
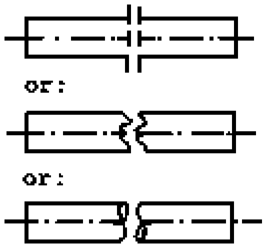
Connection of two pieces with bolt

End of pipe in side-view



Interruption

Long chain, thick: Cutting planes for sections

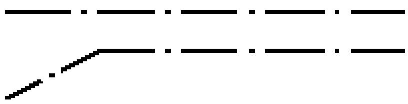
Edges, thin

Short dashes, thin:

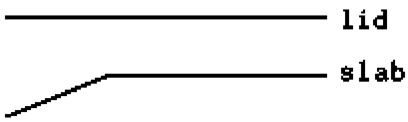
Hidden details, edges not to be seen. The first and the last dash of a hidden detail line should always touch the lines between which it is drawn.

Centre line of a rotational symmetric part:

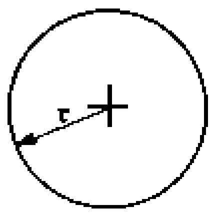
Centre lines must project for a short distance beyond the outline of the feature to which they refer.



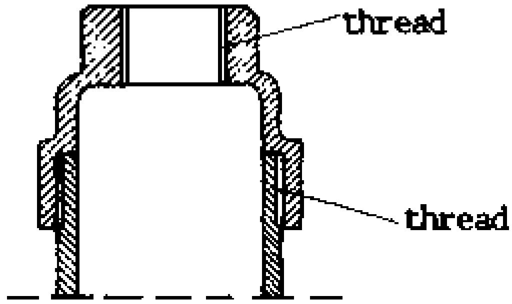
Thin, long chain: Direction of part on exploded diagram



Line, indicating name or part No.



Radius and centre



Two parts threaded together

O) <u>Measurements and Scales</u>

Always indicate on the bottom of your plan: “All measurements in m.” or “All measurements in mm.” Write only the figures into the dimension lines, without the unit. Commonly, steel construction and machinery is measured in mm; concrete, brick and timber work in m and cm. In this case 60 means 60 cm, not 60 m; and 1.60 means 1.60 m and not 1.60 cm.

The measurements in this manual are mostly indicated like the latter, in cm and m.

Indicate also the scale on the bottom of your plan.

The most common scales are:

1:10 means: 1 cm on the plan = 10 cm in reality = 0.10 m in reality
1:20 means: 1 cm on the plan = 20 cm in reality = 0.20 m in reality

1:50 means: 1 cm on the plan = 50 cm in reality = 0.50 m in reality
1:100 means: 1 cm on the plan = 100 cm in reality = 1.00 m in reality
1:200 means: 1 cm on the plan = 200 cm in reality = 2.00 m in reality

You can calculate the scales as follows:

$$\text{scale} = \frac{\text{length on plan}}{\text{length in reality}}$$

1. <u>Example</u>

How long do you draw 5 m in scale 1:20?

$$\frac{1}{20} = \frac{x}{5\,\text{m}}$$

$$x = \frac{5\,\text{m}}{20} = 0.25\,\text{m} = 25\,\text{cm}$$

2. <u>Example</u>

2.5 cm on a plan in scale 1:50 represents which distance in reality?

$$\frac{1}{50} = \frac{2.5\,\text{cm}}{x}$$

$$x = 2.5\,\text{cm} \times 50 = 125.0\,\text{cm} = 1.25\,\text{m}$$

6.2 Marking Rectangular Layout Plan

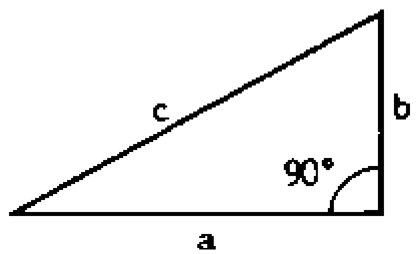
Many buildings are planned to be rectangular. It is very important that they are built in true rectangular shape with 90° angles at each of the four corners. If the walls are out of the rectangular shape, you will face difficulties when placing slabs, roof trusses, zinc sheets, roofing sheets, floor tiles, etc., later on. If the walls are rectangular, these parts will fit without any further adjustment. If not, lots of tiresome cutting or other manipulations will be necessary. Therefore, it saves time in the long run to spend efforts on the correct layout. The walls must be laid out correctly in the first place and the shape must be checked regularly.

There are two ways to mark a rectangular layout plan:

A) <u>3-4-5 Method</u>

This method is based on the Pythagoras theorem (see 5.5/1)

$\boxed{a^2 + b^2 + c^2}$



The numbers 3,4 and 5 fulfil the Pythagoras theorem:

$3^2 + 4^2$	$= 5^2$
$9+16$	$= 25$ ✓

This equation can be multiplied by any number on both halves of the equation and still fulfil the theorem, e.g.

$(3^2 + 4^2) \times 4$	$= 5^2 \times 4$
$3^2 \times 4 + 4^2 \times 4$	$= 5^2 \times 4$
$(3 \times 2)^2 + (4 \times 2)^2$	$= (5 \times 2)^2$
$6^2 + 8^2$	$= 10^2$
$36 + 64$	$= 100$ ✓

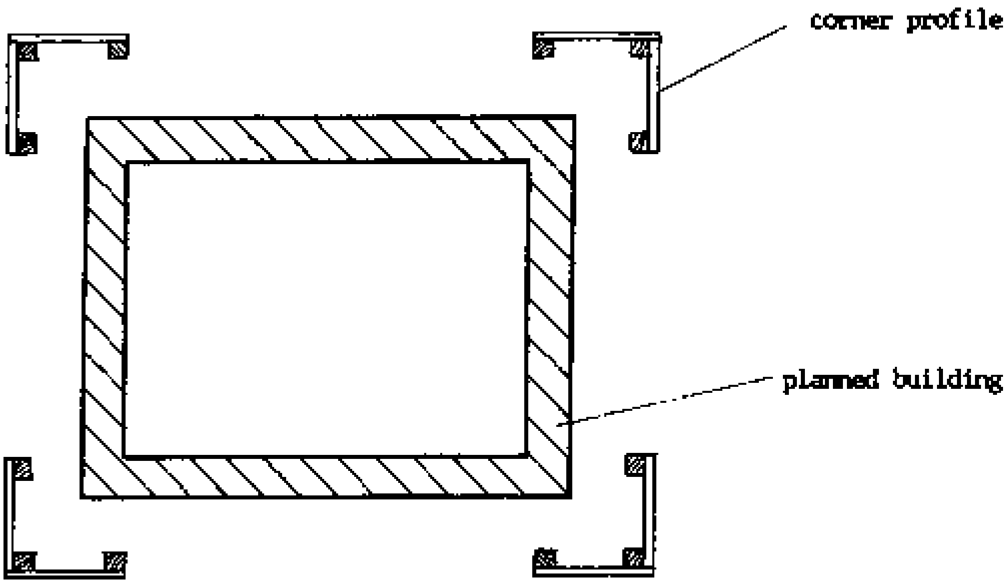
or

$(3 \times 0.50)^2 + (4 \times 0.50)^2$	$= (5 \times 0.50)^2$
$1.5^2 + 2.0^2$	$= 2.5^2$
$2.25 + 4.0$	$= 6.25$ ✓

Any triangle with the sides 3,4,5 or any multiples of 3,4,5 is a right angled triangle.

This connection is applied for marking a rectangular layout plan as follows:

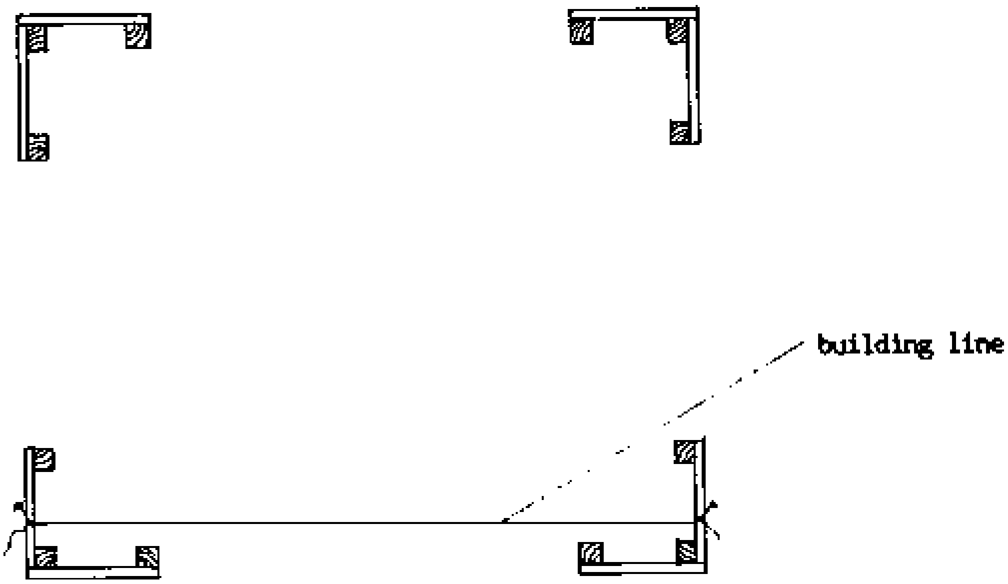
1. Place "corner profiles" outside the four corners of the planned building.



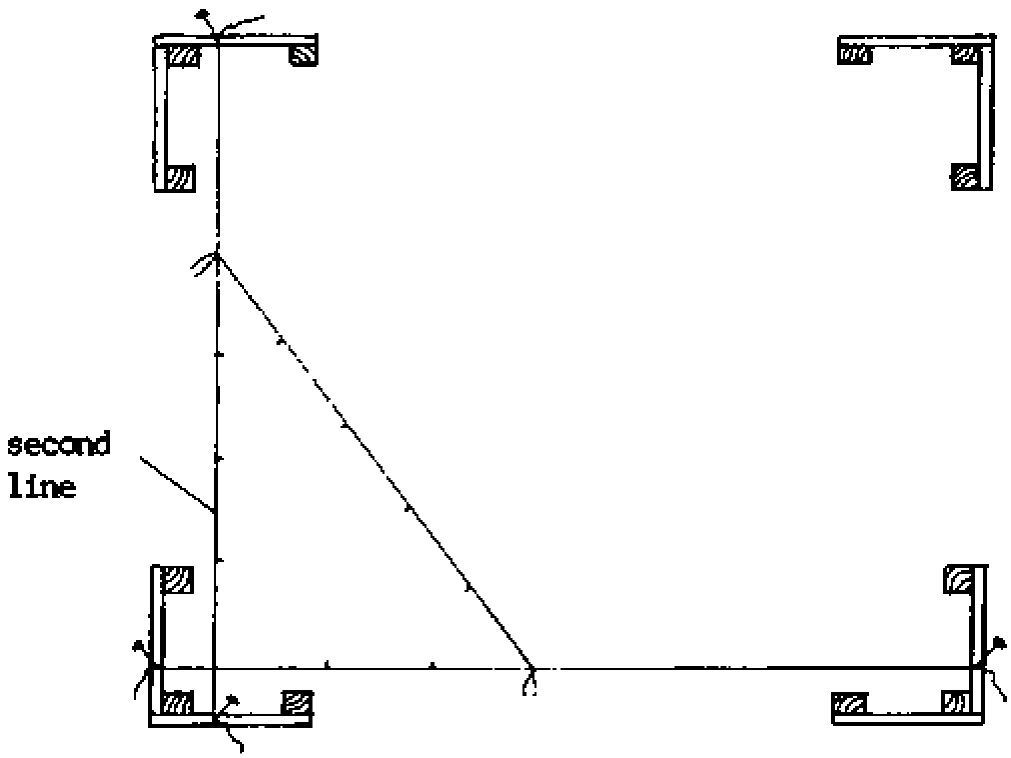
Make the corner profile itself right angled with the help of a carpenter's square.

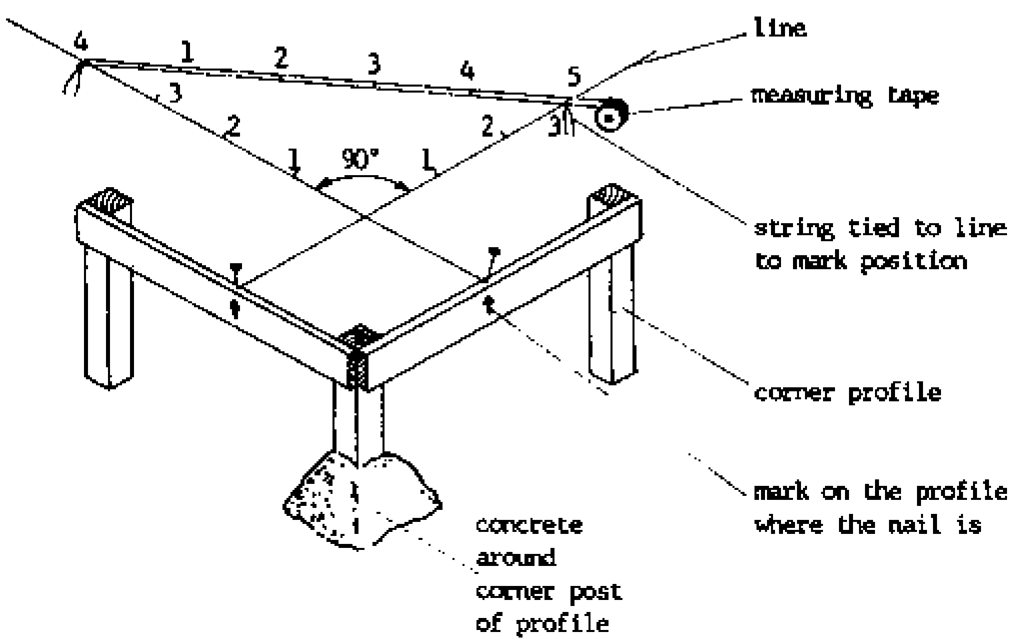
2. Put the corner posts of the profile into concrete to prevent movement.

3. Mark the first side of the building by connecting a line between a nail on one corner profile to a nail on the opposite corner profile.



4. Create a second line crossing the first one using the 3,4,5 method. Mark 3 units (e.g. 3 × 0.50 m = 1.50 m) along one side with a string, mark 4 units (e.g. 4 × 0.50 m = 2.00 m) along the other side. The angle is 90° if the distance between the two marks is 5 units (e.g. 5 × 0.50 m = 2.50 m). Fix the line with nails.





5. Connect all four sides like this taking care that the length of the sides is according to plan.

6. Check to see if the sides of the rectangle are according to plan and if the two diagonals are equal.

7. Mark the nails which indicate the layout plan to avoid confusion.

8. Plumb the layout on the ground with a plumb bob.

9. Remove the lines during construction and connect them again whenever you need measurements.

B) <u>Method Using Diagonal</u>

This method is useful for marking on level ground or on a cast (= poured) concrete floor. For example, you may mark the layout on cleaned and level ground and erect corner profiles afterwards (see A). The method is to be used as follows:

1. Calculate the diagonal of the rectangle with the given sides (see 5.5/1).

Example:

long side	1.90 m
short side	1.60 m
diagonal	2.485 m

2. Mark the long side of the rectangle (1.90 m) with nails (A) and (B).

3. Use a measuring tape stretched from corner (A) to create a diagonal that is 2.485 m long. This diagonal now becomes the radius of a circle drawn around (A) with a nail on the ground.

4. Repeat the method in number 3., using a radius that is 1.60 m long (the short side of the rectangle) around corner (B).

5. The intersection (= crossing point of the lines) of the two circles is the third corner (C). Mark it with a nail.

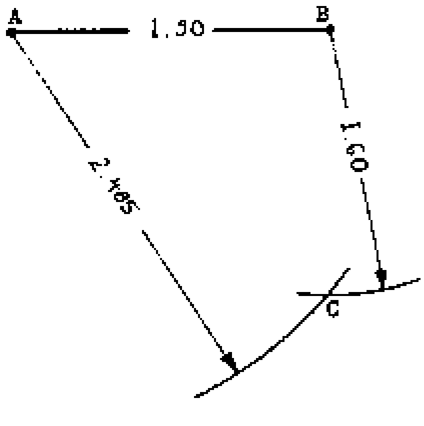
6. Repeat the method in number 3., using a radius that is 1.90 m long (the long side of the rectangle) to draw a circle around the third corner (C).

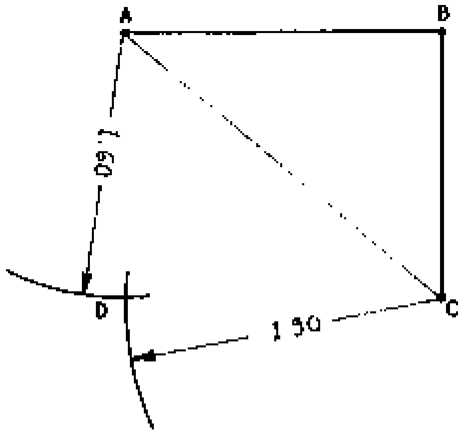
7. Draw a circle with the short side (1.60 m) around the first corner (A).

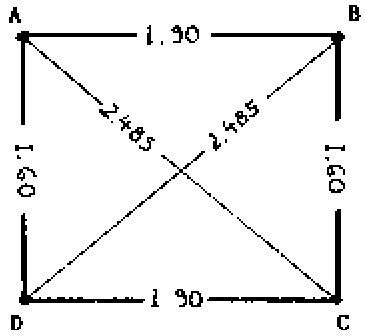
8. The intersection of the two circles is the fourth corner (D). Mark it with a nail.

9. Check if all the sides have the correct size.

10. Check if both diagonals are equal.







This method is very quick once the diagonal is known, and saves you difficult trial and error and corrections.

C) <u>Checking the Rectangular Shape during Construction</u>

The rectangular shape of the walls must be checked regularly (at least every metre). Always check the following <u>two</u> points:

1. Check if the length of the sides is correct.
2. Check if the two diagonals are equal.

The shape is rectangular only if <u>both</u> conditions are fulfilled. If not, make corrections; it may be tolerated if the diagonals differ by 1 cm, but not if they differ by 4-5 cm.

6.3 Tools

Tools are essential for good craft work. The technician must have a basic knowledge about tools in order to be able

- to select the suitable tools when purchasing,

- to use the correct tools for each purpose,

- to handle each tool in the right way to ensure optimal work and to avoid unnecessary damage,

- to maintain each tool properly to ensure its long life.

The most basic information about these points is collected in the chapter for the following kinds of tools (used in well construction and latrine building):

- general tools,
- special tools for concrete and brickwork,
- special tools for wood work,
- special tools for metal work.

Only the most basic tools of these groups are compiled here, because the purpose of the chapter is to give a first introduction about tools for a technician trainee, completely new in the field. She/he is introduced into the new vocabulary and has to learn the names, functions and proper handling. Add the local names by yourself. When the technician is acquainted with the tools compiled here, she/he needs to deepen her/his knowledge by further studies in tools' catalogues and literature and by asking experienced people.

The full names and, if existing, several ones are listed. These names are <u>not necessarily</u> the suitable ones for recording in the store. For example, a "square file", as listed here, is better recorded in the store as "file, for metal, square"; a "triangular file" is recorded as "file, for metal, triangular"; etc. Thus, the stock cards of all different files will be close to each other according to the alphabetical order (see also 7.9/1).

A) <u>General Tools for Different Purposes</u>

No.	Drawing	Name(s)	Description	Function	Remarks
1		measuring tape 2m, 5m = tape measure 2m, 5m = meter 2m, 5m = pocket measuring tape	with steel tape in enclosed metal case with spring return; graduation metric and inch	for measuring short distances in carpentry and concrete work or brickwork	for reading the meter see 6.4/5f; prevent tape from getting wet; if wet, dry immediately and oil it; prevent folds
2	Different alternatives for tape zero positions 	measuring tape 10m, 20m, 50m = tape measure 10m, 20m, 50m = meter 10m, 20m, 50m	steel, glass fibre or cotton tape in plastic frame with grip or in capsule with fold-away rewinding handle; sometimes plumb-loaded	for measuring long distances; for marking layout plans; for measuring well depth	rewind accurately; never rewind tape when it is wet; for reading the meter see 6.4/Iff

No.	Drawing	Name(s)	Description	Function	Remarks
3		caliper = vernier caliper	from polished steel, with knife-edged jaws for internal/external measurements and depth gauge; graduated in mm with vernier scale to read 1/10 mm; with thumb roller or friction lock	for measuring inside/outside diameters of pipes and internal/ external measurements and depth of grooves	for measuring, hold the caliper against the object as shown in the drawing; use the vernier scale if you want to read 1/10 mm
4		spirit level = carpenter's level	from wood or steel, with two vials, one level and one plumb; the vials are from glass filled with ether; a bubble can be seen	for levelling and plumbing short distances; see 6.4/9f	steel spirit levels are more sensitive on sun; never leave a spirit level in the sun!, once spoilt by heat, it cannot be repaired; check the spirit level for its accuracy on every possible occasion
5		plumb bob = engineering bob	from iron with brass knob and plumb line	for plumbing, especially in deep wells	for using the plumb bob see 6.4/11; never knot the plumb line!
6		spring balance	Tandy scale, with hook and spring	for rough measuring of kg	hang the weight to be measured on the hook and read the scale; might not be exact after some time
7		balance	with two bowls, to be used with weights	for exact measuring of weights	
8		blacksmithing hammer	one end rounded, the other flat	for blacksmithing	for all hampers: if loose, fix the head immediately with handle wedges (see No.12,6.3/6)

No.	Drawing	Name(s)	Description	Function	Remarks
9		carpentry hammer	with round, crowned face and split neck	for carpentry work	the neck is suitable to extract nails
10		bricklayer's hammer	square face, the other end sharp for cutting bricks	for bricklaying	
11		sledge hammer	square face and sharp end or double square face, differentiated according to weight	for heavy duty work	the handle must be fixed well
12		handle wedges = hammer bolsters	three-pronged wedges from steel	to fix the handle of a hammer	the handle must tightly fit the hole; additionally, hammer the wedge into the handle from above
13		breast drill = drill brace = carpenter's brace	with four jaws; with eight-tooth ratchet and ball bearing head	for drilling holes in wood	for square shank bits; lean against the breast drill to improve drilling
14		hand drill	with three-jaw chuck, handles, two gears	for drilling holes in metal, wood, etc.	for round shaft bits
15		drilling machine = rotary drill = portable drill	electrical machine with three-jaw chuck, with key for opening the chuck, electrical cable and plug	normal drilling for wood, metal, etc., marked with ; percussion drilling for stone, concrete, marked with ; percussion means that the bit drills <u>and</u> taps against the object	for round shaft bits; start the machine before touching the object; drill straight

No.	Drawing	Name(s)	Description	Function	Remarks
16		drilling bit for stone = masonry drill = concrete drill	with round shank for hand drill or electrical drilling machine; the tip has a hard metal or carbide edge	for drilling brick, stone, concrete, glass, etc.	never use lubricants! the drill should be withdrawn regularly to avoid overheating
17		drilling bit for metal = twist drill	with round shank for hand drill or electrical drilling machine	for drilling metal	avoid blue coloured metal chips by reducing drilling speed; blue colour indicates overheating
18		drilling bit for wood = lamp base drill	with centre tip and side cutters, with round shank for hand drill or electrical drilling machine	for drilling small diameter holes in wood	first press the tip against the wood, then start to drill
19		centre bits	with round shank for hand drill or electrical drilling machine	for drilling large diameter holes in wood	see above
20		expansive bits	with square or round shank for all types of drills	for drilling large diameter holes in wood	see above; the bit is adjustable to any diameter
21		drilling bits for wood = solid centre auger bits	with square shank for breast drill, screw tip and feed screw	for drilling wood	see above
22		pickaxe	From steel, with one broad sharp and one pointed end and wooden handle	for loosening hard soil when digging	the handle must not move in the pickaxe
23		crowbar	thick iron bar with one pointed and one split or sharp flat end in different sizes	for digging pits or wells	keep the edge sharp

No.	Drawing	Name(s)	Description	Function	Remarks
24		shovel	metal shovel with tip and long wooden handle	for lifting sand, earth, gravel, concrete, etc.	wash the shovel always immediately after work
25		spade	shovel-like tool, but with straight edge	for cutting and digging into soft soil with additional help of the foot	put your foot on the spade and press it into the soil with the help of your body-weight; then take the cut soil out using the spade as a lever
26		wheelbarrow	with one tyre (full rubber or with inner tube), strong frame and two handles	to move loads	keep the wheelbarrow clean and well greased; can be made locally from timber
27		whitewash brush = chalk broom	soft nylon brittles in square wood with handle	for quick painting of large areas with whitewash	wash immediately after use
28		flat paint brush	light bristles with wooden handle; in different sizes, sane-times with bucket rest	for painting with all kinds of paints	never allow paint to dry on the brush, but clean it immediately after use
29		universal knife = break-off blade knife	pocket knife with sliding blade with plastic cover; the blade has perforations	for cutting nylon sheets, carton, etc.	break off the tip of the blade when not sharp; the new tip will be sharp
30		funnel	from plastic or metal, sometimes with sieve	for pouring fuel, etc. into small openings	
31		safety helmet	from plastic with rain gully; textile fittings, leather sweat-band, tape fastening	to reduce the risk of injuries from falling objects	always wear a safety helmet inside the well see 8.21

No.	Drawing	Name(s)	Description	Function	Remarks
32		safety belt	with broad belts from nylon around chest and shoulders	for lifting and catching a person	use in all risky situations; see 8.21, 8.22
33		pulley = pulley block	with single or double or triple roll from steel, eye and hook; sometimes with hinged snatch for easy removal of a cable with a swivel hook on the end	for pulling ropes, steel cables, etc.	see 8.17/19; never use a pulley which is broken in any of its parts; grease regularly; avoid friction between rope and frame
34		rope	from sisal, hemp or nylon, with different diameters	for pulling loads	for details see 8.23

B) Special Tools for Concrete and Brickwork

No.	Drawing	Name(s)	Description	Function	Remarks
35		trowels	from forged steel with wooden handle, in different shapes and sizes	for brick and concrete work; for spreading mortar; for rough cutting of bricks	for using the trowel see 6.7/10f; never allow mortar to get hard on the trowel
36		pointing trowel	thin trowel	for pointing and other fine work	see above
37		plasterer's trowel	triangle trowel	for plastering	see above
38		finishing trowel	square trowel	for smoothing and finishing plastering	see above
39		float	wooden smoothing trowel	for rough smoothing of (concrete) surfaces	can be manufactured locally
40		spatula	flat metal with handle in different sizes and shapes	for filling holes with gypsum and smoothening surfaces	

No.	Drawing	Name(s)	Description	Function	Remarks
41		bricklayer's line	nylon thread	for building a straight line	
42		straight edge	from dry timber or steel	for making level floors	check the straight edge by looking along it; do not leave it in sun or rain
43		earth pan	locally made flat bowl from metal	for carrying mortar	never allow mortar to get hard on it, because it will increase its weight
44		bucket	from zinc or plastic	for carrying material	never use buckets with worn handles in wells
45		sieve	with wire mesh in different sizes in wooden frame	for sieving sand and gravel; see 8.20/1	sieve with two people
46		wrecking bar	from a steel bar; one end bent with a slot, the other end sharp	to be used as lever arm; for removing nails, shutters from concrete; for rough work	make full use of the lever arm
47		wire brush = steel hand-brush	brush with wire bristles and wooden handle in different sizes	for dry cleaning of tools and equipment	keep the brush dry
48		nylon brush = panel brush	brush with nylon (synthetic fibre) bristles in a wooden frame	for wet cleaning of tools and equipment	always clean tools immediately after work
49		bolt cutter	with clipper cut jaws and exchangeable blades	for cutting reinforcement rods	place the bolt to be cut at the end of the blade to make full use of the lever arm

C) <u>Special Tools for Woodwork</u>

No.	Drawing	Name(s)	Description	Function	Remarks
50		cross-cut saw	long saw with big teeth and two wooden handles to be used by two people	for cutting logs into sawn timber	<u>for all saws</u>: never use force, but saw with speed instead and avoid bending the saw
51		bow saw	made of oval steel tubing in the shape of a bow; the blade can be exchanged; with tensioning arm to put the blade under tension	for cutting logs, poles, rough work	cut by drawing and pushing motion but with very little pressure downwards
52		turning saw = joiner's bow saw	wooden frame with blade, handles, wire for tightening the blade	for cutting sawn timber; for exact work	fix the blade; tighten the wire and the blade by turning the adjusting nut
53		land saw	with straight teeth or universal teeth; with wooden or plastic handle; in different sizes	for cutting timber	see bow saw
54		tenon saw = dove-tail saw	with square blade and wooden or plastic handle	for cutting deep grooves into timber	
55		compass saw = keyhole saw	very thin blade with handle	for cutting small holes into timber	
56		plane	from steel or wood with handle and knob, smooth sole, blade and screw for adjusting depth of the cut	for smoothing wooden surfaces	always clean the surface of the timber to be planed; the blade must be sharp and straight; never use the plane with force

No.	Drawing	Name(s)	Description	Function	Remarks
57		rebate plane	plane with a special blade for a rebate	for cutting rebates	see above
58		spokeshave	with cap and single cutter	for smoothing and rounding curved surfaces	see above
59		wood chisel	with sharp edge, a chamfered (= bevelled) blade and wooden handle	for cutting holes into wood	use a wooden mallet, never an ordinary hammer; sharpen the chisel often; do not use it as a lever arm; hold it as shown in the drawing
60		wooden mallet	special hammer from wood	for working with wood chisels	see above
61		rubber mallet	special hammer from solid rubber with wooden handle	for hammering without damaging the object	
62		sharpening oil stone = hone stone	stone fixed in wooden box; combination stones are coarse on one side and fine on the other	for sharpening tools	sharpen with long, even movements; always use with oil; sharpen your tools often (after every half hour)

No.	Drawing	Name(s)	Description	Function	Remarks
63		table grinder = bench grinder	hand operated grinder with grinding wheel	for sharpening tools	hold the tool to be sharpened against the turning grinding wheel, it must lay parallel and flat against the wheel; never use force
64		screw auger	auger with screw tip and opening for a handle	to drill large holes into wood without a machine	fix a handle in T-form and drill
65		wood rasp	with a series of pointed, individual teeth	for rasping wood, for coarse work in soft material	keep the rasp dry and clean
66		sand paper = flint paper = abrasive paper	strong paper coated with flint	for manual sanding of wood	put the sand paper around a piece of wood for proper grip
67		clamp	with bar of steel, strong jaws, a screw with plastic-ball jointed shoe and wooden handle, or steel T-handle; with short or long bar	for fixing a piece to the working bench or for pressing wooden frames together after gluing	push the jaws together on the pieces to be fixed, then screw the handle tight
68		sash clamp	long clamp	for pressing door frames or other large objects together	push the jaws together on the piece to be fixed, place the pin into the next hole, then screw the handle tight

No.	Drawing	Name(s)	Description	Function	Remarks
69		work bench	with built in vices; with wood spindles	for carpentry work	locally made work benches can be equipped with a vice
70		trysquare = square	metal square with right angle; with stock and blade	for marking right angles or 45° on timber	the stock must be well pressed against the timber when marking
71		marking gauge	with scribing bar, graduated in mm	for marking carpentry work	
72		axe	with broad edge and wooden handle	for splitting wood, cutting trees, preparing poles, etc.	keep the axe sharp

D) Special Tools for Metalwork

No.	Drawing	Name(s)	Description	Function	Remarks
73		pliers = combination pliers	with single joint, pipe jaws, serrated gripping surfaces and two plastic covered handles	for all kinds of work	
74		pincers	with single joint and two handles	for tying reinforcement with wire, for cutting wire, for extracting nails	for tying reinforcement do not press the pincers too much; for extracting nails use the lever arm (see drawing)

No.	Drawing	Name(s)	Description	Function	Remarks
75		self-grip wrenches = vice-grip pliers	with serrated (= toothed), adjustable jaws with pipe grip; can be locked on the job and stay locked with hands removed; with quick-release lever (spring loaded)	for different kinds of work	adjust by end-adjusting screw until jaws slip over the work, then snap handles shut and jaws will engage with powerful grip; release with release lever
76		zinc cutter=hand snips=hand shears	with snips and two handles	for cutting zinc or other metal sheets	sharpen the snips from time to time
77		punch	with sharp tip	to mark a point on a piece of metal or make a start for a twist drill (No.17, 6.3/8)	
78		screwdriver	with wooden or plastic handle, sometimes with hexagonal shaft which facilitates the use of spanners for tightening	for screwing screws with slot head	never use a screwdriver as lever arm; take care not to damage the tip
79		cross-screwdriver = Philips screwdriver	with wooden or plastic handle	for screwing screws with Philips head	a cross-screwdriver does not slip away easily
80		open-ended spanner = open-ended wrench	double ended, with jaw angles 15°, in different sizes, often in sets	for locking and tightening bolts and nuts	only use fitting spanners; carefully fit them on the nuts; do not damage the jaws
81		ring spanner = box wrench	double ended with 12-faced rings, in different sizes	for loosing and tightening bolts and nuts; more force can be inserted than with open ended spanners	only use fitting spanners; place the spanner carefully on the nut

No.	Drawing	Name(s)	Description	Function	Remarks
82		adjustable spanner = adjustable wrench = crescent wrench	with movable jaws, adjusted by a screw	for loosing and tightening bolts and nuts of any size	adjust the jaws so that they grip the nut exactly
83		alien keys = alien wrench	hexagonal rod in L-shape; in different sizes; often in sets	for hexagonal socket heads	use the long end as a lever arm
84		socket sets	with bi-hexagonal sockets in different sizes and ratchet handle	:or loosing and tightening bots and nuts	fit the socket on the nut and tighten with the ratchet handle; quicker work than with ring spanners; more force can be applied
85		cold chisel	made from specially treated steel	for cutting metal pieces or cutting holes into brickwork and concrete	keep the tip sharp; never allow the other end to become mushroom shaped
86		hacksaw frames	steel frame with handle and blade holders	for sawing metal parts	the blade must always be tight; do not apply force when sawing; always mount blade so that teeth will cut on the push stroke, see drawing; see also 8.32/12
87	 Choice of suitable blade for different materials: At least three teeth should be in contact simultaneously. 	hacksaw blades	steel blade with teeth	for sawing metal parts	do not try to saw with worn-out blades, but replace them; never replace a blade in the middle of a cut, because this would spoil the new blade; see also 8.32/12

No.	Drawing	Name(s)	Description	Function	Remarks
88		angle grinding machine = angle grinder	electrical machine for cutting and grinding discs	for cutting and grinding	hold the machine firmly; always use eye-protectors
89		cutting disc = cutting-off wheel	consisting of cutting medium and bonding agent according to the material to be cut	for angle grinder	use only for cutting, never for grinding; tighten the disc safely; never use force; touch the object to be cut vertically and without pressure
90		grinding disc = grinding wheel	consisting of grinding median and bonding agent according to the material to be ground	for angle grinder	use only for grinding never for cutting; tighten the disc safely; grind without pressure
91		shrubbing disc	from soft material	for angle grinder	use only for smoothing the surface
92		eye protectors = safety goggles	plastic glasses with front and side protection	for protecting the eyes	always use eye protectors when cutting and grinding
93		set of welding equipment	consisting of welder's screen, 2 cables with connections, 1 electrode holder, 1 earth clamp, 1 wire brush, 1 chipping hammer	for welding	the cable area Ø must fit the welding generator's specification

No.	Drawing	Name(s)	Description	Function	Remarks
94		soldering iron	with square copper section and wooden hand grip	for soldering	warm up in open fire and solder
95		anvil	with plane work surface	for blacksmithing	the anvil must be mounted on a wooden block to absorb vibration
96		flat file	of rectangular shape, one edge uncut, with double cut	for sharpening flat metal surfaces and sharp corners and blunts	for all files: keep them dry and clean
97		three-square file = triangular file	double cut sides, uncut top	for finishing inside corners, slots, etc.	
98		square file	double cut on all four sides	for filing grooves, rectangular holes and inside shoulders	
99		round file	double cut	for round and concave surfaces	
100		half round file	double cut, all around	for finishing concave and plane surfaces and larger holes	
101		file brush = file card	fine and flat wire inrush	for cleaning files	keep the brush dry
		<u>Length:</u> The length of the file does not include the tang (= the projecting part by which the blade is held in the handle). The length of the file should be chosen according to the size of the workpiece: the larger the workpiece, the larger the file. It is better to choose a file that is too long than one that is too short to ensure stability when working.		<u>Cut:</u> Files are divided into four cuts: single, double, milled tooth, and rasp. Single cut files are for filing steel and metals with normal working pressure. Double cut files consist of two diagonal cuts. They are used at higher working pressure than single cut files for iron, steel, but also plastics, wood, etc.	

No.	Drawing	Name(s)	Description	Function	Remarks
		Degree of Coarseness: Files are divided into the following degrees of coarseness: rough, bastard, median-fine, fine. Fine files are used for hard material where a good finish is required, while coarse files are used on soft material where a rough surface can be tolerated.		Milled tooth cut files are used for smoothing the surface in car-body repair work. The teeth form curves over the surface of the file. Rasp cut files have a series of pointed, individual teeth. They are used for coarse work in soft material, e.g., wood, plastic, aluminum, leather, etc.	
102		vice	with steel jaws and spindle; sometimes, pipe jaws under the smooth jaws	for holding items firmly	keep the vice well greased; do not use force
103		pipe vice	with pipe support and ringed jaws	for holding pipes firmly	keep the vice well greased
104		chain pipe vice	the pipe is held all around with a chain	for holding pipes firmly	fix the chain as firmly as possible, then screw the handle
105		pipe wrench Swedish type	with two serrated jaws, adjusted with a positioning screw; the jaw angle can be 90° or 75°; with two handles; in different sizes	for fixing threaded pipe joints	for handling pipe wrenches see 8.32/14f; optimal grip only in one direction

No.	Drawing	Name(s)	Description	Function	Remarks
106		pipe wrench British type	with two serrated jaws, adjusted with a positioning screw; with a spring; only one handle	for fixing threaded pipe joints	grip only in one direction
107		chain wrench	with chain, double toothed, reversible jaws and one handle	for fixing and holding pipes or irregularly shaped objects	fix the chain as firmly as possible, then move the handle; grip in both directions possible
108		pipe cutter	with cutting wheel, two guiding wheels and adjustable handle	for cutting pipes	never use force; fit the cutter on the pipe, screw the handle until the cutting wheel touches the pipe cut one round, screw the handle, cut one round, etc.; always use cutting oil; see 8.32/12
109		thread tap	with straight flutes to deliver the swarf (= chips) out of the hole; with square shank	for tapping (= cutting) internal threads for bolts and pipes; the tap must fit to the specifications of the thread (for threads, see 8.32)	always use with thread cutting oil; never apply force
110		series taps	for pre-cutting, medium cutting and fine cutting	for tapping internal threads with very good finish	the three taps have to be used one after the other
111		tap wrench	adjustable for different taps, with two handles	for holding taps	

No.	Drawing	Name(s)	Description	Function	Remarks
112		threading dies = threading dice	round dies	for threading external threads of bolts, pump rods, etc.; the dies must fit to the thread specifications (for threads see 8.32]	check for starting point by noting the tapered side (not the sharp side); use the dies always with thread cutting oil; never apply force
113		die stock	for different dies with two handles	for holding dies	fix the die in the stock as shown in the drawing
114		tap and die sets	contain tap and dies of different sizes, complete with tap wrench and die stock in a box	for cutting internal/external threads of bolts; the taps and dies must fit to the thread specifications (for threads see 8.32)	the taps and dies are well protected and complete in a set, however, some diameters wear out quicker than others
115		pipe thread die stock (with chaser dies) = pipe threader = thread cutter for pipes	with ratchet; automatic centering; right and left hand threading possible; chaser dies can be exchanged Ear taper or cylindrical threads; one set of chaser dies suitable for different pipe diameters, because the diameter can be adjusted	for cutting external pipe threads; one die stock can be used for different threads	always insert the chasers in the indicated order; suitable also if the pipe ∅ is different from the specifications; open the chaser dies after threading, screwing back on the thread is necessary; the ratchet allows to turn the handle conveniently back and forth instead of screwing continuously
116		chaser dies	4 chaser dies in one set, suitable for different pipe diameters, because the diameter can be adjusted	for fitting into pipe thread die stock	replace the chaser dies if worn out or chipped (= part broken off)

No.	Drawing	Name(s)	Description	Function	Remarks
117		pipe thread die stock (with separate screw heads)	separate screw heads for each diameter; with right or left hand ratchet	for cutting external pipe threads; the screw heads must fit to the thread specifications (see 8.32)	quick change between various thread sizes; the pipe diameter must fit exactly to the specification
118		thread gauge = screw pitch gauge	folding blades with gauges for different threads	for measuring internal and external threads	hold the gauge against the thread; if it fits read the specification
119		cutting oil = thread cutting oil	there are two types: 1. on biological base for threading drinking water pipes 2. on mineral base for all other threads	for lubricating and cooling while threading	continuous lubrication is necessary; this will ensure better threads and increased life of the threading tools
120		oil can	with reservoir, spout and pressure pump	for oiling tools, etc.	keep the spout clean
121		lifting hook = swivel hook	from forged steel with safety catch	for lifting weights	the safety catch must be intact and the load must hang inside the safety catch; see also 8.17/20

No.	Drawing	Name(s)	Description	Function	Remarks
122		thimble	drop-shaped, from galvanized steel	for permanent eyes of steel cables	tighten the wire rope grip closely to the thimble; see also 8.17/16
123		shackles = D-shackle	U-shaped with bolt, different sizes for different weights	for connecting the eye of a steel cable with other elements	see also 8.17/19
124		connecting links	eye from steel rod which can be opened; alternatively with screwed connection	for quick connection of steel cables, ropes	see also 8.17/19
125		wire rope grip = wire rope clamp = cable clamp	the cables to be connected are inside a U-bolt and a cross piece is pressed against them by nuts	for fixing two wire ropes (= steel cables) together	for lifting devices use 3 wire rope grips for each connection; see 8.17/16
126		hose clips	from steel band with rolled-up band edges to prevent the band from cracking, tightened with bolt	for tightening hoses on a fitting	use 2 hose clips for each connection

6.4 Using Measuring Tools

Correct measuring is essential for good quality technical work. Many mistakes happen due to incorrect use of measuring tools. The technician needs to learn and practise the correct use of measuring tools.

The most basic measuring tools such as measuring tape, spirit level and plumb bob are explained here.

A) Measuring Tape

The tool for measuring distances is called “measuring tape”, “tape-measure”, or “meter”.

Note:

meter = measuring tool metre = unit of length in metric system

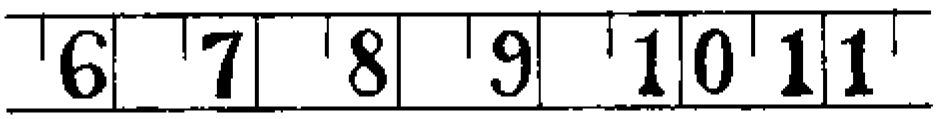
Measuring tapes are supplied in different length: 2m, 5m, 10m, 30m, 50m, etc.

Note that all illustrations in this chapter are not to scale!

1. Reading Measuring Tapes 10m, 30m, 50m (see also 6.3/2f)

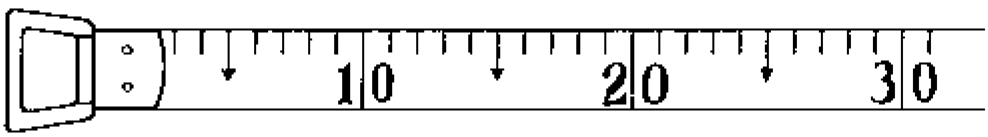
Long measuring tapes are normally from flexible material like plastic. The tape is wound up into a round box. Often metric measurements are on one side of the tape, and British measurements are on the back.

The tape is marked with short lines and long lines crossing the whole width of the tape. Only the long lines are marked with numbers. If the number consists only of one figure, the figure stands left from the line. If it consists of two figures (or a figure and a letter), they are left and right from the line:



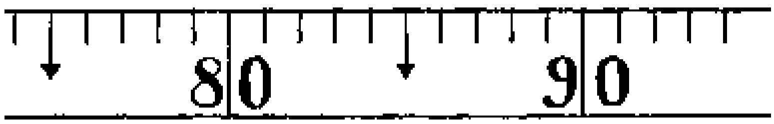
a) Measuring Tape in Metric System

The tape in the metric system measures m, dm, cm.



The short lines indicate cm. Every fifth cm is indicated with a longer line with arrow for better orientation. No numbers are given for cm. You have to count them yourself. Every tenth line is a long line and is indicated with the appropriate length.

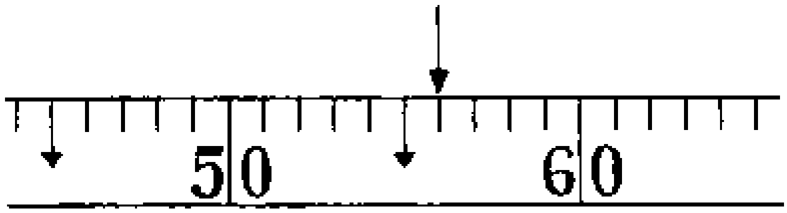
For example:



These numbers in black (the two figures left and right of the long line) indicate cm.

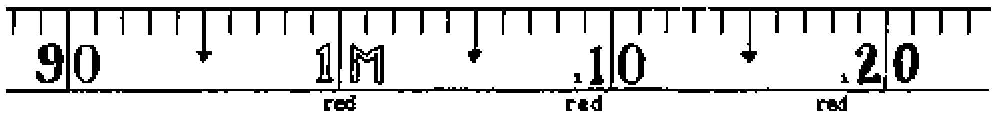
For measuring a length between two numbers:

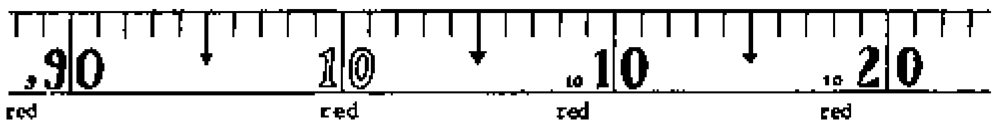
- Read the previous cm indication.
- Count the cm.
- Add the two.



Previous cm indication:	50 cm
cm counted:	6 cm
length measured:	56 cm

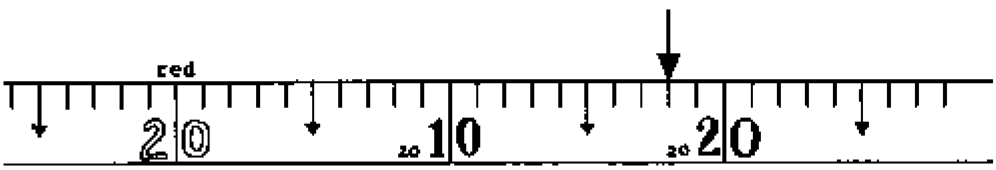
Full metres are indicated as 1 M; 2 M; ... 9 M; 10,11,..., and are printed in red for differentiation. Any black number for cm beyond 1 m is marked with a small red number indicating the metres.





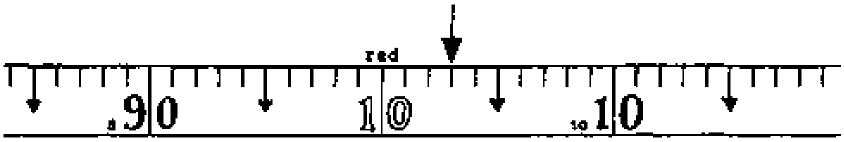
Read measurements bigger than 1 m as follows:

- Read the previous small read number as m.
- Read the previous number in black.
- Count the cm.
- Change all into one unit (e.g. m). For transformation see 5.3/1.
- Add the three.



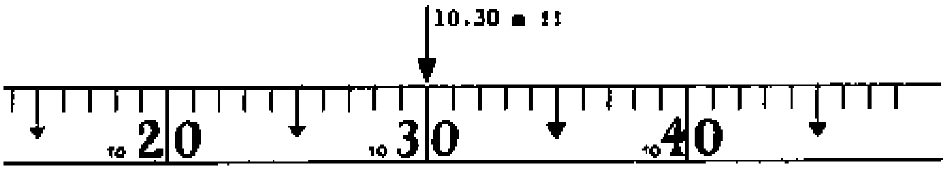
Previous m indication:	20 m =	20.00 m
previous cm indication:	10 cm =	0.10 m
cm counted:	8 cm =	0.08 m
length measured:		20.18 m

Take special care immediately after a m indication:



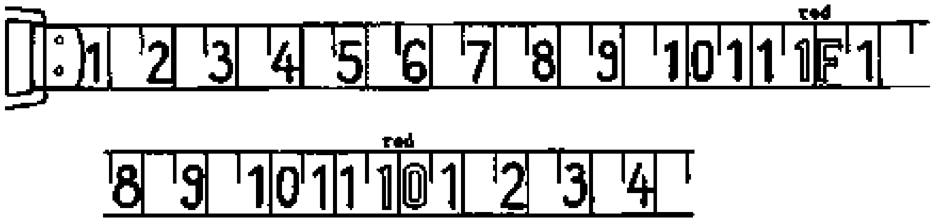
previous m indication:	10 m =	10.00 m
previous cm indication:	- -	
cm counted:	3 cm =	0.03 m
length measured:		<u>10.03 m</u> **!!**

For comparison:



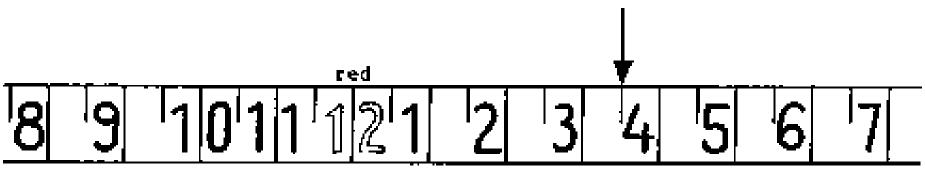
b) <u>Measuring Tape in British System</u>

The tape in British system can measure inch (= ") and feet (= '). The short lines indicate half inches. The long lines indicate inches; the numbers are given in black. If the number consists of two figures, one is left, the other right of the relevant line. Inches are numbered from 1 to 11. The twelfth inch completes a foot which is indicated in red as 1 F, 2 F,... 9 F, 10,11, etc.



Read measurements as follows:

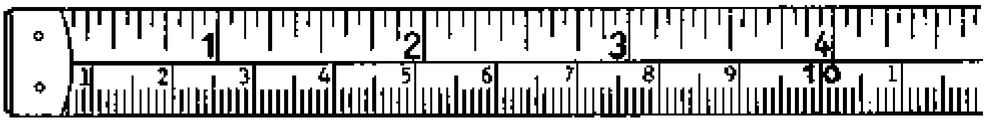
- Read the previous red figure as foot.
- Read the previous black figure as inch.
- Read $\frac{1}{2}$-inch.
- Add up the three.



previous foot indication:	12'
previous inch indication:	3"
half inch:	$\frac{1}{2}$"
length measured:	$12'3\frac{1}{2}$"

2. Reading Measuring Tapes 2m, 5m (see also 6.3/2f)

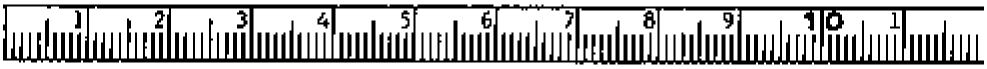
Short measuring tapes are usually made from a stiff metal strip, wound up by a spring into a small, handy round or square box. Often the tape shows British measurements on the top half and metric measurements in the bottom:



Read either of them, but keep them strictly apart, especially the numbers, and be careful not to get mixed up.

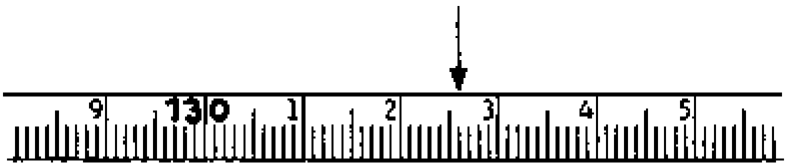
a) Metric Side

On the metric side you can measure cm and mm. The short lines indicate mm without numbers. You have to count them yourself. Every fifth mm (= $\frac{1}{2}$ cm) is indicated with a middle size line for easier counting. Every tenth line is a long line marked with a number which indicates cm from 1 cm to 9 cm. Every tenth cm is indicated with a **fat number: 10, 20,...90.** After each of these, the cm are marked again from 1 to 9. 1 m is indicated as **100** cm.



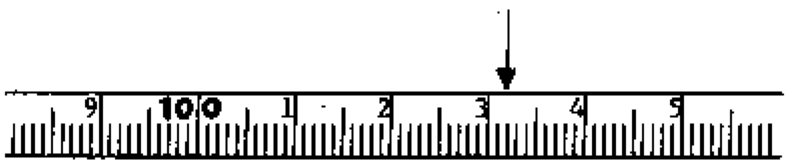
Read the measuring tape as follows:

- Read the previous **fat** number (with 2 or more places) as cm.
- Read the previous single number as cm.
- Count the mm.
- Change the mm into cm. For transformation see 5.3/1.
- Add all three.
- Change to m, if necessary.



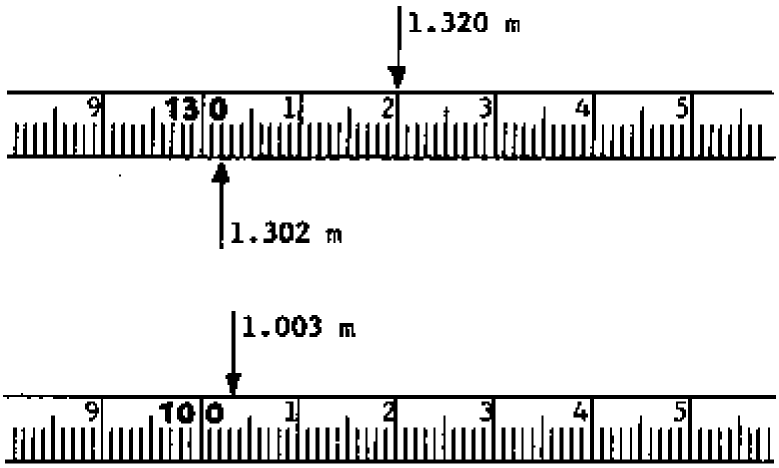
previous **fat** number:	130 cm =	130.0 cm
previous single number:	2 cm =	2.0 cm
mm counted:	6 mm =	0.6 cm
length measured:		132.6 cm = 1.326 m

Take special care immediately after a m indication:



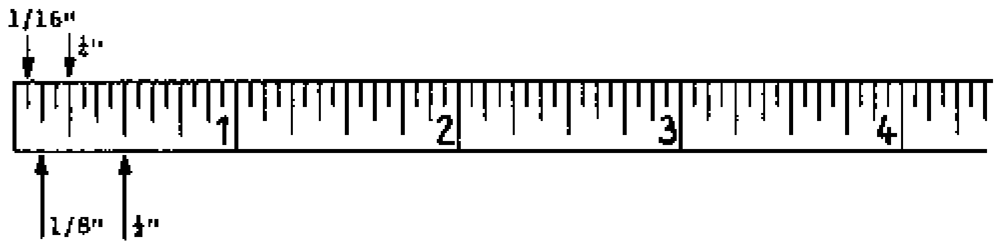
previous **fat** number	100 cm =	100.0 cm
previous single number:	3 cm =	3.0 cm
mm counted:	2 mm =	0.2 cm
length measured:		<u>103.2 cm = 1.032 m</u>

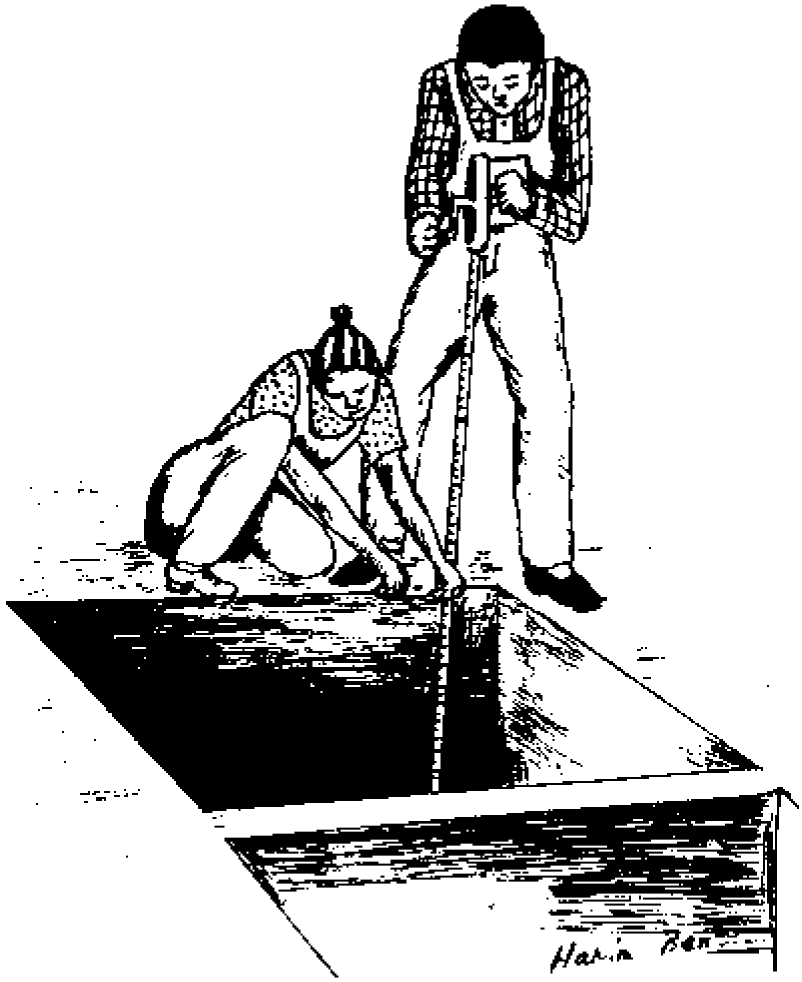
For comparison:



b) <u>British Side</u>

On the British side you can measure inches, $\frac{1}{2}$ “, $\frac{1}{4}$ “, $\frac{1}{8}$ “, $\frac{1}{16}$ “. The short lines indicate $\frac{1}{16}$ “; every second short line is a bit longer and indicates $\frac{1}{8}$ “; every fourth line is middle size and indicates either $\frac{1}{4}$ “ or $\frac{1}{2}$ “, all of them without numbers. Every long line indicates an inch with its number.



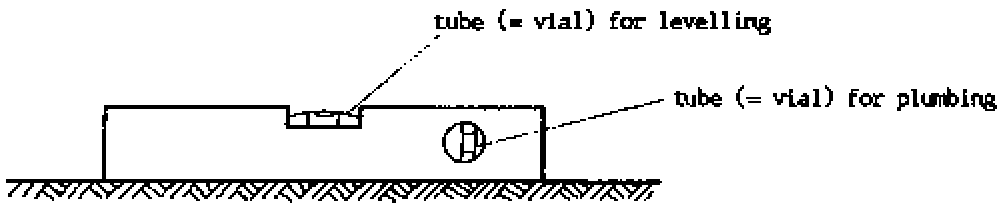


B) Spirit Level (see also 6.3/4f)

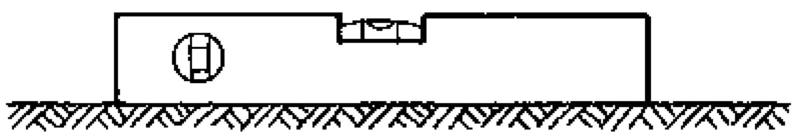
A spirit level (= plumb level) can measure whether a floor is level (= horizontal) or a wall is plumb (= vertical).

For levelling, use it like this:

- Lay the spirit level on the object to be levelled.
- Wait until the bubble has settled in the tube.
- The object is level if the bubble is in the middle between the 2 marks on the tube:



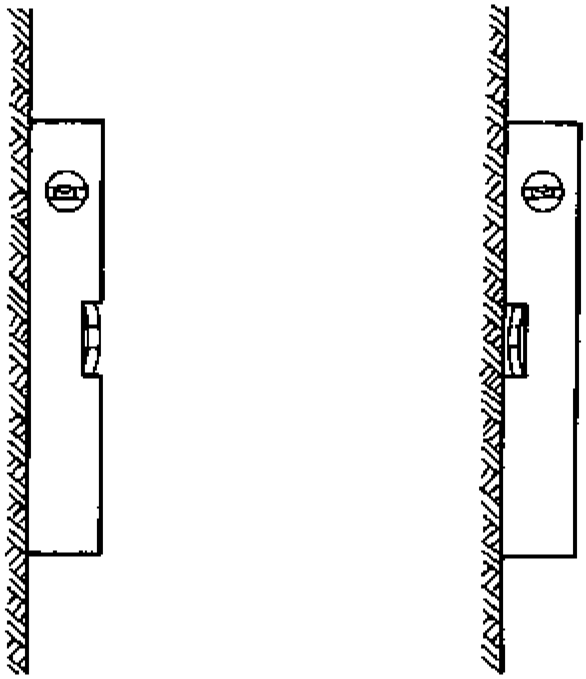
- Turn the spirit level like this:



If the indication is the same, the spirit level is functioning well.

For plumbing use it like this:

- Press the spirit level flat against the wall. There must be no gap between the spirit level and the wall.



- Wait until the bubble has settled in the tube.

- The wall is plumb if the bubble is in the middle between the two marks on the tube.

- Turn the spirit level with its other edge against the wall. If the indication is the same, the spirit level is functioning well. (see drawing above).

C) Plumb Bob (see also 6.3/4f)

A plumb bob (= engineering bob) measures whether a wall, a well, etc., is plumb (= vertical) or not. For a deep well a plumb bob is more practical than a spirit level.

Use it as follows:

- Hold the wooden peg of the plumb bob against the wall.

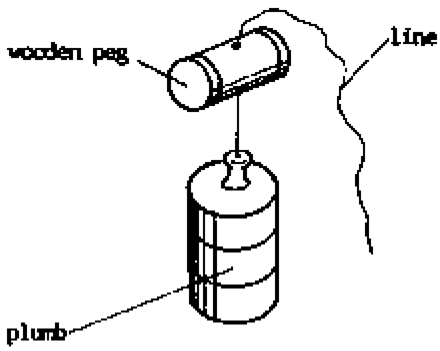
- Slowly allow the plumb to move downwards by releasing the line. Avoid swinging movement.

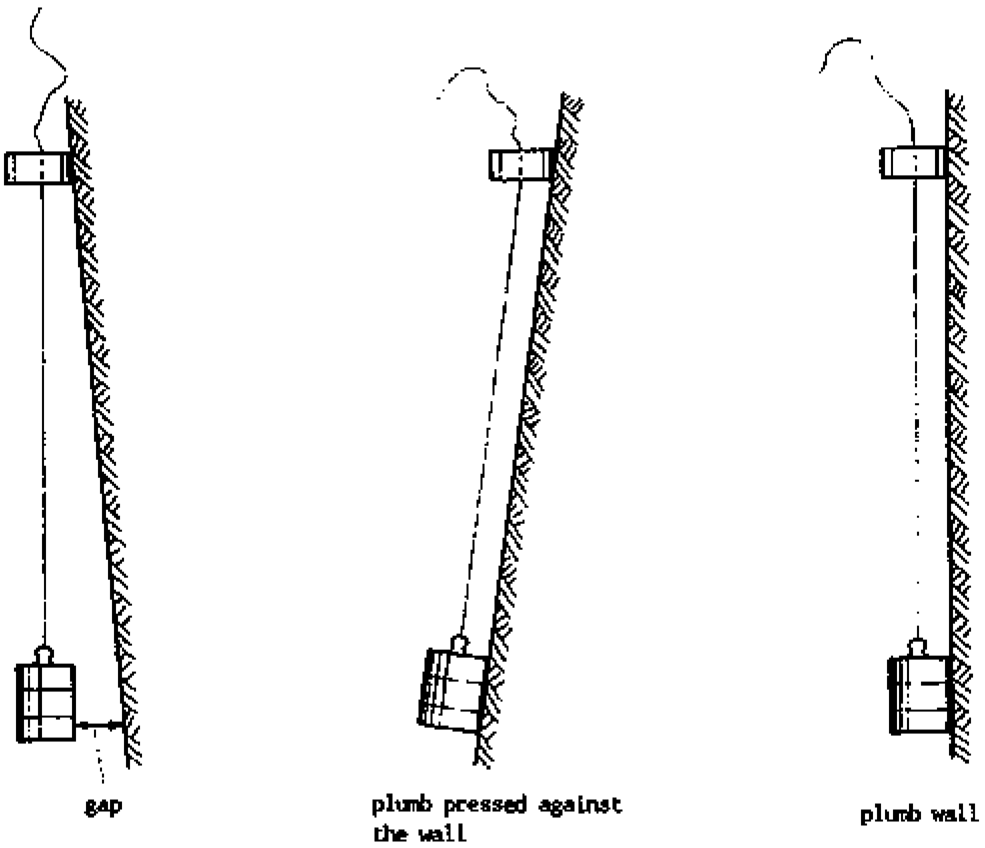
- If there is a gap between plumb and wall, the wall is not plumb.

- If the plumb is resting against the wall, the wall is not plumb.

- If the plumb freely hanging just touches the wall, the wall is plumb.

- If the line is torn, replace it with a new line - never knot it.





6.5 Building and Other Materials

Mt 7,24-27

The main features and properties of building and other materials are listed below in brief form.

A) Materials for Walls, etc.

1. Concrete

see chapter 6.6

2. Brick

- made from fired clay,
- lots of firewood needed and, therefore, deforestation encouraged,
- good strength,

- good resistance against weathering,
- fire resistant,
- good heat insulation,
- good sound insulation,
- allows moisture movement in the wall,
- recycling possible.

3. Mudblocks (see also 6.8)

- produced as sun-dried clay brick

- better quality if about 30% sand and 5 to 30% clay/silt,

- durable if wall protected from rain, ants and soil movement (by foundation and ant course),

- recycling possible.

4. Stabilized Mudblocks (= Mud Bricks)

- produced in block-making machine (Cinva Ram, Bre-Pack) and then air-dried,
- consisting of clay with 7 to 10% cement or lime added,
- partial hydration takes place,
- curing necessary,
- high durability,
- good resistance against rain,
- recycling possible.

B) Mortars and Plasters

1. Cement

see chapter 6.6

2. Lime

- 2 types of lime:

    * hydraulic = capable of setting under water,
    * non-hydraulic = not capable of setting under water,

- produced from heated (to 1,000°C) and ground limestone,
- water to be added before use (= "slaking"),
- slow hydration (over decades),
- durable,
- used for brick and stone walls,
- also used as whitewash for painting,
- expensive in Sudan,
- recycling possible.

3. Mud Mortar

- used for fired bricks and mudblocks,
- durable if protected against rain,
- inexpensive,
- recycling possible.

C) Locally Available Materials

1. Sand

- fine sand suitable for water filters and plastering,
- coarse sand suitable for concrete,
- sand without silt and impurities needed for concrete.

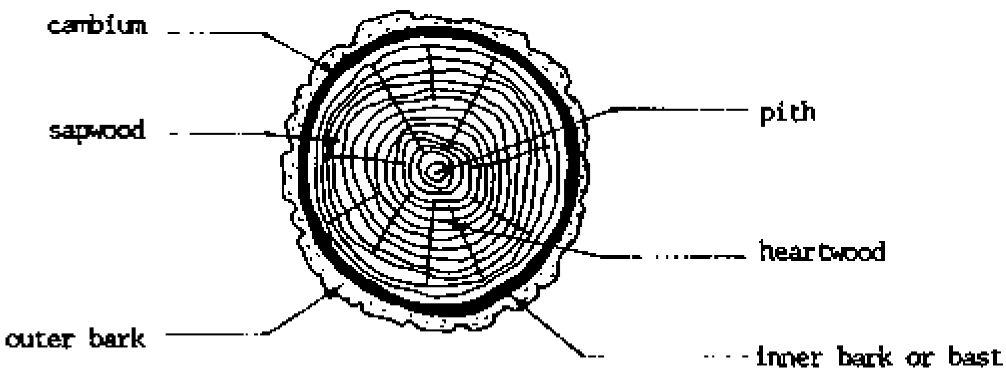
2. Gravel

- gravel without silt and impurities needed for concrete,
- broken rock with rough surface stronger than smooth pebbles.

D) Timber

1. General Properties

- strong; has compressive and tensile strength,
- light,
- durable if protected from moisture and ants,
- weak when wet, and strong when dry,
- strength 30 to 40 times greater along the grain than across it,
- great loss in strength at knots,
- recycling possible.



2. Production

- planting trees,
- cutting logs in dry season,
- drying logs (= seasoning),
- cutting logs into sawn timber,
- drying timber (correct way of storage see 7.10/3),
- ready for use, replanting trees.

3. Decay

- by weathering (sun, rain),
- by fungus attack (in wet and warm atmosphere),
- by insect attack, especially termites.

4. Protection

- by using well seasoned timber,

- by building in such a way that timber parts can dry easily and are not continuously wet,

- by ensuring ventilation,

- by ant courses,

- by painting,

- by avoiding painting before woodwork is dry,

- by painting with chemicals,

- by painting with old engine oil,

- by soaking in tar.

5. Softwood

- very soft,
- easily workable,
- grows quickly,
- no resistance against termites.

6. Hardwood

- the slower the growth, the harder the wood,
- difficult to work,
- very durable,
- termite resistant.

E) Roofing Materials

1. Zinc

- galvanized iron (= iron coated with zinc),
- very much energy needed for production,
- rust prone,
- fireproof,
- light, 
- durable,
- easy to install,
- very hot, no insulation,
- expensive,
- not locally produced,
- no recycling possible,
- rainwater catchment possible.

2. Tiles

- produced from fired clay,
- lots of firewood needed for production, therefore, deforestation encouraged,
- heavy,
- fireproof,
- no corrosion,
- can break,
- durable,
- cool,
- locally manufactured,
- relatively expensive,
- good appearance,
- recycling possible,
- rainwater catchment possible.

3. Grass (see also 6.8)

- produced by nature,

- light,

- not fireproof,

- durable only if thatched in a special way and with sufficient grass,

- prevention from ants by ant course or by separation of wall and roof structure necessary,

- locally available,

- cool,

- skilled thatchers locally available,

- reasonable costs,

- recycling possible,

- not optimal for rainwater catchment.

4. Asbestos Cement Sheets

- made of cement mortar and asbestos fibres in the shape of zinc sheets,

- mining of asbestos and production causes sickness and death of many workers,

- not corrosive,

- light,

- fireproof,

- relatively durable, however, rain washes asbestos fibres into the groundwater (can cause cancer),

- hot,

- easy to install,

- expensive,

- not locally produced,

- no recycling possible,

- no rainwater catchment possible because of asbestos fibres.

5. Fibre Reinforced Cement Sheets (see also 6.6/3 and 6.6/13)

- made of cement mortar and fibres (like sugar cane, coconut, or sisal fibres) in the shape of zinc sheets,

- no danger to humans,

- not corrosive,

- light,

- fireproof,

- relatively durable,

- hot,

- easy to install,

- expensive,

- eventually locally produced,

- no recycling possible,

- rainwater catchment possible.

6. Aluminium Sheets

- aluminum sheet with sharp edged profile: 
- very much energy needed for production,
- corrosion prone,
- light,
- not fireproof,
- moderately hot (because of high reflection of sun rays),
- not durable,
- easy to install,
- very expensive,
- not locally produced,
- recycling eventually possible,
- rainwater catchment possible.

F) Ferrous Metals

1. General Properties

- all made from the raw material iron ore,

- density (= weight per unit volume in kg/dm^3, see 5.7/1): all ferrous metals have a high density, i.e., they are heavy,

- elasticity (= the capability of metal to recover its size and shape after deformation by forces),

- plasticity (= the lack of capability of a metal to recover its size and shape after deformation by forces; the capacity for being molded or altered; the ability to retain a shape attained by pressure deformation),

- ductility (= the capability of metal of being drawn into fine wire),

- malleability (= the capability of metal of being shaped by hammering or rolled into sheets without fractures),

- hardness (= the ability of metal to withstand scratching and wearing),

- corrosion resistance (= the ability of metal to resist corrosion from water, air or acid),

- electric conductivity (= the ability to transmit electricity),

- thermal conductivity (= the ability to transmit heat or cold).

2. Wrought Iron

- less than 0.1% carbon,
- wrought (= formed by application of mechanical force) in either hot or cold state,
- almost pure iron,
- easily formed by blacksmithing,
- used for chains, crane hooks, doors, gates.

3. Steel

- 0.1 to 1.5% carbon,

- made from iron by melting,

- easily formed by blacksmithing,

- weldable,

- cannot be hardened,

- high elasticity,

- limited durability (corrosive),

- used for reinforcement, steel bars like equal angle steel, etc., drums for fuel, parts of cars, pipes.

4. Stainless Steel

- high durability (not corrosive),
- weldable,
- very expensive,
- used for pots, knives, watches, measuring instruments, special machinery parts.

5. Cast Iron

- 2 to 4.5% carbon,
- cast (= pouring the molten metal into a mould),
- blacksmithing not possible,
- not weldable,
- can be hardened,
- brittle (= can crack and break),
- sparking red when ground,
- deep sound,
- used for cast parts like motor block, main part of diaphragm pump, etc.

G) Other Metals

1. Aluminium

- bluish silver-white metal,
- high strength compared to weight (low density),
- low hardness: soft on the surface,
- easy to work,
- no blacksmithing possible,
- welding only with inert gas welding,
- corrosion prone,
- surface gets grey through oxidation which protects against corrosion,
- easily attacked by salty water,

- high reflectivity,
- high ductility and malleability,
- used for tins, aluminium foil, airplanes, etc.
- cast aluminium used for base plate of pipe moulds.

2. Copper

- reddish colour,
- low hardness: soft,
- high durability: no corrosion,
- high ductility and malleability,
- easily workable; also cold workable without cracking,
- can be soldered,
- green surface through oxidation,
- high conductivity for heat and electricity,
- used for electric cables, cooking pots, etc.

3. Brass

- yellow copper and zinc alloy (= molten mixture),
- workable in cold state,
- soldering possible,
- used for coating metal sheets, bearing surface, jewelry and decorations, etc.

H) Paints

1. General Properties

- preserve (= keep from decay),
- protect surfaces,
- decorate surfaces,
- enable the surface to be cleaned easily.

2. Components

- pigment (= base), a powdered substance, gives colour and provides opacity (= the quality of being impervious to the rays of light),

- liquid (= vehicle), carries the pigment and consists of binder, thinner and drier,

- binder, fixes the pigment to the surface to be painted,

- thinner (= solvent), reduces the viscosity of the paint and helps the paint to penetrate into the surface,

- drier, increases the speed of drying.

3. Oil Paints

- paint with oil as vehicle,
- for priming coats,
- for under-coats,
- for finishing coats,
- dries by evaporation of the solvent and oxidation.

4. Synthetic Paints

- paint produced by chemical synthesis,

- has a better flow than oil paint, therefore, easy to apply,

- sets quicker than oil paint, dries by evaporation of the solvent, oxidation and chemical change.

5. Metal Paints

   - paint with powdered metal as pigment,
   - used for primer coats to prevent corrosion.

6. Whitewash

   - paint from lime and water,
   - not water proof,
   - used mainly for whitewashing inside walls.

7. Water Paints

   - paint using water as vehicle with chemical additions,

   - cement paint with white or coloured portland cement as pigment, watertight, for outside paints.

8. Varnishes

   - liquid preparation forming a transparent coating when dry,
   - oil varnishes,
   - spirit varnishes.

6.6 Cement and Concrete

Cement and concrete are very important materials in construction, especially in water supply and sanitation. Only the most basic knowledge, important for the day-to-day work, is compiled here.

A) Cement

Cement is an adhesive substance in powdered form with the ability to bond aggregates together to form concrete.

1. Manufacture of Cement

Cement is manufactured according to the procedure shown on the next page.

The main constituents of cement are:

1. Calcium Oxide (CaO) in the limestone
2. Silicon Oxide (SiO_2) in the clay

During manufacturing and heating, carbon dioxide is removed. The final product, cement, consists of 3 $CaOSiO_2$. The substance produced has completely different properties from the parent substances.

If salty water is used for making concrete, the salt reacts with the cement and, therefore, less cement is left for hydration. Salt can also appear on the surface. Salt will also enhance corrosion of the reinforcement.

Therefore:

Avoid using salty water for concrete, if possible. Otherwise, add more cement.

Procedure for Manufacturing Cement:

1	winning the raw-material	2	mixing	
3	firing	
4	grinding and treatment	

2. Hydration of Cement

The setting of cement is a chemical process called “HYDRATION”. It is a chemical reaction, not just a drying process. Complete hydration takes about one year. Heat is released in the beginning of the process.

$$\text{cement + water + aggregates} \xrightarrow{\text{setting}} \text{concrete + heat}$$

The hydration of concrete is an irreversible process. Comparison between mud and fresh concrete shows that no hydration takes place in mud mortar; the process is reversible.

$$\text{clay + water} \underset{\text{destroyed by crushing or rain}}{\overset{\text{drying}}{\rightleftarrows}} \text{mud brick}$$

If cement once touches water, hydration starts to take place.

Therefore:

Take care that the cement never gets wet before use! Crushing hardened cement into powder never produces cement again.

B) Different Types of Concrete and Mortar

Concrete is an artificial stone made by mixing aggregates, water, and cement as adhesive substance. These components form a new body.

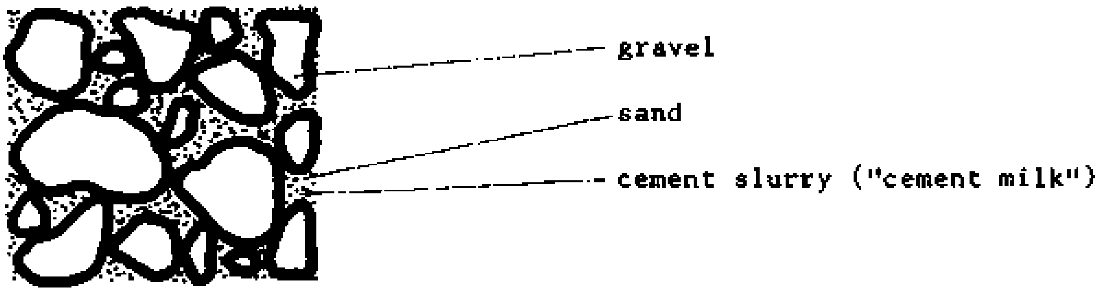
Mortar is a pasty substance made by mixing fine aggregates (like sand) with an adhesive substance (cement or lime or silt).

We differentiate the following types:

Type	adhesive substance	aggregates	water	reinforcement
(plain) concrete	= cement +	sand + gravel +	water	
reinforced concrete	= cement +	sand + gravel +	water +	steel
mudblocks	= silt +	sand + clay +	water	
stabilized mudblocks	= cement +	sand + clay +	water	
cement mortar	= cement +	sand +	water	
mud mortar	= silt +	sand + clay +	water	
ferrocement	= cement +	sand +	water +	chicken wire + welded mesh
fibre reinforced concrete	= cement +	sand +	water +	fibres

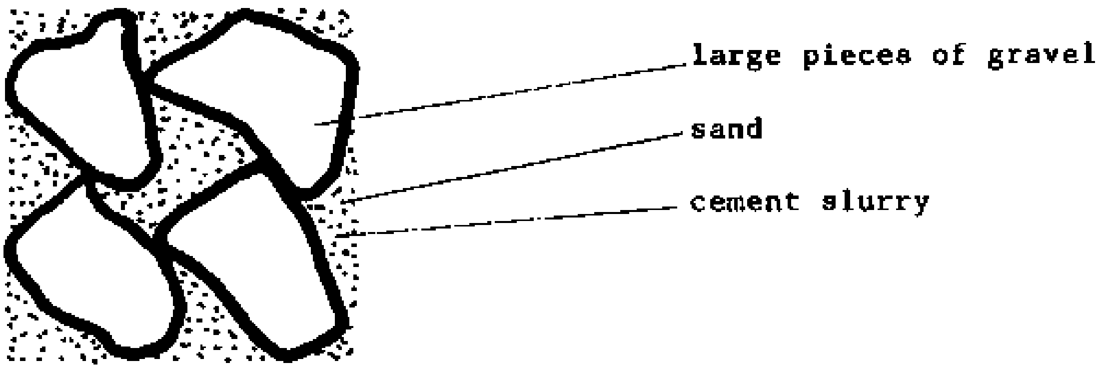
The different mixtures look like this:

1. Concrete (cement, sand, gravel), for example 1:3:4



The stones have great strength themselves and contribute to the final strength of the concrete. The voids between the big stones are filled by smaller ones. All the stones are connected with each other ("glued together") with mortar (cement + sand + water) and, thus, form the final concrete.

2. Concrete with only Big Gravel

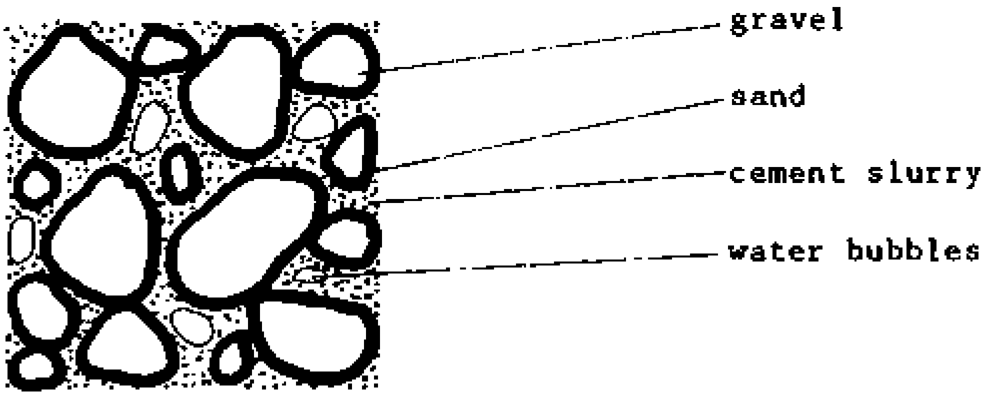


There is no middle-sized gravel to fill the voids. Such concrete is weaker. Therefore, all sizes of aggregate are needed for good concrete, such as big stones, small stones and sand. They are all embedded in "cement milk". The hardening cement milk connects all the aggregates.

Therefore:

The correct proportion of the aggregates is very important.

3. Concrete with too Much Water



Only a certain amount of water is needed for the hydration process. The rest forms bubbles. Gradually the water in the bubbles evaporates and leaves air bubbles behind which weaken the concrete.

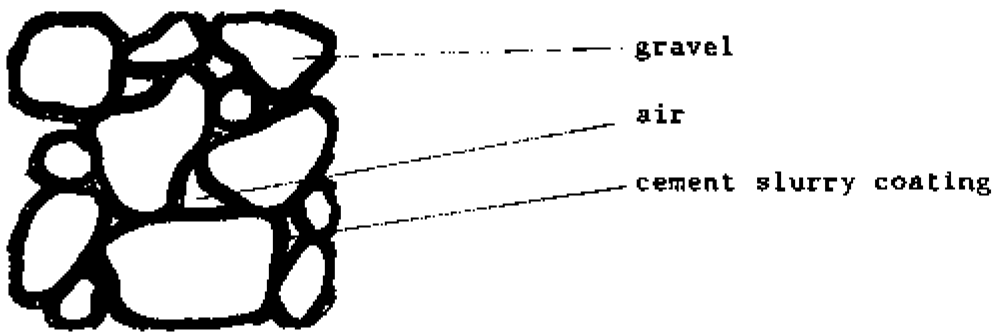
Concrete which is not well compacted also has air bubbles which weaken the concrete.

Therefore:

Too much water and air in the concrete reduce the strength. Mix with just the necessary amount of water and compact properly.

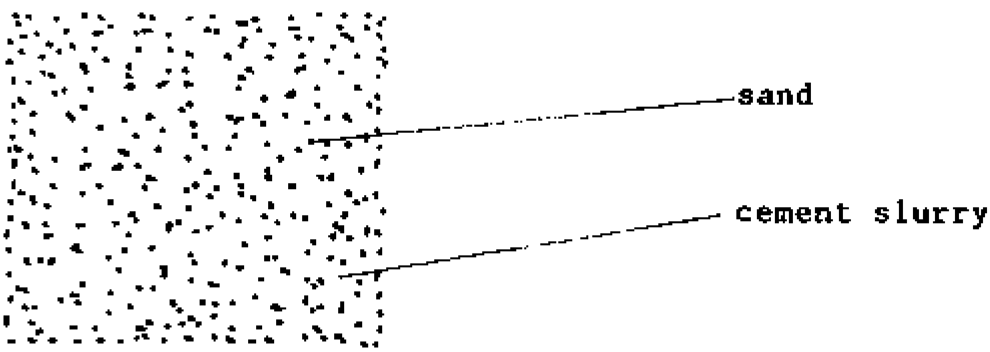
4. Porous Concrete, for example 1:0:4

Porous concrete is concrete without sand for filter rings, permeable for water.



The gravel is surrounded by a thin layer of cement slurry which also connects the different stones. The voids remain empty and, later, allow the water to pass through the concrete. Obviously, porous concrete has less strength than ordinary concrete.

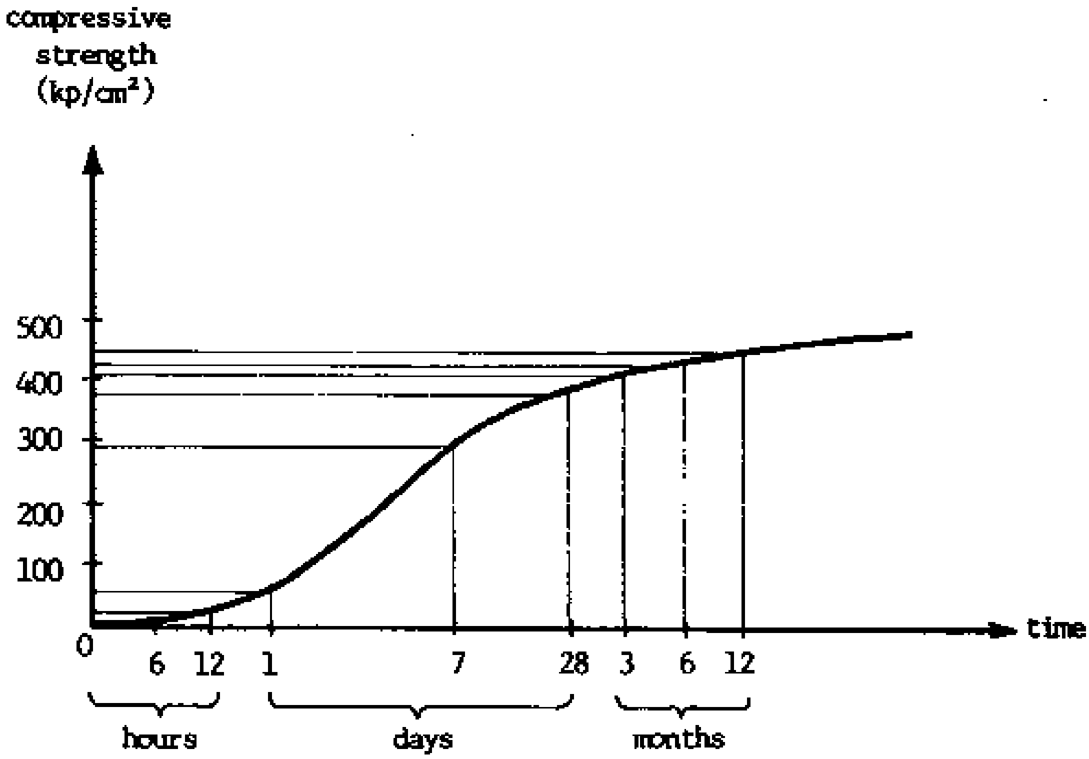
5. Mortar, for example 1:8



The aggregate which in the case of mortar is only sand is connected by the cement slurry.

C) Strength of Concrete

The strength of concrete grows gradually, as shown in this graph:



After one day, concrete is still very weak and can be easily broken. After seven days, it already has about half of its final strength, but not enough, for example, for a beam or slab to be loaded or for a hand pump platform to be used. After 28 days the concrete has almost all its final strength, and there is no need to wait for a further increase in strength. The concrete can be fully used.

Too early loading of concrete may cause inward cracks which are not visible outside but which greatly reduce the strength of the concrete and invite further destruction.

The concrete has no strength in the first days. If it is allowed to dry too quickly or is even exposed to sun, it will shrink and develop cracks. These cracks will never close again. If the concrete is kept wet, cracking is avoided until the strength has developed. Afterwards the concrete will develop no cracks (or fewer cracks). Cracks lead to further destruction: Water will enter and cause corrosion of the reinforcement, and the concrete will start to break and crumble further with time.

Therefore:

- Do not step on fresh concrete on the first day.
- Shutters can be removed after 6 to 12 hours from the side.
- Slabs or beams need to be supported from underneath for 3 weeks!
- Turn over concrete rings after 48 hours, at the earliest.
- Do not lift slabs before 7 days.
- Do not load slabs or beams before 3 weeks.
- Do not lower a concrete ring before 3 weeks.
- Do not pump on a handpump platform before 3 weeks.
- Keep the fresh concrete wet for 3 to 7 days.

D) Making Good Concrete

Two different pieces of concrete work might look the same immediately after completion, but the difference shows later. Making good concrete requires a lot of effort and hard work. The result will be a very durable concrete. Concrete can also be made carelessly. This concrete will later crack and spoil. Although the workers have seemingly saved work and time in the beginning, eventually it will turn out that both work and material were wasted.

For making good concrete, keep the following rules:

1. Use clean, sieved sand (silt content less than 0.5%).

2. Use clean, washed gravel.

3. Remove all organic material like grass, leaves, and mud. Organic material disturbs the chemical process of hydration.

4. Use the materials in the correct proportion (= mixture).

5. Use enough water for good workability, and no more. Too much water reduces the strength.

6. Use clean water and, if possible, not salty water.

7. Mix the concrete very well to ensure that every grain of the aggregate is coated with the binding material so that maximum strength is assured. First, mix sand and cement while still dry. Turn the heap over at least three times until it has an even, grey colour. Add water. Do not pour the water from high, but slowly and gently. Turn over again three times. Add gravel. Turn over again.

8. Pour the concrete gently, not from high, and compact it well. All air bubbles, which weaken the concrete, must be removed.

9. Keep the concrete wet for three to seven days depending on the climate. This is called “curing”. Cover the concrete with wet sand about three hours after pouring and with nylon sheets, or with wet sacks. Pour water over it daily.

E) Properties of Concrete

Good concrete has the following properties:

- It is easy to cast into any form.

- It is very strong.

    It has a high compressive strength (= strength to resist compression or being pressed together).

    It has a very low tensile strength (= strength to resist tension or being pulled or stretched).

- It is very durable.

- It is a bad insulator, because it has no air bubbles. Concrete houses are very hot.

- Concrete walls do not “breathe”, that is they do not allow any exchange of air and, therefore, concrete creates an uncomfortable atmosphere for human beings.

- It has bad sound insulation.

- It is very difficult to break down concrete and discard it when it is no longer needed. It cannot be recycled.

- It needs little maintenance.

- Concrete is <u>not</u> fireproof. Concrete cracks in fire and reinforcement melts.

These properties qualify concrete as the optimal building material for some purposes (e.g. well rings, latrine slabs, etc.) and not the optimal material for others (e.g. walls for accomodation, etc.).

F) <u>Reinforced Concrete</u>

1. <u>Concrete Reinforced with Steel</u>

Non-reinforced concrete is used where only compressive strength is required; that is, in all parts which are continuously supported, like foundations, floors, etc., where the concrete is only pressed.

Reinforced concrete is used where both compressive and tensile strength are required, because the parts are not continuously supported, i.e., in beams, slabs, ventpipes.

The “tasks” are distributed as follows:

- Concrete, cheap and light, takes the pressure.
- Reinforcement, heavy and expensive, takes the tension.

The concrete protects the reinforcement from corrosion, because it prevents air and water from reaching the reinforcement. This protection can only work if the rods are well embedded in the concrete and if there are no (or few) cracks.

Therefore:

Reinforcement must never be seen on the outside surface of the concrete. There must always be 1-2 cm concrete between the surface and the reinforcement.

2. <u>Position of Reinforcement</u>

Correct positioning of the reinforcement is essential. If the reinforcement is put into the wrong position then the beam, slab, etc., will have no strength to carry their load. The correct position of the reinforcement is determined by the planning engineers.

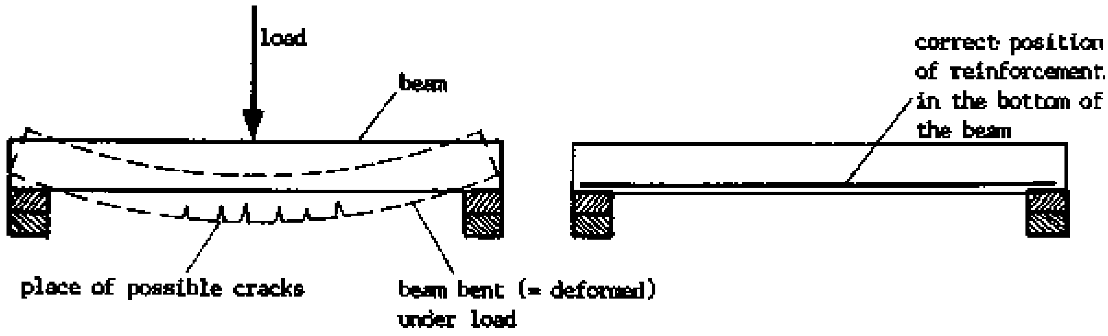
Therefore:

Place the reinforcement <u>exactly</u> into the location where indicated on the plan.

The position of the main reinforcement of some parts is explained here for better understanding.

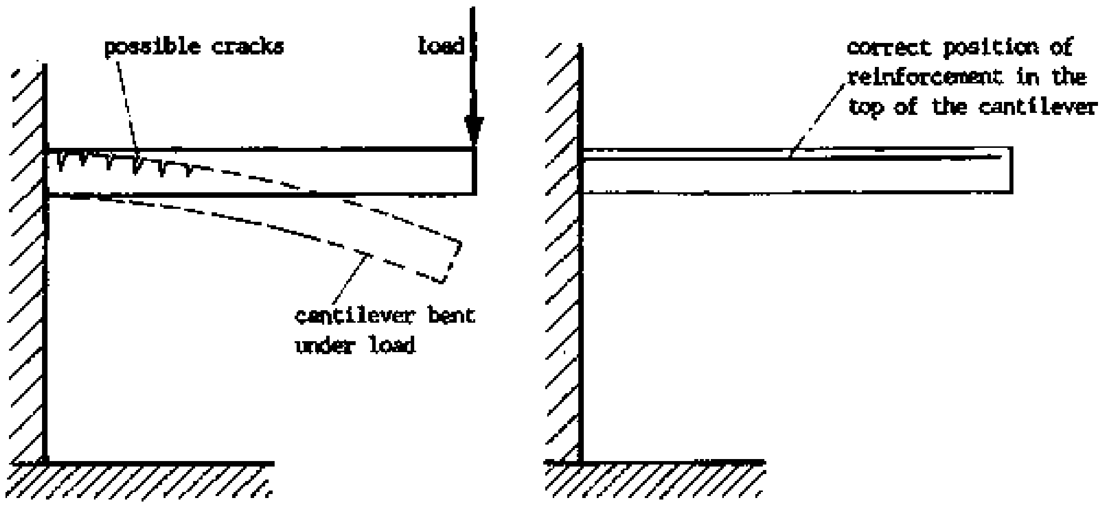
First, imagine how the part would bend under load and where it would start to crack. The reinforcement is placed on the side where the part would be stretched. The reinforcement shall prevent the cracks by holding the part together.

Example 1: <u>Supported Beam (or Slab)</u>

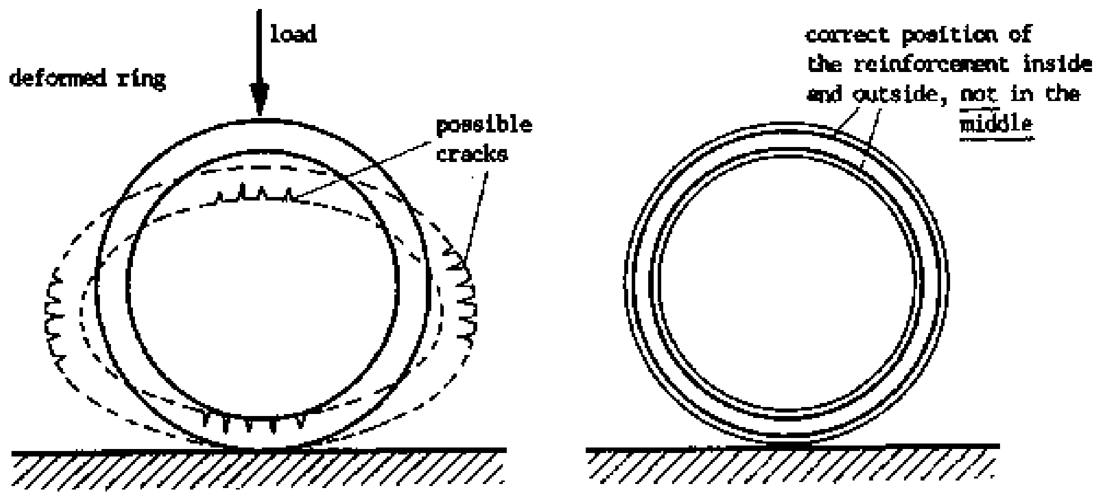


Note: The deformation (= bending) of the part is exaggerated in this and all following drawings!

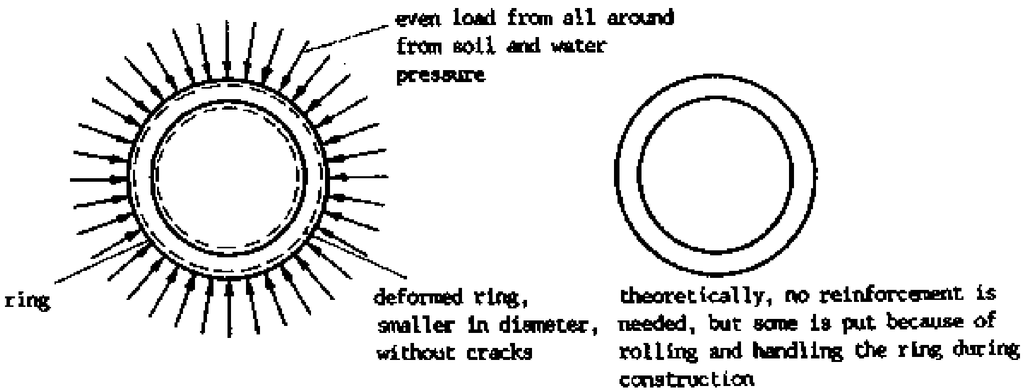
Example 2: Cantilever



Example 3: Concrete Ring (when rolled on the ground or used as culvert)



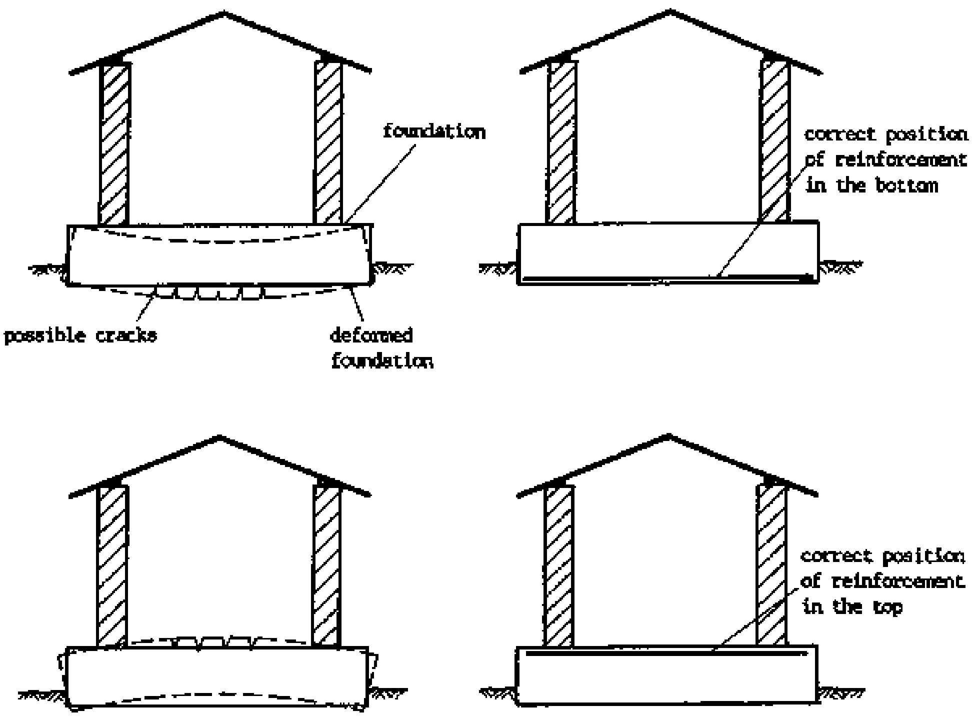
Example 4: Concrete Ring (in the well)



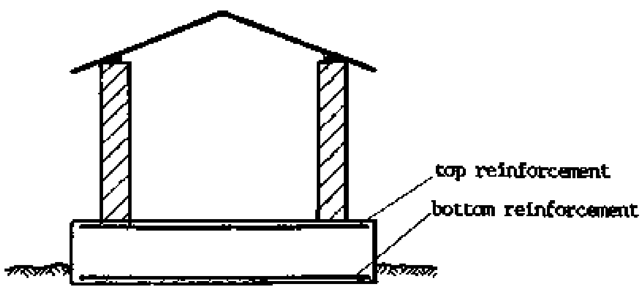
Example 5: Foundation Slabs for Buildings on Black Cotton Soil

Black cotton soil contracts and expands seriously according to the water content and develops big cracks in dry season. It can cause foundations and buildings to crack. Therefore, foundations for buildings on black cotton soil need to be reinforced.

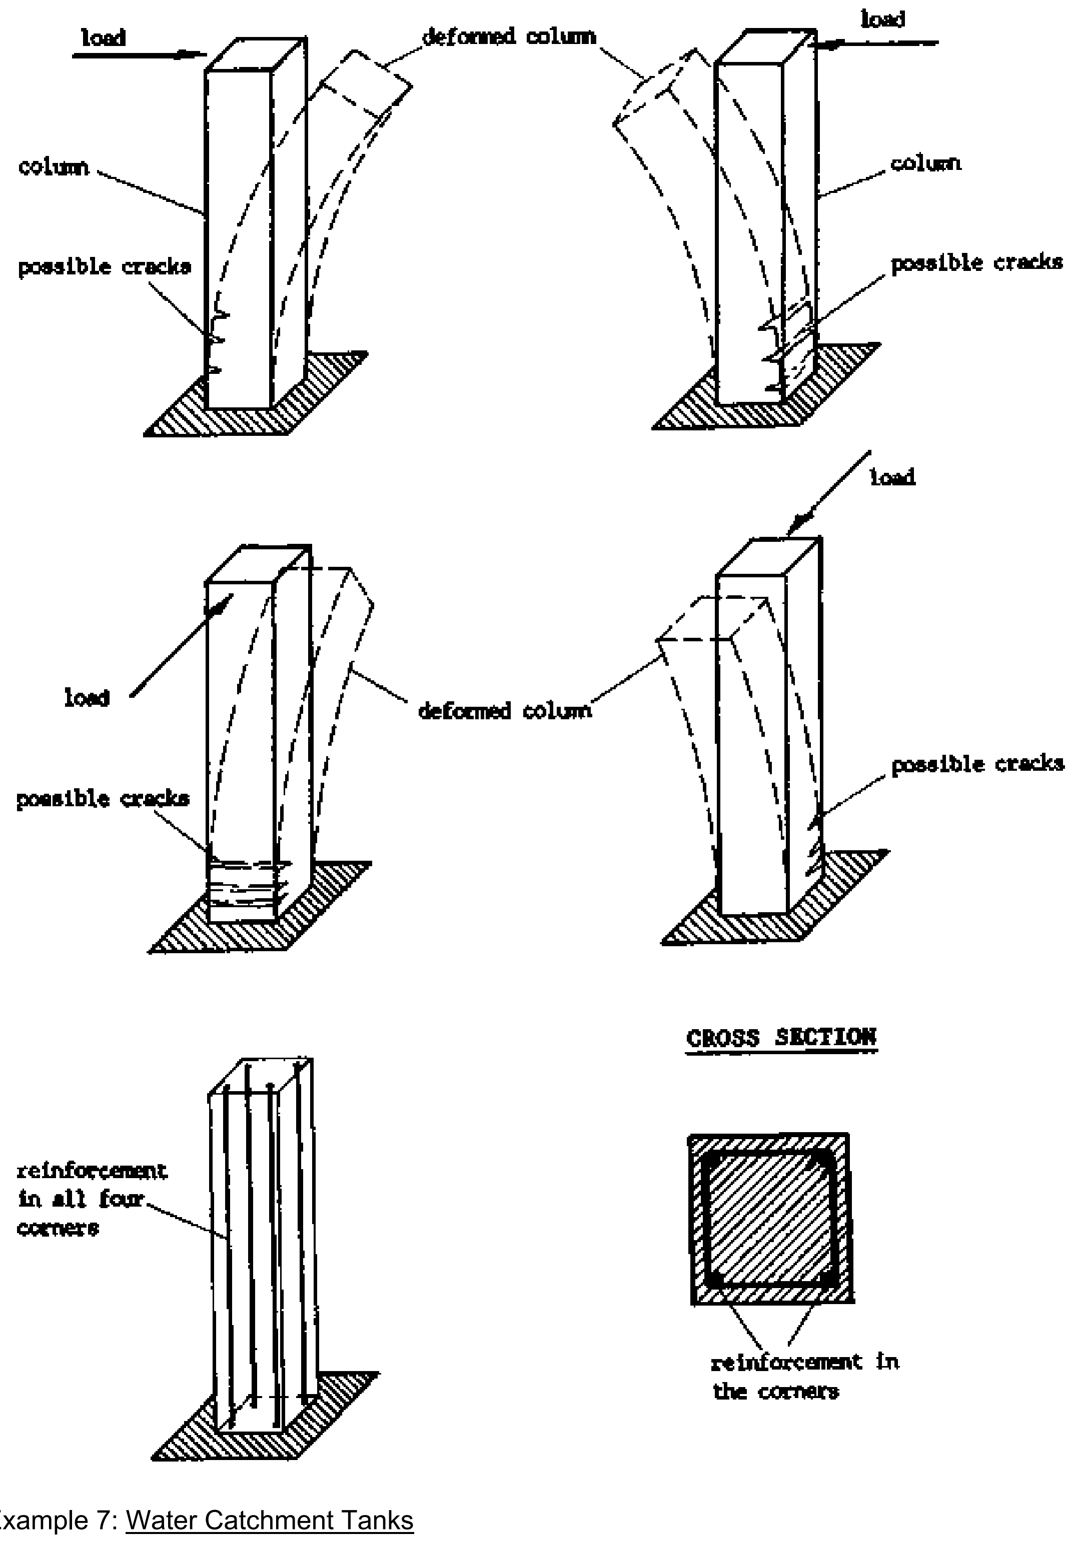
The soil can make the foundation bend in two ways:



Therefore, reinforcement is needed in the top and the bottom of the foundation: not in the middle.



Example 6: Columns (can be bent into any direction; therefore, they need reinforcement in all corners)



Example 7: Water Catchment Tanks

Water catchment tanks are continuously supported. Therefore, they do not need reinforcement to carry loads (to prevent bending). However, they are reinforced with welded mesh or chicken wire to prevent any cracks and ensure they are watertight.

3. <u>Ferrocement</u>

Ferrocement is cement mortar reinforced with chicken wire (or sometimes welded mesh). This reinforcement gives strength and ensures water tightness. The smaller the meshes of the reinforcement the better they prevent cracks in the mortar and, thus, ensure water tightness.

4. <u>Fibre Reinforced Concrete</u>

Fibre reinforced concrete is cement mortar reinforced with fibres. Short fibres which provide the tensile strength are mixed with cement mortar. Then the mixture is formed into diverse shapes like roofing sheets, pipes, etc.

The fibres used can be fibres from plants, like sugar cane, coconut, or sisal, or asbestos fibres. Asbestos is found in underground deposits. The mining and production of asbestos is very harmful to the health of the workers involved. Therefore, the use of asbestos should be avoided.

G) <u>Mixtures</u>

For good concrete, the ingredients must be in the right proportions. For example,

cement : sand : gravel = 1 : 3 : 4

That means:

Mix one part cement with three parts sand and four parts gravel.

We say that the amounts are in the ration 1 to 3 to 4.

Cement is always given as the first figure with 1.

Accordingly, if you need more concrete, you can mix:

1 x 2 = 2 buckets cement		$1 \times 1\frac{1}{2} = 1\frac{1}{2}$ buckets cement
3 x 2 = 6 buckets sand	<u>or</u>	$3 \times 1\frac{1}{2} = 4\frac{1}{2}$ buckets sand
4 x 2 = 8 buckets gravel		$4 \times 1\frac{1}{2} = 6$ buckets gravel

and still have the same proportion (= ratio).

The most important mixtures are:

Ratio	Concrete/Mortar	for
1 : 2 : 4	watertight concrete	water tank
1 : 3 : 4	very strong concrete	concrete rings for wells
1 : 4 : 3	easily workable concrete	latrine slabs
1 : 4 : 6	ordinary concrete	foundation, etc.
1 : 0 : 4	porous concrete	filter rings
1 : 2	very strong mortar	ferrocement
1 : 4	strong mortar	surface of well platform
1 : 8	ordinary mortar	plastering

6.7 Bricklaying

The most basic skills of brickwork, necessary for a water supply technician, are compiled here. They consist of building "half brick walls" and "one brick walls" necessary for compost latrine construction. Obviously, a fully trained bricklayer needs to know much more than is presented here.

A) Bricks

Bricks are made from fired (= burnt) clay. Clay soil is mixed with sufficient water; the mould is wetted; the clay is pressed into the mould; the surplus is removed, then the mould is removed. When dry, the brick is fired in a kiln.

The quality of hand-made bricks can vary a lot. It depends on the type of clay, the quality of manufacturing, the curing and the firing. The quality can be affected in the following ways:

1. Size: great variatons in size
2. Shape: curved bricks
3. Strength: easily breaking or crumbling bricks

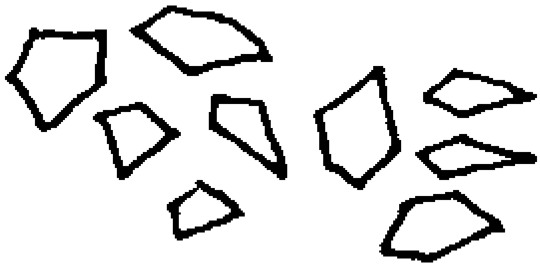
It is an art to build straight and strong walls even with bricks of poor quality.

B) Mortars

Mortar is a composition of certain materials, used for the bedding and connecting of bricks in a wall. Mortar consists of the "body" (= aggregate), which is sand, the "binding" material, which is lime or cement or silt, and water.

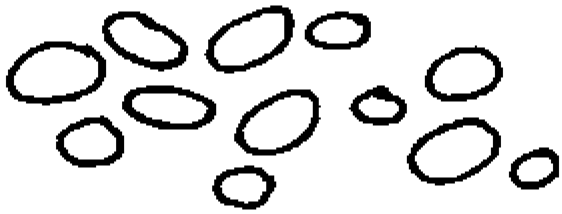
1. Type of Sand

There are two varieties of sand: sharp and loamy. "Sharp" sand has sharp-cornered or angular grains, like this:



Mortar from sharp sand alone has great strength, but is not easy to work with.

“Loamy” or “soft” sand has rounded grains like this:



Mortar from loamy sand alone is weaker than mortar from sharp sand.

It is sticky and tends to hang to the trowel like glue. Sometimes, loamy sand tends to be clayey (i.e. has a clay content), and this type must not be used.

The best aggregate for a bricklayer’s mortar is a mixture of sharp an loamy sand.

2. Proportion of Mixture

If hard, dense bricks of very low porosity and high crushing strength are to be used, then a dense mortar (1:3) is suitable. If porous bricks of low crushing strength are to be used, then a lower grade mortar is suitable. (If a dense or strong mortar is used in conjunction with a porous type of brick, the mortar bed tends to shrink away from the bricks, leaving cracks.)

3. Amount of Water

The amount of water needs to be determined by experience, taking the temperature of the day into account. The mortar needs to be sufficiently fluid to allow the spreading on an even bed. Too much water, however, reduces the strength of the mortar.

C) Terminology

Special vocabulary is used in the bricklaying trade. Some words are explained here:

stretcher:	brick which is laid parallel to the wall	
header:	brick which is laid across the wall	
half-brick wall:	wall with the thickness of half of the length of a brick, built from stretchers only	
one-brick wall:	wall with the thickness of the length of a brick, built from stretchers and headers.	
$\frac{1}{2}$ bat:	cut brick of this shape:	$\frac{3}{4}$ bat:	cut brick of this shape:	closer:	cut brick of this shape:	
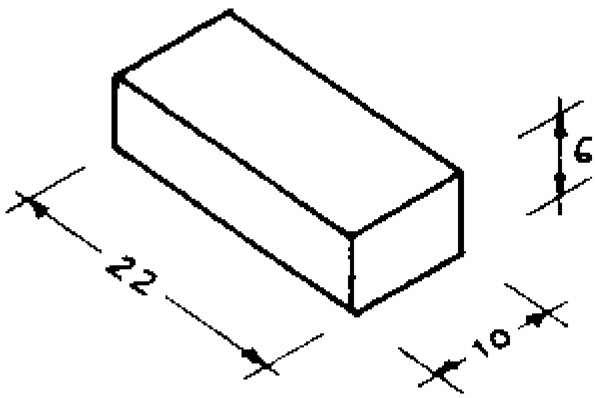
D) <u>Measurements</u>

In Sudan, you find bricks of many different sizes. However, the standard size is:

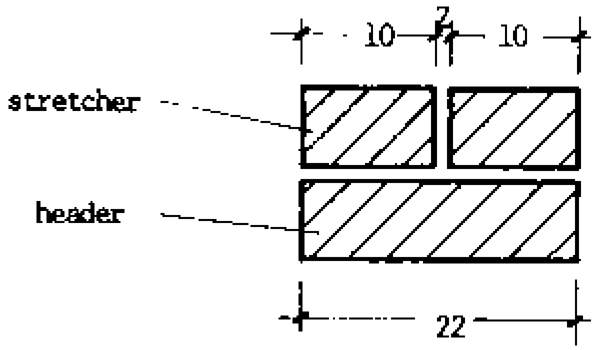


220 mm x 100 mm x 60 mm or 22 cm x 10 cm x 6 cm

20 mm are allowed for the thickness of the vertical mortar joint, 15 mm for the horizontal mortar joint. The space the brick occupies in a brickwall including the mortar joints is called nominal size. It is:

240 mm x 120 mm x 75 mm or 24 cm x 12 cm x 7.5 cm

The size of bricks is standardized in such a way that stretchers and headers can easily form a one-brick wall. Two stretchers in a wall with mortar in between are as wide as one header:

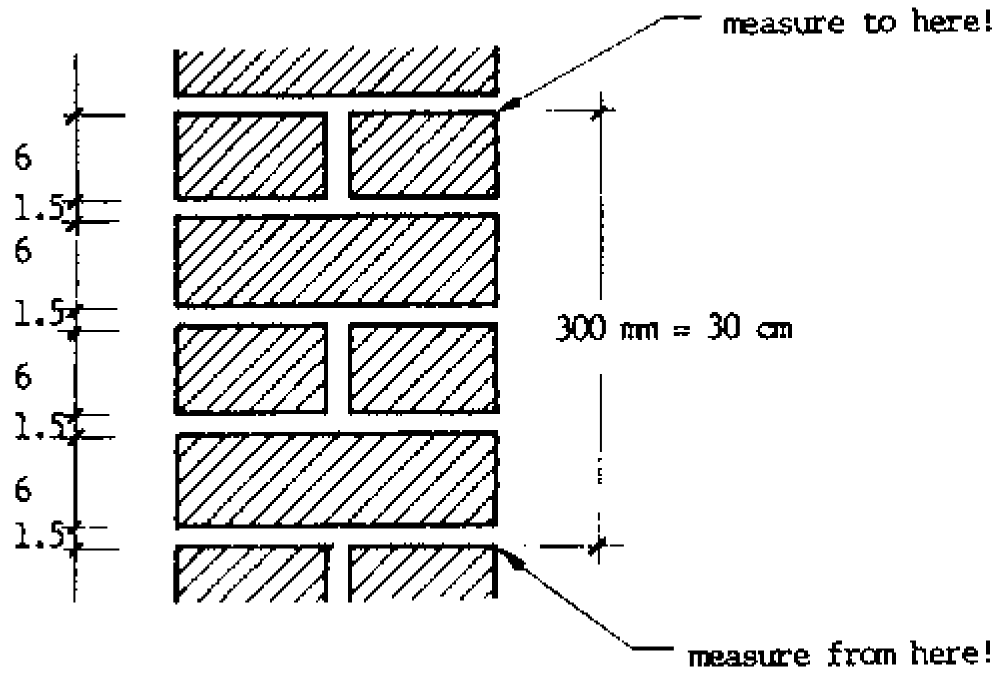


width of one brick:	10 cm
width of one brick:	10 cm
width of mortar joint:	2 cm
length of one brick:	22 cm

In height, 4 rows (= courses) of bricks must equal 30 cm. Each course must equal 7.5 cm.

Measure always from/to the top of a brick in a course.

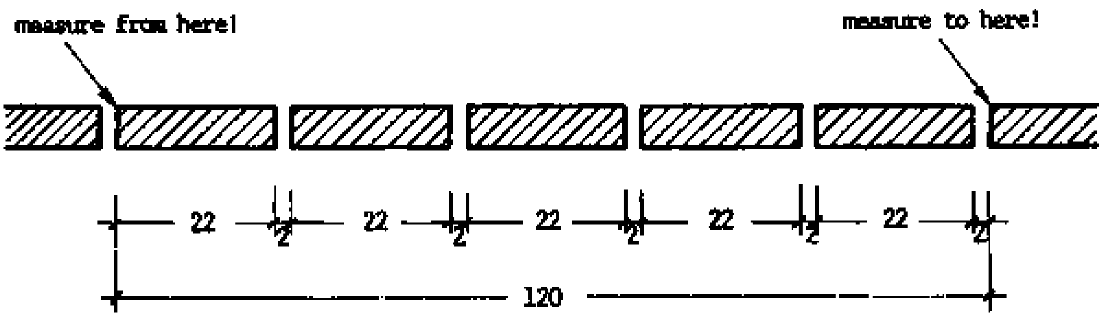
Four courses to 30 cm!



4 x 6 cm =	24 cm
4 x 1.5 cm =	6 cm
	30 cm

Along the wall, 5 stretchers with their joints must equal 120 cm = 1.20 m

Five stretchers to 120 cm!



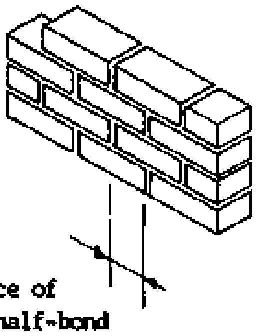
5 x 22 cm =	110 cm
5 x 2 cm =	10 cm
	120 cm

To determine how many bricks make up a wall, divide the length of the wall by the nominal length of the brick. Small differences can be balanced by increasing or decreasing mortar joints sizes. These measurements are valid for bricks which keep more or less to the standard size and shape. For high quality bricks which keep more exactly to the standard size, the mortar joint may be only 1 cm thick.

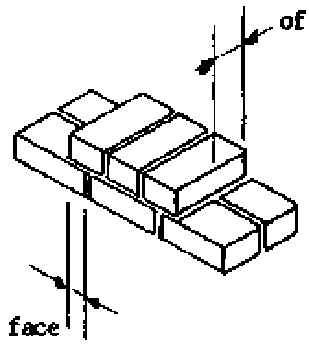
D) Bonding of Brickwork

To maintain strength, bricks must be lapped one over the other in successive courses. A quarter-brick lap is called “quarter-bond”, a half-brick lap is called “half-bond”. If the lap is greater or smaller than these, both appearance and strength are affected. If bricks are so placed that no lap occurs, then the “cross joints” (= vertical joints) are directly over each other, and this is called “straight joint”. An “external straight joint” appears on the face of the wall; an “internal straight joint” occurs inside the wall.

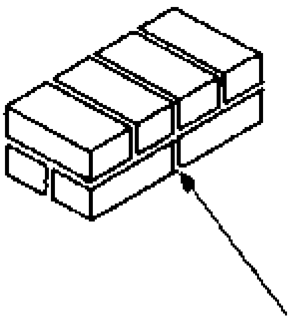
<u>Half-Brick Wall</u>

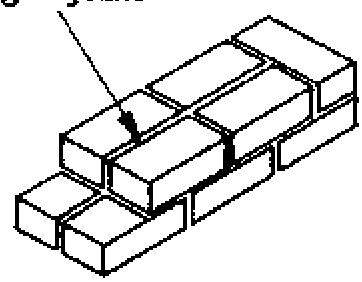


<u>One-Brick Wall</u>



If no closer is inserted, straight joints, either internal or external, occur:

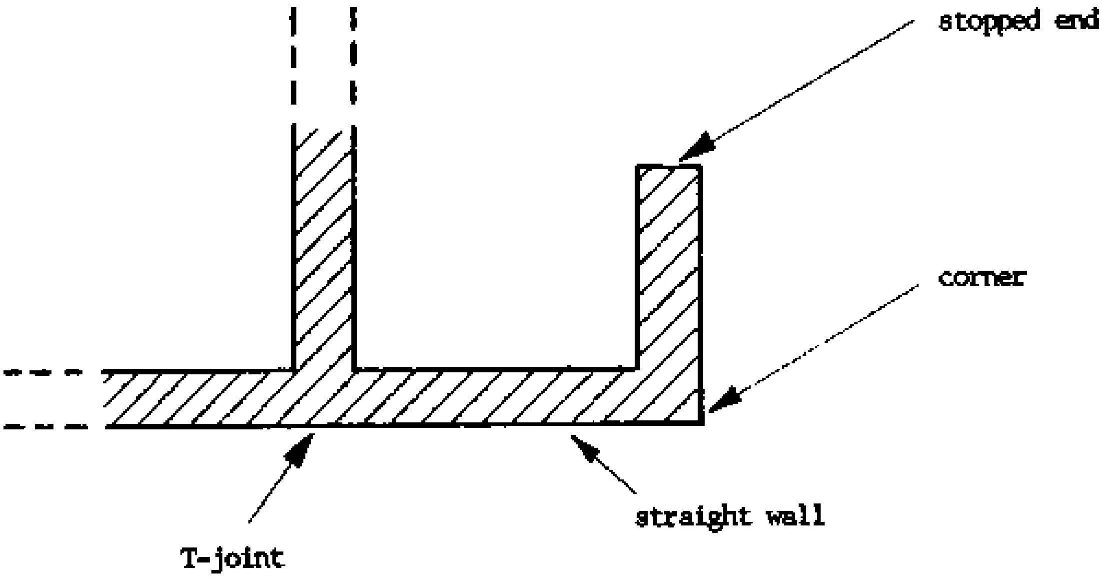




In the following, the bonding of half-brick wall (= stretcher bond) and one-brick wall (= English bond) shall be discussed only. These two types are mostly used in hot climates. The bonding of a one-and-a-half-brick wall (occuring in cold climates) is much more complicated.

For each type of wall we need to know how to build

- the straight wall,
- a stopped end (for doors and windows),
- a corner,
- a T-joint (= cross wall).



The basic rules of bonding are:

1. Avoid external straight joints <u>at all times</u> and 2. Avoid internal straight joints <u>wherever possible</u>. 3. Use whole bricks wherever possible.

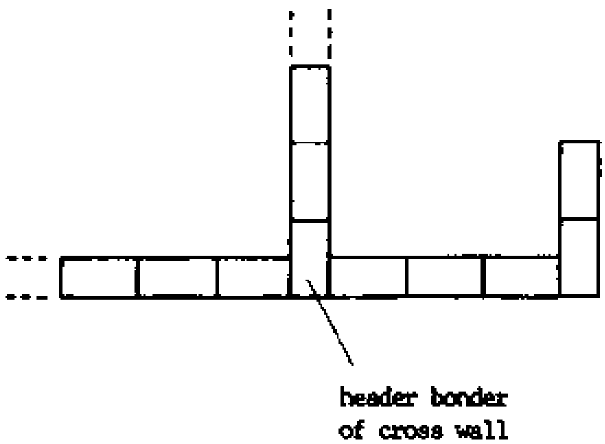
Applied to the different types of bonds and walls this leads to specific rules:

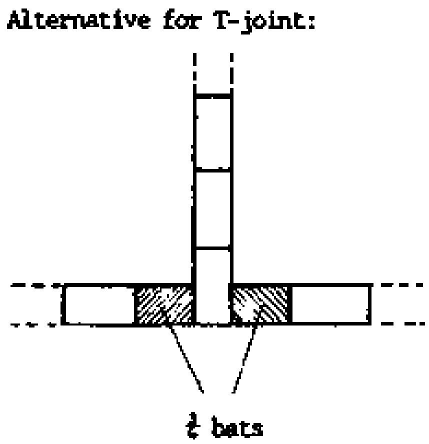
1. <u>Half-Brick Wall in Stretcher Bond</u>

Half-brick walls are built in stretcher bond, consisting entirely of stretchers. Keep to the following rules:

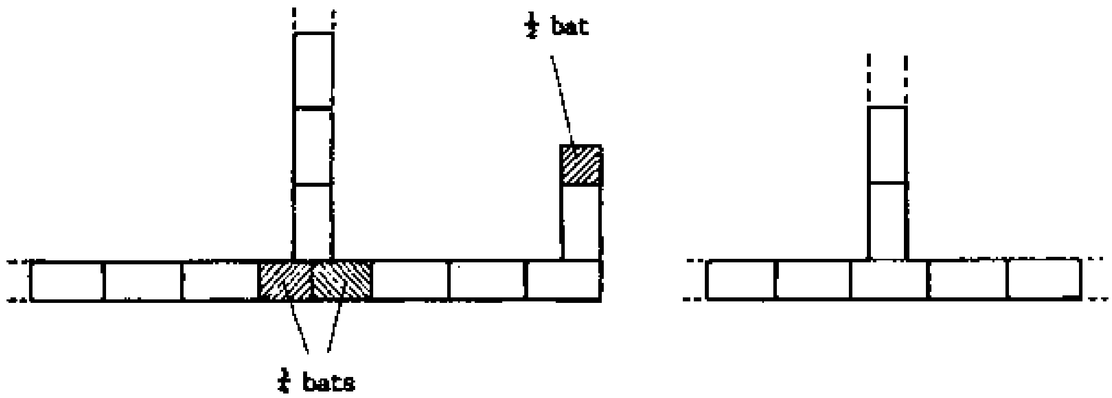
1. Maintain half-bond at all times (except T-joints). 2. No bats are necessary for a corner. 3. Use half-bats for a stopped end. 4. Use 2 three-quarter bats for T-joints.

<u>First Course</u>

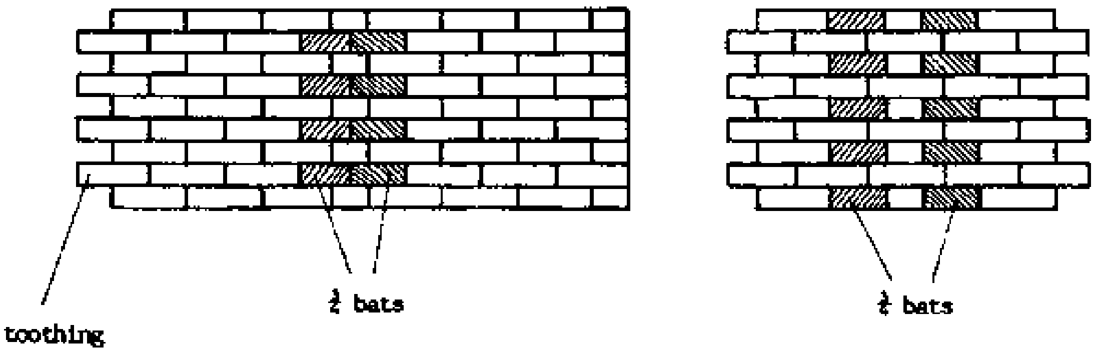




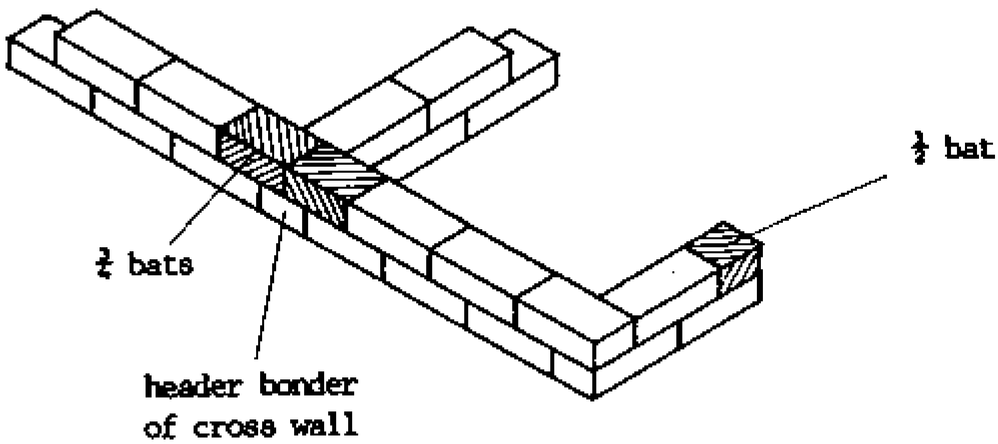
Second Course



Front View



Isometric View



If the first two courses have been set out correctly, they repeat themselves, and the vertical joints in every other course will be upright or “plumb”. The bricklayer checks this by plumbing the vertical joints at every 90 cm or so, along the wall.

2. One-Brick Wall in English Bond

One-brick wall can be built in English or Flemish bond. The latter will not be discussed here. English bond consists of alternate courses of headers and stretchers. It is a very strong bond without any straight joints.

Keep to the following rules:

1. Maintain quarter-bond at all times.

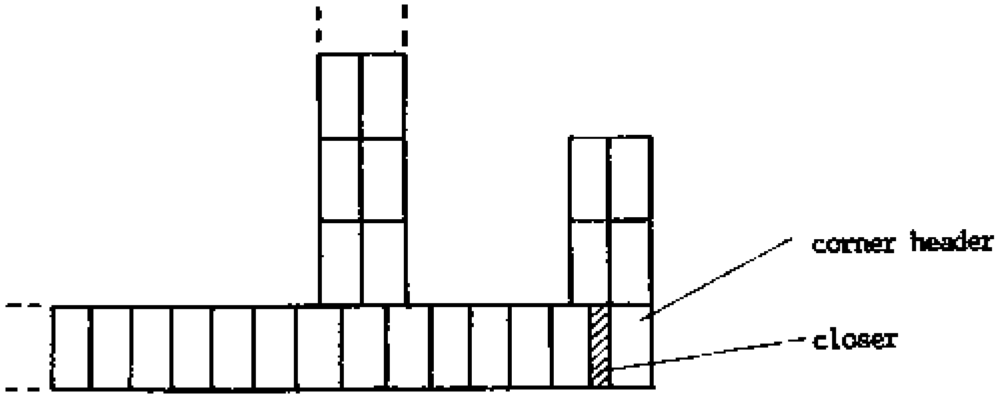
2. A closer (= a brick cut half along its length) must follow the corner header.

3. A closer must follow the last header of a stopped end.

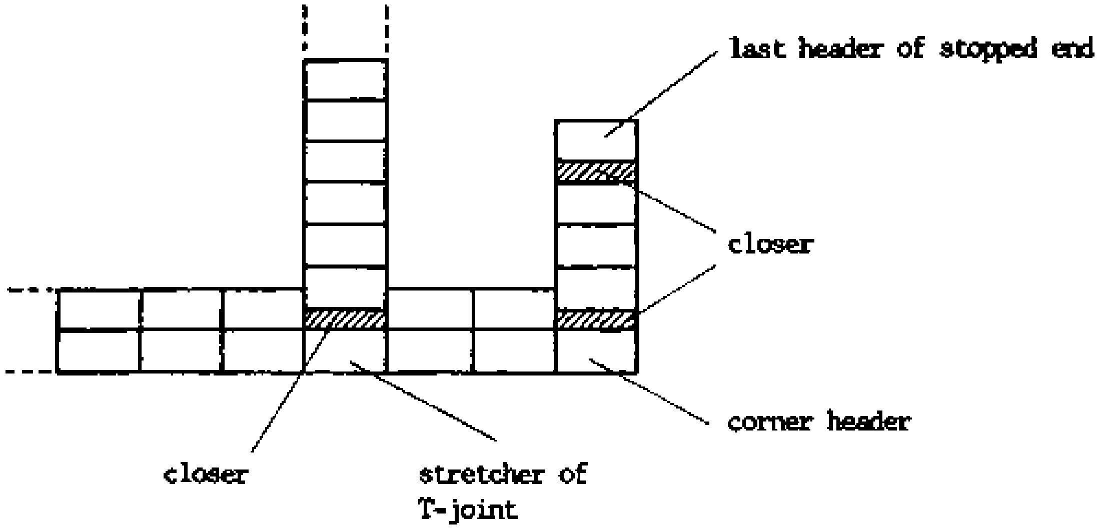
4. A closer must follow the stretcher of a T-joint.

5. In every change of direction on the same course the bond changes from stretcher to header and the other way round.

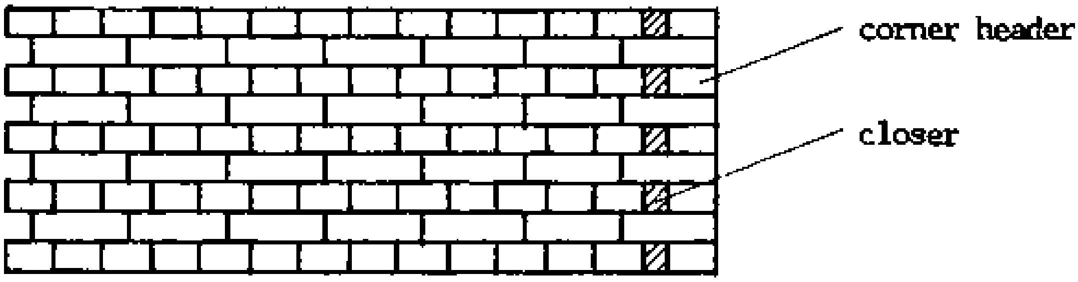
First Course



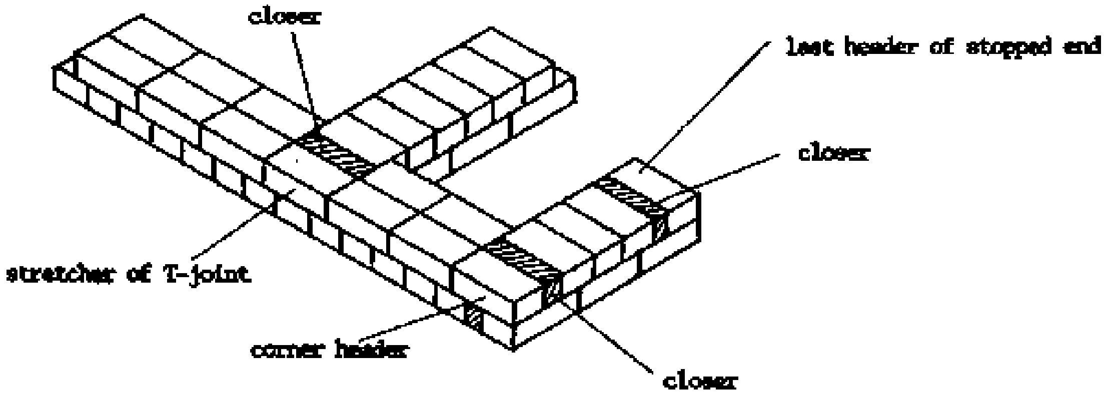
Second Course



Front View



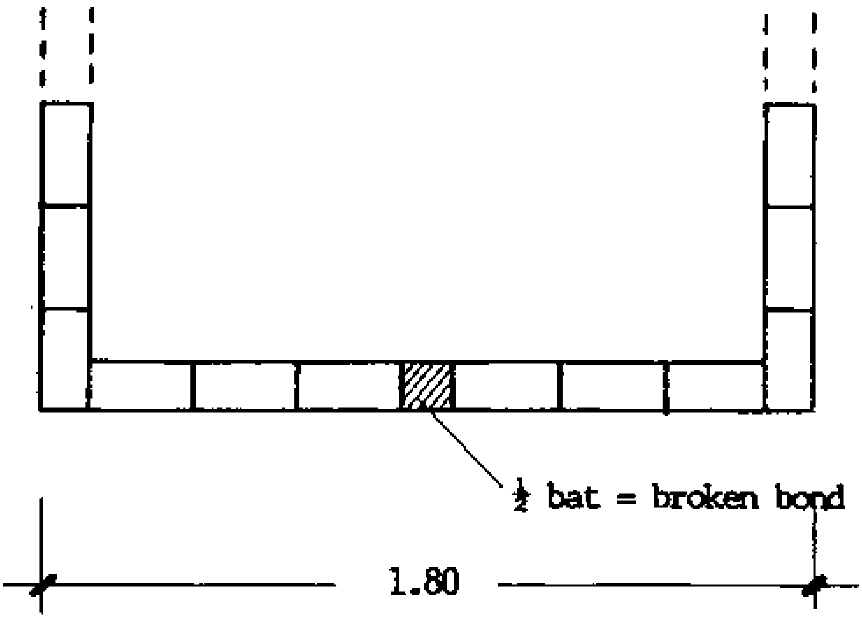
Isometric View



The first two courses repeat themselves when you continue to build the wall.

3. Broken Bond

If the length of a wall does not fit to brick size, a cut brick must be inserted somewhere in the length of the wall to make up its size. The cut brick should not be less than half-brick. The usual procedure is to set out the correct bond from each end of the wall, placing the broken bond as near the centre as possible. However, if there is little difference, the increasing or decreasing of mortar joint sizes will often allow complete bricks to be used.



Some techniques on how to do good brickwork are explained here.

1. Basic Principles

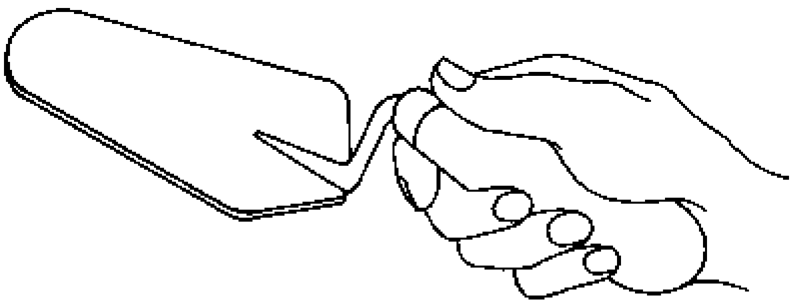
Two basic principles help to do good brickwork:

1. Never allow quality to be sacrificed for speed. 2. Maintain general cleanliness.

Especially the beginner should never allow quality to be sacrificed for speed which will be attained by constant practice. Never allow brick rubble and mortar droppings to collect under your feet. A clean working place, clean mortar board and general cleanliness are important. Mortar should never be allowed to harden on the blade of the trowel, as this creates a rough surface and prevents free and easy movements when picking up and spreading mortar. Clean all tools after work. Your working place should be organised: piled bricks and mortar at a convenient distance.

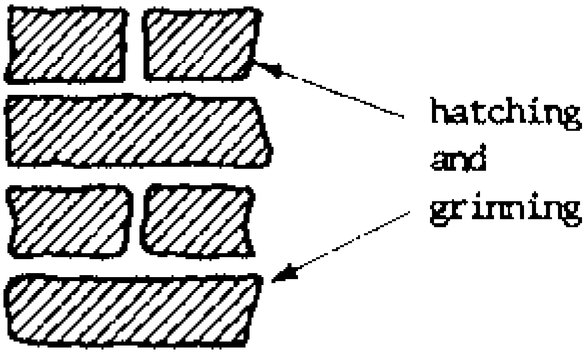
2. Operation

The main bricklaying operation is spreading the mortar to an even bed. This needs practice and a keen eye. Always wet bricks before laying them by dipping them into a bucket of water. This will wash off surplus dust and prevent undue absorption of moisture from the mortar bed. Do not grasp the trowel as if clenching the fist, but place the thumb on the handle lightly so that a flexible wrist action is possible. Pick up the mortar with an easy sweeping motion and spread it on the wall sufficiently thick to allow the brick to be placed by pressure of the hand. Do not place too much mortar under the brick, because this will require considerable hammering before the brick reaches its final position.

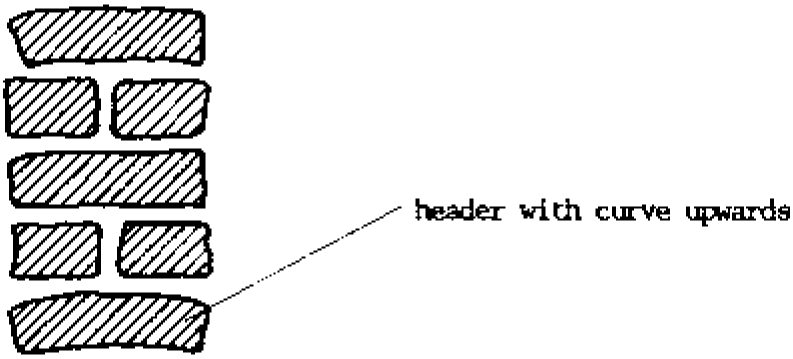


Method of grasping the brick-trowel

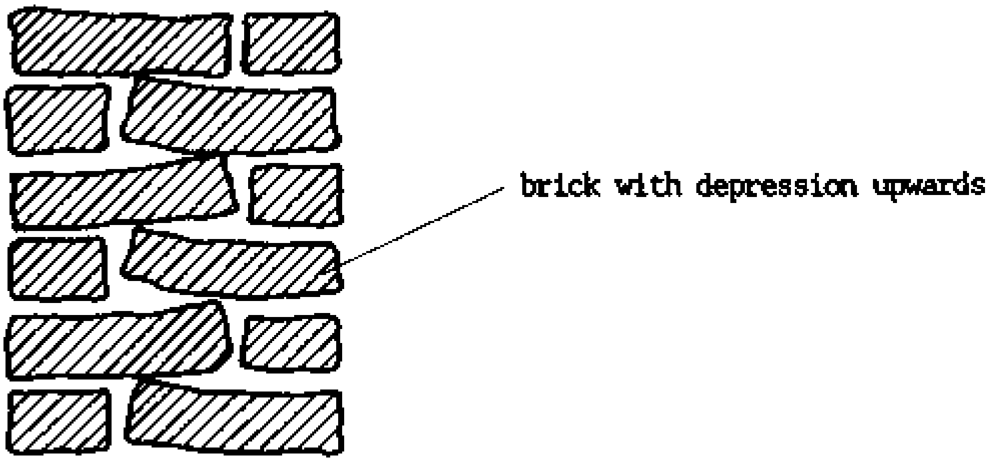
If bricks are curved, it is difficult to keep a flat surface of the wall and to prevent “hatching and grinning”.



f bricks are curved, lay them always with the curve upwards like this:



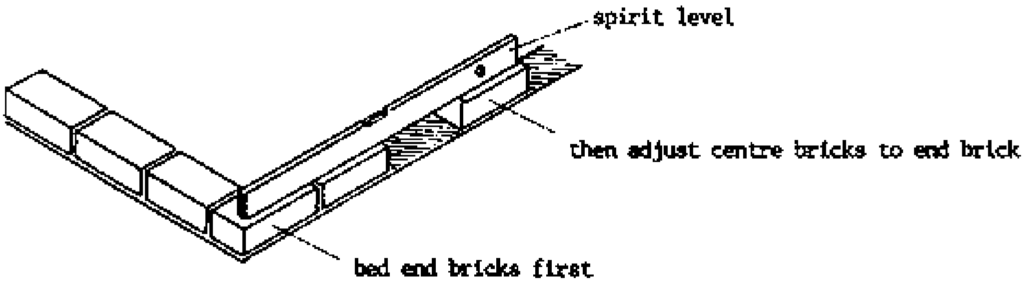
Never lay them with the depression upwards, because this makes the laying of the next course difficult:

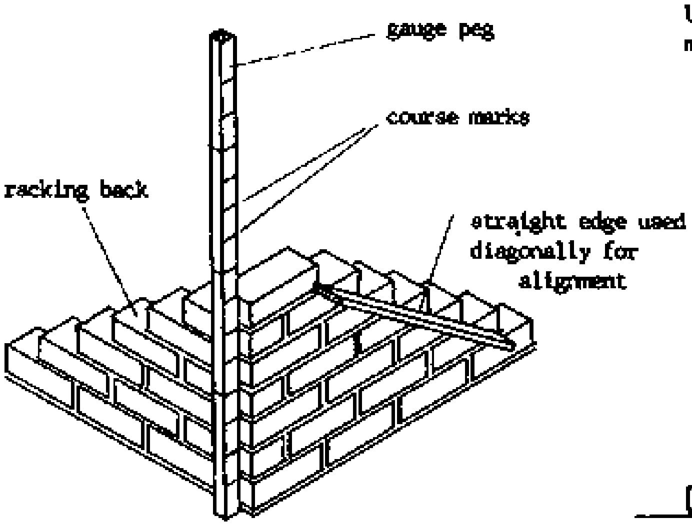


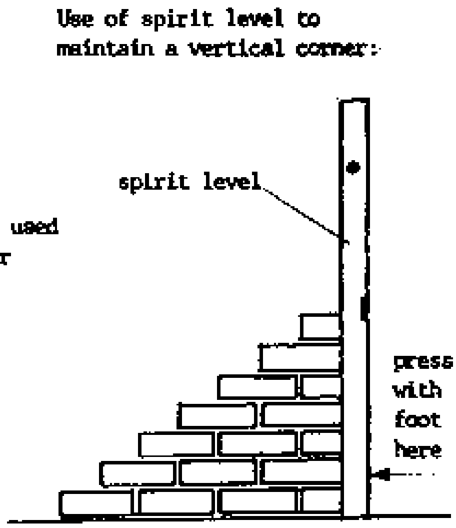
3. Keeping to Measurements

Normally, corners are erected ahead of time before building the walls. First, erect approximately six courses of brickwork at the corners. Make sure that the corner is plumb by using the spirit level or plumb bob. Use a straight edge to make sure that the wall is in alignment. Make sure that the thickness of the courses is kept by a gauge peg. The wall itself is to be racked back.

Building for level:

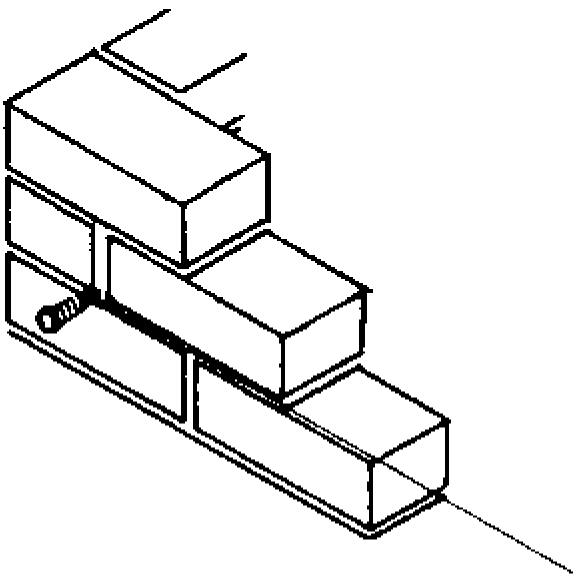




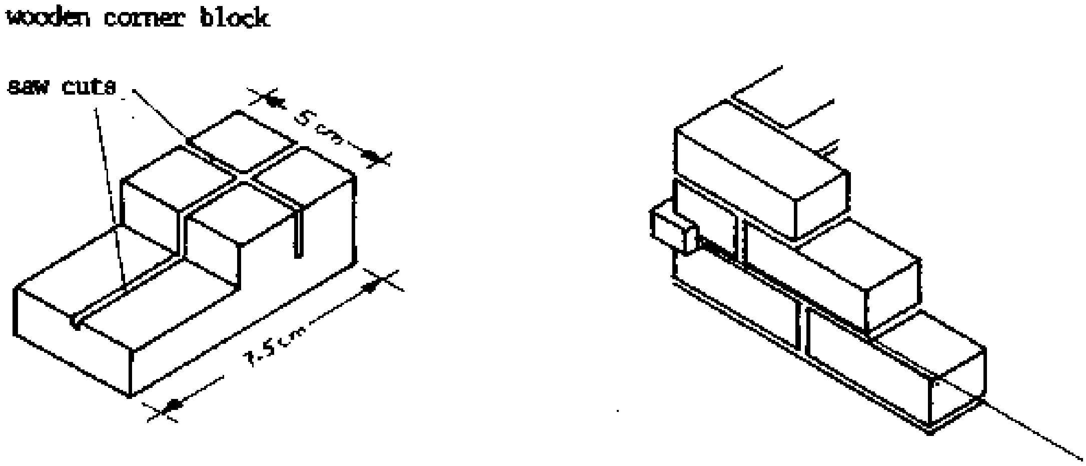


Then use a line and pin for building the straight walls or use two wooden corner blocks.

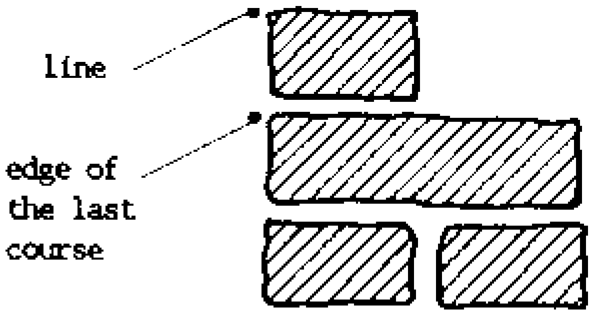
Use of line and pin:



Use of wooden corner blocks: wooden corner block



When laying bricks along a line, always ensure that a trace of daylight can be seen between the line and the brick. This prevents the laying of the bricks too hard to the line. To keep the wall flat (= to prevent hatching and grinning), imagine laying the outside surface of the brick parallel to the line and the edge of the last course. Watch out for this even if it means that the surface of the course is not level.



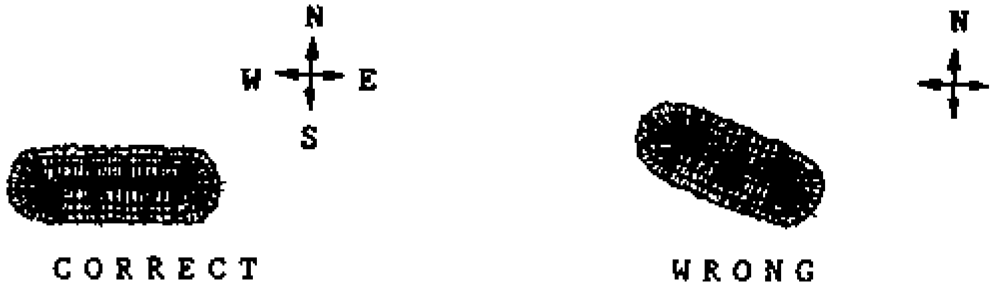
If the bricks are of uneven shape, only one side of the wall can be built flat, either inside or outside.

6.8 Improved Local Building

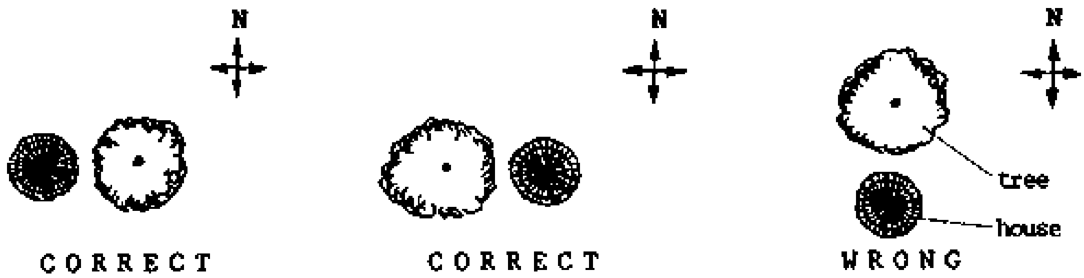
The technologies on how to build with local materials like poles, earth, bamboos, grass, etc. are widely known and are not to be described here. However, some suggestions for improvements are compiled here, both for a house constructed from poles and earth, and for a mudblock house. Select the suggestions which are possible and suitable for your conditions.

A) Measures without Additional Costs

1. Build your house, especially a two-room house, in an East-West direction. The rising and the setting sun should shine on the smaller walls. The sun should never shine on the longer walls. This will make your house cooler.



2. If possible, build your house with a shade-giving tree on the eastern and/or western side of the house



3. Plant trees on the east and west sides of your house.

4. Cut the poles and bamboos in dry season.

5. Choose ant-resistant types of wood.

6. Store them in an elevated place, not directly on the ground.

7. Before building, check the mud with the following tests:

a) **Sedimentation Test**

- Take a transparent glass jar of one litre or more with a sufficiently wide top opening; it must be cylindrical with a flat bottom.

- Fill the jar upto one quarter of its height with the soil to be used for building.

- Add clean water up to the top of the jar.

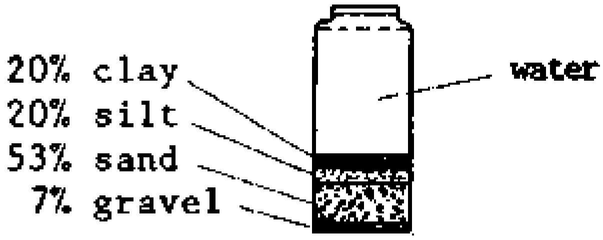
- Close the jar with your hand and shake it well until water and soil are thoroughly mixed.

- Put the jar on a level surface.

- After one hour, shake the jar well and put it on a level surface again. Now the jar must be left untouched without any movement.

- After 45 minutes, you can measure the thickness of each of the different layers and compare each with the total thickness of all the soil in the jar. This gives you the percentage of the amount of gravel, sand, clay, and silt in the soil.

- Soil suitable for building should consist of at least 33% sand and between 5% and 30% clay/silt. If the soil is not suitable, add sand or clay accordingly. A good mixture for example would be



b) **Compaction Test**

- Take a handful of dry, screened (= sieved) earth and moisten it until it is damp enough to form a ball. It should not be so damp that it will leave more than a slight trace of water on your hand.

- Drop the ball from the height of your shoulders onto hard ground. If the ball breaks into a few smaller pieces, the mixture is all right. If it breaks into many pieces, it contains too much sand. If it does not break into any pieces, it contains too much clay and silt for building.

8. Build with mudblocks, if possible.

9. If you build with mudblocks, build a foundation either of mudblocks or of stones.

10. Build the inside floor 10 cm higher than the ground level outside.

11. Mix sand or the soil of anthills or cow dung or merissa residue into the mud for smearing floor and walls.

12. Plaster the walls and use a trowel to smear the floor.

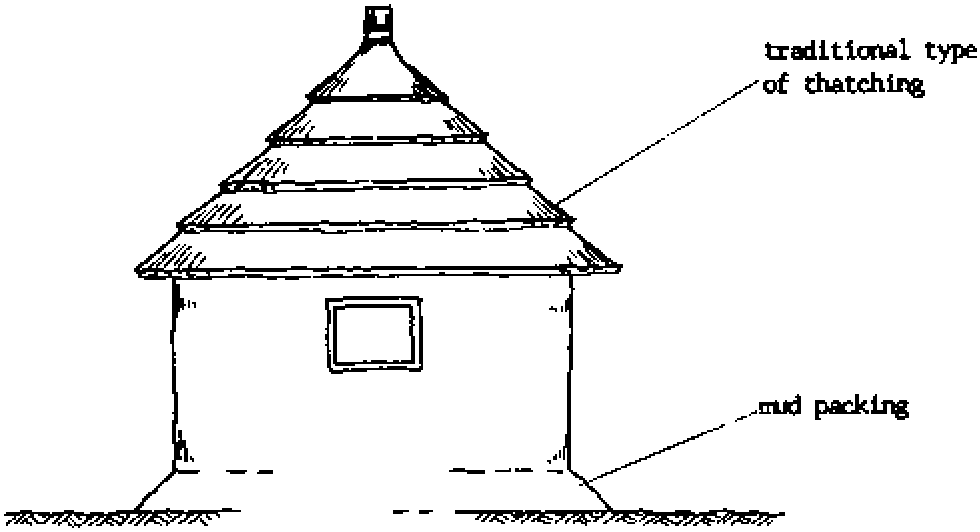
13. Keep all fresh mud work out of the sun.

14. Provide enough ventilation.

15. Leave sufficient space between wall and roof in order to be able to clean the termites away.

16. Fix old tins between the wall and the roof truss to hinder the termites.

17. Protect the wall bottom from being washed out as illustrated in this drawing:

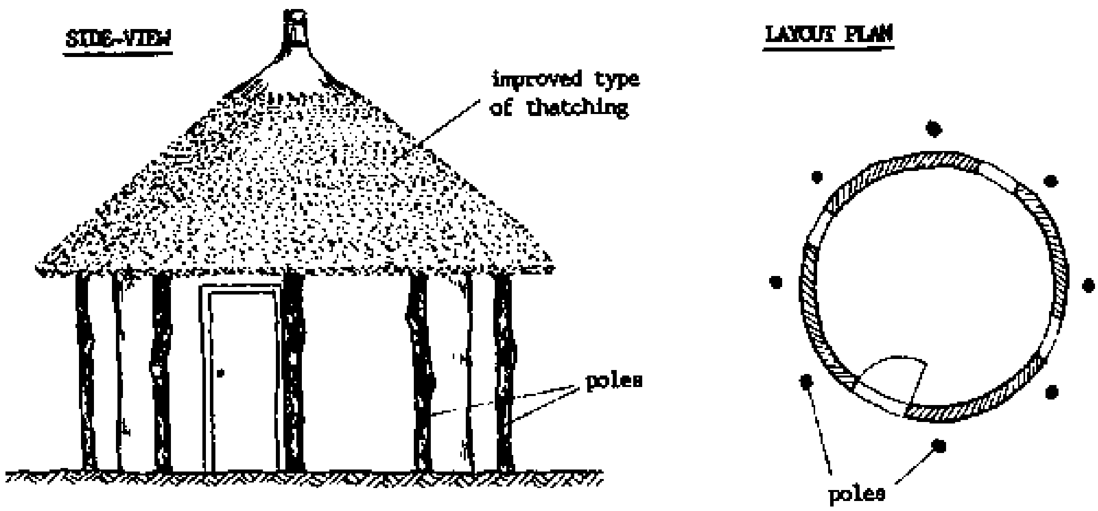


18. Dig a drainage ditch around your house, if necessary.

19. Smear and repair the house frequently. Especially, repair cracks immediately, if possible.

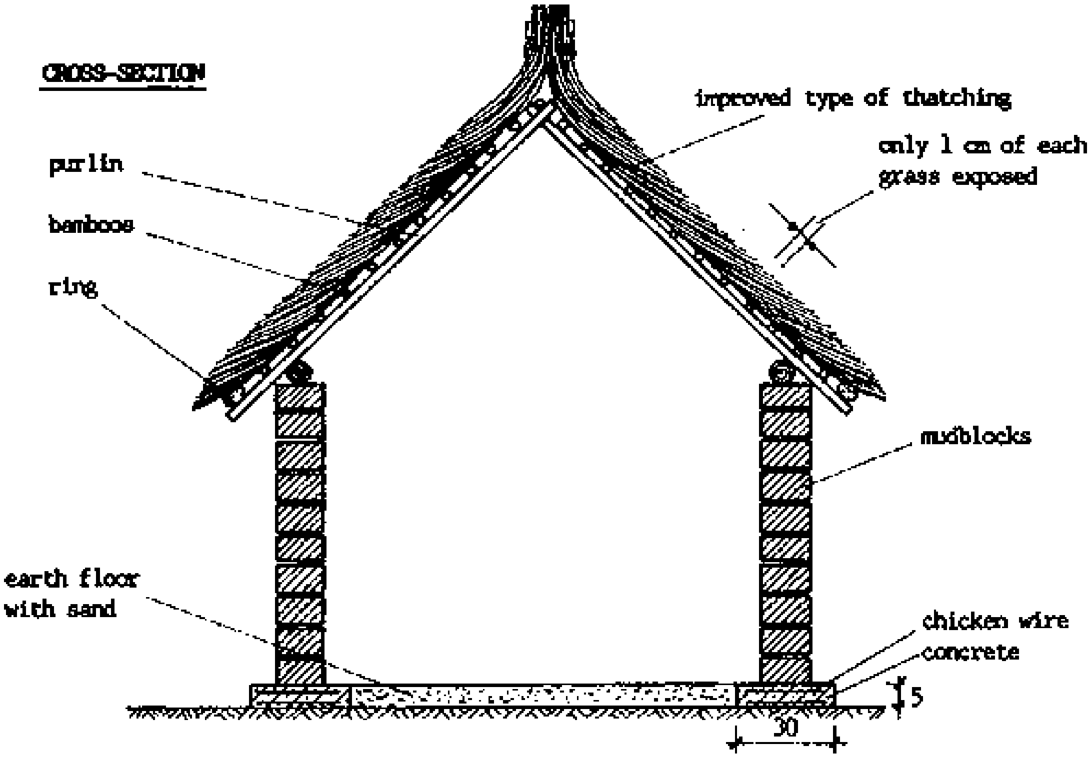
B) Measures with Additional Costs

1. If you build with poles and earth, build the structure for the roof separately from the walls. The poles should not touch the walls at any point in order to control termites.



2. If you build with mudblocks, build an ant course from concrete with two layers chickenwire, 5 cm thick. It is extremely important, to keep the concrete wet for 7 days to prevent cracks which would allow termites to penetrate (see 6.6/7).

Alternatively, you can use bituminous foil or flattened zinc sheets for an ant course. They must be 10 cm above floor level and folded at the joints.



3. Build the walls higher than in the traditional way.

4. Build big windows with shutters on the opposite side of the building.

5. Fix mosquito screening between walls and roof.

6. Thatch with the improved thatching method which builds a roof with a continuous surface without steps. This method requires about 507. more grass, but lasts many years longer. More information is available from the Support Unit, Community Development Department, Juba, or from the literature.

7. Building Administration

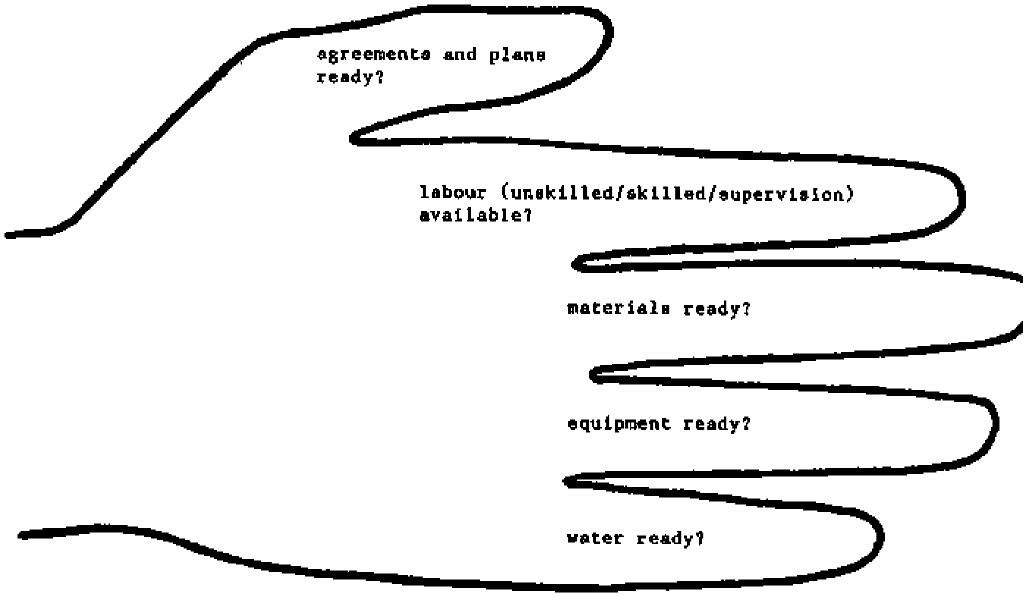
7.1 Planning

Realistic planning is essential for properly organizing the work and to avoid confusion and disappointment of communities and owners. Planning helps to streamline one's efforts, to prepare everything in time for the work, and to avoid unnecessary delays. However, planning should be a helpful tool, not a rigid principle to enforce. Therefore, plans should be made and, if necessary, altered according to circumstances. Having to alter your plans should not discourage you from doing any planning at all. The benefits of regular planning will show in the long run.

Planning of construction work is best done in four steps: checking the resources needed, timing, filling the diary, and preparing lists of materials and equipments.

A) <u>Checking the Resources Needed</u>

When you plan practical construction work, always use the following check list:



Carefully check all these points:

- Did all parties agree on the work to be done?
- Are the technical plans (drawings etc.) ready?
- Is skilled labour available?
- Is unskilled labour available?
- Is supervision possible?
- What materials are needed? Are storage facilities available on-site?
- What equipment is needed? Are storage facilities available on-site?
- Is water available and ready?

If any of these elements is not available in sufficient quantity, the work can not run smoothly.

B) Timing

The timing of building work is done mostly with what is called a “bar chart”. The sequence of work mostly depends on the first two “fingers”, i.e. “Are agreement and technical plans ready?”, and “Is the labour available?”

The form, “WORKPLAN”, is for bar chart planning for the whole project for one month. It is to be used as follows:

WORK PLAN	Fill in the department, month and year.
DATE	Check on which day the first of the month falls; if it is a Wednesday for example, write 1 below We, 2 below Th and 3 below Fr. Sa and Su would be the 4th and the 5th, so write 6 below Mo, 7 below Tu and so on. Cross out any public holiday.
WORK	Write the different work to be done, e.g. latrine No.12, latrine No.13, well No.7, work in the workshop, etc. Only work which takes several days to complete should be recorded.

PLANNING	Mark the days planned for working on latrine No.12 with crosses in pencil, e.g. XXX. If you have two teams who can work parallel, work can overlap. Otherwise, the work on the next latrine, No.13, can only start after No.12 has been finished. In the bar chart, it will look like this:
	XXXXX
	    XXXXX
	        XXXXX
	The time needed for certain work to be completed is to be estimated according to experience. Plan sufficient time for cleaning and for working in the store, etc.

RECORDING It is advisable to use the same form for recording actual work done as well. For example, mark the days on which work on a certain latrine actually took place with red boxes:

The work records have to be entered daily. Thus it will become clear whether or not the timing and the estimated duration of work were correct.

The planning and the filling in of the WORK PLAN is done by the project management team. A copy can be given to the foreman or to the technicians, to be fixed on a noteboard in the workshop.

C) Filling in the Diary

After the overall timing has been fixed, the work is to be planned in detail. Check the last three “fingers” - that is, materials, equipment, and water - and decide when you have to make them available on site according to the bar chart.

Fill in your diary under the appropriate date; for example,

- transport of 5,000 bricks to site,
- transport of six drums water to site,
- transport of building box, etc. to site,
- (instruct, tell) labourers to report to site tomorrow,
- etc.

D) Preparing List of Materials and Equipment

Write lists of materials and equipment needed, either directly into your diary or on separate sheets. The list shall contain all materials and equipment with their quantities.

E) Planning Work for a New Site

Beside the planning as described in A to D, specific planning is necessary before starting work on a new site. Consider the following aspects:

- Where can materials be stored on-site or as near as possible?
- Where can equipment be stored on-site or as near as possible?
- Where can the staff get accomodation (for far-away sites)?
- Which means of transport can the staff use (for near sites)?
- What are the arrangements for feeding?
- How shall communication be kept up between the staff and the office?

For a big building task it is necessary to draw a site plan containing the following:

- the boundaries of the construction site,
- the connection to roads,
- location and size of existing buildings,
- vegetation on site (trees, etc.),
- storage facilities for materials,
- storage facilities for equipment,
- staff accomodation,
- feeding place,
- the north direction,
- the slope of the area,
- eventually necessary drainage channels.

7.2 Work Records

Daily work records are essential, for the following reasons:

1. for the final cost calculation after completion of the well, latrine, etc.;

2. for future estimations of the number of labourers and amount of materials necessary;

3. for deciding if the concrete has already cured enough for further steps;

4. for settling any disputes that may develop with the community or the owner.

Keeping the Work Records

The work records are to be kept by the foreman or technician responsible on site. He/she has to keep the "WORK RECORDS" form (preferably in a protecting plastic envelope) on site with the tools, and has to enter records daily. After completion of the on-site work, the work records are to be handed in to the office for filing.

The work records are to be filled in as follows (see 7.2/3f; 7.4/5f):

WELL No. or LATRINE No.	The number of the well or latrine and the name of the community or owner and location need to be recorded.
DATE	There is one entry for each day.
SCC STAFF	The project staff are to be listed with the abbreviations of their names.
LABOURERS COMMUNITY	The total number of the labourers in the community or the owner present during the whole working day in accordance with the leader of the community workers is to be recorded, including the people caring for food.
WORK	The type of work is to be put into numbers, if possible, e.g. casting 1 concrete ring, ∅ 1.07 m, filter type; digging 0.6 m; etc.

CEMENT	Can be recorded in number of buckets or bags.
SAND/GRAVEL	To be estimated in number of buckets.
MIXTURE	The ratio of the concrete or mortar mixture is to be recorded; e.g., 1 : 3 : 4 (Cement: Sand: Gravel) (see 6.6/13f).
OTHER MATERIALS	All other materials are to be quantified; e.g., 6 m reinforcement ∅ 6 mm, 1 pc welded mesh, 1 handpump body, 400 bricks. Do not forget small materials like padlocks, handles, etc. Do not forget materials provided by the community, like poles, etc.
WATER TABLE	Each morning, the water table should be recorded, in metres from ground level, in order to check the yield of the well during the night.
WELL BOTTOM	The records kept of the depth of the well indicate the progress of the digging work.
SOIL	The soil type (like whitish clay, sand, clay with gravel) along with all changes in the soil type, need to be recorded. This helps for later evaluation of the soil conditions. For recording the soil conditions in a well you can also use the form, "SOIL PROFILE", on 8.13/9.
REMARKS	Special events can be recorded here, especially damage to equipment, technical problems, conflicts with the community or owner, etc.

7.3 Records of Materials

The materials needed for the construction of a well (or any other construction) should be summarized after completion of the work. This is the task of the foreman or technician responsible on site-Records of materials are not necessary for standard compost latrine construction, because the materials needed are always the same.

The following principles should be observed:

- Evaluate the daily work records, add up all materials consumed and fill in the sum on the "COST CALCULATION" form (see 7.3/2; 7.4/1).

- Start with the bulky items like cement (to be recorded by number of bags), reinforcement, sand and gravel (to be recorded in lorry loads or m^3).

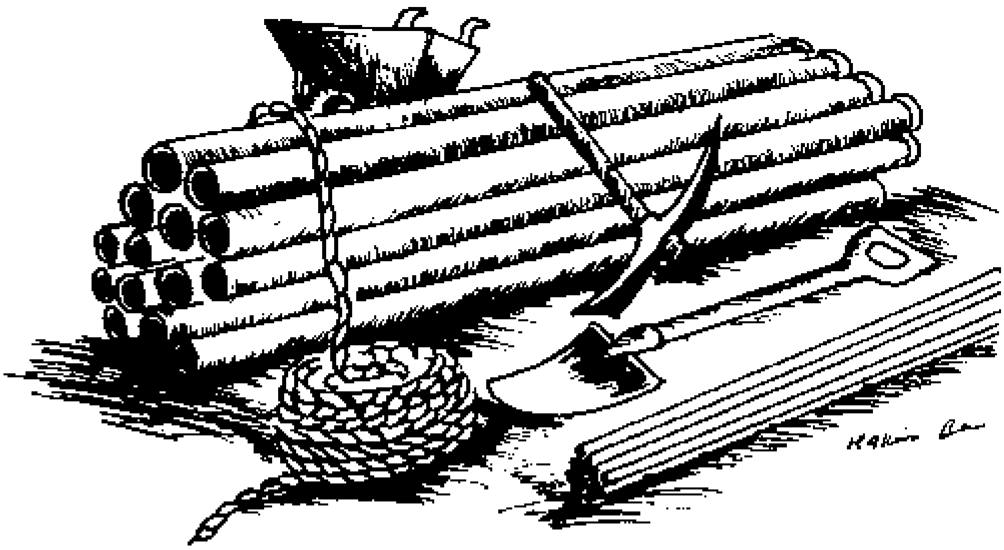
- End the list with the smaller items like padlocks, handles, manhole covers, etc.

- Fill in whether the materials were contributed by the community or by the project (SCC).

- Do not forget local materials contributed by the community.

- After filling in, hand the form to the storekeeper. The storekeeper has to check to see if the recorded materials are in accordance with his/her records in the store. The storekeeper fills in the prices according to the stockcards. The price of small items with unknown value can be estimated.

- Afterwards, the records of materials are handed to the office for final check, final cost calculation and filing.



Sudan Council of Churches * Munuki Water and Sanitation Project

COST ESTIMATION/CALCULATION FOR ......

No.	Quantity	Unit	Item	Unit Price	Total	Contributed by

7.4 Cost Calculation for Community Work

Lk 14,28-30

After the completion of a construction work such as a well, compost latrine, etc., a final cost calculation needs to be made for assessment of the work done and for paying the bills.

A) Form for Cost Calculation

For any cost calculation the form, "COST ESTIMATION/CALCULATION", should be used. It should be filled in as follows:

COST ESTIMATION/ COST CALCULATION	The form can be used either for cost estimation before the work has started, or for cost calculation after the work has been completed. Underline, which purpose you will use the form for and cross out the other.	
FOR	Give the full information about the well/latrine with its number, location, owner or community.	
NO	Number the items 1,2,3,...	
QUANT	Record here the quantity, i.e. only the figures without the unit. If the item cannot be quantified, write "div." (= diverse).	
UNIT	Record here the unit. Possible units are:	
	bags	for cement
	m	for reinforcement, rope etc.
	pcs	for pipes
	kg	for nails
	gal	for fuel
	working days	for labour
	km	for transport
ITEM	Record here the items clearly and unmistakably. Write for example:	
	reinforcement ∅ 6 mm	instead of "reinforcement"
	metal pipe ∅ 2", 3 m	instead of "pipe"
	nylon rope ∅ 10 mm	instead of "rope"
	nails 2 $\frac{1}{2}$ "	instead of "nails"
	diesel, petrol	instead of "fuel"
	unskilled or skilled labour	instead of "labour"
	transport with Toyota pickup	instead of "transport"
UNIT PRICE	Record the price of one unit in £S; i.e., the price of one bag of cement, one kg of nails, one working day unskilled labour, one km driven by the Toyota pickup, etc	
TOTAL	Multiply the QUANTITY by the UNIT PRICE. This gives the TOTAL for the particular item.	
CONTRIBUTED BY	Record whether the item has been contributed (i.e. paid or provided) by the community or by the project (SCC), or by another agency, government office, etc.	

After filling in all the items, draw a line under the column “TOTAL” and add up all the TOTALs. The sum is the GRAND TOTAL, the whole amount spent on the work.

B) Steps of Cost Calculation

The cost calculation itself should be done according to the following steps (for example see 7.4/4-11):

1. Collect the “WORK RECORDS” from the foreman or technician in charge on the site.

2. Collect the “RECORDS OF MATERIALS” from the storekeeper.

3. Divide the expenses into:

   A) MATERIALS
   B) LABOUR
   C) TRANSPORT
   D) PLANNING AND SUPERVISION
   E) DEPRECIATION OF EQUIPMENT

4. Record first the material costs:

Write the heading “A) MATERIALS” on the form “COST CALCULATION” under “ITEMS”. Start by recording the materials below. Record local materials like sand, gravel, and poles. Include the price for transportation and loading if you have paid for “lorry load delivered at site”. If you have paid separately for transport and loading, record these costs under “TRANSPORT” and “LABOUR”. Record also materials which were not paid for but contributed freely. Estimate their costs and record who contributed them. If work was done in the workshop on some material, record it here also and estimate the costs, e.g. “welded adjustment on handpump body”. These costs belong to the material itself. Record all store materials like cement, reinforcement, etc. Do not forget small items. After recording all materials, add them up for a "TOTAL for MATERIALS".

5. Next, record the labour costs:

Write the heading “B) LABOUR COSTS” on the form under “ITEMS”. Count the number of working days from the WORK RECORDS. Record unskilled and skilled labour separately. The “UNIT PRICE” for daily paid labourers is their daily wage; for permanently employed staff it is their gross salary divided by 20 (Each staff works about 20 days per month if we take into consideration absences due to sickness, leave and holidays).

Record also unskilled labour provided by the community (to be counted from the WORK RECORDS), including the time spent for cooking for the staff, etc. Estimate the “UNIT PRICE” according to the market price for unskilled labour.

After recording all labour, add them up for a “TOTAL for LABOUR.”

6. Record the transport costs:

Write the heading “C) TRANSPORT” on the form under “ITEMS”. Check in the logbook to see how often the car went to the particular site and then add up the km. For example, record them as “350 km, Toyota pickup”. The “UNIT PRICE” for each km driven is to be found in the annual report of the previous year. In the annual report the total costs including depreciation, fuel, maintenance, insurance and driver of the vehicle are calculated and drawn down to each km; for example, the price per km for a Toyota pickup is presently £S 1.750 m/ms (1987). For calculation of the cost per km see 3.4. If a lorry was hired on a daily basis from Logistics Department, record the hiring costs per day; for example: “3 days lorry”, the “UNIT PRICE” being the hiring cost per day.

After recording all transport costs, add them up for a "TOTAL for TRANSPORT:[1]

7. Record the costs for planning and supervision:

Write the heading "D) PLANNING AND SUPERVISION" on the form under "ITEM". These costs cover the planning work in the office and the supervision on site. They can be either roughly estimated as a fixed sum (no "QUANTITY", "UNIT", "UNIT PRICE" given, just the "TOTAL"), or as a percentage of the total costs. Alternatively, the working days of the senior staff can be counted.

