, Eprovidence.aol.com

It's not at all unusual for people interested in using herbs to replace over the counter medications with simple herbal counterparts. What has been unusual enough to generate headlines, though, is the conventional medical community's research and acceptance of a traditional European folk remedy, Feverfew, in preventing migraine headaches.

Migraines are believed to be caused by an upset in serotonin metabolism, causing spasms of intracranial blood vessels, which then causes dilation of extracranial blood vessels.

In the 1970s an English research group sought volunteers already using Feverfew before beginning a study of its efficacy. Their advertisement in a London newspaper brought more than 20,000 responses. Since then, several well-documented double-blind, placebo studies in England confirm its value.

An interesting one reported in *The Lancet* (July 23, 1988; 2(8604):189- 192) followed 72 volunteers. After a one-month trial using only a placebo, half of the group received either one capsule of dried Feverfew leaves a day (or a matching placebo) for four months. Neither the group nor the researchers knew which group was receiving the Feverfew. The group kept diary cards of their migraine frequency and severity. After four months, the groups switched medications, and the trial continued for an additional four months. 60 patients completed the study, and full information was available on all but one.

The study found Feverfew to be associated with reducing the number and severity of attacks (including vomiting), with the researchers concluding that there had been a significant

improvement when the patients were taking Feverfew. There were no serious side effects. Feverfew is currently classified as *Tanacetum parthenium*, a member of the Asteracea (or Compositae) family, and was formerly named *Chrysanthemum parthenium*, where you'll still find it listed in some references. Feverfew is a corruption of Febrifuge, based on its tonic and fever-dispelling properties. It's been called Maid's Weed, referring to its emmenagogue qualities, which are also reflected in its Greek name, Parthenion ("girl").

Its primary actions are anti-inflammatory, bitter, emmenagogue and a vasodilator. Aside from migraine relief, long-term users report relief from depression, nausea and inflammatory arthritic pain. Drunk in cold infusion, it can relieve the cold, clammy sweats associated with migraine. Additionally, it's been used externally as an insect repellent, and topically for insect bites. Perhaps the insect-repelling quality accounts for the tradition of planting it around the house to ward off illnesses and to purify the air.

The tea, drunk cold, has been used for sensitivity to pain, and for relief of face-ache or ear ache (all migraine-like symptoms). The Eclectic physicians of the 19th century called it one of the pleasantest of the tonics, influencing the whole intestinal tract, increasing the appetite, improving digestion, promoting secretion, with a decided action on kidney and skin.

John Gerard's Herbal in 1663, said it to be "...good against summer headaches to inhale crushed Feverfew blossoms. Dried and taken with honey or sweet wine good for those as be melancholic, sad, pensive or without speech." Culpepper used in it poultice form for head ache.

Feverfew in blossom is easily identified by its flat or convex yellow disk and numerous short, broad 2-ribbed white rays. The leaves are alternate, petiolate, flat, bi or tripinnate with ovate, dentate segments. It quickly escapes cultivation, and has become naturalized in many areas of the U.S. and Europe, in some places regarded as a nuisance weed.

Among its constituents are a volatile oil, containing pinene and several pinene derivatives, bornyl acetate and angelate, costic acid, B-farnesine and spiroketal enol ethers; Sesquiterpene lactones, the major one being parthenolide); and Acetylene derivatives.

Pharmacologists say it is likely that the sesquiterpene lactones in Feverfew inhibit prostaglandin and histamine released during the inflammatory process, preventing the vascular spasms that cause migraines. It appears to regulate the serotonin mechanism.

To attain the maximum benefit from Feverfew, it should be taken daily as a preventive. For migraine prevention, parthenolide plays an important role. The parthenolide content in Feverfew is highly variable in different populations grown in different locations or harvested at different times of the year.

Recent Canadian tests of U.S. Feverfew products found all of them to be low in parthenolide. Canada, which has recently recognized Feverfew products as official, over the counter drugs for migraine prevention and relief, will require that they contain a minimum of 0.2% parthenolide. So, this is one of the few cases where a standardized extract may be more desirable than the whole plant, with a lot to be said for fresh or freeze-dried preparations. If you want to use the fresh plant, the flowers have a higher parthenolide content than do the leaves. If you are picking the leaves, they are best just before flowering.

In one of those magical bits of synergy that herbalists love, the isolated parthenolides used alone don't work on migraines, nor does the whole plant with the parthenolides removed. The parthenolide is bioavailable only in the whole plant.

PRECAUTIONS: I know of nothing, whether allopathic or herbal medicine, that I would feel free in saying to have absolutely no unpleasant side effects. We're all unique individuals when it comes to body chemistry. Some unfortunate people are allergic to chamomile. They may also be allergic to Feverfew.

A few recent studies of parthenolide in vitro point to toxicity involving smooth muscle tissue. However, no side effect resembling this has ever been reported in human use. Feverfew's safety and usefulness are historic.

Pregnant women should never take Feverfew. Its traditional use as an emmenagogue underlines the risk here.

The bitter tonic qualities, so useful for indigestion, can cause gastric pain in people with gall stones or gall-bladder problems, by making the gall bladder try to empty. Likewise, the increased production of stomach acid would make it highly aggravating to anyone with a gastric ulcer or esophageal reflux.

Some people have developed mouth ulcers from eating the fresh leaves.

DOSAGE: Feverfew is most effective fresh or freeze dried. Take the equivalent of 1 fresh leaf or 125 mg. freeze-dried herb once a day (0.2% parthenolides) 1-3 times daily (don't chew the leaf). In addition to Feverfew on its own as preventive herbal therapy, one would want to look at one's individual migraine triggers or pattern and add herbs whose actions complement Feverfew's anti-inflammatory, bitter and vasodilator actions to support the affected body systems.

Please also check entry [3.2, Herbs for migraine](#).

From Rene Burrough <rburrough.dial.pipex.com>:

Eating feverfew leaves I learned this from a nursery woman here who grows herbs commercially & was a nurse during WW2, and has suffered from migraines from years, and it extremely sympathetic to herbal medicine. She swears that the GREEN leaf is far more efficacious than the yellow or golden version. And she takes one leaf a day for months at a time to keep the migraine at bay. What she does is to make a <bread pill> with the feverfew leaf inside and squished into a tiny ball with a doughy bit of bread around it as a casing. Then the pill can be swallowed without the leaf coming into contact with the lining of the digestive tract.

Feverfew dangers, in the best of the herbal forums:

The Medicinal HerbFAQ

2.10 Kava kava

by Dennis McClain-Furmanski (dynasor.infi.net)

Kava-kava (*Piper methysticum*) is a plant native to the Pacific Islands, originally from the island of Vanuatu. Following the influx of missionaries over the last century, its cultivation and use has decreased but not disappeared. Several botanical houses in the US and elsewhere have begun regular cultivation. The supply remains low, as the harvest rotation period is from 1.5 to 5 years. Restrictions on import have been considered and may be imminent, meaning only locally grown supplies will be available. Indigenous growths are now being protected as endangered in some areas, but this does not preclude cultivation.

Kava is more of a social and ceremonial preparation than it is medicinal. Its primary action is as a relaxant, and at high levels an intoxicant and divinatory preparation. In normal use, the kava drinker becomes relaxed and sociable, and may later drift off into reverie. Large doses, as used by village chieftains and seers, induces a trance-like state with vivid dreaming. It is still used in some areas as a medicinal liniment, being prepared there as a tincture. Modern use of kava has included a preparation given to electroshock therapy patients as a muscle relaxant.

The active constituents of the plant, such as the lactone resins yangonine and kawaine, are found primarily in the root rhizomes, although some preparations such as the Hawaiian liniment make use of the fresh stem. Most preparations use chopped root material. There are some commercial products in the form of tablets made from a powder, but these tend to suffer in strength, apparently due to excessive drying.

Use of kava requires bringing the insoluble resins into emulsion. Traditional preparation is done by chewing the stems and spitting them with copious saliva into a bowl, to which water and coconut juice is added. The mixture is then kneaded and strained through fiber and drunk immediately.

A more palatable preparation is to wrap about an ounce in a single layer of plain cotton cloth or a few layers of cheese cloth, and tied off to form a ball. This is dunked in a quart or so of water, lifted and squeezed out, repeating this until the bubbles forming from the dripping water tend to remain on the surface of the water -- about 10 to 15 minutes. As with the traditional preparation, this tastes strongly musty and not particularly pleasant. It is drunk immediately in gulps. A tablespoon of sugar helps, and my favorite additive is a tablespoon of Ovaltine or other malted

mixture. Most non-traditional preparations such as herb teas and other mixtures are either too low a dosage or improperly prepared and so are ineffective, most probably due to the bad taste of effective dosages.

A tincture is made by soaking the chopped root material in 3 times its volume of alcoholic liquor such as brandy or gin. This is shaken daily over 2 or 3 weeks and then strained. Internal use is 1 to 2 ounces, and external use is an ounce rubbed into sore muscles or soaked into a cloth which is laid over the affected area.

Some reports have been made regarding chewing and swallowing fresh root. All the same effects are noted, with the addition of a decongestant-like opening of breathing passages. This is only in healthy individuals; there is no true decongestant effect in congested individuals.

Heavy daily use of kava for years has been reported to cause dry, flaking skin, yellowing of the eyes and persistent lethargy. The doses involved are those used by local chiefs and visionaries, and normal recreational or medicinal use will not cause this. When this syndrome does appear, 2 to 3 weeks of abstinence cures it. Reports of lowered peripheral blood flow seem to be anecdotal only.

The plant itself is available from some ethnobotanical houses, and seems to thrive even in non-tropical conditions, though it still requires indoor cultivation.

The Medicinal HerbFAQ

2.11 Pau D'Arco

by Dennis McClain-Furmanski (dynasor.infi.net)

Pau D'Arco (*Tabebuia impetiginosa*), also known as Taheebo and Lapacho colorado, is a tree native to the Andes and nearby rain forests. The bark, and in particular the inner bark lining, is scraped and turned into a tea. It has been used for centuries by the indigenous peoples as an immunofortifier.

Recent pharmacologic studies have uncovered the anti-tumor agent lapachol, as well as the anti-candidas agent xylidione, and the consistent effects of both have gathered the interest of the global pharmacological community. Claims that the tea contains a large proportion of oxygen in solution have peaked the interest of the oxygen-therapy movement, and it is being considered for anti-AIDS/HIV testing.

The normal preparation is a small amount of scraped bark prepared as a normal tea. The taste is reported to be heady and pleasant.

From hrbmoore.rt66.com (Michael Moore), as a sidenote in a post on herbs and fibroids: I, frankly, have no idea why you would want to use Pau D'Arco (*Tabebuia* spp.). It is a useful anti-oxidant and anti-fungal. I fail to see its implication with fibroids. Besides, it is a pocket-change byproduct of rain-forest timbering...don't let anyone fool you otherwise.

From Susan Marynowski (sumar.mail.ifas.ufl.edu):

Pau d'arco is a common street and park tree of central and southern Florida. It can easily be grown in a Florida backyard where it would be protected from freezing. Because of the value of this tree, I often encourage people to grow or collect their own in Florida instead of purchasing rainforest product.

The Medicinal HerbFAQ

2.12 Wild yam and contraception

This one is from Henriette, with help from unca Mike and unca Jonno.

A stubborn question, coming up on the newsgroups and mailing lists again and again: "How do you use wild yam for herbal birth control?"

Wild yam (*Dioscorea villosa*) does not work as a herbal birth control. People who try it invariably end up being called "Mom", unless they're naturally infertile.

So why is this myth still going strong?

Back in the early 40's the only hormones available were very expensive, injectable slaughterhouse hormones. An American, Dr. Russell Marker, had this great idea on making oral hormones from saponins (actually they're not really hormones, just hormone look-alikes - but that's another topic), and tried to get backing for research on this from the pharmaceutical companies of the time. None of these thought this worth pursuing ("we -have- hormones, enough for our needs, why would anybody want cheap oral hormones?") (which goes to show just how short-sighted people can be). Dr. Marker then went abroad, and the Mexican ministry of health said yep, sounds like a good idea. So he went to Mexico and started to look for plants with lots of saponins. Both Yucca and Agave roots contain enough saponins, and both were abundant, but neither was acceptable to the Mexican government as they were needed in the Tequila industry. So Dr. Marker settled for a plant that was abundant and easy to grow: *Dioscorea mexicana*, Mexican yam. It took him a couple of years to get the "Marker Degradation Process" going, and he proceeded to make progesterone, in a lab, from the saponin diosgenin found in said Mexican yam. At first the process was not economically feasible (at something like 37 steps), but when he got it down to something like 6 steps, industrial production of oral hormone look-alikes took off. And so did contraceptive pills.

A decade or three later: officials in strategic places in Mexico are looking at OPEC, thinking, "Hmmm, those guys have a monopoly -and- money, we can do that too." So they doubled the prices of the output of their oral hormone precursor factories, and whammy, next thing you see is Japanese looking around for cheap raw material - aha, soybeans. So the Japanese put up a couple of factories of their own, undercut the Mexican prices, and diosgenin the oral hormone raw material was no more. It's all soybeans now, folks.

Back then you also saw lots and lots of semi-scientific herbalists latch on to the sentence

"*Dioscorea* is a hormone precursor". These guys and gals were totally disregarding the fact that a lab is needed between raw root and hormone precursor. People use cholesterols as steroid hormone precursors. The only time you're short of cholesterols is when you're reduced to skin and bones and one big belly - and if so, you've got far worse problems to worry about than an upset hormone cycle.

Now why did the name "Mexican yam" morph into things like "Mexican wild yam", "wild Mexican yam", and later on even into "wild yam" (which properly is another species altogether, *Dioscorea villosa*)? In the 50's and 60's Mexico fell out of fashion and, in the minds of norteamericanos, got an image as a poor country. In a stroke of genius some semi-scientific herbalists, this time exclusively from North America (at least at first), thought "we don't want any of that there imported stuff, we've got wild yam (*Dioscorea villosa*), let's use that".

Now, if you know your plants, you know that *Dioscorea villosa* is a North American plant that's been widely used as an antispasmodic (it's also called "colic root"). It has -never- been used for diosgenin extraction, nor has it therefore ever seen the inside of an oral hormone factory. It probably won't ever be used that way, either, as a) it doesn't contain enough saponins to make industrial hormone precursor manufacture worthwhile, and b) it's really not all that abundant, nor all that easy to gather in quantity.

However, thus was born the name and concept of wild yam cream. Both are completely off the wall, if you ask me. Be honest about it and call it progesterone cream, and tell folks just how much natural progesterone you added to that there cream, so they know in advance just how well the cream will work.

2.12.1 Edible vs. true yam

From Michael Moore:

Edible yams and sweet potatoes are simply different strains of the same plant...edible tubers of several varieties of *Ipomoea batatas*. NO "true yam" (*Dioscorea* spp.) is used in North America for food. Most *Dioscoreas* are about as edible as pencil shavings, with less taste.

From Thomas Mueller:

I can't recall ever tasting pencil shavings, but true yams, *Dioscorea* genus, are cultivated and eaten in tropical countries, and some are available in some ethnic markets in the USA. In my experience, these yams are starchy, not sweet, more like potato than sweet potato, but lower water content than potato.

From bogus.purr.demon.co.uk (Jack Campin):

And they are widely available in the UK, anywhere there's a sizable Asian or Afro-Caribbean population, i.e. pretty much any city. The smaller variety are usually called "eddoes", the large variety just "yams". Nobody calls sweet potatoes yams here any more (they probably did after WW2; that was what my father learned to call them when in the army in India and North Africa, but he unlearned it fast enough in New Zealand).

From Henriette:

Edible yams roots are enormous. Peel, cut into chunks, boil with a bit of oil and salt. They take longer than your usual starchy vegetable to boil. They don't get all that soft. The cooking water transforms into an unappetizing whitish jelly overnight. Not really all that tasty.

Sweet potatoes, batatas, are smaller (in fact, somebody told me, long ago, the smaller the better). Peel, cut into bits, boil. Add a dash of butter - yum, *tasty*! The ones I've tried have all been more or less yellowish internally, with a whitish sap (sticky when dry) that turns gray on exposure to air. They're done about as fast as potatoes, and go about as soft as potatoes, too.

I expect Michael means that the North American species of *Dioscorea* do not sport edible roots.

2.12.2 Wild yam cream and natural progesterone

Wild yam (*Dioscorea villosa*) as such does not contain progesterone nor anything else that would act like progesterone. It's a good antispasmodic, and that's it. So, unless your menopausal symptoms include lots of cramps wild yam won't do squat for them.

The "wild yam" creams that work for menopausal symptoms (like hot flashes) contain synthetic natural progesterone. Natural progesterone is a pharmaceutical term. It doesn't mean that the progesterone is plant-derived, nor that the plants it possibly is derived from are organically grown - it means that the progesterone is identical to the human hormone progesterone. Natural progesterone is all synthetic, i.e. you need a lab to manufacture it from your raw materials. Unless, of course, it's extracted from animal glands, in which case it's *not* identical to our own progesterone (vide the allergic reactions from animal-derived conjugated hormones), and should be called something else.

How come these creams can contain synthetic progesterone without that being stated on the label? Natural progesterone is considered a cosmetic in the USA, because the FDA doesn't recognize that topical progesterone works ("just look at those women, they'll believe *-anything-*..."). Labeling of cosmetics is rather loose, and if you squint hard enough the legislation gets blurred, too. So you end up with creams labeled "wild yam extract" or something equally unlikely. This might be bordering on the illegal, particularly considering that you won't find any progesterone derived from wild yam (*Dioscorea villosa*) on the market.

Like I said, be honest about it and call it progesterone cream, -and- add amounts to your labels.

For further reading you can try John Lee's book "Natural progesterone, the many roles of a wonderful hormone". He's also written "What your doctor may not tell you about menopause". I don't have either so can't say how good they are.

The Medicinal HerbFAQ

2.13 Red raspberry and pregnancy

You use an infusion of the leaf of *Rubus idaeus* to ease pregnancy and/or childbirth. The controversy is when to use it - throughout the pregnancy or just the last trimester. One piece of advice on the paracelsus list:

From: herbal.got.net (Roy Upton)

Almost all popular texts state that red raspberry is good to use throughout pregnancy. On several occasions I have seen first trimester women experience spotting each time they drank moderate amounts of the tea. When they discontinued the tea, spotting stopped. Four tried the tea again and spotting began again. I asked a few midwives about their experience and found that they too had experienced the same thing, so did not generally recommend it in the first trimester. I do not feel that red raspberry is inherently problematic, but also feel that is not necessarily inherently benign.

The Medicinal HerbFAQ

2.14 Green tea and caffeine

The usual question is: does green tea contain caffeine? The answer is yes, if it hasn't been decaffeinated. So does black tea, and oolong. A good post on teas in general and green tea in particular:

From alczap.thorne.com (Al Czap):

It is thought that the traditional use of tea (*Camellia sinensis*) began in China about 4700 years ago. Europeans were introduced to the beverage in the 1500's, and by the second half of the 17th century it was being widely consumed throughout Europe. Today, tea is the second most consumed beverage in the world (water is #1) with 2.5 million tons of tea leaves produced annually.

The Chinese produce over 300 varieties of tea, which can be separated into three basic categories; black tea, oolong tea, and green tea.

These three types of tea can actually be derived from the exact same plant. The difference between them is how the leaves are handled after harvesting. Black tea is allowed to ferment, and is then dried. Oolong tea is partially fermented. Green tea is dried without fermenting. Allowing the tea to ferment oxidizes naturally-occurring catechins, transforming them into theaflavins and thearubigin, chemicals responsible for the color and flavor of black tea. An increase in theaflavins increases the commercial value of black tea, but decreases the catechin content.

Green tea infusion contains intact catechin polyphenols, which give rise to its bitterness and astringency. Six catechin polyphenols have been isolated from green tea; (-)-epigallocatechin, (-)-epicatechin, (-)-epigallocatechin-3-O-gallate (EGCG), gallic acid gallate (GCG), methyl-epigallocatechin-3-O-gallate, and (-)-epicatechin-3-O-gallate (ECG). These substances were tested for their antioxidant activity, and the gallic acid esters EGCG and EGC were found to be the strongest antioxidants, with EGCG being over 200 times more active than Vitamin E in an in vitro model. In another test, EGCG was more active against fat rancidity (lipid peroxidation) than Vitamin C or Vitamin E, and also exhibited synergistic action with those vitamins.

Many nutritive and protective qualities have been associated with green tea, both in infusion and extract form. A Japanese epidemiological study of 9500 non-drinkers/non-smokers age 40 and above showed a decreased incidence of stroke (CVA) in those consuming green tea, with a direct correlation between increased consumption and decreased incidence, so that at 3-4 cups a day the

overall incidence of CVA was 17 percent that of people drinking no tea. Other epidemiological studies show a decreased risk of esophageal, gastric, and colon neoplasms with tea consumption.

Numerous studies have shown that standardized green tea extracts or components of the extract exhibit antioxidant activity, stimulation of glutathione peroxidase and catalase, induction of phase II enzymes, and inhibition of cyclooxygenase, lipoxygenase, and angiotensin converting enzyme. Green tea extract also has anti-platelet-aggregation activity, and inhibits delta-amylase and sucrase, in addition to the known effects of catechin: collagen stabilization, histidine decarboxylase inhibition, and hepatic support.

Green tea extracts can contain a substantial amount of caffeine, and may be standardized to low levels of polyphenols. HPLC isolation and identification reveals that the main constituent of our extract is EGCG (epigallocatechin gallate), the most active compound in the extract.

The Medicinal HerbFAQ

2.15 Comfrey hepatotoxicity

From: Rene Burrough <rburrough.dial.pipex.com>

Comfrey is the victim of a bad press, inaccurate reports, and four true cases of toxicity which in themselves are not straightforward, but suggest overdosing on comfrey. Governments in the UK & Australia have restricted the uses of comfrey root or banned the plant respectively.

The problem is two-fold: firstly there are two "comfrees" and reference to them is often casual. Regular, common, medicinal comfrey is *Symphytum officinale*. Russian comfrey, the great compost heap maker, is *Symphytum x uplandicum*. Medical herbalists in the UK, from whose written reports I am extrapolating, point out that Russian comfrey was probably the herb used in the toxicity trials yet regular comfrey is also restricted or banned.