Add up all the costs for a "TOTAL for PLANNING AND SUPERVISION."

8. Record the costs for depreciation of the equipment:

Write the heading "E) DEPRECIATION OF EQUIPMENT" on the form under "ITEM". This will cover damages and losses of equipment, and the fact that all equipment needs to be replaced after a certain time. Normally these costs are estimated as a fixed sum and this is then recorded as the "TOTAL for DEPRECIATION OF EQUIPMENT."

9. Summarize all the expenses in the form, "SUMMARY OF COST CALCULATION FOR COMMUNITY WORK" (see 7.4/11).

Fill in the costs of material, labour, etc. Add up all the costs. The sum, called "TOTAL COSTS", is the real complete costs of the well/latrine which was built.

Calculate the percentage of the total spent on each heading, from A) to E).

Add up all the percentages. The sum must be 100%; otherwise, look for a mistake.

10. Add up all the contributions of the community/owner in your cost calculation and enter it into the summary. Add up all contributions of the project (SCC). However, if SCC has received cash payment, that means that part of the expenses of SCC has been replaced and that only the remainder is the real contribution of SCC. Therefore, the sum of all amounts contributed by SCC is the expenses of SCC. The cash paid to SCC should be deducted. The result is the contribution of SCC. Enter it into the form. Add up and fill in eventual contributions from others.

Now add up all the contributions. The sum must be equal to the TOTAL COSTS of step no.9, otherwise look for a mistake. Calculate, what percentage each contributor has given. Add up all percentages, the sum of which must be 100%; otherwise look for a mistake.

11. Present the summary to the PMT, the Finance Department, the Programmes Department and the owner or community, if necessary. These summaries are important for comparison purposes and for future decision-making.

12. If there are still payments outstanding, write a bill or payment request to the concerned party and hand it over attached to the cost calculation.

C) Example for Cost Calculation (simplified)

1. Task

Do a complete cost calculation for a well which was built by the neighborhood community Munuki and SCC Munuki. The well is located in Munuki West at the open space beside the planned cinema. The details of the work are recorded on the attached form "WORK RECORDS". The prices of the different commodities are as follows:

2. Prices of Commodities Provided by SCC

1 pc	concrete ring ∅ 1.07 m	£S 311.500 m/ms
1 pc	filter ring ∅ 1.07 m	£S 311.500 m/ms
1 pc	well cover ∅ 1.07 with manhole	£S 700.000 m/ms
1 bag	cement	£S 115.000 m/ms
1 working day	skilled labour	£S 10.000 m/ms
1 day	hiring of lorry	£S 200.000 m/ms
1 km	Toyota pick-up	£S 1.750 m/ms

3. Prices of Commodities Provided by the Community

1 m^3	sand	£S 35.000 m/ms
1 m^3	gravel	£S 65.000 m/ms
1 drum	water	£S 2.000 m/ms
1 bundle	bamboo	£S 15.000 m/ms
1 pc	pole	£S 15.000 m/ms
1 kg	nails 2”	£S 15.000 m/ms
1 pc	door for fence	£S 100.000 m/ms
1 pc	padlock	£S 15.000 m/ms
1 working day	unskilled labour	£S 5.000 m/ms
1 meal	breakfast for one person	£S 2.000 m/ms

4. Additional Information

Breakfast was provided for all SCC workers and community workers on all working days. According to the logbook, 60 km were driven by the Toyota pickup for transport of equipment and supervision. Planning and supervision costs £S 600.000 m/ms. The well siting before the construction of the well costs £S 100.000 m/ms. The depreciation of equipment (tripod, pump and tools) costs £S 1,000.000, m/ms.

5. Cross Section of the Completed Well

SUMMARY OF COST CALCULATION FOR COMMUNITY WORK

Well/Latrine No.:	*15*
Community/Owner:	*Neighborhood Community Munuki West*
Site:	*Munuki West, open space beside planned cinema*

1. Costs Differentiated According to Type

A) Materials	£S	*4,261.500*	*= 60 %*
B) Labour	£S	*858.000*	*= 12 %*
C) Transport	£S	*305.000*	*= 4 %*
D) Planning and Supervision	£S	*700.000*	*= 10 %*
E) Depreciation of Equipment	£S	*1,000.000*	*= 14 %*
Total Costs	£S	*7,124.500*	= 100%

2. Costs Differentiated According to Contribution

A)	Contribution of Community/Owner			
	= Expenses of Community/Owner + Cash paid to SCC	=		
	= £S *1,460.500* + £S *500.000*	= £S	1,960.500	= 28 *%*
B)	Contribution of SCC			
	= Expenses of SCC - Cash paid to SCC	=		
	= £S *5,664.000* - £S *500.000*	= £S	*5,164.000*	*= 72%*
C)	Contribution of	£S	....	= ... %
D)	Contribution of	£S	....	= ... %
	Total Costs	£S	*7,124.500*	= 100%

7.5 Cost Calculation for Contract Work

Cost Calculation for contract work is basically done in the same way as the cost calculation for work on a community basis. However, there is no need for differentiation according to the contributors, as all work is done by the contractor and the owner's contribution is the payment.

Follow these steps for calculation:

1. to 8. see 7.4, B)

9. Summarize all the expenses on the form "SUMMARY OF COST CALCULATION FOR CONTRACT WORK". Fill in the costs for materials, labour, etc. Add up all the costs. The sum is the total of the expenses which were spent by the SCC as a contractor. Calculate what percentage of the total was spent on each heading, A) to E). Add up all the percentages. The sum must be 100%, otherwise look for a mistake.

10. Compare the expenses of SCC with the payments of the owner to SCC. Find out about the payments from administration. If the expenses are higher than the payment, SCC has worked at a loss. Fill in the difference under "LOSS". Supplementary payments may be requested from the owner. If the expenses are less than the payments, SCC has worked with profit. Fill in the difference under "GAIN". If the payment and the expenses are equal, there is no loss or gain.

Cost estimations for future contracted work are done in the same way. However, the amounts need to be roughly estimated. If the cost estimation was done on a realistic basis and no items were forgotten, the total should be very close to the final cost calculation.

Sudan Council of Churches * Munuki Water and Sanitation Project

	Total Expenses	£S	....	=	100%

Expenses of SCC	£S ....
Payment of Owner to SCC	£S ....
LOSS (or subsidy) of SCC	£S ....
GAIN (or profit) of SCC	£S ....

7.6 Purchasing Locally

To keep to a certain procedure of purchasing items from the local market will help to save time and efforts and money and to prevent losses.

Follow these steps:

1. Write a complete, quantified and exact purchase list and discuss it with colleagues and the storekeeper who may add something-It is very annoying to have to repeat the whole purchasing procedure when a single item has been forgotten.

The list needs to be sorted; that is, items to be purchased from the same shop should be listed together (e.g., tools together, stationary together, etc.).

Fill in all the items on the following list:

No.	Quant.	Unit	Item	Unit Price				Total
				Shop1	Shop 2	Shop 3	Shop 4	

Alternatively, the "COST CALCULATION" form can also be used for the purchase list (see 7.3/2).

2. Collect pro forma invoices for the items in the desired quantity. If the item is expensive, collect invoices for the same item from several shops, if possible. Fill in the given prices on the list.

3. Choose the cheapest source or the best quality, underline it on the list and calculate the totals using that figure. Add up the totals.

4. Write a payment request for the total amount, get it approved by the chairperson of the PMT and present it to the accounts office with the pro forma invoices attached.

5. Collect the money. Sign for receiving it (for your own protection). Keep the money in a safe place; for example, in a closed bag. Do not mix it with private money.

Alternatively, you can collect money from the petty cash of the project if you need only a small amount. Take care that the amount, the date and your name are recorded.

6. Purchase the items in the respective shops. Check the quality (e.g., tools operating?, bags not torn?, parts not broken?, timber straight?) Do not accept the item if it is not of good quality. Check the quantity. Count all pieces by yourself. Ask for appropriate packing. Load everything carefully.

7. Pay for the items against an invoice (= receipt). Check to see that the amount is the same as on the pro forma invoice. Carefully count the change. Record any payment immediately on a prepared sheet of paper; that is, as soon as you leave the shop. It is very easy otherwise to forget a payment and to get confused. If you cannot get a receipt (e.g. at an open market), write a receipt yourself in the receipt book and let the shopkeeper sign, if necessary with a finger print. If you have no receipt book at hand and the amount is small, record it and the receipt can be written in the office.

Calculate the balance. The balance must be equal with the money left with you. Thus you can check the money at any time.

Money received:		£S 300.000 m/ms
Shop	Payment	Balance
First shop	25.000	275.000
Second shop	107.000	168.000
....		

8. Put all the receipts immediately together into a separate envelope (not just into your pocket).

9. Transport all the items to the store and hand them over to the storekeeper.

The items need to be recorded on the stock cards including the prices. It is important to record the prices at this point, because the receipts are going to be handed to the accounts office.

10. In the end of every purchasing day, count the money left with you and compare it with the balance according to your records. If it does not fit, look for a mistake.

11. If receipts are written in Arabic, write the quantity, item and amount on the receipt in English.

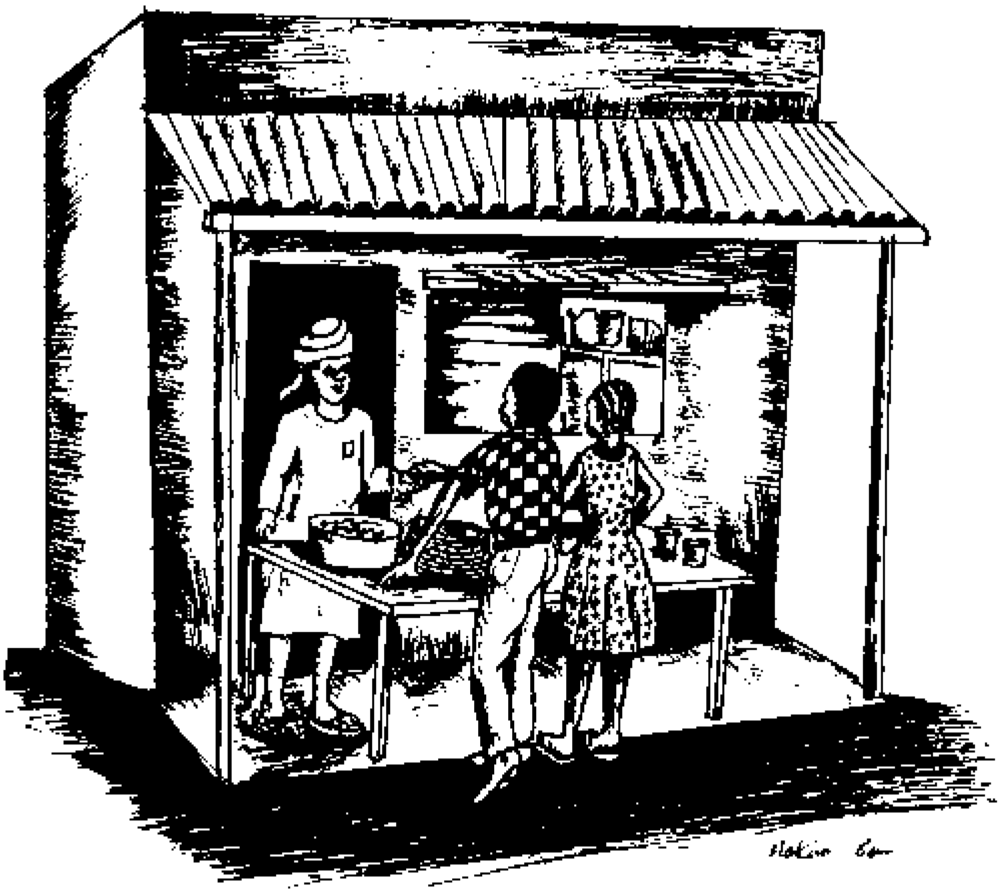
12. When you have finished purchasing and have spent all, or almost all, of the money, number all the receipts 1,2,3, etc. Write on each receipt the budget No. under which the receipt shall be recorded. Summarize the receipts on a separate sheet of paper as follows:

Cheque No: 47812
Date: 3.2.87
Amount: £S 300.000 m/ms

No	Date	Receipt No.	Budget No	Item	Amount	Balance
1	5.2.	1	4.2	hammer	25.000	275.000
2	6.2.	2	3.2	stationary	107.000	168.000
3	...					

For the budget numbers see 2.9/1.

13. Collect all the receipts and an eventual balance and hand it over to the administration, so that they can register it in the finance book and hand it over to the accounts office.



7.7 Purchasing from Khartoum

Purchases inside Sudan, especially from the capital, can be arranged through the Logistics Department of SCC.

The procedure is as follows:

1. Write a complete, quantified and exact purchase list. Each item needs to be described unmistakably. Mention the quantity, the unit, the item itself, the material, the measurements (like 0, length, etc.). If necessary, add pictures or refer to a catalogue. Discuss and decide upon the purchase list with your colleagues and the storekeeper.

No.	Quantity	Unit	Item	Remarks

Let this purchase list be typed in three copies. Check afterwards thoroughly for spelling and typing errors.

2. Write a letter to the Logistics Department in Khartoum, requesting them to purchase and send the items according to the attached purchase list. Send the original to Khartoum, Logistics Department, and a copy to the Finance Department with a note that they should kindly make the money available.

The third copy remains with the project and is to be filed in the respective paper file (e.g., “tools”, “pump”) or in the paper file “RUNNING ORDERS”.

3. Fill in the order on the chart “RUNNING ORDERS” hanging in the office. This helps to follow up outstanding orders.

4. From time to time, inquire about the order by radio message ot letter.

5. When receiving the items, compare the waybill and the purchase list and the items actually received. If everything is correct, sign the waybill. Note missing or damaged items on the waybill (all copies).

6. Put all the items into the store and hand them over to the storekeeper. The items need to be recorded on the stock cards.

7. If there is any difference between the purchase list and the items received, write a new list headed “ITEMS RECEIVED”.

8. Send the list “ITEMS RECEIVED” and an accompanying letter to Logistics, acknowledging receipt of the items and thanking them. Ask for the invoices and transport costs.

9. Alternatively, inquire from the Finance Department about payments made.

10. After receiving the information about payments, tell the administration to record them into the finance book.

11. Divide the transport costs accordingly on each item.

Example:

No	Quant	Unit	Item	Unit Price Khartoum	Total Khartoum	Unit Price Juba
1	20	pcs	zinc sheets 8’	60.000	1,200.000	86.400
2	5	gal	oil paint, green	55.000	275.000	79.200
3	30	pcs	buckets	15.000	450.000	21.600
			PURCHASE COSTS		1,925.000	
			Transport by air Khartoum -Juba		800.000	
			Loading/unloading		40.000	
			TOTAL COSTS		2,765.000	

The TOTAL COSTS are the PURCHASE COSTS plus all other costs of transport, handling, loading, etc.

The TRANSPORT FACTOR is used to include all additional costs, thereby finding the real cost of each item.

$$\text{TRANSPORT FACTOR} = \frac{\text{TOTAL COSTS}}{\text{PURCHASE COSTS}} = \frac{\text{£S } 2{,}765.000}{\text{£S } 1{,}925.000} = 1.44;$$

Multiply each “Unit Price Khartoum” by the TRANSPORT FACTOR. The result is the “Unit Price Juba” which includes all transport and other additional costs.

Note, that the price including transport, etc., is considerably different from the purchase price.

12. Record the “Unit Price Juba” on the stock cards.

7.8 Purchasing from Abroad

Some items are not available within the country and, therefore, need to be purchased from abroad. Purchases from abroad differ considerably from purchases within the country, because foreign currency payments and customs clearance are necessary.

Some items from abroad can be purchased by the Logistics Department. In this case the procedure is similar to “Purchases from Khartoum”. However, the purchasing of special technical items, like specific tools, pumps, hand augering equipment, etc., require special technical knowledge and information about the project’s needs. Therefore, these orders need to be handled by the project staff themselves in cooperation with the Logistics Department.

The procedure is basically as follows, but it may vary on different occasions:

1. Write a complete, quantified and exact purchase list and discuss it with colleagues and the storekeeper.

2. Write a letter to the supplier(s) requesting a pro forma invoice. Describe the items you want exactly. If possible, request pro forma invoices from several suppliers.

3. Upon receival of the pro forma invoices, check them and select the most suitable.

4. Discuss in the PMT and check with the administration whether the money is available in the budget. If necessary, get approval from the Deputy General Secretary or the Finance Director.

5. Write a letter to the supplier ordering the items according to his or her pro forma invoice. Indicate how the items should be packed and transported to your end (by air, by ship, etc.), by which route and by which transport company, if known.

Send copies of this letter to the Deputy General Secretary, Finance Director, Logistics Department in Khartoum/Juba, and to the transport company. One copy remains in the project and is filed in the respective paper file (according to subjects, with a separate file for each type of equipment).

6. Write an accompanying letter to Logistics Department in Khartoum requesting them to obtain an import license for this order.

7. Fill in the order on the chart “RUNNING ORDERS”, hanging in the office.

8. From time to time, inquire about the order by telex or letter.

9. After notice that the items have arrived, ask Logistics Department for assistance in customs clearance.

10. Check the items and compare them with the waybill, with the order, and with the pro forma invoice. If everything is correct, sign on the waybill. Note items missing or damaged on the waybill (all copies).

11. Assemble all machinery, like generators, pumps, etc., and test their operation. If they are not operating properly, write to the supplier.

12. Put all the items into the store and hand them over to the storekeeper. The items need to be recorded on the stock cards.

13. If there is any difference between the order and the items received, notify the supplier in written form <u>immediately</u>.

14. After receiving the bill, compare it with the pro forma invoice. Check to see that transport costs are reasonable. Send a copy of the bill with a request for payment to the Finance Department for settling.

15. Enter payment into the finance book of the project. If in foreign currency, calculate in £S at the official exchange rate.

16. Divide the transport and packing costs accordingly on each item and transform the amount into £S. Conside <u>all</u> transport costs as well as any handling costs that may have been charged.

Example:

No.	Quant	Unit	Item	Unit Price Supplier US $	Total of Supplier US $	Unit Price Juba US $	Unit Price Juba £S
1	2	pcs	diaphragm pump	700	1,400	1,330	4,655
2	4	pcs	hose, 10 m, ∅ 2 $\frac{1}{2}$ "	160	640	304	1,064
3	10	pcs	spare membrane	40	400	76	266
		PURCHASE COSTS			<u>2,440</u>		
		Packing			350		
		Air Transport EUR - NBI			1,250		
		Road Transport NBI-Juba			400		
		Handling by Transport Company/Loading/Unload.			200		
		TOTAL COSTS			<u>4,640</u>		

The "TOTAL COSTS" are the "PURCHASE COSTS" plus all other costs for transport, handling, etc.

The TRANSPORT FACTOR is used to include all additional costs, thereby finding out the real cost of each item.

$$\text{TRANSPORT FACTOR} = \frac{\text{TOTAL COSTS}}{\text{PURCHASE COSTS}} = \frac{4{,}640}{2{,}440} = 1.9;$$

17. Multiply each "UNIT PRICE SUPPLIER" by the TRANSPORT FACTOR.

The result is the "UNIT PRCIE JUBA, US $", which includes packing, transport, handling, etc.

Inquire about the official exchange rate between US $ and £S and transform the "UNIT PRICE JUBA, US $" into the "UNIT PRICE JUBA, £S".

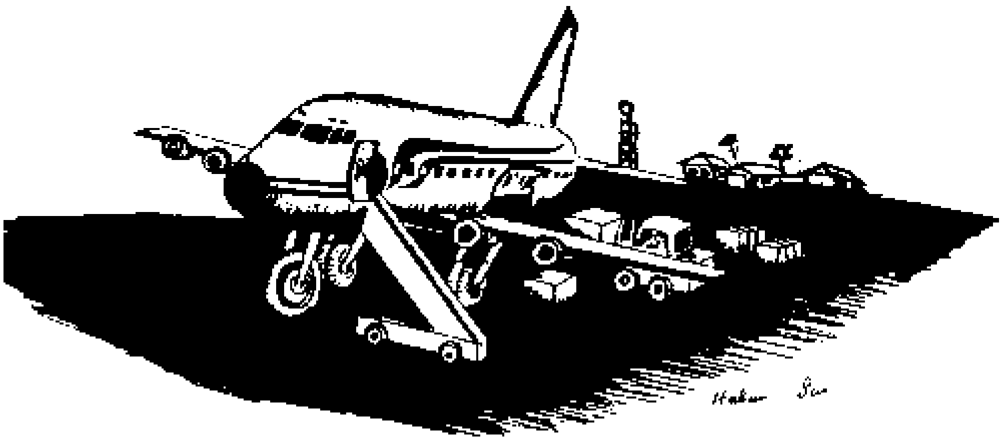
Example:

If US $ 1.00 = £S 3.500, then multiply all unit prices in US $ by 3.5. The result is the unit price in £S.

Note that the price including transport, etc., is considerably different from the purchase price. Knowing the real price is important for future budgeting and eventual sales.

18. Record the real prices (the "UNIT PRICE JUBA, £S") on the stock cards.

19. Write a letter to the supplier, acknowledging receipt of the order and thanking him or her.



7.9 Storekeeping - Recording

Correct records are essential for storekeeping. They are done on stock cards, which are to be filled in as follows (example see 7.9/3)

ITEM

Write a separate stock card for each kind and size of item. Therefore, separate cards for 'nails 2"', "nails 3"', etc. Write under "ITEM" the exact specification. Start with the general name, followed by the material, followed by the size. For example:

pipe, metal, ∅ 2"	not metal pipe
bits for wood	not wood bits

Put spare parts under the main item. For example:

hacksaw blades	not blades, hacksaw
diaphragm pump, spares	not spares for diaphragm pump

Use always the same and only one name for one kind of item. For example:

measuring tape, 2 m	not tape measure 2 m
measuring tape, 5 m	not tape measure 5 m
measuring tape, 10 m	not measuring tape 10 m
measuring tape, 50 m	not meter 50 m

Complete tool boxes are one item like handpump box, building box, well-digging box, etc. Write the name of the box under "ITEM" with the remark "Contents on a separate list". This list is to be kept with the stock card. A copy of the list of contents remains in the box itself for on-site checks.

ALPHABETICAL ORDER	The stock cards are stored in a box in alphabetical order. They are sorted according to the first word under "ITEM", then the second, and so on. Identical items differentiated only by size are sorted according to the size with the smallest first. Therefore, the following cards will be in this order: jerrycan, metal, 4 gallons jerrycan, plastic, 1 gallon jerrycan, plastic, 4 gallons or: timber, hardwood, 2 x 2", 3 m timber, hardwood, 2 x 4", 3 m timber, hardwood, 3 x 4", 3 m timber, softwood, 2 x 2", 3 m timber, softwood, 2 x 2", 6 m The stocktaking list of the previous year is attached to the box of the stock cards and can help you find the relevant cards.
UNIT	Indicate in which unit the item will be counted. For example: kg – nails pcs – hammer, welded mesh, timber, pipes m – rope, reinforcement bag – cement, whitewash set – drill bits, spanners of different sizes lit – oil gal – engine oil, fuel, paint rolls – binding wire The figures in the stock card below are always counted in the units mentioned above.
UNIT PRICE	Record the unit price in £S. If the same item is purchased later at a higher price, cancel the old price and replace it with the new one.
ON	Record the date when the price was valid.
NUMBER RECEIVED	Record the quantity received here. Fill a new line each time you receive or issue an item.
NUMBER ISSUED	Record the quantity issued here. When tools are put into any of the tool boxes, they count as "issued".
BALANCE	Add the number received to the balance of the line above and fill in the result on the same line under "BALANCE". Subtract the number issued from the balance of the line above and fill in the result on the same line under "BALANCE". The "BALANCE" must equal the actual quantity in the store.
TO/FROM	Record to whom the item was issued (e.g. well No.4, latrine No.5, office, handpump box, name of person). Record from whom you received the item (e.g. market Juba, Khartoum, Nairobi, building department).
DATE	Record the date of receiving or issuing.
REMARKS	Note any irregularity like "items spoilt", etc.
SIGNATURE	The storekeeper needs to sign here. Thus it is clear, who is responsible for issuing or receiving this particular item.

It is important to record all movements immediately. If that is not possible, due to lack of time, never allow any item to leave the store without a notice on a piece of paper, which is to be recorded later as soon as possible.

7.10 Organising a Store

A well-kept store contributes to correct storing and the easy finding of items. It keeps us aware of the amount of material in stock and helps to prevent losses. A good store is the foundation of any project work and a mirror of the quality of work.

A) Principles of Storekeeping

Good storekeeping is based on the following principles:

1. The systematic structure according to which the items are stored must be easily understandable for anyone at first glance. Thus, anyone using the store is much more likely to place the items in the correct location without messing up.

2. Every item should be easily accessible without moving other items or climbing over them. Thus, people are less likely to place items anyhow, maybe just in front of the door, or to move items without putting them back in their right places. This also saves time and efforts.

3. The store should be clean, dry and orderly. It is much more likely that people mess up a dirty place than a clean one.

4. Spoiling of items must be prevented and spoilt items need to be removed in order not to occupy needed space.

B) Rules of Storekeeping

For implementing these principles, observe the following basic rules:

1. Store identical items at the same place.

For example, do not store timber of the same size in different places.

2. Store related items near to each other.

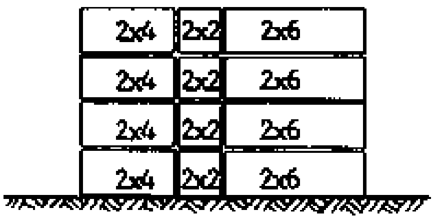
For example, store timber of different sizes or nails of different sizes near to each other. Store different kinds of tools near to each other, and separate them from building materials, etc.

3. Always store the same items in the same place.

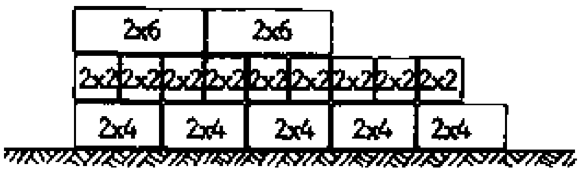
Write the name and/or draw a picture of the item on the shelf, wall, etc. Write the contents on boxes or packed material. Do that even if it seems obvious, since you might forget later. Especially, write difficult names on the shelves (like D-shackle, with drawing).

5. Always store lengthy boxes or other items with the short side facing the outside of the shelf. Thus you can see the side of many boxes instead of few. Store the boxes with the label of their contents facing the outside.

6. Store boxes, timber, etc., of the same kind above each other instead of beside each other with other items on top.



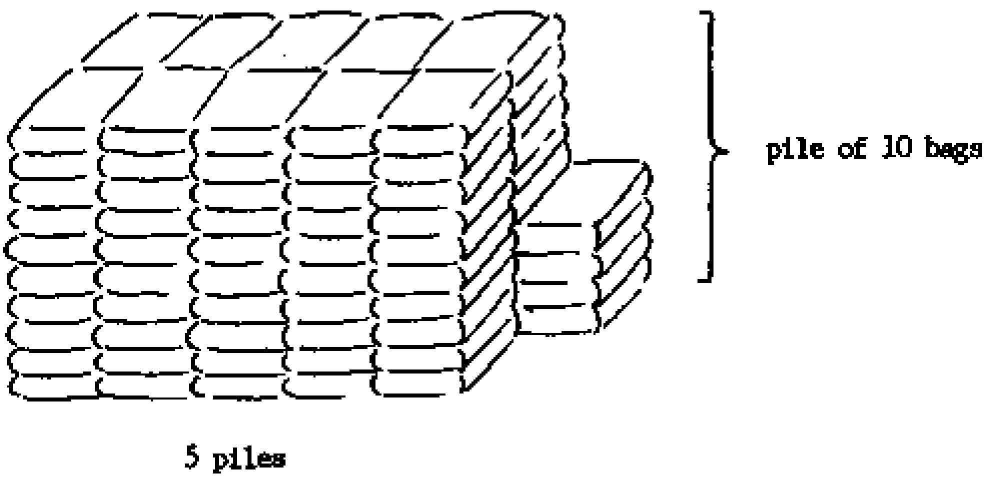
CORRECT



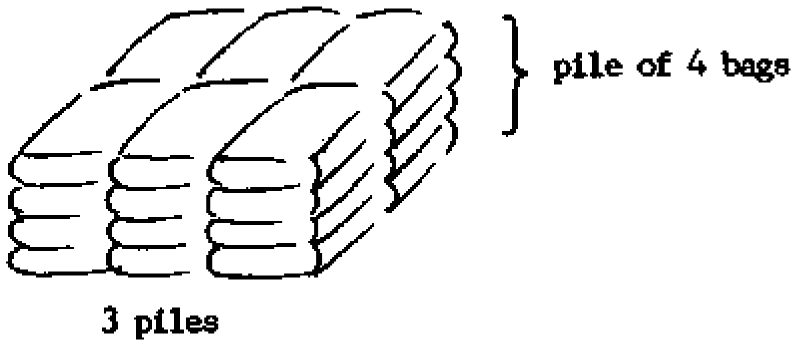
WRONG

Thus, each size/type is easily accessible without moving others.

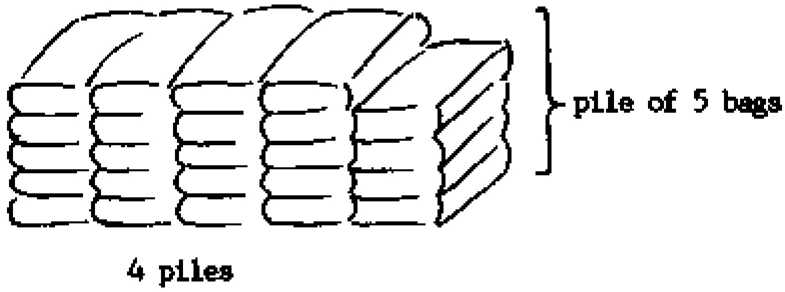
7. Store items so that they are easily countable. For example, store cement, etc., in piles of 5 or ten above each other and 5 or ten piles beside each other. Always remove from one pile until it is finished, then from the next.



easy to count: 104 bags



difficult to count: 24 bags



easy to count: 24 bags

Store nails in 1-kg boxes. Thus it is easier to determine how many are left, as compared with, say, a single container containing 20 kg of nails.

8. Store as few items as possible on the floor. Provide sufficient shelf space. Hang whatever possible on the wall or on the shelves. More can be stored on shelves than spread on the ground.

That way, moving about in the store and cleaning will be made easier.

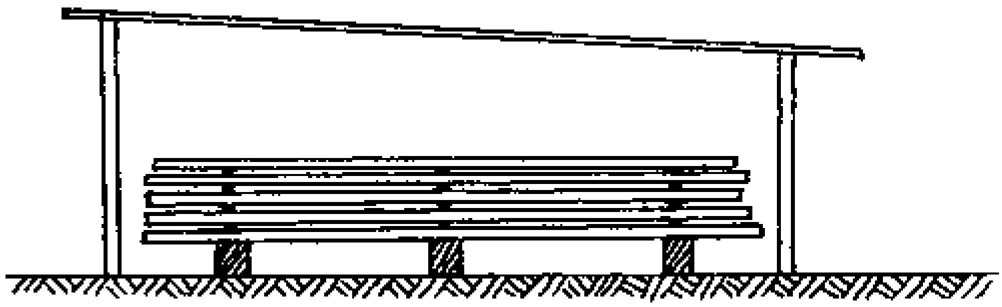
9. Put small items like nails, bolts, pins, etc., into labelled boxes.

10. Store rope and wire on a roll or hanging in rolls on a lever arm, or store rope in a box. Thus any length can be easily cut off.

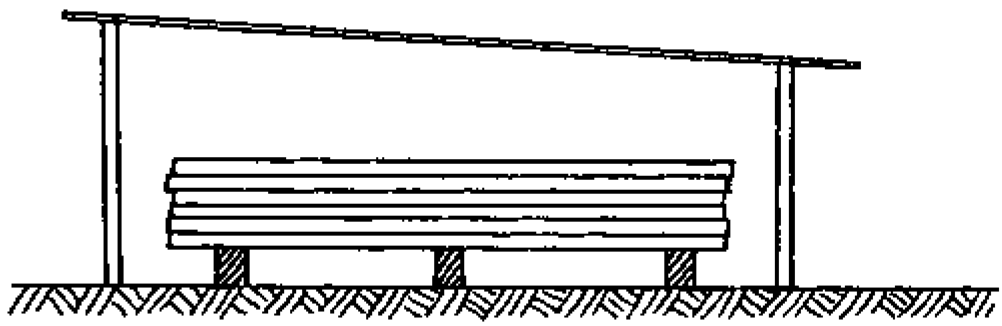
11. Store items in a stable way. Always store heavy items on the lower shelves. Turned-over shelves or collapsed piles are a nuisance and are dangerous.

12. Take care that the store is airy, has ventilation openings and is dry. Immediately repair any leaks in the roof or from below.

13. Store cut timber on a straight ground on at least three logs, never directly on the ground.



Optimal way of storing timber: each log is surrounded by air.



Possible way of storing timber: the air cannot reach all pieces.

Wrong way of storing timber: it gets wet, dirty and twisted, and ants can attack it easily.

14. Never store cement and fuel together. They will spoil each other.

15. Inflammable materials must be stored separately from other combu stible materials in an area especially protected from fire.

16. Materials, such as cement, which deteriorate with the passage of time, must be kept constantly moving by using the earliest arrivals first.

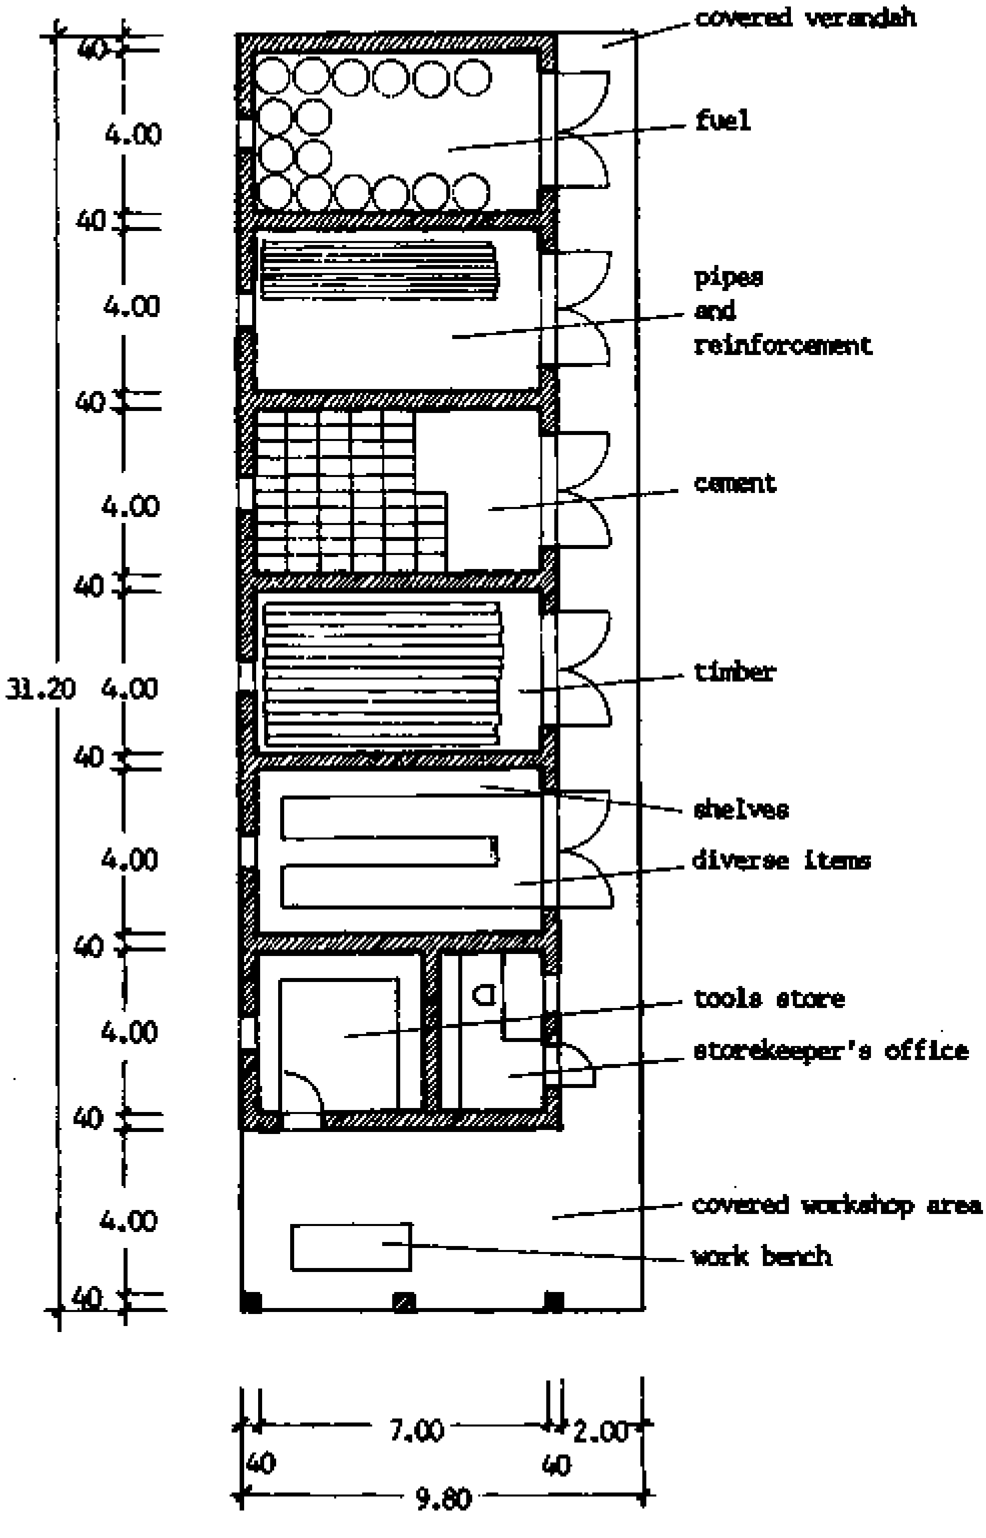
17. Clean the store regularly. Clean all returned items before putting them back into their place.

18. Keep the store carefully locked, even if you leave it only for a short time.

C) Equipment of a Store

- shelves,
- boxes,
- table,
- chair,
- stock cards in a box,
- file “LOANS”,
- file “SALES”,
- forms “WORK PLAN”,
- forms “WORK RECORDS LATRINE”,
- forms “WORK RECORDS WELL”,
- forms “TOOLS ON SITE”,
- forms “COST ESTIMATION/CALCULATION”,
- calculator,
- ruler,
- pens,
- pencils,
- marker pens,
- punch,
- stapler,
- string,
- glue,
- cellotape,
- lined paper,
- plain paper,
- carbon paper,
- jar 1 litre,
- jar 1 gallon,
- stocktaking list,
- balance scales,
- one copy of these chapters about storekeeping.

D) Example of Store Layout Plan



Scale 1:200

7.11 Storekeeping - Procedures

The task of the storekeeper is to implement the basic storekeeping procedures.

A) Issuing Tools for a Site (see 7.11/4)

Record tools to be issued to a site: first on the stock card, secondly on the form, “TOOLS ON SITE”, which is to be filled out in two copies. Give one copy to the foreman/technician responsible for the site; she/he has to account for any losses while on site. Let her/him sign for the tools issued. The other copy remains in the store for the storekeeper to check the tools as they are returned. Record complete boxes with their names (i.e., hand pump box, building box, etc.), without listing each tool.

B) Issuing Materials for a Site (see 7.11/5; also 7.3/1f; 7.4/1,7ff)

Record materials to be issued to a site: first on the stock card, secondly on the form, “COST ESTIMATION/CALCULATION”, which is to be filled out in two copies. Give one copy to the foreman/technician responsible for the site. The other copy remains in the store. This is needed for the final cost calculation.

Record materials for standard compost latrine construction, which are always the same amount, only on the stock card.

C) Receiving Items

Check tools coming back from a site according to the form, “TOOLS ON SITE”, and enter the receipt into the stock card. Check to see if the tools are in good condition.

Check items from the market according to the purchase list and enter them into the stock card, including the prices.

Check items arriving from outside according to the waybill. Note missing or damaged items on the waybill and sign all copies of the waybill. Enter the items into the stock card. Request the prices from the office and enter them into the stock card as well.

D) Sale of Items

Issue items on sale, like latrine slabs, ventpipes, children’s squatting slabs, etc., only when the buyer brings a receipt from the accounts office with a note from the senior staff. Record the item in the stock card and fill in under “REMARKS”: “paid, receipt No...., date of receipt”. Write on the receipt “Issued” with the date and your signature and give the receipt back to the buyer. File the note into the paper file “SALES”.

E) Loans of Items

Items (equipment or tools) can be loaned only in exceptional cases. Issue the item only upon a written approval from senior staff and file the approval in the paper file, “LOANS”. Enter the loan into the stock card.

Write a list of all outstanding loans at the end of each year and present it to the office for follow-up.

F) Purchase List

Note down any items which have been depleted, soon will be depleted, or are missing, on a purchase list. Present these suggestions for re-purchasing to the concerned staff at the time of purchasing.

G) Cost Calculations

When the work on a well or latrine is finished, the foreman or technician on site completes the records of materials on the form “COST ESTIMATION/CALCULATION”, including the materials contributed by the community. She/he hands the list to the storekeeper. The storekeeper adds the prices according to the stock cards and hands the list to the office (for a detailed description, see under 7.3 and 7.4).

H) Prevention of Loss and Misuse

A project store is a great asset but can create danger of loss and misuse. Additionally, the question of misuse can cause founded or unfounded accusations, mistrust, and disturbance in staff cooperation. The following suggestions may help to minimize such disturbances and to prevent or reduce losses and misuse.

1. Suggestions for Senior Staff

- Normally, store keys should be handled by only one person. However, this might cause a lot of inconveniences in the daily running of a project (especially for a small project with no specially assigned storekeeper). The assignment of two people holding store keys is only possible, if there is trust between them and if they keep strictly to recording each item issued and received immediately. Otherwise, insist that only one person be responsible for the store keys.

- In the case of very valuable items stored, provide the store with two padlocks and let two different people hold the keys. Thus the store can be only used during the presence of both.

- Assign one person to be responsible for tools on site or for a specific store, etc., and let her/him sign when taking over. This strengthens the feeling of responsibility among staff.

- If staff members want to take items home (e.g. tools for use, scraps), insist that they keep to the procedures, i.e. ask permission which should be granted whenever reasonable and possible. If not, explain why. The staff should feel that they are treated reasonably and justly.

- Pay a reasonable salary to storekeeper and technicians. Project properties are a great and unfair temptation to underpaid staff with hungry children at home.

- In case of losses, make an inquiry. Do not blame anyone unless guilt is clearly proved. In that case, take whatever steps are necessary. Otherwise, improve your supervision and spend more time on regular checks. In case of proof misuse, dismissal is the only possible action.

2. Suggestions for the Storekeeper

- Keep to the storekeeping procedures, especially, insist on authorizing documents when issuing items.

- Keep the store in order. This helps to keep an overview.

- Label the shelves. Draw pictures of each tool on the wall on the place where you hang it. Thus you realize immediately when it is missing.

- Store items like nails in packed quantities.

- Store items in an easily countable way. Thus you can check the number easily any time.

- Keep your records in order and up-to-date.

- In case of any suspicion against you, insist on the presence of a second person when handling the store.

7.12 Stock-Taking

The annual stock-taking is essential in order to determine the assets of the project and to check if anything is lost. The stock-taking report is part of the annual report of the project. The stock-taking is done at the end of the year and is connected with general cleaning of the store and maintenance of equipment.

Stock-taking and cleaning of a big store takes time. Plan on taking several days with sufficient staff. Follow these steps:

1. Collect all tools and equipment from outside sites.

2. Clean the whole store and put it in good order.

3. Go through all the stock cards. Count the quantity of all items available in the store and compare it with the last balance in the stock card. Tick it if they correspond. If items are missing, consider whether they may be on outside sites or on loan to somebody. If anything else is missing and somebody is responsible for the loss, she or he should be made to pay for it. Record unaccountable losses or losses due to normal spoiling as follows:

Put the quantity missing under “ISSUED” and write “lost” or “spoilt” under “REMARKS”.

4. Write the stock-taking list. Preferably this should be done in a quiet place with a desk.

The stocktaking list looks like this:

<u>Stock-taking List</u>

Year: ....
Project: ....
Store: ....

Quant	Unit	Item	Unit Price	Total	Total Depreciated

Fill in for each stock card one line.

Fill in under “QUANTITIY” the number of the last “BALANCE” on the stock card. Fill in “UNIT”, “ITEM”, and “UNIT PRICE” according to the stock card.

Multiply “QUANTITY” with the “UNIT PRICE” and fill in the result under “TOTAL”.

Calculate the “TOTAL DEPRECIATED” for each item.

Do not depreciate material, equipment and tools, which have <u>not</u> been used, but just stored in stock. For these items the “TOTAL” and “TOTAL DEPRECIATED” are equal.

Depreciate all equipment and tools which were used as shown in the following example:

Year	Depreciation	To get the “TOTAL DEPRECIATED” multiply the “TOTAL” by the factor
1.	25% from original price	x 0.75
2.	50% from original price	x 0.50
3.	75% from original price	x 0.25
4.	100% from original price	The “TOTAL DEPRECIATED” = 0

The first year is the year following the purchase.

Example:

Pipe moulds purchased in 1985

Year		Quant	Unit	Item	Unit Price	Total	Total Depreciated
1985		3	pcs	pipe moulds	4,000	12,000	12,000
1986		3	pcs	pipe moulds	4,000	12,000	9,000
1987		3	pcs	pipe moulds	4,000	12,000	6,000
1988		3	pcs	pipe moulds	4,000	12,000	3,000
1989		3	pcs	pipe moulds	4,000	12,000	

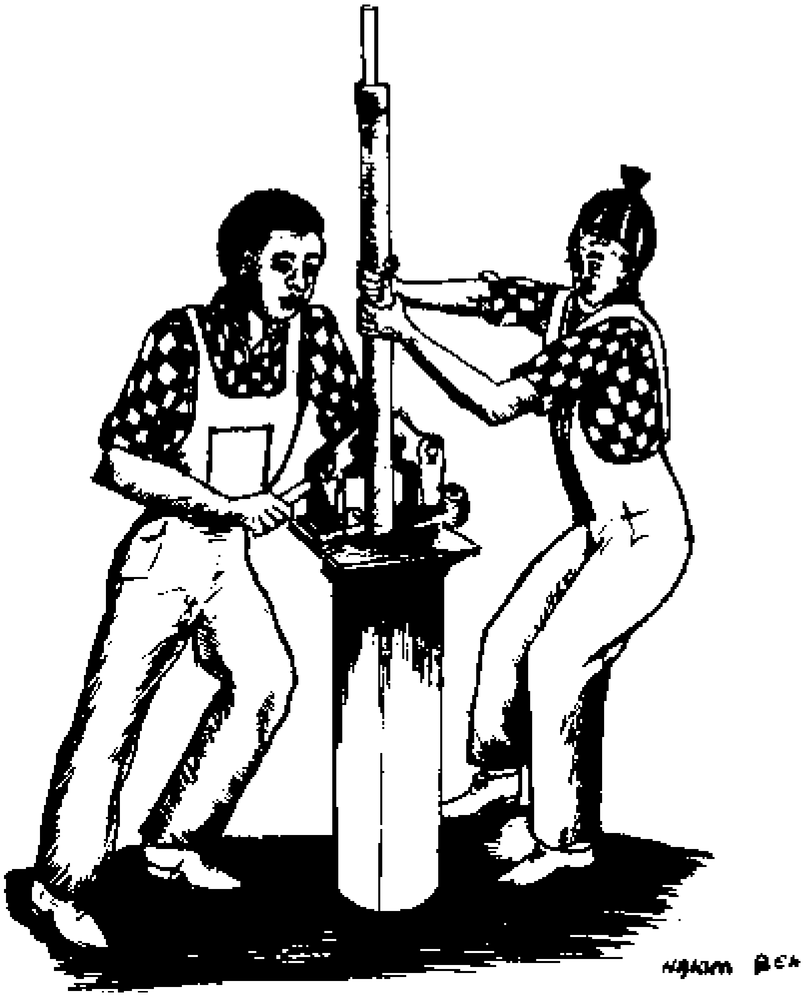
Fully depreciated items are recorded in the stock-taking list (they are still around and may still be used), but the “TOTAL DEPRECIATED” (= the depreciated value) is recorded as nil.

After filling in all items on the stock-taking list, add up all “TOTAL DEPRECIATED”. The result will be the “GRAND TOTAL”.

The work of filling in the stock-taking list can be drastically reduced if a photocopy of last year’s stock-taking list is used and the changes are filled in. Afterwards the new stock-taking list can be typed.

5. Hand the stock-taking list to Administration. There, vehicles and office assets will be added. The final stock-taking list is attached to the annual report (see 2.6/3).

8. Water Supply



8.1 Story about Good Water Supply

Jam 3,11

The following chapters mainly tackle the technical aspects of water supply. However, the technical aspects are only one element of a successful, good water supply. The social and educational aspects are at least as important, but not the main topic of these chapters. A story about good water supply is recorded her as an example which can be used in the educational work with the community.

THE FOOLISHNESS OF MAN

God had created everything: the cattle, the goats, the dura, the fire, and the water. So one day he called the creatures: lion, hyena, bird, hippo, and man. God told them to ask for one of the things he had created. The lion choose the cattle. The hyena wanted the goats. The bird asked for the dura. And the hippo took the fire. Then man was left with only water and he complained: “I wanted the cattle!” But God told him to take the water, that it was a good gift.

So, the lion went away with his cattle and ate one of them. Then he rested. When he woke up, he was very thirsty. When he came to the water, the man said: “Go away. The water belongs to me." "But I am very thirsty. I will give you a cow." "That is not enough, "said the man. So the lion gave man all the cattle, and man let the lion drink.

...and the same thing happened with the hyena, the bird, and the hippo...

And so man had everything: the cattle, the goats, the dura, the fire, and the water. But sometimes the lion or the hyena or the bird or the hippo would sneak up and steal one of these things from man because they had nothing.

One day God looked down at this man who had the water and the cattle and the goats and the dura and the fire. And he saw that man drank water from the river and that he bathed in the same place and that the cattle came into the water to drink. And other people used the river as a place for urinating. And God was unhappy. He looked again at man. Man was crying with indigestion, diarrhea with blood and bilharzia every day. So God called the fox. "Go! Talk to the foolish man. I have given him all the water and he does not know how to keep it safe. Man cannot drink the water where man and cattle bathe. Man cannot bathe in water which is a place for urine and stool. Man will have to find the hidden water I have given him."

So fox went to man. "Oh, foolish man! You have spoiled this big gift of water and now you have many sicknesses. Do you want these sicknesses always?" "Oh, fox! How can these things truly go away?" And fox told man to dig a hole for the hidden water and to put a cover on the top to keep dirt and germs from getting in. Then the fox told man to buy a pump to draw the water out so that no unclean bucket would touch the water.

And man did as fox suggested. And man had healthy water and the diseases stopped. And man was happy again. And God looked down and shook his head and said: "What kind of foolish man!"

8.2 Connection of Water Supply with the Community

Gen 26,12-21; Ex 17,1-7; Num 20,1-13; Dtn 6,11; Js 41,17-20; Jer 14,3 Ez 29,3; Jn 4,5-30

Water supply is not a private, but a community facility. Therefore, the whole community needs to be involved in

1. Decision taking (about price, location, construction, caretaking),
2. Construction,
3. Correct handling,
4. Control of use,
5. Maintenance and repair.

The community is not in need of <u>any</u> water point, but of a water point,

1. considering social connections, to be used by any citizen irrespective of religion, tribe and race,

2. at a suitable location,

3. under control of the proper people,

4. with water in sufficient quantity (the aquifer not being completely exhausted),

5. with water of good quality,

6. easy to operate, especially for children,

7. easy to maintain,

8. with the appropriate infrastructure (spare parts available, etc.).

See also 8.29/1f.

8.3 Process of Community Development - Water Supply Cooperation

Water supply measures without community involvement are a common practice in many places, however, community involvement has invaluable advantages, although difficult, tiresome and slow. Therefore, community involvement should always be pursued.

A community development process with several meetings needs to take place before and during the start of the technical work.

Ideally, the community contributes whatever it is able to contribute depending on the situation, such as:

- unskilled labour,
- local materials,
- feeding of project staff on site,
- cash,
- participation in the operating instruction,
- selection of caretakers for operation and maintenance.

The project contributes whatever the community is not able to provide, such as:

- know-how,
- skilled labour,
- equipment,
- materials from outside,
- transportation,
- supervision,
- operating instruction,
- training for the caretakers.

The form on 2.5/6f is an example of an agreement between a project and a community about the construction of a well.

See also 8.29/1f.

8.4 Cooperation of Water Supply Technicians with the Community

Dtn 6,11b

For successful cooperation between the technical staff and the community, the technicians have to act in certain ways and keep to certain working principles.

The following attitudes need to be observed:

1. Community cooperation is voluntary. If the community wants to achieve its aim, i.e. a well, they need to bring their contribution. If not, no well is going to be built. It is up to them. The project staff should not try to persuade the community or to put pressure on them.

2. The project staff needs to act with great respect towards the members of the community and their capabilities.

3. The project staff needs to be clear and consistent in its relationship with the community.

The following working principles need to be kept:

1. Inform the community ahead of time about your coming.

2. Keep tools, equipment, files, behind when you arrive until people are ready to accept them. At first, they might be frightening.

3. Always greet everybody upon your arrival.

4. Behave in a polite manner, quietly and patiently, with respect.

5. Assemble all people of the community and project before starting work on a new site. This is the time for greetings, explaining the work, discussing questions, and prayer.

6. Talk in an understandable language. Avoid difficult, especially technical expressions. Make sure that everything is translated.

7. Consider women equally.

8. Avoid embarassing illiterates by handing them written documents. If necessary, ask for somebody from the community who knows to read (normally the secretary of the well committee).

9. Accept anything offered to you with kindness (chairs, drink, food). You may ask, but do not request.

10. If you bring your own clean drinking water, do not boast with its cleanliness and do not belittle the water of the village. Share your water, if asked.

11. Do not implement any water supply work if the community did not meet its contribution.

12. For necessary communication approach the members of the committee rather than individuals.

13. Give priority to solve relationship problems and social conflicts during the process of work.

14. Do not let yourself get involved in inner organisational problems of the community.

15. Call for a community meeting in case of any community related problems instead of trying to solve them on your own.

8.5 Importance of Adequate Water Supply

Human beings need water

directly for (in order of their priorities)

1. Drinking,
2. Cooking,
3. Taking bath,
4. Washing kitchen utensils and cleaning,
5. Washing laundry;

indirectly for

6. Cultivating their food (rainwater or irrigation),

7. Watering their animals and thus producing food,
8. Fishing,
9. Building,
10. Generating electrical power,
11. Exstinguishing fire,
12. Running machines,
13. Recreation,
14. Cooling,
15. Flushing latrines,
16. Industries and others.

Water is needed (in order of their priority)

1. in sufficent quantity,
2. in good quality.

Inadequate quantity of water affects the health of people by

1. not enough water to drink	→ dehydration,
2. not enough water to cook, therefore not enough food	→ malnutrition,
3. not enough water for cleaning kitchen utensils	→ transmission of diseases,
4. not enough water for taking bath	→ development of skin and eye diseases,
5. not enough water for the laundry	→ skin diseases,
6. not enough water for cultivation	→ malnutrition,
7. not enough water for animals	→ malnutrition.

Bad quality of water affects the health of people by

- transmitting water related diseases.

See also 8.29/1f.

8.6 Water Related Diseases

Most diseases in Sudan are due to one of the following reasons:

1. Lack of sufficient water,
2. Lack of clean water,
3. Lack of sufficient sanitation,
4. Lack of preventive health care (immunizations etc.),
5. Lack of curative health care (personnel, facilities, etc.),
6. Relying on (traditional) medicine without consulting medical personnel,
7. Unbalanced diet,
8. Poverty,
9. Distribution of land,
10. Difficult life conditions in parts of the country,
11. Great number of household members,
12. Certain values and beliefs.

A great number of the diseases are related to inadequate water supply. They can be differentiated according to five groups:

Name	Description	Diseases	Help
water borne diseases	carried by water, infecting consumers	cholera dysentery typhoid hepatitis amoeba giardia diarrhea polio	provide clean (safe) water
parasitic diseases	organisms causing the disease spend part of their life cycle in an aquatic host	guinea worm bilharzia filariasis	provide clean (safe) water
filth born diseases = diseases of dirt	caused by insufficient water for washing and hygiene	scabies tropical ulcer trachoma eye infections	provide sufficient quantities of water
water associated diseases	spread by insects breeding in water	malaria river blindness sleeping sickness yellow fever	remove pools, flooded la- trines and other breeding places
diseases by polluted water	caused by drinking chemically polluted water	cancer kidney trouble mottling teeth skeletal fluorisis	prevent chemical pollution of water

WATER RELATED DISEASES

Sickness	Other Names	Cause	Vector	Transmission	Preventive Measures	
					before sickness	during sickness
Cholera		toxin, released in gut by bacteria	people, flies	contaminated water and food, incl. ice and cold drinks, uncovered faeces	good hygiene, latrines, safe water	isolation, good hygiene, safe water, disinfect or burn the clothes and blankets, boil plates and cups, disinfection of stools
(bacterial) Dysentry	shigella, shigellosis	bacteria (several different ones)	people, flies	contaminated water or food	good hygiene, safe water, clean and well prepared food, latrines	isolation, separate plates and cups
Typhoid	enteric fever	bacteria	people, flies	contaminated water and food, faeces to mouth	good hygiene, safe water, latrines	isolation, disinfection of stools, wash hands after latrine

Sickness	Other Names	Cause	Vector	Transmission	Preventive Measures	
					before sickness	during sickness
Hepatitis A Hepatitis B		virus	people, flies, monkeys	A: faeces to mouth B: blood - using needles of other people	good hygiene, safe water, latrines, sterilized medical equipment	isolation, separate plates and cups, extremely good hygiene
Polio	poliomyelitis	virus	people, flies	contaminated food or water, close contact	good hygiene, safe water, vaccination, latrines	isolation, good hygiene, safe water
Amoeba	amoebiasis, amoebic dysentry	parasite	people, flies	contaminated food or water, poor sanitation	good hygiene, safe water, latrines, keep flies off food	wash hands after de-faecation and before meals
Giardia	giardiasis	parasite	people, flies	see under dysentry	see under dysentry	see under dysentry, papaya seeds protect
Diarrhea	gastroenteritis	bacteria	people, flies	see under dysentry	see under dysentry	see under dysentry
Guinea worm	dracunculiasis	parasite	cyclops in standing water (well or pond)	infected person stands in water or muddy place, warm lays larvae into the water, people drink contaminated water	safe water supply, drainage of standing water	cleanliness, roll worn slowly on small stick (may take a week, do not break the worm), do not go into water
Bilharzia	schistosomiasis - Mansoni - Haematobium	parasite	snail (releases parasite into water)	swimming or walking in infected water (parasite penetrates the skin)	avoid swimming, walking, bathing in infected water, e.g. the Nile, control snails, latrines	urinate and defaecate only in latrines
Scabies	7-year itch	parasite	scabies mite	close skin contact with infected person	avoid contact with infected person, good hygiene	wash all clothes and furniture with hot water and soap
Tropical Ulcer		bacteria		filth, friction, trauma	good hygiene, safe water	daily cleaning of the ulcer

Sickness	Other Names	Cause	Vector	Transmission	Preventive Measures	
					before sickness	during sickness
Trachoma	chronic conjunctivitis	bacteria	people, flies	by flies or touch by contaminated fingers	good hygiene, safe water, early treatment	wash left and right eye separately
Eye infections	conjunctivitis	bacteria	people, flies	see trachoma	see trachoma	see trachoma
Malaria		parasite (plasmodium)	mosquitoes	mosquito bites	mosquito net, screening, shut doors and windows in the evening, cut grass short fill in pools	early treatment to prevent anaemia
River blindness	onchoceriasis	parasite	black fly	fly bites	control of black fly	control of black fly
Sleeping sickness	trypanosomiasis	parasite	tse-tse fly	fly bites	protecting clothes, clear bush	
Yellow fever	jungle fever	virus	mosquitoes	mosquitoes living in areas with monkeys	vaccinations, drain breeding places	isolation, mosquito net
Filariasis	- Wuckeria Bancrofti - Loa Loa	worms	- people to mosquito - people to fly	mosquito and fly bites	clearing bush and grass, drain water	mosquito net, insect repellants
Cancer		chemicals in water, and others		drinking polluted water	drink chemically clean water	early treatment
Kidney troubles	kidney stones	water with too much salts		drinking polluted water	drink water with low salt content	drink plenty of water
Mottling of teeth Skeletal fluorosis		fluorides in drinking water		drinking polluted water	defluoridation of water supply	early treatment

compiled by Inga Andersson

8.7 Basic Facts about Water

Ez 34, 18-19

A) Distribution of Water

No.	Location	Name	Volume (approx.)	Percentage
1	Water in vegetation, animals, human beings	water in biosphere	1,000 km^3	0.00007 %
2	Water in the air (clouds, rain)	water vapour	14,000 km^3	0.001 %
3	Water in lakes, ponds, rivers, swamps	surface water	135,000 km^3	0.01 %
4	Water in the soil underground	groundwater	8,400,000 km^3	0.6 %
5	Ice caps, glaciers, snow	frozen water	29,350,000 km^3	2.1 %
6	(salty) water in seas and oceans	seawater in oceans	1,362,100,000 km^3	97.3 %
	TOTAL		1,400,000,000 km^3	100.00 %

Water in the air, in the biosphere, frozen water and seawater are not readily available for water supply. Therefore, water supply for humans mainly relies on groundwater and surface water. Surface water is not available in all locations, whereas groundwater is available in many locations and is the main source of water supply.

Distribution of Groundwater

75 % less than 50 m deep
25 % deeper than 50 m

Hand dug wells are ususally constructed up to 50 m depth (depending on the conditions). That means that the majority of groundwater is within the scope of hand dug wells.

See also 8.11.

B) Properties of Water

Some properties of water are listed in the following:

- It consists of hydrogen and oxygen; the chemical formula is H_2O.

- It is transparent.

- It is colourless (with a blue tinge in large bodies).

- It has no taste.

- It exists in three physical stages:

  * solid = ice
  * liquid = water
  * gas = vapour

- The ratio between the weight of water and the weight of (dry) air is 830:1; therefore, water falls in air.

- The ratio between the weight of vapour and the weight of (dry) air is 1:133; therefore, vapour moves upwards in air.

- The freezing point of water is 0°C.

- The maximum density of water is at 4°C.

- The boiling point of water is at 100°C (changing with atmosphere pressure).

- The ratio between the weight of ice and the weight of water is 1:11; therefore, ice floats on water.

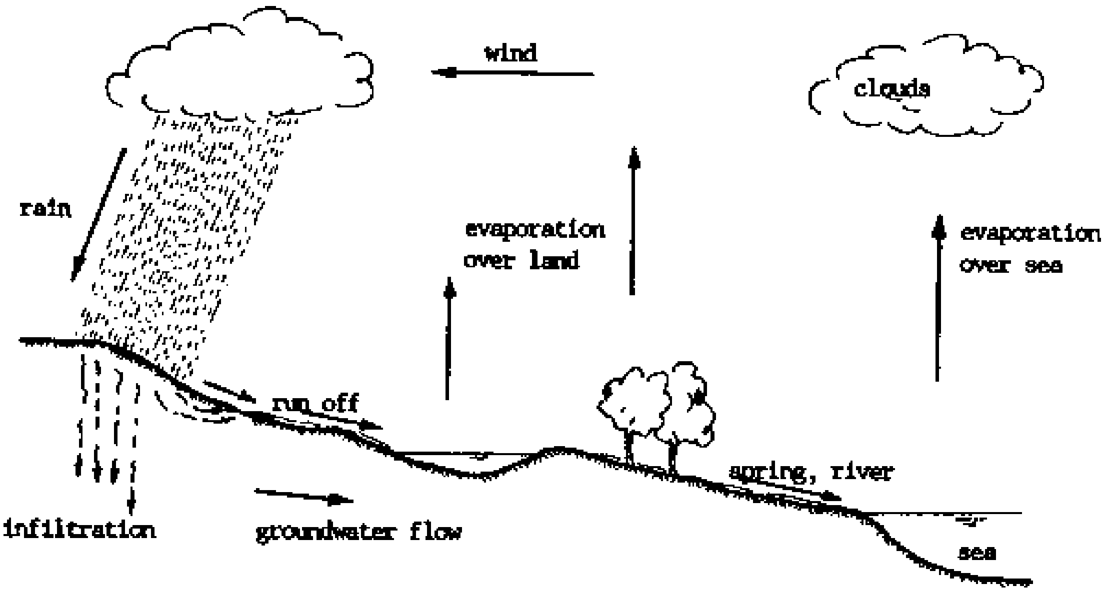
- Water is practically incompressible.

- It has capillarity, that is the ability to move upwards in small diameter openings because of cohesion (= the ability to stick together) and adhesion (= the ability to stick to a surface).

- It is an universal solvent; therefore, natural water contains gases and mineral salts in solution.

C) Movement of Water

1. Hydrological Cycle

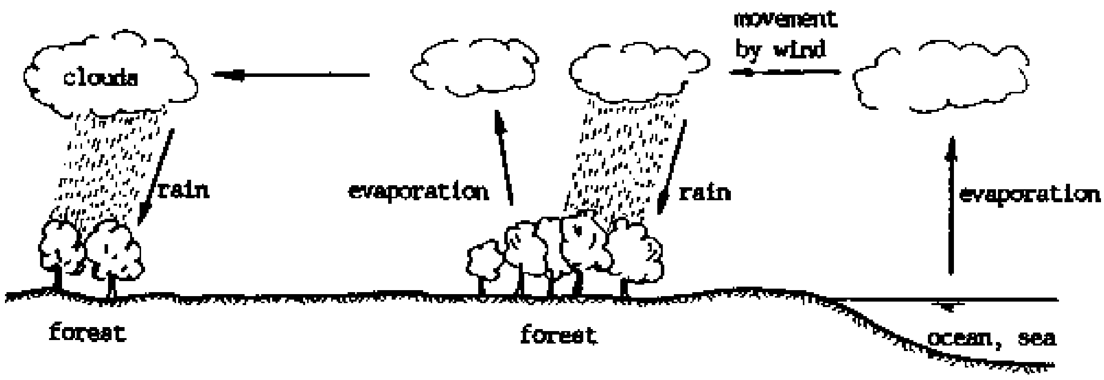


2. Transportation of Water from the Sea into the Continent

Water

- evaporates over the sea,
- travels by cloud several 100 miles,
- rains on forest,
- evaporates from forest,
- builds new clouds,
- travels to next forest several 100 miles away.

That means that water travels in “jumps”. Therefore, forests are essential for the transportation of water into the continent.



D) Dangers for Water

Our groundwater is a most valuable resource essential for life. It is in danger in many ways:

1. Water Is in Danger of Bacteriological Pollution

Flooded latrines, latrines too close to wells, leaking septic tanks, overflow seepage wells of septic tanks, and defaecation in the open pollute the water with disease transmitting bacteria and viruses. Bacteriological pollution can be cleaned through filtering and disappears by itself with time passing (see also 9.8).

Therefore:

- Do not construct latrines which will be flooded!
- Do not construct latrines near to wells!

2. Water Is in Danger of Chemical Pollution

Flooded latrines increase the nitrate and nitrite concentration in the water (nitrate and nitrite are produced in the decomposition process and are then dissolved in the water).

Poisons like DDT, artificial fertilizers and pesticides, spilled engine oil, diesel or petrol, acids, etc. pollute the water chemically. It is very difficult, mostly impossible, to remove chemical pollution from water (see also 3.11/2; 9.13/2f; 9.16/2; 9.22).

Therefore:

- Avoid the use of poisons like DDT, pesticides, etc.!
- Be careful not to spill engine oil, diesel, petrol, etc.!
- Never pour old engine oil on the ground!

3. Water Is in Danger by Removing Vegetation

Rainwater falling on barren soil will run off quickly and will have no time to infiltrate into the ground and, therefore, to add to the ground-water. (Beside that, winds will carry away the top soil which is fertile.) Soil with vegetation retains the rainwater and allows it to infiltrate into the soil(see also 8.9).

Therefore:

- Do not burn the grass on the fields! If burning is absolutely necessary, do it just immediately before planting the new crops and make sure that the area is limited.

- Do not overcultivate and do not allow overgrazing!

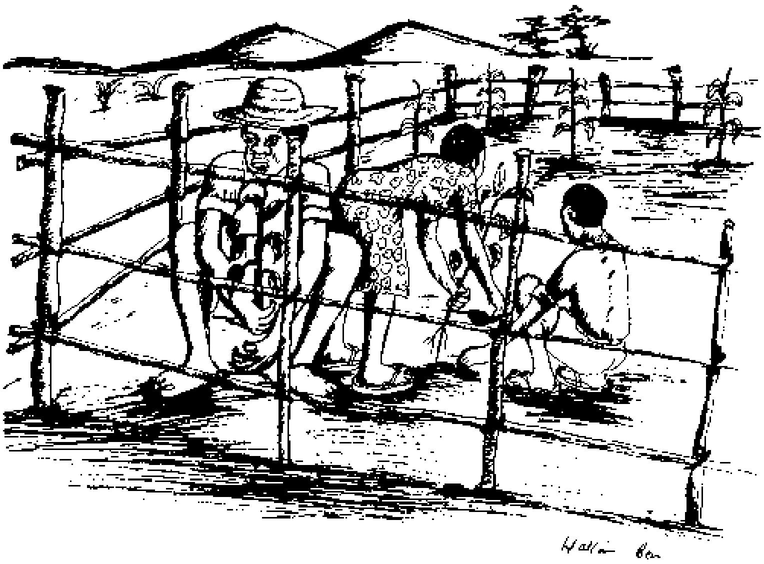
4. Water Is Endangered by Cutting Trees

Trees transport water from the groundwater through their roots up to the leaves. They form clouds through their evaporation. Therefore, forests are essential for creating rain.

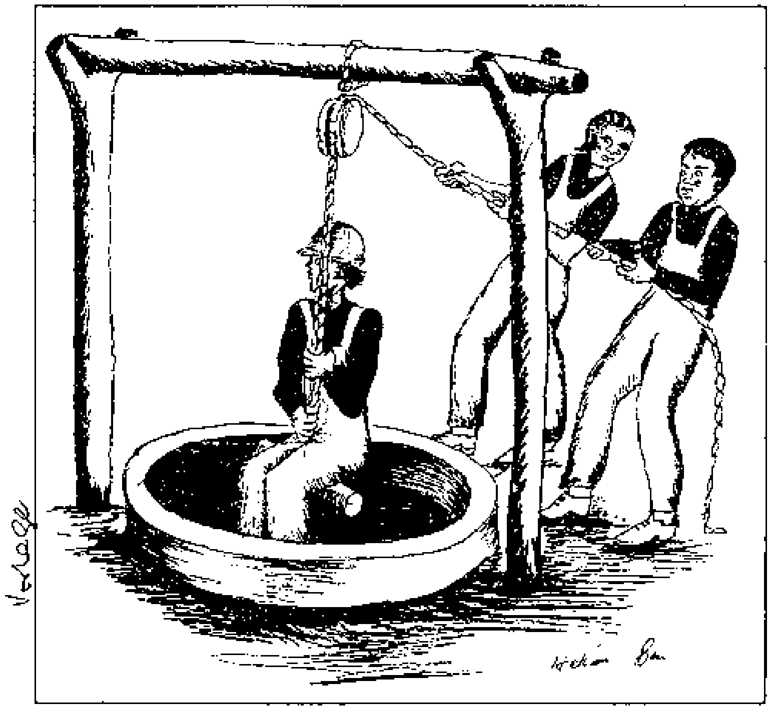
People cut trees for clearing fields (and building houses without planting young trees. Tree seeds and young trees are killed by agricultural fires. People contribute to the reduction of rains by neglecting the trees.

Therefore:

- Plant young trees and protect them!
- Cut only as many trees as absolutely necessary! For each tree cut, plant three young ones!
- Do not burn grass!



8.8 Groundwater



A) Water Storage

The ground soil normally contains air in its pores and is able to store water instead of air in the pores. The water content can be differentiated as follows (see also 8.8/4):

The Soil Is	The Soil Contains	Name	Suitable for Well Intake
dry	air, but no water	soil layer without water	no
wet	air and water	capillary zone or unsaturated zone	no
saturated	water, but no air	aquifer or saturated zone	suitable

B) Properties of Ground Soil

The soil has the following properties regarding water:

- It stores huge amounts of water.
- It prevents evaporation of the water.
- It preserves the quality of water.
- It cleans the water from bacteriological pollution.
- It enriches the water with minerals, etc.
- It makes the water available for trees, wells, springs, etc.
- It balances changes in the climate (dry season - rainy season, droughts).
- It allows vertical transportation (= infiltration).
- It allows horizontal transportation ("underground streams", horizontal seepage).
- It releases water to wells, springs, etc.
- It preserves the water temperature.
- It can make water dirty if the soil is polluted by poisons, old engine oil, fuels, etc.

C) Properties of Aquifers

Two main properties are essential for aquifers (= water bearing layers):

1. porosity = measure for the ability to store water
2. permeability = property of permitting the through-flow of water

Soil	Porosity	Permeability $m^3/day \times m^2$
clay	54 to 557.	0.00005 to 0.1
sand	35 to 407.	5 to 150
gravel	30 to 407.	50 to 750
sandstone	10 to 207.	0.005 to 2.5

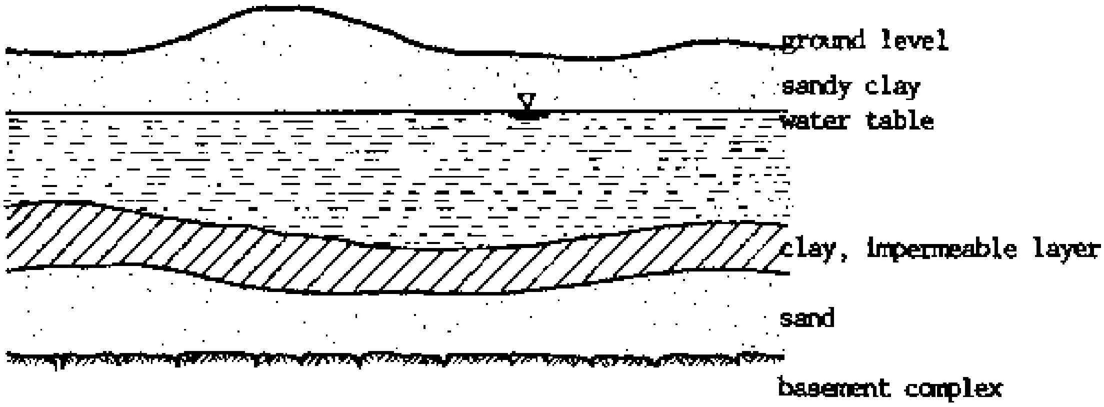
D) Types of Aquifers

Often there are different soil layers above each other. They can constitute the following types of aquifers:

1. (Open) Aquifer (= unconfined aquifer = open groundwater)

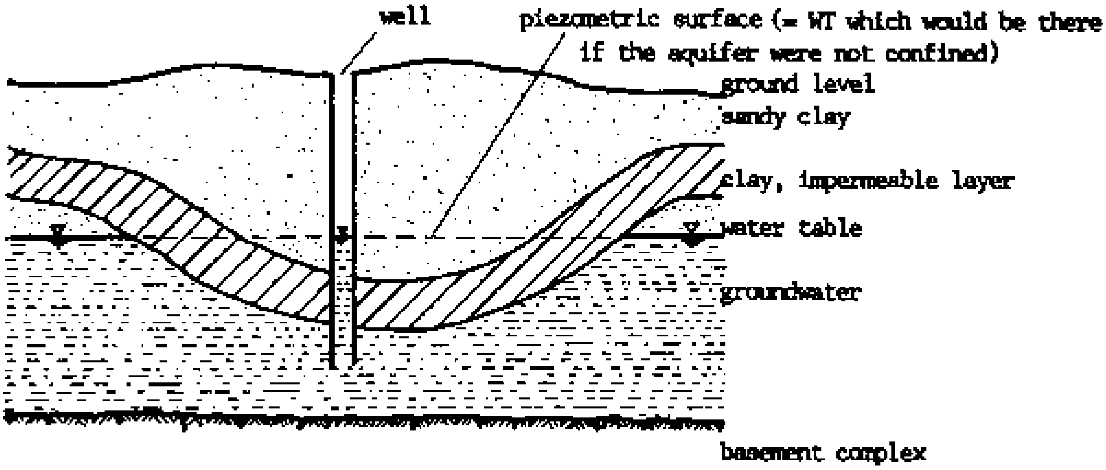
An aquifer is a saturated porous soil layer containing and transporting water. There can be several aquifers above each other, divided by impermeable layers.

An impermeable layer contains no or little water and does not allow water to infiltrate through it. However, impermeable layers are seldom continuous, therefore, water can pass through the incontinuities.



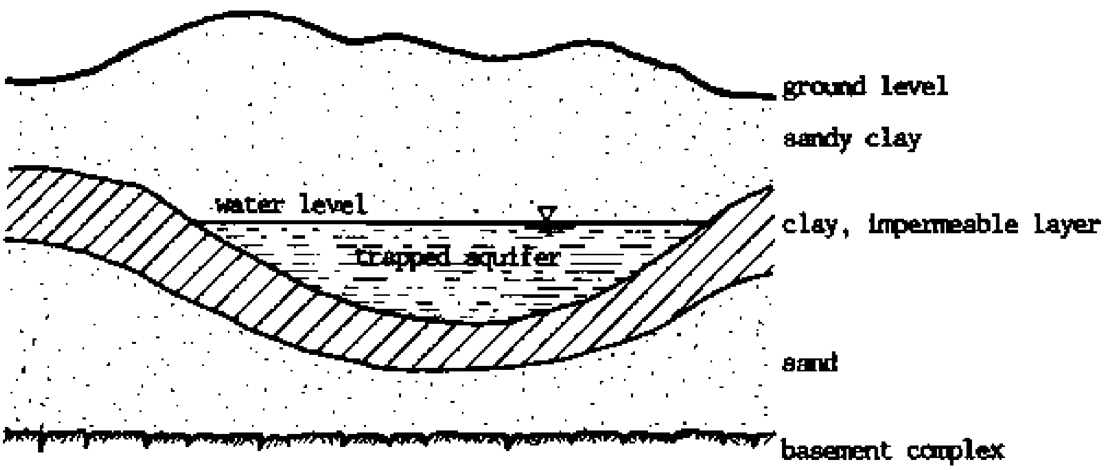
2. <u>Artesian Aquifer (= confined aquifer)</u>

An artesian aquifer is confined by an impermeable layer. If tapped by a well, the water table raises in the well up to the "piezometric surface". See also 8.35/3.



3. <u>Trapped (or Perched) Aquifer</u>

A trapped aquifer is a limited aquifer surrounded by impermeable layers. The recharge is limited; therefore, a well tapping a trapped aquifer can be exhausted and dry out (see also 8.29/1).



E) <u>Movement of Groundwater</u>

Groundwater can move in two different directions (or mixtures of the two):

1. Vertical Movement

Rainwater infiltrates vertically into the ground by gravity. Also, strong pumping in a well can force the water to move vertically downwards through different layers. Vertical movement is the main movement of groundwater.

The infiltration of water into the ground is influenced by the following factors:

- Steep slopes cause quick run-off, and there is little infiltration into the groundwater.

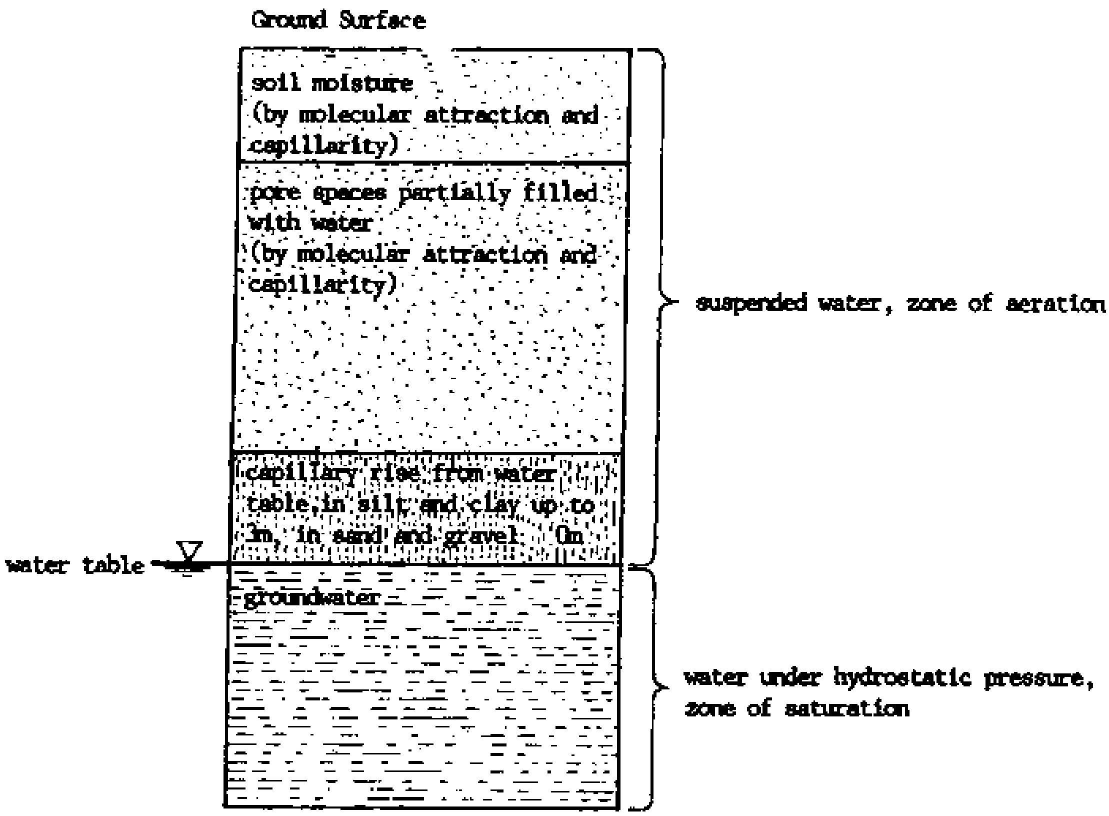
- Gentle slopes hold the water longer and favour infiltration. They often offer more favourable conditions than completely flat areas.

- Flat areas often develop a tight surface which hinders infiltration.

- Moderate rainfall over an extended period favours infiltration.

- Heavy rains saturate the surface quickly and most water is running off. They compact the soil and reduce its ability to absorb water.

In a vertical cross-section, the ground can be divided into different zones according to their water content:



2. Horizontal Movement

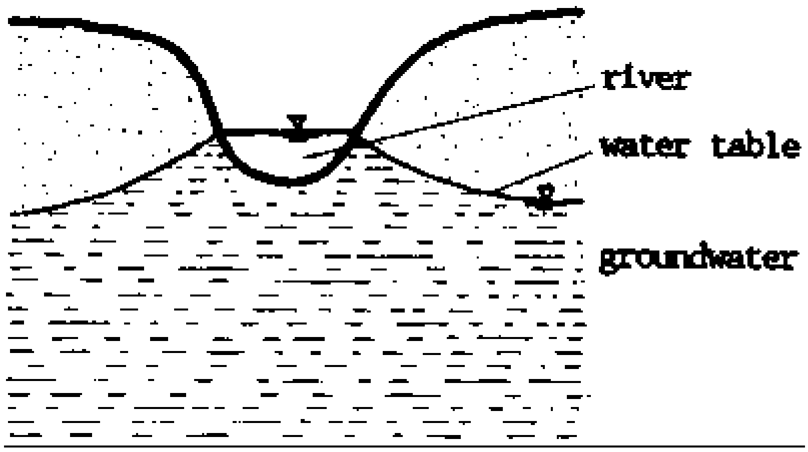
The groundwater moves horizontally into a well. Water also can travel horizontally through an aquifer, especially, if the aquifer is sloping. However, this movement is very slow and very limited in distance.

Therefore:

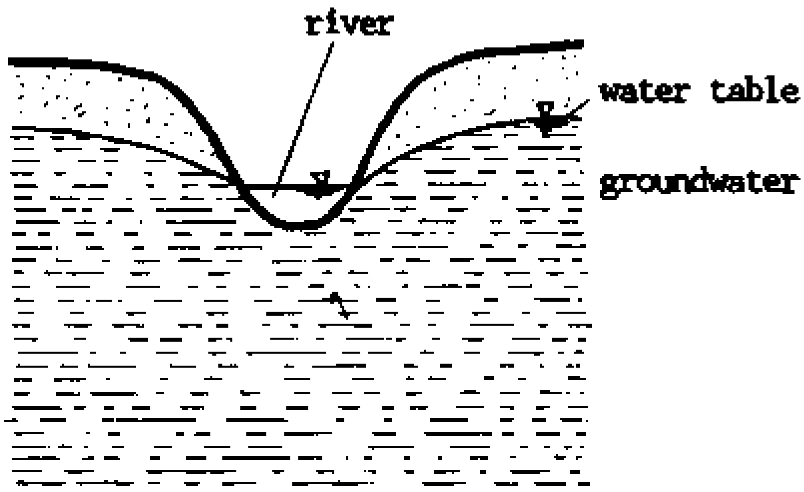
Do not draw more water from a well than is recharged by rain nearby! See also 8.29/1.

F) Connection between Rivers and Groundwater

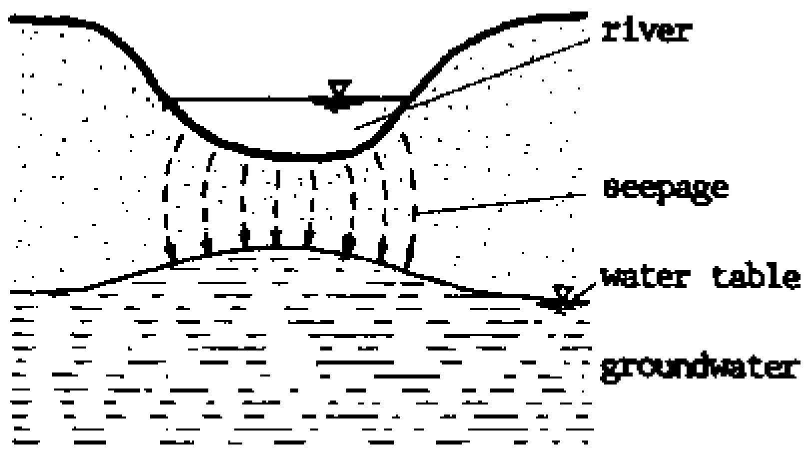
A river and the groundwater can be connected in different ways:



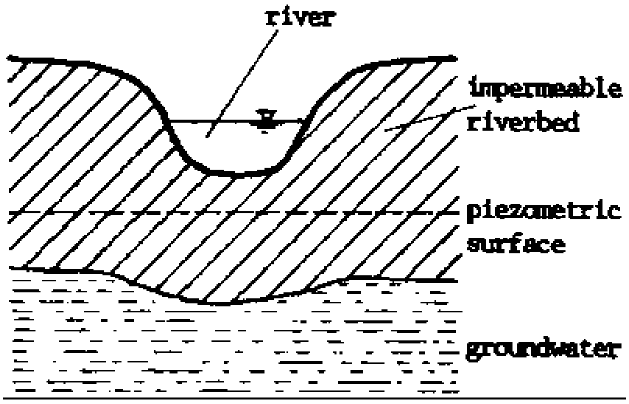
Influent Stream: looses water to the aquifer



Effluent Stream: gains water from the aquifer (the sane stream may have influent and effluent sections)



Stream only Flowing Periodically: dry during drought



Stream Isolated Hydraulically: from an artesian aquifer below it

G) Types of Soils as Aquifers

Type of Soil	Porosity	Permeability	Difference betw. Unsaturated and Saturated Zone	Cleaning Capability	Rechargeability	Quality of Aquifer	Possible Problems
clay	good, can store lot of water	limited or impermeable, however, no continuous layers	several meters	good	fair	fairly good	slow intake, limited recharge
sand	good, can store lot of water	very good	no	very good	very good	very good	quicksand, collapsing
gravel	very good can store lot of water	very good	no	no	good	very good	collapsing, easily polluted
weathered rock	good	good	no	bad	very limited	good if nothing else available	only limited layers, therefore, limited amount of water
rock (= basement complex)	no except in cracks	no, except in cracks acting as pipe	no	no	very limited	good if nothing else available	difficult to hit the cracks, difficult to dig, limited storage water can be salty because of dissolved minerals
mixtures of soil types	properties differ from site to site						

8.9 Desertification

Is 41,17-20; Jer 6,8; Mi 7,13

Sudan is in danger of becoming a desert. The desert in the North approaches the South by 6 km every year. That means, if nothing changes, the desert may reach Juba in 100 years time, that is just four generations.

The following contributes to desertification

- less rain,

- less forests through cutting of trees and burning of grass,

- less fertile soil because the soil is stripped off its vegetation and thus blown and washed away,

- big agricultural schemes (through digging by tractor, cutting of trees, pesticides and artificial fertilizers),

- Jonglei Canal,

- bombing, spraying of herbizides in war, atomic bomb,

- too many animals and, thereby, overgrazing,

- overpopulation and, thereby, overcultivation,

- exporting timber and charcoal,

- boreholes with water tanks in remote areas (attracting many people and animals).

What can people do to stop desertification?

- Stop burning grass!

- Plant and care for trees!

- Plant hedges around fields!

- Slow down the run-off of rainwater by small dams and ditches across the run-off direction in your gardens!

- Minimize firewood, charcoal and paper consumption!

- Reduce the number of animals!

- Do crop rotation!

- Manure your fields!

8.10 Wells

A) Tapping Groundwater

A hole dug or drilled into a saturated soil layer and lined to prevent collapsing is called a well.

The static water table (= undisturbed water table) is the level of groundwater if no water is pumped from the well.

The draw-down of a well is the difference between the undisturbed water table and the water table in the well while pumping (= disturbed water table).

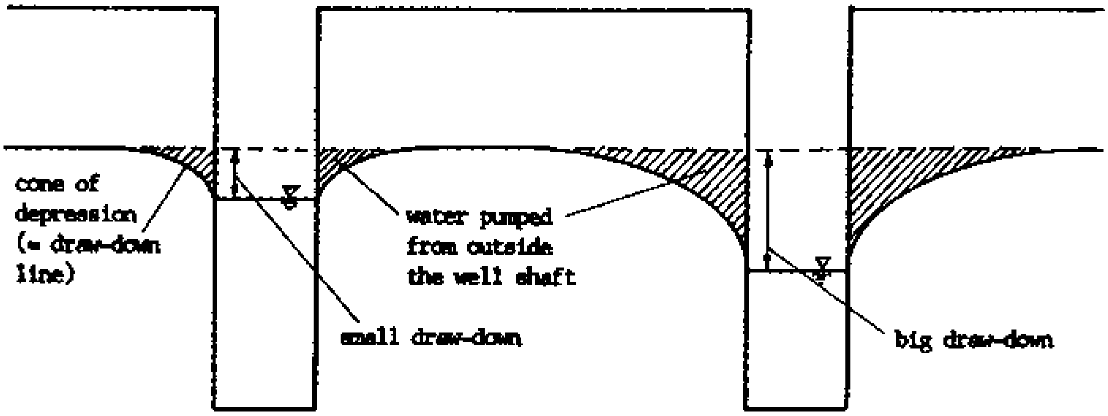
If more water is pumped from the well than enters from the surrounding groundsoil into it, the water table will sink.

If less (or no) water is pumped than entering the well, the water table will rise (but, of course, never above the static water table). If the same amount of water is pumped as enters the well, the water table remains constant. This water table is called "dynamic water table". The amount pumped is equal to the yield of the well (which is the capacity of the groundsoil to fill the well). The yield of a well can be measured by test pumping. The pump's yield is gradually increased. When the water table remains constant, the pump's yield is equal to the well's yield.

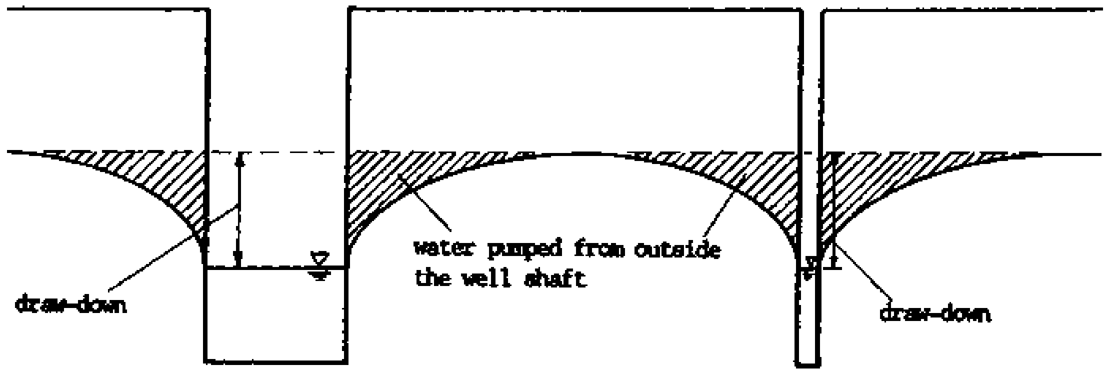
Summarizing, we differentiate three different types of water tables:

No.	Name	Description
1	static = undisturbed water table	water table without pumping
2	disturbed water table	water table while pumping at any rate, either sinking or raising
3	dynamic water table	water table while pumping with a specific rate equal with the water entering the well; water table remains constant

During pumping the water is drawn from an extended area around the well. By pumping we do not only empty the volume inside the well, but also a space in the shape of a funnel around the well (also called “cone of depression” or “draw-down line”). The volume pumped from outside the well can be as big or even much bigger than the volume pumped from inside the well, depending on the diameter and the draw-down. The greater the draw-down, the more water needs to be pumped from outside, and the more difficult it is to lower the water table further.



Big diameter well and small diameter well (borehole) with the sane draw-down:



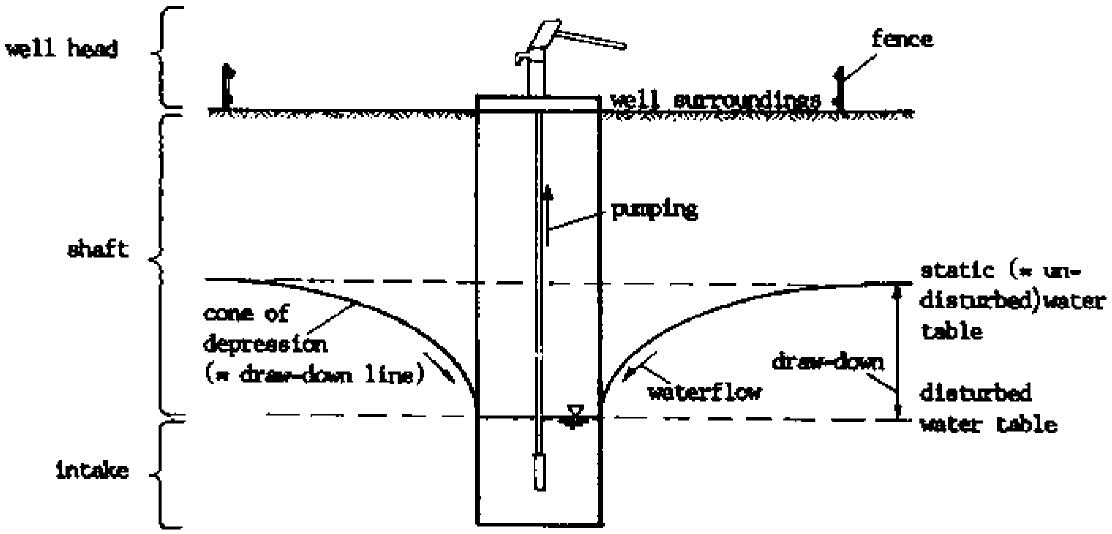
The cone of depression differs in shape and size depending upon

1. pumping rate,
2. length of pumping period,
3. aquifer characteristics,
4. slope of water table,
5. recharge within the zone of influence of the well.

B) <u>The Elements of a Well</u>

Each well consists basically of the following elements:

Name	Function	Construction
intake = bottom section	- allows water to enter from the ground into the well excluding the soil - provides storage reservoir	- lining with seepage holes, or - porous lining (filter rings), or - filter pipes for casing
shaft = middle section	- provides access to the well bottom - prevents pollution by surface water - prevents collapsing	- lining with concrete rings, or - brick lining, or - casing pipes
well head = upper section	- prevents or reduces pollution - provides facilities for drawing water	- preferably sealed (concrete cover, apron, drainage) - hand pump, engine pump, or bucket system
well surroundings	- prevent pollution by animals - control use	- cleaned, fenced area



C) Influence of Diameter

The diameter of a well has the following influence on the function:

Influence on	Increasing Diameter	Reducing Diameter
water	- increase in yield - more storage capacity	- less yield - less storage capacity
construction	- more digging - thicker lining necessary - more materials needed - more difficult to pump during construction - more space during construction for 2-3 people - more danger of collapsing - better ventilation	- less digging - less lining - less materials - easier to pump during construction - narrow for digging (only one person can dig) - more stable - danger of ventilation problems
suitability	- in aquifer with low permeability (slow intake) - in not too deep wells	- in aquifer with high permeability (quick intake) - in deep wells

It is important to choose the correct diameter suitable for the particular location. Huge diameters (up to 10 m) are suitable for aquifers with very slow seeping in.

Big diameter wells (Ø 1.40 to 4.00 m) are suitable where the permeability of the soil is limited and the water enters slowly into the well. In these cases a big filter surface and a big storage capacity are necessary.

Medium diameter wells (Ø ca. 1.10 m) are suitable where the groundwater is deep.

Small diameter wells (boreholes) are suitable in rock, in case of very deep water tables. The soil must be permeable, because the storage capacity of boreholes is very little.

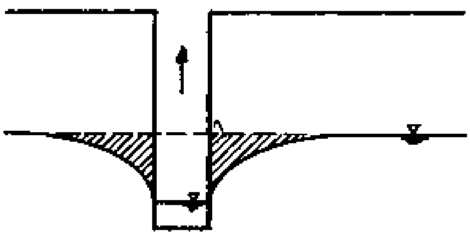
For diameters of concrete rings, used for well construction, see also 8.16/4ff.

D) <u>Increasing the Yield of a Well</u>

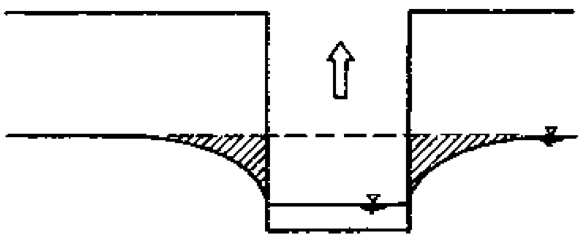
The yield of a well can be attempted to be increased by one or several of the following measures:

1. Increase the depth of the well.
2. Increase the diameter of the well.
3. Clean cracks in the intake area.
4. Clean away collapsed clay around the lining and replace it by gravel.
5. Increase the porosity of the intake lining (i.e. by additional holes).
6. Pump the well for few days as much as possible (This opens ways in the groundsoil).

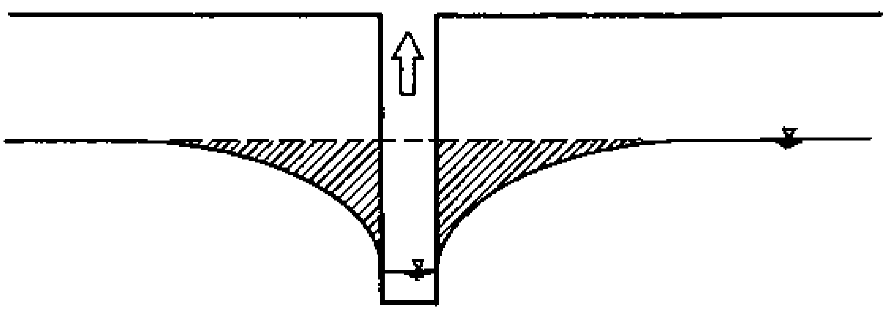
However, the yield of a well can only be influenced to a certain degree. It depends on the location chosen, the soil conditions, and the quality of the aquifer. Even a limited yield of a well can be useful in a certain location, and the conditions given by nature need to be accepted.



original well



increasing the yield by increasing the diameter



increasing the yield by increasing the depth

8.11 Comparison of Borehole and Hand Dug Well

Boreholes and hand dug wells can be differentiated according to the following features:

No	Feature	Borehole	Hand Dug Well
	Drawing		1	Definition	well excavated with equipment from the surface	well dug by people enter-ring the well
2	Depth	deep: 10 to 200 m see 8.7/1	shallow: 3 to 50 m (in exceptional cases up to 150 m)
3	Diameter	small: 5 to 20 cm	big: 1 to 4 m (a person can enter)
4	Form	round	round or square
5	Intake	only from the side through filter casings	from the side through filter rings and from the bottom
6	Storage capacity	relatively small because of small diameter	large because of big diameter
7	Well shaft	casing from steel or PVC pipe or no lining in rock	lining from brick wall or stone wall or concrete rings or no lining in rock
8	Well head	pump with platform see 8.19/3f	open with platform or closed with concrete slab and pump; see 8.19/5f
9	Drawing of water	by handpump or by engine pump or by bailer see 8.24	by rope and bucket or by winch or by handpump or by engine pump; see 8.24
10	Digging	drilled by drilling rig, sometimes by hand	dug by hand

No	Feature	Borehole	Hand Dug Well
11	Labour needed	high-skilled labourers in small numbers	some skilled and many unskilled labourers needed (= labour intensive)
12	Time needed	relatively fast	time consuming
13	Material needed	casing pipes, cement, sand, gravel, water, pump, etc.	cement, sand, gravel, reinforcement, pump, etc.
14	Equipment needed	highly sophisticated machinery (= capital intensive)	hand-tools like pick axe, shovel, bucket, rope, etc.
15	Energy needed	fuel, engine oil	human energy
16	Space needed	large area needed for rig	large area needed for excavation
17	Accessability required	for heavy lorry	for pick-up, eventually only for people footing
18	Transport needed	lot of transport needed	little transport needed
19	Risks involved	common dangers of working with lorries and heavy machinery	danger of working inside a well
20	Costs	very expensive	moderately expensive
21	Availability of resources	most resources from abroad (rig, fuel, casing, highly skilled labour)	most resources from with in the country
22	Community participation	very limited	community can easily participate in construction
23	Water quality	safe if surroundings clean, platform intact, groundwater not polluted	safe if closed and surroundings clean and groundwater not polluted
24	Yield	depending on conditions, often limited, esp. in rock	depending on conditions, often quite high
25	Maintenance	maintenance of pump, daily cleaning of surroundings	inside cleaning yearly, daily cleaning of surroundings, maintenance of pump, if installed
26	Rehabilitation if yield drops	hardly possible	cleaning and digging deeper possible
27	Life time	limited by corrosion of casing, clogging of filter casing, break-down of pump	limited by eventual dropping of water table
28	Beneficiaries	well users, few local labourers, foreign companies	well users, local labourers, local manufacturers and suppliers

The above mentioned factors determine whether a borehole or a hand dug well is suitable for a particular situation. Under certain conditions, a hand dug well is not suitable, but a borehole can be drilled. Under certain conditions, a borehole is not suitable, but a hand dug well can be constructed. Under certain conditions, both borehole and hand dug well are possible (see 8.7/1).

When both borehole and hand dug well are possible, governments, development agencies and many people tend to favour boreholes. In many countries facilities and training are readily available for boreholes, but neglected for hand dug wells. This is a bias towards foreign resources and technology.

SCC's water and sanitation project pursues a different policy: Wherever construction of hand dug wells is possible, they should be favoured because of maximum utilization of local resources and possible community involvement. The resources for boreholes shall be utilised where hand dug wells are not possible.

8.12 Selection of Well Sites

Gen 26,32

The selection of a suitable well site is essential for the success of a well.

A) <u>General Requirements</u>

A suitable well site has to meet the following requirements:

1. It should be within walking distance (1-2 km) from the relevant village.

2. It should be accessible by pick-up/truck during the construction phase, and accessible for the villagers throughout the year.

3. It should not be within 100 m of cattle pools, latrines or other health hazards (like septic tanks, workshops, etc.), and preferably upstream of these. The distance depends on the soil conditions. However, 100 m lies on the safe side. 50 m distance can be acceptable under certain conditions. Closed compost latrines require a distance of 6 m to the next well.

4. It should be safeguarded against flooding. Especially near rivers, the location has to be chosen so that the well is not threatened by any meandering of the river. Furthermore, the danger of flooding of low-lying areas should be taken into account.

5. The subsoil should not render the construction of a well impossible. It is difficult to make hand dug wells in rocky materials, even if these contain sufficient quantities of water in cracks.

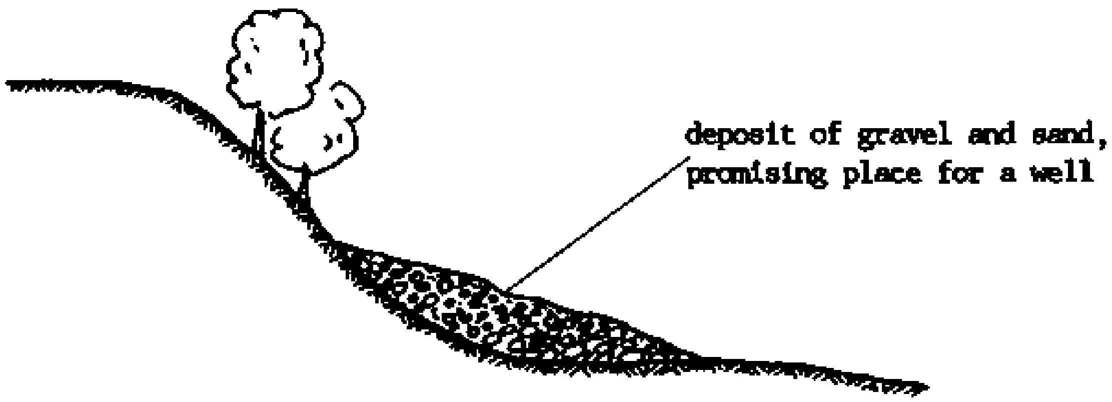
B) <u>Geological Guidelines</u>

1. Layers of sand and gravel are the best aquifers.

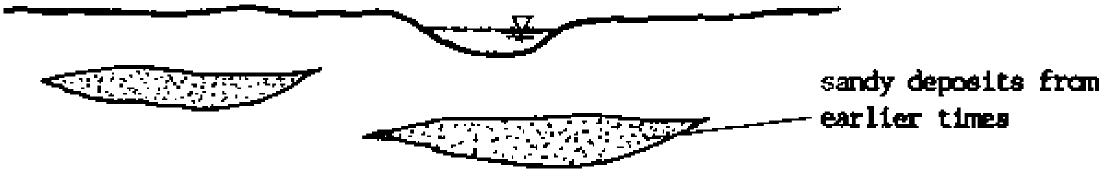
2. In karstified limestone, the danger of pollution of groundwater from the surface is very great.

3. In granite areas, weathered rock may contain good aquifers.

4. In mountaineous areas, the best aquifers are found along the edges of the valley.

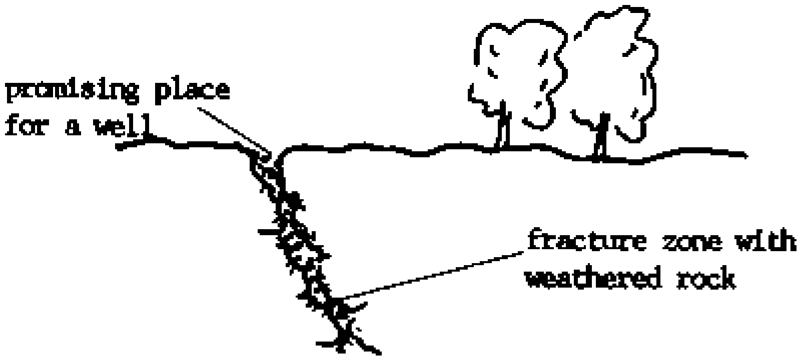


5. Good aquifers can be found under the riverbed and in the river banks (i.e. in “buried” rivers) or at lake sides.



6. Outcropping granite hills in connection with small dry valleys and depressions are promising areas.

7. Crushed zones at fault lines (fractures, folds) are very good water bearing layers.



8. Vegetation such as banana trees, date palms, sugar cane, ever green areas, indicates shallow groundwater (0-5 m).

9. Vegetation such as mango trees, nim trees, etc., indicate deeper groundwater.

10. Certain vegetation (certain trees, grasses, salty taste of sugar cane) indicates salty groundwater.

11. Deposits of clay suitable for making pots can indicate near ground-water.

C) Methods for Well Siting

The following methods can be used for well siting:

1. Gathering information from existing wells
2. Gathering information from local well diggers
3. Hand augering
4. Divining
5. Well siting with instruments like resistivity meter, seismograph, etc.
6. Evaluating groundwater maps
7. Evaluating aerial photographs
8. Evaluating satellite photographs

The first three methods will be mostly available for small water projects. Good water supply technicans continuously gather information when they come across wells and, thus, gradually develop a feeling for soil and groundwater conditions, geology and vegetation. We also need to build up a respectful relationship with local well diggers and thus share knowledge and benefit from their rich experience.

8.13 Site Survey by Hand Augering

Hand augering is drilling a small diameter borehole by hand. It is a helpful tool amongst others for selecting a suitable location for a hand dug well (see also 8.12/2). The method is comparatively cheap and simple. It can be learnt quickly and does not require complicated equipment.

Hand augering is not possible under all circumstances. The limits depend on the hardness of the soil, the depth of the water table, and the perseverance of the technicians.

If the water table cannot be reached by hand augering, it might still be possible to construct a good hand dug well - the water table might be just below the reach of the hand auger.

A) Purpose of Hand Augering

Hand augering can be used for gathering the following information:

1. Presence or Absence of Groundwater (within the reach of the augering);

2. The Depth of the Water Table;

3. The Thickness of the Aquifer (= water bearing layer);

4. The Nature of the Aquifer: the type of soil of the aquifer, its content of gravel, sand, clay, and silt, and, thus, the permeability of the soil;

5. The Possible Recharge Rate (= yield) of the well, concluded from the permeability of the aquifer soil;

6. Water Quality (salty or not salty, etc.);

7. Possible Movements of the Water Table, concluded from the colours of the augered material;

8. Minimum Depth of the Well, concluded from the depth to hard rock or the first impermeable (= impervious) layer.

9. Possible Storage Capacity of the well, concluded from the depth to hard rock or the first impermeable layer;

10. Suitable Construction Method for the well, concluded from the thickness of the soil layers and their stability; (Is temporary lining or caissoning necessary? How thick is an eventual sand layer?); see also 8.14;

11. Presence of Single, Invisible Rocks Underground: in some areas single blocks of rocks are dispersed above and underground - if you hit such an underground rock, a well site suitable for digging might be just a few metres away;

12. Investigation of an Extended Area, like a river bank by augering a number of holes in a systematic way;

13. Presence of Water Table below a Dry Well by drilling inside the already dug and so far dry well.

B) Selecting Location and Time for Hand Augering

We will waste energy if we just start to drill holes without previous planning. Consider the following:

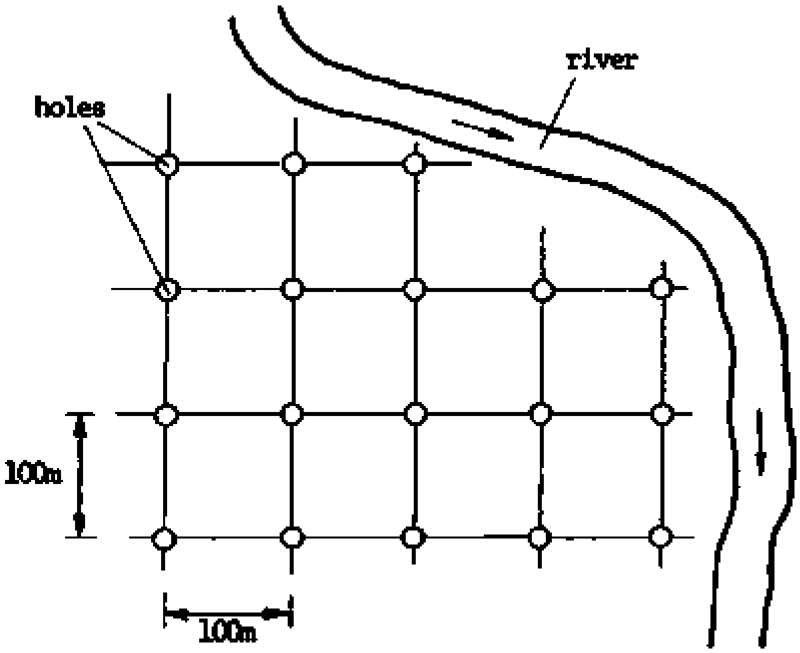
1. Collect all available information (see 8.12).

2. Study the map and see where there would be the best sites for augering.

3. Have a careful look at the area on site before you start augering.

4. Preferably drill when the soil is wet. Drilling in completely dry clay is very difficult.

5. If necessary, drill a systematic net of holes over a certain area, e.g. every 100 m:



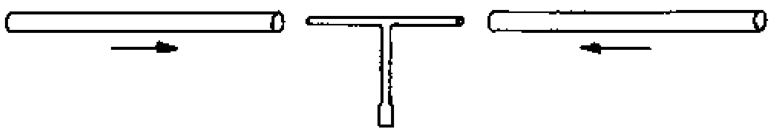
C) Hand Augering Equipment

Light weight hand augering sets can drill small holes of 5 or 7 cm diameter. Heavy weight sets can drill larger holes up to 10 cm diameter or even more. These types differ in the diameter of the bits, the thickness and strength of rods, handles, the type of couplings, and the number of people required; but they consist of the same elements and are to be handled in the same way.

A set of hand augering equipment consists of the following elements:

1. Handle

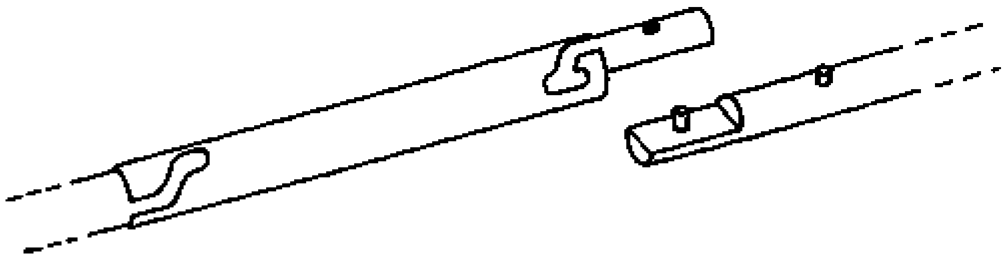
The handle can be extended by short pipes to increase the lever arm. The heavy weight set can be drilled by two or more people.



2. Extension Rod

Usually, extension rods are 1 m long. A sufficient number is required. The rods can be connected either by a bayonet coupling for light weight sets or threaded couplings for heavy weight sets. The threads are protected by thread protectors when stored.

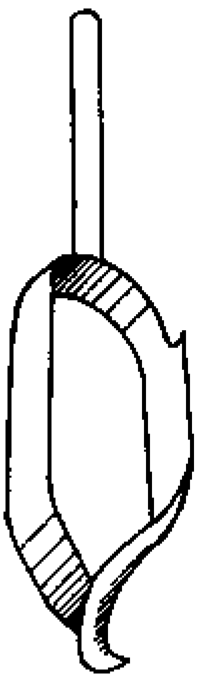
Bayonet Coupling:



Threaded Coupling:

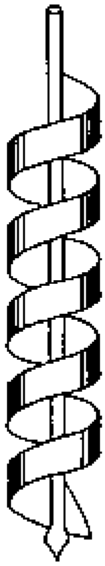
3. Open Clay Auger

The auger body of the open clay auger (= combination bit = combination auger) consists of two blades, the ends of which are forged into the auger's end. Upwards the blades diverge gradually up to the desired diameter. Depending on the width of the blades, the auger is suitable for clay, sand or coarse sand if the soil is very soft.



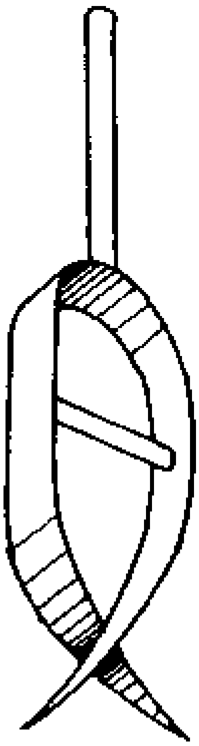
4. Flight Auger

This bit is made of a steel strip wound around the central rod in a spiral form. It is suitable for soft soils.



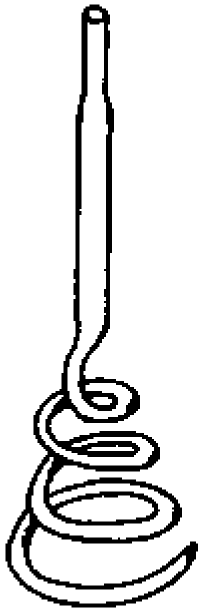
5. Stone Auger

The stone auger resembles the open clay auger, but the blades are longer. The bit is suitable for weathered rock.



6. Stone Catcher

The stone catcher is made from a strong rod, curved in spiral form. It is suitable to catch stones and gravel embedded in clay soil.

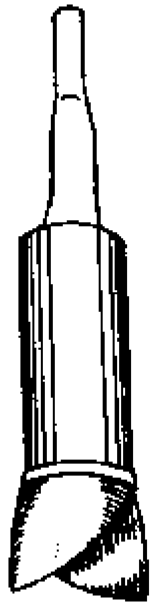


7. Screw Auger (= Spiral Auger)

This bit is made of a steel strip, forged in a spiral form. The diameter is smaller than the one of the other bits. With this bit hard layers can be broken loose and the material brought out with other auger types afterwards.

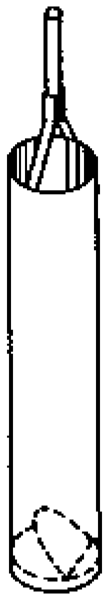
8. Riverside Bits

The auger body of these bits is a tube with two blades welded at the bottom. The sharp extremeties of the blades point at an angle downwards, a little outside the tube. The blades are spoon-shaped so that the soil is steadily pushed into the tube. This bit is suitable for use in hard, stiff soils and in all kinds of materials below water level.



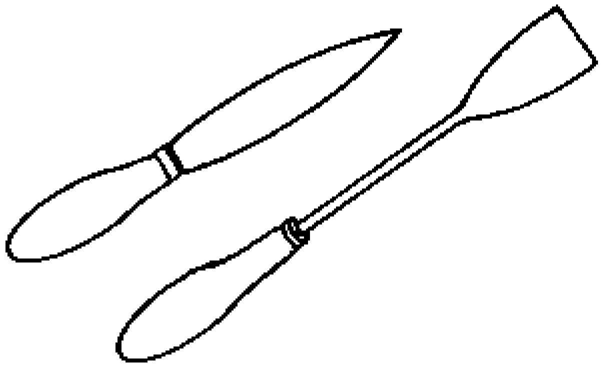
9. Bailer (= Pulse Auger)

The bailer is a 60 cm long tube fitted with a valve at the bottom. It is used for penetrating saturated layers by moving it up and down or for dewatering the hole for test purposes.



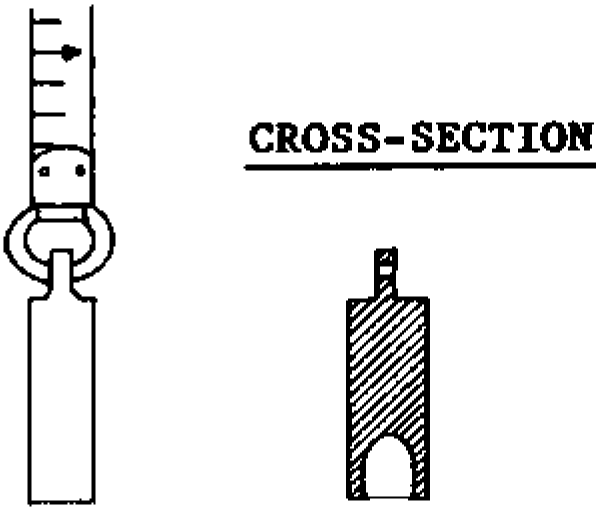
10. Auger Cleaner

The auger cleaner resembles a knife and is used for cleaning the augers.



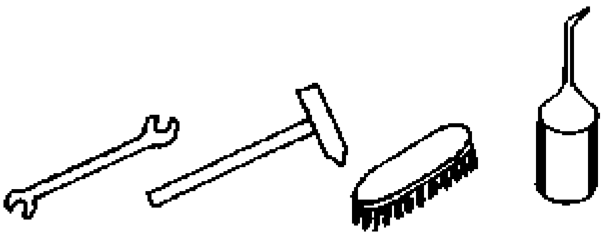
11. Meter

A water level meter has a plumb with a small cave in the bottom which produces a sound when reaching the water table in the borehole.



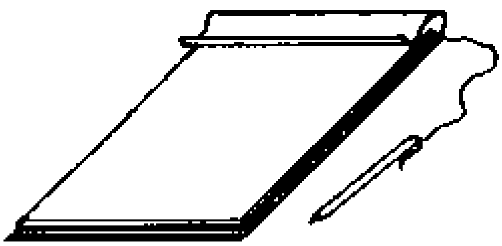
12. Diverse Tools

such as spanners, hammer, wire brush, nylon brush, oil, grease, etc.



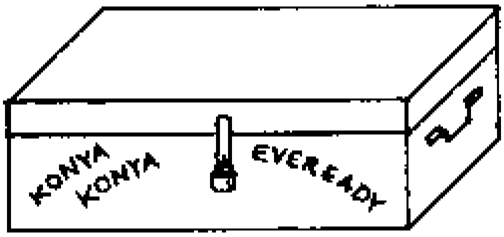
13. Equipment for Recording

such as writing pad, paper, pencils, forms, etc.



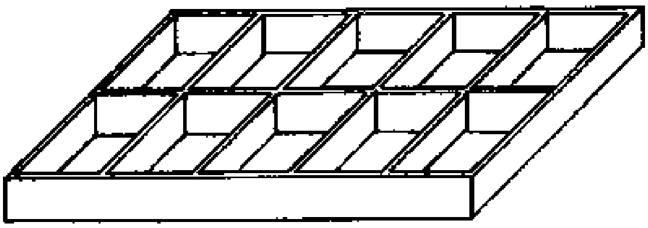
14. Tool Box

big enough for all parts of the equipment, including list of the contents of the tool box.



15. Sample Box

A sample box is a coverless, long and narrow wooden box, divided into a number of compartments. During the drilling, a sample of each 50 cm is placed in the box to prevent mistakes in the description.



D) Step-by-Step Procedures of Hand Augering

For hand augering, follow these steps:

1. Connect the handle, a rod and a bit.

2. Drill by one or several people (for heavy weight set).

3. When drilling becomes hard, remove the auger and clean it.

4. Drill again. Continue in this way.

5. When the rod has almost disappeared into the hole, add another extension rod. Continue in this way.

6. Change the bits according to the soil type.

7. Never force the auger; if it will not turn with ease, change to a more suitable bit, e.g. the screw auger for breaking the material loose, and remove the soil with another auger.

8. Keep the threads always clean and greased. For storing, always protect them with a thread protector.

9. Put samples into the sample box every 50 cm.

10. Record <u>any</u> changes in the soil in a log (example for a well log see under E).

11. Try to drill as deep into the water table as possible.

12. If pumping equipment is available, make a test pumping.

13. Otherwise, dewater the hole with a bailer (= bail out the hole). Record the number of times the hole needs to be bailed and, thus, the number of litres you have bailed out.

14. If the hole goes dry, measure the depth of the water in the hole at 5 minutes intervals to gain the recharge rate.

15. After finishing augering, clean, dry and oil the equipment.

16. Record the water table after few hours.

17. Complete the records.

E) Hand Augering Log

Keeping careful records is much easier with the help of forms: Fill the form, "1. General Information", immediately after augering. Fill the form, "2. Soil Profile", during augering. Whenever there is a change in the soil, measure the depth. Draw a horizontal line on the form, "Soil Profile", at the measured depth. Note down all the information about the soil above this level also above the horizontal line. When you take a soil sample, record its number. Cross which type of soil you found, cross which colour it has, and cross if it is permeable or impermeable. Record all the information about the next soil layer below the horizontal line. Continue in this way for all the layers in the borehole.

F) Evaluation of Hand Augering

The evaluation of hand augering requires experience. However, consider the following aspects when filling in the form, “HAND AUGERING EVALUATION” (see 8.13/12):

1. If you have drilled several holes for locating one well, choose the hole with the thickest aquifer as well site.

2. The water table measured after few hours is the static water table for the season at the time of augering.

3. Conclude from the colour of the augered material on the expected change of the water table between the seasons:

- Reddish soils are well drained and well aired. Such layers are most likely not below the water table at any time.

- Yellowish soils indicate that the soil is full of water for long periods. Such layers might be below water table for a part of the year (during rainy season).

- Bluish colours in dark grey soil indicate that the soil is water-logged most of the time - similar to the yellowish soils.

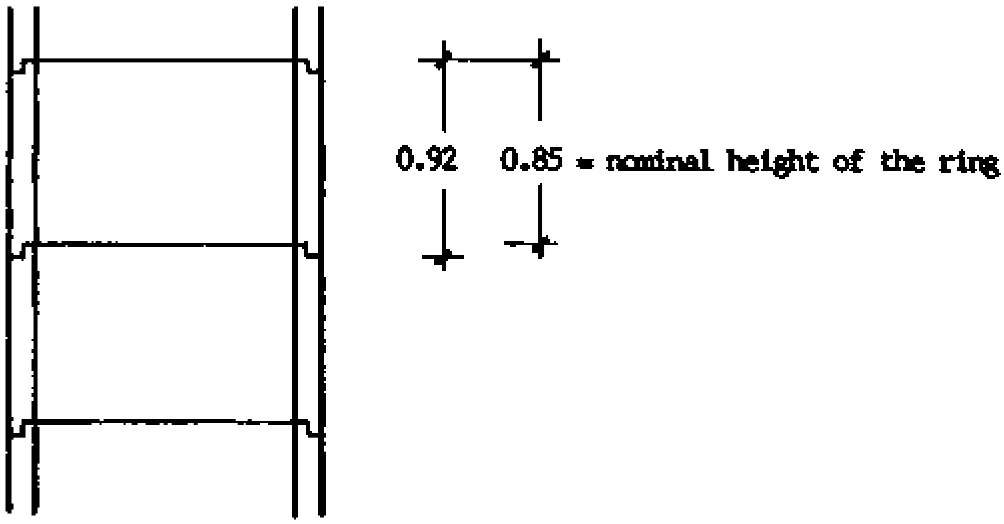
- Black and dark grey soils are usually badly drained and, therefore, likely to be permanent below the water table.

Also, consider your knowledge about the change of the water table during the seasons in the area; generally, the deeper the water table, the less is the seasonal change. Seasonal changes of several metres are more likely in shallow wells (but they must not necessarily be as great).

4. Conclude from the aquifer's soil type and the thickness the expected recharge rate. The coarser the material, the easier it will release its water content.

5. Judge whether the water is expected to be drinkable or not, considering the salt content.

6. Conclude from the depth of hard rock or the first impermeable layer how deep the well must be. It is advantageous to dig 0.50 m or 1.00 m into these layers, if possible. Add about 0.40 m for the well head. Divide the minimum depth by 0.85 cm, the nominal height of a concrete ring, to get the required number of rings. Add one or two rings to be on the safe side.



7. Determine the required number of filter rings by looking at the expected height of the water column in the well.

8. Decide which diameter is suitable (see also 8.10/4 and 8.16/6).

9. Suggest a suitable construction method according to the stability of the soil in shaft and intake (see 8.14).

10. Suggest a suitable water lifting device according to the expected depth, recharge rate and the social circumstances (see 8.29 and 8.24).

8.14 Construction Methods for Hand Dug Wells

There are many different ways to construct a hand dug well. The following overview should help to select the suitable method for a specific situation. You might be forced to use different methods for wells within the same area.

A) Types of Lining

The lining of a well is a layer of material added to the inside surface of a well. The lining serves the following purposes:

- It prevents the well from collapsing.

- It protects people working inside the well.

- In the bottom section (= intake), it allows water to enter the well.

- In the top section (= shaft) it prevents contaminated surface water from entering the well.

- It serves as a foundation for the well head.

The most important types of well lining are:

1. <u>No Lining at All</u>

No lining at all is, of course, the cheapest and simplest possibility, but only under suitable soil conditions like hard rock or, above the water table, in very hard clay.

2. <u>Lining with Masonry</u>

Masonry lining can be

- from bricks
- from stones.

Masonry lining is advisable if bricks or stones are easily available near by, and cheap. However, more cement is needed for masonry than for concrete rings which, again, increases the cost. A very important factor in the decision might be if masons are available locally who are able to do brick lining, but no technicians for constructing a concrete lining are available. A masonry lining is not as strong as a concrete ring lining. It also requires a soil which is temporarily stable on its own until the lining is built up. In soft, sandy soil a masonry lining is excluded for the above reason. The depth possible for masonry lining is limited because the transport of materials gets much more difficult with increasing depth.

3. <u>Lining with Concrete Rings</u>

Concrete ring lining can be

- cast outside the well and lowered into the well later on;
- cast in situ (= inside the well).

Concrete lining is suitable in any soil condition. However, the equipment, the materials (cement, sand, gravel, reinforcement) and the skilled labourers must be available at reasonable distance and price. Lowered concrete rings are the best option for very deep wells.

Other types of lining, e.g. timber shuttering, are of no importance.

B) <u>Constructing a Collar</u>

A collar is a short wall around the mouth of the well. It serves the following purposes:

- It protects the well mouth from being washed out and widened by rain.

- It protectes the well mouth from collapsing due to the work on top.

- It protects the well shaft during digging.

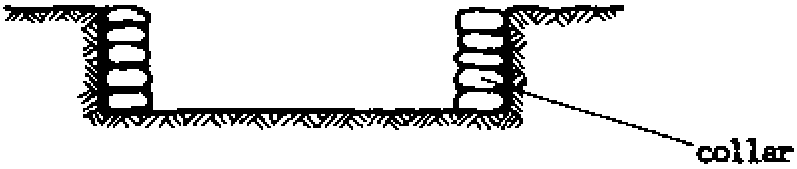
- It provides a firm and safe working place for the labourers at the well mouth.

It is advisable to build a collar whenever the well is expected to be deep and digging will need a long time (for all methods described under C, except No. 5 and 7).

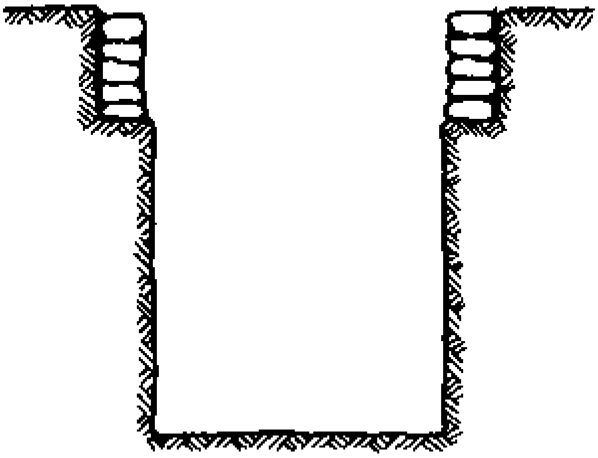
Construct the collar as follows:

1. Dig a pit wider than the well diameter:

2. Build the collar from bricks or stones in cement mortar:

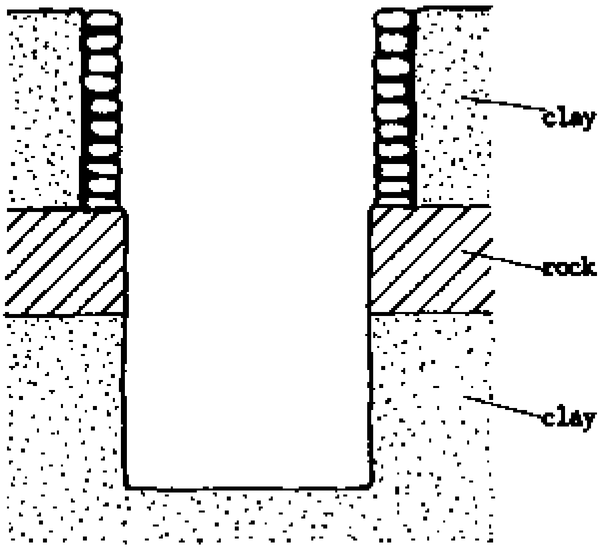


3. Continue digging inside the collar:



SCALE 1:50

4. If there is a rock layer near, use it as foundation for the collar:



SCALE 1:50

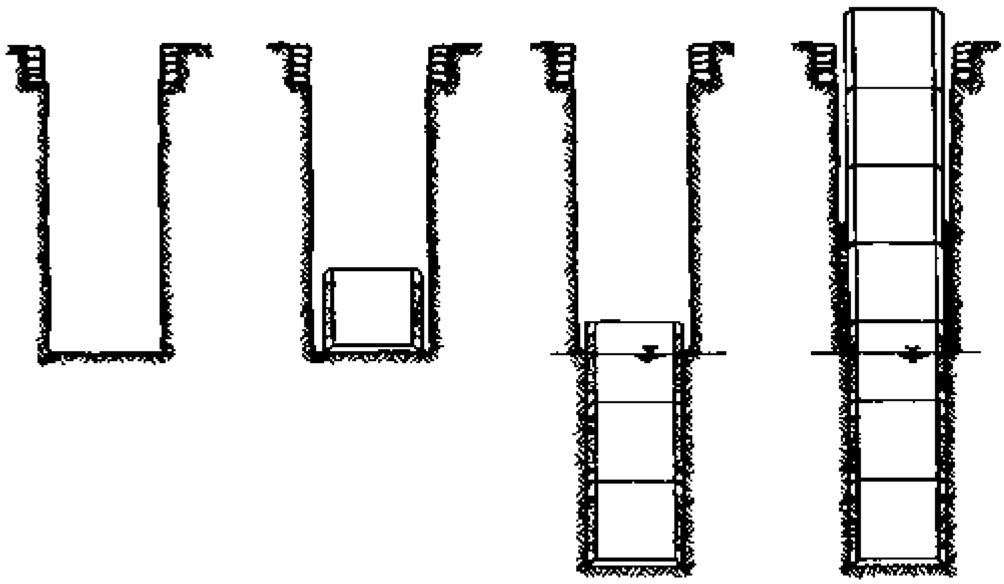
C) <u>Different Construction Methods</u>

When constructing a hand dug well, different types of lining can be used separately or can be combined. Different methods are briefly described and compared in the following (incomplete) list:

1. Caissoning below Water Table and Concrete Ring Lining

For this method, follow these steps:

- Build a collar.
- Dig until the water table is reached. Stop at the first signs of water.
- Lower a ring.
- Dig into the water table inside the ring while the ring slides down.
- Lower more rings on top whenever necessary.
- Dig into the water table as far as possible.
- Line the whole well with concrete rings and backfill it.



SCALE 1:80

This method is suitable for soil types which are stable above the water table, but unstable below the water table (such as clay, sandy clay, etc.). This method is very handy because it allows easy and quick digging above the water table, but provides protection below the water table. It allows for easily digging deep enough into the water. Constant observation is necessary because of the risk of collapsing. It is most important to stop digging before entering the water table because the soil becomes immediately soft and muddy when saturated. It is very difficult to correct a ring askew in mud, rather than digging in a straight, proper way from the beginning.

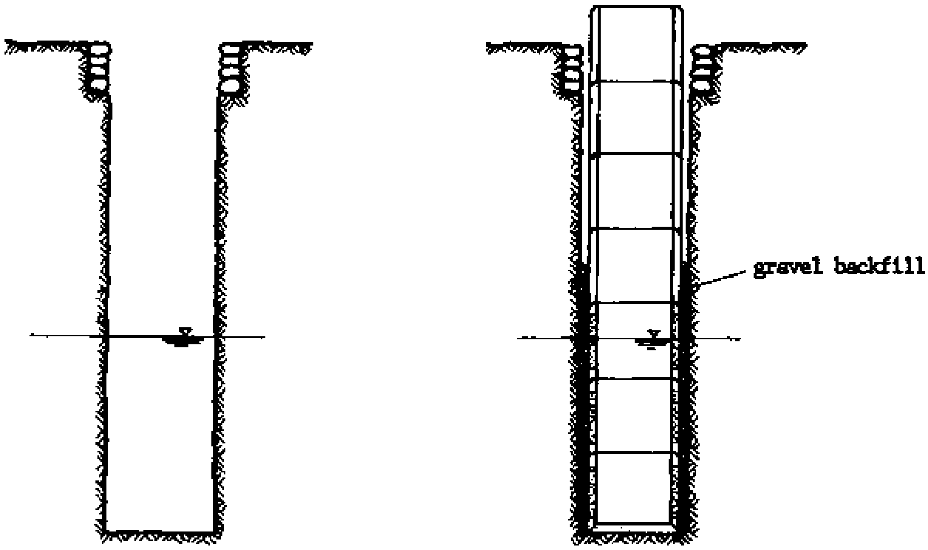
2. Lining after Digging

For this method, follow these steps:

- Build a collar.

- Dig the well until its bottom is sufficiently below the water table.

- Lower concrete rings to line the well below and above water table and backfill them.



This method is only suitable in soil types which are also stable below the water table. This is the case, for example, for rock or weathered rock which is stable for the time being, but needs a lining in the long run because of cracks or mud fill-ins. The method is very handy.

3. <u>Completely without Lining</u>

This method consists only of two steps:

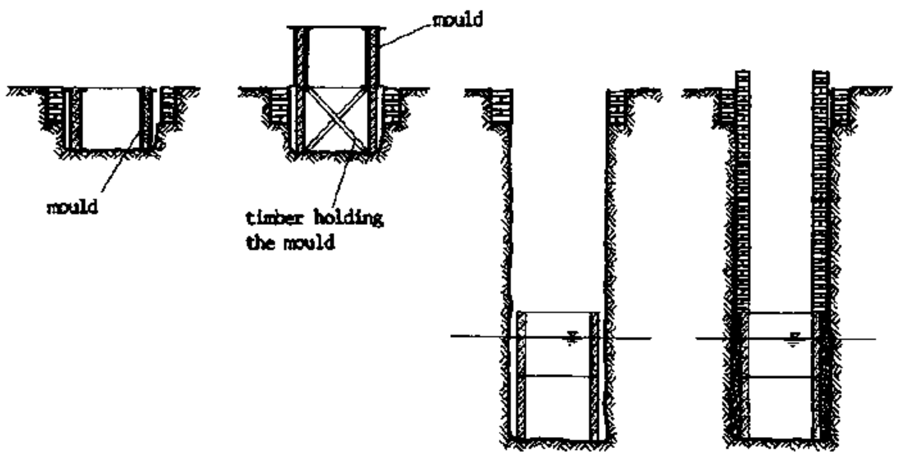
- Build a collar.
- Dig the well until its bottom is below the water table.

This method is only suitable in pure hard rock, without major cracks or mud fill-ins. You have no work with the lining, but digging itself will be very difficult and slow.

4. <u>Caissoning with Two Rings and Brick Lining</u>

For this method, follow these steps:

- Build a collar.
- Excavate 90 cm deep.
- Cast a ring in the hole with pipe moulds (see 8.16/7).
- Cast a second ring on top.
- Dig the well inside the rings while the rings slide down (= caissoning).
- Dig as deep into the water table as possible.
- Build a brick or stone lining on top of the rings and backfill it.



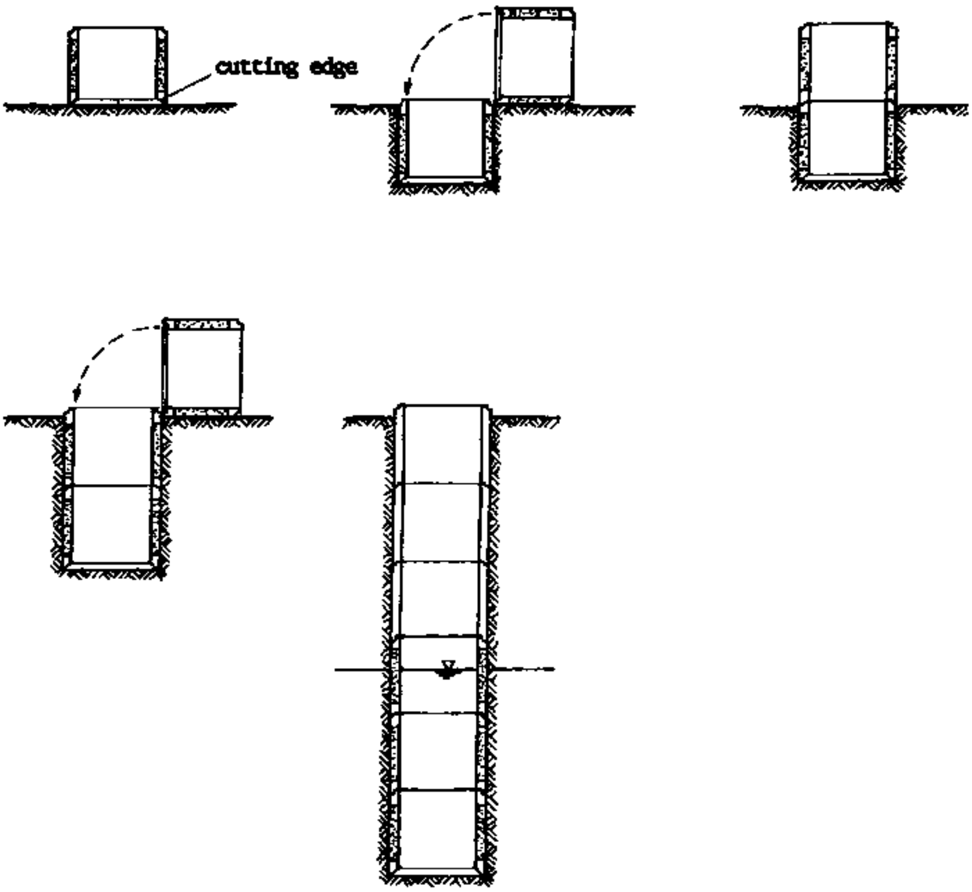
SCALE 1:80

With this method, it is easy to dig deep enough into the groundwater. No lowering equipment for rings is required, only a wooden scaffold and a pulley and a mould for the rings. Therefore, the method has advantages for very remote areas. Digging the full length of the well with two rings caissoning is not very handy, but helps to dig straight. The method is only suitable in soft, but stable soils, not in weathered rock or rock, because the rings tend to get stuck at the slightest protrudings of rock.

5. Caissoning the Complete Length of the Well

For this method, follow these steps:

- Cast the necessary number of concrete rings.
- Place the first ring with cutting edge on ground level.
- Dig inside the ring until the ring has almost disappeared into the ground.
- Roll the second ring near by.
- Turn it over until it sits on top of the first ring.
- Continue to dig until the second ring has almost disappeared into the ground.
- Place the next one on top, etc.
- Continue until you are deep enough into the water table.



SCALE 1:80

With this method, it is easy to dig deep enough into the groundwater. No lowering equipment for rings is required. The method is only suitable for wells up to about 6 m deep, in soft soil, because the friction between rings and soil becomes too great and the rings would just not move downwards anymore.

6. Telescoping

For this method, follow these steps:

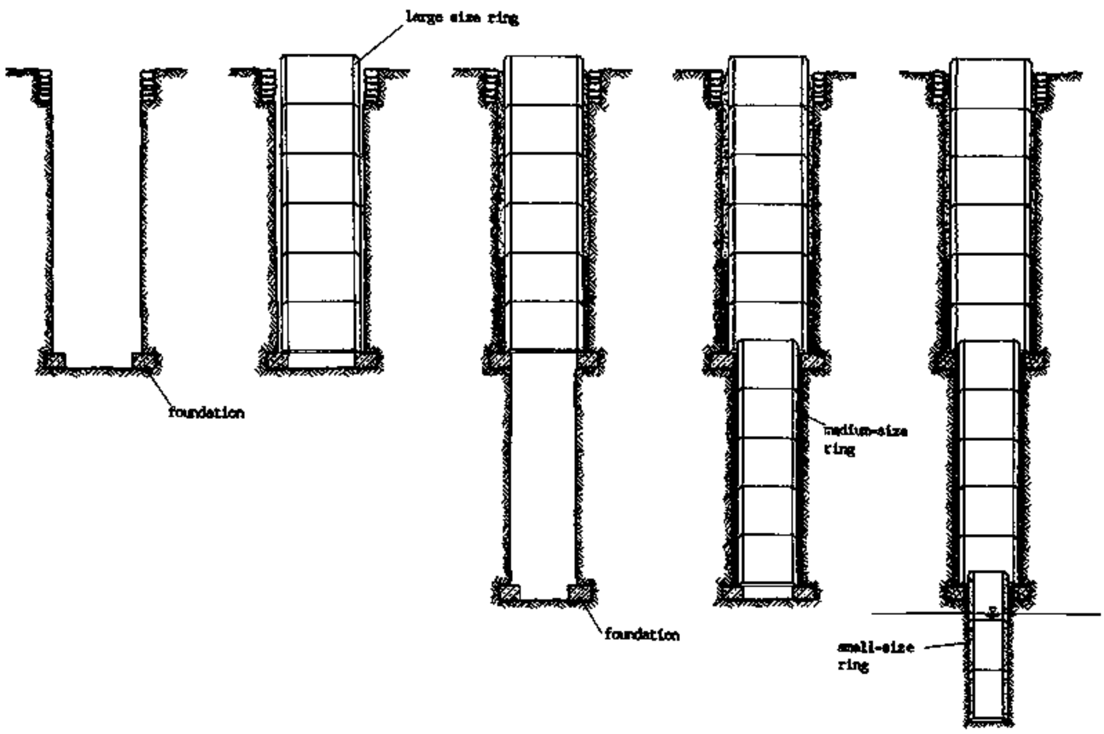
- Build a collar.
- Dig inside the collar 15 to 20 m deep.
- Build a foundation in the bottom from concrete or stones in cement mortar.
- Line this section by lowering concrete rings of large size (or by masonry).
- Dig inside the lining until the water table is reached.
- Build a foundation in the bottom.
- Line the second section with concrete rings of medium size (or masonry).
- Lower rings of small size.
- Dig into the water table while caissoning.

Drawing see next page.

This method is suitable for very deep wells because it enables us to dig deep and it provides more safety for the technicians. If there are rock layers in between, they can be used as foundation. The method is obviously quite laborious. The diameter of the well below the water table is narrow.

Telescoping can also be used for deepening an already existing well in order to increase its yield, e.g. because the water table has dropped (see also 8.16/4).

Telescoping:



SCALE 1:80

7. Digging and Lining in Sections

For this method, follow these steps:

- Dig one section deep.

- Line the section with brick lining or concrete lining cast in situ (= concrete poured between an inside mould and the well wall).

- Dig the next section (The lining above is held by friction.).

- Line it.

- Continue like this to the well bottom below the water table <u>or</u> dig into the water table by caissoning concrete rings.

Drawing see next page.

This method is suitable in very unstable types of soil (e.g. sand). Sandy soil can be provisionally stabilized by making it wet. The length of a section depends on the type of soil and can vary between 50 cm and several metres. Digging in sections below the water table can be continued if the water inflow into the well is slow and it is easy to keep the well dry during construction. Otherwise, caissoning with concrete rings is advisable. The method is not very handy, but might be necessary under certain circumstances.

For more details see No. 17 in the bibliography.

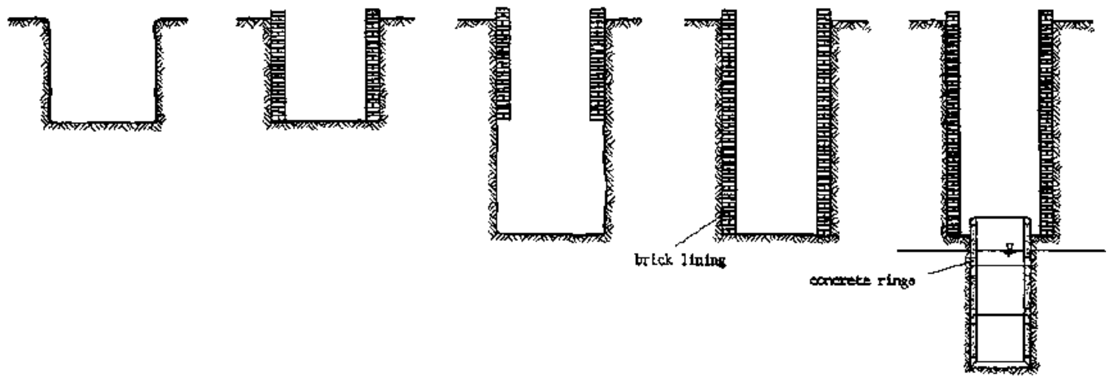
8. Selecting the Suitable Construction Method

The selection of the suitable lining and construction method depends on

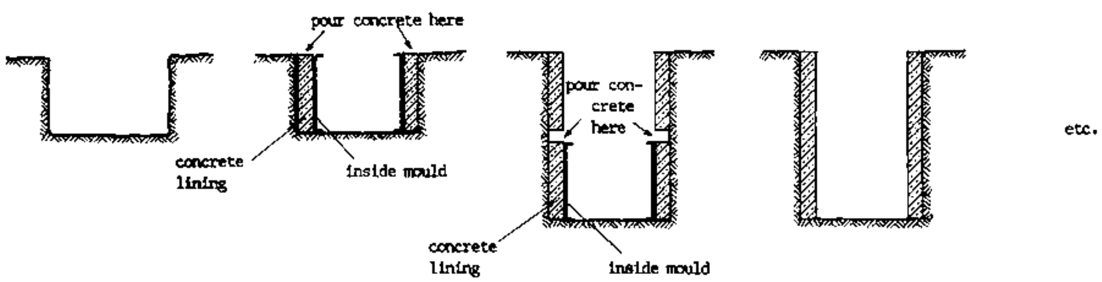
- the soil conditions,
- the depth of the well,
- the materials available,
- the equipment available,
- the skills available,
- the prices.

However, the first two are the really decisive factors. Carefully select the suitable method according to these criteria and the information given above.

Brick Lining in Sections:



Concrete Lining in Sections



SCALE 1:80

8.15 Well Digging Techniques

A carefully dug well

- is exactly round,
- has the same diameter everywhere,
- has exactly vertical walls.

Careful and exact digging has the following advantages:

1. An exactly vertical and cylindrical well is more stable and is in less danger of collapsing.

2. No unnecessary extra material has to be dug out and pulled out of the well.

3. Lining or lowering concrete rings is easiest if the well is vertical and cylindrical.

4. No unnecessary material has to be backfilled.

A) <u>Digging without Lining</u>

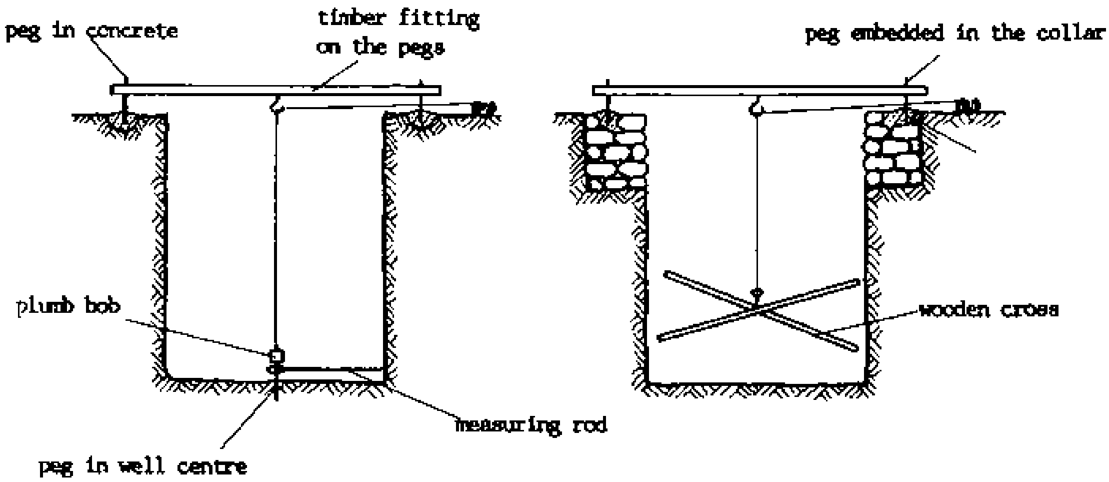
The following techniques will help you to dig a straight well:

1. <u>Keeping the Measurements while Digging</u>

It is advisable to set pegs in concrete in the ground or into the collar before starting digging (see drawing below). Place a piece of timber with two holes on the pegs. Screw a hook into the middle of the timber to mark the well centre. Use two sets of wooden crosses while digging. First, dig roughly according to the short set; then trim the edges exactly according to the long set. Example for big size rings: Short set 1.30 m; long set 1.45 m.

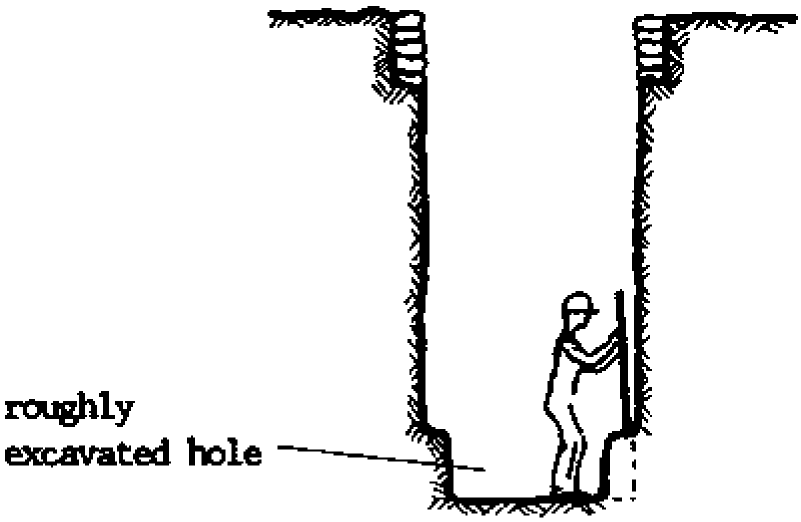
Alternative:

Drive a peg in the centre of the well bottom. Turn a measuring rod around it. Measure the centre from the top with the plumb bob.



2. <u>Digging the Well Shaft</u>

When digging the well shaft, first roughly excavate a hole about 10 cm smaller than the diameter of the well and about 50 cm deep. In a second step, trim the walls to reach the exact diameter.

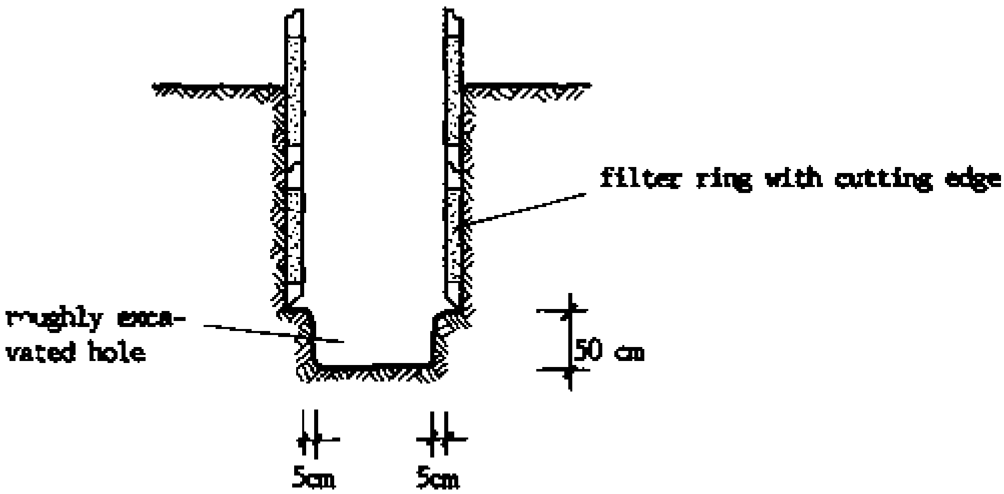


B) Digging with Concrete Rings

Digging inside concrete rings and allowing them to slide downwards during digging is called “sinking a caisson”. It is done according to the following technique:

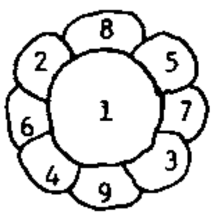
1. Steps of Digging

First dig a rough hole inside the ring, about 10 cm smaller than the inside diameter of the ring. Dig it about 50 cm below the bottom edge of the ring. This can be done by unskilled labourers.

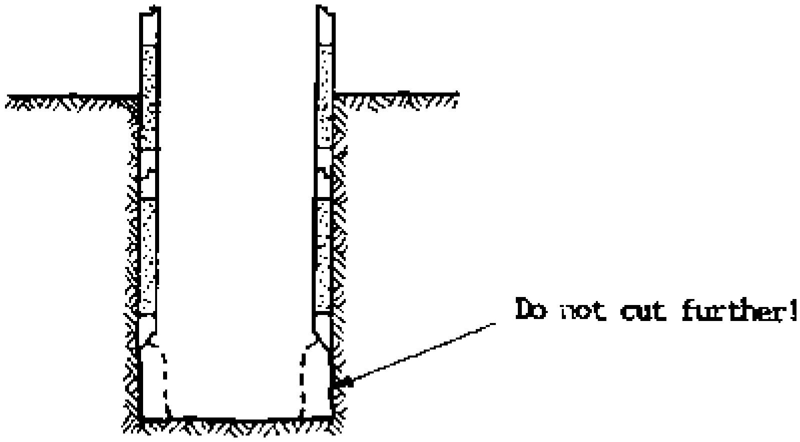


In a second step, cut back in layers all around to the outside diameter of the ring. However, do not start at one point and dig around clockwise, because this would cause the ring to sink askew.

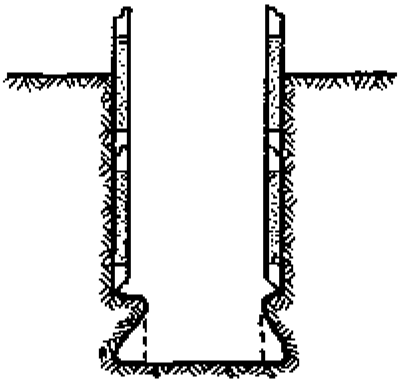
Cut small pieces always opposite to each other in this order:



Do not cut much beyond the outside diameter of the ring.



You can also cut like this:

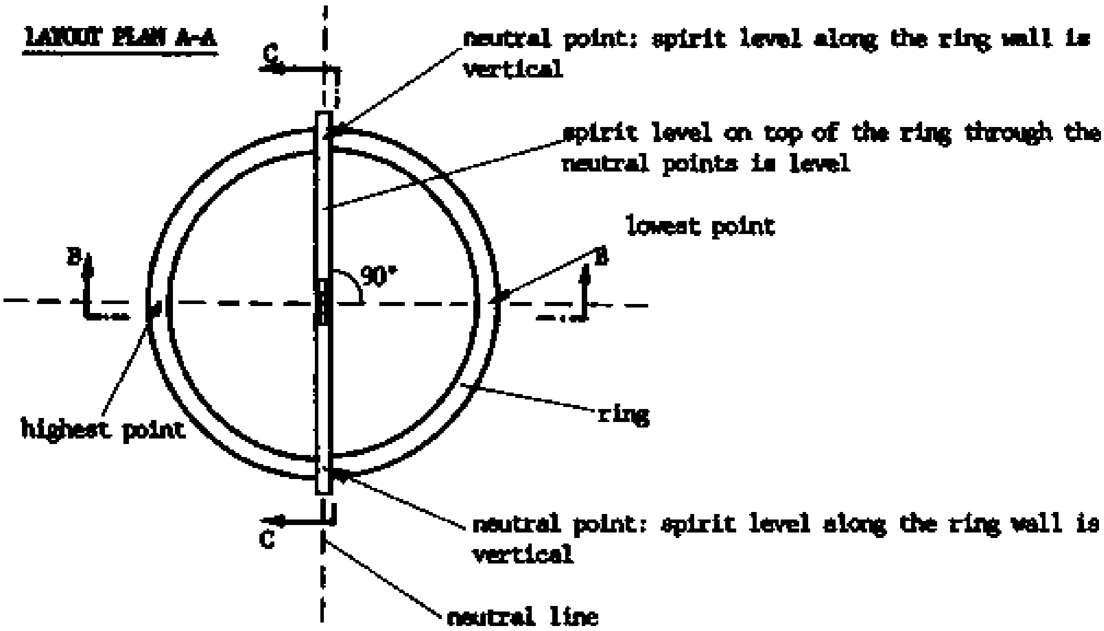


When the weight of the ring is greater than the friction, the ring will slide down the whole section. Before it slides, it announces itself by slight movement or a sound. Pay attention that your feet or hands or a tool are not underneath the edge of the ring.

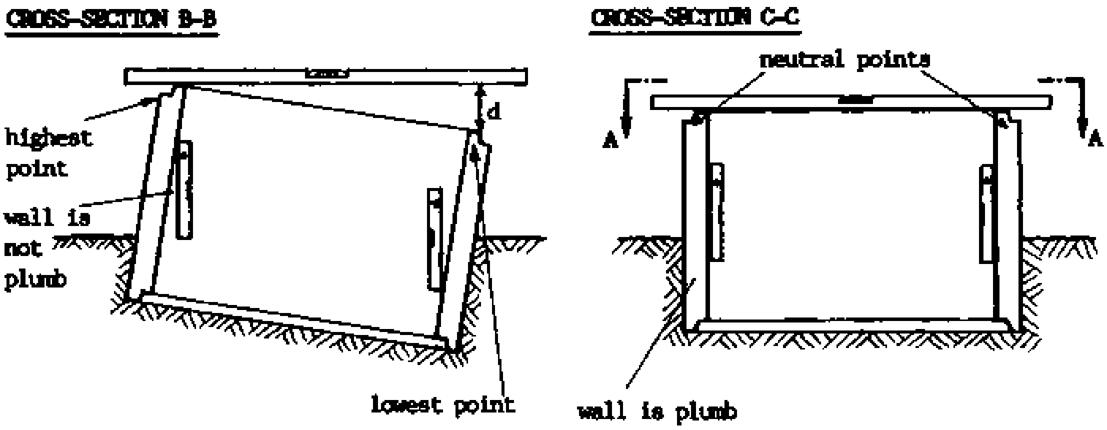
2. Checking the Position of a Ring

Whether a ring is askew or not can be checked either by checking whether the ring-wall is plumb, or by checking whether the ring-top is level. We select the method according to the circumstances. Plumbing is suitable if the top of the ring is occupied by equipment (like a beam, sling, etc.; see 8.17/22) or if a column of several rings is to be checked. Levelling is suitable whenever the top of the ring is free. For reading spirit level and plumb bob see 6.4/9ff).

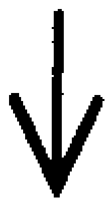
When using either method, always look first for the “neutral points” which lay opposite each other. The neutral points are where the spirit level or plumb bob are vertical along the ring wall. A long spirit level laid on top of the ring through the two neutral points is level. Mark the two neutral points with chalk or charcoal or mud. The lowest and the highest points lie in the middle of the two neutral points on opposite sides. A spirit level laid across the top of the ring through the lowest and the highest points shows the greatest slope.



Check the distance d which indicates by how many cm (or "fingers") the spirit level is out of level:



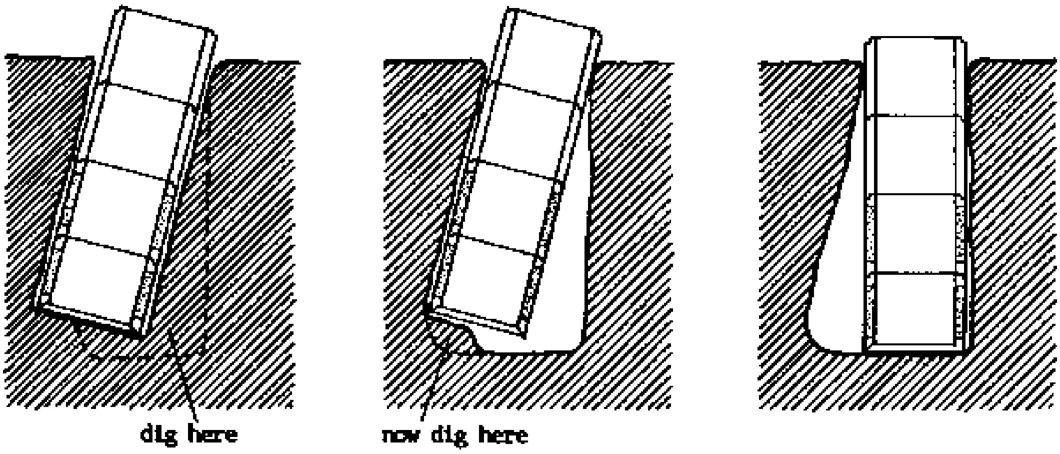
Mark the lowest point with a big arrow:



3. Straightening Askew Rings

When you know where the highest and the lowest points are, remove soil from beneath the lowest point (up to the neutral points). Dig underneath and beyond the outside edge of the ring. Then carefully dig soil away from underneath the highest point, but do not dig further out from the ring than necessary. Such rings can gradually sink again into vertical position. This is the case if the spirit level is vertical all around the ring.

Alternatively, you can check it with the plumb bob.



C) Possible Complications during Digging

Different complications can occur while digging a well. Two common ones are described in the following.

1. Rock

The appearance of rock makes digging much more difficult. There are different possibilities how to continue:

- to continue digging with heavy crowbars and drastically reduced speed;

- to leave the site and start new;

- to use more sophisticated methods like a compressor or blasting with dynamite; these need special skills.

2. Quicksand

Water and sand entering the well in great speed is called quicksand. It is very dangerous because it can hold your feet so that you are unable to pull them out. Additionally, it can fill the well quickly or/and cause collapsing of the surrounding area. If you encounter quicksand, leave the well immediately and remove all tools. It might be necessary to leave the site and dig a new well nearby, planned in such a way as to caisson through the sandy layer as quick as possible. Never enter a well with quicksand without safety belt and rope connection to the top.

8.16 Manufacturing Concrete Rings

Lining wells with ready made concrete rings has the following advantages:

1. It is very stable.
2. It protects the diggers while “caissoning” into the groundwater.
3. It is thin and, therefore, requires less excavation.
4. The rings are easily prefabricated outside the well.
5. Finishing the well (i.e. lowering the rings) can be completed within short time.
6. Less cement is needed than for other lining like brick lining or stone lining.

The Disadvantages are:

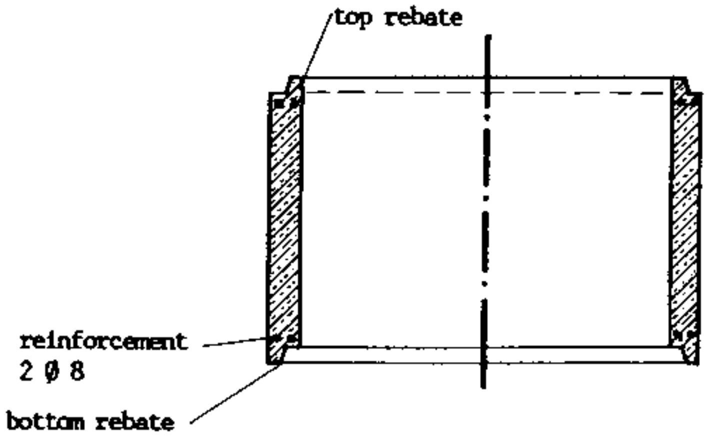
1. Moulds and other equipment are needed for casting the rings.
2. Special equipment is needed for lowering the rings.
3. Skilled labour is necessary for lowering and caissoning.

A) Types of Concrete Rings

The following three types of concrete rings are needed to construct ordinary wells:

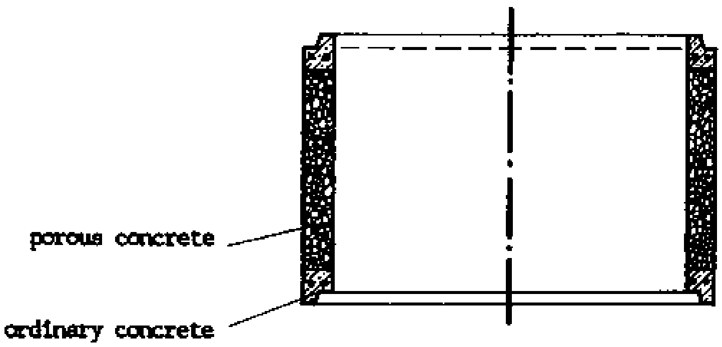
1. Fully Concrete Ring

- rebate on top and in bottom
- to be used in well shaft above water table
- prevents water from entering the well



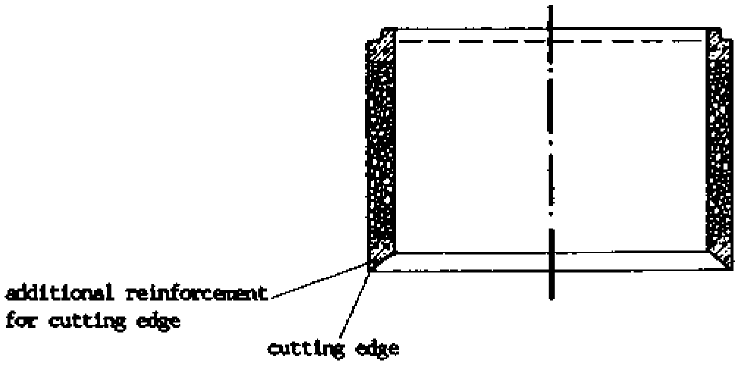
2. Filter Ring

- rebate on top and in bottom
- to be used in well shaft under the water table
- allows water to enter the well



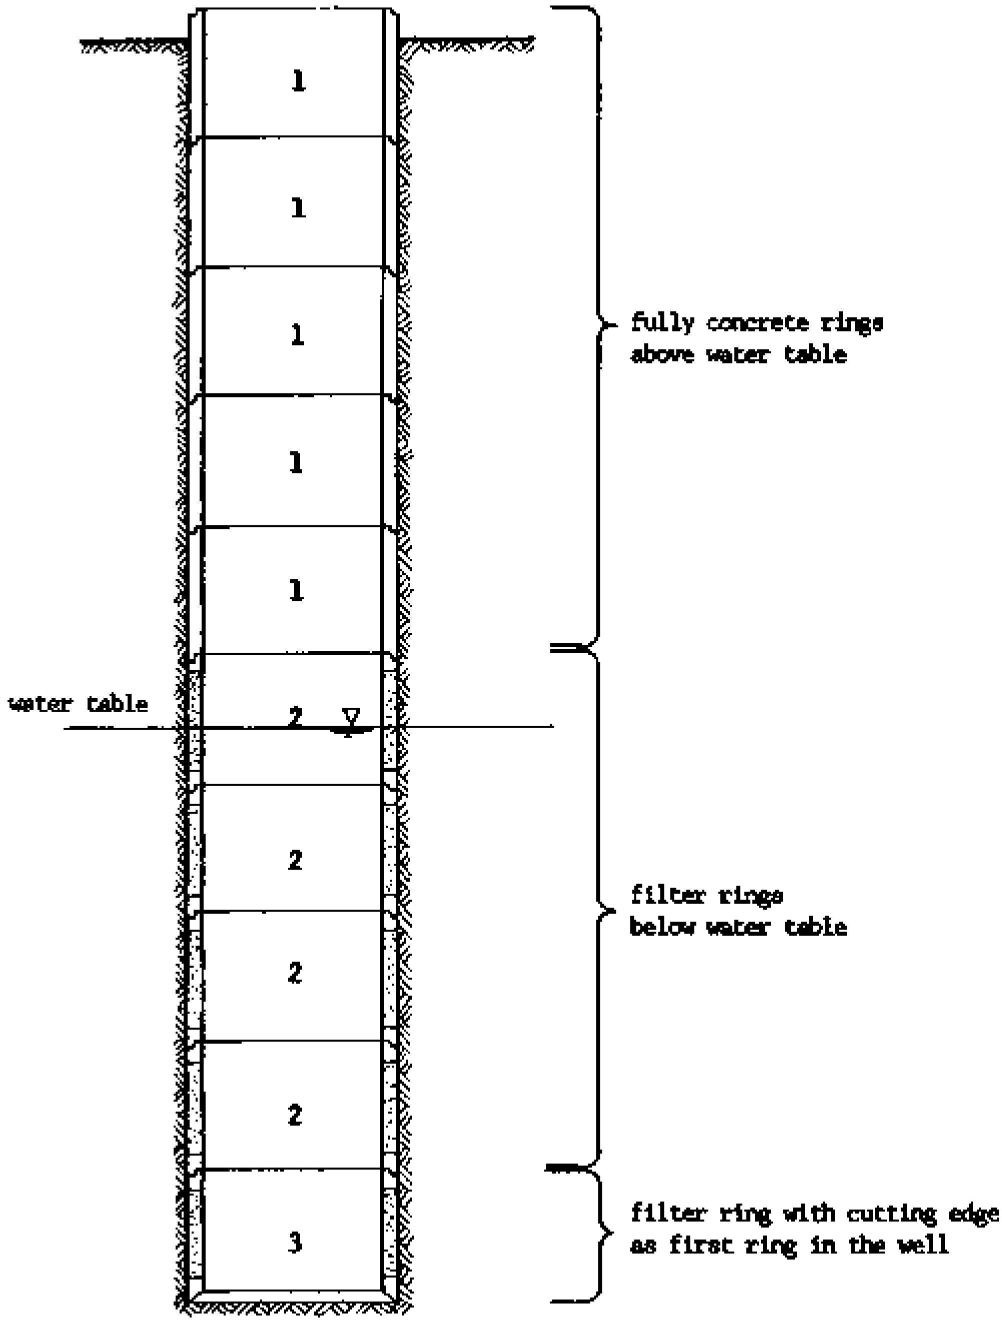
3. Filter Ring with Cutting Edge

- rebate on top, cutting edge in bottom
- to be used as the first ring in the well
- allows water to enter the well
- cutting edge makes digging easier



B) Application of the Different Ring Types

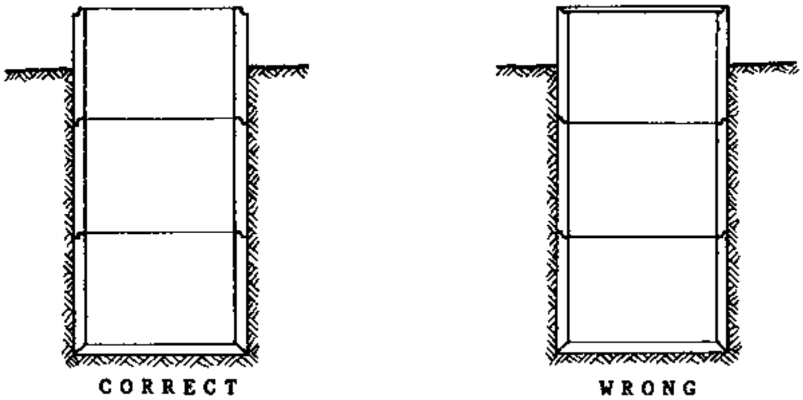
The different types of rings are to be utilised in a well as follows:



SCALE 1:50

The rings have rebates on the top and in the bottom edges. A rebate is a step-shaped channel along the edge of the ring to receive the corresponding edge of another ring. On the top edge of the ring, the channel is outside. This corresponds to the bottom edge of another ring where the channel lies inside.

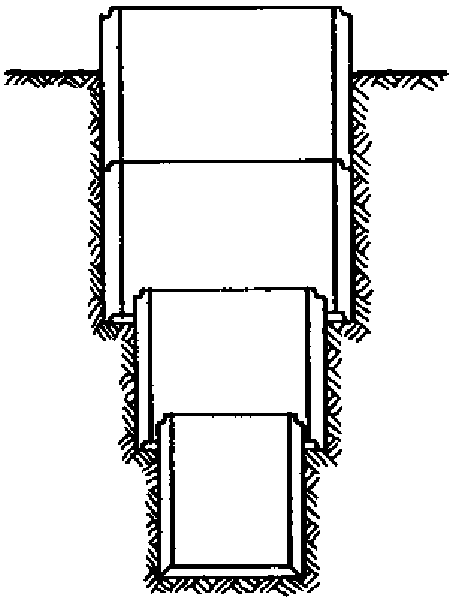
The rings have to be stacked on top of each other in such a way that no surface water can enter the well through the rebates. They have to slope outwards. The moulds described in D) produce rings which can only be stacked in the correct way if the first ring in the well is one with a cutting edge.



The filter rings below the water table are just stacked on top of each other without mortar. The rebates provide the connection. The fully concrete rings above the water table are connected with cement mortar to make a watertight joint.

C) <u>Sizes of Concrete Rings</u>

It is advisable in a project to have moulds of different sizes for different purposes. The dimensions should be chosen in such a way that the next smaller ring can be used inside a previous ring when deepening the well becomes necessary later on. This is called "telescoping"(see also 8.14/7f).



SCALE 1:50

The advisable height of the concrete rings depends on the equipment available for lowering them into the well. Rings 50-60 cm high are light and, therefore, can be lowered with light weight equipment. Small rings also cause fewer problems during transportation if manufactured in a central workshop. But they require more reinforcement. The work progress during lowering is slower and more joints need to be constructed. For very deep wells small rings are not advisable.

Concrete rings 90-100 cm high are heavy and require strong, more expensive and heavier lowering equipment. If this equipment is available, high concrete rings are preferable, because of the easy manufacturing process and quicker work progress during lowering. If rings are to be manufactured on site, this height is advantageous. Rings higher than 100 cm are not advisable at all.

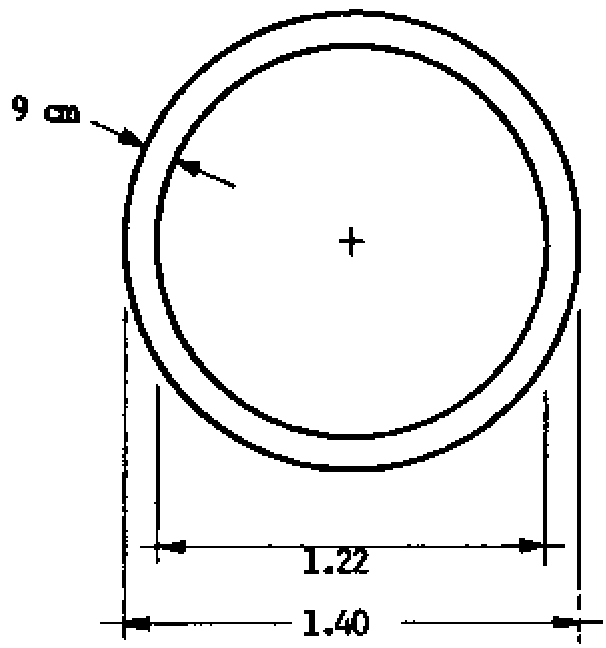
The thickness of the wall of a concrete ring should be between 6 and 10 cm, depending on the diameter of the ring. A wall thinner than 6 cm cannot accomodate the reinforcement properly and will break easily; a wall thicker than 10 cm makes the ring too heavy without adding to the strength accordingly and is, therefore, a waste of material.

The following sizes for concrete rings are suggested for a water project:

(All rings are 0.92 cm high.)

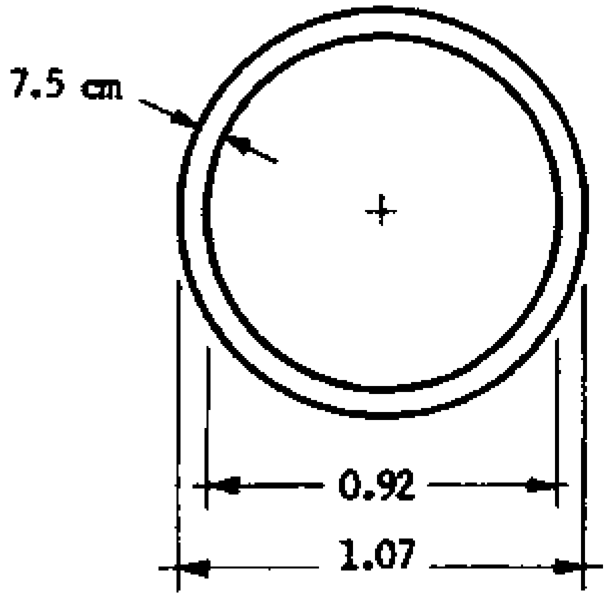
1. <u>Large Size:</u>

- big water reservoir can store large quantities of water
- more digging is necessary
- 2 or 3 people can dig in the ring at the same time
- it is suitable in soft soil and if the water table is not too deep



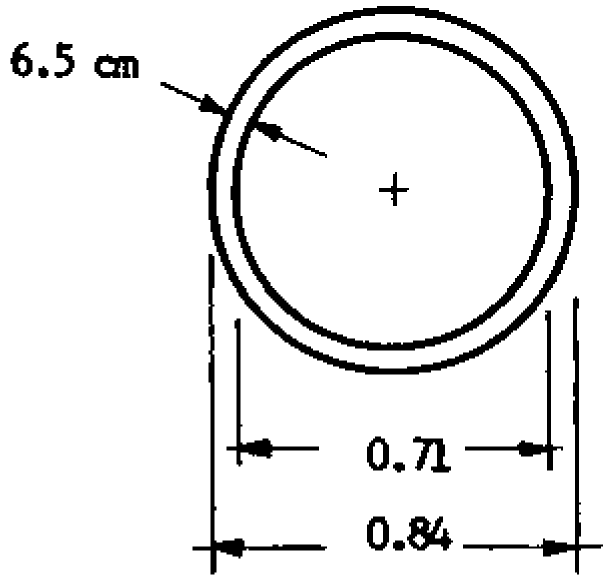
2. <u>Medium Size:</u>

- a moderate water reservoir
- less digging is necessary
- 1 to 2 people can dig in the ring at the same time
- usually used
- suitable also in deep wells and in rock
- suitable for telescoping within a large ring



3. Small Size:

- small water reservoir
- little digging is necessary, but digging is difficult due to little space
- only one person can dig in the ring
- suitable only in special cases
- suitable for telescoping within a middle size ring



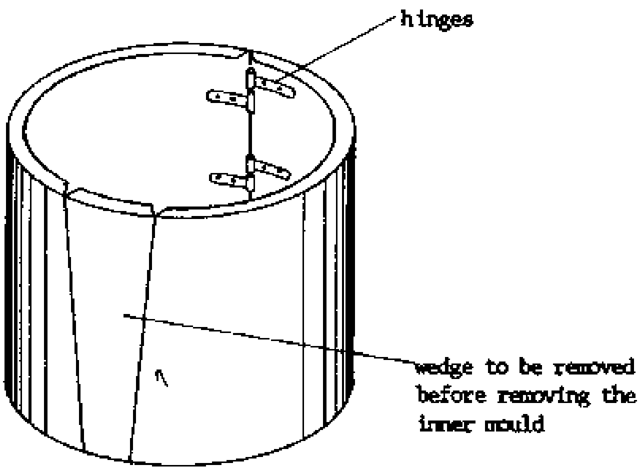
SCALE 1:30

D) Pipe Moulds

Pipe moulds are steel forms for casting concrete rings. They are very durable, can last for a long time, and produce rings which always have the same size and shape. However, they need to be handled with great care.

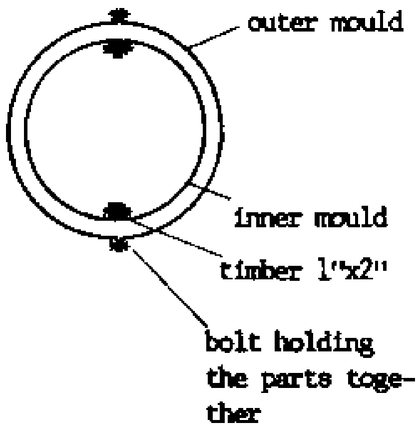
Pipe moulds consist of the following parts:

1. Inner Mould (with two pieces and wedge)



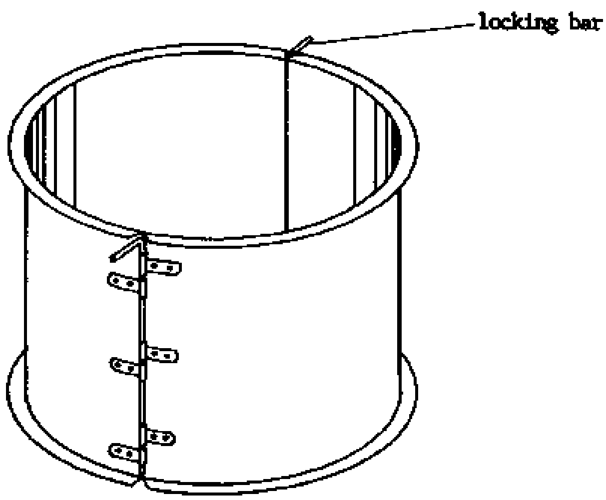
Inner mould without wedge:

LAYOUT PLAN:



If the inner mould has no wedge, but consists of two pieces similar to the outer mould, you <u>must</u> place a piece of timber 1”×2” in between the parts of the inner moulds. Otherwise, you will not be able to remove the inner mould after casting the ring without breakage.

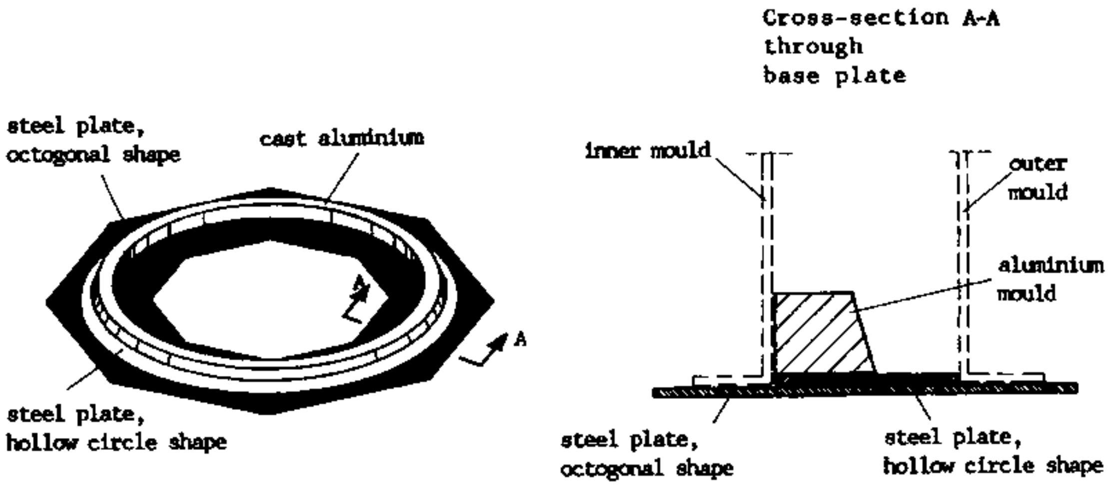
2. <u>Outer Mould (two pieces)</u>



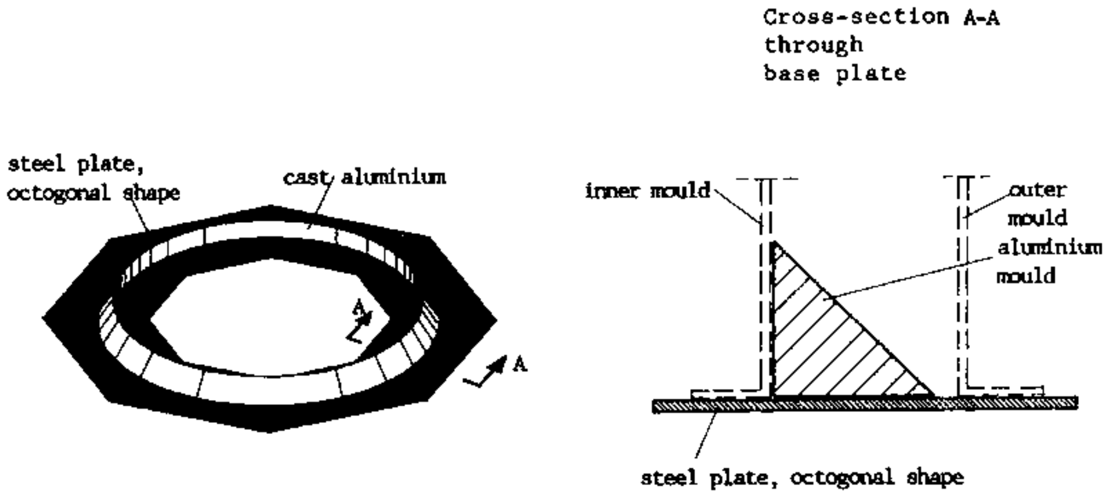
design: Harrtz & Bell, Nairobi

SCALE 1:25

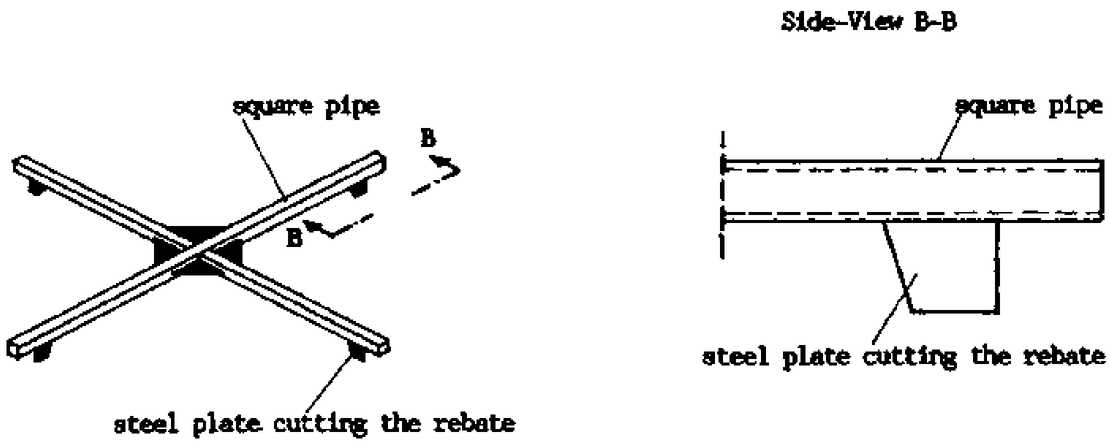
3. Base Plate for Rebate



4. Base Plate for Cutting Edge



5. Cutting Cross (for cutting rebate on the top of the ring)



E) Casting Concrete Rings

Manufacture concrete rings according to the following steps:

No.	Step	Reasons
1	Load and unload the moulds very care fully. Avoid dropping them and bending them out of shape.	Out-of-shape moulds produce rings which are not round. They do not fit into each other when lowered into the well.
2	Place the base plate on level, clean ground.	This ensures easy compaction and minimizes movement.
3	Place the inner mould inside the base plate. Check if the wedge can be pulled out easily; otherwise, clean and grease it. Check if the mould can be easily hinged inwards.	After concrete is cast, the moulds are much more difficult to move.
4	Bend the reinforcement around the mould; cut it and tie it using the appropriate diameter:	The reinforcement should never touch the moulds but be well covered by concrete from all sides. Concrete prevents steel from corroding. See 6.6/8ff.
	One reinforcement in one layer for rings Ø 1.07 m: 	Two reinforcements in one layer for rings Ø 1.40 m: 5	Take the reinforcement out.	It will be needed later on.
6	Paint the base plate, the inner mould (outside), and the outer mould (inside) with old engine oil.	Engine oil prevents the concrete from sticking to the steel mould (like oil when baking bread).
7	Place the outer moulds and connect them with locking bars. Check if the mould is in correct position all around. 	The correct position on the base plate assures that the mould is really in a round shape. It should not sit on the hollow circle shaped steel plate.
8	Place the cutting cross on the mould and check if you can easily turn it.	The round shape of the mould can be checked with the cutting cross.
9	Wash the gravel if necessary.	Soil particles make the concrete weaker. See 6.6/7.
10	Sieve the gravel if necessary.	The biggest parts shall not exceed 20 mm diameter.
11	Mix the concrete thoroughly. For mixtures see F). Mix cement and sand dry. Then add water and mix thoroughly. Add as little water as possible. Add gravel, and mix thoroughly. The water content is correct if the concrete is just workable for pouring and compacting. The concrete should look dry. If compacted a little, water needs to appear on the surface.	Only a well mixed concrete is strong. The cement needs to be evenly distributed inside the concrete. The concrete is weaker if there is too much water in it. See 6.6/7

No.	Step	Reasons
12	Pour a little concrete into the mould evenly all around. Compact it with wooden stampers. 	This ensures that the concrete is compacted evenly. All air bubbles need to be removed, because they make the concrete weaker.
13	Fill to about 10 cm high all around. Place the reinforcement. Take care that the reinforcement does not touch the moulds.	The top and bottom reinforcement prevent the rings from breaking.
14	Fill the mould, layer by layer, and compact each layer.	The ring must be well compacted throughout for high strength.
15	When the mould is filled 80 cm high, place the reinforcement.	see No. 13
16	Fill the rest of the mould. Compact it well. Cut the top rebate with the cutting cross. Remove the surplus concrete.	The top and bottom rebates are corresponding and ensure a strong connection between the rings.
17	Fill in some cement mortar 1:4. Cut again with the cutting cross.	The rebate becomes smoother if cement mortar is used.
18	Write the date into the fresh concrete.	If the date is recorded, you know if the ring is hard enough for lowering. See 6.6/6f
19	Wash away all concrete spilled outside on the moulds.	Otherwise the concrete will get hard on the mould. It will be difficult to clean it later. Old concrete makes the mould heavier.
20	Cover the mould.	Fresh concrete becomes stronger if kept wet (= cured).
21	Remove the moulds (without the base plate) 3 hours after casting at the earliest. Lift the wedge of the inner mould. Hinge the inner mould inwards and carefully remove it. Open the outer moulds and remove them. Clean the moulds immediately.	Take care not to damage the fresh concrete. The outer mould still protects the ring when removing the inner mould first. The concrete is of good quality if the surface is smooth without air bubbles. It is easier to clean the moulds immediately when they are still wet.
22	Cover the ring with wet sackcloth and nylon (or wet grass). Or water it continuously. Keep it wet for at least 3 days, better for 7 days.	Curing the concrete by keeping it wet prevents cracks and makes it strong.
23	Remove the base plate after 2 days (48 hours) at the earliest. Place a “cushion” of sand beside the ring. Pull the ring over on its side by a sling. Remove the base plate. Clean it. Let the ring down again. Cover the ring again.	If 48 hours have not yet passed, the rebate is not hard enough and could easily be damaged. If you pull over the ring before time, it would crack or break.
		24	After three to four weeks the rings are hard enough to be lowered into a well.	To lower them before is a danger to the workers and can cause heavy losses of time and material. See 6.6/6f.

F) Mixtures and Reinforcement

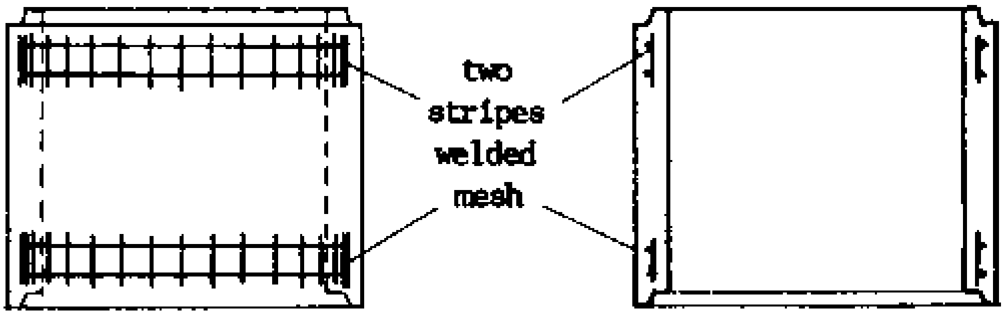
Use a strong mixture of 1:3:4 for fully concrete rings to compensate for ingredients of variable quality and mistakes in work. Even if cement is very expensive, the safety of the workers is much more important than minimizing cement costs. Breaking of rings at any stage (during moving, lowering or digging) can easily cause bad injuries.

The same mixture 1:3:4 is used for the bottom and the top of filter rings. Together with the reinforcement this gives strength to the filter ring. In spite of that, the filter ring is weaker than the fully concrete ring and, therefore, needs to be handled with even more care. The filter part consists of a mixture 1:0:4 (one part cement, no sand, four parts gravel). The voids between the gravel make the concrete porous and allow the water to enter through the filter ring. Alternatively, a mixture of 1:1:4 could be used. When mixing concrete for the filter part, mix the cement with water first and add the gravel afterwards.

For medium size rings, 2 reinforcement rods, 0 8 mm, all around the ring, one in the bottom, one on the top, are sufficient, both for fully concrete and for filter rings. Add another ring of reinforcement in the cutting edge.

If reinforcement is not available, it can be substituted by one layer of chicken wire all around the ring. This is only possible for fully concrete rings; it also makes compacting more difficult.

To substitute the reinforcement by welded mesh all around the ring is very expensive. Alternatively, you can cut 2 stripes of welded mesh:



Middle size rings might also be manufactured without any reinforcement at all (only fully concrete rings!), although it is not advisable. In that case, the mixture must be stronger, the curing must be continuous for seven days, and rolling the ring is very delicate. Casting rings without reinforcement should only happen in emergencies. You run the great risk of loosing the whole cement through breakage of the ring.

For large size rings, 4 reinforcement rods, Ø 8 mm, are necessary, 2 in the top, 2 in the bottom. Add another reinforcement in the cutting edge. The reinforcement can be substituted by <u>2</u> layers of chicken wire or 1 layer of welded mesh all around the ring. Large size rings cannot be manufactured without reinforcement.

The above instructions are valid only for rings which are to be turned over, rolled and lowered into a well. Rings cast in situ (on the site), for example for water tanks, which are never to be moved, can be cast without reinforcement. See also 6.6/10.

On the other hand, rings to be used as culverts (= channel carrying water under a road) need much stronger reinforcement. They have to bear the load of cars and lorries driving over them. The reinforcement depends on the type of cars using that road and the thickness of soil between the culvert and the road. The reinforcement must be at least one layer of welded mesh, but could be as much as 1 reinforcement 0 10 mm every 10 cm. See also 6.6/10.

Mixtures, approximate quantities and reinforcement for well rings are compiled in the following table:

Ring Size	Type of Ring		Mixture	Cement Buckets	Sand Buckets	Gravel Buckets	Reinforcement Rings
Ø 1.40	fully concrete ring		1:3:4	5	15	20	4 Ø 8
	filter ring,	top and bottom	1:3:4	1	3	4	4 Ø 8
		filter part	1:0:4	5	0	20	- -
	filter ring with cutting edge	top and bottom	1:3:4	1	3	4	5 Ø 8
		filter part	1:0:4	5	0	20	- -
Ø 1.07	fully concrete ring		1:3:4	3	9	12	2 Ø 8
	filter ring	top and bottom	1:3:4	$\frac{1}{2}$	$1\frac{1}{2}$	2	2 Ø 8
		filter part	1:0:4	3	0	12	- -
	filter ring with cutting edge	top and bottom	1:3:4	$\frac{1}{2}$	$1\frac{1}{2}$	2	3 Ø 8
		filter part	1:0:4	3	0	12	- -

1 bucket is about 10 lit. 1 bag of cement is about $3\frac{1}{4}$ buckets.

8.17 Lowering Concrete Rings into a Well

Concrete rings are heavy; the middle size weighs about 540 kg, the large size weighs about 940 kg. Lowering them into a well is a delicate work and requires skilled technicians and reliable equipment. See also 5.7.

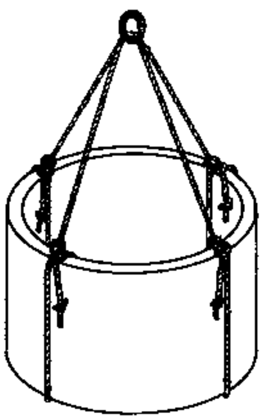
A) Methods of Holding a Concrete Ring

Concrete rings can be held for lifting and lowering by different methods:

1. Tying the Ring with Rope

Step-by-step procedures:

- Sling a rope underneath the ring and tie it around the ring walls.
- Do this on 3 or 4 spots around the ring.
- Lift the ring.



Advantages:

- Nothing else other than rope is needed.

Disadvantages:

- The method is not very handy.
- The ropes wear out very quickly.
- The ropes are difficult to remove once the ring is placed on top of another ring.
- It is not easy to balance the rings horizontally.

2. Tying to Hooks in the Ring

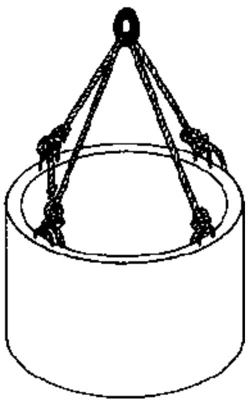
Step-by-step procedures:

- Tie 3 or 4 hooks made from steel Ø 10 mm to the reinforcement before pouring the concrete into the ring moulds.

- Cast the hooks into the concrete.

- When you want to lower the rings into a well, tie ropes to the hooks.

- Lift the ring.



Advantages:

- The connection is strong.

Disadvantages:

- Extra work is needed when casting the rings.

- Rebates are not possible.

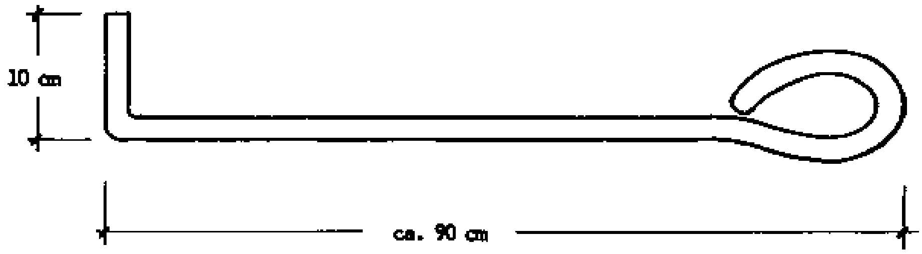
- The next following ring will not sit properly on the previous one because of the hooks. More mortar is necessary.

- If the hooks are to be bent inwards after lowering, the concrete can break easily.

3. Holding by Steel Hooks

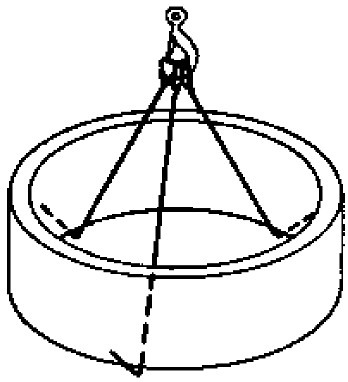
Step-by-step procedures:

- Manufacture three steel hooks from reinforcement Ø 20 mm.



- Grasp the bottom edge of the ring with the three hooks.

- Tie the eyes of the hooks together and lift them at a go.



Advantages:

- The equipment is simple and can be manufactured locally.
- The method is relatively handy.
- Little space is needed outside the ring.
- No hooks have to be cast into the concrete.

Disadvantages:

- The method is only suitable for small, light weight rings (up to Ø 1.10 m and 60 cm height).

- It is difficult to balance the ring during lowering.

- The bottom rebates can be easily damaged by the hooks.

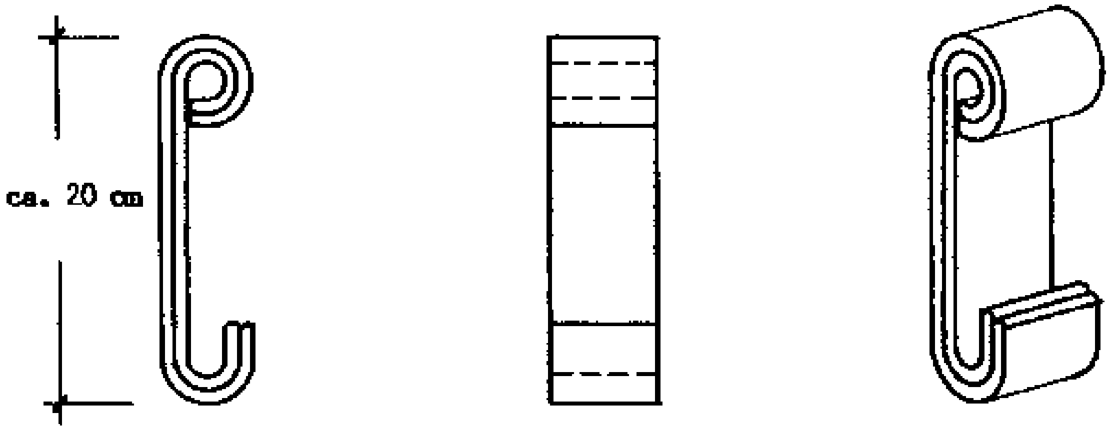
- It is difficult to get the hooks out, once the ring is placed on top of another.

- There is little working space for the technician on top of the ring.

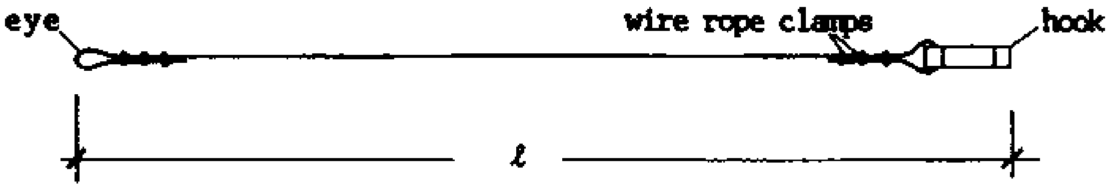
4. <u>Holding by Steel Cable</u>

Step-by-step procedures:

- Prepare a strong hook from double flat iron, 60 x 8 mm, (or from car springs) by blacksmithing and welding.



- Prepare a steel cable with an "eye" on one end and the hook from flat iron on the other as follows:



The total length (including the hook and the eye) should be about

$$\ell = h + \pi \times D + 1.41 \times D = h + 4.55 \times D$$

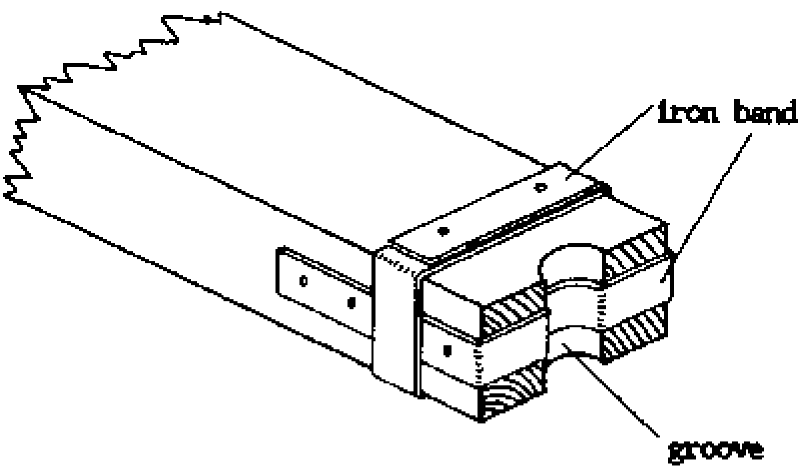
h = height of concrete ring
D = diameter of concrete ring
π = 3.14

Cut the steel cable. Weld its ends by gas welding to prevent splitting and injury to people. Fix the hook and the eye, each with two wire rope clamps.

- Prepare a piece of timber 2" x 4". The length should be:

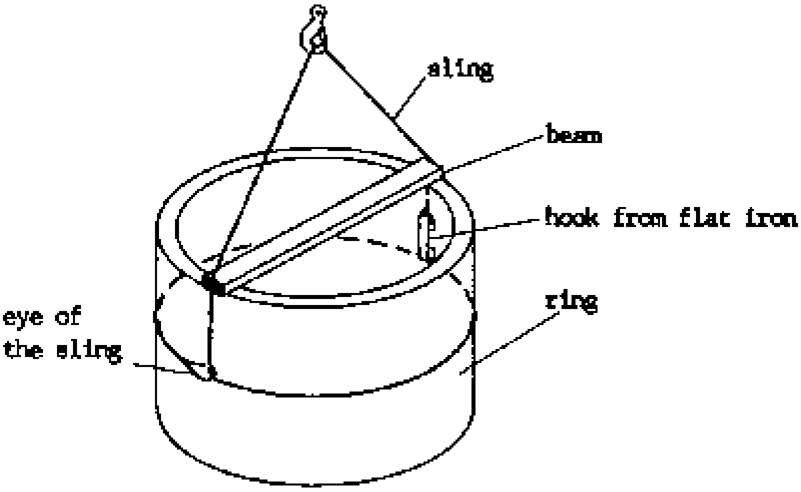
$$\ell = D + 3\,\text{cm}$$

Cut a slight groove into its ends and reinforce it with iron band as shown:



- Once the steel cable and the piece of timber (= "beam") are made, they can be used many times.

- Fix the steel cable with the beam around the ring like this:



The beam prevents the cable from cutting and damaging the concrete. The cable should be at the middle of the ring or below.

- Lift the ring with a swivel-hook. The sling is able to lift the heavy concrete ring through friction between cable and concrete.

- If not balanced, put down the ring again and move the swivel-hook accordingly until the ring is balanced.

Advantages:

- The equipment can be produced locally.

- No hooks have to be cast into the concrete.

- Any type of ring can be lifted, with or without rebates.

- The ring is held in the middle and all around.

- The method is very handy, quick and safe.

- The rings are easily balanced and directed during lowering.

- Only little space is occupied outside the ring.

- There is nothing underneath the ring; the ring can be placed directly on top of another ring.

- There is enough working space for the technician on top of the ring.

- The equipment is long lasting.

Disadvantages:

- Steel cable and iron hook are needed.

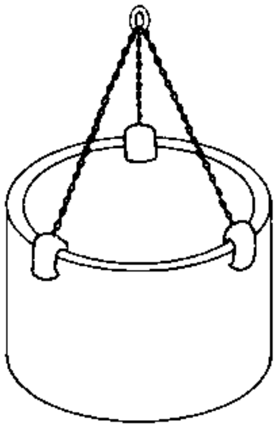
(In emergency cases triple rope can be used instead of steel cable.)

5. Holding by Self-Locking Lifting Clamps

Special lifting clamps are industrially available for lifting concrete rings. They consist of three clamps attached to chains. When pulling the chains, the clamps automatically tighten and hold the ring by friction. They are “self-locking” when pulled.

Step-by-step procedures:

- Place the three clamps on the ring at equal distances.
- Lift the ring by the chain.



Advantages:

- The method is very handy and quick.
- Any type of ring can be lifted.
- The rings are easily balanced.
- There is nothing underneath the ring.

Disadvantages:

- The special lifting device is not easily available and cannot be produced locally.

- The clamps require space outside the ring.

- The ring is held only on three small spots; if the concrete is of weak quality, it can break and the method is not safe.

- There is little working space for the technician on top of the ring.

6. <u>Selecting the Suitable Method</u>

The selection of the suitable method depends on the circumstances and the equipment available. whenever possible it is advisable to use method No. 4.

B) <u>Methods of Lowering a Concrete Ring into a Well</u>

Concrete rings can be lowered into a well by different methods:

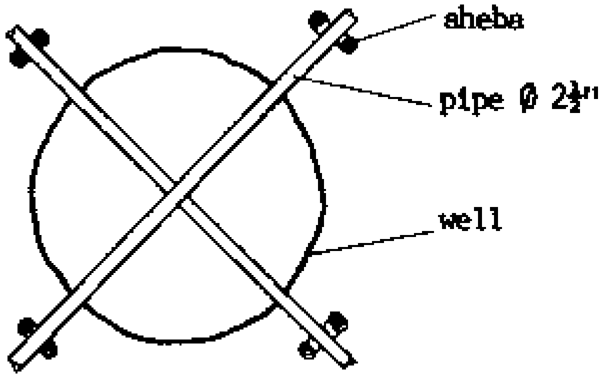
1. <u>Lowering with Local Equipment</u>

The equipment necessary for this method should be available locally and/or within the country.

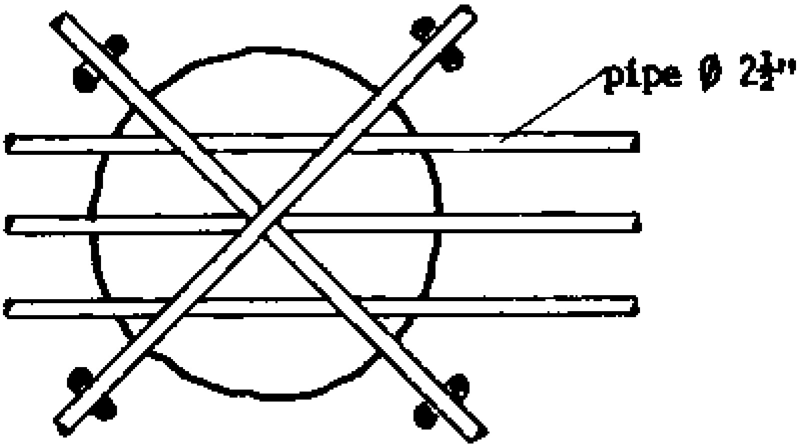
Step-by-step procedures: see also drawing 6.17/9

- Erect 4 strong Y-shaped poles (“shebas”) around the well and fix them in concrete.

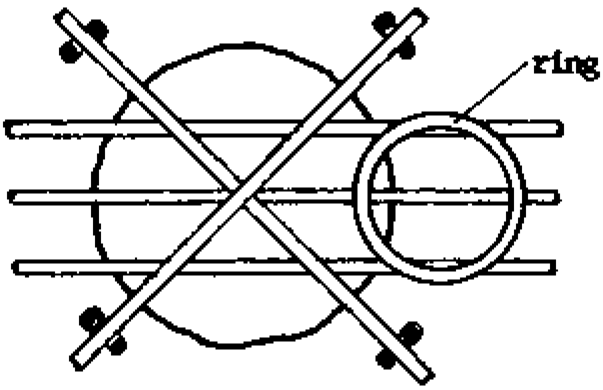
- Lay 2 strong metal pipes, Ø 2½, or strong poles, across them and tie them to the shebas.



- Lay three strong, long poles, or pipes Ø 2½, across the mouth of the well.



- Place the ring on top of these poles or pipes outside the well mouth.

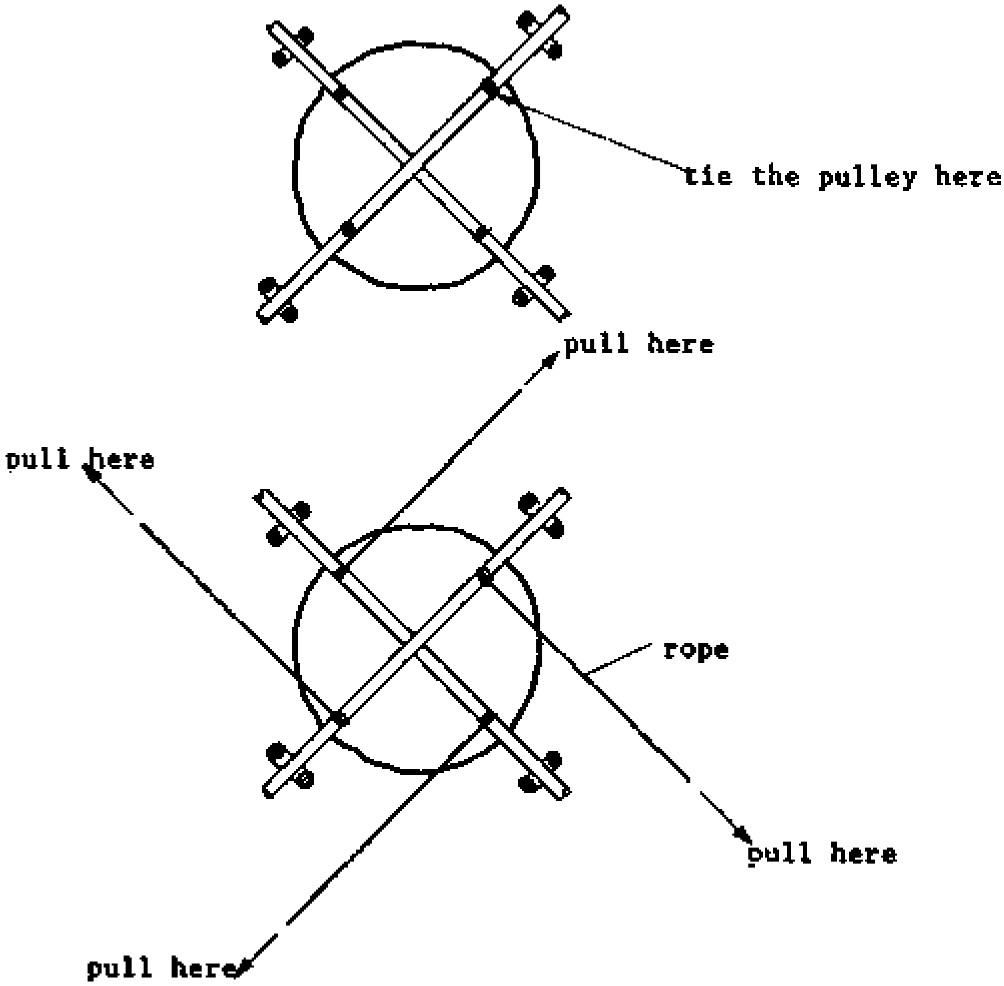


- Tie four pulleys on the crossing pipes.

- Pull four long sisal ropes Ø 25 mm through the four pulleys.

- Tie the ring with the four ropes by method 1 or 2 as described under A).

- Let about 8 to 10 people pull at <u>each</u> rope.



- Lift the ring and let it slide into the middle above the well.

- Remove the poles from underneath.

- Lower the ring into the well.

Advantages:

- No sophisticated equipment is necessary; most of it is available in the village. Pulleys, pipes, ropes should be available within the country.

Disadvantages:

- Very much rope of good quality is required. The rope wears out quickly during lowering. New ropes are required for each well which is very costly.

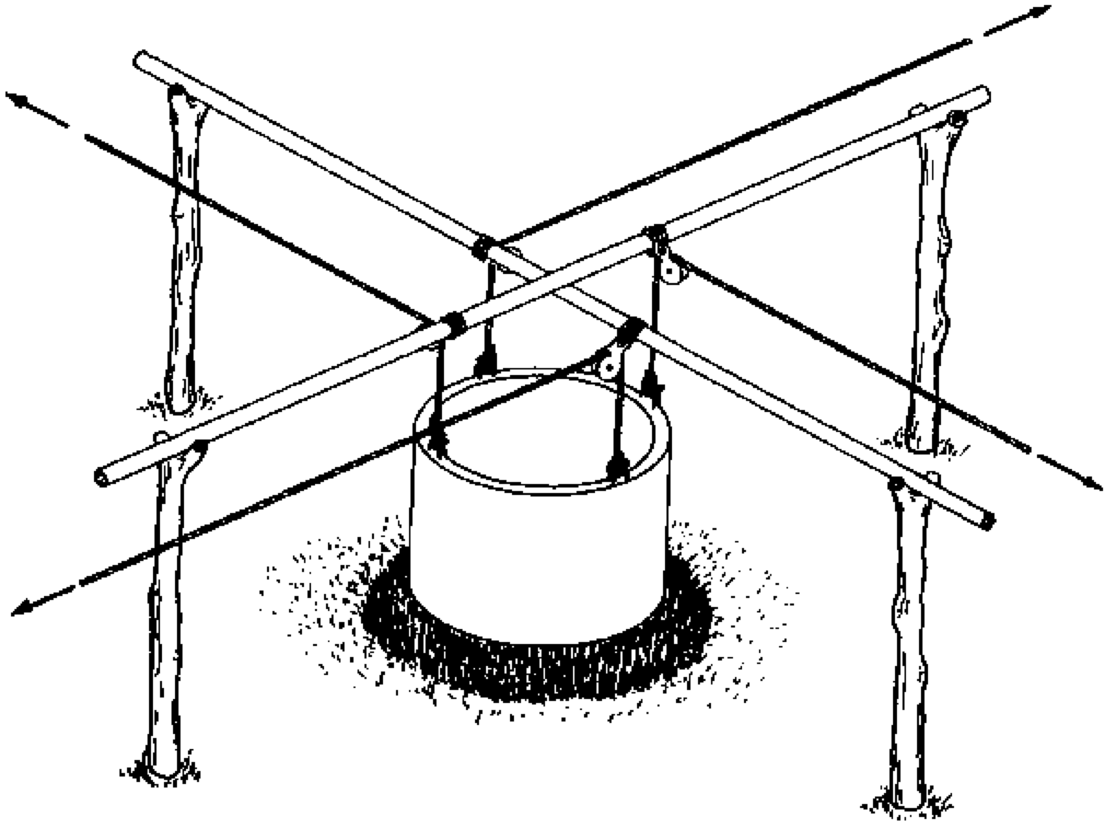
- Many people (about 40) are needed for lowering rings. It is difficult to get the required number of people (adults!) continuously for the necessary period of time and it is also difficult to coordinate such a number of people. Some will be redundant in between while the technicians work in the well.

- Precise lowering and balancing of the ring is difficult with this method.

- Rings cannot be lowered deeper than 15 m by this method.

Lowering a Concrete Ring with Local Equipment

ISOMETRIC VIEW



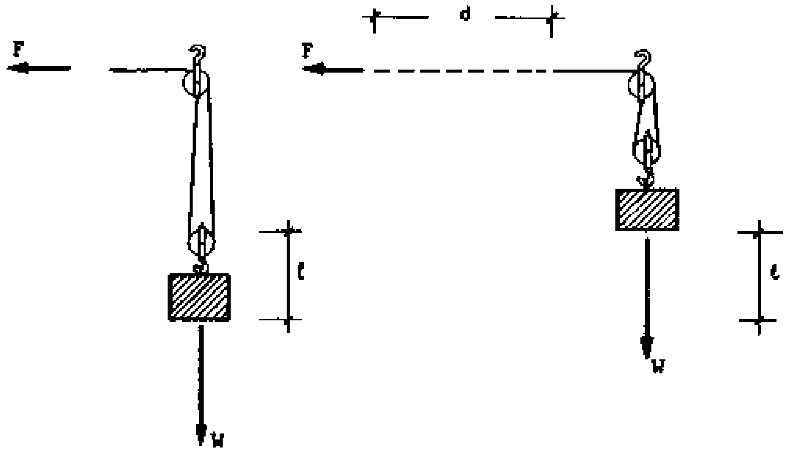
2. Lowering with Light Weight Tripod and Pulleys

Only light concrete rings (maximum Ø 1.10 m, height 60 cm) can be lowered with a light weight tripod consisting of three metal pipes, Ø 2", 3 m long, connected with a steel cable. The weight of the ring is lifted by a tackle.

Tackles

A tackle (= "block and tackle" or "pulley system") is an assemblage of ropes, pulleys, and hooks to lift weights, arranged to gain mechanical advantage for hoisting and pulling. For tackles, four different parameters (= features, characteristics) are to be considered:

ℓ = lift or distance the item has to be lifted;
d = distance the rope is to be pulled to gain the lift (ℓ);
W = weight of the item to be lifted;
F = force needed to pull the rope in order to lift the weight



They are connected as follows:

If the distance you pull the rope (d) is a multiple of the lift (ℓ) by the factor (a), then you need to pull with a force (F) which is the weight (W) divided by the same factor (a):

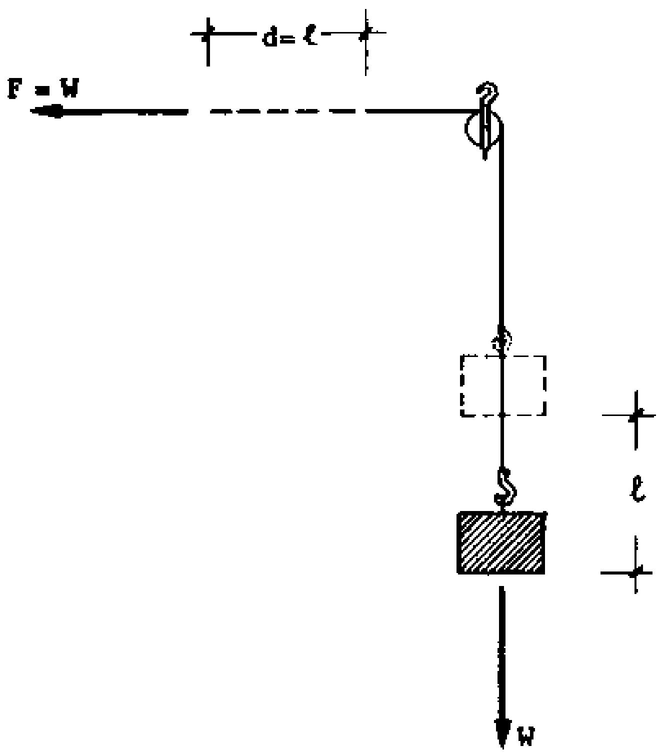
$$d = \ell \times a$$

$$F = W \times \frac{1}{a} = W \div a$$

Check how many rope connections there are between the two pulley blocks. This number is the factor (a), because each rope connection has to be shortened by the lift *(ℓ).*

Applied to the three most simple tackles, this means:

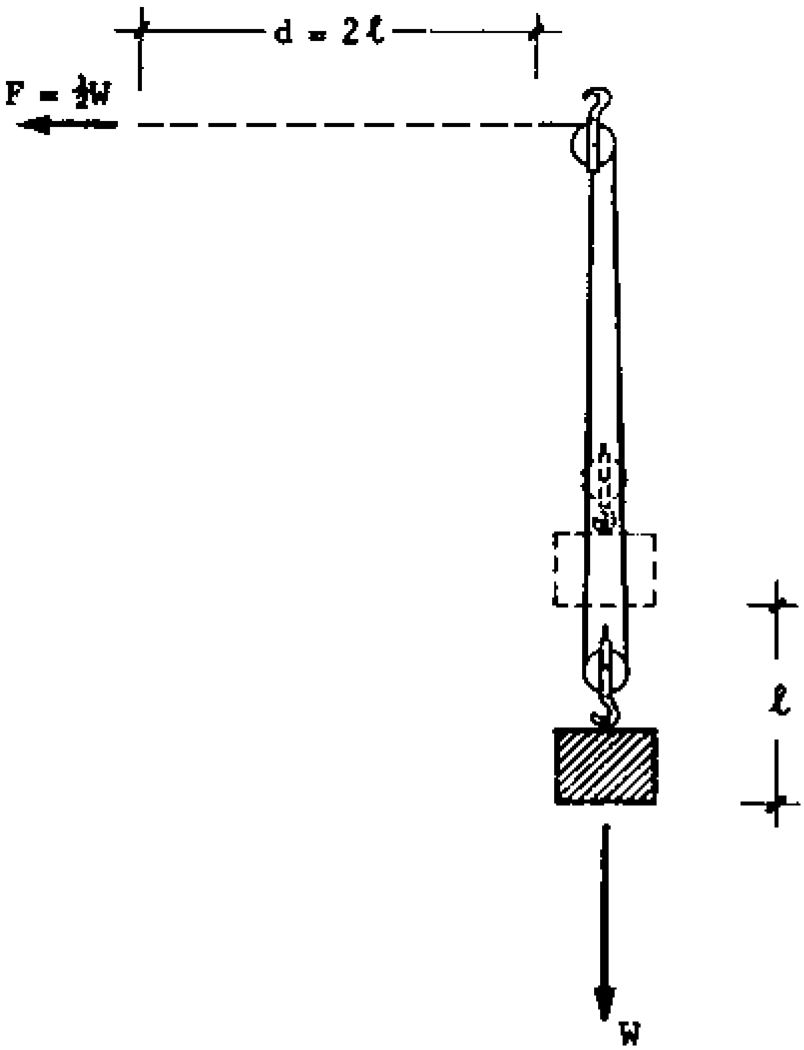
<u>One Pulley Block</u>



$d = \ell$
$F = W$

You pull the same distance as you lift an item.
You pull with a force as big as the weight of the item.
No mechanical advantage.

Two Single Pulley Blocks

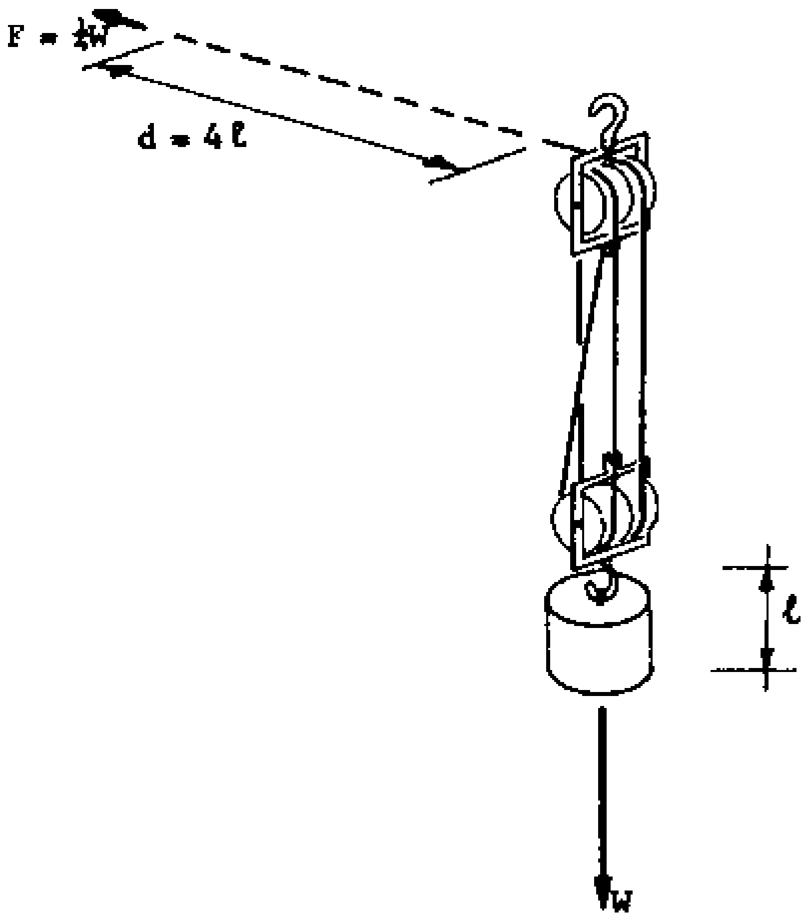


$d = 2 \times \ell$

$F = \frac{1}{2} \times W$

There are 2 rope connections between the two pulley blocks.
You pull twice as long as you lift the item.
You pull with a force half of the weight of the item.

Two Double Pulley Blocks



$d = 4 \times \ell$

$F = \frac{1}{4} \times W$

There are 4 rope connections between the two pulley blocks.
You pull four times as long as you lift the item.
You pull with a force a quarter of the weight of the item.

Use this information for calculating the length of rope needed and the number of people requested for a certain task.

Example:

A 400 kg heavy ring should be lowered into a 6 m deep well by a tackle with 2 double pulley blocks.

factor of the tackle	a = 4
distance between ground level and pulley	2 m
lift + distance to head of tripod	ℓ = 6 m + 2 m = 8 m
length of ropes in the tackle	p = 4 × 8 = 32 m
extra rope from pulley to people	10 m
length of rope required	L = 32 m + 10 m = 42 m
weight	W = 400 kg
force for pulling rope	$F = \frac{1}{4} \times 400$ kg = 100 kg
approximate pulling capacity of one person	25 kg

number of people required $\frac{100\,kg}{25\,kg} = 4\,people$

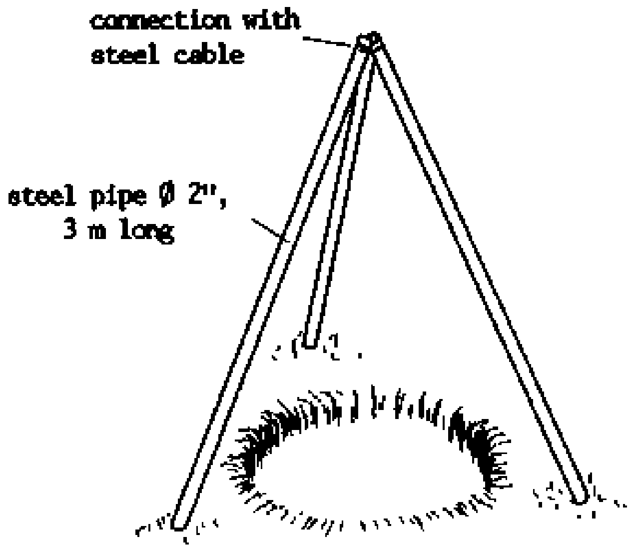
Note:

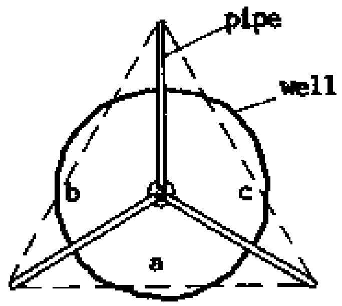
The lift of a tackle is not unlimited! Beyond a certain length, the item lifted tends to turn along its axis, thus twisting the ropes of the tackle around each other. This danger is even greater if the rope is new. Once the ropes are twisted, it is hardly possible to unwind them and they might even break.

Step-by-Step Procedures for using light weight equipment:

- Place the tripod over the well. All three legs must be in equal distance from each other:

a = b = c





Check with a measuring tape.

- Fix a tackle with two double pulleys on the tripod.
- Connect the rope with the ring with method 1, 2, 3 or 4 of A (see 8.17/1ff).
- Lift the ring and pull it to the centre of the well mouth.
- Lower the ring.

Advantages:

- The equipment is very simple and can be manufactured locally.
- The equipment can be transported from site to site easily.
- The equipment can be erected quickly and with few people.
- The method is handy.

Disadvantages:

- The method can lift only light weight rings.

- This method can be used only for wells up to about 15 to 20 m deep. Below this, there is great danger of twisting the tackle cables.

- The method cannot be used if the mouth of a well is completely washed out (because such a small tripod cannot span a big opening).

- Very long rope is required.

- The rope wears out quickly.

3. Lowering with Heavy Duty Tripod and Winch

Concrete rings can also be lowered with a heavy duty tripod and a hand operated winch with steel cable. The equipment is described in detail under C (see 8.17/15ff).

Step-by-step procedures

see under D (see 8.17/20ff).

Advantages

- Any type of ring, even large ones, can be lowered.

- Rings can be lowered into wells up to 50 m deep.

- The method can be used even if the mouth of a well is completely washed out and wide.

- The method is very handy, quick and precise.

- It is easy to direct the rings inside the well.

- The number of people required is only about 10.

- The steel cable is durable and will not wear out quickly.

- The method is safer than methods 1 and 2.

- Part of the equipment can be manufactured locally.

Disadvantages

- A pick-up with roof-carrier is needed for transporting the equipment.

- Erecting the tripod and fixing the winch is rather time consuming and requires about 10 people.

- It is costly and difficult to purchase the equipment.

- If even only one part of the equipment does not function, the method cannot be used.

4. Selecting the Suitable Method

The selection of the suitable method depends on the number of wells to be constructed, the average depth, the size of the rings and the availability of equipment. Whenever several wells are to be constructed, a permanent tripod from metal pipes is advisable (method 2 or 3).

Method 2 is suitable in an area with shallow wells (up to 20 m) and with good roads. In that case, small rings can be manufactured in a central workshop, transported to the site and lowered there with light weight equipment.

In an area with bad roads, central manufacturing of rings is not suitable-Large rings can be produced on site and lowered by method 3. For deep wells beyond 20 m and rehabilitation of wells which have been washed out very much on top, only method 3 is possible. This method is suitable for most conditions and is advisable if the size of the project and the financial possibilities allow; it is described in more detail under C and D.

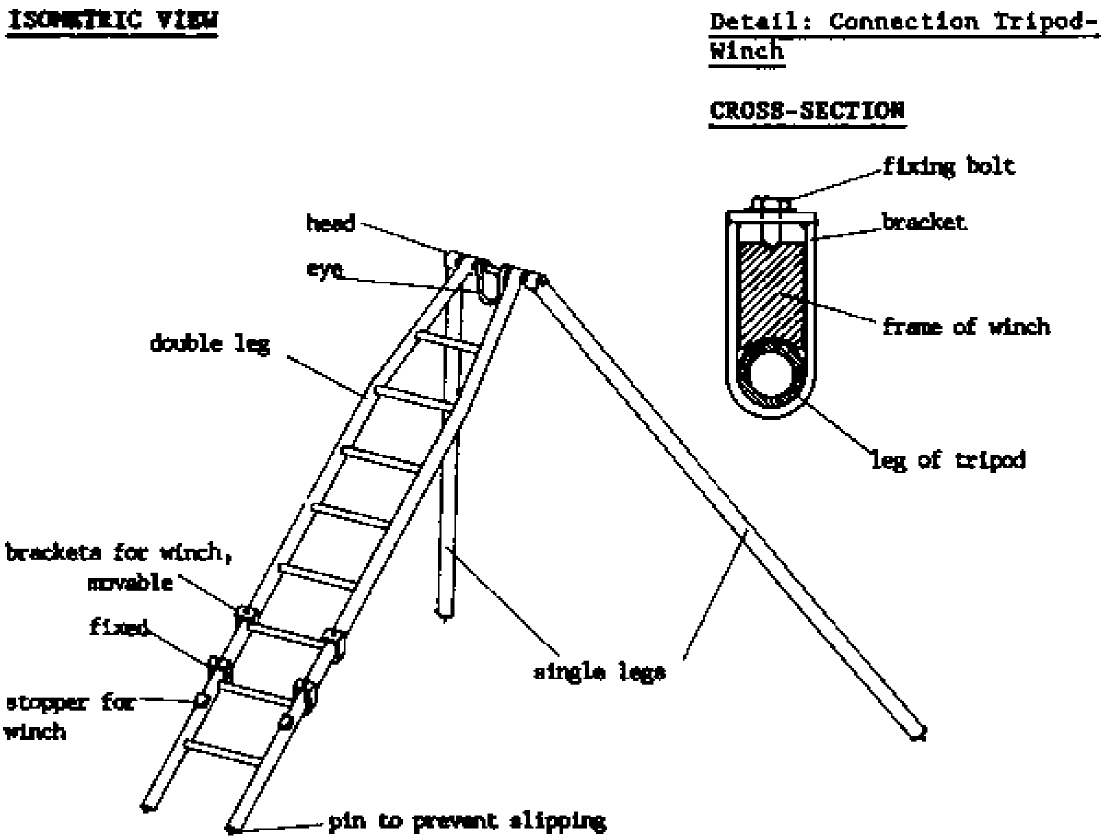
C) Heavy Duty Equipment for Lowering Rings

Heavy duty equipment for lowering concrete rings into a well consists of the following elements:

1. Tripod

A heavy duty tripod consists of the following elements:

- 2 single legs, Ø $2\frac{1}{2}$ “ or Ø 3”, 6 m long
- 1 double leg from the same pipes, with steps
- head of tripod, connecting the legs, with an eye to hold the pulley
- device to take up the winch



Design: Van Reekum Materials, Netherlands

Check the connection between the legs regularly for damage.

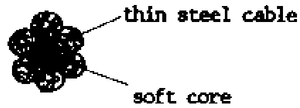
Never load the tripod if one of the legs has even a slight bend!

Watch the tripod when you put it under load.

Tripods can be manufactured locally in a welding shop or purchased ready-made.

2. Steel Cable

Steel cable of Ø 10 nun is suitable for lifting concrete rings. It has a soft core with several thinner steel cables wound around it.



If handled carefully, steel cable is very strong and durable.

Steel cable must always be wound up “under tension”. If necessary, provide the tension by pulling the cable by hand while winding up. Never attempt to fold steel cable.

Steel cable is only strong if all parts are intact.

Never use steel cable for heavy loads if even one of the parts is split or broken.

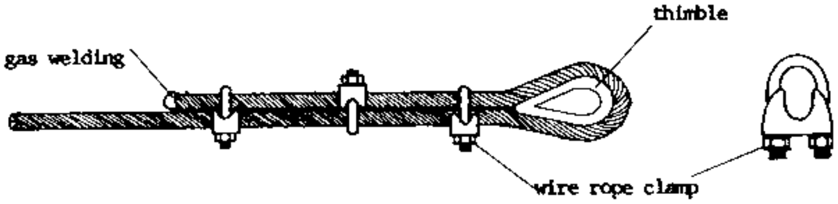
After lowering several rings, the cable might be more twisted than usual due to the turning movements of the ring. In this case, the cable tends to fold itself while not under tension:

In the long run, this spoils the cable at the fold. Never try to straighten the cable by force, but untwist it carefully. Prevent folds by untwisting the cable from time to time.

Protect the ends of steel cables by gas welding. Otherwise, the cable will unwind itself and get weak. The split ends of a steel cable can also badly hurt people.

Use two wire rope clamps (= cable clamps) and a thimble for the ends of a steel cable.

Tie the wire rope clamp firmly, but do not squeeze the cable. Tie the clamps in opposite direction. See also 6.3/40.



3. Winch

A hand-operated winch for lifting concrete rings consists of the following elements:

- a drum for winding up the steel cable,
- a gear,
- two winding handles,
- a safety device which blocks if the load is suddenly released (= ratchet),
- a lever brake,
- a connecting device to the tripod (see 8.17/15).

Operate the winch with great care. There should be always at least one person at the winch who is familiar with its operation.

Be alert that the safety device is operating at all times. You hear it by the continuous tak-tak-tak sound while lifting.

The safety device is to be suspended only during the actual lowering by a special handle. The person holding this handle must be prepared to release it at any time in case of danger and to brake at the same time. This handle must move freely and fall against the ratchet by its own weight.

Make Sure that the gear is properly engaged.

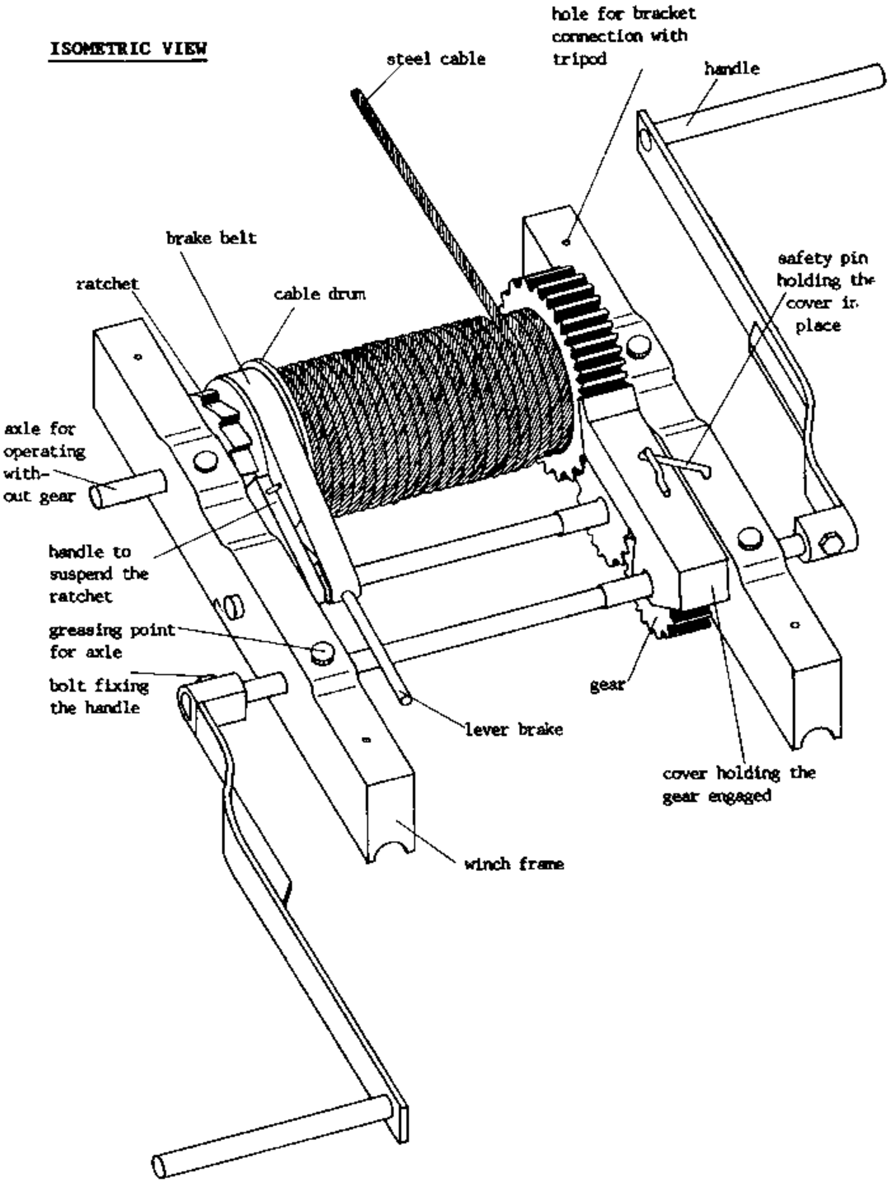
The pin holding the cover must be well closed. If the cover gets loose, the gear can suddenly disengage and release the load.

Sudden release of a load like a concrete ring is extremely dangerous. The well can collapse; the ring will break; parts of the equipment may break; the handles of the winch will turn with terrible speed and can hurt somebody very badly.

Do not load the winch suddenly. Use the brake to make the movements smoother and to assist controlling the load when lowering.

For details of the winch see the picture next page.

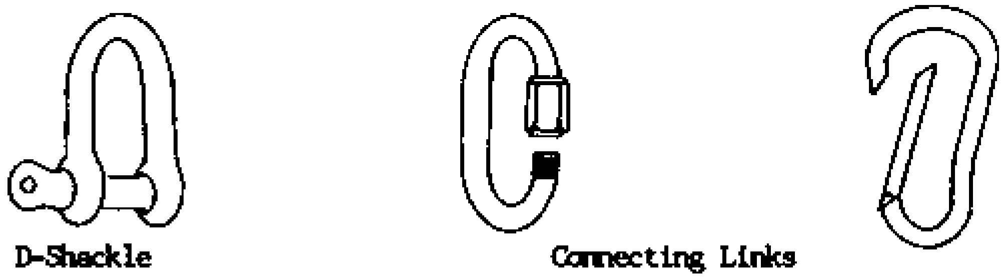
Winch



Design: Van Reekum Materials, Netherlands

4. Shackles

The eye of a steel cable can be connected to a swivel-hook, a pulley, another steel cable, or a load by the help of a D-shackle or a connecting link.

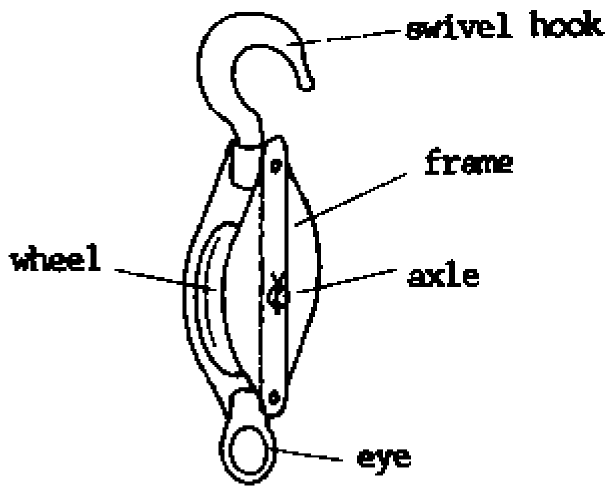


These connections are safe and can be quickly assembled and disassembled. The shackles and connecting links are available in different sizes. The size has to be selected according to the cable diameter and the load. See also 6.3/40.

5. Pulleys

Pulleys consist of the following elements:

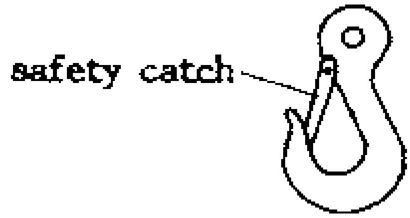
- a wheel with a grooved rim to hold the cable or the rope
- an axle
- a frame holding the axle
- a swivel hook
- an eye



Clean and grease the pulley regularly. Check the hook and the eye. Make sure that the pulley is carefully tied on the tripod and the cable is running smoothly on the wheel without rubbing against other parts. See also 6.3/10.

6. Swivel Hook

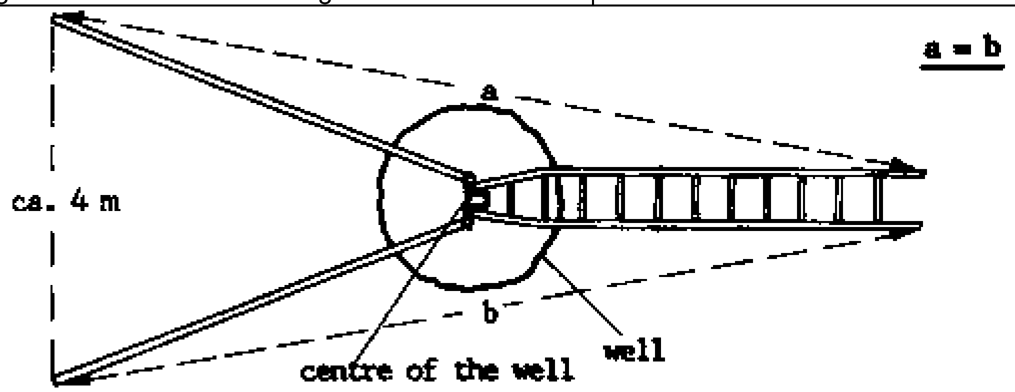
A swivel hook (= lifting hook) is a hook from forged steel to lift a given load. Good swivel hooks always have a safety catch. See also 6.3/40.



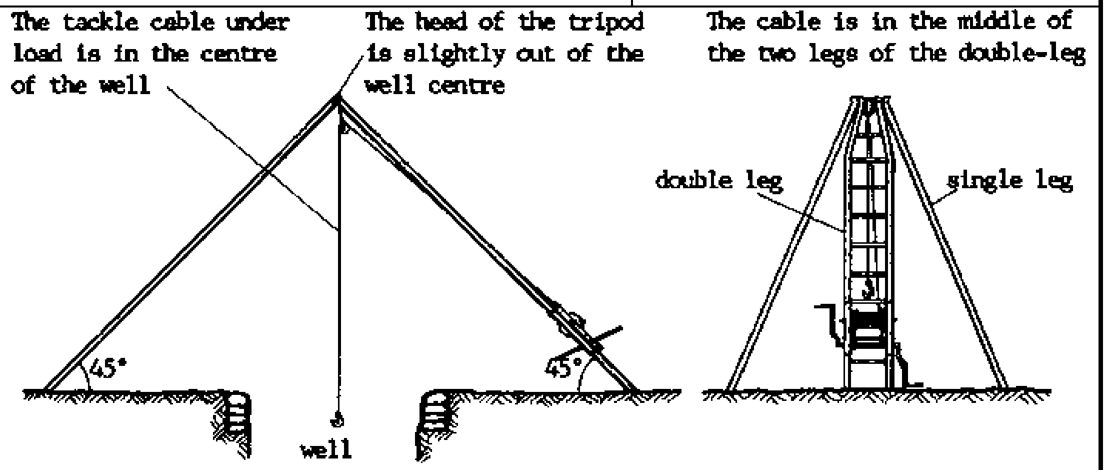
D) <u>Steps of Lowering Rings with Heavy Duty Equipment</u>

When lowering rings with heavy duty equipment, follow these steps:

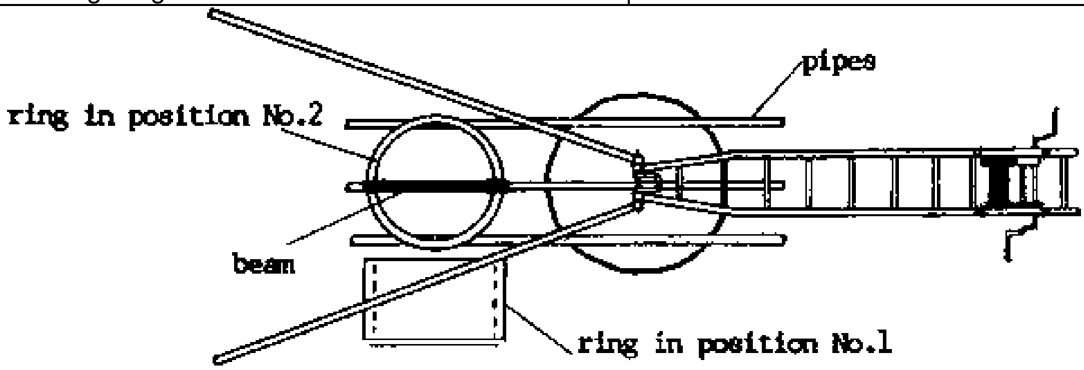
1. <u>Erecting the Tripod</u>

No	Step	Reasons
1	Erect the tripod. The top shall be exactly over the centre of the hole. The angle between the tripod legs and the ground level should be about 45°. Both single legs must stand at the same distance to the double leg. The distance between the feet of the single legs should be about 4 m. Measure the distances between the legs with a measuring tape. Dig holes for the feet of the legs.	If the tripod is not properly erected, it can tip over during the work and cause damage and danger.
		


2	Fix the winch on the double leg and a pulley at the top of the tripod. Standing behind the winch, the cable must be seen hanging exactly between and parallel to the legs of the double leg. from the other side, the tackle cable must be in the centre of the well.	Thus the centre of gravity of the ring hanging on the tripod will be within the three legs and will not pull the tripod over.
		



2. <u>Lowering the First Ring</u>

1	Level the bottom of the well. Check with a spirit level.	The bottom must be level so that the first ring will be level, too.
2	Lay three pipes Ø 3” across the hole, parallel to the double leg. Role the ring near to the hole (position No. 1) and turn it over into horizontal position (No. 2) with the help of a rope sling and enough people. Be very careful. The ring should stand between the two single legs.	If the ring rolls into the well, it will break and damage the well.
		


3	The cable sling is fastened around the ring with the beam by method No. 4 in A. and attached to the tackle cable. The beam shall be parallel to the double leg. For middle size rings, a tackle with one pulley block and one cable is sufficient. For deep wells, lowering is only possible with <u>one</u> tackle cable. For very shallow wells up to 8 m and large rings, a tackle with two cables and two pulley blocks should be used.	The beam prevents the top of the ring from being crushed. The sling provides safe lifting. In deep wells the ring is bound to turn. Two cables would twist around each other and block.
4	Pull the cable gently upwards and push the ring on the pipes into the centre of the hole. <u>Nobody must ever be underneath a ring</u>. Nobody should put a hand or foot underneath a ring.	The ring moves into the middle of the hole in a controlled way. <u>Safety first</u>. In case of an accident the ring can kill somebody underneath.
5	Re-adjust the sling. Lift the ring and check if it hangs horizontally.	If the ring does not hang horizontally, it can loose balance and it can get stuck in the well.
6	Pull the pipes away from the hole.	They are not needed for loring, but in the way.
7	Pay out (= release) the tackle cable and lower the ring into the well until it reaches the bottom of the well. <u>Nobody</u> must sit on the ring while lowering.	In case of any failure, a person sitting on the ring while lowering would be in great danger.
8	Lower a technician into the well by a second pulley, rope, and piece of wood (see 8.21/2). Check the position of the ring with the spirit level (see in detail 8.15/4). If not exactly level, lift the ring slightly and remove some soil from underneath until the ring is exactly level.	A well is less stable if the walls are not vertical. In a deep well, the top rings will not fit, but touch the wall, if the first ring is not level. To straighten the rings later on is much more difficult.
9	Remove the sling from the ring and wind up the steel cable.	The swivel hook is heavy enough for winding up the cable under tension.

3. <u>Lowering the Rings below Water Table</u>

<table>
<tr><td>1</td><td>Lower the next ring in the same way (repeat No. 2, steps 2 to 6)</td><td>All rings are lowered in the same way.</td></tr>
<tr><td>2</td><td>Pay out (= release) the tackle cable and lower the ring until the ring has reached the previous ring. You can direct the ring from the top by pressing a pipe against the tackle cable in the desired direction.</td><td>Sometimes the ring must be directed because the well is narrow at some spots.</td></tr>
<tr><td></td><td colspan="2"></td></tr>
<tr><td>3</td><td>Lower a technician into the well. She/he should sit on the beam with the legs on both sides of the beam against the walls of the well. The hands should also lean against the wall. Lift the ring by about 5 cm. While being lowered again, the technician can direct the ring so that it is placed exactly on the previous one, with the rebates fully attached.</td><td>In most cases the ring will not get placed automatically in the correct position, but it must be directed. The described position keeps the ring in balance and enables the technician to direct the ring easily.</td></tr>
<tr><td></td><td colspan="2"></td></tr>
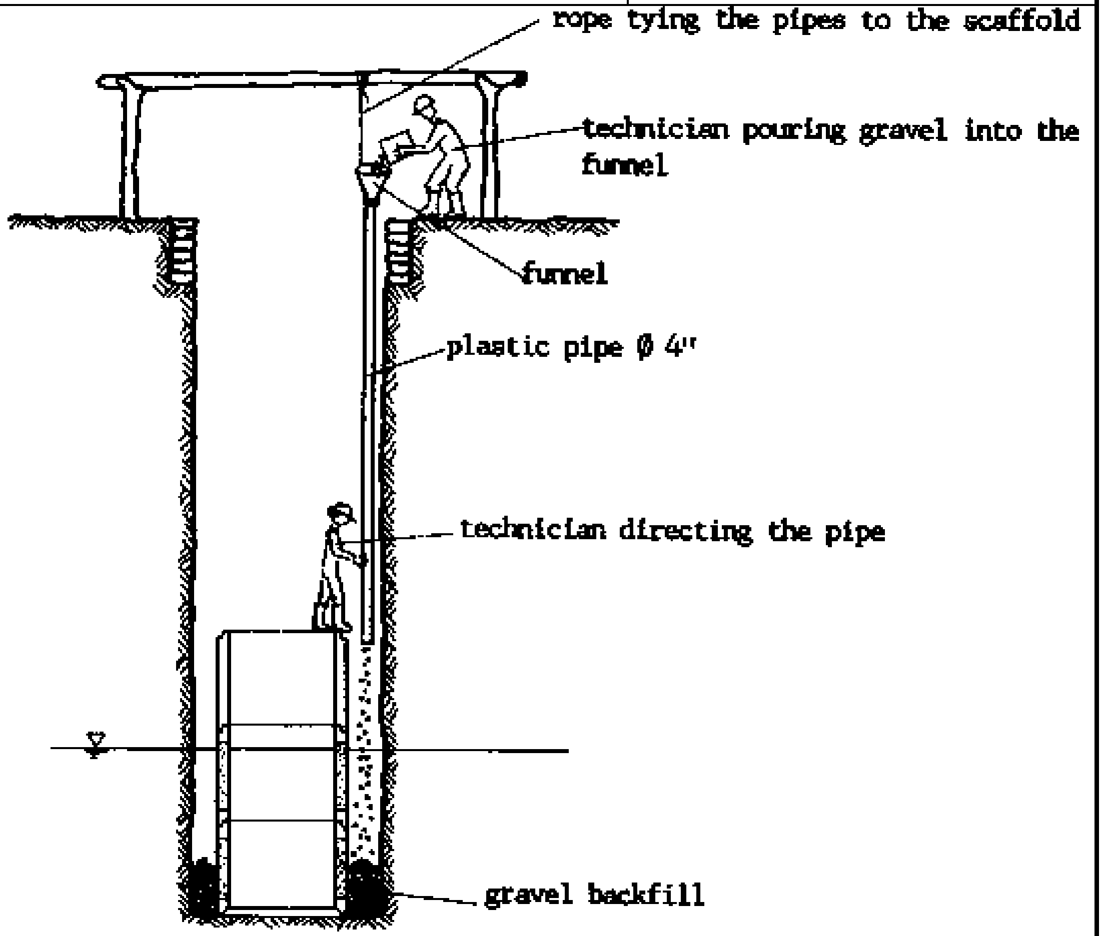
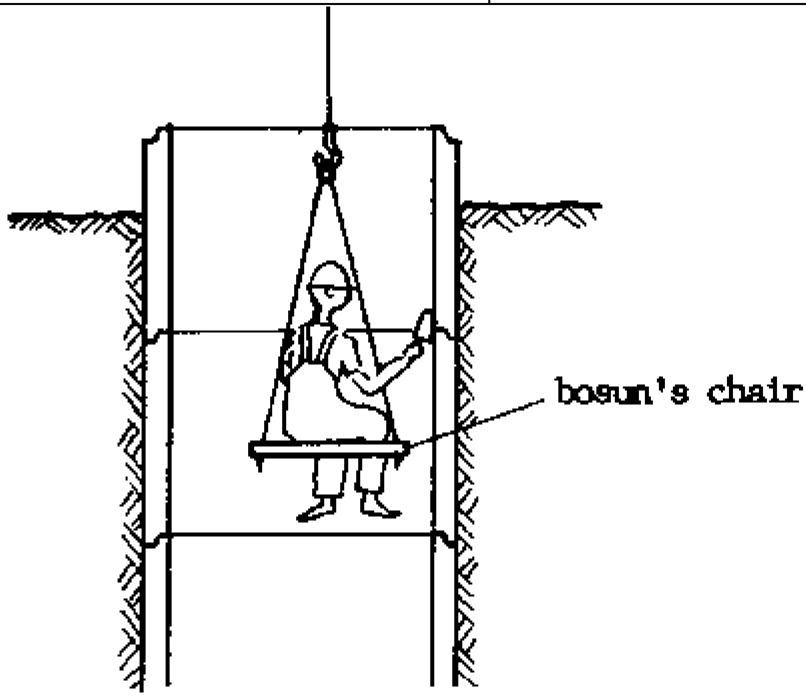
<tr><td>4</td><td>Check if the ring is level. Remember the direction of the neutral line (= connection between the two neutral points). If necessary, correct by putting sand or mortar between the rings on the lower side.</td><td>It is acceptable if the ring is out of level by 0.5 to 1 cm, especially, if the direction of the neutral line changes with each ring.</td></tr>
<tr><td>5</td><td>Remove the sling from the ring and wind up the steel cable.</td><td></td></tr>
<tr><td>6</td><td>Continue to lower rings in the same manner. In between you might need to dewater the well.</td><td>For dewatering wells during construction see 8.25, 8.26, 8.27,8.28.</td></tr>
<tr><td>7</td><td>If the cable is too much twisted after lowering some rings, untwist it.</td><td>See 8.17/16</td></tr>
</table>

8	Backfill after stacking <u>maximum 4 to 5</u> rings above each other. Fill clean gravel between the rings and the wall all around. This work becomes much easier if you use plastic pipes Ø 4” and a funnel and pour the gravel directly from the top evenly all around. Take great care that the pipes are properly connected and suspended and no gravel misses the funnel.	The backfill prevents the rings from horizontal movement and bears part of the rings’ weight through friction. 6 or more rings put on top of each other, without horizontal support, is a very unstable and dangerous construction. It might cause breakage, uneven sinking or tilting to the side. Gravel backfill below the water table allows the water to enter the well. A single stone, missing the funnel, is a great danger for the technician below.



4. Lowering the Rings above the Water Table

1	For rings above the water table, spread mortar on the rebate before lowering the next ring.	Above the water table, the joints should be watertight to prevent surface water from entering the well (8.16/4;
2	Lower the ring. Repeat No. 2, step 2 to 9.	
3	Lower a technician sitting on a bosun's chair. She/he should close the joint between the two rings with cement mortar.	The joints between the rings should be smooth from inside.
		


4	Backfill the rings above water table with clay. Compact it well.	Clay backfill is an additional protection to prevent surface water from entering the well.

8.18 Manufacturing a Well Cover

A well cover is a cover made from concrete to be placed on top of the lining. The purposes, the types and the manufacturing procedures of a well cover are described in this chapter.

A) Purposes of a Well Cover

A well cover serves the following purposes:

1. It prevents (or reduces) possible pollution of the water in the well.
2. It holds the pump or any other water lifting device.
3. It provides an emergency opening in case of pump break-down.
4. It is removable in case major maintenance or deepening the well becomes necessary.

B) Well Covers for Different Water Lifting Devices

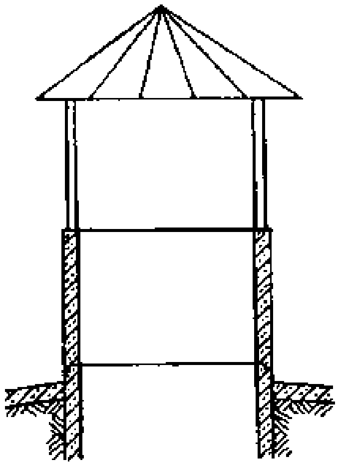
The well covers differ according to the water lifting device to be used.

1. Well Covers for a Bucket

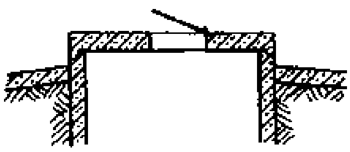
Lifting water by bucket and rope is appropriate wherever maintenance of more sophisticated systems cannot be ensured. In this case, any well cover is already an improvement on wells without.

These are possible well covers for buckets:

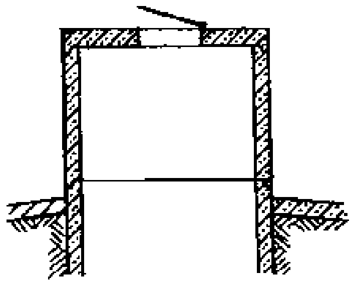
Open well with elevated ring and roof:



Concrete well cover with door:



Elevated concrete well cover with door:

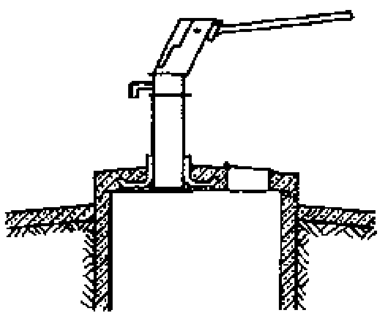


The elevated concrete well cover provides most protection from pollution.

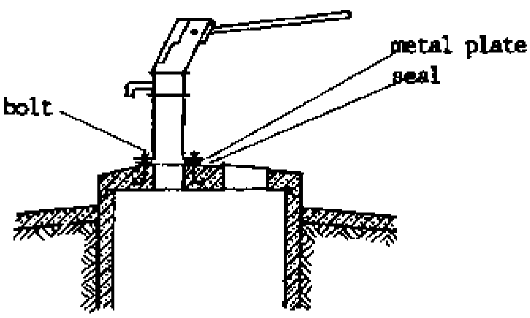
2. Well Cover for a Hand Pump

If a hand pump is to be installed, the well cover must be from reinforced concrete in order to withstand the movements and vibrations of the hand pump. The hand pump body can be either cast directly into the cover, or bolts are cast into the cover and the pump is later fixed with nuts. The former is a very strong, watertight connection, the latter has the advantage that the pump can easily be replaced by another type. However, if the seal is not intact, the connection might not be watertight.

Hand pump cast into the well cover:



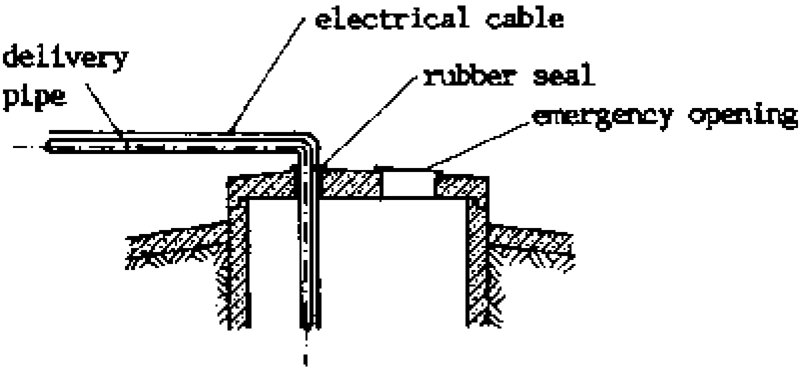
Hand pump fixed with bolts to the well cover:



3. Well Cover for Electrical Pump

The installation of an electrical submersible pump requires only a cylindrical opening of 10 to 20 cm Ø. The electrical cable and the delivery pipe will enter the well through this opening. However, the opening must be sealed watertight by a metal sheet or rubber cut to fit exactly to prevent pollution.

Well cover for electrical pump:

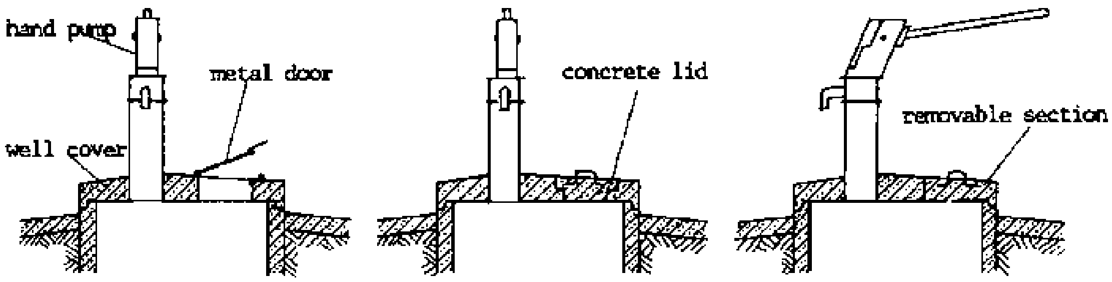


C) Emergency Openings on Well Covers

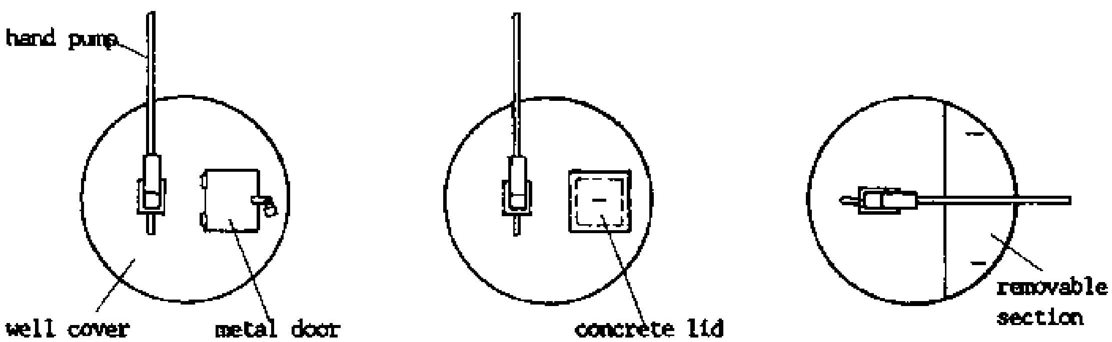
The advantage of a large diameter hand dug well is that the cover is big enough for an emergency opening. This is to be used whenever the pump breaks down, cannot be repaired immediately, and people need the water, or when cleaning of the well bottom becomes necessary. The emergency opening can be constructed in three different ways: a manhole with metal door, a man hole with concrete lid, or a cover cast in two sections, one of them being removable.

CROSS-SECTION

Manhole with metal door: Manhole with concrete lid: Well cover with removable section:



LAYOUT PLAN



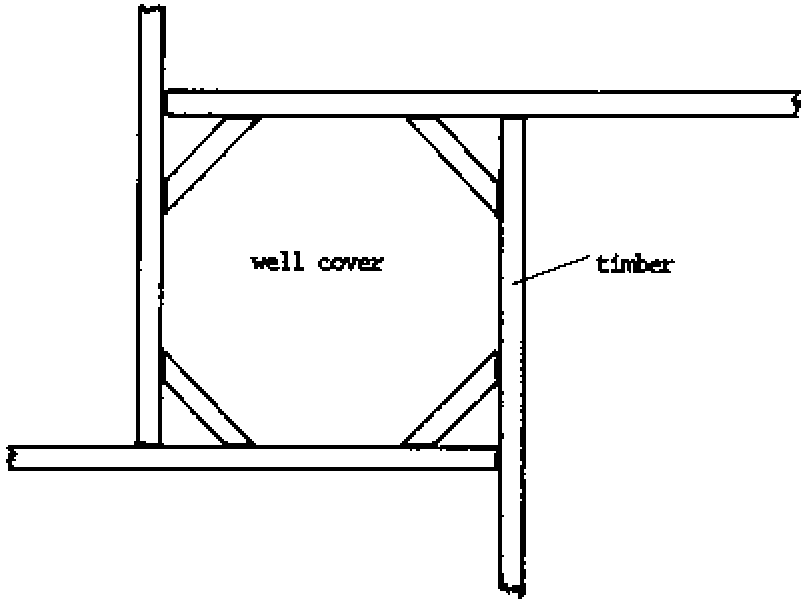
Having an emergency opening is one of the advantages of a hand dug well over a borehole and, therefore, it is not at all advisable to build a well cover without an emergency opening.

D) Moulds for Making Well Covers

A well cover should fit properly on the top of the lining. Different moulds can be used:

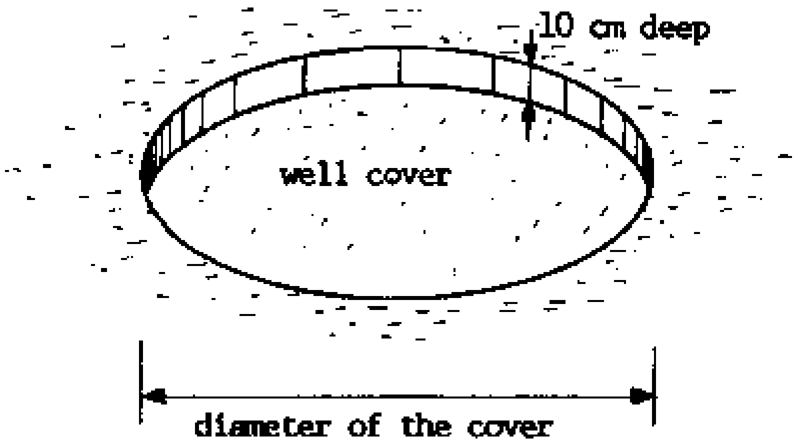
1. Mould from Timber for Well Cover on Top of Brick Lining

A simple mould can be made from timber for an octogonal (= having eight sides) well cover instead of round shape. Only the corner pieces have to be cut to size. An octogonal cover is lighter than a square cover.



2. A Hole as Mould for a Round Well Cover

A hole dug into the hard ground can serve as a mould, but only once.

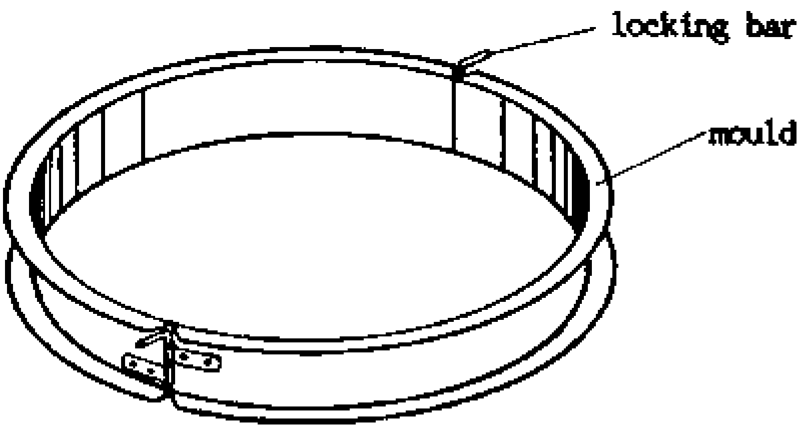


3. Outside Mould for Concrete Rings

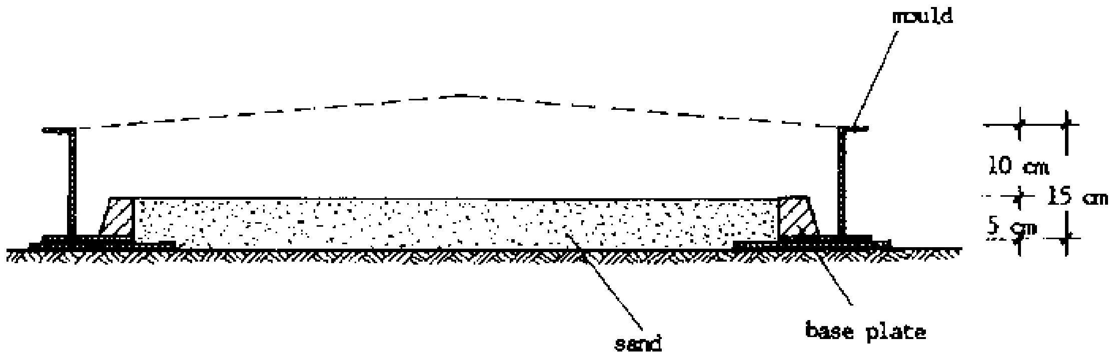
The outside mould for rings can be used to manufacture an exactly fitting well cover. This method, described under E), is not very handy, because the big mould hinders the work, but it should be used if a special mould for well covers is not available.

4. Special Mould for Well Covers

A special mould for well covers looks exactly like the outside mould for a ring, although the height is only 15 cm.

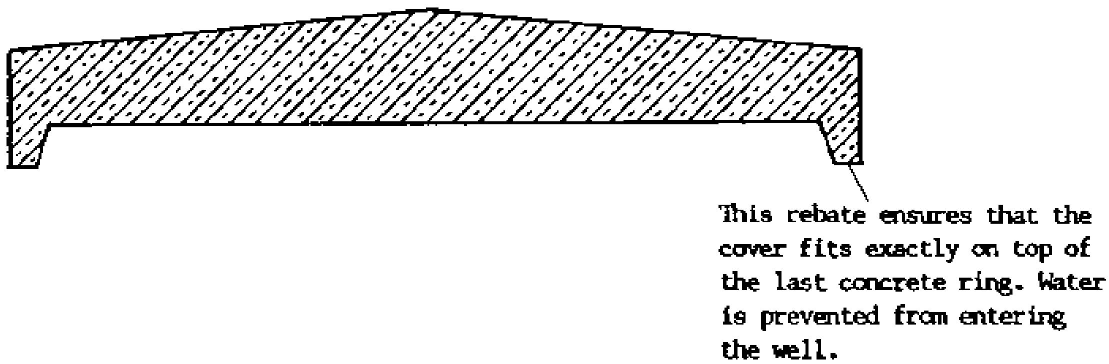


Manufacturing a Well Cover:



SCALE 1:10

The Finished Well Cover:

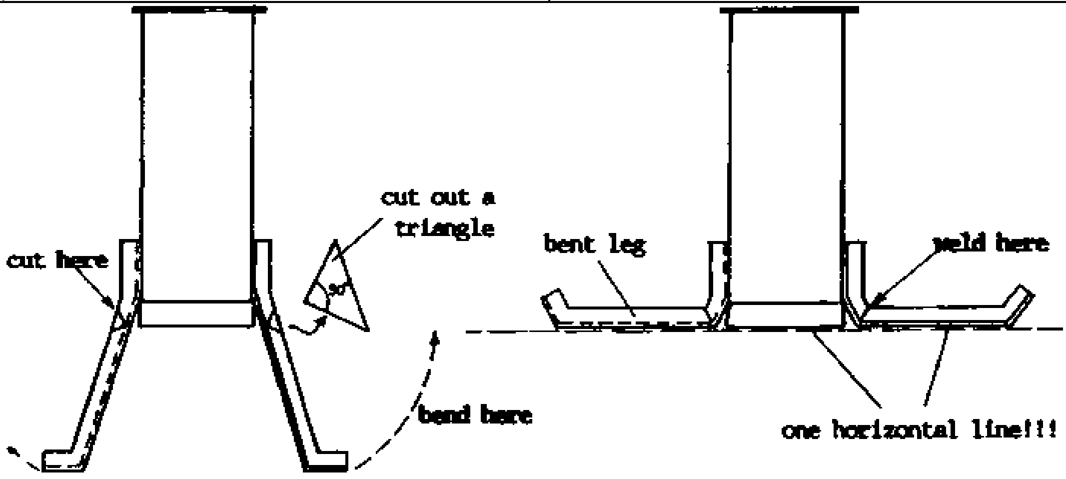


E) Casting a Well Cover

Casting a well cover is explained here for an India Mark II hand pump which is cast into the cover, and has a manhole with metal door. An outside ring mould is used. The other types can be manufactured in a similar way with minor modifications. The different parts of the pipe mould are explained in 8.16/7f.

The described well cover with its reinforcement is strong enough to withstand the dynamic load of a hand pump and will not develop cracks if well made.

Step-by-Step Procedures

No	Step	Reason
1	Cut a triangle from each of the legs of the pump body. Bend them into horizontal position and weld the cut.	The pump body suitable for boreholes needs to be adjusted for a hand dug well cover.
		


2	Provide the metal door of the man hole with locking facilities (e.g. iron bar with hinge for padlock) and anchors (“dastours”). Nail a wooden frame as shuttering for the man hole.	A man hole is necessary for cleaning the well bottom or for drawing water when the pump is broken. It must be lockable in order to prevent contamination.
		3	Place the base plate of the pipe mould horizontally and fill it with wet sand up to the brim.	The base plate needs to lay horizontally because the position of the pump body and the slope of the slab need to be measured from horizontal ground.
	 Scale 1:15	

4	Make a ring from reinforcement (8 6 mm laying 2 cm inside the edge of the base plate. Cut welded mesh into round shape slightly smaller than the pipe mould.	The reinforcement ring Ø 6 mm shall reinforce the edge of the cover. The welded mesh prevents the cover from bending and breaking.
	 Scale 1:15	
5	Place the pump body and the man hole shuttering and door on the welded mesh in correct position. One leg of the pump body must be in direction of the spout. Cut openings into the welded mesh accordingly. Cut reinforcement Ø 16 mm and place the bars under the tip of the legs of the pump body. Fix additional reinforcement Ø 6 mm outside the man hole. Fix all reinforcement with wire.	If the different parts are too near to each other, the legs of the pump will not be properly embedded in the concrete. The reinforcement bars Ø 16 mm carry the pump body and take up the movements.
	 Scale 1:15	
6	A ring from zinc is placed in the position of the pump body, the shuttering in the position of the manhole, and both are filled with sand. All other parts are taken away. The outside pipe mould is placed on the base plate. Paint mould and base plate with old engine oil. Pour 2 cm concrete (mixture 1:3:4) into the edge and compact it. The reinforcement rod Ø 6 mm is placed on top.	The base plate and the outside mould ensure that the cover will fit exactly on top of the last ring. The zinc ring prevents concrete from pouring through the gap below the pump body. The shuttering will provide the manhole opening.

	 Scale 1:15	
7	Pour concrete 2 cm thick all over the cover and compact it well. Place welded mesh, reinforcement bars Ø 16 mm and the pump body on top. Check the position of the pump body with the spirit level (in all directions).	Concrete 2 cm thick must be <u>underneath</u> the reinforcement in order to prevent it from corroding. The pump body's top needs to be horizontal so that the riser main pipes will hang vertically.
	 Scale 1:15	
8	Pour concrete into the cover and compact it until the legs are almost covered. Place small pieces of welded mesh above the tips of the pump legs. Place the manhole door with a slight slope outside.	Welded mesh above the tips of the pump legs prevents the surface of the slab from cracking due to pump movements. The water should run quickly over the manhole instead of entering.
	 Scale 1:15	

9	Poor concrete up to the brim of the door frame. It should well cover the pump legs (the slab will such become 10 to 12 cm thick). Cover the slab with cement mortar (mixture 1:4). It should have a slope in all directions, however, a bigger slope under the spout. Smooth the surface with the trowel and sprinkle cement on top with a small sieve.	The pump legs needs to be well covered in order to prevent cracking and corroding. The slope ensures that rain water and spilled water runs away quickly. A smooth finish is slippery and dangerous. A rough finish is not slippery and strong.
	 Scale 1:25	
10	Write the date into the fresh concrete. Cover the slab three hours later with wet sand. Keep it wet for one week.	Curing the concrete (= keeping it wet) makes it very strong and prevents cracks. This is especially necessary because the cover will be subjected to dynamic load.
11	Place the cover on the well only <u>after two weeks at the earliest</u>.	Before that the cover is not yet strong enough. See 6.6/6f.
12	Install the pump <u>after three weeks at the earliest</u>.	Dynamic loads must not be exerted earlier because they are heavier than static loads. If cracks have once developed, they will widen through the pump movement.

8.19 Well Head with Hand Pump

For the users, the well head is the only visible and most important part of a well. It is as important for the functioning of a well as the parts below. The elements of a good well head are explained here, both for a borehole and a hand dug well, as they are almost alike. For other types of water-lifting devices, the well head is basically the same except for the pump parts.

It is a completely false economy to try to <u>save money</u> by making a smaller platform or by using a weak cement mixture, or to <u>save time</u> by installing the pump before curing is complete. Such measures will certainly lead to cracks in the platform, which subsequently leads to quick pump break-down and pollution of the water. To repair a cracked platform means having to destroy it completely and to replace it by a new one. This, obviously, is much more expensive than making a proper platform in the first place. To repair the hand pump repeatedly without repairing the cracks is a waste of money because cracks allow the pump body to move and to shake, and the constant unnecessary vibration is bound to wear out the hand pump parts quickly.

How to construct a good well head is described in 8.20.

A) Elements of a well head

A well head with hand pump (or a water point with tap) consists of the following elements, both for borehole and hand dug well:

No	Part of the Well Head	Description	Function	Pay Attention at	Work of
1	pump body	body with three legs	to hold the whole hand pump incl. pipes and pump head	one leg in the direction of the spout, positioned level	WS
2	pump foundation	concrete block 0.80 × 0.80 × 0.80 m or well cover	to prevent pump from moving	pump legs well covered with concrete	WS
3	platform	concrete slab 0.10 m thick, with elevated edges	to prevent dirty water from entering the well	slight slope towards drainage channel, a jerrycan must fit under spout	WS
4	pumping stand	elevated concrete slab	to give the user a firm stand	located at the end of the handle	WS
5	drainage channel	ditch made of concrete	to drain spilled water far away from the well	slope from the pump away	WS
6	soak-away Pit	dug pit 1.00 x 1.00 x 0.80 m filled with stones/gravel	to prevent the place from becoming muddy and to prevent mosquito breeding	at the end of the drainage channel	WS
7	fencing	fence around the platform with door	to keep animals away from the well	can also be a hedge	WS +CD
8	lock	lock for door or chain and padlock for the hand pump	to control the use of the pump, to lock when damaged, to prevent further damage	dismantling the chain daily spoils the pump	CD
9	clean surroundings	not muddy, free of rubbish and high grass	to prevent containers, people and groundwater from getting dirty	continuous cleanliness is necessary	CD
10	a good caretaker	duties and behaviour see 8.33	to ensure proper use and implement the wishes of the community	the caretaker has technical and social duties	CD +WS

WS = Water Supply Department; CD = Community Development Department

If only one of these elements is missing or not well functioning, there will be problems in the daily operation of the hand pump.

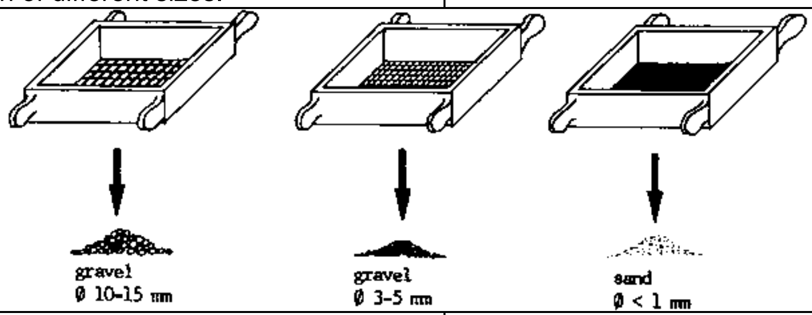
8.20 Completion of a Well

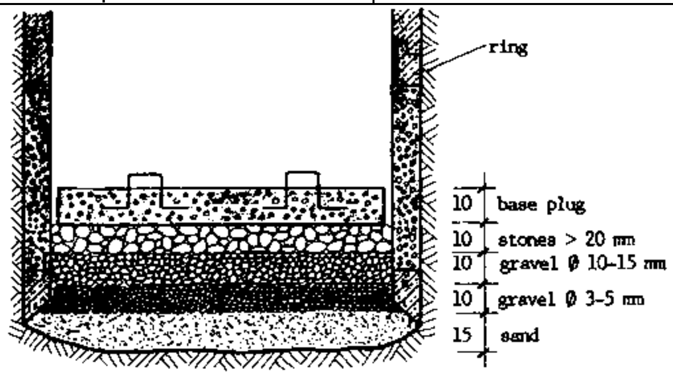
After lowering the rings, the well still needs to be completed. A completed well is shown on 8.19/5f. For completing a well, follow these steps:

Step-by-Step Procedures:

No	Step	Reasons
1	After the well has been dug deep enough into the water and all the rings have been lowered, check if the rings are horizontal. If not, dig until the rings are horizontal, or balance the difference with mortar in the joints of the rings.	The rings need to be horizontal so that the cover will be placed horizontally as well.
2	Wash the rings inside and outside if necessary.	Mud and rests of old engine oil spoil the groundwater.
3	Backfill the rings with gravel in the bottom and clay in the top. Compact the backfill well layer by layer. A simple method for backfilling is described in 8.17/23f. See also 8.19/5.	Gravel backfill in the bottom allows the water to enter the well. Clay backfill in the top prevents contaminated surface water from entering the well. Not properly compacted backfill will settle later on and cause the platform to crack.
4	Sieve filter material (sand, fine gravel Ø 3-5 mm, rough gravel Ø 10-15 mm, and stones Ø 20-25 mm) and wash it. Use three sieves from mesh of different sizes.	Organic material in the well spoils the water.
		


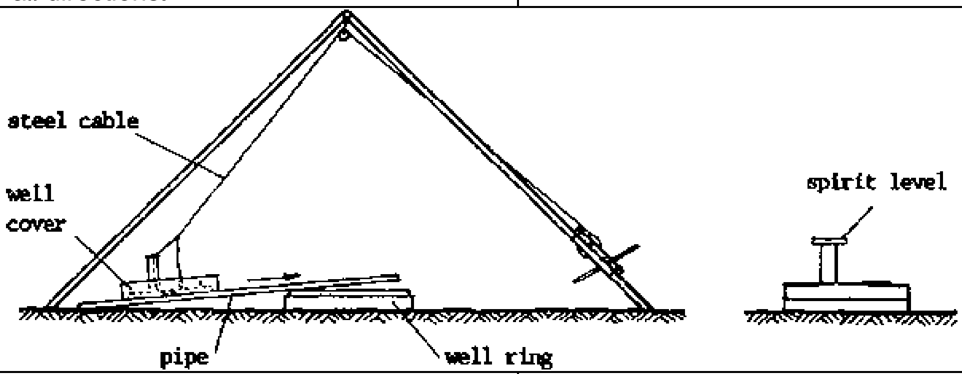
5	Clean the bottom of the well from all mud and organic material and level it. For this work, dewatering of the well might be necessary. Pour one layer of sand evenly over it, afterwards a layer of fine gravel, then a layer of rough gravel and then a layer of stones. If the well has a very great yield, place a base plug on top. A base plug is a round slab with two handles from filter type concrete (mixture 1:1:4), slightly smaller than the diameter of the ring.	Rotting organic material spoils the water quality. For dewatering a well during construction see 8.25-28. The filter prevents sand and mud from entering the well and thus makes the water clear. A base plug is only necessary where the inflow is so strong that it might wash out the sand.

No	Step	Reasons



Scale 1:20

6	Remove all dirt, like grass, animals, etc. from the water.	Animals left in the well will die and decay, also grass and other dirt, and spoil the water.
7	Pump the well as much as possible.	Pumping eventually removes still dirty water and allows clean water to enter the well.
8	Place cement mortar on the rim of the top ring. Lift the well cover by a steel cable through the pump body and the man hole and let it slide over strong pipes until it is on top of the well. Place it on the top ring and adjust it until the top of the hand pump body is level into all directions.	The well cover seals the well from contamination and supports the hand pump. If the top of the hand pump body is level, the riser main pipes will hang vertically.



9	Carefully smear the space between the top ring and the cover with cement mortar.	The well must be properly sealed against dirty water and animals.
10	Pour a 10 cm thick layer of gravel around the well, Ø 3.00 m. It shall have a slight slope outwards.	The gravel is the foundation for the well apron.
11	Put one ring of reinforcement 0 6 mm around the top ring at 2 cm distance from it.	The reinforcement shall prevent cracks in the immediate neighbourhood of the well cover.
12	Pour concrete (mixture 1:3:4) over the gravel in a 10 cm thick layer as an apron of 3 to 4 m diameter. Compact it well. It shall have an outside slope. The top of the apron must be 2 cm lower than the lowest edge of the well cover. Build an elevated round edge of concrete around the apron. Cover the slab with cement mortar (mixture 1:4) and smooth the surface with the trowel. Sprinkle cement on top with a small sieve. All corners shall be rounded, because sharp edges and corners are more easily damaged than rounded ones.	The apron prevents spilled water from entering the ground and polluting the well. Also it prevents the surroundings of the well from becoming muddy. Thus the water containers will remain cleaner. The elevated edge helps collect spilled water and direct it to the drainage channel. It is easily possible to remove the well cover at any time because the apron is not connected to it.

No	Step	Reasons
	 Scale 1:20	
13	Construct a drainage channel with slightly elevated round edges and sufficient slope (e.g. 1:10) in front of the spout. Dig a soak-away pit, 1 m deep, at the end of the drainage and fill it with stone layers in the opposite way as the filter (see 8.19/6).	The drainage channel transports spilled water far enough away from the well to prevent contamination. The spilled water can also be used for gardening or watering animals.
14	Cover the apron and drainage channel 3 hours after construction with wet sand. Keep them wet for one week.	Curing the concrete (= keeping it wet) makes it very strong and prevents cracks.
15	Fence the area around the well (at least an area of 10 m × 10 m) and construct a door. Alternatively, you can plant a hedge. Clean the well compound properly.	A fence prevents animals from polluting the area around the well and it makes the well easier to be controlled. The fence must be built before hand pump installation.
16	Install the hand pump. See 8.31.	Pulling water by a hand pump from a hand dug well prevents pollution of the water.
17	Disinfect the well. See 8.36	The well has been contaminated during construction. This needs to be eliminated before handing the well over to the community.
18	Conduct the operating instruction for the whole community where the importance of water, proper use, running and maintenance are discussed. See 8.39.	As water supply is a technical and social issue, community structures need to be built beside the construction

8.21 Safety Measures

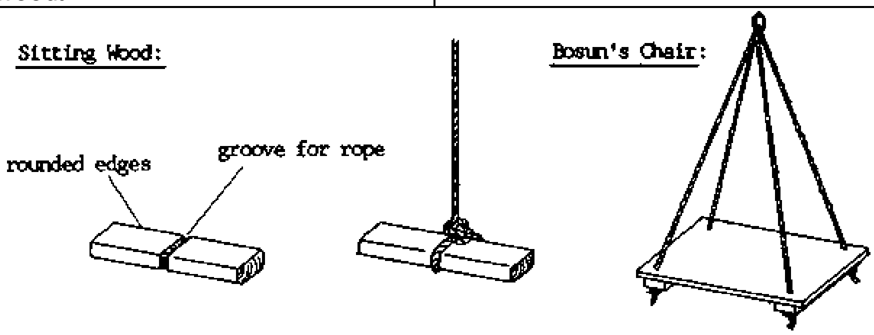
Well construction is a dangerous work. We need to take great care to prevent risks as much as possible. Therefore, keep strictly to the following safety measures.

A) Safety through Stability of the Well

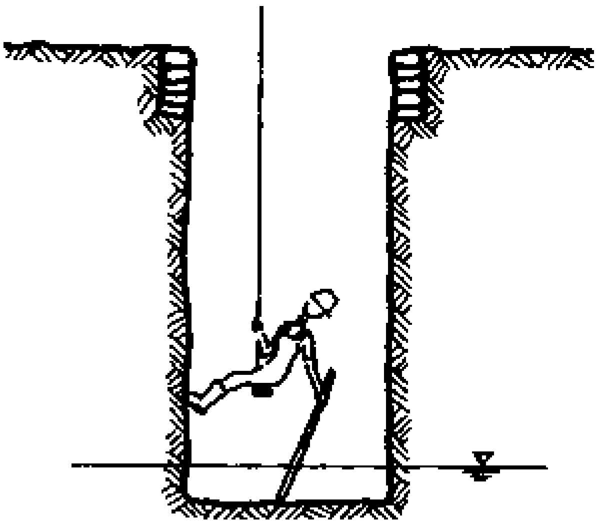
No	Safety Measure	Reasons
1	Watch the walls of the well constantly.	Slight changes in the appearance may suggest collapse.
2	Make dry sand in the well wet before digging.	Wet sand is more stable than dry sand.
3	Below water table, always work in the protection of a ring.	The soil below the water table is always much more unstable than above.
4	Never step on the very edge of a well without collar.	You could loosen a part of the soil and induce partial collapsing, endangering yourself and somebody working down in the well.
5	Dig drainage channels around the well head and cover the well with zinc sheets over nigths.	Rain water entering the well increases the danger of collapsing.

B) <u>Safety through Good Equipment and Cleanliness</u>

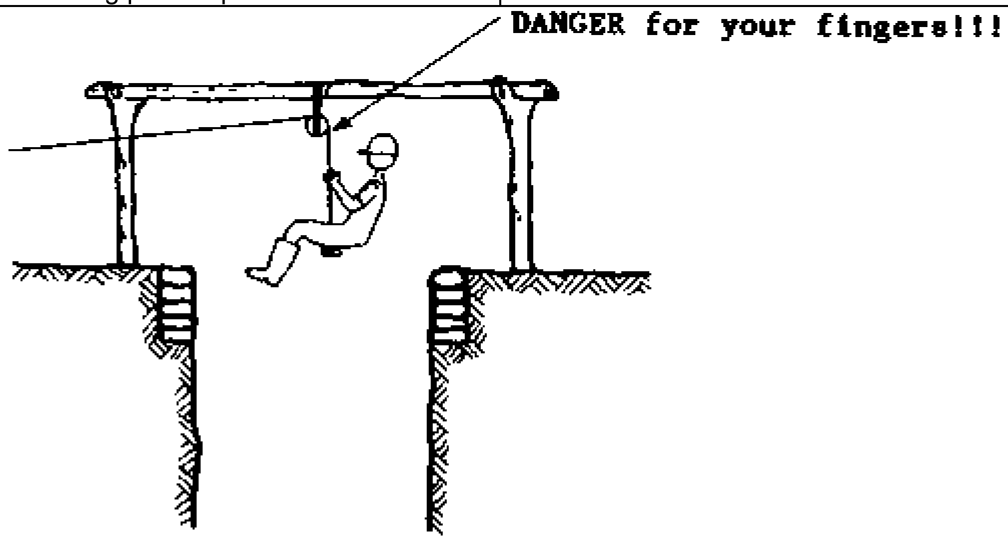
No	Safety Measure	Reasons
1	Check all equipment daily, like buckets, ropes, knots, pulleys, scaffold. Replace them if they show signs of old age or damage.	First signs of damage can easily develop into major breaks when under load. The scaffold must be very stable and well embedded into the ground soil.
2	Inspect tripod and winch before using them. Brake and safety device <u>must</u> work (see 8.17/17f).	Sudden release of load causes the winch handles to turn with terrible speed and can cause bad injuries. Failure of the tripod can cause bad injuries or kill somebody, too.
3	Tie the pulleys properly to the scaffold.	The pulley can get untied under load.
4	Keep the area around the well free from gravel, stones and unnecessary tools. Clean each day.	Small items can fall accidentally into the well and harm the diggers.

No	Safety Measure	Reasons
1	Always wear a safety helmet when entering the well.	The helmet prevents small particles falling down from damaging your head.
2	Enter a well on a sitting wood, a bosun's chair, or over a ladder. Sit properly on the sitting wood.	Other methods of entering are unsafe because you can easily slip.
		


3	Check the bottom of the well with a stick for snakes before you enter the water. Keep the surroundings of the well free from vegetation. When meeting a snake, do not panic, but move slowly.	Sometimes there are snakes in the well.
		

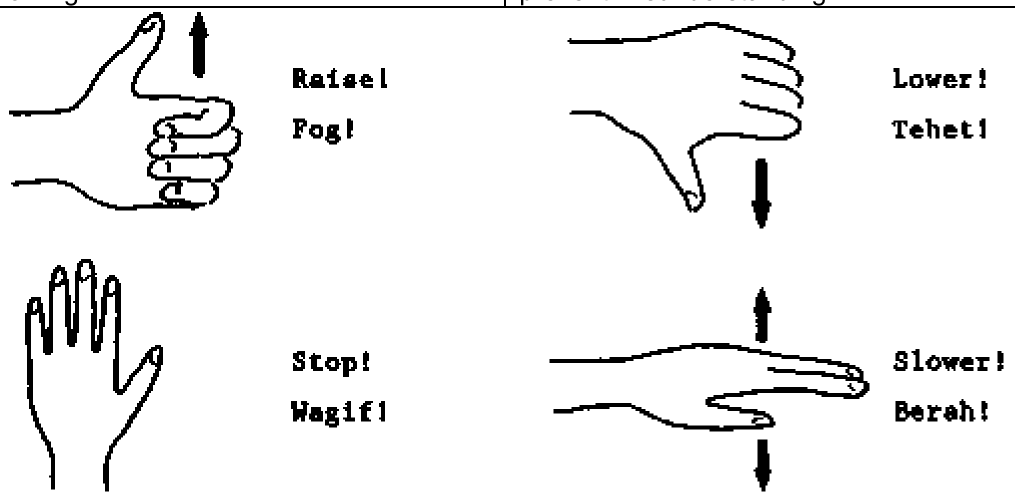


No	Safety Measure	Reasons
4	Pull the rope evenly with enough people. Avoid bumping against the walls.	Abrupt pulling can cause swinging of the bucket and puts a bigger load on the rope. Enough people prevent accidents if one of them fails during pulling. Buckets bumping against the wall can cause collapse and result in spilling the contents.
5	Tie shovels, crowbars, etc. properly when lowering them with a bucket according to the drawing.	Otherwise heavy tools can make the bucket tip over.
		6	Do not overload buckets. Use buckets reinforced with flat iron.	Overloaded buckets can tilt easily and the rope wears out quicker.
7	Never urinate or defaecate inside the well, but exit the well for these purposes.	Excreta will contaminate the water of the well.
8	Do not let your fingers enter the pulley when being pulled up.	The pulley can hurt your hand badly.
		



No	Safety Measure	Reasons
9	If you get wet during work in the well, immediately take off the wet clothes after leaving the well and put on dry ones. Take an extra set of clothes with you for this purpose. Drink enough water. Women should take special care.	Wet clothes on the body, especially if exposed to wind or draft, can cause sicknesses of the kidneys, urinary tract and female reproductive organs. The bad effects are not felt immediately, only later.
10	Keep the danger of bad air in mind.	See 8.22
11	Use the safety belt in any dangerous situation like bad air, work under water, etc.	See 8.22

D) Safety through Good Communication

No	Safety Measure	Reasons
1	Solve any quarrels between labourers before continuing work.	Unsettled quarrels make people careless and inattentive and cause danger.
2	Somebody at the well head must be assigned to constantly watch the. diggers down, to communicate between diggers and labourers above, and to direct the work.	The diggers at the bottom are helpless in the face of problems unless somebody can hear them.
3	Use clear signals according to the drawing:	Clear signals, known to everybody, prevent misunderstanding.
		


4	Keep passers-by and children away from the well (if necessary by an improvised fence).	Curious people want to watch, but do not know the dangers. They can endanger themselves and the workers

8.22 Ventilation in Wells

Air is the first priority physical need of any human being. Without air human beings suffocate and die within a few minutes. Therefore, it is most important to take care that the workers down a well have a sufficient supply of air. There are cases where several people have died in a well because of bad air.

A) Possible Reasons for Bad Air Conditions in a Well

The following reasons can cause bad air conditions in a well:

1. The ground soil releases dangerous gases (suffocating, explosive or poisonous gases).

2. The well is very deep and narrow and the natural ventilation is not sufficient.

3. The well dried out and no natural ventilation through evaporation takes place.

4. The workers stayed long time down in a deep well and, thus, consumed the oxygen and increased the carbon dioxide content by exhalation.

5. Fumes from the exhaust pipe of a generator, car or pump descend into a well.

6. The well is closed by a cover and has only a small man hole.

7. Something was burnt in a well.

8. Rotting organic material can cause dangerous gases.

Be very careful in any of these cases!

B) Methods to Check the Air Conditions in a Well

1. Check the air with the candle test. Fix a candle in a bucket, light it and gently let it down the well shaft. If the candle burns until the bottom, the air conditions can be expected to be reasonable. The air is bad if the candle extinguishes. Carry out the candle test before starting work on the site in any well deeper than 10 m. Carry out this test daily in any well deeper than 30 m.

2. Check the air for bad, foul smell (but not all kinds of bad air have a bad smell!).

3. Check the air with specialized instruments. These might not be available.

Use any of the methods available at the site.

C) Possibilities to Improve the Air in a Well

To improve the air in a well, you may use one or more of the following methods:

1. Use an airblower with a hose, pumping fresh air into the well. The hose shall reach until 1-2 m above the workers to avoid catching a cold.

2. Use a small compressor with hose to blow air into the well. The hose shall end high above the workers.

3. Use a blacksmith's fan with a hose.

4. Sprinkle water into the well.

5. Raise and lower a basket or a bundle of twigs quickly and several times.

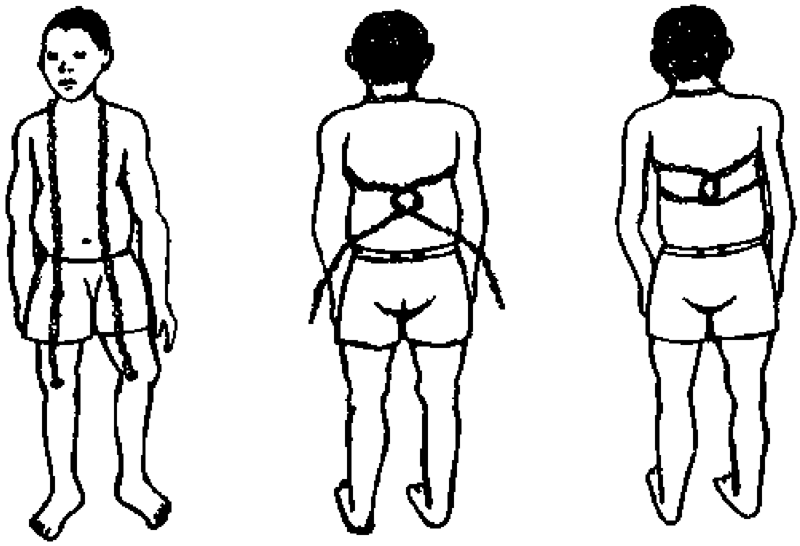
6. Make sure that the well has always a bit of water.

Use the method(s) available and appropriate and check the air afterwards again. Repeat if necessary.

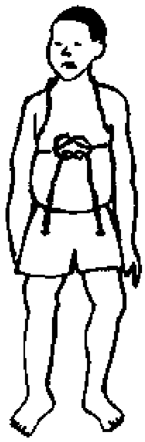
D) Other Precaution Measures

1. In case of any doubt about the air conditions, tie the worker entering the well to the rope. Even if she/he falls unconscious, she/he can be pulled out before serious damage. Do not fear people laughing about such precautions, because you are just protecting your live. You can tie somebody with ordinary rope or use a safety belt.

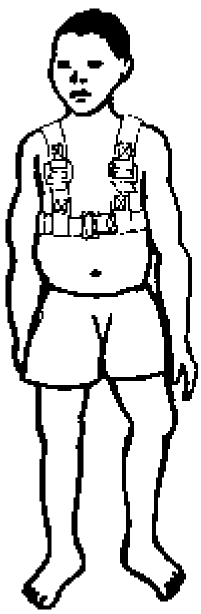
How to Tie the Rope:



How to Wear the Rope



How to Wear the Safety Belt



2. Somebody at the well mouth has to watch the workers at the bottom constantly and carefully.

3. Allow workers to work only for short periods (1 to 2 hours, maximal 3 hours) down in the well. Exchange them afterwards.

4. Place a generator, car or another machine as far from the well as possible, preferably downhill. The exhaust pipe should point away from the well. Exhaust fumes are heavy and, therefore, easily descend into a well.

5. For respiratory emergency see 1.7/3.

8.23 Ropes and Knots

A rope can transmit tension, but not compression. In other words, you can pull with a rope, but never push. Ropes are flexible and can be wound up for storage.

A) Types of Ropes

Three different kinds of ropes can be used in well construction:

No	Type of Rope	Usual Ø for well constr.	Pulled by	Strength	Protection of Rope End	Maintenance	Used for
1	steel rope or steel cable	10 mm	winch, difficult to pull by hand	very strong	welding (gas welding) or braiding	- always roll the cable properly - prevent it from remaining wet - inspect it regularly	heavy loads like rings in permanent installation
2	nylon rope	10 mm	by hand, however, it gets hot and is slippery and difficult to hold	strong	burning (melting) and knot	- carefully roll it - inspect it regularly	any quick work in between
3	manila or hemp or sisal rope	25 mm	by hand, does not get hot	strong	tying with string and knot	- let it dry if it gets wet - carefully roll it - inspect it regularly	lowering and lifting people and buckets into the well

Handle ropes according to these guidelines:

- New ropes tend to twist when first loaded. Pay attention!

- Provide the ends of ropes with some protection before you start to use them. The rope looses strength when untwisted.

- The strength of ropes is reduced by about half when they get old.

- Avoid friction between rope and pulley or any other item.

- Check the ropes every morning for weak spots.

- If one of the three fibres of a rope is broken at one spot only, the rope must not be used any more for heavy loads.

- Store rope in a dry, airy place, rolled up or in a box and protected from rats.

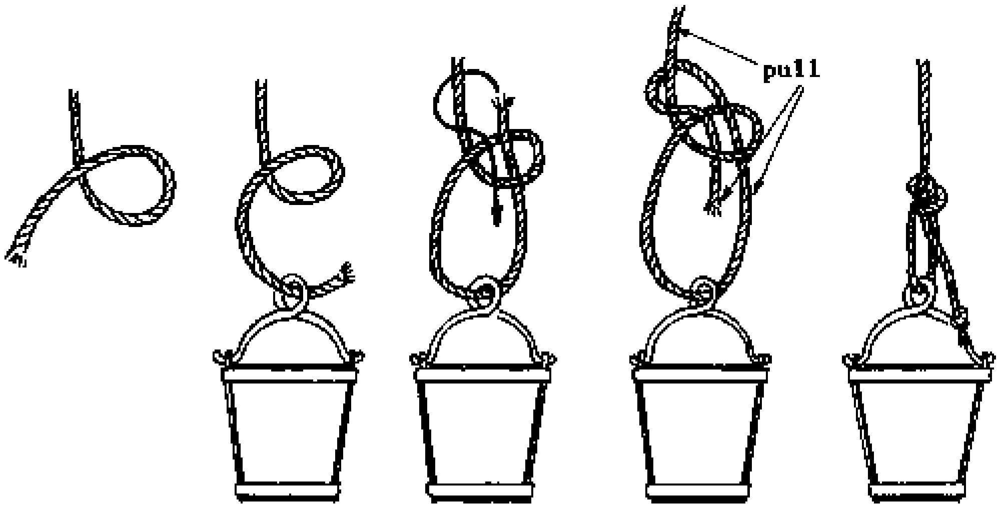
- Steel cable is a special kind of rope. How to handle it is explained in detail in 8.17/16.

B) Types of Knots

Nylon and sisal ropes are connected with knots. Use the following kinds of knots which are quick to make, safe to use, and easy to untie. Practice them until you know them by heart.

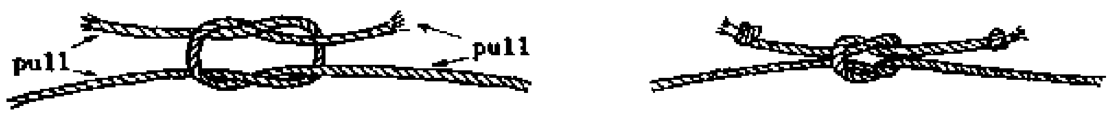
1. Bowline

for tying buckets, etc.



2. Square Knot

for connecting ropes



Steel cable cannot be connected with knots. The ends of steel cable have to be provided with eyes; the eyes are then connected with D-shackles or connecting links. For details see 8.17/16.

8.24 Types of Pumps and Other Water Lifting Devices

This chapter gives a rough overview about the diversity of pumps and other water lifting devices.

A pump is a device capable of transporting a fluid (or gas) by using energy supplied from outside.

A) Distinction of Water Lifting Devices and Pumps

Pumps and other water lifting devices can be distinguished according to

1. source of energy used,
2. principle of transporting the fluid,
3. type of fluid transported,
4. maximum lift.

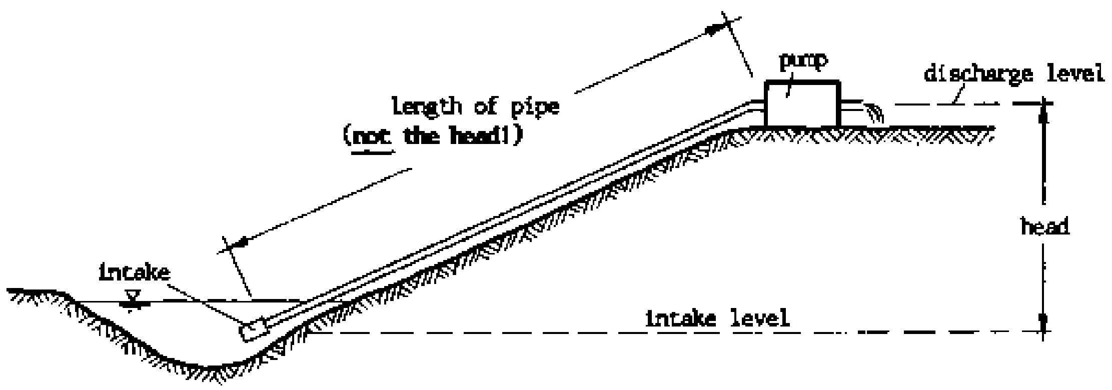
1. Source of Energy Used	Examples (see 8.24/6ff)
- human power	No. 1 to 14, 16, 17, 18, 19, 22;
- animal power	donkeys pulling water from a well
- solar energy	solar pump
- wind energy	No. 15;
- water energy	No. 21, 26;
- electrical energy	No. 30, 31;
- fossil fuel energy (combustion engine)	diesel and petrol pumps such as No. 20, 23, 24, 25, 27, 28, 29, 32;

2. Principle of Transporting the Fluid	
- bucket	No. 1 to 5;
- continuous rope and bucket system	No. 6 to 8;
- piston pump (positive displacement)	No. 9 to 15, 18, 28;
- membrane pump (positive displacement)	No. 16, 17, 19, 20; blacksmith's belly;
- centrifugal pump	No. 29 to 31; airblower; "fan";
- impulse pump	No. 21;
- ejector pump	No. 32;
- helical rotor pump	No. 22 to 24;
- coil pump	No. 26;
- rotary pump	No. 25, 27;

3. Type of Fluid Transported	
- clear, clean water	No. 1 to 32;
- dirty water	No. 1 to 8, 16, 17, 19 to 26, 29, 30;
- mud	No. 24 and special pumps;
- fuel or oil	fuel or oil pump in the car;
- air	airblower;

4. Maximum Lift (=Head)

The head is the vertical distance between the intake level and the discharge level:



- shallow well pump = suction pump (head: 0 to 7 m)	No. 2, 9, 19, 20, 24, 25, 26,29;
- deep well pump = lift pump (head: 0 to 7 m and deeper)	No. 1, 3 to 8,10 to 18, 21, 22, 23, 27, 28, 30, 31, 32;

B) Work of a Pump

A pump has to overcome

- the gravitational forces of the water,
- the friction in the pump and the pipes,
- the inertia of the moving parts of the pump.

C) Possible Reasons for Poor Performance of a Pump

There are many different reasons why a pump is not performing well in a certain situation. It is important to identify the exact reason.

Possible reasons are listed below:

- The pump is of poor quality.

- The pump is of poor design.

- The pump is not suitable for the given situation.

- The pump does not work in its optimal range (e.g., the head is too high after the water table has dropped).

- The pump is not being used properly.

- The pump is not maintained regularly (cleaning, greasing, etc.).

- The pump is unduly exposed to sun, rain, dust, etc.

- The pump is overused.

- The pump was not repaired properly after a break-down.

- Supply of spare parts is difficult because there are too many different types of pumps in the region.

D) Criteria for Selecting the Right Pump

To avoid poor performance, it is important to select the right type of pump for a specific task. The following questions will help you to identify the specifications for the pump you need for a specific purpose. First, answer them all, then check if the proposed pump fulfils these requirements.

1. Which head do you want to pump the water (in metres)?

2. What yield do you require (in m^3/h or l/sec)?

3. What type of water should be pumped (clear, sandy or muddy water)?

4. What source should the water be pumped from (hand dug well, borehole, river)?

5. For how long should water be pumped subsequently: How many hours a day; the whole day; sometimes; daily; for how many months?

6. What kind of energy is available and should run the pump (human, animal, diesel, petrol, electricity, etc.)?

7. What kind of spare parts are available and where?

8. What kind of maintenance facilities are necessary and available?

9. What kind of operating skills are necessary and available?

10. Do you require that the pump ensures that the water is not polluted?

11. What level of technology is suitable?

12. Where can you get the required pump from?

13. What kind of pump would be accepted by the future users?

14. How much money are you able and ready to invest in the pump (including running and maintenance costs)?

E) Comparison of Different Pumps

In the following table a number of pumps are compared. The necessary information is compiled to answer the questions asked under “D) Criteria for Selecting the Right Pump”. The drawings under F illustrate the different pumps.

COMPARISON OF DIFFERENT PUMPS

Pump	Drawing No.	Source of Energy	Principle of Fluid Transport	Type of Fluid	Lift from Water to Pump	Lift from Pump to Higher Level	Yield in m^3/hour	Well Ø required	Possibility of Contamination	Costs	Operation and Maintenance	Suitable Areas
unprotected bucket system	1, 5	human, animal	pulling by rope	clean or dirty water	0-50 m	-	0.05-1	large Ø (100 cm)	yes	low	very simple	remote areas
shaduf	2	human	pulling by counterweight	clean or dirty water	0-5 m	-	"	"	"	"	simple	with simple maintenance facilities
protected bucket system	3, 4	"	pulling by rope	clean water	0-10 m	-	"	"	avoidable	"	"	"
chain, rope and washer pump, bucket pump	6, 7, 8	"	"	"	0-10 m	-	2-3	"	"	reasonable	"	"
suction hand pump with piston	9	"	piston, pos. displacement	"	0-7 m	-	2	borehole or large diameter	"	"	reasonable	where maintenance secured
suction hand pump for irrigation with piston	9	"	"	clean or dirty water	0-7 m	-	8	large Ø (100 cm)	yes	"	"	"
direct action hand pump	10	"	"	clean water	0-25 m	-	2	borehole or large diameter	avoidable	"	"	"

F) Drawings of Different Pump Types

In the following, drawings are given of a number of pumps, compiled as teaching material. They shall give an impression about the diversity of pump types. Some of them will need further explanation by a teacher or further study in the literature (see in the bibliography especially No. 18 from which many pictures were taken). A few pump types are described in more detail in later chapters.

Illustrations are given for the following pumps and water lifting devices:

1. Unprotected Bucket System
2. Counterweighted Bailer (=Shaduf)
3. Protected Bucket System with Trough
4. Protected Bucket System with Hose
5. Bailer for Boreholes
6. Bucket Pump
7. Chain and Washer Pump
8. Rope and Washer Pump
9. Suction Hand Pump with Piston
10. Direct Action Hand Pump with Cylinder
11. Piston Hand Pump with Chain Link
12. Piston Hand Pump with Uganda Type Handle
13. Piston Hand Pump with Fly-Wheel
14. Force Pump
15. Wind Pump
16. Vergnet or Mengin Pump
17. Petro Pump
18. Blair Pump
19. Diaphragm Hand Pump
20. Diaphragm Engine Pump
21. Hydraulic Ram
22. Helical Rotor Hand Pump
23. Helical Rotor Engine Pump
24. Archimedean Water Screw
25. Water Wheel
26. Coil Pump
27. Rotary Pump
28. Piston Engine Pump
29. Centrifugal Pump
30. Submersible Pump for Dirty Water
31. Submersible Pump for Clean Water
32. Jet Pump

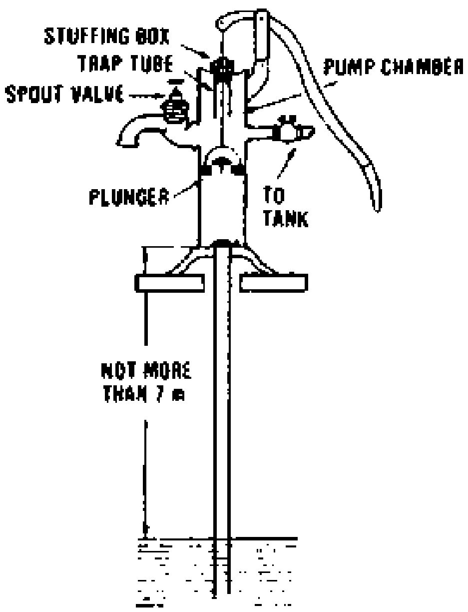
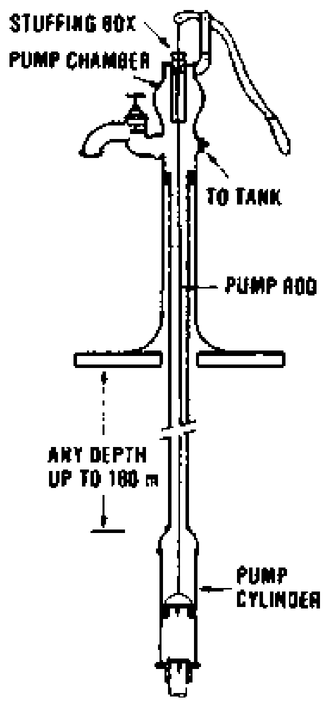
14. Force Pump either suction type (like No. 9) or with cylinder (like No. 11) for pumping water from a well to an elevated tank.

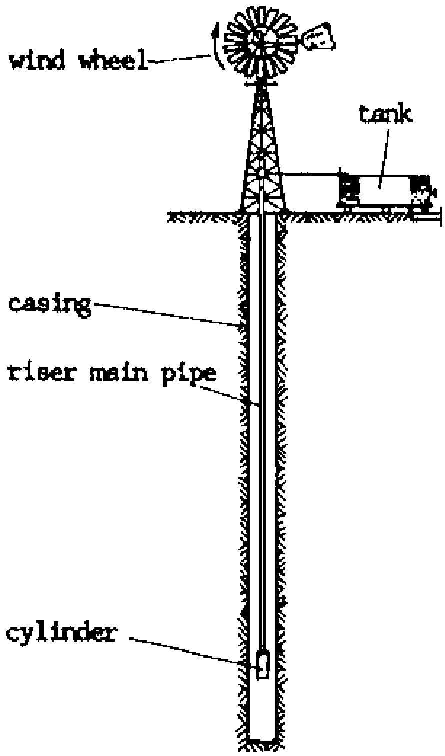
Force Pump Suction Type



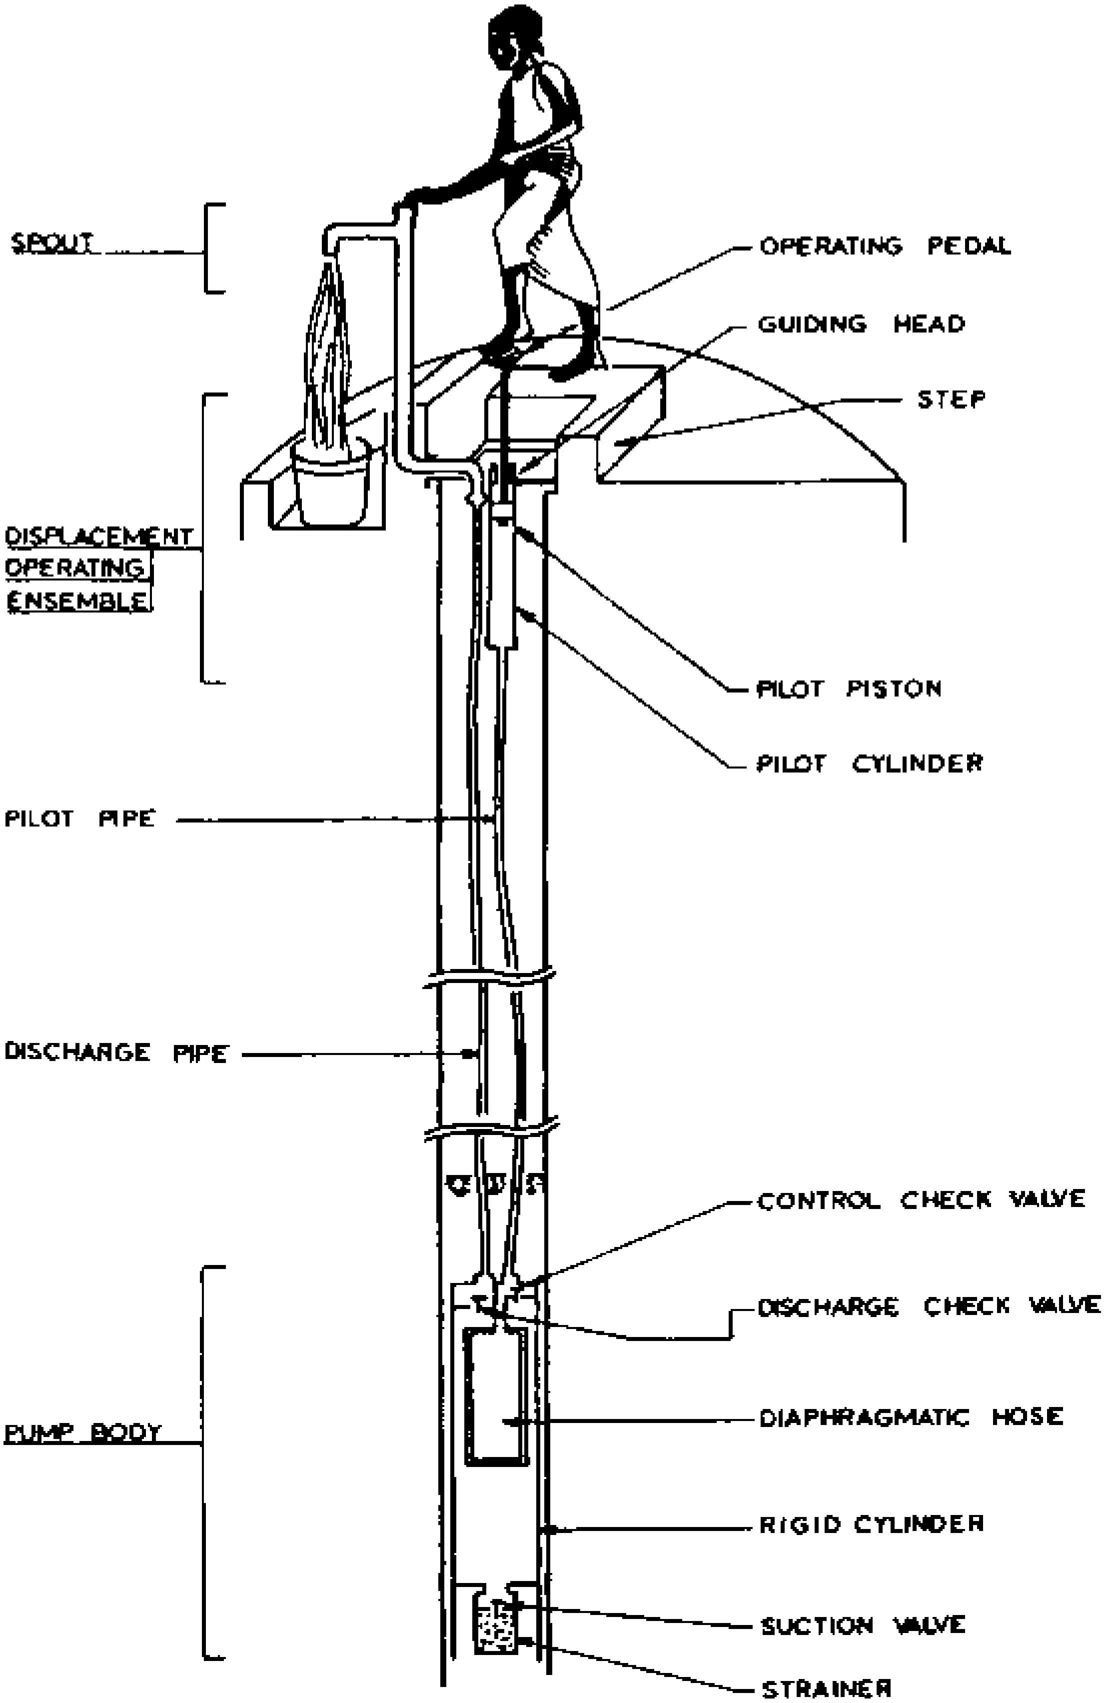
Force Pump with Cylinder



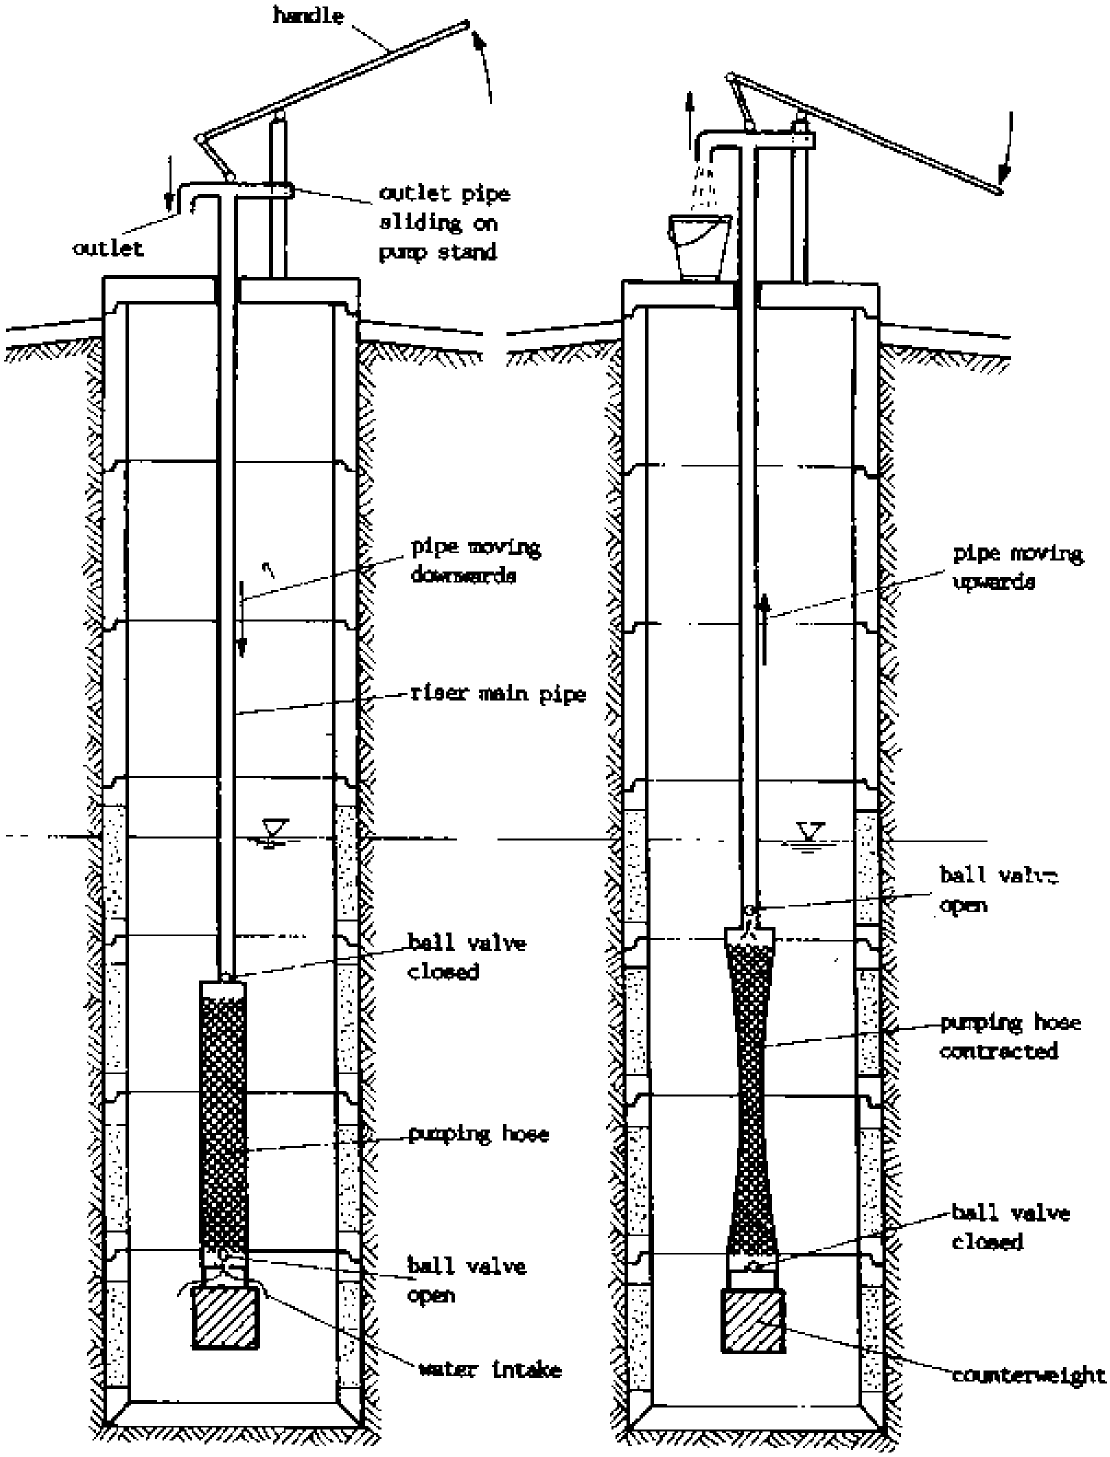
15. Wind Pump with cylinder, riser main pipe, rod, connection to water tank, and wind-wheel moving the rod by rotary crank; for deep wells.



16. Vergnet or Mengin Pump with pilot cylinder, pilot pipe, rigid cylinder (with three valves), discharge pipe and outlet, foot-operated.

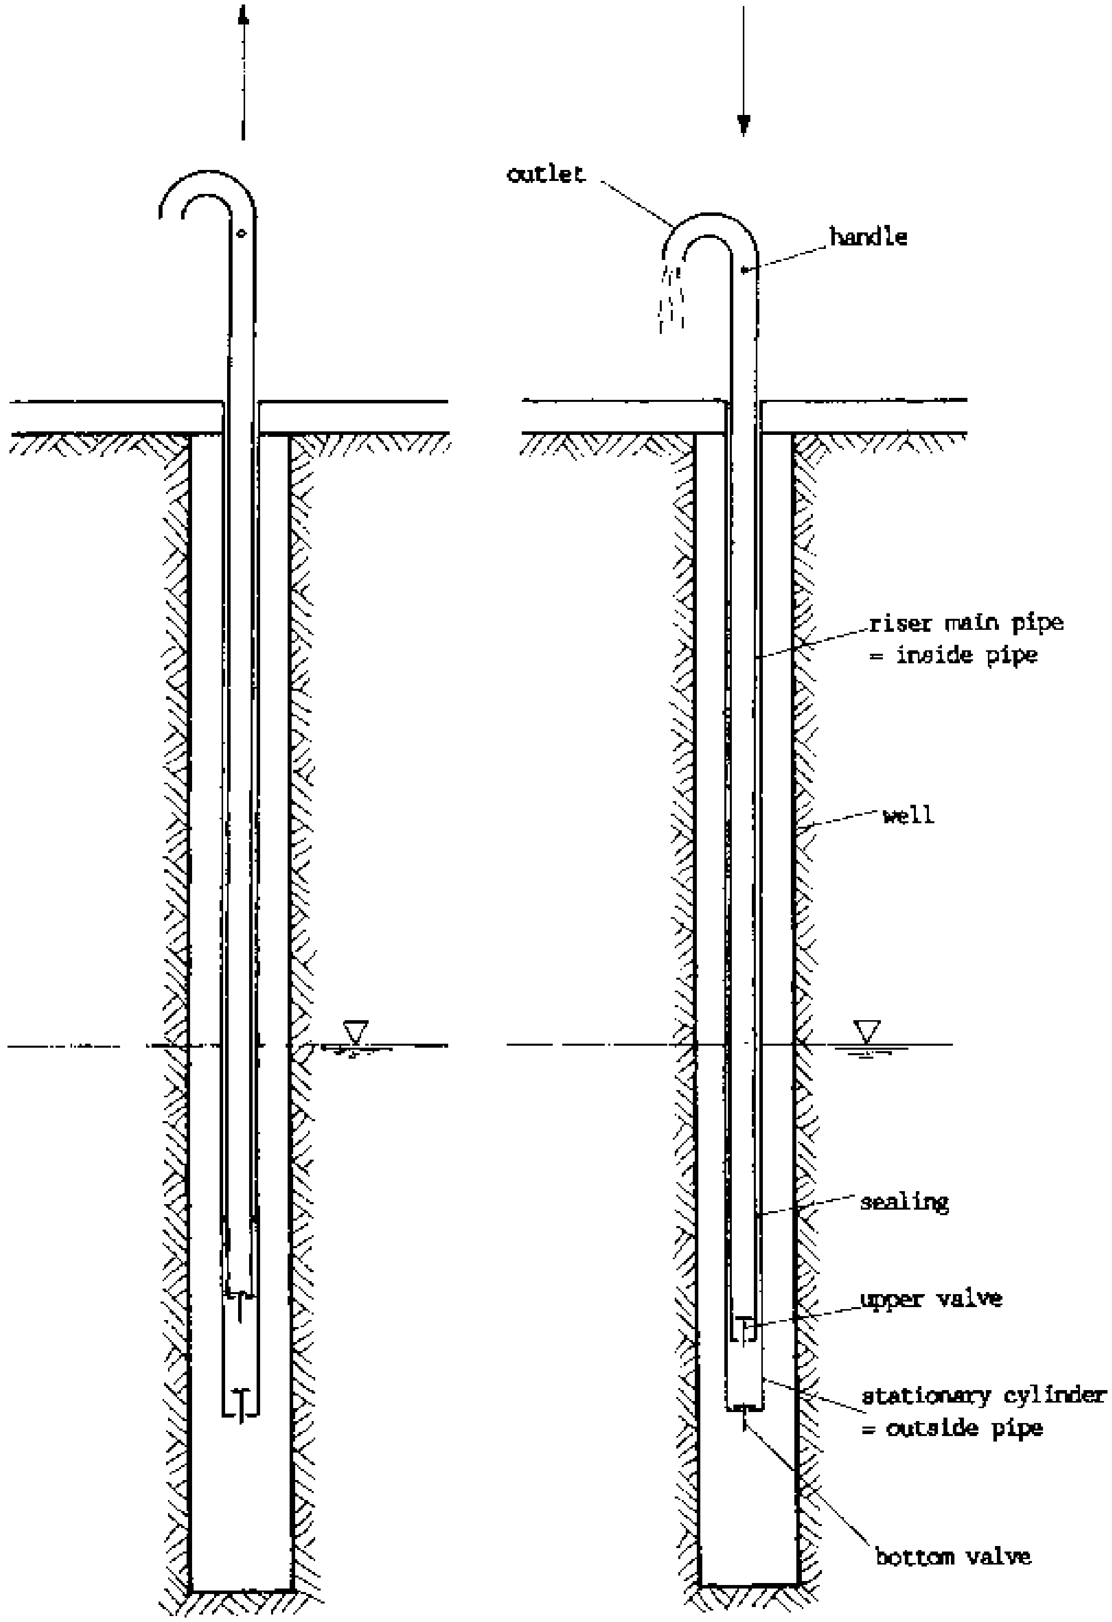


17. Petro Pump with counterweight holding the lower end of pump in position, a pumping hose from flexible membrane creating the suction, two valves, riser main pipe moving up and down, outlet moving up and down, and handle.



Schematic Illustration

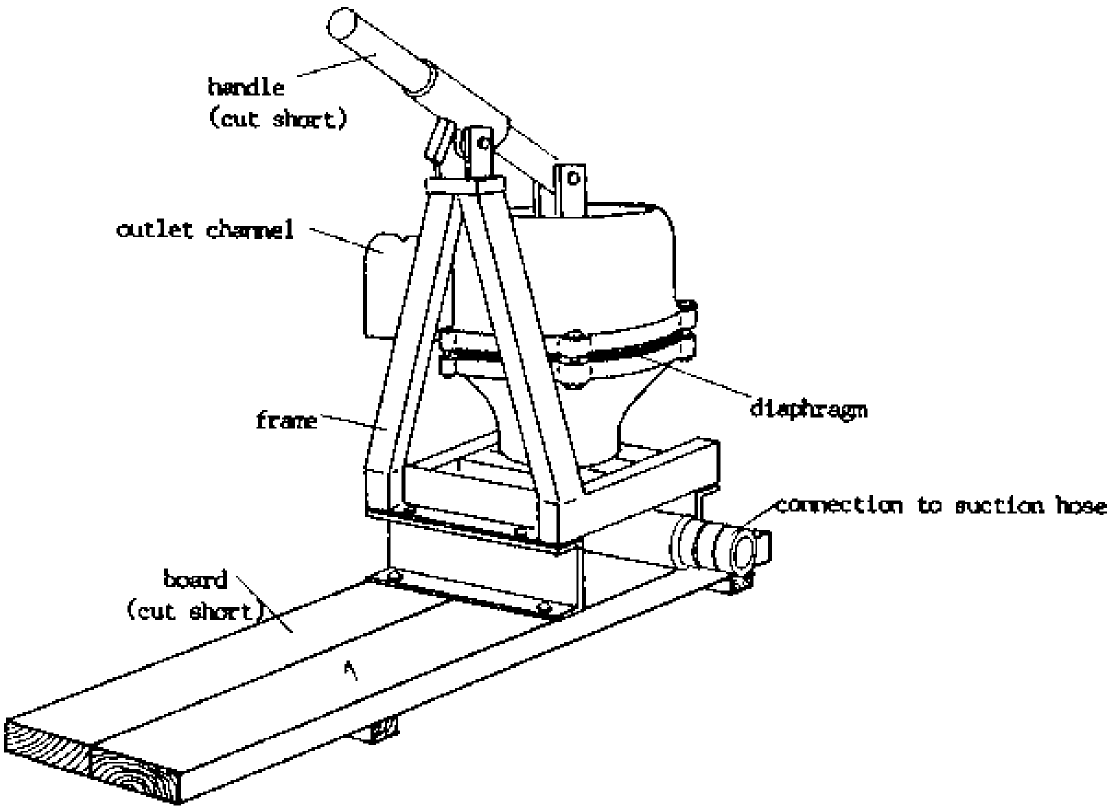
18. Blair Pump with stationary cylinder, foot valve, riser main pipe which is at the same time pump rod and plunger with a valve, with bent end of riser main pipe as outlet, and handles.



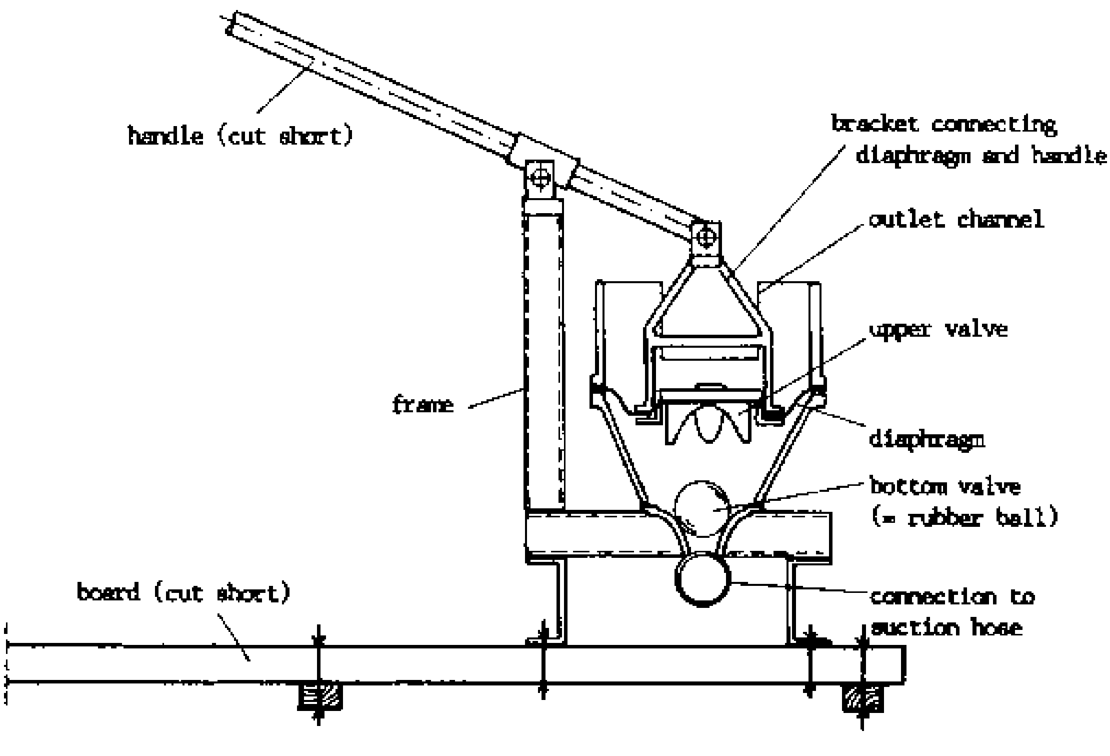
Schematic Illustration

19. Diaphragm Hand Pump with foot valve (= suction sustainer), suction hose, pump body with two valves, rubber membrane (= diaphragm), handle, outlet; for wells up to 7 m; see also 8.26 for operation.

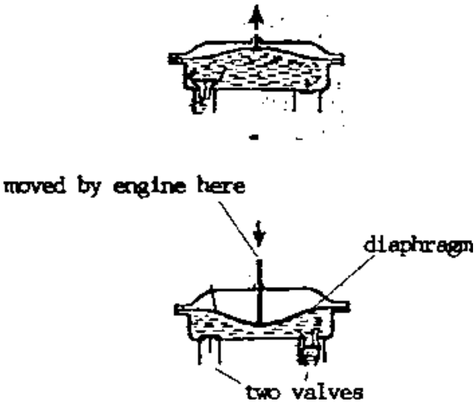
ISOMETRIC VIEW



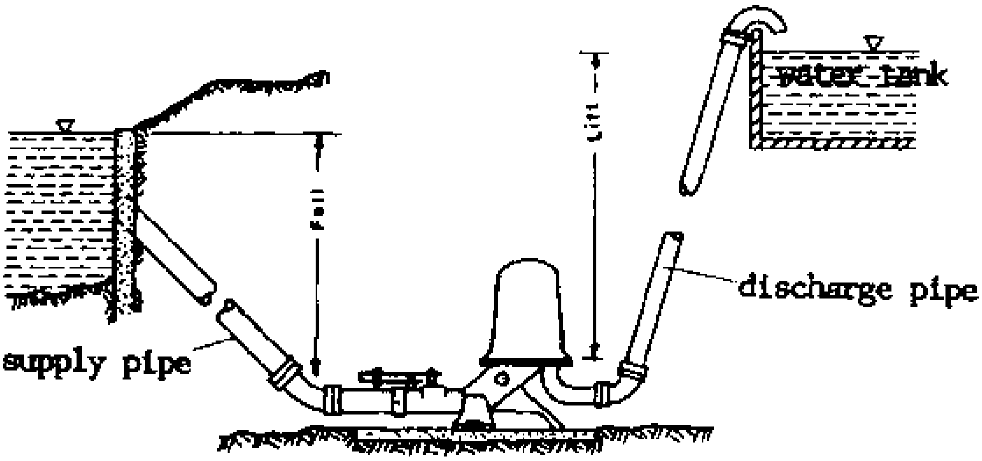
CROSS-SECTION (not in operation)

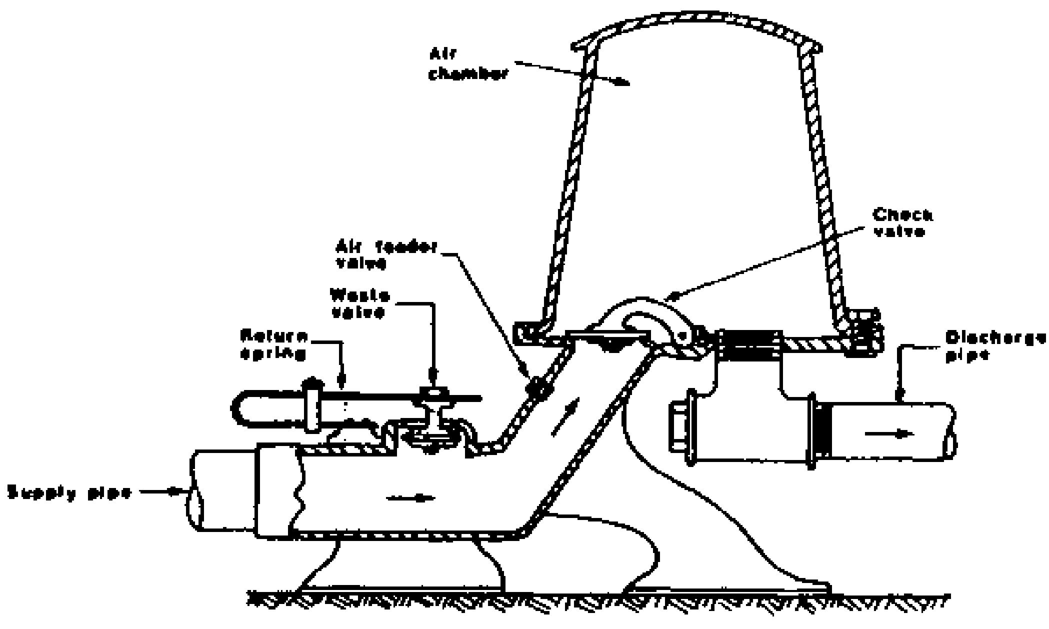


20. Diaphragm Engine Pump with foot valve, suction hose, pump body, membrane moved by engine; for wells up to 7 m.

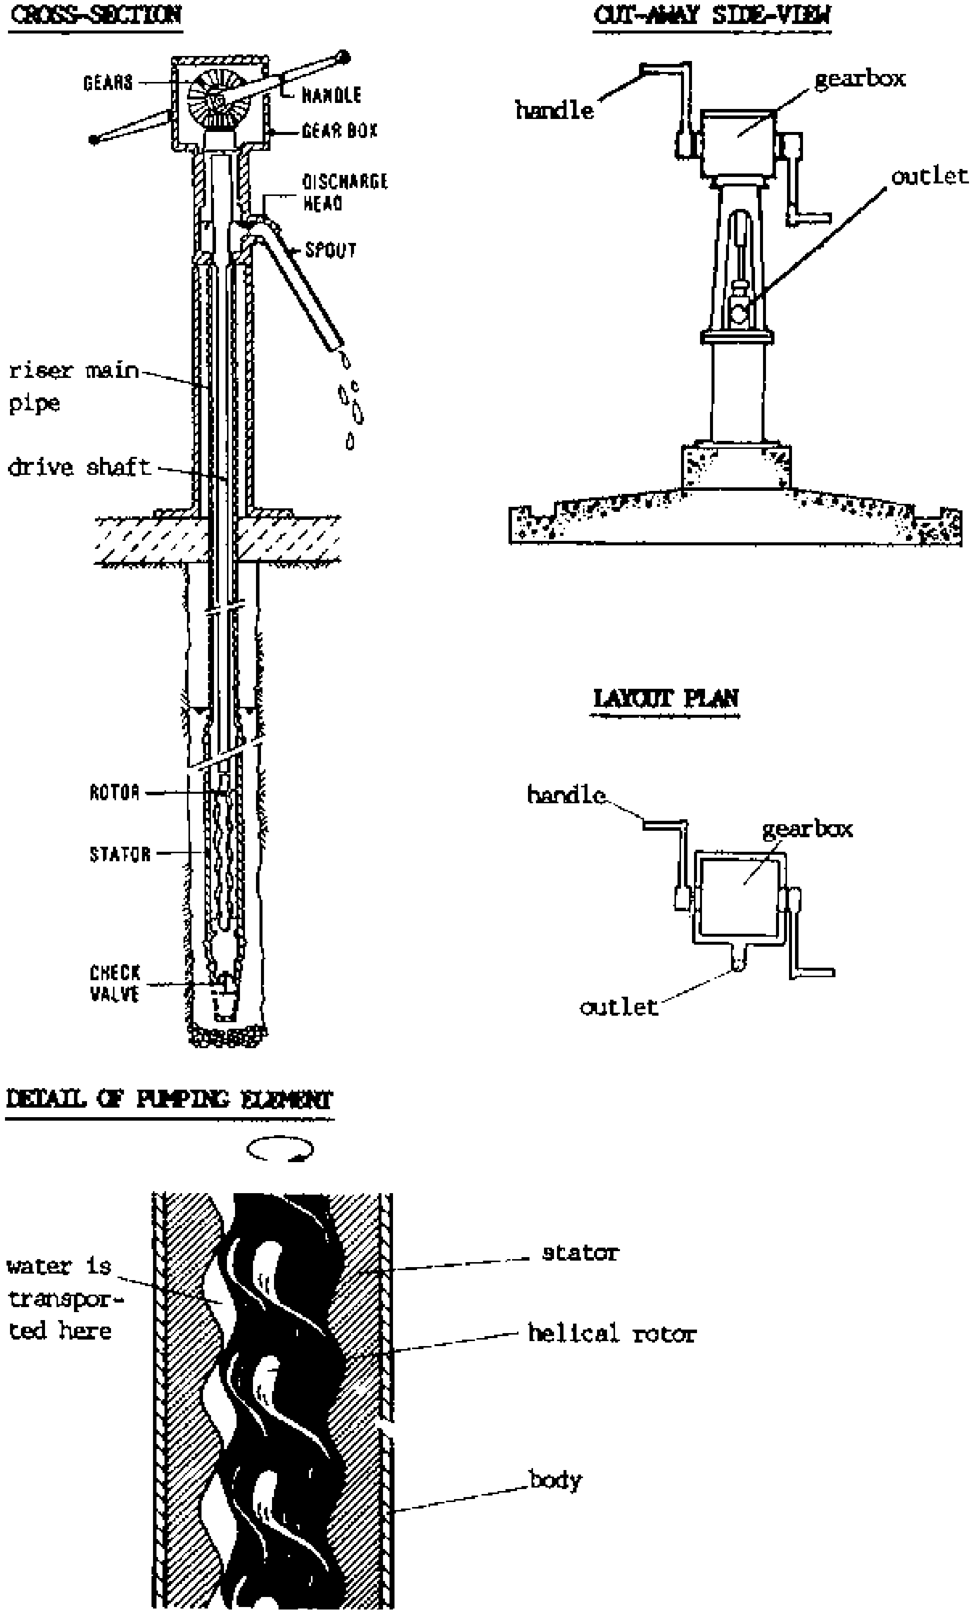


21. Hydraulic Ram with water storage higher than the ram, supply pipe (= drive pipe), check valve, air chamber, discharge pipe (= delivery pipe), return spring, waste valve, outlet for waste water; requires a constant flow from the storage and pumps a small part of this flow to a higher level.