Secondly, when the toxicity tests were done in the late 70s, a chemical constituent called pyrrolizidine alkaloid was isolated, extracted from <comfrey> leaves & injected into baby rats at what many medical herbalists consider an "unrealistic level". In other words far more comfrey than a human would eat to get such a toxic level of <PAs>. Also baby rats are smaller than humans; they do not have the same metabolism as humans; and an isolated chemical injected outside the rat's stomach wall is not the same as a human eating leaves with many chemical constituents and digesting them normally. A chemical in isolation will cause different reactions from a group of chemical constituents containing that one as well.

To digress, but to explain, I hope. Aspirin is a synthesized chemical, acetylsalicylic acid, based on a real life plant constituent found in meadowsweet & willow. Aspirin can cause ulcerations of the stomach lining; meadowsweet has a soothing, gummy constituent called mucilage which lines the

stomach, preventing erosion of the stomach wall but allowing the anti inflammatory properties of the salicylates of the herb to be utilized. OK?

So -- the bad guys in <comfrey>, the <PAs> were isolated & did bad things. But that too must be qualified.

The early research, late 70s, concluded that these <PAs> do indeed cause liver damage in humans. Medical herbalists would point out that Pyrrolizidine alkaloids can cause obstructions of the veins in the human liver, known as hepatic veno-occlusion, but <were not shown to cause liver cell abnormalities> and that the level of alkaloids in comfrey was too low to <cause specific damage to liver circulation> in any case.

And finally, is comfrey carcinogenic? The carcinogenic alkaloid has been identified as symphytine which apparently is about 5% of the total alkaloids in comfrey.

The original, often cited report was written by Culver et al in 1980. There have been many criticisms since of the research itself; how the scientific testing was conducted, which comfrey was really used, etc. What I found most interesting was the tumors in all but three of the rats were benign -- out of three groups of 19-28 rats and 3 groups of 15-24 rats. <And the three malignant tumors were of low malignancy>. There were clear cut cases of liver damage. That's in rats.

There are four cases involving humans which do implicate comfrey. One involved a woman who was finally diagnosed as having veno-occlusive disease & did consume a quart of herbal tea/per day that contained comfrey. A second case involved a boy with Crohns disease who was treated with conventional medicine for some time before going over to comfrey root & acupuncture. The long running malnutrition may have weakened the liver predisposing it to the venal obstruction problem. Comfrey root was blamed. The drugs were not considered as possibilities. The third case involves a woman who overdosed: 10 cups of comfrey tea a day & handfuls of comfrey pills. After 9 years, she had serious liver problems. The fourth case became a fatality. A vegetarian, given to specific food binges for weeks, took an unknown amount of comfrey for flu like symptoms possibly over a period of four months. The particulars of his case are blurred. All cases involve comfrey; in at least three, there are suggestions of overdose or abuse of the plant. WHICH plant, I don't know.

There are also disagreements about the efficacy & safety of leaves vs. root. Some studies show the leaf to be almost alkaloid free -- thus safe. The UK finally restricted the internal use of comfrey root... saying that there are still too many unanswered questions. Most medical herbalists I know will politely to vigorously disagree, but the law restricts the root. At least externally the root's OK here & the leaves can still be used as tea or poultice.

I'm sorry this is so long, but bear with me one more paragraph, please. I must credit Penelope Ody, MNIMH, former Editor, writing in Herbs, the British Herb Society magazine & Margaret Whitelegg, MNIMH, whose paper for the National Institute of Medical herbalists to the UK government in <Defence of Comfrey> was later published in the European Journal of Herbal Medicine. Both were published in 1993. I cannot do justice to their articles so briefly, but I do hope I have fairly summarized their writings. Any misstatements, confusion of explanations here are mine.

2.15.1 Hepatotoxicity update

Comment from Henriette:

Yes, the pyrrolizidine alkaloids (PAs) in comfrey do hurt your liver. Yes, you have to take lots of the herb in order to get veno-occlusive liver disease. No, you can't blame that disease on pharmaceuticals taken at the same time - they'd hurt the liver in other ways. So don't take lots of comfrey every day for weeks at a time; if you do believe that you need it (and not, say, *Calendula*, which works much the same in wounds, or *Plantago*, which works much the same way both in wounds and in coughs; neither of these are problematic), take it in small amounts.

Know that if your liver is healthy it'll get hit worse than if it's already compromised. That is because the hepatotoxic PAs are catalysts, much like freons in the ozone layer - each cell tries its best to detoxify this molecule, can't do it, dies, and the next one tries, until the PA is passed out unchanged.

And know, too, that PAs are absorbed through the skin. That means that it's a really bad idea to use comfrey long-term for wounds.

Some comfrees are more toxic than others. Russian comfrey (*Symphytum x uplandicum*) is one of the worst. And there's more hepatotoxic PAs in comfrees that are grown without a real winter, eg. in California.

Other plants contain the same kinds of hepatotoxic PAs. Among these are, for instance, borage (not in the seeds, not much in the flower), some of the senecios, germander (*Teucrium chamaedrys*), and lungwort (*Pulmonaria* sp.). The most toxic ones of the lot are the *Lithospermums*.

The Medicinal HerbFAQ

2.16 Pennyroyal

by Rene Burrough <rburrough.dial.pipex.com>

In answer to your question...how deadly & which one. The very brief answer is both IF you're talking about ingesting the isolated, essential oil. So, here's a longer answer.

Pennyroyal, European Pennyroyal (*Mentha pulegium*). Labiatae.

American Pennyroyal, Mock Pennyroyal (*Hedeoma pulegioides*). Labiatae.

Other synonyms for American Pennyroyal: Pudding grass, Lurk-in-the-ditch, Squaw mint, Mosquito plant.

I knew very little about pennyroyal, except that it seems to keep the ant population down in a large stone planter I have. Six feet long by 2 feet wide & 3 feet deep to ground level, it has been a hotbed of ant breeding for 15 years or so. Anything that grew there was by courtesy of millions of ants. I put two creeping pennyroyals in...and for the last two years there have been considerably fewer massive colonies of ants. Some have moved underground and over to the veggie patch, but that's beside the point. Ants don't like pennyroyal, so that's my starting point.

Certainly the essential oil used topically or the fresh leaves crushed and rubbed onto the skin will ward off mosquitoes and fleas (see section IX). Philbrick & Gregg, in their ancient & treasured Companion Plants agree. They also state that the American pennyroyal yields a commercial oil which can repel gnats & mosquitoes. Soak a dog collar in an infusion of pennyroyal or add a strong decoction into the floor washing water are well regarded folklore remedies by Adele Dawson. Richard Mabey claims pennyroyal is also good with bites of all kinds, repelling ticks as well as the above. Tierra suggests using citronella oil with pennyroyal oil for external application against mosquitoes.

Topically, it is a refrigerant, antiseptic, insect repellent, and thus good for skin eruptions, itching, formication [the sensation of small insects crawling all over the skin] & gout [presumably for its cooling property applied to the affected, <burning> joint in an acute attack]. Parenthetically, it is only the British Herbal Pharmacopoeia that includes gout in the pennyroyal portfolio.

I HISTORY OF THE NAME

from Malcolm Stuart's Encyclopedia of Herbs & Herbalism

Pennyroyal was held in very high repute for many centuries throughout Europe & was the most popular member of the mint family. Pliny is regarded as the originator of its name "pulegium" ...derived from "pulex" meaning flea...since both the fresh herb & the smoke from the burning leaves (smudging) were used to eradicate the insects. Linnaeus retained the association with fleas when he gave the plant its botanical name. Prior to that scientific classification, the unusual aroma led some to consider it a thyme.

"Puliot" was an old French name for thyme, & this plant was designated the royal thyme or "puliot royale" which was corrupted into pennyroyal. In modern French, the herb is called "la menthe Pouliot".

Herb books written in the US tend to list American Pennyroyal (*Hedeoma pulegioides*) first, and medical herbals written in the UK & Europe prefer Pennyroyal (*Mentha pulegium*). All agree the <other> pennyroyal has the same or similar properties. Where the real differences lie are in the appearance & life cycle of the two herbs.

II DESCRIPTION OF PENNYROYAL

Pennyroyal (*Mentha pulegium*) is an aromatic Perennial and is common wild or garden plant in the UK, France & Germany; found in wet grounds around the Med & in Western Asia. Mrs. Grieve says the more common, at least in the UK, is the creeping or <decumbens> pennyroyal. With weak, prostrate stems, though quadrangular -- as all mints have square stems -- it roots easily where ever the leaf nodes touch the ground. H 10-15cm or 4-6in. S indefinite. <Erecta> the upright or sub-erect has stouter stems, & obviously there's no rooting at leaf nodes. It is less common in the UK but better for cultivation according to Mrs. G.. H 20-30cm or 8-12in. S indefinite. A planting will last 4-5 years, though Mrs. G says frost may kill it, & a new planting should be made each year. Deni Brown lists pennyroyal as fully hardy [minimum -5C or 5F). Ethne Clarke's Herb Garden Design shows pennyroyal appropriate for Zones 5-9.

The leaves of Pennyroyal are generally small, ovate, slightly serrate, slightly hairy, and opposite. For the record, the leaf of the non-creeping pennyroyal can be up to 3cm or 1.5in long and may be entire rather than slightly toothed. The color depends on the variety and whether wild or cultivar. Greyish-green to light green. The IMPRESSION of the appearance of the leaves is similar to that of wild oregano (*Origanum vulgare*), marjoram (*O. majorana*, *O. onites*) & thymes...that is... tiny & crowded together on thin stems but with more rounded leaves. Not surprisingly Mrs. G described pennyroyal as <the smallest of the mints & very different in habit>.

The small flowers are produced in distinctive, dense whorls (similar to corn or fieldmint & gingermint in bloom.) The tight, axillary clusters appear in July-August with colors ranging from reddish -purple to lilac. There are few flowering stems on the prostrate form; they lie on top of what appears to be "a dense green turf". Seed is light brown, very small & oval.

To harvest: for drying, the stems should be gathered just before flowering in July. Pungently aromatic, it can be added to potpourris & insect sachets. The dried herb can also be made into infusions, liquid extract, tinctures for medicinal uses. (see section X)

III DESCRIPTION OF AMERICAN PENNYROYAL

According to Deni Brown, there are 39 species of annuals & perennials in the NAmerican genus, *Hedeoma*. They have no great merit as garden plants, but are often seen in herb gardens. Its neat habit & aromatic foliage makes it especially suitable for containers & planting near seats & entrances, or between paving stones.

American pennyroyal is an Annual, found in dry fields & open woods from the East coast to Minnesota/Nebraska. It is bushy plant with erect, square stems. H 10-40cm (4-16in) S 7-24 cm (3-10in) it bears small, opposite, thin ovate leaves sparingly toothed. Axillary clusters of small, tubular lavender or purplish flowers appear from June-October. The whole plant has a pleasant, aromatic, mint-like smell. The name *Hedeoma* comes from the Greek <hedys> for sweet and <osme> for scent. It has also been described as having an acrid taste and aroma; none-the-less it is used as the basic flavoring herb of North Carolina black pudding... hence the local name of Pudding Grass.

A culinary aside: In the north of England, Pennyroyal (*Mentha pulegium*) is also used in black pudding, and in Spain it is added to sausages.

To harvest: plants should be cut when in flower for drying. The fresh herb can be gathered and used almost as a "strewing herb" for deterring fleas.

IV THERAPEUTICS OF *MENTHA PULEGIUM*

For the basic framework, I am using the information from the *British Herbal Pharmacopoeia, 1983* supplemented by Potter's, Culpepper's Colour, David Hoffmann, Deni Brown, & Simon Mills.

Actions: Carminative, Spasmolytic = arresting or checking spasm especially of smooth muscle. [Antispasmodic means preventing or relieving.] Diaphoretic. Uterine stimulant/ Emmenagogue... principally used for delayed menses. (see section VIII)

Topically: Refrigerant. Antiseptic. Insect repellent.

Indications: Flatulent dyspepsia. Intestinal colic. The common cold. Delayed menstruation.

Topically: Cutaneous [skin] eruptions. Formication. Gout.

Specific indications: Delayed menstruation owing to chill or nervous shock.

Contraindication: Inadvisable in pregnancy. (see section VIII)

In small doses & as an infusion, pennyroyal is used for colds (as it promotes sweating), With its richly aromatic volatile oil, pennyroyal will ease indigestion, wind, nausea, colic, dyspepsia, and painful menstruation. It is considered a warming & stimulant herb by Culpepper, while Adele Dawson also suggests its use in cases of stomach spasm & hysteria. Hoffmann explains that the volatile oil will relax spasmodic pain & ease anxiety. NB: This should NOT be construed as ingesting the isolated, essential oil which could be fatal. (see section IX) The volatile oil is a constituent of the plant & will be released in the preparation of the infusion.

Pennyroyal is given to children with stomach & bowel upsets & also to ease feverish symptoms in measles & whooping cough. Taken by infusion according to Culpepper.

BHP suggested dose: for an infusion: 1- 4gm of dried herb in 1C ** boiling water; steeped for 10-15 minutes. 3 times a day.

Or 1-4ml of liquid extract (1:1 in 45% alcohol). 3 times a day.

Other herbals consulted tend to suggest smaller doses: up to 2 or 3gm dried herb; up to 2ml tincture...though Potter's range is from 0.5ml - 5ml of the liquid extract.

**NB: the general proportions for infusions are: 30gm dried herb or 75gm fresh herb to 500ml boiling water. So "one cup" is the proverbial length of a piece of string.

Pennyroyal is available on the General Sales List in the UK. [In itself, that is an indication of its considered safety.]

The BHP suggests the following combinations: for acute amenorrhea - may be combined with Chamaelirium (False Unicorn Root), Achillea millefolium (Yarrow), & Picrasma (Quassia, Quassia Wood, Jamaica Quassia); for flatulent dyspepsia - may be combined with Filipendula (Meadowsweet), Althaea Root (Marshmallow root) & Melissa (Lemon Balm); in the common cold - may be combined with Sambucus (Elderflower) & Achillea millefolium (Yarrow)

V THERAPEUTICS OF *HEDEOMA PULEGIOIDES*

The basis of this information came from Lust's *_Herb Book_*, Deni Brown's *_Encyclopedia of Herbs_*, Tierra's *Plant Herbology*, & Earl Mindell's *_Herb Bible_*

Properties & uses: carminative, diaphoretic, emmenagogue, sedative, expectorant. The Amerindian tradition shows use of pennyroyal for headaches, feverish colds, & menstrual cramps & pain. It was also used as a digestive herbal tea. It was listed in the *_US Pharmacopoeia_* (1831-1916).

It is still used internally for colds, whooping cough(the expressed juice can be made into a lozenge/sucking candy). In childbirth, the PLANT is used.

NB: the essential oil taken internally could be fatal. (see section IX). It should be used by qualified practitioners only.

Topically: as a wash for skin eruptions, rashes, and itching.

Suggested dose: 1 tsp. herb/1C water. 1-2 cups/day. Tinctures 20-60 drops at a time, as needed. For children, small, frequent doses.

VI CONSTITUENTS OF *MENTHA PULEGIUM*

(The American pennyroyal has similar constituents.) Sources: Potter's, Malcolm Stuart, Tierra, & David Hoffmann.

Volatile oil (0.5-1%) of which approx. 85% is a ketone, pulegone; also isopulegone, menthol, isomethone, limone, piperitone, neomenthol. There are also misc. bitters, tannins, & flavone

glycosides.

Pulegone is described as a toxic compound, "notorious for causing abortions". It is present in both *Mentha pulegium* & *Hedeoma pulegioides*.

VII ADDITIONAL MEDICAL INTERPRETATIONS

Tierra in *_Planetary Herbology_* collectively describes *Hedeoma pulegioides* & *Mentha pulegium* ...in much the same way as mentioned above. He does add the following: The Energetics are spicy, bitter, warm . The Meridians/organs affected are liver & lungs.

In David Bellamy's & Andrea Pfister's *_World Medicine_* they have a large section called The Families of Healing Plants. *Mentha pulegium* is listed with two sources of information: The 1907 British Pharmaceutical Codex and Book I of Avicenna's *_Canon_*. The BPC states that Oil of Pennyroyal (Ol. Pulegii) is given as an emmenagogue. During excretion, it mildly irritates the kidneys & bladder, and reflexly excites uterine contractions. Avicenna lists the herb as Mint (Podina in Urdu). The leaves are the part used. The herb's Temperament is described as Hot & Dry in the 2nd Degree.

VIII HOW DEADLY IS DEADLY...AND WHICH PENNYROYAL ARE WE TALKING ABOUT?

Simon Mills in *_Out of the Earth_* issued the strongest warning that I found in my trawl of herbals. There are a number of herbs which should be avoided altogether because they can damage the fetus or provoke a miscarriage. In many popular herb books the term emmenagogue is found, widely but erroneously, having come to refer to a gynecological remedy. In fact, the effect of an emmenagogue is to bring on a delayed menstruation: it takes little imagination to realize that the most common reason for a delayed menstruation is pregnancy and that emmenagogues are thus abortifacients. Pennyroyal (*Mentha pulegium*) is among 21 herbs Simon Mills lists. This information was part of a short section of herbs in pregnancy..those quite safe, and those not so.

In his first book, *_The Dictionary of Modern Herbalism_* written 6 years earlier, Mills quite carefully does NOT list emmenagogue among the actions. He does include uterine stimulant with this caution: <pennyroyal should not be used in pregnancy or when any delayed menstruation might denote pregnancy; it is as likely to damage the fetus as procure the abortion.>

The second most complete, cautionary listing was found in Earl Mindell's *_Herb Bible_*. He is talking about American pennyroyal (*Hedeoma pulegioides*).

<Back in the days when abortion was illegal, this herb was used to induce abortion. In some cases, it resulted in hemorrhaging & serious complication for the mother. Therefore, it should never be used for this purpose. Today, pennyroyal is one of the herbs used by herbalists to facilitate labor & delivery. It should be used only under the supervision of a knowledgeable practitioner. If you do use this herb, do not exceed the recommended dose & do not take for more than a week at a time.>

Richard Mabey in *_The Complete New Herbal_* warns <...the oil taken internally can be highly toxic and there are a number of cases of the deaths of women who tried to procure abortions by

taking the oil.>

Tierra in Planetary Herbology goes further in his explanation. <To take the oil internally to terminate an unwanted pregnancy is very dangerous, and in a few cases has resulted in death. All essential oils are life-threatening if taken internally. There is a possibility of fetal damage from the use of pennyroyal (*Hedeoma pulegioides* or *Mentha pulegium*) to induce abortion, but this may be true only of the undiluted oil and not the infusion.>

Malcolm Stuart raises an important, tangential danger. <Although long considered an abortifacient, it has been found that this effect is usually only possible with a dose of the oil which is highly toxic and leads to irreversible kidney damage.>

He then goes on to state:

<The plant oil can therefore be used as a flavoring agent, but only when the concentration of pulegone does not exceed 20mg parts per 1kg of the final product being flavored.>

IX PS ON PESTS

And just to round things out, he adds that the plant may cause contact dermatitis which is certainly worth noting before rubbing crushed, fresh leaves on your skin to avoid mosquito bites. He adds that the pennyroyal leaves are also good for insect bites after-the-fact. They act as a rubefacient...that is drawing more blood to the area which improves its cleansing action on the affected tissue.

X ODDS AND SODS

While some herbalists maintain that a fresh herb/plant is medically more efficacious, I have not seen any preferences specified for either Pennyroyal or American Pennyroyal. Most herbals referred to the dried herb...so by omission one can assume dried is the preferred state. Why? I don't know.

Forms of internal dosage:

The British Herbal Pharmacopoeia, Mrs. Grieve, & Potter's call for a liquid extract to be taken. Hoffmann & de Bairacli Levy use infusions. Lust calls for a tincture to be used.

As a reminder, the differences are:

Tincture: solution of substances (both active & inactive therapeutically) extracted from medicinal plants by the maceration or percolation of the plant with alcohol or alcohol-water solutions.

Liquid extract: product obtained by treating plant material with a solvent or mixture of solvents designed to extract the desired constituents.

Infusion: made by pouring a given volume of boiling or just boiled water over a given quantity weight of herb and letting it steep/infuse for a given time.

Always cover to keep the volatile oils in the infusion...otherwise they'll escape...evaporating into the air.

The Medicinal HerbFAQ

2.17 Cat's Claw

From Kris Gammon <ancientone.gnn.com>

Latin name: *Uncaria tomentosa*. Peruvian name: una de gato.

Cat's Claw is a thick, long, slow growing woody vine that grows between 400 and 800 meters above sea level in the Amazon jungle. This vine gets its name from the small, sharp thorns, two at the base of each pair of leaves, which looks like a cat's claw. These claws enable the vine to attach itself around trees climbing to a height of 100 feet or higher.

In 1959, Nicole Maxwell made a journey to the Rio Putumayo. She painstakingly began her collection of specimens and data of medicinal plants in the Amazon. This was her first long jungle trip although she had made previous excursions. Her findings are well written in "Witch-Doctor's Apprentice: Hunting for Medicinal Plants in the Amazon". She describes a number of plants and their applications, among which is una de gato.

Research began on Cat's Claw in the early 1970's. Mr. Klaus Keplinger filed the first patent in the US on *Uncaria tomentosa* in 1989 when the plant's alkaloids were isolated and tested. There are mainly six oxindole alkaloids most prevalent in the Cat's Claw bark, known as: isopteropodine, pteropodine, mitraphylline, isomitraphylline, ryncophylline, and isorynchophylline. Three of these have been proven to be effective immuno-stimulants. Ryncophylline has been shown in laboratory testing to display an ability to inhibit platelet aggregation and thrombosis. This means this alkaloid may be useful in the prevention of stroke and reducing the risk of heart attack by lowering blood pressure, increasing circulation, and inhibiting both the formation of plaque on the arterial walls and formation of blood clots in the vessels of the brain, heart and arteries.

As well as these alkaloids, Peruvian and Italian researchers have discovered other beneficial phytochemicals inherent in the plant, including proanthocyanidins, polyphenols, triterpines, and the plant sterols: beta-sitosterol, stigmasterol and campesterol. These might explain the antioxidant, anti-microbial, anti-tumor and anti-inflammatory properties attributed to this plant.

In 1991 there was a new study to isolate the chemical compounds found naturally within the plant that would be responsible for anti-inflammatory principles. This led to "the isolation and characterization of a new quinovic acid glycoside called glycoside 7 as one of the most active anti-inflammatory principles to be uncovered."

Many species of the genus *Uncaria* exist in nature...more than 30. It is the *U. tomentosa* species that offers the most promise as a therapeutic agent. *Uncaria guianensis* is frequently confused with *Uncaria tomentosa*. Consumers should check the Cat's Claw bottles they buy for "*Uncaria tomentosa*" and choose from a reputable company. Cat's Claw is available in capsules, extract and the raw bark for brewing tea.