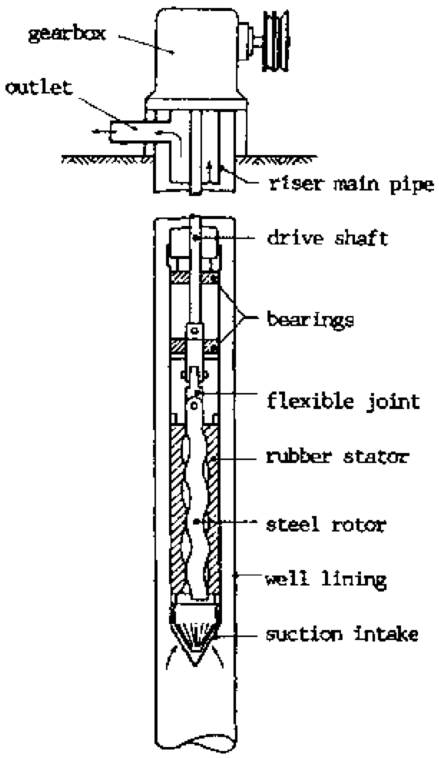


22. Helical Rotor Pump, Hand-Operated with check valve, helical rotor in a fixed stator, riser main pipe, drive shaft (= rod transmitting the rotation from the pump head to the helical rotor), outlet, gears (transmitting the rotation of the handles into rotation of the drive shaft), gear box and handles; for deep wells.

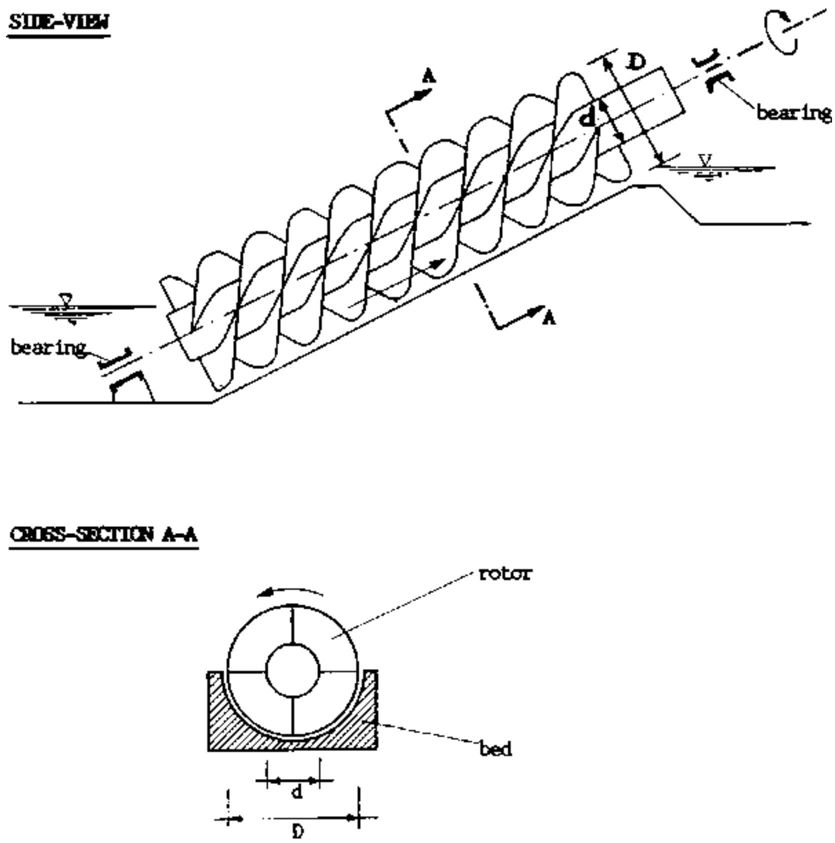


Taken from leaflet, Mono Pump

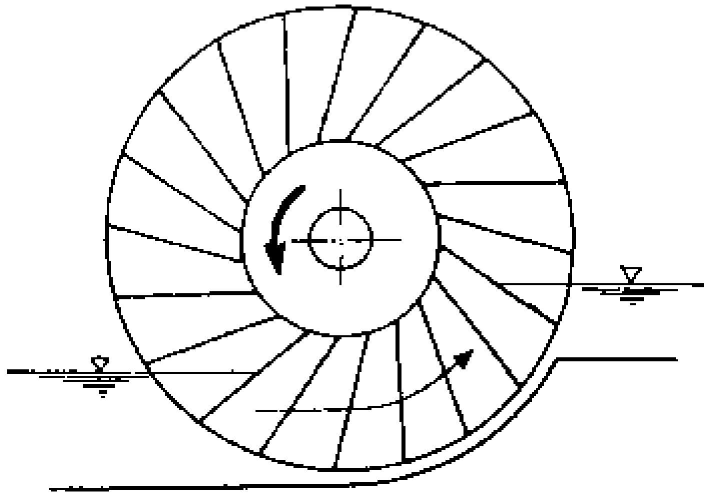
23. Helical Rotor Pump, Engine-Driven with helical rotor in a fixed stator, riser main pipe, gears, gear box, engine; for deep wells.



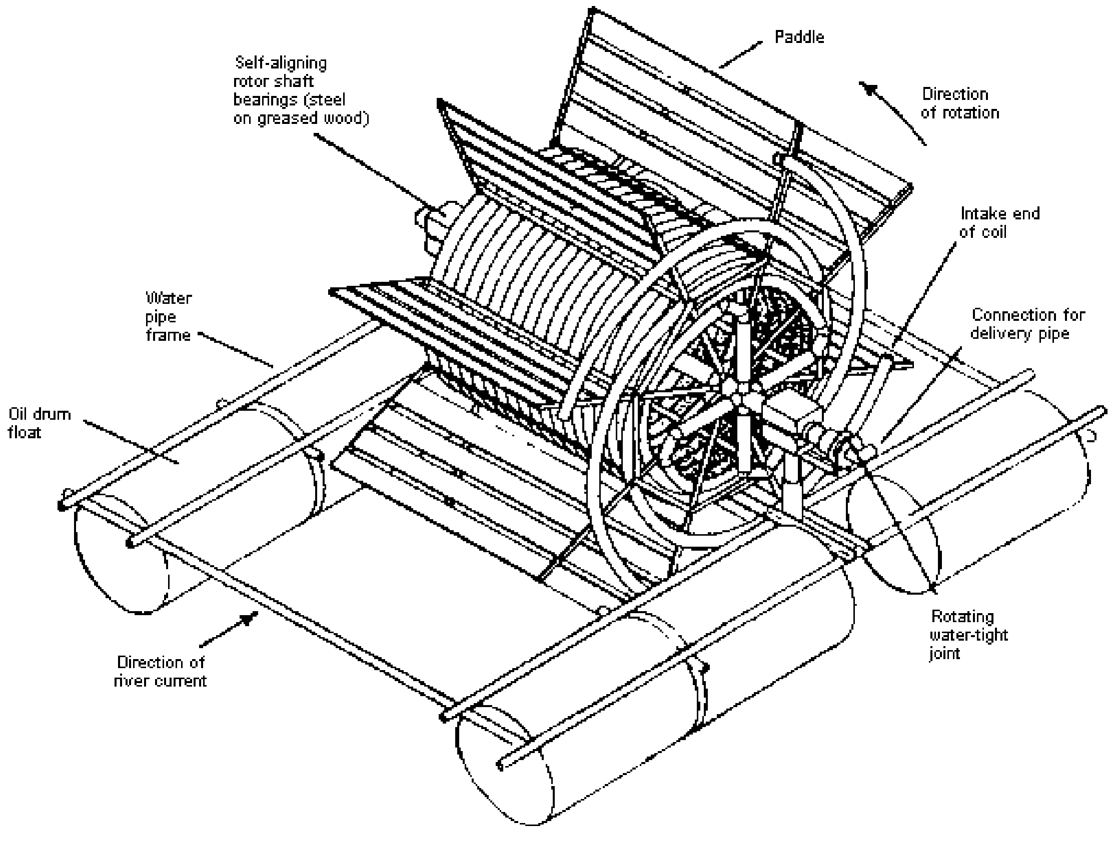
24. Archimedean Water Screw with an inclined rotor rotating in a fitting bed (in the shape of a half cylinder), engine driven; for water or mud



25. Water Wheel with a rotating water wheel lifting the water; engine driven; for low lifts.

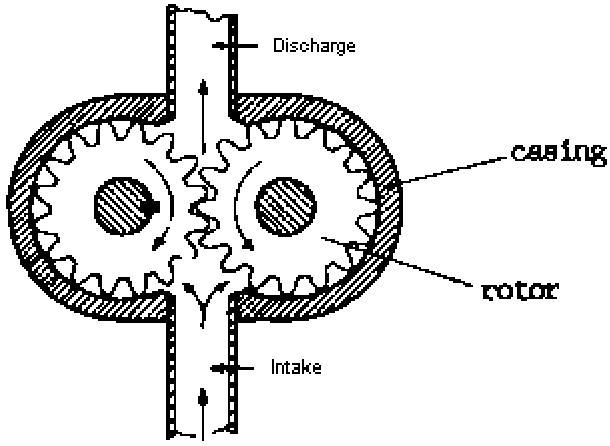


26. Coil Pump with plastic pipes coiled around a frame work rotating by the action of the river current on paddles; pump floating on drums; delivery hose to elevated tank; for small lifts from a river.



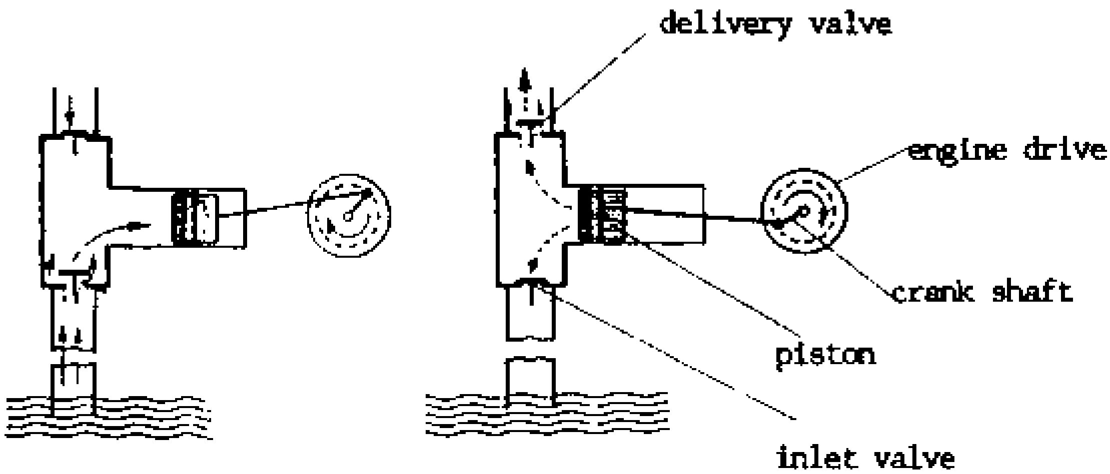
27. Rotary Pump with rotors within a fixed casing (= stator).

CROSS-SECTION



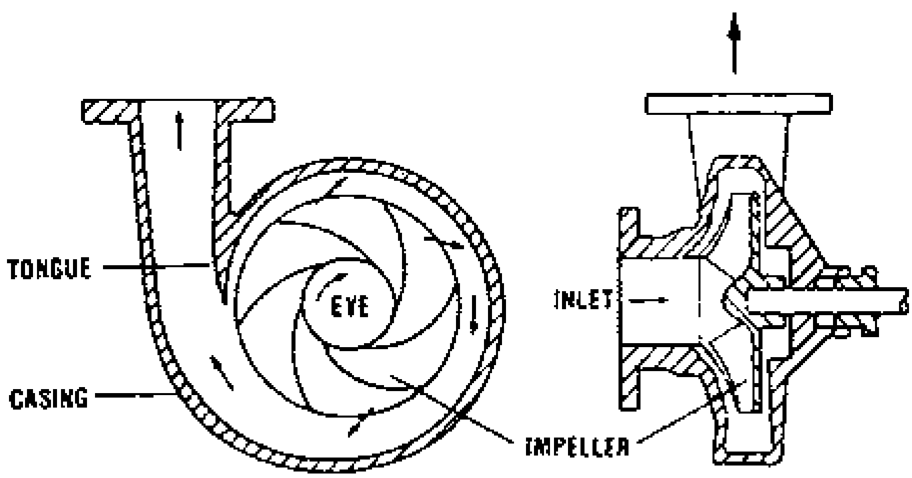
28. Piston Pump with a piston moved by an engine to create suction for pumping.

CROSS-SECTION in two stages of operation

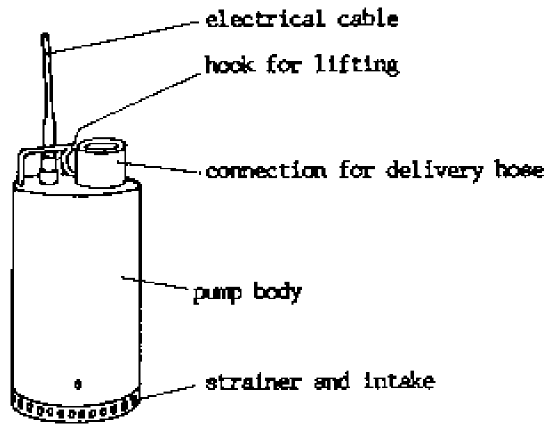


29. Centrifugal Pump installed on ground level; with rotating impeller within a casing, suction pipe and delivery pipe; for suction heads up to 7 m and delivery heads up to 30 m; see also 8.27

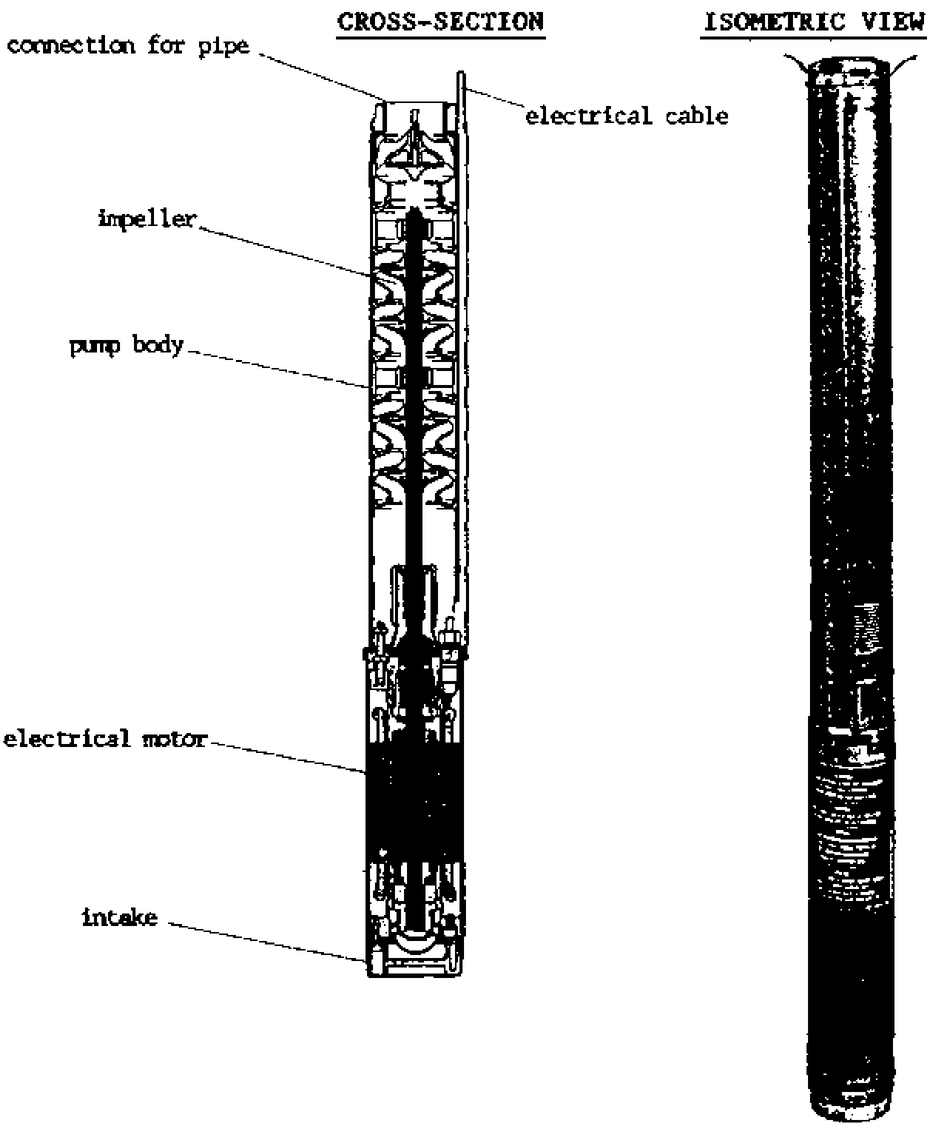
CROSS-SECTION



30. Submersible Pump for Dirty Water with electrical motor and pump within a pump body submersed into the water, with power supply supplied by electrical cable, and a delivery hose; for deep wells; see also 8.28.



31. Submersible Pump for Clean Water used in boreholes; with slim shape especially designed for boreholes; for clean and not salty water and deep wells.



Taken from leaflet, Homa Pump

32. Jet Pump with centrifugal pump installed on ground level, pressure pipe, jet body with jet nozzle, mixing chamber, return pipe, delivery pipe, and elevated tank; pumps water into the well through pressure pipe, the flow speed is increased by the nozzle and, thus, water sucked in from the well; the water moves up through the larger diameter return pipe to the pump; a part is delivered to the tank, the other part is pumped again into the pressure pipe, etc.; no moving parts in the well

8.25. Dewatering Wells during Construction

When digging below the water table, dewatering of the well becomes necessary in order to enable the technicians to continue the work. Dewatering can be done by the following different means. Concerning the yields of different pumps see 8.34 or 8.24/4f.

A) Dewatering with a Bucket, Rope and Pulley

Small amounts of water can be extracted with the bucket used for excavating the soil.

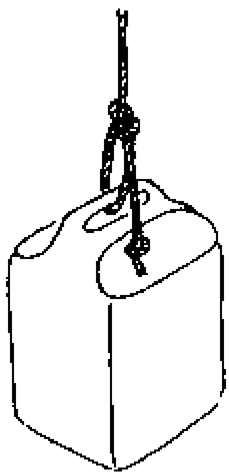
B) Dewatering with Jerrycan, Rope and Pulley

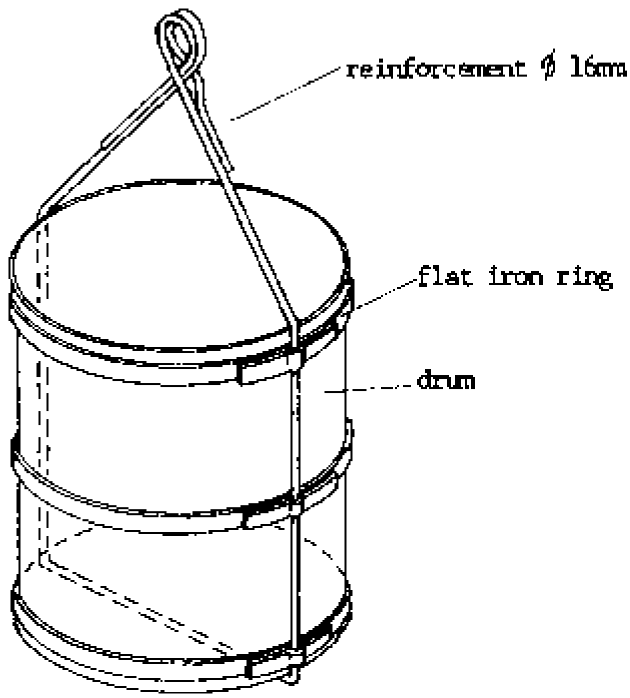
A jerrycan, cut open at its top, pulls in one go twice as much as a bucket, and is light-weight. Therefore, it is quite suitable for dewatering wells during construction by hand. However, many people are required. They have to work in shifts. Two jerrycans can be used parallel on two pulleys.

C) Dewatering with a Large Bucket, Steel Cable, Pulley and Winch

A large bucket, both for dewatering and lifting excavated soil, can be manufactured locally from a metal drum. Cut off one third of the drum and reinforce it with three rings of flat iron. A reinforcement rod Ø 10 mm must go all around the bucket to bear the weight and to serve as a handle.

Such a large bucket can be filled half way with soil, or completely with water. It is to be pulled by steel cable and winch. The method empties a well quickly, but requires a number of people to work in shifts as the work is very heavy.





D) Dewatering with Hand-Operated Diaphragm Pump

The method is described in detail in 8.26. It can be used only for wells up to 8 m deep, because a diaphragm pump is a suction pump. It requires heavy manual labour, but no fuel, few spareparts and little skill. If the yield of the well is not extremely high, this is a very good method for dewatering a well.

E) Dewatering with a Fuel Powered Suction Pump

The method is described in detail in 8.27. It can be used only for wells up to 8 m deep. It requires fuel, spare parts and skilled labour. The method is appropriate if the yield of the well is very high.

F) Dewatering with Submersible Pump

The method is described in detail in 8.28. It can be used for deep wells, too, depending on the pump selected. It requires a transportable generator, fuel, spare parts, and skilled labour. The yield is normally less than for fuel powered suction pumps. The method is suitable if dewatering by hand becomes too tiresome, especially in deep wells.

G) Selecting the Suitable Dewatering Method

The method suitable for a particular well has to be selected according to the available manpower and equipment. Sometimes, two or three of the above methods can be used at the same time (= in parallel = simultaneously) or one after another (= consecutively).

Often, the dewatering facilities determine how deep a well can be dug into the water table. If the water returns into the well more quickly than you can dewater it with the available facilities, digging cannot be continued any more.

It is very important to dig as deep into the water table as possible in order to have some reserve for dry years. With careful planning you can reach the maximum depth possible with the given facilities:

1. Plan the work so that you combine all available people and dewatering facilities. Work overtime for a short period until digging and lining below the water table are finished.

An example for bad planning would be: You start dewatering on Friday morning. Up to 14.30, the end of the working hours, you have just managed to empty the well and the actual work could start. During Saturday and Sunday, the well fills up again. On Monday, you again dewater until 14.30, and stop work. On Tuesday, you dewater until 13.30 and dig for one hour. On Wednesday, you dewater until 13.30 and dig for one hour... - with completely demoralized staff.

2. Keep careful record of all your activities including the time, water table, number of pumps, buckets, etc. used. Keep track of how quickly the water returns into the well over night (how many cm per hour).

3. Plan the work so that digging into the water table will take place at the end of the dry season when the water table is at its lowest.

8.26. Diaphragm Pumps

Diaphragm pumps suck up the water through up-and-down movement of a flexible rubber membrane called a diaphragm.

A) Types of Diaphragm Pumps

Diaphragm pumps can be differentiated according to the type of energy which drives them:

1. Engine driven diaphragm pumps pump very high yields and are not discussed here.

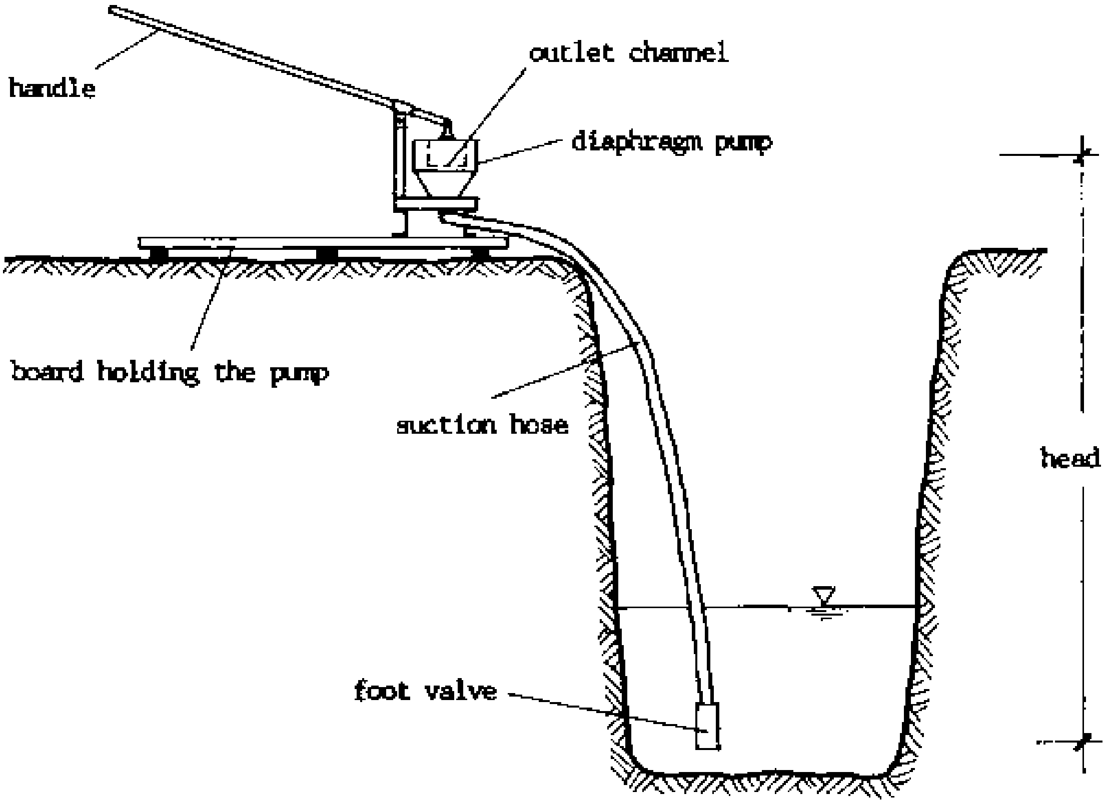
2. Hand operated diaphragm pumps are designed for irrigation purposes in order to lift a big amount of water with a small head. This type of pump is also very suitable for dewatering shallow wells during construction and will be discussed in the following.

B) <u>Range of Use</u>

Being a suction pump, the possible lift of a diaphragm pump is limited to 8 m.

C) <u>Elements of a Pumping System with a Diaphragm Pump</u>

A pumping system with a diaphragm pump consists of the following elements:



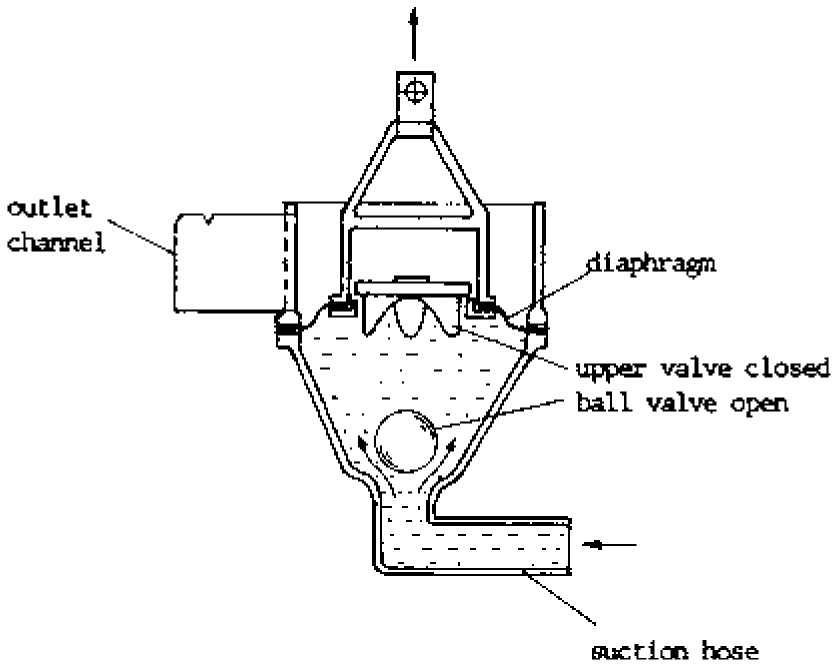
D) <u>Description of the Diaphragm Pump</u>

A diaphragm pump consists of a metal body holding the flexible rubber membrane, the diaphragm. The membrane has a round opening in the middle, reinforced with a steel ring. The ring is connected to the handle and also holds the upper valve. The bottom valve, made of a rubber ball, is placed at the inlet of the suction pipe.

The operation of a diaphragm pump has two distinct and alternative phases:

<u>1. Phase</u>

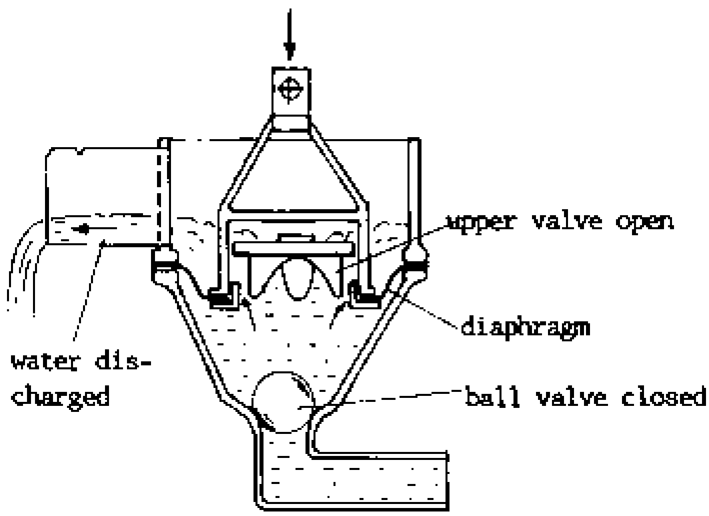
- The handle moves downwards.
- The membrane moves upwards.
- The upper valve closes by its weight.
- The membrane creates suction and opens the bottom valve.
- Water is sucked in through the suction pipe.



Schematic Illustration Diaphragm assembly turned by 90° for clarity; see also 8.24/22.

2. Phase

- The handle moves upwards.
- The membrane moves downwards.
- The backflow of water closes the bottom valve.
- The water wants to escape and opens the top valve.
- The water is delivered in an open outlet.
- The water in the suction hose does not move.



The two valves open and close alternately and, thus, the water is lifted in steps (not continuously). The foot valve at the bottom of the suction hose (the third valve!) is indispensable. It allows the water to be primed, i.e. to be gradually lifted until the hose is full. The foot valve also makes it possible to rest during pumping without having to prime all over again.

E) Advantages and Disadvantages

The advantages of a hand operated diaphragm pump are:

- It is very simple.

- It is sturdy (= strong, not easily damaged).

- Its operation is very simple.

- It does not require fuel.

- The yield is high.

- It can pump sandy water because there are no sensitive parts which can wear out quickly.

The disadvantages are:

- The pump can only pump up to 8 m depth.
- Pumping is hard work and requires enough people to work in shifts.
- The suction hose can wear out quickly.
- The membrane needs to be replaced from time to time.

F) Operation of a Diaphragm Pump

The operation of a diaphragm pump is extremely simple:

- Assemble pump, suction hose and foot valve.
- Pump.

However, take care of the following points:

- The pump must be fixed on a board of 2 pieces of timber 2” × 8”, 2 m long. The board must stand on level and stable ground and should not move.

- Handle the suction hose with great care to avoid damage. Do not pull it over the rough edge of the well. The suction hose must be airtight (without the slightest hole), otherwise, the pump cannot suck.

- Tighten all bolts firmly.

- Two or three people can pump, but they should move the handle from the highest possible to the lowest possible position in an even rhythm. They should not jump with the handle.

- After work, do not leave the membrane exposed to sun, but cover it. This prolongs its lifetime.

8.27 Fuel-Powered Suction Pumps

The most common type of fuel-powered suction pump is a centrifugal pump with suction and discharge hose or pipe.

A) Types of Fuel-Powered Suction Pumps (Centrifugal Pumps)

Suction pumps can use diesel or petrol as fuel:

1. Diesel powered suction pumps are heavier and, therefore, more suitable for permanent installation. They will not be discussed here.

2. Petrol powered suction pumps are usually light-weight and, therefore, transportable and

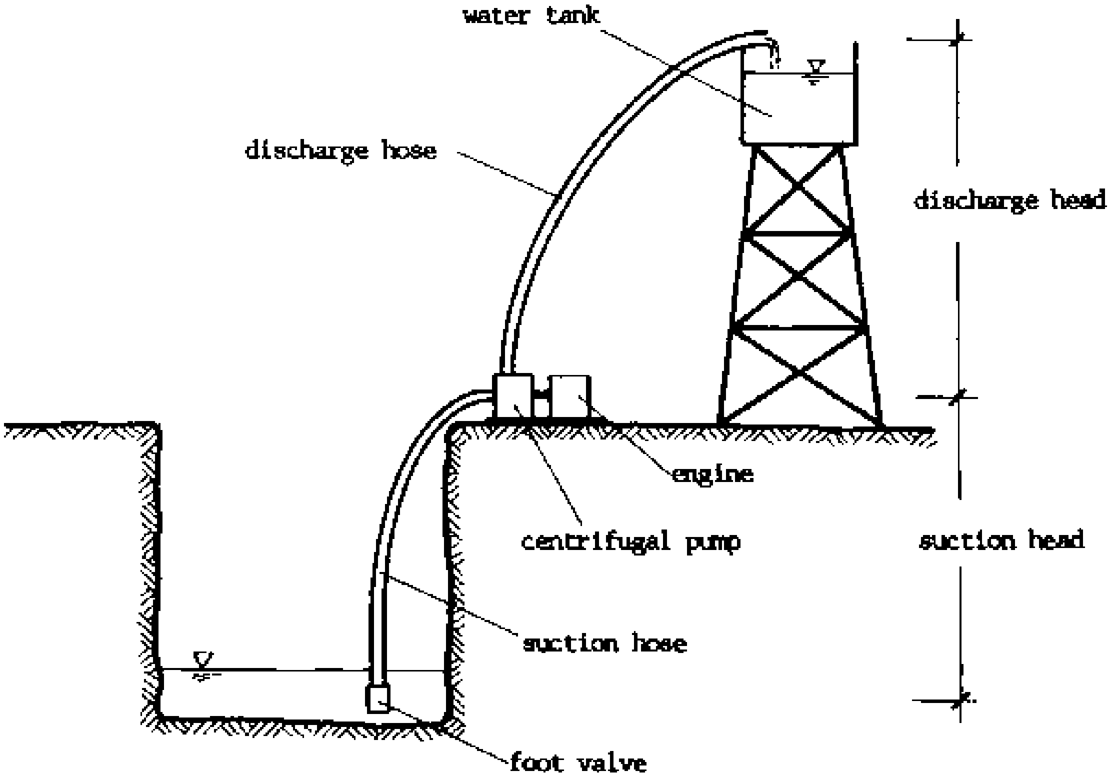
very suitable for dewatering wells during construction. They will be discussed in the following with the HONDA WA 30 X as an example.

B) Range of Use

Fuel powered suction pumps are, like all suction pumps, limited to a depth of 8 m.

C) Elements of a Pumping System with a Petrol Suction Pump

A pumping system with a petrol powered suction pump consists of the following elements:



D) Description and Specifications

A petrol engine produces rotational movement and directly turns the axle of the attached centrifugal pump. The rotating blades suck water through the suction hose and press it through the discharge hose to a higher level. As the energy of the fuel is directly converted into mechanical energy which turns the pump, there are small losses and the pump has a high efficiency.

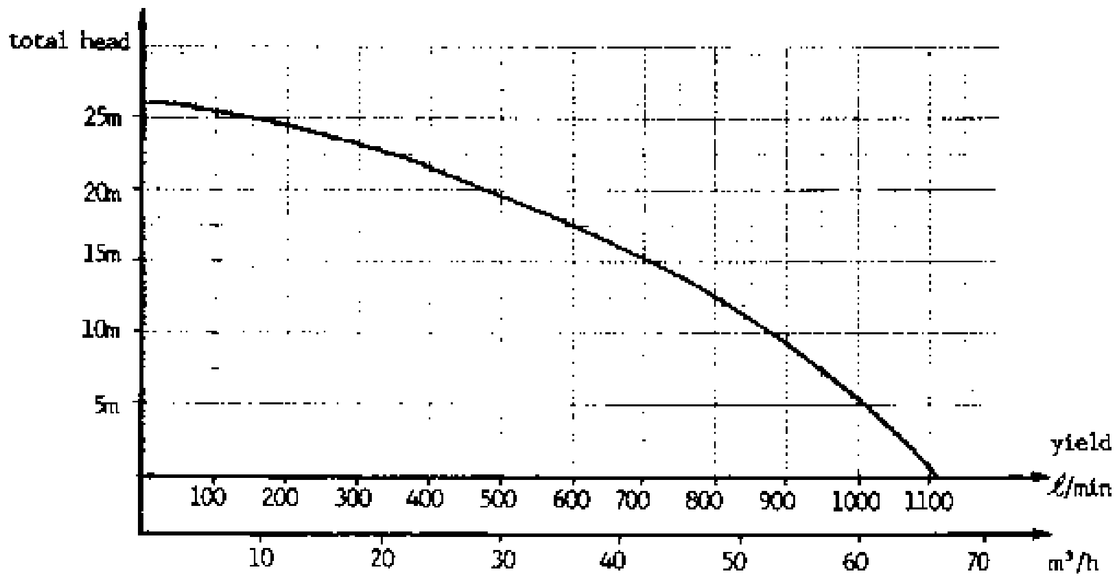
The pump is started mechanically by a recoil starter. A foot valve (= suction sustainer) at the bottom of the suction hose makes priming much easier. The centrifugal pump is cooled by the water pumped and, therefore, must never run dry.

The specifications and the performance curve of the HONDA WA 30 X pump are given here as an example:

Specifications		Remarks
pump type	centrifugal, self priming	a suction sustainer helps priming
suction hose	Ø 3”	
discharge hose	Ø 3”	
suction head	8 m	
discharge head	20 m	
total head	28 m	

max. capacity(yield)	1100 ℓ /min = 66 m^3/h	
direction of rotation displacement	counter clockwise 144 cm^3	= the volume displaced by the piston in a single stroke
engine	4 stroke overhead valve, air cooled single cylinder	
maximal output	5.0 HP	= horse power (Engl.) = PS (German)
	3,600 rpm	= revolutions per minute
fuel tank capacity	3.6 ℓ	
fuel	petrol	
fuel consumption	230 g/HPh -> 1,150 g/h =1.5 ℓ /h	
aircleaner	semidry	
starting system	recoil starter	battery starter is heavier
cooling system	forced air	
dimensions	620 × 410 × 485 mm	
dry weight	35 kg	easily transportable; diesel engines are heavier
self priming time continuous running time	120 sec at 5 m head 2 h 40 min	after that the engine runs too hot, therefore stop.

Performance Curve



Example:

Water is to be pumped from a well 5 m deep and discharged into a container 7 m above ground level.

Total Head	=	Suction Head	+	Discharge Head	
	=	5 m	+	7 m	=12 m

According to the curve, the yield is to be expected about 820 ℓ /min or 49 m^3/h (for transformation see 8.34/1).

E) Advantages and Disadvantages

The advantages of a petrol suction pump are:

- The pump is light-weight and easily transportable.

- Only a hose is lowered into the well which leaves enough space for the technicians in the well.

- Technicians can work in the well during pumping.

- The pump is able to pump dirty, sandy and muddy water.

- The pump has a high yield.

The disadvantages are:

- The pump can only pump up to 8 m depth.
- The pump needs fuel.
- The equipment is relatively sophisticated and can break down easily.
- Spare parts are difficult to get.
- The pump requires great care during operation.
- The hoses wear out quickly.

F) Step-by-Step Procedures for Operating the Pump

For dewatering a well with a petrol suction pump, follow these steps:

No	Step	Reasons
1	Place the pump near the well in the shade on a level surface. The exhaust pipe must direct away from the well.	Otherwise the pump easily gets overheated. On a sloping area the fuel will spill. Exhaust fumes are poisonous and heavy and can easily descend into the well(8.22/Iff)
2	Connect foot valve, suction hose, pump and discharge hose. If you have no foot valve, use a strainer. Place the suction hose into the well, and the discharge hose far away. The strainer should be well submersed, but not stand on the ground.	Gravel sucked into the pump will cause serious impeller damage.
3	Check engine oil level.	Running the engine without sufficient oil can cause serious damage.
4	Check the fuel level. Do not spill fuel when refilling.	Spilled fuel might ignite.
5	Check the air cleaner element.	Clean, if necessary.
6	Pour water into the priming water filler plug.	Otherwise the pump will overheat. Extended dry operation will destroy the pump seal.
7	Turn the fuel valve “ON”.	
8	Close the choke lever (only in cool climate).	The choke is not to be used if the engine is warm or the surrounding temperature high.
9	Turn the engine switch to the “ON” position.	
10	Move the throttle lever slightly to the left.	
11	Pull the starter grip lightly until resistance is felt, then pull briskly. Return it gently to the starter.	
12	As the engine gradually warms up, gradually open the choke.	
13	Set the throttle lever at the desired speed.	
14	Watch if the pump is operating properly and yielding water.	Continuous watching is necessary to avoid running dry.
15	Stop the pump immediately when it runs dry.	Otherwise the pump will overheat and break down.

No	Step	Reasons
16	Move the throttle lever fully to the right (i.e. close it).	
17	Turn the engine switch to the "OFF" position.	To stop the engine in emergency, just turn the engine switch to the "OFF" position
18	Turn the fuel valve "OFF".	
19	After pumping muddy, sandy or salty water, always pump clean water through the pump before storing.	Sediments settling in the pump spoil the impeller.
20	Do not allow the pump to run continuously longer than 2 to 3 hours.	After 2 to 3 hours, the pump needs to cool down, because it has no cooling system with ventilator.
21	Store the pump in a dry, clean place in the shade.	Sun overheats the pump. Rain causes corrosion.

8.28. Submersible Pumps

A submersible pump is a unit consisting of an electrical engine and a centrifugal pump submersed into the water to be pumped.

A) Types of Submersible Pumps

Submersible pumps can be differentiated according to their size, from tiny ones to huge models requiring a very strong power supply. They can also be differentiated according to the type of water they pump. In wells they can serve two purposes:

1. Permanent installation for pumping clean drinking water after the construction is completed (often used for boreholes).

2. Temporary pumping of dirty water for dewatering wells during construction.

The two purposes are different and require different pumps. The first will not be discussed here, because, in rural areas, hand pumps are more appropriate for drinking-water supply in most cases. The second is described in the following.

B) Range of Use

Submersible pumps can be designed for heads between 5 and 150 m. For dewatering wells during construction, they are suitable if the water table is 8 m or deeper.

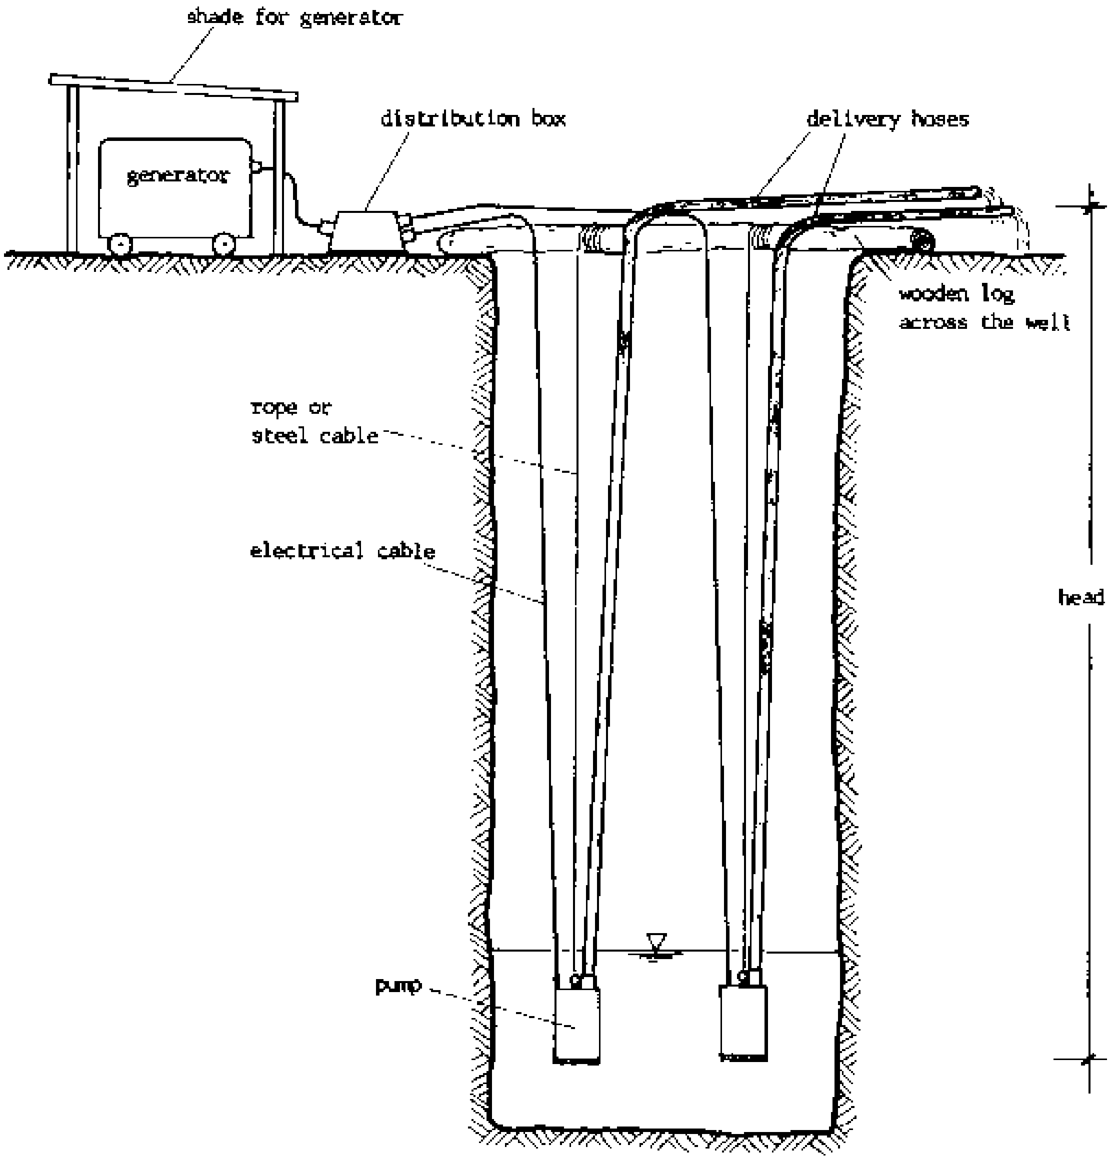
C) Elements of a Pumping System with two Submersible Pumps

A pumping system with a transportable generator and two submersible pumps consists of the elements shown in the drawing next page.

D) Description and Specifications

In the generator, a diesel engine produces rotational movement and turns the axle of the attached generator part. Here, the mechanical energy is converted into electrical energy. The electricity is transported through the electrical cable to the pump in the well. The electrical engine of the pump converts the electrical energy into rotational movement and turns the blades of the attached centrifugal pump. The rotating blades suck in the water through the inlet and press it through the delivery pipe to a higher level (out of the well). As the energy is converted several times and transported through the electrical cable, there are a great number of losses and the efficiency of the system is low. (There are four conversions of energy: fuel - -> mechanical energy = rotation of the generator axle - -> electrical energy - -> mechanical energy = rotation of pump axle - -> water pressure).

Elements of a Pumping System with two Submersible Pumps



Schematic Illustration

The pump in the well always has three connections to the well head:

1. a rope or steel cable bearing the weight of pump and hoses;
2. an electrical cable supplying the energy;
3. a delivery hose or pipe for the water.

When purchasing a submersible pump check the specifications and pay attention to the following aspects:

- The pump must be designed to pump dirty, sandy and muddy water because the water in a well is never sand-free during construction.

- The generator for running the pump must be transportable and strong enough for the pump.

- The pump should be as light as possible for easy handling.

- The diameter of the outlet should be reasonable (between 1” and 2”), otherwise, the delivery hose will be very heavy and difficult to handle.

r dewatering wells are as follows:

- It is suitable for deep wells.
- It is small and can easily be lowered into the well.
- It is able to pump dirty, sandy and muddy water.

The disadvantages are:

- It needs fuel.
- The efficiency is low.
- The equipment is relatively sophisticated and can break down easily.
- Spare parts are difficult to get.
- It requires great care during operation.
- It occupies space in the well.
- Nobody can work in the well while the pump is operating.

In spite of the disadvantages, the submersible pump is often the only option for dewatering (deep) wells.

F) Step-by-Step Procedures to Operate Submersible Pumps

For dewatering wells with two submersible pumps, follow these steps:

No	Step	Reasons
1	Put the generator into the with the shade exhaust away from the well.	Otherwise the generator runs too hot and gets spoiled. Exhaust fumes are dangerous (see 8.22/1,3)
2	Check engine oil and fuel.	If not full, engine oil and fuel need to be refilled.
3	Lower pumps hanging on rope or steel cable connected with the hoses. The pumps should be well submersed, but not stand on the ground. Connect the electrical cables to the distribution box of the generator.	The hose and its joints are not strong enough to carry the pumps’ weight. If standing on ground, the pump will dig itself into the sand and get blocked.
4	Measure and record well diameter and water table.	This is necessary for calculating the discharge of the pump (see 8.34).
5	Start the generator with the crank handle. Remove the handle immediately after the generator has started. Let it run for 3 minutes.	The generator should be warm before loaded with pumping work.
6	Record the time.	see No. 4
7	Switch on the first pump. Listen for a slight change in the sound of the generator. Watch if the pump makes a sudden rotational movement when starting.	If you hear a change of the sound, the generator supplies electricity to the pump. If the pump makes a sudden movement, the impeller started to rotate.
8	Watch if water comes. Switch off if no water comes.	The pumped water has to cool the pump. If running dry, the pump will become hot and can be broken within three minutes.
9	Switch on the second pump.	The generator should not be overloaded with starting both pumps at once, because the pumps need more power during starting than during running.
10	Watch if water comes. Switch off if no	see No. 8.

No	Step	Reasons
	water comes.	
11	No people should be in the water during pumping.	If the pump has a short circuit, the person in the water is in danger.
12	If the top of the pump appears above the water table, lower the pump further.	see No. 8
13	Switch off immediately when water stops to flow. Therefore, watch the pump continuously.	see No. 8
14	Record time, water table and well diameter.	see No. 4
15	Store pumps and generator in dry clean place in the shade and handle them with care.	Sun overheats the machines; rain causes corrosion.

8.29. Drawing Water from a Well for Human Consumption

There are many different ways to draw water from a well for human consumption. Which is the best water drawing device?

There is no "best pump" for all conditions everywhere.

Instead, the most suitable solution must be selected for each area, even for each well, again and again, considering not only technical, but also social aspects.

In the following section, we give suggestions on how to select the suitable method of drawing water for certain conditions. These suggestions are subjective and based on the given criteria and priorities.

A) Criteria for Selecting the Suitable Method

We suggest that the following criteria (= guidelines) should guide our choice of the water-lifting device (in the order of their priority):

1. Protection of groundwater in the long run.

2. Durability, maintenance and repair.

3. Protection of health.

4. Provision of water for the majority of the population.

5. Acceptability by the community.

6. Economic suitability.

On No. 1.:

Protection of groundwater in the long run, i.e. preventing the aquifer from being exhausted, is the first priority. To install a water supply system which draws more water from the aquifer than is recharged by rain or from other sources, means to deceive the users. They will get used to the abundant water supply and plan their activities accordingly, only to get into great trouble when the water table drops. Such installations are also irresponsible for the future generations. The aquifer might not be able to provide a large water supply in the long run, but a limited water supply might be possible for generations. See also 8.8/3f.

On No. 2.:

To consider durability, maintenance and repair is essential, too. The water supply installation must have a realistic chance of being kept-up for years. It is easier to reach a remote place with high-level technology for the short construction period, than to reach it continuously with middle-level technology for running and maintenance. We need to look honestly into the question of whether the infrastructure, the fuel supply, the spare parts' supply and the skilled labour are available to run and maintain the proposed water supply system. Often, the local people in the village are more realistic about the issue than planning personnel and politicians. See also 8.24/2-6.

On No. 3.:

To provide clean and safe water is an obvious criterion (= guideline), although not the first priority. It comes after the two already mentioned. To provide clean water for a short period only is no real improvement for the health situation of the users. The water supply in large areas and for many people is in such a state that the people struggle to get any water rather than good water. This is a sad, but true fact. Under these circumstances, provision of easily available and sufficient quantities of any water is already an improvement, even an improvement in health (enough water for cleaning and washing, less efforts spent on securing the water supply). Providing clean water alone is not sufficient as well, because the general situation, poverty and the level of knowledge might prevent the users from keeping the water clean after taking it from the supply. Therefore, stressing the cleanliness of the water, while the other factors remain untackled, is not enough. See also 8.5 and 8.6.

On No. 4.:

We have to examine exactly who is to benefit from the proposed water system. We suggest as a guideline to try to supply water to the majority of the population, rather than to a minority. It is questionable spending lots of money and resources on high level water supply for a priviledged minority, rather than a lower level water supply for many. See also 8.2.

On No. 5:

The chosen water supply system must be understood and accepted by the users. However, this depends very much on, and can be influenced by, relevant education and community development work. See also 8.38 and 8.39.

On No. 6.:

The system should be within the economic means of the users; if not the installation, then at least the running costs. See also 8.3.

B) Methods of Drawing Water for Human Consumption from Wells

The diverse water-lifting devices are described in 8.24. Those devices suitable for drawing water for human consumption can be arranged into three main groups with variations. These three groups also represent different levels of sophistication:

C) Water-Lifting with Bucket and Rope

The simplest way to lift water with a bucket or another container and rope (see 8.24, No. 1, 2).

1. Advantages

Its advantages are:

- The equipment can be completely local, if necessary, consisting of gourds and ropes from local fibres.

- No outside input is required.

- No maintenance structure is required.

- The method is very reliable.

- No water is going to be wasted because the amount of water pulled is limited.

- Large numbers of animals cannot be watered.(This could also count as a disadvantage). Therefore, overgrazing due to availability of water cannot occur.

2. Disadvantages

The disadvantages are:

- The water is not protected from pollution.
- The amount of water which can be pulled is very limited.
- The depth from which the water can be pulled is limited.
- The method is tiresome and time consuming.

3. Suitability

Drawing water with bucket and rope fulfils guidelines No. 1, 2, 4, and 6. Guideline No. 5 is fulfilled in many cases. Guideline No. 3 is not fulfilled in most cases and improvements are advisable.

Drawing water by bucket and rope is suitable if the infrastructure for hand pump installation, operation and maintenance is not available in the long run. In that case, improve the situation within the given circumstances by

- providing enough wells;
- constructing the wells with a lining and, thus, digging deep into the water table;
- providing an elevated well mouth with a lid;
- providing a proper concrete apron;
- conducting a health education campaign.

D) Water-Lifting with a Hand Pump

Hand operated pumps or other simple devices are the next level of technology for lifting water (see 8.24, No. 3-14, 16-18,22).

1. Advantages

The advantages are

- The well can be sealed and protected from pollution.

- The maintenance is relatively simple and local people might be able to learn it.

- No fuel is required.

- The method is less tiresome for the users than C).

- No water is going to be wasted because the amount of water pumped is limited.

- Large numbers of animals cannot be watered.(This could also count as disadvantage). Therefore, overgrazing due to availability of water cannot occur.

- Greater depth can be reached than with the method under C).

2. Disadvantages

- The pump might be available only from abroad.

- The spare parts' supply must be secured. It might require foreign currency and an organisation to acquire it.

- People able to repair the pump must be available.

- A higher degree of organisation within the community is required than for the method under C).

- The method is more expensive than C).

- Only one person can draw water at a time.

- The depth is limited to 70-80 m, in exceptional cases up to 110 m.

- Some people can try to get control and make private profit from a hand pump on cost of the community.

3. Suitability

Drawing water with a hand pump fulfils the guidelines No. 1 and 4. Guideline No. 2 is fulfilled if the infrastructure for maintenance is available. Guideline No. 3 is fulfilled if the well is properly constructed and the platform has no cracks. Guideline No. 5 depends on information and health education. Guideline No. 6 depends on the resources of the community.

To achieve water supply by hand pump is a goal for all rural communities and many urban communities.

Install a hand pump only if

- operation and maintenance can be secured in the long run;
- the community is organised to take the responsibility of the pump;
- women are being trained for hand pump caretaking and repair;
- there are enough resources to construct the well head properly;
- the hand pump can be installed properly; When installing a hand pump, take care
- to provide enough wells;
- to conduct a health education campaign;

Do not install a hand pump if maintenance cannot be secured in the long run.

Water-Lifting with Fuel Powered Pumps into an Elevated Tank

This method is considerably more sophisticated than the two before. The water is pumped into an elevated tank from where it is supplied in pipes either directly to households or to public taps (see 8.24, No. 20, 23, 27-29, 31,32).

1. Advantages

The advantages are

- The well can be protected from pollution.
- Water can be pumped from greater depths than by methods C) and D).
- Piped water supply becomes possible.
- The method is less tiresome for the users than methods C) or D).

2. Disadvantages

The disadvantages are

- The pump and other parts of the installation most likely come from abroad.

- A constant supply of fuel is required.

- The spare parts' supply must be secured, most likely from abroad.

- Highly skilled people are required for installation and maintenance.

- Skilled labour is required for the daily running.

- A structure is required to organise installation, supplies and maintenance.

- The costs are very high.

- Waste of water is very likely.

- There is a danger of exhausting the aquifer and of lowering the water table in the long run.

- Overgrazing and desertification are possible if a large number animals are attracted by the well.

3. <u>Suitability</u>

Water supply by fuel powered engine pump and elevated tank should fulfil guideline No. 3. Whether the method fulfills the other guidelines, depends on the situation and has to be questioned.

Water supply by fuel powered engine pumps and elevated tanks is not a reachable goal for all rural communities, and is a reachable goal for some urban communities.

Install such a system only if

- it does not exhaust the groundwater in the long run;

- operation and maintenance can be secured in the long run;

- fuel supply can be secured in the long run;

- no flush latrines are to be supplied by the system and, thereby, large amounts of water wasted; see also 8.37/7 and 9.8/2;

- the community is organised to take responsibility for the system;

- women are being trained for operation and maintenance;

- the community can afford the system;

- the system is safeguarded against being exploited by a few people;

- you have to supply densely populated town areas with public taps

When installing this system, take care to conduct a health education campaign. Do not install this system at all in scarcely populated rural areas with many animals because of the danger of overgrazing and desertification.

8.30. Hand Pump Parts and Functions

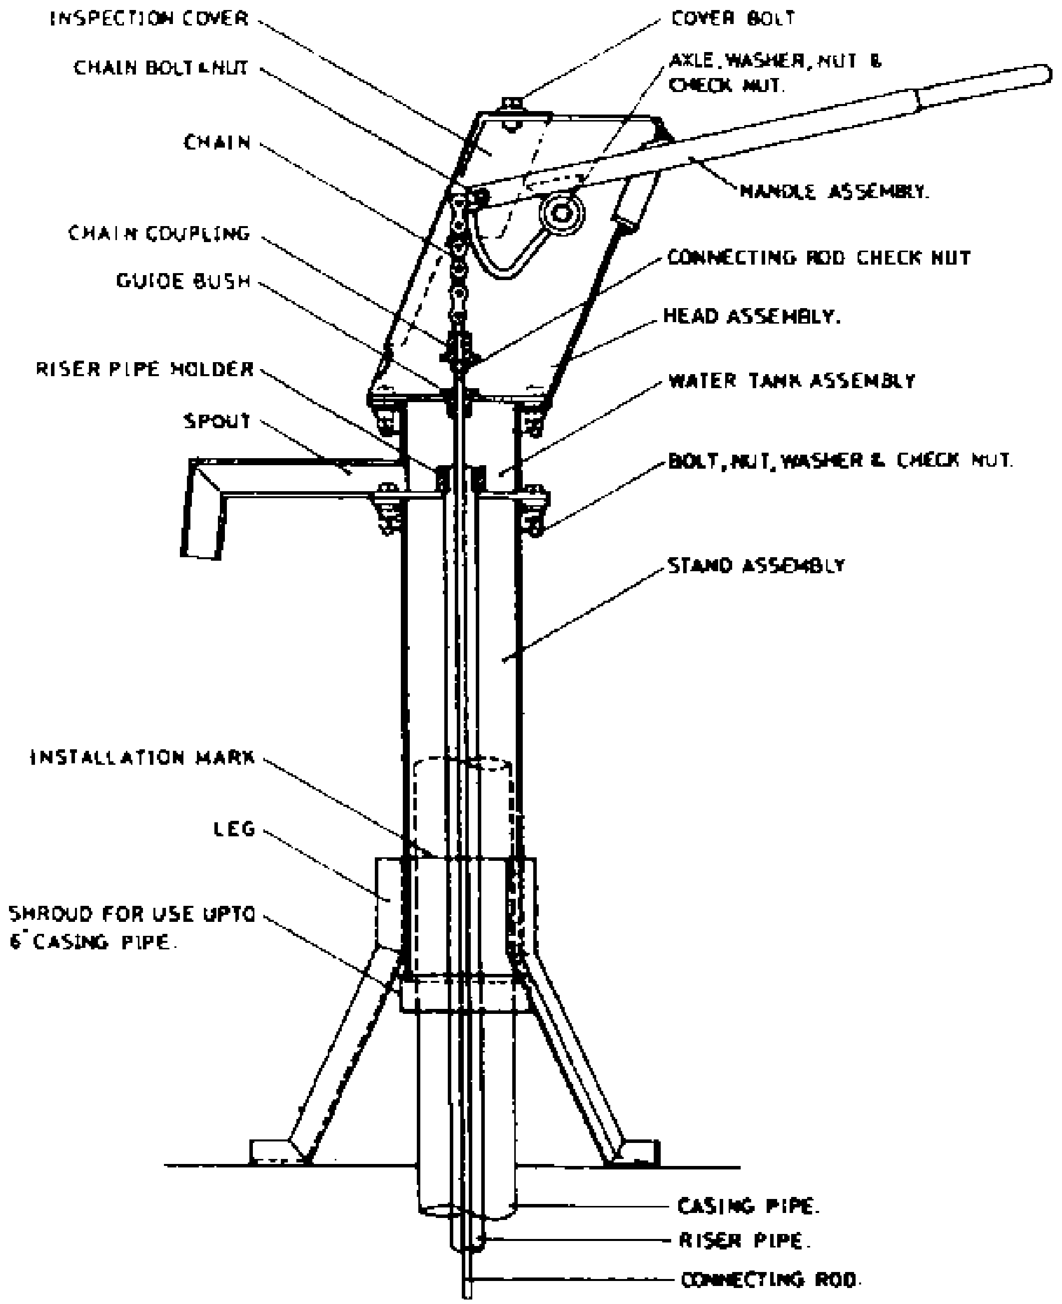
It is very important for a technician to know the names of the parts of a hand pump and to understand their functions. This background knowledge will enable her/him to understand why the hand pump has to be installed and repaired in a certain way.

The parts and functions are explained here for the INDIA MARK II hand pump; other hand pumps of a similar type consist of principally the same parts. The different types of handpumps are explained in detail in No. 18 of the bibliography.

A) Parts of Pump Head Assembly

For learning about the parts of a hand pump, disassemble a pump and get familiar with the parts.

CROSS-SECTION

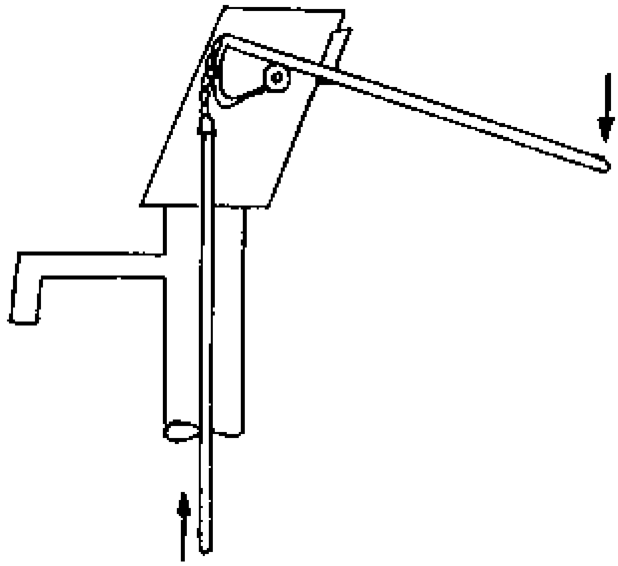


B) Function of Pump Head Assembly

The operation of a hand pump has two distinct and opposite phases:

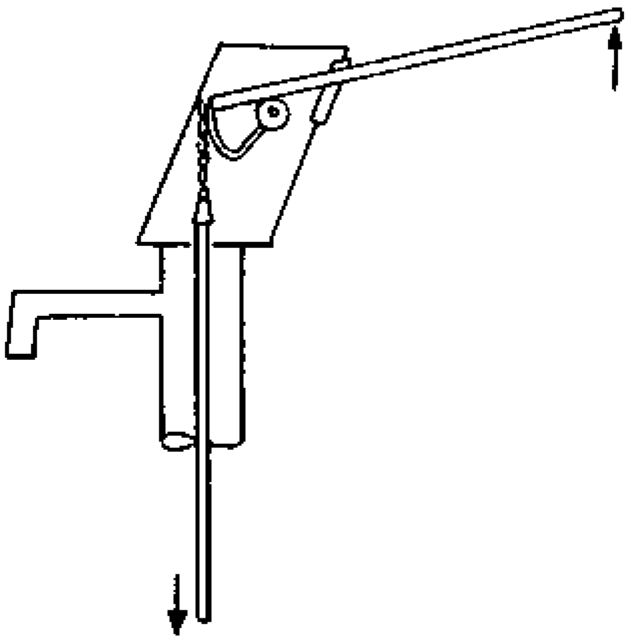
1. Phase

- handle moving downwards
- rod moving upwards



2. Phase

- handle moving upwards
- rod moving downwards



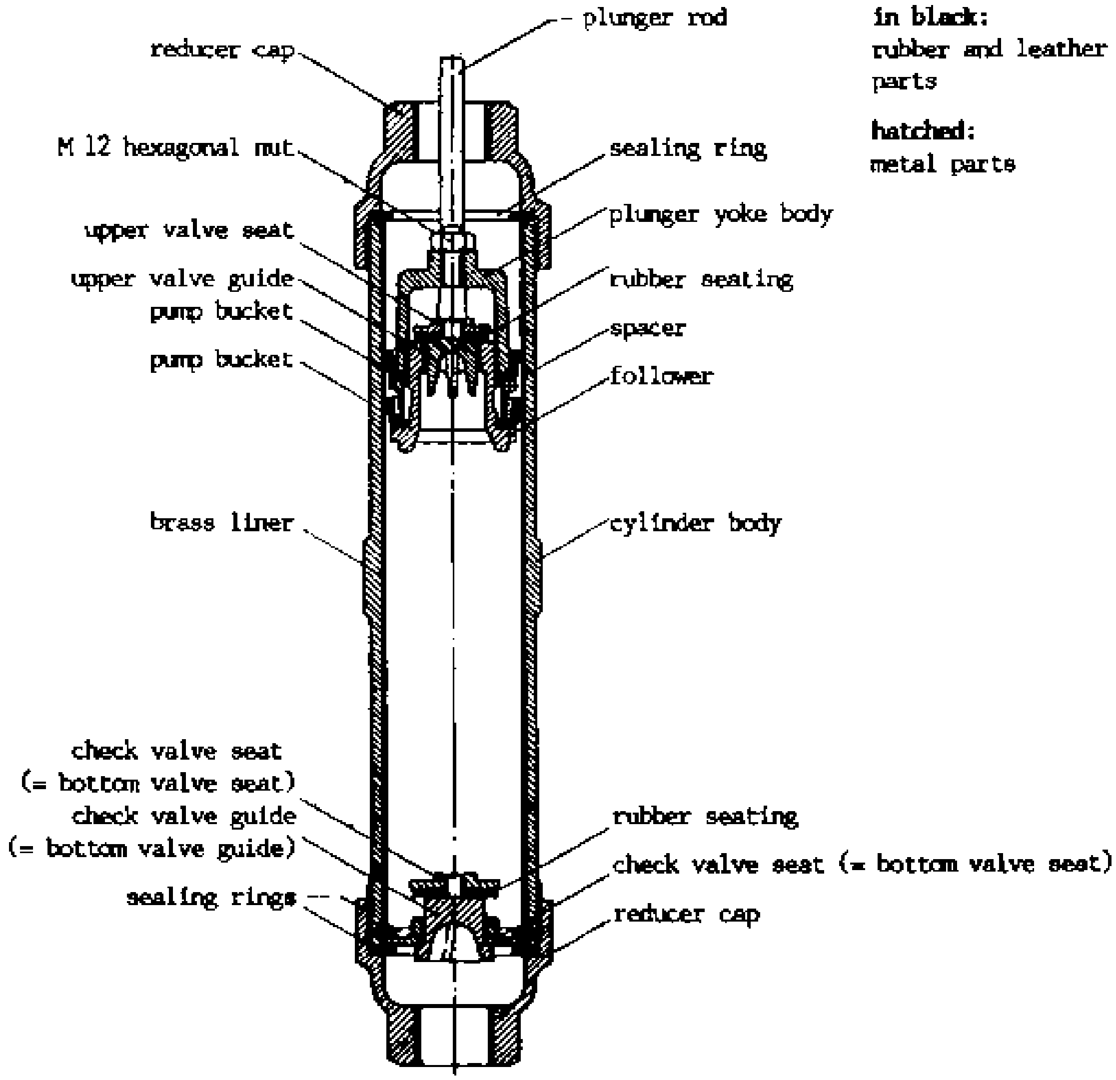
UP and DOWN movement of handle results in DOWN and UP movement of rod.

The pump head assembly, as shown here, has a chain link. The rod is lifted by an active downwards stroke of the handle. The rod moves downwards and, thus, lifts the handle by itself because the weight of all the rods together overcomes the friction and the weight of the handle. This is the case if the pump cylinder is installed at about 20 m or deeper.

If the cylinder is installed in a depth less than that, the weight of the rods is not enough, and the flexible chain cannot push the rods down. In that case, a solid link is required between the handle and the rod so that the upward movement of the handle can push the rod downwards. The disadvantage of the solid link connection is that there will be a slight lateral (= horizontal) movement of the rod with each stroke. The pump head with solid link is suitable for wells up to 20-25 m depth.

C) Parts of the Cylinder Assembly

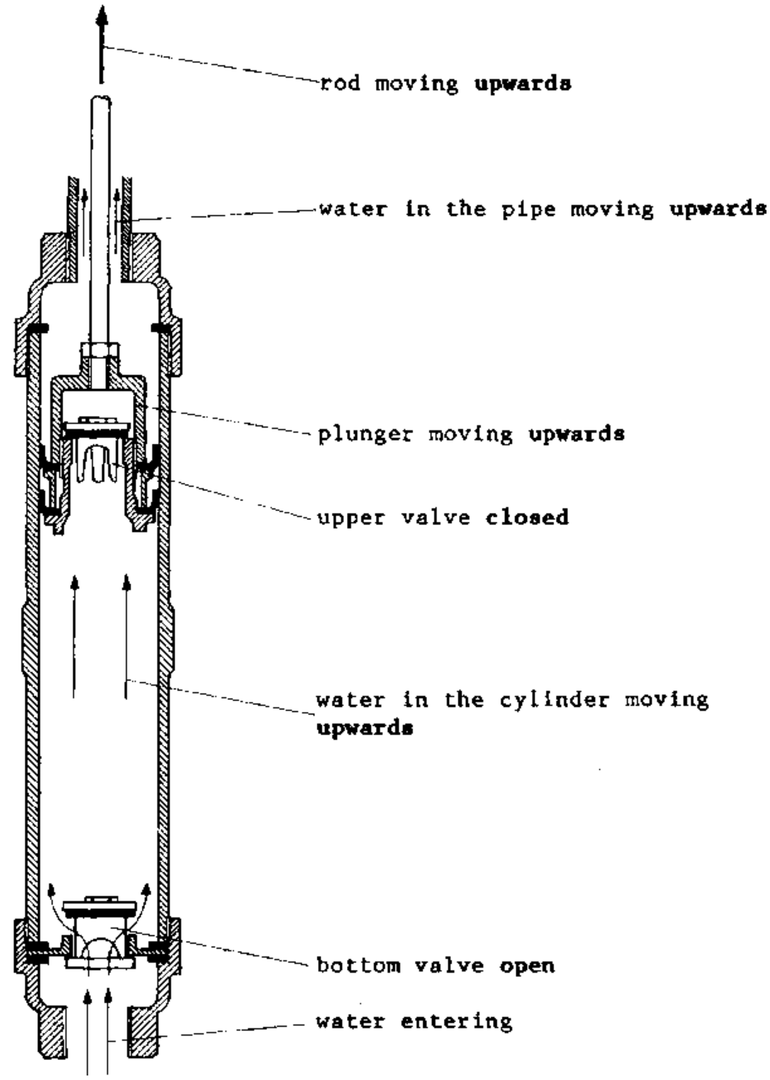
Disassemble a pump cylinder and get familiar with its parts:



D) Function of the Cylinder Assembly

The cylinder operates in two distinct phases as well:

1. Phase

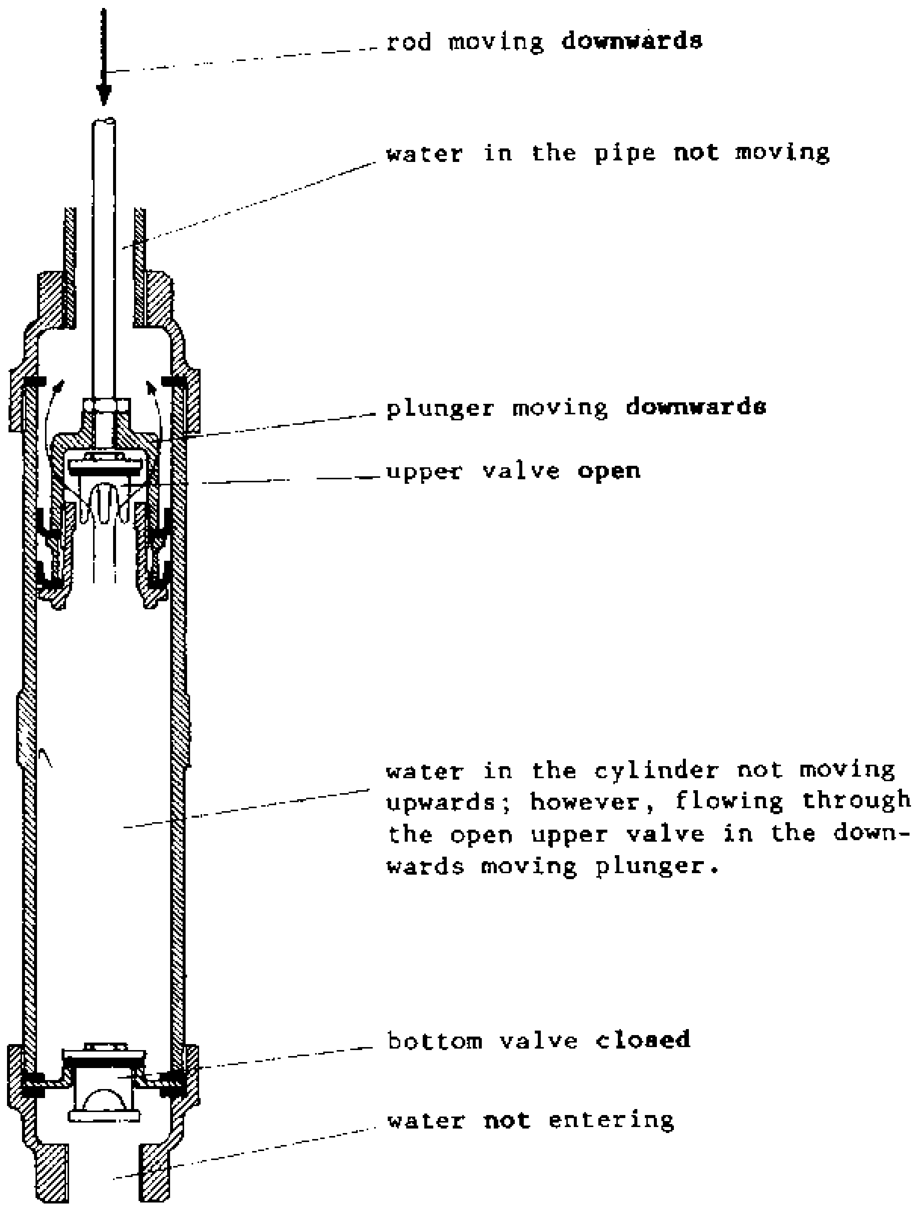


Schematic Illustration; some details left for sake of clarity; valves in side-view.

How do the valves open and close?

1. The water in the pipe tries to move downwards by gravity → This closes the upper valve. 2. The plunger moving upwards creates suction → This opens the bottom valve.

2. Phase

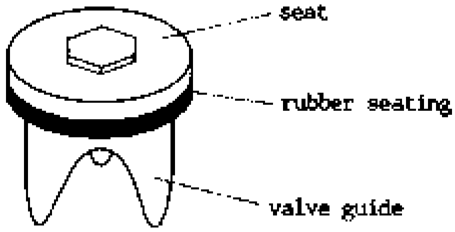


Schematic Illustration: sane details left for sake of clarity; valves in side-view.

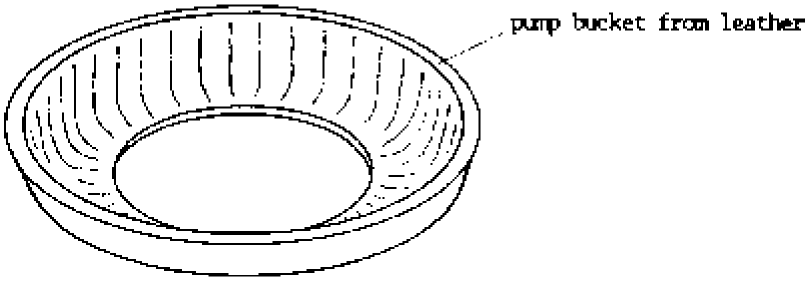
How do the valves open and close?

1. The water in the cylinder tries to move downwards by gravity → This closes the bottom valve. 2. Rod and plunger are moving downwards → The resistance of the water in the cylinder opens the upper valve.

The two valves open and close alternately and, thus, the water is lifted in steps (not continuously!). The valve (consisting of seat, rubber seating, and valve guide) moves up and down (open and closed). It is essential that the valves close watertight. This is ensured by the rubber seatings of the valves which must be intact.



The pump buckets (= leather cups) provide the watertight sealing between the plunger moving up and down, and the inner wall of the cylinder (with a brass liner). Although the pump buckets seal, they allow the plunger to move. If the pump buckets are worn out, the sealing will not be complete and the yield of the pump will decrease. The pump buckets are the parts which usually wear out the quickest, especially, if there is sand in the cylinder due to improper installation. They need to be replaced regularly.



8.31. Hand Pump Installation

There are specific manuals for each type of hand pump, published by the manufacturers (e.g. No. 22 in the bibliography for the India Mark II hand pump). Follow the steps of the manual when installing or repairing a hand pump. Some general principles, valid for all kinds of different pumps, are compiled here.

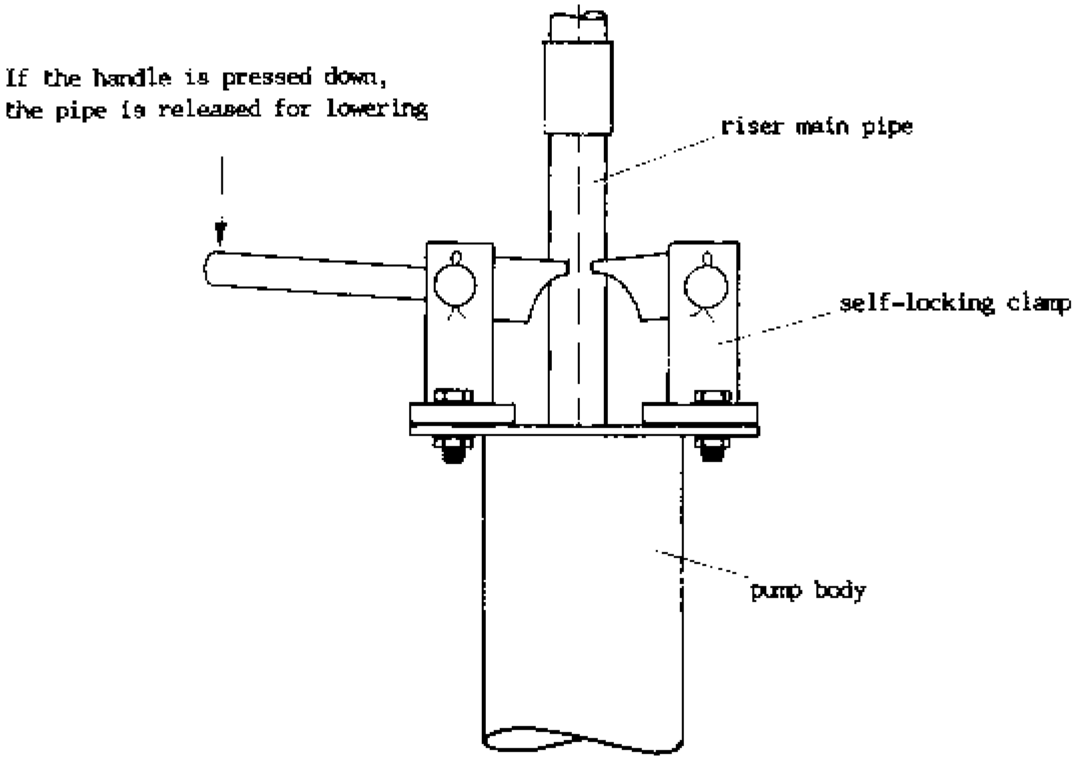
A) Lowering and Lifting the Riser Main Pipe

During installation and repair the riser main pipe (= rising main = = rising pipe) has to be lowered into and lifted from the well. This can be done in different ways depending on the depth of the well.

1. Blocking the Riser Main Pipe

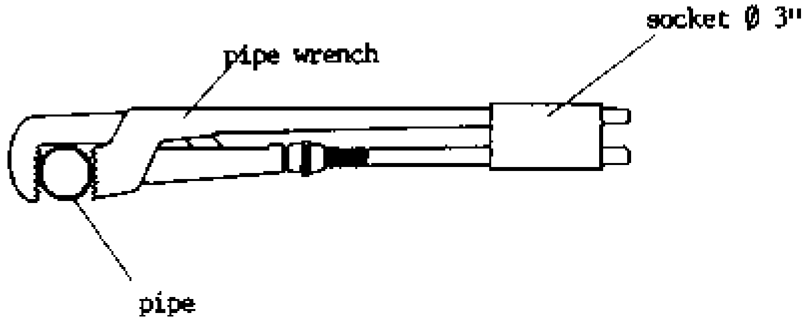
While lowering the riser main pipe, one must stop in between to join the next following pipe. For this operation, the riser main pipe must be blocked temporarily. This can be done

- by a special self-locking clamp,



- by an ordinary pipe vice (see 6.3/34), laid across the pump body,

- by pushing a socket (9 3" over the two handles of a pipe wrench (6.3/34)



In any case, make sure that a socket is fixed to the top end of the riser main pipe. This is an extra precaution.

The lowering itself can be done by one of the following methods:

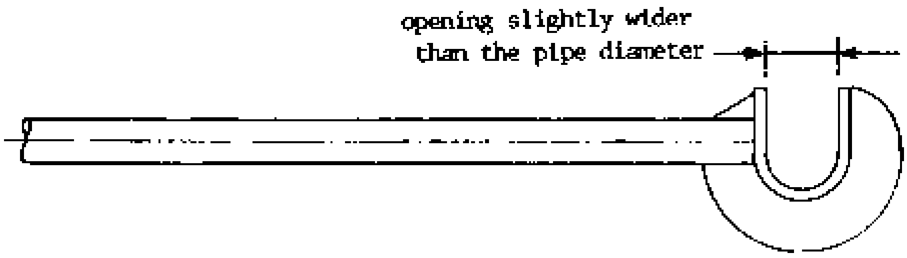
2. Lifting by Hand

For very shallow wells (up to about 10

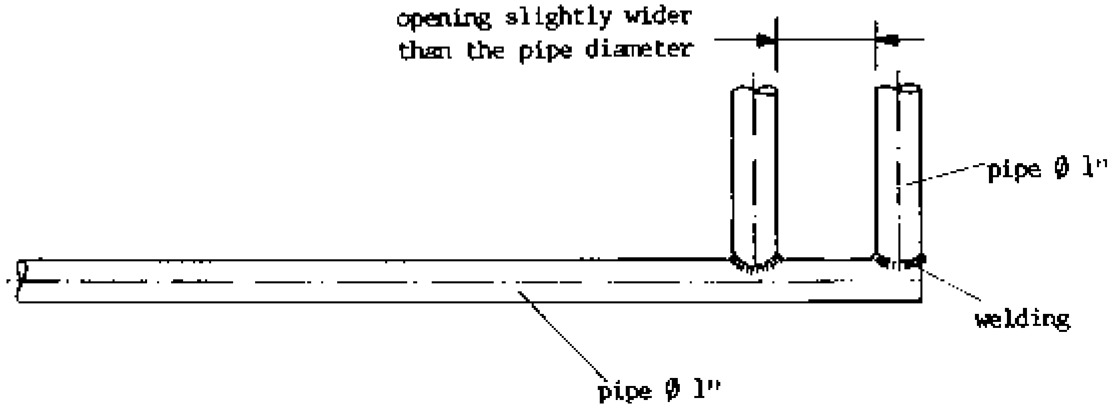
m) the riser main pipe (together with the cylinder and the rods) can be lifted by hand directly. Enough and well coordinated people are necessary for that.

3. Lifting by Lifting Spanners

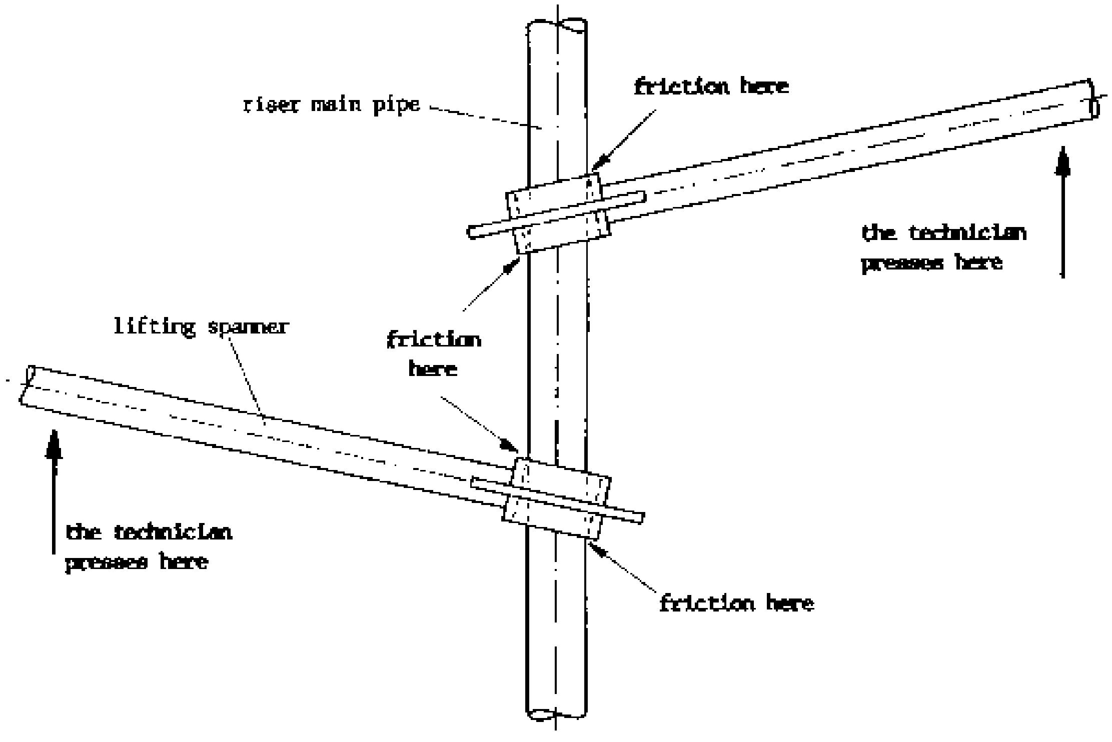
For medium depth wells (up to 35-40 m), the pipes can be lifted with 3 to 4 lifting spanners which hold the pipe by friction and provide an advantageous lever arm.



Lifting spanners can also be manufactured locally from metal pipe Ø 1”



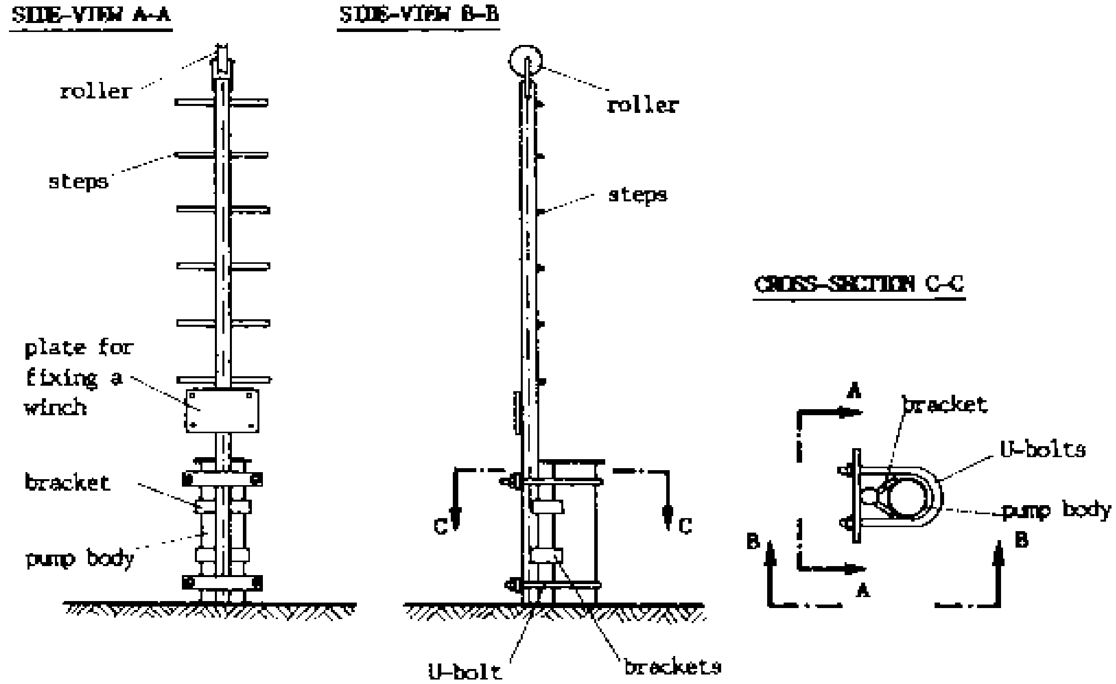
The technicians place the lifting spanners around the riser main pipe and get hold of it by pressing the handle upwards. They must be well coordinated.



4. <u>Lifting with Lifting Spanners and Simple Scaffold</u>

For deep wells, lifting with lifting spanners can be made easier with a scaffold made from a pipe Ø 2” with steps. This scaffold is fixed to the pump body with U-bolts. A technician at the top can easily direct the pipes while lowering or lifting.

Design: Norwegian Church Aid - Sudan Programme, Torit, Sudan



Additionally, a small winch can be fixed on the scaffold and the steel cable directed over a roller on the top.

5. Lifting with Tripod, Winch and Steel Cable

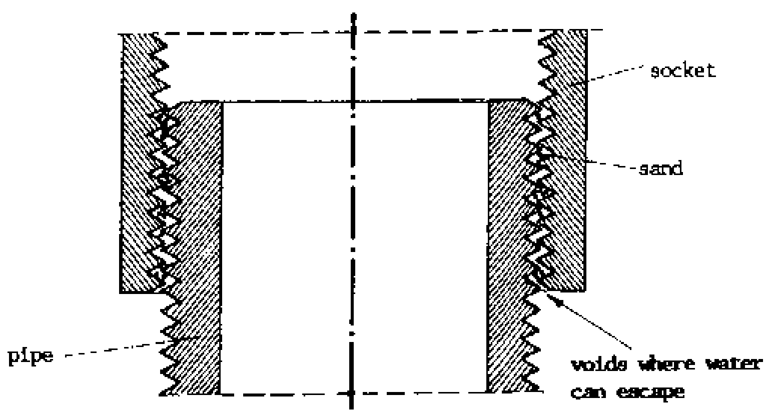
It is difficult to lift pipes from depths more than 40 m. In this case a light weight tripod (see 8.17/13) and a small winch can help. The riser main pipe is fixed to the steel cable with a chain pipe vice (see 6.3/34).

B) Tightening the Joints of the Riser Main Pipe

Watertight joints of the riser main pipe are essential, otherwise the yield of the pump will decrease. Tight joints can be achieved with the following measures:

1. Clean all threads with a wire brush and lay the pipes on two pieces of timber, not directly on the ground. The threads must be completely sand-free when you join them. Sand on the thread prevents the thread from fully closing, and thus causes leakage. Constant leakage causes corrosion, and the pipe is likely to break sooner at the thread.

CROSS-SECTION TROUGH JOINT WITH SAND



2. Smear jointing compound on the thread or cover the thread by thread-tape before tightening. This materials fill the tiny voids between the threads and make the joint watertight.

3. Tighten all joints properly, but do not overdo it. Handle the pipe wrenches as described in 8.32/14.

C) Handling the Pump Rods

Handle the pump rods as follows:

1. Clean the threads of all pump rods.

2. Grease the threads if they are corroded.

3. Take great care not to bend a pump rod.

4. Do not install any bent pump rod.

5. Tighten the joints of the rods properly.

6. Hold the rod by a rod-vice when you cut it to length, to avoid bending.

7. When threading the pump rod, prevent cuttings from falling into the riser main pipe by a piece of cloth (cuttings quickly wear out the pump buckets).

D) Handling the Pump Cylinder

Handle the pump cylinder as follows:

1. Check it before you install it even if it is new.
2. Open the cylinder and the plunger and tie all elements properly.
3. Tighten the valve seats, but do not squeeze the rubber seatings.

E) Handling the Pump Head

Handle the pump head as follows:

1. Only untie the pump head as much as necessary for installation. Do not dismantle axle and handle unnecessarily.

2. Grease the chain properly.

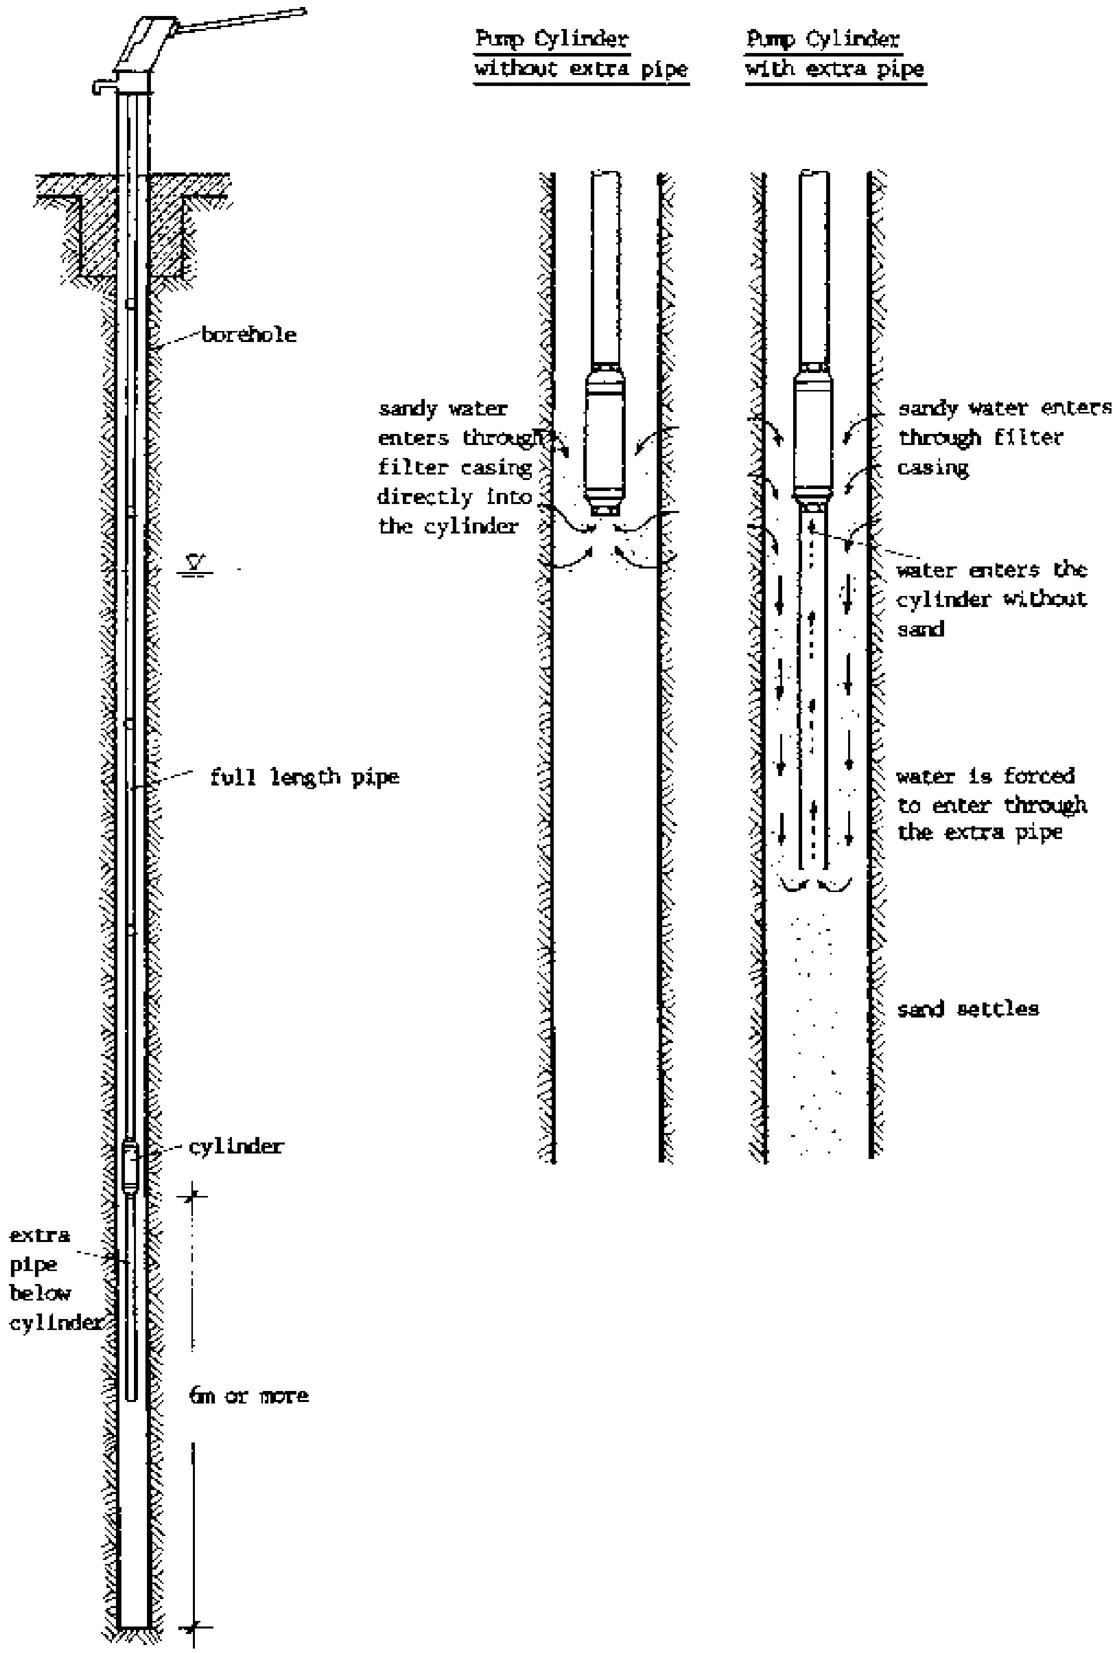
3. Grease the threads of all outside bolts and nuts to prevent corrosion due to rain. Thus it will be easy to open them any time.

F) Locating the Pump Cylinder

The cylinder must be installed at different positions in a borehole and in a hand dug well.

1. Pump Cylinder in a Borehole

The bottom of a borehole is not closed with a filter. Therefore, never install a cylinder in a borehole less than 6 m from the bottom of the borehole. Apart from that, install in a borehole a number of full length (3m) pipes, because it does not matter if the cylinder is higher or lower by 1 or 2 m as the water column is normally high. Join an extra pipe to the bottom of the cylinder. This forces the water to enter through the pipe. Eventually, sand would settle and clean water will enter the cylinder.



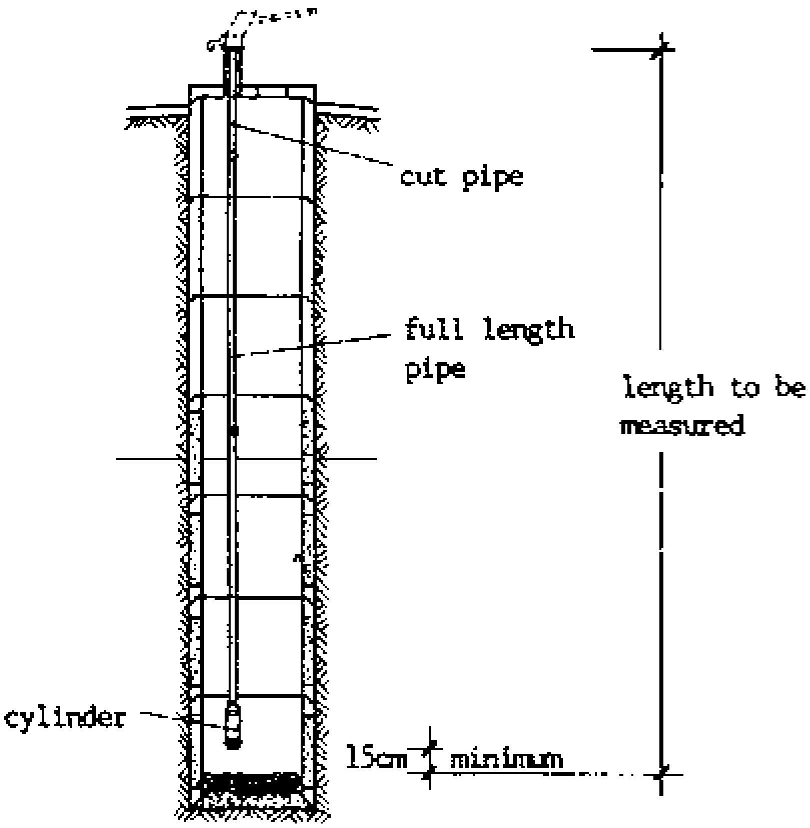
Schematic Illustration

2. <u>Pump Cylinder in a Hand Dug Well</u>

The water column in a hand dug well is limited and, therefore, the cylinder has to be installed as deep as possible to utilize the water reservoir fully.

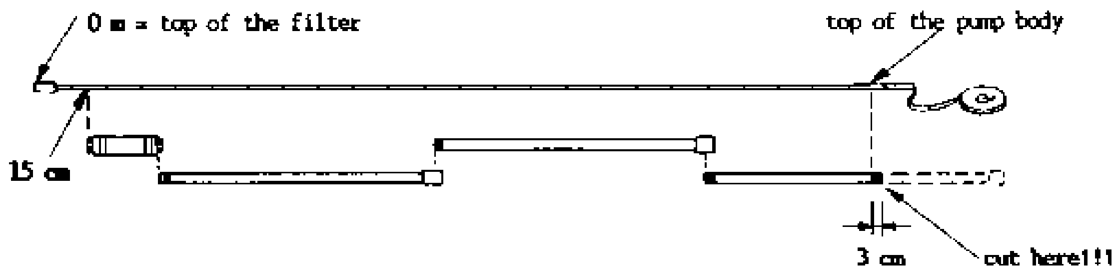
There must be a filter in the well bottom (see 8.20/1f). Install the cylinder so that its bottom is about 15-20 cm above the top of the filter. This will most probably require cutting and threading of one riser main pipe. To get the correct length, you can proceed as follows:

- Measure the distance between the top of the pump body and the top of the filter with a plumb loaded measuring tape.



SCALE 1:80

- Lay the measuring tape on flat ground. Lay the pump cylinder and the pipes with sockets beside it. Overlap them according to how they will be tightened. Leave 15 cm for the gap between filter and cylinder. Add 3 cm for the thread connection with the water tank.



Not to scale!

- Mark where you have to cut the last pipe.

Be very careful when determining the length of the last pipe. Too short means that you waste a part of the water reservoir and the pump might unnecessarily run dry during dry season. Too long means that the cylinder might sit on the filter. By the method above you are less likely to make mistakes than by calculation.

8.32. Basic Plumbing

Plumbing is the installation and repair of pipe systems for water supply (or other purposes), like a hand pump or the water distribution system in a house. The most basic knowledge about plumbing is compiled here.

A) Threads

The different types of threads for both bolts/rods and pipes are described and compared in the following chapters.

1. Thread Types

Threads can be differentiated according to six pairs of opposites:

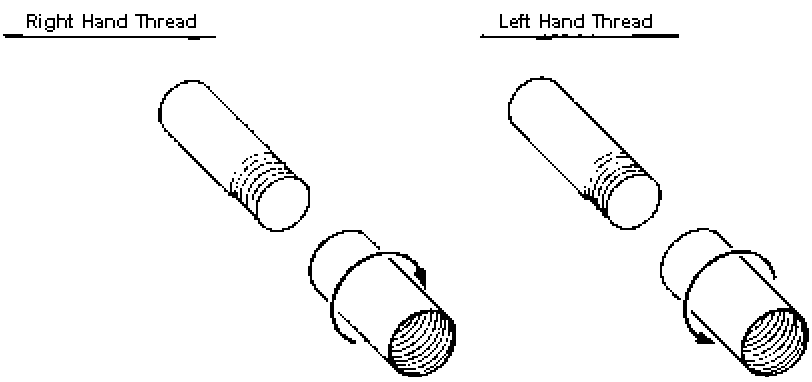
a) Internal/External Threads

Name(s)	Internal Thread = Female Thread	External Thread = Male Thread
drawing		
thread cutting operation	to cut a thread = to tap a thread	to cut a thread
tool for thread cutting	tap	die
handle of thread cutter	tap wrench	die stock = die handle

Internal and external threads of the same size fit together and can be screwed together to form a joint.

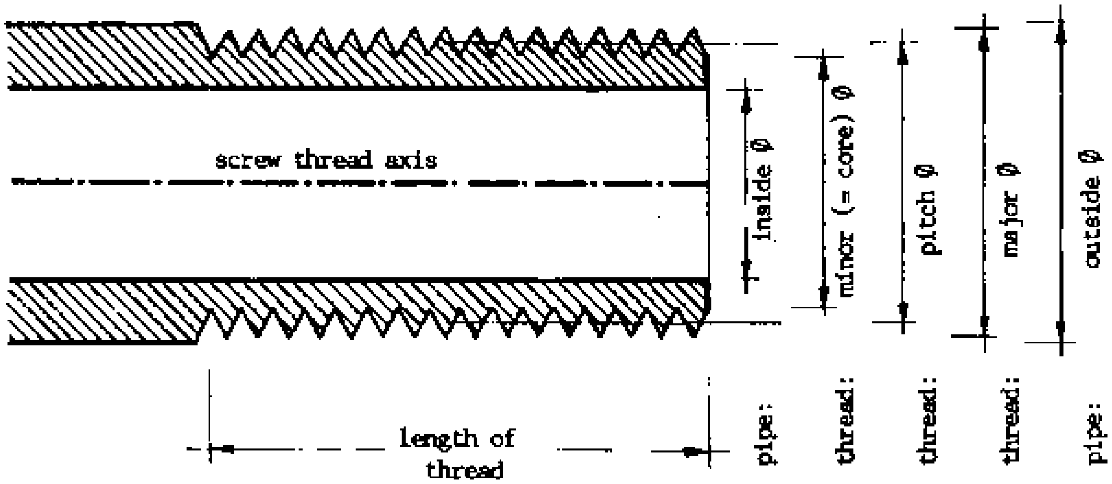
b) Right Hand/Left Hand Threads

Right hand threads are tightened clockwise, left hand threads opposite (= anti-clockwise). Right hand threads are usually used, left hand threads are not common.

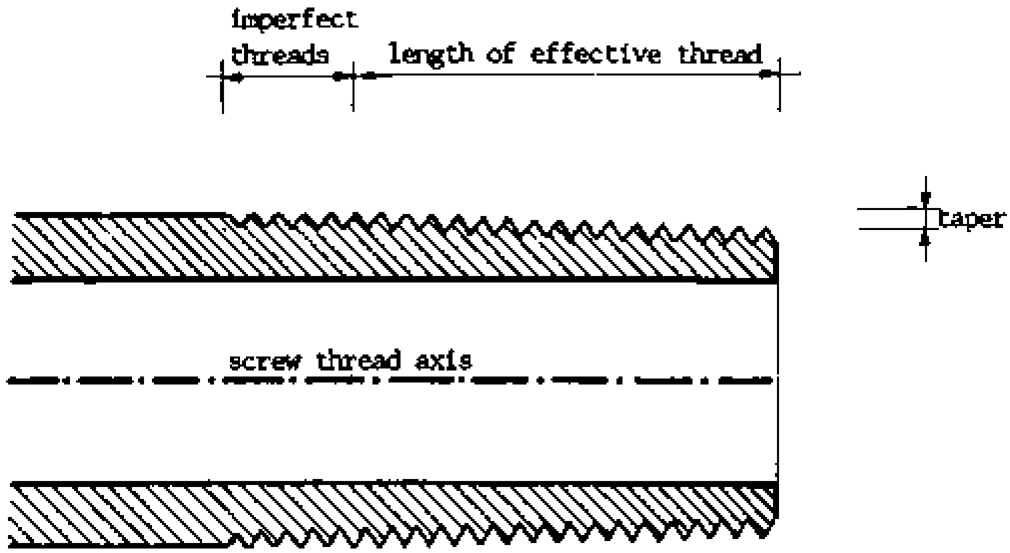


c) Parallel/Taper Threads

A parallel thread (= cylindrical thread = straight thread) has the same diameter from beginning to end. The threads look clearly cut all over.



A taper thread (= tapered thread = conical thread) is growing gradually smaller towards one end like a cone. The slope of the thread is the taper/length of thread, e.g. 1:16. A taper thread can easily be recognized because it looks imperfect at the end.



Bolts and nuts have always parallel threads to ensure maximum transmission of force along the full length. Pipes can have parallel or taper threads. Tapered pipe threads are much more common, because they are easily tightened watertight to avoid leakage. Tapered pipe threads do not have a high resistance against bending. In emergency cases, a tapered thread can be screwed to a parallel thread of the same size, but the joint will not fit exactly.

d) Coarse/Fine Threads

Coarse threads have fewer threads per inch than fine threads. Coarse threads are more common, fine threads can transmit more force. Whether a thread is coarse or fine is indicated either by the pitch or the number of threads per inch (= TPI).

The pitch is the distance between two threads and indicates how dense the total thread is (see drawing next page).

Metric threads are marked by their pitch:

$$\text{pitch (in mm)} = \frac{1}{\text{No. of threads per mm}}$$

For threads in inches, the following is valid:

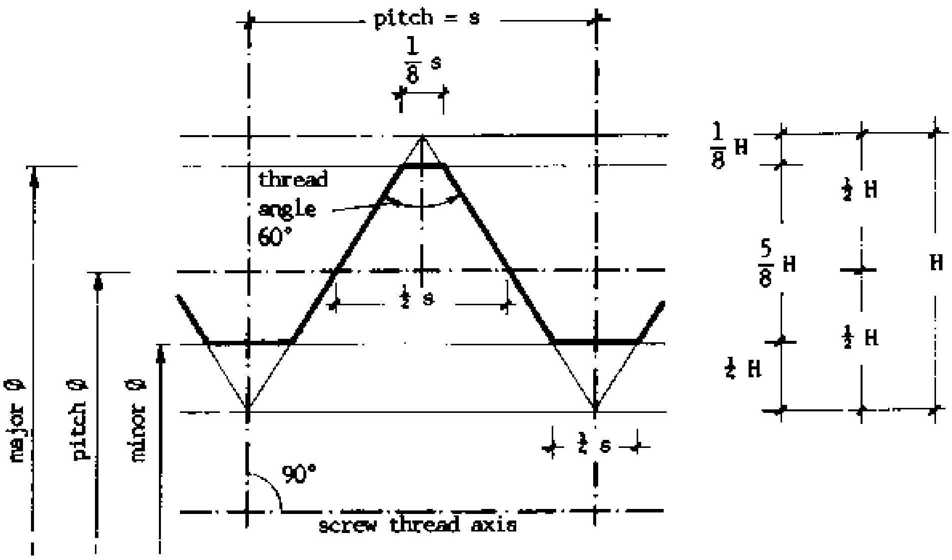
$$\text{pitch (in inch)} = \frac{1}{\text{No. of threads per inch}} = \frac{1}{\text{TPI}}$$

For threads in inches, the TPI is indicated.

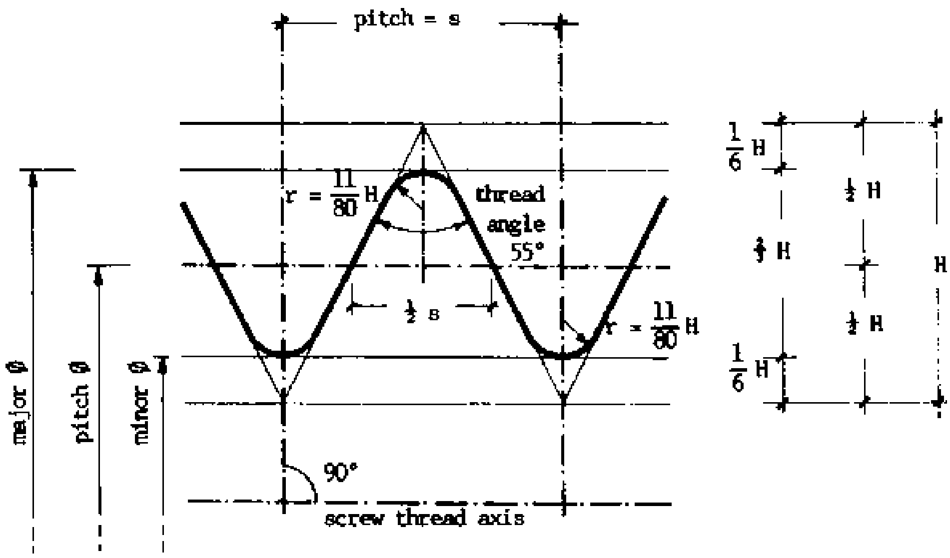
e) <u>Threads with Sharp Edged Profile/Threads with Rounded Edged Profile</u>

Threads can be cut with either sharp edges or with rounded edges:

Sharp Edges



Rounded Edges



Sharp edges are more common. Threads with rounded edges are stronger, but uncommon.

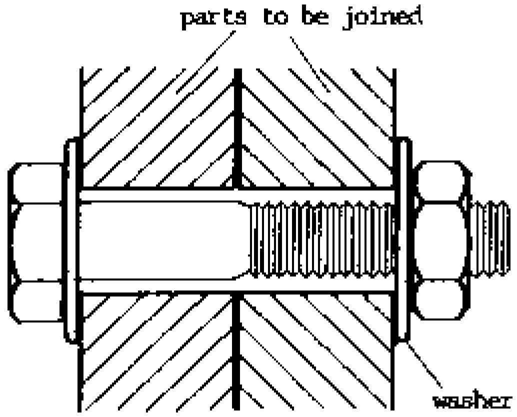
f) <u>Threads for Bolts and Nuts/Threads for Pipes</u>

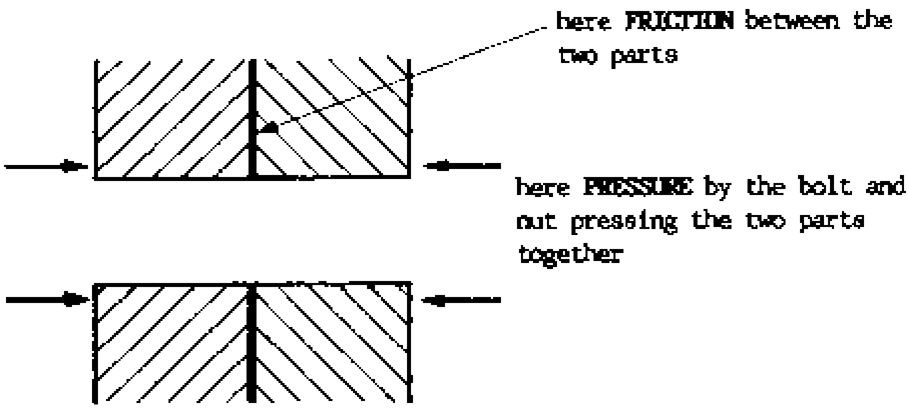
Threads can be categorized in two main groups: threads for bolts and nuts (and rods), and threads for pipes. Within the two groups a variety of different threads exists according to different countries and traditions. The main thread types are listed on the following pages.

2. <u>Thread Standards for Bolts and Nuts</u>

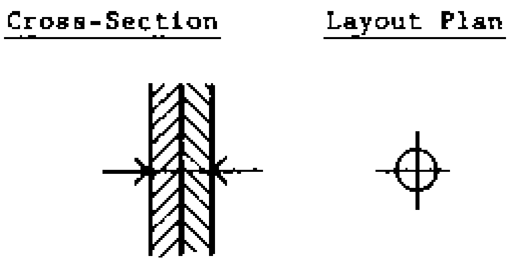
The purpose of a bolt is to press the objects between the nuts together and to connect them thus by friction. A bolt has to transmit force.

The two parts joined together are shown in Cross-Section, bolt and nut are shown in Side-View;





Sometimes, the following signs are used for a bolt and nuts:



See also 6.1/17,19,23.

The function of the washer is to prevent the nut from getting loose.

Threads for bolts and nuts are both internal (on the nut) and external (on the bolt). Threads for bolts and nuts are mostly right hand, but left hand threads can be found, too.

Threads for bolts and nuts are always parallel.

Thus, maximum force can be transmitted along the full length of the thread; the thread is exactly fitting.

Threads for bolts and nuts can be coarse or fine; they can have sharp or rounded edges.

The following thread types are used for bolts and nuts (for sizes see thread tables):

a) Metric Coarse Threads M

- thread for bolts and nuts;
- measured in metric system in mm;
- specification (example):

M 10 × 1.5 (= major Ø in mm × pitch in mm)

- both internal and external threads;
- mostly right hand threads; left hand threads uncommon;
- always parallel thread;
- coarse thread;
- sharp edged profile with 60°: 
- common in Sudan and on the European continent; uncommon in USA and Britain.

b) Metric Fine Threads M

- thread for bolts and nuts;

- measured in metric system in mm;

- specification (example):

M 10 × 0.75 (= major Ø in mm × pitch in mm), or MF 10 × 0.75

Note that some diameters can possibly have different pitches, e.g. there are three different fine threads with Ø 10:

M 10 × 0.75
M 10 × 1
M 10 × 1.25

- both internal and external threads;
- mostly right hand threads; left hand threads are uncommon;
- always parallel thread;
- fine thread;
- sharp edged profile with 60°: 
- common in Sudan and on the European continent; uncommon in USA and Britain.

c) Unified Coarse Threads UNC

- thread for bolts and nuts;
- measured in inches;
- specification (example):

UNC No. 12 7/32 × 24, or

UNC $\frac{1}{2}$ × 13 (= thread Ø in inch × thread per inch [TPI])

- both internal and external threads;
- mostly right hand threads; left hand threads uncommon;
- always parallel thread;
- coarse thread;
- sharp edged profile with 60°: 
- common in USA and Britain; less common in Sudan; uncommon on the European continent.

d) Unified Fine Threads UNF

- thread for bolts and nuts;
- measured in inches;
- specification (example):

UNF No. 12 7/32 × 28, or

UNF $\frac{1}{2}$ × 20 (= thread Ø in inch × thread per inch [TPI])

- both internal and external threads;
- mostly right hand threads; left hand threads uncommon;
- always parallel thread;
- fine thread;
- sharp edged profile with 60°: 
- common in USA and Britain; less common in Sudan; uncommon on the European continent.

e) Whitworth Coarse Threads W

- thread for bolts and nuts;
- measured in inches;
- specification (example):

W $\frac{1}{2}$ × 12 (= thread Ø in inch × thread per inch [TPI])

Note that the diameters are the same as for UNC, but the TPI can differ sometimes;

- both internal and external threads;
- mostly right hand threads; left hand threads uncommon;
- always parallel thread;
- coarse thread;
- round edged profile with 55°: 
therefore very strong;
- up to very large diameters (4”);
- common in Britain; uncommon in other places.

3. Thread Standards for Pipes

The purpose of a pipe thread is to join two pieces of pipe in such a way that the transported fluid or gas does not leak. Watertightness or airtightness are more important than strength.

Pipe threads are both internal (in the socket) and external (on the pipe). They are mostly right hand, left hand only in exceptional cases.

Pipe threads can be both parallel and taper. Tapered pipe threads are much more common because of their water tightness and they are required for water and gas installations. When buying thread cutting tools, you have to indicate if you want parallel or taper pipe threading tools.

Pipe threads are mostly coarse, fine pipe threads are very rare. Pipe threads can have sharp edged and round edged profiles.

The following pipe threads are most common (for sizes see thread tables):

a) Whitworth Parallel Pipe Threads BSP

- thread for pipes;
- measured in inch;
- specification (example):

BSP R $1\frac{1}{4}$ × 11, parallel (= nominal Ø in inch × thread per inch [TPI]), or

BSP R $1\frac{1}{4}$, parallel, or

R $1\frac{1}{4}$, parallel, or

R $1\frac{1}{4}$, DIN 259 z (= German specification)

BSP stands for British Standard Pipe. The figure given is the nominal diameter in inch; it is neither the internal nor the external diameter of the pipe. The number of threads per inch (TPI) needs not to be indicated, because for each nominal diameter only one TPI is possible.

- both internal and external threads;
- mostly right hand threads, left hand threads only in exceptional cases;
- coarse thread;
- round edged profile with 55°: 
- common in Sudan and Europe, but less common than tapered pipe threads.

b) Whitworth Taper Pipe Threads BSP

- thread for pipes;
- measured in inch;
- specification (example):

BSP R $1\frac{1}{4}$ × 11, taper (= nominal Ø in inch × thread per inch [TPI]), or

BSP R $1\frac{1}{4}$, taper, or

R $1\frac{1}{4}$, taper, or

R $1\frac{1}{4}$, DIN 2999 k 1:16 (= German specification)

see also 8.32/9;

- both internal and external threads;
- mostly right hand threads; left hand threads only in exceptional cases;
- coarse thread;

- round edged profile with 55°: 
- very common for pipe threads in Sudan and Europe?

c) (American) National Parallel Pipe Threads NPSF

- thread for pipes;
- measured in inch;
- specification (example):

NPSF $1\frac{1}{4}$, or

NPSF $1\frac{1}{4} \times 11.5$ (= nominal Ø in inch × threads per inch [TPI])

see also 8.32/9; the TPI of the NPSF pipe thread is different from the TPI of a BSP pipe of the same diameter;

- both internal and external threads;
- mostly right hand threads; left hand threads only in exceptional cases;
- parallel thread;
- coarse thread;

- sharp edged profile with 60°: 
- common in USA.

d) (American) National Taper Pipe Threads NPT

- thread for pipes;
- measured in inch;
- specification (example):

NPT $1\frac{1}{4}$, or

NPT $1\frac{1}{4} \times 11.5$ (= nominal Ø in inch × thread per inch [TPI])

see also 8.32/9 and 10;

- both internal and external threads;
- mostly right hand threads; left hand threads only in exceptional cases;
- taper thread;
- coarse thread;

- sharp edged profile with 60°: 
- common in USA.

4. <u>Pipe Measurements</u>

Pipes are indicated by the diameter in inch. Note that this diameter is a <u>nominal</u> diameter and is neither the inside nor the outside diameter, e.g.

pipe Ø $1\frac{1}{4}$ " = 31.75 mm
outside Ø = 41.91 mm
inside Ø = 34 mm

The diameter can be abbreviated as

Ø 3" = nominal diameter
Ø 3" OD = outside diameter = external diameter
Ø 3" ID = inside diameter = internal diameter

Measure the outside and inside diameter of a pipe with a caliper (see 6.3/2).

Measure the thread type with a thread gauge (see 6.3/38).

B) Basic Operations of Plumbing

Some basic operations of plumbing are described in the following:

1. Cutting with a Hacksaw

When cutting a metal piece with a hacksaw, follow these steps:

- Fix the part to be cut in a vice.

- Select the right type of hacksaw blade according to the size of the part to be cut (see 6.3/28).

- Never change the blade in the middle of one cut. (A worn out blade cuts a narrower slot than a new blade. The new blade would be quickly spoilt in the narrow slot.) Take a new blade if the old one is not good enough for a full cut.

- Tighten the blade in the hacksaw frame.

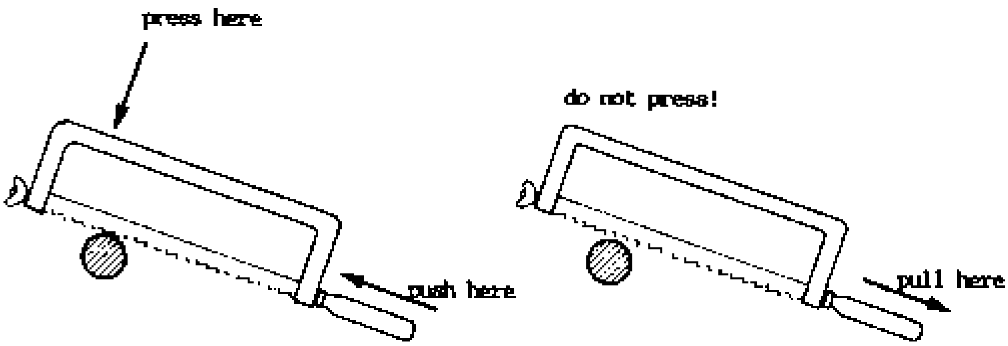
- Mark where to cut.

- Hold the hacksaw straight.

- Use the full length of the blade in even movements.

- Press downwards when pushing the hacksaw forward. Do not press when pulling the saw back. The blade must be fixed to the frame accordingly. See also 6.3/26f.

Correct Use of Hacksaw



2. Pipe Cutting

It is very difficult to cut a pipe straight with a hacksaw. Instead, use a pipe cutter. Follow these steps:

- Fix the pipe in a pipe vice.
- Mark where to cut.
- Push the pipe cutter (see 6.3/36) onto the pipe.
- Tighten it until the cutting wheel touches the pipe.
- Oil the cut.
- Turn the pipe cutter one or two turns until slightly loose.
- Tighten the cutting wheel again.
- Cut another turn.
- Continue like this with constant oiling for cooling until the pipe is cut.
- Clean the chips away with a flat file.

3. <u>Thread Cutting</u>

Thread-cutting oil is needed for threading. There are two types of oil for thread cutting. Use the thread-cutting oil for drinking water (without any poison) for water supply systems and pump installation. Use the other type for all other threads.

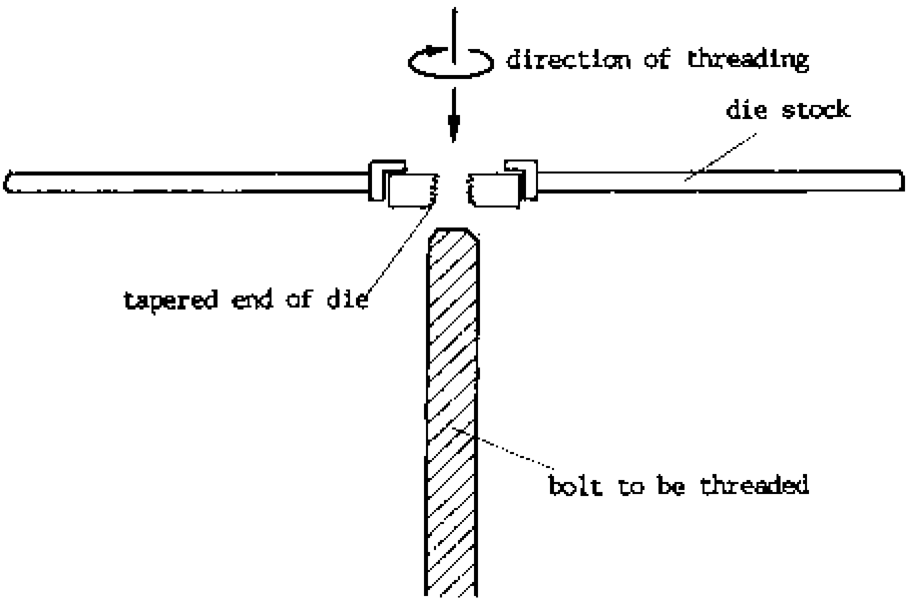
Internal threads are normally cut in workshops and factories. For ordinary water supply work, external threads have to be cut. When cutting external threads, follow these steps, both for bolts and pipes(see also 6.3/36-41).

- Cut the bolt or pipe straight, i.e. orthogonally to its axis. Cut a pipe with a pipe cutter.

- File the end conically(= with a tapered end):

- Fix the bolt or pipe firmly in a vice.

- Take the die with the correct size and fix it in the die stock. The tapered end of the die has to start the threading (both for bolts and pipes).



- Start cutting the thread(clockwise for right hand thread). Hold the handle vertical to the bolt/pipe. Oil continuously with thread-cutting oil.

- Turn one full turn (or until turning becomes difficult). Turn a quarter turn backwards to remove the chips. Turn another full turn forward and so on.

- Never use force.

- Continuously oil.

- When the thread is long enough, remove the chips, and turn the die loosely backwards until it is off the thread. When using a thread cutter with chaser die, open the dies and you can remove the tool without screwing back.

- Clean the thread and the die.

- The thread is of good quality if you can screw the nut or the socket easily onto the thread.

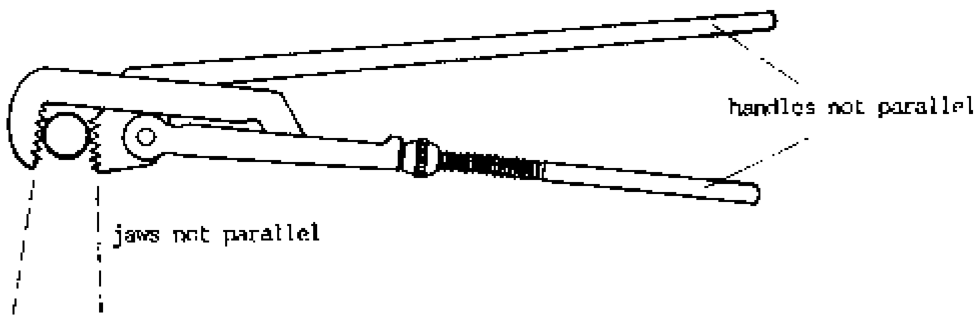
4. Using Pipe Wrenches (see also 6.3/34)

Pipe wrenches are used to tie or untie pipe connections. Use them like this:

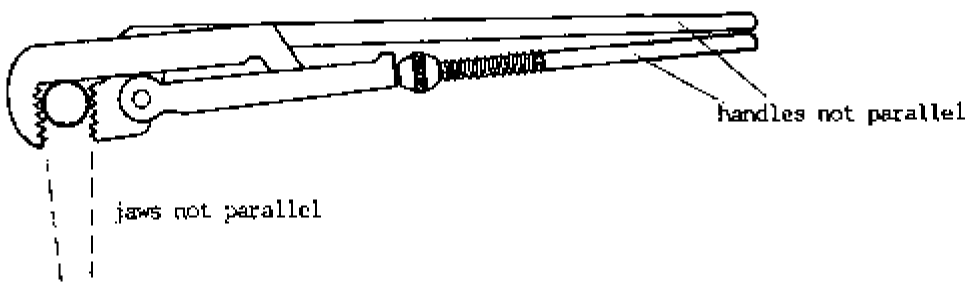
- Take the pipe between the two jaws of the pipe wrench. The two jaws must be parallel, as well as the handles.

- Tighten the positioning screw.

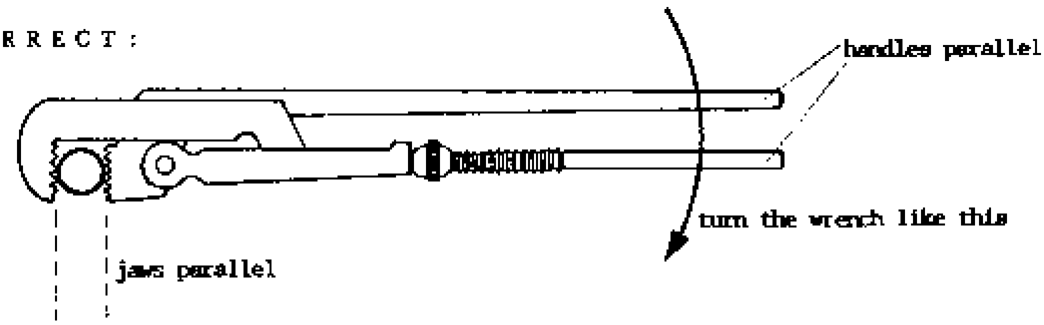
WRONG:



WRONG:

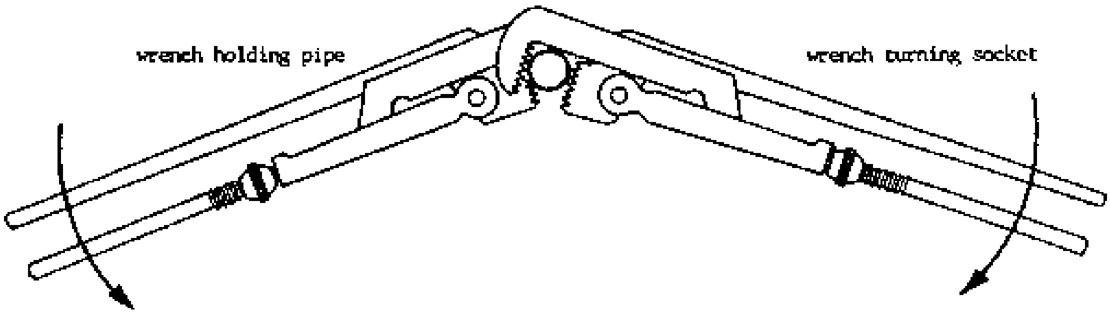


CORRECT:



- Grip the two handles properly. If you have correctly adjusted the wrench, the two handles will be near enough to be easily pressed together, but not too near.

- Screw the pipe by turning the wrench as indicated in the drawing. For tightening a pipe and socket, the two wrenches must be held in the opposite way:



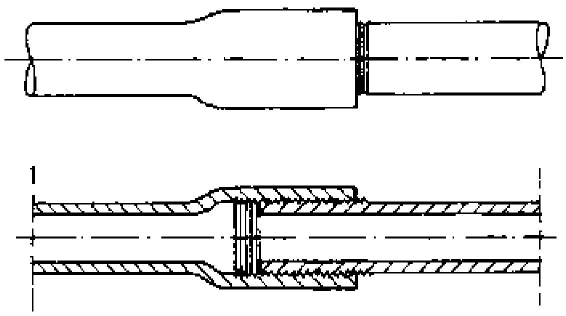
- When installing several pipes and sockets after each other, use always the same wrench for the socket and the other for the pipe. Thus, you will not have to re-adjust the wrenches every time.

- Never turn the serrated (= toothed) jaws of the wrench on the pipe, because this damages the teeth of the jaws as well as the pipe. The pipe will start to corrode at those spots. Good plumbing work leaves hardly any marks on the pipe.

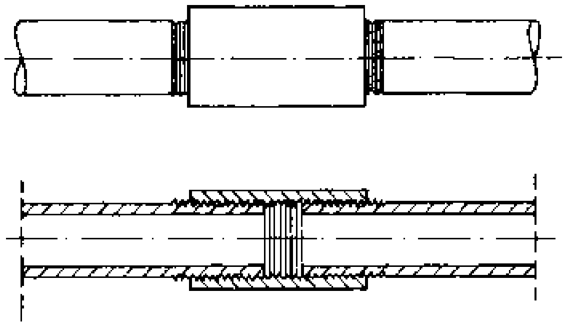
C) Pipe Joints

Pipes can be joined together by different methods. The joining pieces are called fittings. Different types of pipe joints and other fittings are compiled here.

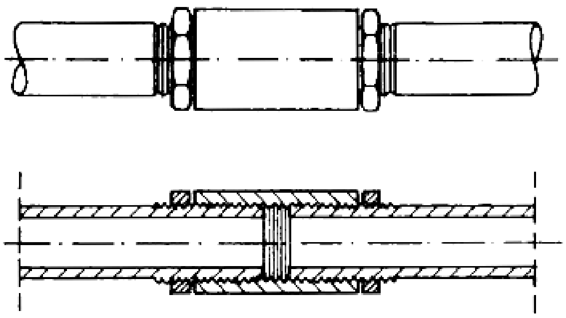
1. Male and Female Pipe Threads
Pipes with male and female threads can be joined directly.



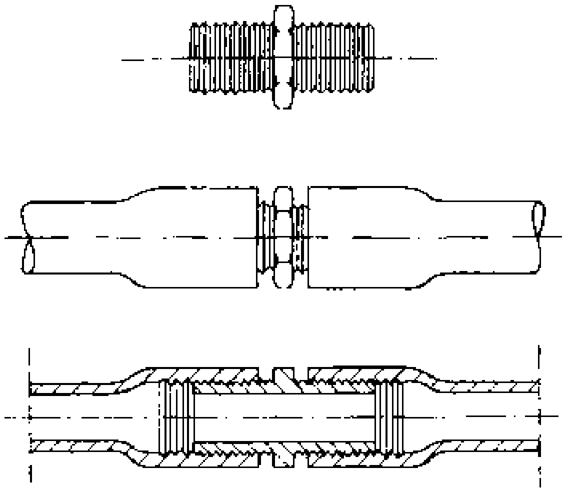
2. Socket (= Coupling)
for joining tapered pipe threads. You must be able to turn one of the pipes for connecting.



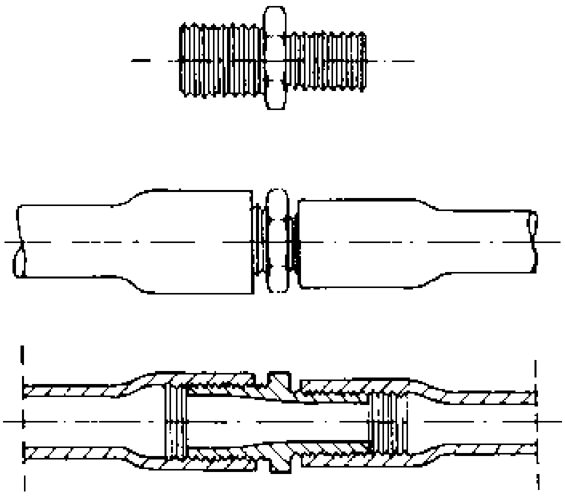
3. Socket with Backnut
for pipes with parallel threads. The backnut ensures water tightness.



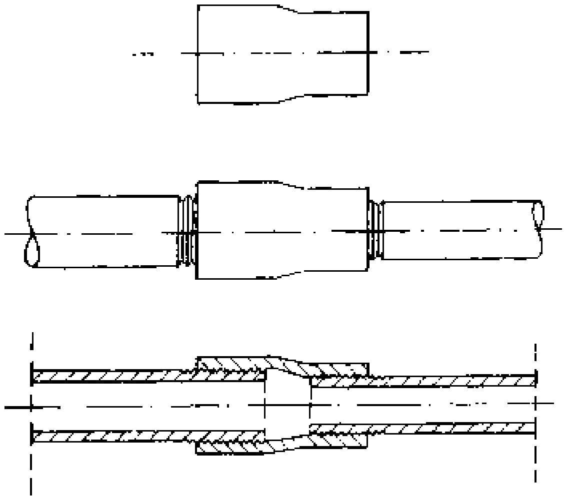
4. Nipple
for joining two pipes with internal threads.



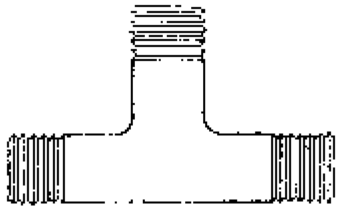
5. Reducer
for joining two pipes with different diameter and internal threads.



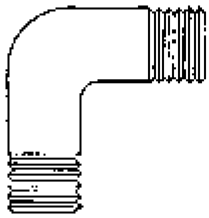
6. Reducer Socket
for joining two pieces with different diameter and external threads.



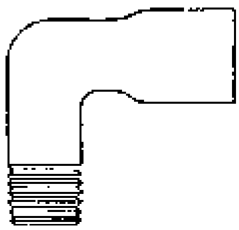
7. Tee-Joint (= Tee-Piece)
for branching pipes.



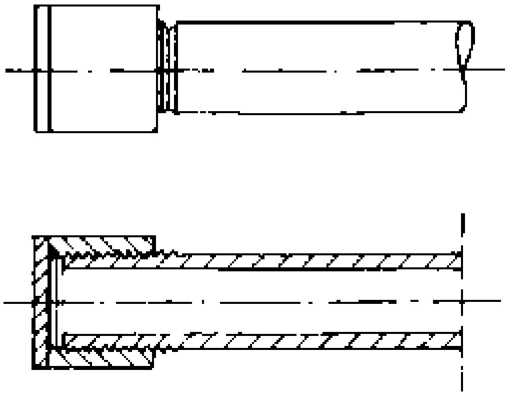
8. Elbow for corners.



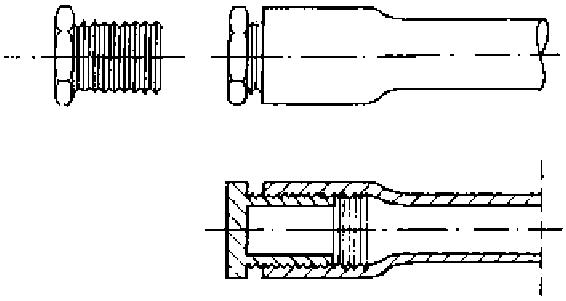
9. M & F - Elbow
male-female elbow, for corners.



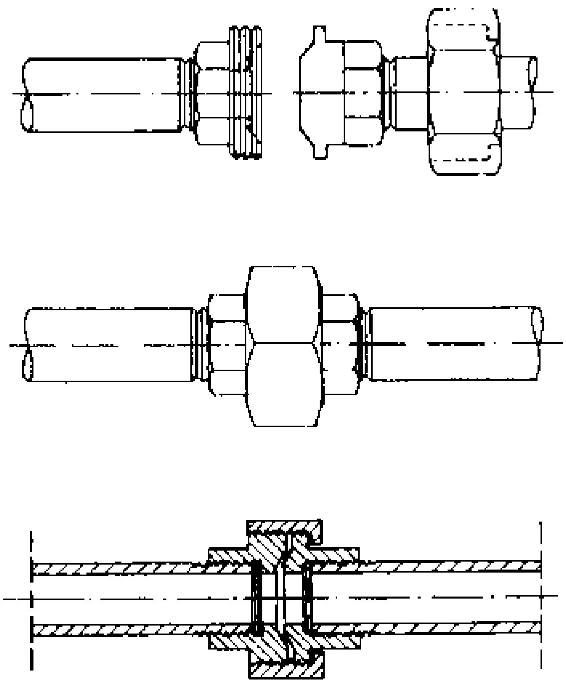
10. <u>Pipe Cap</u>
for closing a dead-end pipe with external thread.



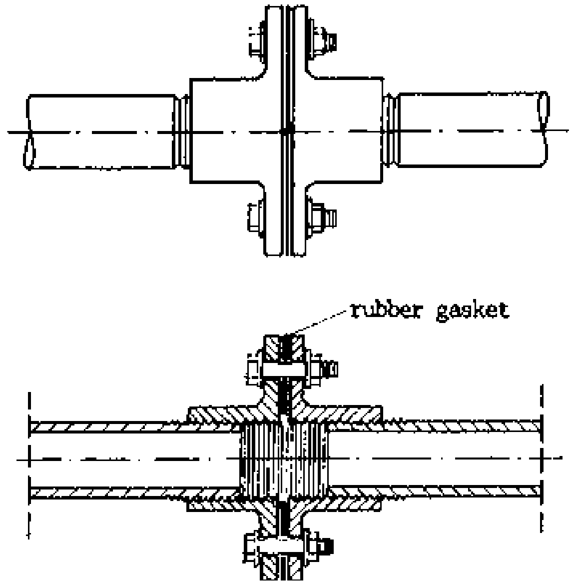
11. <u>Plug</u>
for closing a dead-end pipe with internal thread.



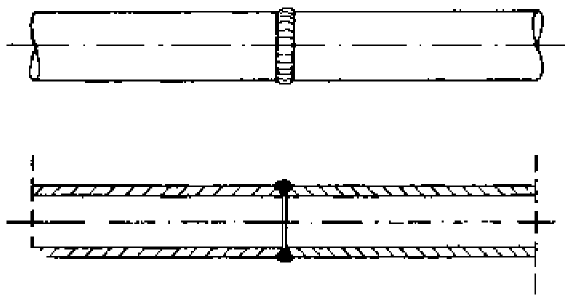
12. <u>Union Joint</u>
for connecting already installed pipes which cannot be turned.



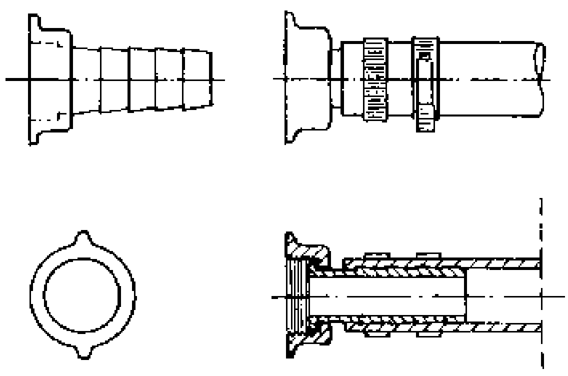
13. Flange Joint
for large diameter pipes (Ø 3” and more).



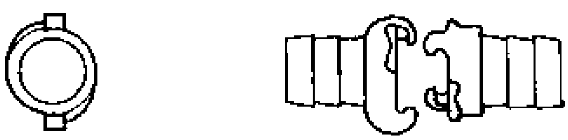
14. Welded Joint
for permanent Installations.



15. Hose Connection
for connecting a hose to a pump or a tap with thread.



16. Dog Clutch
for quick connection of two pipes or hoses with dog clutches by a quarter turn, e.g. for fire brigade.



8.33. Hand Pump Caretaking

The crucial question in operating a water point is: Whom does the water point belong to? The caretaker? The Community? The contractor? The ownership will determine whom the water point will serve and who will be favoured.

A hand pump caretaker is essential for the functioning of a hand pump. She/he has technical and social duties and functions.

A) Daily Technical Duties

No.	Duty	Reasons
1	Sweep the platform and the surroundings. Keep the drainage free.	A water point needs to be clean in order to provide clean water.
2	Open and lock the pump according to opening hours.	The pump shall be used according to the regulations set up by the community.
3	Pump some water and check if operation and discharge are normal.	Any break-down is easier to repair if discovered immediately.
4	Report break-down of the pump immediately and lock the pump.	

B) Weekly Technical Duties

No.	Duty	Reasons
1	Grease the chain.	A greased chain lasts longer and makes operation easier.
2	Tighten all bolts.	Loose bolts cause unnecessary movement and lead to breakage.
3	Check if the platform has any cracks and repair it with cement mortar.	Cracks allow dirty water to enter the well.

C) Social Duties

No	Duty	Reasons
1	Be in time and keep to opening hours.	To be hand pump caretaker means to serve the community. People will appreciate and respect you if the] see that you are reliable, honest and just.
2	Behave politely.	
3	Make sure that the queue is kept correctly, and nobody favourised.	
4	Do not allow people to pump if they do not join the queue.	
5	Collect the money for the water.	
6	Do not give water to anybody free of charge or for less than the community decided.	
7	Deliver the money collected correctly.	
8	Teach the users to operate the pump correctly.	
9	Prevent the users from dirtying the platform and surroundings.	
10	Be honest and just.	

If the above duties are fulfilled, the hand pump will serve the community members equally and justly. This is only possible if the community controls the hand pump and the caretaker by a functioning committee. In this case, the income can be used for maintenance and other community projects (e.g. building new wells or latrines), beside a reasonable "salary" for the caretaker.

At present, few caretakers in Juba act according to these principles. The reason is first, that somebody who has not paid for the well claims ownership over the hand pump(or is given it as a contractor by the government) and, thus, makes profit out of the users and even abuses them. Secondly, the users act individually and do not organise themselves as a community and accept the present situation without readiness for commitment and change.

See also questionnaire about water sources and hand pump use, 4.23/5-9.

8.34. Calculation of Pump Discharge

It is important to know the yield of every pump

- for observation (any decrease of the yield means technical problems in the pump and requires maintenance).
- for estimating the required time to pump a well empty;
- for comparing different types of pumps.

There are special devices to measure the waterflow in a pipe and, thus, the yield of a pump, but these are mostly not available. Therefore, we have to measure the yield of a pump by other, simple methods.

A) Units of Pump Discharge

The discharge or yield of a pump can be expressed in different units:

$\frac{\ell}{sec}$ =	ℓ/sec	= ℓps	= litre per second
$\frac{\ell}{min}$ =	ℓ/min	= ℓpm	= litre per minute
$\frac{\ell}{h}$ =	ℓ/h	= ℓph	= litre per hour
$\frac{m^3}{h}$ =	m^3/h	= m^3ph	= cubic metre per hour
$\frac{m^3}{min}$ =	m^3/min	= m^3pmin	= cubic metre per minute

The different units are connected as follows:

1 ℓ/sec = 60 ℓ/min = 3,600 ℓ/h = 3.6 m^3/h = 0.06 m^3/min
1 ℓ/min = 60 ℓ/h = 0.06 m^3/h = 0.001 m^3/min

Use this transformation table to change one unit to another:

		to these:				
		ℓ /sec	ℓ /min	ℓ /h	m^3/h	m^3/min
If you want to change these units	t/sec		x 60	× 3,600	× 3.6	÷ 16.7
	ℓ /min	÷ 60		× 60	÷ 16.7	÷ 1,000
	ℓ /h	÷ 3,600	÷ 60		÷ 1,000	÷ 60,000
	m^3/h	÷ 3.6	÷ 16.7	× 1,000		÷ 60
	m^3/min	÷ 16.7	÷ 1,000	× 60,000	× 60	

How to use a transformation table is explained on 5.3/1.

B) First Method to Measure the Yield of a Pump

No.	Step	Example
1.	Record the time you start pumping and measure the water table.	t_{start} = 9.31, WT_{start} = 12.05 m
2.	Record the time you stop pumping and measure the water table.	t_{end} = 9.45, WT_{end} = 12.65 m
3.	Measure the diameter of the well at the water table.	Ø = 1.20 m
4.	Calculate the time needed for pumping $t = t_{end} - t_{start}$ For how to calculate a period of time see 5.8/3.	t = 45 min - 31 min = 14 min
5.	Calculate the volume of water pumped from the well (see 5.6/2): d = diameter r = radius h = drawdown = $WT_{end} - Wt_{start}$ $V = \frac{1}{4} \times \pi \times d^2 \times h = V \times r^2 \times h$ $\pi = 3.14$	d = 1.20 m h = 12.65 m - 12.05 m = 0.60 m $V = \frac{1}{4} \times 3.14 \times 1.20^2\ m^2 \times 0.60\ m = 0.678\ m^3$
6.	Calculate the yield: $\text{yield} = \frac{\text{volume}}{\text{time}};\ Q = \frac{V}{t}$	$Q = \frac{0.678\ m^3}{14\ min} = 0.0484\ m^3/min$
7.	Transform the result into m^3/h.	$Q = 0.0484 \times 60\ m^3/h = 2.90\ m^3/h$

If the diameter when starting pumping is not the same as the diameter when ending pumping, take the average diameter for an approximate calculation:

$$d = \frac{1}{2}(d_{start} + d_{end})$$

C) Second Method to Measure the Yield of a Pump

No.	Step	Example
1.	Record the time and start to pour the water discharged by the pump into an empty barrel.	t_{start} = 8.06, 0 sec
2.	Record the exact time in seconds when the barrel is full.	t_{end} = 8.07, 25 sec
3.	Calculate the time needed for filling the barrel (see 5.8/3): $t = t_{end} - t_{start}$	t = 1 min + 25 sec = 60 sec + 25 sec = 85 sec
4.	Determine, measure or calculate the volume of the barrel(see 5.6)	V = 200 ℓ
5.	Calculate the yield: $\text{yield} = \frac{\text{volume}}{\text{time}}$; $Q = \frac{V}{t}$	$Q = \frac{200\,\ell}{85\,\text{sec}} = 2.35\,\ell/\text{sec}$
6.	Transform the result into l/min with the transformation table.	Q = 2.35 × 60 ℓ/min = 141 ℓ/min
7.	Transform the result into m^3/h.	Q = 2.35 × 3.6 m^3/h = 8.46 m^3/h

D) Yields of Some Pumps for Comparison

Average yields of some pumps are roughly estimated here and expressed in different units for comparison. It is advisable to memorize pump yields only in one chosen unit, e.g. m^3/h.

No.	Pump	Average Yield (Approximately)			
		ℓ/sec	ℓ/min	ℓ/h	m^3/h
1.	India Mark II hand pump	0.22	13.3	800	0.8
2.	submersible pump HOMA 725 DHD	0.83	50	3,000	3
3.	diaphragm pump, handoperated	2.22	133	8,000	8
4.	petrol suction pump Honda WA 30X	8.33	500	30,000	30

8.35. Spring Protection

This chapter compiles the most basic information about spring protection. For more details see in the bibliography No. 44, 45, 46.

A) Purpose of Spring Protection

A spring is a place where water is naturally issued from the ground by continuous flow. A spring protection is being artificially constructed to serve the following purposes:

1. It shall protect the spring from contamination.
2. It shall improve the accessibility of the spring for the users.
3. It shall increase the water flow, if possible.

B) Different Spring Types

Springs can be differentiated according to the shape of the opening the water flows from. We differentiate seepage springs, where the water comes out of many tiny openings, and springs with a single opening like a fracture or a round hole.

However, springs are mainly differentiated according to the type of aquifer (open or confined aquifer) and the form of the surface. So, we differentiate the following types:

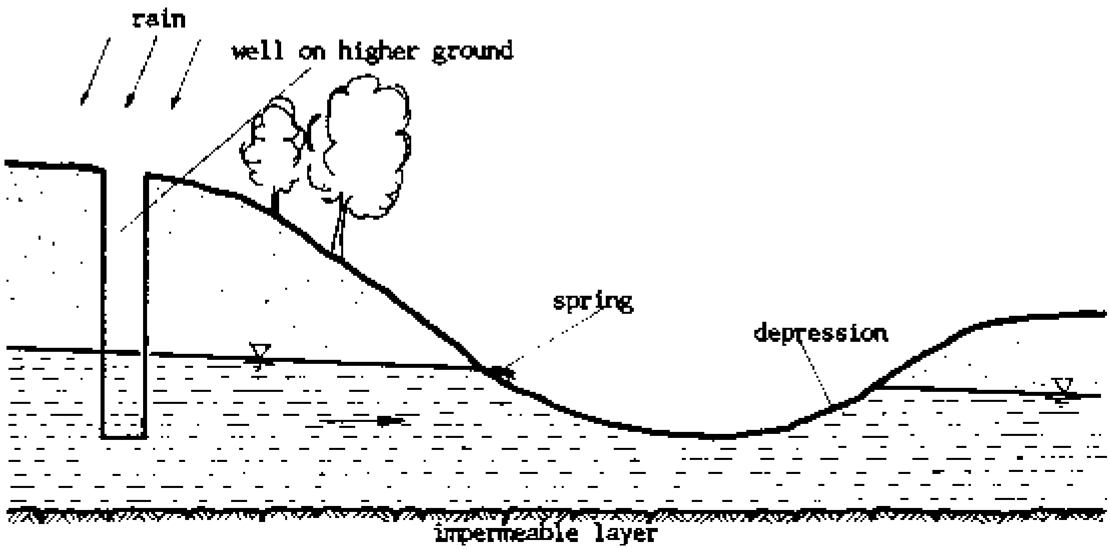
OVERVIEW ABOUT SPRING TYPES

No	Spring Type	Construction	Type of Water Outlet
	Gravity Springs		
1	Gravity Depression Spring	- preferably as well	- for seepage spring or single opening
2	Gravity Overflow Spring	- without springbox, or - with springbox with open side, or - with seepage trench and spring box, or - as combination spring-well, or - as horizontal well	- for single opening - for single opening - for seepage spring - for seepage spring or single opening - for single opening
	Artesian Springs		
3	Artesian Depression Spring	- with springbox with open bottom	- for single opening
4	Artesian Overflow Spring	- with springbox with open sides, or - with seepage trench and springbox	- for single opening - for seepage spring

The different spring types are briefly introduced in the following:

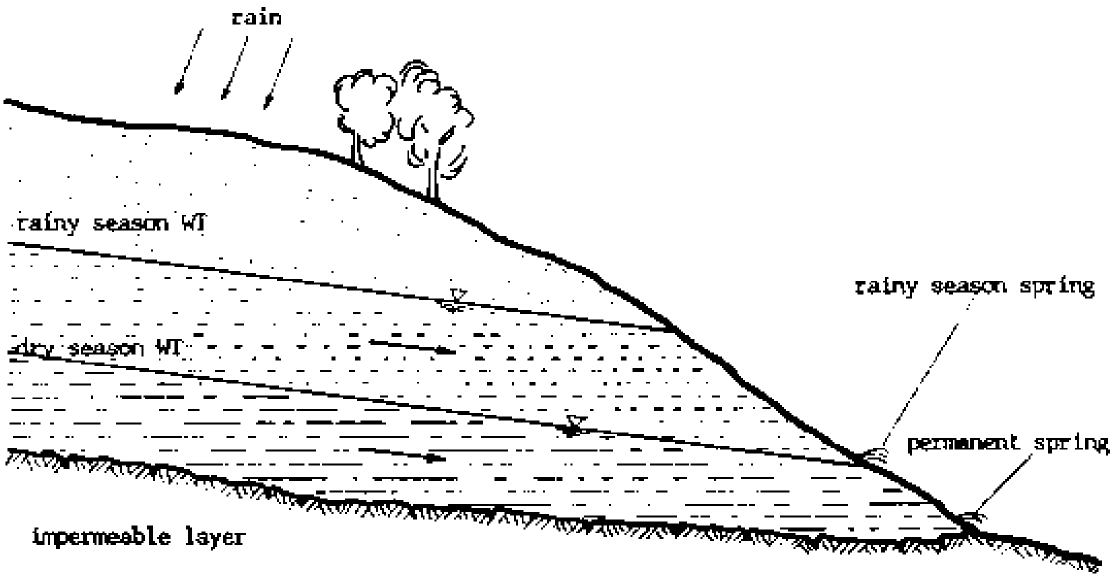
1. Gravity Depression Springs

Gravity depression springs occur where groundwater emerges at the surface because an impervious (= impermeable) layer prevents it from seeping downwards. A gravity depression spring emerges in a sunk area (= depression). It usually has a very small yield and is difficult to seal against contamination. Its presence shows the level of the water table. Water can be extracted safely if a well is constructed nearby on a higher ground.



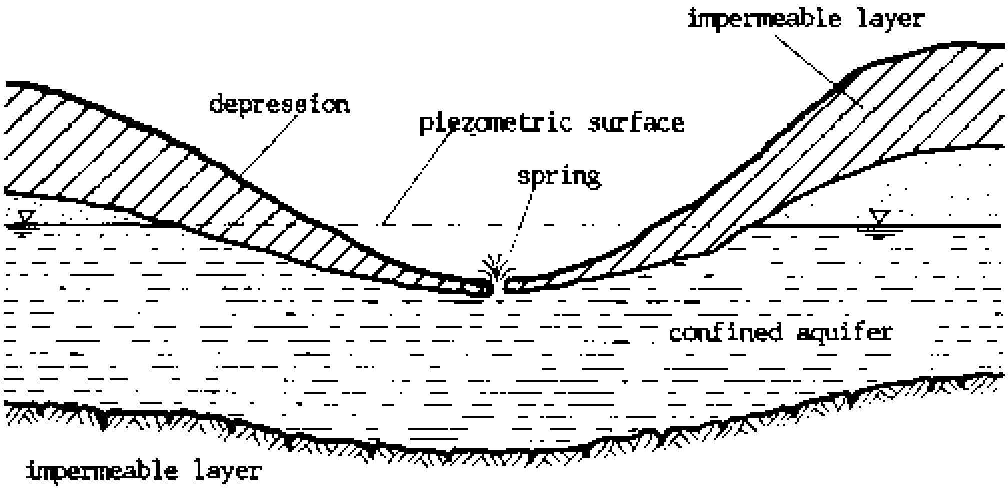
2. Gravity Overflow Springs

The gravity overflow spring usually occurs on slopy ground as a hillside spring. Its flow changes with variations of the water table during the different seasons.



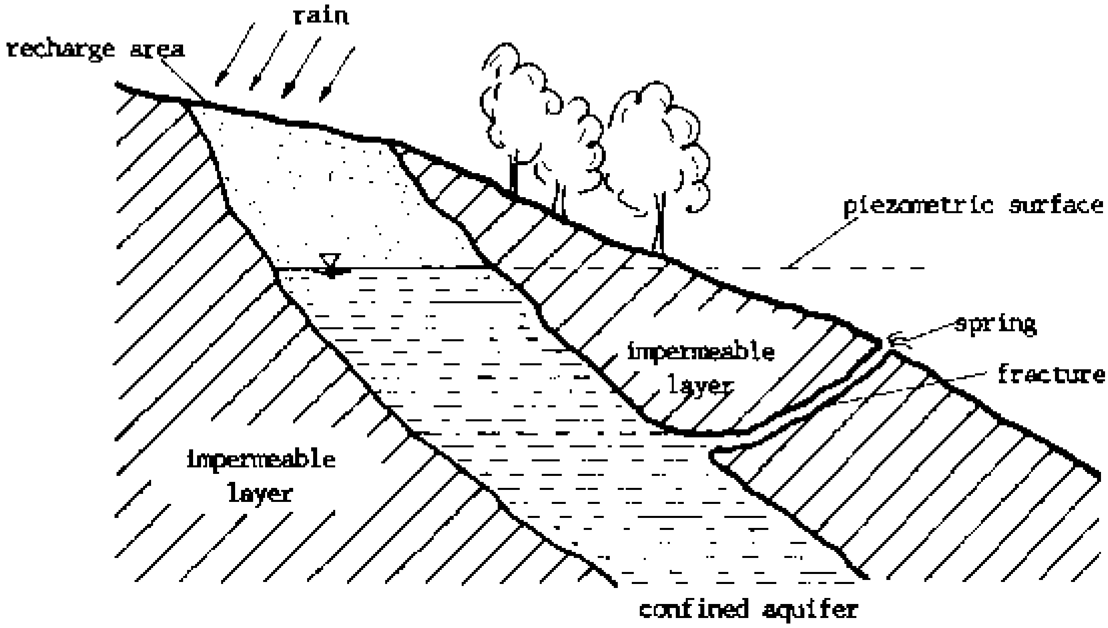
3. Artesian Depression Springs

Artesian depression springs occur where groundwater emerges at the surface after being confined (= shut up, kept) between two impermeable layers. The water emerges due to the internal pressure within the confined aquifer. The yield is usually very consistent and higher than of a gravity depression spring. An artesian depression spring emerges in a sunk area. A spring box with an open bottom is required for protection. See also 8.8/2.



4. Artesian Overflow Springs

At an artesian overflow spring, the confined aquifer emerges at a hillside through a fracture in rock or an opening in the impermeable layer. The water flow is usually very constant. They are a very good source for community water supply, because they are protected from contamination by the overlying impermeable layer. If the spring flows through a single opening, a spring box with open side is suitable. If the water flows out through several openings, seepage trenches become necessary. See also 8.8/2.

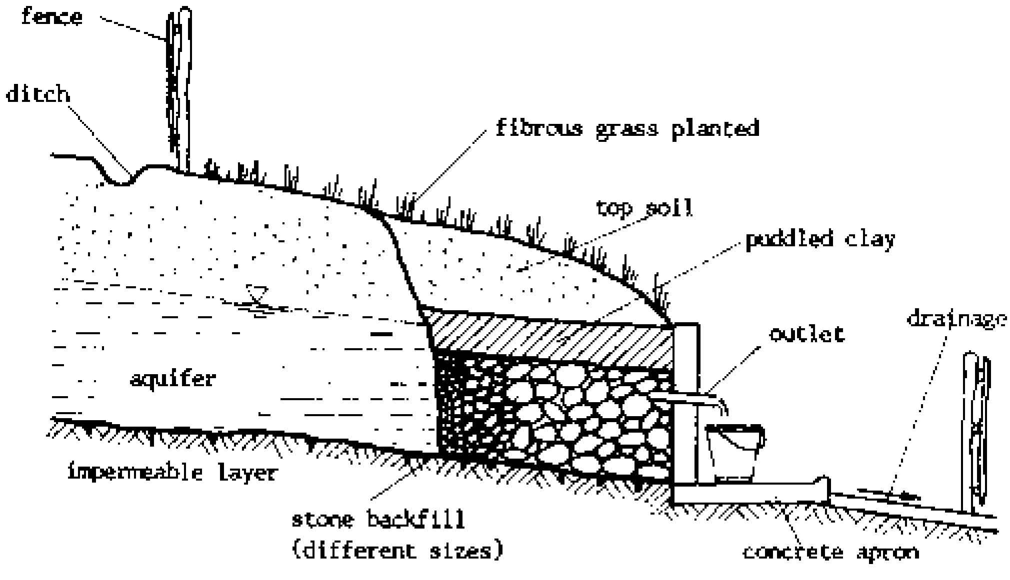


C) Different Spring Protection Designs

The different types of designs how to protect a spring are described in the following. Some designs are suitable for different types of springs.

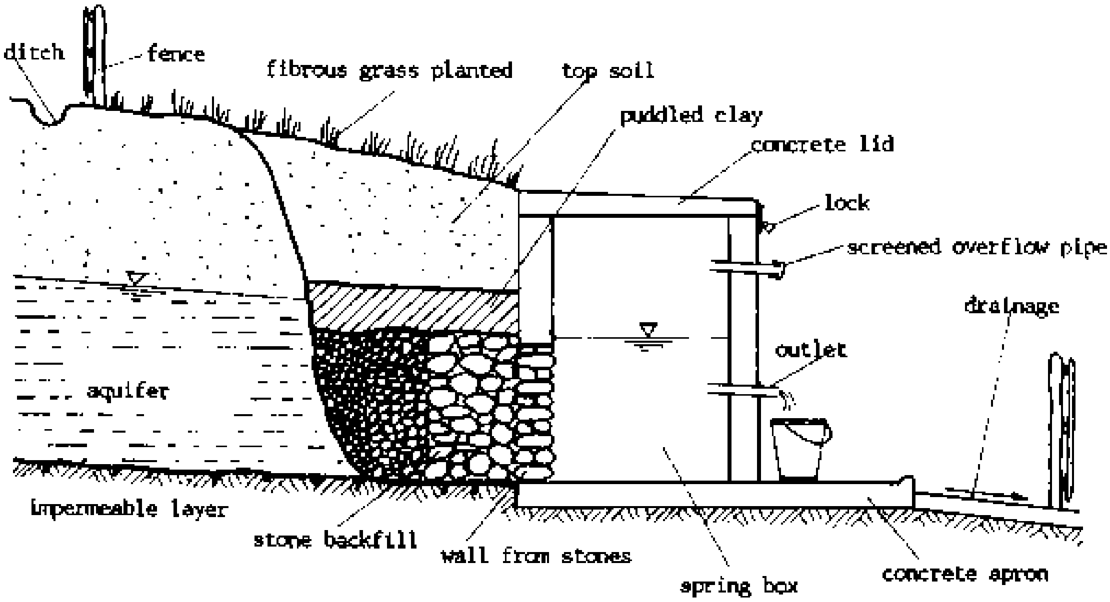
1. Spring without Springbox

A spring without a springbox, but protected, consists of an impervious retaining wall with an outlet backfilled with stones and covered with puddled clay. It is suitable for gravity overflow wells with a single opening.



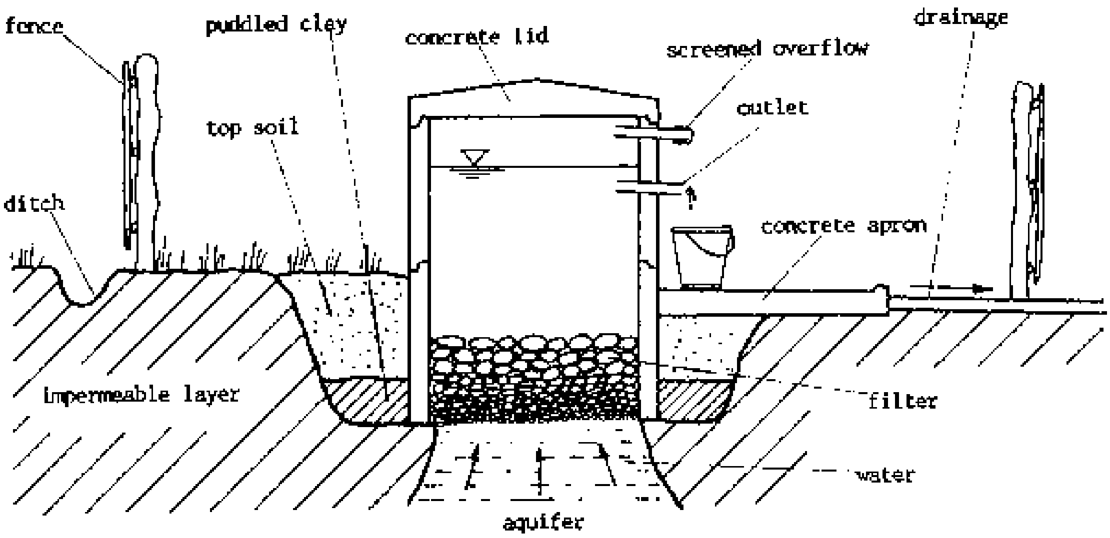
2. Spring with Springbox with Open Side

A springbox (= chamber = intake box = collection box) serves for collecting and storing the water. It can be built from concrete (with one side open), from masonry (with one side built without mortar), or from a concrete ring (with one side open or as filter). It has a removable, watertight, and lockable concrete lid. It is suitable for gravity overflow springs or for artesian overflow springs.



3. Spring Box with Open Bottom

If a spring flows from a single opening on more or less level ground, a springbox with an open bottom is suitable. This is the case for artesian depression springs. The box can be built on site from concrete or bricks, or a concrete ring can be used.



4. Spring with Infiltration Trenches and Springbox

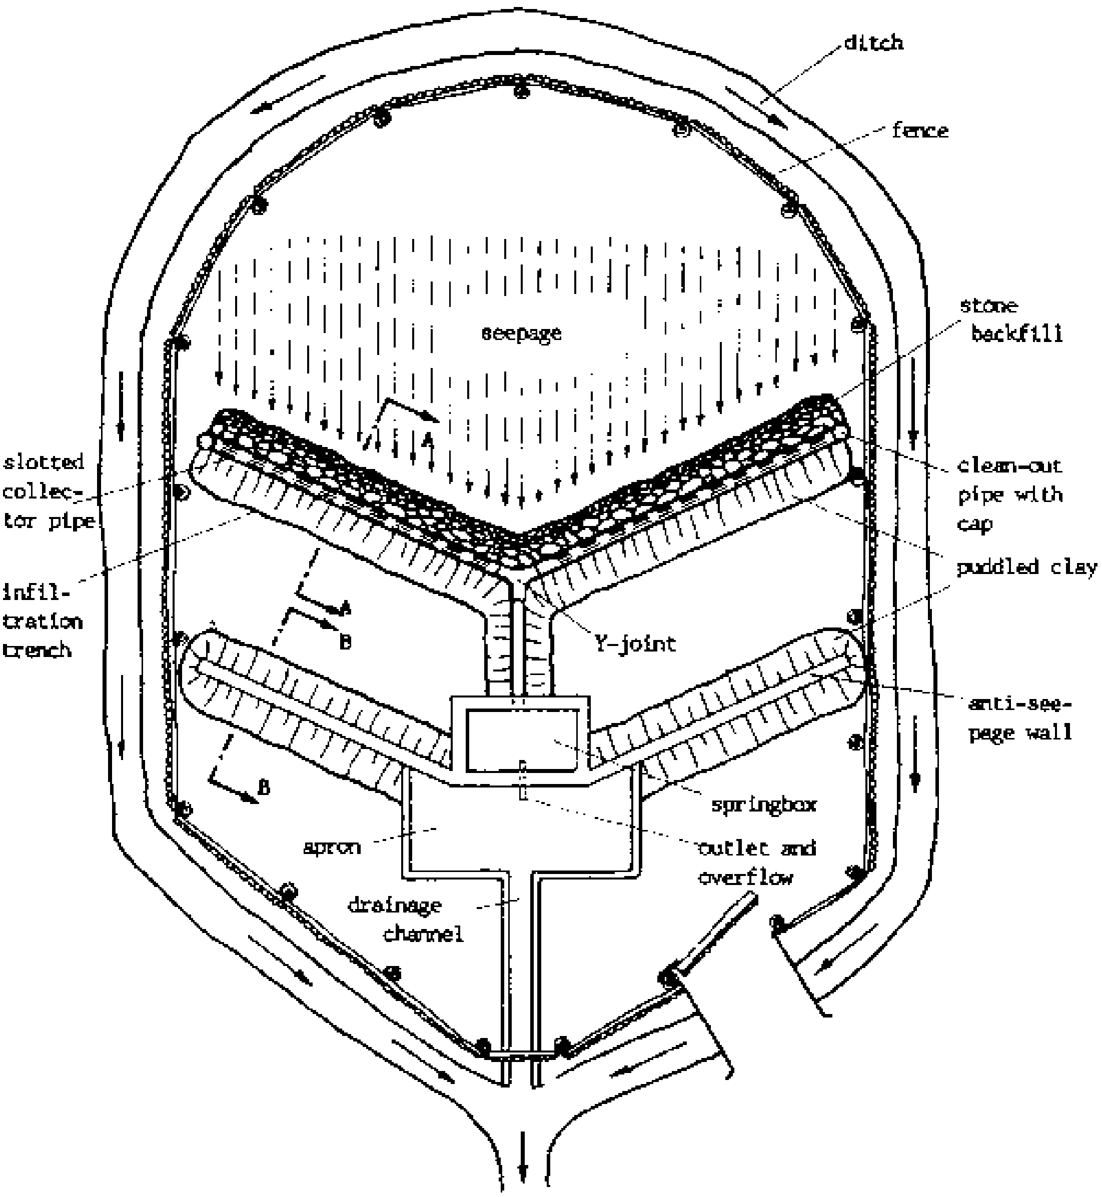
If a gravity or artesian overflow spring occurs for a distance along the hillside, the water must be collected with infiltration trenches. They are dug deep into the hillside to contact the aquifer even in dry season. Slotted plastic pipes or short clay pipes surrounded with rocks and gravel collect the water and pipe it to the spring box. The pipes must have a slope. The openings on the pipes must be big enough to allow water to enter, but small enough to keep out sediments and to prevent blockage. Vertical clean-out pipes connected with elbows to the end of the collectors extend a little above ground and are capped. They can be used to clean the system by flushing it.

It is important to collect all water and to prevent the spring from flowing around or under the construction and wash it out. The anti-seepage wall (= cut-off wall) prevents loss of water due to underflow. It must reach into the impervious layer. Alternatively, it can be made from compacted clay which acts as a dam.