Cat's Claw is used for: Crohn's disease, diverticulitis, leaky bowel syndrome, colitis, hemorrhoids, fistulas, gastritis, ulcers, parasites, intestinal flora imbalance, cancer, arthritis, diabetes, chronic fatigue syndrome, environmental toxic poisoning, organic depression and those infected with the HIV virus.

Most of the clinical research which show these alkaloids to be antiviral, anti-inflammatory, immunostimulating, antimutagenic, antioxidant, etc., are tests done "in-vitro" (proven in the test tube) not "in-vivo" (proven in the human body).

Cat's Claw root should never be used as the medicinal qualities are most prevalent in the inner bark and harvesting the root kills the plant. Consumers should refuse to buy any Cat's Claw root products in order to ensure the plant is not destroyed. Peruvian law is now in place to help protect *Uncaria tomentosa*.

The Medicinal HerbFAQ

2.19 Ma Huang or Ephedra sinica

From T. R. Hastrup:

Ephedra contains ephedrine which is a drug very similar to adrenaline but with a longer halflife. It acts on exactly the same receptors as adrenaline does and has exactly the same side effects and dangers. It does not induce hallucinations and it's stimulative effect is not very far from caffeine. Even when taken in extreme doses with constant use, it is questionable if ephedrine can cause a psychosis. It has nowhere the power to push the body to the limits. I know some people out there love to spread scare but ephedrine is a very safe and natural drug. The only dangers from ephedrine is because it can cause high blood pressure and vaso-constriction, exactly like adrenaline. People with high blood pressure or heart problems should naturally be careful with this herb.

Also, ephedrine is chemically related to the amphetamines but everybody should know that similarity in molecular structures does not mean the action of the drugs are similar. Ephedrine acts purely on adrenergic receptors, unlike the amphetamines which have powerful CNS stimulative effects.

From Henriette:

The problem with *Ephedra sinica* (and other Eurasian species of Ephedra - there is no ephedrine to speak of in the American species) is that we as a culture are -used- to 4- or 5-hour drugs. Take coffee, or aspirin, and it'll be out of your system in 4-5 hours. Ephedrine will let you stay jittery for 8 hours - but because you're used to dosing yourself every 3-4 hours you overdose -very- easily on

ephedrine. Especially if you abuse the plant (ie. you use it to keep awake), or worse, mix it with things like caffeine and aspirin to -really- get that weight down.

That way lays your first (and perhaps last) heart attack, a -lot- of jittery nervous overstrung adrenergic problems, and that way lays madness.

Chinese Ephedra (Ma Huang) is not -used- by the great unwashed masses in the US, it's -abused-. That's a big difference, even if it only looks like two letters.

As an herb Ma Huang has its uses in TCM, and in western herbalism it's used in small discrete doses for things like bronchial spasms. NOT long-term, nor for frivolous things like "but I have to keep awake". Herbalists try to keep you -in- balance, not get you -out- of balance. If you value your health you should do the same.

On Ma Huang and drug tests:

From "Michael M. Zanoni" <zanoni.netcom.com>:

Ma Huang (the Chinese variety *Ephedra sinensis*, not the American *Ephedra* plant) can produce a positive urine test for amphetamine metabolites that will also be read by the mass spec as being meth metabolites. It is because of the combination of both l- and d- forms of ephedrine. Things such as *Ephedra nevadensis* have only the non-psychoactive form of ephedra.

If someone were to take a moderate amount of Ma Huang for a few days it is possible that the serum titer could go high enough to be beyond the threshold level of detection used by most labs for gas chromatograph screening.

Pseudophedrine found in OTC drugs will not test as a meth metabolite.

The Medicinal HerbFAQ

2.20 Skullcap and *Teucrium* adulteration

The question, on the herbinfo -list in July 1998:

>I remember reading somewhere about the possibility of liver toxicity from pyrrolizidine alkaloids or adulteration of skullcap. A web search didn't turn up anything useful. (Would you believe you can type "skullcap" and "liver" into a search engine and bring up x-rated sites?)

I found plenty of information about comfrey and PAs but that's not really what I needed.

My reply (thanks for all those tidbits, Uncle Mike):

Scutellaria, aka Skullcap is not dangerous.

However, it has been adulterated with Germander (*Teucrium* sp.) for decades, if not centuries; though that matters a great deal qualitywise it has no implications on toxicity as long as only the 'mercans did it, as the 'mercan species of *Teucrium* do not contain toxic pyrrolizidine alkaloids.

Again HOWEVER, then the Europeans thought "Hmmm, that's a great idea, money for nothing, chicks for free", (sorry, got carried away). So they imported *Scutellaria* from America and added their local -European- *Teucrium* species to it. Then they re-exported the mix to the folks on the other side of the pond... there is a very big problem with quality here, AND in this case there is a problem with toxicity. The European species of *Teucrium* do contain toxic pyrrolizidine alkaloids. So it's not good for your liver to buy your skullcap from sources you do not trust, like the -really-large herbal houses; THEY ALL DO IT.

To get them to stop it you'll have to ask your suppliers where they got their skullcap from. If they bought it, ask them where from; ask them to ask -their- supplier(s) where from... if it's one of the big houses ask them to PROVE that there is no *Teucrium* in that there *Scutellaria*.

Perhaps, if enough of us do this, we'll have unadulterated *Scutellaria* in another couple of decades.

The Medicinal HerbFAQ

2.21 Mellow mallows

Malva sylvestris

By Miriam Kresh, Tsfat, Israel

Some weeds grow just anywhere, pervasive green presences of which you don't take much notice as you hike along. The common mallow is one, and I welcome it whenever I see it, for it is a friendly and useful plant. From it's roots to it's edible seed pods, mallow's nutritious and medicinal properties have been known since Pharaonic times, and probably before.

Here in Israel, mallow starts putting forth tiny, heart-shaped leaves everywhere at the beginning of the winter rains in October. By December the leaves are shapely and large, looking something like the geranium; in some parts of the country they grow as big as soup plates. Throughout the winter and spring, the stands will grow up to four feet high, given the right conditions of moisture. In the meadows, on the roadsides, in any vacant lot, competing with cultivated vegetables in the fields, invading your garden - there seems to be no end to that green Nosey Parker. And pollution seems to bother it not at all: sometimes the most beautiful stands will be seen flourishing next to a crowded parking lot.

The roots of mallow are rich in beneficial mucilage. Boiled, they make a drink which is diuretic and soothing to the urinary tract at the same time. This is good wherever there is painful urination. A painful chest, as in bronchitis or flu, can obtain relief from this drink too.

The leaves, dark-green and coarse, are a powerhouse of minerals and vitamins (calcium, iron, vitamin C, copper traces and more) and an abundant, free source of organic nutrition. They also release soothing mucilage. I decoct mallow leaves for my cough or iron tonic syrups, slice it into

soup for a cold or flu patient, add them to the infusion for moisturizers.

As a poultice, mallow leaves will draw out boils and pus from old infections. Put a few large leaves in your blender with some mineral water, and apply the green, goopy mask to your teenager's acne for cleansing and healing. If he or she objects, add a drop of essential oil of lavender to make it smell good. Allow it to dry, then rinse off. The skin will look brighter and feel silky.

Rashes and burns can be successfully treated with mallow leaves, crushed or blended. When gathering nettles, I look for a nice big mallow leaf to wrap around the hairy, stinging stalks so I can cut them easily. If I do get stung, a poultice of crushed mallow will take away the irritation quickly.

During the siege of Jerusalem during the War of Independence in 1948, food supplies to the city were cut off and near-famine conditions prevailed in the city. Mallow was an important source of nutrition to the imprisoned population then: the leaves were gathered, chopped fine and fried as patties or eaten raw. The seed pods were collected to eat raw or cooked. (They're not bad raw; I often stop to nibble a few. This I learned from the children, who call them "arab bread", and forage for them all the spring.) Folks who lived in Jerusalem then will serve mallow patties, or stuff the leaves like cabbage rolls on Israeli Independence Day, to commemorate that time.

The pink or purplish, flowers can (and should) be added to any formula for cystitis, coughs, and inflammation in the digestive tract. Again, the abundant mucilage, easily released from the flowers, benefits all irritable, painful conditions in these areas.

Mallow has only a neutral, greenish taste, so you can add it to almost any dish at all. Following are some ideas for using mallow to boost the nutritional content of your family fare; you'll get the idea as you read along.

- Wash your mallow carefully, and check for bugs, as you would any other edible leaf. Don't be put off by a few holes: birds peck at mallow, so the holes don't mean that the leaf is infested. Little yellow bumps imbedded in the underside do, however.
- Add whole small leaves to your salad greens: make sure the dressing is a little stronger-tasting than usual, since the taste of raw mallow is sort of uninteresting.
- Almost any soup you cook will accept a handful of chopped leaves, added the last 15 minutes of cooking. Allow the soup to sit a further 10 minutes before serving, to allow the beneficial mucilage (or goop) to be extracted out of the leaves.
- Further tip: soup made for invalids, i.e., cold or flu sufferers, or someone needing a Strengthening Tonic as for after surgery, a bout of illness, etc., can be enriched with the scrubbed, chopped roots of mallow, as well as the leaves. The roots are especially rich in minerals and mucilage, and so especially benefit a patient with a cough.
- Saute your chopped mallow leaves; add to an omelet.
- Stuff and roll the leaves as you would cabbage leaves.
- Stir-fry mallow chopped into ribbons as part of your vegetable stir-fry medley.

Mallow Soup (serves 6 - 8)

- 1 large onion
- 1 large tomato
- 2 bell peppers, preferable of different colors
- ½ bunch of celery
- 4 carrots
- 3 large potatoes
- 3 garlic cloves
- olive oil to cover the bottom of your soup kettle
- 6 cups of water, enriched with 2 Tblsp. of good-quality soy sauce or the same quantity of chicken broth
- 2 tsp. salt plus black pepper to taste.
- 2 large handfuls of clean mallow leaves and/or roots

1. Dice the onion; chop tomato, peppers, celery, carrots and potatoes.
2. Sauté the onions, adding the other vegetables as the onions start to wilt
3. Chop the garlic finely; add to the sautéed vegetables when they are looking golden and start smelling cooked.
4. Add water and seasonings; simmer for 15-20 minutes. A nice touch at this point is to blend the cooked vegetables, with some of the soup, and return the blended mass to the pot. Children especially appreciate blended soups.
5. Chop the Mallow into narrow ribbons: if using roots, slice finely. Add to the pot and cook a further 10 minutes.

Serve with croutons, or chopped parsley, or simply on its own.

Henriette's comments:

You can use most any Malvaceae in the same way as you can use *Malva sylvestris*. So you've got *Althaea* sp., *Alcea* sp., *Malva* sp., *Lavatera* sp., *Hibiscus* sp., *Sphaeralcea* sp., *Sidalcea* sp. etc. etc. growing in your garden or in that nearby wild spot? Pick the leaves and (where applicable) roots, and use them. Some species (for instance, most species in the genus *Sphaeralcea*) have itchy hairs, so don't use the leaves of these as wild food, and use a coffee filter before you ingest teas made from them. Other species (like *Hibiscus sabdariffa*) have a very sour tang to the flowers, so don't use them in quite as large quantities. But they all contain loads of mucilage in all parts, and they all help your mucous membranes.

The Medicinal HerbFAQ

2.22 Melatonin

from Paul Bergner (bergner.concentric.net), Editor, Medical Herbalism (<http://medherb.com>):

I'm not surprised that melatonin is gone in Canada, and I predict that it will go the way of DHEA here in the U.S. -- meaning that it will be a prescription-only controlled item, treated like opiates.

I've just researched and written a lengthy article about melatonin, and frankly I am shocked that natural healers would use this substance casually like a sleeping pill. Melatonin is a powerful hormone that affects the entire metabolic cycle, not just the sleep- wake cycle. We rail against hormone-replacement therapy with estrogen- progesterone, and then casually offer patients enough melatonin to raise blood levels 10-20 times their normal levels. This is bound to be a Devil's bargain, and it is only a matter of time till regulatory agencies throughout the world discover this and rightfully take measures to protect the public.

For instance: melatonin production by the pineal gland appears to be an important part of the aging clock. The pineal glands of young mice, transplanted to old mice, make the old mice "younger" and they live about 1/3 longer. On the other hand, the pineal glands of older mice, transplanted into younger mice, immediately makes them "older" and they live about 1/3 shorter lives.

So what happens when some guy named Joe in Iowa takes ten mg of melatonin (about twenty times what you need to achieve normal blood level peaks) to sleep most nights for three years (this is actually happening all over the place today) and then can't get the melatonin? Will his pineal have lost its ability to produce the same levels as previously? Most hormones have a negative feedback loop of one sort or another -- would levels that high reduce endogenous production over time? Will poor Joe then age ten years over the next few months?

I think melatonin has a proper place in natural medicine, in the treatment or palliation of cancer, used for brief periods for jet lag, and possible for the elderly, and may be a few more uses. But IMO over-the-counter status is inviting health disaster.

The Medicinal HerbFAQ

3.1 Herbs for mosquitoes and other bothersome bugs

[repelling](#) - [bites](#)

Actually this isn't medicinal - if you don't count doing something for the bites. But it's asked every year come bug time, so I'm including it anyway.

3.1.1 Repelling them

>I'd heard rumors of vitamins and herbs that naturally repel insects, though I'm not sure which ones.. any help is greatly appreciated

From Aine Maclir (amaclir.unibase.unibase.com):

There are a couple of things that I know of.

1. Wear Citronella essential oil (which isn't the greatest smelling stuff around, but I guess it beats Off).
2. Take the equivalent of 1500 mg of fresh garlic clove (a 15 mg capsule of garlic powder or 3 x 5 mg capsules) orally every day. Taking garlic will cause your skin to secrete a natural insect repellent.

For best results, do both. Don't wear perfumes or scented deodorants and wear light-coloured clothing as darker colours attract bugs...this is particularly true of blue denim jeans. To make sleeping more comfortable, burn either an insect coil or a couple of sticks of citronella incense in your cabin before going to bed, making sure that all the doors and unscreened windows are closed, so no more of them get in.

If you do get bitten, applying a small dab of ammonia to the bite immediately after being bitten can help ease the itching. And there's always the old favorite...calamine lotion...if you're not going to be anywhere that being coated in pink polka dots will be unfashionable (g). Aloe vera and witch hazel will also soothe insect bites.

If you are going to be in an area that's also known for tics, just be on the lookout for them whenever you've been in a wooded area and if you find one stuck to you, use rubbing alcohol to make it let go and carefully remove it with a pair of tweezers. Salt applied to a leech will get rid of it (in case you're around water that has any of those "suckers" (g)).

I think that should about cover every blood-thirsty creature you're likely to run into at a summer camp, recalling my own experiences. I've been on canoe trips through Algonquin Park, Ontario (known for having some of the biggest and thirstiest mosquitos, blackflies and leeches in Canada) and I live in Saskatchewan, where we could make mosquitos our provincial bird!

From "Peter & Janine" pjerlandsen.cox.net:

> 1. [Wear Citronella essential oil \(which isn't the greatest smelling](#)

I would not wear Citronella when out camping where there is bears. They have found that the female black bear love the smell of Citronella. It does not attract the male bear.

From sfrye.interaccess.com (amethyst):

I've had good results taking B-complex supplements daily. Seems the bugs like the odor of B-1 about as much as I like the taste of it. ;P

From starla lacy (lacys.cadvision.com):

Here in Canada, we struggle with flies the size of horses! This essential oil mix has always worked great for me:

3 parts lemongrass (or citronella)

1 part thyme

2 parts lavender

1 part peppermint (or eucalyptus)

Mix together in a new plant sprayer (you may dilute with springwater if desired). This mix also has the advantage of smelling pleasant and is safe for use around kids and pets.

Shake the mixture well before using if you decide to dilute it with water.

From Henriette to above:

Remember to dilute essential oils in carrier oils (like almond, jojoba, olive ...). As a general rule you should not ingest essential oils.

From Mateo Rutherford (mcrutherford.lbl.gov):

I have used tobacco tea to kill lice and gnats. It is easy to prepare. Buy a cigar or some rolling tobacco and boil the hell out of it in a liter or so of water. When cool shlop it on your hair and cover your hair with a plastic shower cap or something like that for 20 minutes then shampoo. One application should be enough, but I would often do a follow up about three or four days after the first application.

From fukada.uhunix.uhcc.hawaii.edu (Mach T. Fukada)

However, keep in mind that nicotine that is extracted from the tobacco is also toxic to humans (people don't get too much of it when the smoke it because it burns up). It should be used with care if there are cuts on the scalp which may increase the rate that it is absorbed into the bloodstream

> I was wondering if there are any herbals that can be taken to reduce the attack of mosquitos. I happen to live in an area where they are abundant.

From amy.winans.psl-online.com (Amy Winans) to above:

I do well know what you mean! Here's what I've gathered on that subject, and keep (all) on hand as needed:

1. You can join the rest of America and buy a caseload of Avon's Skin So Soft. I have about a dozen friends who worship it religiously.
2. You can stock up on anything containing Citronella, although I fear it may still be too new to really know if there is Life for it after the Candles. I'm seeing a lot of oils and lotions saying it's in there, though.
3. Continue to use the old standby's with DEET in them, like Off's Offtastic, or whatever, or Cutter's. Have heard personal testimonials on Cutter's.
4. Investigate local ancient customs; as I discovered when I read the area's native Indians, the Karankawas, employed an effective remedy to a problem which was (unbelievably) much more horrid than it presently is; that is, they killed them an alligator, skinned him, liquified the fat and slathered it on! Kept quite a few things away, one of which WAS mosquitos!

Seriously, though, there is probably something in that we could replicate today with something similar but more sweet-smelling. So, if anyone has any ideas, as well as things to ingest that might make your "scent" less attractive to mosquitos, please post!

3.1.2 And now you're bitten...

From EderChiro.aol.com:

Use lavender oil (small drop) applied directly on mosquito bites.

From Henriette:

Lush Stellaria media does the trick, too - just roll into a ball and let the juice drop onto your bite(s).

From Noel Gilmore (ngilmore.gate.net):

Allow me to pass on my husband's rather simplistic (and annoying) remedy to keep mosquito bites from itching and swelling...DON'T SCRATCH 'EM. For years I suffered all summer while he did not and he would always tell me it was because he disciplined himself not to scratch. Last year we went to the Yucatan jungle for vacation and I couldn't bear to cover myself from head to toe each day with repellent, so I asked him to help me remember not to scratch, and I have to admit it worked!

From Tim Keenan (tkeen.an.uoguelph.ca) to above:

As someone who has lived and worked on the arctic tundra and in the boreal forest for decades, I have to agree...I never use DEET or any other repellent. If the bugs are so thick I can't breath

without inhaling them, I use a "SkeeterGuard" fine-mesh net jacket, with a net hood that zips across the throat. Otherwise, I hit 'em if I feel 'em. If I don't feel 'em, I hardly ever develop any reaction. If I have a reaction, usually if I get bit somewhere where the skin is thin (over a wrist bone, etc.) I generally ignore it and it goes away. I never get a bump _unless_ I scratch. This goes for black flies, too. I think the best answer is to get bit early and often, and you will become acclimatized to it. Rubbing and scratching causes all sorts of local histamine response, which really aggravates the situation.

From Lane.monty.rand.org (Janis Lane) to above:

I have been getting TERRIBLE spider bites. The doctor told me that I was having a chemical reaction (arm was burning hot and swollen). He told me the SAME thing..."do NOT scratch". I stopped scratching and it seems that the bites are not swelling but are just turning to bruises. Any suggestions for THIS?

From Sharon Rust (ntlor.primenet.com) to above:

For spider bites I have used fresh papaya and when I haven't had the fresh stuff papaya - pineapple enzymes, these work for bee and wasp and scorpion stings as well. I chew up the enzyme tablet to make a paste and stick it on the bite , the papaya I just stick a chunk on . When I use to live where plantain (*Plantago rotundifolia*, or *lanceolata*) grew I used it for bites, it seemed to work on bee, spider and mosquito bites. To use plantain I would get a fresh leaf and chew it up with my front teeth, taking care not to swallow the juices and then stick this wad of chewed up plant on the bite(s). When my daughter and niece stepped into a swarm of yellow jackets luckily it was in a field filled with plantain, I started chewing up and applying the plantain to my daughter and my sister-in-law did the same for her daughter, the bites on my daughter were disappearing but my niece was getting no relief, so when I was finished with my daughter's bites, I started applying plantain to my nieces, the ones that I worked on were also disappearing , the key was that my sister-in-law was swallowing the juices released from the plant and I was not. I suppose you could use a blender or something but most of the time I feel that this is the fastest and simplest way to treat a bite.

The Medicinal HerbFAQ

3.2 Herbs for migraines

by Eugenia Provence, Eprovence.aol.com

What are migraines? A whole variety of headaches associated with vascular constriction and dilation make up the unpleasant world of migraines. The two most common are classic migraine and common migraine. They may first appear in childhood, but usually in the late teens or early twenties. More women than men are subject to them, and they frequently end after menopause.

Classic migraines start with warning signs (called the aura by medical folks). Before the headache begins, you may temporarily lose some of your vision, see flashing lights and feel very strange altogether, maybe even feeling a burning sensation or muscle weakness.

The pain usually begins on one side of the head, but can spread. The headache may take hours to develop and several days before it goes, leaving a desire to sleep (replacing the desire to die!). You may experience nausea and sensitivity to light and noise.

I've had only one of this kind and never want another. I thought I was losing my vision (along with my wits and my lunch). Other symptoms may include muscle numbness, tingling, scalp tenderness, dizziness, dry mouth, tremors, sweating and chilliness.

Common migraines don't begin so dramatically, but a few hours or days before onset, you may feel tired, depressed (or paradoxically) have a burst of energy, be anxious or feel hyper. The common migraine may begin more slowly and last longer than the classic type. Except for the aura, the symptoms are the same.

What causes migraines? The exact range of mechanisms producing migraines isn't well understood, but is believed to be an upset in serotonin metabolism that causes dilation of cerebral arteries, followed by vascular spasm in extra-cranial blood vessels.

Migraine triggers are as varied as the individuals afflicted by them. About 70% of sufferers have family histories of migraine.

Food triggers are common, and can be nearly anything. Some of the most frequent food triggers are anything aged, canned, cured, pickled or processed or that contain tyramine or nitrites. Aged cheese, bananas, caffeine, chicken livers, MSG, alcohol (especially red wine,) yeast products (including bread), chocolate, red meat, shellfish are common, but the list is extensive and

individual. Try eliminating these first. If that doesn't work, see if you are sensitive to citrus, lentils, nuts, any kind of green beans or peas, vinegar or yogurt.