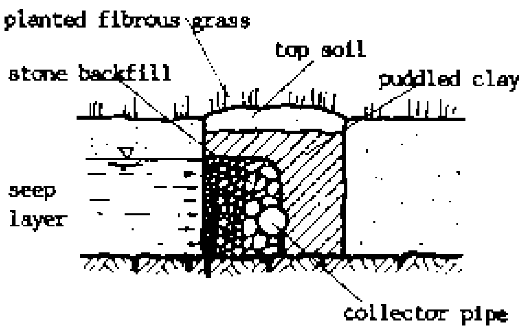
Spring with Infiltration Trenches and Springbox

LAYOUT PLAN

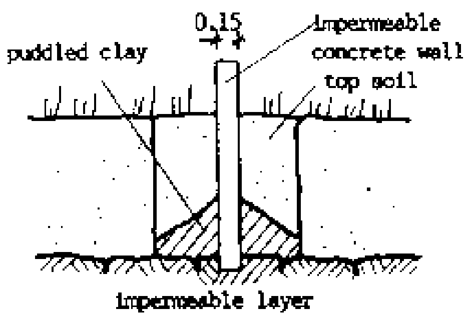
LAYOUT PLAN



CROSS-SECTION A-A: INFILTRATION TRENCH

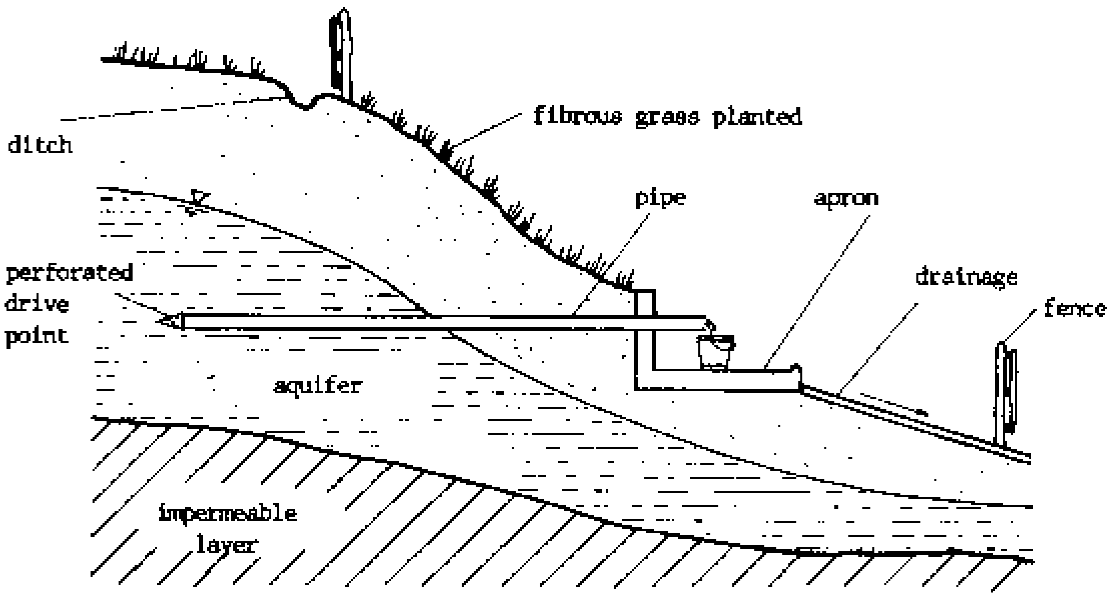


CROSS-SECTION B-B: ANTI-SEEPAGE WALL



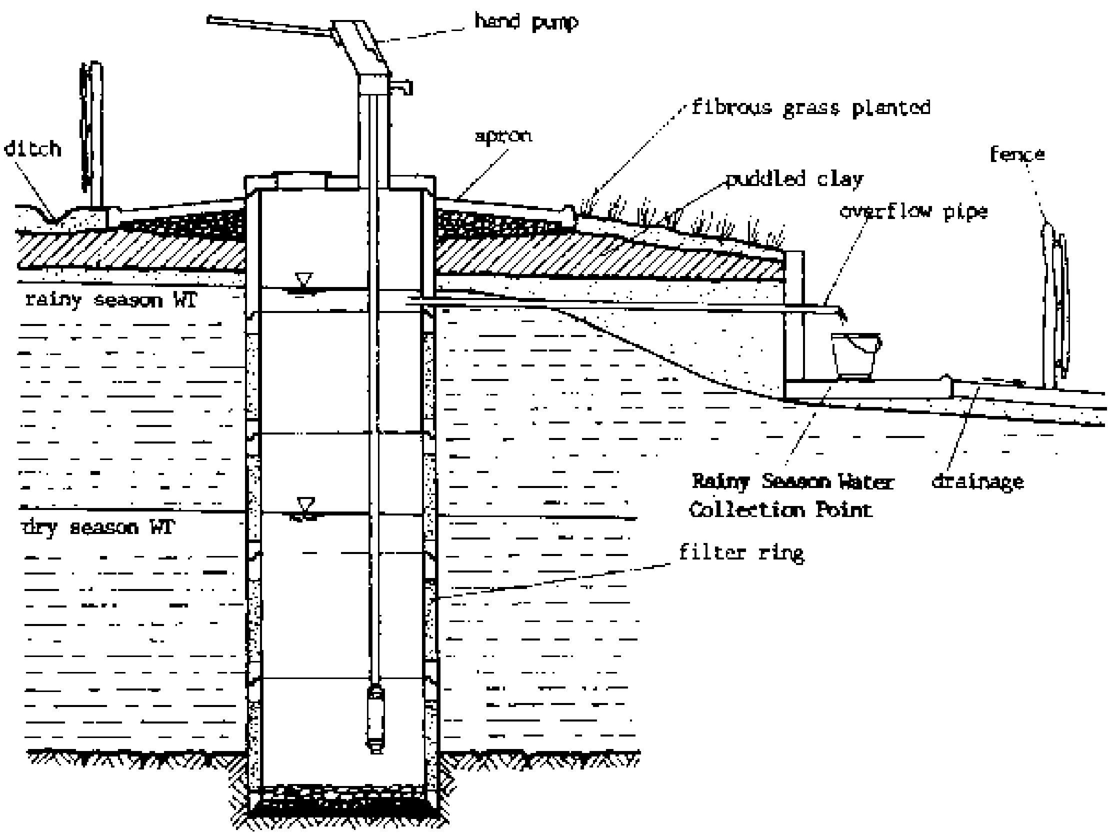
5. Horizontal Well

A horizontal well is suitable for a gravity overflow spring if the aquifer has a steep slope following the ground surface. A pipe with an open end or a perforated drive-point is driven into the aquifer horizontally and sealed all around.



6. Combination Spring-Well

If a gravity overflow spring may dry up during dry season, then a well with a rainy season overflow (= water collection point) should be built. This is called a combination spring-well.



D) Essential Elements of a Spring Protection

A well protected spring has the following indispensable elements:

1. Springbox

It must be durable, impermeable on three sides, and permeable towards the spring.

2. Cover

The cover, preferably from reinforced concrete, must be heavy, lockable, and have a slope to drain the rainwater.

3. Overflow Pipe

The overflow pipe is installed at the highest water level to prevent building up of pressure inside the springbox. It must be screened with a non-corroding screen from copper or plastic to keep animals out. It can serve as air-vent at the same time.

4. Distribution Pipe (= Discharge Pipe = Outlet = Spout)

The distribution pipe supplies the water to the users. It can also lead to a separate storage tank downhill. If the yield of a spring is low, the distribution pipe can be equipped with a tap to allow water to collect inside the springbox.

5. Sealing with Puddled Clay

Different parts of the spring protection system have to be sealed with puddled clay. Puddled clay is clay which is worked while wet into a compact mass that becomes impervious to water when dry. It is the same type of “mudding” which is used to build a tukul. Puddled clay has to be smeared in 5 cm thick layers, to be compacted with the feet, and to be well compacted. An impervious layer must be at least 30 cm thick, i.e. it must be smeared in six layers.

6. Protective Planting

The area around the spring must be planted with a strong type of grass (fibrous grass) to prevent erosion (= the surroundings from being washed out).

7. Fencing

The spring must be fenced to prevent animals. Preferably, a hedge should be planted for easier maintenance and cheaper costs.

8. Surface Drainage Ditch (= Diversion Ditch)

A surface drainage ditch must be constructed around the spring to divert all rainwater. It should be about 8 to 10 m away from the spring-box. It should be lined with gravel or stones to increase flow and to prevent erosion of the sides.

9. Area Cleanliness

The area around the spring in a radius of 50 to 100 m must be free from latrines and other sources of pollution.

E) Planning a Spring Protection

For planning a spring protection, consider these steps:

1. Consult the local people where the springs are in the area. Ask which ones stop flowing during dry season.

2. Investigate around the area and check to see if the spring is not in reality a stream which has gone underground and is reemerging.

3. The springbox should not be built on swampy ground.

4. The springbox should not be threatened by flood or erosion.

5. Check if the water looks clear.

6. Check the flow of the spring. Measure it with buckets (l/min).

7. Check if there are possible sources of contamination nearby.

8. Identify what kind of spring you have (see B) and what type of design to use (see C).

9. Check if the water rights in the area allow the construction of a spring protection.

10. Get or draw a map of the area, including the spring site(s), the nearest houses, latrines, etc., the distances, the elevations, and important land marks.

F) <u>Constructing a Spring Protection</u>

The construction of the different designs for spring protection shall not be discussed here in detail. However, some basic principles shall be listed here, valid for all designs:

1. Set the distribution pipe level first before the construction begins. Drive a large wooden peg into the ground outside the area to be excavated. Never disturb this reference peg.

2. While excavating, take care not to disturb the ground formations. Without care, the flow of the spring might be deflected into another direction. Careful digging around the eye of the spring might increase the flow.

3. The foundation of all parts of the spring protection must reach into the impermeable layer.

4. Dig a temporary drainage channel while building the springbox to be able to work in a relatively dry area.

G) <u>Maintenance of a Spring Protection</u>

A spring protection needs a small amount of maintenance in order to prevent water contamination, ensure long life and give optimum service to the users. How water distribution and maintenance are organised is up to the community (see also social duties of a hand pump caretaker 8.33). In the following we list only the technical steps of maintaining spring structures, which should be done regularly, at least once a year.

1. Check if water from the surface is likely to enter the spring and contaminate it.

Surface water is likely to enter the spring - if the water temperature is higher during the day than at night; - if the yield increases after a rain; - if the turbidity increases after a rain.

2. Check if any water is seeping beside or underneath the spring structure. If water seeps out, seal the leak with clay or concrete.

3. Check the surface drainage ditch. Clean it, remove any obstacles and improve it, if necessary.

4. Check the fence and repair it, if necessary.

5. Check if the springbox and anti-seepage walls are solid or are washed out by erosion. If there are signs of erosion, fill the holes with earth and gravel, plant grass and improve the drainage ditches.

6. Clean the springbox from sediments.

7. If there are infiltration trenches, flush them with water through the clean-out pipes.

8. Check if the cover of the springbox is watertight.

9. Check the screening of the pipes and replace it, if necessary.

10. Disinfect the spring once a year (see 8.36).

11. Take periodically samples from the spring and let them be examined in a water laboratory, if possible.

8.36. Well Disinfection

Hand dug wells are contaminated by workers and equipment during construction.(Urinating and defaecating in the well during construction are strictly forbidden). Boreholes are contaminated by equipment and casings. Hand pumps are contaminated by pipes, rods and tools. Therefore, after completion of a well and after each hand pump maintenance a well needs to be disinfected in order to provide safe and uncontaminated water to the consumers.

There are different methods to clean the water of a well:

A) Chlorination

Chlorination is a way of chemical disinfection and is the most commonly used form of disinfection. Basic information about this method is compiled here.

1. Dosage

Different dosages are used. They are indicated in mg/ℓ or ppm. 1 mg/ℓ is the same as $1\frac{mg}{\ell}$ and stands for 1 milligram per litre. 1 mg/ℓ means that there is 1 mg chlorine (the chemical chlorine available for disinfection) in 1 ℓ water. 1 ppm stands for 1 part per million and means 1 mg chlorine per 1 million mg water, as 1 ℓ water = 1 kg = 1,000 g = 1,000,000 mg (see also 5.3/5).

Dosage	Description
30 ppm	strong chlorination for disinfecting wells after construction or maintenance. Not drinkable.
5 ppm	moderate chlorination for disinfecting wells under use or water in the household. Not drinkable.
3 ppm	dosages above 3 ppm can cause diarrhea.
0.3 - 1.0 ppm	residual chlorine in drinking water. Drinkable.

Chlorine is available in different forms, as powder or as liquid.

Bleaching powder has 25-35% available chlorine, that means that only 25-35% of the powder is chlorine and is available for disinfecting the water.

Old bleaching powder has become weak and has lost most of its initial chlorine. Therefore, we assume only 5% available chlorine in it.

High strength calcium hypochlorite has 70% available chlorine; it is more expensive than bleaching powder and more difficult to get.

Liquid bleach is a chlorine solution, e.g. 5%. sodium hypochlorite. 5% solution means that 5% of the solution is the chemical, the rest is water. 1 ℓ of a 5% solution contains (as 1 ℓ = 1000 g)

5% of 1,000 g = 50 g chlorine = 50,000 mg chlorine.

Thus a 5% solution is the same as 50,000 mg/ℓ or 50,000 ppm.

2. Handling Chlorine

Once a container with chlorine is opened, it fairly rapidly looses its initial chlorine content, especially, if exposed to air, moisture, heat and light. Also, chlorine is very corrosive.

Therefore:

Store chlorine in dry, close, dark, non-rusting containers in a cool place, like - plastic jerrycan, painted black; - nylon bag put into a closed tin; - dark bottle well closed.

During chlorination take into account that the disinfectant may have lost strength and, in this case, add more.

It is essential to add sufficient chlorine to satisfy the chlorine demand of the water and to have a little spare chlorine left which is called "free active chlorine" or "residual chlorine".

The water should be clear (that is without turbidity) before chlorination. Otherwise a higher dose is needed.

Treat chlorine powder and solution carefully. Do not touch the disinfectant. Never drink a chlorine solution. It is extremely dangerous because it eats up the stomach inwardly. Mind your eyes; if chlorine has touched your eye, rinse it with water immediately for 10 minutes.

3. Steps of Chlorination

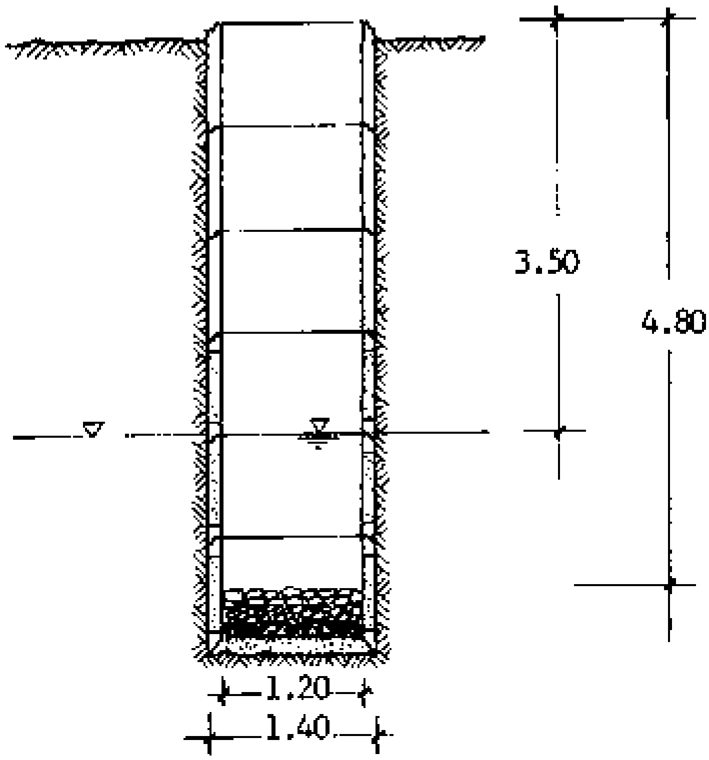
For chlorinating a well after construction, follow these steps:

a) Calculate the volume of the water in the well (see also 5.6/2):

$$V = \pi \times r^2 \times h$$

Volume (m^3) = inside diameter (m) × $\frac{1}{2}$ inside diameter (m) × 3.14 × depth of the water from the bottom to the water table (m)

Example:



SCALE 1:80

h = 4.80 - 3.50 = 1.30 m
r = 1.20 ÷ 2 = 0.60
π = 3.14

V = 0.60 m × 0.60 m × 3.14 × 1.30 m = 1.47 m^3

b) Check what kind of disinfectant you have and its percentage of available chlorine.

c) From table 1 (see 8.36/4) find the amount of chlorine that will have to be added to the volume of water to produce a strong chlorine solution (30 ppm).

d) Dissolve the required amount of the chemical in a bucket of water before adding it to the well. This solution must have a strong chlorine odour (= smell); otherwise, it has less available chlorine content than you assumed and you must add more.

e) Pour the solution into the well. It is best to agitate the water to ensure that the chlorine is evenly mixed. Pump the hand pump a bit until the pipes are filled with chlorine solution.

f) The strong chlorine solution should be left in the well for at least 12 hours and preferably 24 hours; it must be stressed that this strong chlorine solution is <u>not suitable</u> for humans or animals.

g) After 12 to 24 hours contact time, the strongly chlorinated water should be pumped from the well until the residual chlorine level is below 1.0 mg per litre of water (with little chlorine taste). The pumping equipment to be installed on the well can be disinfected by using it to remove the excess chlorine. Choose a disposal place for the chlorine solution where it will have as little contact with plants and animal life as possible.

TABLE 1 FOR DISINFECTION OF WELLS AFTER CONSTRUCTION

The approximate dosage is 30 mg/ℓ (= 30 ppm). Do not drink this water after disinfection. Empty the well after 12 to 24 hours contact time until the residual chlorine is about 0.3 to 1.0 mg/ℓ (= 0.3 to 1.0 ppm) and the water has only slight chlorine odour and taste. Then you can drink it.

Water			Powders								Liquid		
			old (weak) bleaching powder 5%		bleaching powder 25-35%			high strength calcium-hypochlorite 70%.			liquid bleach 5%. sodium hypochlorite

	15	m^3	9.0	kg		1. 5	kg	650 g =	$8\frac{2}{3}$	salsal		9.0	ℓ
	20	m^3	12.0	kg		2	kg	860 g =	$11\frac{1}{2}$	salsal		12.0	ℓ
	30	m^3	18.0	kg		3	kg	1300 g =	1.3	kg		18.0	ℓ
	40	m^3	24.0	kg		4	kg		1.7	kg		24.0	ℓ
	50	m^3	30.0	kg		5	kg		2.2	kg		30.0	ℓ
	100	m^3	60.0	kg		10	kg		4.3	kg		60.0	ℓ

Comparative measurements see Table 2, 8.37/3;	ml = millilitre ℓ = litre } see 5.3/4 m^3 = cubic metre	g = gram kg = kilogram } see 5.3/5

4. Further Information

The amount of chlorine in the table was calculated as follows:

for powders:

$$\boxed{\text{amount of disinfectant (mg)} = \frac{\text{dosage (mg/}\ell = \text{ppm)} \times \text{quantity of water (}\ell\text{)}}{\text{percentage of available chlorine (\%)} \times \frac{1}{100}}}$$

Example:

1 m^3 water, 30 mg/ℓ (= 30 ppm), high strength calcium hypochlorite 70%;

$$\frac{30\ \text{mg}/\ell \times 1{,}000\ \ell}{70 \times \frac{1}{100}} \cong 43{,}000\ \text{mg} = 43\ \text{g}$$

for liquids:

$$\boxed{\text{amount of liquid (ml)} = \frac{\text{dosage (mg/}\ell = \text{ppm)} \times \text{quantity of water (}\ell\text{)}}{\text{percentage of solution} \times 10}}$$

Note that 1 ml of a 5% solution contains, as 1 ml = 1 g:

5% of 1 g = 5% of 1000 mg = 5 × -^ × 1000 mg = 5 × 10 mg (see also 8.36/2)

Example:

1 m^3 water, 30 mg/ℓ (= 30 ppm), liquid bleach 5%;

$$\frac{30\ \text{mg}/\ell \times 1{,}000\ell}{5 \times 10} = 600\ \text{ml}$$

B) Pumping

If no disinfectant is available, clean the well first thoroughly by hand and then pump the well as much as possible. This will reduce the contamination, but it is not a 100% safe method.

C) Treatment with Sand Filters

Locally made sand filters may be used to treat drinking water. They are simple and provide clean water, but need maintenance. For further details see the literature, especially No. 44 in the bibliography.

8.37. Water Treatment at Home

It is very important to have safe drinking water in the household. Different methods to treat the water at home in order to get safe drinking water are discussed here. Choose what is available and appropriate under the given circumstances.

A) Water from Safe Sources

To get water from a safe source is the best solution and, in this case, no treatment is needed. Hand dug wells with hand pumps and boreholes can be safe sources if the groundwater is not polluted and the platform has no cracks. Inquire if the water was tested in a laboratory and is safe.

However, if you cannot get your drinking water from a safe source, you can treat it with the following methods.

B) Sedimentation

If the water is of brownish colour and not clear (= turbid), it has a lot of suspended matter. This is called "turbidity". Before any further disinfecting, the suspended matter must be removed. Let the water stand over night until the suspended matter settles. Carefully pour off the clear water. This will reduce the contamination; therefore, you should do it even if you cannot treat the water further. But the water is not safe after sedimentation only.

C) Coagulation with Alum

Mix alum (= aluminium sulphate) with the water and let it settle. The particles of the alum will combine with the suspended matter and form small lumps. The lumps will settle. This process is called coagulation. Treating water with alum is a clarification process. The higher the turbidity, the more alum you need. It removes the turbidity and reduces the contamination, but does not provide safe drinking water.

D) Coagulation with Plants

The seeds of certain trees (e.g. moringa olifera) act like alum when powdered and can be used for coagulation. For further details see the literature.

E) Pouring Water through Cloth

Pouring water through a clean cloth can reduce the turbidity, but it does not remove the contamination; it is a pre-treatment method. Wash the cloth after each use.

F) Chlorination

Chlorination is a common and simple form of water treatment in the home. For detailed information about chlorine see 8.36.

For chlorinating drinking water in the home, follow these steps:

1. Clarify the water by one of the methods mentioned above before chlorination.

2. Determine the quantity of water you want to disinfect:

1 water jerryccan	= 20 ℓ	= 0.02 m^3
1 drum	= 220 ℓ	= 0.22 m^3

3. Check what kind of disinfectant you have (if possible, from the label of the package) and its percentage of available chlorine. Commonly available powders are mostly bleaching powder.

4. From TABLE 2 on the next page, find the amount of chlorine to be added to the water to produce a moderate chlorine solution.

5. Dissolve the disinfectant in a cup of water.

6. Pour the solution into the water and stir it well. This initial dose shall produce a 5 ppm solution; it must have chlorine smell. Otherwise the chlorine has lost its strength and you must repeat the dosage.

7. Let the water stand for at least 30 minutes. The chlorine reacts with the organic and inorganic matter present in the water. After 30 minutes, the chlorine concentration ought to be reduced to less than 1 ppm.

8. After 30 minutes (or more), check for the residual chlorine. The treated water should have a slight chlorine odour and taste. If not, repeat the dosage (Return to step 3). If the water has still no chlorine odour, the disinfectant is expired and useless. If the water has too strong a chlorine taste, allow it to stand for a few hours. Contact with the air removes the taste and smell of chlorine.

G) Treatment with Iodine

Iodine can be used for disinfecting water. The water must be clear; treatment with iodine is not suitable for water with a high turbidity.

1. Clarify the water with one of the above methods before treatment with iodine.

2. Pour 2 drops of iodine per litre into the water (e.g. 40 drops per jerrycan and 440 drops per drum). Double the dose if the water is highly polluted. Stir the water.

3. Let it stand for 30 minutes. Then you can drink.

TABLE 2 FOR DISINFECTION OF DRINKING WATER

The approximate dosage is 5 mg/ℓ (= 5 ppm). Do not drink the water immediately after disinfection. After 30 min contact time the residual chlorine should be about 0.3 to 1.0 mg/ℓ (= 0.3 to 1.0 ppm). The water should have a slight chlorine odour and taste. Then you can drink it.

Water			Powders									Liquid		
			old (weak) bleaching powder 5%			bleaching powder 25-35%			high strength calcium hypochlorite 70%			liquid bleach 5% sodium hypochlorite		
20 ℓ =	1	jerryc.	2 g =	1	teaspoon	0.3	g		0.1	g		2 ml =	1	teaspoon
220 ℓ =	1	drum	22 g =	$2\frac{1}{2}$	tablespoons	3	g = 1	teaspoon	1.6	g = $\frac{1}{2}$	teaspoon	22 ml =	$2\frac{1}{2}$	tablesp.
1000 ℓ =	1	m^3	100 g =	$1\frac{1}{3}$	salsal	14	g = $1\frac{1}{2}$	tablespoons	7	g = $2\frac{1}{2}$	teaspoons	100 ml =	$1\frac{1}{3}$	salsal
	1.2	m^3	120 g =	$1\frac{1}{2}$	salsal	17	g = 2	tablespoons	9	g = 1	tablespoon	120 ml =	$1\frac{1}{2}$	salsal
	1.5	m^3	150 g =	2	salsal	21	g = $2\frac{1}{3}$	tablespoons	11	g = $1\frac{1}{3}$	tablespoons	150 ml =	2	salsal
	2	m^3	200 g =	$2\frac{2}{3}$	salsal	29	g = $3\frac{1}{3}$	tablespoons	14	g = $1\frac{1}{2}$	tablespoons	200 ml =	$2\frac{2}{3}$	salsal
	2.5	m^3	250 g =	$3\frac{1}{3}$	salsal	36	g = 4	tablespoons	18	g = 2	tablespoons	250 ml =	$3\frac{1}{3}$	salsal
	3	m^3	300 g =	4	salsal	43	g = $4\frac{3}{4}$	tablespoons	21	g = $2\frac{1}{3}$	tablespoons	300 ml =	4	salsal
	4	m^3	400 g =	$5\frac{1}{3}$	salsal	57	g = $6\frac{1}{3}$	tablespoons	29	g = $3\frac{1}{3}$	tablespoons	400 ml =	$5\frac{1}{3}$	salsal
	5	m^3	500 g =	$6\frac{2}{3}$	salsal	71	g = 8	tablespoons	36	g = 4	tablespoons	500 ml =	$6\frac{2}{3}$	salsal
				$\frac{1}{2}$	kg		= 1	salsal		= $\frac{1}{2}$	salsal		$\frac{1}{2}$	ℓ

Comparative Measurements(approximately)

1 teaspoon, flat 1 tablespoon, flat 1 salsal tin = tin for tomato paste	= 3 g chlorine powder = 9 g chlorine powder = 75 g chlorine powder	= 8 tablespoons chlorine powder
1 teaspoon 1 tablespoon 1 salsal tin = tin for tomato paste	= 3 ml = 9 ml = 75 ml	= 8 tablespoons

ml = millilitre; ℓ = litre; m^3 = cubic metre (see 5.3/4); g = gram; kg = kilogram (see 5.3/5)

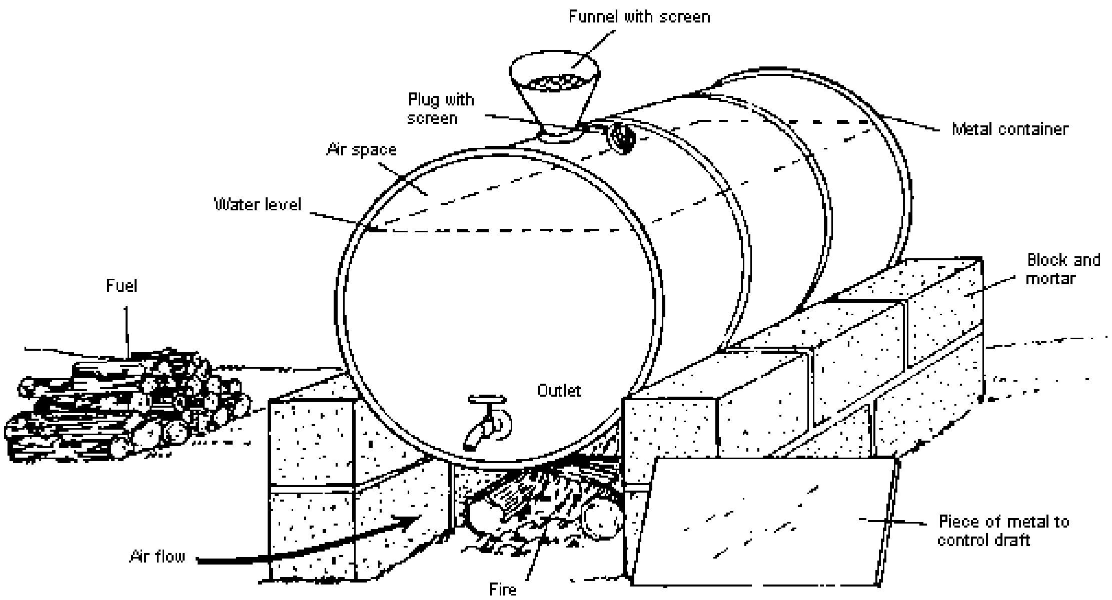
H) Boiling

Boiling destroys all forms of disease organisms in water. However, boiling requires a lot of firewood or other fuels and is very expensive.

Bring the water to a rolling boil; the water must be bubbling rapidly. Let it boil for 2-3 minutes.

Store the water in the same container in which it was boiled to prevent new contamination.

To boil a large quantity of water for many people, the boiler can be built from a drum (see drawing):



I) Filtering with Sand Filter

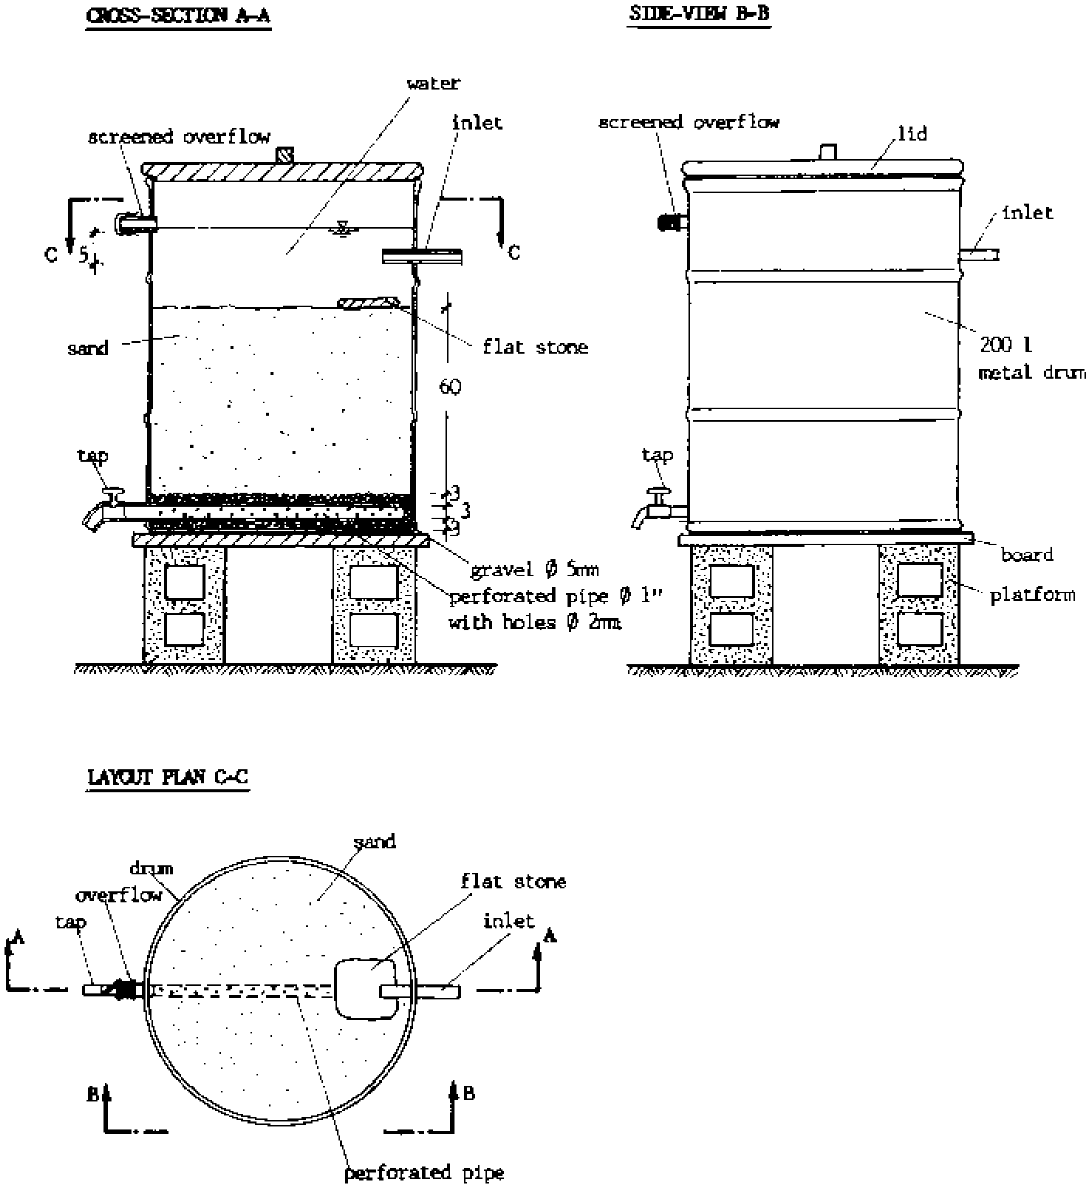
Household sand filters made from locally available materials can be used for cleaning the water.

Sand filters where the sand is not constantly covered by water clarify the water, but do not remove the bacteria. Sand filters where the sand is constantly covered by water remove most of the bacteria.

For details see No. 44 in the bibliography and other literature.

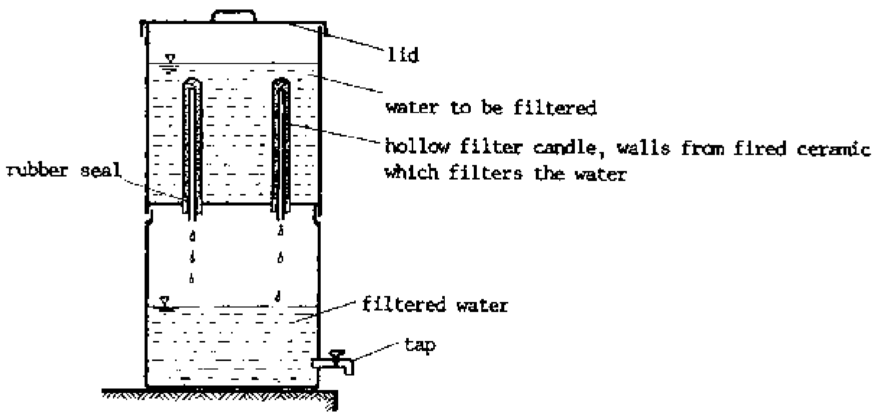
A household sand filter is shown on the drawings next page. See also 6.1/22.

Household Sand Filter



J) Filtering with Commercial Filters

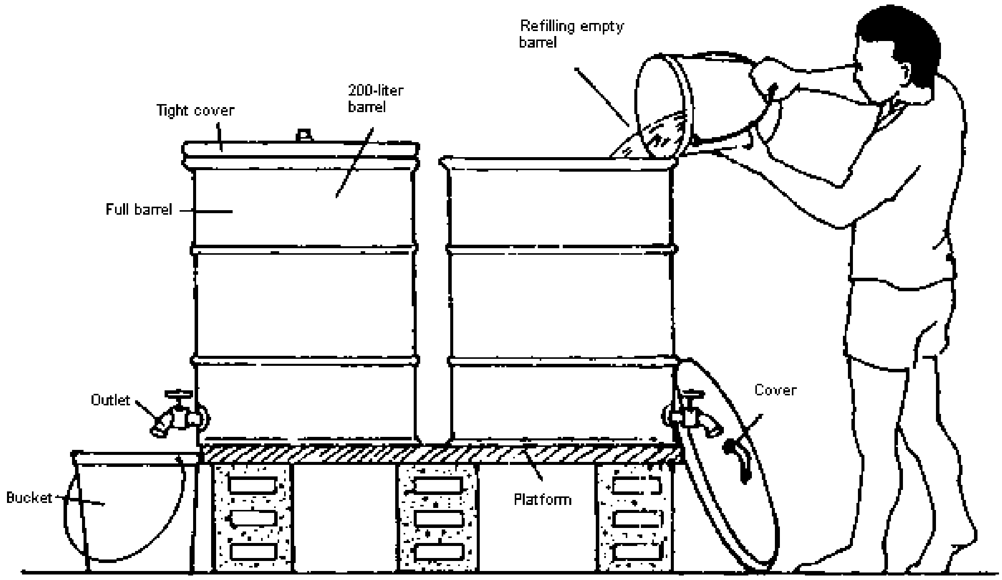
Commercial filters with filter candles made from fired ceramics provide water free from bacteria, if maintained according to the instructions. They are relatively expensive and can filter only a limited amount of water per day.



K) Storage

Five or six days water storage is enough to reduce the level of bacteria enough so that people can safely drink the water. If the water quality is poor, increase the length of storage.

Use two barrels with taps and covers. Fill both barrels and empty one completely before using water from the second. When use from the second barrel begins, refill the first barrel. Each time, clean the barrels carefully. Use the water from the barrels only for cooking and drinking.



L) Heating

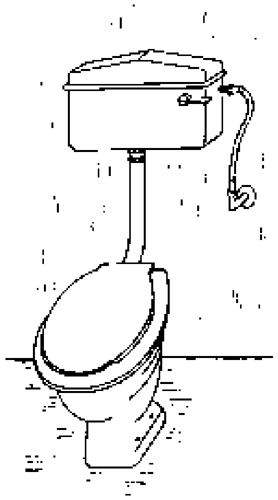
Expose jerrycans of water to the sun for one day. The water will be heated to 50-60°C. This will reduce organic contamination, but not remove it completely. See in the bibliography 46, July 1986.

M) Restriction of the Use of Safe Water

Restrict the use of the available safe water to basic needs like drinking, cooking, washing dishes, brushing the teeth. Use different water for bathing and washing the laundry.

ONE JERRYCAN = 20 LITRES

ONE SHORT-CALL = 20 LITRES



DO NOT WASTE DRINKING WATER!

See also 8.29/5 and 9.8/2.

8.38. Handling Water at Home

A) Possible Ways of Contamination of Water from a Clean Source

Even if water is taken from a clean source which is safe for human consumption, we may afterwards still experience diseases. The reasons may be that the water is contaminated

- during collection and delivery to the home,
- during storage and use in the home.

This can happen in the following ways:

1. During Collection and Delivery to the House

- The container for fetching the water can be contaminated, e.g.

    * if it is not kept clean or has holes,

    * if people use their hands or other dirty items as a funnel to direct the water into the container,

    * if people wash hands and face, etc., while filling the container at the same time,

    * if the container is used for fetching drinking water from the borehole and then the same container is used for water for other purposes from an unsafe source,

    * if the container is left open at home and flies, cockroaches and other animals have access to it.

- The container is left without cover when fetching: animals may drink; the hand of the one carrying may go into the water while lifting and carrying the container.

- The cover used is not clean, e.g. the lid of the jerrycan is put on the ground or leaves are used as cover for a bucket or claypot.

- The water is put from the pump into an open barrel and then taken to the house by jerrycan. The wind can blow dirt into the barrel and the jerrycan will dirty the water when dipped into it for filling after standing on the ground.

2. During Storage and Use in the House (see also 9.5/3)

- The container for storage is contaminated, e.g.

    * It is not cleaned regularly.

    * Members of the family do not wash their hands after going to the latrine. Their hands remain dirty. The person is thirsty and takes water from the pot with a cup, but is not careful and reaches with their hand into the water. The germs enter the water and infect others drinking later on.

    * The pot has no lid or the lid does not close properly or is not relaced after each use. Dust and dirt can enter the pot; flies, cockroaches and other animals can contaminate the water, especially, if it is placed directly on the ground.

- The cup used for taking water from the pot is contaminated, e.g.

* It is not washed regularly.

* People use the same cup for dipping and for drinking. Saliva of a sick person enters the water and brings germs to it. Others drinking later get infected.

* Many people use the same cup and infect the water and each other.

B) Possible Ways to Avoid Contamination

1. Generally

Never touch drinking water with your hands.

2. Container for Transport

- Clean your hands before fetching water.

- Clean the container before fetching water.

- Always use a closed container with a clean and fitting lid.

- Use separate containers for drinking water and other water. Do not use the container for drinking water for any other purpose. If you have only one container, wash it thoroughly with sand, soap and hot water and rinse it afterwards, each time before you fetch water for drinking.

3. Container for Storage

- Equip the pot with a tight lid and tap.

- Remove water from the pot only through the tap.

- If there is no tap, teach everybody in the home how to take water carefully not touching it with the hands, to pour water into another cup for drinking, and to replace the lid.

- Clean the pot regularly and do not keep water for more than 2 weeks.

- Put the pot on a stand to prevent algae and fungi growing into the pot, animals having access to it and small children touching the water.

- Insist that everybody in the home washes his/her hands with soap after going to the latrine.

4. Container for Drinking

- Clean the cups regularly.

- Ensure that everybody uses his/her own cup, if possible; at least ensure that somebody sick uses a separate cup for drinking.

- Never use the same container for dipping and drinking.

- If there is no tap, use a container with a long handle for dipping, stored inside the pot, below its cover.

C) How to Equip a Claypot with Tap and Lid

One possibility to prevent contamination of the water in the home is to equip the pot for storage with a tap and a lid. In the following, it is described how that can be done.

1. Instructions How to Fix a Tap

a) Materials and Tools Needed

Quant	Item	Drawing
1	claypot (can be an old one, but it should not have any cracks)	1	$\frac{1}{2}$" tap with joining piece (should be joined together in the shop to see whether it fits properly)	2	tablespoons of cement	1	for drilling: reinforcement rod Ø 6 mm, 25 cm long (can be sharpened by cutting with a bolt cutter or with a stone)	1	or 6" nail	1	or hand-operated drilling machine with stone bits	1	rasp (if available)	
1	big bowl for soaking the pot	1 1	small bowl table spoon	 2	nylon bags	
	cloth or paper	
	sand and water (not salty)	

b) <u>Step-by-Step Procedures</u>

No	Step	Drawing
1	Mark the place you want to fix the tap on the pot. Soak the pot in water and also pour water into the pot. The location of the tap needs to be well soaked.	2	The tap should be connected with a joining piece of pipe. This should be done in the shop where you buy the tap. Hold the tap with the joining piece against the pot at its future location and draw a circle around it. The location should be not too low or too high on the pot.	3	Make a big hole for the tap by making first several small ones. Scratch the pot carefully with the 6” nail or reinforcement in the way you stir food until you have made a hole, or drill with a hand-operated drilling machine with a bit for stone. Never use a hammer. Smoothen the edge of the hole with a rasp; it shall be just big enough to push the tap in.	4	Close both sides of the tap with a piece of cloth or paper.	5	Choose a place where the pot can remain unmoved for 2-3 weeks. Put sand on the ground and position the pot in it so that the opening for the tap is on the top. The tap shall be in vertical direction.	6	Mix in a small bowl 2 tablespoons of cement with <u>very, very little</u> water. The mixture must be very stiff, like asida (= ugali).	

No	Step	Drawing
7	Place the tap into the opening in such a way that it is horizontal in the final position. Make the place wet. Smear the cement mortar around the joining pipe from inside and outside. The mortar shall be as thick as a finger at the tap and smooth on the edge.	8	<u>Do not move the pot at all.</u>	
9	Wait until the mortar is a bit hard. Then cover it with wet sand and a nylon. Pour some water into the pot and close the mouth of the pot with a nylon bag.	10	Keep the sand wet continuously for five days. This is most important.	
11	After one week, the pot can be carefully moved and the lid can be manufactured. After a second week or later, the pot can be used.	
12	Remove the cloth or paper from the tap and clean the pot carefully before use.	

2. <u>Instruction How to Make a Lid</u>

a) <u>Materials and Tools Needed</u>

Quant	Item	Drawing
1	claypot	1	handle, bent into shape from reinforcement rod or any other scrap metal.	1	support piece, from hard carton, plywood, or an old plate	2	nylon bags	
2	cups of sand	

Quant	Item	Drawing
1	cup of cement water (should not be salty)	1	sieve (used for flour) or a piece of mosquito wire	1 1	bowl tablespoon	1	6" nail (for scratching a mark on the pot)	
b) Step-by-Step Procedures

No	Step	Drawing
1	Scratch two marks into the edge of the pot.	2	Position the pot vertically in sand and pour some water into the pot.	3	Cut a support for casting the lid from carton paper or plywood, or use any fitting plate. Place it into the mouth of the pot) it should not fall in, but leave an edge of the pot free.	
4	Bend a piece of reinforcement into the shape of the handle.	

No	Step	Drawing
5	Place a nylon bag on top of the supporting piece on the mouth of the pot, hanging over the edge of the pot.	
6	Sieve sand. Mix 2 cups of sand with 1 cup of cement and a little water. The mortar should be very stiff like asida.	7 8	Smear the mortar on the nylon as thick as your smallest finger. Place the handle on top.	9	Finish the lid with mortar. When completed, it should be as thick as two fingers. Smear the mortar tight on the edges of the pot. The edge of the lid shall not be too thin. Smoothen the surface.	
10	Scratch two marks on the lid, matching the marks on the pot.	
11	Wait until the mortar is a bit hard. Then put sand, soaked in water, on top of the lid. Cover it tightly with a nylon bag and and tie the bag around the mouth of the pot.	12	Do not remove sand and nylon bag for one week. Afterwards remove the sand, nylon bags and support Clean the lid and the pot thoroughly. The pot is now ready for use.	

8.39. Health Education about Water/Operating Instruction for Wells

A) Health Education about Water

People need to be made aware about the facts concerning water and health in order to improve their situation and change wrong habits. Therefore, the aim of the health education about water in the project is

- to inform people about the importance of clean water and the connection with sanitation;

- to make people understand the importance of keeping the well properly and how to use it in a good way;

- to make people understand the importance of maintenance and continuous care for the well.

B) Connection of Water and Health

A change in the health situation can only happen if all people use good water and sanitation facilities and use them properly.

Water supply and sanitation are very closely connected; improvement can only happen if none of them is neglected. In this chapter, we deal with the water side, the sanitation side is mentioned in 9.5, 9.6, 9.21, 9.22.

Water must be sufficient, clean and safe in order to contribute to reducing disease, not only for drinking and cooking, but also for

- bathing, hand-washing and cleaning the teeth;
- cleaning vegetables, fruit and kitchen utensils;
- washing the laundry;
- watering animals(see also 8.5 and 8.6).

The problem is that one cannot see or easily know whether water is really clean and safe. Water which looks clean can still carry disease, and other water which may have a salty taste and not be liked by the people may be safe.

In order to have water which is really clean and safe, that means it contains nothing which can cause disease, we have to prevent contamination of water which we know is safe, that is normally groundwater. Contamination needs to be prevented

- at the water source,
- during collection and delivery } see 8.38
- during storage and use in the household } see 8.38

Water can be polluted at the source by	How to prevent/cure it
chemicals, like fuels, DDT, etc. washed into the ground by rain	- Do not use dangerous chemicals where water is used for human consumption. See 9.13/3; 9.16/2 - There is **<u>no cure</u>**.
poor sanitation facilities or wrongly constructed latrines or WCs and septic tanks, through germs and nitrates/nitrites	- Keep “safe” distances (at least 50m) between latrines and water source. See 4.15/6; 8.12/1; 9.8/3. - Never have a latrine reach into the groundwater. See 9.8/3. - Cure for germs: chlorination.(8.36) - **<u>No cure</u>** for nitrates/nitrites.
Dirty water around the well, see- ping into it (surplus water from the pump or rainwater)	- Care for a proper platform, big enough, without cracks, and with a drainage channel and soak-away pit. See 8.19. - Care for a hedge or fence not to let animals come near and dirty the place. - Keep the area around the well dry and clean and without rubbish. - Do not wash laundry near the well but provide a place for that at a distance.
dirt or small animals falling into the well	- Care that the well cover is closing properly. See 8.20/3. - Care that there are no cracks in the platform. See 8.33/1.

C) Operating Instruction for a Well

In the project, handing over of a well to a community is used as a chance for health education. This is reinforced by regular follow up visits. The operating instruction takes place at the well site and is based on the knowledge people already have on the subject, e.g.

- It is bad to drink dirty water.
- Little rain will give little water in the well.
- If the well is misused, there will be no other nearby source of good water.
- If the well is open, it is dangerous for children and animals.
- If a pump breaks down, there will be no water.

The topics covered are the water cycle, keeping the well and its surroundings clean, taking care of the hand pump, and using it properly. The methods used are practical demonstration, drama and posters together with explanations. For hand pump caretakers this topics will be covered, together with the duties and technical information, in a small seminar.

The following posters are used for operating instruction of a well.

6. GEOMETRICAL CONSTRUCTIONS
6.1 Lines and Angles
6.1.1 To bisect a straight line AB
6.1.2 To divide a straight line into a given number of equal parts
6.1.3 To divide a straight line AB into any ratio
6.1.4 To construct an angle of 90°
6.1.5 To construct an angle of 45°
6.1.6 To construct an angle of 60°
6.1.7 To construct an angle of 30°
6.1.8 To bisect any given angle
6.1.9 To construct an angle similar to a given angle
6.1.10 To draw a line PARALLEL to a given line
6.2 Triangles
6.2.1 To construct an EQUILATERAL triangle
6.2.2 To construct a triangle with given BASE ANGLES and ALTITUDE
6.2.3 To inscribe a circle in a given triangle ABC
6.2.4 To circumscribe a circle around a triangle ABC
6.3 Circles
6.3.1 Basic CIRCLE-constructions
6.3.2 To draw a tangent to a point A on the circumference of a circle
6.3.3 To draw an internal tangent to two circles of equal diameter
6.3.4 To find the centre of a given circle arc
6.3.5 To join two straight lines at RIGHT ANGLES to each other by an ABC of given radius
6.3.6 To draw a curve of a given radius joining two circles
6.3.7 To join two straight lines by two arcs of equal radius
6.4 Basic ARCH-Contructions

1. AIMS AND PURPOSE OF ARCHITECTURAL DRAWINGS

Architectural drawings are made as a MEANS of COMMUNICATION between
- the client
- the architect
- the engineer
- the building authority and
- the people, who are executing the construction work.

One can define architectural drawings as a LANGUAGE. Therefore the drawings should be:
- easily understandable
- clearly arranged
- unequivocal
- correct
- standardized and
- clean

in order to avoid mistakes and misunderstandings, which may become very expensive.

1.1 Contents of architectural drawings

Architectural drawings should show

I. the ideas and immaginations of the designer (architect)

II. the type of the building or structure, which has to be in accordance with
   - the rules of building construction
   - the availibility of building materials
   - the financial possibilities of the client
   - the regulations, bylaws and building rules of the local authority

1.2 Types of Architectural Drawings

Each type drawing has its special contents and has to save its own purpose.
There are different types of architectural drawings:

1. Sketch Drawings: show the solution of the job with the approximate measurements of the rooms and construction members as well as the arrangement of the buildings on the site.
   common scales 1:500, 1:200.
2. Design Drawings: Show the agreed solution of the job with the exact measurements of the rooms and construction members. For submission to obtain a Building Permit they have to be in accordance with the regulations of the LOcal Authority.
   common scales: 1:100 (1:200)
3. Working Drawings: Have to content all necessary specifications and measurements of the rooms and construction members in order to carry out the job properly.
   They also have to specify the used building materials and structures.
   common scale : 1 : 50
4. Detail Drawings: complete the Working Drawings for specific parts of the buildings in a bigger scale.
   common scales 1:20, 1:10, 1:5, 1:1
5. Special Drawings: give particulars about special constructions such as:
   Reinforced concrete work, steel - and timber work, sanitary or electrical systems etc. For such drawings, other construction members are only shownas far as necessary to understand the drawing correctly.
   Scales as necessary.
6. Accounting Drawings: give all necessary informations for the accounting.
   Scales as necessary.
7. Stock-Taking Drawings: indicate all - for a certain purpose - necessary particulars and informations about an existing building
   Scales as necessary.

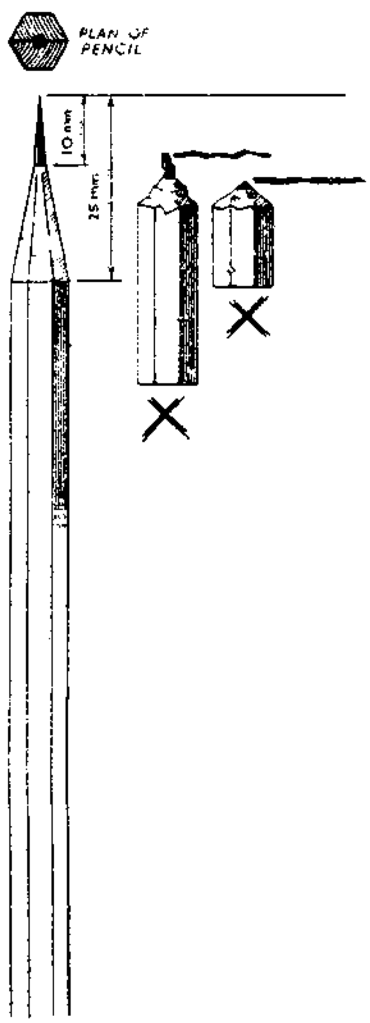
TYPE OF DRAWING	SCALE
1. Sketch Drawings	1:500,1:200
2. Design Drawings	1:100,(1:200)
3. Working Drawings	1: 50
4. Detail Drawings	1: 20,1:10, 1:5, 1:1
5. Special Drawings	as necessary
6. Accounting Drawings	as necessary
7. Stock-Taking Drawings	as necessary

2. DRAWING EQUIPMENT

2. DRAWING EQUIPMENT

In the following, only the principle items of drawing equipment required by the draughtsman are mentioned.
The draughtsman, especially the beginner, is advised to purchase the best available instruments he can effort and he should handle and maintain them carefully.
Well kept drawing equipment is the prior condition for making good drawings.

PENCILS



PENCIL

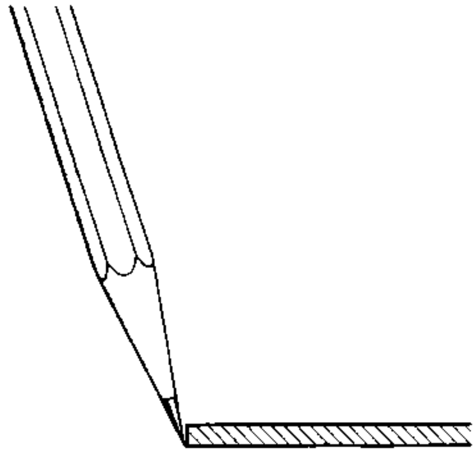
2.1 PENCILS
Ordinary drawing pencils are made of cedarwood with leads of compressed clay and graphite and are about 175mm long. There are round and hexagonal types available. The hexagonal type is more easily held in the fingers and the pencil does not roll off the board or table. Always try to by the best pencils you can obtain because the leads of which are gritty or crumbly make good draughtsmanship impossible.

When a pencil has been reduced to about half its length by sharpening, the 'balance' tends to be destroyed and it becomes difficult to control. The short length should be put in a holder. In case you cannot find any holder, a stripe of paper can be rolled around the end an gummed, to increase the length and make the pencil more manageable.

Pencil points should be long, round and evenly tapering the exposed lead should be about 10 mm long, and the wood cut back a further 10-15 mm. The point must be round, and then, if the pencil is slowly revolved as lines are drawn,it will wear away evenly and remain sharp for some time.

Clutch pencils are a popular alternative to the ordinary pencil of similar shape and size, consisting of a metal lead holder into which leads of varying degrees or various colours can be inserted. A push bottom operates the clutch and enables the lead to be withdrawn or fully protected as required. The main advantage of the clutch pencil is that balance is always constant, but it is heavier than the wooden pencil.

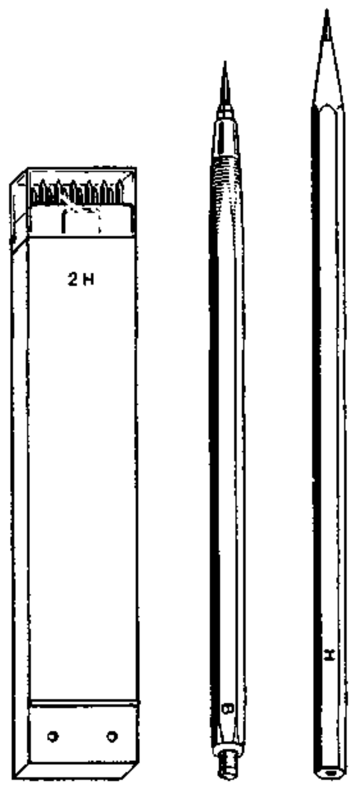
There is a special type of clutch pencil for thinner leads (between 0.3 - 0.9 mm) which makes sharpening unnessesary.



Leads are made in varying degrees of hardness and softness, ranging from 9 H, the hardest, to 6 B, the softest. The extreme grades are very little used. Most drawings can be carried out by using

2 H
H (-hard)
F (-firm)
HB
B (-back)
2 B

Setting out lines and fine work may be done in H, rogh sketching in B. Beginners should not use pencils harder than H on cortridge and similar drawing papers. It is a common error to resort a hard pencil because the point lasts longer and the line is less likely to smudge, properly used HB pencil will keep its point just as long and will give a much better line whilst pomitting greater freedom of wrist action. Hard pencils bite into the paper and make harsh wiry lines. Smudging is due to carelessness and the student should learn to avoid rubbing the lines of his drawing.



Sharpening: The best way of sharpening an ordinary pencil is by means of a penknife. The pencil is held in the left hand, below table-level and pointing downwards so that chips and lead dust cannot fall on the drawing paper. And with the penknife in the right hand inclined cuts are made firmily and regularly to remove the wood ground the point. The final sharpening is done with the penknife blade held more or less at right - angles to the lead - this reduces the risk of a sudden cut going right through the point.

PENKNIFE

Pencils should not be sharpened with the lead held against a thumb - a sure way to make hands and clothes dirty - nor should safety - razor blades be used - they are much too sharp and difficult to control.

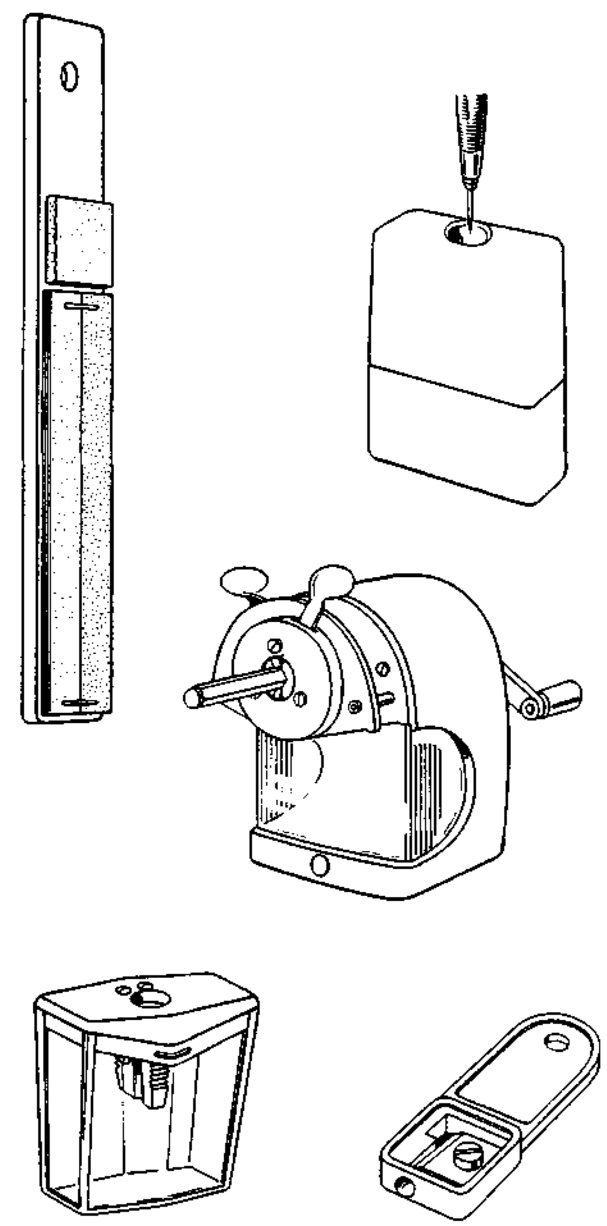
Sand paper pads: should never be used They are not only too coarse to produce anythin like a good point, but they make an intolerable amount of dust which is rapidly transferred to fingers, clothes, and drawing papers.

Mechanical pencil sharpeners which can be screwed either to the table or wall ar generally efficient and save a certain amount of labour, although the points usually need a final touch of the penknife.

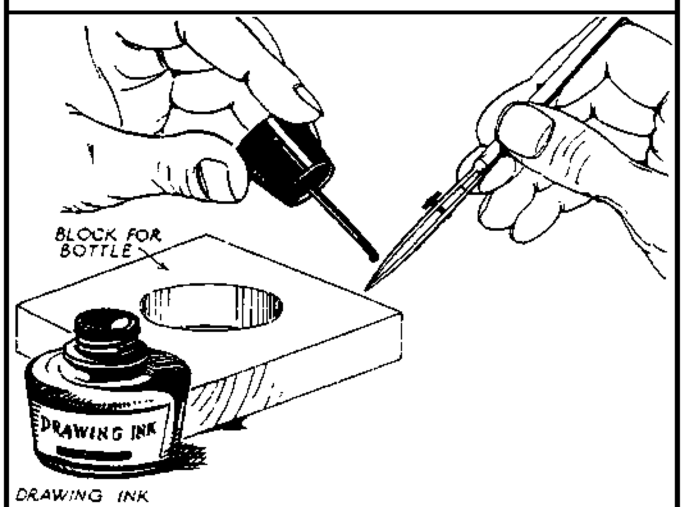
The small sharpeners that can be held in the fingers are quite useful, although care must be taken that lead dust and shavings fall into the waste basket or otherwise safely disposed of.

It must be realised that pencils require frequent sharpening when in continous use, and the beginner should start with a good stock and not be surprised if they wear out quickly.

Sharpening a clutch pencil, small lead pointers are often used, although its use is a potential source of black dust on fingers and paper; it is better to use a special pointing machine.



DRAWING PENS

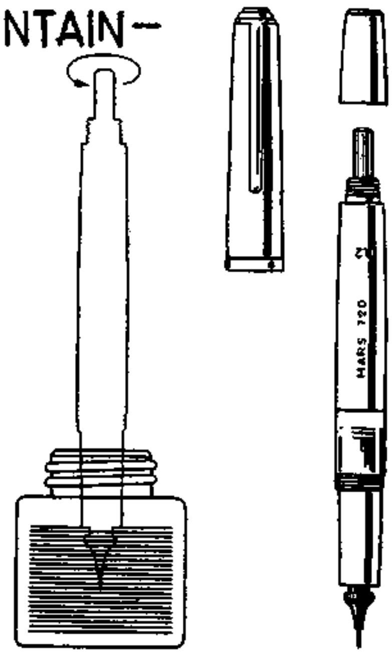


2.2 DRAWING PENS:Straight lines in ink are ruled in conjuction with the T-square and set-square (with the drawing board equipment or with a drafting machine) by means of special drawing pens. There are three types of drawing pens
- Ruling pens
- Graphos
- Rapidographs

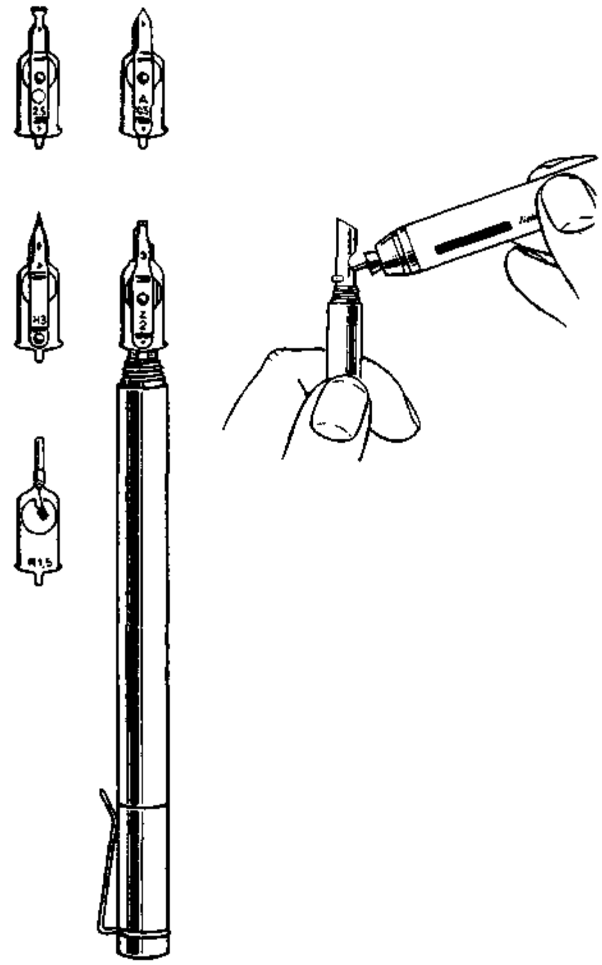
The old type of Ruling pen has frequently to be filled either by means of the dropper from the ink bottle, or dipping an ordinary freehand pen into the bottle and transferring the ink to the blades. It is better not to put much ink between the blades. Practice will indicate how much is satisfactory. The thickness of the line required is obtained by means of the adjustment screw and by testing at the side of the drawing paper or on scrape of similar paper.

DRAWING PENS

FOUNTAIN-PEN

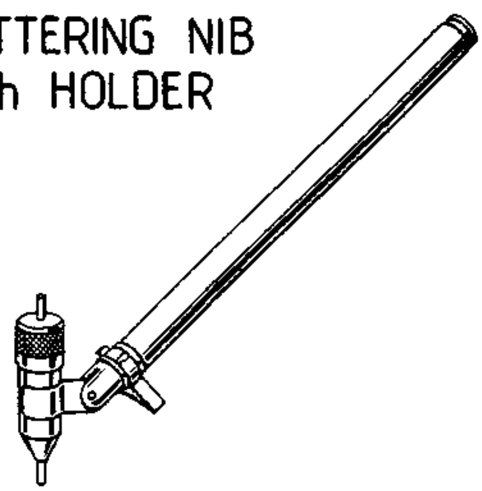


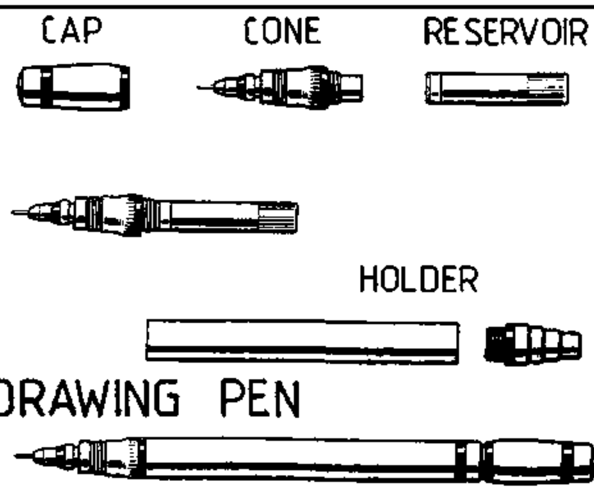
GRAPHOS



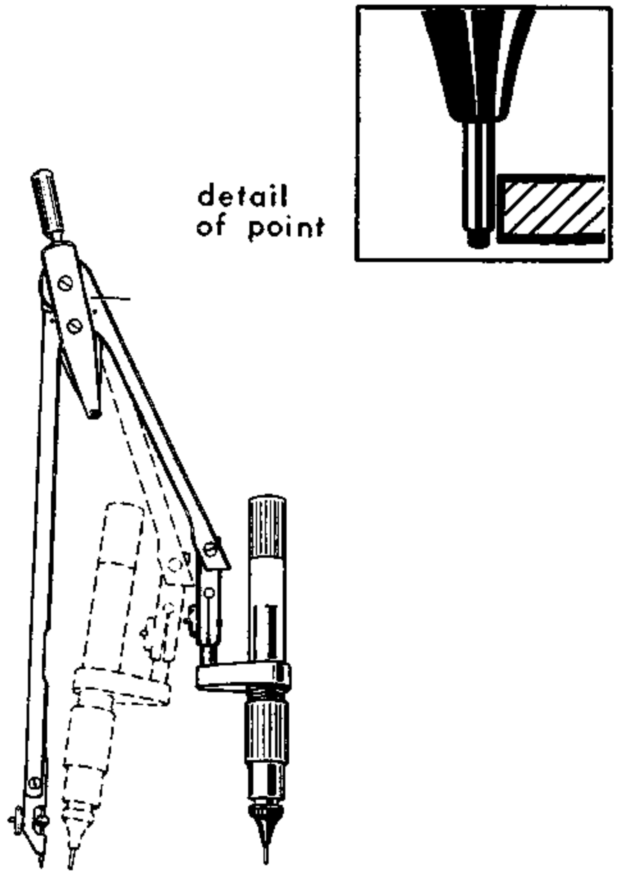
Graphos and Rapodographs are based on the fountain-pen principle, with ink reservoirs, so that they can be used for long periods without refilling. Interchangeable nips or drawing elements are used for different thick - nesses of lines. The most common set consists of 0,18, 0,25, 0,35, 0,7, 0,5 1,0, 1,4, (2,0) mm. The pens are also be used for free-hand drawing of lines and for freehand and stencil lettering. The graphos pen has special nibs for freehand lettering.

LETTERING NIB with HOLDER

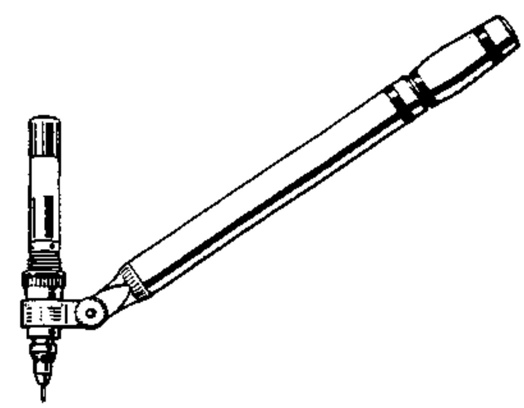


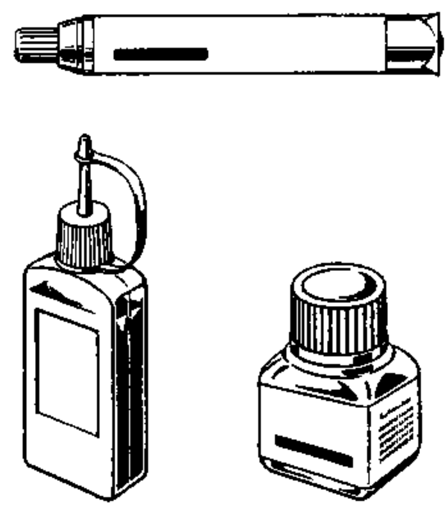


DRAWING PENS



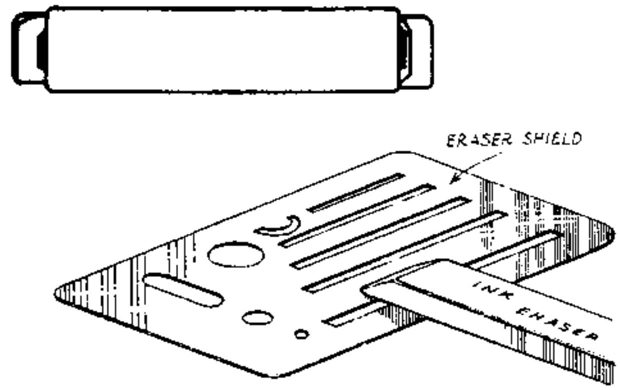
Instruction for use and care come with the pens and it is very important to follow these instructions, especially in regard to cleaning.Keep the pens always clean and do not allow them to become clogged or encrusted with ink, so that undue time has to be wasted in making them work.
All kinds of Drawing Pens should be held perfectly upright against the edge of T - square or set - square, and should be drawn smoothly with even pressure from left to right or in upwards direction.





Drawing ink: Water proof black ink is used for line drawing. It can be taken from small glass bottles with dropper or pipette for filling ruling pens and other instruments, from plastic bottles for Rapidographs and similar pens, or from special cartridges for graphos pens etc.
Not all inks are suitable for the drawing pens described earlier or for the use on all kinds of film and the maker's recommendations should be followed.
Containers should always kept closed (exept when pens or instruments are being filled) to keep out dust and to lessen the risk of accidental spills.

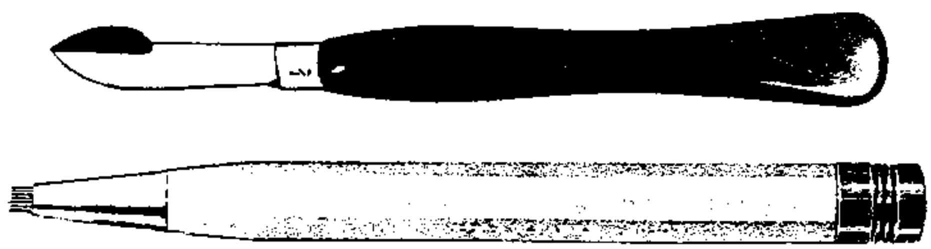
In warm weather it may be found that the ink will run more freely if it is slightly diluted with clean, preferably distilled water. Bottles should not be shaken once they are in use.
Inks should never be mixed and dirty pens must not be used: Chemical action may be set up and the ink becomes lumpy.
Drawing inks are obtainable in different colours.



Erasers: Alterations, corrections, and the removal of unwanted lines are best made by rubbing with a soft rubber or vinyl eraser. Erasers should be large enough to be easily gripped, but very large rubbers last too long and, as the outside surface becomes hard and useless in time, it is probably better to keep to small sizes. When the surface of the eraser is affected, it can be cut away or, if not too bad, rubbed clean on an old scrap of paper.

For a large area of paper the so called gum eraser is probably quicker and more gentle to the surface. For removing soft pencil shading, which are smeared by on ordinary eraser, a special putty rubber must be used.

So called 'glass erasers' are generally efficient. They consist of a holder (metal or plastic) into which bristles of glass are inserted. A screw bottom operates a mechanism which enables the glass bristles to be withdrawn or fully protected as required. The main advantage of the glass eraser is that glass bristles are gentle to the surface of tracing paper, but they have to be handled carefully to avoid small particles sticking in your hand, which is quite painful.



Ink lines on drawing paper are removed by hard erasers. As usually only a small portion of an ink drawing has to be removed and the surrounding lives disturbed as little as possible, the rubbing can be don through a thin metal or celluloid rubbing shield, which has openings to suit areas to be erased. Lines on tracing paper are best removed by scraping gently backwards and forwards with a safety razor blade held vertically between finger and thumb.

Electrically operated erasers are sometimes installed in large drawing offices. The machine is suspended over the drawing table and is drawn down to the surface of the paper and a small motor rotates rapidly a piece of pencil rubber or ink eraser.

The small particles of rubber which result from rubbing out should be carefully removed from the surface of the paper by blowing or by lightly flicking with a clean, smooth DUSTER.

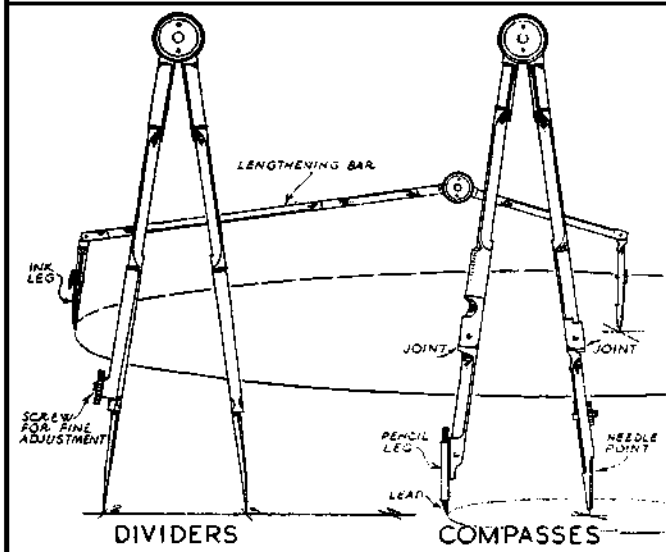
COMPASSES

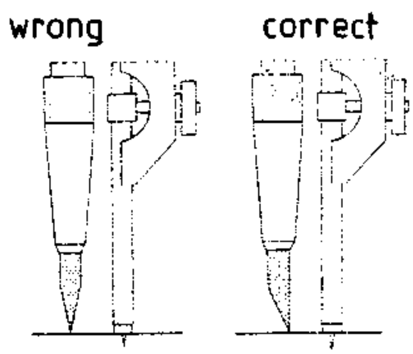
2.3 COMPASSES
The fig. shows a common pattern of compasses, which are used for drawing circles and arcs. One leg terminates in a needle point and the other leg can be fitted with pencil or pen. An additional needle pointed leg can also be obtained for converting this instrument into a pair of dividers. For large circles and arcs a lengthening bar is valuable. Both legs of the compasses are jointed so that they can be bent to keep the point more or less perpendicular to the paper.

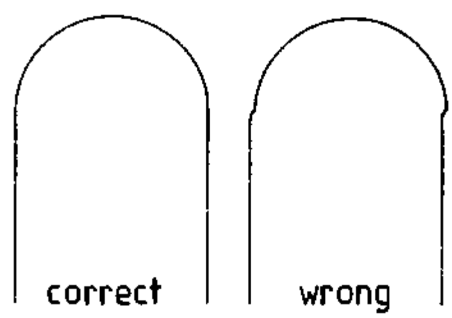
Needle points are removable and are usually shouldered at one end - this end is best for use in drawing circles, as the point does not penetrate the paper too far. The instrument should be held at the top and pressure must be only sufficient to keep the centre from slipping and to maintain a smooth, even line for the curve. The two points of the compasses must be carefully adjusted. The pencil lead should be the same grade as the ordinary pencil being used on the same drawing. A 12 mm length can be out from the bottom of the pencil for the purpose.

It should be sharpened to a fine chisel point and arranged tangential to the circumference, although for small circles a round point is probably better.

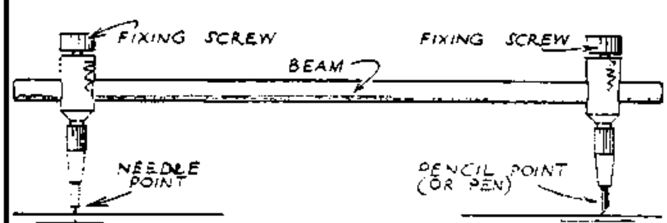
Pens are capable of ajustment in the manner of ruling pens. The thickness of.the ink line should be tested at the side of the paper before the required curve is drawn.
Special compass/pen attachments are available for use with the Rapidographs and with small pump compasses for drawing small circles.







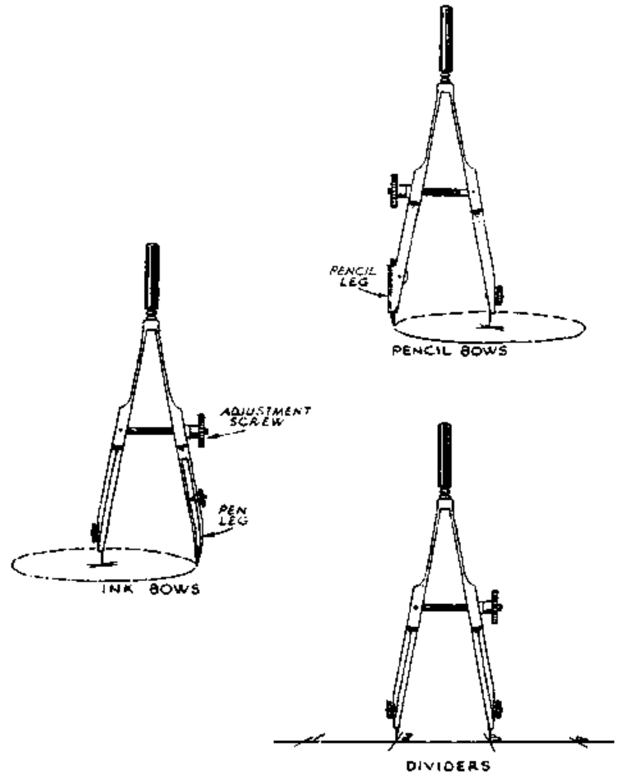
Beam compasses
For drawing larger circles than are possible with ordinary compasses and the lengthening bar, beam compasses can be used. They consist of a centre point and a fitting, with interchangeable pencil and pen legs, which are screwed to a bar to give the radius required.



BEAM COMPASSES

Dividers
The fig. illustrates a pair of dividers used for dividing lines into equal units by trial and error and for multiplying or transferring distances. A convenient size is about 140 mm long. A spring screw attachment to one leg for fine adjustment is an advantage. This hinge should move easily but should not be loose.

Spring bows and pump compasses.
Small dividers and pencil and pen compasses for accurate and fine work are called spring bows. Adjustment is made by means of a screw either at the side, or in the middle at the instrument. There are a number of variations of theses instruments including precision - made pump compasses and rapid adjustment compasses. It should be mentiones, however, that for general work small circles and arcs are drawn through templates.



SPRING BOWS

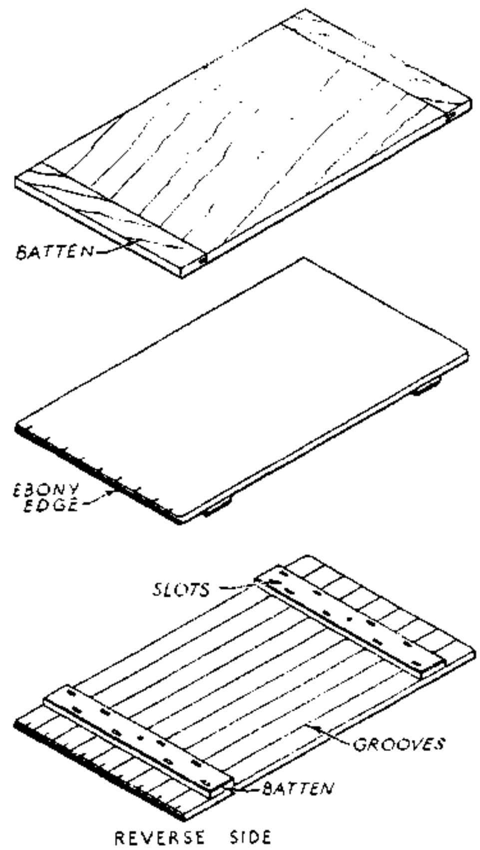
TCA TECHNICAL COLLEGE ARUSHA CHUO CHA UFUNDI ARUSHA	CIVIL ENGINEER. DEPARTMENT	9

2.4 DRAWING BOARDS:
Drawing boards are made in sizes to correspond with standard sizes of drawing sheets. The most suitable for general use are:

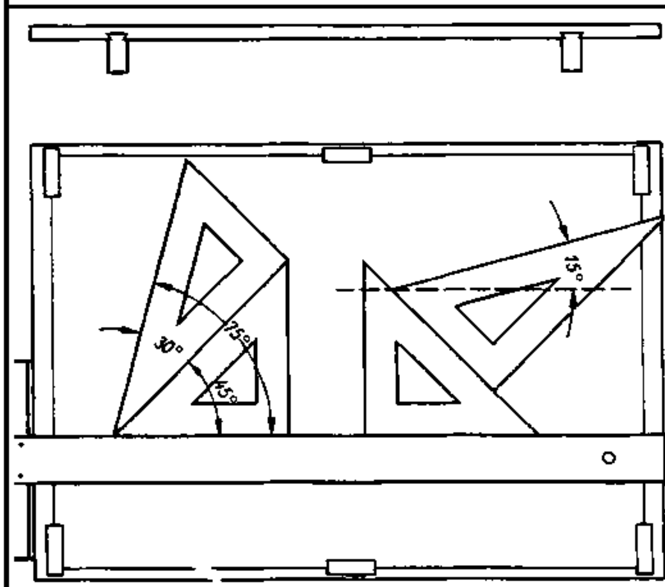
A 1 : 920 x 650 mm
A 0 :1270 x 920 mm

The fig. illustrates three types of drawing boards. Types A and B, not bigger than size A 1, are suitable for the student as they are light for carrying about and are relatively inexpensive. Such boards can be obtained with metal edges. Type C, which is best for office use, is usually made from spruce and has beech battens secured by screws in elongated washers to allow for expansion and contraetion. The back of the board is grooved to resist warping.
Small drawing boards accapting paper up to A 3 size are now becoming generally available. They are precision made with smooth plastic surface, are light and easily transportable and are often supplied with a carrying case. They are provided with positive sliding drawing heads or rules operating rather linke T-squares for drawing horizontal lines and with matching set squares multipurpose design. Alternatively, they can be fitted with miniature drafting machines. They usually have devices for holding drawing paper in position as pins or staples cannot be used and adhesive tapes tend to spoil the board.

DRAWING BOARDS



DRAWING BOARDS



It is important with all types of drawing boards that the faces are perfectly flat and smooth and that they will not twist or buckle with normal use. Edges should be at right-angles to one another. Wooden boards should have a firm even grain, free from knots and should be soft enough to take drawing pins or staples easily and allow the removal without diffeculty. Boards with compostion surfaces can have paper attached by means of spring clip or strips of drafting tabe.

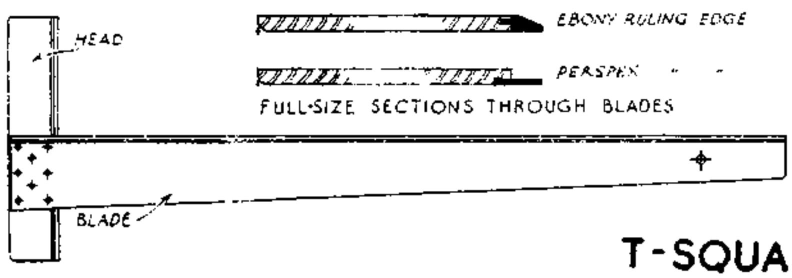
T-SQUARES

2.5 T-SQUARERS

Are used in conjuction with the board for drawing horizontal lines. The head of the T-square being held against the left hand side of the board by the right handed person (reverse T-squares are made for the left handed draughtsmen). Sizes correspond to the lengths of the drawing boards:

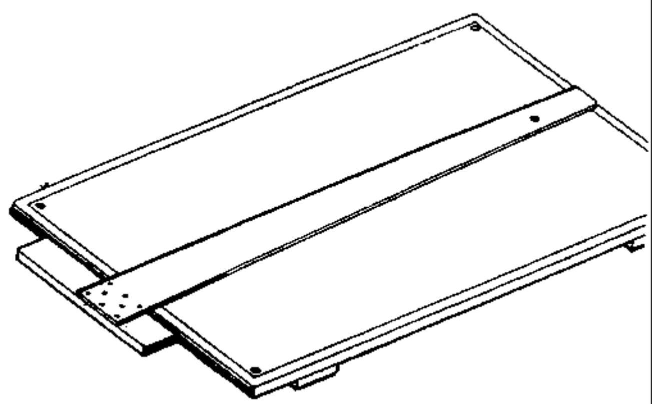
A 1   920 mm blade
A 0   1270 mm blade

T-squares are best when made of mahogony with ebony or clear plastic ruling edges or of clear or coloured plastics. For lightness blades have to be made of thin strips of wood (plastics), but this renders them liable to fracture. Therefore: Dont leave them lying about in bridge positions or leaning against walls.
They should either be left flat or hang on pegs.



T-SQUARE

- Dont use a T-square as a hammer to knock in drawing pins, a loosing of the fixing between head and blade will be the result.
- Dont use the blade as a straight edge in cutting paper in order to avoid indentations along the ruling edge.
- It is important to keep the underside of the blade smooth and clean, and this is best achieved by wiping it periodically with a soft cloth with a few drops of petrol or similar spirit. Water can be used, but is less effective and may cause warping.



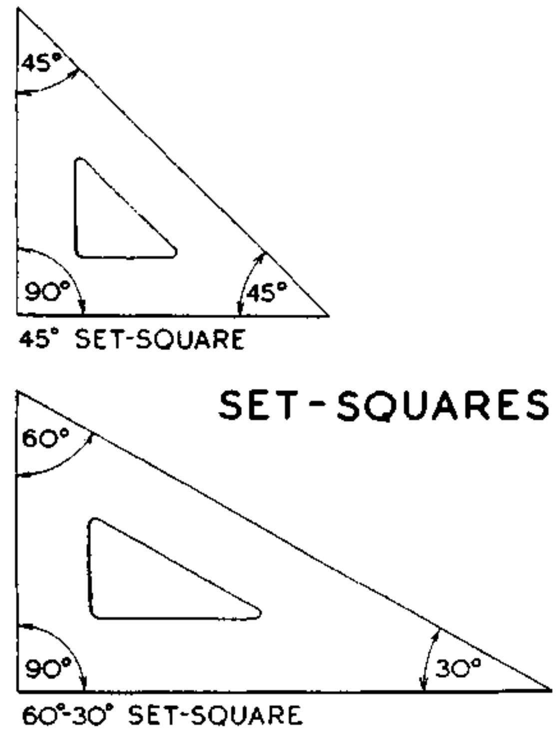
2.6 SET SQUARES

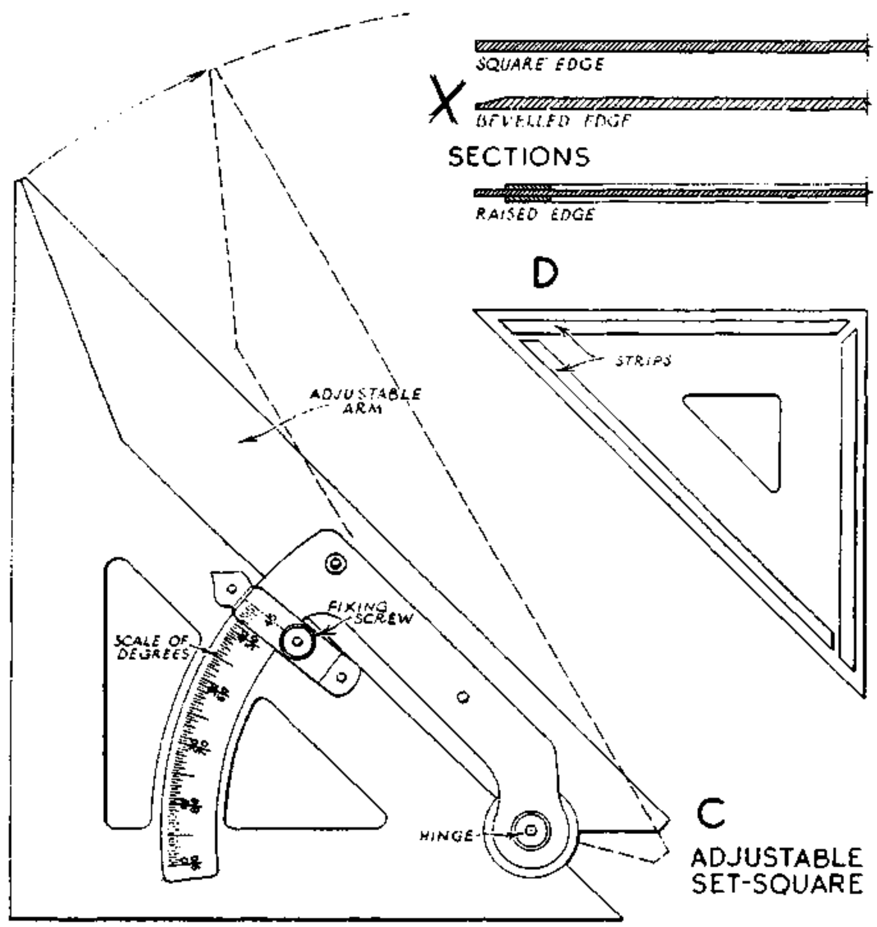
Set-squares are used for drawing vertical and inclined lines. They are triangles of clear plastic about, 2mm thick, and there are three basic kinds as illustrated:

A - 45 degrees
B - 60 - 30 degree
C - adjustable

For general use the length of the longest side should be about 250-300 mm and the edges should be square.

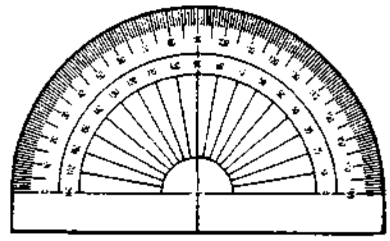
Set squares to be protected from damage. Dents are caused by hard knocks and cutting with a razor blade, etc, along the edge can easily ruin them. They should be kept clean, because dirty set squares quickly transfer the dirt to the drawing.





2.7 PROTRACTORS

PROTRACTORS



A protractor is used for measuring or for setting out angles. It is a semicircular (or circular) piece of metal or clear plastic with the arc divided into degrees, reading both to left and right, and with the centre and diameter indicated. The protractor is placed so, that the centre coincides with the apex of the angle and the diameter lies along one line the position of the other line on the scale giving the reading.

The most convenient sizes have diameters from 100 mm to 150 mm. The transparent protractor is to be preferred.

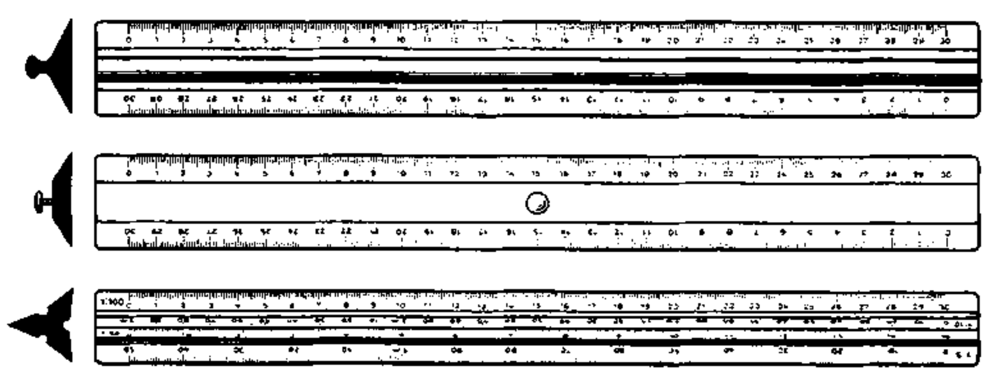
2.8 SCALES

SCALES

Scales are thin narrow strips of plastic or boxwood with divisions along each edge. These divisions are in various recognized proportions to actual destances and dimensions, and can be used for making new drawings 'to scale' of for measuring, by 'scaling' existing drawings. There are scales available for metric drawings as well as for drawings in which drawings are related to feet and inches.

Now commonly used by architects and draughtsmen are three edge scales with divisions along each edge in the proportion of 1:1 or 1:10/1:100, 1: 200, 1:5/ 1:50, 1:250/1:2500 and others.

Scales are usually 300 mm long. They never should be used for ruling lines or for any other purpose for which they are not intended, the edges are soon chipped and broken.

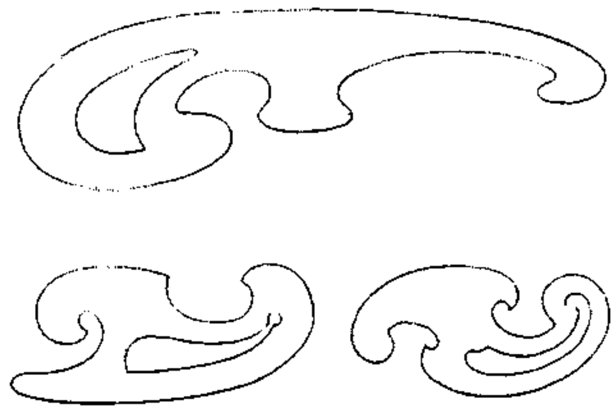


2.9 FRENCH CURVES

French curves are made of clear (or coloured) plastic like set-squares. They can be used for drawing irregular or complex curved lines which cannot be conveniently made up of arcs of circles. Many shapes are available, but one is usually sufficient for architectural drawing. They are not essential, and with practice curved lines can be drawn freehand more rapidly and often with better effected. Long slow curves can be drawn by a series of blended straight lines with acceptable accuracy.

Another device is the flexible ruler consisting of a length of pliable plastic which can be bent to any required curve. Patience is needed to get the correct curvature, but once set the ruler is particularly useful for repetition work.

FRENCH CURVES



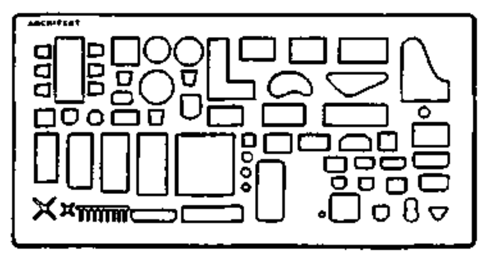
2.10 TEMPLATES

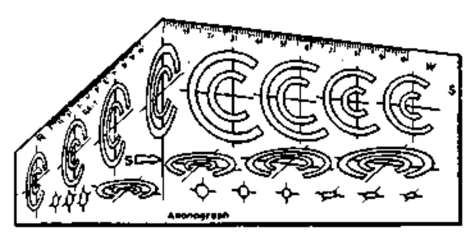
Small circles and ellipses, or parts there of, can often be more easily drawn with the help of plastic templates, which are available for figures of various metric and imperial sizes. There are also special templates available such as Symbol templates for:
- Electrical installation
- Plumbing work
- Furnitures in different scales (1:200, 1:100, 1:50) etc.

The main advantage of these templates is saving time.

Lettering guides, stencil-lettering, transfer-lettering. These are described later under LETTERING.

TEMPLATES





FIXINGS

2.11 DRAWING PINS AND OTHER FIXINGS

Small, flat - headed pins are best for fixing the paper to the board in most cases. They should be well made of brass with sharp round points. The type with the point stamped out of the head is of little use.

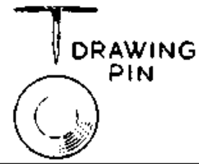
As the heads should hold the paper, the pins must be pressed well into the board. Four pins, one at each corner, should be sufficient if put in about 10 mm from the edge of the sheet. Whenever a drawing is repinned the previous pin-holes, unless enlarged or torn, should be used again. Pins can usually be taken out easily by finger and thumb-nail but the blade of an old penknife can be inserted under the head to rise it up in the case of a stubborn one.

Other means of holding the paper to the board are spring steel clips, staples, and drafting tape. Clips are not always secure and sometimes get in the way of border lines, etc. Staples (the smalles tsize is best) are quick and convenient for fastening the paper and do not interfere the running of T - square and set square, but are a nuisance to get out. Drafting tape tends to be an intidy and rather messy fixing method except for short term use. For holding one piece of tracing paper over another, especially where the piece is relatively small and pins cannot be used because they would damage the sheet below as well as get in the way of T-square and set-square, transparent self adhesive tape, such as sellotape, is most suitable as it can be placed away on completion without effecting the paper.

MINOR ITEMS

2.12 MINOR ITEMS OF EQUIPMENT

In addition to the essential equipment already described the following should be readily available for use as the need arises:



- A good pair of scissors. Cutting knives for thick card and a lighter knife, of which there are many kinds, for thin cardboards and paper. In this connection, a metal ruler or straightedge is useful.

- A piece of cotton-cloth often washed or soft toilet paper for cleaning drawing pens etc.

- A handy scratch pad for notes, memos, rough calculations, testing pens, etc.

- Provisions for the safe-keeping or transporting of drawings.

- Soap, towels and a hand wash basin with water.

PRINTING PAPERS

2.13 PRINTING PAPERS

Printing papers are used for making copies of drawings by photocopying processes. Copies are usually referred to as 'Prints'.
There are different types of photocopying processes (semi-dry dyeline or dry developed by ammonia gas). They all require a transparent or translucent negative e.g. a drawing or tracing media. This is passed in contact with diazo paper sensitive to ultraviolet light, through a machine in which it moves around a special tubular lamp emitting such light.

Where no machine is available the so called 'sun-print' method can be used. A timber or metal frame in accordance with the size of the drawing, covered with glass, the negative, printing paper, and sun: thats all you need for that method. For developing the same method is used as with a printing machine depending on the type of printing paper.

Dyeline prints can be made on different type of papers e.g. on airmail paper, which is very flimsy and difficult to

TRACING PAPERS

2.14 TRACING PAPER, CLOTH AND FILM

These materials are specially treated paper and linen, and polyester film of transparent or semi-transparent nature; when placed over an original drawing they allow the lines underneath to be clearly seen and so copied or traced. The tracings thus made can then be used as negatives for the making of any number of further copies by the photo-printing processes. Drawings can of course be made directly on the materials in question. Almost all production drawings are negatives of one kind or another.

Tracing paper is most economical if purchased in rolls, but for final drawings it is increasingly the practice in offices and in schools of architecture to use pre-cut sheets in the A-sizes, often with printed border lines, title blocks, and sometimes modular or other grids, etc. Tracing paper can be roughly classified into three categories. thin, medium and stout, and two surfaces: smooth and rough. Different makes vary, however, so that it is difficult to particularise as to the most suitable; personal preference plays some part in selection. Thin papers are usually good enough for preliminary sketches but are too flimsy for final negatives.

Smooth surfaces are best for pencil drawings, as the rough kinds wear down the leads and tend to smudge and smear. For roughing out design and many other uses rolls in short widths are handy.
Tracing cloth is nearly always supplied in rolls, although short lengts can be purchased. The material is usually tinted blue, but white is also available. It is much more expensive than tracing paper, and is used mainly for master negatives in ink, but to a lesser extent than formerly as it is being superseded by film. Film is also expensive but has superior transparency and is stated to be stretch-proof and waterproof. It should be used in accordance with the manufacturers recommendations, for example in regard to type of backing sheets, prepartion before inking, and use of erasers.

BACKING SHEETS

2.15 BACKING SHEETS

Drawing boards should be covered with backing sheets, over which the actual drawing paper or tracing media is placed to provide a firm, even working surfaces. This is particularly important if boards have become pitted, scored, damaged or worn.
Thick white cartridge paper is a satisfactory material, cheap enough to be discarded as it becomes soiled drawing pins can be used. Other and harder materials for backing sheets of a semi-permanent nature are thick, flexible plastic sheets usually with a green surface and cellulose-acetate sheets, which can be printed to standard lay-outs and grids.
In connection with backing sheets, a useful device to minimise the marking of drawings by rubbing of the T-square is the fixing of a strip of folded drawing or tracing paper - three or four thicknesses are sufficient - about 20 mm wide along the left-hand edge of the board. Fixing by drawing pins or staples at the ends only is best.

Drawing boards with an integral plastic surface do not normally require backing sheets, but for working on tracing paper a white under sheet is an advantage.

DRAWING PAPERS

2.16 DRAWING PAPERS

There are two main classifications of drawing papers: 1) machine-made papers, such as cartridge, which are used for exercises and line drawings, and 2) handmade or mouldmade papers used for rendered drawings. Mention is made of other types of paper, where necessary, in later chapters.

CARTRIDGE

2.17 CARTRIDGE

This is sold in rolls and A-size sheets, including pads of 30 sheets up to A2 size, as well as in the old standard sizes of antiquarian, double elephant, and imperial.
The paper is made in three thicknesses: 'thin', 'medium', and 'stout'. The thin is usually too flimsy to be of much value, it is also obtainable in rolls either unmounted or mounted on cotton or holland. The rolls can be conveniently cut into the various standard sheets or used for extra large drawings, and are probably more economical for the busy office.

Unmounted cartridge paper has right and wrong sides which can be distinguished by examination - the wrong side has a slightly but regularly pitted surface, and the cut edge of the sheet is usually turned down towards the wrong side.

The surface is fairly satisfactory for pencil drawing and the 'stout' quality will take ink moderately well, but it is not really suitable for colour washes except those of a most limited nature. White cartridge paper, which is usually of better quality, is to be preferred to that which is cream in colour.

HANDMADE PAPERS

2.18 HANDMADE AND MOULDMADE PAPERS

These are obtainable in sheets of standard sizes, and usually in three surfaces: HP (hot pressed) - smooth; NOT - medium; R - rough. The firstnamed is the kind most used for pencil and ink drawings and various types of renderings, particularly work in wash. All the papers can be 'stretched' and some can be obtained already mounted on stiff card or board. Water colour paper is also sold in pads.

PLASTIC-COATED CARD

2.19 PLASTIC-COATED CARD

For particularly fine pencil line and pen and ink drawings some draughtsmen prefer an extremely smooth plastic-coated card, such as CS 10. Great care is needed, however, in working with thi medium as ink lines are easily smudged. Any removal of lines must be made by gently rubbing with a soft eraser.

handle, on medium paper, which is normal and suitable for general use on stout paper which is the best for mounting, colouring and presentation and cotton-backed paper.

Master copies or new negatives, from which further copies can be made, can also be produced on tracing paper, tracing cloth and polyester-based materials. Such copies are used for the adding of specialist information, as a basic for the preparation of working drawings and for supplying remote sites with means of obtaining local reproductions. All dyeline prints tend to fade on long exposure to daylight.

Mention may be made here of other methods such as: -

- true - to - scale (TTS)
- photostats
- microfiling of drawings
- various kinds of ordinary office coppies: thermographic, electrographic and diffusion transfer. Although these types of copies are developed for the copying of typed or printed documents they are excellent for the rapid copying of small drawings - or large drawings in parts which can be subsequently joined. For paper sizes (up to A 1) the dyeline process should be used.

3. LETTERING

3. LETTERING

Little progress can be made in draughtsmanship without attention being paid to lettering. Almost every drawing has to be titled and many of them, particularly working or production drawings, require descriptive words and notes in order that they can be clearly understood.
Therefore, it is important for the draughtsman, to aquire as quickly as possible the habit of using good lettering on all his work.

And as the study of lettering also affords excellent practice in drawing, it is particularly suitable that it should be dealt with at an earlystage in the training.

PRINCIPLE of LETTERING

3.1 Principle of lettering:

1. Legibility
   depends on
   - a shape or form of each individual letter
   - b spacing of letters and arrangement of words
   - c the size and positions of the lettering according to relative importance.

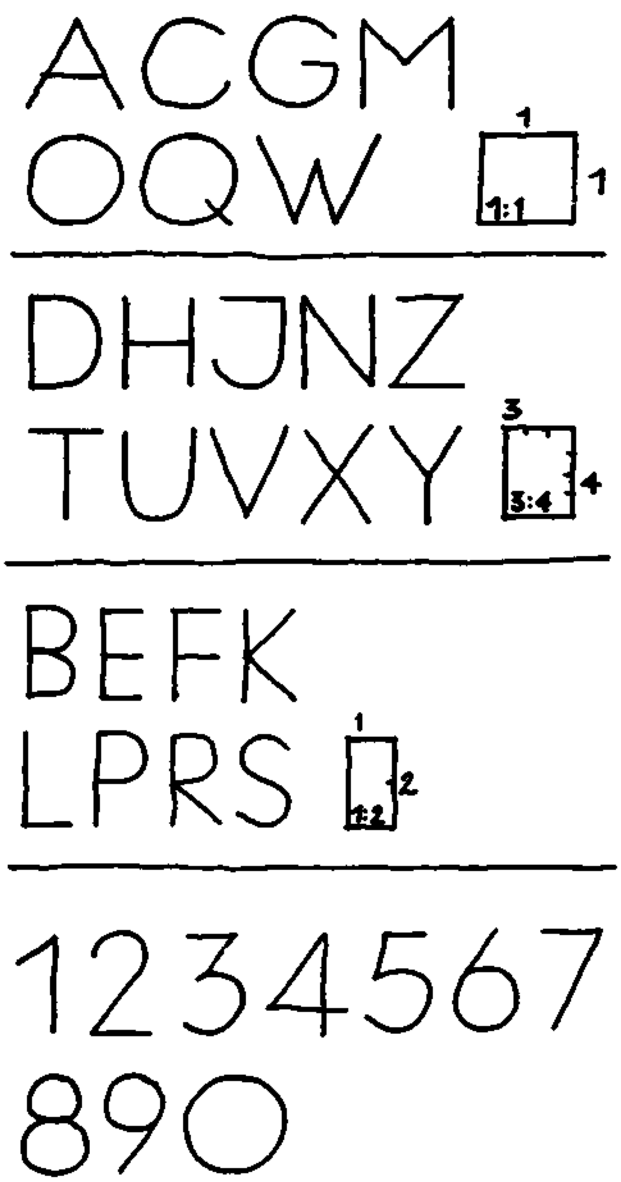
2. Suitability
   of shape to materials and method of execution, thus, lettering drawn in pencil on paper will differ in form to some extent from lettering incised in stone.

3. The Character
   must be appropriate to its purpose. The type of letters and general composition of the wording should be expressive of the quality or use of the drawing, e.g. decorative lettering is completely out of place on a working drawing, just as crude stencil lettering would be on a highly finished perspective drawing.

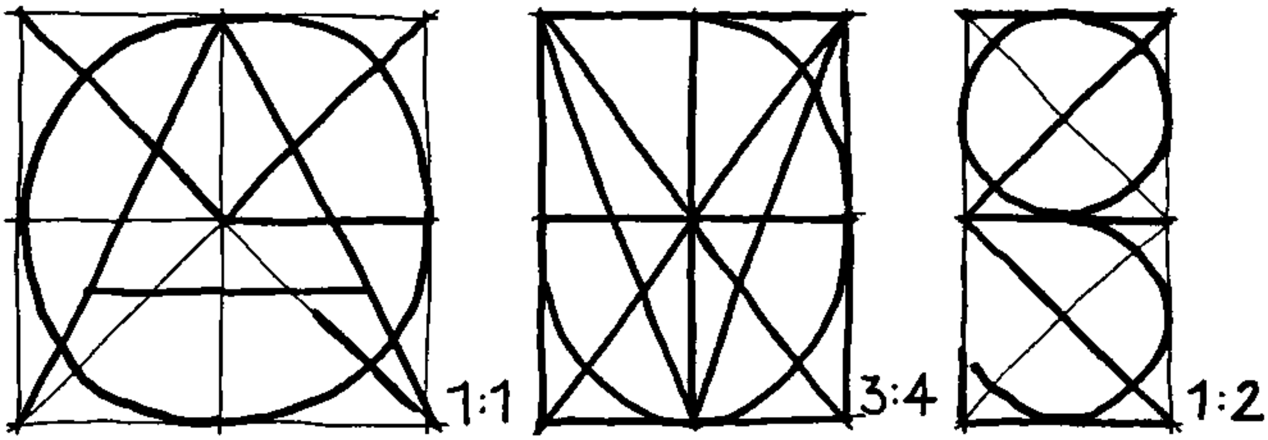
FREEHAND LETTERING

3.2 FREEHAND LETTERING

Absolutely sufficient for Architectural Drawings are 'block letters' with simple, vertical letters, represented with straight lines, circles or parts of circles. Important are the proportions of the letters which are described in the following scheme.



In the following please find som explations how to draw or to write capital block letters:



A take the area of a square. The horizontal stroke should be in the lower third. Other forms look too wide or too thin.

B Should be inwritten into two squares, which are on top of each other. The roundings are parts of a circle.

C consists of a three quater (3/4) part of a circle

D has to be drawn in a full semi-circle

E again should be in written into two squares, which are on top of each other.

F is equal to E, without the horizontal bottom stroke. Both remains horizontal stroke should have the same length.

G has almost the shape of a circle. The horizontal stroke has to be drawn from the centre of the circle to the external line on the right hand side.

H is in-written in a rectangle with the proportions of 3:4. The horizontal line should be drawn right in the centre.

I is only a vertical line without any additions.

J is again in-written in a rectangle with the proportions of 3:4. The lower rounding consists almost of a semicircle.

K fits in an area of 2 squares, one on top of each other. The inclined strokes are drawn from the centre to the top and the bottom under 45^0.

L this horizontal stroke is half as long as the vertical line

M takes again the area of a square. It has to be taken care, that the lines at the left and the right are exactly vertical.

N is to be in-written in a rectangle with proportion of 3:4 three to four.

O has to be drawn as a full circle not oval or in the form of an ellipse.

P has a proportion of two to one, the upper part is drawn as a semi-circle with horizontal parts at the top and the centre of the vertical line.

Q is written like an O the inclined stroke has to be added under 45^0 in the right hand bottom corner.

R is similar to P from the centre of the letter an inclined stroke under 45^0 has to be added.

S is a difficult letter. It may help you to draw it, if you imagine that S is constructed out of two circles, one on top of each other, and which lines are not completely closed.

T fits in a rectangle with the proportion three to four.

U consists of a semi-circle at the bottom, the two ends extend in vertical lines.

V again fits in a rectangle with proportions three to four.

W draw V twice next to each other, fitting in a square.

X all have to be drawn in a rectangle
Y with proportions of three to four.

Writing numerals we have to follow the same rules, their elements are straight lines, circles and parts of circles.

1 The small inclined stroke should never be horizontal, otherwise it could be mixed up with 7.

2 Is in the upper part a semi-circle which continues as a inclined line under 45^{o} downwards.

3 Is only in the lower part a semi-circle the upper parts consists of an inclined stroke under 45^{o} with a horizontal stroke on top.

4 ends at the top as a triangle

5 the upper stroke on the left hand side has to be drawn exactly vertical, other wise it might be mixed up with 3

6 should be drawn as full circles with
+ an tangential inclined stroke under
9 45^{o} up or downwards.

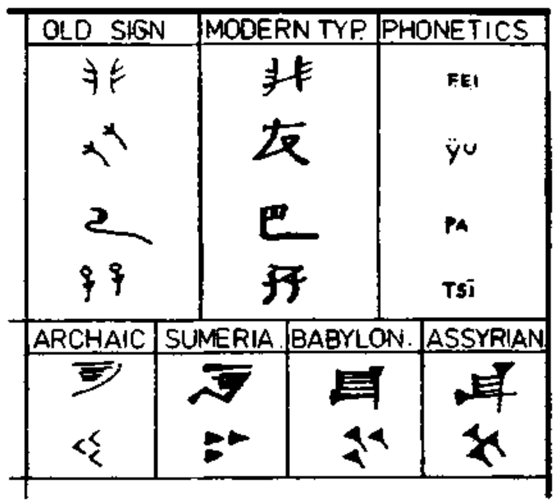
7 it is advisable to draw a short horizontal stroke crossing the inclined line at the centre, in order to avoid a confusion with 3.

8 consists of 2 full circles, one on top of each other

TYPES OF LETTERS

3.3 TYPES OF LETTERS

Writing is a sort of 'language of sings' and it serves the purpose of fixing informations. About 5000 years ago people in China, Mesopotania and Egypt have started to write down their informations. As letters, they used signs and symbols. Later on these sings and symbols have been changed to letters and numerals of different types and even the types of letters and numerals have been modified up to the present day.



ROMAN

3.3.1 THE ROMAN ALPHABET

In architectural drawings the historical types of letters should not be used except for special purposes, e.g. as decorative lettering in perspective drawings or for titeling in stock-taking drawings of historical buildings. However, there is one alphabet in the history which should be studied carefully. Our modern lettering is derived from that of the ROMANS, and the generally accept as standard is the lettering which was carved on Trajan's Column, Rome, in the second century. A.D. The forms of these letters have now become familar in printing types and flat letters, and the Roman alphabet will always be the basis of good lettering.

The construction of each letter is shown and should be understood:

Practicing capital block lettering, always try avoid inclined letters or unnecessary decorations. The same passes for the numerals.

3.3.2 SANS SERIF LETTERS

In more recent times, letters without serifs, known as 'sans serif alphabets' have been designed and are much used because of their simplicity, clarity and ease of execution. The fig. shows the setting-out of such an alphabet, suitable for the titling of drawings, etc.

3.3.3 INCLINED LETTERING

Sometimes it is necessary to distinguish between two types of lettering, e.g. names of rooms on plan and notes regarding construction. While this might be effected by variations in size, it may be more convenient to use upright lettering for the one and inclined lettering for the other.

The fig. shows inclined lettering sloping uniformly at an angle of about 75 degrees. The slope should not be exaggerated.

3.3.4 SCRIPT LETTERING

The figure shows individually formed capitals, numerals and lower case letters which can be written in pencil or pen. If well executed it is an attractive way of labelling certain types of project presentation drawings.

3.3.5 STENCIL LETTERING

Stencil letters can be used for titling drawings and are a means of achieving uniformity at negligible cost when a number of drawings are similarly titled. The fig. shows an example and how a stencil is used. Special stencil ink can be used or indian ink or opaque colour, etc. The brush must be almost dry, and the plate must be held down perfectly flat and firmly for good results. The description 'stencil lettering' is also commonly applied to guided pen lettering.

3.3.6 GUIDED PEN LETTERING

The figure shows examples of the leters produced by means of special pens and guides. Such lettering is used extenslively for drawings of all kinds, particularly working drawings and details. Its popularity is due to its legibility, speed of execution, and the uniformity which it gives, especially when different draughtsmen are working on the same set of drawings.

Both upright and sloping guides are obtainable for capital, lower-case letters, and numerals in a variety of sizes with corresponding pens. Also drawing pens like 'graphos' or 'rapidographs' can be used.

Used carelessly, this lettering is as bad as the worst freehand and a certain amount of practice is necessary to obtain lettering which is pleasing in appearance as well as very legible.

A few hints are
1) only a small quantity of ink should be put in the pen,
2) keep the pen perfectly upright in use,
3) wash the pen out immediately after use and see that the wire is pushed well home
4) keep the guides clean, do not let the ink clog the letters. A special cleaning liquid can be obtained for pens and guides.

Always rule faint guide-lines for letters and consider the spacing before starting. Sometimes it may be advisable to make a trial setting-out.

PRESSURE TRANSFER LETT.

AD I compiled : D.VOLKE JUNE '83	LETTERING	ARCH. DRWNG. LECTURE CET 1o43/13.327
TCA TECHNICAL COLLEGE ARUSHA CHUO CHA UFUNDI ARUSHA	CIVIL ENGINEER. DEPARTMENT	27

3.3.7 PRESSURE-TRANSFER LETTERING

This kind of lettering, also known as pressure sensitive, is extensively used on all kinds of architectural and planning drawings, particularly for titling and labelling. It is reasonably quick and most effective. It's only serious disadvantage is that it is rather expensive, especially as many letters of each sheet are never used.

The letters are printed on thin plastic sheets, usually 254 mm x 381 mm, although smaller sheets are available, in a variety of types of alphabets, numerals, punctuations, etc. and are protected by silicon-treated backing sheets. A typical example is illustrated. The characters can be applied to any smooth dry surface in any desired arrangement. Having decided on the type and size of letters to be used and estimated the placing on the drawing - this requires some experience - the technique of application is to remove the backing sheet and to position the first letter, on a previously ruled guide line if there are to be a series of letters, and then to shade across the letter from top to bottom using a ball-point pen with moderate pressure. This action is continued until the letter appears lighter, which shows that it has been transferred to the surface of the paper. The lettering film is carefully peeled back until the letter is exposed, it is then moved to position the next letter and the transfer procedure is repeated. On completion of a word, or every few letters, even after each letter of the larger sizes, the backing sheet should be laid over and additional firm pressure applied by the finger or the edge of a scale in order to obtain maximum adhesion. When application is made to tracing paper or film from which dyeline prints are to be obtained it may be necessary to spray the letters with a matt fixative or they will be damaged in the printing process. As the spray will also 'fix' any parts of the drawing on which it may fall, it is advisable to vonfine the area by masking.

Points continually to be kept in mind are: avoid accidentally pressing any other letter when making a transfer; keep sheets flat and unfolded and uncreased in a box, wallet or stout envelope away from excessive heat or humidity when not in use. However, the accidental transfer of a letter to drawing or tracing materials is not usually a serious matter as it can be removed by scraping gently with a razor blade. Incomplete letters can be patched by applying part of another letter or can be made good in indian ink.

Complete words such as PLAN, ELEVATION, EAST, WEST etc. at a size suitable for the majority of production drawings, are available, as are N points, direction arrows, section lines, electrical symbols and other useful architectural characters.

4. LINEWORK and DIMENSIONING

4. LINEWORK AND DIMENSIONING

4.1 Types of Lines
In architectural drawings five different types of lines are broadly used:
1. continuous lines
2. broken lines
3. broken and dotted lines
4. dotted lines and
5. freehand lines

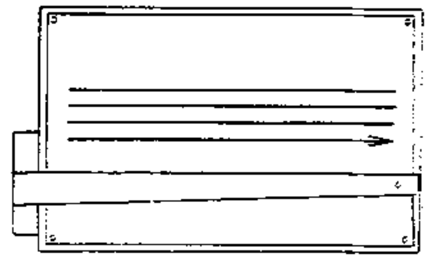
The thickness of these lines is due to their functions in the drawing as well as to their scale and their is classified into
- thick lines
- medium lines and
- thin lines

The following schedule shows type and thickness of lines as well as their use in architectural drawings.
PROPORTION of thickness:

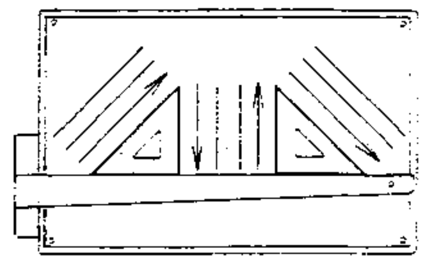
thick	medium	thin
2	1	0,7

Practice the exercises shown in the following as PENCIL drawings with a thickness of lines from 0,18 mm to 1,4 mm for CONTINUOUS lines as well as for BROKEN and DOTTED lines.
Also, the correct and neat drawing of lines meeting or crossing under right or inclined angles should be practiced.

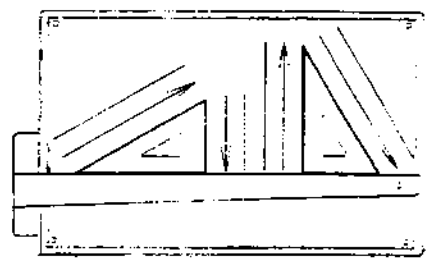
4.2 Pencil drawing
- Use pencils of 2 H to 4 H
- For thicknesses from 0.18 to 0.5mm ONE line is sufficient
  For thicknesses from 0.7 to 1.4 mm (or thicker) a DOUBLE line with the required distance has to be drawn, which has to be filled in afterwards.
- All corners and crossings of lines have to be drawn very exactly.
- It is important to take care that the thickness of the line is INCLUDED with the area of the drawn figure, so that the drawn EXTERNAL dimension is equal to the REQUIRED measurement.
- Draw with the pencil as close as possible along the T- or set-square under an inclination of about 60°



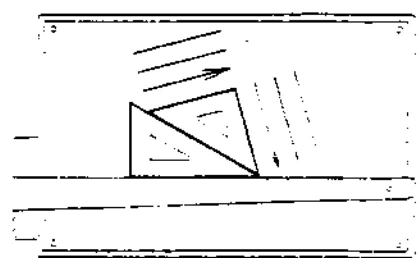
1. HORIZONTAL



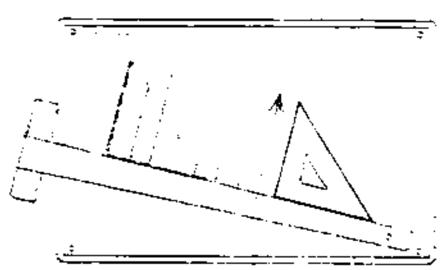
2. VERTICAL AND 45°



3. VERTICAL, 30° AND 60°

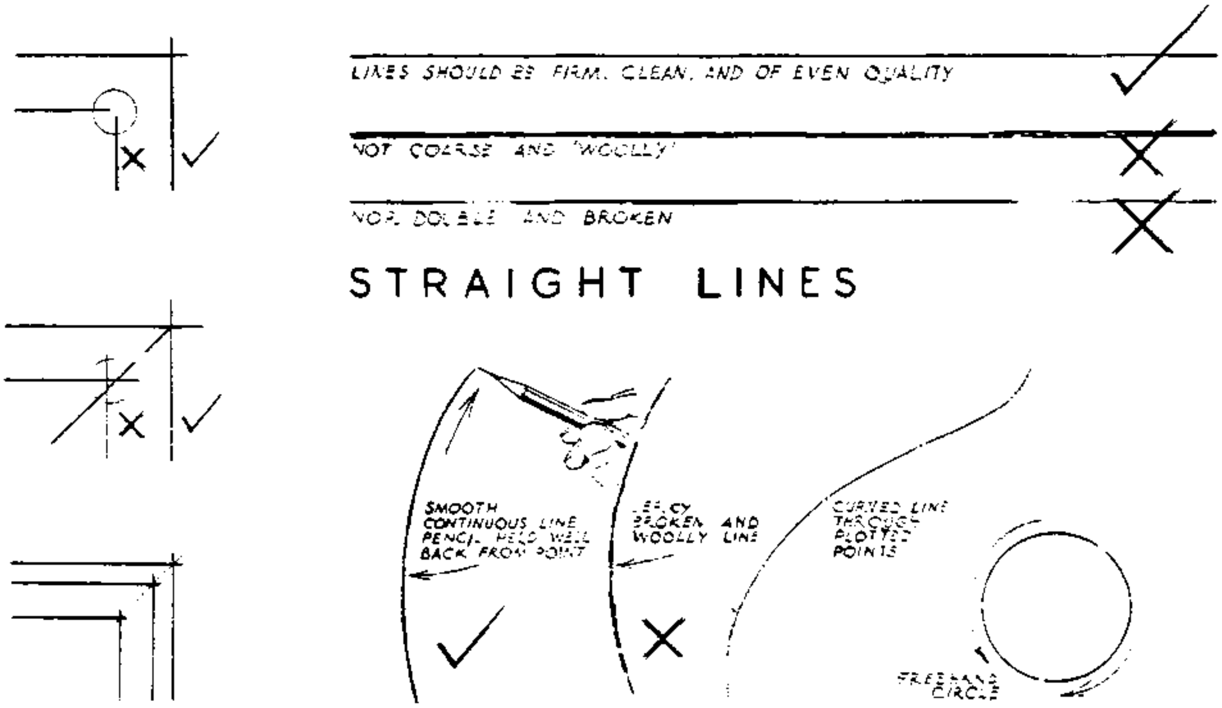


4. 15° AND 75°



5. PARALLEL TO ANY GIVEN LINE

	TYPE OF LINES			USE
A	CONTINUOUS THICK		1.0 mm 0.7 mm	VISIBLE LINES DETERMINATION OF CUT BUILD. MEMBERS, WALLS ≥ 15 cm, CONCRETE, etc.
B	CONTINUOUS MEDIUM		0.5 mm 0.35 mm	VISIBLE LINES DETERMINATION OF ELE- VATIONS OF WALLS AND OTHER BUILD MEMBERS
C	CONTINUOUS THIN		0.25 mm 0.18 mm	DIMENSION AND HATCHING LINES
D	BROKEN and DOTTED THICK		1.0 mm 0.7 mm	SECTION PLANES
E	BROKEN and DOTTED MEDIUM		0.5 mm 0.35 mm	CENTRE LINES, AXES, etc. (big scale)
F	BROKEN and DOTTED THIN		0.25 mm 0.18 mm	CENTRE LINES AXES, etc. (small scale)
G	BROKEN MEDIUM		0.5 mm 0.35mm	HIDDEN OR OVERHEAD ELEVATION LINES, PROPOSED ADDITIONS AND ALTERATIONS
H	BROKEN THIN		0.25mm 0.18 mm	SCREEN OR RASTER LINES
I	DOTTED		0.35mm 0.25mm	PARTS TO BE DEMOLISHED, MINOR BUILD MEMBERS
J			0.35mm 0.25mm	ROLLED STEEL JOISTS PIPELINES etc.
K			0.35mm	BREAKLINE



FREEHAND CURVES

- In order to keep the drawing CLEAN:
. Use clean equipment and good pencils
. keep hands clean and touch the paper with your fingers as little as possible
. avoid unnecessary rubbing
. sharpen pencils away from the drawing board or table
. make any erasures carefully and remove all rubber crumbs
. if much drawing is to be done on several small areas of the sheet, cover the whole of it with tracing paper in which suitable'flap windows' through which to work can be cut

4.3. Inking - In

Follow a certain sequency in the procedure of INKING-IN of a drawing. Ink-in:
1. All centre lines
2. All circles and arcs
3. All horizontal lines
4. All vertical and inclined lines
5. Hatchings and black-in sectional parts
6. All dimension lines, freehand lines, arrows and arrowheads
7. Lettering, dimension figures, notes
8. Titles etc.

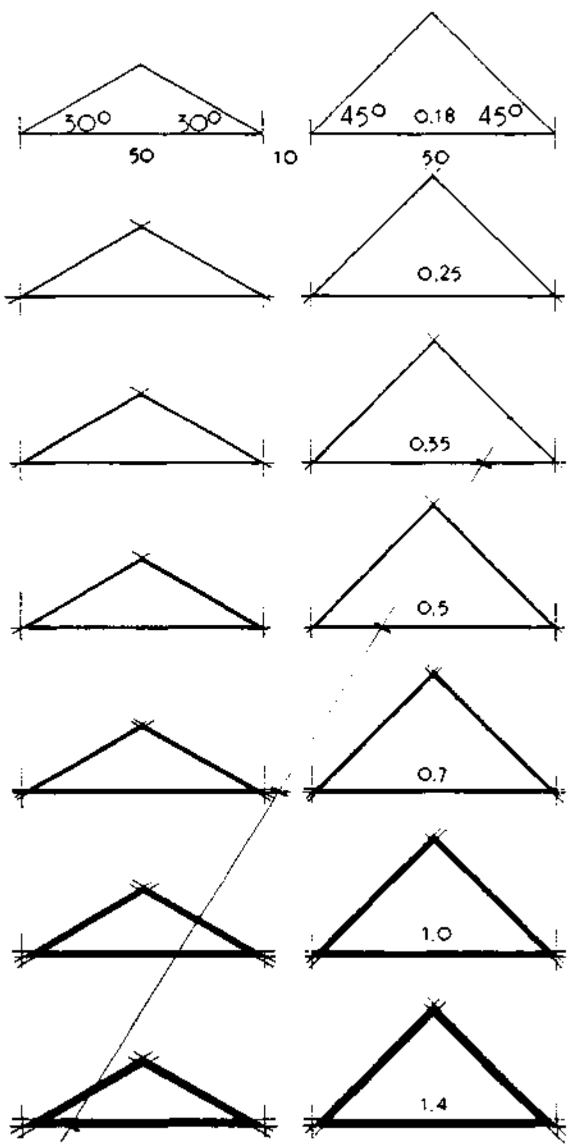
EXERCISE



4.4 Basic Rules of Dimensioning

- The METHOD of dimensioning is due to the type of the drawing (Sketch-, design-, working-, detail drawing etc)
- All for clarification of that particular drawing required measurements have to be indicated
- In FLOOR PLANS there are three main types of dimensionings:
  1. Dimensioning of openings, columns and piers,
  2. Dimensioning of axes of openings
  3. Dimensioning with coardinates
- Different alternative DETERMINATIONS of dimension lines are indicated in the figure

4.4.1 Types of Dimensions

- OVERALL DIMENSIONS indicate the overall LENGTH, WIDTH and HEIGHT. Each object has three overall dimensions.
- DETAIL DIMENSIONS indicate the size of each part or detail of the object

NOTE: dimension lines and extension lines (they indicate the limits of a dimension and extend this dimension to a convenient place on the drawing) should never cross!

Therefore the smallest dimension lines are placed nearest to the view.
Overall dimensions are drawn outside the detail dimensions.

4.4.2 Placement of Dimensions

- There are plenty of rules concerning the dimensioning of crawings, and some of them are contradictory. In case two rules conflict, choose the most logical and practical solution.
- Dimensions should be placed so that they can be read from the bottom-side or from the righthand-side of the drawing.
- Normally dimensions should be placed OUTSIDE the outer lines of the views, close to the contour. The should be placed INSIDE, if this could avoid long extension lines.
- Place dimensions in the way they are likely to be measured during the construction work.
- Place dimension lines in line
- For dimensioning CIRCLES or PARTS of CIRCLES refer to the figure.

5.ENLARGEMENT & .REDUCTION

5. ENLARGEMENT AND REDUCTION OF LINE DRAWINGS

There are various methods of enlarging or reducing a line drawing. Some of the most useful are:
The drawing in the figure consists of irregular or complex lines, draw over it a square grid of light lines (or, if the drawing is to be protected, draw the grid on a piece of tracing paper and place over the original), and then for the new drawing make a similar grid but proportionately larger or smaller as required.With this grid as a guide it is comparatively easy to make the copy to the size wanted.

If a line and its divisions, e.g. a scale, is to be enlarged or reduced in other than a simple mathematical proportion this is a useful method to employ. Line AB with points C and D along it is to be reduced; with centres A and B and radius equal to AB two arcs are drawn to intersect at O, and lines are drawn from O to A,B,C and D. The new length of the line is now measured along OA from O, and a line A'B' is drawn parallel to AB to which it corresponds. Where this line cuts CO and DO points C' and D' corresponding to C and D on the original are found.

The proportinal enlargement or reduction of rectangles is made by drawing a diagonal so that the alteration of the length of one side automatically gives the required length of the adjacent one. Example: ABCD is the rectangle, BD is a diagonal EFGD is a proportionately reduced rectangle.

Proportional Compasses. These instruments consist of two slotted pieces of metal with points at each end joined by a centre screw, which can be so set that the distance between the long points is equal to that between the short points or is two, three, four or more times that distance up to ten.
They can therefore be used for enlarging or reducing simple drawings in such ratios, although they seem to find little favour with present-day draughtsmen.

Pantograph: an instrument for enlarging or reducing drawings in various ratios. By following the lines of the original with one marker, the other traces them to a larger or smaller scale, as the case may be, and in the proportionate ratio to which the instrument has been set. The illustration shows a simple type. The Eidograph is a somewhat similar instrument, but having only one point of support, is steadier in action. The cost of these instruments is only justified if dealing with a large number of town plans and surveys.

Two other methods are commonly used and they are known as
- OFFSET METHOD and
- RADIAL PROJECTION

For their construction method refer to the drawing.

6.GEOMETRICAL CONSTRUCTION

LINES AND ANGLES

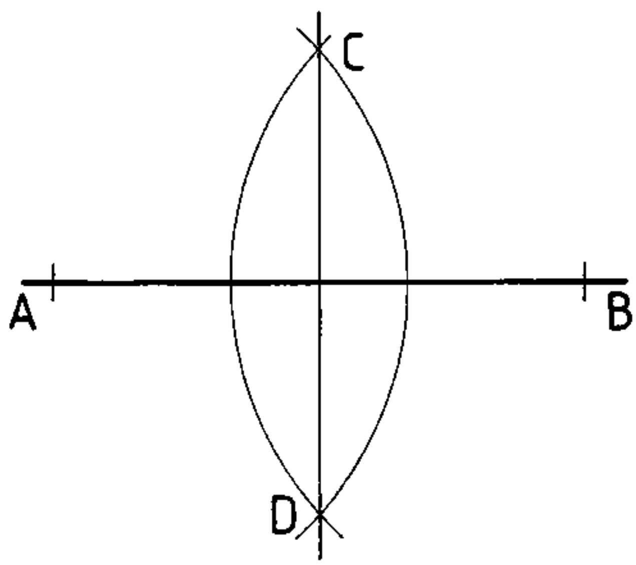
6. GEOMETRICAL CONSTRUCTIONS
In Architectural Drawing a good knowledge about GEOMETRICAL CONSTRUCTIONS is of high importance. In the following constructions are shown with the aim

1. To demonstrate the principles of BASIC geometrical constructions
2. To practice the use of drawing equipment

6.1 Lines and Angles

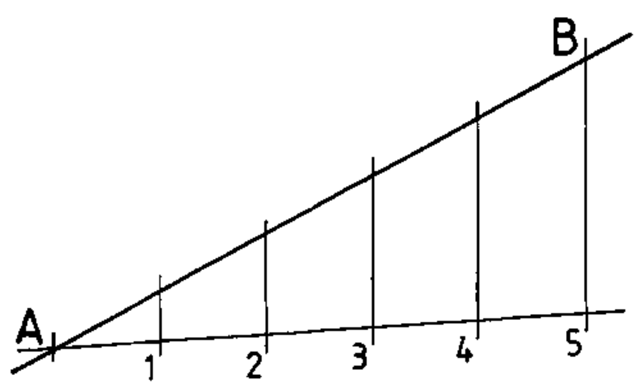
6.1.1 To bisect a straight line AB

- Draw AB
- With centre A and any suitable radius draw an arc
- With centre B and the same radius as before draw an arc to cut the arc with centre A in C and D
- Join CD. CD is the required bisecting line.



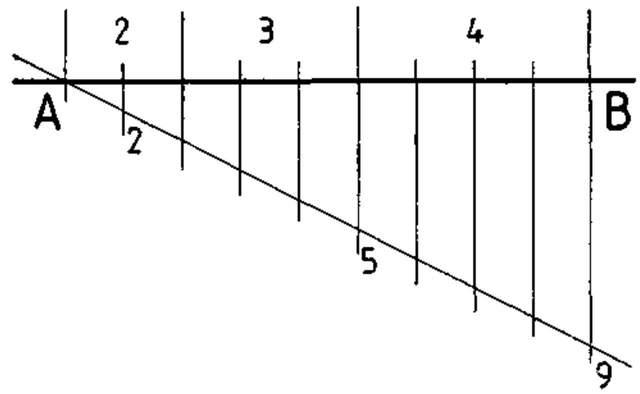
6.1.2 To divide a straight line AB into a given number of equal parts

- Draw AB
- At any suitable angle to AB draw a straight line
- Step off along this line the required number of divisions of equal length (here 5 divisions are shown)
- Number the divisions from A along the line as shown
- Join the last number (5) to point B
- Draw parallel lines to 5 B from the other numbers as shown. AB is now divided into the required equal parts.



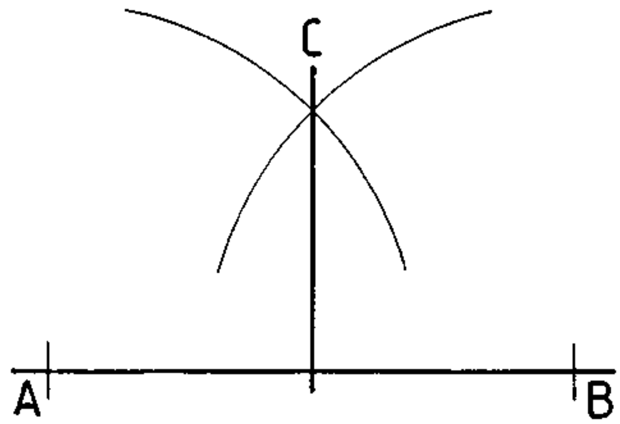
6.1.3. To divide a straight line AB into any ratio

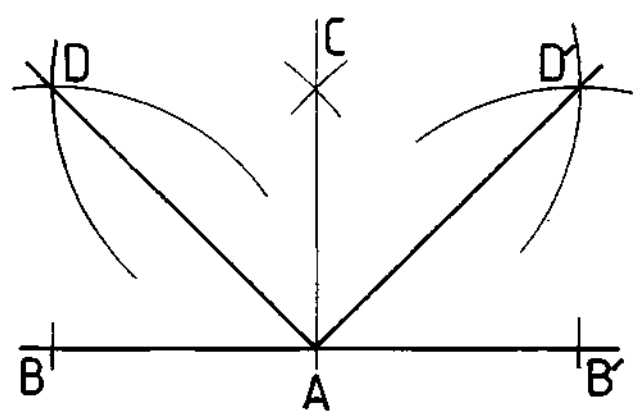
- Let the ratio be 2:3:4
- Draw AB
- Draw a straight line at any angle to AB
- Sum up the ratio (i.e. 2+3+4=9) to geht the number of eaqual divisions required
- Step off, along the straight line the number of divisions of equal lengths required (i.e. 9 divisions).
- Join the last division (9) to B and draw parallel lines to 9B through 5 and 2
- Now AB is divided into the ratio 2:3:4.



6.1.4 To construct an angle of 90^{0}

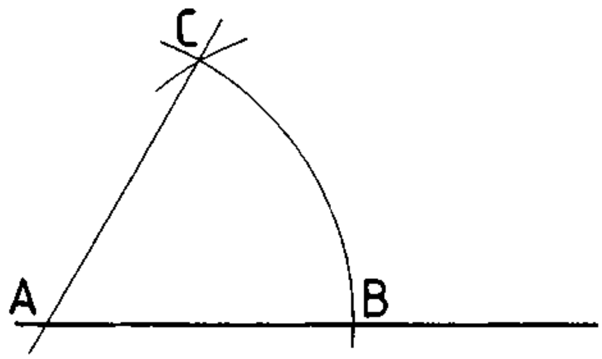
- Draw a straight line
- With centre A on that line and any suitable radius draw a semicircle to cut the line in B and C
- With centres B and C draw arcs of any the same radius to intersect each other at D
- Join AD. The Aangles ABD and ACD are the required angles of 45^{0}.



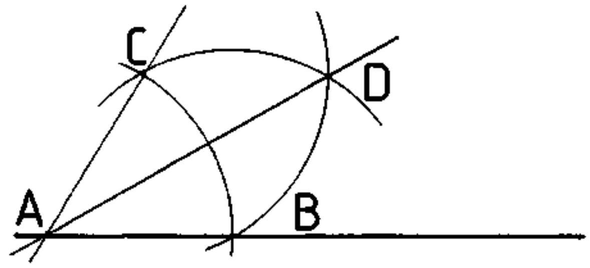


AD I compiled : D.VOLKE JUNE '83	GEOMETRICAL CONSTRUCT.	ARCH. DRWNG. LECTURE CET 1o43/16.141

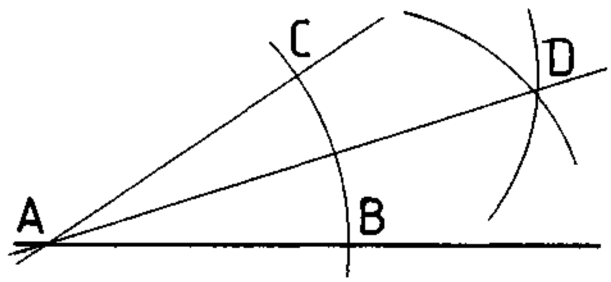
6.1.6 To construct an angle of 60^{0}.
- Draw a straight line
- With centre A on that line and any suitable radius draw an arc to cut the line at B
- With centre B and the SAME radius draw an arc to cut the former arc at C.
- Join AC. The angle ABC the required angle of 60^{0}.



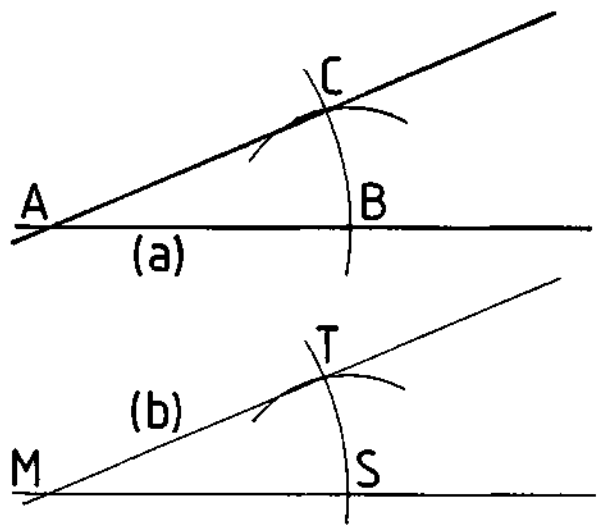
6.1.7 To construct an angle of 30^{0}
- This can be reached by bisecting an angle of 60^{0} as described under 6.1.5.



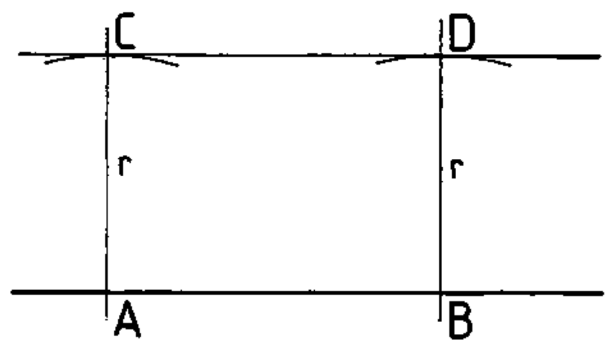
6.1.8 To bisect any given angle
- The same method as in 6.1.5 should be employed here.



6.1.9 To construct an angle SIMILAR to a given angle
- Let the angle shown in (a) be the giver angle.
- Draw a straight line through M as shown in (b)
- With centre A and any suitable radius draw an arc to cut the legs of the given angle in B and C
- With centre M draw the same arc to cut the line through M at S (AB = MS)
- From (a) with centre B take radius BC.
- With centre S and radius BC cut former arc at T
- Join MT and extend the line. The angle MST is similar to ABC.



6.1.10 To draw a line PARALLEL to a given line
- Draw the given line
- Using any 2 centres at suitable intervals along the given line and a radius, equal to the required distance between the 2 lines, draw the arcs C and D.
- Draw a straight line tangential to the arc C and D. This is the required line which is parallel to the given line at the distance of the radius.



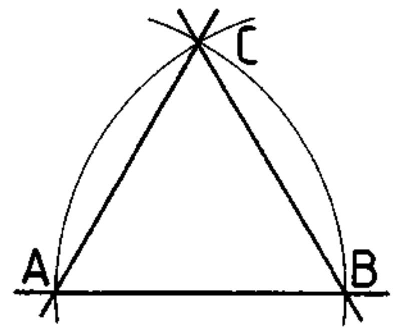
TRIANGLES

6.2 Triangles
Definition: A TRIANGLE is a PLAIN, bounded by three straight lines.

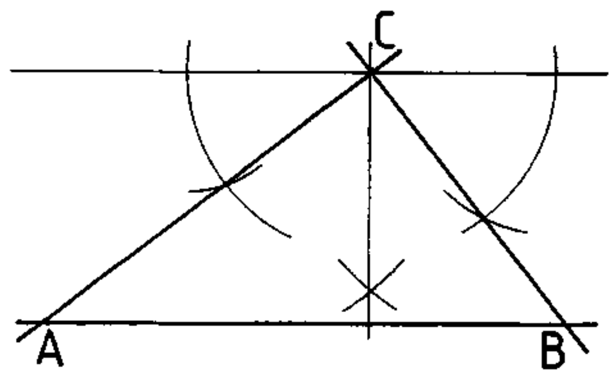
There are 4 types of triangles:

1. scale triangle: all angles and sides are UNEQUAL
2. Isosceles triangle: two sides and angles are EQUAL
3. Equilateral triangle: all angles and sides are EQUAL
4. Right-angled triangle: contains one right angle.

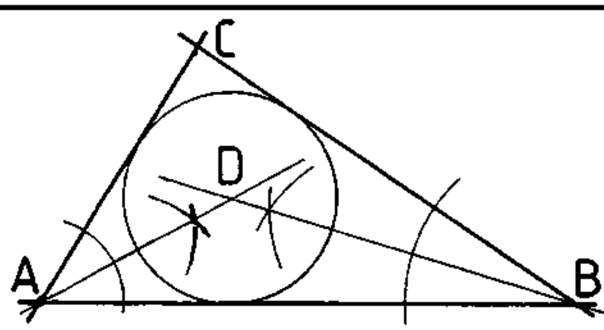
6.2.1 To construct an EQUILATERAL triangle. Given is one of the sides AB
Draw AB
With centres A and B and the radius AB draw arcs to intersect at C
Join AC and BC, the triangle ABC is equilateral.



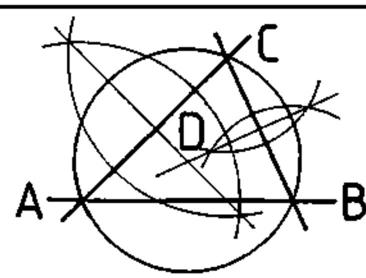
6.2.2 To construct a triangle with given BASE ANGLES and ALTITUDE.
- Draw a straight line
- Construct a straight line PARALLEL to the drawn line so that the distance between the two lines is equal to the altitude (ref.to 6.1.10)
- From any point C on the parallel line draw the given angles as shown so that they cut the straight line in A and B
- Join AC and BC. The triangle ABC is the reuqired triangle.



6.2.3 To inscribe a circle in a given triangle ABC
- Bisect any two of the angles, as shown, so that the bisectors intersect at D
- The centre of the inscribing circle is point D.

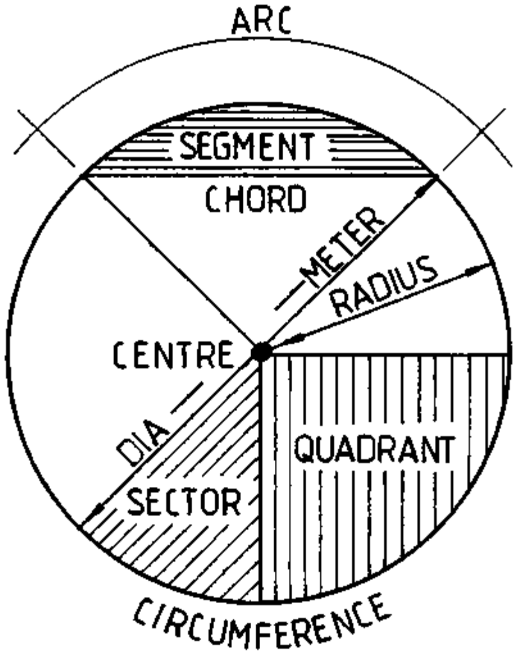


6.2.4 To circiumscribe a triangle ABC
- Bisect any two of the sides of the triangle, as shown, so that the bisectors intersect at D.
- The centre of the circumscribing circle is point D.



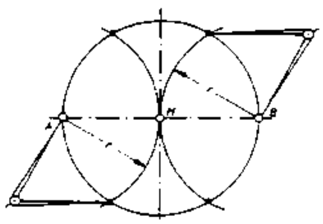
CIRCLES

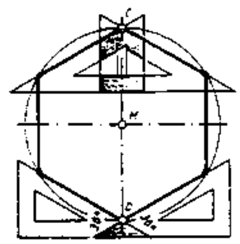
6.3 Circles
A circle is a plane figure hounded by a curved line called the CIRCUMFERENCE; which is always at equal distance from a fixed point called the CENTRE of the circle. This distance from the centre O to the circumference is known as the RADIUS. Other terms are: -

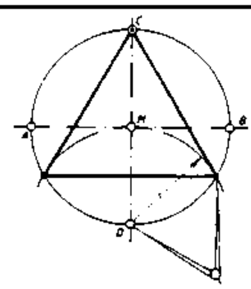


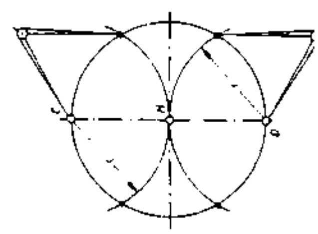
DIAMETER:	A straight line passing through the centre and bounded by the circumference
ARC	Is a name given to a part of a circumference
CHORD	A straight line joining two points on the circumference
SEGMENT	An area bounded by a chord and the arc it cuts
SECTOR	An area bounded by two radii and the arc between them
QUADRANT	An area bounded by two radii at right angles and the arc between them. It is a quarter of a circle.

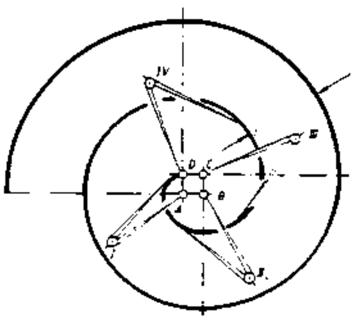
6.3.1 Basic CIRCLE-Constructions

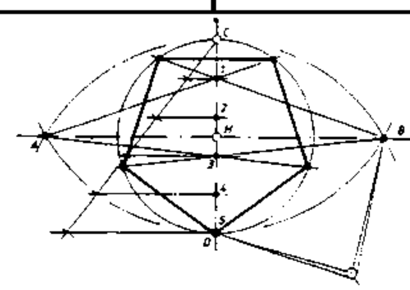


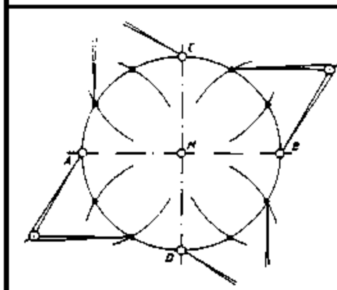


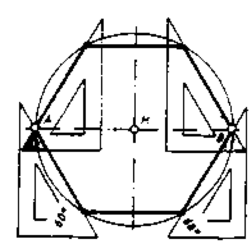






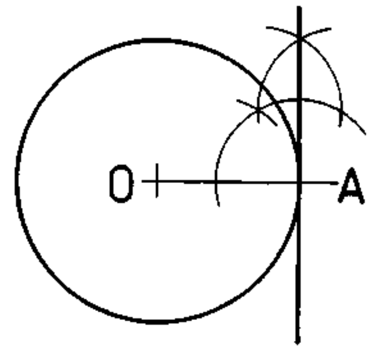




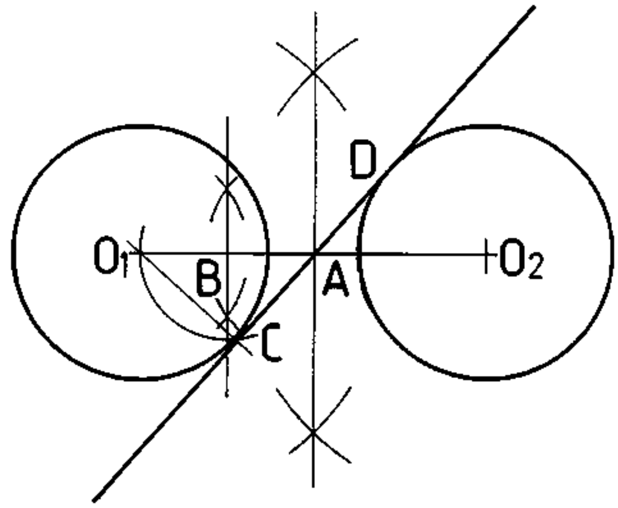


6.3.2 To draw a tangent to a point A on the circumference of a circle centre O

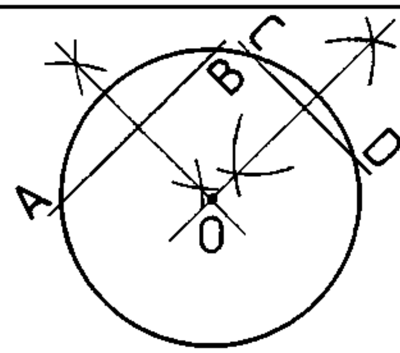
- Join OA
- Erect a perpendicular at point A as shown. The perpendicular is the re- required tangent.



6.3.3 To draw an internal tangent to two circles of equal diameter
- Join the centres of both circles by line O_1O_2
- Bisect the line O_1O_2 to get the point A.
  Then bisect O_1A to geht the point B.
- With radius BO_1 and centre B describe a semi-circle to cut the circumference of one of the given circles at C
- Join CA and estend it to tough the other circle at D. Line CAD is the required tangent. O_1C and O_2D are normals.



6.3.4 To find the centre of a given circle arc
- Draw any two chords AB and CD
- Draw perpendicular bisectors of AB and CD
- Produce the hisectors to meet at O. O is the required centre of circle.



6.3.5 To join two straight lines at Right Angles to each other by an arc of given radius

- Draw the given straight lines at a right angle to meet at O
- With the centre O and the radius equal to the required radius of the arc, draw arcs to intersect the straight lines at A and B
- With the centres A and B and the same radius draw arcs to intersect at C
- With the centres C and given radius, draw the required arc.

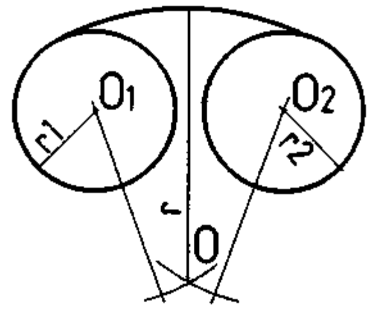
6.3.6 To draw a curve of given radius joining two circles (The circles have to be inside the radius R)

- With centre O and radius T_1 draw an arc,
- With centre O_2 radius T_2 draw an arc to intersect the first arc in O. O is the required centre.



6.3.7 To join two straight lines by two arcs of equal radius

- Draw the two straight lines XA and YB at their correct positions.
- Join AB and bisect it at C
- Bisect AC and CB and estend the two bisectors to meet perpendiculars from A and B at points D and E respectively.
- With centre D and radius AD draw an arc from A to C
- With centre E and radius EB draw an arc from B to C. These are the required curves and give a smooth continuous curve ACB.

1.TYPES OF PROJECTIONS

1. TYPES OF PROJECTIONS

Drawings are a medium through which the draftsman or designer conveys his ideas and instructions to others. Therefore an understanding of all types of drawing is necessary in order to present informations in the clearest and most effective manner.

The theory of any type of projection drawing assumes that the drawing can be made by locating the intersections of lines, which are called PROJECTORS from points on the object with a plane of projection called the PICTURE PLANE:

The lines connecting the points thus located on the picture plane make the projected drawing of the object.
The three factors which determine the type of projection drawing are:

1. The relation of the object to the picture plane
2. The relation of the projectors to the picture plane, and
3. The relation of the projectors to each other.

Various types of ORTHOGRAPHIC and PERSPECTIVE PROJECTION are obtained by changing the relation between the object and picture plane. In OBLIQUE PROJECTION the different types are obtained by changing the relative positions of the object and picture plane and by changing the scale of the receding lines. Variations in pictural effect of any type of oblique drawing can also be secured by using different directions for the projectors.
In actual drawing the paper is the picture plane on which the drawing is constructed by drafting methods to conform to the assumed relations of the object, projectors, and picture plane.
PROJECTION DRAWING is the science of constructing drawings of different types by the most efficient and direct drafting methods.

2.ORTHOGRAPHIC PROJECTION

2. ORTHOGRAPHIC PROJECTION

In any type of drawing those parts of the object which are parallel to the picture plane are shown in their TRUE SHAPES.

In ORTHOGRAPHIC PROJECTION where the projectors are parallel lines, all parts of the object which are parallel to the picture plane are shown in their correct RELATIVE SIZES, that is, at the same scale - regardless of their distances from the picture plane.

Since only one set of planes of an object can be shown parallel to the picture plane in a single drawing, it is necessary to have a minimum number of three views of an object to give all of its sizes and shapes.
These three basic views are obtained by looking in three mutually perpendicular directions, and these views are drawn on planes perpendicular to each of the three directions respectively.

The basic views, which are drawn true to scale, are taken at 90^{0} to each other and when set on paper are said to be drawn in the principal planes.

At present there are two methods of relating the principal views to each other, namely FIRST-ANGLE PROJECTION (used in Europe) and THIRD ANGLE PROJECTION (used in Canada and U.S.A.)

These terms FIRST ANGLE and THIRD ANGLE have been derived from the mathematicians convention of annotating the four right angles which make up the 360^{0} of a circle, the first being 0^{0} to 90^{0} and the third angle from 180^{0} to 270^{0}.

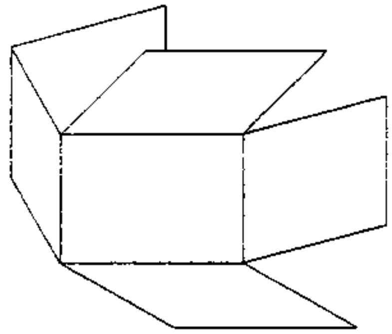
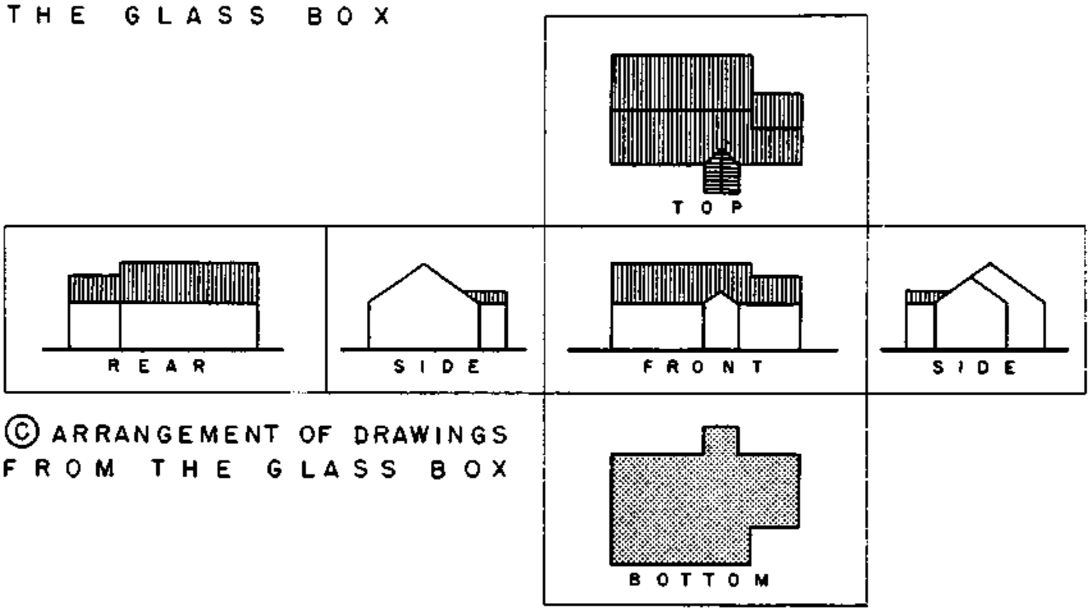
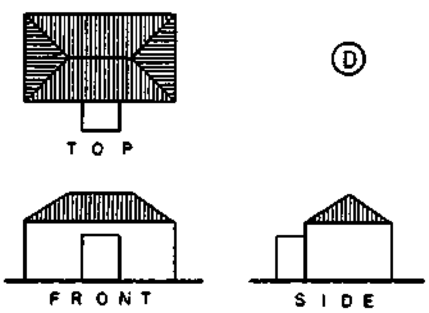
Ⓐ PROJECTING ONTO THE GLASS BOX



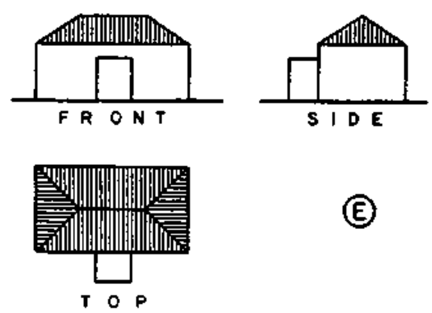
Ⓑ REVOLVING PLANES OF THE GLASS BOX



Ⓒ ARRANGEMENT OF DRAWINGS FROM THE GLASS BOX



ARCHITECTURAL ARRANGEMENTS



The planes provided by the transparent box - shape of the figure are not always adequate to give TRUE SHAPE VIEWS of all sides of a building. If a wall of the building is not parallel one of the typical planes and consequently one of the faces of the transparent box, its TRUE SHAPE will not be shown by any of the conventional elevations. Picture planes, which are added to the transparent box - shape in order to obtain true shape views of planes of the object not parallel to the original planes of the box, are called AUXILIARY PLANES (see figure A and D) and the projections made on these planes are called AUXILARY VIEWS.

The true shape of any oblique surface, such as a slating roof or wall, can then be obtained by projecting onto an auxiliary plane parallel to the oblique surface.

ELEVATIONS

2.2 Elevations

The most common auxiliary views in architecture are ELEVATIONS. The drafting process by which an auxiliary elevation is made may vary in details of construction. However, in all cases the heights may be taken from any other elevation of the building and the horizontal dimensions from plan.

The figure shows two methods of making the auxiliary elevation from a front elevation and plan.
In B the auxiliary drawing is made to show the entire building, as would usually be done in architectural drawing. In C only the part of the building parallel to the picture plane is shown in each elevation.

The front roof plane of E is shown by the front elevation to be a rectangle. The length of this roof area is shown in the front view and its true slant-height is shown in the side view. The rectangle made by using these two dimensions is the correct auxiliary view of the front roof plane.

In F all four planes of the simple hip roof are drawn in the auxiliary views. Such drawings are useful to show the true shapes and areas of the roof planes and the true lengths of lines in those planes. The slanting lines in the auxiliary view of F show the true length of the hips. The length of any straight line can be determine graphically by making an auxiliary view on any picture plane parallel to the line

PLANS and SECTIONS

2.3 Plan s and Sections

In addition to the exterior views of building it is usually necessary to have one or more views made which CUT through the structure and shows the interior. These views are known as

1. PLAN, which is the term applied to any view on a HORIZONTAL PICTURE PLANE either from the exterior or cut through, and
2. SECTION, which is the name given to any view cutting through the building on a VERTICAL PLANE.

Both, the ARCHITECTURAL PLAN as well as the ARCHITECTURAL SECTION are demonstrated in the figure.

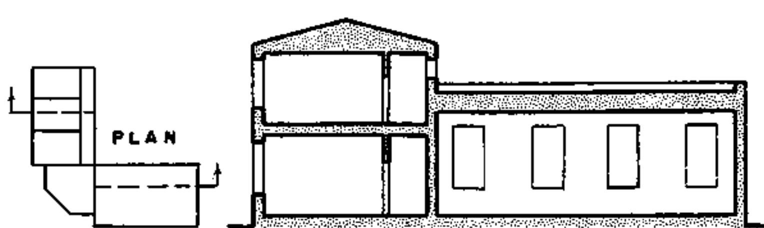
(E) LONGITUDINAL SECTION



(F) OFFSET SECTION

3. PICTORIAL DRAWING

AXONOMETRIC

3.1 Axonometric Projection

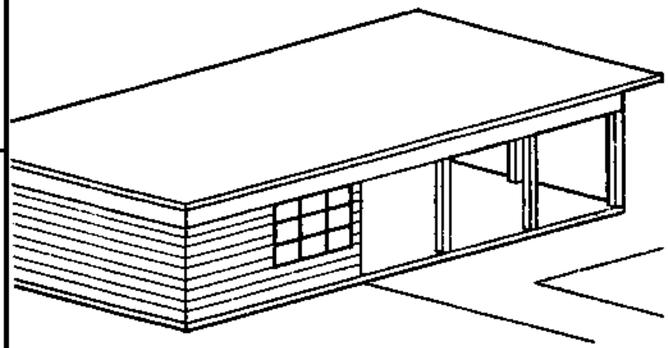
Axonometric and oblique drawings are similar in many respects. Both give views of the object which show all three typical sets of lines and planes in ONE drawing. Both are more easily understood than orthographic drawings because they show all three dimensions in one drawing and indicate the relations of the various parts of the object to each other.

In both axonomic and oblique drawings parallel lines in any direction are drawn parallel. This simplifies construction but causes the more distant parts of the object to appear to be too large. This pictorial defect is the principal criticism of these types of drawings.

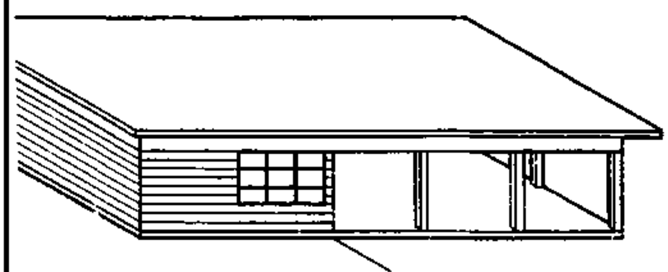
The three typical sets of lines of the object are all measured to scale in axonometric and oblique drawings. Therefore, most of the measuring can usually be done directly on the lines of the drawing itself, and it is practical to give dimensions on the drawings. Simplicity of construction is the chief advantage of these drawings over perspective drawing.

An AXONOMETRIC projection is an orthographic projection in which the object is tilted so that none of the three typical sets of planes, and consequently none of the axes at the intersections of these planes, are parallel to the picture plane.

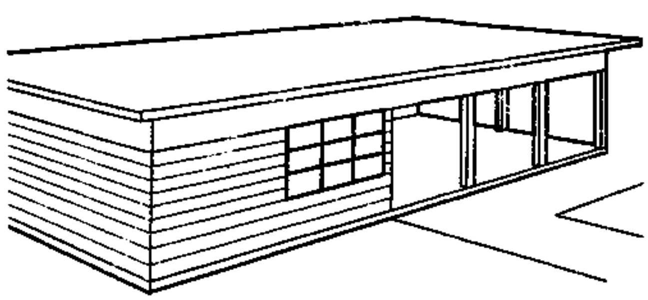
Projectors from the object, perpendicular to the picture plane, locate points on the projected drawing of the object.



(A) AXONOMETRIC



(B) OBLIQUE



(C) PERSPECTIVE

AXONOMETRIC

All axonometric projections may be divided into three classifications:

1. ISOMETRIC projections, in which all three of the axes make equal angles with the plane of projection,

2. DIMETRIC projections, in which two of the axes make equal angles with the plane of projection, and the third axis is at different angle,

3. TRIMETRIC projections, in which all three axes are at different angles with the picture plane.

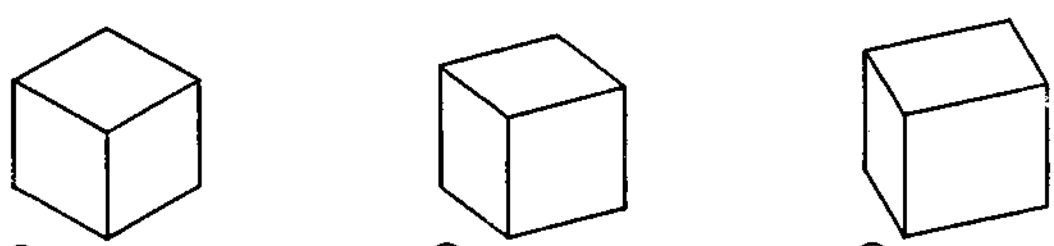
The axonometric drawings of a cube in the figure indicate the relation of the cube to the pictureplane in each case:

- In the isometric drawing all edges of the cube are represented as being of the same length because they are all turned at the same angle to the picture plane

- In the dimetric drawing of the cube two of the sets of edges are the same length and the third set a different length.

- In the trimetric drawing all three sets of edges of the cube are shown at different sizes, because the three sets of lines make different angles with the picture plane.

The relative sizes of the edges of the cube in the dimetric and trimetric drawing can be varied, but the relation is isometric drawing does not allow any variation.



(A) ISOMETRIC (B) DIMETRIC (C) TRIMETRIC

ISOMETRIC

3.2 Isometric Projection.

A scale is assumed for the object and the projected or foreshortened size drawing for that scale is shown in an siometric projection. The projected size of the axis lines is 0.816 of the actual length of the lines. An isometric drawing of an object is measured at any desired scale without considering the scale size of the object represented. The figure shows the difference in size between the isometric projection (B) made with the isometric scale and the isometric drawing (C) measured with the ordinary scale. Although isometric drawings are satisfactory for most practical purposes isometric projections sometimes have advantages.

Making an isometric drawing the angle between two adjacent axes of an isometric drawing is 120^0. When one axis is vertical the other two are at 30^0 with the horizontal.
To make an isometric drawing of a simple rectangular object: from a point selected for one of the front corners of the object draw the three axis lines and lay out on these lines their scale sizes. From the ends of the lines draw lines parallel to the axes to complete the drawing.

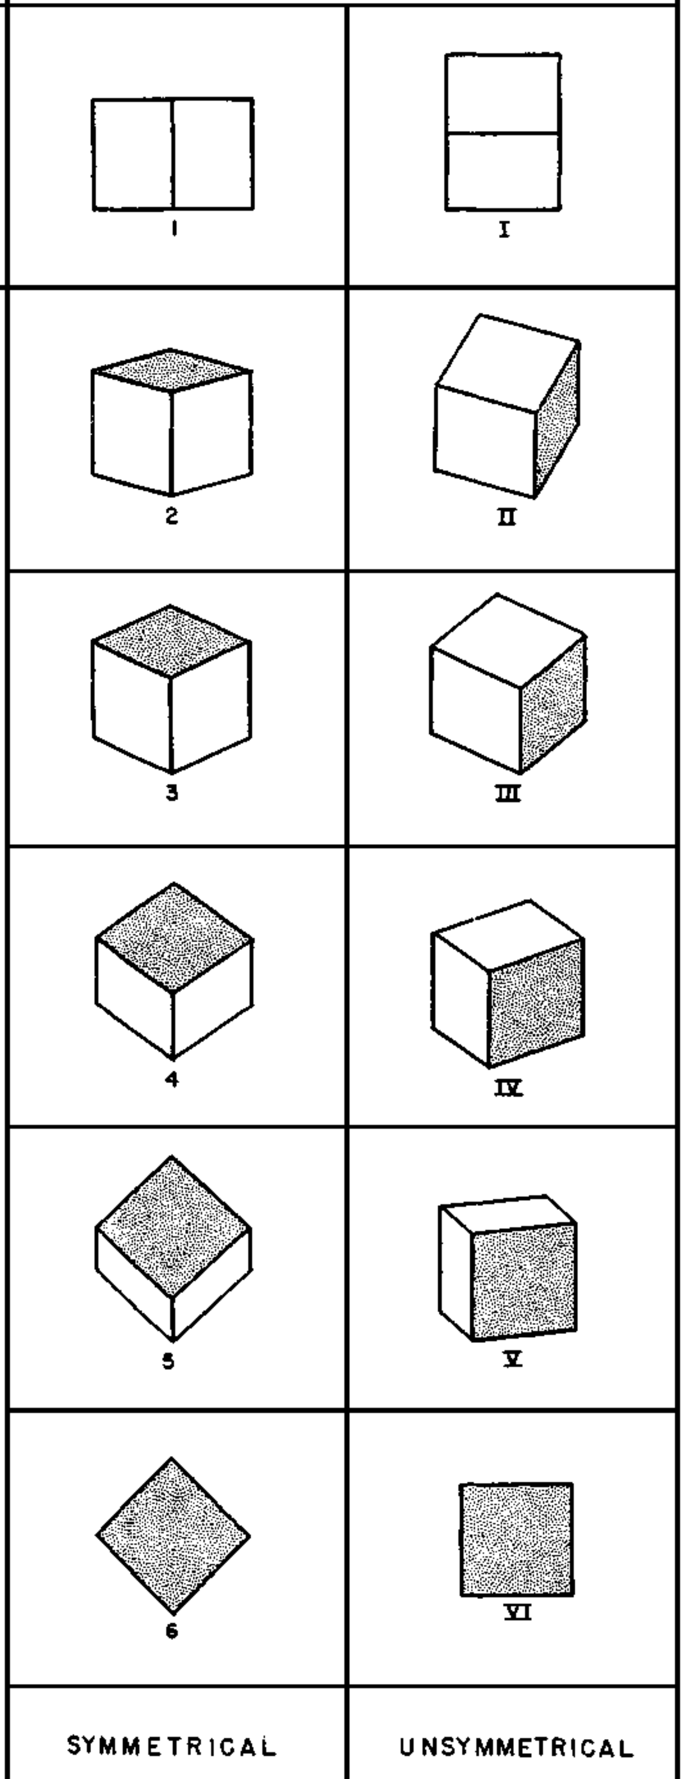
DIMETRIC



3.3. Dimetric Projection

The figure shows a cube placed so that the top and bottom are horizontal and the two visible sides make equal angleswith the picture plane. Imagine the cube to be rotated forward on a horizontal line which is parallel to the picture plane, thus keeping the sides allways at equal angles to the picture plane until the top is in a vertical position.
As the cube was rotated between these two positions the projections of its axes passed through all possible dimetric relations to each other. A few of the infinite number of possible dimetric positions obtained in this manner are illustrated in the figure.
In these illustrations the two equal axes are turned to make equal angles with a horizontal line. If one of these equal axes is turned vertically then the axes to either side will be at different scales and at different angles with a horizontal line.
Thus it is possible to use the same spacings of the axes that are shown in the left column of the figure and twist them to new positions with one of the two equal axes in a vertical position and get a new set of pictorial effects, such as are illustrated in the right column of the figure.
Dimetric drawings can then be made with the angles and scales giving either a symmmetrical or an unsymmetrical arrangement.

Isometric drawing is rigid and inflexible. There is only one possible view of the three typical planes which meet in any corner of the object because the exes must be equally spaced.

Because of its great varety of possible pictoral effects dimetric drawing overcomes the following faults and shortcomings of isometric drawings:

1) The lines of a hip roof and of equal projections of the near corner form parts of continuons vertical line in isometric drawing. This pictorial defect can be avoided in dimetric drawing by using the position of axes, which causes the two sides of the object to be turned at different angles to the picture plane.

2) One of the three typical planes of the object can be emphasized in dimetric drawing by turning the object so that this plane is seen more directly and consequently occupies a greater proportionate area in the drawing. The emphasis on one plane and subordination of the other two can be in any desired ratio.

3) Two of the planes of the object can be emphasized equally and the third subordinated. Thus, it is possible to subordinate the roof or floor area and emphasize the walls or to subordinate one wall. An example of subordination of roof areas and relatively increased importance of wall areas are shown in the figure. By showing less of the roof it is also possible to see more of the wall under an extending roof.

4) The unpleasant effect of wall planes at 45° in isometric projection can be avoided in dimetric drawing.

Dimetric drawing has the advantage of allowing the choice of a symmetrical or unsymmetrical view of the object and emphasis on one or two of the three planes. It permits variation in the pictorial effect obtained, while isometric drawing is rigig and inflexible.

A carefully chosen dimetric drawing usually gives the most pleasing results of any of the usable types of parallel line pictorial drawing. It ranks next to perspective in desirability for presentation work.

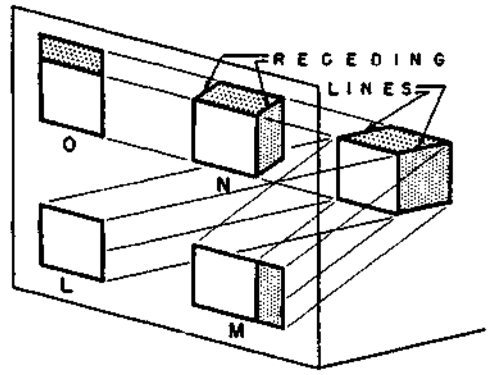
OBLIQUE

3.4 Oblique Projection

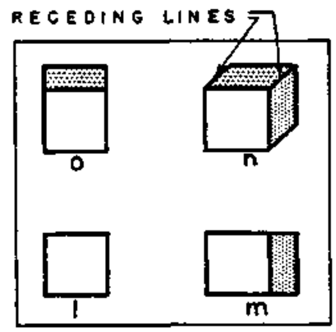
In oblique projection the projectors are oblique to the picture plane and the object is usually turned with one of the typical planes parallel to the picture plan (see fig. A)

In axonometric projection the projectors are perpendicular to the picture plane and the object has all three typical planes oblique to the picture plane. Thus, both the relation of the object to the picture plane and the direction of the projectors in oblique drawing differ from those of axonometric drawing.

Although the drawings M and O of figure A may be considered oblique drawings they are made with the projectors in planes parallel to one of the typical planes of the object and are neither good pictorial drawings nor charcteristic oblique drawings. Drawing N shows the characteristic oblique drawing in which the projectors are oblique to the three typical planes of the object. Fig. B shows these drawings as they would appear from in front of the picture plane.



(A) PICTORIAL VIEW OF OBJECT AND DRAWINGS

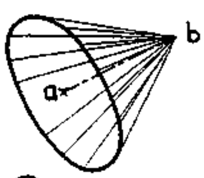


(B) DRAWINGS SEEN ON THE PICTURE PLANE

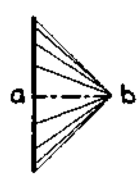
3.4.1 Length of Receding Lines

The angle of the projectors with the picture plane determines the length of the receding lines of an oblique drawing. If the projectors make an angle of 45^0 with the picture plane the receding lines will be projected in their true length.

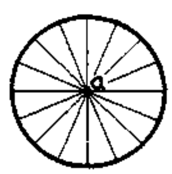
From the end b of a given receding line a - b (fig. C) any number of projectors can be drawn making an angle of 45^0 with the picture plane. The intersections of these projectors with the picture plane will form a circle with the end 'a' of the line 'a-b' as a centre and the projectors will form a right cone with 'b' at the apex and 'a' at the centre of the base. The possible projections of the receding line 'a-b' radiate in all directions from the end 'a' of the line.



(C) PICTORIAL VIEW



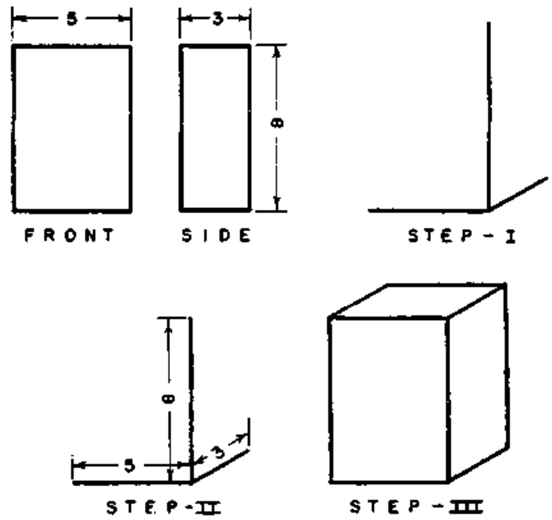
(D) SIDE VIEW



(E) FRONT VIEW

DIRECTION OF RECEDING LINES

Therefore a line can be drawn at any angle from a (fig. E), to represent the receding line 'a-b' in an oblique drawing, and the projection of the line 'a-b' will be equal to the length of the line itself if the projectors make an angle of 45^0 with the picture plane. By varying the angle of the projectors with the picture plane the receding lines can be made larger or smaller than scale size.