Stress, strong emotional reactions and fatigue may be triggers, in addition to compounding the symptoms. Weather or altitude changes may contribute to them. There's a hormonal trigger for some women, causing migraines prior to or during menstruation or when using birth control pills or estrogen replacement therapy. There seems to be an association with sluggish liver function from eating too much fatty food or heavy drinking.

How can they be prevented or treated? If you can categorize your migraines as being related to physical stress or emotional upheaval, stress reduction techniques, meditation and biofeedback have been found to be helpful, as have acupuncture and bodywork. Chiropractic or Osteopathic treatment may help if there is a structural problem in the neck. Again, it's very individual and complex issue, and you may need the assistance of a professional conventional or complementary practitioner.

HERBAL THERAPIES:

- To ease pain, David Hoffmann suggests that at the first sign of attack equal parts of Black Willow, Meadowsweet, Passion Flower, Valerian and Wood Betony may be helpful.
- For migraine associated with stress, use equal parts of Hawthorne berries, Lime Flowers, Wood Betony, Skullcap and Crampbark.
- Nervine tonics, such as Oats and Skullcap are appropriate long-term therapy, accompanied by Siberian Ginseng as an adaptogen.
- Massage Lavender oil into the temples at first sign of an attack.
- If the migraine is accompanied by nausea or vomiting, Chamomile, Meadowsweet or Peppermint may help.
- If migraine is associated with hormonal problems, long-term treatment should include herbs to try to balance the hormonal system. Vitex, Black Cohosh, or Wild Yam may be useful.
- European herbalists emphasize the importance of liver support in migraine treatment. Herbs like Burdock, Dandelion root or Milk Thistle would be ideal.

The following delicious Migraine Tea from Ana Nez Heatherly of Gatesville, Texas, appears in the July 1995 Mother Earth News. She prepares a cold infusion of:

6 parts Rosemary leaves 4 parts Peppermint leaves
4 parts Lemon Balm leaves 4 parts Sweet Violet
3 parts Feverfew 1/2 part sweet Violet Flowers

Please also check the entry [2.9, Feverfew and migraine](#); and then you could search the net for the Natural Migraine Treatment FAQ by Catherine Woodgold <an588.freenet.carleton.ca> - archive name: medicine/migraine/natural-cures.

The Medicinal HerbFAQ

3.3 Herbs for vivid dreams

From Colette Gardiner, on mugwort (*Artemisia vulgaris*) as a dream enhancer:

There's quite a bit of info out there about this topic, probably recently discussed on this list as well. I've used it to induce more vivid dreaming for years and have seen strong effects in many people. Some people have been known to wake up in the night cursing loudly and toss the pillow across the room, they were dreaming so vividly. A bundle of it hanging near your head at night works as well as a pillow of the cut and sifted stuff available in stores. It's also useful as an incense or in incense blends before any divinatory work such as tarot, rune reading etc. Just take a small amount of the dried herb and toss it on top of a wood stove or on a small charcoal disc that's been lit (available in magic stores or sometimes in catholic supply stores). Mostly I'd recommend simply getting some and trying it out for yourself. I've heard a lot of stories over the years from students who've used it.

Other herbs for vivid dreams:

Plantain- *Plantago majus* or *P. lanceolata* - tea in evening.

Watercress - Ingested at daybreak to increase dreams that evening.

Peppermint - *Mentha* spp. burned as an incense at sunset and thru the evening for visionary dreams.

From Dennis McClain-Furmanski (dynasor.infi.net):

Calea zacatechichi (Dream Herb) is a shrub from the Chiapas region of Mexico, related to the mint family. It has been used by the Chontal people as a divinatory for many years. Traditional use as a

tea brings about a drowsy dream state, in which answers to questions are revealed and lost objects are located.

Clinical testing in double blind studies have been shown to induce sleep and vivid dreaming, with the subjects reporting profound meaning in the dreams.

Preparation is almost invariably as a tea. However, zacatechichi is intensely bitter and soapy tasting and little can be done to mask the taste (though mixture with the sweetener herb Stevia or preparation by taking Miracle Berry which makes everything taste sweet sound like reasonable suggestions). My experience has been to mix a rounded teaspoon of zacatechichi with an ounce of kava kava and preparing it as normal kava. The berries/seeds seem to have more effect, though the leaf material itself is potent.

Little empirical or pharmacologic data exists so far, one notable study being Lilian Mayagoitia's (1986) "Calea Zacatechichi: Psychopharmacologic Analysis of an Alleged Oneirogenic Plant" in vol. 18 of the Journal of Ethnopharmacology.

Please also see entry [2.10, Kava kava](#).

The Medicinal HerbFAQ

3.4 Herbs and weight loss

From Patricia Harper <harperp.aol.com>:

Many herbs are used for temporary weight loss, including some that you can buy at an herb store. However, there are many herbalists who consider weight loss formulas to be harmful, and will not make them for their clients. Typically, herbal diet pills use herbs with the following properties to cause weight loss:

1. Stimulants: encourage the body to burn more calories.
2. Diuretics: cause the body to excrete water through excess urine.
3. Cathartics: cause evacuation of the bowels, reduce calorie consumption by impeding full digestion.
4. Appetite suppressants: reduce hunger by expanding in the stomach, altering mood, or satisfying taste.

They may also use herbs to increase perspiration, (more "water weight" loss), and kill pain, or balance nerves.

Some formulas are definitely going to be better balanced than others, but in general, we are not talking here about gentle herbs that nourish and support you, as you bring your habits into balance. Herbal weight loss formulas may have drastic physical effects on your body. "Effective" diet pills --herbal or not-- are potent, depleting, and temporary, if effective. They do not cure overweight conditions.

There are herbs which can be used as supplements while you diet, but weight loss involves your whole lifestyle. Why not consider using herbs to change your lifestyle?

Instead of just using dried, capsulated, herbal products, start including *whole* herbs in your life. Eat them everyday, as fresh as possible, (e.g. take walks, check out the vegetable stand, or tend a garden), everyday. Instead of taking a capsule, eat a handful of fresh parsley. Experiment with tasting each of your favorite culinary herbs made up as "diet" tea. Collect dandelion leaves, plantain, mints, lettuce, whatever, and whip it up in your blender as special diet "green drink." Almost no calories in most herbs.

Also, get to know specific weeds and plants in your neighborhood. Learn their names and uses;

look at them. Watch how they grow, Think about their growing condition and responses to it. You can even keep a journal noting everything you learn about each plant. Spring is the perfect time to bring herbs into your lifestyle.

Eating and living with herbs can bring you a lifestyle which may be more conducive to weight loss.

The Medicinal HerbFAQ

3.5 Insomnia

Also see entry [2.1, Valeriana](#).

> I REALLY need some herbs to take for insomnia. My doctor says I am in excellent health, and I am not depressed, but insomnia has been a terrible problem for me since I was a child. Can anyone recommend some herbs to me that either taste good-ok (not valerian--it smells so bad to me :() OR tell me how to make a herbal sleep pillow?

From trowan.ivory.trentu.ca (The Literate Tomboy):

Rub a little lavender oil under your nose and breathe deep as you lie in bed...

From burleigh.tcg.anl.gov (darin)

Organic chemistry textbooks. It was a surefire thing in college.

From dsm2.ix.netcom.com (sherree moore)

Okay, I've been lurking around reading the herbal newsgroup and I JUST have to give my remedy for insomnia. When I can't sleep I make a tea from chamomile (of course), valerian, hops, and a smidge of passion flower. Works every time. Of course, this combination might become a bit too much every single night! Therefore, a hops pillow might help. Make a small pillow and fill it with hops. Really doesn't smell bad at all. Oh yes, the tea is an acquired taste, but honey helps.

From carl.mork.nwcs.org (Carl Mork):

The various mints are good in tea for making you relax. I make a nice mix of peppermint, cat mint and apple mint to brew up the tea. A pillow is simple to make. Use the same mints plus lavender. There are other herbs that are used for sleep, but those are the ones I know from practical

experience.

The mix for tea and pillows should be to your taste. Oh and I suggest honey in the tea.

3.5.1 Insomnia therapeutics

From Henriette:

Insomnia. The first thing to do is to cut out all caffeine. That means coffee, tea, cocoa, cola drinks, guarana, mate, etc.

Do you exercise? You might not be tired if you don't move during the day. 30 minutes daily walking is good, but more is better (up to a limit).

Don't eat too heavily before bedtime.

Do you have problems with depression? SJW (*Hypericum*, St. John's wort) helps with mild to moderate depression, and one of the signs of depression is that you wake up early in the morning and can't go back to sleep. Simple insomnia is another sign. SJW needs to be taken regularly for a few weeks before you notice a difference.

Is your room dark enough? Before you shop for dark dark drapes for your windows you can test by investing in a set of those thick cloth goggles to put over your eyes. You know, the type that makes it easier to sleep when you travel by plane.

If all that is OK here's a herbal blend that has worked nicely for all people I have given it to:

1 part *Hypericum* tincture (fresh flowering tops, 1:2 95 %)

1 part *Eschscholtzia* tincture (fresh herb, 1:2 95 %)

Mix, take 30 drops as needed. Keep the bottle near your bed, or make a tea of the recently dried herbs and keep the tea ready on your bedside table.

Another blend would be

1 part *Hypericum* tincture (fresh flowering tops, 1:2 95 %)

1 part *Avena* tincture (fresh milky seed, 1:2 95 %)

Mix, take 30 drops as needed. This can't be substituted with a tea, as *Avena* milky seed has to be used fresh.

Or you could try some of the herbal suggestions given above. Whatever you do, don't put lavender essential oil (EO) on your upper lip - that smell will keep you awake. If you want to use lavender EO, put it on a tissue and keep that under your pillow. That way, when you get tired of the smell, you can remove the tissue.

The Medicinal HerbFAQ

3.6 Aphrodisiacs

From Peter L. Schuerman <plschuerman.ucdavis.edu>:

Try this:

2 parts safflower (or 1 part saffron)

2 parts hibiscus flower

2 parts rose flower

in tea (1 tsp. per cup) or capsules (1-2 OO caps).

According to Ayurvedic philosophy, the floral structures of plants have their medicinal effects on the reproductive system. This formula is made of three flowers; the first is an aphrodisiac, the second exerts an influence on the sexual chakra and the third exerts an influence on the heart chakra and acts to harmonize the blend.

From Back in Black <skeevers.netcom.com>, to above:

If you find the effect of this mixture too overwhelming (depending on your constitution, it might be) you can also add 1 part myrrh to soften the effect. Without the myrrh, it has quite a punch, with the myrrh, it has a much more diffuse effect, spread throughout the entire body rather than being so focused on the lower two chakras (or at least, those are the effects it had on me).

Personally, I couldn't stomach this mixture as tea -- capsules are preferable -- but it's also not bad in vanilla yogurt, if you don't have capsules.

From Henriette:

Germans use celeriac root as an aphrodisiac. It works because it enhances blood flow to the pelvic area; but any aphrodisiac will work better if both partners know about it.

So here's a recipe for a **Waldorf salad for two**:

1,5 dl grated raw celeriac

1 apple, grated or cut into pieces

1-2 tblspoons walnuts

dressing: 1 dl sourcream, 1/4 teaspoon mustard, herbsalt.

Mix and enjoy.

The Medicinal HerbFAQ

3.7 Herbal Abortives and Birth Control

[common sense](#)

Disclaimer: This is not anything you should try at home without supervision from a knowledgeable herb person.

From Colette Gardiner <coletteg.efn.org>:

Current and reliable information on herbal birth control is rare. In the Western tradition much information on birth control as well as safe birthing techniques was destroyed during the European Witch hunts circa 1450-1700. Having such knowledge was proof positive that you were a witch. Other historical information is often incomplete, with only a local common name, or no exact dosages. Researchers often discard supportive techniques such as fasting or ritual as mere superstition. Current studies tend to be anecdotal rather than strictly lab controlled data. This does not mean they are not of value, but again pertinent info may be missing. Such as was the woman pregnant in the first place? Anecdotal info can give us ideas on where to start and what the possibilities are. They have also shown us that herbal abortives are not themselves without side effects, often severe. All herbal info on abortives should be thoroughly researched before use. Some herbalists feel that herbal abortions are more dangerous than clinical abortions. Abortive herbs are toxic and do have side effects. They are not safer because they are natural. Clinical abortions are certainly more effective. Most importantly an herbal abortion should never be undertaken unless a women is willing to follow up with a clinical abortion if the herbs fail.

EFFECTIVENESS

Varying success rates have been claimed for herbal birth control. Estimates vary from 20%-80%. It is important to remember that most of these rates are based on the incidence of successfully bringing on a delayed period, not in aborting a definite pregnancy. Since many herbs seem to work the best close to the time of the first missed menstrual period, many women have not had a pregnancy test at the time they took herbal abortives. Studies on the success rate of herbal abortives in non-confirmed pregnancies is quite high (70%-80%). Success rates with confirmed pregnancies is substantially lower, 20% or less. Also there's not as much research on herbal

abortives with confirmed pregnancy.

SPECIFICS

Rina Nissim, founder of the Dispensaire des Femmes in Switzerland claims a success rate of 60%-80% in women who believed they were pregnant (non-tested). Their method involved the use of at least two herbs at a time. Generally one emmenagogue (bleeding stimulator) with an oxytocic (uterine contraction stimulator) for no more than six days starting as soon as a woman's period is late. They have found that starting the herbal regimen later than six days overdue drops the success rate to 20%.

In a survey I conducted (appendix A) with a small group of women there appeared to be a high success rate (about 75%). However only one of the women had a positive pregnancy test, so actual success rates were certainly much lower. My experience with women where there has been more complete information, such as positive pregnancy tests and follow up leads me to guess at a realistic success rate of 20% at this time. In a highly quoted New Mexico study, Cotton root bark had a very high success rate, with a fairly low toxicity. However it appears that very few of the women were actually pregnant based on blood tests and screening.

Less info is available on prevention of pregnancy with herbs. In an informal study (appendix B) by Robin Bennett with Wild Carrot Seed used on a semi- regular basis as an implantation preventer she had a 98% success rate with few side effects. There is also a much quoted seven year study involving one hundred women in Alaska that also claimed high success rates for wild carrot seed. But no one seems to have any specifics on it.

SAFETY

In general many herbal abortives are mildly poisonous to potentially fatal in large doses. Almost all women report at least one of the following side effects:

- Increased bleeding
- Dizziness and nausea sometimes extreme enough to cause fear.
- Visual disturbances
- Sweats or chills
- Diarrhea

Less commonly reported side effects:

- Incomplete abortion
- Irregular cycles for 1-3 months

The above can also occur in clinical abortions.

- Kidney irritation
- Breast Lumps (Tansy)

Almost all women reported heavier bleeding and clotting than normal and felt that this was an indication of an aborted pregnancy. While this is indeed a sign of aborted pregnancy it's also common with use of emmenagogues. Common sense would indicate that when using emmenagogues there would be the chance of hemorrhage, but it appears to be a not very common side effect compared to the other effects. Most side effects appear to be of short duration. I do know of one case where a women experienced severe long term endocrine imbalance after using herbal abortives.

SERIOUS SIDE EFFECTS

The most serious side effects seem to occur when women use herbal abortives, remain pregnant and attempt to carry to term. There is a high enough rate of reported instances to call for extreme caution.

- Incomplete or low implantation of the placenta (reported frequently by many practitioners)
- Premature detachment of the placenta before or during birth

Consequences of these side effects can be severe and potentially fatal. Severe hemorrhage can and does occur under these circumstances. In one case a women lost 1/3 of her blood volume before bleeding could be stopped. Treatment consists of total bed rest and staying close to a hospital. The risks to both mother and fetus are extreme.

- A few isolated reports of toxemia possibly related to herbal abortives.

ONE FINAL VERY SUBJECTIVE NOTE

Clinic workers who see many clinical abortions note that women who used herbal abortives on their current pregnancy seem to have darker, thicker blood with more clotting.

USE OF HERBAL ABORTIVES AS A LABOR FACILITATOR

A few of the herbs that are used as herbal abortives maybe safely used in the last trimester of pregnancy under specific conditions to help facilitate healthy labor. While safe if properly used they should not be used unless a problem exists and only with the help of a practitioner.

HERBAL SPECIFICS

There are two main types of herbs used as abortives. Emmenagogues and oxytocins.

EMMENAGOGUES

Emmenagogues stimulate blood circulation to the pelvic area and uterus and help to stimulate menstruation.

- Vitamin C - no buffers or fillers. Dose: 500 mg every hour for 12 hours up to 5 days.
Toxicity: possible kidney irritation, loose bowels.
- Ginger - *Zingiber officinale*, Dose: 1 oz. fresh or dry root to pint of water.
Toxicity: possible light-headedness.
- Pennyroyal - *Mentha pulegium* & *Hedeoma pulegiodes*, Dose: 1/4 cup of herb to 1 quart water once a day for no more than 6 days.
Toxicity: nausea, numbness in hand and legs, liver irritation, kidney and bladder irritation, diarrhea, The essential oil is fatal internally. Contraindications: kidney conditions.
- Angelica root - *Angelica archangelica*, Dosage: 1/4 cup herb to 1 quart water as tea.
Tincture - 10-20 drops every two hours. Dried root less toxic than fresh.
Toxicity: irritant to kidney and liver, not studied as much as pennyroyal. Contraindicated in diabetes as it raises blood sugar levels.
- Mugwort Leaf - *Artemisia vulgaris*, Dosage: 3 teaspoon per cup tea, 3 cups per day, for no more than six days.
Toxicity: higher doses can cause liver damage and convulsions. Nausea. Contraindications: Uterine inflammation or recent pelvic infection.
- Black Cohosh Root - *Cimicifuga racemosa*, Dosage: 3 teaspoons per cup, 4 times a day.
Tincture 20 drops every 6 hours.
Toxicity: Diarrhea, dizziness, headache, decreased pulse rate, tremors, fatalities can occur in large enough doses.
- Tansy - *Tanacetum vulgare*. Note: Do not confuse with tansy ragwort, *Senecio jacobaea*, which is a poisonous plant known to cause death in cattle thru liver failure. Dosage: Tea, 4-8 teaspoons per qt. sipped throughout day. 10 drops tincture in warm water every two hours til bleeding commences, for no more than 5 days.
Toxicity: breast lumps, possible hemorrhage, liver irritant. Essential oil is fatal - do not ingest.

OXYTOCIC HERBS

They imitate oxytocin in the body to stimulate uterine contractions and release prostaglandin hormones. All oxytocic herbs are toxic to some degree. Women can experience very painful contractions. They are generally hard on the liver. Women with a history of liver disease such as hepatitis may wish to avoid them all together.

- Blue Cohosh root - *Caulophyllum thalictroides*, Dosage: Tea - 3 teaspoons herb per cup, 3 cups per day, tincture - 20 drops every 4 hours, for six days or til bleeding commences.
Toxicity: nausea, vomiting, headaches, convulsions in large doses, kidney and liver irritant, Contraindications: low blood pressure. Some of the constituents of Cohosh are more soluble as tincture.
- Angelica - see emmenagogues.
- Cotton root bark - *Gossypium herbacetum*, Dosage: 12 teaspoons per quart, 1/2 - 1 quart thru day. Tincture 10 drops every few hours til bleeding commences, for no more than 6 days.
Toxicity : seemingly low based on the New Mexico study. Cotton is a heavily sprayed crop with pesticides that are only used on non food crops. Those pesticides can cause liver

irritation, and other problems. Organic cotton root bark may be difficult to find.

OTHER HERBS USED

- Wild Carrot Seed - *Daucus carota*, used as a preventative. Dosage: 1 teaspoon a day chewed and washed down with fluid. Believed to work as an implantation preventor by making the uterine lining unsuitable. See appendix B.
Toxicity: So far appears to be low toxicity, long term effects unknown. Identification must be absolute as many wild members of this family look similar and can be fatal.
- Trillium root - *Trillium* spp. Dosage: tincture 30 drops 3-4 times a day. Tea 3 teaspoons per cup, 1 quart per day. Trillium root is used by midwives to facilitate softening of the cervix and is often used as a labor adjunct in the case of rigid os or as a preparatory agent before trying to induce labor with stronger herbs. It occasionally will start labor on it's own. As an abortive there is not a lot of current use info on effectiveness and side effects. Trillium root should only be harvested from garden grown plants as it is rare in the wild due to habitat destruction by logging and urban growth.
- Parsley - *Petroselinum* spp. Used as a fresh plant vaginal insert for 24 hours. Personally I have heard of no cases of even bringing on a delayed period with this method.
Toxicity: low.

Misc. Herbs listed as abortives: Agave, Osha, Mistletoe, Rue, Peyote, Sweet flag, Papaya seed, Feverfew, Motherwort, Wood Sorrel, Damiana.

The above is by no means an exhaustive list, many mild emmenagogues are listed as abortives in literature both scientific and folkloric: Marjoram, Oregano, Beet, Celery, Papaya fruit, Peppermint, Valerian, etc. While they may help facilitate onset of a slow period, such as the type where there's cramping and pelvic heaviness but bleeding has not yet commenced, it's doubtful they would act as abortives.

Dosages mentioned above may be on the conservative side in many cases. However, since the serious side effects show up at higher doses it's best to be cautious. I've seen better results with tea than with tincture and with mixing 2 -3 herbs together in a blend. Herbal abortives effects may be enhanced by a day of fasting, working with ritual, and massage of the uterine acupuncture points along the ankles several times a day for at least ten minutes at a time. Again the success rate is very low for actual pregnancies.

Ideally if a woman wished to use herbal abortives I would recommend finding a clinic that does early pregnancy testing of the type that can detect pregnancy within a few days of conception, preferably one that can see women on a walk in basis so you don't have to wait for an appointment. Then if you are not pregnant you can use a mild emmenagogue such as marjoram, without stressing your body. Since early testing is not 100% accurate and if you are fairly sure you are pregnant, you may wish to use one of the less toxic abortives such as Vitamin C. Since most of the abortives are so hard on the body they should only be used in cases of confirmed pregnancy. Why put your liver thru more stress than it already gets in today's world?