3.4.2 Construction of Oblique Drawings

The block shape shown in fig. A is drawn in oblique by proceeding as follows:

Step 1: Draw the horizontal and vertical axes and from their intersection lay out the receding axis at any desire angle.

Step 2: Lay out the dimensions of the object on the axis lines

Step 3: Draw lines from the measurements to complete the drawing.

Offset Method: The way of construction is illustrated in fig. B. Usually most measurements on an oblique drawing can be made on lines parallel to the axes. However, the planes of the object which are parallel to the picture plane appear in their true shapes and measurements can be made on them at any angle. Furthermore, any slanting lines which are parallel to the picture plane are drawn in their true directions and lengths.

3.4.3 Rules of Oblique Drawing

There are two rules of oblique drawing which should be followed when it is practical to do so (see fig. C)

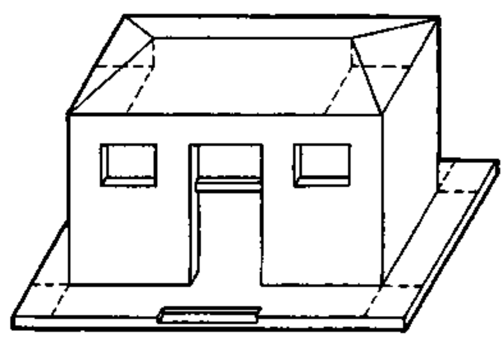
Rule 1: Turn the length of the object parallel to the picture plane

Rule 2: Turn the most complex or characteristic face of the object parallel to the picture plane

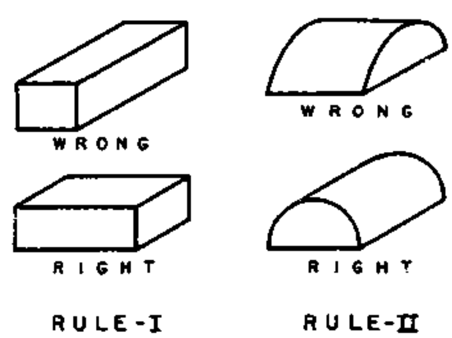
The purpose of the first rule is to decrease the appearance of distortion by making the reciding lines represent the short dimension of the object.

The purpose of the second rule is to show the true shapes of characteristic forms of the object and simplify construction .

CONSTR./RULES



(B) OFFSET CONSTRUCTION



(C) SELECTING THE VIEW

SCALE

3.4.4 Scale of the Receding Lines.

Since the projectors can be at any angle with the picture plane the receding lines of an oblique drawing can be drawn at any scale.

The four drawings of the cube in the figure show the effect of different scales for the receding lines on the proportions of the drawings.

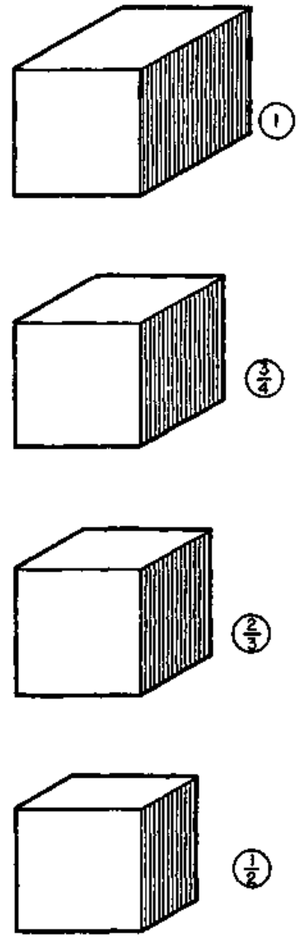
- The receding lines of the CAVALIER-PROJECTION in which the same scale is used on all lines, appear to be too long.

- The CABINET PROJECTION, with half-scale on the receding lines, has gone too far in the other direction, making the receding lines appear too short and the object appear thin.

When the scale of the receding axis is made 3/4 or 2/3 of the scale of the horizontal and vertical axes the proportions of the drawings are better.

Cavalier projection has the advantage of simplicity of contruction. The use of 3/4 or 2/3 scale on the receding lines gives a better pictorial effect.

One of these scales should be used when appearance is an important factor.



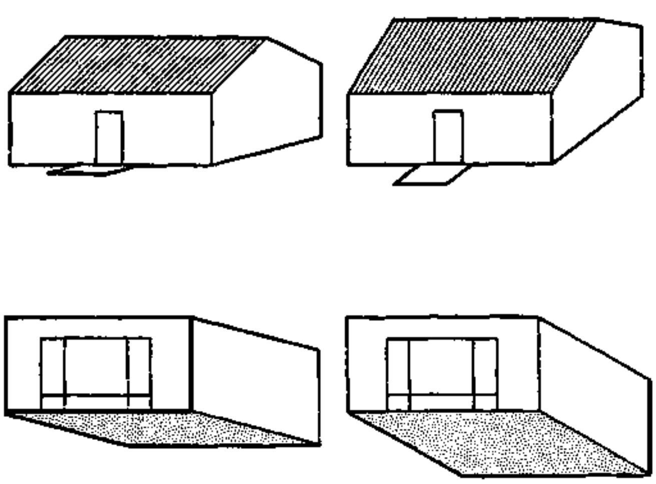
(A) CAVALIER PROJECTION TOO LONG

(B) IMPROVED PICTORIAL PROPORTIONS

(C) IMPROVED PICTORIAL PROPORTIONS

(D) CABINET PROJECTION TOO SHORT

DIRECTION



3.4.5 Direction of Receding Lines

Since the receding axis of an oblique drawing can be drawn in any direction it is possible to secure a great variety of pictorial effects. The figure shows three variations of direction of the receding lines for an exterior and an interior.

POSITION

3.4.6 Position of Axes

In all the preceding illustrations of oblique drawing one axis has been horizontal and another vertical.

However, the axes may be turned in any position, if two of the three are kept at 90° with each other.

In A: One axis is vertical, another horizontal
In B: The oblique axis is horizontal
In C: None of the axes is vertical or horizontal
In D: The oblique axis is vertical

The PLAN OBLIQUE axis position, shown in D, is often used in drawing pictorial views in which it is advantageous to have the picture plane horizontal and parallel to the floor plane. This position of the axis allows all horizontal areas to appear in their true forms.

For either interior or exterior designs having horizontal, circular or other complex forms this arrangement of the axes is to be recommended for simplicity of construction and for clearest representation of the shapes. With the oblique axis vertical, the other axes must remain at 90° with each other but may be turned in any desired relation to the vertical axis. The oblique lines (vertical) should be drawn at 2/3 or 3/4 scale.

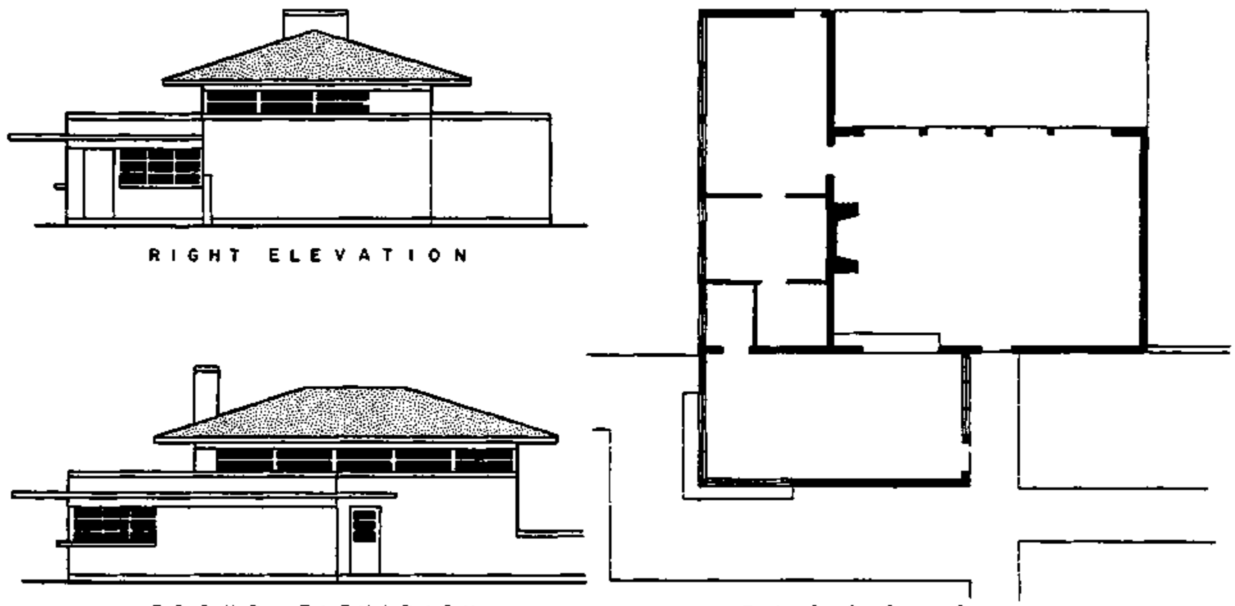
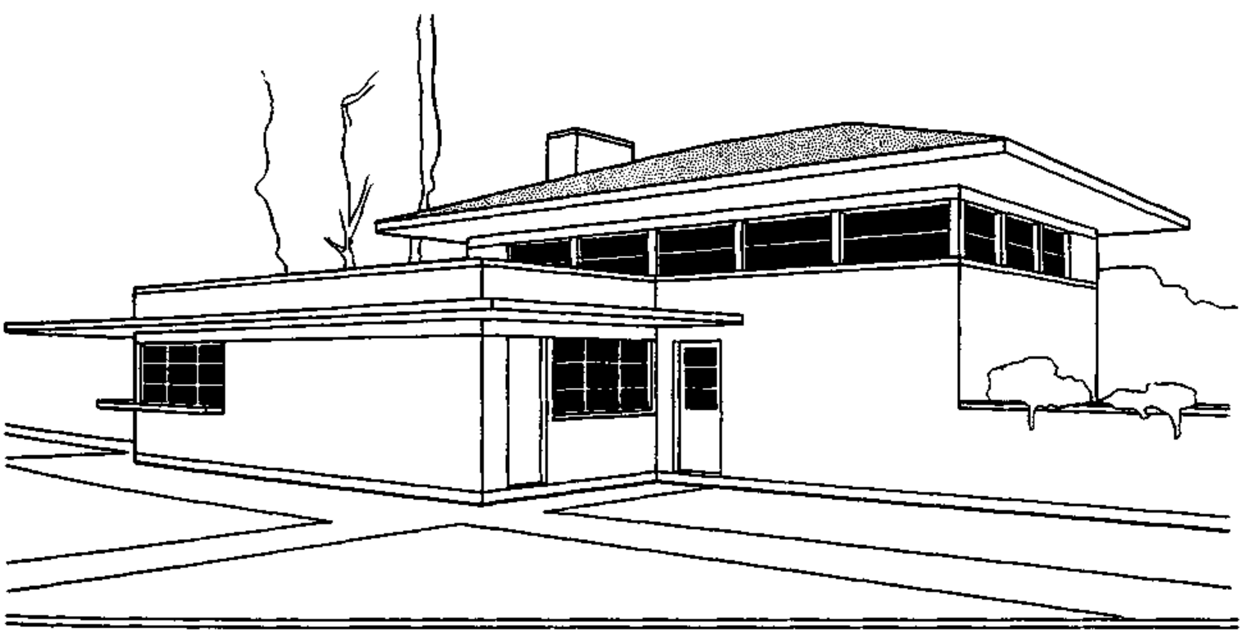
4. PERSPECTIVE DRAWING



(A) MULTI-VIEW DRAWINGS



(B) PERSPECTIVE DRAWING

PERSPECTIVE

4. PERSPECTIVE DRAWING

Perspective drawing is essential in the work of the architect and designer, because it is the only type of drawing which represents an object in the natural and pleasing way that it would actually appear to the eye. In all other types of pictorial drawing all parallel lines are drawn parallel and produce the unpleasant illusion of becoming farther apart on the more distant parts of the object.

PERSPECTIVE is of value for:

1. drawings which can be easily understood by anyone,
2. an accurate method of studying and perfecting designs, and
3. explanatory sketches and drawings.

TERMS

4.1 Perspective Terms

STAND POINT (S.P.) is the position of the observers eye and is assumed to be the position from which an object is seen.

PROJECTORS. In perspective drawing the projectors converge to a station point instead of being parallel as they are in all other types of drawings.
Perspective projectors are imaginary lines of sight from the eye of the observer to points on the object.

PICTURE PLANE (P.P.) is an imaginary plane which intersect the perspective projectors in order to give points through which the perspective drawing is made, as though drawn on the picture plane.

VANISHING POINT (V.P.) is a point at which lines, not parallel to the P.P. appear to meet on the horizon line.

CENTRE OF SIGHT is the point at which the line of sight meets the P.P. and should be as near as possible to the centre of the object.

GROUND PLAN (G.P.) is the horizontal plane on which the object rests.

GROUND LINE (G.L.) is the intersection of the ground plane and the picture plane.

HORIZON LINE (H.L.) is the line parallel to the ground line and passing through the centre of sight on EYE LEVEL (E.L.).

PHENOMENA

4.2 Phenomena of Perspective Drawing

- Sizes.

In a perspective drawing sizes are shown as they appear to the eye from the position of the station point, NOT as they actually are.
The converging projectors reduce the perspective sizes of distant objects causing them to appear to be smaller than identical objects nearer the picture plane.
Objects in front of the picture plane are enlarged in the size by the projectors.

ONLY THE LINES IN THE PICTURE PLANE ARE DRAWN TO THEIR SCALE SIZES:

- Measurements.

Since lines of equal length on the object may appear in an infinite variety of sizes in a perspective drawing, it is impossible to measure sizes directly on the drawing exept in special cases. The determination of sizes, and especially of heights, is one of the most difficult features of making an perspective drawing.

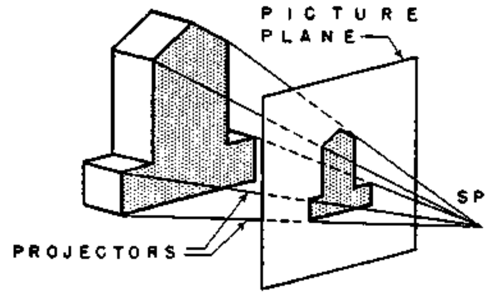
Any lines of the object which lie in the picture plane can be measured to scale.
Parts of the object in front of the P.P. will be larger than scale size.
Parts of the object in the back of the P.P. will be smaller than scale size.

The various methods of perspective drawingobtain this correction of sizes in different ways.

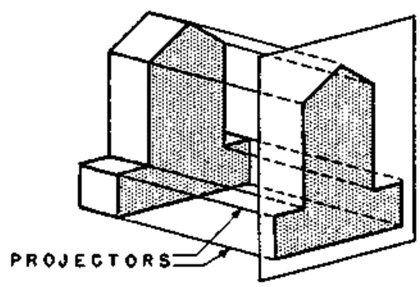
- Shapes.

In perspective drawing the object is represented as it appears to the eye. Areas and angles usually do not appear in perspective as they really are.

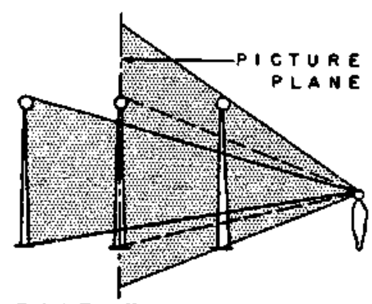
Rectangles and squares are often drawn as irregular quadrilaterals with four unequal sides and four unequal angles.
A right angle seldom appears as such in a perspective but is drawn as an acute or otuse angle. A circle usually appears as an ellipse in perspective.



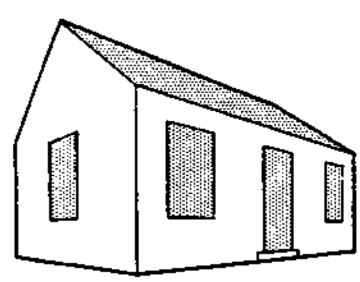
(A) CONVERGING PROJECTORS IN PERSPECTIVE



(B) PARALLEL PROJECTORS IN ALL OTHER DRAWING



(C) EFFECT OF DISTANCE ON PERSPECTIVE

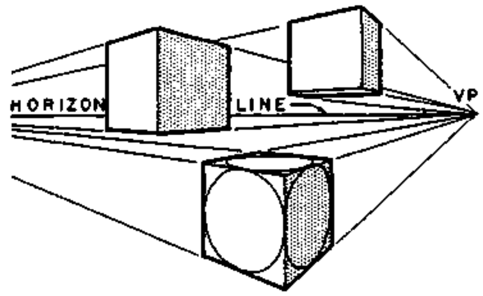


(D) VARIATIONS OF SIZE IN LINES AND AREAS

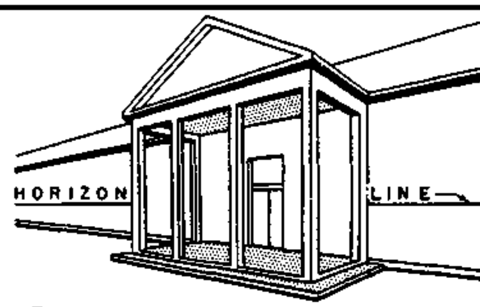
- Horizontal Surfaces.
The horizon is at the level of the station point in a perspective drawing. The eye looks up at things above the horizon and down on things below the horizon. Horizontal surfaces above the horizon (eye level) are visible from below and horizontal surfaces below the horizon. Such as steps, are visible from above. Thus, both the ceiling and floor of a room may be seen in the same perspective drawing, if the horizon line is located at some position between the floor and ceiling.
The size of a horizontal area in a perspective drawing depends on the distance and angle from which it is seen.
With the area at a constant horizontal distance from the station point, at the level of the horizon, a given horizontal area appears as a line and increases in visible size with its distance above or below the horizon.

When the height of a horizontal or vertical area is constant, its visible size increases as it approaches the station point and diminishes as it recedes farther from the station point.
Except that, whenever the line of vision passes through the plane of a surface the surface is always seen as a LINE. I.e.: any horizontal plane at the level of the horizon would always appear as a straight line.

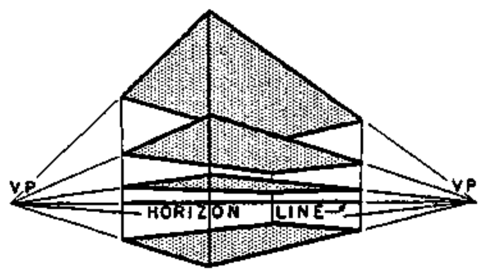
- Lines Parallel to the Picture Plane.
These lines retain their true direction in perspective. Thus, horizontal and vertical lines parallel to the picture plane remain respectively horizontal and vertical. Sets of parallel lines which are parallel to the picture plane remain parallel perspective just as they do in orthographic projection.
However, the length of the parallel lines in perspective varies with the distance from the picture plane, instead of being projected in actual size relations.



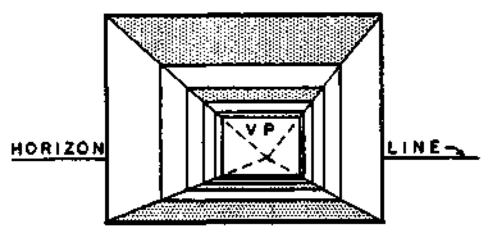
(A) APPEARANCE OF SHAPES OF AREAS AND MASSES



(B) HORIZONTAL AREAS IN PERSPECTIVE



(C) EFFECT OF HEIGHT ON HORIZONTAL AREAS



(D) EFFECT OF DISTANCE ON LINES AND AREAS

- Lines NOT Parallel to the Picture Plane.
In perspective each set of parallel lines which is not parallel to the picture plane converges to its vanishing point. The vanishing points of all sets of horizontal lines are located on the horizon, which is alsways on a level with the eye of the observer, the Station Point.

PERSPECTIVE SYSTEMS

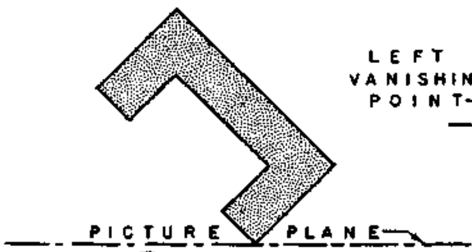
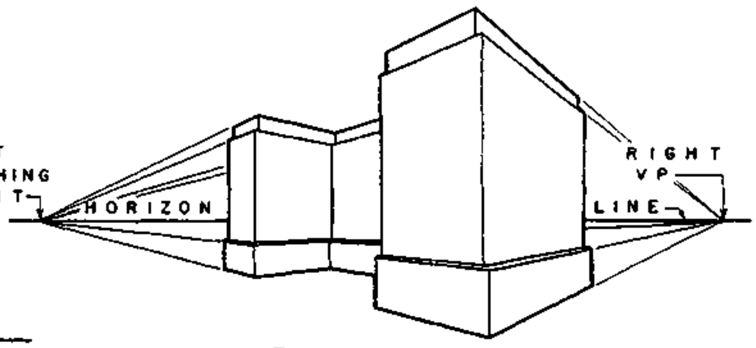
PARALLEL OR ONE-POINT PERSPECTIVE SYSTEM

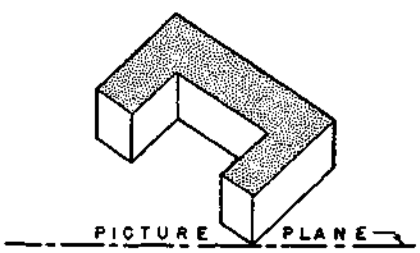


(C) PLAN

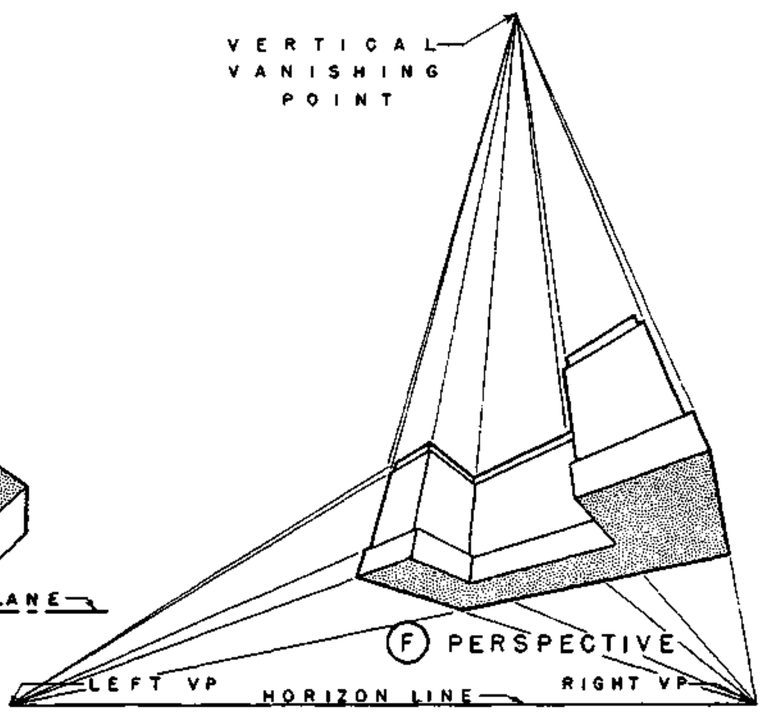


(D) PERSPECTIVE

ANGULAR OR TWO-POINT PERSPECTIVE SYSTEM



(E) PLAN



(F) PERSPECTIVE

OBLIQUE OR THREE-POINT PERSPECTIVE SYSTEM

SYSTEMS

4.3 Systems of Perspective Drawings.
There are three systems of perspective drawing which are classified according to the relation between the object and the picture plane and the resulting number of vanishing points for the three sets of typical lines.
Most buildings have as important elements three sets of planes which are illustrated by a box.
One of these sets of planes is horizontal (top and bottom). The other two are vertical and at right angles to each other. These planes meet in the three sets of typical lines of which one set is vertical and the other two horizontal and at right angles to each other.
In the PARALLEL or ONE POINT perspective system one set of planes and two sets of lines of the object are parallel to the picture plane, Fig. A. Lines of these two sets remain respectively vertical and horizontal in perspective, Fig. B. The remaining set of horizontal lines is perspendicular to the picture plane and vonverges to a vanishing point.
In the ANGULAR or TWO POINT perspective system the object is turned with both sets of horizontal lines at an angle to the picture plane, as shown in the plan of Fig. C. There are, therefore, two vanishing points, one for each of these sets of horizontal lines, Fig. D. Since the vertical lines are parallel to the picture plane they remain vertical and parallel in the perspective.

In the OBLIQUE or THREE POINT perspective system the object is turned, or the picture plane tilted, so that none of the three sets of typical planes and lines of the object is parallel to the picture plane, plan Fig. E.Since all three sets of lines are at an angle to the picture plane, there are three sets of converging lines and three vanishing points, as shown in Fig. F.
The three vanishing points of the typical sets of lines are the only ones mentioned in this discussion of systems of perspective drawings. However, vanishing points of other sets of parallel lines are sometimes useful. Their location and use will be explaned later.

METHODS

4.4 Methods of Perspective Drawings.

A perspective of an existing object can be sketched on a picture plane made of a sheet of glass in the following manner:Place the picture plane at arms length, keep the eye in one position, and draw lines to exactly cover the lines of the object as seen through the stationary picture plane (see fig.). A window glass makes an excellent picture plane for this purpose. Whenever the object ist not conveniently located, when greater accuracy is required, or when there is no existing object but only the drawings of some proposed structure, it is necessary to use some other method of making the perspective. However, the various drafting methods of making perspective drawings are based on this method of sketching the perspective of an existing object on a transparent plane.
A perspective drawing is made by working out by one of the drafting methods the positions of the lines of the object as they would appear on a given picture plane from a given station point. Three of these mechanical methods of constructing perspective drawings:

1) the direct projection method
2) the perspective plan method
3) the common method.

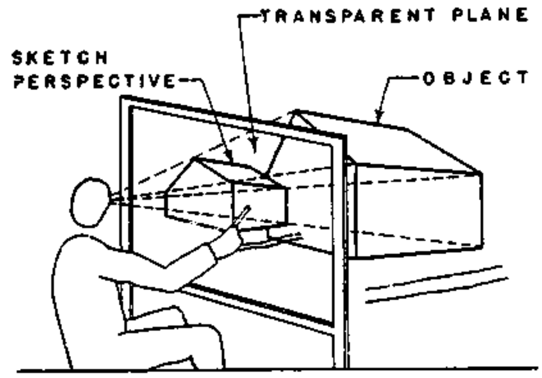
These methods are described in a general way in the following paragraphs and are explained in detail in the chapters on one- and two-point perspective.

METHODS

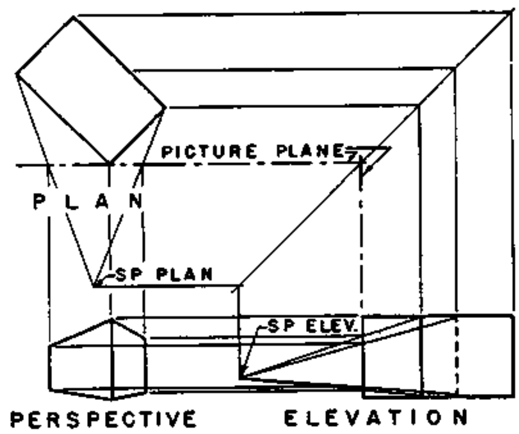
THE DIRECT PROJECTION METHOD has the simplest theory of any method of perspective drawing. Plan and elevation views parallel to the picture plane showing the object, picture plane, and station point are first drawn the fig. The converging projectors are then traced to the picture plane in plan and elevation. Points on the perspective drawing are located from their heights, which are determined from the projectors in plan. The drawings are so arranged that the heights can be carried across horizontally with the T-square and the widths brought down vertically with the triangle to their positions in the perspective from the intersections of the projectors with the picture plane.

The direct projection method is a good method for one-point perspective because the auxiliary drawings used are the plan and elevations, or sections. These drawings are easily understood by the draftsman, and are often available at the correct scale. In two-point perspecktive one or two special drawings are required for the direct projection method. These drawings are auxiliary elevations or sections from a corner (parallel to the picture plane) and are more difficult to construct and understand than the ordinary elevations and sections. If this method is used without vanishing points very slight inaccuracies will change the directions of short lines and produce a warped effect. This method requires a great deal of space on the drafting board and many construction lines. Although vanishing points are not required their use will simplify the construction and make the drawing more accurate.

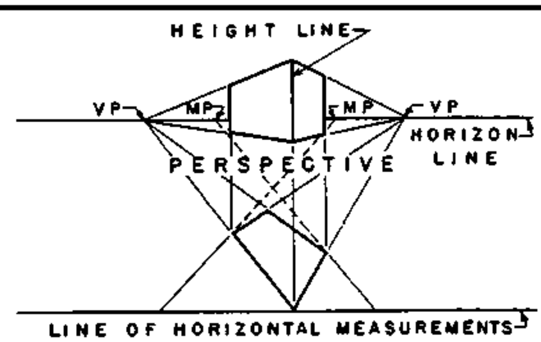
THE PERSPECTIVE PLAN METHODallows the entire perspective to be constructed from measurements made in the picture plane and broght into correct perspective sizes and positions by tracing line to their vanishing points. The plan is first drawn in perspective. The vertical lines of the perspective drawing are then obtained by drawing



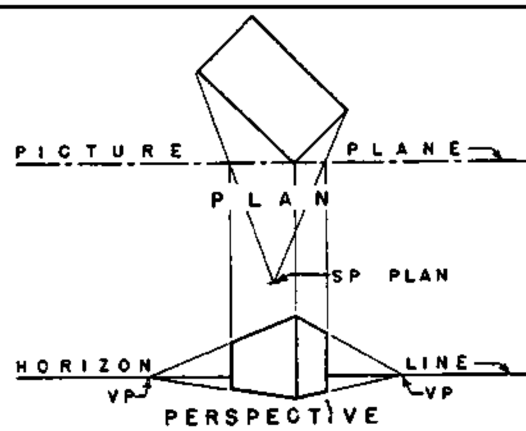
SKETCHING A PERSPECTIVE



DIRECT PROJECTION METHOD



PERSPECTIVE PLAN METHOD



COMMON OR OFFICE METHOD

METHODS

vertically from the perspective plan. The scale heights are laid out on any convenient vertical line in the picture plane from which they can be traced by lines toward the vanishing points into their correct perspective positions.

Since this method divides the construction into two steps, the construction lines are easier to trace to the perspective. In addition to the vanishing points of the sets of typical lines not parallel to the picture plane, the perspective plan method requires one or more measuring points to be used in drawing the perspective plan. A measuring point is the vanishing point for the set of parallel lines , which transfers scale measurements of horizontal dimensions from the horizontal measuring line to a base line of the perspective plan. The location and use of measuring points is explained under one- and two-point perspective.

The perspective plan can be drawn at any convenient height either above or below the perspective drawing. It can be placed on an important plane of the perspective, such as the floor of an interior or ground plane of an exterior. It is practical and sometimes very convenient to use more than one perspective plan for tall buildings. The perspective plan method requires less space on the drawing board than any other widely used method and is considered the best method by some expert draftsmen.

THE COMMON METHOD is also called the OFFICE METHOD and the MIXED METHOD. It combines the plan construction for horizontal spacing of vertical lines of the direct projection method and the height contruction of the perspective plan method.(Fig.) It is widely used in offices and schools. One reason for its popularity is that plans and elevations which are available at the correct scale may be attached to the drawing board and used as auxiliary drawings from which the perspective is made.

CHOOSING A METHOD Each of these methods of making perspective drawings has advantags and disadvantages. Som problems are more easily solved by one method, some by another. This is partly due to the varying nature of designs, and partly because of the information furnished by available drawings of the object of which the perspective is to be made. All accomplish the same result - a true picture of the object from some chosen position.

TWO-POINT PERSPECTIVE

4.5 TWO-POINT PERSPECTIVE

Two - point perspective is the most widely used of the three perspective systems. It is typical of the way in which buildings are usually seen and of photographs of buildings. It is, therefore, of greatest importance to the architect and draftsman. When only one kind of perspective is to be learned twopoint perspective is in most cases the one.

THE COMMON METHOD. The most popular and most widely used method of two-point perspective is called the common method. In this method the plan of the object, picture plane, and station point is used to work out the horizontal spacing of points, and vertical lines for the perspective. The plan is turned with the line of the picture plane horizontal. It is convenient to have an elevation at one side of and below the plan. From this elevation the heights can be carried across with the T-square to the construction for the correct heights for the perspective. Any elevation, or section, or part of either drawing which gives all of the heights necessary to construct the perspective drawing will serve for this purpose. Although it is not necessary to have an elevation or section included in the construction its use makes the construction more easily understood, decreases the chance of error in working out heights, and makes the checking of construction easier.

THE CONSTRUCTION OF A SIMPLE TWO-POINT PERSPECTIVE.
The construction by the common method has been divided into a series of steps, illustrated in fig. A,B, and C, These steps are typical of the procedure followed in this method of two-point perspective.

- THE AUXILIARY DRAWINGSare a plan and elevation. The plan of the object, picture p lane, and station point is drawn with the picture plane line horizonal (fig. A). The elevation is drawn and the horizon line and ground line placed to suit it.

The horizon line is at the height of the eye of the observer. The ground line is drawn at the bottom of the elevation. The station point should be approximately on a line perpendicular to the picture plane through the center of the plan.

- THE VANISHING POINTS are located on the horizon line in the following manner (fig. B). From the station point SP lines are drawn parallel to the two typical sets of horizontal lines of the plan to meet the picture plane. From these intersections A and B vertical linesare drawn to the horizon to locate the two vanishing points, VL and VR. All of the horizontal lines of the object which are parallel to the line SP-B in plan vanish in VR in the perspective drawing. Likewise, all of the horizontal lines of the object which are parallel to the line SP-A in plan vanish in VL in the perspective drawing.

- MAKING THE PERSPECTIVE requires the use of a plan and elevation. The horizontal spacing of all points and vertical lines of the perspective drawing are obtained from the plan. This is done by drawing lines from the necessary points on the plan toward the station point to meet the picture plane, then drawing vertical lines from these intersections to the perspective (Fig. C.).

Since the nearest corner of the wall is in the picture plane its height is laid out to scale by drawing horizontal lines from the top and bottom of the wall in elevation to the line of the corner in the perspective. From these height measurements lines are drawn to VR to locate the top and bottom of the right side. Likewise, lines are drawn to VL to locate the top and bottom lines of the left side.
The illustrations of Fig. A, B, and C show the elementary principles of two - point perspective by the common method.

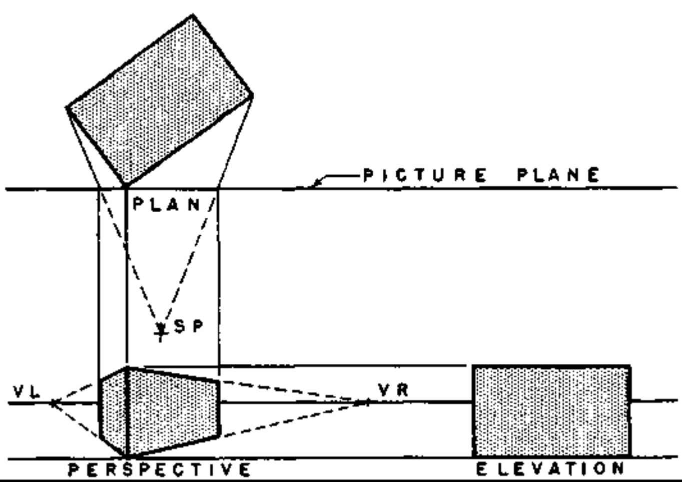
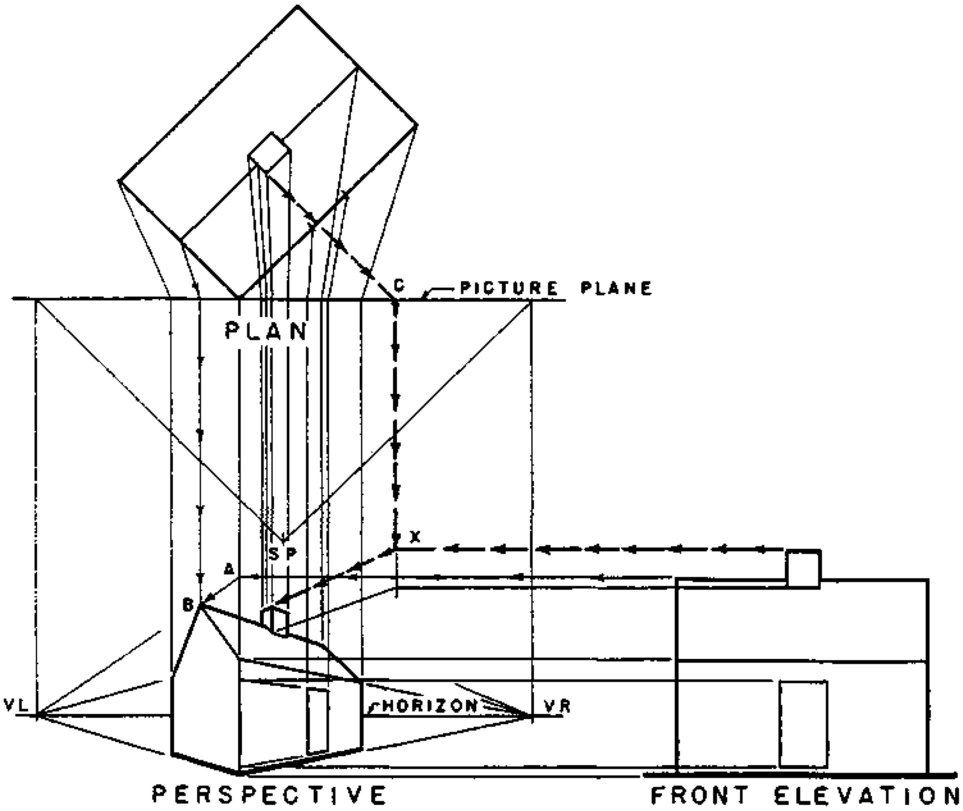
MAKING THE
PERSPECTIVE





TWO-POINT PERSPECTIVE OF A SIMPLE EXTERIOR

- THE DETERMINATION OF HEIGHTS.

Two important facts should be kept in mind while studying the following illustrations:

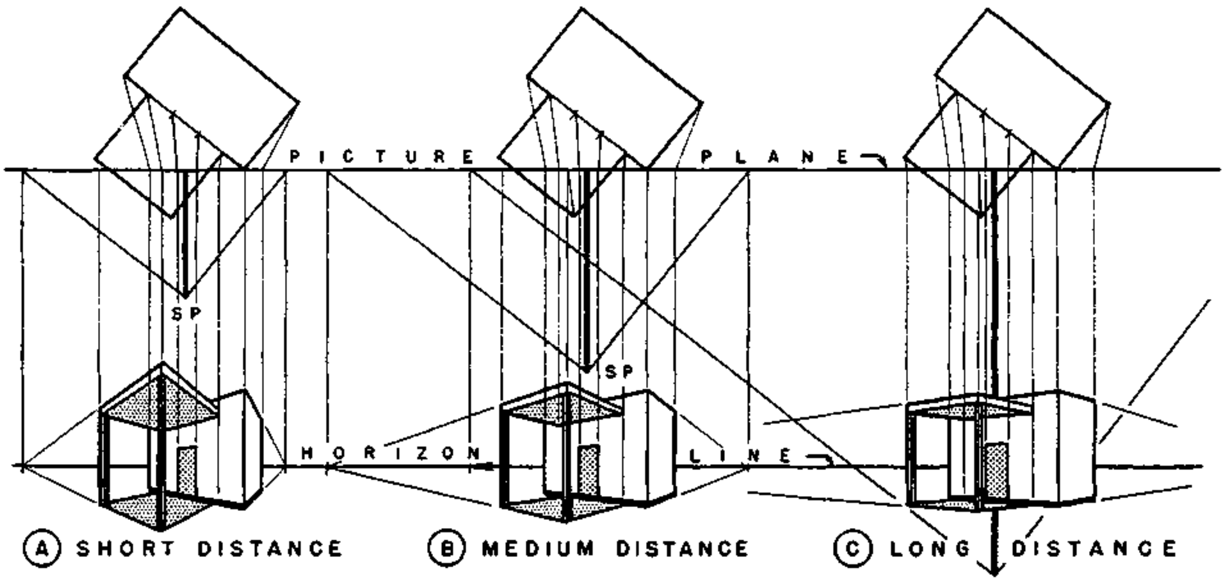
1. All heights are laid out to scale in the picture plane only,
2. Heights are carried from their scale sizes in the picture plane into correct perspective positions by tracing them along lines which vanish in the vanishing points and lead to the on the object where the heights are used.

- THE LOCATION OF THE STATION POINT.

The pictorial effect obtained in a perspective drawing is determined by the position of the station point. Since it would be possible to have the eye of the observer in any one of an infinite number of positions in viewing an object it is possible to have an infinite number of different perspective drawings of the object.

The location of the station point can be varied in three ways:
1. distance from the object
2. height
3. angle of view.

These variations and their effects on the perspective are discussed in the following paragraphs. The general theory applies to interiors as well as exteriors.



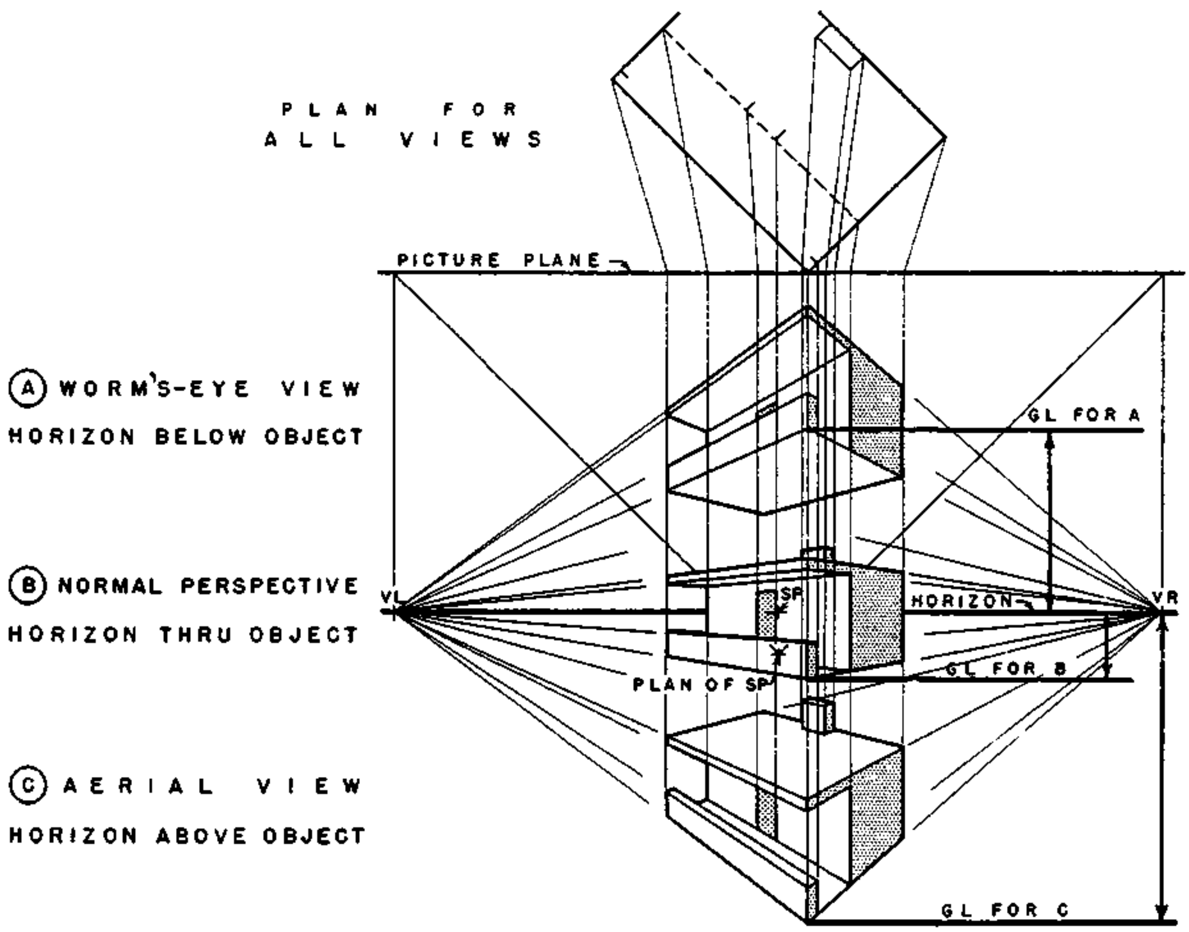
DISTANCE FROM STATION POINT TO OBJECT

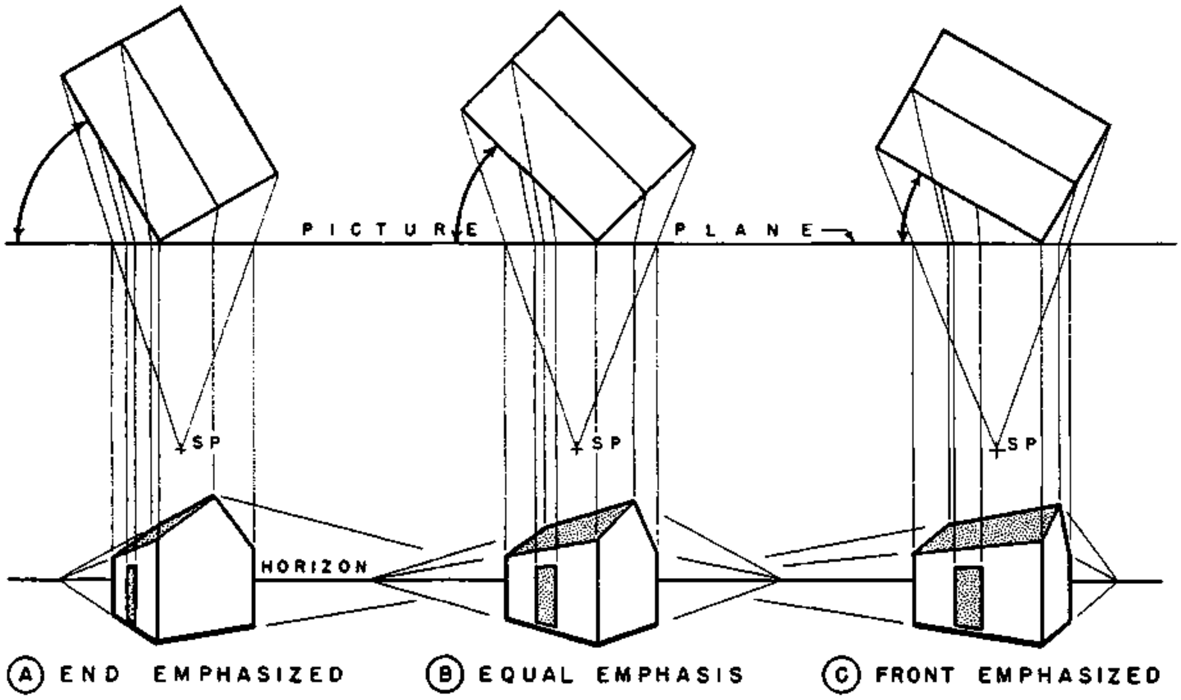
THE DISTANCE FROM THE STATION POINT TO THE OBJECT influences the pictorial effect and size of the perspective. When the station point is near the object the horizontal lines not parallel to the picture plane slant sharply (Fig. A). As the distance from the object is increased the horizontal lines flatten out and the perspective approaches the form of an elevation perpendicular to the picture plane in which all horizontal lines are parallel and horizontal (Fig. B and C). Parts of the object which are in front of the picture plane become smaller as the distance from the object to the station point increases, and parts behind the picture plane become larger. Both approach scale size as the distance increases and conversely, both vary more from scale size as the distance diminishes. When the station point is near the object the bottoms of horizontal surfaces above the horizon are large, as are the top surfaces of horizontal areas below the horizon. As the station point moves farther away these areas become smaller and disappear from view when the station point is at infinity (Fig. A,B, and C).

The maximum angle of vision of the eye is usually assumed to be 45^0 or 60^0. This angle should include everything shown in the perspective. When the height of the object is greater than its width the height will determine the angle of vision. In one-point perspective the limit of vision is considered to be a cone of rays from the eye, thus avoiding the distorted effect sometimes found in the corners of one-point perspectives. To avoid excessive distortion in perspectives of spheres and circles, these shapes should be kept within a 30^0 cone of vision in any type of perspective.

As a practical consideration the farther the station point is located from the object, the greater the distance from the drawings to the various centers of converging lines. It is usually desired that these centers be in reach of the T-square for drawing lines and that they be on the area of the board. When the picture effect of the perspective is entirely satisfactory it is more convenient to keep all centers of converging lines on the board.

THE HEIGHT OF THE STATION POINT determines whether the object is seen from above, below, or from its own level in the perspective drawing. The relation of the station point, vanishing points, and horizon is constant for varying heights of the station point if the distance from the picture plane to the station point and the angle between the object and picture plane are constant. The perspective position of the station point is always on the horizon when the picture plane is vertical. The picture plane is alsmost always vertical in one- and two point perspective. The vanishing points of horizontal lines are always found on the horizon. When the eye of the observer (SP) moves up or down, the horizon and VP`s of the horizontal lines move with it. The distance from the horizon to the ground line is the height of the eye of the observer above or below the base of the building. Fig. A, B, and C uses the same position of the horizon, SP and VP`s but uses three different distances to the ground line, so that the view in the center has the SP opposite the center of the object, while the other two have the SP above or below the object. The relation of the horizon and ground line then determines whether the perspective is a view from below (A), normal perspective (B) or an aerial view (C).

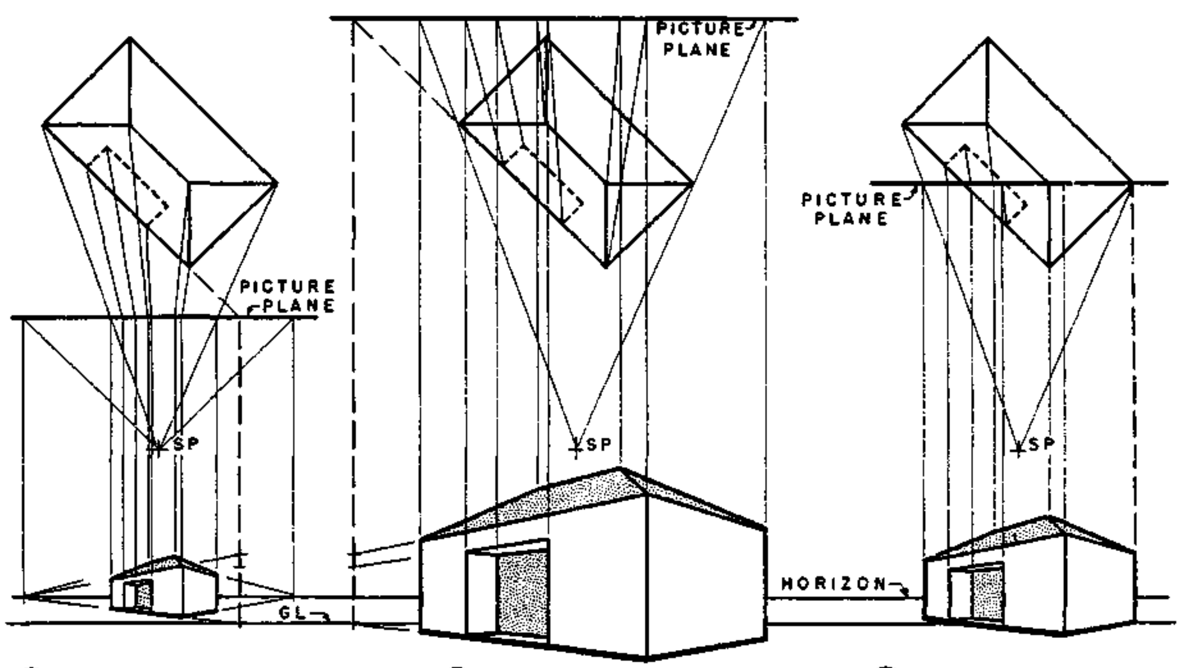




THE ANGLE OF VIEW determines which sides of the object are seen and their relative widths in the perspective. When a photographer takes a picture of a free standing building he walks around it to find the best position for his camera. The draftsman can get similar information in two dimensions from a plan of the building of which the pespective is to be made. He can choose a trial station point and, by turning a straight-edge on this point as a pivot, he can determine which wall areas will be visible in a perspective made from this point. Furthermore, he can determine the relative perspective widths and importance of these areas and whether there is any unfortunate alignment of corners in an irregular plan. From these observations he may be able to select a more satisfactory station point. The experienced draftsman develops the ability to visualize the perspective effect from different positions around the plan of the object and thus choose the station point best suited to his purpose. The relative importance of the sides shown in the perspective has probably the areatest influence on the angle of view. Ordinarily it is desirable to look more directly at the imprtant side and less directly at the unimportant one. In most perspectives of exteriors the entrance to the building is considered as an essential. A reasonable amount of the entrance should be visible when the shape of the building does not allow all of it to be shown from the chosen direction. When a model of the proposed building is available it is very useful in selecting a station point. All three of the variables can be considered with a model. The figure shows three views of the same object from different angles.

Regardless of the angle from which the object is seen, the station point should always be located approximately on a line through the center of the plan and perpendicular to the picture plane. The perspective is distorted when the station point is located very far to one side of this line. It is a great temptation where the plan is set up and the correctly located station point does not give satisfactory results, to take the easy way out and push the station point to one side. However, such a procedure causes the perpendicular to the picture plane to be off center on the plan and perspective. It will, therefore, cause the perspective to be out of proportion.

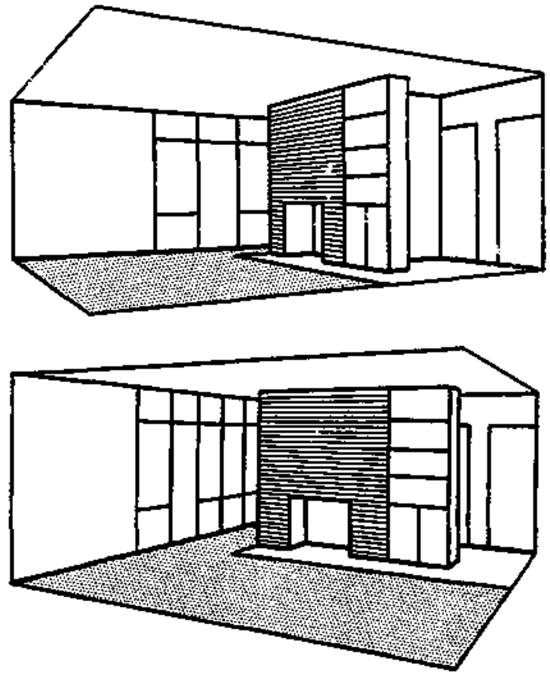
THE POSITION OF THE PICTURE PLANE.
The size of the perspective drawing obtained with a given object, given scale, and given relation between station point and object, can be varied by changing the position of the picture plane (fig. A, B, and C) The nearer the picture plane to the station point the smaller the perspective, the farther the picture plane from the station point the larger the perspective. If all positions of the picture plane are parallel the resulting perspective drawings will be identical in all respects except size.
The shifting of the position of the picture plane is a very helpful device for obtaining any size perspective desired. However, there are limits to its use. Extreme enlargements may be lacking in accuracy, while extreme reductions in size require space for the construction which is out of proportion to the size of the resulting perspective drawing.
The most common position of the picture plane is through the nearest main corner of the object. Simplicity and directness of construction are the principal advantages of this location of the picture plane. However, similar advantages are secured by having the picture plane pass through any visible corner of the object.
Other positions of the picture plane can be used to increase or diminish the size of the drawing without greatly complicating the construction. The constructions for points in front of and behind the picture plane have been given in the preceding pages.

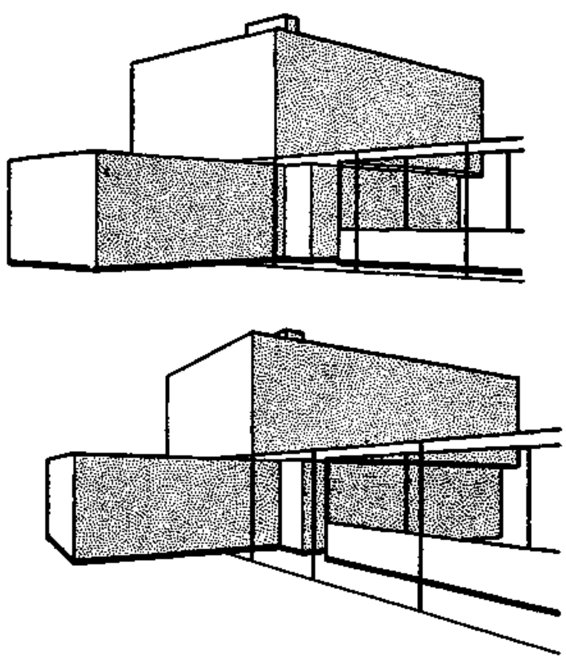


(A) BEFORE OBJECT (B) BEHIND OBJECT (C) THROUGH OBJECT

VARIATIONS OF THE PICTORIAL EFFECT IN PERSPECTIVE are obtained by changing the height, distance, and angle of view through manipulation of the station point. Variations in size of the perspective drawing can be obtained by change of scale of the auxiliary drawings, and by varying the position of the picture plane. An active imagination and the ability to visualize final results are as important to the draftsman as to the photographer in obtaining interesting pictures. The draftsman who understands the effect of the variables in perspective should be able to get the exact view that he wishes and make it the size best suited to his purpose.

When several perspective studies are made from a given design and none of them looks well, the designer may be reluctantly forced to the conclusion that he has not designed a beautiful building. It is even more difficult for the draftsman to make a dramatic perspecktive of a mediocre design than for the photographer to make a glamorous photograph of a homely person. Furthermore, the architect must prove the design in the actual building, and there is a question of professional integrity involved.





BLOCK STUDIES AT SMALL SCALE, which show only the masses and principal features of the object, can be made very quickly. They are of great value in choosing a station point for a larger and more detailed perspective drawing. They often save time because the large perspective can be made correctly the first time. With several possible variations considered in block form a better pictorial effect can be secured. These simple preliminary studies may be compared to the proofs furnished by a photographer. One of the proofs is selected for the final pictures or perspective.

While the beginner in perspective drawing needs the information from a number of block studies, he is usually not as willing to make them as the expert draftsman who appreciates their value from experience. On these speedy drawings the designer feels free to try arrangements which he would be very unlikely to try for a single large perspective.
There is, therefore, a psychological advantage in a number of block studies which leads to greater imaginative freedom, and often to more dramatic results. Freehand studies are used by many designers for ideas for perspectives.

ONE POINT PERSPECTIVE

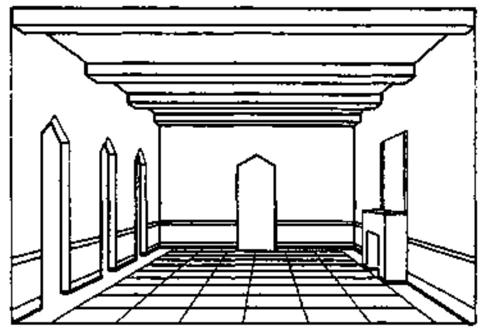
4.6 ONE — POINT PERSPECTIVE

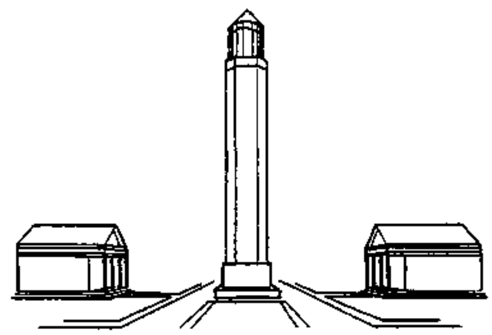
The most striking and characteristic views of streets, landscape garden scenes, groups of buildings, single buildings, and parts of buildings both exterior and interior, often show them as they would appear in one-point perspective. One-point perspective is therefore important to the architect and draftsman, because it is frequently more suitable for the subject to be drawn or gives a more characteristic view than could be obtained with two - point perspective.

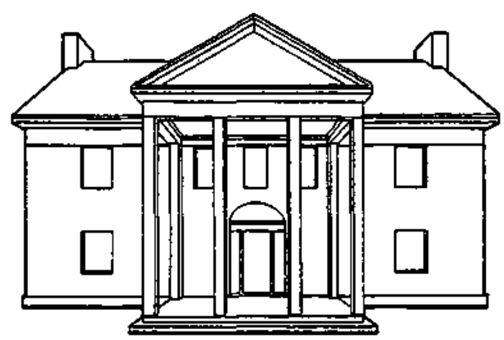
One-point perspective is so named because only one of the three typical sets of lines converges to a vanishing point. The remaining two sets of lines are parallel to the picture plane. Since lines which are parallel to the picture plane retain their true directions, the lines of each of these two sets remain parallel in perspective. In most one-point perspectives the picture plane is vertical. The vertical lines and one set of horizontal lines of the object are parallel to the picture plane, and remain respectively vertical and horizontal in the perspective drawing. The remaining set of horizontal lines is perpendicular to the picture plane and converges to a vanishing point.

One-point perspective can be used appropriately and effectively whenever the object presents a good appearance with the line of the center of vision of the observer perpendicular to one set of planes of the object, and consequently parallel to one set of lines; that is, when the conditions under which the object is naturally seen are those of one-point perspective.

Typical subjects for one-point perspectives are shown in the illustrations of the figure.







Although one-point perspective is not as widely used as two-point perspective it is extremely useful for both exterior and interior subjects and deserves the careful study and consideration of the person who wishes to become proficient in perspective drawing. Some of the most striking photographs used in illustrations of architectural magazines are one-point perspective views. Since the photographer usually has a wide range of choice of views, the one-point perspective position is chosen in most cases because of its pictorial merits and not from necessity.

THE COMMON METHOD OF ONE-POINT PERSPECTIVE. The use of a plan showing the object, picture plane, and station point is required for the construction of the perspective drawing.

Step I of the figure shows the location of the plan and elevation as the first step in making the perspective. The elevation is in this example located below the station point of the plan and to the right of the edge of the plan to leave a clear area for the perspective drawing. The horizon has been located near the center of the height of the elevation.

In Step II vertical lines are drawn from plan and horizontal lines from the elevation to give the intersection of walls, floor, and ceiling of the room with the picture plane. This line of intersection is at scale size since it lies in the picture plane. The vanishing point is located by drawing a vertical line from the plan of the station point to meet the horizon. When the position of one end of a line perpendicular to the picture plane has been located in the perspective drawing the line can then be drawn through this point toward or away from the vanishing point.

Step III shows how the plan is used to determine the correct horizontal spacing of vertical lines for the perspective drawing. The projectors are drawn from the two rear corners of the plan toward the station point to meet the picture plane. From these intersections with the picture plane vertical lines are drawn to the perspective locating the two vertical corners at the rear of the room. The lines of the intersections of walls with floor and ceiling are drawn from the corners A,B, C, D toward the vanishing point to meet the rear corners of the room. Horizontal lines from the two rear corners complete the simple perspective.

Step IV shows how lines can be traced around the walls and along the floor and ceiling from their correct scale positions on the lines in the picture plane.

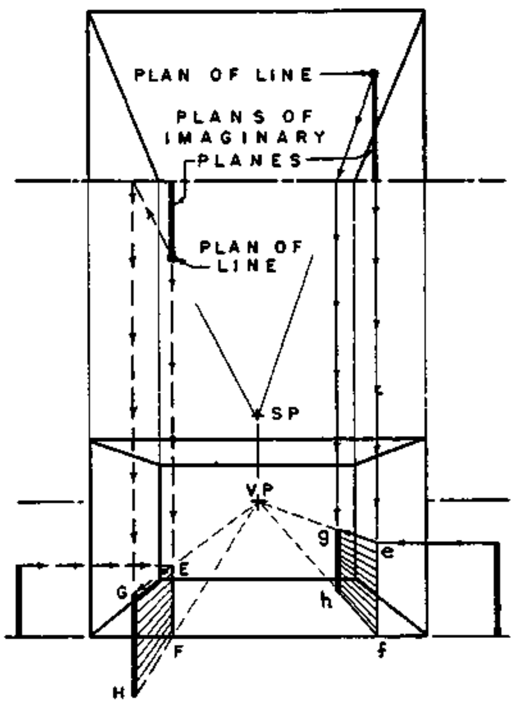
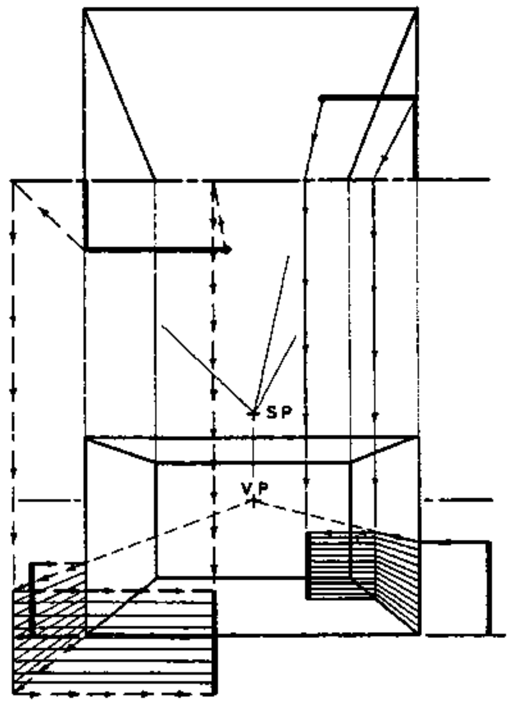
Fig. A and B shows two methods of determining heights of objects which do not lie in or touch the wall surfaces or picture plane of a one-point perspective drawing. In these examples the freestanding objects are vertical lines which rest on the floor.

In each example there are two freestanding lines. The line object on the right of each example is behind the picture plane and the one on the left is in front of the picture plane. When the object is a solid, the method shown can be repeated as many times as necessary for different parts of the object to obtain a number of points which can be connected to make the drawing.



(A) DIRECT METHOD



(B) INDIRECT METHOD

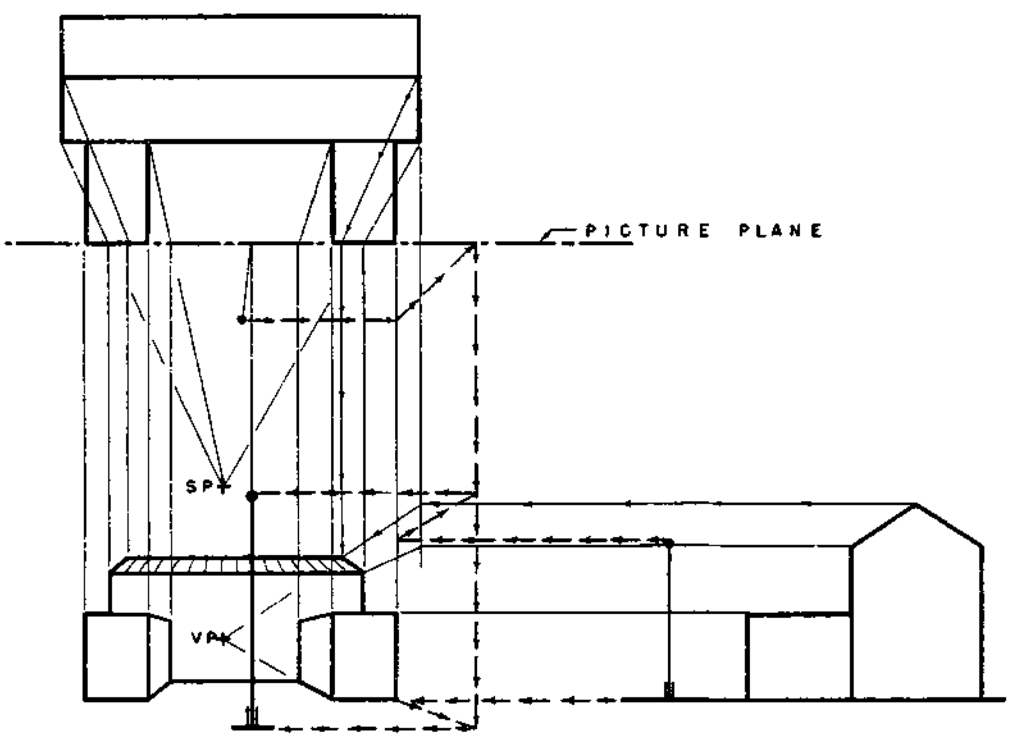
IN THE DIRECT METHOD, Fig., an imaginary plane which is parallel to the side walls of the perspective drawing and perpendicular to the picture plane is extended through the point plan of the freestanding line to meet the picture plane in plan. The height of the line is laid out to scale on the line E-F of intersection of the imaginary plane and picture plane in the perspective drawing. The height is then traced directly along the imaginary plane by lines through the vanishing point and brought to correct perspective position at G-H as shown. This is the most convenient and simple method of determining most heights of freestanding objects. However, in the special case when the freestanding line is on a vertical through the vanishing point this method cannot be used, because the line from the vanishing point is a vertical line and will not intersect vertical lines brought down from plan to establish heights. Furthermore, the lines from the vanishing point must be at a sufficient angle, so that their intersections with vertical lines can be accurately located. Objects which are very near a vertical line through the vanishing point cannot be accurately located by this method.

THE INDIRECT METHOD carries the heights along the walls or other planes perpendicular to the picture plane to the required distance, then along imaginary planes parallel to the picture plane to the correct perspective position. In the two examples of Fig. the wall serves as the plane perpendicular to the picture plane for the object behing the picture plan. An extension of the wall has been used for the object in front of the picture plane.

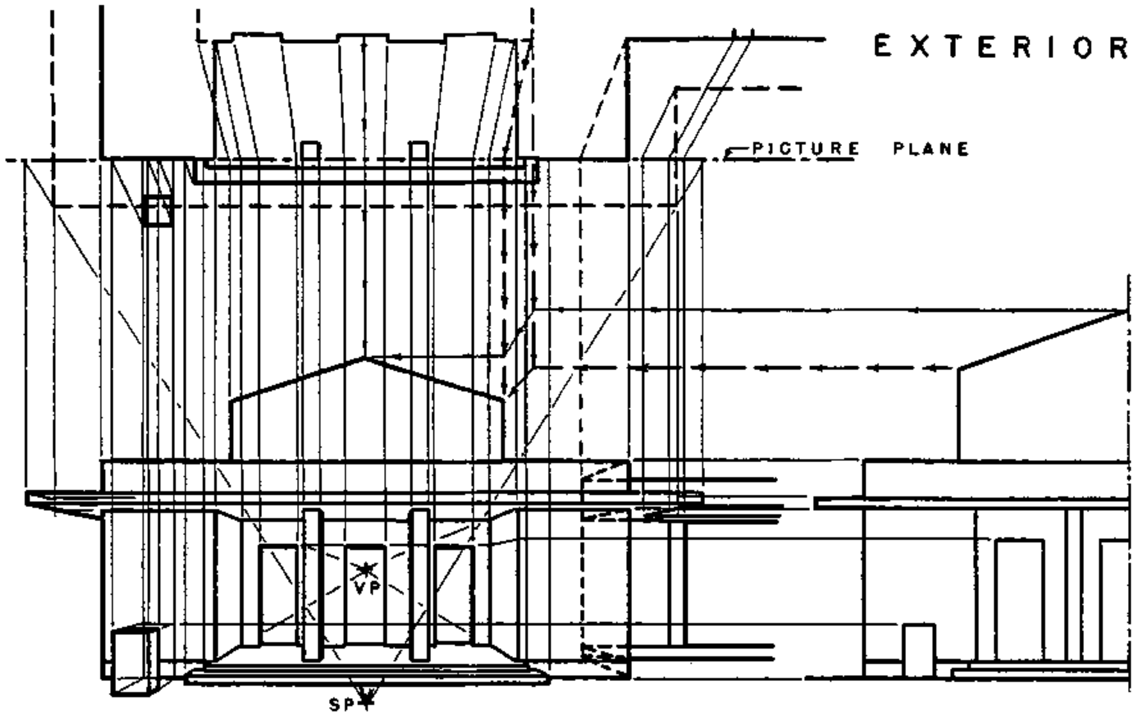
The three examples of one-point perspective by the common method (see figures) show the application of principles previously explained to more detailed subjects. An elevation or section has been drawn in each example in order to make the methods of determining heights as clear as possible. It is not necessary to draw the elevation or section as a part of the construction of a perspective by the common method.

The heights and widths of the parts of the object in the picture plane are drawn to scale size.

In the figure the ends of the projecting wings of the building lie in the picture plane and are drawn to scale size by dropping verticals from plan to meet horizontals from elevation. The top and bottom lines of the wings, which are perpendicular to the picture plane, are drawn to the vanishing point to meet the construction lines broght down from the junction of the wings and main building in plan. The indirect method is used to determine the height of the flagpole since it is too nearly on a vertical line throgh the vanishing point to use the direct method accurately. These construction lines are heavy dotted lines. The height of the roof is traced back into position by the direct method using an extension of the end wall to the picture plane for the height construction.



ELEMENTS OF ONE-POINT PERSPECTIVE - COMMON METHOD



In the figure the lines made of short dots on the right side of the perspective show the construction of heights by tracing around hidden surfaces. The lines with longer dots and arrows in this example show the construction of a height, by the direct method, around one imaginary corner. The indirect method is used to determine the height of the highest point of the building.

The figure illustrates the tracing of heights around visible wall surfaces for the wainscoting, windows, and ceiling line. The height of the rectangular box is found by the indirect method, using an imaginary extension of a plane of the box to meet the wall. The lines of the sofa are projected directly from the scale profile (drawn in dotted lines) in the picture plane to position in the perspective drawing.

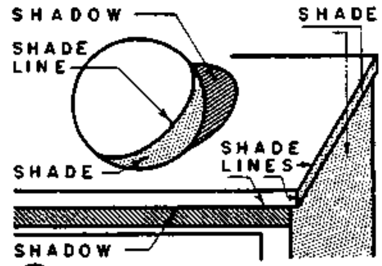
5. SHADES and SHADOWS

5. SHADES AND SHADOWS

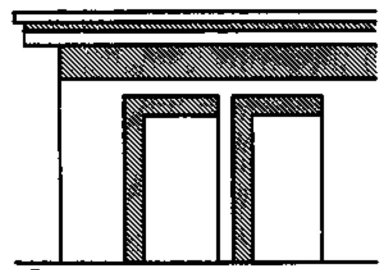
Wherever there are buildings, clouds, trees, rocks, or other objects extending above the surface of land or water there are shadows when the sun shine. These shadows form an essential part of the pattern of a landscape, a piece of pottery, or a building. Since shadows are inevitably a part of any object which is to be placed in the light, their forms and masses must be considered in studying a design if that design is to be completely successful.
A knowledge of shadow shapes and of the methods by which they are correctly and accurately constructed on various types of drawings is an essential part of the training of any draftsman or designer of objects in three dimensions.

5.1 THE USE OF SHADOWS. Shadows are especially useful in architectural drawing and design because they make the drawings more easily understood. The shades and shadows express the shapes of surfaces, showing whether they are curved or flat, slanting or vertical. In drawings shadows are especially valuable because they bring out the third dimension; the distance back, in what would otherwise be a two-dimension drawing. The lines and masses of shadows form an important part of an architectural design and should be a part of the studies made in the development of the design. When the correctly drawn shadows are unpleasant or disturbing there is something wrong with the design and it should be revised to produce a more harmonious effect.

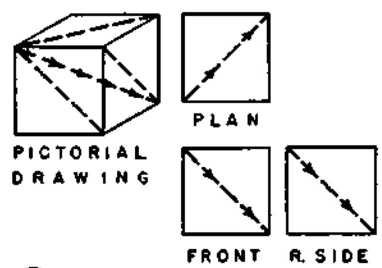
Shadows are almost indispensable on rendered presentation drawings. They add to the picture effect of drawings, making them much more easily understood by the client. The rendered shadows give even the designer a clearer conception of the appearance of the projected building and aid him in perfecting its design.



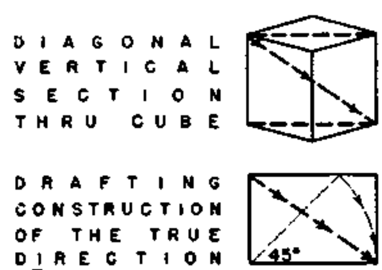
(A) DISTINCTION BETWEEN SHADE AND SHADOW



(B) SHADOW WIDTHS MAY EQUAL PROJECTIONS



(C) THE CONVENTIONAL DIRECTION OF LIGHT

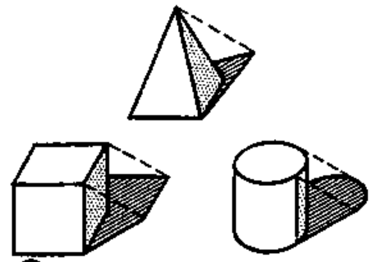


(D) TRUE DIRECTION OF A CONVENTIONAL RAY

DEFINITION OF SHADOW TERMS

5.2 SHADES AND SHADOWS.

A shade occurs when the shape of the object excludes the light rays from part of its surface (Fig. A) The lines between the areas of light and shade are called shade lines. On a curving surface, such as that of a sphere, the shade line is the line of tangency of light rays to the curving surface. On objects made up of plane surfaces a shade line is the edge where a surface in light meets a surface in shade. A shadow travels through the air from one object to another, or from one part of an object to another part of the same object.

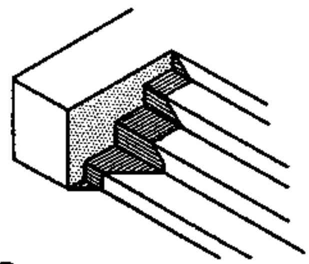


(I) THE SHADE LINES
CAST SHADOW OUTLINES

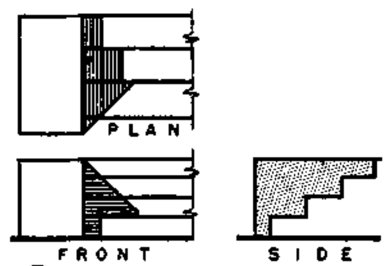
5.3 THE CONVENTIONAL DIRECTION OF LIGHT.

In casting shadows it is necessary to assume a source and direction of light. The source of light is usually assumed to be the sun and the rays of light are considered to be parallel The direction of light used in practically all shadow-casting gives shadow widths which are equal to the projections from wall surfaces of vertical and horizontal shade lines which are parallel to the picture plane and the wall. Characteristic examples of shadows which are equal to the projections making them are those of the cornice and window shown in fig. B.

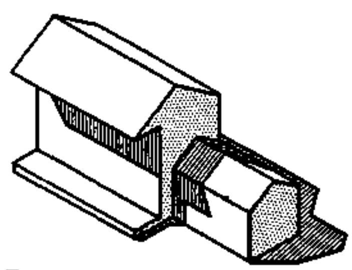
If a cube is placed so that its sides are parallel to the three coordinate planes of elevation, plan, and side elevation, then its diagonal from the top left front corner to the lower right rear corner gives the conventional direction of light and the three views of the cube give the apparent directions of light in the three typical drawings (fig. C).



(II) SHADOW SEEN IN A
PICTORIAL DRAWING



(III) SHADOW SEEN IN THE
MULTI-VIEW DRAWINGS



(IV) SIMPLE MODELS HELP
TO EXPLAIN SHADOWS

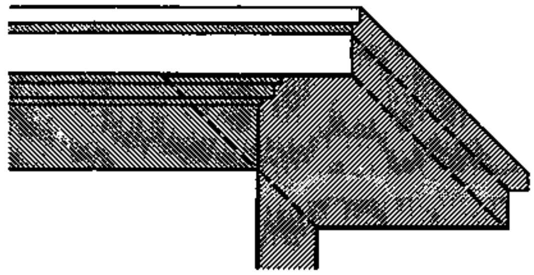
5.4 THE 45° DIRECTION.

Since the direction of light in front elevation, plan, and side elevation views is the diagonal of a square it is a 45° line in all three drawings. Therefore, shadows may be traced by using the 45° triangle on these drawings. A ray of light travels equally in three directions:

1. to the right
2. down, and
3. back,

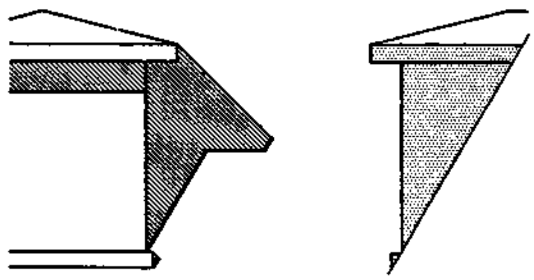
as shown by edges of the cube.

The 45^0 triangle should be regarded as a tool for measuring equal distances in two directions, in front elevation down and to the right, in side elevation down and back, and in plan back and to the right. It is usually the most convenient way to measure shadow widths, but any means of measuring equal distances such as dividers, scale, or paper strips may be used if more convenient.

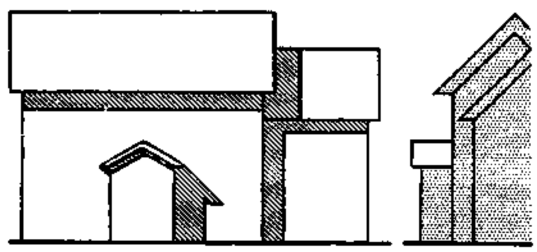


(A) LINES WHICH CAST SHADOWS

5.5 THE TRUE DIRECTION OF LIGHT.
Since the light rays are at an angle to all the planes of projection the true direction of light is not seen in any of the multi-view drawings. In order to see the true direction of the conventional ray of light it is necessary to use an auxiliary plane perpendicular to plan and parallel to the direction of light. The true direction of a ray of light is represented by the diagonal of a cube, which is the diagonal of a rectangle, of which the short sides are edges of the cube and the long sides the diagonals of the top and bottom of the cube. The true direction of light may readily be constructed as shown in the bottom drawing of fig. D, and will be found useful in constructing some shadows.



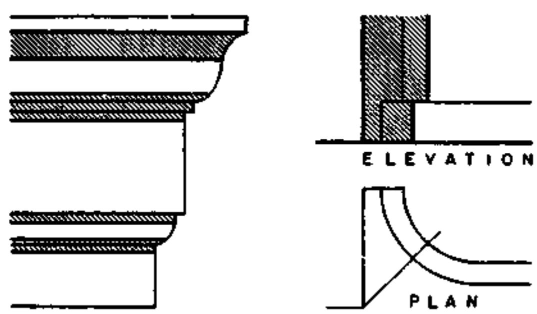
(B) SHADOWS OF PARALLEL LINES



(C) SHADE LINES PARALLEL TO SURFACE RECEIVING SHADOW

5.6 SHADOWS OF SOLIDS
Architecture is made up of volumes and masses which are usually the shapes of the simple geometric solids used either singly or incombinations. Shadows on architectural drawings are the shadow of solids or of hollow masses.

The shadow of any solid is bounded by the shadows of the shade lines of the object.
Only those lines which mark the divisions between light and shade on an object can cast shadows. There fore, if the shade lines on the drawings of an object can be located by inspection, the shadows of these shade lines can then be determined to give the outline of the shadow of the object.



(D) SHADE LINES PARALLEL TO LINES IN SHADOW SURFACE

PRINCIPLES OF SHADES AND SHADOWS

5.7 PLANES OF SHADOW

The straight shade lines of an object make planes of shadow. Therefore the shadows of these straight lines are the intersections of their planes of shadow with the surfaces on which the shadows fall.

1. The position of the shade line
2. the location of the eye of the observer
3. the direction of light, and
4. the shape of the surface on which the plane of shadow ends are the factors which determine the shape of the shadow as shown on the drawing.

5.8 PRINCIPLES OF SHADOW-CASTING

A knowledge of some of the simple geometric and self-evident principles used in casting shadows will make the problems of working out shadows more easily understood. Several of these helpful principles are described in the numbered paragraphs, and illustrated on this and the following page. The use of a light and a simple model will help the reader to verify and understand these principles.

I - A LINE IN SHADE OR SHADOW CANNOT CAST A SHADOW because light does not strike it. The lines of the moldings underneath the cornice in fig. A are entirely in shadow and do not cast shadows. When part of a line is a shade line in light and part of the line is in shadow, then only the part of the line which is in light will cast a shadow. The corner of the wall in fig. A is an example of a line which is partly in light and partly in shadow. By first determining which parts of the object are in shadow it is possible to locate the shadow of the object without wasting time finding the shadows of lines which do not make parts of the shadow outlines.

2-SHADOWS OF PARALLEL LINES ARE PARALLEL when they fall on the same plane or on parallel planes (fig. B). This is true regardless of the relation of the parallel lines to the plane receiving the shadow and of the direction of the plane receiving the shadow. This principle can often be applied to problems to simplify the working out of shadows of parallel lines and to secure greater accuracy. In the case of slanting shadow lines such as those from the dormer onto the roof the direction can be determined most accurately from the longest shadow; then the others can be drawn parallel to it. When the direction of a shadow line is known the construction of the shadow is simplified.

3-THE SHADOW IS PARALLEL TO THE LINE MAKING THE SHADOW when
1. the line is parallel to the plane receiving the shadow, or
2. the line is parallel to the straight lines in the surface receiving the shadow.

The shadows on the house of Fig. C illustrate the first condition. The shadow of the cornice onto the wall below, the shadow of the vertical corner of the wall onto the second wall surface and the shadow of the right edge of the main roof onto the parallel lower roof surface are all illustrations of this principle. The second condition is illustrated by the molding and the shadow of the vertical line onto a vertical cylinder in Fig. D.

4-THE SHADOW OF ANY PLANE FIGURE ON A PARALLEL PLANE is identical in shape size, and direction with the figure. This relation is true regardless of the angle at which the area and the parallel plane are turned (fig.). When part of the shadow is behind the plane figure making the shadow, as in the center example, the visible part of the shadow is identical with the part of the figure which makes the shadow. When the plane figure is part of a solid, as in the case of the example of the block on the right of Fig. I, then the part of the shadow made by the end of the block follows this rule since it is parallel to the plane receiving the shadow.

5-A SHADOW IS VISIBLE only where it falls on a visible surface which is in light. The triangular shadow below the left edge of the dormer roof in Fig. II is visible because it falls on the main roof. There is no similar visible shadow at the left edge of the main roof because there is no visible surface receiving the shadow. The block at the left of Fig. II is set out from the wall so far that none of its shadow is visible in elevation. All of the shadow falls on the floor plane. The distance of the block on the right side is such that part of the shadow is visible in elevation and part in plan.

6-ANY LINE ON A PLANE SURFACE APPEARS TO BE A STRAIGHT LINE WHEN THE OBSERVER LOOKS PARALLEL TO THE PLANE SURFACE. (Fig. III) Since the entire plane surface will be seen as a line when the observer looks parallel to the plane, then any line in the plane will appear to be straight. Objects, areas, and lines are shown in drawings as they would appear from a certain viewpoint.

7-WHEN THE OBSERVER LOOKS AT THE END OF ANY STRAIGHT LINE, so that the line is seen as a point, then the shadow of the line will appear to be straight regardless of the shape of the surface receiving the shadow. The line makes a plane of shadow. Since the observer is looking parallel to the line he is also looking parallel to the plane of shadow made by the line and any line in the plane of shadow appears to be straight. The shadow line lies in the plane of shadow and therefore appears to be a straight line when seen parallel to the plane, as illustrted in the elevation of fig. IV. Any line seen in end view in elevation, plan, perspective, or any other drawing will cast a straight line shadow in that view where it is seen as a point. A simple model made of boxes and cans with either sunlight or a single artificial light will help the reader understand this type of shadow.

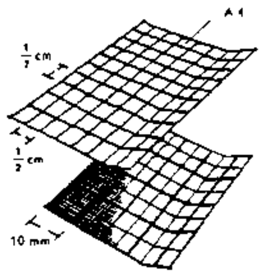
(IV) SHADOWS OF LINES WHICH ARE SEEN AS POINTS

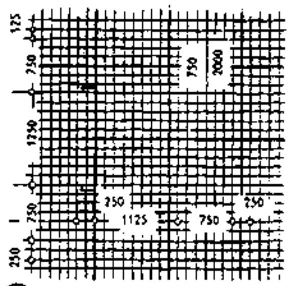
PRINCIPLES OF SHADES AND SHADOWS

6.DRAWING PRACTICE

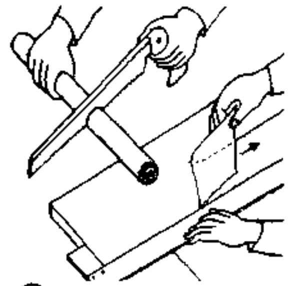
The designer's language is the drawing. It formulates his statements clearly and is internationally readable: factually, by geometrical drawings; attractively, by perspectives. A drawing helps to present ideas and to convince the client. The architect's production drawings and perspectives are only a way of presenting the proposed building clearly, not an end in themselves as are paintings.



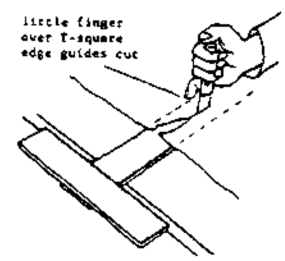
(1)



(2)

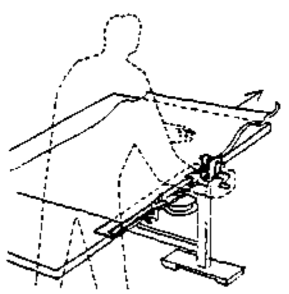


(3)

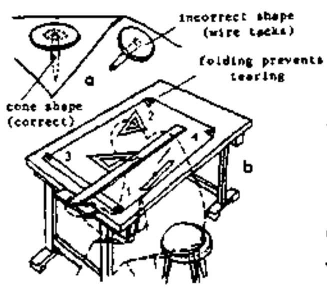


(4)

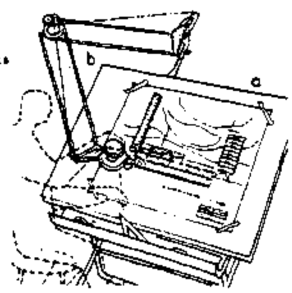
Sketch pads (A4 size) with 5 mm ($\frac{1}{4}$ in) squared paper are convenient for freehand designing to scale; for more exact sketches, mm squared paper with bold 10 mm and less bold 5 mm division lines, → (1), (2). For sketching with soft pencil, thin transparent paper; roll is cut to required sizes and single pieces torn off along T-square, → (3), or cut on T-square, → (4). Plans on good translucent, unglazed tracing paper in standard sizes, → p. 2, to be used with edge protection, → (5). For ink and water colour drawings, tracing



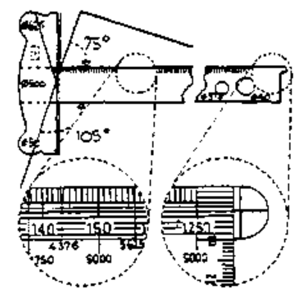
(5)



(6)

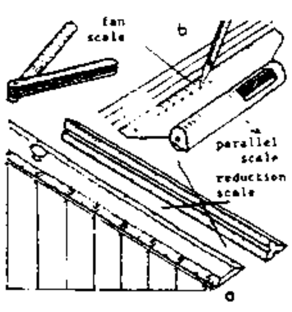


(7)

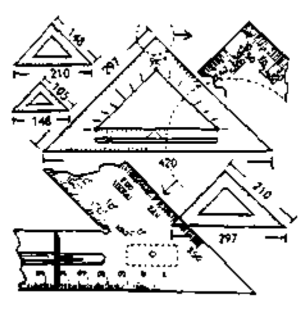


(8)

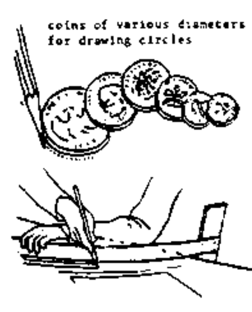
linen is best; for painting and perspectives, special papers. Fix paper to drawing board or table with clips or drawing pins, not wire tacks which leave holes, → (6a). First, fold 20 mm ($\frac{3}{4}$ in) wide edge of the paper which later becomes the fastener hem and lifts T-square slightly off paper to avoid blurred lines (for same reason draw from top to bottom). Then fold remaining corners 2 and 4 of



(9)



(10)



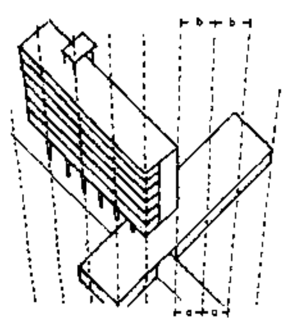
(11)

(12)

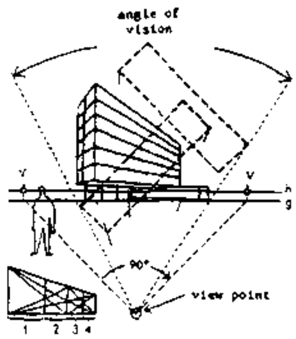
sheet, → (6b); pin corner in 1, smooth sheet in direction 2; after fixing this corner, repeat the action from corner 3 to 4. Instead of drawing pins, clips or adhesive tape may be used, → (7a). Mechanical drawing equipment originally used only by engineers is finding its way into architects' offices, → (7b). In addition to ordinary T-square, special (Patent Neufert) T-square, which makes it possible to apply various angles; has octameter and centimetre scale, → (8).

DRAWING PRACTICE

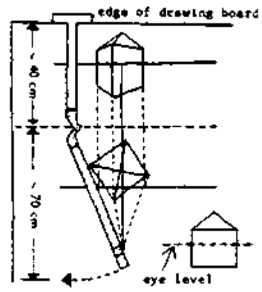
Scale with 1 mm divisions is best, $\frac{1}{2}$ mm markings are confusing. For sketching to scale and drawing lines at set distances, parallel rules or rolling parallel rules are useful, → (9b). Use of triangle rules is discouraged, → (9). Best set squares are transparent uncoloured plastic with mm division, sometimes degrees, → (10), (rigid or adjustable). Various aids to drawing circles and curves,



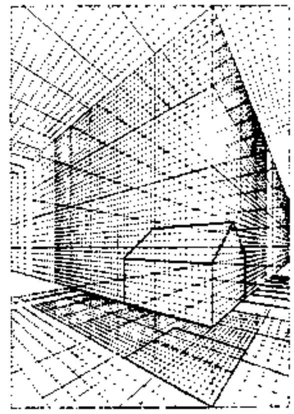
⑬



⑭

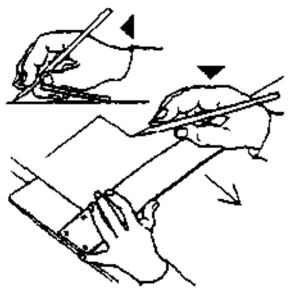


⑮

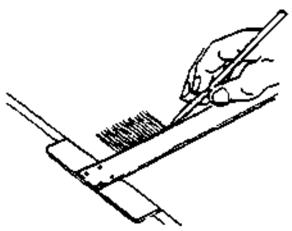


⑯

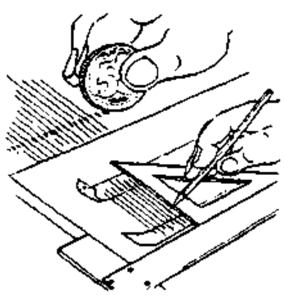
→ (11) (improvised) and (12) (manufactured). Perspectives and models clarify the ideas of the designer and usually convince better than words. Perspective should be constructed to give an exact picture of the real building. Isometric projections can replace perspective birds-eye view if they are drawn to sc. 1:500, → (13). Easy method to set up perspective, → (14). Perspective apparatus, → (15). Perspective screen which may also be used for interiors, → (16). Drawing tricks: fast and exact drawing of rectangular



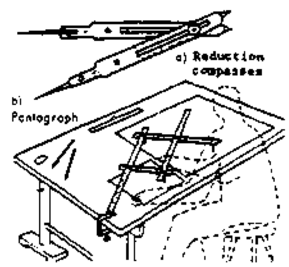
⑰



⑱

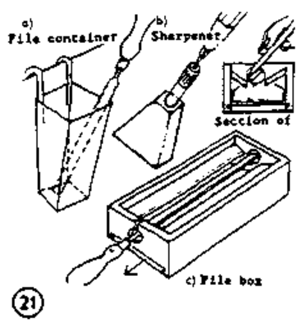


⑲

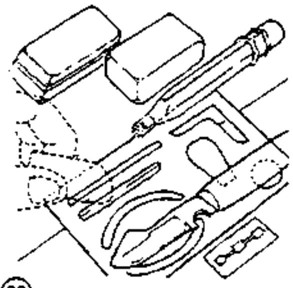


⑳

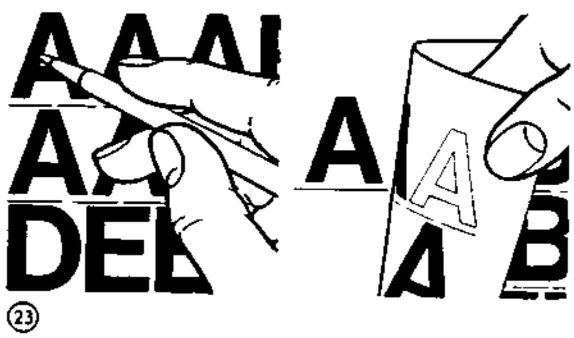
diagrams with T-square only, without set square, → (17); correct holding of T-square and much practice essential to success. Division of line into equal parts facilitated by putting a scale rule at slant, → (9). Various aids, → (18), (19). Enlargement of drawings to scale through pantograph, → (20). Reduction compasses facilitate drawing of fixed lines in adjusted relation to original, → (20).



㉑



㉒



㉓

Retractable pencil suitable for 2 mm dia leads of all grades 6B-9H. When sharpening leads, graphite catcher essential, → (21). To erase indian ink; glass eraser, erasing knife or razor blade; to erase pencil lead: non-smearing india rubbers. In drawing with many lines use erasing shields, → (22). Lettering best unaided; for technical drawings stencil with pen or brush, or use instant dry transfer system such as 'Letraset' which also provides architectural symbols, → (23).

6.1 DRAWING SHEETS

(→ BS 1192:1969)

Standard sizes
A0 841 x 1189 mm (33 1/8 x 46 3/4 in)
A1 594 x 841 mm (23 3/8 x 33 1/8 in)
A2 420 x 594 mm (16 1/2 x 23 3/8 in)
A3 297 x 420 mm (11 5/8 x 16 1/2 in)
A4 210 x 297 mm (8 1/4 x 11 5/8 in)

These sizes are all proportional, leading to simple reduction and enlargement and sheets may be easily folded for filing and despatch. The relatively small sizes should lead to easier handling in the drawing office and on site. Keep the number of sizes to minimum, to facilitate binding and reference.

Original drawings and contact copies should both be of standard sizes, therefore trimming of sheets that makes them less than A sizes should be avoided.

Folding
Prints may be folded to A4 size quite easily from any larger A size.

When prints are to be filed it is necessary to fold them in such a way that the punch holes penetrate only one layer. Methods of folding, → (1) and p. 3.

A0
841 x 1189

AD II compiled : D.VOLKE AUG. '83	DRAWING PRACTICE	ARCH. DRWNG. LECTURE CET 3o43/16.158

LAYOUT and IDENTIFICATION

Layout and identification

(→ BS 1192: 1969)

Layout: every sheet should have filing margin, title and identification panel.

Filing margin: at left hand edge ≥ 20 mm ($\frac{7}{8}$in) wide. Filing **punch marks** and **fold marks** printed as ticks at edges of sheet. Where microfilming likely, → BS 4210.

Title panel: place in bottom right hand corner of sheet to aid reference when prints are filed or folded, → (1), (2).
Include: job title; subject of drawing; scale; date of drawing; job number; SfB and UDC reference if appropriate; name of architect, etc. Panel may also give initials of person drawing, tracing and checking sheet.

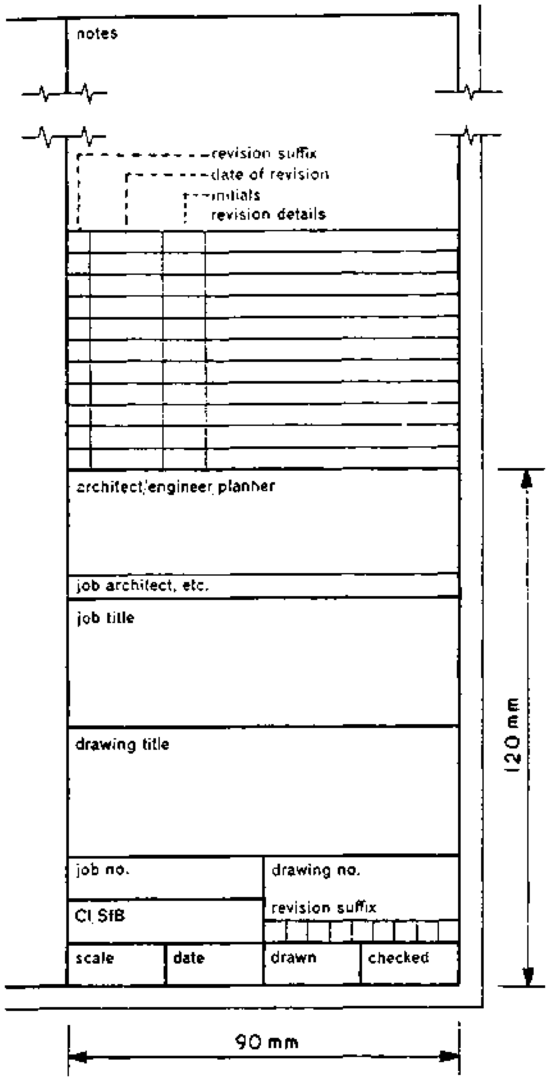
Revision suffix should be changed each time drawing is issued after revision.

Printed blank title panels or use of stencils, transfers or rubber stamps save time and labour.

Information panel: note nature and date of each revision, with architect's initials; start at bottom of panel and work upwards. When general notes included, start at top and work down.

Key: on large projects give key diagram showing continuous drawing sheets, with appropriate part blacked in on each relevant drawing.

Orientation: show north point on every plan. When practicable all plans should have same orientation, except for site location plan. For latter, draw with north at top of sheet to aid identification with Ordnance Survey maps.



(1) Typical title panels - vertical

(2) Typical title panels - horizontal

6.2 LEVELS

(→ BS 1192: 1969)

Levels

General
Levels record distance of a position above or below a defined datum.

Datum
A suitable fixed point should be taken as TBM (temporary bench mark) such that all other levels are positive (minus sign is easily misread). This datum should be clearly indicated or described on drawings, and all levels and vertical dimensions related to it. Vertical dimensions in metres to three decimal places (or in feet and decimals of a foot) above this datum. On large jobs, particularly, it is usually necessary to relate job datum to OS datum (OS levels at present in feet). State clearly whether Newlyn or Liverpool Ordnance Datum is used.

OS are preparing bench mark lists giving heights in metres to two places of decimals.

Levels on plan
It is important to differentiate on site layout drawings between existing levels and intended levels:

existing level: x 58.210

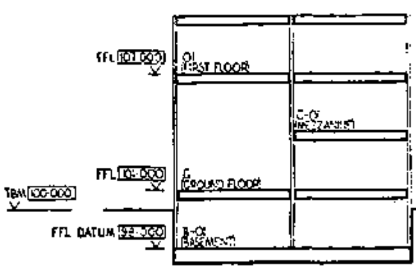
intended level: x $\boxed{60.255}$

Exact position to which level applies should be indicated by 'X'

Finished floor levels should be indicated by letters FFL followed by figures of level:

FFL $\boxed{12.335}$

Levels on section and elevation
Use same method as for levels on plan except that level should be projected beyond drawing with arrowhead indicating appropriate line, → (1).



(1) Levels on section and elevation

6.3 REFERENCING

Referencing

Classification and coding of building components and elements shown on drawings may be achieved through use of SfB system (UK application known as CI/SfB; → 'Construction Indexing Manual', published by RIBA, for details of system and its tables).

SfB enables information contained within different kinds of documents, such as bills of quantity, drawings, specifications, texts, trade literature, etc, to be co-ordinated and correlated for maximum benefit of user.

SfB system is a facet system of alpha-numerical symbols forming three tables which may be used individually or in combination to indicate concepts and terms required. Three tables of SfB system cover building elements, components/products, and materials.

Each type of component or element shown on a drawing may be identified by appropriate SfB notation, e.g.:

concrete blocks	Ff2
concrete lintels	Gf2
aluminium sections	Hh4
hardwood sections	Hi3
manholes	(52)
external walls	(21)
windows	(31)
doors	(32)
radiators	(56)

Notations may be combined, e.g.:

external walls, concrete block	(21) Ff2
windows, aluminium	(31) Hh4
doors, hardwood	(32) Hi3

Number and length of component and element notations should be kept to minimum compatible with a rational system of identification for each particular job.

A specific component within any range may be identified by a suffix giving nominal sizes for length, width, height, etc:

concrete block Ff2 400 mm x 100 mm x 200 mm
Ff2 1 ft 4 in x 4 in x 8 in

Alternatively, where principles of modular coordination are applied, such a suffix may give nominal sizes for a component or element in multiples of 100 mm or 4 in (M), e.g.:

concrete block Ff2 4M x 1M x 2M

6.5 REPRESENT.

Representation of materials

(→ BS 1192:1969)

Table shows recommended methods of indicating materials on drawings. These methods should only be used where confusion is likely to occur in interpretation of drawings, but in all cases they should be accompanied by a descriptive note, stating type of material, thickness, etc. Existing and proposed work should be clearly indicated. Spacing of hatching lines should be adapted to scale of drawing and should not normally be used on small scale drawings.

Colouring is costly, laborious and conducive to error and consequently to be avoided. Hatching is preferable where it is necessary to show different materials.

6.6 GRAPHICAL SYMBOLS

(→ BS 1192:1969)

A drawing is a symbolic representation of a real or imagined object. Aspects or parts of a drawing may themselves be symbolically represented. Symbols for this purpose are termed graphical symbols, use of which enables maximum information to be contained within the drawing, clearly and legibly, with minimum effort.

Types of symbols
Principal types used in building drawing practice are graphical. Many of these, as well as other kinds of symbols such as letters, numbers and signs, are covered by British Standards, of which the following are relevant:

BS 108 Graphical symbols for general electrical purposes (power and lighting).

BS 1553 Graphical symbols for engineering:
Part 1 Pipes and valves
Part 4 Heating and ventilating systems.

BS 1635 Graphical symbols for fire protection drawings.

BS 1991 Letter symbols, signs and abbreviations
Part 1 General
Part 4 Structures, materials and soil mechanics.

BS 3939 Graphical symbols for electrical power, telecommunications and electronics diagrams.

Graphical symbols
Building drawing practice requires use of graphical symbols on drawings which are additional to those covered in above British Standards. Examples of most commonly used graphical symbols are given below

GRAPHICAL SYMBOLS AND REPRESENTATION

Draughtsmanship

Description	Symbol	Description	Symbol
Centre to centre	c/c	Existing level on section	⊻ 0·000
Centre line	℄	Finished floor level	FFL

Rise of ramp		Planted area	
Bench mark	BM	New trees	Existing level on plan	× 0·000	Existing trees			Existing trees removed	

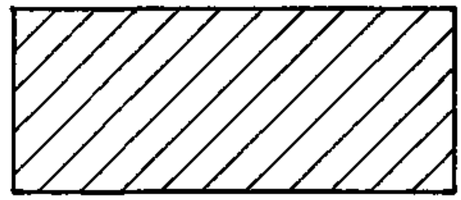
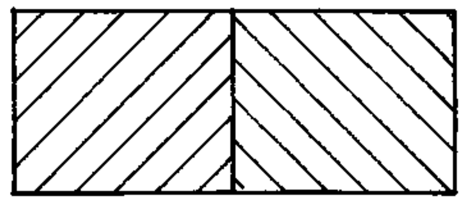
6.7 HATCHING

HATCHING RULES

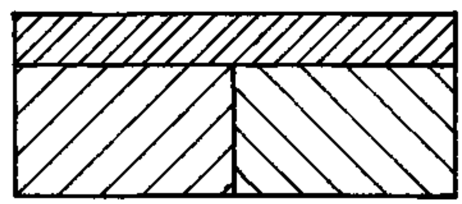
1. Draw HATCHING LINES preferably at 45^{o} as thin lines with a spacing of - preferably - not less than 4 mm.



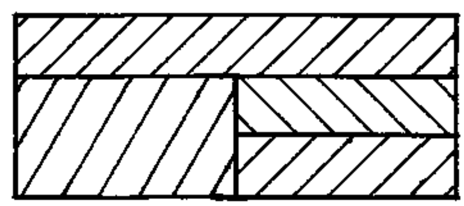
2. If two adjacent parts to be hatched, draw the HATCHING LINES in opposite directions.



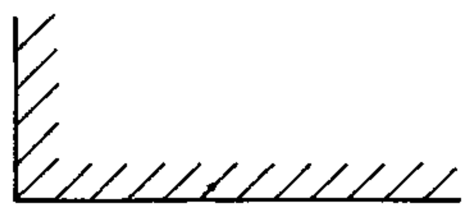
3. Where more than two adjacent parts to be hatched, draw the HATCHING LINES of one area - preferably the smallest - closer together.



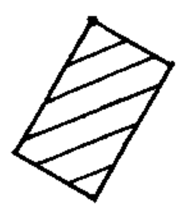
4. In order to simplify distinguishing between more than two adjacent parts, HATCHING LINES drawn at 60^{o} and/or 30^{o} my be used additionaly.



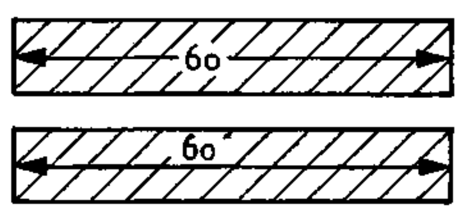
5. Large areas may be hatched along the borderline only.



6. If a part is drawn at such an angle that the HATCHING LINES become parallel to one edge of the part, the angle of hatching may be chaused.



7. Interrupt HATCHING LINES to give space for dimensioning figures, words etc.



7.APPLICATION for BUILD.PERMIT

7.1 PROCEDURE OF APPLYING FOR PERMISSION TO ERECT A BUILDING

Application for and Allocation of a plot:

a) Request to the (District) Land Officier
b) Land Officier submit all applications to the Urban Planning Committee
c) Plots are allocated by the Urban Planning Committee
d) Right of Occupancy of the plot is issued through the Land - Officier.

Application for Permission to erect a Building

a) Submission of the Application to the Town Council Authority
The application includes:
- A properly filled Form of Application for Permission to erect a Building
- A properly filled Form of Application for Planning Consent.
- 4 sets of drawings:

Blockplan	scale 1:2500 (better 1:1000)
Siteplan	scale 1: 500
All floor plans	scale 1: 100
Sections	scale 1: 100
Elevations	scale 1: 100
R.C. Details	scale 1: 20 - 1: 5

- Schedule of doors, windows, opening arrangements.
- Details of the Drainage system including septic tank and soakage, pit, inspection chambers, gully traps, vent. pipes, etc.

b) Before submitting the Application to the Urban Planning Committe, forms and plans will be checked by:

- the Land Officier
- the Health Officier
- the Town Engineer
- the Town Planning Officier
- the Fire Master

In case the application does not comply with the technical requirements of the Authority the Application may be disapproved and send backs for amendments resubmission to the applicant. After the technical approval, the application will be submitted to the Urban Planning Committee. The Committee approves or disapproves the application and issues the Building Permit.

c) The Building Permit will be sent to the applicant together with one set of plans (with stamp and signature of the Authority) and one set of proceed sheets.

Form of Application for Permission to Erect a Building

FOR OFFICE USE ONLY
Plan submitted ....
Registered No. of Plan ....
Date of Registration ....

To, TOWN DIRECTOR
ARUSHA TOWN COUNCIL
P. O. Box 3013, Arusha

.... 19 ..

I beg to submit herewith Plans, Sections and Elevations for ....

....
(State here if New Building, Alteration or Addition or Sanitary Reconstruction)

....

to be used as ....
(Insert whether a Domestic Building or for what purpose the building will be used)

to be executed by me on Plot No. ....

such plot having frontage to ....

I also submit the following proposed means of construction and other particulars:

External walls to be built of ....

Internal walls to be built of ....

Mortar in walls to be composed of ....

Dampcourse to be of ....

Foundations to be of .... Mortar in foundation composed of ....

Roof to be constructed of ....

Water supply from ....

Drainage to sewer/permeable cesspit/impermeable septic/tank (erase words which do not apply). In the of septic tanks state how the effluent will be disposed of ....

Material of drain pipes ....

Closet accommodation — (state type)

Indoor ....

....

Outdoor ....

Name of Architect or Draughtsman ....

Address of above ....

Name of Builder (if known) ....

Signature of Owner or Agent ....

Address of Owner or Agent ....

SUBMISSION OF PLANS

All Plans to be submitted to the ....

One set of Plans to be made on cloth (paper on cloth is not accepted)

All Drawings to be signed by owner or his agent.

All Drawings to be accompanied by application form duly completed as required by the ....

....

All Drawings to be submitted in duplicate and to be of a quality approved by the ....

....

DRAWINGS REQUIRED

Scale 1:100 — Plans of each floor or level; having thickness of wall shown in figures. Section through Building (more than one if building is large or if required by Authority).

Scale 1:50 — Sections are required of Floors and Roofs, Verandas, and Balconies, Stairs, iron or steel Beams, Pillar and Principal Timbers, Pavements, Openings, etc., on public Streets

Colours — The above drawings are to be coloured thus:

Brick, stone or concrete	Red
Fire-proofing, damp-proofing or impervious floors of stables, closets, etc.	Thick black line
Work to be removed	Dotted line
Steel or iron	Blue lines, in skeleton
Work existing	Natural Colour

Scale 1:500 — Block plan as follows:

To show plot on which buildings are to be erected.

To show plots immediately adjoining and names of the proprietors thereof.

To show buildings, existing or proposed. on all these plots.

To show numbers of plots, names of streets, and township.

To indicate of what materials existing buildings are composed, i.e. bricks wood and iron, or stone, etc.

To show lines of drainage, giving size and fall of drains.

To show level and width of the steet or streets upon which the proposed buildings will abut with reference to their ground-floor level.

This form MUST be submitted in its proper sequence prior to any **rther work proceeding.**

o. 1885

.... Date..............................

....

Plot No. Block No. Area

I hereby give notice that the work of construction has now roceeded to wall plate level.

lan No. **Refers**

Signed..............................

WO DAYS NOTICE REQUIRED

F

This form MUST be submitted in its proper sequence prior to any **rther work proceeding.**

o. 1885

.... Date..............................

....

Plot No. Block No. Area

I hereby give notice that all the roofing timbers in the building re in position and are ready for examination.

lan No. **Refers**

Signed..............................

WO DAYS NOTICE REQUIRED

G

This form MUST be submitted in its proper sequence prior to any further work proceeding.

No 1885

.... Date..............................

....

Plot No. Block No. Area

I hereby give notice that the drainage and sanitary work are ready for testing.

Plan No. **Refers**

Signed..............................

TWO DAYS NOTICE REQUIRED

H

This form MUST be submitted in its proper sequence prior to any further work proceeding.

No. 1885

.... Date..............................

....

Plot No. Block No. Area

I hereby give notice that the whole of the work has been completed and I hereby apply for a certificate of occupation in respect of the premises.

Plan No. **Refers**

Signed..............................

SEVEN DAYS NOTICE REQUIRED

A

This form MUST be submitted in its proper sequence prior to any further work proceeding.

No. 1885

.... Date..............................

....

Plot No. Block No. Area

I hereby give notice that I intend commence the work approved in

Plan No. ....on..............................197......

Signed..............................

TWO DAYS NOTICE REQUIRED

B

This form MUST be submitted in its proper sequence prior to any further work proceeding.

No. 1885

.... Date..............................

....

Plot No. Block No. Area

I hereby give notice that the foundation trenches are now ready for inspection.

Plan No. **Refers**

Signed..............................

TWO DAYS NOTICE REQUIRED

C

This form MUST be submitted in its proper sequence prior to any further work proceeding.

No. 1885

.... Date..............................

....

Plot No. Block No. Area

I hereby give notice that the foundation concrete in now ready for inspection.

Plan No. **Refers**

Signed..............................

TWO DAYS NOTICE REQUIRED

D

This form MUST be submitted in its proper sequence prior to any further work proceeding.

No. 1885

.... Date..............................

....

Plot No. Block No. Area

I hereby give notice that the ground floor concrete and damp proof course are ready for inspection.

Plan No. **Refers**

Signed..............................

TWO DAYS NOTICE REQUIRED

4. CONTRACT PLANNING and SITE ORGANISATION

4. CONTRACT PLANNING AND SITE ORGANIZATION

Buildings, and consequently their construction, have become more and more complex and the proper management of a contract as well as the control of cost (on the part of the architect at design stage and the contracter during erection) are more than essential.

Because mechanisation of building operations and the use of expensive plant has increased, the contractor must obtain maximum use of the plant and speed the construction of the job in order to keep his costs to a minimum. The design/erection continuum must be seen as a production process from inception to completion and there must be a programme on which the job may be organized, against which performance may be assessed and within which control may be exercised.

Contract planning and site organization, together with general control are the construction aspects of production management which itself is a part of overall management in building.

PLANNING makes efficient and economical use of labour, machines and materials.

ORGANIZATION is the means of delegating tasks

CONTROL enables planning and organization to be effective.

4.1 CONTRACT PLANNING

4.1 CONTRACT PLANNING

Contract Planning involves working out a PLAN OF COMPAIGN or PROGRAMME for the contract as a whole and assembling the necessary data.

Such a programme is to promote the flow of the various building operarions during the course of erection, by planning in advance
- the times and sequences of all operations
- the requirements in labour
- the requirements in materials
- the requirements in equipment.

The BUILDING RESEARCH STATION DIGEST 91 states that such a programme should:

a) show the quickest and cheapest method of carrying out the work consistent with the available recources of the builder.
b) by the proper phasing of operations with balanced labour gangs in all trades, ensure continous productive work for all the operatives employed and reduce unproductive time to a minimum.

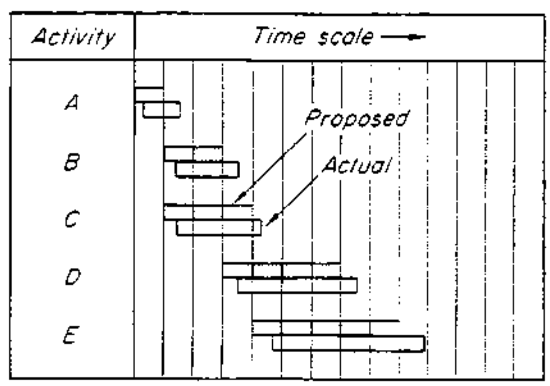
c) provide an assessment of the level of productivityin all trades
d) determine attandance dates, and periods for all subcontractor^s work
e) provide information on material quantities and essential delivery dates, the quantity and capacity of the plant required and the periods it will be on site.
f) provide, at any time during the contract, a simple and rapid method of measuring progress for the builders information for the architect´s periodical, for the valuation of work for accounting purposes.

If a builders tender is to be realistic, planning must start at the estimating stage.
The following considerations should be taken into account:
- use of the most economic methods for each operation
- sequence and timing of the operations
- resources at the contractors disposal
- use of hand or mechanical methods, type of plant
- space available and best positions for the various machines to be used.
- the best methods of handling material and most suitable places on the site for the storage of materials and for the placing of hut
- suitable points of access to the site for lorries and machines.

4.1.1 BAR CHART

4.1.1 BAR CHART

A typical site orientated control device is the GANTT CHART or BAR CHART which allows a fairly simple and easily read plan of perations to be made available to all site personnel against which may be plotted actual performances. However, this device only takes into account one of the resources - TIME - and unless further schedules of the recources needed for each operation are also available (adjacent ot the BAR CHART) it does not inform on the critical relationships between the various activities nor does it enable procedures involving a number of variables to be optimised since the complex interrelationships affecting the outcome of any plan (or alteration of plan) are not readily evident or quantifiale. (see fig.)
This can be achieved by means of a technique known as NETWORK ANALYSIS.



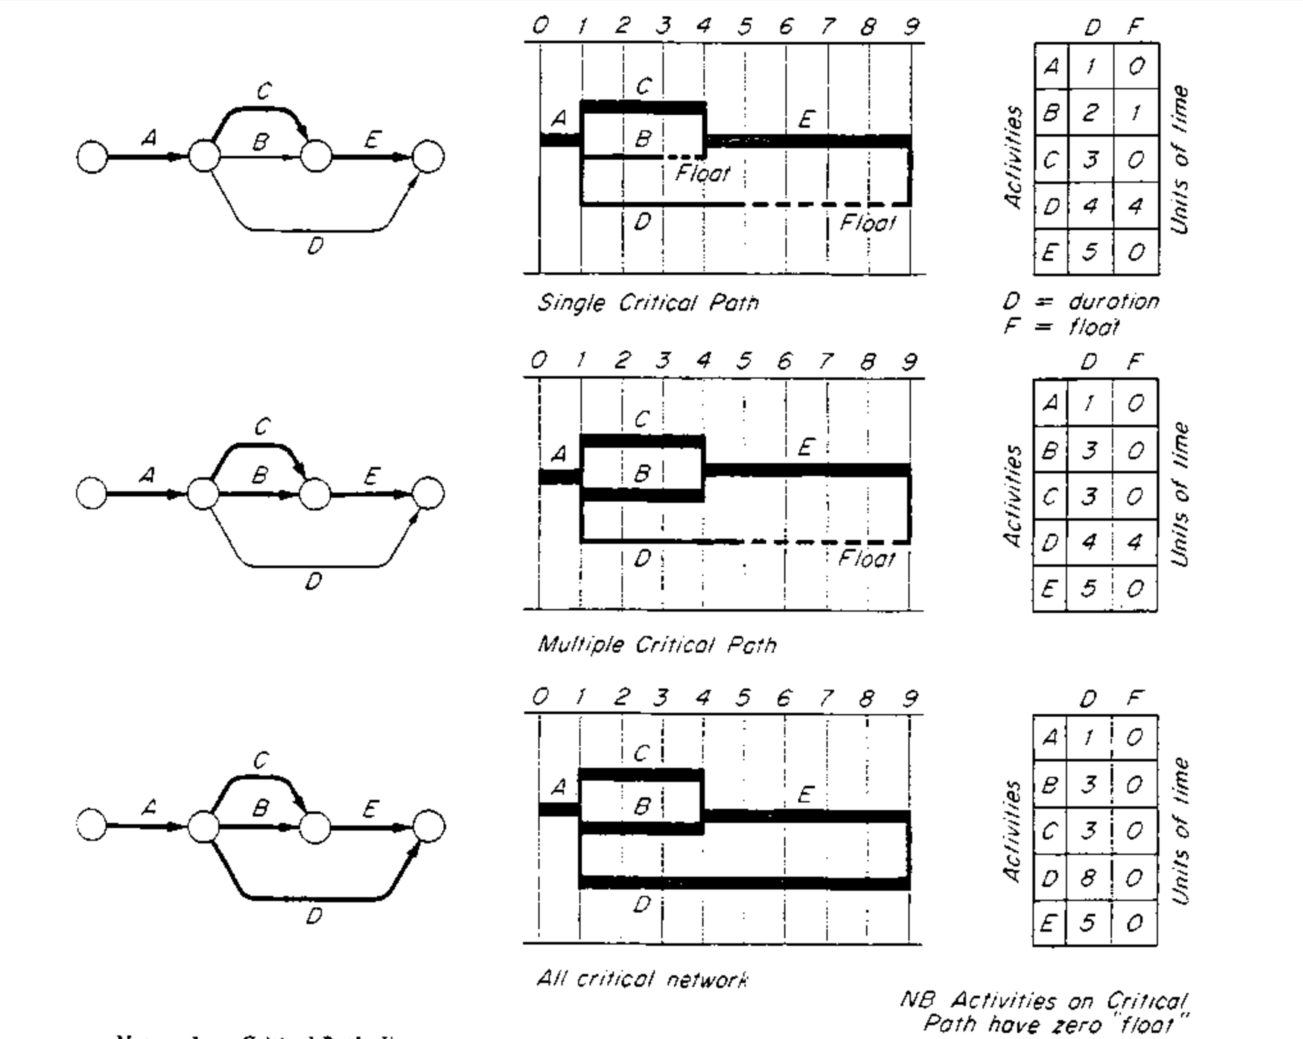
4.1.2 NETWORK ANALYSIS

4.1.2 NETWORK ANALYSIS

The essential difference between analysing a production problem by NETWORK and LINEAR or PARALLEL LINEAR methods lies in the identification of the dependency between operation.

This approach leads to interelated networks through which certain sequences can be seen to be 'critical' to the anticipated outcome in that they occupy the longes and irreducible time necessary to execute the project (or parts of the project). to which they are necessary.

The fig. shows this in a simple set of 5 intorelated activities A,B,C, D,E of time values 1,2,3,4 and 5 days.



Network or Critical Path diagrams

ARROW DIAGRAM

The way how to prepare a NETWORK in the form of an ARROW DIAGRAM is described in the following:

1) Project to be broken down into a series of stages (or elements of work) called
ACTIVITIES
represented by ARROWS (Length not important)
Head of arrow = finish of activity

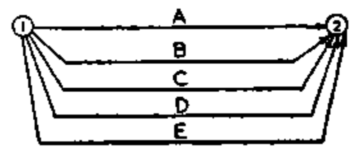
2) Any junctions of activities are called
EVENTS
represented by CIRCLES.
An event indicates the completion of one activity and the start of the next (except first and last!)

3) Example: 5 operations carried out continuously:

4) Each activity may be identified by the numbers of the beginning and end as follows:

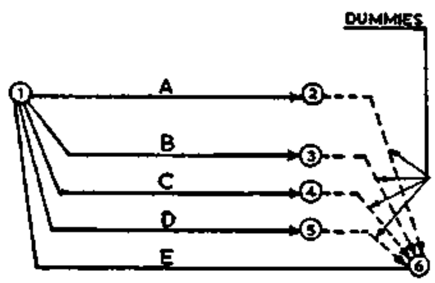
Activity	*Identity*
A	1–2
B	2–3
C	3–4
D	4–5
E	5–6

5) If these 5 operations had been started and finished at the same time, it is not convenient to show them as follows:



because each has the same identity.

Therefore, to give each a seperate identity, DUMMY ACTIVITIES must be introduced (dotted lines)



ACTIVITY	INDENTITY
A	1 - 2
B	1 - 3
C	1 - 4
D	1 - 5
E	1 - 6
DUMMY	2 - 6
DUMMY	3 - 6
DUMMY	4 - 6
DUMMY	5 - 6

A dummy arrow has no duration and shows only the logical relationship which cannot be shown by activity arrows (no time, no recources, they have only transfer information from one event to another)
Arrows should always be identified by ascending order of numbers (lower number: the tail, higher number : the head).

6) Which questions should be asked, when setting out an arrow diagram for a project?

a) what controls the start of each activity?
b) what controls its finish or end?
c) what job or jobs must be done before the next activity can be started?
d) what jobs must follow the activity?
e) what jobs can run concurrently?

7) Examples (should be thoroughly understood)	EXAMPLES
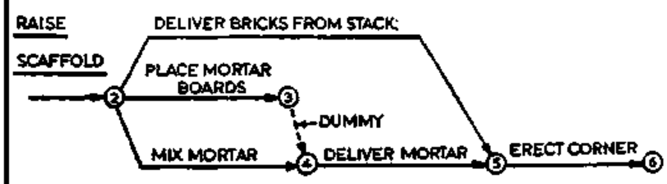
1 Activity X depends upon activity	2 Activity X and Y depend upon activities A and B	3 Activity X depends upon activities A and B and activity Y depends upon B only	4 Activity Y depends upon activities A and B and activity X depends upon A only	5 Activity X depends upon A and B and activity Y depends upon B and C	6 Activity X depends upon activities A and B, activity Z depends upon activities B and C and activity Y depends upon B only	7 Activity Z depends upon activities A,B,C, activity X upon A only and activity Y upon A and B	8 Activity Y depends upon activities A,B,C, activity X depends upon A only and activity Z depends upon activity C only	9 Activity X depends upon activity A, activity Y depends upon activities A and B and activity Z depends upon activities B and C	
8) Example: Errecting a corner

Activities:
1 raise scaffold
2 deliver bricks from stack to scaffold
3 place mortar boards
4 mix mortar
5 deliver mortar to scaffold
6 build corner

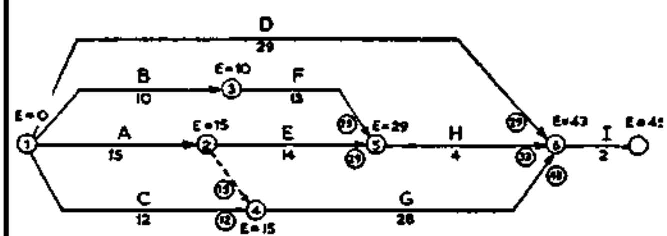


9) The time element
We have so far been concerned only with the placing of the activities in a logical order.

Now the time element has to be considered, and to be applied to the network, in order to obtain the EVENT IMES and the TOTAL PROJECT TIME.
- The duration of the activities should be written under each arrow.
  these items must be very carefully estimated (according to the work content contained within each activity) otherwise the network would not be of any value.

TIME ELEMENT

10) Earliest starting times
When the durations of the activities have been entered, the times of starting and finishing the events can be calculated. The earliest times for starting and finishing activities can be found by adding the duration of each activity to the finishing time of the previous activity. Begin at 0 with the first activity and calculate each path separately. Where two ore more paths meet at an event or node, the longer or longest total time must be taken as the earliest starting time to the next activity.



E = Earliest starting time

	ACTIVITY	DURATION	EARLIEST START	EARLIEST FINISH
A	1–2	15 days	0	15
B	1–3	10 days	0	10
C	1–4	12 days	0	12
D	1–6	29 days	0	29
	2–4	dummy	15	15
E	2–5	14 days	15	29
F	3–5	13 days	10	23
G	4–6	28 days	15	43
H	5–6	4 days	29	33
I	6–7	2 days	43	45

11) Latest starting times
This is a similar analysis carried out only in a reverse direction, which means beginning at the last event time and working backwards by deducting the activity time from the end event time. Where two or more paths meet at an event, the shorter or shortest time is adopted for the calculation of the latest starting time. The total times for each path have been indicated by the figures in circles, and it will be seen that the highest figures have been taken in each case.

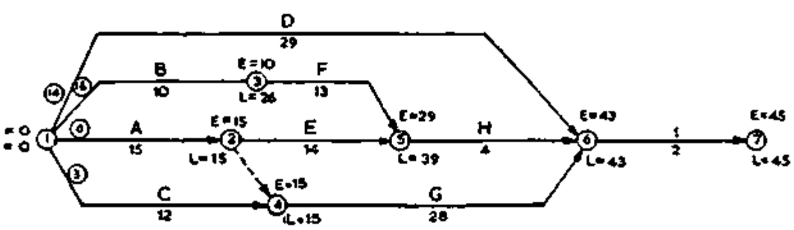
12) Latest finishing times
The times for each path have been shown in circles as before, but this time the lowest figure have been used in each case.
It is most important that the dummy activity is taken into account when calculating the earliest starting and latest finishing times. These times could have been analysed as before, but in this case the calculating is started at the bottom of the table and the durations are deducted from the latest finishing times.

			LATEST	
	ACTIVITY	DURATION	START	FINISH
A	1–2	15 days	0	15
B	1–3	10 days	16	26
C	1–4	12 days	3	15
D	1–6	29 days	14	43
	2–4	dummy	15	15
E	2–5	14 days	25	39
F	3–5	13 days	26	39
G	4–6	28 days	15	43
H	5–6	4 days	39	43
I	6–7	2 days	43	45

start here

The two tables can now be combined as follows

			EARLIEST		LATEST	
ACTIVITY		DURATION	START	FINISH	START	FINISH
A	1–2	15 days	0	15	0	15
B	1–3	10 days	0	10	16	26
C	1–4	12 days	0	12	3	15
D	1–6	29 days	0	29	14	43
	2–4	dummy	15	15	15	15
E	2–5	14 days	15	29	25	39
F	3–5	13 days	10	23	26	39
G	4–6	28 days	15	43	15	43
H	5–6	4 days	29	33	39	43
I	6–7	2 days	43	45	43	45



L = Latest finishing times

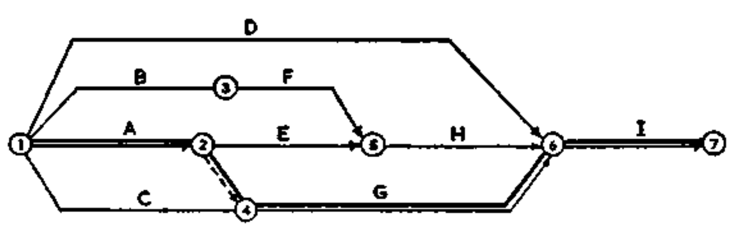
13) Floating times
From the diagrams and the analyses it will be seen that, if the earliest starting times are deducted from the latest finishing times, some activities have a greater length of time available for carrying out the activity then the work content requires. The spare time in each case is called the total float.
The total float for each activity is calculated as follows:
Latest finishing time - earliest starting time - duration of the activity.

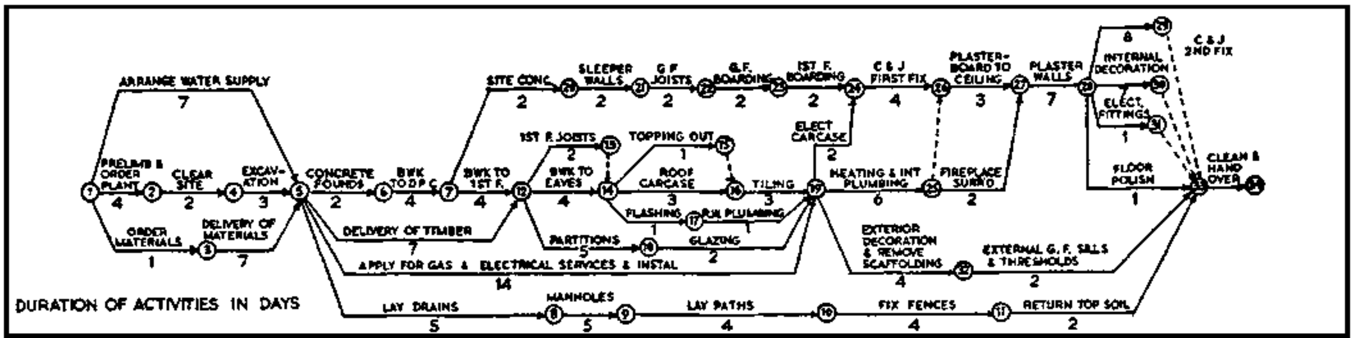
14) Critical path
Where there is a zero float against an activity, this activity will be a critical item. This means that such an item must not be delayed otherwise it will delay the whole project. These activities will form a continous chain through the network, and this chain is called CRITICAL PATH in a network.

The critical path includes the dummy activity. All of the other activities have longer times than the durations need.

Besides TIME (as the main planner´s parameter) other factors such as COST, LABOUR and MATERIAL AVAILABILITY, the DEMAND of other Projects under the planner´s control will affect the final assesment of times to be ascribed to the constituent activities of network.

ACTIVITY		DURATION	EARLIEST START	EARLIEST FINISH	LATEST START	LATEST FINISH	TOTAL FLOAT
A	1–2	15 days	0	15	0	15	0
B	1–3	10 days	0	10	16	26	16
C	1–4	12 days	0	12	3	15	3
D	1–6	29 days	0	29	14	43	14
	2–4	dummy	15	15	15	15	0
E	2–5	14 days	15	29	25	39	10
F	3–5	13 days	10	23	26	39	16
G	4–6	28 days	15	43	15	43	0
H	5–6	4 days	29	33	39	43	10
I	6–7	2 days	43	45	43	45	0





ACTIVITY	NO.	DURATION	EARLIEST START	EARLIEST FINISH	LATEST START	LATEST FINISH	TOTAL FLOAT
Prelims and order plant	1–2	4 days	0	4	0	4	0*

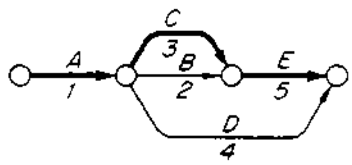
Clean and hand over	33–34	2 days	53	55	53	55	0*

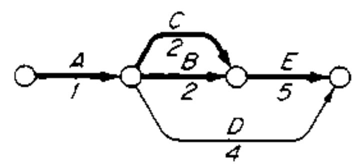
15) Time/cost optimisation
This technique explores the possibilities of altering production time in order to optimise the costs.
In building work:
increased speed of production leads to increased cost (due to having to use more operatives, and /or machinery, or to pay high rates).

Any reduction of the activity times on the critical path will reduce the overall production time, but will probably reduce the 'float' on other activities to the point that they also become critical (case 1) Activities A,B,C,D,E are given to be carried out in 'normal' times shown in column X. Activities A,C, and E are capable of being carried out by different means at 'crash' times for increased rates shown in column Y. It is then possible to define three basic outcomes from the application of these figures:
- normal cost programme (case 1)
- all 'crash'programme (case 5)
- best time/least cost programme (case 4)

Case 1



9 days



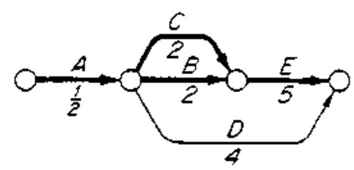
8 days

Case 2

Cost data X Y

Activity	Dur'n	Cost	Dur'n	Cost	
A	1	120	½	200	CC
B	2	80	2	80	
C	3	100	2	150	CC
D	4	60	4	60	
E	5	200	3	300	CC

CC = crash costs



7½ days

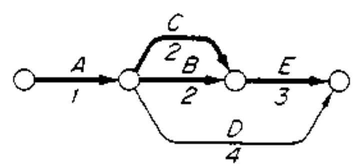
Case 3

I.C = rate of Indirect Costs – 70 00 per day

Activity	Duration (days)				
	9	8	7½	6	5½
A	120	120	200	120	200
B	80	80	80	80	80
C	100	150	150	150	150
D	60	60	60	60	60
E	200	200	200	300	300
I.C	630	560	525	420	385
Totals	1190	1170	1215	1130	1175

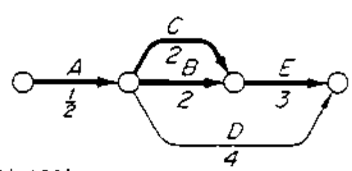
Summary of cases 1 – 5 — Best time for least cost

Time-cost optimisation



6 days

Case 4



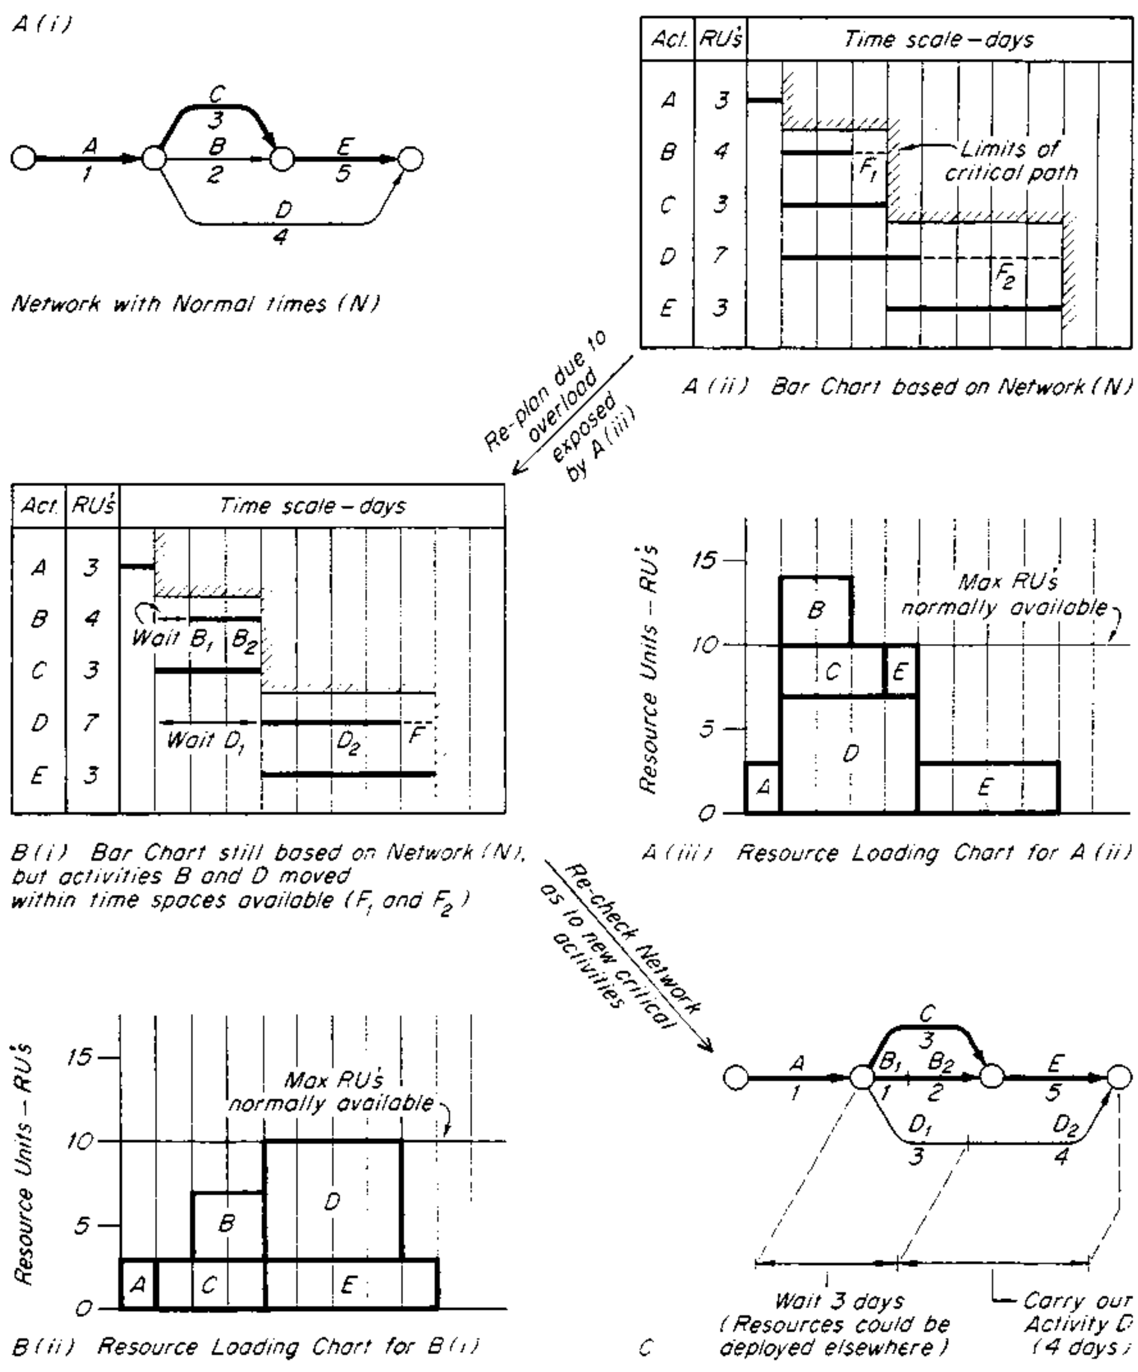
5½ days

Case 5

16) Resource levelling and control

This technique enables a planner to assess the requirements of varous resources to serve any given network of activities and to utilise 'float' in uncritical activities to optimise his use of resources or to reduce imbalances of resource demand.

- The technique ascribes the various resources to each activity and by comparison with established norms identifies excessive demands.
- It is possible to reposition activities requiring excessive use of resources and to balance the total requirements within the resources available or at least to reduce the time of excessive demand.
- The repositioning of certain activities will often render them critical when they are taken together with fixed waiting periods necessary to the planned use of resources.



Network with Normal times (N)

A (ii) Bar Chart based on Network (N)

B (i) Bar Chart still based on Network (N), but activities B and D moved within time spaces available (F_1 and F_2)

A (iii) Resource Loading Chart for A (ii)

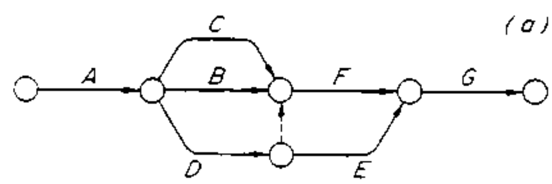
B (ii) Resource Loading Chart for B (i)

C

This technique is illustrated in fig.
The network A (i) yields the scaled network in bar chart form A(ii)
By allocating the resource units - RU's - for each activity, a resource loading diagram (A(iii) can be prepared.
In this case it shows an excetive demand of four RU's above the resource units normally available during the second and third days, due to activities B and D coming together.
B (i) shows the repositioning of activities B and D in the excess times available for their execution and a resulting 'levelling' of the loading diagram to bring the requirements for resources within the limits of normal availibility as in B (ii).
This manoeuvre involves specific positioning of waiting periods B_1 and D_1 and examination of the resulting network at C shows that these constrains on the commencement of activities B_2 and D_2 leads to the former becoming critical and reduces the float of the latter to one day only.

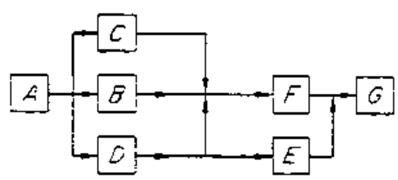
The foregoing brief description of some of the uses of network analysis has been based on a simplified description of the network involved. For further informations one of the many books dealing specially with these techniques should be consulted.

The most useful aspect of network analysis lies in exercising the logic used to set up the basic network of activities since the planner has a full knowledge of the practical consequences of any sequence of activities and the importance of their relationships. This aspect of a network approach to planning is illustrated in the method of presentation of the logic known as a Precedence Diagram. The fig. shows a typical network restated in this form which eliminates the need for dummy activities normally used in conventional networks to indicate dependency.



(a)

Dependencies:
C, B and D depend on A being completed
F depends on B, C and D being completed
E depends on D being completed
G depends on F and E being completed



Precedence diagram (b)

4.1.3 The OVERALL PROGRAMME

On acceptance of the tender a WORKING or OVERALL PROGRAMME is prepared by the contractor's planning staff together with the plant engineers and the site agent or foreman for the job. This will be used as a guide for:
- site activities
- detailed planning
- purchasing and delivering of materials
- coordination of sub-contractors and main contractors work
- assessing job progress

At this point it is essential to have full information from the architect in the form of
- site survey
- a full set of wirking drawings
- specifications
- bills of quantities and
- a full list of all nominated subcontractors.

The preparation of the overall programme consists broadly of
- breaking the job down into a series of basic operations involving only one trade.
- establishing the quantities of work in each operation and the time content of each in terms of men and machines.
- arranging the operations in a sequence and balancing the size of gangs to give a maximum continuity of work for each trade
- breaking down a large job into phases so that several operations may proceed simultaneously.

The programme is usually expressed in the form of a chart, covering
- all main operations throughout the contract
- the phasing of the work
- the duration of each operation

Together with this chart a written report or schedule has to be prepared including
- the methos to be used
- a schedule of plants
- the labour requirements
- informations regarding site offices, storage huts, equipment, and small tolls.

Besides the overall programme, showing the major operations and phasing of a job, a detailed short - term planning at regular intervals on the site is necessary:
1) a reasonably detailed programme is prepared at mothly intervals, to cover four weeks ahead,
2) a detailed programme is prepared each week. This indicates in detail the materials/labour requirement/ and operational methods to be used.

4.1.3.1 Break down of job

Smaller jobs are commonly divided into the following stages:
1) foundations and walling up to DPC
2) carcase to completion of roofing in
3) finishes and all services
4) drains and site works

In large jobs and multi - storey work the break - down stages can be.
1) sub-structure, or foundation work
2) frame, or basic structure
3) cladding, infilling, weather - proofing etc.
4) drains and site works.

Each stage is planned separately rist.
Compenstion for any variations from the programme arising within the stages can be made by increasing the gang sizes to speed up certain operations or, at times when productivity is greater than that assumed at the planning stage, labour can be put on to isolated jobs which can be carried out at any time without interfering with the sequence of other operations.

4.1.3.2 Quantities of work and time content.

In order to relate the various operations throughout the job a schedule of basic quantities has to be worked out from which the number of MAN HOURS and MACHINE HOURS required to complete the job can be obtained. (so-called LABOUR and PLANT standards.)
These standards in each case are established on the basis of information fed back from
- previous contracts or
- work studies, having regard to the type of labour which will be available and the likely demand on plant.

The work content for each operation is inserted on a schedule of basic operations which can be in the form of a series of DATA SHEETS.
These sheets form a detailed analysis of the complete work and give informations to all planning activities during the course of the contract.

4.1.3.3 Plant and Labour outputs
As soon as the probable availability of resources has been estimated, the outputs of men and machines must be evaluated, so that the times for elements of work can be determined These LABOUR CONSTANTS must be realistic and allowances must be made for rests, bad weather, tea breaks and other interferences with normal output.

An element of work on site is 1,ooom^2 of 1-brick internal walling. If the firm's estimated labour constant for this work is 1.50 men/h/m^2 then the number of men/h required for this work will be:

1,ooom^2 x 1.50 men/h/m^2
= 1,5oo men /h

If 10 bricklayers are available in a gang, the time to be taken will be

$$\frac{1{,}500 \text{ men/h}}{10 \text{ men}}$$
= 150 h

If an 8 hour day is worked on site, this element will take 18 3/4 days to complete.

The following examples are typical of reasonable standard times for various operations, but these should be carefully checked and verified, and, if necessary, adjusted to suit any special conditions before aplying them to actual work on site.

MACHINE EXCAVATION

Machine excavation	cbm/h
Surface excavation not exceeding 300 mm deep $0.375\ m^3$ bucket	11
Surface excavation not exceeding 300 mm deep 0.625 m2 bucket	21
Surface excavation not exceeding 300 mm deep 0.375 m3 bucket	12
Surface excavation not exceeding 300 mm deep 0.625 m3 bucket	24
Excavate foundation trenches not exceeding 1.5 m deep 0.375 m3 bucket	6
Excavate foundation trenches not exceeding 1.5 m deep 0. 625 m3 bucket	12
Excavate basements not exceeding 1.5 m deep 0.375 m3 bucket	9
Excavate basements not exceeding 1.5m deep 0.625 m3 bucket	18
Excavate basements exceeding 1.5 m and not exceeding 3 m 0.375 m3 bucket	7 1/2
Excavate basements exceeding 1.5 m and not exceeding 3 m 0.625 m3 bucket	15
Add for each additional 1.5 m depth	1.25
Excavate spoil from heap and load into barrow	0.5
Wheel 20 m	0.25
Load excavated material into lorries	0.6
Spread and level in layers not exceeding 300 mm thick	0.3
Return fill and ram	0.85
Level and ram bottoms	0.06/m2
Planking and strutting	Hours per square metre
excavations not exceeding 1.5 m deep:	
poling boards and struts	0.075
open boarding	0.2
close boarding	0.4
excavations exceeding 1.5 m and not exceeding 3 m deep:	
open boarding	0.3
close boarding	0.8

HARDCORE FILLING

Hardcore filling	h/cbm
Filling in making up levels	0.5
Concolidated in 150 mm layers	1.0

HAND EXCAVATION

Hand excavation	h/cbm
Surface excavation not exceeding 1.5 m deep	2.0
Add for each additional 1.5 m of depth	0.75
Excavate trenches not exceeding 1.5 m deep	2.5
Add for each additional 1.5 m of depth	1.0
Excavate pits not exceeding 1.5 m deep	3.0

CONCRETE WORK

Concrete work	h/cbm
Mixing	
By hand for small quantities	4 to 6

By machine allow 4 to 5 minutes per batch according to type of mixer

TRANSPORTING

Transporting	h/cbm
By hand in barrows and wheel not exceeding 18 m or raise not exceeding 3 m	1.5
By machine plant and labour to suit required output and placing conditions	

PLACING & COMPACTION

Placing and compaction	h/cbm
Foundations in trenches over 300 mm thick	0.5
Foundations in trenches not exceeding 300 mm thick	0.7
Isolated pier holes	1.0
Beds over 300 mm thick	0.75
Beds over 150 mm thick not exceeding 300 mm thick	1.0
Beds not exceeding 150 mm thick	1.25
Add to the above for working around reinforcement	1.0

SURFACE TREATMENT

Surface treatment	h/square metre
Grading to falls	0.3
Tamping	0.2
Trowelling	0.25

BRICKWORK

Brickwork
(The following outputs are based on the ratio of 2 bricklayers to 1 labourer).

	Men/h per unit
General brickwork in plasticised or gauged mortar 60 bricks	1.0
General brickwork in cement mortar 60 bricks	1.1
General brickwork overhand in gauged mortar 60 bricks	1.1
Walling curved on plan ex 15 m n.e. 22 m rad 60 bricks	1.5
Walling curved on plan ex 7.5 m n.e. 15 m rad 60 bricks	1.66
Walling curved on plan ex 4.5 m n.e. 7.5 m rad 60 bricks	1.75
Walling curved on plan exceeding 3 m rad	
Underpinning 60 bricks	2.00
Rough arches 60 bricks	3.0
Form cavity inc. laying wall ties, and keeping cavity clean per m2	0.25
Rough cutting per m2	0.7
Close cavity per m	0.3
Cut chase for small pipe per m	0.6
Eaves filling per m	0.3
Engineering bricksper 60	1.50

FACE BRICKWORK

Face brickwork	men/h per unit
General facing bricks per m2	1.25
Fair faced walling / m2	1.10
Rake out joints and point on completion per m2	0.75
Fair straight cutting per lin.m.	0.3
Fair raking cutting per lin.m	0.4
Fair curved cutting per lin.m	0.5

ARCHES

Arches	men/h per unit
Soldier arches or brick lintels per m2	3.6
Fair axed arches per m2	5.5
Rubbed and gauged per m2	12.25

COPINGS & SILLS

Copings and sills	men/h per unit
Brick on edge coping including pointing per lin.m	0.4
Two courses of tile creasing per lin. m.	0.6
Brick on edge per lin. m.	0.75

PARTITIONS

Partitions	men/h
Clinker, concrete and hollow clay 50 mm thick per m2	0.5
Clinker, concrete and hollow clay 75 mm thick per m2	0.6
Clinker, concrete and hollow clay 100 mm thick per m2	0.7
Lightweight blocks 50 mm thick per m2	0.4
Lightweight blocks 75 mm thick per m2	0.5
Lightweight blocks 100mm thick per m2	0.6
Bonding to brickwork per lin. m	0.2
Rough cutting at irregular angles and soffits per lin. m.	0.15

	men/h
Air bricks each	0.2
Flue linings per lin. m.	0.6
Set chimney pot and flaunch each	1.0

D.P.C.

Damp-proof courses	men/h
Two courses of slates horizontal per m2	0.9
Two courses of slates vertical per m2	1.35
Bituminous felt per m2	0.3

SUNDRIES

Sundries	men/h
Bed plates and sills per lin. m.	0.1
Bed frame and point one side per lin. m.	0.25
Bed frame and point two sides per lin m	0.35
Rake out joints and point flashings per lin. m.	0.3
Cut groove for asphalt skirting and point per lin.m	0.45
Fix metal windows inclu-ding cut and pin lugs to brickwork not exceeding 0.4 m2 each	0.5
Fix metal windows inclu-ding cut and pin lugs to brickwork not exceeding 0.8 m2 each	0.75
Fix metal windows inclu-ding cut and pin lugs to brickwork not exceeding 1.6 m2 each	1.0
Add for pointing one side per lin. m.	0.08

SCAFFOLDING

Scaffolding	men/h per 100 m2 erect and dismantle
Putlog scaffold up to 6 m high	25
Putlog scaffold 6 to 9 m high	30
Putlog scaffold 9 to 18 m high	35
Putlog scaffold over 18 m high	40

Independent scaffolds add 25 per cent to the above

Drainage	men/h		
Stoneware drain pipes	100 mm	150 mm	225 mm
Lay and joint 600 mm pipes per lin. m.	0.45	0.6	0.75
Lay and joint 900 mm pipes per lin. m.	0.35	0.45	0.6
Extra for bends each	0.1	0.12	0.15
Extra for junctions each	0.2	0.25	0.3
Gulleys each	0.5	0.66	-
Interceptors each	0.66	0.75	-

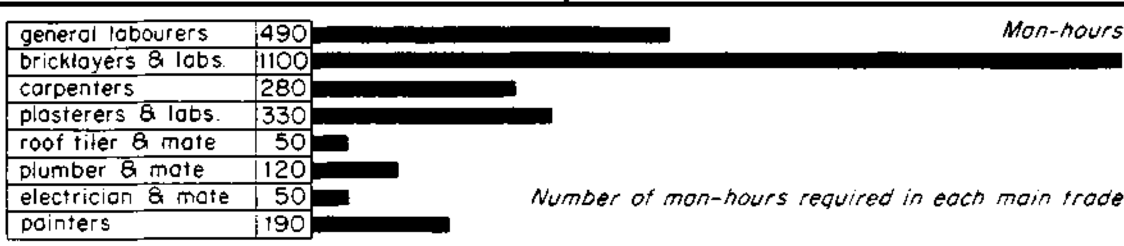
Concrete drain pipes	225mm	300 mm	375 mm	450 mm
Lay and joint per lin.m.	0.8	0.9	1.1	1.25
Extra for bends each	0.2	0.25	0.3	0.35

Manholes	100 mm	150 mm	225 mm
Channels each	0.2	0.3	0.4
Three-quarter section channels each	0.3	0.5	0.7
Covers and frames bedding and fixing each	0.75		
Step irons each	0.1		

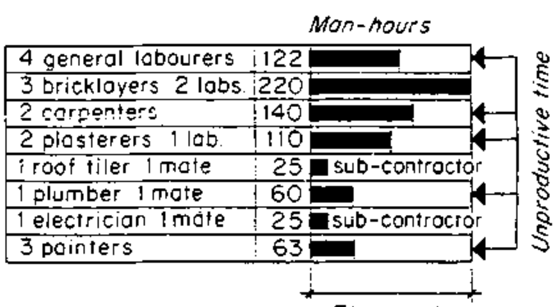
4.1.3.4 Sequence and timing of operations

In each stage into which a job may be divided, there will be one operation or a group of related operations governing the production time of the complete stage. This KEY OPERATION takes the longest time, when the time cycles of all the operations are based on the use of the optimum size of gang for each.

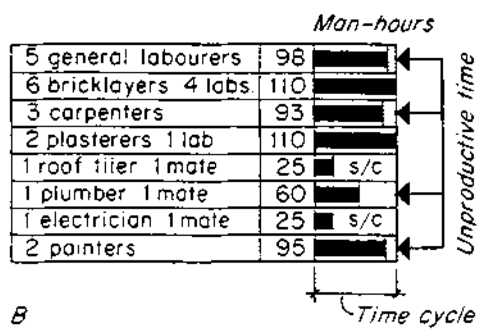
The largest of the key operations in each stage is termed the MASTER OPERATION. The speed of the master operation is governed by:
- the time, in which the work has to be completed
- the size of the gang or
- the amount of labour available(in which case the size of the gang which can be put on it will fix the time required to complete the operation)



Number of man-hours required in each main trade



A



B

It is necessary to bring all other operations into phase with the master operation, in order to ensure continuity of productive work for each trade or gang and to minimize unproductive time.

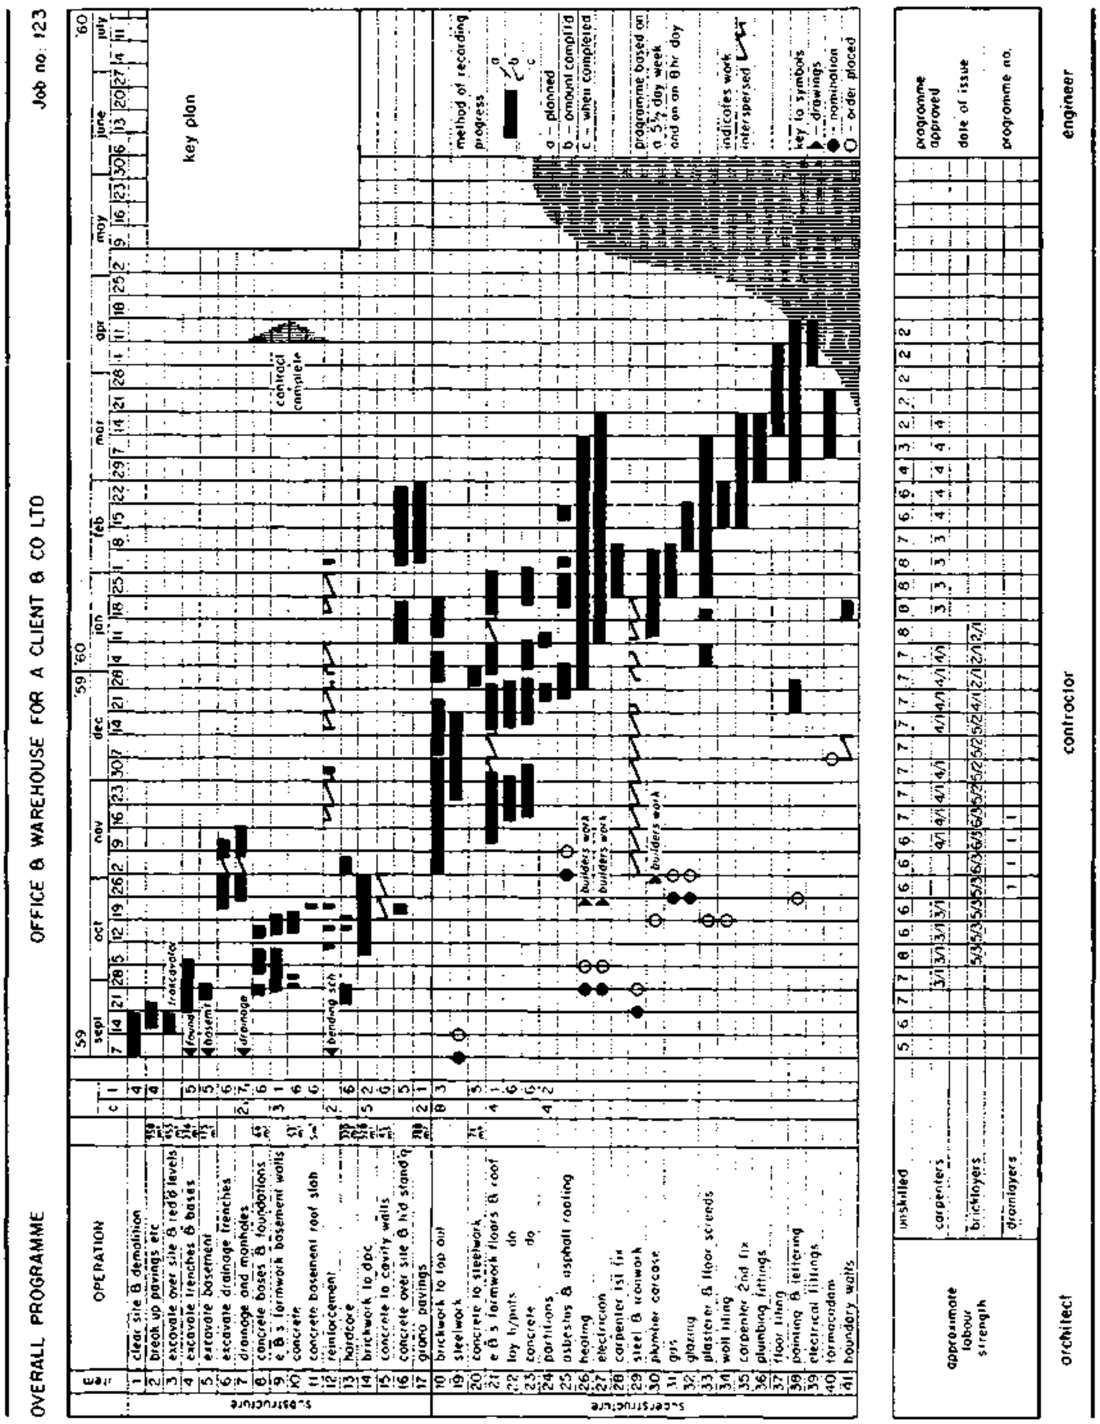
The time cycles of the operations in each stage are brought into phase by adjusting the size of the gangs, so that the working time of each gang is (as far as possible) the same as that of the key operation. Figure illustrates the effect of the balancing of trade gangs.

4.1.3.5 The programme chart

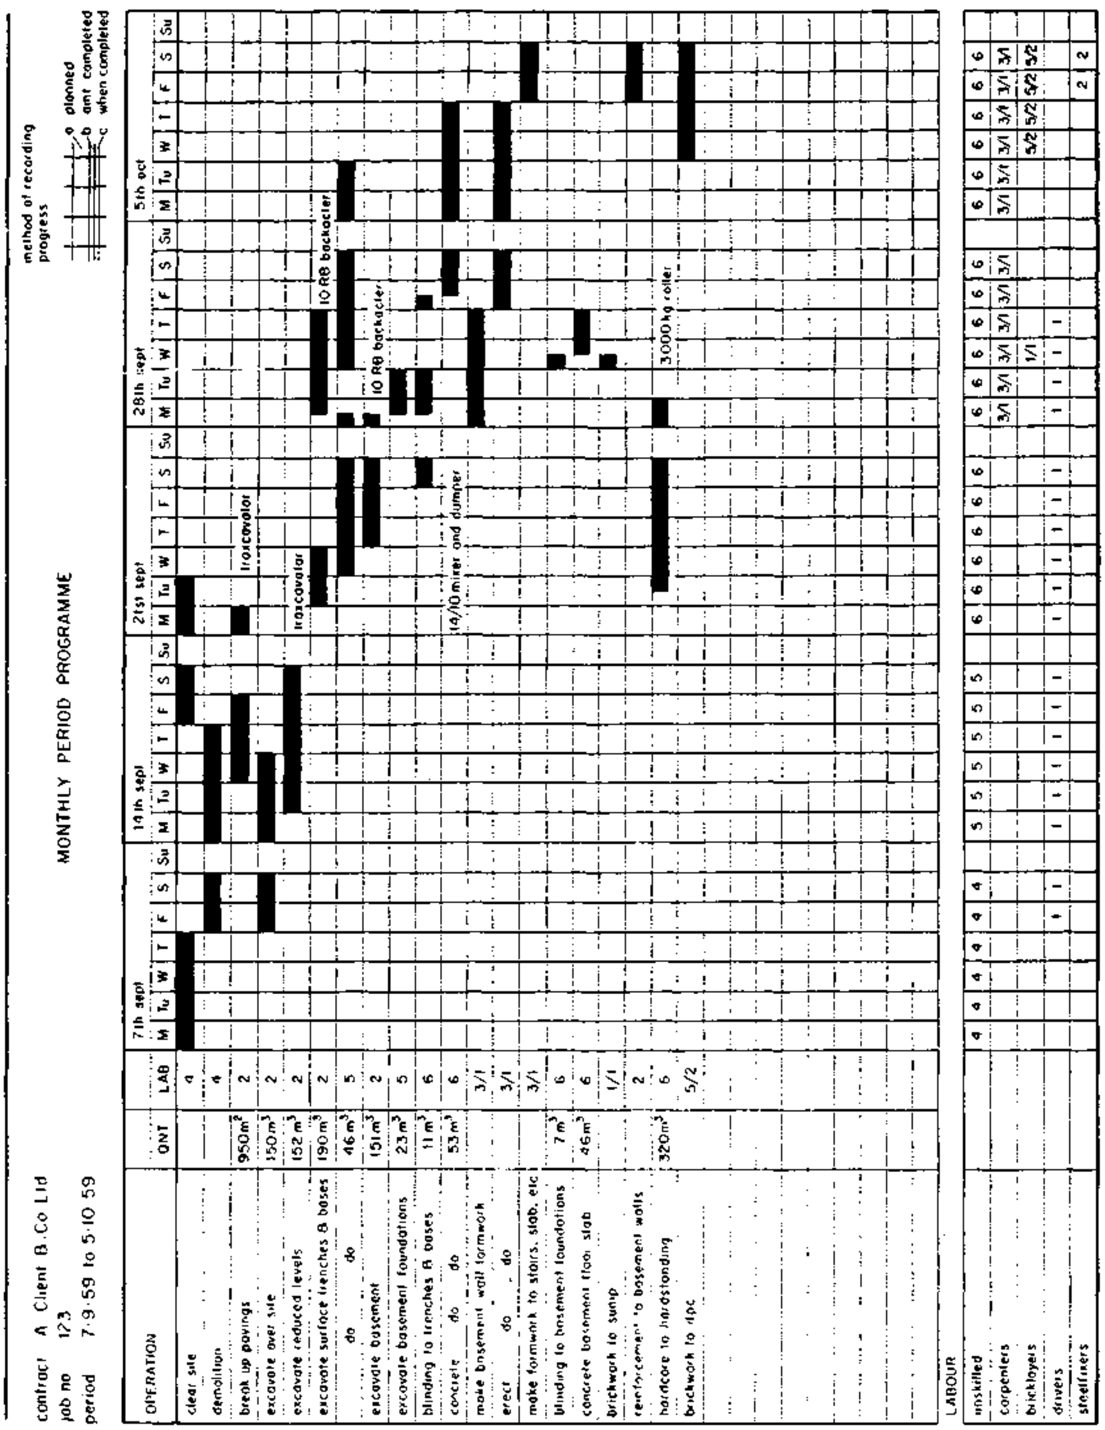
The final step is to prepare a working schedule an the basis of the balanced production in each stage, from which programmes for the various stages are drawn up.
The stage programmes are combined to give the final overall programme.
(A short intervall may be left between the stages to provide for delays due to bad weather or other causes).
A typical overall programme chart is shown in fig.
In addition to the data sheets and the overall programme, a SCHEDULE of CONTRACT INFORMATION is prepared giving
- the recommended labour force for each stage of the contract under trades
- details regarding the sequence of operations given on the data sheets
- details of equipment and methods of construction to be used.
- full details concerning all sub contractors

A site layout plan and a site preparation programme will also be prepared at this stage as well as the detailed programme for the first four week period of the contract.
(ref. to 'site organisation')

OVERALL PROGRAMME



MONTHLY PERIOD PROGRAMME



4.1.4. PLANNING CONSIDERATIONS

4.1.4 PLANNING CONSIDERATIONS
A number of factors which have a bearing on the decisions made during the contract planning stage are briefly considered here.

4.1.4.1 Site conditions and access
Site conditions will limit the type of plant that may be used:
- on wet sites it will be necessary to use tracked machines in the case of excavators and mobile cranes, and dempers for transport
- sloping sites may make the use of rail mounted cranes unsuitable or uneconomical.
- on confined sites there may be insufficient room for a mixer or mixing plant and it may be necessary to use truck mixed concrete.
- Limitations of access may fix the maximum size of plant which can be brought on the site.

4.1.4.2 Nature of job
The type of structure, the general form, size and detailing of the building will all have an effect upon the way in which the contract is planned.
The contractor has to consider the nature of the structure in relation to the site so that he can decide where best to place his equipment and materials. All plant should be so placed on the site that the structure can be erected without moving the plant until most of it is completed. Plant should also be so placed that it can be removed easyly at the completion of the job.
In some circumstances the contractor may request the adjustment of the structure in some way, in order to permit the most efficient planning of the contract. It may be desirable to enlarge a lift shaft slightly in order that a climbing crane may be accomodated within it.
OR : For certain parts designed originally as in situ cast work to be carried out as precast work in order fully to utilize a crane on the job etc.

4.1.4.3 Plant
The choice of the most suitable plant for any particular operation necessiates a consideration of the capabilities, limitations, and outputs of different types of plant.

- EXCAVATION can be carried out either mechanically by a number of different types of plant or by hand.
  The SPOIL can be transported in various types of vehicle and the length of haul to tip will vary with the job, so that many combinations of excavator and transporting machines are posibble.

The method adopted for excavating operations will depend upon
a) the type of excavation to be carried out
b) the nature of the soil to be excavated
c) the volume of soil to be excavated
d) the length of haul to tip and the terrain over which the machinery has to dig and travel
e) the type of plant available for the contractor

For small quantities, handexcavation is cheaper than mechanical excavation and the type of transport will depend on the distance to be hauled, the nature of the ground to be traversed and the cost of temporary roads, where necessary.

- HANDLING of structural units and materials in fabrication and erection can be carried out by crane or forklift truck.
  If a crane is used the work must be planned round the crane. Consideration must be given to the quantity and nature of materials to be handled and whether or not there is sufficient to keep a crane fully accupied throughout the working day.

  The careful timing of materials as near as possible to the point at which they will be used, together with the correct siting of hoisting plant, materials dumps and mixing plant in relation to the building and to each other is an important factor in planning for high productivity and for the reduction of double-handling.

- MIXING Type and size of concrete mixer are dictated to a large extent by the quality and quantity of concrete required.
  When small to medium quantities (say up to 20 m3/day)are required a mixer together with hand loading of the aggregate skip, some form of weight batching and hand barrow delivery can be economical.
  When steady outputs of not less than 30m3 per day are required, complete mechanisation (with a mechanical scoop ar gravity loading of the mixer skip, gravity fed bulk cement and - for delivery - a crane carrying a full batch skip or, alternatively, a pneumatic concrete placer) is best.

- CONTRACTORS MECHANICAL PLANT
  In its widest sense 'contractors plant' implies the machinery, tools and other equipment used in the contractor's yard and workshop, and on the site.
  The machines and power tools are divided into three classes according to their degree of mobility:
  - fixed (operating from a fixed position on site)
  - portable (being moved about by pulling, pushing or carrying by hand)
  - mobile (moving from one place to another under their own power)

  They may further be devided into classes according to their function.
  The following figures show a collection of mechanical plant and power tools used on the building site only.

SCAFFOLDING

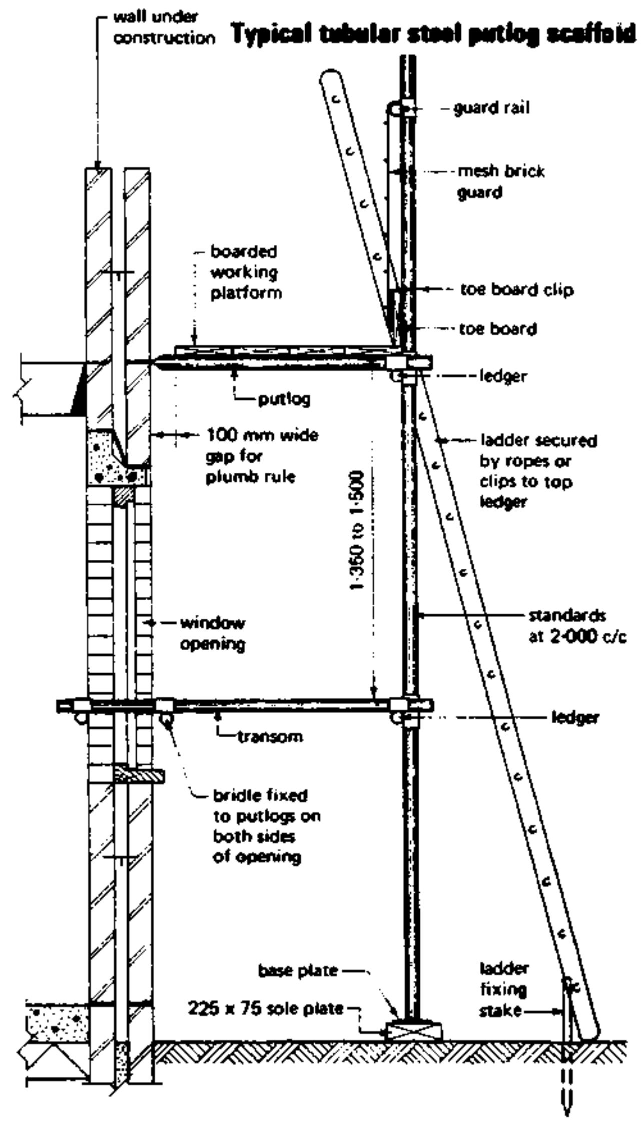
4.1.4.4 SCAFFOLDING
A scaffold is a temporary structure from which persons cangain access to a place of work in order to carry out building operations, it includes any working platforms, ladders and guard rails. Baically there are two forms of scaffolding:
1) Putlog scaffolds.
2) Independent scaffolds.

PUTLOG SCAFFOLDS This form of scaffolding consists of a single row of uprights or standards set a-way from the wall at a distance which will accommodate the required width of the working platform. The standards are joined together with horizontal members called ledgers and are tied to the building with cross members called putlogs. The scaffold is erected as the building rises and is mostly used for buildings of traditional brick construction (see Fig.).

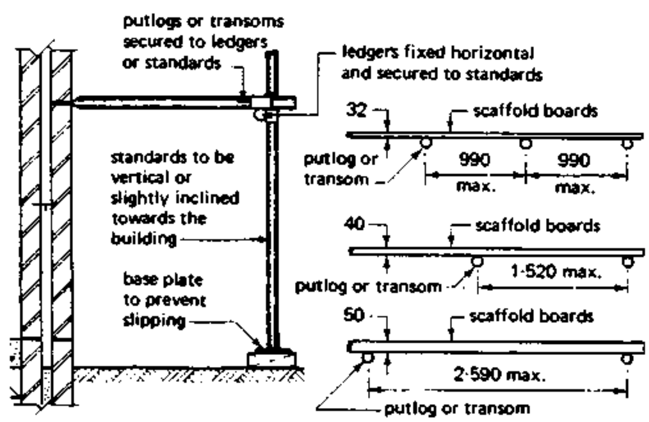
INDEPENDENT SCAFFOLDS An independet scaffold has two rows of standards which are tied by cross members called transoms. This form of scaffold does not rely upon the building for support and is therefore suitable for use in conjunction with framed structures (see Fig.).
Every scaffold should be securely tied to the building at intervals of approximately 3.600 m vertically and 6.000 m horizontally. This can be achieved by using a horizontal tube called a bridle bearing on the inside of the wall and across a window opening with cross members connected to it (see Fig.); alternatively a tube with a reveal pin in the opening can provide a connection point for the cross members (see Fig.). If suitable openings are not available then the scaffold should be strutted from the ground using raking tubes inclined towards the building.

MATERIALS Scaffolding can be of:
1) Tubular steel
2) Tubular aluminium alloy
3) Timber

Typical tubular steel putlog scaffold



Scaffolds and Construction Regulations



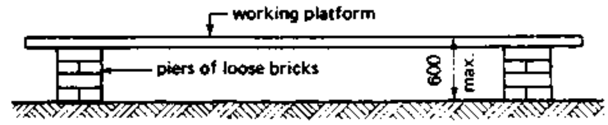
Regulation 13 ~ Standards, putlogs and transoms

TUBULAR STEEL British Standard 1139 gives recommendations for both welded and seamless steel tubes of 48mm outside diameter with a nominal 38 mm bore diameter. Steel tubes can be obtained galvanised (to guard against corrosion); ungalvanised tubes will require special care such as painting, varnishing or an oil bath after use. Steel tubes are nearly three times heavier than comparable aluminium alloy tubes but are far stronger and since their deflection is approximately one third of aluminium alloy tubes, longer spans can be used.

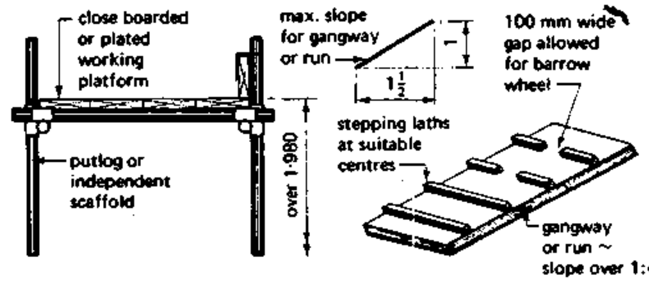
ALUMINIUM ALLOY Seamless tubes of aluminium alloy with a 48 mm outside diameter are specified in BS 1139 for metal scaffolding. No protective treatment is required unless they are to be used in contact with materials such as damp lime, wet cement and sea water, which can cause corrosion of the aluminium alloy tubes. A suitable protective treatment would be to coat the tubes with bitumastic paint before use.

TIMBER The use of timber as a temporary structure in the form of a scaffold is now rarely encountered in this country, although it is still used extensively in other countries. The timber used is fir of structural quality in either putlog or independent format, the members being lashed together with wire or rope instead of the coupling fittings used with metal scaffolds.

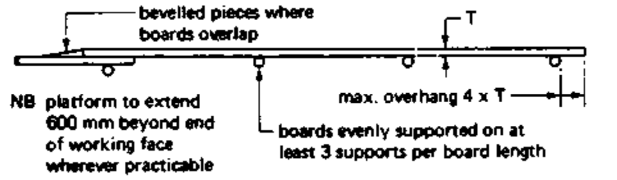
SCAFFOLD BOARDS These are usually boards of softwood timber complying with the recommendations of BS 2482 used to form the working platform at the required level. They should be formed out of specified softwoods of 225 x 38 section and not exceeding 4.800 m in length. To prevent the ends from splitting they should be end bound with not less than 25 mm wide x 0.9 mm galvanised hoop iron extending at least 150 mm along each edge and fixed with a minimum of two fixings to each end. The strength of the boards should be such that they can support a uniformity distributed load of 6.7 kN/M2 when supported at 1.2oom centres.



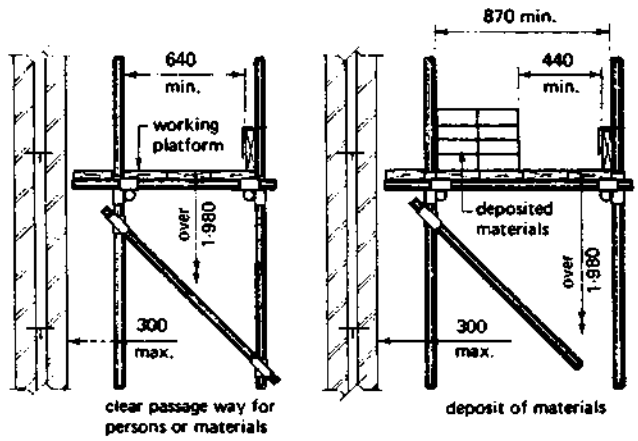
Regulation 15 ~ Stability of scaffolds



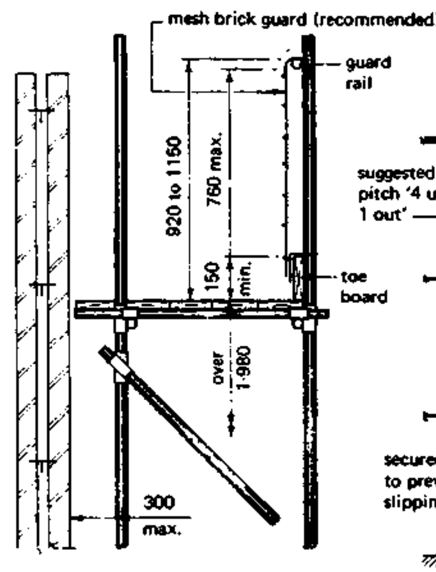
Regulation 24 ~ Platforms, gangways and runs



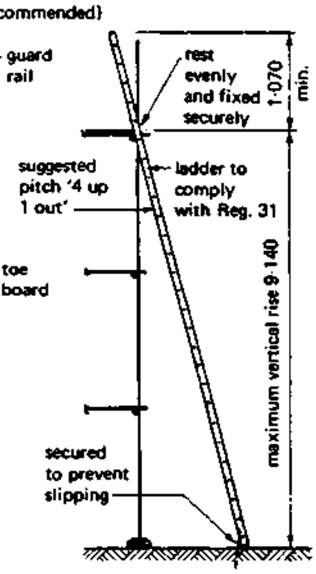
Regulation 25 ~ Boards in working platforms



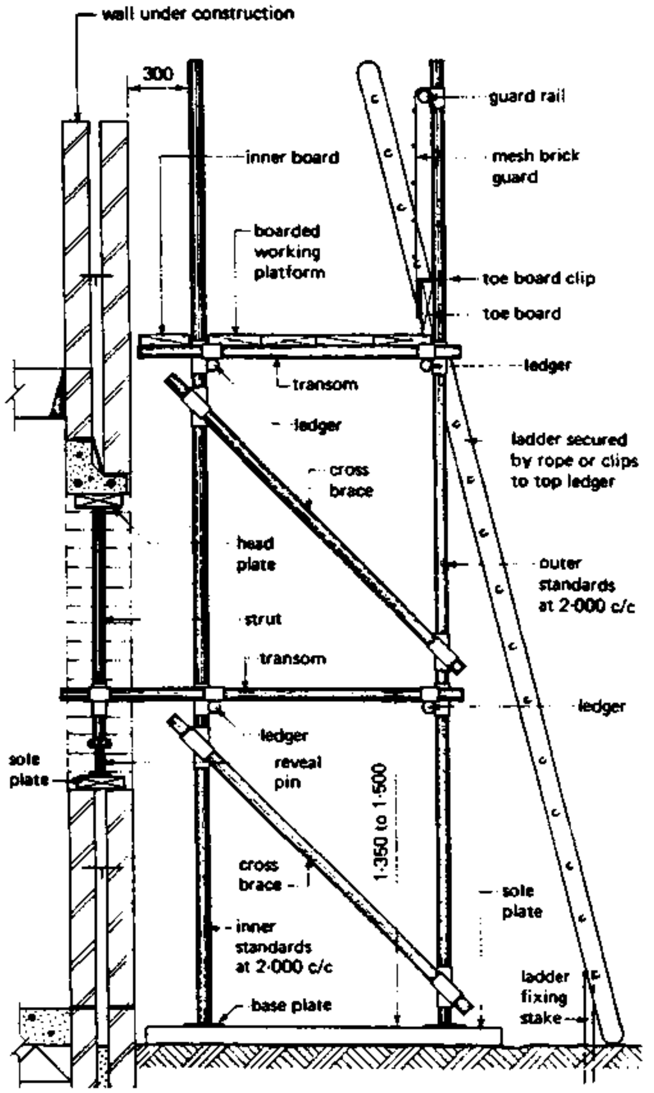
Regulation 26 ~ Widths of working platforms for putlog and independent scaffolds



Regulation 28 ~ Guard rails and toe boards for putlog and independent scaffolds



Regulation 32 ~ Use of ladders



SCAFFOLD FITTINGS Fittings of either steel or aluminium alloy are covered by the same British Standard as quoted above for the tubes. They can usually be used in conjunction with either tubular metal unless specified differently by the manufacturer. The major fittings used in metal scaffolding are:

Double coupler: the only real load bearing fitting used in scaffolding and is used to join ledgers to standards.

Swivel coupler: composed of two single couplers riveted together so that it is possible to rotate them and use them for connecting two scaffold tubes at any angle.

Putlog coupler: used solely for fixing putlogs or transoms to the horizontal ledgers.

Base plate: a square plate with a central locating spigot used to distribute the load from the foot of a standard on to a sole plate or firm ground. Base plates can also be obtained with a threaded spigot and nut for use on sloping sites to make up variations in levels.

Split joint pin: a connection fitting used to joint scaffold tubes and to end. A centre bolt expands the two segments which grip on the bore of the tubes.

Reveal pin: fits into the end of a tube to form an adjustable strut.

Putlog end: a flat plate which fits on the end of a scaffold tube to convert it into a putlog.

Typical examples of the above fittings are shown in the Fig.

TCA TECHNICAL COLLEGE ARUSHA CHUO CHA UFUNDI ARUSHA	CIVIL ENGINEER DEPARTMENT	37

4.2 SITE ORGANIZATION

4.2 SITE ORGANIZATION

4.2.1 Preliminary work

Before site work begins, a PERMISSION to erect a building has to be obtained from the local Authorities. For the procedure of application as well as for the contents of all necessary documents to be submitted refer to 'ARCHITECTURAL DRAWING, Vol II'

The general foreman should visit the site at the earliest opportunity to note such details as:
rainfall / humidity / prevailing wind / orientation / contours.
These factors will influence the site layout plan as far as drainage, shade storage of materials, etc. are concerned.

The following items will also require his attention:
- Adjacent buildings
- Ground surface
- Soil
- Site surround
- Access road
- Water supply
- Electric power
- Transport
- Existing services, etc.

4.2.2 SITE PLANNING
A PROGRAMME covering operations during the first four weeks will have been drawn up at planning stage, in the preparation of which, where possible, the general foreman will have assisted, so that he is in agreement with the proposals lad down.
This programme will be generally in two parts:
a) Site preparation programme, which will cover the demolishing of any existing buildings the setting out of the site and marking out of starage areas, the erection of huts and the construction of temporary access roads where necessary
b) Period 1 programme, on the lines of that shown in the fig., which will cover work during the first four weeks or so of the contract.

Together with these will be provided site layout plans to show a) traffic routes, on which will be indicated any areas requiring particular attention, such as levelling-off or covering with temporary Summerfield track, and any direction signs required; b) the location of offices, huts and stores; c) the position of bulk storage areas both during and after excavation together with the location of any equipment.
The general foreman will in addition also be provided with copies of the:
- overall programme
- schedule of contract information
- data sheets

as well as all other necessary documents such as
- bills of quantities
- specifi cation
- set of contract drawings
- details of all material orders placed and to be placed at various dates during the contract
- details of the type and quantity of equipment to be used and the approximate periods when they will be required on the site.

4.2.2.1 PERIOD PLANNING

Work on the site will commence on the basis of the first monthly programme and during the third week of this period, and all subsequent stages, the next monthly programme will be prepared on the basis of the overall plan and data sheets. In the preparation of the monthly plan consideration must be given to the labour force desirable and practicable in the circumstances at the time, to plant requirements and availability, to the phasing and overlapping of operations to ensure completion of the work in the minimum time and to the planning of labour to maintain group identities. Steps must be taken to give adequate warning to all su-contractors when they will be reauired on site.

4.2.2.2 WEEKLY PLANNING

Towards the end of each week progress will be reviewed and the next week's planned progress confirmed or modified if necessary. The following week's planned labour requirements will be reviewed and an stimate made of materials required for the next week but one and of any action required to be taken regarding equipment. This weekly review will be prepared by the general foreman in consultation with his trade foremen and any sub-contractors' foremen, and a written report will be submitted to the contractor,s planning department.

In certain cases where close integration of fully mechanized operations is required over a short period, particularly in the case of reinforced concrete structures, a weekly programme would be drawn up in chart form by the planning department. Such a chart is illustrated in the Fig. In addition to weekly planning, the general foreman will hold a brief meeting each day with his trade foremen and sub-contractor foremen to review the next day's work and to make the necessary preparations in regard to the placing of materials and equipment in readiness for the next day's operations.

The general foreman will, at the beginning of the job whenever possible, indicate to the local employment office his anticipated 'build up'of labour force during the course of the contract.

4.2.2.3 PROGRESS CONTROL

Good site planning is a prior necessity to smooth and effective progress in construction work, but a regular review of the progress of all perations and its comparison with the programme or plan is essential.
Progress is maintained by the foreman, or on larger jobs by a progress engineer, by the proper organization of the delivery and placing of materials, by ensuring that all equipment and plant is in its correct position at the right time, and by adjusting the size of labour gangs when progress is likely to fall behind the programme because of unforeseen circumstances.
Progress is checked during weekly planning by estimating or measuring the work completed, the percentage of each operation or group of operations completed being established and compared with the programme.
Progress is marked on the charts as indicated in the fugure. When progress varies appreciably from the overall programme and where for this and any other reason it is considered desirable to alter the planned sequence of operations, the general foreman would consult the planning department beforemaking such changes.

Close co-operation between the site staff and the planning department is often maintained by means of regular and formal site production meetings between the general foreman and the planning engineer responsible for the job.

When considering any changes, the effect on the supply of materials must be borne in mind, and when progress is faster than planned, the supply of materials in time for the work becomes the predominating factor. All subcontractors must be notified immediately of any changes in the planned programme of work.

The general foreman should maintain a record of current and planned labour strength in the form of a schedule or chart on which the following week's planned labour requirements will be entered during weekly planning. In addition, all incoming material will be recorded on a form, one for each main item, which should show amongst other information dates of order and receipt, quantity delivered ant the balance of material outstanding.

As an aid to progress control on a job of any size, regular site meetings should be held at which should be present
- the contract manager
- site agent or general foreman
- architect
- clerk of works
- quantity surveyor and
- any subcontractors (when necessary)

At these meetings all aspects of the job requiring attention are discussed and decisions for future action made.

4.2.3 SITE LAYOUT

The layout of every site may be divided into an administrative area and a construction area. In the former will be located stores, offices, subcontractors'huts and canteen and similar accommodation if this is provided, and in the latter, which will be the actual site of the buildings being constructed, will be located consumable stores adjacent to the various buildings and all equipment required for construction purposes.

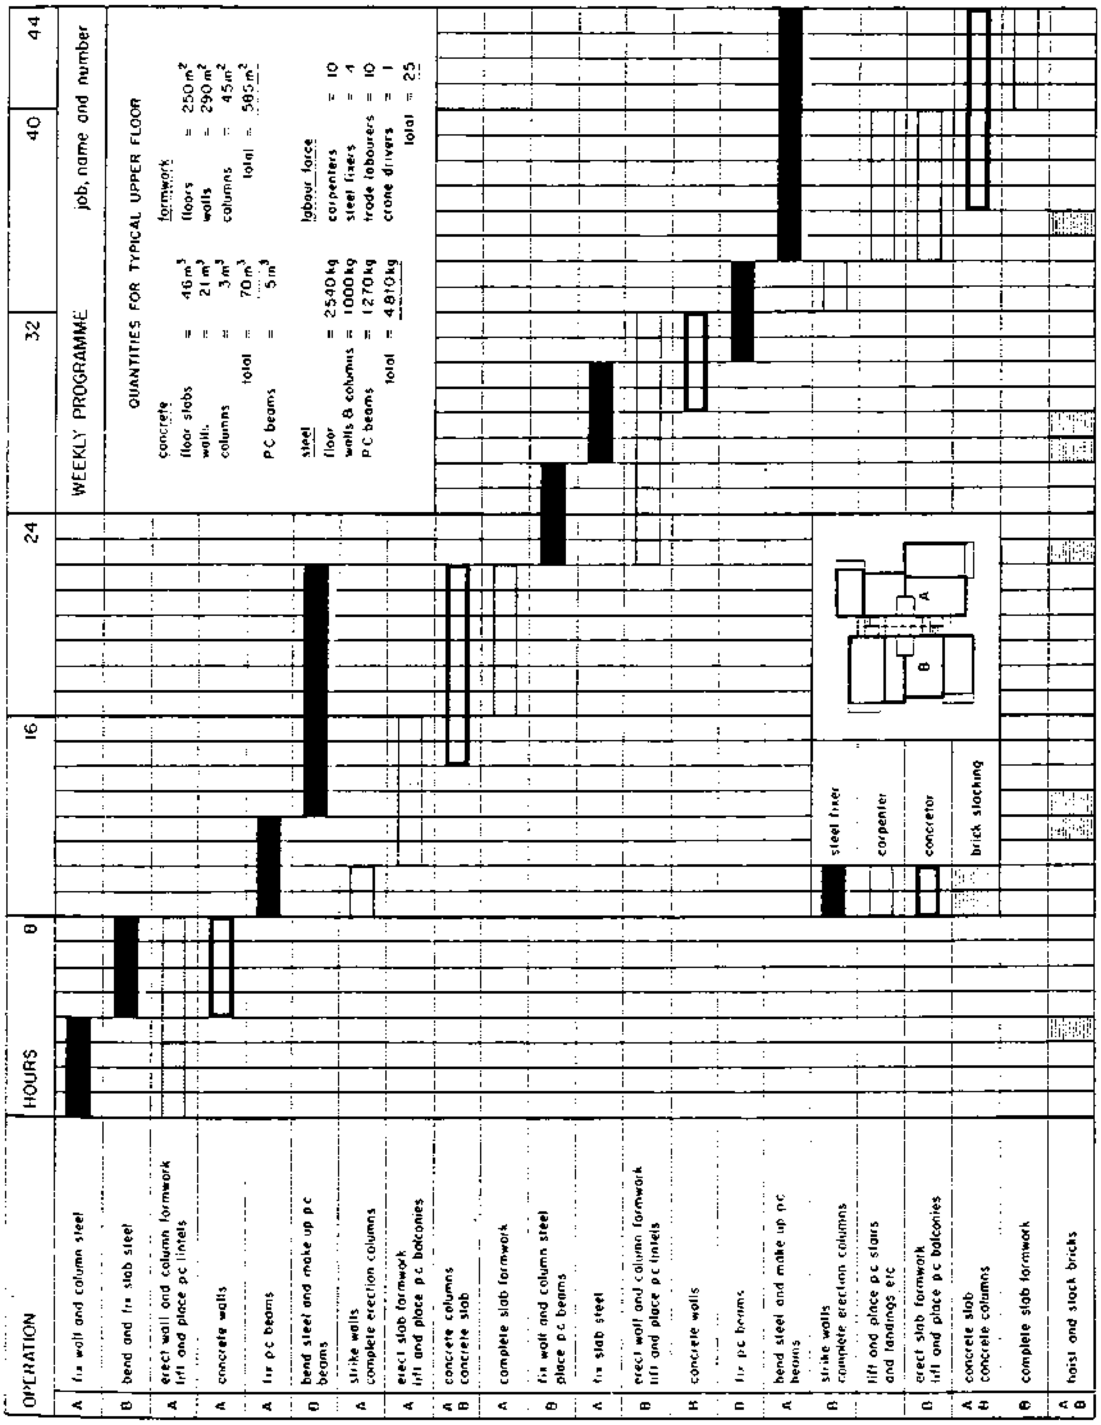
Proper access and departure routes for lorries should be provided and these should be clearly signposted. In determining the traffic routes attention must be paid to the position of all main services, such as water, gas and electricity, and to drains and excavations. Temporary roads must be positioned with sufficient distance between them and future buildings to allow for the movement or positioning of all mechanical plant.

The administrative area should be located to give quick access to that area of the site which will require maximum labour controll and the main storage area, sub-contractors' huts and canteen, should be so located that accessibility for unloading materials is good and so that they are a minimum distance from the construction areas. The site office should be sited on the route into the administrative area and with as good a view as possible of the construction areas.
All contracts of bigger size require adequate telephone facilities for communication, electricity for power, and lighting facilities for office huts.

The stores area should be situated near the site office and will consist of covered huts for valuable or non-weatherproof stores, such as paint and iron-mongery, and a locked pen for larger valuable stores which are weatherproof, such as metal window frames and pipes. Areas for sub-contractors'stores will be located near the sub-contractors'huts and sometimes they will be situated within the main stores area.

The construction area should contain the minimum practical quantities of materials and of necessary equipment and these should be so positioned that handling and movement is kept to a minimum. As the position of equipment, particularly mixers, hoists and cranes, will influence the position of materials such as sand, aggregates and bricks, the position of all plant should be planned before that of the materials.
Materials arrive on the site in the order decided at planning stage, or in accordance with instructions issued from the site, and sufficient area must be provided to accommodate the size of batch ordered. In addition, overflow areas should be allocated. In planning the layout of the site, consideration must be given to the excavation stages as these may seriously restrict proposed storage areas.
Standardized materials, such as bricks, tiles and drainpipes, should be stacked in unit dumps, the numbers in which remain constant although the length, breadth and height may be varied to suit site conditions.

PERIOD PLANNING



•REPETITION•• exercises ••REPETITION•

Try to answer the following questions and use sketches for illustration

1. CONTRACT PLANNING

- Which considerations should be taken into account in 'Contract Planning';

- Explain the function of a 'Bar Chart'

- What is the difference between analysing a production problem by 'Network' and by a 'Linear Method';

- Describe step by step the way how to prepare a 'Network'in the form of an ARROW DIAGRAM

- Explain the terms:
  - Earliest starting time
  - Latest starting time
  - latest finishing time
  - Floating time
  - Critical path
  - Time /cost optimisation
  - Resource levelling and control

- Who prepares the OVERALL PROGRAMME and where will it be used for;

- Where does the OVERALL PROGRAMME consist of, and in which form is it usually expressed;

- Explain and write notes on the following headings:
  - Break down of job
  - Quantities of work and time content
  - Plant and Labour outputs
  - Sequence and timing of operations
  - Programme chart

- List and describe factors which have a bearing on the decisions made during the contract planning stage.

- Write notes on contractors mechanical plant

- Explain different types of SCAFFOLD refering to their form as well as to the materials and fittings used for construction.

2. SITE ORGANIZATION

- What has to be obtained before site work begins ?

- List items which should require the attention of the general foreman during his first site visit

- What is the contents of the 'site planning programme' ?

- What are the two areas of the 'site layout' ? Write notes and explain the requirements of these areas.

5.FOUNDATIONS

5. FOUNDATIONS

A FOUNDATION is the BASE on which a building rests and its purpose is to safely transfer the load of a building to a suitable subsoil.

Apart from solid rocks all soils are compressible in varying degrees, so that under the building load foundations will - to some extent - move in a downward direction. This is known as SETTLEMENT and is due mainly to the consolidation of the soil particles.

Excessive settlement will result from overloading the soil to such an extent that the loaded area of soil SHEARS past the surrounding soil in what is known as PLASTIC FAILURE of the soil.

In addition, settlement may be caused by a reduction in the MOISTURE CONTENT of certail soils which shring on drying out or by a general movement of the earth due to various causes.

Provided the settlement is UNIFORM over the whole area of the building and is not excessive, the movement does little damage.
If the amount of settlement VARIES at different points under the building (known as realtive or differential settlement) distortion of the structure will occure which, if too great, may result in damages or possible failure of the structure.

Such differential movements must be kept within limits which avoid harmful distortion. These limits will vary with the type of structure and its ability safely to withstand differential movements.

5.1.1 Site exploration

Tall, wide-span or heavily loaded buildings exert greater pressures on the soil resulting in greater settlements, and lead to greater possibility of shear failure of the soil than do small-scale buildings. To overcome this, types of foundations may be required which affect the soil and to considerable depths. In such cases the various soil characteristics take on greater significance and a closer considaration of the soil and its properties is required than is often necessary for small-scale buildings.

This may require an extensive examination of the subsoils involving boring to considerable depths and carrying out field and laboratory tests on the soils.

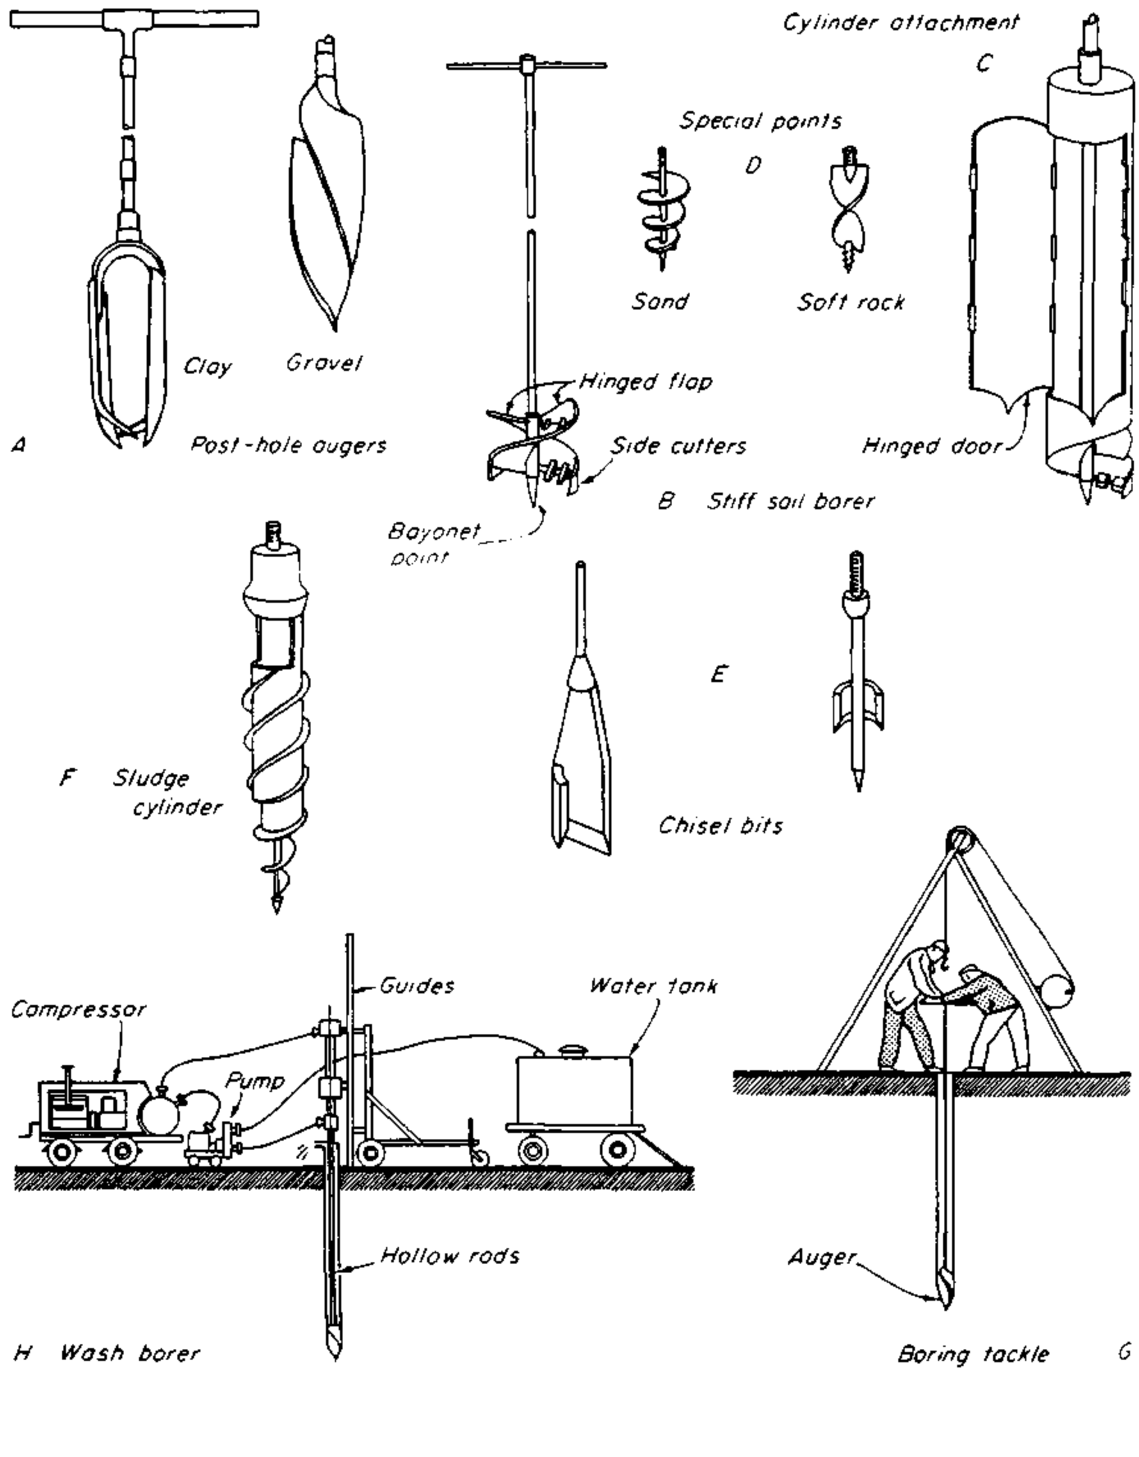
An extensive investigation of the soil is not usually necessary in the case of small-scale buildings on soils of adequate strength, where (by means of simple stripe or pad foundations near the surface) the pressure on the soil can be kept well within the known SAFE BEARING CAPACITY of a particular soil type. What is required is a simple method of establishing the TYP OF SOIL to a sufficient depth and a means of determining its bearing capacity.

The bearing capacity can be found from standard tables and the soil type can be established by exposing the soil to view for the shallow depths by digging holes- known as TRIAL HOLES (or PITS) - and using simple visual and tactile means of identification.

5.1.1.1 Trial holes

- Should not be further apart than about 30 m and not less than one per 900 m2 of site.
- Should be large enough to accomodate a man (say 1.20 m x 1.00 m or larger if timpering is required.
- Depth: Usually up to 3.oo m, it rarely exceeds 6.oo m.
- The soil should be inspected at all levels as soon as possible after excavation.
- As a check on the possible existance of a very weak layer of soil below the trial hole, a probe of about 1 m may be made by means of a hand anger. This can also be used when the presence of ground water makes the completion of the trial hole difficult.
- The soils excavated and exposed in the trial holes can be identified within broad types by simple field tests.
- Foundations are invariably formed in concrete. The durability can be affected by sulphate salts in the soil, particularly in the ground water.
  The nature of any groundwater should be checked and where sulphate salts are known to be present precautions must be taken (e.g. by use of suitable cement).
- A trial hole also gives to the contractor valuable informations affecting labour costs (ease of excavation) and amount of timbering, underground water (pumping, dewatering).
- Excavations should not be carried out too close to the proposed foundations, they may be a source of weakness, and the should be filled and consolidated ofertwards.

SOIL BORING METHODS



5. FOUDATIONS compiled: D. VOLKE MAY '83	SOIL INVESTIGATIONS	BUILDING CONSTR. LECTURE CET 2031/15.1o3
TCA TECHNICAL COLLEGE ARUSHA CHUO CHA UFUNDI ARUSHA	CIVIL ENGINEER DEPARTMENT	3

BORE HOLES

5.1.1.2 Bore holes

- Are fomed as required on site for the purpose of raising samples of soil for examination.

- Tools:
  a) post-hole anger (simple) having arod with crosshead, it is capable of forming holes in clay or soft soils up to about 6 m deep and Ø 150 mm or more.
  b) for cleeper borings or where rock is expected, either the
     - percussion or the
     - rotary
     method is employed.

A hole is formed by percussion method with a chipsel-shaped steel bit, screwed to a rod;
this is driven vertically in to the ground, lifted, partly rotated and again driven. It has to be repeated rapidly until the desired depth is obtained.
Samples of the soil are obtained during the process.

The rotary method is usually applied to rock formations.
A small hole (Ø 50 mm) is drilled with a rotating bit (having diamonds set round the cutting edge) jointed to a hollow rod.
The cylindrical core of rock thus formed within the tool is broken off at intervals and removed for inspection and testing.

SAMPLING

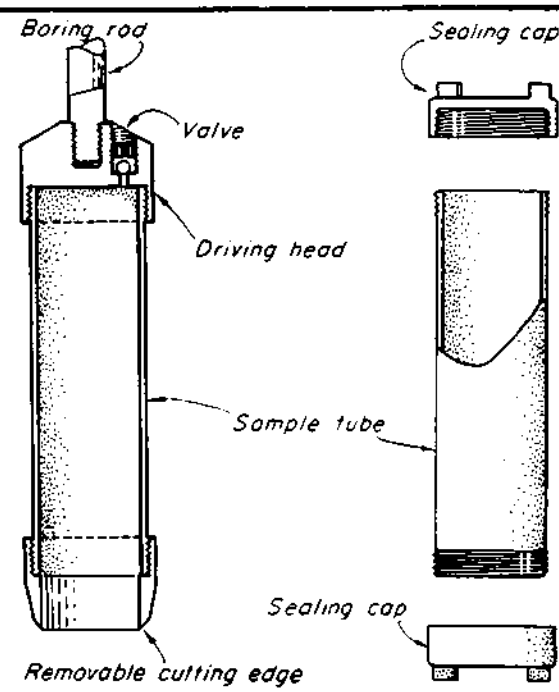
5.1.1.3 Sampling

The form of samples depends upon the
- nature of the soil
and whether it was
- disturbed or
- undisturbed.

e.g. an undistrubed sample of rock can be obtained if such stratum has been exposed in a trial pit.
It has to be dressed to a cube (at least 75 mm each side).
When it can be tested for
- compression
- permeability etc.
and slides prepared from it can be exmamined.

An undisturbed sample of clay from a trial hole is cut by a knife in the form of a cube, coated with paraffin wax to prevent loss of moisture, placed in an airtight container and labelled ready for testing.

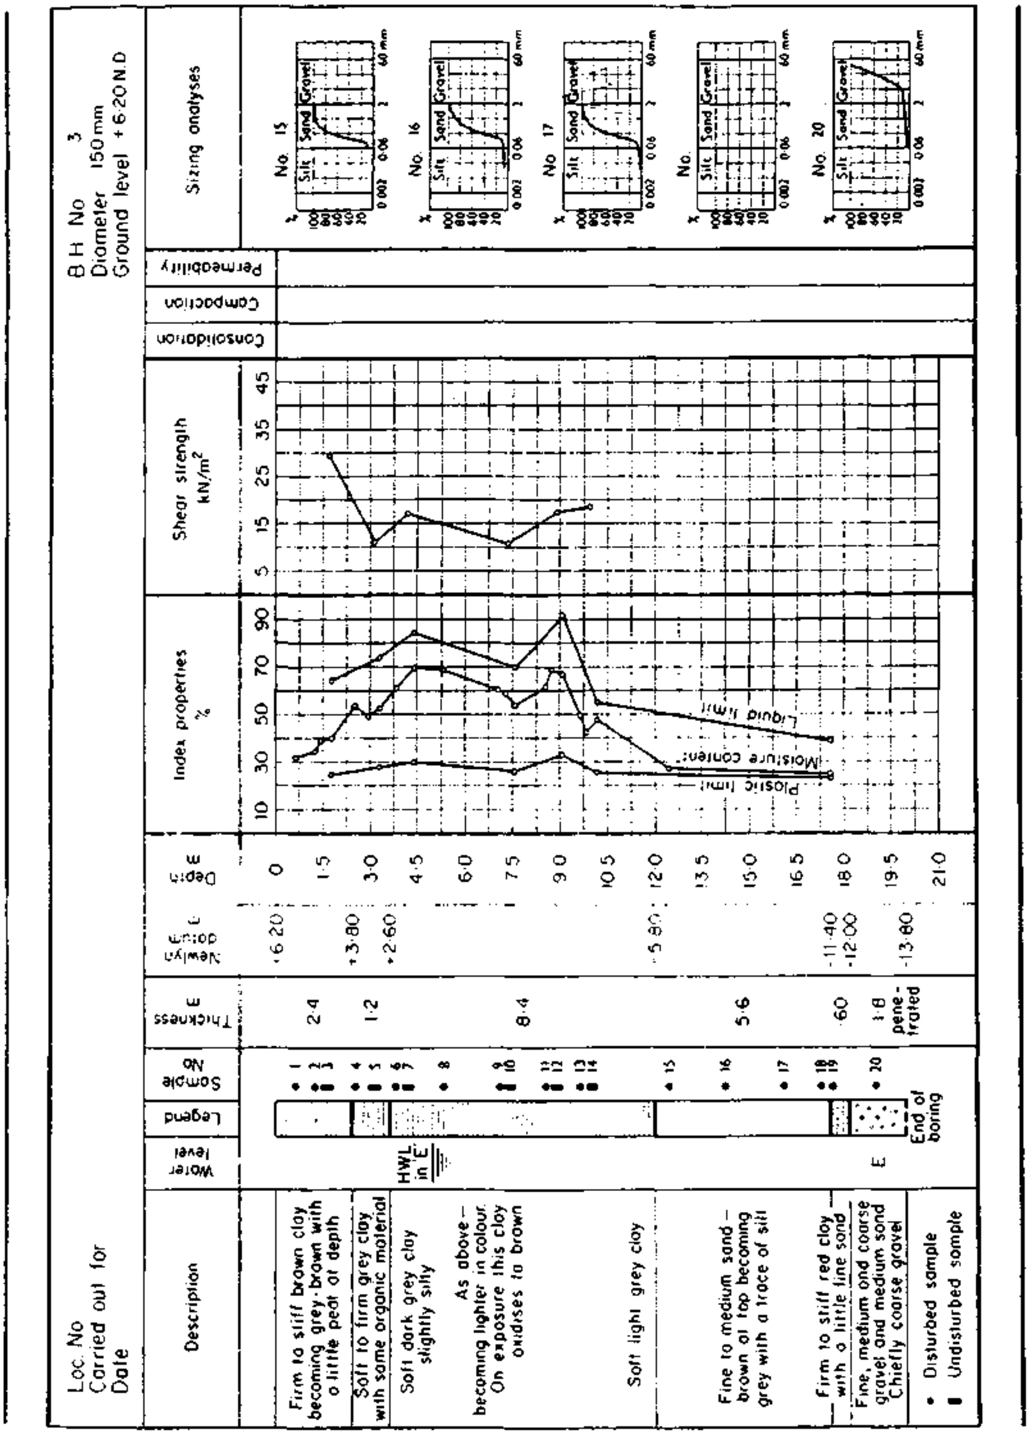
Such a sample can also be obtained from an exposed clay stratum by using a tool called
 - 'sampler' or 'spoon'
There are several types of samplers (e.g. a metal tube Ø 100 - 150 mm, 1 m - 1,5 m long; having an open



end with a cutting edge and at the opposite closed end there ist an air valve; as the sampler is driven down it gradually fills with clay (air excaping through the valve) it is withdrawn when full and the sample is removed.

Disturbed samples of soils are obtained during the actual boring operation. The sampler is attached to

BOREHOLE RECORD



the boring rod in the place of the bit, forced down into the loosened soil and withdrawn when full.

The soil cores are carefully removed from the sampler and placed in a box (about 1,5 m long, divided into compartments) in correct sequence and numbered in their proper order.

When laid end-to-end according to depth they reproduce a section showing the nature and thickness of each stratum.

Small specimens for laboratory tests are taken from the cores as required. These should be placed in an airtight container until needed.

5.1.1.4 Tests

After having examined the samples carefully and the characteristics of the various soils noted and classified, a complete record is made, including a dimensionel sketch of the section showing the thickness and various strata.

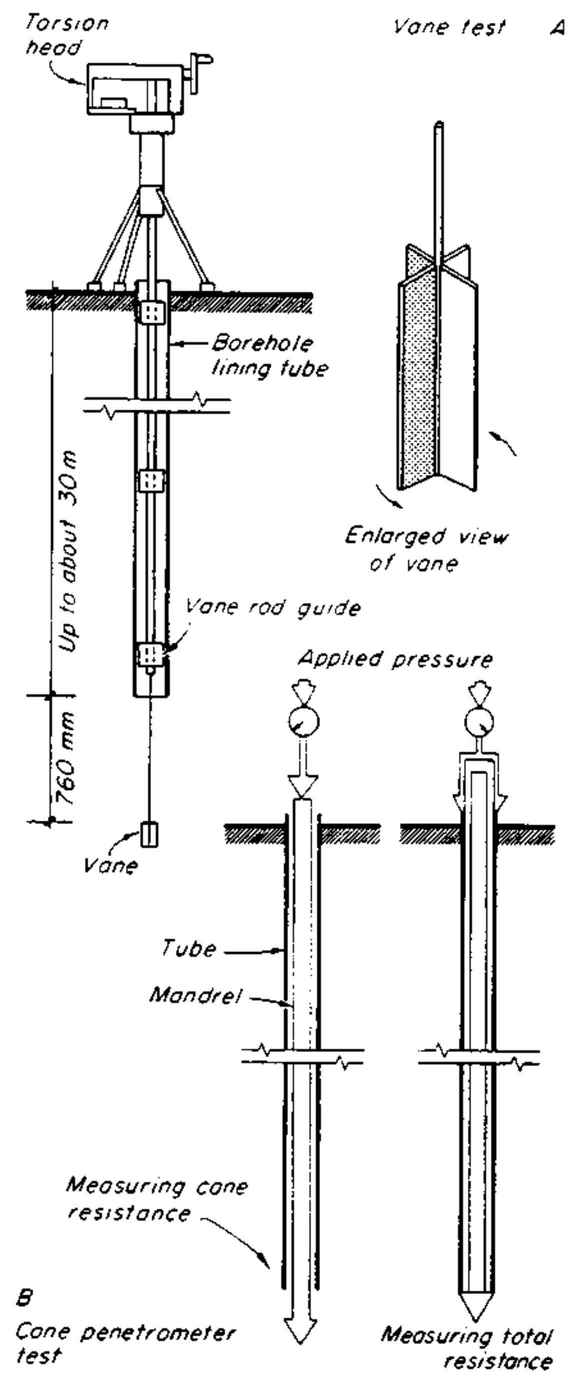
Two tests are most important to the foundation designer:

1) consolidation test
2) shear test.

1) Consolidation test is usually applied to clay soils.
   The weight of the Building tends to consolidate the soil by squeezing out the water between the particles - and so producing settlement of the building.
   Test: The soil specimen is placed in a metal Cylinder between two porous stone discs. Pressure is applied and increased by stages, the amount and rate are noted at each stage, a time settlement curve is plotted.
   Result: Probable amount of settlement.

2) The load of a building sets up compression and shear stresses in the soil. The soil tends to squeeze out from under the load.
   The shear stresses are the forces tending to produce this sliding movement between adjacent portions of soil (clay., normally not gravel)
   The safe load which can be supported by a soil depends to a large extent upon its shear resistance.

TESTS



In situ soil tests

Test: A metal box is used(100 mm2 by about 75 mm deep). Two portions (upper and lower halves) are welded to one side of the top half as a projecting arm to which is fastened a length of wire fixed to a scale pan. The bottom half is clamped to the bench top and the wire is passed over the pulley, clamped at the edge of the bench, suspending the pan.
The box is filled completely with clay specimen and weights are placed on the pan until the upper half begins to slide over the lower - as the clay shears through at this level.
The total weight producing this, divided by the internal area of the box gives the shear strength of the soil.

5.1.1.5 Load or bearing test

This test is applied at the proposed level of the foundations (not at ground level!!).
There are several forms of equipment used for this test, two will be described below:

1) Consists of a level concrete raft (say 1,5m2; 30 cm thick) formed at foundation level. It serves as the loading table;

2) a hole is dug at foundation level to recive a square or circular steel sole plate of known area (say 1 m2) bedded level on a cushion of sand;
This supports centrally a steel tube or spindle (say 1,2 m high) having a cross-head forming the base of the loading platform (say 2 m2).
The whole is prevented from tilting by guys or other means, which must be arranged not to restrict the downward movement of the platform.
The weight of the apparatus must be known.

Loading: (same for (1) and (2)

- the table is loaded carefully and uniformly (bars of pig-iron- each of equal weight or bricks - the average weight of twelve being taken as the unit - may be used.)
- the load is applied in increase (say 204 bricks at a time) and at least two hours must elapse between the time one increment has been completed and the next started.
- Fine readings are taken with a dumpy level (with the staff at the centre and at each corner of the table top) immediately before and after each loading.
- The mean settlement is obtained. A record is kept of the readings and a load / mean - settlement curve is plotted.
- The amount of settlement after each increment - loading will depend upon the character of the soil, but if the bearing capacity is satisfactory it will only amount to a few mm.
- When the 'yield point'of the soil has been reached, as indicated when there is an appreciable increase in settlement after the last increment, this increment is removed from the table and the readings again taken after an interval of three or four days.
  If no further settlement has taken place, half the total load on the table (together with the weight of the apparatus) divided by the area of the sole plate is taken as the safe bearing value of the soil.

$$\frac{\text{Total load table}}{2} : \text{area of sole plate}$$

= safe bearing capacity of the soil.

5.1.2 Soils and soil characteristics

The topmost layer of sil at ground level is an unsuitable material on which to found.
- It has been weathered,
- is relatively loose
- contains decayed vegetable matter
- is soft and exessively compressible

It is known as:
- Topsoil or vegetable soil (thickness varies from about 15 - 30 cm).

Below this lies the
- subsoil, from which the topsoil has developed and which consists of solid particles of varying shape and size devived from the weathering of solid rock. The spaces between are filled with water and - to some extent - air.

It is to this subsoil that the word 'soil' refers when used in relation to foundations.

5.1.2.1 Rocks and Soils

A broad classification, comprising five groups is:

1) rocks
2) cohesive soils
3) non-cohesive soils
4) peat
5) made ground.

The table below shows how these are classified and distinguished.

Group	Types of rocks and soils	max. safe - bearing capacity (MN / m2)
I Rocks	Ingeous rocks in sound condition	10
	Massively - bedded lime - stone and hard sandstones	4
	Slates	3
	Hard shales, soft sandstones	2
	Hard clay shales	1
	Hard solid rock	0,64
	Thinly-bedded limestones and sandstones	To be determind after inspection
	Heavily shattered rocks	
II Cohesive Soils	very stiff boulder clays and hard clays with a shaly structure	0.4 - 0.6
	stiff clays and sandy clays	0.2 - 0.4
	firm _"_	0.1 - 0.2
	soft _"_ and silts	0.05- 0.1
	very soft clays and silts	0.05- nil

III non-cohesive soils	sompact well-graded sands and gravel-sands	0.4-0.6
	loose well-graded sands and gravel sands	0.2-0.4
	compact uniform sands	0.2-0.4
	loose uniform sands	0.1-0.2
IV	Reat	To be determind after investigatie
V	Made ground	-"-

These embrace igneons rocks (which include granits) up to heavily shattered rocks

I Rocks

II Cohesive soils

These are soils, the particles of which stick together, such as clays. The degree of cohesion depends upon the size and shape of the particles and the water content. These clays are classified as:
very stiff boulder clays
up to
very soft clays and silts (see fig.)

- Clay soils are subject to shrinkage and cracking in hot dry weather, followed by expansion in wet weather - The change in volume according to their water content.

- Adequate precontions have to be taken!
  Such movement may cause considerable damages to buildings errected on subsoils of very soft clay.

- As the movement decreases with the depth below ground level it is important that foundations should be relatively deep.
  - under external walls at least 90 cm
  - or of pile and beam type
  - or of raft construction

  In addition to having this undesirable property of expanding and contracting, clay soils have a relatively low shear strength and a small safe load bearing capacity.

III Non-cohesive soils
include gravel and sands.
The strength or bearing capacity depends upon
- the grading,
- the packing and
- the average size of the particles.

In general : The better the grading (as distinct from uniformity) - the tighter the packing and : the larger the grains, the bigger the load bearing capacity.

These soils are divided into:
- compact well graded sands and gravel sands

up to
- loose unform sands (see table)

Non cohesive soils vary considerably in their value as building sites.
e.g. A deep bed of dry compact gravel provides an exellent support.
A subsoil of loose, uniform sand (if not confined by sheet piling) may develop considerable settlement when loaded.

The presence of groundwater affects the bearing capacity of soils. Thus, pumping operations may lossen a compact bed of gravel (and reduce the bearing capacity).

IV Peat
is decayed vegetable matter, black or darf brown in colour. It is highly compressible and quite unsuited to receive foundations (even those of light structurs).

If used for foundations - it must be supported on piles which ar driven down to an underlying firm stratum.

V Made ground or fill

This is excavated soil or house refuse, which has been depositied in a depression.

Such sides have to be avoided
- house refuse is in sanitary
- injurious conicals may be in industrial waste
- even excavated soil, such as quarry waste well compacted in thin layers beats a risk of unequal settlement. (foundations to be carried down to the original stratum or be supported by piles.)

SOIL CHARACTERISTICS and BEARING CAPACITIES

Subsoil types	*Condition of subsoil*	*Means of Field Identification*	*Particle size range*	*Bearing capacity kN/m²*	*Minimum width of strip foundations in mm for total load in kN/m of loadbearing wall of not more than* 20	30	40	50	60	70
Gravel	Compact	Require pick for excavation. 50 mm peg hard to drive more than about 100 mm. Clean sands break down completely when dry. Particles are visible to naked eye and gritty to fingers. Some dry strength indicates presence of clay	Larger than 2 mm	> 600	250	300	400	500	600	650
Sand			0·06 to 2 mm	> 300						
Clay	Stiff	Require a pick or pneumatic spade for removal. Cannot be moulded with the fingers. Clays are smooth and greasy to the touch. Hold together when dry, are sticky when moist. Wet lumps immersed in water soften without disintegration	Smaller than 0·002 mm	150–300	250	300	400	500	600	650
Sandy clay			See Sand and Clay	150–300						
Clay	Firm	Can be excavated with graft or spade. Can be moulded with strong finger pressure	See above	75–150	300	350	450	600	750	850
Sandy clay			See Sand and Clay	75–150						
Gravel	Loose	Can be excavated with a spade. A 50 mm peg can be easily driven	See above	< 200	400	600	For loadings of more than 30·0 kN/m run on these types of soil: the necessary foundations do not fall within the provisions of Regulation D7 from which these figures are taken.		Pad foundations generally and surface rafts are designed using the bearing capacities for soils given in this Table. *Note.* See note on facing page regarding the use of values given in this table for bearing capacities of sands and gravels.	
Sand			See above	< 100						
Silty sand			See Silt and Sand	May need to be assessed by test						
Clayey sand			See Clay and Sand	ditto						
Silt	Soft	Readily excavated. Easily moulded in the fingers. Silt particles are not normally visible to the naked eye. Slightly gritty. Moist lumps can be moulded with the fingers but not rolled into threads. Shaking a small moist pat brings water to surface which draws back on pressure between fingers. Dries rapidly. Fairly easily powdered	0·002 to 0·06 mm	75	450	650				
Clay			See above	75						
Sandy clay			See Sand and Clay	May need to be assessed by test						
Silty clay			See Silt and Clay	ditto						
Silt	Very soft	A natural sample of clay exudes between the fingers when squeezed in fist	See above	< 75	600	850				
Clay			See above	< 75						
Sandy clay			See Sand and Clay	May need to be assessed by test						
Silty clay			See Silt and Clay	ditto						
Chalk	Plastic	Shattered, damp and slightly compressible or crumbly	—	—	Assess as clay above					
Chalk	Solid	Requires a pick for removal	—	600	Equal to width of wall					

5.1.2.2 Stresses and pressures

Cohesive soils present serious problems when giving consideration to foundation choice and design.
The two major conditions to be considered are:

Shearing stress: the maximum stress under a typical foundation carrying a uniformly distributed load will occur on a semi - circle whose radius is equal to half the width of the foundation and the isoshear line value will be equal to about one-third the applied pressure - see Fig. The magnitude of this macimum pressure should not exceed the shearing resistance value of the soil.

Vertical pressure: this acts within the mass of the soil upon which the unacceptable settlement of the structure.
Vertical pressures can be represented on a drawing by connecting together points which have the same value forming what are termed pressure bulbs.
Most pressure bulbs are plotted up to a value of 0.2 of the pressure per unit area which is considered to be the limit of pressure which sould influence settlement of the structure.
Typical pressure bulbs are shown in the fig.
A comparison of these typical pressure bulbs will show that generally vertical pressure decreases with depth, the 0.2 value will occur at a lower level under strip foundations than under rafts, isolated bases and bases in close proximity to one another which form combined pressure bulbs. The pressure bulbs illustrated in the fig. are based on the soil being homogeneous throughout the depth under consideration. As in reality this is not always the case it is important that soil investigation is carried out at least to the depth of the theoretical pressure bulb.

Great care must be taken where an underlying strata of highly compressible soil is encountered to ensure that these are not over stressed if cut by the anticipated pressure bulb.

Contact pressure
It is very often incorrectly assumed that a foundation which is uniformly loaded will result in a uniform contact pressure under the foundation. This would only be true if the foundation was completely flexible such as the bases to a pin jointed frame. The actual contact pressure under a foundation will be governed by the nature of the soil and the rigidity of the foundation, and since in practice most large structures have a rigid foundation the contact pressure distribution is not uniform. In cohesive soils there is a tendency for high stresses to occur at the edges which is usually reduced slightly by the yielding of the clay soil. Non-cohesive soils give rise to a parabolic contact pressure distribution with increasing edge pressures at the depth below ground level of the foundation increases. When selecting the basic foundation format consideration must be given to the concentration of the major loads over the position where the theoretical contact pressures are at a minimum to obtain a blanced distribution of contact pressure - see fig.

Plastic failure
This is a form of failure which can occur in cohesive soils if the ultimate bearing capacity of the soil is reached or exceeded. As the load on a foundation is increased the stresses within the soil also increases until all resistance to settlement has been overcome.
Plastic failure, which can be related to the shear strength of the soil, occurs when the lateral pressure being exerted by the wedge of relatively undisturbed soil immediately below the foundation causes a plastic shear failure to develop resulting in a heaving of the soil at the sides of the foundation moving along a slip circle or plane. In practice this movement tends to occur on one side of the building, causing it to tilt and settle - see fig. Plastic failure is likely to happen when the pressure applied by the foundation is approximately six times the shear strength of the soil.

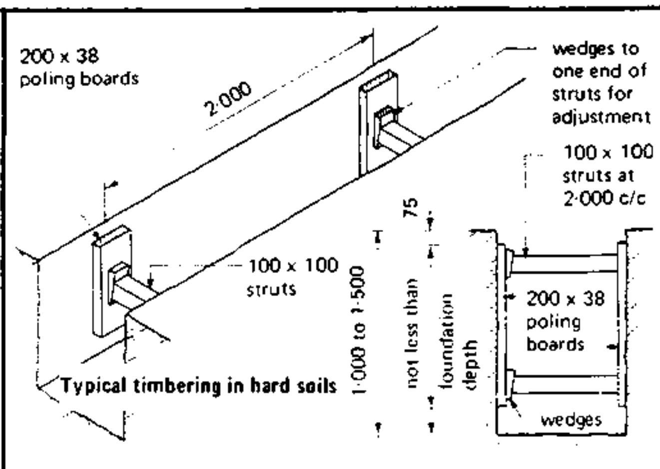
5.2 EXCAVATIONS AND TIMBERING

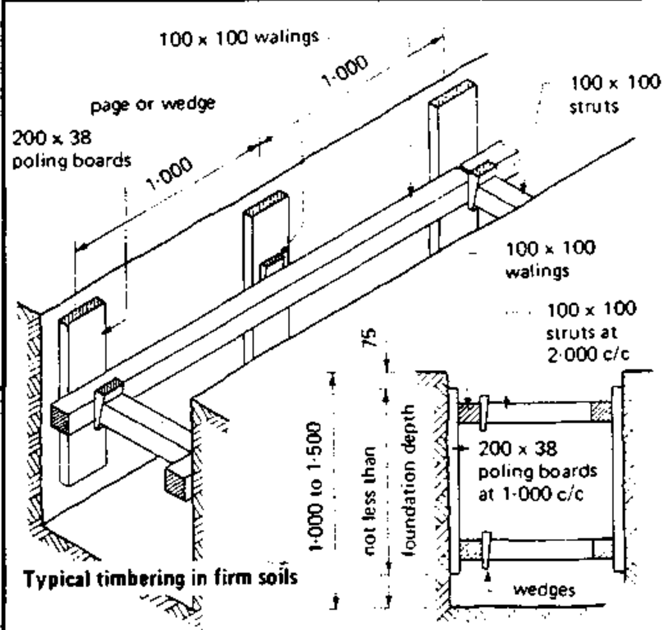
5.2 EXCAVATIONS AND TIMBERING

- Trenches which have to be dug for the foundations of walls are usually excavated by hand - in bigger building projects also mechanical trench diggers are used.
- If the trenches are of any depth it may be necessary to erect temporary timber supports to stop the sides of the trench from fallin in.
- The nature of the soils being excavated mainly determines at what depth of trench timber supports to the sides should be used.
- Soft granular soils readily crumble and the sides of trenches have to be supported for the full depth.
- Dry granular soils such as sand and made up ground may need closely spaced timbering to the sides. See fig.

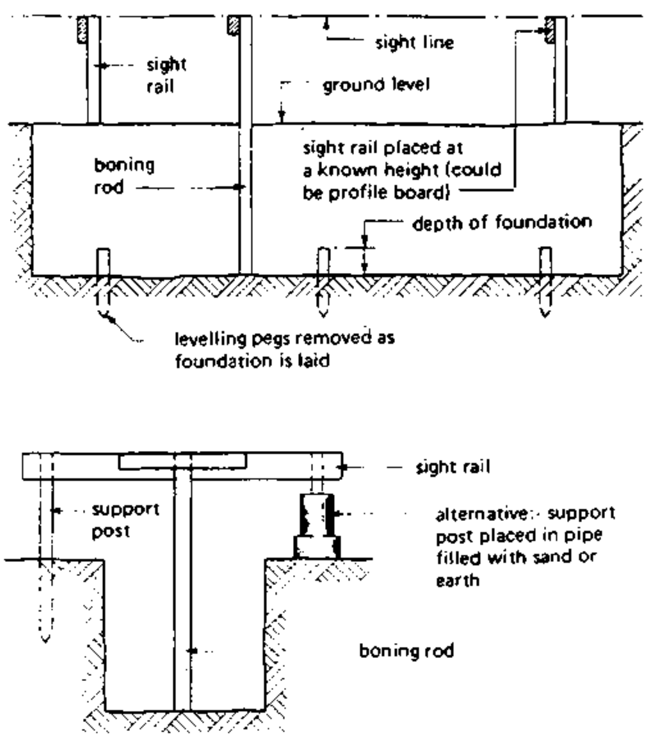
The sizes of timbers shown in the drawings are for guidance only.



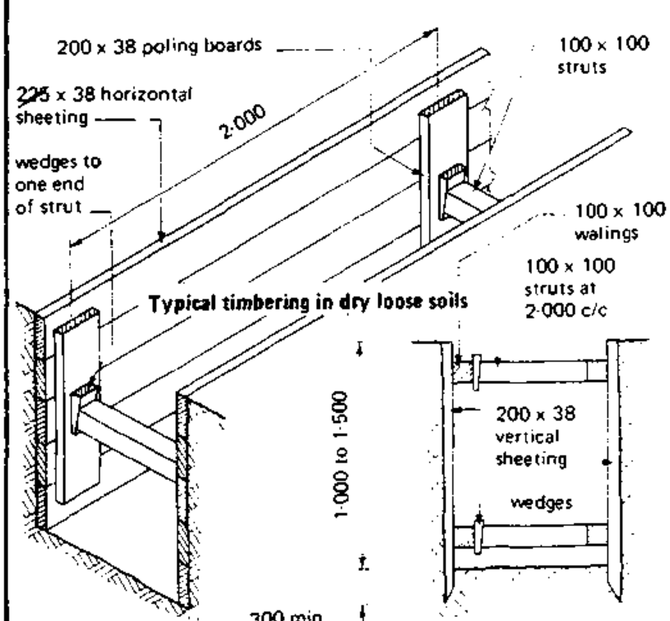
Typical timbering in hard soils



Typical timbering in firm soils



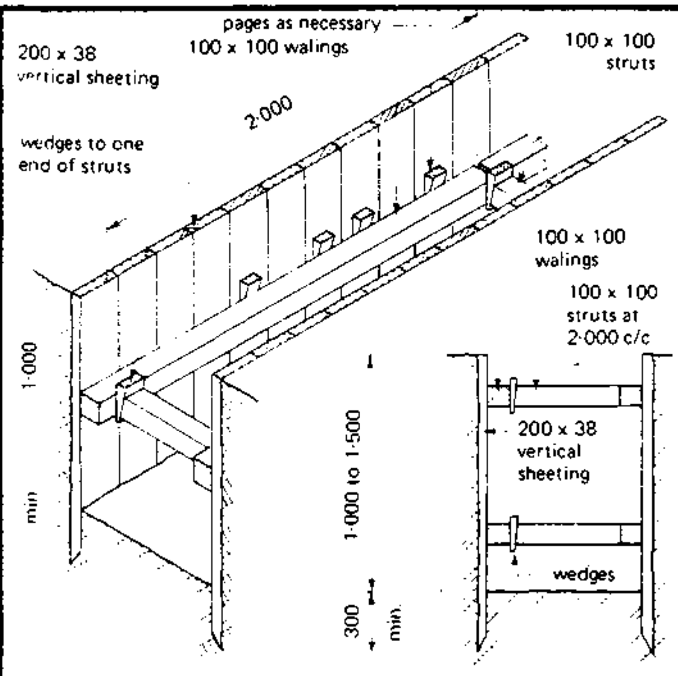
Trench excavations



Typical timbering in dry loose soils

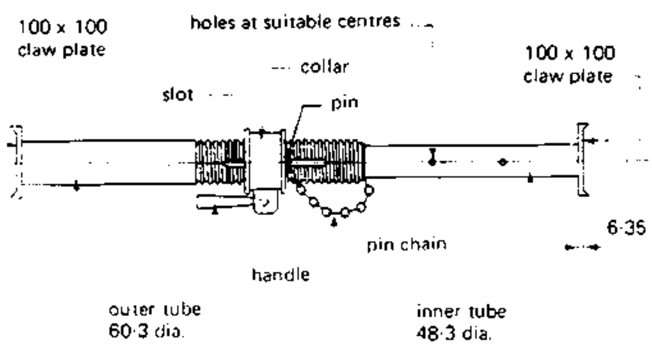
Once the excavations are finished, the foundations should be laid as soon as possible to prevent the ground from drying out and causing movement by shrinking. The ground immediately below the foundation is called the GROUND BEARING or the NATURAL FOUNDATION and should be levelled of and well rammed to receive the base. This is to ensure that there is no loose earth beneath the concrete base which could fail to hold the loading and thus cause a fracture.

- Clay soils do not usually require support for some depth (say 1.5 m) particularly in dry weather.
  In rainy weather, if the bottom of a trench in day soil gets filled with water, the water may wash out the clay from the sides at the bottom of the trench.
- The purpose of temporary timbering supports to trenches is to uphold the sides of the excavation as necessary, to avoid collapse of the sides.
- Whatever timbering is used there should be struts, that is horizontal members, fixed across the width of trenches. All struts must be firmly secured so that they are not easily knocked out of position.
- The sides of deep trenches in compact soils such as clay should - if necessary - be timbered as shown in the fig.
- If the soil is soft, such as loam, more closely spaced timbering will be needed as shown in the fig.

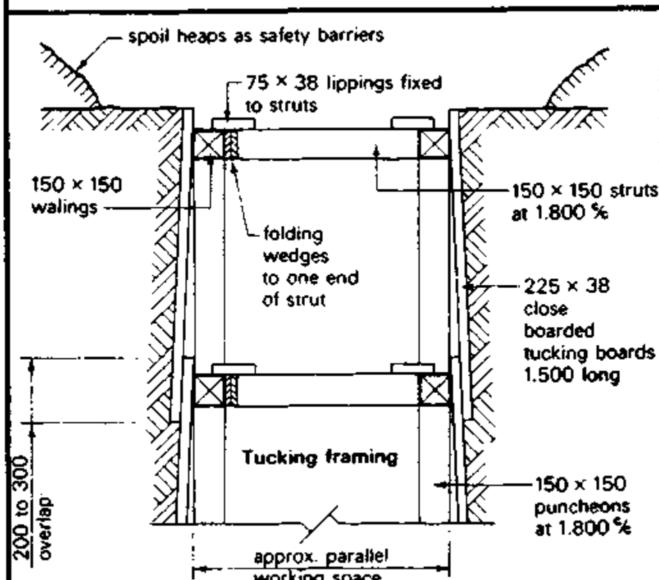


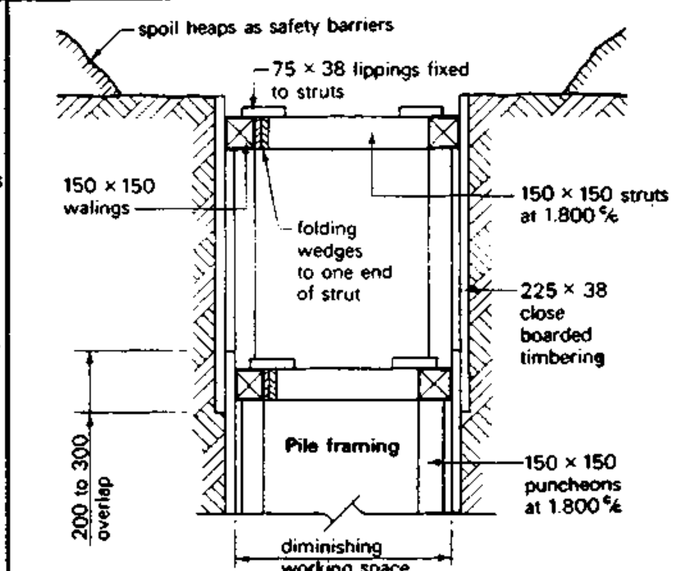
Typical timbering in loose wet soils

Adjustable metal struts—BS 4074



SIZE No.	MINIMUM LENGTH	MAXIMUM LENGTH
0	0·30 m	0·45 m
1	0·45 m	0·68 m
2	0·68 m	1·06 m
3	1·06 m	1·67 m





5.3 TYPES OF FOUNDATIONS

5.3.1 Classification
The many forms of foundations used in building work may be divided broadly into
I SHALLOW FOUNDATIONS and
II DEEP FOUNDATIONS

I Shallow foundations transfer the load to the soil at a level close to the lowest floor of the building and include SPREAD FOUNDATIONS in the form of
- strip foundations
- pad foundations and
- raft foundations

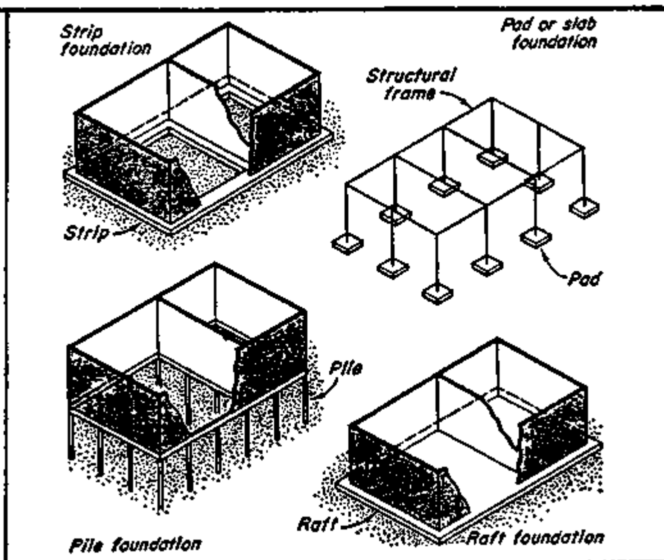
II Deep foundations include
- pile foundations and
- various types of piers which transfer their loads to the soil at a considerable distance below the underside of the building.

Shallow foundations are always the cheapest. An exeption may be the use of short bored piles instead of strip foundations in shrinkable clays.

STRIP foundations = under continous walls
PAD(or slab) -"- = under isolated piers or colums
are used on sites where a sufficient depth of reasonably strong subsoil exists near the surface of the ground.

RAFT foundation =
by which the whole of the building area is covered, are used e.g. where no firm bearing strata of soil exists at a reasonable depth below the surface and a maximum area of foundation is required to bring the imposed pressures within the low bearing capacity of the weaker soils and of some made-up ground.

PIERS and PILES =
may be viewed as columns passing through weak soil to transmit the building load to lower strata where the pressure can be safely resisted. They may also be used to transfer loads to the soil below the level likely to be affected by moisture movement.



5.3.2 Choice of foundation

The choice of a foundation must take account of both - soil and superstructure

For example: A stiff rigid building, one with plain monolithic concrete walls, will be affected by differential movement to a greater extent than one with brick or block walls. Within certain limits distortion can be accommodated in the latter by fine cracks distributed throughout the joints whereas in the former the distortion will rapidly cause large cracks to be formed.
In the case of small scale buildings the nature of the structure in respect of different movement is less important.

- Foundation design requires an appreciation of the ability of the structure to withstand relative movements without dangerous overstress and damage to the structure.

- Small scale buildings affect the soil at shallow depth only, so that account need to be taken only of soil movement due to causes other than loading.

- Where the soil is stable the possible causes of movement will be changes in moisture content of the soil. Movement can be avoided by placing the foundation at an adequate depth.

- on unstable soils, special measures must be taken whatever the scale of the building.

- Overall or total settlement must be limited so that services and drains connected to the building are not damaged, alternatively, provision must be made for flexible connections.

- The table below indicates the sutibility of the foundation types described above to the various types of soil.

CHOICE OF FOUNDATIONS

Soil type and site condition	Foundation	Details	Remarks
Rock, solid chalk, sands and gravels or sands and gravels with only small proportions of clay, dense silty sands	Shallow strip or pad footings as appropriate to the load-bearing members of the building	Breadth of strip footings to be related to soil density and loading (see Fig. 4.2). Pad footings should be designed for bearing pressures tabled in CP 101 : 1963. For higher pressures the depth should be increased and Civil Engineering Code of Practice No. 4. 'Foundations' consulted	Keep above water wherever possible. Slopes on sand liable to erosion. Foundations 0.5 m deep should be adequate on ground susceptible to frost heave although in cold areas or in unheated buildings the depth may have to be increased. Beware of swallow holes in chalk
Uniform, firm and stiff clays: (1) Where vegetation is insignificant	Bored piles and ground beams, or strip foundations at least 1 m deep	Deep strip footings of the narrow widths shown in Fig. 4.3 can conveniently be formed of concrete up to the ground surface	Downhill creep may occur on slopes greater than 1 in 10. Unreinforced piles have been broken by slowly moving slopes
(2) Where trees and shrubs are growing or to be planted close to the site	Bored piles and ground beams	Bored piles dimensions as in page 65.	
(3) Where trees are felled to clear the site and construction is due to start soon afterward	Reinforced bored piles of sufficient length with the top 3 m sleeved from the surrounding ground and with suspended floors, or thin reinforced rafts supporting flexible buildings, or basement rafts		
Soft clays, soft silty clays	Strip footings up to 1 m wide if bearing capacity is sufficient, or rafts	See page 63 and CP 101 : 1963	Settlement of strips or rafts must be expected. Services entering building must be sufficiently flexible. In soft soils of variable thickness it is better to pile to firmer strata (See Peat and Fill below)
Peat, fill	Bored piles with temporary steel lining or precast or *in situ* piles driven to firm strata below	Design with large safety factor on end resistance of piles only as peat or fill consolidating may cause a downward load on pile (*see Digest 63*) Field tests for bearing capacity of deep strata or pile loading tests will be required	If fill is sound, carefully placed and compacted in thin layers, strip footings are adequate. Fills containing combustible or chemical wastes should be avoided
Mining and other subsidence areas	Thin reinforced rafts for individual houses with load-bearing walls and for flexible buildings	Rafts must be designed to resist tensile forces as the ground surface stretches in front of a subsidence. A layer of granular material should be placed between the ground surface and the raft to permit relative horizontal movement	Building dimensions at right angles to the front of long-wall mining should be as small as possible

Soil type and site condition	*Foundation*	*Remarks*
Rock, solid chalk, sands and gravels or sands and gravels with only small proportions of clay, dense silty sands	Shallow strip foundations, pad foundations, (as appropriate to the load-bearing members of the building) Surface raft See Table 10	Keep above water wherever possible. Slopes on sand liable to erosion. Foundations to be 460 mm below ground level on ground susceptible to frost heave (see text)
Uniform, firm and stiff clays: 1 Where vegetation is insignificant	Strip or pad foundations at least 1·07 m below ground level Bored piles See Tables 10 & 12	With these soils downhill creep may occur on slopes greater than 1 in 10. Unreinforced piles have been broken by slowly moving slopes
2 Where trees and shrubs are growing or to be planted close to the site	Bored piles See Table 12	
3 Where trees are felled to clear the site and construction is due to start soon afterward	Reinforced bored piles of sufficient length with top 3 m sleeved from the surrounding ground and with suspended floor Thin reinforced rafts supporting flexible superstructure Basement rafts See Part 2	
Soft clays, soft silty clays	Strip foundations up to 850 mm wide if bearing capacity is sufficient See Table 10 Rafts See Part 2	Settlement of strips or rafts must be expected. Services entering building must be sufficiently flexible. In soft soils of variable thickness it is preferable to pile to firmer stratum
Fill (made up ground) Peat	Pier foundations Piles driven to firm stratum below Special raft foundations with or without flexible superstructure See Part 2	If fill is sound, carefully placed and compacted in thin layers, strip foundations are adequate
Mining and other subsidence areas	Special raft foundations with or without flexible superstructure See Part 2	

Table 11 Suitability of foundation types to various soils
Based on information in Building Research Digest 67

5.3.3 Spread foundations

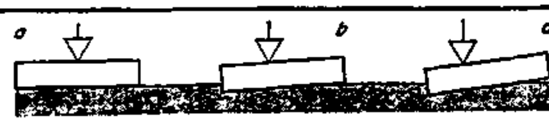
Must be designed so that
- the soil is not overstressed
- the pressure on the soil under them is equal at all points

in order to avoid unequal settlement under the actual foundation.

This is ensured by providing sufficient area of foundation and by arranging the centre of gravity of the applied loads to coincide with the centre of area of the foundation.

Strip foundations and pad foundations require the foundation to be placed symmetrically with the wall or column it supports

- If the load is applied eccentrically, the pressure on one side will be greater than the average pressure, causing greater consolidation of the soil on that side of the foundation.
- When the eccentricity is great, the increased stress could exceed the safe bearing capacity of the soil, even though the average stress might be well below it.
- When the eccentricity is greater than 1/6 of the foundation width, tensile stress occurs and causes the foundation to rise off the soil.

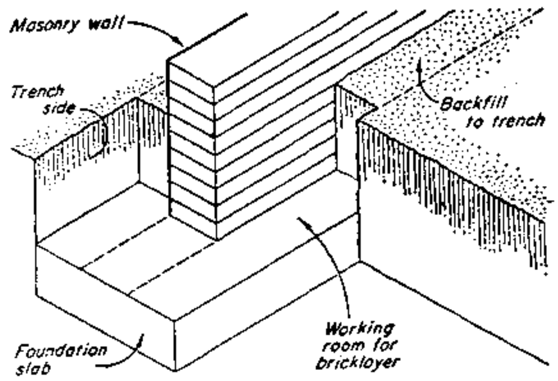


Effect of eccentric loading on foundations

STRIP FOUNDATIONS

5.3.3.1 Strip foundations

Consist of a strip of concrete under a continous wall carrying a uniform by distributed load.



Strip foundation

The required area (as in case of all spread foundations) is related to the imposed load and the bearing capacity of the soil.

The imposed load is considered as load /m the width of the strip is made such as to give sufficient area/m run of foundation.

e.g. If the loading is 30 KN/m and the soil is stressed not more than 50 KN/m2 the min. width should be 0.60 m. (load : stress). That means : In every metre run of foundation the load of 30 KN will be distributed over 0.60 m2 of soil, resulting in a pressure of 50 KN/m2.

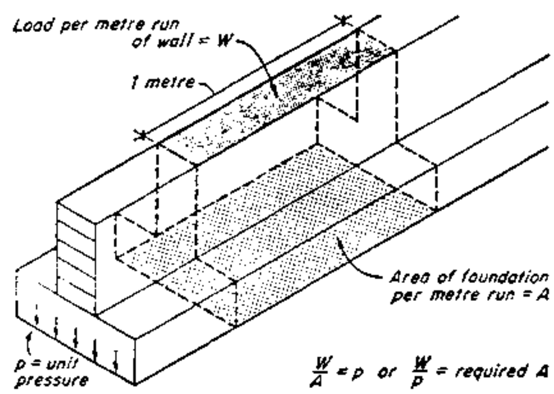
In cases of light loading on reasonably strong soils a strip no wider than the wall it carries may be sufficient.
In practice, with masonry walls some spread is usually provided (12,5-15,0 cm on each side) to allow working room. This also provides some stability to the wall before it is tied in by floors and roof.

For hand excavation : min. width 60 - 75 cm depending on the depth.

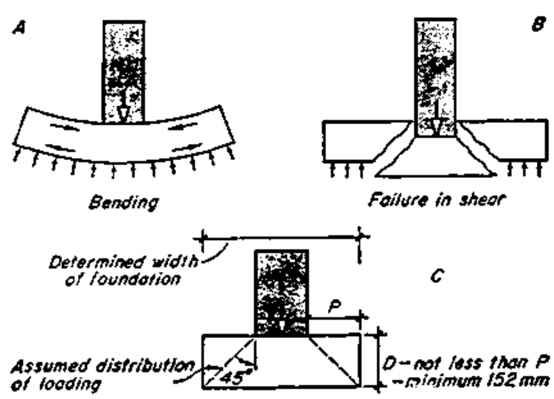
The stresses in the soil due to loading have to be well within the lowest limit of safe bearing capacity for any particular soil type, resulting in wider foundations than those which would fully stress the soil. This is the basis of the minimum widths laid down for stripe foundations in the Building Regulations and given in the table below.

Where the adges of a foundation project beyond the faces of the wall it supports bending due to contilever action will occur as a result of the resistance of the soil, causing bending and shear stresses in the foundation.

The tensile strength of unreinforced concrete is low, and in order to keep these stresses within the capacity of the concrete : the strip must be of adequate depth.



Foundation width



Foundation depth

DEEP STRIP FOUNDATIONS

Concrete fails under a compressive load usually by tensile shear failure along planes lying at an angle of about 45° to the horizontal.

Code of Practice 101: 1963 requires an angle of spread of load from the wall base to the outer edge of the foundation of not more than 45° which results in the thickness being not less than the projection of the base beyond the face of the wall it carries.

Vary wide strips are reinforced to keep their depth within economic limits.

Heavy loads concentrated at points in the run of a wall carrying otherwise uniformly distributed load will result in greater loads on the foundation at these points.
In order to ensure equal stresses at all points in the soil these extra loads must be distributed to the soil through larger foundation areas.

For mass concr., a 1:3:6 mix is commonly used, with fairly large aggregate - say 38-50 mm. Concrete should be poured as soon as possible after excavation of trences.
(Clays and chalk soils losing strength when become wet; clay drying -out causes shrinkage which is followed by expansion).
If concr. cannot be placed on completion of excavation, the bottom should be protected by 5 cm of weak concr. blinding, or 7,5 cm to 10 cm of soil should be left for excavation immediately prior to concreting.

Brick footings: Another way of speading the load of the walls to the soil is to make the base of the wall thicker by means of off-sets called footing courses.
The wall is built with 1/4 B off-sets each side for every course of bricks.
The effect is: a larger surface area in contact with the ground

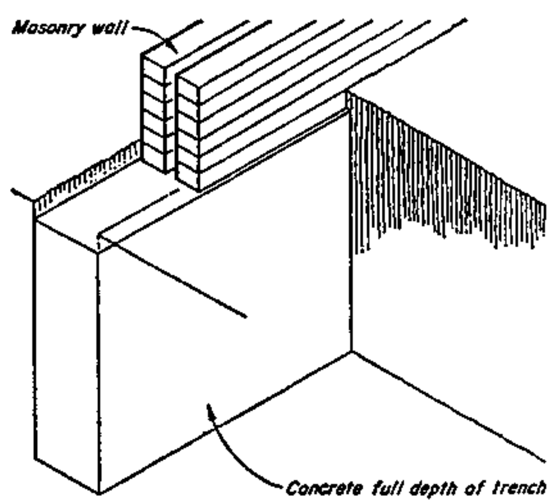
5.3.3.2 Deep strip foundations

Firm or stiff shrinkable clays are strong and when carrying light loads necessiate quite small foundations (possibly not wider than the wall carried). But these soils move considerably with changes in moisture content, therefore the bottom of the foundation should be at least 1 m below ground level.
Narrow excavation is required (perhaps 30 cm wide and more than 1 m deep)

- it has to be dug by mechanical means and filled with concrete to within a few cm of the ground surface.
- much less soil has to be excavated and backfilling is eliminated.
- where conditions are suitable it is cheaper to construct and quicker to complete than the wider strip foundations.

The conditions necessary to make it economic are

1) a self-supporting soil to avoid timbering (firm, shrinkable clays possess this characteristic)
2) adequate runs of straight trenching with a min. amount of corner trimming (to justify the cost of a mechanical excavator).



Deep strip foundation

STEPPED FOUNDATIONS

5.3.3.3 Stepped foundations

Exept in certain types of structures transferring inclined thrusts to the ground all foundations must bear horizontally on the soil.

If strip foundations to a building on a sloping site are at the same level throughout, those on the higher side will be greater distance below ground level than the remainer, necessiating deeper trenches and a greater amount of walling in the soil.

There are two ways in which this building into the soil may be reduced:

1) by cut or cut-and-fill to provide a horizontal plane off which to build

2) by stepping down the slope of the foundations to those walls parallel to the slope.

Overlap to be not less than T or 2 x H, which ever is the greater with a min. of 30 cm.

Foundations on sloping sites

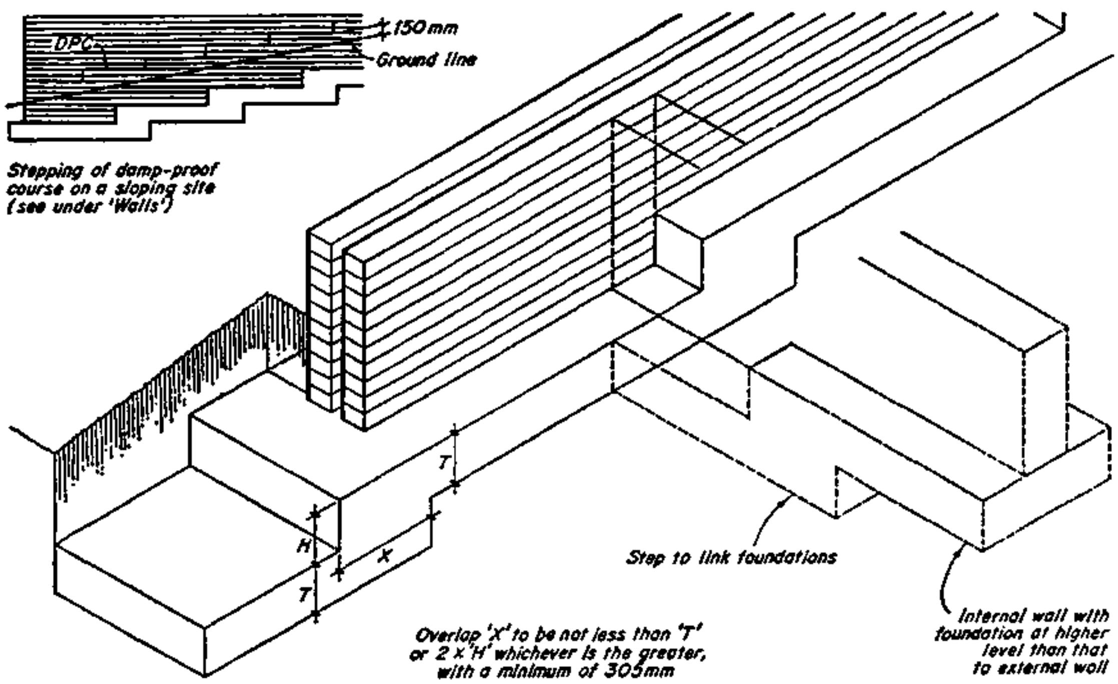
The steps should be relatively short and sufficient in number to keep their heights small and uniform. (Height of step should not exceed the thickness of the foundation).

The lengths need not be uniform, but should be varied (where necessary) to keep the heights as uniform as possible.

Ex each step the higher foundation must lap over the lower.

The foundations should be so arranged that a step accurs at any intersection with a cross wall, the step being on the side where the groundlevel is highest.

On sloping sites it is advisable to lay subsoil drainage, in the form of land drains, across the slope on the uphill side of the building.



Stepping of damp-proof course on a sloping site (see under 'Walls')

Stepped foundation

PAD FOUNDATIONS

5.3.3.4 Pad foundations

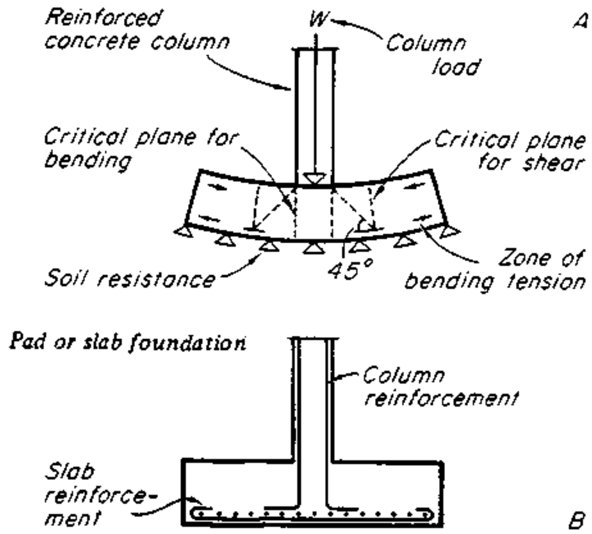
Isolated piers or columns are normally carried on an independet slab of concrete, commonly called a PAD FOUNDATION the pier or column bearing on the centre point of the slab.

The area of foundation is determined by dividing the column load by the safe bearing capacity of the soil and its shape is usually a square.

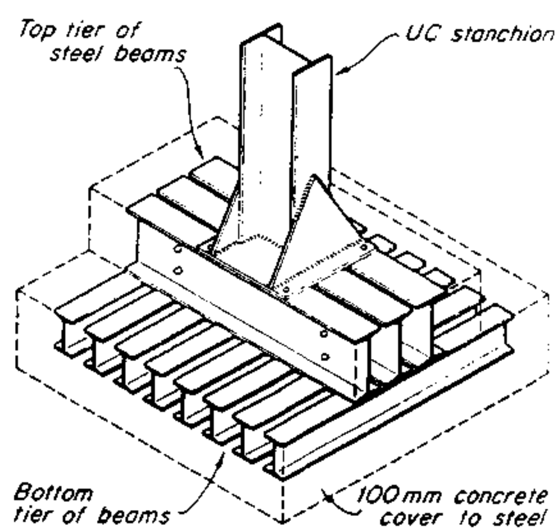
Its thickness is governed by the same considerations as for strip foundations and is made not less than the projection of the slab beyond the face of the pier or column or the edge of the baseplate of a steel column.

It should in no case be less than 150 mm thick. As in the case of strip foundations when a column base is very wide a reduction in thickness may be effected by reinforcing the slab.

In a framed structure where loads on different columns vary, the sizes of the bases must vary in order to maintain equal soil pressure under each and thus eliminate differential or unequal settlement.



Pad or slab foundation



Steel grillage foundation

RAFT FOUNDATIONS

5.3.3.5 Raft foundations

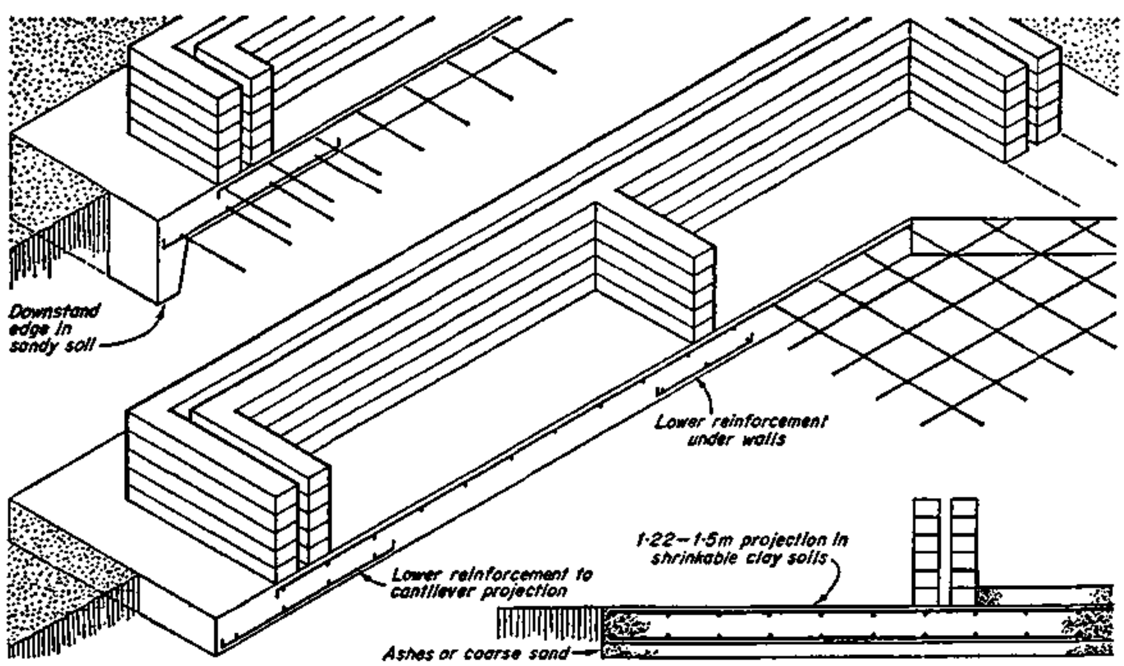
A RAFT FOUNDATION is a large slab foundation covering the whole building area, through which all the loads from the building are transmitted to the soil. When used for the purposes described here they are laid on, or just below the surface of the ground and are termed surface rafts.

Solid concrete ground floor slab construction is normal today. This slab, if about 150 mm thick and lightly reinforced, may be used as a light raft on all types of firm soils. Reinforcement is required at the top for crack control with some steel at the bottom under walls or columns to resist tensile stress in these zones, see fig. The raft should be extended about 300 mm beyond the perimeter walls. On sands it is preferable to form a 'downstand'edge all round to prevent erosion of the soil under the perimeter of the slab. If used on shrinkable clays the soil under the external walls should be protected from moisture changes and consequent movement by an extension of the slab 1.22 m to 1.5 m beyond the walls, see fig.

In this case reinforcement is generally as for rafts on other soils but top and bottom reinforcement must be provided under the external walls and in the extension to resist the tensile stresses at the top due to loads on the extension when the soil has shrunk under the slab edge and at the bottom due to the pressure of the clay when it swells.

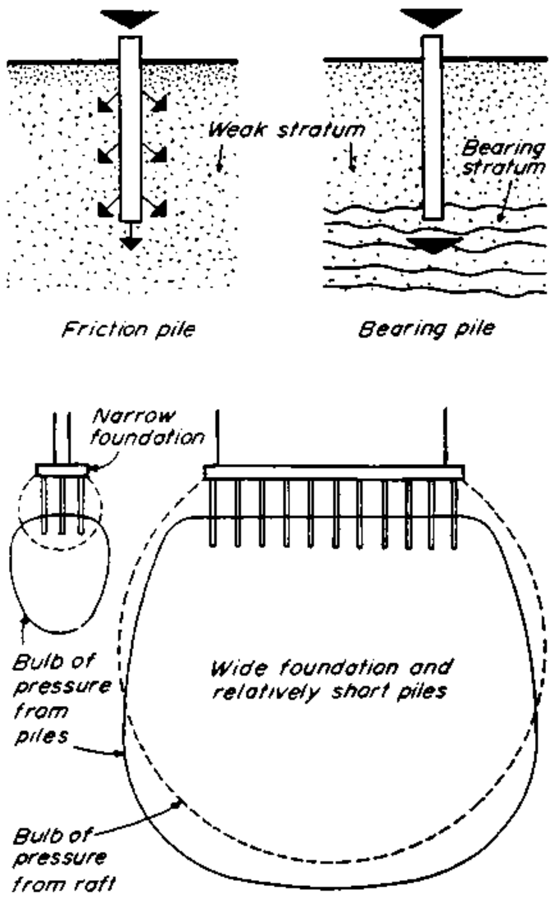
Light surface rafts can also be used to carry lightly loaded structures of certain types on soils subject to general earth movement.

As in all spread foundations the centre of gravity of the loads should coincide with the centre of area of the raft. This is facilitated when the building has a simple regular plan form with loadbearing elements such as walls, columns, stacks, disposed symmetrically about the axis of the building. Heavy elements such as stacks are best situated near the centre of the plan Excessive variation of loading results in problems which need careful consideration in the design of the foundation.



Surface raft foundation

PILE FOUNDATIONS



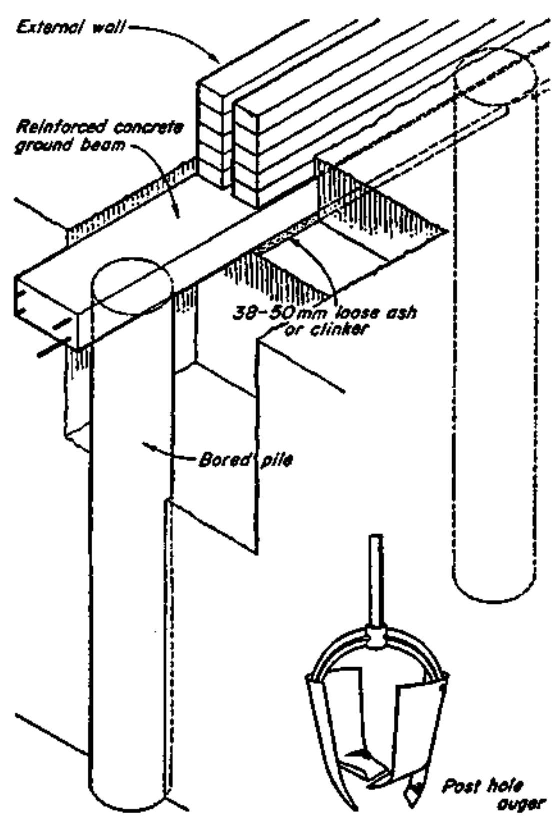
Pile foundations

5.3.4. Pile foundations

PILES are often used to transmit loads through soft soils or made-up ground. IN such circumstances, unless large in diameter, the piles will normally need to be reinforced. Piles of relatively short length can, however, be used economically in firm shrinkable clay as a means of founding below the zone of moisture movement. Such piles require no reinforcement because the diameter being large relative to length, the piles are stiff and they also receive considerable support from the firm soil through which they pass. In this type of soil the piles can be easily and quickly formed by boring. This particular form of pile is, therefore, called a short bored pile.

5.3.4.1 Short bored pile foundations

In shrinkable clays this foundation has a number of practical advantages over strip foundations: a reduction in the amount of excavated spoil, a cleaner site, faster construction and the fact that work can continue in weather which would make tranch digging impracticable. When mechanically bored in sufficient numbers this type of foundation is competitive in cost with a traditional strip foundation of appropriate depth. For a single building it may be slightly dearer than a deep strip foundation, although against this must be placed the advantages of the piles. Generally speaking, the stiffer the clay the cheaper will this type of foundation be relative to strip foundations.



Short bored pile foundation

In order to obtain the advantages of greater speed and economy relative to strip foundations the clay must be suitable for easy boring. If many tree roots are present and the soil contains a great number of stones, especially if large, trench digging is likely to be quicker and cheaper than boring for piles, although if mechanical boring can be used, auges larger than hand boring will permit can be adopted which cope more easily with stones.

Mechanical boring is much quicker than hand boring, especially when the holes must be large, but to be economic requires a sufficiently large contract of work on one site and, as for any mechanical plant, requires adequate preparation of the site and the programme of work to be carefully planned in advance to avoid idle time.

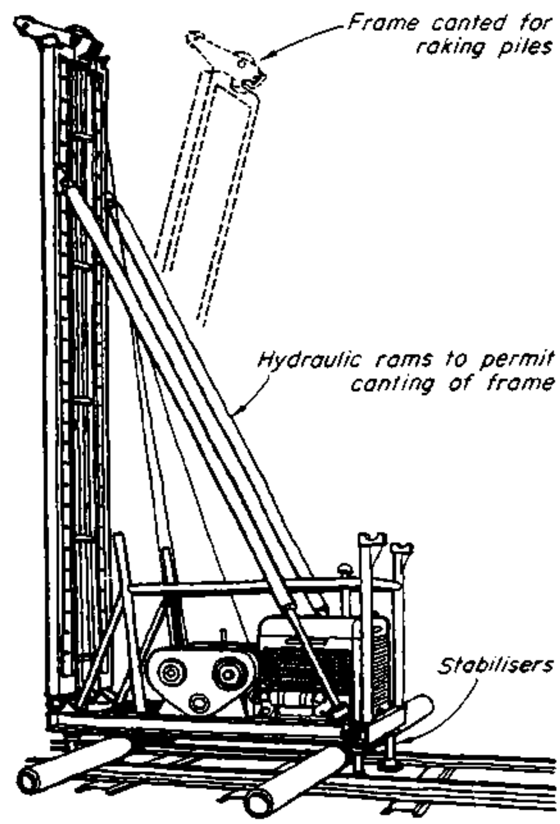
This type of foundation consists of a series of short concrete piles which, in the case of load-bearing wall structures, are spanned by a shallow reinforced concrete beam on which the wall is built (see fig.). Holes for the piles are bored manually or mechanically on the centre line of the beams to the required depth and diameter (see fig.). Small stones and layers of gravel present no problem but large stones must be broken up by a heavy chisel on extension rods. Larger augers cope with stones more easily than smaller ones but above 350 mm diameter the weight of the spil is too great for easy hand boring. A 250 mm diameter hole can be sunk 2.4 m in about 60 minutes, including rest periods, in soil free from stones.

In framed structures a pile or group of piles is placed under each column. In loadbearing wall structures piles are placed at the corners, at wall junctions and under stacks with further piles distributed between, sufficient to carry the imposed load, spaced as far as possible to produce uniform loading and to bring ground floor door and window openings centrally between piles.

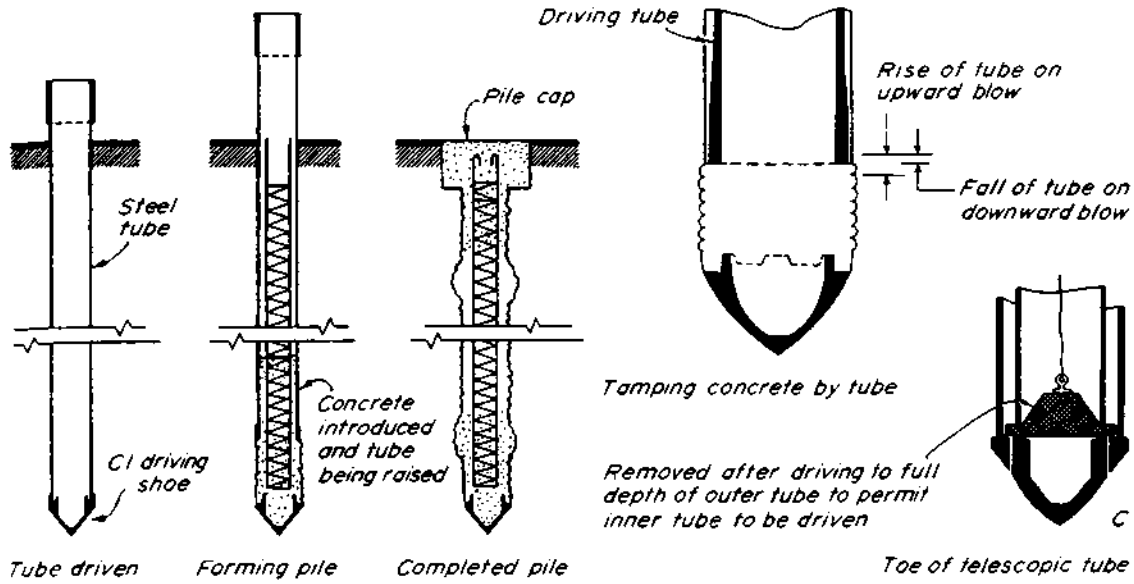
Soil strength classification	*Diameter of pile (mm)*	*Length of pile (m)*			
		2·4	3·05	3·66	4·27
		kN	kN	kN	kN
Stiff—cannot be moulded with fingers	254	40	50	60	70
(unconfined shear strength	305	50	60	75	90
more than 72 kN/m²—see Part 2)	356	65	80	95	110
Hard—brittle or tough	254	55	65	80	90
(unconfined shear strength	305	70	85	100	115
more than 143 kN/m²—see Part 2)	356	95	110	125	140

The figures are for clay which increases in strength with depth to the 'stiff' and 'hard' classifications near the bottom of the piles. The figures should not be applied to piles in other situations.

Table 12 Permissible loads on short bored piles
Based on information in BR Digest 67 (second series)



Piling frame



Top driven tube piles

The shallow reinforced concrete ground beams should have a depth/span ratio of 1/15 to 1/20. Reduced 'equivalent bending moments' are used in their design taking account of the fact that the brickwork on the beam tends to act with the beam and as an arch tending to concentrate the load towards the supports. Top reinforcement is placed over the pile positions to take up the negative tensile stresses at these points.

A 1:2:4 mix concrete is used for the work with a miminum water content to prevent excessive wetting and thus weakening of the clay. This is placed immediately each hole is bored, using a hopper to prevent soil entering the hole, each 305mm to 610 mm lift being thoroughly tamped. The beams are normally cast in a trench to avoid shuttering. If this is excavated before the holes are bored the concreting of piles and beams can be done simultaneously. If the beams are to be poured after the piles have set 9.5 mm diameter steel bars should be cast in the tops of the corner piles, set 610 mm in the pile and projecting 610 mm and bent over for casting in with the beams. A layer of 38 mm to 50 mm of loose ash or clinker must be placed under the beam to form a compressible layer to allow for ground movement below the beam.

Where trees exist on shrinkable clay soil closer to a building than their mature height or, in the case of groups or rows of trees, one and a half times their mature height, this type of foundation should always be used.

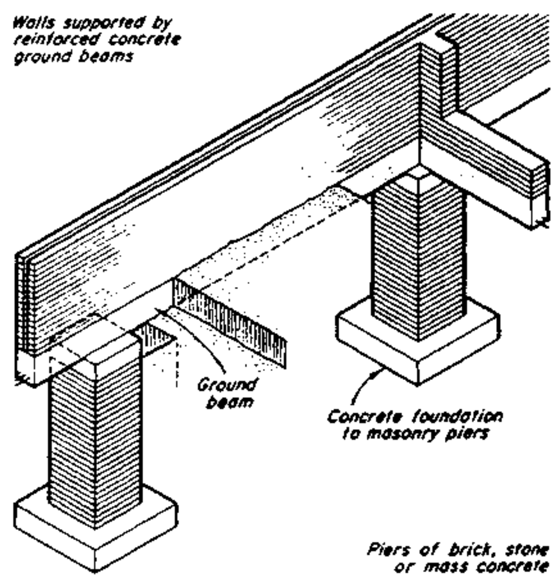
PIER FOUNDATIONS

5.3.5 Pier foundations

These are frequently used on made-up ground where ordinary strip or pad foundations will often be inadequate to prevent excessive and unequal settlement, especially when the fill is poorly compacted. They can be economic up to depths of about 3.5 m to 4.5 m and consist of piers of brick, stone or mass concrete in excavated pits taken to the firm natural ground below. They are usually square and the size is dependent on the material used and the strength of the bearing soil below, but the smallest hole in which hand excavating can be carried out is about 1 m square. The foundation size is calculated as for a column base.

When this type of foundation is used the structure is carried on reinforced concrete ground beams spanning between the piers as shown in the fig.

Piles may be used in similar conditions but will need to be reinforced and as boring is not suitable through many types of fill on made-up ground piers provide a useful alternative within the economic limits of depth given above.



Pier foundations

•REPETITION••exercises••REPETITION•

Try to answer the following questions and use sketches for illustration

1. Foundations

   - Define the purpose of FOUNDATIONS!

2. Soil Investigations

   - When becomes SITE EXPLORATION necessary?
   - What has to be considered digging TRIAL HOLES?
   - Where are BOREHOLES used for and how are they made?
   - Write notes on soil sampeling!
   - Which tests are most important to the foundation designer and how are they carried out?
   - Describe the LOAD or BEARING TEST!
   - Write notes on SOILS and SOIL CHARACTERISTICS!
   - Classify rocks and soils into 5 groups and describe briefly the type of soil of each group as well as their max. safe-bearing capacity.
   - Explain the following terms:
     . shearing stress
     . vertical pressure
     . contact pressure
     . plastic failure

3. Excavations and Timbering
   - What do you have to consider in EXCAVATIONS and TIMBERING of trenches?

4. Types of Foundations
   - Classify the many forms of foundations
   - Which factors must be taken into account in the CHOICE OF FOUNDATIONS?
   - Write notes on
     . spread foundations
     . strip foundations
     . deep strip foundations
     . stepped foundations
     . pach foundations
     . raft foundations
     . pile foundations
     . short bored pile foundations
     . pier foundations

   and use neat sketches for illustration.

6. Walls

6.1 Function and Properties of Walls

- Walls are the vertical ele - ments of a building

- They have to fulfill two func- tions:
  (1): Loadbearing
  (2): space enclosing and di- viding

- There are certain requirements which a wall must satisfy:
  Adequate - strength and stability
  - weather resistance
  - thermal insulation
  - fire resistance

  (these functional requirements are not given in order of im - portance, since this will vary with the main function of the wall).

- STRENGTH and STABILITY:
  The strength of a wall is mea- sured in terms of its resistance to the stresses set up in it
  o by its own weight
  o by superimposed loads and
  o by lateral forces (such as wind)
  Its stability in terms of its resistance to overturning
  o by lateral forces and
  o by buckling caused by excessive slender- ness.

The Building Regulations (which lay down requirements for the cal- culation of wall thicknesses) provide means for determining thicknesses other than by calcu- lating.

The Table below gives
RULES FOR DETERMINING THE THICK- NESS OF BRICK AND BLOCK WALLS (NON-CALCULATED)

TABLE 19 RULES FOR DETERMINING THE THICKNESS OF BRICK AND BLOCK WALLS (NON-CALCULATED WALLS)

Rule Number	Type of Wall	Building of which Wall Forms a Part	Height of Wall	Length of Wall	Minimum Thickness of Wall	Additional Requirements as to Thickness and Construction of Wall
1	Certain external walls and and separating walls not exceeding 12 m high	1. Single storey 2. Two storeys or more if the imposed load on each floor is less than 3 kN/m²	Not exceeding 3.6 m	Any length	200 mm for the whole height	(i) Subject to Rules 4 to 8 below the thickness of these walls shall be as in adjoining column. (ii) In addition the thickness of the wall, in any storey, for not less than one-quarter of its length, shall not be less than one-sixteenth of the height of that storey.
			Exceeding 3.6 m but not exceeding 9 m	Not exceeding 9 m	200 mm for the whole height	
				Exceeding 9 m	300 mm from the base for the height of one storey and 200 mm for the rest of its height	
			Exceeding 9 m but not exceeding 12 m	Not exceeding 9 m	Ditto	
				Exceeding 9 m	300 mm from the base for the height of two storeys and 200 mm for the rest of its height	
2	Certain other and external walls and separating walls not exceeding 12 m high	Other than those in Rule 1	Not exceeding 7.5 m	Unlimited	Subject to Rules 4, 5, 7 and 8, the thickness must be not less than 300 mm (200 mm for the top storey)	(i) In addition (*a*) the thickness of the wall between the base and 5 m below the top shall not be less than the thickness which would be obtained if the wall were to be built solidly throughout the space between straight lines drawn on each side joining the thickness at the base to the thickness at 5 m below the top. (*b*) The thickness of the wall in any storey for not less than one-quarter of its length to be not less than one-fourteenth of the storey height. (*c*) No offsets allowed in the wall except at the level of lateral supports.
			Exceeding 7.5 m but not exceeding 9 m	13.5 m		
			Exceeding 9 m but not exceeding 12.2 m	10.5 m		
3	Certain internal load-bearing walls (excluding a separating wall)	Any building other than a house of one or two storeys	Heights in Rule 1 or 2 (as the case may be) with lengths twice those in Rule 1 or 2 (as the case may be)		Half the thicknesses in Rule 1 or 2 (as the case may be)	
4	Certain external walls and separating walls of pier construction	Any	Heights and lengths in Rule 1 or 2 (as the case may be)		Subject to Rule 6, if the wall has piers distributed throughout its length and a pier at each end, the mean thickness of the wall (the plan area of the wall divided by its length) shall be not less than the thickness required by Rules 1 or 2 (as the case may be) and the thickness of the wall between the piers shall not be less than 200 mm.	
5	Cavity walls. *Ties placed 900 mm apart horizontally and 450 mm vertically, with an additional tie every 300 mm height at jambs to openings. Cavity not less than 50 mm or more than 75 mm wide.*	Any	Heights and lengths in Rule 1 or 2 (as the case may be)		Leaves to be not less than 100 mm thick. The overall wall thickness shall be not less than (i) 250 mm, or that required for a solid wall by Rules 1 or 2 (as the case may be) increased by the cavity width, *whichever is the greater.* Note that the *inner* leaf may be not less than 75 mm thick if: (*a*) the wall is of a single storey house or the upper storey of a two-storey house; and (*b*) the leaf is not more than 8 m long and 3 m high (5 m for a gable); and (*c*) the wall is built with mortar not weaker than 1 : 2 : 9; and (*d*) the number of ties given in column 2 is doubled; and (*e*) the roof load is supported by the outer leaf.	
6	External walls of certain small buildings and annexes	1. Single storey building other than a house if its width, measured in the direction of the roof span is not more than 9 m	Not exceeding 3 m	Any length	The walls may be not less than 100 mm thick provided: (i) it is bonded at each end and intermediately with piers or buttresses which are not less than 200 mm square on plan (including the wall thickness), or of such greater size as may be needed for stability, and so placed that the wall is divided into lengths not exceeding 3 m; and (ii) the wall is built with mortar not weaker than 1 : 1 : 6; and (iii) the wall is not subjected to any load other than the distributed load of the roof of the building or annexe of which it forms a part and is not subject to lateral thrust from such roof.	
		2. An annexe not more than 3 m high (*e.g.*, verandah, garage, tool shed, lavatory, etc.) attached to a house	Not exceeding 3 m	Any length		
7	Bays and gables over bay windows	Any	Rules 1 and 2 shall not apply to any part of an external wall which forms a bay for a bay window; and is above the level of the sill of the lowest window opening in such bay; and built with mortar not weaker than 1 : 2 : 9.			
8	Parapets	Any	Not to exceed six times the thickness	Any	Not less than 200 mm or that of the wall on which it is carried (whichever is the less)	

NOTES

Openings. The number and size of these shall not be such as to impair the stability of the wall. (It is considered that the maximum of window lengths in a wall is three-quarters of the wall length.)

Chases. Vertical chases to be not deeper than one-third of the wall thickness (one-third of the leaf thickness in cavity walls). Horizontal chases to be not deeper than one-sixth of the wall thickness (one-sixth of the leaf thickness in cavity walls).

RAIN

- WEATHER RESISTANCE:
  The external walls of a building are required to provide adequate resistance to rain and wind penetration.

The actual degree of resistance will depend
- upon the height of the wall and
- upon the locality and exposure.

- Wind penetration to walls rarely presents difficulties in solid wall construction only with some types of modern walling of dry construction (consisting of external cladding or sheathing and dry internal linings on some form of frame) problems may arise.

- Wind has considerable influence on rain penetration, forcing the water through pors and cracks which otherwise it might not penetrate (especially on high buildings).

WIND

- Rain penetration through walls can be resisted in three ways:

  (1) by ensuring a limited penetration only into the wall thickness
  (2) by preventing any penetration through the outer surface
  (3) by interupting the capillary paths through the wall.

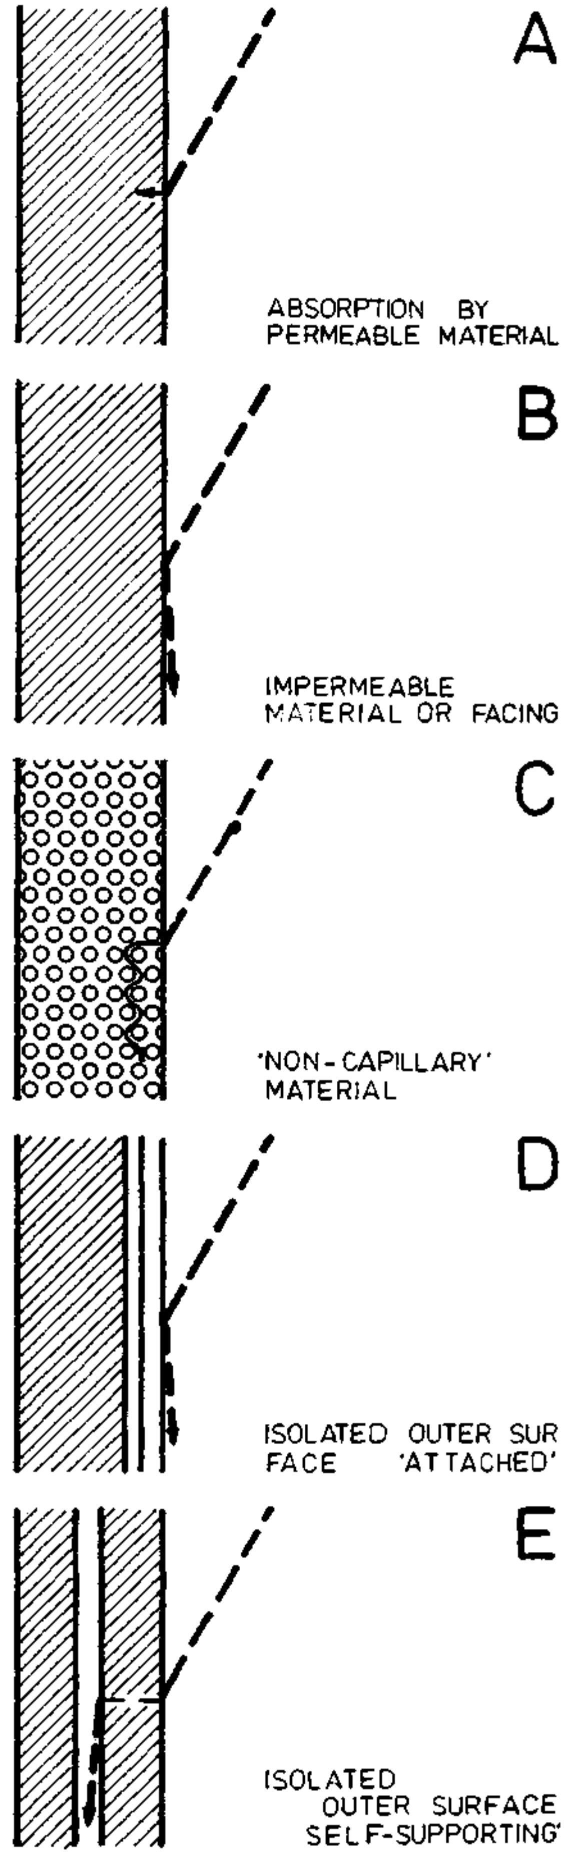
  o In the first the water will be absorbed by a premeable walling material and held as in a sponge, near the outer surface until dry weather conditions, permit it to evaporate

  o In the second the use of an impermeable walling material (or facing) will force the water to run down the wall face without entering the wall thickness
    - (Both methods present difficulties)-

  o The alternative to either the first or the second is the third method:
    The breaking of the capillary paths by the use of a solid wall structure in which no capillary path exist such as:

RAIN

- no-fines concrete (composed of cement and coarsed aggregate alone, the fine aggregate being omitted) or
- by the provision of an outer surface which is isolated from the inner surface by a continous gap or cavity. The outer surface or skin may be non - load bearing (i.e. tile hanging or large suspended cladding panels, or load bearing as in cavity wall construction)
- In addition to protection against lateral penetration of rain a wall must be protected at his base against ground moisture, in form of horizontal and vertical damp - proof. barries. Protection may be also necessary against the entry of subsoil water under pressure through basement walls.



FIRE

BS 476
PART 8 1972

- FIRE RESISTANCE:
  According to the Building Regulations chapter 5:
  'FIRE RESISTANCE of an element of structure, a door, or other part of a building means the period of time for which a specimen construction (of the same specification as the particular element, door, etc.) would satisfy the requirements of the test by fire to BS 476 : Part 8 1972 in respect of
  a) stability
  b) integrity and
  c) insulation'

  The term fire resistance is a relative term applied to elements of structure and not of material. It is not to be confused with non-combustibility.

THERMAL INSULATION

- THERMAL INSULATION:
  The external walls of a building, together with the roof must provide a barrier to the passage of heat in order to maintain satisfactory internal conditions without the wasteful use of an air conditioning system.
  Adequate thermal insulation depends mainly on the locality where the building will be erected. (At the coast region other provisions have to be introduced than in regions like Arusha, Iringa or Mbeya.)
  . Heat trnsmission values for various forms of construction are given in special handbooks (i.e. Mitchel Building Construction: Enviroment and Services) where the principles of thermal insulation are fully discussed.

WALL under LOAD

6.2 The Behavior of the WALL under load

- Under vertical loading, a wall may
  - o crush
  - o buckle or
  - o settle.

-crushing
-buckling
-settling

- CRUSHING:
Is caused by over-stressing the material of which the wall is constructed. This is avoided by adequate thickness at all points to keep the stresses in the wall within the safe compressive strength of the materials.

Eccentric loading (that is loading applied not through the centre of gravity of the wall) has the effect of increasing the compressive stress in the wall on the loaded side and of decreasing it on the unloaded side and tends to cause bending in the wall whatever its thickness.

The reason:
A moment is set up in the wall and to maintain equilibrium this must be resisted by an opposite moment within the wall (the forces for which must be provided by the walling material itself.)

This causes COMPRESSION on one side of the axis of the wall and TENSION on the other

The result of this can be twofold:

1 the increased compressive stress could become greater than the safe compressive strength of the walling material.

2 if the eccentricity is too great tensile stresses will be set up in the side opposite that on which the load is applied.

Fig. indicates the increasing compressive stress and the development of tensile stress with increasing eccentricity of load.

In practice the actual stresses in the wall are determined by the formula

$$\frac{W}{A} \pm \frac{We}{Z}$$

Where $\frac{W}{A}$ = stress due to the load applied axially

We = moment caused by eccentric loading

Z = a geometrical property relating to the shape and size of the crossection of the wall such that

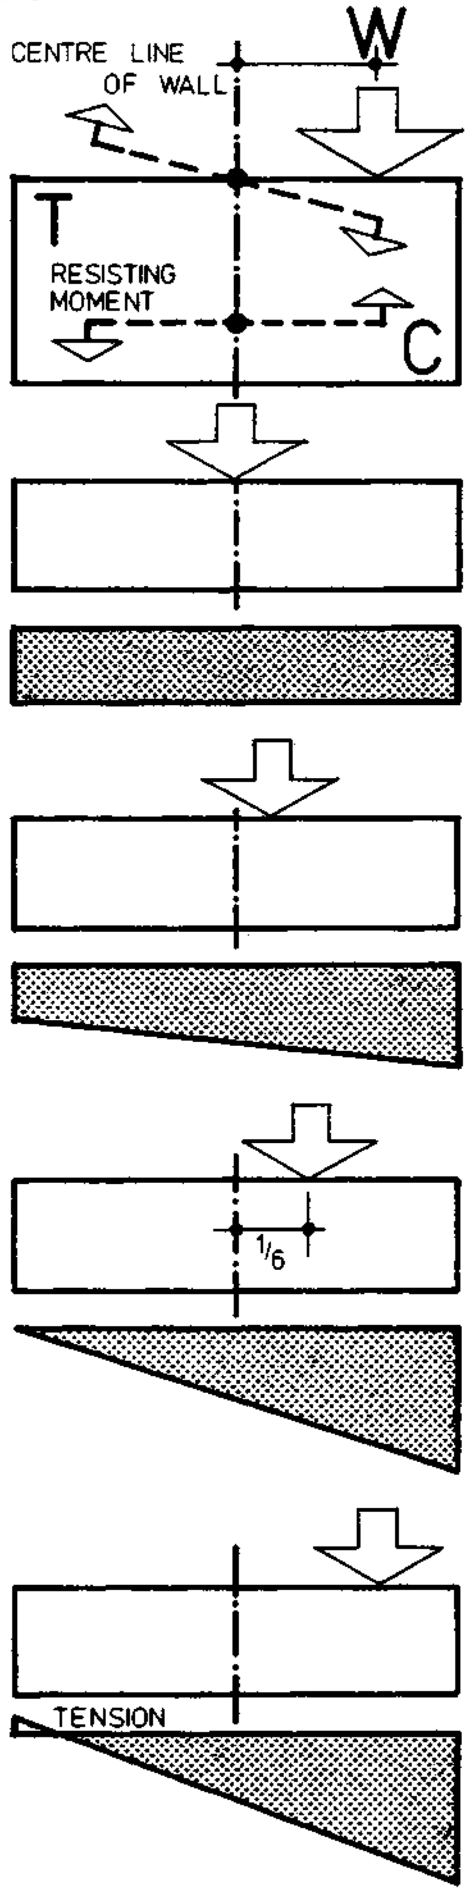
$\frac{We}{Z}$ = stress at the faces of the wall due to eccentric loading.

Z: Methods for computing this for any given section are given in standard textbooks on the theory of structures.

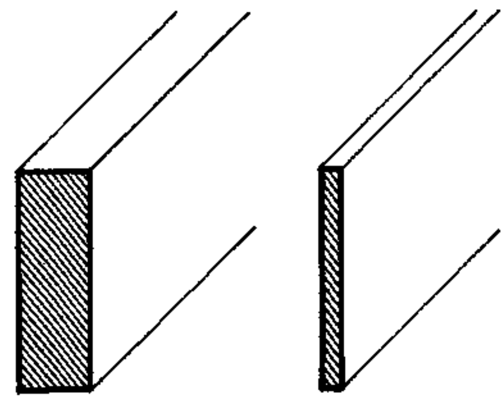
- tension will occur when the eccentricity is greater than 1/6 of the wall thickness.

- when the stress due to eccentric loading are too great they are reduced either by reducing the eccentricity or by increasing the thickness of the wall.

The last has the double effect of reducing the relative eccentricity and of increasing the value of Z.



- BUCKLING
  Will accur when the thickness of the wall is small relative to its height. Short walls or piers ultitately fail by crushing, but as the height increases they tend to fail under decreasing loads by buckling.



The terms "SHORT and TALL' in this context are relative to the thickness of the wall not to its actual height. They are defined in terms of the ratio of unsupported height to horizontal thickness known as

SLENDERNESS RATIO

The greater this is the tendency to buckle. Buckling is not related to the <u>strength of the walling material</u> but to the <u>stiffness of the wall</u>.

Buckling may be controlled either by
- o restricting height,
- o increasing thickness
- o stiffening by buttresses
- o intersecting walls or by
- o reducing the applied load.

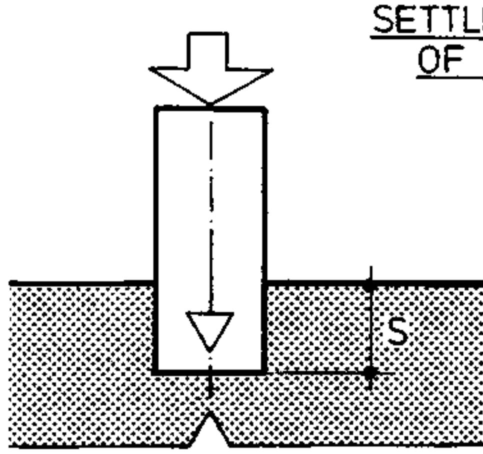
- SETTLEMENT
  The downward force of a wall must be resisted by an equal, upward reaction from the soil on which it rests in order to maintain equilibrium.

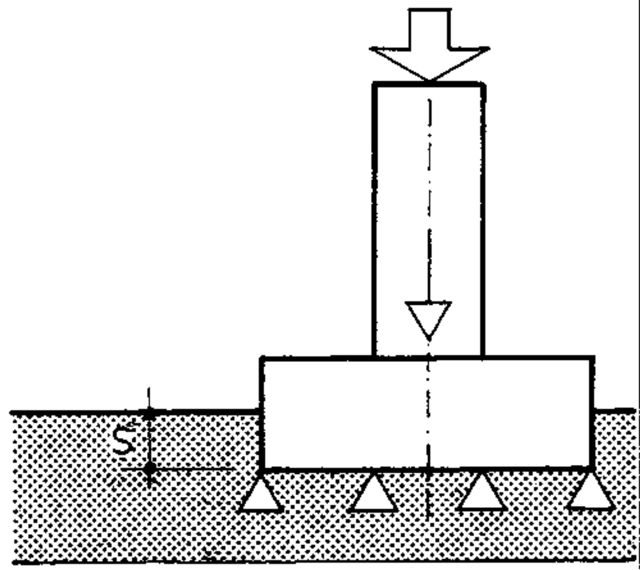
  Soils vary in strength (some, verging on rock, are very strong, other are relatively weak).

  All of these consolidate under-load but rock can resist very high stresses with little consolidation while the same stresses would cause excessive consolidations in others.

  This consolidation causes a vertical downward movement of the wall which is known as SETTLEMENT.

SETTLEMENTS OF WALLS

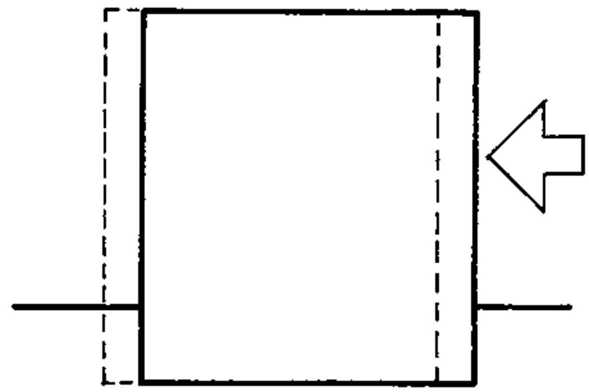




In order to keep the settlement within acceptable limits, the base of the wall has to be made of such a size that the load is distributed over a sufficiently large area of soil.

- Under horizontal loading a wall may
  - o slide or
  - o overturn

- SLIDING
  Occurs more likely in a free-standing wall than in a wall forming part of a building.



SLIDING

<u>Friction</u> and the <u>passive pressure of the soil</u> on which the wall rests are utilized to prevent sliding action.

The amount of friction (or the frictional resistance) depends upon the weight exerted on the soil. That is the pressure between the two surfaces, and upon the degree of smoothness of the surfaces

The ratio of frictional resistance to weight is constant.

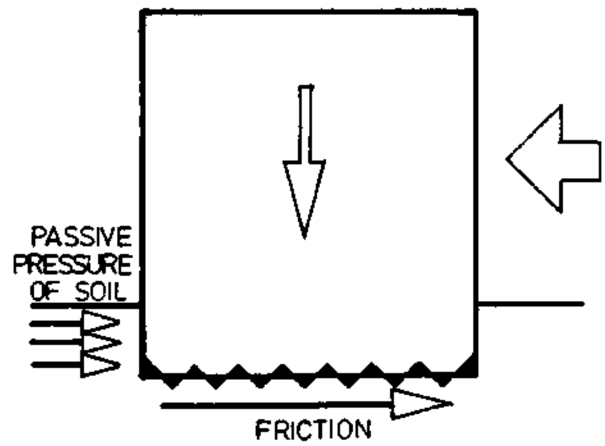
The ratio is termed COEFFICIENT OF FRICTION and varies according to the types of surface in contact.

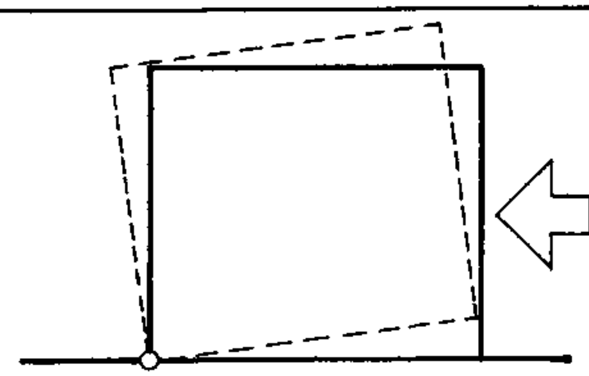
Therefore:

Frictional resistance = coefficient of friction x weight.

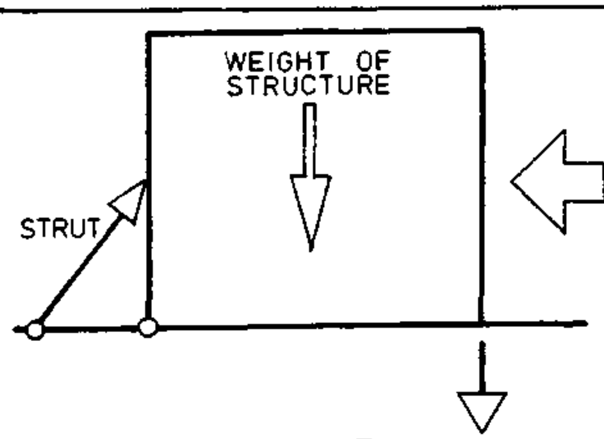
The other force which may resist the tendency of the wall to slide is the passive pressure of the soil.

The stresses in the soil caused by this pressure must be kept within the safe limits of the particular soil by taking the wall deeper into the soil (so that the pressure is distributed over a greater area.





OVERTURNING



TENSION ELEMENT

- OVERTURNING
  may be caused by

  1 rotation or
  2 settlement.

Overturning by rotation occurs when the counter-moment We set up by the weight of the wall acting through its centre of gravity is too small to resist the moment Fe set up by the overturning force.

In these circumstances the resultant of the weight of the wall W and the overturning force F falls outside the base of the wall so that the base is wholly under tension and overturning occurs.

To prevent this:
The weight of the wall can be increased by increasing

its height
or thickness.

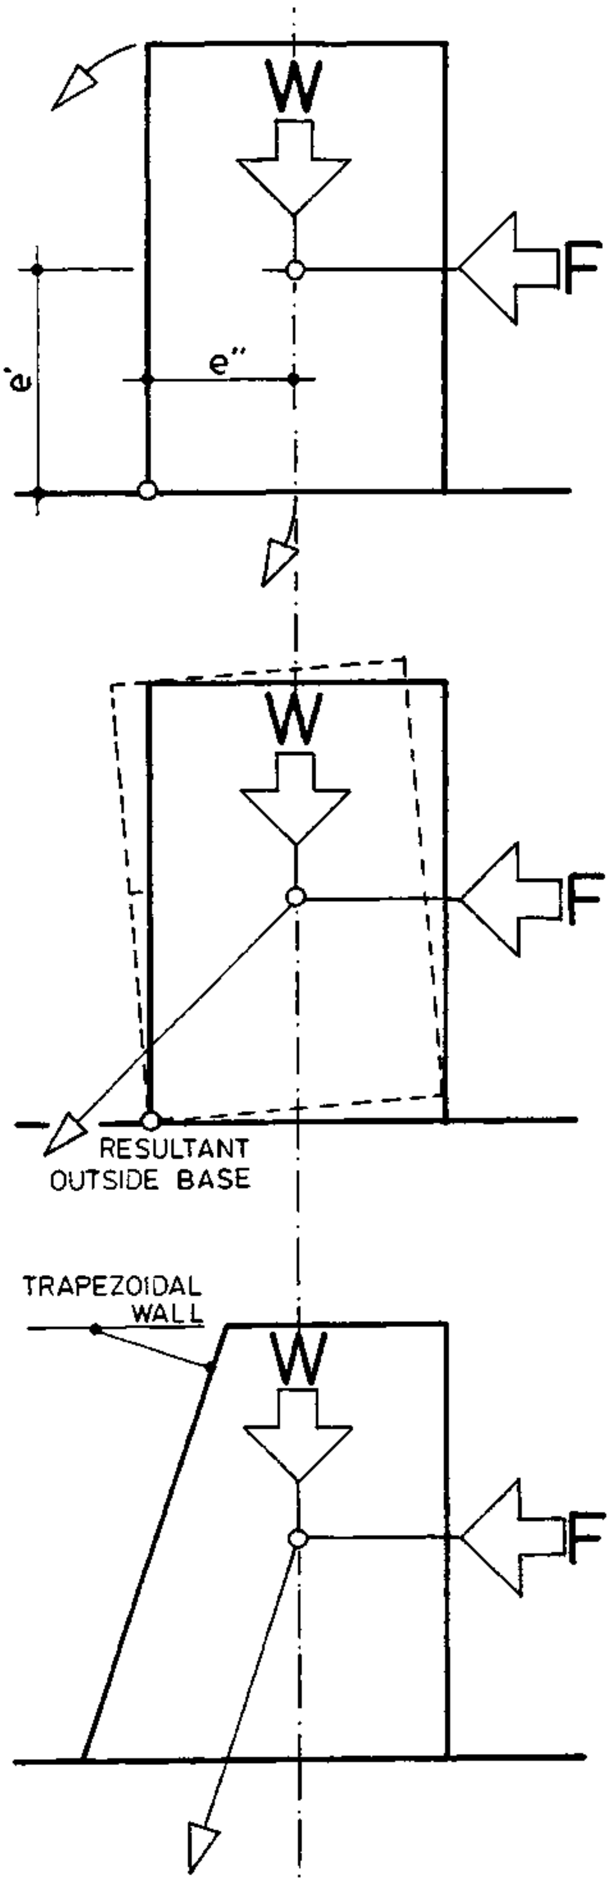
The latter is most beneficial because it also increases the width of the base within which the resultant must fall.

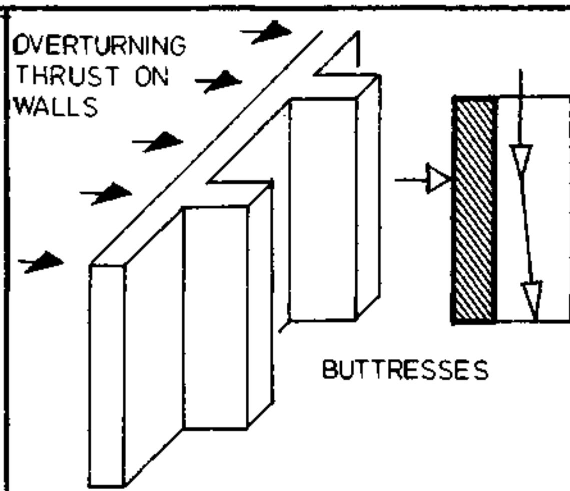
Alternatively (or in addition) the shape of the wall may be made trapezoidal to shift its centre of gravity relative to the base towards the overturning force thus reducing the eccentricity of the resultant at the base.

Another alternative is to use Buttresses

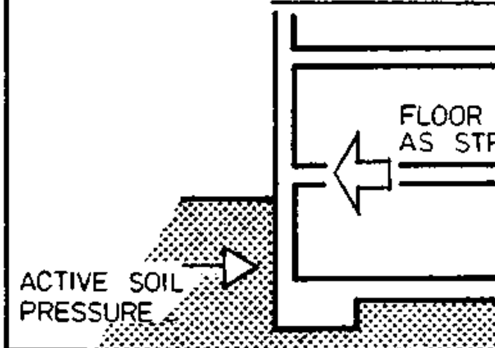
These methods are adopted for walls having little tensile strength. Alternative and (in case of tall walls) more ecconomic methods may be adopted when materials with adequate tensile strength are used, such as reinforced concrete.

The use of a strut to prevent rotation may be adopted and where a wall undergoing a lateral force forms part of a building a floor can often be made to function as a strut.





STABELISING of WALLS



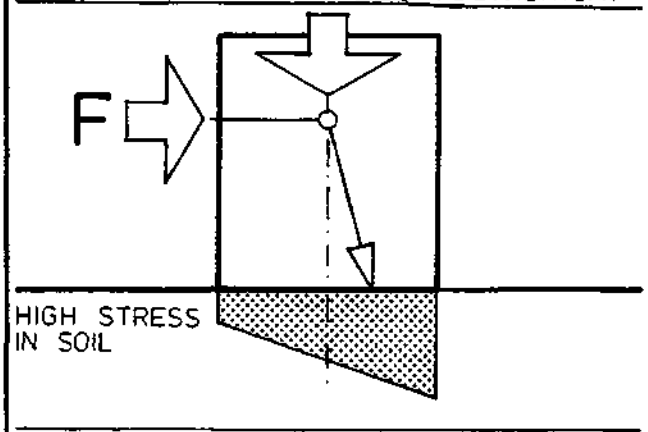
- OVERTURNING due to SETTLEMENT: may occur though overstressing of the soil causing excessive consolidation under the wall and the overturning force will always cause excentric pressure at the base of the wall leading to simular stress distributions to those in an eccentrically loaded wall.

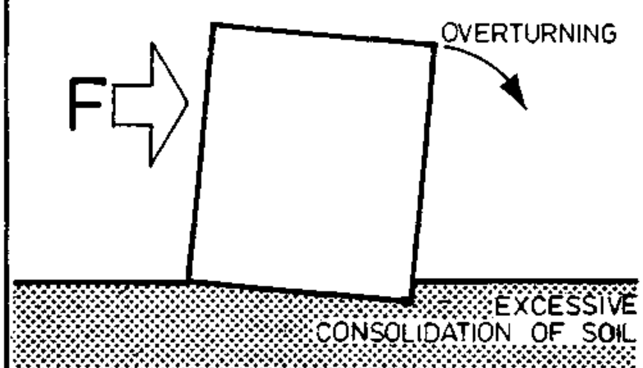
  This will result in a distribution of pressure in the soil with a pressure at the toe which might be considerably greater than the average pressure.

  If this overstresses the soil, excessive consolidation might occur at this point causing overturning through unequal settlement of the wall.

  This problem can be overcome by reducing the eccentricity of the resultant
  - o by increasing the thickness of the wall or
  - o by increasing the width of its foundation, or
  - o by making the wall trapezoidal in shape.

OVERTURNING of WALLS : settlement





CALCULATION of WALL THICKNESS

Calculation of wall thickness:

For determining the thickness of walls and piers certain terms have to be defined in relation to this.

SLENDERNESS RATIO

- SLENDERNESS RATIO = the ratio of effective height to effective thickness. (But in the case of walls it may be based alternatively on the effective length. if this is less than the effective height. This takes account of the stability which is provided by vertical as well as by horizontal lateral supports

EFFECTIVE HEIGHT

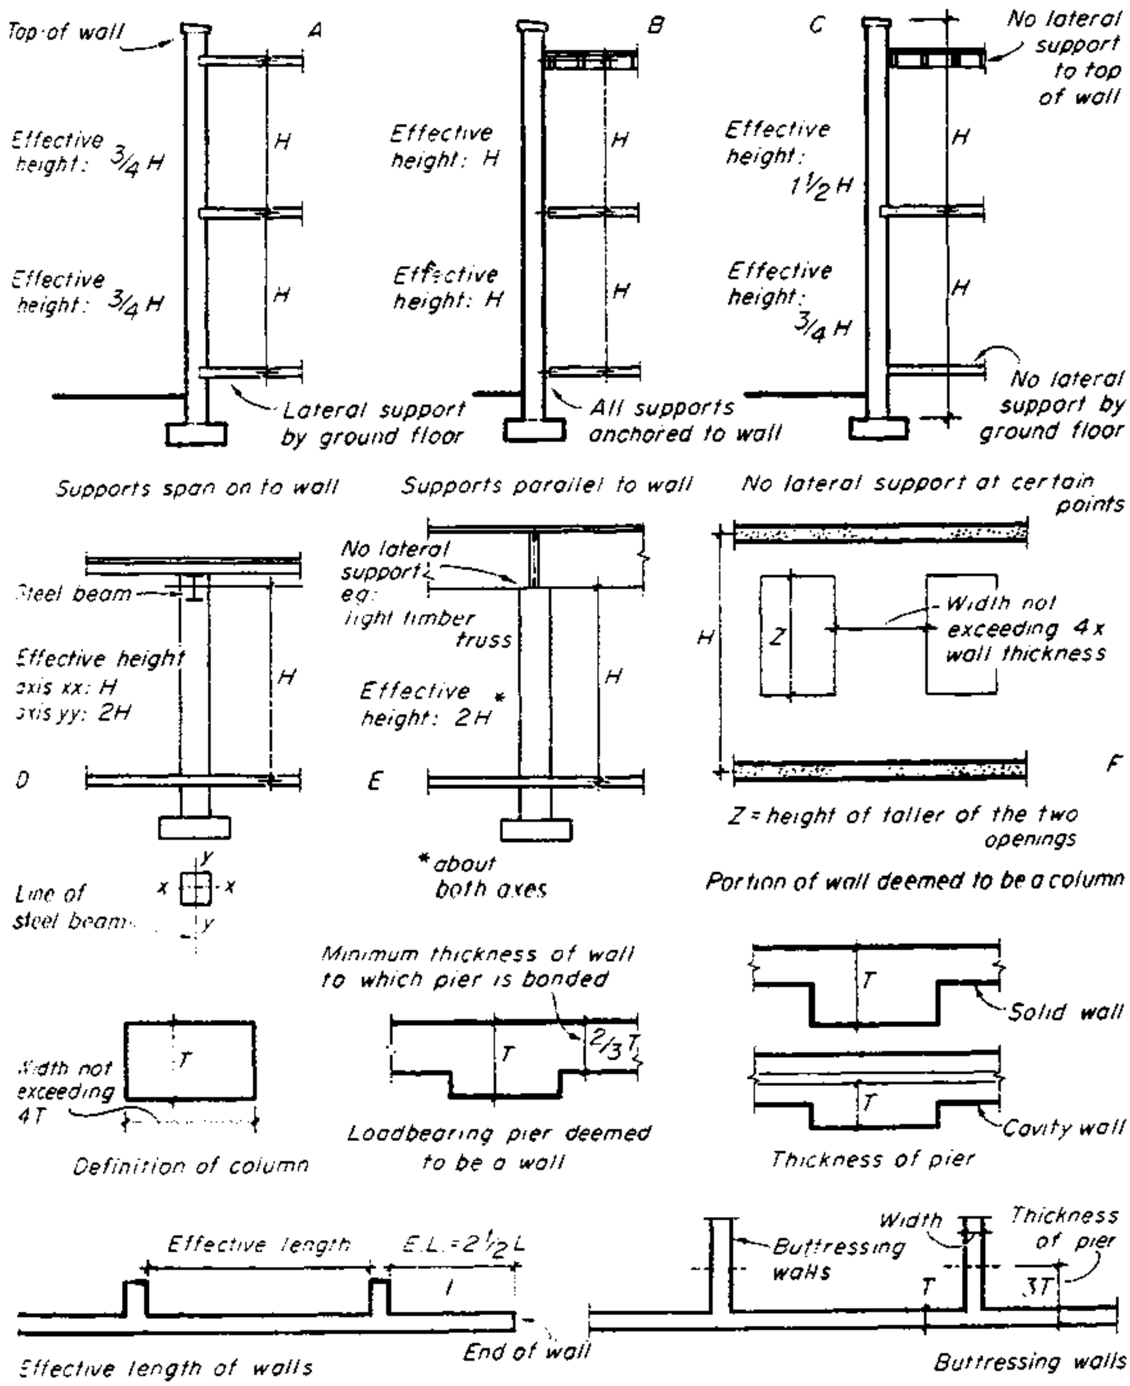
- EFFECTIVE HEIGHT = is based on the distance between adequate lateral supports provided by floors and roof and depends upon the degree of support they are assumed to provide. The greater the degree of support the smaller is the proportion of the distance between centres of support taken as the effective height. This is illustrated in the figures A to C in respect of walls and D, E in respect of columns.

  Columns must be considered about both axes. If lateral support is provided in one direction only, as indicated by the beam in (D), the effective height relative to that direction will be as shown, but in the other direction it must be twice its height above the lower support. In the absence of any top support (E) the latter value must be taken relative to both directions.

  Where the wall between two openings constitutes a column as in (F) its effective height is based upon the height of the taller of the openings, Z. Where Z does not exceed H/2 the effective height is 1 1/2Z. Where Z exceeds H/2 it must be taken as 1 1/2 Z or H, whichever is the less.

CALCULATED WALLS

- EFFECTIVE HEIGHT
- EFFECTIVE LENGTH



6. WALLS compiled: D.VOLKE JULY '80	CALCULATED WALLS	BUILDING CONSTR. — LECTURE — CET 3031/1 6.2 14

EFFECTIVE LENGTH =

EFFECTIVE LENGTH = This is the distance between adjacent piers, buttresses or intersecting or return walls. The effective length of the end of a wall with no end stiffening is shown in the figure.

EFFECTIVE THICKNESS = This is the actual thickness of a solid wall excluding plaster, rendering, or any other applied finish or covering. Allowance is made for any stiffening piers which may be bonded to the wall by multiplying the actual thickness by a factor which varies with the size and spacing of the piers, resulting in an effective thickness greater than the actual thickness. Table 1 gives these factors. (Buttressing or intersecting walls may be considered as pier of width equal to the thickness of theintersecting wall and of a thickness equal to three times the thickness of the stiffened wall (figure).

If a column has no lateral support or has support in both directions the effective thickness will be based on the least dimensions, and the larger be adopted.

The maximum values for the slenderness ratio of masonary walls are shown in table 2

In many buildings where loading is light and the necessary wall thickness is small the slenderness ratio becomes the controlling factor, limiting as it does the height for any given thickness.

Thickness of pier / *Thickness of wall*	*Pier spacing* / *Width of pier* 6	8	10	15	20
1.0	1.0	1.0	1.0	1.0	1.0
1.5	1.2	1.15	1.1	1.05	1.0
2.0	1.4	1.3	1.2	1.1	1.0
2.5	1.7	1.5	1.3	1.15	1.0
3.0	2.0	1.7	1.4	1.2	1.0

Brickwork or blockwork set in other than hydraulic lime mortar	27
ditto in walls less than 90 mm thick in buildings of more than two storeys	20

Table 2 *Maximum permitted slenderness ratios*

PERMISSIBLE STRESS

PEMISSIBLE STRESS = The stresses permitted in a wall or column are regulated according to the strength of the bricks or blocks, the type of mortar to be used and the slenderness ratio of the wall or column. Basic stresses, arising from combined uniformly distributed dead and superimposed loads and rebted to the strength of the units and the type of mortar used, are shown in table 3.

Table 3 *Basic stresses for masonry walls*

Non-hydraulic	0.21	0.23	0.42	0.55	0.60	0.70	0.75	0.85	1.05

* The inclusion of lime in cement mortars is optional

† These periods should be increased by the full amount of any time during which the air temperature remains below 4.4°C plus half the amount of any time during which the temperature is between 4.4°C and 10°C

‡ Linear interpolation is permissible for units whose crushing strengths are intermediate between those given in the table

§ Plasticizers must be used according to manufacturers' instructions

‖ Masonry cement mortars must be used according to manufacturers' instructions, and mix proportions of masonry cement to sand should be such as to give comparable mortar crushing strengths with the cement: lime: sand mix of the grade

¶ A longer period should ensue where hardening conditions are not very favourable

Note: Where the cross-sectional plan area of a wall or column does not exceed 0.3 m^2, the basic stress should be multiplied by a reduction factor equal to

$$0.75 \times \frac{A}{1.2}$$

where A is the area (in m^2) of the horizontal cross-section of the wall or column

REDUCTION FACTORS FOR

Slenderness ratio	Stress reduction factor* Axially loaded	Eccentricity of vertical loading as a proportion of the thickness of the member 1/6	1/4	1/3†
6	1.00	1.00	1.00	1.00
8	0.95	0.93	0.92	0.91
10	0.89	0.85	0.83	0.81
12	0.84	0.78	0.75	0.72
14	0.78	0.70	0.66	0.62
16	0.73	0.63	0.58	0.53
18	0.67	0.55	0.49	0.43
20	0.62	0.48	0.41	0.34
22	0.56	0.40	0.32	0.24
24	0.51	0.33	0.24	–
26	0.45	0.25	–	–
27	0:43	0.22	–	–

*** Linear interpolation between values is permitted**
† Where in special cases the eccentricity of loading lies between $\frac{1}{3}$ and $\frac{1}{2}$ of the thickness of the member, the stress reduction should vary linearly between unity and 0.20 for slenderness ratios of 6 and 20 respectively

Table 4 *Reduction factors for slenderness ratios*

SLENDERNESS RATIO

For members with slenderness ratios up to six the basic stresses in the wall or column must be established by the application of a reduction factor to the basic stress. Values for this factor for varying slenderness ratios and eccentricities of loading are given in table 4.

In order to keep the thickness of walls within reasonable limits and, preferably, of the same thickness for the full height of the building, particularly in the case of cross wall construction, variations in the types of bricks and in the mortar mixes are made according to the stresses at different heights. Excessive variation is uneconomic and leads to difficulties in supervision on the site. Sufficient flexibility in strength can, however, be obtained in most buildings by the use of three to four grades of bricks with one or two mixes of mortar.

A non-calculated brick or block wall shall have a thickness at any level not less than onesixtieth of the height measured from that level to thetop of the wall.

A minimum thickness of 190 mm at any point is required in the case of an external wall, whether calculated or not.

Walls built of materials of differing strengths bonded together are less important now as load-bearing structures since the general practice is to use a thin 'veneer' of non-structural facing material attached to a stuctural backing, but provision is made for dealing with such a combination in two ways. The weaker material may be considered to be used throughout the full thickness and the permissible stress established on that basis. Alternatively, the area of that portion of the wall built of the strongest material only may be considered as carrying the load, in which case the permissible stress is established using a slenderness ratio calculated on the thickness of that material alone.

Random rubble walling should be based on permissible stresses of 75 per cent of the corresponding stresses for coursed walling of similar materials.

PROCESS of DESIGN

The design process may be summarized briefly as follows:

1. Calculate total load (W) per metre run of wall or on column at level under consider ation

2. Assume wall or column thick ness and establish slenderness ration.

3. Establish any eccentricity of loading.

4. Ascertain appropriate stress reduction factor (RF) (table 4)

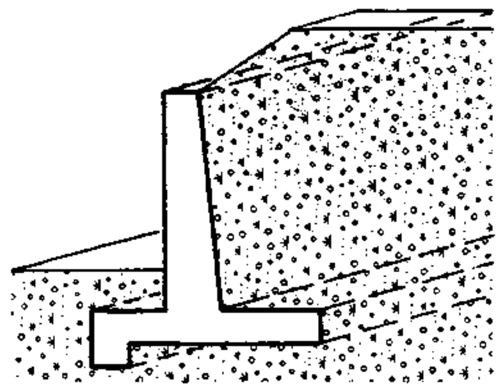
5. Establish bearing area per metre run of wall or of column (A)

6. Establish 'euqivalent basic stress' = $\frac{W}{A \times RF}$

7. Select grade of brick and mortar with strengths appropriate to the equivalent basic stress (table 3)

TYPES OF WALLS

- RETAINING WALLS:
  There primary function is to resist the thrust of soil (or subsoil water) on one side. The most important functional requirement therefore is strength and stability.



RETAINIG WALL

6.3 Types of Walls

- Walls may be divided into two types:

  1 LOAD - BEARING WALLS
  which support loads from floors and roof in addition to their own weight and resist side pressure (wind, stored material or objects)

  2 NON-LOAD-BEARING WALLS
  which carry no floor or roof loads.

- Each type may be further divided into EXTERNAL (or enclosing)WALLS and INTERNAL (or dividing) WALLS

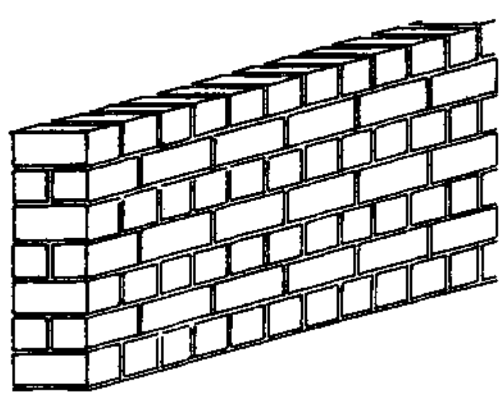
- The external -non-load-bearing wall (related to framed structures) is termed
  PANEL WALL (if of masonry construction)
  INFILLING PANEL (if of tighter construction)
  CLADDING (when applied to the face of the structure)

- The term PARTITION is applied to walls (generally non-load-bearing and only one storey high) dividing the space within a building into rooms.

  Internal walls which seperate different excupancies within the same building ore divide the building into compartments for the purpose of fire protection are termed
  PARTY (or PARTING) WALLS
  SEPERATING WALLS or
  DIVISION WALLS.

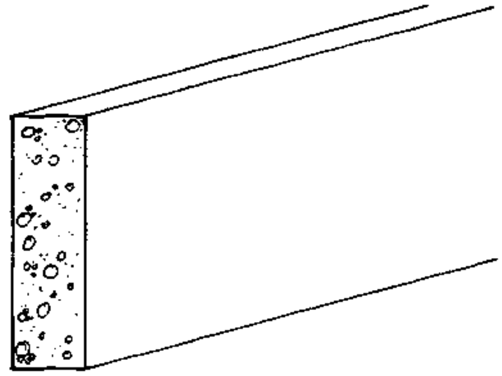
Regarding to the FORM OF CONSTRUCTION Walls may be described by the following terms:

- MASONRY WALL = The wall is built of individual blocks of materials, such as bricks clay or concrete blocks, stone etc., usually in horizontal courses cemented together with some form of mortar.



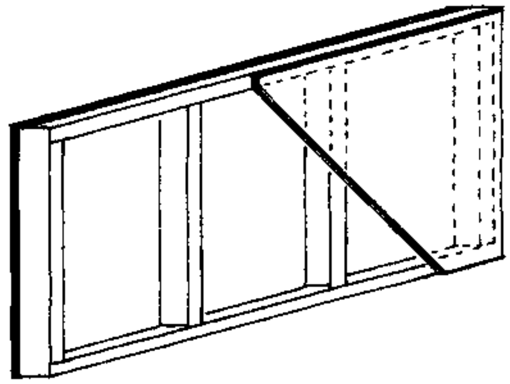
MASONRY WALL

- MONOLITHIC WALL = The wall is built of material requiring some form of support or shuttering in the initial stages. The traditional earth wall and the modern concrete wall are examples of this.



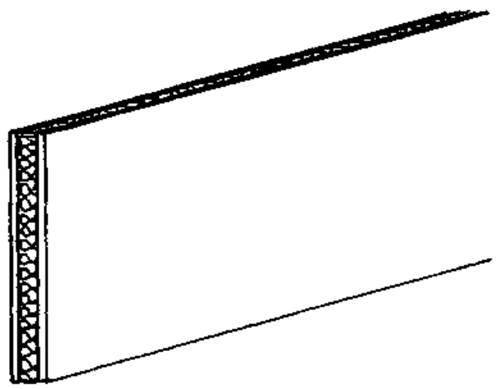
MONOLITHIC WALL

- FRAME WALL = The wall is constructed as a frame of relatively small members (usually of timber) at close intervals which together with facing on each side form a load bearing system.
  N.B. This is a wall construction not a struct. fram of a building.



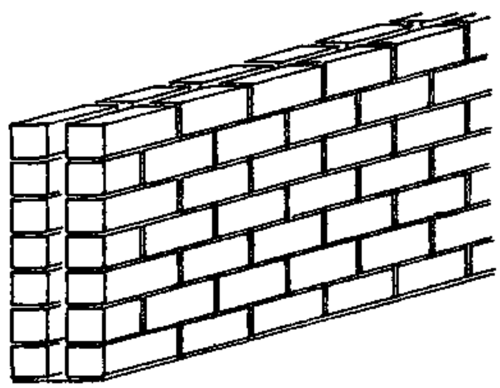
FRAME WALL

- MEMBRANE WALL = The wall is constructed as a sandwich: two thin skins or sheets of reinforced plastic, metal, asbestos-cement or other suitable material bonded to a core of framed plastic to produce a thin wall element of high strength and low weight.



MEMBRANE WALL

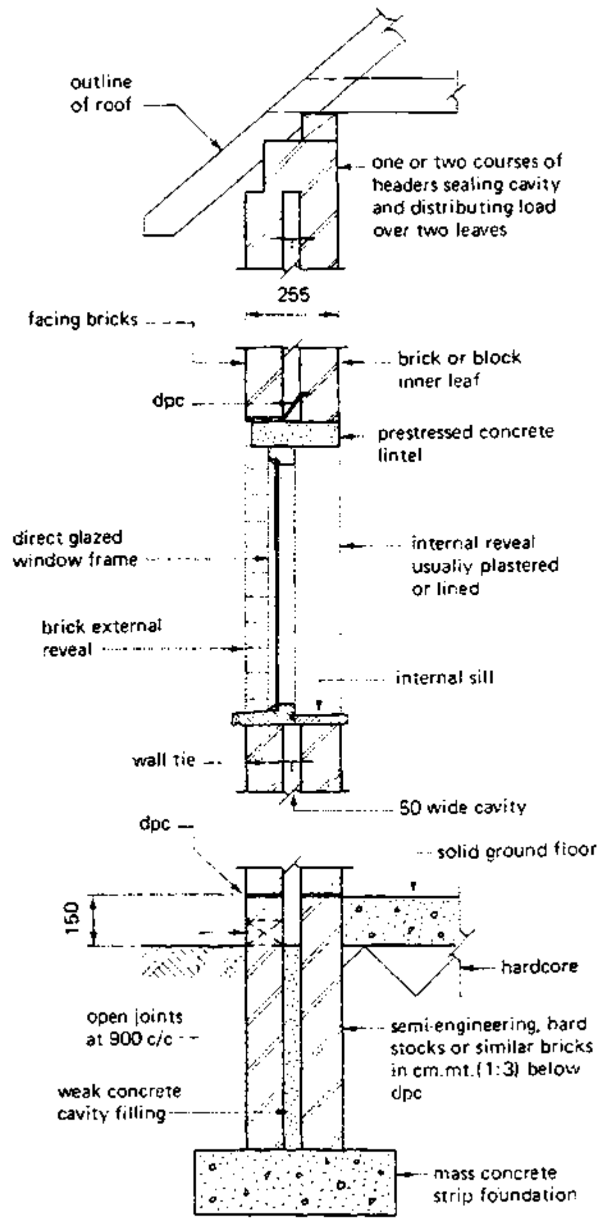
- CAVITY WALL = The wall is constructed in two leaves or skins with a space between, so that the outer surface of the wall is isolated from the inner surface by a continous gap.

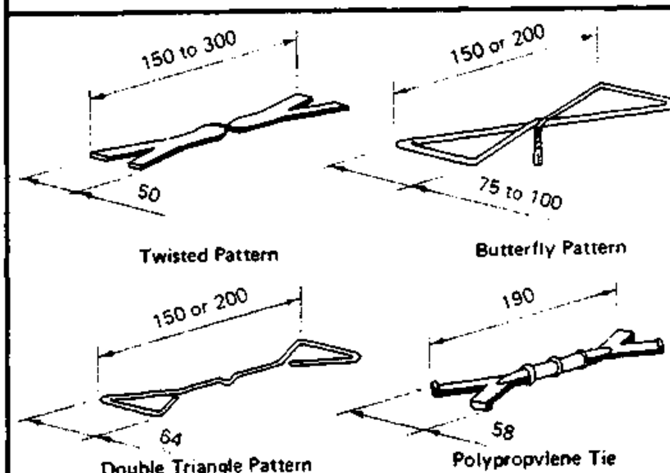


CAVITY WALL

CAVITY-WALLS

- Main purpose: to prevent the penetration of rain to the internal surface of the wall.
- It is essential that the cavity is not bidged in any way as this would provide a passage for the moisture.
- Air bricks are sometimes used to ventilate the cavity (- at the head and the base of the wall).
- There is a tendency for the 2 leaves to move towards each other (below ground level). To overcome this problem it is common practice to fill the cavity below g.l. with a work mix, of concrete thus creating a solid wall in the ground
- It is advisable to leave out every 4th vertical joint in the external leaf at the base of the cavity and above the cavity fill, to allow any moisture to escape.





Building Regulations 1972 Schedule 7

Rule 4: This gives the requirements of the strength of brick or blocks to be used in the construction of walls.

It sets out in detail the various crushing strengths and aggregate volumes of solid material required for various situations and classifications.

Rule 11: This sets out the constructional requirements for cavity walls and is of the utmost importance.

1. Bricks and blocks to comply with Rule 4 and be properly bonded and solidly put together with mortar.

2. The leaves to be securely tied together with ties complying with B.S. 1243:1964 or other not less suitable ties, details of horizontal and vertical spacing are given (Fig. II.21)

3. The cavity shall be not less than 50 mm nor more than 75mm in width at any level.

4. The leaves shall be each not less than 100mm in thickness at any level (unless covered by paragr. 6 of Rule 11).

5. The overall thickness to comply with paragraphs 3 and 4 or thickness required by Rules 7 or 8 for solid walls + the width of the cavity (for a nominal 255mm wide cavity wall of any length the maximum height is 3.60 m.

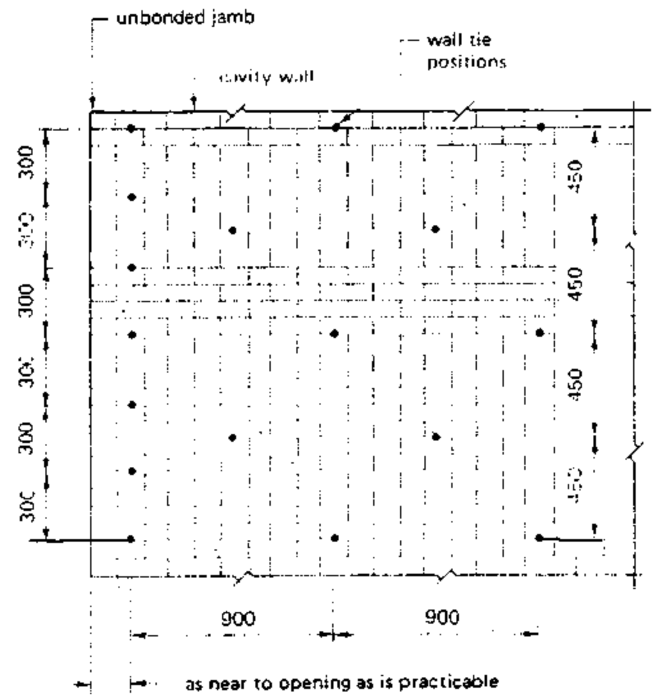
6.a) Inner leaf can be not less than 75mm thick if the wall forms part of a private dwelling house of one story or is the upper story of such a dwelling having only two storeys.

6.b) Inner leaf size not more than 8m in length and not more than 3m in height or 5 m in height if it is a gable wall.

6.c) A gauge mortar not weaker than 1:2:9 to be used.

6.d) Not less than twice the number of wall ties required by paragraph 2 of Rule 11.

6.e) The roof load is supported partly by the outer leaf.



Advantages of cavity wall constructions.

a) Able to withstand a driving rain in all situations from penetrating to the inner wall surface.

b) Gives good thermal insulation.

c) No need for external rendering.

d) Enables the use of cheaper and alternative materials for the inner construction.

e) A nominal 255mm cavity wall has a higher sound insulation value than a standard one brick thick wall.

- Disadvantages of cavity wall constructions.

a) Requires high standard of design and workmanship.

b) The need to include a vertical D.P.C. to all openings.

c) More expensive than a standard one brick thick wall.

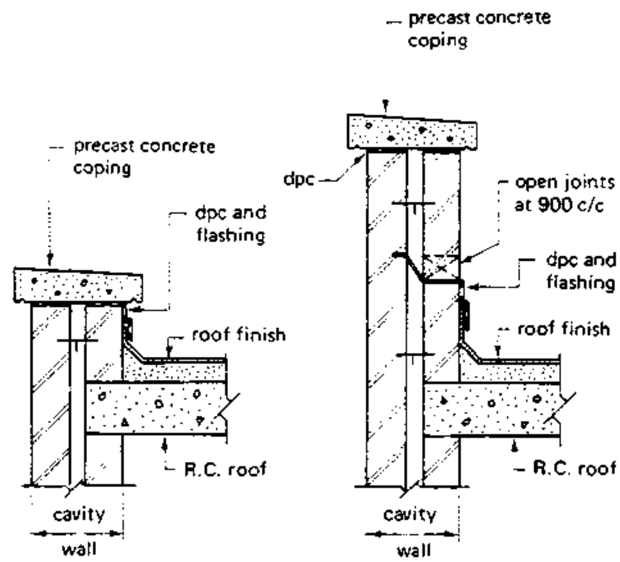
- Parapets, whether solid or cavity constructions are exposed to the elements on three sides.

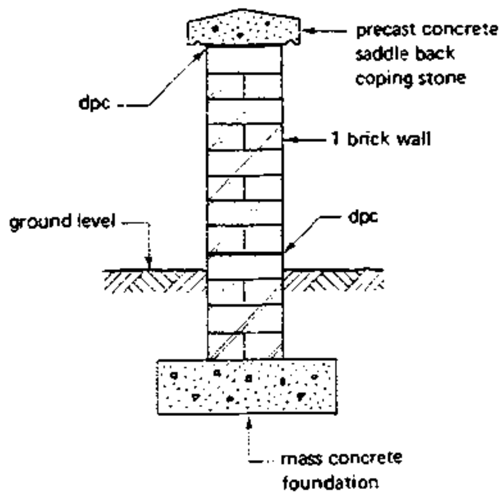
- Therefore an adequate barrier to moisture in form of d.p.c. must be provided.

- A parapet must not be less than 20 cm thick or not less than the thickness of the wall on which it is carried and its height must not exceed 6 x its thickness.
  (Schedule 7, Rule 14, Build. Reg.)
- The presence of water in brickwork can lead to
  - frost damage
  - mortar failure
  - efflorescence

- The incorporation of adequate D.P.C. and overhanging throated copings is of importance in this form of structure.

PARAPETS





- BOUNDARY WALLS
- are subjected to severe weather conditions and therefore should be designed and constructed correctly.

- as retaining walls = condition even more extrem, but the main design principle remains the same:Exclution of water.

- CROSS-WALLS

The term "cross-wall construction" is applied to buildings in which the walls at right angles to the principal axis are designed to carry the loads from the floors and roof, the lateral front and rear external walls being non-load-bearing.

Cross-wall construction being adopted for certain types of building is illustrated in its simplest form in the figure below.

BUILDING STONES

6.4.1 Building stones

- Stones used in building can be divided into 3 classes as follows:
  (1): Igneous
  (2): Sedimentary
  (3): Metamorphic

- Igneous stones: Originate from volcanic action being formed by the crystallisation of malten rockmatter derived from deep in the earth's crust.

- granites are typical of this class of stone: hard/durable and capable of a fine polished finish.
- granites are mainly composed of quartz, felspar and mica.

- Sedimentary stones: composed of material derived from the breakdown and erosion of existing rocks deposited in layers under the waters, which at that time covered much of the earth's surface.

- Sandstones and limestones are typical examples of sedimentary stones.
  - o Sandstones are stratified sedimentary rocks, produced by the eroded and disintegrated rocks, like granite, being carried away and deposited by water in layers. The brown and yellow tints in sandstones are due to the presence of oxids of iron.
  - o Limestones may be organically formed by the deposit of tiny shells and calcareous skeletons in the seas and rivers, or may be formed chemically by deposits of lime in ringed layers. Limestones vary considerably from heavy crystalline form to a triable material such as chalk.

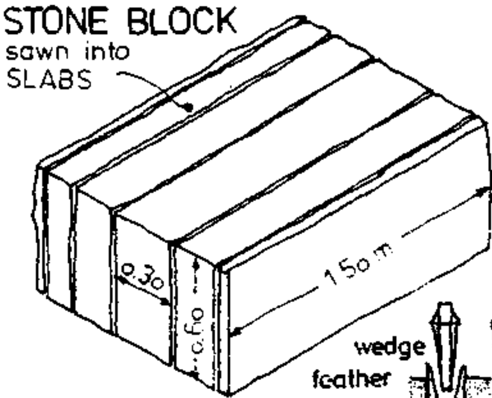
- Metamorphic stones: have altered and may have been originally igneous or sedimentary rocks have been changed by geological processes such as
  - pressure
  - movement
  - heat

  and chemical reaction due to infiltration of fluids.

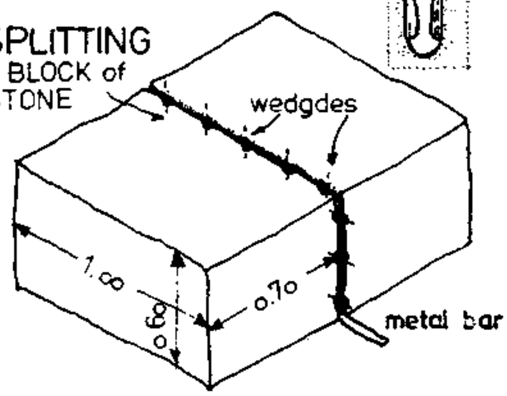
- Marbles and slates are typical examples.
  - o Marbles are metamorphic limestones, being changed by pressure. Being capable of taking a high polish/are used mainly for decorative work.
  - o Slate is a metamorphic clay, having been subjected to great pressure and heat; being derived from a sedimentary layer it can be easily split into thin members.

STONES

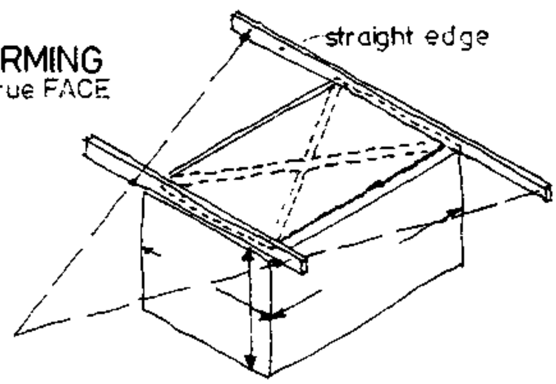
STONE BLOCK
sawn into
SLABS



SPLITTING
a BLOCK of
STONE

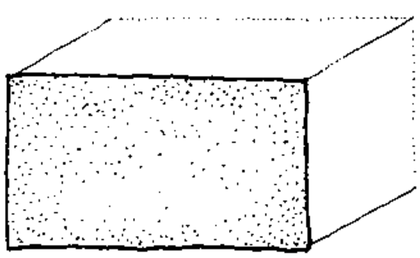


FORMING
a true FACE



- <u>Stones</u> are obtained from quarries by blasting and wedging the block away from the solid mass. They are partly worked in the quarry and then sent to store yards where they can be
  - saw
  - cut
  - moulded
  - dressed or/and
  - polished.

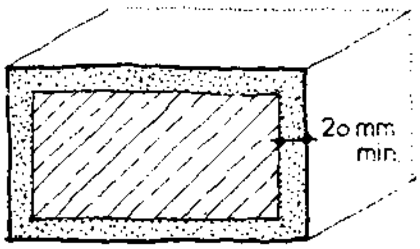
Today, natural stones are sometimes used for:-facing prestige buildings;-constructing boundary or similar walls.



RECONSTRUCTED

- <u>Reconstructed stones</u>: are substitutes for natural stones. They are homogeneous throughout and therefore has the same texture and colour as the natural stones they are intended to substitute.

  - They can be worked in the same manner as natural stone or alternatively
  - they can be cast into shaped moulds.



ARTIFICIAL

- Artificial stones: consist partly of a facing material and partly of a structural concrete.

  - The facing is a mixture of fine aggregate of natural stone and cement.

  - The facing should be cast as an integral part of the stone and have a minimum thickness of 20 mm.

  - They are cheaper than reconstructed stones but have the disadvantage that if damaged the concrete core may be exposed.

DEFECTS IN STONE

- DEFECTS IN STONE

o Vents: are small fissures or hollows in the stone which may cause it to deteriorate rapidly, especially if exposed. Stone with vents should not be used for building purposes.

o Shakes or snailcreep: are minute cracks in the stone containing calcite (a carbonite of lime) and forming hard veins which - in course of time - project beyond the general face on account of their greater durability.
It is not advisable to use stone containing them on account of the difference in texture which results.

o Sand-holes: are cracks which appear in the stone and which are filled with sandy matter. Clay-holes are vents which contain matter of a clayey nature. Both are readily decomposed when subjected to the action of weather, and the stone should be rejected.

o Mottle: is a defect which causes the stone to have a spotted appearance due to the presence of small chalky patches. Such stone is unfit for building purpose.

o The presence of clay and oxide of iron is apt to cause disfigurement of the stone, producing brown-coloured bands which interfere with the uniformity in colour of the stone and diminish its durability.

o An inherent defect is the presence of shells fossils, cavities and flints. These are often not detected until the large blocks from the quarry are being converted into smaller units, the saw-arts revealing their presence. The affected portions must be removed and therefore wast results.

STONEWORK TERMINOLOGY

6.4.2 Stonework Therminology

Arris: meeting edges of two worked surfaces.

Ashlar: a square hewn stone; stonework consisting of blocks of stone finely squared and dressed to given dimensions and laid to courses of not less than 300 mm in height.

Bed joint: horizontal joint between two courses.

Bonders: through stones or stones penetrating 2/3 of the thickness of a wall.

Cramp: non-ferrous metal or slate tie across a joint.

Dowel: non-ferrous or slate peg morticed into adjacent joints.

Yoggle: recessed key filled with a suitable material, used between adjacent votical joints.

Lacing: courses of different material to add strength.

Natural bed: plane of stratification in sedimentary stones.

Quarry seep: moisture contained in newly quarried stones.

Quoin: corner stone

Stool: flat seating on a weathered sill for jamb or mullion.

String course: distinctive course or band used mainly for decoration.

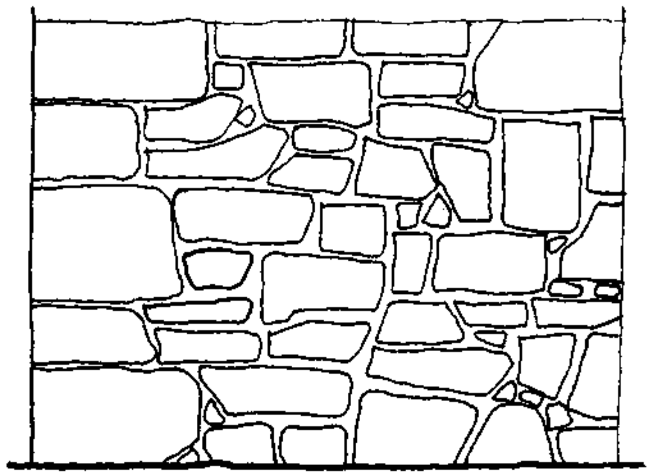
Weathering: sloping surface to part of the structure to help shed the rain.