APPENDIX A

SURVEY ON HERBAL BIRTH CONTROL AND ABORTIVES

Colette Gardiner

Of the 10 women in the study:

None had used herbs preventatively as contraception

6 had previously been pregnant

8 could tell very accurately when they ovulated

8 of the women had used herbal abortives

1 women had delayed ovulation time with herbs use

1 women was a practitioner who counseled about herbal abortives

6 of the women had side effects

6 of the 8 women who used herbal abortives brought on a delayed period with herbs. Only one of these women had a confirmed pregnancy, but all the women felt they were pregnant. Two of these women were a few weeks late. A few of these women had unsuccessful herbal abortive attempts at other times.

Time Frame Abortives Used:

Brought on period with herbs at:

Three weeks overdue - 1 women

Two weeks overdue - 1 women

When period was due - 4 women

Many of the women reported friends who used herbal abortives successfully, but I did not use those accounts in my survey. In general the second hand reports were very similar to the survey results.

A practitioner reported that several women in her area were drinking sassafras tea as a contraceptive. She didn't give details on safety or effectiveness.

One women reported that either Vitamin A or Goldenseal seemed to delay ovulation. I've heard no other instances of this.

My next project is to do a larger survey on herbal abortives with women who have had a positive early pregnancy test. For info or to participate contact me at:

coletteg.efn.org

or

P.O Box 10914

Eugene,Or.

APPENDIX B

Wild Carrot Seed as an Herbal Contraceptive

Survey conducted by Robin Bennett

In Robin's info she stresses that it was a small study, and that she did not use scientific, double blind methods etc.

In her survey there were three dosage regimes

- 1) Every day
- 2) Daily for 7 -8 days surrounding ovulation
- 3) For 7 days following intercourse

The dosage for all women was one teaspoon daily chewed and washed down with fluids. Half of the women in the study used it as their only form of birth control. The study lasted for one year. Out of the ten women in the study: one became pregnant and had a clinical abortion. She became pregnant when she used the seeds for only three days around ovulation instead of the recommended 7-8. She had a clinical abortion. Two other women suspected they were pregnant and used herbal emmenagogues to bring on their period. One of these women was using the seeds daily. The other woman was using them for 7-8 days surrounding ovulation. One of the women discontinued seed use in order to become pregnant and did. There were some mild side effects such as gas and slightly earlier periods. Some women felt that anything less than the full dose actually enhanced fertility. None of the women reported any symptoms of uterine irritation and subsequent exams showed no signs of it. In her handout Robin mentions some lab studies using WCS as an implantation preventor in mice, but did not give details.

Her address:

Robin Bennett
R.R. 2 - Box 301
Garrison, N.Y.
U.S.A. 10524

From allissa.foxcomm.net (Allissa Gaul): the lab studies are:

- Comparative Physiology and Ecology, 9:70-74, "Abortifacient effect of carrotseed extract and its reversal by progesterone in albino rats", by Kaliwal, BB, first author.
 - Journal of Advanced Zoology 7:36-41, "The estrogenic efficacy of carrot seeds" by Kant, A., et al.
-

3.7.1 Herbal Abortives and Common Sense

Somebody wrote:

>> A friend of mine does not use birth control. Is there an natural form for the abortion process?

Somebody else tried to be helpful:

- > Here is a formula that is intended to induce a miscarriage:
- > 20 drops blue cohosh
- > 20 drops black cohosh

- > 20 drops pennyroyal
- > Measure the tinctures into a cup of warm water ...

And finally some Common Sense; Jonathan Treasure <jonno.teleport.com> replied to above:

It is debatable whether using herbal medicine to cause uterine rejection of a conceptus is any more "natural" than an a D&C. Herbs can be potent and potentially dangerous - just because they grew out of the ground doesn't confer the status "natural" on anything they may be used for especially when the only alternative is orthodox procedural medicine. However the answer is YES, herbal abortion is possible, in certain circumstances.

It would however be quite insane to take a recommendation from an internet list and simply believe that is the end of it...we are not talking about a common cold here. The reply giving cohosh/pennyroyal recipes was just plain daft - how late is she, how old is she, what is her general health, nutritional status, psychological state, emotional strength, domestic situation, support network etc etc etc etc etc. All these questions come before some generic formula can be given. Then the formula given was not related to strength of tincture, dried or fresh plant used, etc. The dose pattern given was potentially excessive. It might harm or her or it may not work at all. Would you then write to this list again? Grow up! I would urge your friend to consult someone who is experienced in the herbal management of ob/gyn if there is a real need (e.g. legality/finance) to go this route.

The Medicinal HerbFAQ

3.8 Herbs and female infertility

By Roy Upton (herbal.got.net).

There are a number of options to try for <this person>. I have worked with infertility for many years with a decent degree of success. As I do not know what is specifically the cause of <this person's> infertility; i.e. inability to conceive, incompatibility with sperm, low level infection, inability to maintain the pregnancy due to insufficient progesterone levels, etc. I will provide some general rules of thumb. Most of what I will outline is based on traditional Chinese medicine.

Gynecological imbalances are considered to be associated with poor pelvic circulation which prevents the gynecological system from being as healthy as it can be. Most botanical formulas are geared to promoting pelvic circulation. The most commonly used are formulas that include at least four herbs; Dang Gui (*Angelica sinensis*), Ligusticum, Rehmannia, and White Peony. This is a classic Chinese formula known as Dang Gui Four and can be found in any Chinatown and some health food stores. There are many variations of this formula. Another is called Women's Precious, or Eight Precious Pills. Either would be a good general formula to try. They should not be used during bleeding, menses, and generally not during pregnancy.

Another botanical to use in conjunction with any Dang Gui-based formula is Chaste berry (*Vitex agnus-castus*). *Vitex* is a progesterone agonist which can help to minimize the risk of miscarriage. In addition, it can also stimulate ovulation. It works specifically by enhancing pituitary function, thus improving ovarian function. A few other herbs that I add either to the Dang Gui formula or to the Chaste Berry are False unicorn, Partridge Berry and Cramp Bark. I sometimes recommend a thyroid glandular as well, and insure the woman is not anemic or borderline anemic.

The basic protocol is to utilize the Dang Gui Four formula in conjunction with Chaste Berry throughout the month except during menses. We could get fancy and give one formula during the estrogenic phase of the cycle, and the Chaste Berry for the progesteronic phase, but this is seldom necessary. I use custom-blended teas or ready made commercial formulas. My suggestion would be to go to a health food store, TCM practitioner or naturopathic physician and ask which are the best Dang Gui/Chaste Berry products available. You have to be diligent in getting a decent product. There are many Dang Gui products consisting of only Dang Gui, or which are not put together that well. There is also a lot of bogus chaste berry floating around on the market, especially that available from Chinatown. One of the more popular capsuled products is 85%

millet, and is largely ineffective.

Lastly, it is important to encourage those trying to conceive to look at conception just as you would look at a garden. Before you ever plant a seed you cultivate the soil. In this case, you do not want to attempt conception for at least three cycles, ideally six cycles. Both the man and women should be brought into this process by recommending the man use herbs that increase sperm count and motility (Ashwagandha, Astragalus, Kidney tonics, avoiding excessive sexual activity and hot tubs, etc.). The woman should also be exercising regularly, focusing on improving abdominal tonicity. Kegels are excellent exercises to try. This is to insure adequate tonicity of tissue internally so implantation can hold.

Focusing on nutritional well-being is very important for obvious reason, even if the women is not anemic. This basic protocol has worked in dozens of women that I have worked with, with conception taking place anywhere from 3 weeks to four months. I do not know of anyone specifically that it has not worked for, but this may be due to the fact that if it didn't work they may not have come back to me, or went on to try something else. I have had several women who continued to use the Dang Gui formula even after conception, one for up to six months because she forgot that I told her not to use it during pregnancy. The reason it is generally contraindicated is because it increases blood flow, something you do not want to do in pregnancy. However, once the system is healthy and conception takes place, nothing short of a strong abortive is going to dislodge the fetus. She had a normal pregnancy, and the baby was apparently healthy and happy.

I hope this helps. Best of luck.

The Medicinal HerbFAQ

3.9 Herbs, ADD, and replacing Ritalin

>Does anyone know of any viable substitutes for Ritalin for ADD? I have heard of a substance called Pycnogenol. Are there any other substitutes for taking Ritalin? How long does a person need to take Pycnogenol in order for it to take effect?

From herbal.got.net (Roy Upton):

I have seen at least 70 children weaned of Ritalin. I usually recommend weaning off of Ritalin for a 2-3 week period, while administering the herbs. Usually, the program consists of dietary modification, exercise, and nutritional and herbal supplementation. Though treatment is similar, differentiate between ADD and ADHD. ADD might be a direct result of under/poor nourishment. The brain is the most energy intensive organ of the body. If the body is deprived of energy, the brain is first to suffer. In ADHD there is often a rapid heart beat that may have varying underlying causes such as specific allergies.

DIETARY

- Elimination of most simple sugars including fruit juices, foods with colors and preservatives. Concentrate on a whole foods diet.
- Magnesium supplementation. Dosage based on weight, age of child.
- I have used a combination of the following herbs with significant success (according to parents and teachers): Chinese zizyphus, chamomile, lemon balm, catnip, hawthorn berry, and gotu kola flavored with cinnamon, anise, and a touch of cloves. Usually this is prepared as a glycerite extract (approx. 1:3-1:5 concentration). 20 drops 2-3 daily. I alternate this with Hawthorn berry syrup, 1 tsp 2 x daily.
- Exercise is a must for ADHD.

In Germany, Chamomile tea, and small doses of valerian root are utilized.

I think it is important to note that ADD and ADHD is one of the most frequently diagnosed conditions in children, and that is rising dramatically, much to the concern of many practitioners who feel that the diagnosis is handed out much too casually. I believe the makers of Ritalin have done an excellent job of marketing. There have been a series of articles (and a few books) I have seen over the past number of years on the need to provide a "proper diagnosis" of these children

rather than labeling them as "bad". Teachers have become the prime target for providing the initial grounds for diagnosis. Oftentimes, a child will be diagnosed in kindergarten or early grade school and not adequately reassessed for a number of years. The inherent problem in both of these is obvious. I also do not believe the diagnosis should be made until all lifestyle protocols (including supplementation, diet, exercise, etc.) have been attempted and failed.

I am of the firm belief, from many of the parents that I have seen, that it is often the parents that primarily require the help, the children secondarily. This is especially true of ADHD. Relative to the energy levels of the majority of exhausted, "burned-out at the end of the work day" parents, the majority of children are "hyperactive". We try to force them to be little adults before they have developed the coping mechanisms or social skills we design to stifle their natural impulses. We expect them to sit still when they have boundless physical energy. We ask (tell) them to pay attention to educational materials that mean little to them. This is an indictment of our education system as well.

Also, the typical American child is raised on nutritionless foods, challenged with numerous stresses, and spends an average of six hours a day in front of the television, when they should be expending the physical energy. While I believe that medicating, especially with amphetamines, is beneficial for some, by-and-large, it should be a last resort.

I hope this is of some help.

The Medicinal HerbFAQ

3.10 Herbs for sunburn

From Howie Brounstein <howieb.TELEPORT.COM>:

I have found plant tannins to be the best sunburn treatment. Tannins are found in most plants, and are particularly high in many plants. They bind with alkaloids and proteins. This is helpful in the case of burnt skin --- broken proteins. The tannins bind with the broken skin proteins to form a layer of tannoproteins, or was that proteotannins (it's a little late). This layer is protective and soothing.

I generally throw some Manzanita leaves into water and boil. If you're preparing a wash for sunburn and are primarily concerned with extracting tannins, you can just boil it, no matter what the herb. You can wash the sunburn with the tea when it cools.

Some astringents with tannins (to name a few):

- Manzanita
- Uva ursi (kinnikkinik)
- *Polygonum* roots (bistort)
- *Heuchera* (alum root)
- Currant and Gooseberry Bark (*Ribes*)
- *Geum*
- *Potentilla*
- *Rosa's* Bark and roots
- *Rubus* (blackberry root)
- *Ceanothus* bark and root
- *Cornus* Dogwood Bark
- *Chimaphila* Prince's Pine pipsissewa
- *Pyrola*
- Black Tea

These contain salicylates which may have some topical analgesic effects:

- Willow Bark
 - Oak Bark
 - Poplar Bark
 - Meadowsweet (*Filipendula*)
-

From Satin <satin.TOPAZ.USAF.AF.MIL>:

I use an aloe and comfrey lotion on sunburn. I am a strawberry blonde with my red-headed Mom's complexion - I don't tan. It's either burn or nothing. So I wear sunscreen and keep the aloe/comfrey lotion on hand.

From Craig Roberts <croberts.MAGNUS.ACS.OHIO-STATE.EDU>:

For some reason, aloe vera hasn't proven to be the miracle for my skin that it is for some people's.

One of the best burn treatments I know of is lavender essential oil, applied neat. The aromatherapy literature is full of references and documentation of its use in this connection and the impressive results. Since lavender e.o. is quite benign and doesn't sting, this would be quite good for a child. In my experience, the burning and redness begin to subside quite soon after application. In contrast, the aloe takes much longer and at least initially the relief seems to be due more to the cooling effect of its evaporation.

Another therapy that has been used for burns, as well as infected wounds, for thousands of years is human urine, or its derivative, urea. There are a number of articles on this and other medicinal uses of human urine and its derivatives in the contemporary establishment medical literature, such as *The Lancet* and *JAMA*, for those who find this reassuring. (As usual, a simple, inexpensive remedy doesn't receive the press or research money that patentable, synthetic drugs do.) I haven't

tried this myself on burns yet, but apparently one applies urine or urea-soaked compresses to the affected area, keeping them wet with fresh applications of urine. Though urea is said to sting a bit, straight urine supposedly does not.

From Mary Jo Gilsdorf <viomist.CASTLE.NET>:

For burns, I find oatmeal poultices and cold tea bags works best to take out the sting and stop the rash like effect. Also know some who swear by taking two to three regular aspirins.

From JunieWrite.aol.com:

Mary Jo writes that she knows some people who swear by two or three aspirin: may I point out that taking aspirin even in small quantities (less than 300mg) may be positively dangerous to hypertensive BP sufferers. OTOH, aspirin is proving to be invaluable in the prevention of coronary occlusion and CVA in normotensives; especially in diabetics and those suffering from lipid dysfunction.

All burns are less painful and less damaging if the 'heat' is countered asap, preferably by immersing the affected part in cold water and keeping it there until help arrives.

N.B. It may be supposed that Heatstroke victims (who are often also suffering from sunburn) would also respond to cold water; but that is not so; heatstroke victims should be placed in tepid water as a first-aid measure to reduce body-core temp until medical help arrives.

BTW, severe sunburn occurs to people with my skin type even when the sky is overcast as I discovered after falling asleep on a Moroccan beach (January) on a very overcast day. Standing under a cold shower made me yelp and shriek like a banshee; but later, the only 'peeling' was to nape of neck and backs of knees.

The Medicinal HerbFAQ

3.11 The gall bladder flush

From: James Mally, N.D. <jmally.usa.net>:

I am suspicious of gallstones that dissolve or that liquefy when passing. I have done several gall bladder flushes myself using a formula from a book titled "Encyclopedia of Digestive Disorders" by ? Roberts, of Roberts formula fame. The flush involved taking divided doses of olive oil and lemon juice every fifteen minutes over a two hour period to stimulate the gall bladder to contract and release stones. The effects were very dramatic - one time causing drastic elimination out both ends simultaneously. It also made me lose my taste for olive oil for many years.

I also worked as a massage therapist in a clinic where a similar flush was used for detox and cleansing. The "stones" people would pass needed to be kept in the freezer or they would melt. I then read in a book the suggestion that these "stones" were a product of saponification, the olive oil mixing with the alkaline bile salts creating a soap (similar to mixing lye and fat).

At naturopathic college I obtained a real gallstone from the gall bladder of the cadaver we worked on in anatomy lab. It was as hard as a rock and it would not dissolve in olive oil and lemon juice, even after several months. I didn't try dissolving it in coke or ortho-phosphoric acid.

I believe it's possible that a gall bladder flush may cause stones to be eliminated, but these stones will sink to the bottom of the toilet. The "stones" that float and that are easily squashed are most likely soap. I have heard of people passing hundreds of such "stones" which would imply that they must have a huge gall bladder.

I still think there may be some benefit in the flush as it will thin the bile by removing some of the bile salts so they won't be recycled.

Several areas for conjecture: I wonder if such a loss of bile salts would cause any mineral deficiencies? Also has anyone done any blood tests for direct and indirect bilirubin and/or any lipid panels before and after a gall bladder flush? How about X-ray or diagnostic ultrasound of the gall bladder before and after?

Maybe you could get harder "gallstones" to pass by doing a flush using a more saturated oil such as coconut oil. :) Do not try this at home.

From: Sara Klein Ridgley, PhD SaraKlein.aol.com

I tend to agree with you somewhat on the nature of the soluble stones. However, when I did the cleanse both for myself and with clients, what I found was both kinds were there. In several cases where the people were scheduled for gallbladder surgery and we did the cleanse beforehand, there was no sign of the stones upon ultrasound scan. One woman, who was 86 at the time (11 years ago), collected the stones (that were rock hard) and put them in a jar, and took them to her physician. She announced that "this doctor from America (I was visiting another country when this happened...) took my stones out". The doctor first thought that she was nuts, but when she showed him the jar, he went white in the face. Then he ordered another ultrasound and found the gallstones that were there the week before were gone. This woman is still alive and kicking happily and in good health!

Regarding your second, very valid question regarding mineral depletion following the cleanse, I have found that it CAN be the case, but not always. I have noticed, for example, that many, many people who undergo gallbladder removal surgically, become depressed shortly thereafter. I also have thoughts and "speculations" regarding the energy/spiritual factors behind gallbladder problems, but that's another story..

I have used another flush, which is very simple, very safe, yet very dramatic, and even old people with various ailments can do it safely. However, I always like to observe, assist and take care that nothing strange goes on (My control issues? maybe, or just caution...). This one involves 5 days of preparation with eliminating all fat from the diet, and it includes epsom salts, olive oil and freshly squeezed grapefruit juice. I usually do a kidney cleanse prior to the liver/gallbladder flush, which dramatically improves the body's ability to handle the flush.

From: Michael Moore <hrbmoore.primenet.com>

In the early 1980s, after recommending and teaching Robert's protocol, a PhD physiologist **STRONGLY** suggested that these "stones" were probably artifacts of the therapy. The next time someone passed some, I took them in a cooler to a local Santa Fe medical lab I had a working relationship with. They showed only traces of chenicholic and cholic bile salts, and had no discernable cholesterol content. Their educated guess was that they were saponified fatty acids...probably linoleic or oleic acid salts. They were **DEFINITELY** not "gallstones". I have not recommended this grim regimen since.

One of the great scams amongst 19th century medicine shows was this **HUGE** capsule, made out of a colored and sealed gelatin capsule. It cost \$1, and was **GUARANTEED** to pass a tapeworm. Indeed, everyone who took one raved about this long "worm" they passed.

The capsule contained a long coiled spiral of a thin strand of gutta percha (crude rubber), dusted in Lycopodium. This was the "worm".

Robert's protocol, similarly, seems to result in the consistent passing of "stones" consisting of saponified olive oil, acted on as well as possible by the stressed digestive apparatus.

That doesn't mean that the shocked pancreas and gall bladder don't, on occasion, vomit out a small cholesterol stone. But, as anyone who has worked with cholelithiasis will vouch, this is risky stuff,

since an obstruction by a REAL stone of the biliary duct or common duct from the gall bladder spasms may be just as likely. Most gallstones exist WITHOUT symptoms. Most obstructions require surgery.

I find the tapeworm "pill" a safer phenomena-inducing placebo.

The Medicinal HerbFAQ

3.12 Herbs for cough

By Barbara Heller (BHpurple.aol.com) and Carolyn Mohney (Ccmoherb.aol.com)

Coughs are one of the main signs of a respiratory tract disease and also a very common symptom associated with a variety of physical problems. For example, a cough may be the result of an infection, or a defensive response to inhaled irritants like cigarette smoke, or an allergy symptom. Coughs may also signify a more serious illness like chest tumors or lung congestion from heart insufficiency. Chronic coughs, like any chronic symptom, should be evaluated by a healthcare professional.

(For an in-depth discussion of the various types of coughs, see Treatment of Coughs with Herbal Remedies at Healthy Net; <http://www.healthy.net/>)

In this article we will discuss the herbal treatment of "ordinary, common" coughs. Coughing, itself, may be beneficial since it helps clear the airways for us to breathe better. We generally treat the cough symptoms when the cough is unproductive or it becomes irritating to the throat or chest. We are partial to herbal treatments which are easily available and have few cautions associated with them.

Herbal treatment will include teas and tinctures, steams, and cough drops and syrups. The latter have more direct contact with the throat and are locally soothing. Some are store-bought; others can be made at home from garden or wildcrafted plants.

Common-sense aids for coughs include reducing ones exposure to irritants like smoke, drinking more fluids and increasing moisture throughout the household. Individual **steam inhalation** can be very helpful too:

- Fill a basin with hot water and a handful of fresh or dried herbs (or 3 drops of an appropriate essential oil). "Tent" a towel over your head and the basin so you can carefully breathe in the healing warmth and aroma. Suggested herbs include sage, eucalyptus, peppermint, or hyssop.

Some of the medicinal properties we look for in cough remedies include the following: anti-tussives, which prevent coughing; suppressants, which limit the coughing reflex; expectorants, which help remove excess mucous from the respiratory system; and demulcents, which heal inflamed tissue. Herbal antihistamines are helpful in the treatment of postnasal-drip coughs due to

allergies. Immunostimulants and antibiotics may be used to build up the system and fight infection.

Echinacea (*angustifolia* or *purpurea*), primarily in tincture form, is highly recommended at the first sign of a cold, flu, or cough. Considered "the herbalists herb" it receives high praises as an immunostimulant and antibiotic. Revered by Native Americans, it is easy to grow in the garden where its common name is the purple coneflower. (Note: wild echinacea is being overharvested; consideration to its source is important.)

Mullein (*Verbascum thapsus*) is my specific favorite for coughs. Dr Weil, in *Natural Health, Natural Medicine*, recommends tincture of mullein to relieve chest congestion and dry, bronchial coughs. He also states that the plant has no known toxicity. So it is a remedy I feel confident using with my family. Whenever my adolescent daughter gets a cold or flu, it seems to settle in her chest as a cough. This year we have treated the coughs with mullein tincture and the symptoms diminished quickly. Mullein is a beautiful biennial plant that grows wild in the Eastern US. In present-day herbal medicine its primary form is as a tincture. Historically, Native Americans smoked dried mullein and coltsfoot cigarettes as a remedy for asthma and bronchitis. If used as a tea, it should be well-strained because the small hairs of this fuzzy plant can be irritating.

Coltsfoot (*Tussilago farfara*), whose botanical name *Tussilago* means "cough dispeller", is not surprisingly another very popular cough remedy. A nice image of the flower is evoked by Grieve in her statement that it was painted on the doorpost of the apothecarie's shop. This is the first blooming wildflower in our area of upstate NY; it flowers before its leaves appear. The flowers and leaves are used medicinally for their demulcent and expectorant properties. Coltsfoot has traditionally been used to treat coughs, whooping cough, asthma, excess mucous, bronchitis, and laryngitis. Because of its low-level of pyrrolizidine alkaloids (the same controversial substance found in comfrey), coltsfoot is recommended for only short-term use. Use as a tea or a tincture.

Herbalist David Hoffmann (in his book *The Complete Illustrated Holistic Herbal*) recommends a **cough tea** made of equal parts of mullein, coltsfoot, and licorice:

- An infusion of 1 tablespoon of the mixed herbs is steeped in one cup of water. Sip 3 cups of this brew throughout the day.

Licorice (*Glycyrrhiza glabra*) and marshmallow (*Althea officinalis*) are included in cough remedy recipes for their demulcent qualities. They are soothing herbs that reduce inflammation and add flavor. In addition, licorice itself may have an anti-tussive effect similar to codeine for cough suppression, without the side-effects of codeine. A reminder here to be aware of the cautions of the various herbs added to a mix - in this case, licorice may have its own side-effects. Specifically, it is not recommended for continued use by people with high blood pressure.

Thyme (*Thymus vulgaris*), a very common culinary herb also has medicinal properties qualifying it as a wonderful cough remedy. Thymol, thyme's volatile oil with antiseptic, antibiotic, and expectorant properties, is used in commercial cough syrups. At home, one can benefit from these properties by drinking a hot tea of thyme or a mixture of thyme and plantain; or by drinking a small amount of water with a few drops of thyme tincture. Do not use thyme oil as a home remedy. Even a few teaspoonfuls can be toxic. In Germany, thyme is used to treat coughs, whooping cough, and emphysema.

"German medical herbalist Rudolph Fritz Weiss, M.D. writes: "Thyme is to the trachea (windpipe) and the bronchia what peppermint is to the stomach and the intestines."" (Quoted in M Castleman, *The Healing Herbs*).

Elecampane (*Inula helenium*) is also considered an important resource as an expectorant and anti-tussive. It can be taken on a long-term basis and is helpful for healing the irritating bronchial cough as well as for asthma. Elecampane is a wonderful garden plant of tall stature that bears bright yellow, sunflower-like flowers (one of its "nicknames" is wild sunflower); it can also be harvested wild. A tea or tincture is made from the dried root gathered in the fall.

Most contemporary herbalists recommend horehound (*Marrubium vulgare*) and hyssop (*Hyssopus officinalis*) for treating minor respiratory problems - coughs, colds, and bronchitis. In addition to horehound's expectorant and demulcent qualities, as an antispasmodic it helps to relax the coughing spasms so common with bronchitis. The added sweetness of horehound candy/coughdrops that are available commercially make the very bitter herb more accessible. Or

one can obtain horehound's healing qualities with a tea, tincture, or syrup. Hyssop is similar in chemical makeup and function to horehound but is much less bitter. Both of these herbs mix well with peppermint. Tea formulas for colds might also combine them with yarrow and elder.

Some other herbs that can be helpful in treating coughs are: wild cherry bark, violets, osha, bee balm, slippery elm, nasturtium, red clover and plantain.

Wild cherry bark (*Prunus serotina*) continues to be a favorite ingredient in cough and cold remedies, primarily due to its sedative effect on the respiratory system. Susun Weed suggests a homemade violet flower syrup for cough treatment which turns a beautiful lavender shade but is a very labor-intensive remedy to make. Bee balm was another Native American remedy for coughs and headcolds, drunk as a tea three times a day. The Peruvian Indians utilized the natural antibiotic qualities of nasturtium leaves to treat coughs. The leaves were eaten fresh daily or drunk as a tea. And last, Native Americans also used slippery elm bark as a tea, gargle, or by chewing on small pieces of the bark to soothe the annoying symptoms of a cough.

Red clover (*Trifolium pratense*) and plantain (*Plantago major* and *lanceolata*) are two very common wildplants in the area we live and write, the Northeastern US. Red clover is an expectorant and anti-spasmodic especially good for children (over the age of 2) with whooping cough. A tea of the dried flower tops is the most convenient; a tincture may also be used. The expectorant and demulcent qualities of plantain are often used in teas for bronchitis and whooping cough.

One cough syrup you can make at home is **Kathy Kevilles Homemade Honey Cough Syrup:**

- 1 tablespoon licorice root
- 1 tablespoon marshmallow root
- 1 tablespoon plantain leaf
- 1 teaspoon thyme leaf
- 1 pint water
- 4 tablespoons honey
- 4 ounces glycerin
- 1/8 teaspoon anise essential oil (optional)

Prepare a triple-strength tea by simmering the herbs in water for 10 minutes, then steeping for 20 minutes. Strain the tea, then stir in honey and glycerin while the tea is still warm. Add optional essential oil. Take 1 tablespoon at a time. Stored in a cool place, this syrup will keep for 2 weeks. In the refrigerator, it will keep for several months.

This recipe is suitable for children, but not for infants, who should not have honey.

The Medicinal HerbFAQ

3.13 Herbs for constipation

Barbara Heller - BHpurple.aol.com

WHAT IS CONSTIPATION

Constipation, the "difficult, incomplete, or infrequent evacuation of dry hardened feces from the bowels" (The American Heritage Dictionary) can be an occasional, acute, or chronic problem. It can be caused by many factors including lack of fluids, poor diet, sedentary lifestyle, emotional state, or as a side-effect of specific medications. Be aware of the constipating effect of other drugs or supplements you may be taking, like iron tablets, opiates, antidepressants, and antihistamines. Constipation is almost always a nuisance; it can also be a sign of a more serious condition. Chronic constipation should be evaluated in conjunction with a healthcare professional.

NATURAL REMEDIES TO TREAT CONSTIPATION

Laxatives, even herbal laxatives, should be used with caution. Other natural remedies should be tried first. The gentlest remedies for constipation include increased movement and exercise, certain yoga postures, increase of fluid intake, and dietary changes including increased fiber and fruit. Acidophilus liquid or powder relieves chronic constipation (says herbalist Susun Weed in her Wise Woman Ways for the Menopausal Years). And prune juice may be the most effective and gentlest remedy for constipation.

Dr. James Duke, a scientist who worked for the USDA, recommended in his typical iconoclastic fashion, that Dan Rather ask the commissioner of the Food and Drug Administration (FDA) if he considered prune juice a safe and effective laxative. "If he answered no, I suggested that Rather request that Dr. Kessler (the commissioner) drink some and experience the results for himself. If he answered yes, I suggested that Rather ask why FDA labeling regulations prohibit prune juice marketers from stating that prune juice is a safe, effective, gentle laxative." "...(It) is probably the cheapest, least unpleasant laxative now available." (The Green Pharmacy, p140)

Apple-pear juice is also highly recommended; and stewed fruits like prunes, figs, or dates especially when mixed in licorice tea makes a tasty laxative snack

SOME OTHER OPTIONS

Not a usual topic of discussion, at least here in middle-class America, is the position in which one attempts a bowel movement. Squatting can really help alleviate mild constipation - but may be

awkward on traditional toilets. Some families find that using a small footstool to raise and open the legs helps to facilitate an easier evacuation. Massaging the abdomen with essential oils with laxative properties (in a carrier oil base) like chamomile, marjoram, or peppermint can also be helpful.

HERBAL LAXATIVES

There are three classes of herbal laxatives - bulk, mild (but not bulk) and purgative.

Whichever category you use, remember that it takes time for laxatives to work. The bulk herbs may need 12 to 24 hours to encourage a bowel movement, and irritating herbs somewhat less time, perhaps 6 to 12 hours. So be patient, and do not take another dose prematurely.

BULK LAXATIVES

Bulk laxatives are the gentlest for occasional constipation. Flaxseed (also known as linseed), psyllium, and fenugreek are three well-known herbal bulk laxatives. In *The Family Herbal*, the authors recommend flaxseed as a "laxative without side effects". You can take one tablespoon of whole seeds two to three times a day, followed by two cups of liquid. To help bulk laxatives do their job properly, one must drink a lot of water, otherwise gastrointestinal obstructions can occur.

Psyllium, another bulk laxative, is more well-known to most consumers as the main ingredient in Metamucil. A combination of psyllium seeds and a large glass of water can help lubricate the bowels and ease the passage of dry stools. In addition, this seed may also help cut cholesterol. It is quite popular in Germany to take 3 to 10 tablespoons a day for chronic constipation. The seeds swell; they also need plenty of water to motivate their transit through the digestive tract. Caution - asthmatics shouldn't take this herb; if you generally have allergies, take only with caution. ("There have been several reports of allergic reactions to psyllium, including a few serious asthma attacks from inhaled seed dust." - reported by James Duke in *The Green Pharmacy*)

MILD (NOT BULK) HERBAL LAXATIVES

Dandelion root is a mild laxative often recommended by practicing herbalists. Susun Weed says it is especially helpful for bed-ridden elders and others with chronic constipation. "The root in tea will have little effect on constipation due to nervousness, diet, fevers, and such occasional causes, but acts reliably when it is chronic, related to age, long-term illness, or general intestinal blahs; a teaspoon of the root boiled in water three or four times a day." Use dandelion leaves in salad, or 1-2 teaspoons of dandelion vinegar or 10 - 20 drops of tincture taken with meals.

Chickweed as a laxative is controversial but not seemingly harmful. It would seem from the debate surrounding it that the worse that can happen while using chickweed for constipation is - more of the same. Varro Tyler heavily disparages its medicinal use "...there is no indication (in the "extensive scientific literature devoted to chickweed") that any of the plant's constituents possess pronounced therapeutic value; ... most writings concern various methods of controlling this pesky weed. (HeK comment: check this to see why Tyler isn't very respected as a herbal authority: <http://www.herbological.com/deconstructing.html>) " This is in sharp comparison to how Susun Weed sings this herb/weeds virtues:

"Those with digestive system problems crave plates of chickweed salad, for mineral-rich bulk and soothing, cooling energies to nourish their weak stomachs and bowels. Chickweed eases and helps those with yeast overgrowth, constipation, hard stools, hemorrhoids, stomach ulcers, intestinal

ulcers, colitis, internal inflammation, stomach cancer, and those healing after treatment for appendicitis, peritonitis, or the like." (Healing Wise, p 121).

Both Susun Weed and Deb Soule also recommend yellow dock root tincture as a remedy for constipation.

CONSTIPATION AS A MENOPAUSAL SYMPTOM

In *Wise Women's Ways for the Menopausal Years*, herbalist Susun Weed explains that "Menopausal constipation and indigestion are generally due to the slowing of the gastrointestinal tract (estrogen is a gastrointestinal stimulant) and heavy demands on the liver." Again yellow dock root, as vinegar or tincture, and dandelion are highly recommended. "Menopausal women will want to avoid the use of bran as a laxative in deference to building strong bones." Instead try prunes, figs, or rhubarb with maple syrup. Daily doses of 1 teaspoonful vinegar or 5 - 10 drops tincture of yellow dock eliminate constipation, indigestion, and gas. "Yellow dock is especially recommended for the woman who finds her early menopausal menses getting heavier."

PURGATIVE OR CATHARTIC LAXATIVES

Purgative laxatives is the category most utilized; and purgative herbs are used in healthfood store formulations and in many commercial over-the-counter laxatives. This group includes aloe, buckthorn, cascara sagrada, rhubarb, and senna. All the herbs in this category contain anthraquinones, strong and irritating chemical compounds that force the bowels to evacuate. They should be used only as a last resort.

Pregnant or nursing mothers should not use these irritants, nor should people with gastrointestinal problems including ulcers, ulcerative colitis, irritable bowel syndrome, and hemorrhoids.

Avoid the prolonged use of purgative laxatives. The continual use can cause lazy bowel syndrome. When this negative cycle develops the result is a sluggish digestive system unable to evacuate without the use of more laxatives. Studies also show that chronic over-use of constipation relieving drugs can lead to disturbances of the bodies electrolyte equilibrium. In turn this can result in potassium deficiency and a concomitant problem for those who are taking heart medications. ("In Germany, the law requires that the labels on all anthraquinone preparations must bear the warning that possible potassium deficiency can intensify the effect of chemical heart drugs -cardiac glycosides"; *The Family Herbal*, p.188)

The gentlest of this class of cathartic laxative herbs is cascara sagrada, known as "sacred bark" from a native American tree (*Rhamnus purshiana*). Michael Castleman says cascara sagrada is the "World's most popular laxative". Many herbalists claim that in addition to its laxative quality it also tones the intestinal tract and colon. It can be purchased in over-the-counter preparations or taken as a tincture (1/2 teaspoon at bed). Although a decoction (tea) is sometimes recommended, it is very bitter. It should never be used for more than 2 weeks, and a reputable source is important because unless the cascara is prepared correctly it can have negative side-effects. (Fresh bark cannot be used; the bark needs to be dried and stored for at least a year).

Dr. Weil, the well-known physician/author and lecturer, says "If you must use an irritant laxative, try rhubarb root (*Rheum officinale*). It is one of the safest and least violent, but it should be reserved for occasional use only. You can get preparations of rhubarb root in health food stores. (*Natural Health, Natural Medicine*, p 274)

Senna (*Cassia acutifolia*) is a bit stronger and also quite popular. It, too, is a main ingredient of many over-the-counter laxatives. Kathi Keville states that it is the most often purchased laxative herb in North America. And my perusal of over-the-counter laxatives supports this. In fact, the company that manufactures Ex-Lax recently updated its formula. Senna has replaced the key ingredient, the chemical phenolphthalein, which proved to have carcinogenic tendencies. Again, taste is a reason that herbalists might not recommend this remedy in its natural state. "The taste of senna is nauseating... herbalists generally discourage using the plant material and instead recommend over-the-counter products containing it."

Some herbalists recommend blends that pair the strongly bitter herbs with others that are better tasting and more easily tolerated. Kathi Kevilles approach is to combine the irritant herbs with tasty ones like peppermint, ginger, and fennel, that also relax the intestines and prevent cramping.

A commercial example of such a mixture is the blend Smooth Move sold by Traditional Medicinals. The main ingredient is senna, combined with licorice, and cinnamon, ginger, orange peel, fennel and coriander seed.

Another herb in this category, aloe, is even more problematic. Its popularity has recently increased and it is a wonderful herb to use externally for skin care. But because of its use, its name is becoming more known, and some people assume that because it is safe for one purpose, that it is ok to try for another reason. But this is not so!

A recent magazine article suggested drinking aloe vera juice on a daily basis. But many western herbalists do not recommend aloe as a laxative because it is too strong, although it has a history of use in Ayurvedic medicine. Michael Castleman in his popular book *The Healing Herbs*, has a headline under aloe, "Never a laxative". He says it is the "most drastic" of the cathartics and that it is least recommended "because it often causes severe intestinal cramps and diarrhea."

AYURVEDIC HERB MIXTURE

Dr. Andrew Weil suggests using Triphala, an herbal mixture from the Ayurvedic tradition. He says this mixture of three herbs is a "superior bowel regulator rather than a laxative,...take it regularly, it's benefits accumulate the longeryou stay on it." Available in health food-stores in capsule form, follow the directions on the label.

RECIPES FOR RELIEVING CONSTIPATION, compiled from some popular herbal guides

Constipation tea/tincture (Deb Soule, *The Roots of Healing*, p92)

Dandelion root 2 parts

Yellow dock root 1 part

Angelica root 2 parts

Burdock root 1 part

Ginger root 1 part

Licorice root 1/2 part

Place 7 to 8 tablespoons of herbs in 1 quart of water and simmer, covered for 30 minutes. Drink warm as needed. As a tincture, take 25-50 drops as needed. For chronic constipation, take 3x a week for 1 to 3 weeks.

Laxative Tea (Michael Moore, *Herb Formulas for Clinic and Home*)

3 parts Psyllium seed
3 parts Licorice root
2 parts Rhubarb root (*Rheum officinale*)
2 parts Senna pods, crushed
2 parts Angelica root
Drink as a simple tea/infusion in the evening.

Herbal Laxative Syrup - for adults (Kathi Keville, *Herbs for Health and Healing*, p 84)

1 teaspoon honey (or barley syrup or some other natural liquid sweetener)
2 teaspoons cascara sagrada bark tincture
1 teaspoon licorice root tincture
1/2 teaspoon tincture of fennel, ginger, or peppermint
Warm honey enough to make it liquid. Combine it with the remaining ingredients and stir well.
Take 1 teaspoon.

CHILDREN'S CONSTIPATION - Keville suggests tea (recipe below); elderberry jam; catnip enema; ground psyllium seed in juice; and slippery elm gruel. For children's constipation, Susun Weed suggests violet flower syrup.

Slippery Elm gruel - for children (Kathi Keville, *Herbs for Health and Healing*, p 221)

1 tablespoon slippery elm powder
3/4 cup water
1 teaspoon lemon juice (optional)
Combine powder and water in saucepan and heat until warm, stirring the mixture to prevent clumping. Add optional lemon juice for flavor. Can also sweeten the gruel with child's favorite herbal or fruit based sweetener. Child can drink entire amount (for every 50 lbs of body weight).
Drink before it cools - as gruel cools down, it thickens and the thicker it gets, the more likely your child will push it away.

Constipation Tea - for children (Kathi Keville, *Herbs for Health and Healing*, p.220)

1 cup boiling water
1/2 teaspoon licorice root
1/4 teaspoon ginger root (or fennel seeds)
1/4 cup apple juice (optional)
1/4 cup prune juice (optional)
Steep first 3 ingredients; strain; add juices. Recommended - 50 lb child, 1/4 cup every 2 hours "until a change for the better becomes apparent".

The Medicinal HerbFAQ

4.1 Making essential oil

This info is copyright by the Australasian College of Herbal Studies, Aromatherapy Certificate Home Study Course. Posted with permission.

>I would really be interested in finding out how to make essential oils.

From Dorene Petersen <dorenep.EUROPA.COM>:

The most important production method for Essential oils is distillation. The basic principle of distillation is the same but it is carried out in different ways depending on the botanical material and the condition of the material.

Three types of distillation are used:

1. Water
2. Water and steam
3. Direct steam

Distillation is basically, producing steam. The steam is passed through the herbal material. The steam carries the Essential oil from the plant in suspension which means the droplets of Essential oils are not dissolved in the steam but remain separate as droplets of oil. When the steam is cooled it reverts to the liquid state which is water and in most cases the oil floats on the surface of the water. The oil is then separated from the water by dripping or pouring.

1. Water distillation is used when the plant material has been dried and will not be damaged by boiling. It is also used for powdered materials such as powdered almond, and flowers, such as orange and rose, that need to float freely as they tend to lump together when just steam is passed through them. The material comes into direct contact with the boiling water and much care needs to be taken that the water does not boil away and cause the plant material to burn. Another example of an oil prepared by this method is turpentine gum. Turpentine gum is collected from a species of Pine (*Pinus palustris*) and the gum, wood chips and pine needles are placed in the distilling chamber with rain water. This mixture is heated until the plant and oil are condensed in the condensing chamber. Turpentine oil is not affected by very excessive heat.
2. The second method of distillation is water and steam. This is used for either fresh or dried

plant material that would be damaged by boiling. The plant material is supported on a perforated grid. The water level is below the grid and low pressure, wet steam passes through the plant material. The most important aspect of this method is that the steam is never really hot and always at low pressure. Cinnamon and clove oils are prepared by this method.

3. Direct steam distillation is similar to the second method but the steam is hotter and passed through the plant material at a higher pressure. This method is used for fresh plant material that has a high boiling point such as seeds, roots and wood. It is also used for fresh plant material such as peppermint and spearmint. The crop is cut and placed in a metal distilling tank on a truck. It is then taken to the distilling tank on the truck. Steam is forced through the fresh herbs and the oil droplets are carried by the steam through a vapor pipe at the top of the tank onto a cool condensing chamber.

Cold Pressing or Expression:

This method is mainly used to prepare citrus oils such as orange, lemon and tangerine. One method involves puncturing the oil glands by rolling the fruit over sharp projections that actually pierce the oil glands. The fruit is then pressed which removes the oil from the glands. It is then washed off with a fine spray of water.

The juice is extracted by another tube. The oil is then separated from the water by rotating it at a very high speed. Another method involves separating the peel from the fruits and then cold pressing them. The Essential oil is collected along with small amounts of juice, which is separated.

Enfleurage:

This is an old method which was used in the production of perfumes and pomade extracts for perfumery. Flower petals such as rose or jasmine are layered onto warm oils, cold fat or wax. This process is repeated each day until the base is saturated with the Essential oil. The resulting waxes or pastes contain up to 1 percent of Essential oil. The Essential oil is then extracted from the wax with a volatile liquid such as ethyl alcohol. In the final step the ethyl alcohol is evaporated at low temperatures and reduced pressure so that the pure Essential oil remains as a fairly thick liquid. Cold enfleurage has the advantage that even the most delicate components of the flower oils are preserved. The disadvantages are that it is not very effective and it is very expensive. Flower oils prepared with this method do not contain terpene-hydrocarbons, which indicates that these compounds are not present as such in the flower, but form during distillation.

Solvent Extraction

This is the most widely used modern method to prepare oils from flowers. The petals are mixed into a volatile solvent such as petroleum, ether or benzene, until the Essential oil is completely dissolved in the solvent. The solution is then filtered and the solvent is evaporated at reduced pressure. The result of solvent extraction is a concrete. The solvent is removed from the concrete by vacuum pressure without the use of heat to avoid any harmful effect to the oil. The concentrated essence that results is called an absolute. Absolutes are highly concentrated flower products without the natural waxes.

The main advantage of extraction over distillation is that uniform temperatures are maintained throughout the process. High temperatures during the distillation process can produce altered chemical composition of the oil which alters the natural odor. However, this method is expensive

compared to distillation, and chemicals or solvents used in the process may still be present after evaporation.

I know this is kind of lengthy but it is not a quick topic. Hope this helps.

Dorene Petersen

The Medicinal HerbFAQ

4.2 Pointer to the How-to of Tinctures

Go get the latest edition of Michael Moore's Materia Medica from his WWW site:

<http://www.swsbm.com> .

If you wish to use anonymous FTP go to ibiblio.org or to sunsite.sut.ac.jp and cd to /pub/academic/medicine/alternative-healthcare/herbal-medicine/SWSBM/

Go for the manuals.

A question on the herblast in November 97:

>Hi All, when it says on a bottle of tincture that the herb to menstruum ratio is (say) 1:5, is this by weight? volume? and then if it is (say) 60% alcohol, 40% water, does this mean that the 5 in the ratio is made up of 60% alcohol and 40% water?

>Also, how do you personally decide how much dried herb to put in that canning jar before you add the vodka? I've recently been thinking that I have probably been putting too much dried herb in, since in most jars it doesn't have an easy time sloshing around.

From Henriette:

A specification of 1:5 60% is most probably for **dried** herb. Weight the herb - let's say it's 100 g. The menstruum is by volume; metric is easier (for me)(1 g water = 1 ml), so to get 5 parts of menstruum you add 500 ml (= 1/2 liter) 60 % alcohol to the 100 g of herb. With dried herb you can either macerate or percolate. Maceration is the normal 'put herb in a jar, pour menstruum over, put lid on, leave 2-4 weeks, shake every day or two'. Percolation is faster, and actually quite easy, but the description of it is lengthy...

You'll want a reliable materia medica to get ratios and percentages for different herbs - a good one is available on Michael Moore's website at <http://www.swsbm.com> (go for the Manuals, go for the Materia Medica).

Fresh herbs are usually done at a ratio of 1:2 and 95 % alcohol - unless you use the 'simplers' -approach, which is to jam as much shredded herb as you can fit into a jar, cover it with 95 % alcohol, close the lid, wait a day, and top it up. Fresh herb is usually macerated.

The simplers approach doesn't give you very consistent quality from batch to batch, so most more

professional herbalists stick to given ratios and menstruum strengths.

The Medicinal HerbFAQ

4.3 Herbal Oils

From Dorene Petersen <dorenep.EUROPA.COM>:

I have made quite a lot of infused oils and the following is from the Aromatherapy Certificate Correspondence Course offered by the Australasian College of Herbal Studies.

It's not that technical but hope its helpful:

HOW TO PREPARE YOUR OWN INFUSED OILS AT HOME

There is nothing more satisfying than gathering a basket of fresh jasmine, honeysuckle or rose blossoms on a warm summers day and then preparing your own infused oil. There are three methods for preparing an infused herbal oil. You can use fresh or dried herbs. Flowers are best fresh, although the perfume of some flowers intensifies with drying such as gardenia, daphne and boronia. If using fresh, double the quantity as all recipes given are for dried herbs. If using fresh herbs for any of these methods leave the herbs to wilt for six hours to reduce their water content which will spoil the final product.

WATERBATH METHOD

15 gm (1/2 oz) dried or if fresh use 30 gm (1 oz) herb (this is the total amount so if you are using a blend make sure you do not have more than this)

1 cup of oil

Measure the herbs and oil and mix the oil to the herbs in a stainless steel bowl. Heat over water bath (a saucepan 1/4 filled with water) also known as a double boiler, which should be simmering. Make sure the bowl is not sitting on the bottom of the pot but is floating in the water. Keep the lid on the oil. Stir occasionally and simmer for 30 minutes. Watch the oil does not get too hot. It should not smoke or bubble. It can burn easily and will develop an acrid smell if it overheats, which is very difficult to disguise. Strain through four layers of butter muslin or some other very fine non-metal strainer. Strain twice if necessary as it is important to get all herbs out of the oil to prevent the herbal oil from going rancid or moldy. Essential oils can be added at this stage for perfume and added therapeutic benefits.

SOLAR METHOD

Use the same quantities of herbs and oil as for the waterbath method or approximately 3 tablespoons of finely cut herbs to 300ml (10 oz) of oil. The quantity of herb can be increased to produce a stronger oil. Put the herbs in a jar with a tight fitting lid and pour over the oil. Make sure the herbs are completely covered with oil. Add one tablespoon of apple cider vinegar or white wine to help break down the plant material. Leave the jar to sit in the sun all day and in a warm cupboard at night for two weeks. Strain through four layers of muslin. This process can be repeated two to three times to give a stronger oil. The final product should be strong enough to leave an aroma when massaged on the skin. Always test infused oils on the skin. Don't rely on just your nose.

CROCKPOT METHOD

Use the same quantities of herbs and oil as for Waterbath method. Place the herbs and oil in a crockpot and leave on a low heat for two hours. Follow the recipe above for straining.

TO PRESERVE OILS

This is only necessary if you are preparing large quantities that you intend to store.

1. Add 1/4 tsp. simple tincture of Benzoin to 1 cup vegetable oil. Tincture of Benzoin is prepared from the gum of an Indonesian tree, Styrax Benzoin. Make sure it is simple tincture of Benzoin. Compound tincture of Benzoin, also known as Friars Balsam, is not suitable.
2. Add 500 I.U. of natural mixed Tocopherols or Vitamin E to 1 cup of vegetable oil.

The Medicinal HerbFAQ

4.4 Balms and liniments

> Hi,I just wonder if anyone has any info about how to make your own balms and liniments.

From: Shannon Brophy <shannon.yoga.com>:

To make a liniment:

First infuse the plant in oil. Do this by baking at low heat (120-170 degrees) in a glass pan with herb and oil together, stir occasionally.

Then strain with cheesecloth and a funnel to separate plant material from the oil. Squeeze out the cheesecloth. Then grate beeswax and add to hot oil, maybe heating again over a double boiler on the stove. Pour the viscous green stuff into jars and allow to cool. Can keep in the fridge for a longer shelf life. Also, adding vitamin E oil to the mixture helps preserve it.

Shannon Brophy, Midwife

visit the Roots & Wings Website at <http://www.yoga.com>

From: Andy & Sharon <email.naturesway.ukonline.co.uk>:

One of the most popular liniments for muscle-, head- and backache is Tigerbalm.

Tradition will have it that the Mongolian Horsemen from Genghis Khan, roaming the plains of central Europe, had a very effective ointment against saddle and back ache. Part of this ointment came from the Siberian Birch Tree. A mixture was made out of lard, camphor and birch tree oil. For ages this ointment was in use and got quite famous.

At the end of the last century many products were replaced by synthetic components. The useful part of the birch oil (methyl salicylate) and the camphor oil (the crystals) were available in synthetic form. This made the ointment cheap and within reach for everyone.

A Chinese merchant composed a mixture of methyl salicylate, camphor crystals and petroleum jelly, which he called Tigerbalm. It became famous throughout the Orient and parts of Europe under this name.

How to make it: First you have to blend the oils. You can use the mix pure or add it to petroleum jelly (vaseline) later on to make a balm.

Tigerbalm Oil - Natural - Recipe 1

Wintergreen oil	45 ml
Camphor oil	15 ml
Eucalyptus oil	7 ml
Lavender oil	5 ml
Peppermint oil	8 ml
Almond oil	20 ml

Tigerbalm Oil - Natural - Recipe 2

Peppermint oil	25 ml
Camphor oil	15 ml
Wintergreen oil	20 ml
Lavender oil	15 ml
Eucalyptus oil	15 ml
Jojoba oil	10 ml

Tigerbalm Oil - Partly natural

Methyl salicylate	25 ml
Menthol crystals	5 g
Camphor crystals	10 g
Eucalyptus oil	10 ml
Lavender oil	5 g
Paraffin oil	45 ml

Tigerbalm

To make tigerbalm take 100 gram petroleum jelly (vaseline) (acid-free) and melt this by placing, for instance, a glass with vaseline in a pan of hot water. The vaseline will melt quickly.

Once melted place the glass in a pan of cold water, and as soon as the vaseline hardens again on the side of the glass, add 20 ml of your Tigerbalm oil mix. Stir until cool. If you prefer the balm to have a colour, add a drop of chlorophyll.

Apply a little bit to the forehead for headaches, or use it for muscle pains and insect bites.

>I find tiger balm/vaseline, to be too greasy for me. I created a simple rub for my lower back pain (due to herniated disk) that provides some relief. It consists of essential oil of Wintergreen and oil of St. John's Wort, added to a base of Aloe Vera gel.

>The Aloe Vera gel is non-greasy and absorbs completely (to the touch). This mixture also feels like it absorbs completely, and no staining of my clothes as of yet.

>Can I make the above "Tigerbalm", but use the aloe vera gel? As well, my herb book indicated that oil of wintergreen is good for pain and inflammation. Could you also post what the other herbs are targeted for?

From: email.naturesway.ukonline.co.uk to above:

I cannot see any reason why you should not use your gel; the vaseline is used to hold the oils together.

Here are some ways the oils react with your skin; as you can see lavender detoxifies, while eucalyptus vitalizes, peppermint refreshes etc.

Essential oils and how they affect your skin

1. GREASY SKIN

Sage : relaxes, improves blood circulation
Peppermint: refreshes, cools
Valerian : calms
Clove : disinfects
Camphor : Disinfects, sedating
Cypress : Refreshing, relaxing

2. UNCLEAN SKIN

Cajeput : Improves perspiration
Rosemary : Improves blood circulation
Valerian : Calming
Camphor : Disinfects, sedates

3. THICK, PALE AND WEAK SKIN

Oregano : Widens the blood vessels
Melissa : Refreshes, tonic
Geranium : Refreshing
Linden blossom : Soothing

4. INFECTED SKIN

Juniper : Disinfects
Lavender : Healing
Cajeput : Improves perspiration
Fir : Refreshes, regulates

5. SENSITIVE, THIN, QUICKLY IRRITATED SKIN

Cypress : Relaxes, refreshes
Pine : Balances, refreshes
Melissa : Against cramps
Chamomile : Sedating
Therebinth : Softening

6. TIRED SKIN

Lavender : Detoxifying
Eucalyptus : Vitalizing
Cajeput : Improves perspiration
Verbena : Calming
Lemongrass : Improves blood circulation

7. BODY CARE (GENERAL)

Oregano : Strengthening
Thyme : Disinfecting
Mint : Tonic

Geranium : Refreshing

by Jonathan Treasure <http://www.herbological.com>

This introduction concerns WESTERN medical herbs and their clinical use. Some herbal agents are common to different traditions but the indications and methods of use may vary between e.g. TCM, Ayurvedic and Western practices.

The purpose of these notes is to provide a general understanding of the actions of herbal medicines, and hence a background for understanding questions of safety and toxicity - NOT to provide a list of problematic herbs. A brief bibliography gives sources of reliable information on the safety of herbal medicine and further reading.

Conventional medicine considers that if a drug is to be effective, it will inevitably have side effects. The medical establishment considers herbal medicines as drugs, and as such, they must either have side effects - or ergo be ineffective.

Paradoxically tens of thousands of people every year turn to herbal medicine because they regard plant remedies as being free from undesirable side effects. Herbal medicines are considered to be generally safe AND effective agents.

Although there is a spectrum of viewpoints in western herbal medicine, most herbalists reject the view that plant medicines are naturally occurring analogues of the pharmaceuticals used in orthodox clinical medicine i.e. drugs.

This is ultimately a rejection of the dominant paradigm of orthodox clinical science. It is necessary to outline the elements of the alternative paradigm shared by most herbalists, before questions of toxicity and safety can be discussed in context of clinical herbal therapeutics, rather than of orthodox medical science

5.1.1 Medicinal plant actions cannot be reduced to the effects of their isolated 'active constituents'

There ARE a few plants that are almost "drug like" and whose action approaches that of pharmaceuticals. Digitalis is the classic example. Herbalists use these plants in near allopathic treatment strategies if at all, and in some countries e.g. UK, their availability is restricted by law. The number of herbs in this category is relatively few.

The vast majority of medicinal herbs contain dozens of different compounds, often of great complexity, mucilages, tannins, polysaccharides etc. that buffer, modulate and modify the effects of any "active principles". Study after study has shown that effects produced by extracts of whole plants cannot be mimicked by administering isolated purified constituents of the plant.

(It is ironic this proposition even has to be asserted given that biological sciences have for some time used a systems theory model in which the whole being greater than the sum of the parts is axiomatic - this simply reflects the inherent conservatism of the medical establishment. However for most herbalists the view of the whole being greater than the parts is derived from vitalism, not systems theory!)

5.1.2 Medicinal herbs act 'multi-systemically'

Pharmaceutical drugs are designed to elicit very specific reactions. Their associated "side effects" are undesired actions, usually traded as a "risk" against the "benefit" of the primary effect. Herbs tend to have several broad actions on a number of whole physiological systems at the same time. These actions are usually oriented in the same general therapeutic direction, and are usually complementary or synergistic, often non-specific, and very rarely adverse. Herb actions cannot be adequately described using the vocabulary of "drug" action terms, e.g. diuretic etc. - they are too

complex. The clearest example of this is the coining of the term "adaptogenic " used to describe the multiple non-specific effects of herbs such as Ginseng.

5.1.3 Herbs act on the healing processes in the body

A pharmaceutical drug addresses symptoms caused by specific disease mechanisms as understood by scientific pathology. Herbal medicines are directed towards aiding the body's own healing processes. These approaches are diametrically opposed. Herbal medicines act gently, usually attempting to "nudge" or "support" systems and processes that have become deficient or help remove excesses that have become preponderant. Symptom relief is only a component of herbal therapeutic strategy.

This is a crucial difference. For example, serum arthritic conditions are conventionally treated with steroid anti-inflammatory drugs. These have widespread and disturbing side effects, which at sustained high doses become intolerable and potentially dangerous if not lethal. The herbal approach to these conditions uses dietary modification of metabolism; facilitation of elimination via kidneys and hepatic/ biliary routes; stimulation of circulation in the affected regions, moistening of dry synovia, etc. Topical treatments for acute joint pain or systemic anti-inflammatory herbs that help joint pain are used as required, but this is not the thrust of the treatment strategy. Lay persons often make the related mistake of seeking a "natural alternative" to a pharmaceutical they have been prescribed rather than challenging the diagnosis and therapeutic strategy.

5.1.4 Herbs act multi-dimensionally

Herbal medicine is a wholistic therapy, it integrates mental, emotional and spiritual levels seamlessly into its understanding of both human function and of the plant remedy, while respecting the planetary and ecological dimensions of natural medicine provided by plants. Although subject to differing interpretations this view is held in one form or another by most herbalists .

Life style, mental, emotional and spiritual considerations are part of any naturopathic approach, herbalism included. Flower essences, homeopathic preparations and drop doses of standard herb extracts all demonstrate that herbal agents can produce consistent and powerful effects at subtle levels in ways quite inexplicable by the pharmacokinetic model underlying orthodox pharmacology.

Centuries of medicinal plant usage overarch even the Graeco - Roman heritage of medical thought, itself already forgotten by its amnesiac infant technological medicine, extending into magical, esoteric and religious domains of prehistory. The great Asian systems of medicine have continued

uninterrupted for thousands of years to today, integrated into profound cosmological and philosophical systems. From any serious study of the application of herbs to healing a perspective emerges that reveals modern doctors to be tragically "like educated peasants running around pretending to be chiefs" (Grossinger).

5.1.5 Side effects vs. contraindications

Many herbalists would tend toward the radical homeopathic view that the "side effects" of orthodox medicine are in fact iatrogenic developments of the very disease for which the pharmacological intervention was intended. The symptoms simply change, and the real underlying dysfunction is further obscured - or driven further into the interior to manifest in deeper and more intractable ways.

Notwithstanding this iatrogenic view of side effects, we have seen that the use of herbs anyway does not generally involve "drug" actions or adverse effects. Of course, if the body processes are nudged in the wrong direction for long enough, then imbalances can worsen rather than improve. Hence the need for informed knowledge of the effects of herbs as well as a clinical training to understand their appropriate medical application. Herbalists learn about the **CONTRAINDICATIONS** as well as the indications for using a herb. This term is more useful and appropriate than "side effects".

CONTRAINDICATIONS are incongruences between the metabolic/systemic predisposition (constitution) of the individual - and the spectrum of multi-systemic actions of a given herb agent or class of agents. Essentially, herbalists use their in depth knowledge to devise a mix'n'match prescription tailored precisely to fit an individual's unique profile. This approach is most sophisticated in the tonic energetics of the Oriental medical traditions, but is empirically applied by most herbalists.

Contraindicated remedies can account for apparently idiosyncratic "bad reactions" to a herb. Valerian is a classic example, its powerful autonomic effects can make it "disagree" with stressed adrenergically hyperactive individuals, who paradoxically are often those seeking sedative treatment for insomnia. Anyone experiencing such reactions to a herb for more than a couple of days should stop taking it and seek further advice. However a second and vital aspect of contraindications especially today is the question of **DRUG INTERACTIONS**.

Many people seeking herbal medical treatment are already involved in pharmaceutical therapies. Herbal remedies may act either as agonists or potentiate some drug therapies, and an understanding of conventional drugs is an essential prerequisite for effective herbal therapeutics. In many cases, herbalists would not treat the primary presenting symptom undergoing drug treatment - be it ulcers treated with Zantac or cardiac arrhythmia treated with Digoxin - but rather concentrate on supporting other systems and functions stressed by the primary symptom. This allows the body to recover its strength and healing potential so it can then direct these capabilities toward repairing the presenting condition. In other cases, it can be a priority to wean someone off drugs, e.g. steroids, in which case supportive therapy to restore adrenal function is vital.

5.1.6 Safety and toxicity of herbal medicines

The definition of *toxic* is ultimately a matter of viewpoint. Many ordinary foods contain constituents that could be regarded as poisonous, such as the alpha gliadin produced by gluten in wheat oats and rye, the cyanogenic glycosides in many fruit seeds, the thiocyanates of the brassica vegetables, alkaloids of the Solanaceae and lectins of many pulses including soya and red kidney beans. Nonetheless these foods are generally regarded as safe. Similarly, both water and oxygen - can kill in excessive amounts, so quantity is often an important consideration. In practice however, three groups of herbs can be identified from a safety point of view.

Firstly there are a handful of herbs that contain near pharmaceutical concentrations of poisonous constituents which should on no account be taken internally by unqualified persons except in homeopathic potencies. Examples are *Atropa belladonna*, *Arnica* spp, *Aconitum* spp, *Digitalis* spp. In many countries availability of these herbs is limited by law. Regulations vary from country to country and the appropriate regulatory authorities or Herb Organisations can be consulted for details. Wildcrafters should be unshakably confident in their identification of the local variants of these species, and children warned to avoid them. Fortunately this is a numerically tiny category.

Secondly, are herbs with powerful actions, often causing nausea or vomiting, (that usually were traditionally prized for this action). They are perfectly safe used under appropriate conditions. Some of these herbs are restricted in some countries but freely available in others. *Lobelia* and *Eonymus* spp are examples. There is some inconsistency here, for example *Ephedra* is restricted, perhaps with justification, in the UK, but is freely available in the US.

Finally, there is an idiosyncratic grouping of herbs which have been alleged, with some scientific support, to exhibit specific kinds of toxicity. The best known is the hepatotoxicity of pyrrolizidine-alkaloid-containing plants such as *Comfrey* (*Symphytum*). Other examples are *Dryopteris* (Male Fern), *Viscum* (Mistletoe) and *Corynanthe* (*Yohimbe*). Although much of the evidence is contentious (see below), lay users would be advised to avoid internal consumption of these herbs.

The vast majority of medical herbs are safe for consumption, but for those without specialised knowledge, it would be prudent to follow simple but sensible guidelines in self treatment:

- Use only herbs recommended in respected herb books, especially in countries like the US where there are few restrictions on availability.
- Avoid new or unproven *wonder remedies*.
- Do not persist with a remedy if no benefit or result obtains after a moderate period, and if adverse reactions take place, stop the treatment and seek experienced advice.
- Do not persist with a treatment that has brought improvement without testing to see if continued further consumption is necessary to maintain improvement.
- Do not engage in self treatment for complex conditions without experienced advice. Drug interactions and contraindications must be considered on an individual basis and herbal treatment strategies are often involved and multifaceted.

Unfortunately, training and licensing of herbalists is not internationally consistent. In the US the situation is especially complex - no recognised herbal licensing exists. ND's are licensed in a few states, but their herbal training could theoretically be less than that of an unlicensed but experienced herbal practitioner. In the UK, the NIMH accredits herbalists who have trained at approved courses: practitioners are recognised by MNIMH or FNIMH qualifications.

5.1.7 Pregnancy

It is axiomatic that pregnancy should be a time of minimal medical intervention, and herbalists in particular regard pregnancy as a "contraindication" to taking herbal medicines. Nutritive "food herbs" such as nettle, and uterine tonics such as raspberry leaf are encouraged, and perhaps gentle treatments against typical symptoms such as constipation or morning sickness are in order. There is NO evidence of teratogenicity in humans arising from herbal remedies, but since such evidence would be hard to come by, erring on the side of caution is regarded as prudent.

5.1.8 Understanding toxicity research - politics and ideology

Medical orthodoxy at best does not understand herbal medicine, and at worst, sees it as a threat which it attempts to rubbish, regulate or ridicule. Quackery has a fascinating role in the history of medicine and its institutions, but much of the hostility towards herbal medicine comes from its apparently greater proximity to orthodoxy than say acupuncture or homeopathy. This is the unfortunate political context in which toxicity and safety of herbal medicines are debated.

Additionally, both professional herbalists and regulatory authorities exhibit differing degrees of education, organisation and aptitude in different countries. In the United States, the situation is particularly lamentable, with scare mongering stories regularly aired in medical, scientific and popular press, whilst the lack of accredited professional herbalist training means that well intentioned self-appointed spokespersons for herbalism can cause more harm than good, and the quixotic federal regulatory stance on herbs as foodstuffs means that the potential of lay self-iatrogenesis with freely available OTC herbal products is a serious possibility.

Toxicity of herbal medicines needs to be seen in context however. As Paul Bergner, Editor of the journal *Medical Herbalism* and author of several articles on herbal toxicity recently pointed out:

*Approximately 8% of all hospital admissions in the U.S. are due to adverse reactions to synthetic drugs. That's a minimum of 2,000,000. At least 100,000 people a year die from them. That's just in the U.S., and that's a conservative estimate. That means at least three times as many people are killed in the U.S. by pharmaceutical drugs as are killed by drunken drivers. Thousands die each year from supposedly "safe" over-the-counter remedies. Deaths or hospitalizations due to herbs are so rare that they're hard to find. The U.S. National Poison Control Centers does not even have a

category in their database for adverse reactions to herbs.*

Similar figures apply in the United Kingdom, and even hepatotoxicity, where perhaps the strongest case against some herbs lies, the statistics are horrendously clear - over 80% of cases of fulminant hepatic failure presenting for liver transplant (or death) over ten years in the UK were due to poisoning by freely available OTC non-prescription NSAID's, such as paracetamol and aspirin. Not one case was due to ingestion of medicinal herbs.

For the lay person, analysis of so called "scientific evidence" about toxicity is clearly problematic. Some of the most useful sources of information are to be found in review presentations made by representatives of the herbalist community to regulatory authorities such as the FDA or MCA. Informative reviews of the literature in defence of Comfrey and Mistletoe have been made in this way.

Herbalists justifiably point out that scientific studies with isolated compounds, on non human or even non mammalian organisms, or in vitro, with doses tens or even hundreds of times the equivalent medicinal dose, simply have no arguable extrapolation to the clinical situation using whole herb at appropriate medicinal doses.

Lack of herbal knowledge by some scientific investigators (let alone journalists or self appointed defenders of the public) leads to often ludicrously misleading results - one of the commonest mistakes being the failure to verify the actual identity of plant material used in their experiments, let alone the detection of contaminants!

These points beg the question of what paradigm can be used for research into the safety and efficacy of herbal therapies. That shibboleth of orthodoxy - the double blind placebo controlled clinical trial is open to a range of criticisms from the paradigm employed by herbalists - but that, as they say, is another story.

5.2 Wildcrafting Ethics and similar things

- 5.2.1 [Wildcrafting checklist](#)
- 5.2.2 [How do I find out about endangered plants \(in the USA\)?](#)
- 5.2.3 [What plants shouldn't I pick?](#)
- 5.2.4 [United Plant Savers](#)

by Howie Brounstein (<http://www.teleport.com/~howieb>) (posted with permission)

This are the guidelines I teach to my students. It is copyrighted material that took me years to develop. Please respect this copyright. I ask you not to publish it without permission. Happy Herbing.

5.2.1 Wildcrafting checklist

- Do you have the permission or the permits for collecting at the site?
- Do you have a positive identification?
- Are there better stands nearby? Is the stand big enough?
- Are you at the proper elevation?
- Is the stand away from roads and trails?
- Is the stand healthy?
- Is there any chemical contamination?
- Is there any natural contamination?
- Are you in a fragile environment?
- Are there rare, threatened, endangered, or sensitive plants growing nearby at any time of the year?
- Is wildlife foraging the stand?

- Is the stand growing, shrinking, or staying the same size?
- Is the plant an annual or a perennial?
- Is tending necessary and what kind?
- How much to pick?
- Time of day? Time of year?
- What effect will your harvest have on the stand?
- Do you have the proper emotional state?
- Move around during harvesting.
- Look around after harvesting. Any holes or cleanup needed?
- Are you picking herbs in the proper order for a long trip?
- Are you cleaning herbs in the field? Do you have the proper equipment for in-field processing?
- **Wildcrafting is stewardship**

c1993hb

5.2.2 How do I find out about endangered plants (in the USA)?

Check your local Heritage Program Database, call the Dept. of AG or a local Native plant society chapter to find its address. This will connect you to experts on particular plants and current lists.

The endangered species act has many flaws, I personally believe there should be an endangered ecosystems act instead but it's all we've got and better than nothing.

Some listed plants are truly rare, once numerous but destroyed by loss of habitat through man or nature.

Many listed plants are endemics, located in a specific area. These may be geographically isolated islands of flora as are often found in the intermountain west, or they can be found at the border of major plant systems. Many endemics are found in southern Oregon, where the Northern California system blends with the Pacific Northwest system, with a spattering of Great Basin plants. This does not mean these plants are sensitive, just unique. The threatened *Penstemon peckii* grows only within twenty miles of my house, and nowhere else on earth.

It can withstand trampling, wildlife grazing, and disturbance. In fact, now that the forest service has realized that this species thrives with moderate disturbance (partial cuts), it has become a reason to log, i.e. increased health of the population of this plant.

Plants become listed due to political boundaries. *Gentiana newberryi* grows nearby, and is threatened in Oregon. It's northernmost sighting is within a half hours drive. There you can see people play football on it, run horses on it, pick its beautiful flowers only to find they wilt

immediately, and then the flowers end up on the ground.

Sometimes hundreds of them. Elk graze it heavily. It isn't a sensitive plant, and it's population is healthy and stable in California, but the population happens to cross over to Oregon where there isn't that many stands. Thus it receives the same protection as the truly rare plant. Southern Oregon has many of these kinds of listed plants.

There has to be a perceivable threat to the plant population in order for it to be listed. Sometimes the threat is obvious, and sometimes the threat is obscure.

What about an introduced plant that has become a pest, or a native out of control in a system out of balance. When the St. John's Wort, *Hypericum perforatum*, is down to a handful of populations, it will fit the definition of threatened, even though humans intentionally eradicated it!!

5.2.3 What plants shouldn't I pick?

Some plants are not damaged easily. Blackberry (*Rubus* sp.), and Dandelion (*Taraxacum officinale*), are two that are nearly impossible to eliminate, even if you dig their roots. If a piece of root stays in the ground, it will grow back. Yarrow (*Achillea millefolium*), can be cut with a lawnmower and still flourish regularly. Nettles (*Urtica dioica*), when grown for fiber can have 3-4 aboveground harvest in a growing season. Plants that fit into this category are generally perennials. You can pick them and not threaten their survival.

Rare, Threatened and Endangered Plants

Endangered plants are species in danger of becoming extinct in the foreseeable future. Threatened plants are likely to become endangered in the foreseeable future. A species can be threatened or endangered throughout its range, which means if it goes extinct we will lose its hidden secrets forever.

Many of these plants only grow in one special area (endemic). The Columbia Gorge on the border of Oregon and Washington hosts many endemic species. Peck's Penstemon, *Penstemon peckii*, grows only in the Ponderosa Pine Forest in Deschutes and Jefferson Counties. A species can also receive protection for part of its range. Newberry's Gentian, *Gentiana newberryi*, has stable populations in California, but is listed as threatened in Oregon. Deschutes County is at the end of its range, and there are less of them. Rare plants have small, localized populations. They may not be listed as threatened or endangered if the populations are both stable and numerous.

The US. Fish and Wildlife Service determines which plants receive federal protection. Unfortunately, they are very slow in reviewing candidate species.

Many have become extinct while waiting to be listed. The Department of Agriculture and the Department of Fish and Wildlife of each state is responsible for determining state protection. We also have the Oregon Natural Heritage Program. This program has its own list of plants that deserve protection, but haven't made it into the clogged federal and state lists. They also have a list of plants to watch and monitor. A copy of Rare, Threatened and Endangered Plants and Animals

of Oregon is available from:

The Oregon Natural Heritage Program
1025 NW 25th Avenue
Portland, Oregon 97210
(503)-229-5078

Do not pick these plants. Unfortunately, they are not always easy for an amateur to identify. They are not always showy. There may be large amounts of them in one spot, so that they appear plentiful.

There are some good picture books available. All folks who pick plants from the wild should try to familiarize themselves with the local protected plants. When in doubt, don't pick it.

Sensitive Plants

Some plants are sensitive to disturbance. Please do not pick them even if they aren't protected. The Calypso Orchid, *Calypso bulbosa*, is a fragile plant that lives partially off leaf mold. Its little root is close to the surface, and easy prey to slugs and others. Minor disturbances can easily dislodge the root from the mold. If someone picks its flower, it can ooze fluid and essentially "bleed" to death. Even disturbing the area around it during flowering could kill it. The law does not protect this plant because it is too numerous.

It is our responsibility to help sensitive plants survive.

How can you tell if a plant is sensitive? Most plants that are not green (contain no chlorophyll) are "no picks." These weird species are white, brown, red, or purple and just plain eerie. Botanists call them parasites or saprophytes. They are particularly fascinating. These include Broomrape, *Orobanche* sp., Coral Roots, *Corallorhiza* sp., and Indian Pipe, *Monotropa uniflora*. Other "no picks" include the Orchid Family (Orchidaceae) and almost all the Lily Family (Liliaceae). The Orchid Family includes Calypso Orchid, *Calypso bulbosa*, and the Rein Orchids, *Habenaria* sp. The Lily Family includes Trillium, *Trillium ovatum*, and Mariposa Lilies, *Calochortus* sp. These families are easy to recognize with a little practice. Not every Lily and Orchid is sensitive, but it's a good place to start.

Most (but not all) of the unusual or showy plants are no picks. If you are not sure, don't harvest it.

5.2.4 United Plant Savers

From Gregg Pond <gpond.integ.micrognosis.COM>:

United Plant Savers - Statement of Purpose

These are exciting times for herbalists. The current "herbal renaissance" in American health care is accompanied by an ever growing demand by the American public for herbs and herbal products. While positive on one hand, this situation has endangered a unique new set of problems for the wild plant world and for herbalists who love plants.

The pressure on our wild medicinal plant communities is growing yearly. Vast numbers of plants have been and continue to be taken, and indiscriminate wild harvesting has devastated many areas of former abundance. Perhaps even more disturbing, native North American medicinal plants are being exported to meet the demand in other countries, where wild plant populations have already been gravely depleted.

United Plant Savers was formed in a spirit of hope, as a group of herbalists committed to protecting and re-planting threatened species and to raising public awareness of the plight of our wild medicinal plants. Our membership reflects the great diversity of American herbalism and includes wildcrafters, seed collectors, manufacturers, growers, botanists, practitioners, medicine-makers, educators, and plant lovers from all walks of life.

Our Goals

- Identify and compile information on threatened medicinal plants in each state and/or bioregion.
- Make this information accessible to herbal organizations, communities and individuals.
- Provide resources for obtaining seeds, roots, and plants for replanting and restoration.
- Secure land trusts for the preservation of diversity and seed stock for future propagation efforts.
- Raise public awareness about the tragedy of over-harvesting and the current plight of native wild herbs.
- Identify and disseminate information on the therapeutic alternatives to threatened species.
- Encourage more widespread cultivation of endangered medicinal plants and greater use of cultivated plants.
- Develop programs for school systems and communities to re-plant threatened plant species back into their native habitats.

5.3.1 Traditions in Western Herbal Medicine

by Peter Cook, DBTh, FETC

This Article is taken from The Herbalist, newsletter of the Canadian Herbal Research Society. COPYRIGHT June 1989.

Thanks to Jonathan Treasure for sending this one over.

The Development of Theory in North America

Introduction: To one trained as a medical herbalist in Britain, it is a curious fact that herbal medicine, as it seems to be most widely known in Canada and the U.S., has been so little influenced by the great systems of herbal thought which once flourished here. Only remnants of these systems can now be found in the writings of Kloss, Christopher, Shook and others whose primary sources appear to be the European and native North American folk traditions.

These folk traditions are very valuable medical resources in their own right; a fact which has been recognized and supported by the World Health Organization (1978). It has also been recognized and increasingly exploited by the pharmaceutical industry. Folk medicine however, is also important as a rich source for the periodic historical development of major systems of traditional medicine. Examples of the development of two such systems in North America will be discussed here, together with some of the more important theoretical and practical contributions to herbal medicine which these systems generated.

Early American Folk Medicine: Eleanor Sinclair Rohdes (1922) has written very eloquently of the hardships faced by early American settlers in their efforts to cultivate the familiar medicinal plants of England and Europe. In many cases it seems these efforts failed completely and the pioneers were forced to supplement their folk medicine traditions with lore relating to indigenous plants obtained from the native people. To the extent that any special knowledge would have been likely, then as now, to remain a closely kept secret by the native medicine societies, it is probable that the native plant-lore passed onto these settlers was a matter of common knowledge amongst the native people. In fact, it may be said that a distinguishing feature of any folk tradition is that the lore contained in that tradition is, or has once been, common knowledge.

Another distinguishing feature of folk medicine, regardless of its historical or ethnic origin, is that the indications for the use of individual remedies are always given in terms which refer to specific

symptoms or illnesses. Thus, comfrey (*Symphytum officinale*) is said to be useful in healing fractures, while white horehound (*Marrubium vulgare*) is recommended for cough. Typically, such lore has been handed down from generation to generation, often for hundreds if not thousands of years. Each new generation learns at first hand the look and 'feel' of particular symptoms and illnesses. They learn which plants may be used to treat these illnesses, and the best methods for collecting, preserving and administering them. Such a tradition is entirely dependant upon repeated experience and observation; usually only minor changes can be detected in these traditions over relatively long periods of time.

Thomsonianism: The popular medicine of all peoples however, has always given rise to, and been counterbalanced by a more specialized type of knowledge, acquired by individuals who have devoted their entire lives to the study and practice of healing. As resource persons, these individuals have served their communities by providing access to that specialized knowledge in circumstances where the more common folklore was insufficient to meet the needs of the moment.

A very popular figure in early American medicine, who managed to combine native and settler folklore with a more specialized approach, was Samuel Thomson (1769-1843). Thomson came from a farming family and evidently learned some of the 'root and herb' practice at an early age. Later, he seems to have become an avid reader of medical literature and was particularly impressed with the Hippocratic writings.

Probably as a consequence of his regard for Hippocrates, Thomson believed that medicine should be based exclusively upon observation. The formulation of theories, he felt, prevented ordinary people from taking responsibility for the care of their own health, and that theories obscured the simplicity and made a needless mystery of medicine.

Thomson himself however, after 'long observation and practical results', borrowed theory from Hippocrates and used it as a basis to explain the 'why and how' of his own medical system. According to this theory, disease was the result of a decrease or derangement of the vital fluids, brought about by a loss of animal heat. The resulting symptoms were interpreted as efforts of the Vital Force to rid itself of the toxic encumbrances thus generated. Essentially, treatment was aimed at restoring vital energy and removing disease-generated obstructions. In specific terms, Thomson believed that in restoring vital heat by means of steam baths and cayenne (*Capsicum annum*), toxins which obstructed health would be thrown into the stomach where they could be eliminated by emetics such as *Lobelia inflata* (Griggs, 1981).

This simple theory constituted a dramatic departure from pure folk medicine in that it recognized and sought to treat an underlying, fundamental cause of illness. Moreover, in perceiving symptoms as an expression of the organism's defensive efforts, this theory implied that the treatment of symptoms and illnesses, per se, might actually hinder the healing process. It is interesting to note that Thomson believed this theory was quite complete and needed no further refinement or extension. Nevertheless, despite his vehement opposition, Thomsonianism became a potent influence on the development to two major streams of thought within American herbalism.

Eclecticism: The earliest of these was 'Eclecticism', founded by a man who had originally apprenticed to an old German non-Thomsonian herbalist, and who later qualified as a 'regular' medical doctor. Although the founder of this system, Wooster Beach (1794-1868), had been horrified by the 'regular' medicine of his day, and fervently wished for radical reform,

Thomsonianism had impressed him negatively in two ways. First, Beach was keenly aware of the bitter antagonism which Thomson had roused in the regular medical profession. As a result he decided to attempt reform (unsuccessfully as it turned out) from within, rather than as another medical 'outsider'. Secondly, Beach was disgusted by Thomson's evident arrogance in thinking that no further learning could possibly enhance the practice of herbal medicine.

Beach was well acquainted with the developments then taking place in such fields as chemistry, physiology, pathology and even botany. He was also quick to realize that this new thinking might have a valuable role to play in botanic practice, and began to move in this direction with the creation, in 1829, of his own school of 'Reformed Medicine'.

In terms of the study of medicinal plants, Beach's orientation resulted in the development and proliferation of an entirely new style. Eclectic monographs on individual herbs became more formal and typically included notes on the plant's chemistry, toxicology, physiological and therapeutic actions, as well as appropriate forms of preparation and dosage (e.g. King, 1900). Later Eclectic physicians became increasingly interested in obtaining preparations which represented the entire chemistry of the original plant as closely as possible. Although this preoccupation had near-disastrous consequences in at least one instance (Griggs 1981a), in general their research supported and developed the fundamental position of the value of using whole plant preparations rather than isolated extracts of a particular plant constituent (Lloyd, 1910).

Eclecticism was also a major contributor to herbal medicine in other areas. Beach himself, for instance, realized the fundamental importance of the blood and circulatory system in maintaining health, and began to develop herbal methods for 'equalizing the circulation'. Several valuable techniques used in the modern herbal treatment of fevers are probable directly attributable to Beach's work.

A later physician by the name of W.H. Cook (1879) expanded on this work in his correlation of the functions of the nervous and circulatory systems. Cook also developed a concept which related illness to deviations in trophic (i.e. structural) and/or functional tone. According to this view, disease consisted of excessive or diminished tone in organs, or in the functions of those organs. Corresponding herbal approaches to the correction of these kinds of imbalance were also eventually developed (Priest & Priest, 1982).

Another major development fostered by Eclecticism, was the clinical emphasis placed on treating a group or pattern of symptoms, usually with small doses of only one so-called 'specific' remedy. As the pattern of symptoms changed with the progress of disease, a new and more currently appropriate remedy would be indicated (Felter, 1922; Lloyd 1927).

Perhaps significantly, this approach was and is still fundamental to the practice of homeopathic medicine, which was rapidly becoming the most popular of all medical systems in the U.S. during the mid-19th century (Coulter, 1973). In fact Hahnemann (1810), the founder of homeopathy, had already written at some length concerning the relative merits of prescribing for what he called the 'Totality of symptoms', versus the treatment of individual symptoms or named diseases. The use of small doses of a single remedy was also an established fundamental tenet of homeopathy (e.g. Kent 1900).

Prescribing for patterns of symptoms had also been typical in traditional Chinese medicine for

many generations. Clear examples of the fluidity of prescribing in accord with changes in symptom patterns may be found in the Chinese classic, 'Shang Han Lun' (Hsu & Peacher, 1981). However, although the use of a single remedy is an established technique within Chinese medicine under certain circumstances, Chinese herbal prescribing more often involves the use of formulae (e.g. Bensky & Gamble, 1986).

Physiomedicalism: The second major stream of thought in American herbal medicine, which arose directly out of the Thomsonian movement, was 'Physiomedicalism'. Although not so heavily influenced by the developing sciences as Eclecticism, the originator of this 'neo-Thomsonian' movement, Alva Curtis, felt, like Beach, that Thomson's resistance to theoretical development was a mistake.

Above all, Curtis wanted to open a school based upon Thomsonian principles, but encouraging a freer atmosphere for broader intellectual enquiry and learning. In 1835, despite Thomson's opposition, Curtis realized his ambition and opened the 'Botanico-medical School and Infirmary' at Columbus, Ohio. As evidence that he was not alone in his thinking, during that same year, a colleague opened the 'Southern Botanico-Medical School' in Georgia (Griggs 1981b).

Ultimately this new system of herbal medicine retained much of what had been accepted as fundamental in the Thomsonian theory. Thus, organic function was thought of as the aggregate expression of Vital Force, acting through cellular metabolism to maintain the functional integrity of the entire organism. Illness was seen as a disordered response at the cellular level, brought about by internally or externally generated toxic obstructions. Essentially, treatment remained a matter of supporting the efforts of the Vital Force, and of eliminating the toxic encumbrances which hindered those efforts.

A significant departure from Thomsonian thinking however, came with the recognition that some symptoms represented positive, eliminate and reconstructive efforts of the Vital Force, while others resulted from physical impediments to those efforts. If treatment was to be directed to the underlying cause of illness, therefore, symptoms which expressed a purely functional disorder had to be distinguished clinically from those produced by organic changes in cells and tissues.

Eventually it was also realized that the organism was capable of establishing a compensatory equilibrium in which toxic encumbrance would be tolerated to a degree, in order to maintain a relative functional integrity. This was a major step forward in understanding and had important implications for herbal therapeutics. Certain symptomatic crises which had been observed, particularly in the context of treatment with herbal alteratives and eliminatives, could now be explained and avoided.

Another significant development in Physiomedical thinking was stimulated through the work of W.H. Cook (see above). If health could be understood as the unimpeded and balanced function of all cells and tissues, then it was clear that the blood and circulatory system played a vital role in maintaining health, both in terms of nutrient delivery, and of waste and toxin transport to eliminative organs.

Cook had shown that, in addition to the quality of the blood itself, the chronic relative contraction or relaxation of tissues and particularly arterioles and capillary beds could also have serious consequences. Cellular function, and eventually cellular structure, could be strongly influenced by

a relative excess or deficiency of blood and tissue fluid. Further, as understanding of human physiology increased it became obvious that hyperaemia in one part of the body would necessarily imply a relative ischaemia elsewhere.

The implications of this thinking for herbal medicine were threefold. Firstly, herbs which acted to increase or decrease tone in the three primary divisions of the circulatory system (arterial, capillary and venous) had to be distinguished. Secondly, the general, portal and pulmonary aspects of circulation had to be considered in treatment, as did the distinction between visceral and somatic components. Thirdly, the circulation to particular organs and tissues had to be taken into account, not only to support or modify the related functions, but also to restore normal trophic conditions, where possible.

The achievement of these goals became much more accessible following the work of J.M. Thurston (1900), which stressed the regulatory importance of the autonomic nervous system. Thurston made many important contributions to Physiomedical thought in the areas of diagnosis, prognosis, treatment and, perhaps especially, in the area of herbal pharmacy. A number of aspects of his work, and of Physiomedicalism in general, have been described by Priest & Priest (1982a).

Even by the close of the 19th century, Physiomedicalism could be described as a system which emphasized the role of herbal remedies in supporting Vital Force, balancing the circulation to various tissues, modifying and enhancing body functions, restoring optimum trophic or structural conditions, and in eliminating toxic encumbrances (Mills, 1985).

Unfortunately, the publication of the Flexnor report in 1910 and the subsequent forced closure of the 'irregular' medical schools put an end to any further developments of the kind described here in American herbal medicine (Cody, 1985; Gort, 1986).

Conclusion: Curiously, despite the slightly more open attitudes which prevailed in Canada (e.g. the government regulation of naturopathy on Ontario, 1925; Govt., 1986), neither the Eclectics nor the Physiomedicalists seem to have moved north across the border. In fact both systems, together with a version of Thomsonianism, had been taken to England where they were eventually integrated into one system of professional herbal medicine, regulated by law and still taught in the U.K.

In Canada and the U.S. however, only traces remain of these once influential and effective systems. The Dominion Herbal College in British Columbia for instance, has referred in its course notes to the need for 'equalizing the circulation' (1969). References can also be found in these notes and elsewhere to 'relaxing' or 'stimulating' herbs (i.e. plants capable of increasing or decreasing functional tone). The importance of supporting vital force and of eliminating accumulated toxins is also still widely recognized and practised. Nevertheless, there are probably few today however, who can apply physiomedical principles in distinguishing for instance, those lung, bowel and kidney conditions respectively requiring relaxing or stimulating expectorants, laxatives and diuretics.