STONEWORK CLASSIFICATION

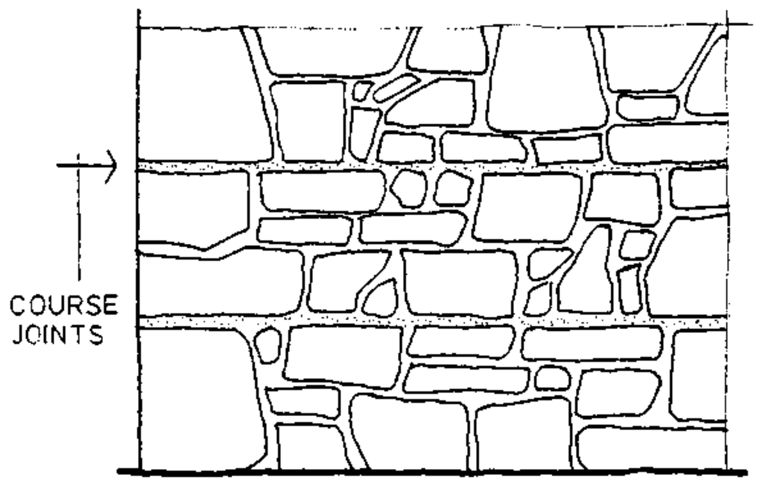
6.4.3 <u>Stonework Classification</u>
The various classes of stonework may be devided into:

(1) Rubble Work and
(2) Ashlar Work

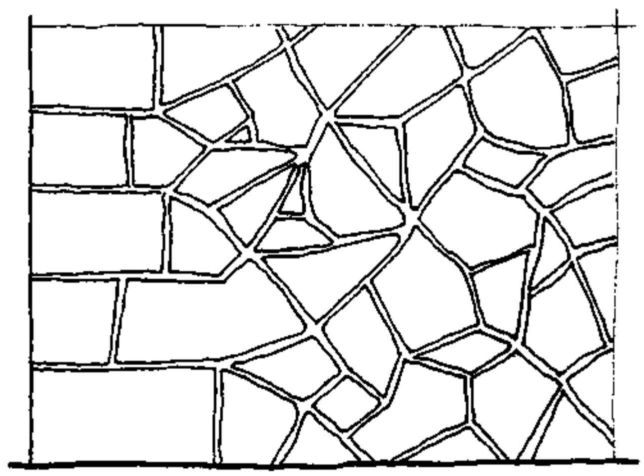
<u>RANDOM RUBBLE</u>
uncoursed



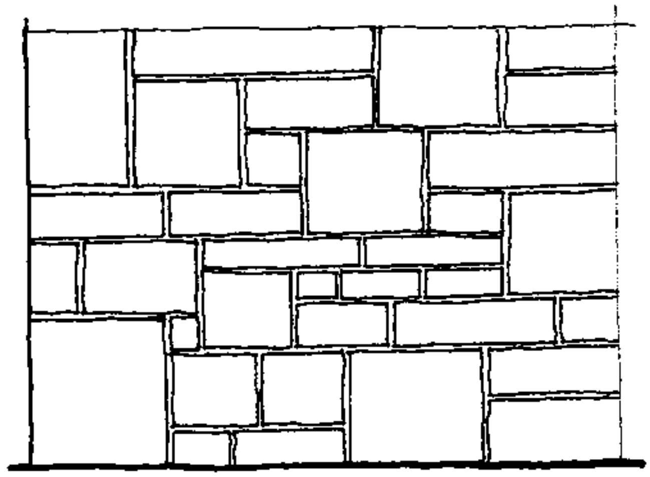
<u>RANDOM RUBBLE</u>
brought to courses



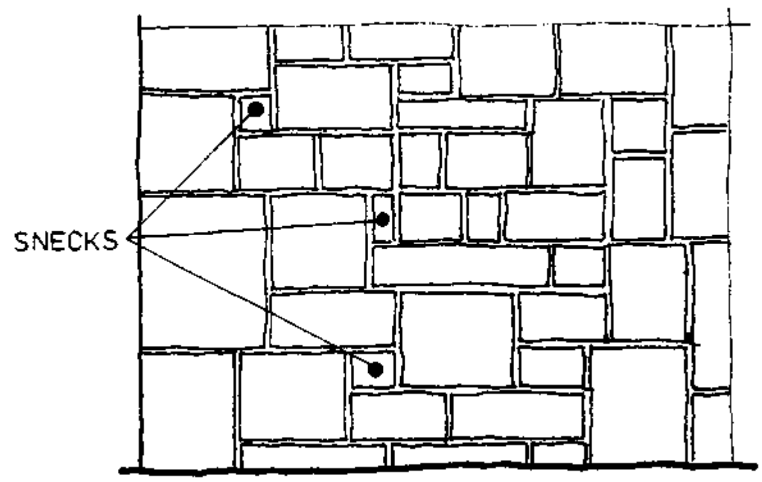
<u>POLYGONAL RUBBLE</u>



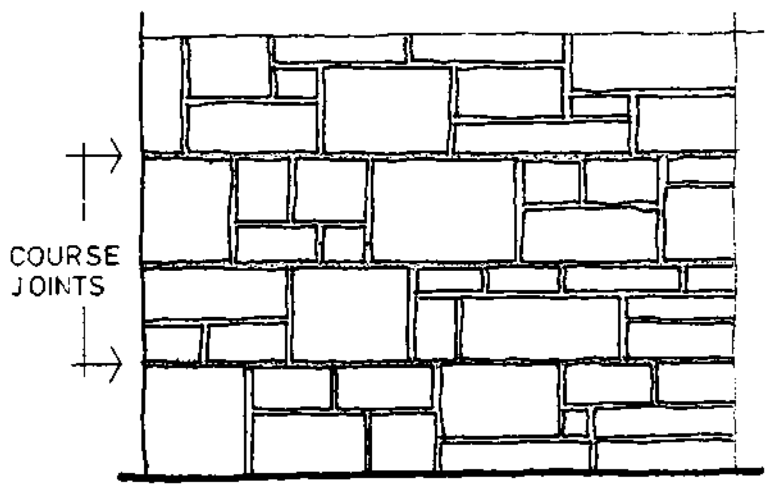
SQUARED RUBBLE
uncoursed



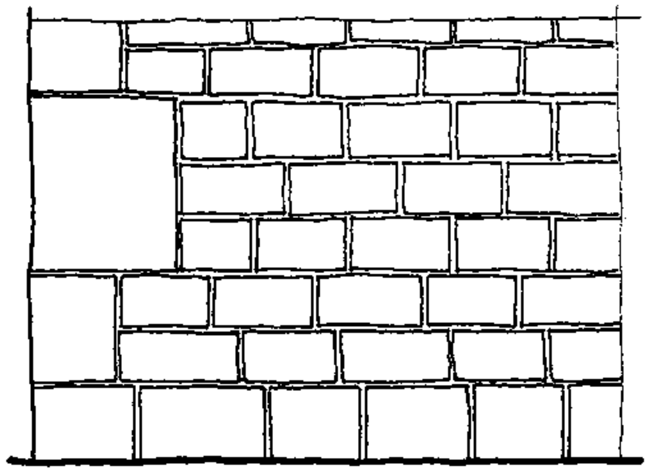
SNECKED RUBBLE



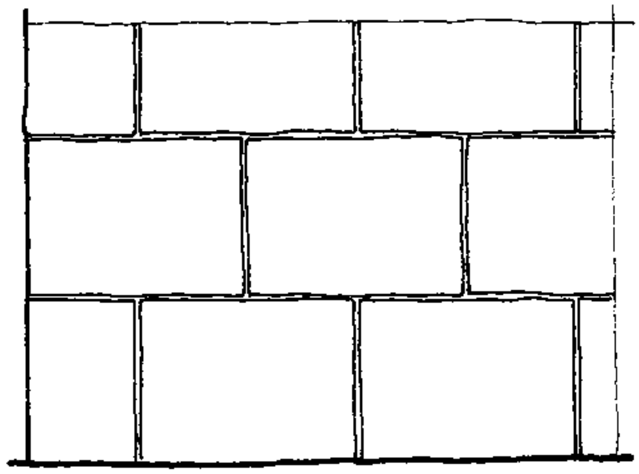
SQUARED RUBBLE
brought to courses



RUBBLE
regular coursed



ASHLAR



RUBBLE WALLING

6.4.4 Rubble Walling

- These walls are made of stones which are left rough or uneven thus presenting a natural appearance to the face of the wall.

- The stones are usually laid with a wide joint and are used in various forms.
  They can be laid:
  o dry
  o bedded in earth (in boundary walls)
  o bedded in Limemortar (i.e. outbuildings of farm houses)
  o bedded in cement or gauged mortar (in ashlar walls).

- Commonly the quins to corners, windows and door openings are dressed or ashlar stones.

- The face of any backing material to be treated with a suitable water-proofing coat (to prevent the passage of moisture).
- Precautions in form of d.p.c. are necessary to comply with Part C - Building Regulations.

- Rubble work includes:

  (a) Random Rubble
  (1) uncoursed
  (2) build to courses

  (b) squared Rubble
  (1) uncoursed
  (2) build to courses
  (3) regular coursed

  (c) Miscellaneous
  (1) polygonal walling
  (2) flint walling

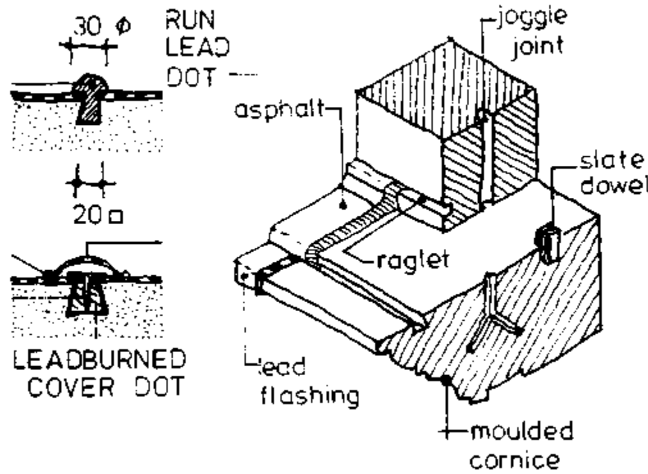
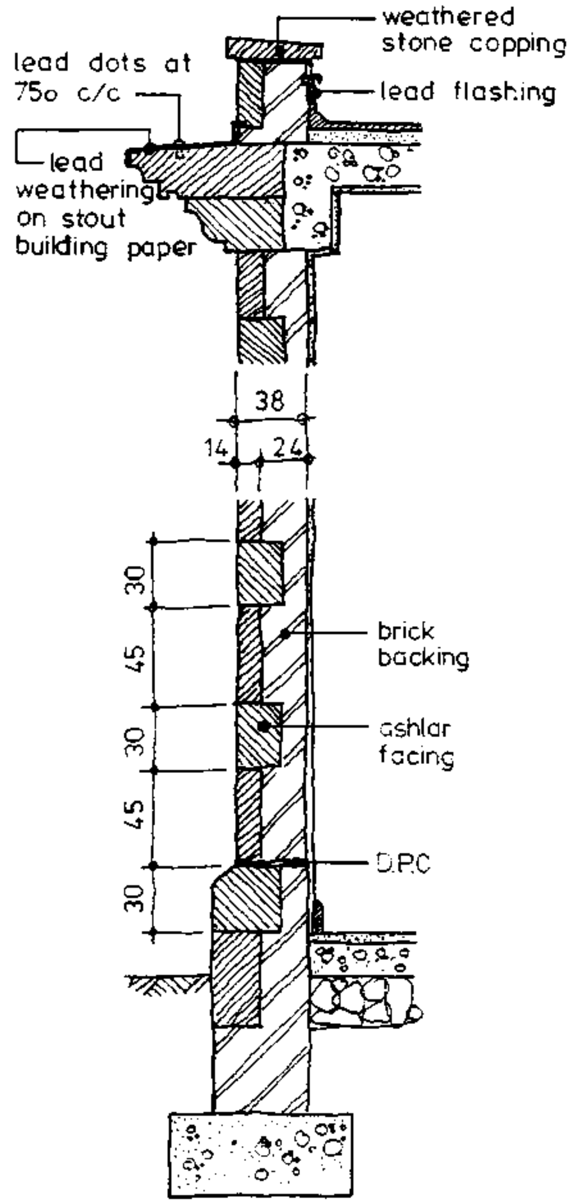
ASHLAR WALLING

6.4.5 Ashlar Walling

- This form of stone walling is composed of
  - o carefully worked stones
  - o regular coursed
  - o bonded
  - o set with thin rusticated joints

  and is used for the majority of high-class facingwork in stone.
- The quoins are sometimes given a surface treatment to emphasize the opening or corner of the building.
- Most of the ashlar work is carried out in Limestone (10-30 cm thick) and set in mason's putty which is a mixture of stonedust/lime putty/portland cement.
  Typical ratio: 7/5/2.





RULES

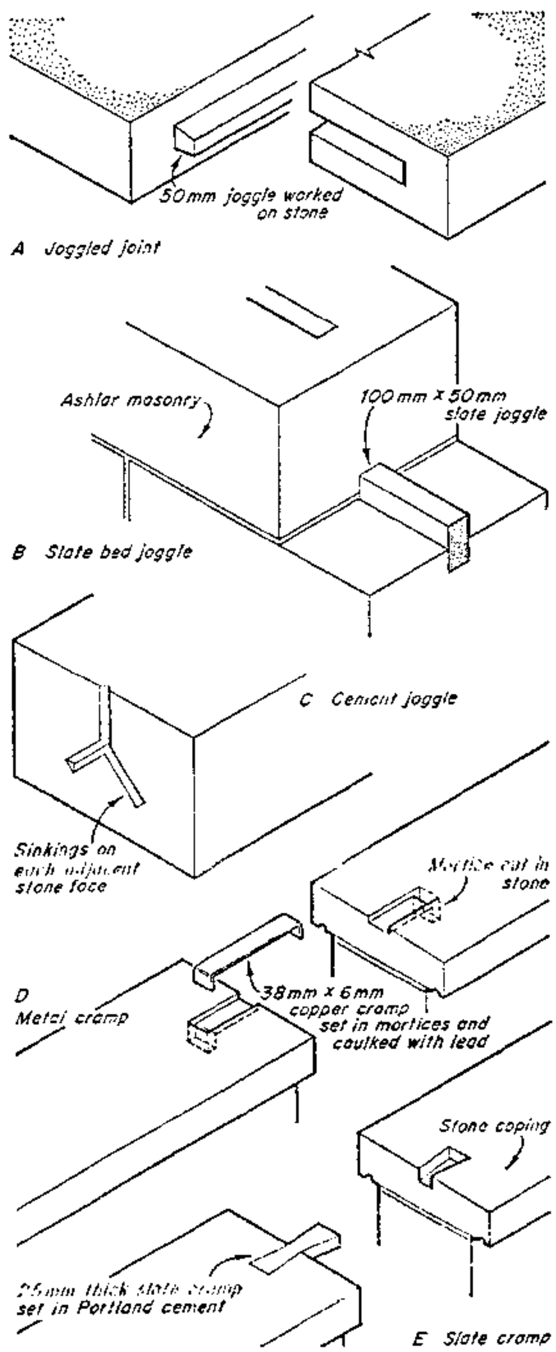
6.4.5.1 Rules for ashlar work

1. Back faces of ashlar stones should be painted with a bituminous or similar waterproofing paint.
2. External stone work must not be taken through the thickness of the wall since this could create a passage for moisture.
3. Ledges of corcices and external projections should be covered with LEAD, COPPER, or ASPHALT to prevent damage by rain or birds.

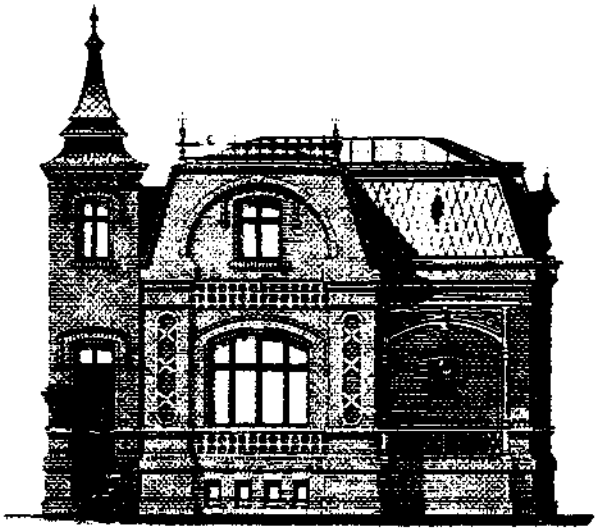
4. Moulded cornices should be raked back at 45° to counteract the cantilever action.

5. Face of stones should be given a protective coat of slurry during construction, the slurry being washed off immediately prior to completion.

JOINTS & CONNECTIONS



BRICKWORK



BRICKWORK : 19th CENTURY

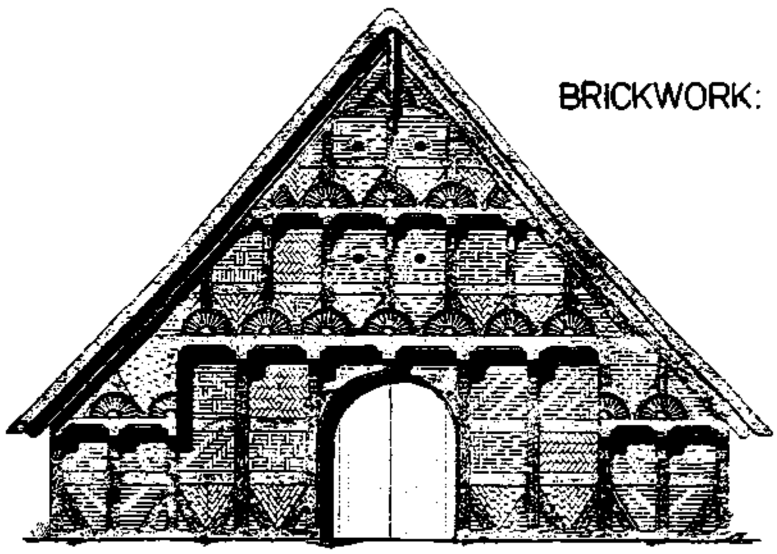
6.5 Brick work

- In BS 3921, Part 2, a brick is defined as a walling unit not exceeding
  337,5 mm in length
  225,5 " " width
  112,5 " " height

This particular standard deals with bricks made of fired brick-earth, clay or shall; other standards deal with those made of calcium silicate or concrete.

Bricks are known by their format size (= actual size + 10 mm joint allowance to three faces).

BRICKWORK: 17th CENTURY



MODERN BRICKWORK : arch.RUDOLPH

- Brick work is used primarily in the construction of walls by bedding and jointing of bricks into established bounding arrangements.

  The term also covers the building in of - hollow blocks and other
  - light weight blocks.

BRICKWORK TERMINOLOGY

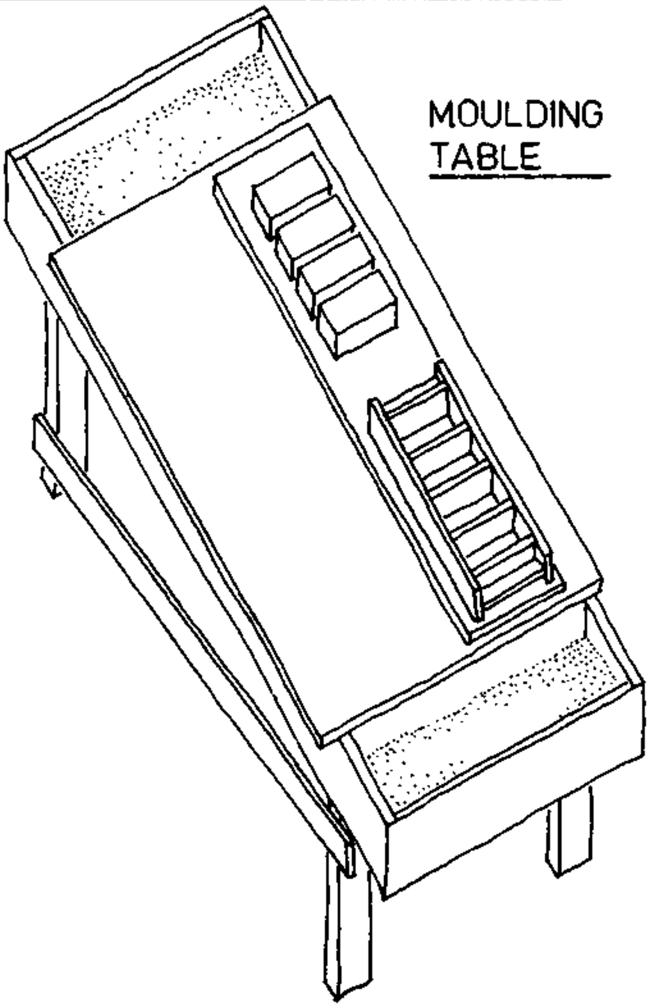
MANUFACTURE : clay BRICKS

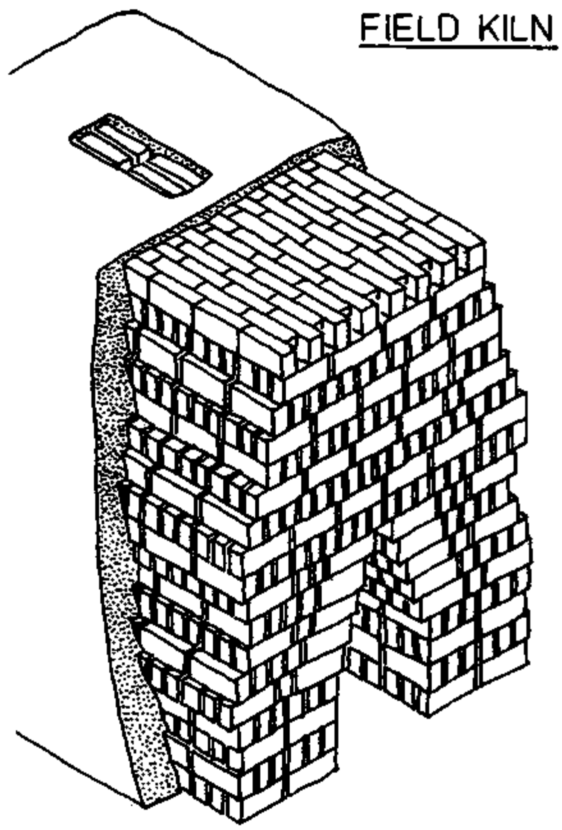


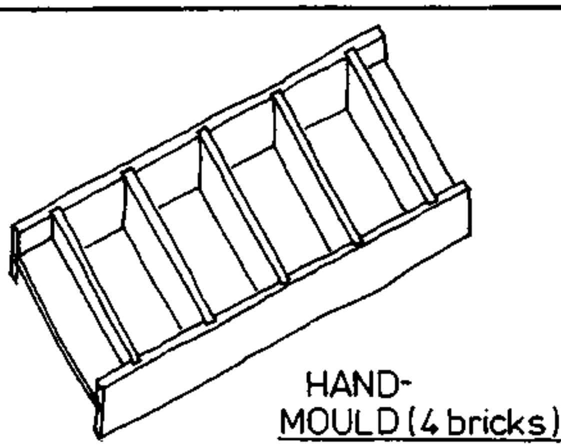
6.5.2 Manufacture of clay bricks

- The basic raw material is:
  - clay
  - shale or
  - brickearth

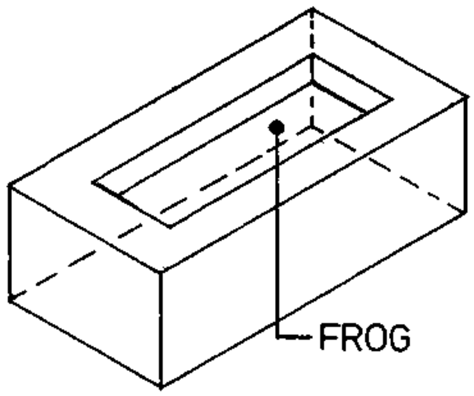
- The raw material to be
  - dug
  - prepared (by weathering or grinding)
  - mixed with water (to the right plastic condition)
  - formed (into the required brickshape)
  - dried (under a shed)
  - fired in a Kiln.

- Different clays have different characteristics (such as moisture content, chemical composition) therefore: distinct variations of the broad manufacturing processes have been developed.





PRESSED BRICKS



6.5.2.1 Pressed Bricks

- This type of brick is the most common used.
- There are 2 processes of pressed brick manufacture:

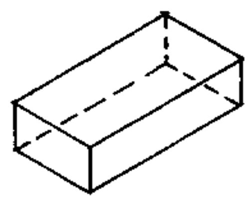
  (1) semi dry = clays which have a low natural plasticity. The clay is ground, screened and pressed directly into the moulds.

  (2) stiff plastic = The clays require more grinding and the clayclust needs tempering (mixing with water) before being pressed into the mould.

Most pressed bricks contain frogs which are sometimes pressed on both bed faces. In general pressed bricks are more accurate in shape than other clay bricks with sharp arrises and plain faces.

6.5.2.2 Wire cut bricks

- The clay, which is usually fairly soft and of fine texture is extended as a continous ribbon and is cut into brick units by tightly streched wires spaced, at the height or depth for the required brick.
- Allowance is made during the extension and cutting for the shrinkage that will occur during firing.
- Wire cut bricks do not have frogs and on many the wire cutting marks can be clearly seen.



WIRE CUT BRICKS

EFFLORESCEN-CE

6.5.2.3 Efflorescence

= White stain appearing on the face of brickwork
    caused by deposits of soluble salts formed on or near the surface of the brickwork
  as a result of evaporation of the water in which they have been dissolved,

- it is usually harmless and disappears within a short period of time,
- dry brushing or with clean water may be used to remove the salt deposite but the use of acids should be left to the expert.

CLASSIFICATION

6.5.3 Brick classification

- No standard system for the classification of bricks has yet been devised.
  Bricks are generally known by the terms given in B.S. 3921 or by the description given by the brick manufacturer (or a combination of the two).

  BS 392, Part 2
  This standard gives 3 headings:

  (1) Varieties: - common
  - facing
  - engineering

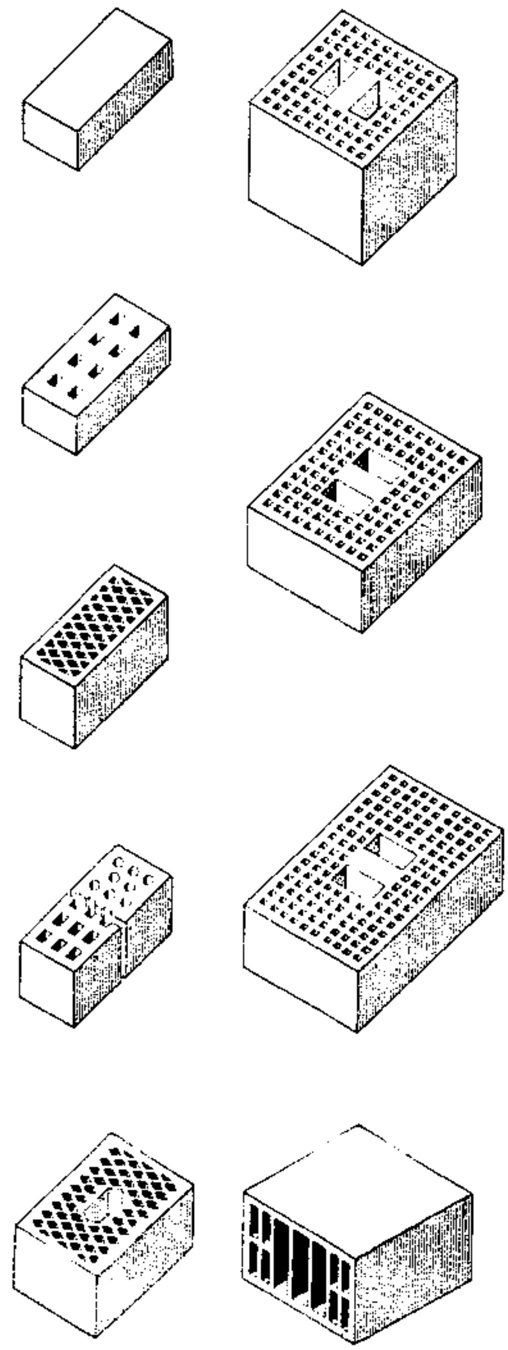
  (2) Qualities: - internal
  - ordinary
  - special

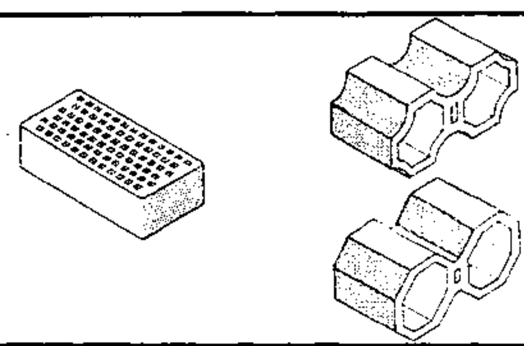
  (3) Types: - <u>solid</u>/ holes do not exceed 25% of volume.
  Frogs do not exceed 20% of volume.
  (A small hole is difined as a hole less than 20 mm wide or less than $500mm^2$ in area).

  - <u>perforated</u>: holes exceed 25% of volume.

  - <u>hollow</u>: holes exceed 25% of volumes holes are larger.

  - <u>cellular</u>: holes are close at one end and exceed 20% of the volume.





Bricks may also be classified by one or more of the following:
- place of origin
- raw material (i.e. clay)
- manufacture (" wire cut)
- use (" foundation)
- colour
- surface texture (i.e.sand-faced)

CALCIUM SILICATE BRICKS

6.5.4 Calcium silicate bricks

- These bricks are also called sandlime and sometimes flint-lime bricks and are covered by B.S. 187, Part 2, which gives 8 classes of bricks - the higher the numbered class the stronger is the brick.

- The formate size = standard clay brick.

- These bricks are carefully selected clean sand and/or crushed flint mixed with controlled quantities of lime and water.
  (At this stage colouring pigments can be added if required). The relatively dry mix is then fed into presses to be formed into the required shape.

- The moulded bricks are then hardened in sealed and steam pressurised into claves.

- This process, which takes from seven to ten hours, causes a reaction between the sand and the lime resulting in a strong homogeneous brick which is ready for immediate delivery and laying the bricks are very accurate in size and shape but do not have the individual character of clay bricks.

CONCRETE BRICKS

6.5.5 Concrete Bricks

- These are made from a mixture of aggregate and cement in a similar fashion to calcium silicate bricks and are cured either by natural weathering or in an autoclave.

  Details of the types and properties available as standard concrete bricks are given in B.S. 1180.

MORTARS

mixes:

1:3

1:3

1:1:6
1:2:9
1:3:12

6.5.6 Mortars for brickwork

The mortar used in brickwork transfers the stresses, tensile, compressive and shear uniformly between adjacent brick. To do this it must satisfy certain requirements:

1. Adequate strength (not greater than the required for the designed strength).
2. Good workability
3. Plasticity long enough for the bricks to be laid.
4. Durable over lay period.
5. Bond well to the brick.
6. Able to be produced at an economical cost.

- If the mortar is weaker than the brick shrinkage cracks will tend to follow the joints of the brickcoat and these are reasonably easy to make good.

If the mortar is stronger shrinkage cracks will tend to be vertical through the joints and the brick thus weakening the fabric of the structure.

Typical mixes (by volume)

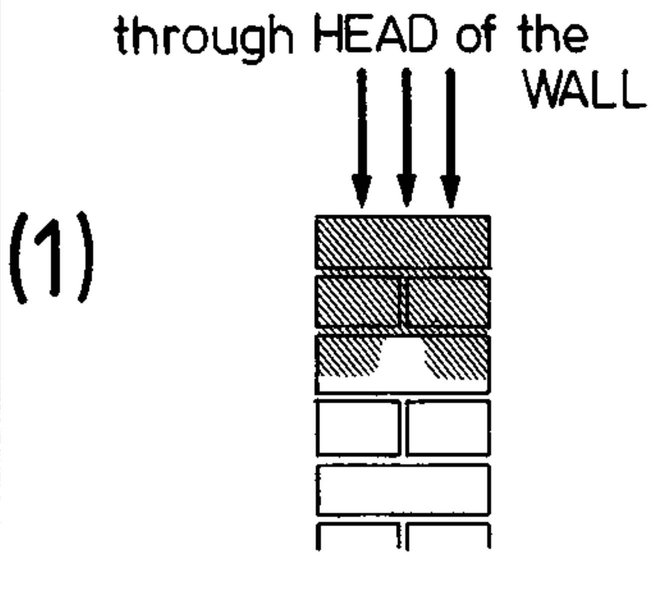
Cement mortar (1:3) suitable for brickwork in exposed conditions such as parapets and for brickwork in fondation.

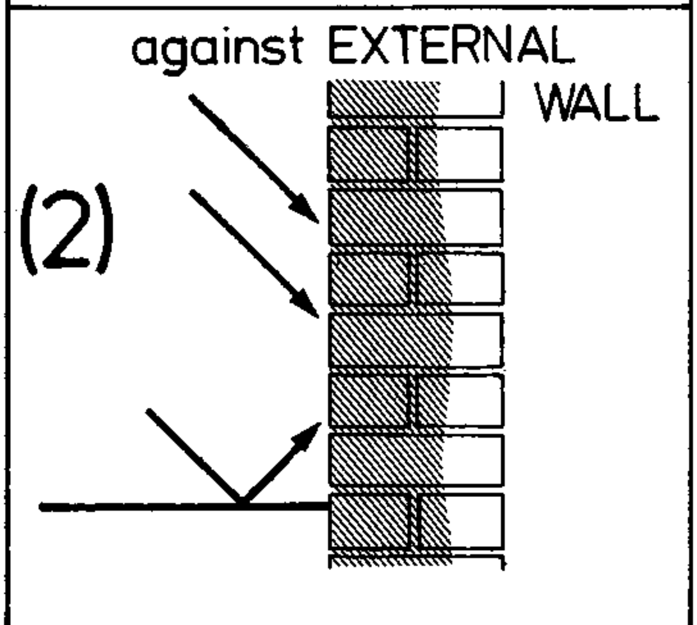
Lime mortar (1:3) for internal use.

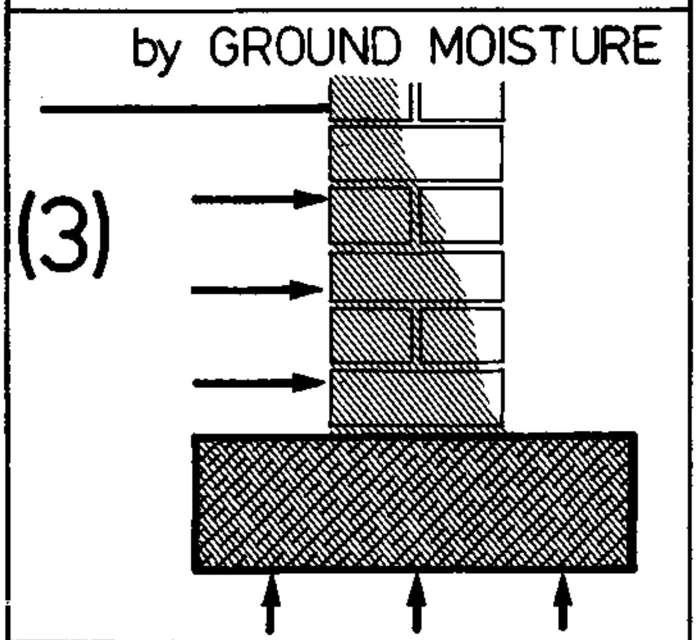
Gauged mortar (cem./lime/sand)

1:1:6 suitable for most conditions.
1:2:9 suitable for most conditions except those of severe expose.
1:3:12 internal use only.

DAMPNESS PENETRATION







6.5.7 <u>Dampness penetration</u>

- It is possible for dampness to penetrate into a building through the walls by one or more of three ways:

  (1) By the rain penetrating the head of the wall and soaking down into the building below the roaf level.

  (2) By the rain beating against the external wall and soaking through the fabric into the building.

  (3) By ground moisture entering the wall at or near to the base and creeping up the wall by capillary action and entering the building above the ground floor level.

- Nos. 1 and 3 can be overcome by the insertion of a suitable D.P.C. in the thickness of the wall.

- No. 2 can be overcome by one of the two methods:

  (a) Applying to the exposed face of the wall a barrier such as cement rendering or some suitable cladding like vertical tile hanging.

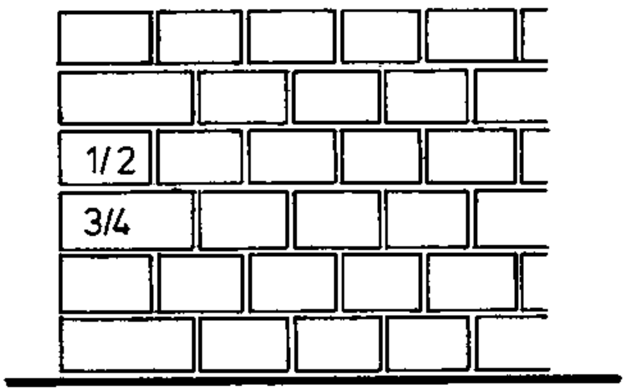
  (b) By constructing a cavity wall, whereby only the external skin becomes damp. The cavity, providing a suitable barrier to the passage of moisture through the wall.

BONDING

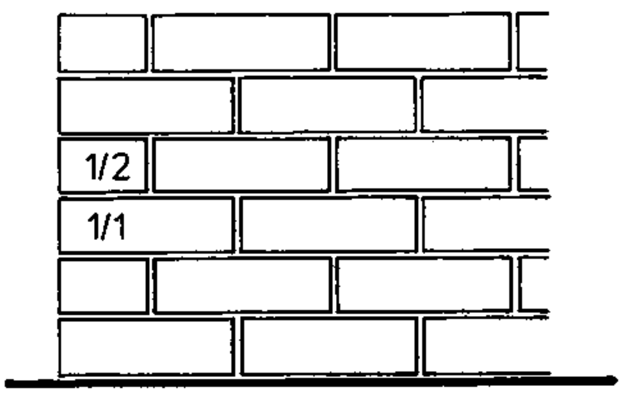
6.5.8 Brickwork bonding

- Bricks are layed to bonds, in order
  - to ensure stability of the structure and
  - to produce a pleasing appearance.
- No vertical joint in any one course to be directly above or below a vertical joint in the adjoining course.
- Special bricks are produced (or cut from whole bricks on site) to simplify this requirement (Fig. II 11)
- The various bonds are planned to give the greatest practical amount of lap to all bricks. (= not to be less than 1/4 of a brick length).
- Properly bonded brickwork distributes the load over as large an area as possible (angle at spread of the load = 60°)

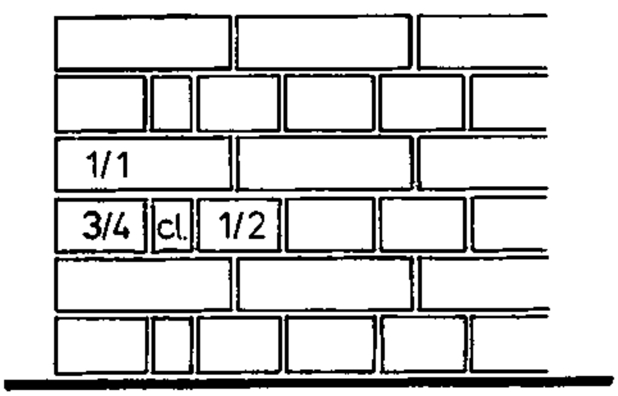
6.5.8.1 Common bonds



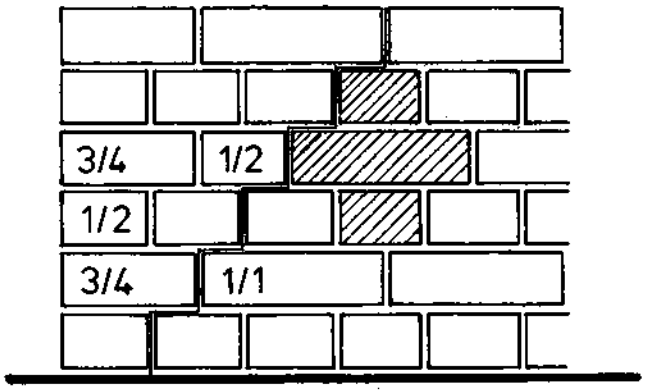
Header bond: Consists of all headers, with the bond being formed by 3/4 bats at the quoins. It is used for one-brick walls in footing courses or walling curved on plan.



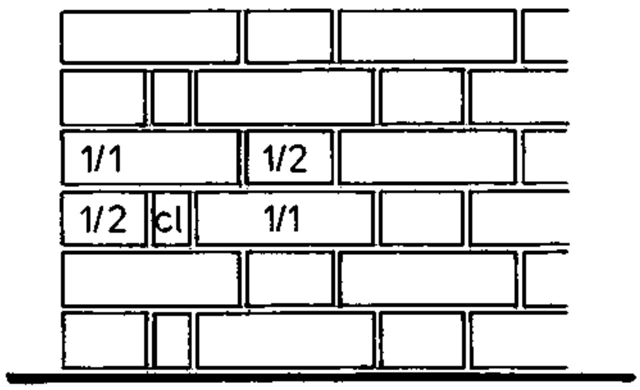
Stretcher bond: consists of all stretchers in every course and is used for half brick walls and the half brick skins of hollow or cavity walls.



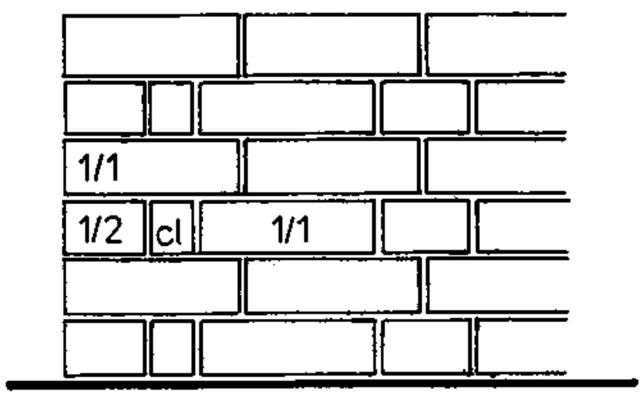
English bond: A very strong bond consisting of alternate headers and stretchers, with a queen closer placed next to the quion heder to form the lap.



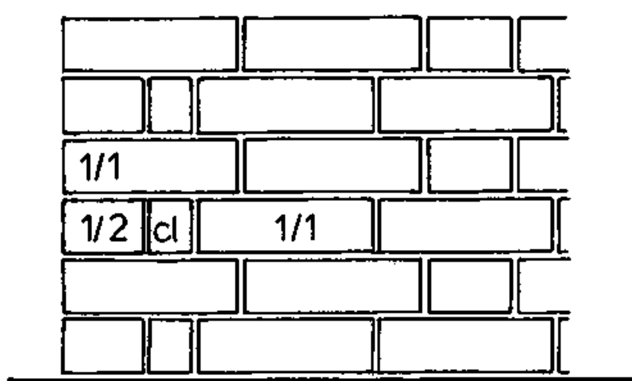
Cross bond: The strongest possible bond used for one-brick walls consisting of alternate courses of headers and stretchers, with the bond being formed by 3/4 bats at the quoins of the stretcher courses. In every second stretcher course the 3/4 bats are followed by a header.



Flemish bond: each course consists of alternate headers and stretchers, its appearance is considered to be better than English bond but it is not quite so strong. This bond requires fewer facing bricks (than Engl. bond) needing only 79 bricks/m^2 (Engl. bond: 89 bricks/m^2).

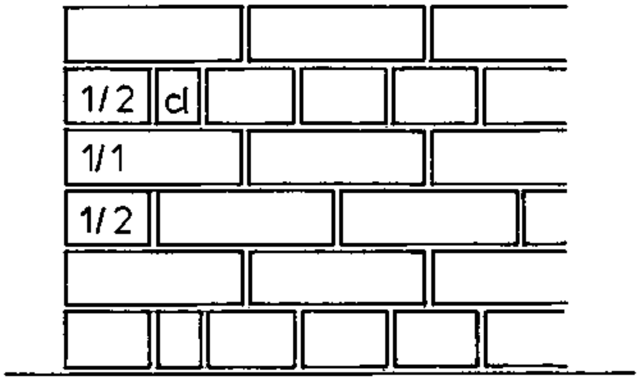


Monk bond: Consists of 2 stretchers to 1 header in each course. The header is laid centrally over the cross-joint between 2 stretchers in the course below.



Flemish garden wall bond: = 1 header/3 stretchers in every course.

This bond is fairly economical in facing bricks and has a pleasing appearance.



<u>English garden wall bond:</u> = 3 courses of stretchers/1 course of headers.

<u>Special bonds:</u>

METRIC

6.5.9 Metric Modular Brickwork

- The standard format brick does not fit reasonably well into the system of dimensional co-ordination with its preferred dimension of 300 mm, therefore METRIC MODULAR BRICKS have been designed (4 different formats).
  (Fig. II.16)

  - 300 x 100 x 100
  - 300 x 100 x 75

  - 200 x 100 x 100
  - 200 x 100 x 75

- The bond arrangements are similar to the well-known bonds but are based on
  THIRD BONDING: overlap = 1/3 of a brick (not 1/4 as with stand. form. bricks).

JUNCTIONS

6.5.10 Junctions

- Junctions are classified into
  - o right-angled junctions and
  - o squint junctions.
- There are 2 forms of right-angled junctions:
  - o tee-junctions and
  - o cross junctions (or intersections)
- The examples shown in the figures are only few of several methods of bonding at junctions. The essential requirements are the avoidance of continous vertical joints with the employment of the minimum number of cut bricks.

QUOINS

6.5.11 Quoins or External Angles

- There are two forms of quoins:
  - o right-angled (or square) quoins and
  - o squint quoins.

- A right-angled quoin is formed by two walls which meet at 90°, squint quoins are of two forms:
  - (a) obtuse quoins (internal angle greater than 90°)
  - (b) acute squint quoins (internal angle less than 90°).

PIERS

6.5.12 Piers (also known as pillars or columns) of brickwork are adopted either to support concentrated loads or to strengthen walls. Such piers may be isolated (detached) or attached to walls.

- The keyplan below shows a portion of a building in which piers are employed.
  (A) detached piers
  (B) attached piers.

6.5.12.1 Detached piers: may be either square, rectangular, circular or polygonal on pla. The figures below show some alternate details of detached piers
(1) English bond
(2) Double flemish bond
Piers may be formed with rounded arrises by using bullnose bricks.

6.5.12.2 Attached Piers (or Pilasters).
The figures below show some alternate plans of attached piers.
(1) English bond
(2) Double flemish bond.
The width of a pier is usually a multiple of 112 mm and the projection may be either 112 mm, 225 mm or upwards.

6.5.12.3 BUTTRESSES are piers which are provided to resist thrusts from roof trusses or to strengthen boundary walls, etc.

- Examples of buttress cappings are illustrated in the fig. below.

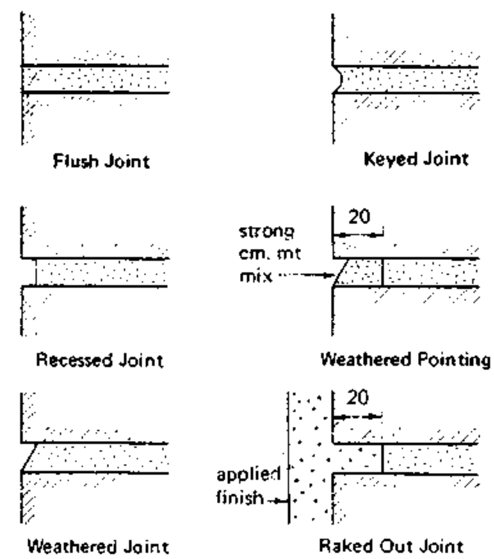
JOINTING & POINTING

Joint and pointing

- These termes are used for the finish given to both the
  - vertical and
  - horizontal joints in brickwork

  irrespective of whether the wall is of brick, block, solid or cavity construction.

FLUSH JOINT
KEYED JOINT
RECESSED JOINT
WEATHERED POINTING
(strong cem. mt. mix)
WEATHERED JOINT
RACKED OUT JOINT



- Jointing is the finish given to the joints when carried out as the work proceeds.
- Pointing is the finish given to the joints by raking out to depth of approx. 20mm and filling in on the face with a hard setting cement mortar which could have a colour additive.

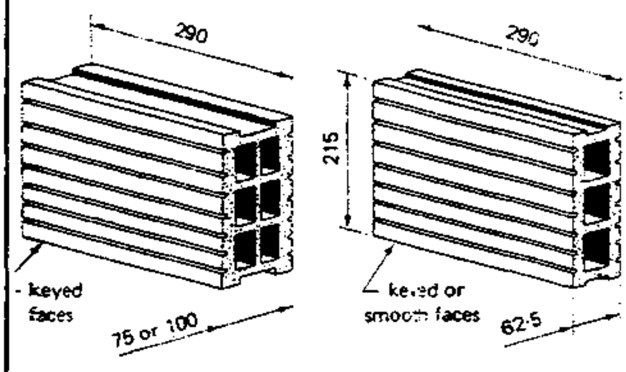
This process can be applied to both new and old buildings.

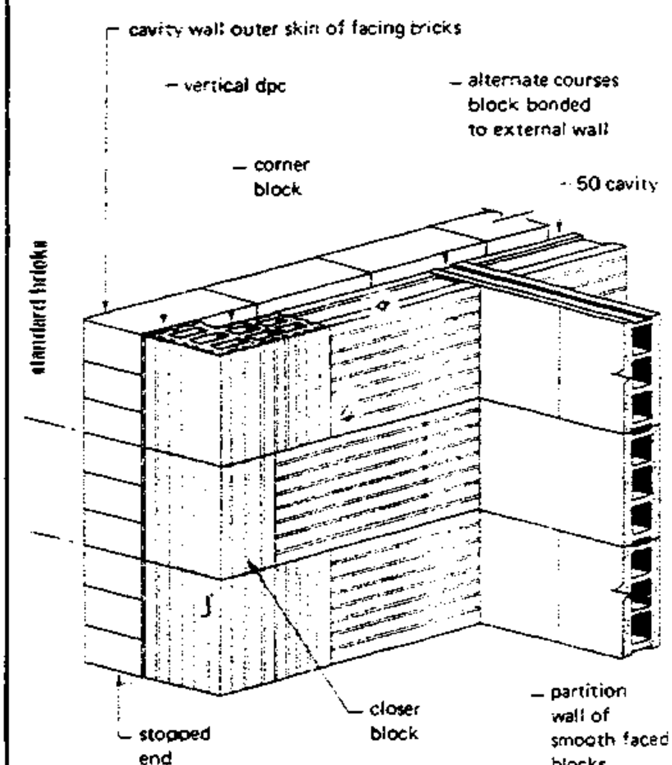
6.6 Blockwork

- A block is defined in BS 2028 as a walling unit exceeding the dimensions specified for bricks given in BS 3921 and that its height shall not exceed either its length or six times its thickness to avoid confusion with slabs or panels. Blocks are produced from clay, precast concrete and aerated concrete.

6.6.1 Clay Blocks

- These are covered by BS 3921 which gives a format size of 300 x 225 x 62·5; 75, 100 or 150 mm wide. These blocks, which are hollow, are made by an extrusion process and fired as for clay bricks. The standard six cavity block is used mainly for the inner skin of a cavity wall, whereas the three block is primarily intended for partition work. Special corner, closer, fixing and conduit blocks are produced to give the range good flexibility in design and layout. Typical details are shown in Fig. II.19.





PRECAST CONCR. BLOCKS

6.6.2 Precast concrete Blocks

- The manufacture of precast concrete and aerated concrete blocks is covered by B.S.2028: 1364 which gives three types:

Type A: for general use in buildings including the use below B.L. - D.P.C. Suitable aggregates are dense aggregates such as crushed gravel, crushed slag, broken brick.

Type B: for general use in buildings. Lightweight concrete blocks for load bearing walls.
Suitable aggregates include
- sintered pulverized fuel ash,
- foamed slag
- expanded clays and shalls
- furnace clinker
- expanded vermeculite and aerated concrete.

Type C: = similar to Type B but are intended for non load bearing walls.

6.6.3 Aerated Concrete Blocks

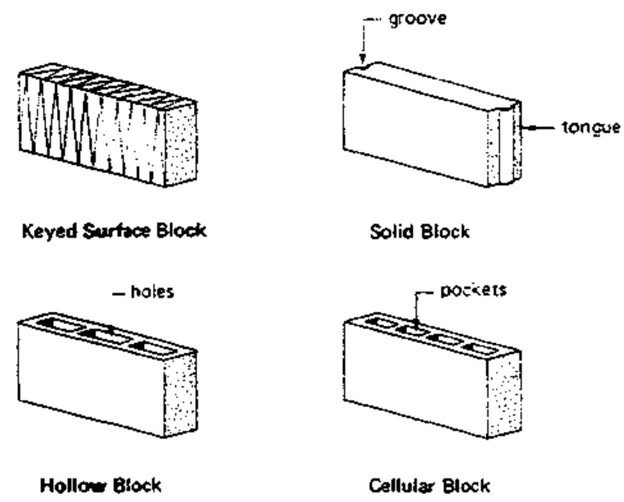
- Aerated concrete for blocks is produced by introducing air or gas into the mix so that when set a uniform cellular block is formed.

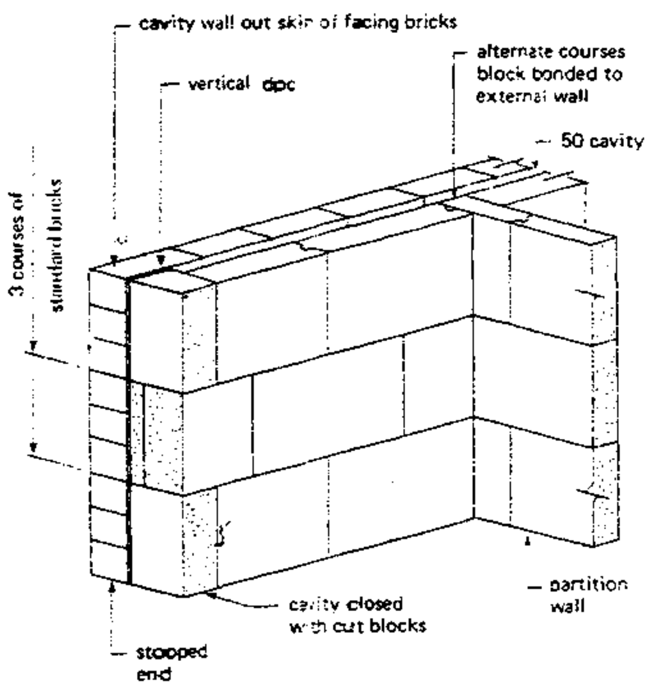
- The usual method: A controlled amount of aluminium powder to the mix reacts with the free lime in the cement to give off hydrogen which is quickly replaced by air and so provides an aeration.

AERATED CONCR. BLOCKS

PRECAST CONCR. BLOCKS

- Precast concrete blocks are manufactured to a wide range of standard sizes. The most common face format sizes are:
  400 x 200 mm and
  450 x 225 "
  with a thickness of 75/100/140/215 mm. (Typical details: Fig. II.20)
- Concrete blocks are laid in <u>stretcher bond</u>, and are joined to other walls by <u>block bonding</u> or leaving <u>metal ties</u> or <u>strips</u> projecting from suitable bed courses. The mortar again should be weaker than the material of the walling unit. (1:2:9 gauged mix. for work above G.L.)
- Concrete blocks shrink on drying out. They should not be laid until the initial drying shrinkage has taken place. (About 14 days) and should be protected on site to prevent them becoming wet, expanding and causing subsequent shrinkage possibly resulting in cracking of the blocks and any applied finishes (such as plaster).





- The main <u>advantages</u> of blockwork over brickwork are:
  1. Labour saving - easy to cut, larger units.
  2. Easier fixings - most take direct fixing of screws and nails.
  3. Higher thermal insulation properties.
  4. Lower density.
  5. Provide a suitable key for plaster and cement rendering.
- The main <u>disadvantages</u> are:
  1. Lower strength.
  2. Less resistance to rain penetration.
  3. Load bearing properties less (one-or two-storey application.)
  4. Lower sound insulation properties.

CONCRETE WALLS

6.7. Concrete Walls

6.7.1 General

- Concrete Walls may be broadly classified as:
  - Plain monolithic concrete walls.
  - reinforced concrete walls

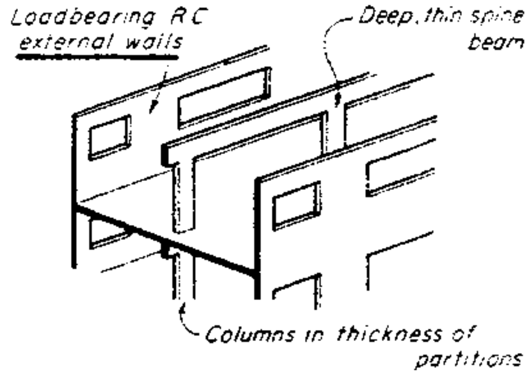
  The later can be subdivided into:

  - in-situ cast external walls
  - concrete box frame &
  - pre-cast panel structures.

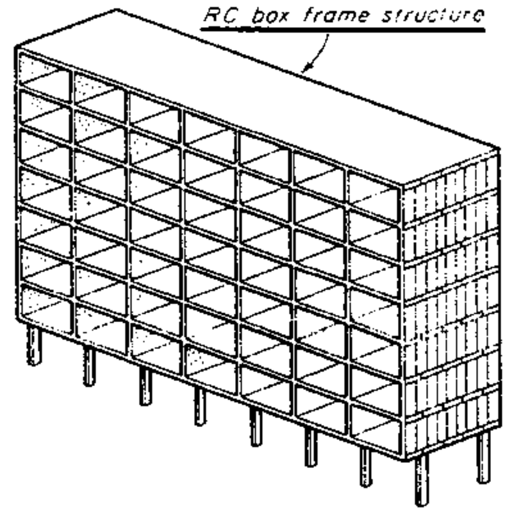
- A well graded and carefully mixed and placed Cement Concrete Wall can be impervious to water:
  - small areas can be quite water proof
  - with larger areas problems of cracking arise due to shrinkage and thermal movements and to possible settlement.

- Precautions against cracking are taken by controlling shrinkage and moisture movement by:
  - steel reinforcement
  - by allowing for thermal movement by means of expansion joints and
  - by careful detailing and execution of Construction Joints.

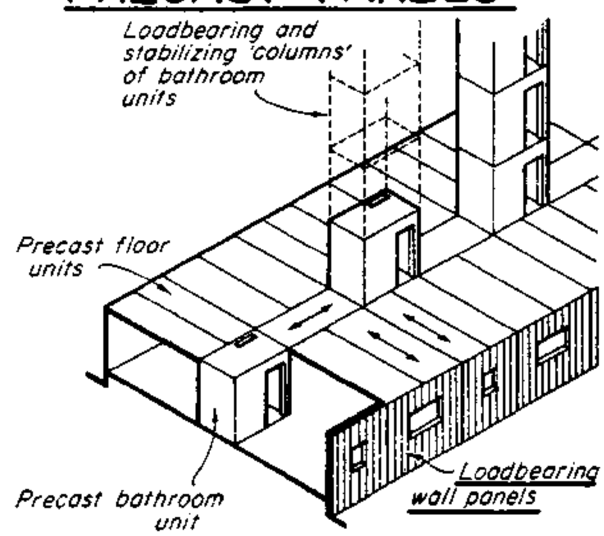
IN SITU CAST EXTERNAL WALLS



BOX FRAME STRUCT.



PRECAST PANELS



FORMWORK

6.7.2 Formwork

- Formwork is required to support the concrete until it is firm.
- It has to be strong enough to bear (without sagging, the weight of the concrete as well as the concreting sand and plant used for placing.
- The joints of the boards must be tight enough to prevent loss of water and fine material
- Easy stripping through proper use of strutting, bolting, nailing and wedging should be possible.
  In order to resist vibration and movement when the concrete is being placed, extra props may be temporarily inserted under form work. (They can be removed immediately the concrete is in position, and re-erected elsewhere as the work proceeds).
- Adjustable steel props are excellent for this purpose.
- Formwork is usually of timber, but can be of metal as well.
- Potent methods also include
  - plastic
  - wood fibre
  - metal ceiling panels
  - precast concrete panels
- Permanent steel tubular scaffolding may also be used as a support for shuttering.
- Metal formwork must be cool when concrete is being placed.
- There are a number of systems of WALL-Formwork available (in wood, steel, concrete, etc.)
  Straight foreword methods are shown in the figure.

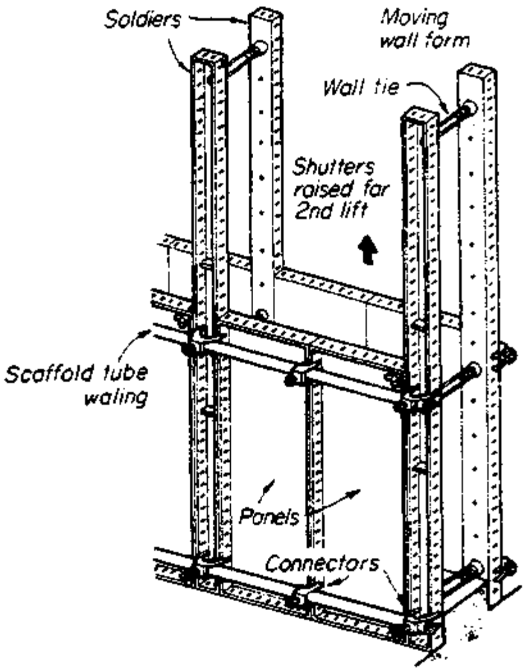
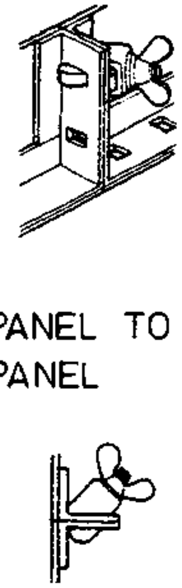
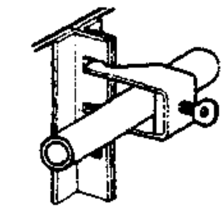
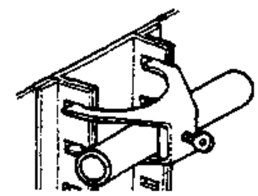
STEEL CONNECTORs







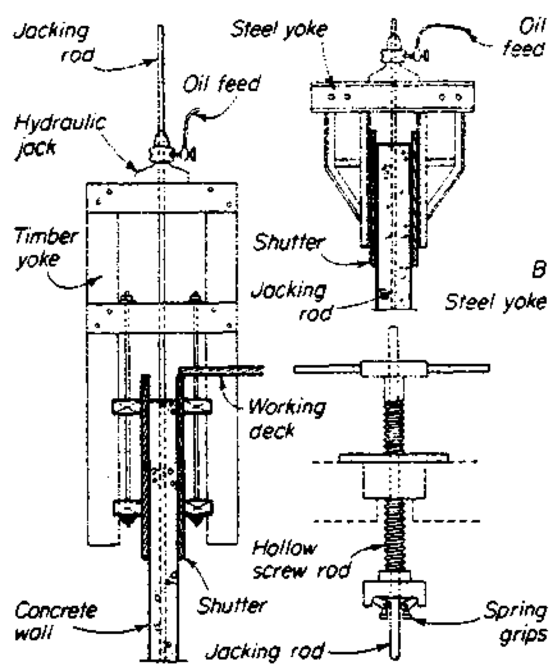


SLIP FORMs

Slip forms or sliding shutters

For the rapid construction of constant section walls it is possible to use a continuously rising form, usually known as a slip form or sliding shutter. By this means work may proceed continuously, the shutter rising from 150 to 300 mm per hour depending upon the rate of hardening of the concrete, since the cast concrete very rapidly becomes self-supporting. The form is about 900 mm or 1.20 m deep, fixed to and held apart by timber or steel frames or yokes, as shown in figure 260 *A*, *B*. On top of each yoke is fixed a hydraulic jack, through which passes a high tensile steel jacking rod, about 25 mm in diameter, which is cast into the wall as it rises. The jack contains a ram and a pair of upper and lower jaws which can grip the jacking rod and it works in cycles, each cycle giving a rise of about 25 mm. The jack works against the lower jaws to raise the yoke and the form with it. When the pressure is released, the upper jaws grip the rod and the lower jaws are released and raised under the action of a spring. An alternative to the hydraulic jack is the manually operated screw jack which is also illustrated (*C*).

A working deck is constructed level with the top of the form, from which is usually suspended a hanging scaffold from which the concrete may be inspected and rubbed down as it leaves the shutters.



A Timber yoke Screw jack C

PLAIN MONOLITHIC CONCR.

6.7.3 Plain Monolithic Concrete Wall

- The term 'monolithic' has been taken from the Greek language:
  mono = single (
  litho = stone
  Therefore a 'monolithic wall' is erected without any joints (like brick or blockwalls) having a structure like a rock or a 'single stone'

- The ideal material for such a 'monolithic' construction is concrete. (or reinforced concrete)

- The Plain monolithic concrete wall means a wall of cast in-situ concrete containing no reinforcement - either of normal, nonfines or lightweight concrete.

- As with reinforced concrete walls they are most economic when used both to support & to enclose or divide, provided they are at reasonably close spacing. That is to say, up to about 5.5 m apart. They are, therefore, used mainly for housing of all types, both as external and internal loadbearing walls, when low building costs can be attained.

- Dense concrete is generally used for high buildings although no-fines concrete has been used for heights up to ten storeys in this country. In Europe blocks as high as 20 storeys have been constructed with no-fines loadbearing walls more cheaply than with a frame.

- Plain monolithic concrete walls suffer certain defects which, in some respects, makes them less suitable as external walls than other types. With normal dense aggregates the thermal insulation is low and the appearance of the wall surface may be unsatisfactory, requiring some form of finishing or facing. In addition the unreinforced concrete wall, and particularly the no-fines wall, is unable to accommodate itself to unequal settlement as does a reinforced wall by virtue of the reinforcement or a brick or block wall to a certain extent by the setting up of fine cracks in the joints. Thus, as a result, large cracks tend to form in the wall. Nevertheless, where foundations are designed to reduce unequal settlement to a minimum such walls can successfully be used.

- Aggregates used for dense plain concrete are natural aggregates conforming to the requirements of BS 882, air-cooled blast furnace slag and crushed clay brick. Aggreggates for light-weight concretes are foamed slag, clinker, pumice and any artificial aggregate suitable for the purpose. No-fines concrete may be composed of heavy or lightweight aggregate.

DENSE CONCr. WALLS

6.7.3.1.

Dense concrete walls are constructed from concrete made with a well-graded aggregate giving a concrete of high density. The London By-laws require, the thickness of any concrete external or party wall to be not less than 150 mm thick and CP 123, 101, 'Dense Concrete Walls', recommends a similar thickness for external walls.

In most buildings the thickness of any type of plain concrete wall must, by reason of other functional requirements, be thicker than the minimum dicteted by loadbearing requirements. An example of this is the dense concrete separating wall, which must be 175 mm thick in order to provide an adequate degree of sound insulation between houses and flats.

LIGHT WEIGHT AGGREGATES

6.7.3.2

Light-weight aggregate concrete walls will give better thermal insulation than dense concrete when used for external walls but care must be taken in the choice of aggregate for external use because of the danger of excessive shrinkage and moisture movement occuring with certain types. Clinker has a corrosive action on steel and should not be used if shrinkage reinforcement is to be incorporated.

All types of light-weight aggregate concrete are more permeable than dense concrete and where the wall is exposed to the weather a greater thickness of cover to the steel is required, with possibly the further protection of rendering. Concrete with a wide range of density and compressive strength can be obtained by the selection of appropriate aggregate and mix.

NON-FINES CONCr. WALLs

6.7.3.3 No-fines concrete walls are constructed with a concrete composed of cement and coarse aggregate alone, the omission of the fine aggregate giving rise to a large number of evenly distributed spaces throughout the concrete. These are of particular value in terms of rain exclusion. No-fines concrete is suitable for external and internal loadbearing walls or for panel wall infilling to structural frames.

The weight of no-fines concrete is about two-thirds that of dense concrete made with a similar aggregate. Aggregates graded from 19 mm down to 9.5 mm are used with mixes of 1 to 8 or 10 for gravel aggregate and 1 to 6 for light-weight aggregates. The aggregate should be round or cubical in shape and no more water should be used than that required to ensure that each particle of aggregate is thoroughly coated with cement grout without the voids being filled. The hydrostatic pressure on form work is only about one-third of that of normal concrete. This is an advantage since horizontal construction joint should be minimized and form work one or two storeys high can be employed without it being excessively heavy. Any normal type of shuttering can be used.

No-fines concrete walls should not be subjected to bending stresses nor to excessive eccentric or concentrated loads. Slender piers and wide openings are, therefore, unsuited to no-fines construction. Isolated piers should not be less than 450 mm in width or one-third the height of adjacent openings.

The bond strength of no-fines concrete is low but for open ings up to about 1.5 m wide the walling itself may be reinforced to act as a lintel provided there is a depth of wall not less than 230 to 300 mm above the opening. As a precaution against corrosion the steel should be galvanized or coated with cement wash and bedded in cement mortar. For wider openings an in situ or precast reinforced lintel of dense concrete is generally necessary. Even when the wall above openings is not required to act as a lintel to carry floor or roof loads, horizontal reinforcement equivalent to a 13 mm steel bar should be placed above and below all openings. In buildings with timber floors the steel above the openings in external walls is usually made continuous.

Because of its weakness in tension, walls of no-fines concrete are sensitive to differential settlement. Particular attention must, therefore, be paid to the design of the foundations. For small buildings the lower part of the walls and the strip foundation should be of dense concrete, reinforced if necessary. For high buildings adequate stiffness is usually obtained by the use of rigid reinforced dense concrete cellular foundations.

BASIC STESSES FOR PLAIN CONCRETE WALLS

Cement	Aggregate	Nominal mix	Volume of aggregate per 50 kg of cement		Cube strength* within 28 days after mixing		Maximum permissible stresses
			Fine	coarse	Preliminary test	Works test	
			m^3	m^3	MN/m^2	MN/m^2	MN/m^2
Portland cement, Portland blast-furnace cement and other cements included in CP 110	Concrete with: (i) Natural aggregates to BS882 (ii) Air-cooled blast-furnace slag (coarse aggregate) to BS1047	1:1:2 1:1½:3 1:2:4 1:3:6 1:4:8	0.03 0.05 0.07 0.10 0.14	0.07 0.10 0.14 0.20 0.28	40 34 28 15 12	30 25.5 21 11.5 8.6	7.6 6.5 5.3 2.4 1.7
Portland cement, Portland blast-furnace cement and other cements included in CP 110	Concrete with: (i) Foamed blast-furnace slag to BS 877 (ii) Clinker aggregate to BS 1165 (iii) Such other artificial aggregates as may be suitable having regard to strength durability and freedom from harmful material	Proportions to be selected to give the required cube strength				14.0 11.0 8.3 5.5 2.8	2.6 2.1 1.6 1.1 0.5
	No-fines concrete with: (i) Natural aggregates to BS 882	Special mixes		0.28		7.0†‡ 3.5	1.3 0.6
	(ii) Air-cooled blast-furnace slag to BS 1047	1:8		0.28		2.8	0.5

NOTES on the table :

Intermediate values for other mixes may be found by interpolation.

* these requirements may be deemed to be satisfied if two-thirds of the value is obtained at 7 days.

† The average cube strength for mix design purposes should be 2.10 MN/m^2 in excess of the cube strength specified

‡ The attainment of this strength increases the density of the concrete to an extent where the thermal insulation properties may be impaired.

THICKNESS

6.7.3.4

Thickness of plain concrete walls

The procedure in calculating is the same as for masonry walls but using different permissible stresses based on varying types and grades of concrete (table A)[1] and a different set of reduction factors (table B) to apply to these stresses for slenderness ratios over fifteen, up to a maximum of twenty-four. An increase in the permissible stresses in a plain concrete wall may be made when the ratio of its storey height to length is less than 1 1/2. This varies linearly from zero at a ratio of 1 1/2 to 20% at a ratio of 1/2 or less. The length of the wall in this case is either the overall length or the length between adjacent openings.

The same increases may be made in the permissible stress in respect of eccentric and concentrated loads and lateral forces as for masonry walls.

It should be noted that notwithstanding the thickness established by calculation the London By-laws require the thickness of an external or party wall of concrete to be not less than 150 mm.

Slenderness ratio	15	18	21	24
Reduction factor	1.00	0.90	0.80	0.70

Linear interpolation between values for the reduction factors is permissible

Plain-concrete walls: reduction factor for slenderness ratios

SHRINKAGE

6.7.3.5.

Shrinkage reinforcement may be required in in situ cast concrete walls, other than those of clinker aggregate or no-fines concrete, particularly in external walls, in order to distribute the cracking due to setting shrinkage and thermal movement, and thus minimise the width of the cracks. Where this reinforcement is considered to be necessary, the Code recommends that it sh should be not less in volume than 0.4 per cent of the volume of the concrete in an external wall. It also makes recommendations in respect of internal walls, the positioning and distribution of the reinforcement and the provision of extra reinforcement round openings where shrinkage effects are greatest

As the drying shrinkage of no-fines concrete is low, reinforcement for this purpose is not usually necessary except, perhaps, with some lightweight aggregates, because the stresses set up by the slight shrinkage are relieved by the formation of fine cracks round the individual particles of aggregate. Shrinkage reinforcement may also be omitted from dense concrete walls where the mix is lean and of low shrinkage and where end restraints on the walls are small and work can be carried out continuously.[2]

R.C. WALLS

6.7.4 REINFORCED CONCRETE WALLS

IN-SITU CAST

6.7.4.1 In-Situ Cast external walls

The reinforced concrete load-bearing wall used as the enclosing wall to a building is the alternative to its use as a dividing element in the concrete box frame described below. The wall areas over openings act as beams and those areas between openings as columns. These openings may be wide, since with normal sill heights there is ample depth of wall between window head and cill above to act as a deep, thin beam and the wide, narrow window is a characteristic of this form of construction. Alternatively the whole height of the wall may be regarded as a beam pierced by any necessary openings for windows.

Sufficient width of wall must, of course, be left between openings to act as columns taking all the vertical loads. The problems of appearance and thermal insulation are the same as with the plain concrete wall, but the danger of cracking due to possible unequal settlement is reduced because reinforcement is present to resist any tensile stresses set up.

BOX FRAMES

6.7.4.2 Concrete Box Frames

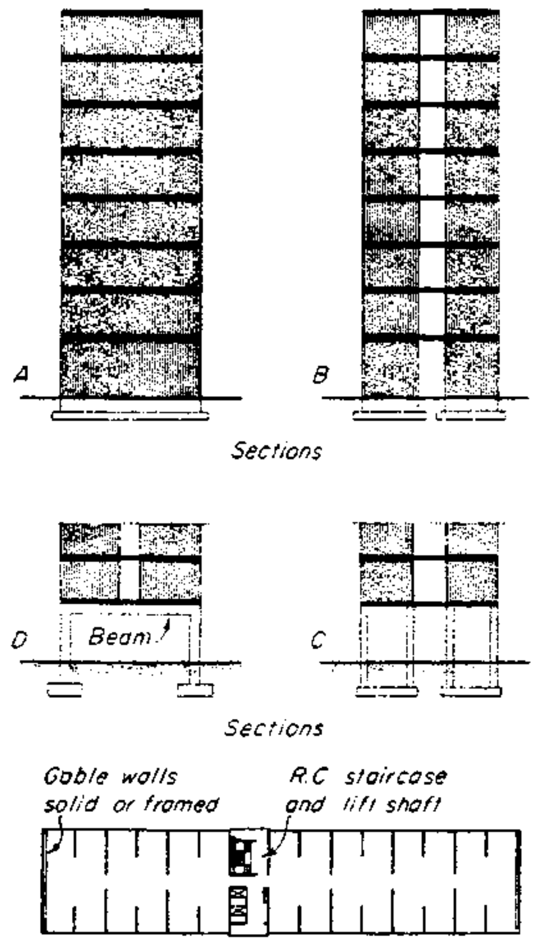
This is a form of cross-wall construction in which the walls are of normal dense concrete and, with the floors form box-like cells as shown in the fig. As in the case of brick or block cross-wall construction,

BOX FRAMES

it is suited to those building types in which separating walls occur at regular intervals and are required to have a high degree of fire resistance and sound insulation. The most common building type in this category for which it is suitable is the multi-storey flat or maisonette block.

In concrete walls of normal domestic scale, about 2.75m high and 100 mm thick, failure is almost wholly related to the strength of the concrete and very little to the slenderness of the wall. Reinforcement, therefore, may be nominal in amount or may be omitted altogether provided that the concrete is sufficiently strong to resist the stresses set up under load. For multi-storey blocks in the region of ten or eleven storeys high the mix would be designed to give a strength of around 15.5 N/mm^2 at 28 days, although for the two lowest storeys a stronger mix might be necessary as well as the inclusion of reinforcement.

Cracking due to the shrinkage is normally overcome by the inclusion of shrinkage reinforcement. Such cracking generally occurs only if the shrinkage is resisted by some restraint, such as that offered by changes in the plane of a wall or by a previously poured lift of concrete which has been permitted to take up its shrinkage before the next lift is poured on to it. Provided that concreting can proceed without undue delay and that the walls are in simple, straight lengths, shrinkage reinforcement in the walls may safely be omitted.



Typical plan

Although the junctions of walls and floors in a box frame are monolithic, if the walls are not reinforced the structure can only provide rigidity in the length of the building to the extent of the precompression set up in the walls by the floor loads and self-weight of the walls, as explained in the case of normal cross-wall construction (see page 132). Additional stability must normally be given by staircase and lift shafts of reinforced concrete, or by the inclusion of longitudinal walls at certain points in the plan. The box-walls themselves provide rigidity in the transverse direction.

In its simplest and most economic form all the box walls run in a straight, unbroken line from back to front of the building and are supported directly by a strip foundation (fig.A). They may, however, be pierced by openings or be in completely separate sections on the same line, or staggered relative to each other provided that each section is in the same position throughout the height of the building (b). If the upper floors are to be supported on columns at ground level the necessity of beams and the disposition of the columns will depend upon the arrangement of the walls above. Straight, unbroken box walls can act as deep beams spanning between the supporting columns with any necessary reinforcement placed in the tension and shear zones. If the walls are broken extra columns must be introduced to enable each wall section to act as a beam (C) or, alternatively, a separate beam must be introduced to pick up the sections and transfer the loads to the columns (D).

BOX FRAMES

P.C. PANELS

6.7.4.3. Large precast panel structure

In this form of construction the loadbearing elements are large panels not less than storey-height, used with precast floor and roof units (figure 6.7.4.2 D) Window openings may be cast in the external panels which are usually finished with an exposed aggregate or tooled or profiled surface and incorporate thermal insulation, either sandwiched between two leafs or applied to the internal face. Internal panels can be made smooth enough to make plastering unnecessay

Solid external panels are insulated internally. They are simpler to produce than sandwich panels but usually require a vapour barrier near the inner face. Certain types of these panels are in cavity or cored form.

Internal loadbearing wall panels are solid or cored and between 125 and 225 mm thick with nominal reinforcement. Adequate sound insulation can be achieved with a thickness of 175 mm if plastered on both sides and rather thicker if not.

Floor panels may be of solid or cored construction. The former may be reinforced as two-way spanning slabs and they also provide better air-borne sound insulation. The latter are lighter in weight, but can span in one direction only.

P.C. PANELS

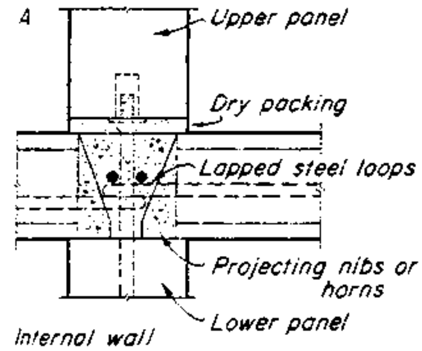
CASTING

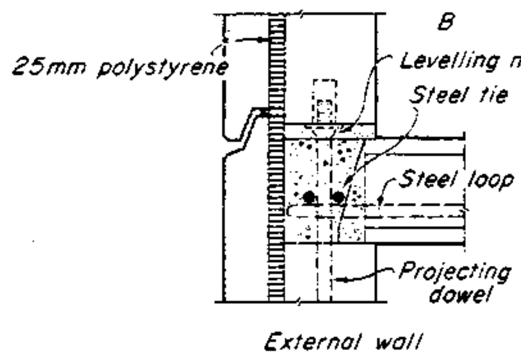
- Casting panels

Horizontal casting is used for complicated panels which present some difficulty in casting, such as sandwich-panels for external walls, those with openings in them and those which are to have an integral or applied surface finish. When cast these are preferably removed from the moulds by means of pivoting mould beds or by vacuum pads, in order to avoid damage. The former method avoids the need for reinforcement to resist lifting stresses.

Vertical casting is preferable for wall and floor panels required to have a fair face both sides since this has the advantage of eliminating face trowelling. The moulds can be arranged in batteries with ten or more compartments, the division plates being of thick steel or concrete panels or of ply facing on both sides of a steel frame. The system of using two concrete panels, initially cast horizontally with a very smooth, true face, as the mould faces to reproduce a run of similar units was developed by the Building Research Station. The first panel is cast between the initial pair and has a true face on each side. After curing the three panels are spaced apart to provide the mould for two further panels, the five then being used to produce four more, and so on.

The method is most suitable for residential buildings since the dense concrete panels can provide, as well as the strength for load bearing, the degree of fire resistance and sound insulation required at the separating walls. Cellular, cross-wall and spine-wall plan forms may be used. The advantage of the cellular plan is its inherent stability and the fact that all walls may be loadbearing so that the floor panels may be two-way spanning.

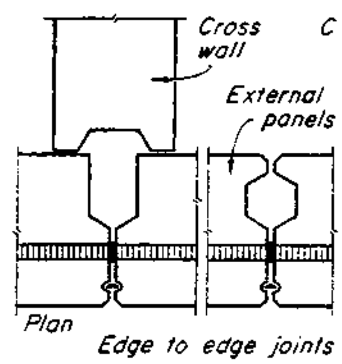


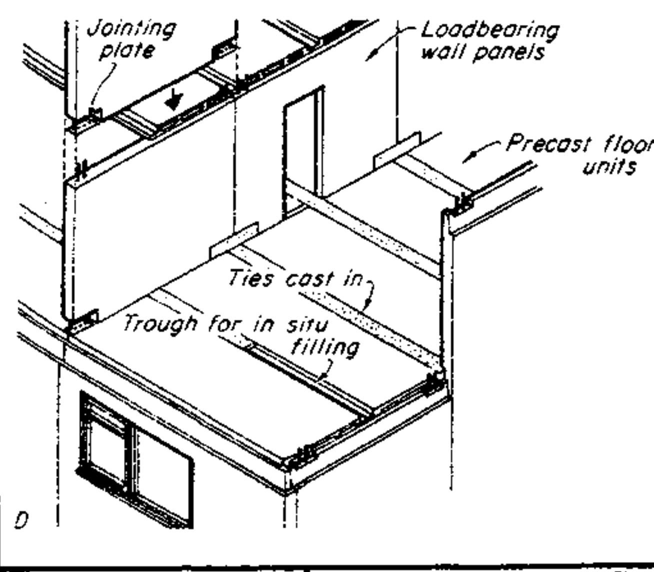


- Types of panels

External wall panels are commonly either of solid or of sandwich construction although waffle slabs are also used. The latter, however, have a number of disadvantages.

Sandwich panels have a layer of insulation incorporated either symmetrically or asymmetrically in the thickness of the slab (fig.6.7.4.2.). In the former both internal and external leaves are loadbearing with transverse ties strong enough to ensure that both act together. The restraint thus offered to thermal and moisture movement in the external leaf can cause it to warp. This is overcome by an asymmetrical positioning of the insulation since the thinner non-loadbearing leaf, usually external, required only to be attached to the loadbearing leaf by lighter forms of ties. These ties, either of hot-dipped galvanized mild steel, or of suitable non-ferrous metal, must have ends formed to ensure a mechanical anchorage between the leaves.





STRUCTURAL CONNECTIONS

- <u>Structural connections</u>

In situ concrete is commonly used to form the structural joints between panels. The method used to form the horizontal joint between the wall panels is shown in the fig. A, B.

It is preferable to limit the bearing of the floor slabs on the heads of the wall panels by the provision of projecting nibs or horns at about 150 to 225 mm centres along the edge of the floor panels, which provide the necessary support for the floor slabs. This permits the load from the upper wall panel to be transferred across the whole width of the wall directly to the panel below as shown. A threaded bar or dowel projecting from each end of the lower panel provides, by means of nut and washer, temporary support and a means of levelling the top panel. The joint is filled with in situ concrete and after this has set the gap above it is dry packed with cement mortar. When this in turn has set the nuts are run down to ensure contact between the upper slab and the packing thus off-setting the initial shrinkage of the mortar.

With cross and spine wall plans overall ridigity can be provided by in situ cast lift and stairwells, but this has the disadvantage of mixing precast and in situ work on the site. Fully precast construction uses bathrooms precast as reinforced concrete boxes complete with floor and ceiling and lift and stairwells precast in storey or half-storey heights which, when erected on each other, form structural 'columns' running the full height of the building. A number of these vertical units along the centre of the block form a structural spine to the remainder of the structure which is fabricated from large precast floor panels and storey height loadbearing wall panels (E).

OPENINGS IN WALLS

6.8. Openings in Walls

- An opening in an external wall of a
  - o head
  - o jamb (or reveal) and
  - o sill (or threshold)

6.8.1 HEAD: its function is to carry the triangular load of brickwork over the opening and transmit this load to the jambs at the sides. To fulfil this task it must have the capacity to support the load without unacceptable deflection.
A variety of materials and methods is available in the form of a LINTEL or BEAM such as:

- o timber: suitable for light loads and small spans, the timber should be treated with a preservative to prevent attack by beetles or fungus.

- o steel: for small openings a mild steel flat or angle section can be used to carry the outside leaf of a cavity wall, the inner leaf being supported by a concrete or steel Lintel,
  for medium spans - a chanel or joist section is usually suitable,
  for larger spans - a universal beam section to design calculations will be needed.

  Steel lintels which are exposed to the elements should be either galvanised or painted with several coats of bitumious paint to give them protection against corrosion.

- o Concrete: these can be designed as insitu or precast reinforced beams or lintels and can be used for all spans. Prestressed concrete lintels are available for the small and medium spans.

- o Stone: these can be natural, artificial or reconstructed stone but are generally used as a facing to a steel or concrete lintel.

- o Brick: unless reinforced with mild steel bars or mesh, brick lintels are only suitable for small spans up to 1 m, but like stone, bricks are also employed as a facing to a steel or concrete lintel.

LINTELS

6.8.11 LINTELS: Require a bearing at each end of the opening, the amount will vary with the span but generally it will be:
100mm for the small spans and up to
225mm for the medium and large spans.

- In cavity walling a D.P.C. will be required where the cavity is bridged by the lintel and this should extend at least 150mm beyond each end of the lintel.
- Open joints are sometimes used to act as weep holes; these are placed at 900mm centres in the in the outer leaf immediately above the D.P.C.

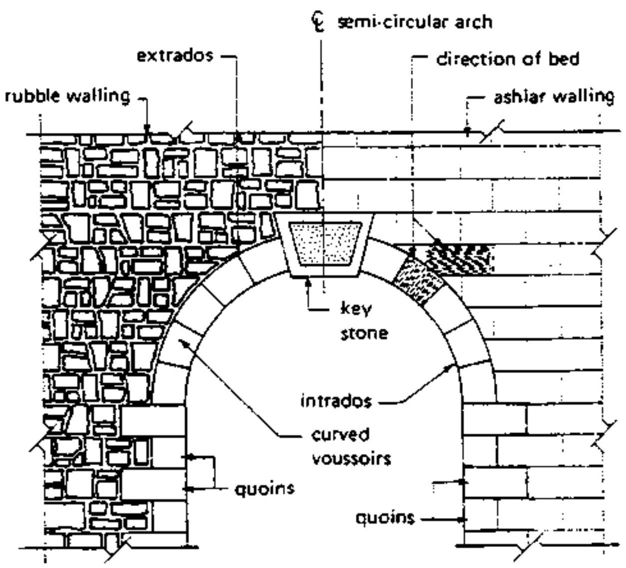
ARCHES

6.8.12 ARCHES: These are arrangements of wedged shaped bricks designed to support each other and carry the load over the opening round a curved profile, to abutments on either side.

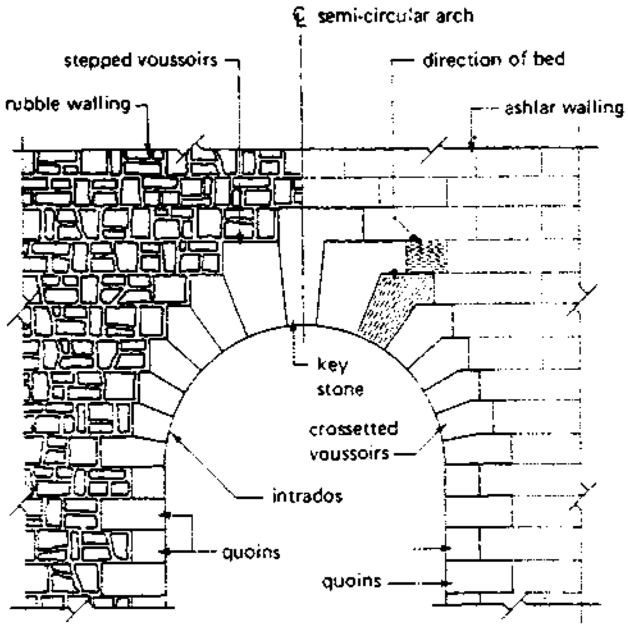
An exception to this form is the flat or "soldier" arch constructed of bricks laid on end or on edge.

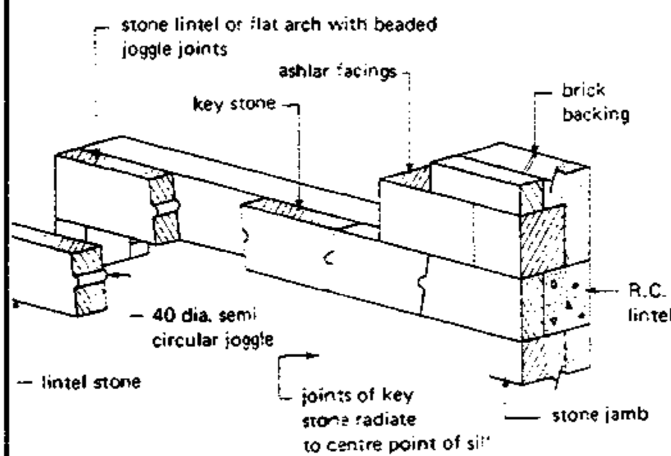
When constructing an arch it must be given temporary support until the brick joints have set and the arch has gained sufficient strength to support itself and carry the load over the opening. These temporary supports are called CENTRES and are usually made of timber; their design is governed by the span, load and thickness at the arch to be constructed.

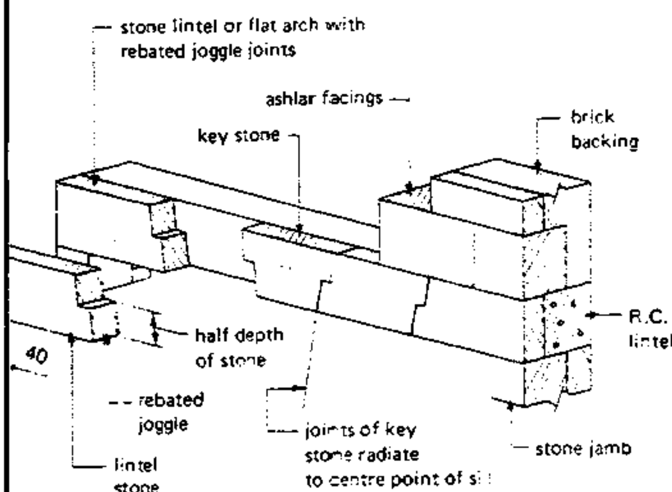


- ARCH Terminology:

- Voussoirs: The wedge-shaped bricks or blocks of stone which comprise an arch; the last voussoire to be placed in position is usually the central one and known as the KEY Brick or KEY Stone.
- Ring, Rim or Ring Course: The circular course or courses comprising the arch.
- Extrados or Back: The external curve of the arch.
- Intrados: The inner curve of the arch.
- Soffit: The inner or under surface of the arch.
- Abutments: the portions of the wall which supports the arch.
- Skewbacks: The inclined or splayed surface of the abutments prepared to receive the arch and from which the arch springs.







- Springing Points: The points at the intersection between the skewbacks and the intrados.
- Springing Line: The horizontal line joining the two springing points.
- Springes: The lowest voussoirs immediately adjacent to the skewbacks.
- Crown: The highest point of the extrados.
- Haunch: The lower half of the arch between the crown and a skewback.
- Span: The horizontal distance between the reveals of the supports.
- Rise: The vertical distance between the springing line and the highest point of the intrados.
- Centre (or striking point) and Radius: (See Fig.)
- Depth or Height: The distance between the extrados and intrados.
- Thickness: The horizontal distance between and at right angles to the front and back faces; it is sometimes referred to as the width or breadth at the soffit.
- Bed joints: The joints between the voussoirs which radiate from the centre.
- Spandril: The triangular walling enclosed by the extrados, a vertical line from the top of the skewback, and a horizontal line from the crown.
- Impost: The projecting course (or courses) at the upper part of a pier or other abutments to stress the springing line.

- CLASSIFICATION OF ARCHES:

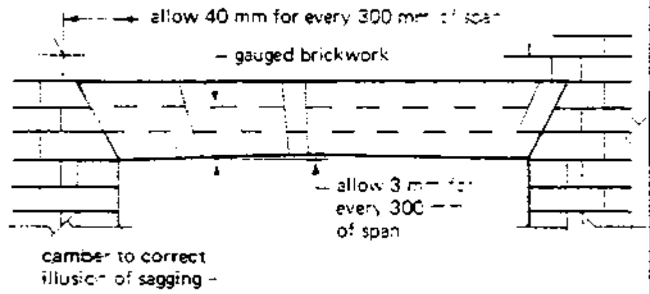
Arches are classified according to their
(a) shape and (b) materials and workmanship employed in their construction.

CLASSIFICATION

a

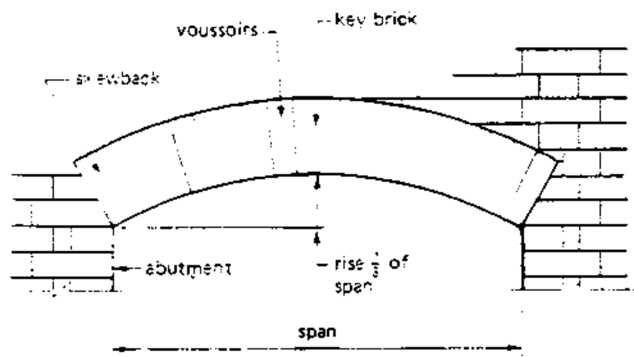
(a) The more familiar forms are:

flat (straight or camber) Archs.
- o gauged flat arch
- o purpose-made flat arch
- o axed brick flat arch.



Camber Arch

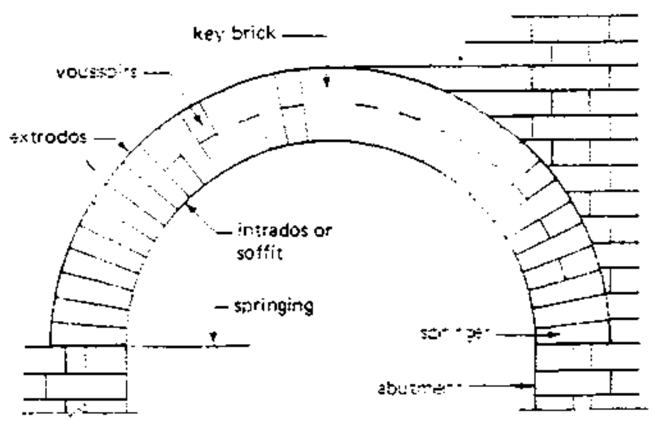
- Segemental Archs:
  - o gauged segmental Arch
  - o purpose-made brick segmental Arch
  - o axed brick segmental Arch
  - o rough brick segmental Arch.



Gauged Segmental Arch

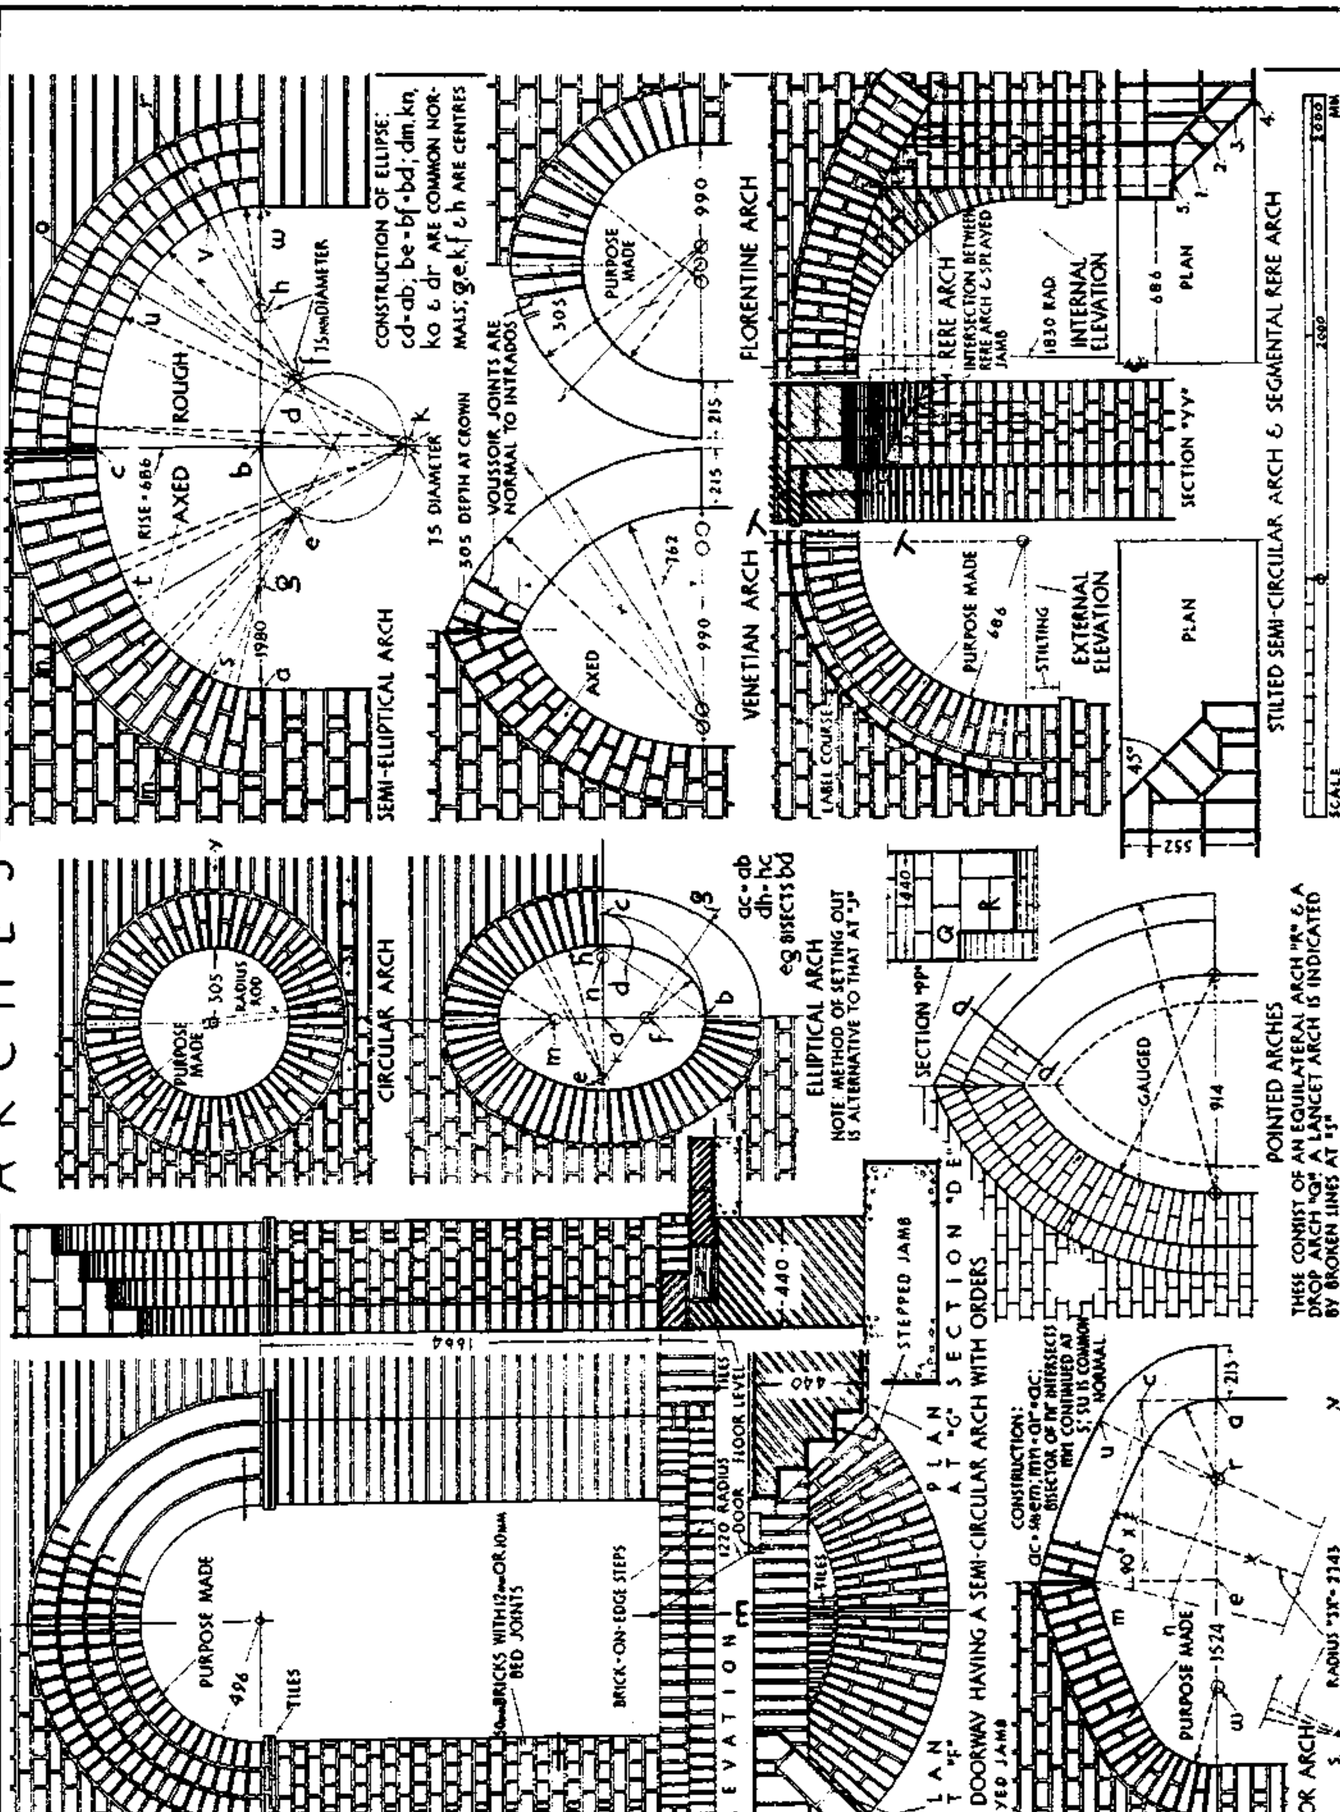
- Semicircular Archs:
  - o gauged semicircular Arch
  - o purpose-made brick semicircular Arch
  - o axed brick semicircular arches
  - o rough brick semicircular arch.

Others which are not so generally adopted are: Circular Archs, Semi elliptical Archs, Elliptical Archs, Pointed Archs.



Gauged Semi-circular Arch

b	(b) The voussoirs may consist of: o rubber bricks o purpose-made bricks o ordinary or standard bricks cut to wedge shape (known as axed bricks) o Standard uncut bricks.
RUBBER BRICKS (Rubbers, Cutters or Malms): soft bricks; various sizes; can be readily sawn and rubbed to the desired shape;are used in the construction of " gauged arch ".	GAUGED ARCHES
PURPOSE-MADE BRICKS: specially hand-moulded to the required shape; used for good class work of "Purpose-made brick Archs".	PURPOSE-MADE BRICK ARCHES
ORDINARY BRICKS CUT TO WEDGE SHAPE: are standard bricks, roughly cut to the required wedge shape by using a bolster and dressed off with a scutch, or axe. Used in the construction of "Axed brick Archs".	AXED BRICK ARCHES
ORDINARY STANDARD UNCUT BRICKS: When such bricks are used in the construction of arches, the bed joints are not of uniform thickness, but are wedge shaped. They are used for "Rough brick Archs".	ROUGH BRICK ARCHES



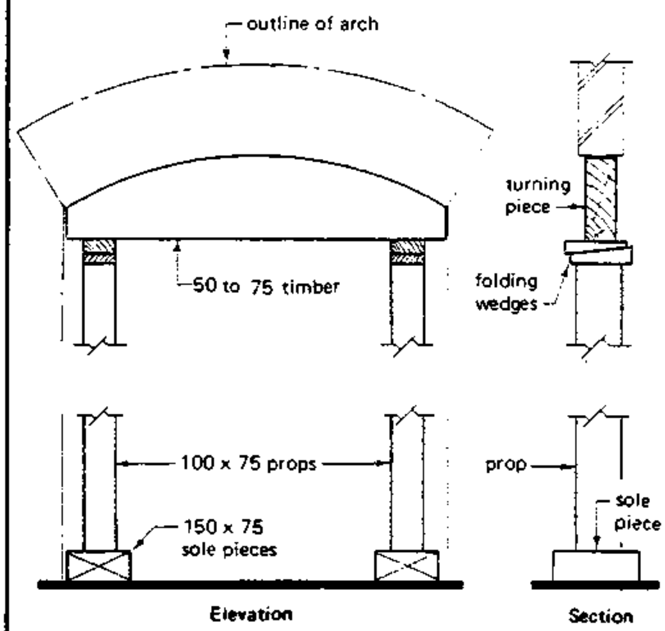
6.WALLS compiled: D.VOLKE JULY '80	OPENINGS IN WALLS	BUILDING CONSTR. — LECTURE — CET 3031/16.8 89
TCA TECHNICAL COLLEGE ARUSHA CHUO CHA UFUNDI ARUSHA	CIVIL ENGINEER DEPARTMENT	89

CENTRES

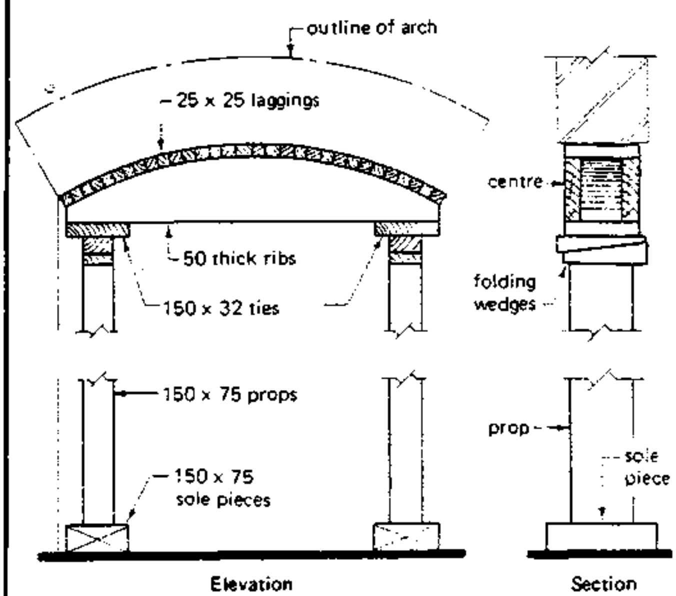
- CENTRES:
  Are temporary structures (usually of light timber construction) which are strong enough to support archs of bricks or stone while they are being built and until they are sufficiently set to support themselves and the load over the opening.

  A Centre is always less in width than the soffit of an arch to allow for plumbing (that is: alignment and verticality of the face with a level or rule.) The type of Centre to be used will depend upon:

  (1) The weight to be supported
  (2) The span
  (3) The width of the soffit.

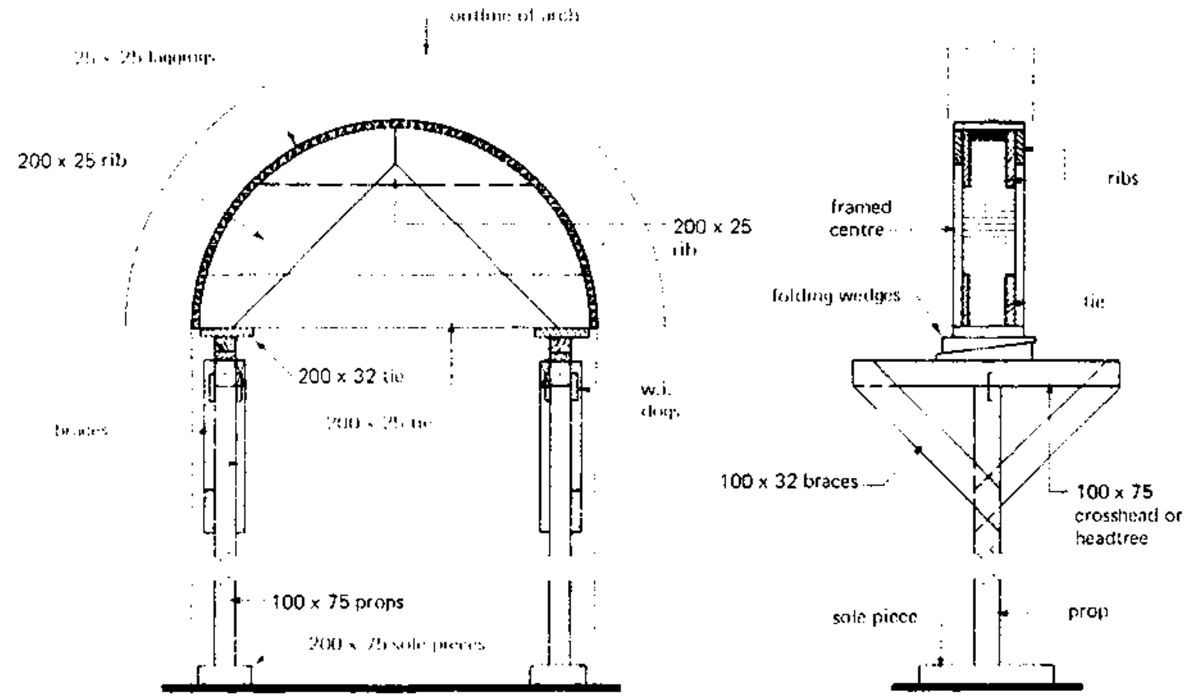


Generally soffits not wider than 150mm will require one rib at least 50 mm wide and are usually called turning pieces.
Soffits from 150-350mm require two ribs which are framed together using horizontal tie members called laggings.
Soffits over 350mm require three or more sets of ribs.
The laggings are used to tie the framed ribs together and to provide a base upon which the arch can be built.
Close laggings are those which are touching each other, forming a complete seating for a gauged arch.
Open laggings, spaced at twice the width of laggings, centre to centre, are used for rough arches.

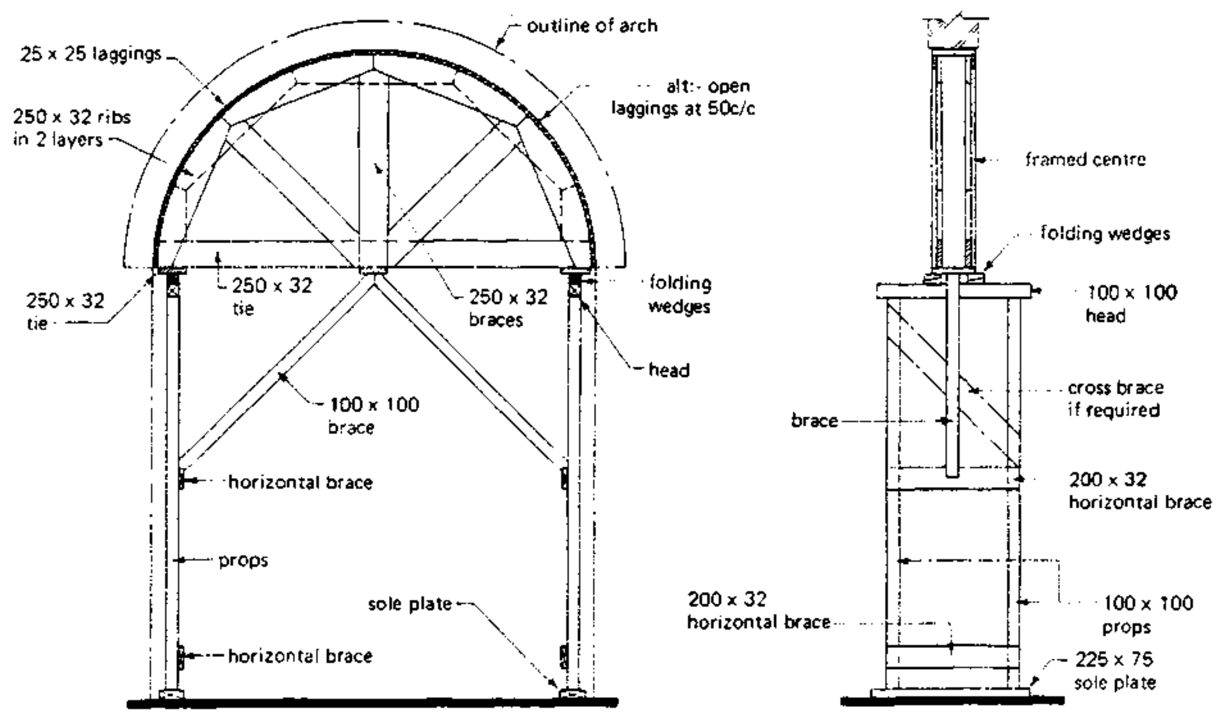


Centres for small span arches

If the arch is composed of different materials, i.e. a stone arch with a relieving arch of brickwork, a separate centre for each material should be used.



Typical framed centre for spans up to 1500 mm



Typical framed centre for spans up to 4 000

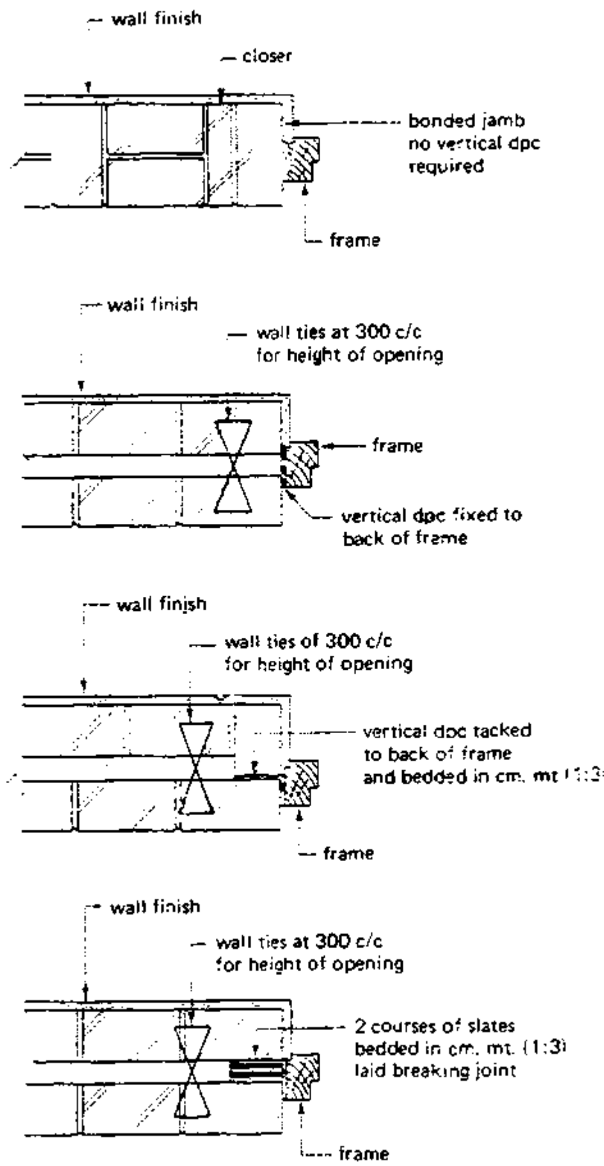
compiled : D.VOLKE		LECTURE
JULY '80		CET 3031 / 16.8 91

JAMBS

6.8.2 <u>JAMBS</u>: in solid walls these are bonded to give the required profile and strength.

In cavity walls the cavity can be closed at the opening by using a suitable frame or by turning one of the leaves towards the other forming a butt joint in which is incorporated a vertical D.P.C. (as required by the B.R.)



SILLS & THRESHOLDS

6. .3 SILLS and THRESHOLDS

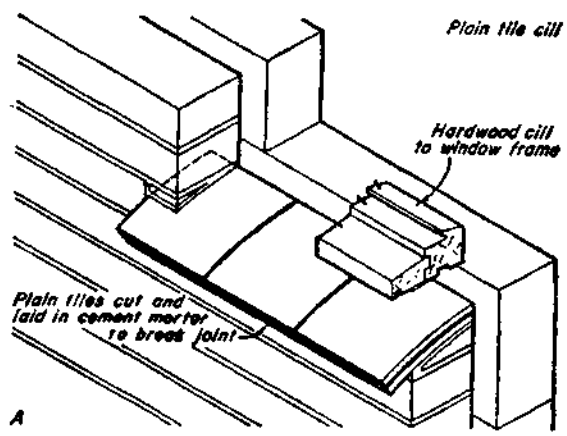
6. .3.1 SILLS: Are defined as the BOTTOM of a Window Opening.

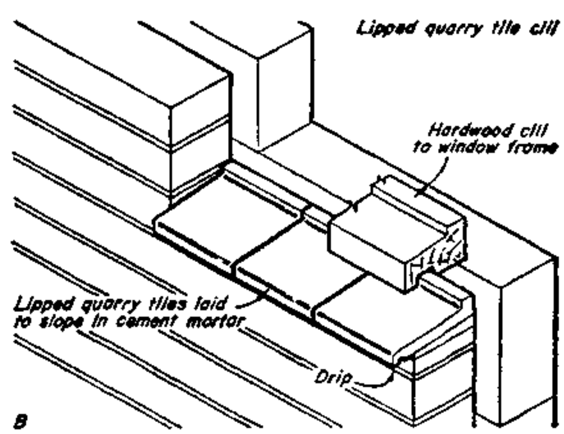
SILLS :

the function of a sill is to shed the rain-water, which has run down the face of the window or door and collected at the base, away from the opening and the face of the wall.

- o Many methods and materials are available.
- o Appearance and durability are the main requirements.
- o Sills (unlike lintels) do not require a bearing at each end.

- Usually a window frame is less thick than the wall in which it is built, so that there are horizontal surfaces of brickwork at the foot of the window.
- Most of the area of a window is glass which does not absorb water, and rain runs off it on to the external surface below.
- The FUNCTION of the SILL, therefore is to protect this part of the wall from the penetration of considerable quantities of water.
- Suitable materials for the construction of sills are:
  - stone
  - concrete
  - brick, slate, stone or quary tiles laid in cement mortar
  - roofing tiles laid to break joint in cement.
  - metal



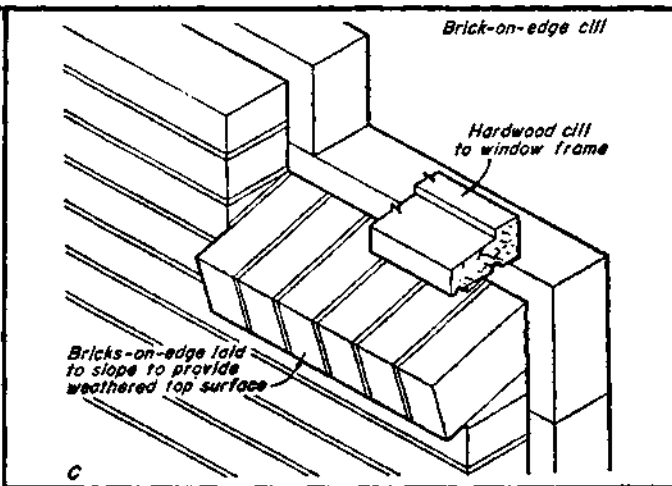


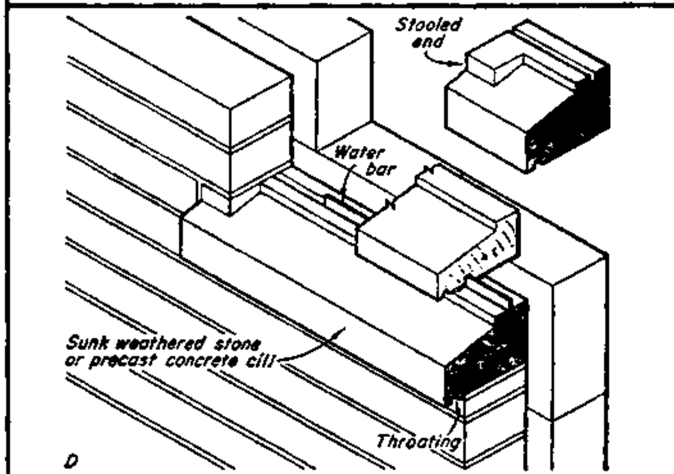
- The top surface of the sill is made to slope downwards and outwards: It is weathered in order to discharge rain water falling on it and the sill itself is made to project not less than 25mm to 40mm beyond the wall face in order to direct the discharge of water away from the face of the wall below.

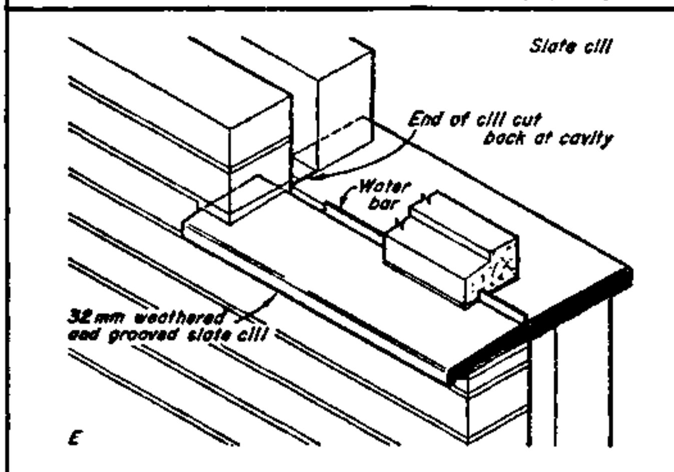
- To prevent backward flow across the undersite of this projection through wind or capillary attraction a drip is formed at the bottom front edge of the sill projection (a halfround groove 12mm in diameter is satisfactory)

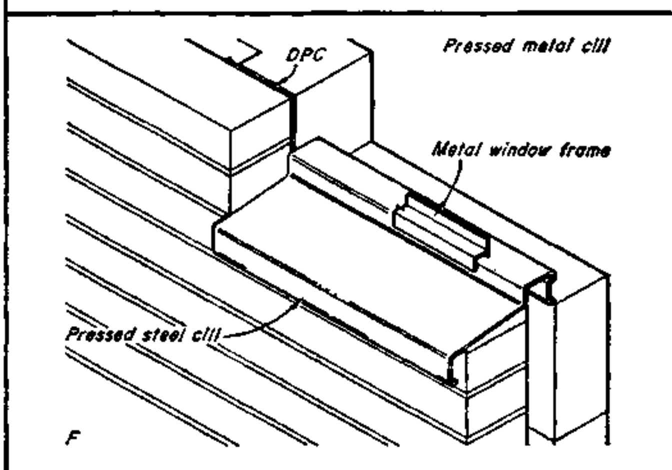
- The joint between sill and window frame is normally sealed with mastic. A feather barrier to water penetration may be incorporated in form of a strip of galvanised steel called a WATER BAR (20mm x 32mm to 32mm x 6.4mm) bedded half its depth in cement mortar in a groove formed in stone, concrete or moulded clay sills the upper projecting half engaging in a similar groove in the under side of the window frame, which is filled with white lead and oil or a mastic before the frame is bedded on the sill.

- As an additional means of protecting the joint, the weathered top surface of the sill, may be sunk slightly at the top. This has the effect of raising the joint above the water-retaining surface and serves to break the force of water blown back to the joint.









- Lipped quarry tiles may be used to achieve this and to fulfil the function of a water bar at the same time.

- The weathering to a stone or precast concrete sill may be stopped short of the ends to provide a flat seating for the brick jambs. This is called STOOL or STOOLING.

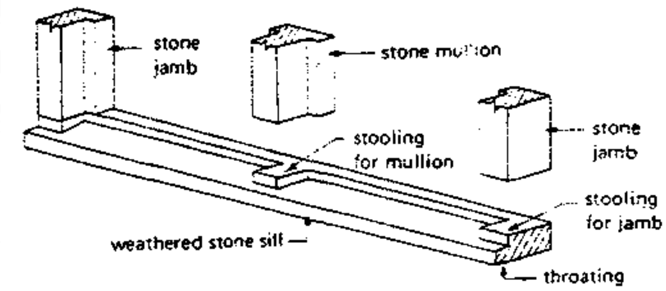
- Natural stone and precast concrete sills are similar in section and are normally not less than 75mm fluck with the depth varying according to the depth of the window reveal.

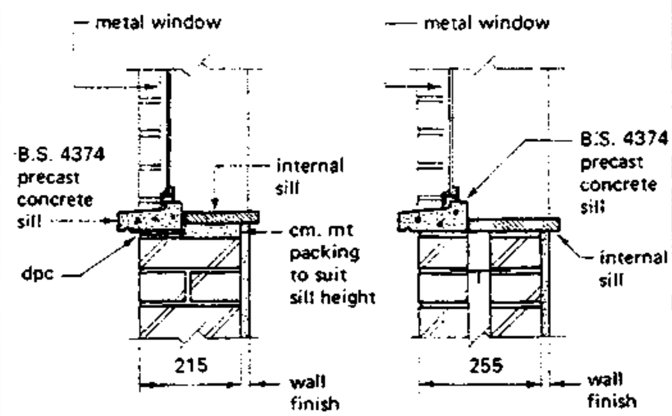
- Slate (by its nature) can be used in thin sections and slate sills may be safely carried across a vacity to form the internal sill.

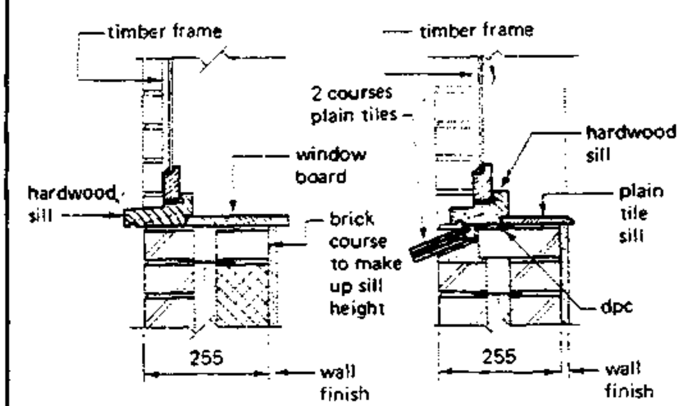
- Metal sills may be of
  - cast metal
  - hand-formed out of sheet copper or zinc.
  - pressed out of sheet steel
  - and secured to the wall by MS bracket.

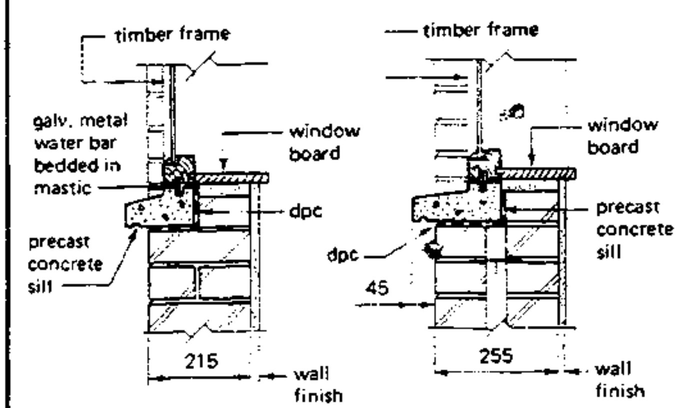
- When the windowframe is set close to the outer face of the wall the main sill (external sill) may be eliminated and its functions be fulfilled by a projecting timer sill to the windowframe.

- There are different ways of finishing the <u>internal</u> sill of windows. The figures show examples of typical internal sill constructions.







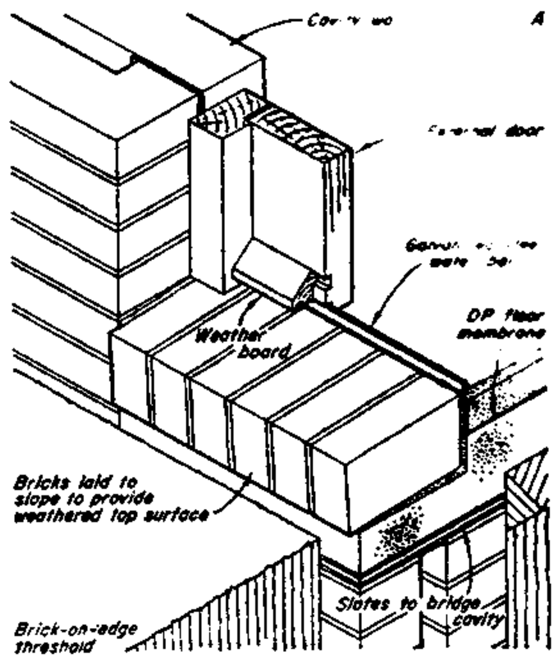


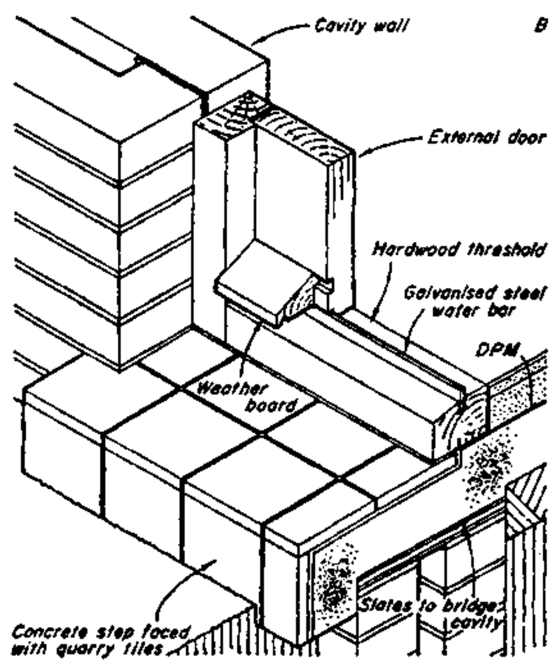
THRESHOLDS

6.8.3.2. THRESHOLDS

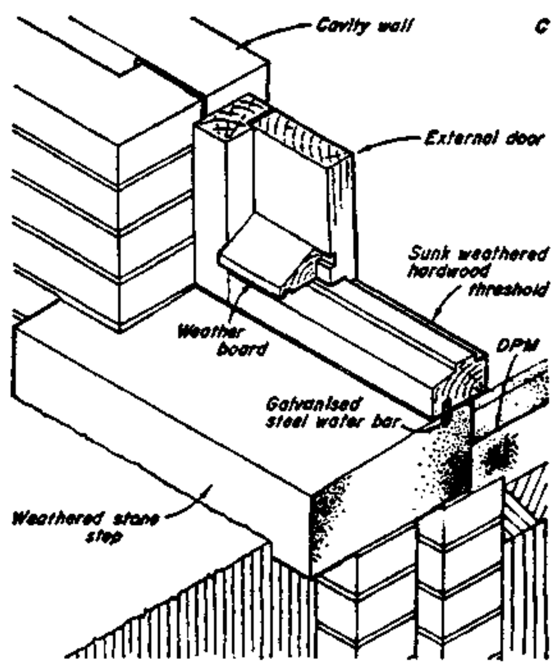
Are defined as the Bottom of a <u>Door Opening</u>.

- The width of a threshold should be wide enough to accommodate a human foot and be weathered on the top surface.
- Usually external doors open inwards and the incorporation of a water bar in the threshold and a weather - borad (or weather mould) on the door is advisable in order to prevent the entry of water under the door.
- A hardwood threshold is sometimes incorporated as a part of the door frame, especially where the door is set within a prefabricated wall unit including door, window and infilling panel. This is useful when the distance between ground and floor levels is somewhat greater than a reasonable rise for a single step. (See fig.)
- The provision of a timber threshold results in a drop in level immediately below the weatherboard and if the later is made to project slightly beyond this, water from the door does not fall on to the water retaining surface immediately in front of the water bar.
- People are less likely to trip over a water bar set in a relatively large and visible timber threshold than when it is set in a flush threshold as shown in the fig.





- In case of external doors it is applied to those members with the function of forming a firm and durable base to the doorway and to exclude water.
- Suitable materials are:
  - stone
  - concrete
  - brick
  - quarry tile
  - timber.
- As the floor level is normally above the ground level outside the door an external threshold usually incorporates a step. This may be formed in various ways, either:
  - as an extension of the concrete floor slab or
  - as a separate member of some other material shown in detail in the figure.



Try to answer the following questions and use sketches where ever necessary and possible

1. Function and properties of walls:

1.1 Name the functions of a wall

1.2 List and give brief explanations (by means of sketches) on the functional requirements of walls

2. Behavior of walls under load:

2.1 Explain the following terms:
a) crushing; b) buckling; c) settling;
d) excentric loading e) slenderness ratio;
f) sliding ; g) frictional resistance
h) passive soil pressure i) overturning by
1. rotation, 2. settlement

2.2 Write notes on 'Calculation of wall thickness' and summarize briefly the design process.

3. Types of walls

3.1 Divide walls into different types

3.2 Explain the differences between:
a) partition walls ; b) party walls
c) seperating walls; d) division walls.

3.3 Describe briefly the characteristics of

a) Retaining walls	b) masonry walls
c) monolithic walls	d) frame walls
e) membrane walls	f) cavity walls
g) cross walls	g) parapets.

4. Stonework

4.1 Classify Building stones and explain briefly their characteristics.

4.2 Write notes on the use and treatment of Building stones.

4.3 What is the difference between 'Reconstructed' and 'Artificial' stones.

4.4 List and describe the main Defects in stone

4.5 Explain the following terms:
a) arris ; b) ashlar ; c) bed joint ; d) bonder
e) cramp; f) dowl ; g) yoggle ; h) lacing
i) natural bat; j) quarry seep ; k) quoin
l) stool m) string course n) weathering

4.6 Give the characteristics of RUBBLE WALLING
4.7 Give the characteristics of ASHLAR WALLING

5. Brickwork
5.1 Define a Brick (according to BS 3921, Part 2)
5.2 Give the size of Standard Bricks
a) British standard ; b) German standard

5.3 Explain by means of sketches:
a) $\frac{1}{2}$ bat b) $\frac{3}{4}$ bat ; c) bevelled bat (large)
d) bevelled bat (small); e) queen closer (half)
f) queen closer (quartes) g) bevelled closer;
h) mitred closer; i) king closer j) double bulluose
k) splay - stretcher e) splay header;

5.4 Describe briefly how bricks are manufactured.

5.5 What is meant with EFFLORESCENCE?

5.6 According to BS 392, Part 2 there are different types of bricks, such as: - solid / - perforated/ - hollow/ - cellular bricks. Explain the differences!

5.7 What are calcium silicate bricks?
What are concrete bricks?

5.8 Write brief notes on Mortars used in brickwork and give typical mixes.

5.9 Explain how to overcome the penetration of dampness in walls, which are affected
a) by rain, penetrating the HEAD of the wall,
b) by rain, beating against external walls;
c) by ground moisture of the base of the wall.

5.10 Sketch common bonds in brickwork such as
a) Header Bond; b) strecher Bond;
c) English Bond; d) cross bond
e) Flamish Bond; and list other kinds of brickwork bonding.

5.11 Explain the Metric Modular Brickwork and compare British standard and the German system.

6. Blockwork
6.1 What is the difference between Brickwork and Blockwork?
6.2 Characterize different types of blocks such as
a) clay blocks; b) precast concrete blocks;
c) aerated concrete blocks.

7. Concrete walls

7.1 How are concrete walls broadly classified?

7.2 What can be used as precaution against cracking in concrete walls?

7.3 Write notes on FORMWORK and sketch three different straight foreward methods used for concrete walls.

7.4 Explain the following terms.

a) Plain monolithic concrete walls;

b) Dense concrete walls;

c) Light - weight aggregate concrete walls
d) Non - fines concrete walls
e) in - situ cast reinf. concrete external walls?
f) concrete box frames
g) large precast panel structures.

8. Openings in walls.

8.1 What are the members of an opening in a wall?

8.2 Explain (by using sketches) the function and the way of construction of R.C. Lintels

8.3 List different forms of archs

8.4 What are JAMBS ?

8.5 Explain the function of a) a sill and b) a threshold.

8.6 List suitable materials for the construction of a) sills and b) thresholds

8.7 Sketch and explain different typical sill details, such as:
a) plain tile sill
b) lipped quarry tile sill
c) Brick - on edge sill
d) sunk weathered stone or precast concrete sill
e) weathered precast concrete sill
f) slate sill
g) pressed steel sill

8.8 Sketch and explain different typical threshold details, such as:
a) Brick - on edge threshold
b) concrete step, faced with quarry tiles
c) weathered stone step

8.9 Explain (if necessary by sketching) the terms:

a) internal sill ; b) stool or stooling, c) water - bar:
d) weather - board; e) hardwood threshold.

7. FLOORS

LOCAL BYLAWS

7. FLOORS

7.1 General

- Traditionally the GROUND-FLOOR of most small buildings were formed directly of the ground, the soil being rammed until it was firm and sometimes on it where laid flag-stones or bricks to form a hard surface.

  This was unsatisfactory, because the moisture which was continously withdrawn from the soil below the building made the floor DAMP, unconfortable and unhealthy.Therefore other types of floors have been developed in order to make buildings more comfortable and healthy.

- The <u>CONSTRUCTION</u> of a floor - especially in warm climates - will depend largely on its purpose and the material available. The <u>chief factors</u> affecting its design are
  - strength
  - comfort
  - coolness (or thermal insulation)
  - sound insulation
  - flexibility (especially in earthquake areas)

- LOCAL BYLAWS demand a certain capability of carrying load according to its destination; e.g.:
  - a <u>domestic floor</u> may be required to carry only 14,6 MN/m^2 (146 kg/m^2)
  - an <u>industrial floor</u> may be required to carry 48,8 MN/m^2 (488 kg/m^2)

SOLID GROUND FLOORS

7.2 Solid Ground Floors

- Concrete Ground Floors are most widely used today and are usually solid.
- On poor, or uneven ground, or where heavy loads are to be carried, they may be REINFORCED.
- The floor should be laid on HARDCORE of broken stones, concrete, rock, laterite, lumps or burned bricks - if obtainable.
- Where these items are in short supply, 25 cm of compact FOUNDATION SOIL will serve.
  Not TOP SOIL, because:
  1. to prevent plants, shrubs and trees from attempting to grow under the concrete.
  2. it readily contains moisture and would cause the concrete over it to be damp.

7.21 Site Concrete:

- A continous layer of CONCRETE at least 10cm thick to be spread over the site of all buildings within the external walls on a bed of HARDCORE at least 15cm thick.

  OR

- A continous layer of CONCRETE at least 15 cm thick can be used without HARDCORE underneath.
- The MIXTURE of concrete generally used is

1	:	3	:	6
cement		sand		aggregate

SITE CONCR.

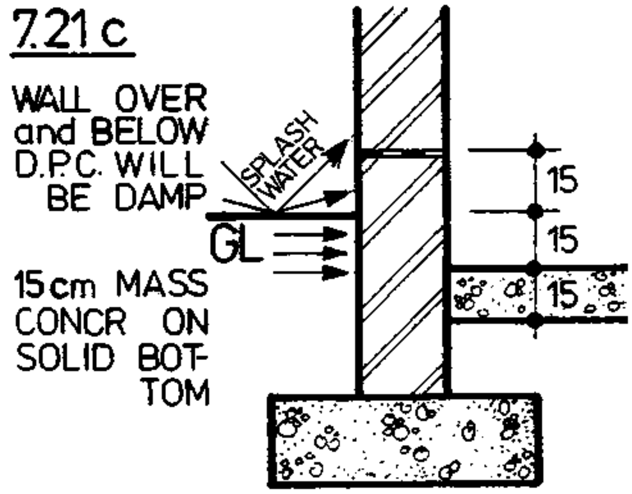
CIVIL-ENGINEER DEPARTMENT

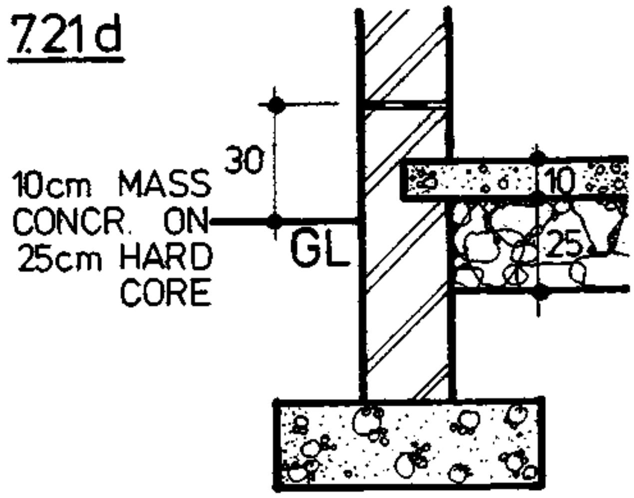
- The building regulations do not allow this site concrete to be laid directly on the turf or to soil of the site. All vegetable and top soil has to be removed first for reasons, which are already mentioned above.
- The depth of vegetable or top soil varies and on some sites it may be necessary to remove 30 cm or more. If the 15 cm site concrete were then laid, the top surface of the concrete would be 15 cm below the site outside GROUND LEVEL. It will be remembered that DPC in all walls should be 30 cm above the ground, so that there would be 45 cm of the external walls below the DPC and 30 cm above the floor, making the building very liable to damp. One possibility would be to make the site concrete 45 cm thick to bring its top surface up to the correct level, but this would be an unnecessarily expensive method.

Instead - HARDCORE is spread to raise the level of the concrete. (The soil excavated from foundation trenches should not be taken for backfilling or raising the level of the concrete. The excavated soil will have been broken up in digging and would need quite thorough ramming to make certain it did not sink. Further, this soil would tend to retain moisture and make the site concrete damp.

7.21 c

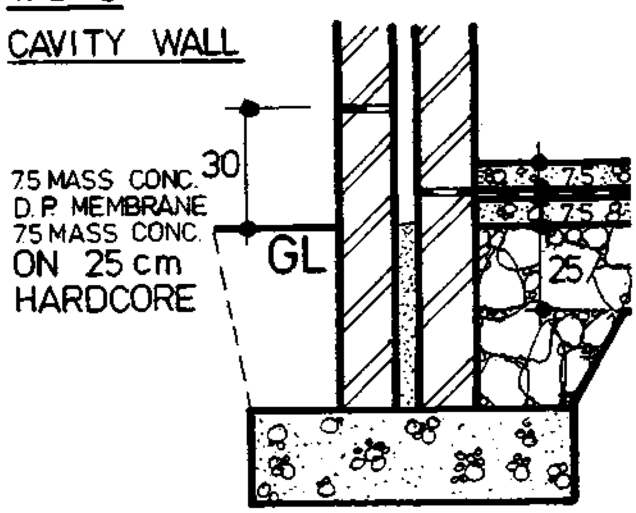


7.21 d



7.21 e

CAVITY WALL



HARDCORE

7.22 Hardcore:

- consists of irregular shaped lumps of
  - . broken bricks
  - . stone or concrete
  - . laterite lumps e.t.c.

  which are hard and do not readily absorb water.

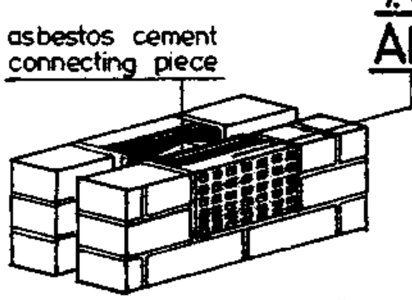
- HARDCORE is spread over the site within the external walls of buildings to such thickness as required to raise the finished surface of the site concrete.
- HARDCORE should be spread until it is roughly level and rammed until it forms a compact bed for the over-site concrete.
- The HARDCORE-BED is usually between 15 cm and 30 cm thick.
- The material used has to be reasonable clean to make it difficult for water to rise by capillary action.
- Before the concrete is laid one has to BLIND the top surface of the concrete - to prevent the wet concrete running down between the hardcore.
  For BLINDING (or sealing) the hardcore a thin layer of very dry coarse concrete can be spread over, or a thin layer of
  coarse clinker or ash
  or aggregate
  can be used.
  The BLINDING LAYER (or coat) will be about 5 cm thick.
  On it the site concrete is spread and finished with a true level top surface.

WATERPROOF MEMBRANE

7.23 Waterproof membrane:

- The waterproof membrane, sandwiched in the concrete prevents damp rising to the floor surface. Fig. 7.21e showes the arrangement.
- The membrane is formed by laying
  1. a 7,5 cm thickness of site concrete and allowing it to thoroughly dry out.
  2. a thin coat of tar or bitumen is poured and spread on the concrete.
  3. a second layer of concrete on to of the hardened tar or bitumen.

SUSPENDED TIMBER GROUND FLooR



7.3 AIR BRICK
OF GALVAN. CAST IRON OR TERRA COTTA

7.3 Suspended Timber Ground Floor

- Consists of:
  TIMBER BOARDS (or other suitable sheet material) fixed to JOISTS spanning over SLEEPER WALLS.
- A timber floor is used occasionally only because it has properties which a solid groundfloor lacks: Some flexibility and it will easily accept nail fixings.
- It is a more expensive form of construction than a solid ground floor and can only be justified on sloping sites which would need a great deal of filling to make up the ground to the required floor level.
- Suspended timber floors are susceptible to
  DRY ROT and
  DRAUGHTS
  the problem of DRY ROT, which is a fungus that attacks damp timber, can be overcome by adequate ventilation under the floor and the correct positioning of D.P.C. to keep the underfloor area and the timber dry.
  THROUGH VENTILATION is essential to keep the moisture content below 20 % of its oven-dry-weight (which would allow fungalgrowth to take place.
  - The usual method is to allow a free flow of air under the floor covering by providing in the external walls, AIR-BRICKS, sited near the corners and at approximately 2 m centres around the perimeter of the building.
- If a suspended timber floor is used in conjunction with a solid ground floor in an adjoining room, PIPES are used under the solid floor to convey air to and from the external walls.

7.31 Building Regulations

- Fig. 7.31 showes the minimum dimensions required under B.R.C 4 but in practice a greater space between the timber is usual.
- HONEYCOMB sleeper walls are usually built two or three courses high to allow good through ventilation.
- SLEEPER WALLS spaced a 2 m centres will give an economic joist size.
- The width of joists is usually taken as 50 mm (This will give sufficient width for the nails securing the covering.
- The depth can be obtained by reference to Table 1, Schedule 6, B.R. or by design calculations.
  The usual joist depth for domestic work is 125 mm.

BUILDING REGULATIONS

TABLE 1, SCHEDULE 6, B.R.

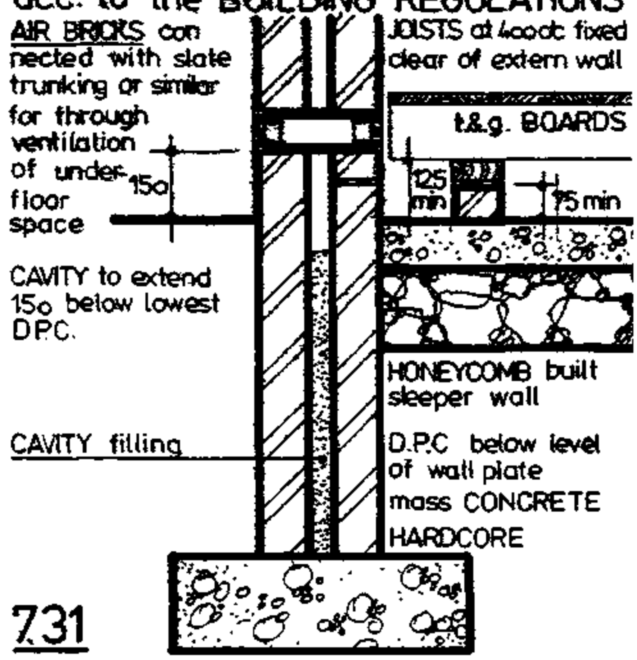
SUSPENDED TIMBER FLOOR

acc. to the BUILDING REGULATIONS



7.31

LAY OUT

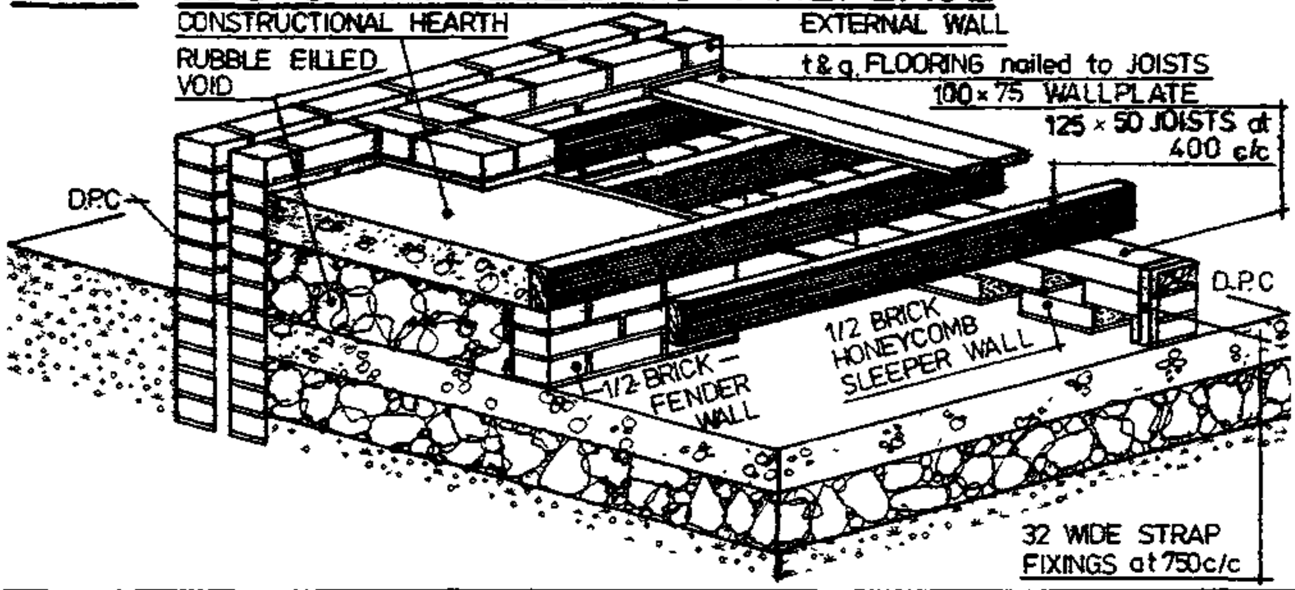
7.32 Lay out:

The most economic lay-out is to span the joists across the shortest distance of the room.

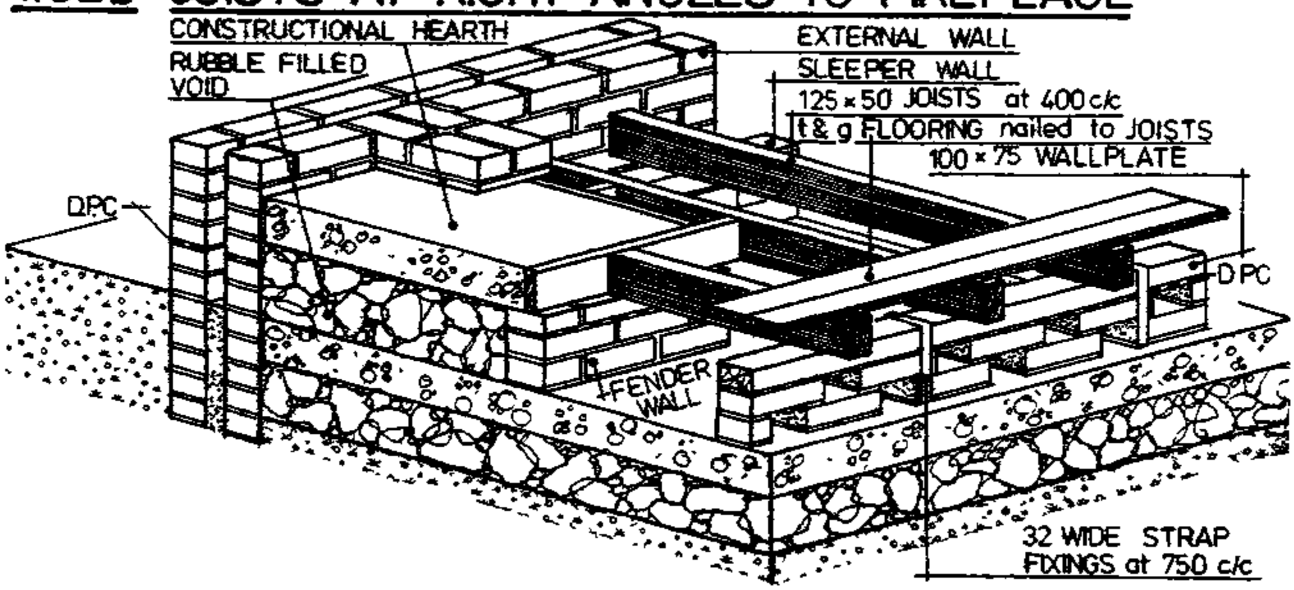
- This means the joists could be either parallel or at right - angles to a FIRE - PLACE.
  The fireplace must be constructed of NON-COMBUSTIBLE materials and comply with B.R. L3 and L 4.

- The figures 7.32 a+b show typical exemples.

7.32a JOISTS PARALLEL TO FIREPLACE



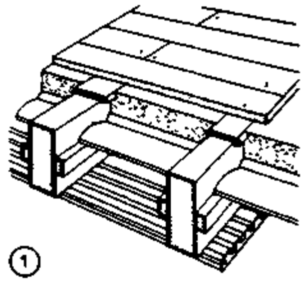
7.32b JOISTS AT RIGHT ANGLES TO FIREPLACE



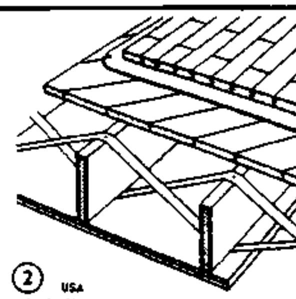
- Constructing ground floors and upper floors, problems of another kind have to be concidered.
  The main differences are:
  1 Ground floor
    - The floor rests directly on the ground
    - Good insulation against <u>moisture</u> is required.
  2 Upper floor
    - The floor is supported only at its edges
    - Good insulation against <u>noise</u> is required.

7.4 UPPER FLOORS

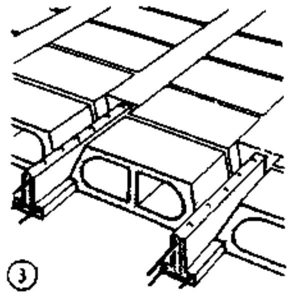
7.41 Types of UPPER FLOORS



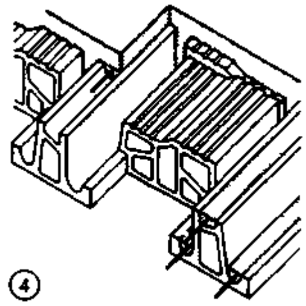
1 Timber joist floor with tree segments and infill ~200-250 kg/m²



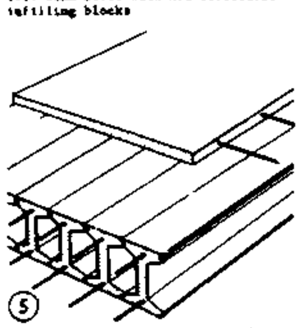
2 USA plank floor with hoop iron bracing, weight without infill 65-90 kg/m²



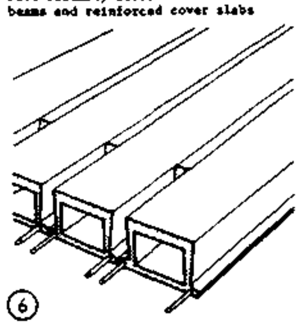
3 r.c. beam floor with non-structural infilling blocks



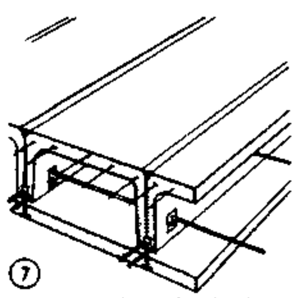
4 Part assembly floor with hollow beams and reinforced cover slabs



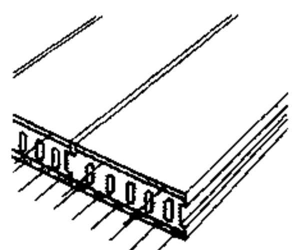
5 Complete assembly r.c. I-beam floor, precast



6 Complete assembly r.c. hollow beam floor, precast



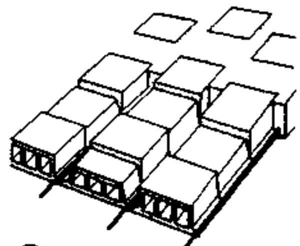
7 U-shaped r.c. beams close butting and bolted give lateral bracing



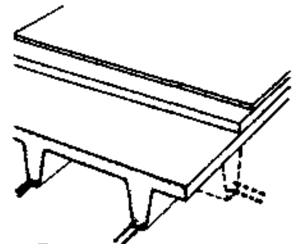
8 Pre-stressed hollow concrete plank floor: 20-30 mm concrete bottom layer with pre-stressed twist steel reinforcement, light weight concrete core and 10 mm concrete cover

7.41 types of UPP. FLOORs

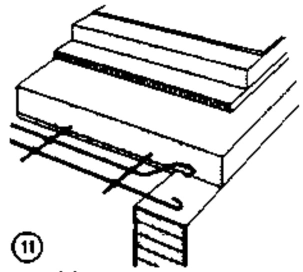
- One can divide types of upper floors into different categories
  - according to the <u>statical system</u>:
    - beam floors
    - slab - beam floors
    - slab - floors
  - according to the <u>kind of construction</u>:
    - constructed on site
    - partly prefabricated
    - prefabricated.
  - according to the <u>material used for construction</u>
    - timber floors
    - concrete or reinforced concrete floors
    - floors made out of masonry or brickwork (arches / domes)
    - floors made out of steel



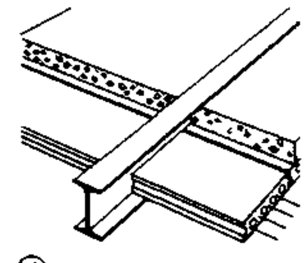
(9) Steel and hollow blocks with extended bottom flange. Ribs and cross jointing of in situ concrete



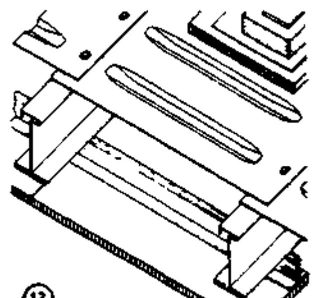
(10) r.c. ribbed floor cast in situ. Ribs c/c ≦ 700 mm, rib width ≧ 50 mm, thickness of slab = 1/10 beam spacing, bearing of beams ≧ 150 mm



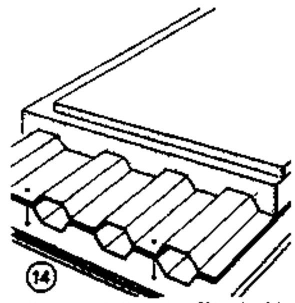
(11) r.c. slab cast in situ, 1 or 2-way reinforcement. ≧ 70 mm thick, economical ≦ 150 mm. With 2-way reinforcement proportion of width to length ≦ 1:1.5



(12) R.S.J. floors with infilling; lightweight or breeze concrete slabs reinforced (900-1 300 mm l, 350 mm w, 65 mm thick), topped with lightweight concrete



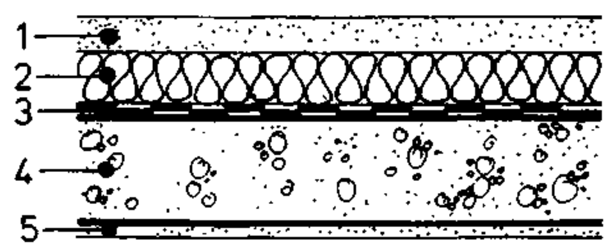
(13) Sheet metal floor for office and industrial buildings. Poor impact noise insulation



(14) Sheet metal floor in office buildings; good ducting for services; ceiling suspended on hangers and concrete topping give good sound insulation

7.42 Structure of upper floors:

7.42 structure of an UPPER — FLOOR



1 FLOOR FINISH
2 INSULATION : thermal or sound
3 BARRIERE LAYER
4 LOAD BEARING MEMBER
5 CEILING

susp. timber UPPER FLOOR

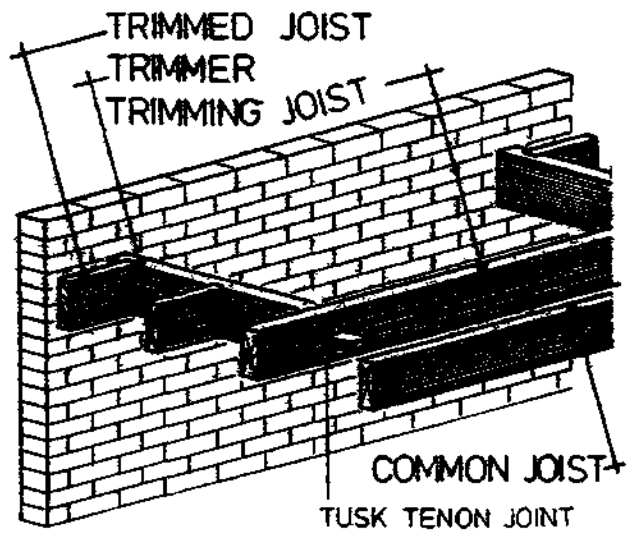
7.43 Suspended Timber upper Floors:

- Timber, being a combustable material, is restricted by Part E of the Building Regulations to SMALL DOMESTIC BUILDINGS as a structural flooring material.
- The construction of suspended timber upper floors is cheap in relation to other structural flooring methods and materials and does not involve WATER for construction.
- Structural soft wood is readily available, easily worked, has a good strength to weight ratio and is therefore suitable for domestic buildings.

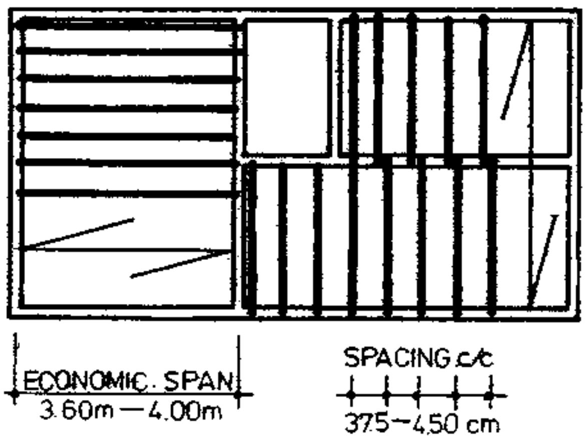
7.431 Floor joists

- The load bearing members of a timber floor are the FLOOR JOISTS.
- Terminology
  - Common Joist: a Joist spanning from support to support.
  - Trimming Joist: span as far as common joist, but it is usually 25 mm thicker and supports at TRIMMER JOIST.
  - Trimmer Joist: a joist at right-angles to the main span supporting the TRIMMED JOISTS and is usually 25 mm thicker than a comman joist.
  - Trimmed Joist: a joist cut short to form an opening and is supported by a trimmer joist, it spans in the same direction as common joists and is of the same section size.

7.431

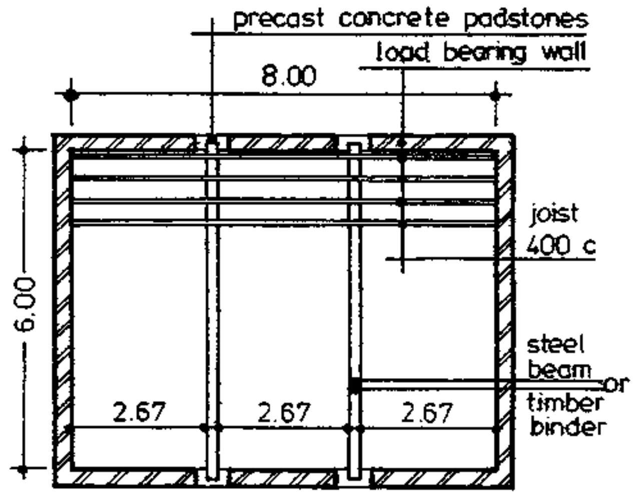


7.431 SPACING OF JOISTS

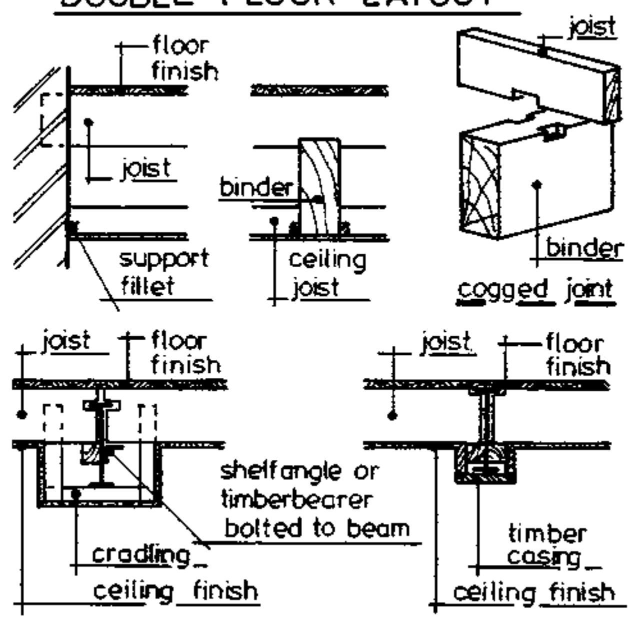


- Spacing of the Joists
  - The spacing of the joists is usually from 37,5 cm to 450 cm, measured from the centre of one joist to the next.
  - To economise in the use of timber the floor joist of upper floors usually span (are laid across) the least width of rooms from external wall to internal partitions.
  - The maximum economical span for timber joists is between 3.60 m and 4 m. For greater spans (than about 4,5 m) it is usually economic to reduce the span of the joist by the use of steel beam or timber binders, which is known as DOUBLE FLOOR CONSTRUCTION.

7.431 a DOUBLE FLOOR DETAILS



DOUBLE FLOOR LAYOUT



DETAILS USING TIMBER BINDER OR STEEL BEAM

7.FLOORS compiled: D.VOLKE OCT. '80	SPACING OF JOISTS DOUBLE FLOOR DETAILS	BUILDING CONSTR. — LECTURE — CET 2031/1 7.4 11
TCA TECHNICAL COLLEGE ARUSHA CHUO CHA UFUNDI ARUSHA	CIVIL-ENGINEER. DEPARTMENT	

- Strutting between joists: Timber shrinks when it is seasoned and timber - such as floor joists - which is not cut on the radius of the circle of log does not shrink uniformly. The shrinkage will tend to make the floor joists twist, or wind, and to prevent cracking of a plaster ceiling which this twisting would cause, timber strutting is used.

The commonly used type is

- HERRINGBONE STRUTTING
  This consists of short lengths of 4 x 4 cm soft-wood timber nailed between the joists.
- Alternatively a system of solid strutting is sometimes used. This consists of short lengths of timber of the same sections as the joists which are nailed between the joists - either in line or staggered

  It is not as effective as the herringbone system, because the solid lengths have to be cut very accurately to fit to the sides of the joists; they do not firmly strut between the joists.
- As with herringbone strutting the end joists are blocked and wedged up to the surrounding walls.
- Usually: one set of struts is used for joists spanning up to 3,60m and two sets of struts are used for joists spanning more then 3.60 m.

  A single set of struts is fixed across the floor at mid span.

JOIST SIZING

- <u>Joist Sizing:</u>

  There are three ways of selecting suitable joists for supporting a domestic type floor:

  1. Rule of Thumb:

     $$\frac{\text{span in mm}}{24} + 50\text{mm} = \text{depth in mm}$$

  2. Calculation:

     $$BM = \frac{fbd^2}{6}$$

     where
     BM = bending moment
     f = max fibre stress
     b = breadth (assumed to be 50 mm)
     d = depth in mm

  3. Building Regulations, Table 1, Schedule 6.

TABLE 1

END SUPPORT: FLOOR JOISTS

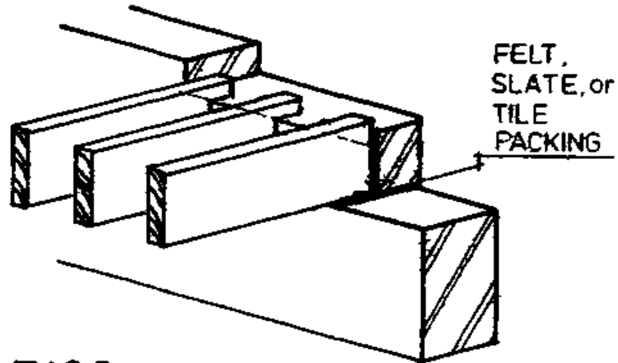
7,432 End Support of Floor Joists

The end of timber floor joists must in some way either be built
- into or
- supported against

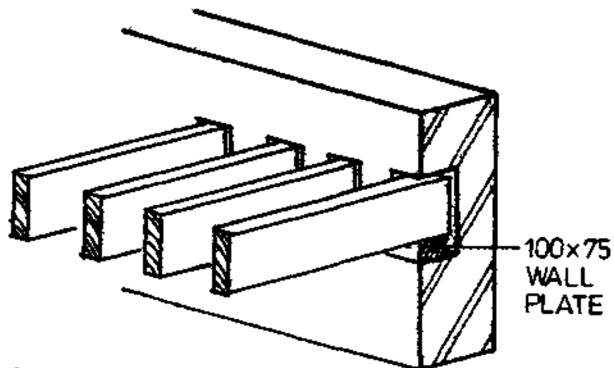
load bearing partitions and external walls.

- The most commonly used method of giving support to the ends of timber floor joists is to build them <u>into</u> walls and partitions.
  - There was a common practice to build the joistends some 10 cm into walls and partitions and to pack up under each joist with <u>small peaces of slate or tile</u> so that the top of the joists are level, if the underside of the joist does not comply with a brick course.
    - Distadvantage: displacing of tiles - out of level.

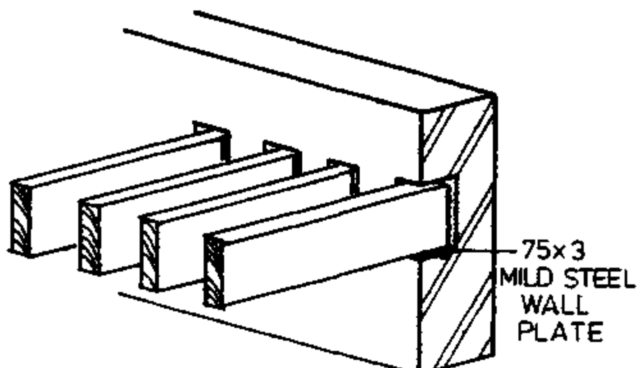
END SUPPORT OF FLOOR JOISTS



7.432 a BUILT INTO



7.432 b BUILT INTO



7.432 c BUILT INTO

BUILT INTO

- A better solution is to build a wallplate (100 x 75 mm) into the wall as shown in Fig. 7.432 B
- Another possibility is the use of a mild steel wallplate(75 x 3 mm) as demonstrated in fig. 7.432 C.

SUPPORTED AGAINST

- If the ends of timber floor joists are built into a solid external wall, 1 brick thick, there is only 1/2 brick between the ends and the rain falling on the outside of the wall.
  Therfore: Joists will at time become saturated and then: the dry rot fungus may attac.
  This danger can be reduced by painting the ends of the joists with <u>oily preservative</u>.
  If the external wall is of cavaty construction, the joist-ends must not run into or across the cavaty (moisture!!).

REINFORCED CONCRETE upper floors

7.44 Reinforced concrete upper floors.

- Reinforced concrete floors have a better resistance to demage by fire and can safely support greater superimposed loads than timber floors. Therefore they are used for most offices, larger blocks of flats, factories and public buildings.
- There are many different types of reinforced concrete floors. Some of the most common r.c. upper floors are demonstrated in the following

7.441 Monolithic Reinforced Concrete Upper Floor

A monolithic r.c.floor is poured 'in situ' on formwork, consisting of concrete and reinforcement steel bares. After drying out it becomes a new "monolithic" building material: REINFORCED CONCRETE which is capable to resist both <u>compression</u> and <u>tension</u> forces.

- R.C. upper floors are in most cases between 10 cm und 30cm thick
- Usually mild steel is used for reinforcement (either bares or mats)
  Reinforcement and concrete mix have to be in accordance with the statical calculations.
- Disadvantages of Monolithic R.C. Upper Floors:
  - Need Forwork
  - Time taken for the concrete to cure before formwork can be released
  - very little is contributed by a large portion of concrete to the strength of the floor.
- Fig. 7.441 showes an typical example of a monolithic r.c. upper floor.

7441 MONOLITHIC R.C. UPPER FLOOR

5 TIMBER FORMWORK
6 TIMBER CENTERING
7 TIMBER SUPPORT FOR CENTERING

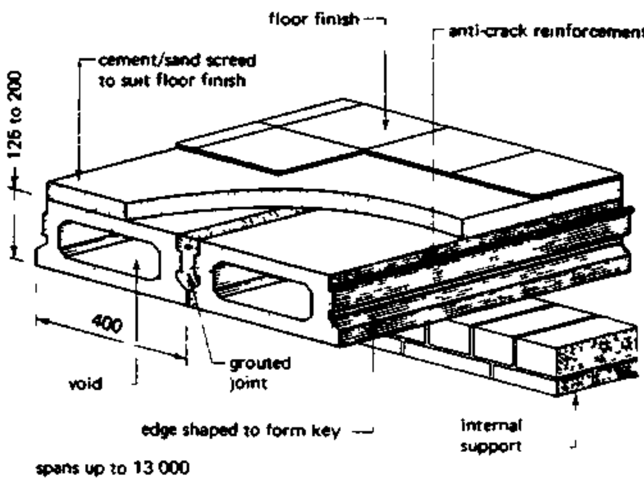
PRECAST CONCRETE upper floors

7.442 Precast Concrete Upper Floor

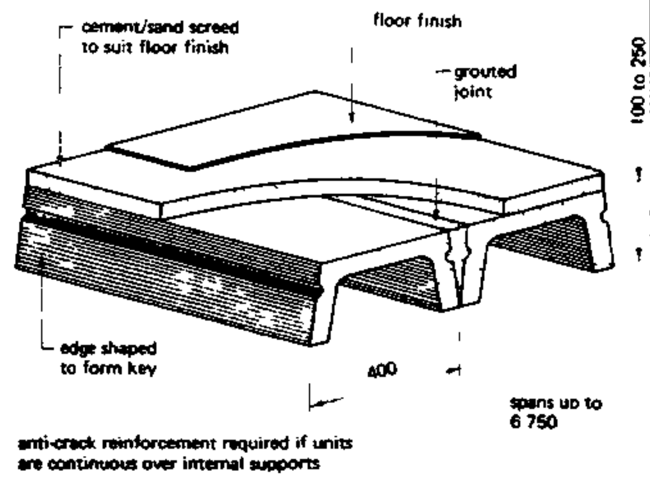
- Floors composed of reinforced precast concrete units have been developed over the years to overcome some (or all) the disadventages of monolithic reinforced concrete slab.
  To realise the full economy of any one particular precast flooring system the design of the floors should be within the SPAN, WIDTH, LOADING and LAYOUT LIMITATIONS of the units under consideration.
- The systems available can be considered either PRECAST HOLLOW FLOORS or COMPOSITE FLOORS.

• <u>Precast hollow floors</u>
  Units are available in a variety of sections such as boxplanks or beams, tee sections, I-beam sections and channel sections.

- The economies which can be reasonable expected over the 'in situ' floor are:
  1.50 % reduction in the volume of concrete
  2.25 % reduction in the weight of reinforcement
  3.10 % reduction in the size of foundations.
- The units are cast in precision moulds, around inflatable formers or framed plastic cores.
- The units are laid side by side with the edge joints being grouted together.
- No structural topping is required, but the upper surface of the units are usually screeded to provide the correct surface for the applied finishes.
- Means of mechanical lifting is required to offload and position the units.
- Hollow units are normally the cheapest form of precast concrete suspended floors for simple straight spans with beam or wall supports to maximum a span of 20 m.
- They are not suitable for heavy point loads.



Typical hollow floor unit details



Typical channel section floor unit details

Precast concrete hollow floors

COMPOSITE FLOORS

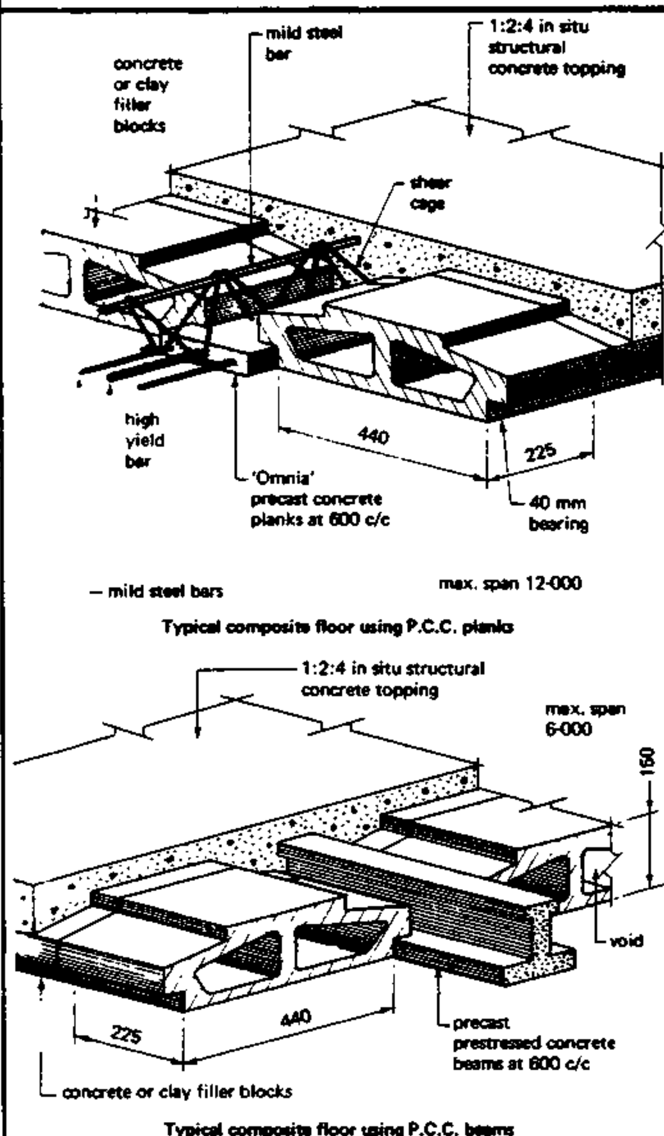
- Composite floors.

  Are a combination of PRECAST UNITS and IN SITU CONCRETE.

- The precast units (usually prestressed or reinforced with high yield steel bars) are used to provide the strength of the floor and at the same time act as a permanent form-work to the in situ topping which provides the compressive strength required.
  It is essential that an adequate bond is achieved between the two components (in most cases this is provided by the upper surface texture of the precast units).

- Generally there are two forms of composite floors:
  1. Thin pressed planks with a side key and covered with an in situ topping
  2. Reinforced or prestressed narrow beams which are placed at 600 mm centres and are bridged by concrete filler blocks.
     The whole combination being covered with in situ topping.
     Most of the beams used in this method have shear reinforcing cage projecting from the precast beam section.

- In both forms temparary support should be given to the precast units by props at 1,80 m to 2,40 m centre until the in situ topping has cured.



Typical composite floor using P.C.C. planks

Typical composite floor using P.C.C. beams

Composite floors

7 FLOORS compiled: D.VOLKE OCT. '80	COMPOSITE FLOORS	BUILDING CONSTR. LECTURE CET 2031/1 74 19

HOLLOW-BLOCK & WAFFLE FLOORS

7.443 Hollow Block and Waffle Floors.

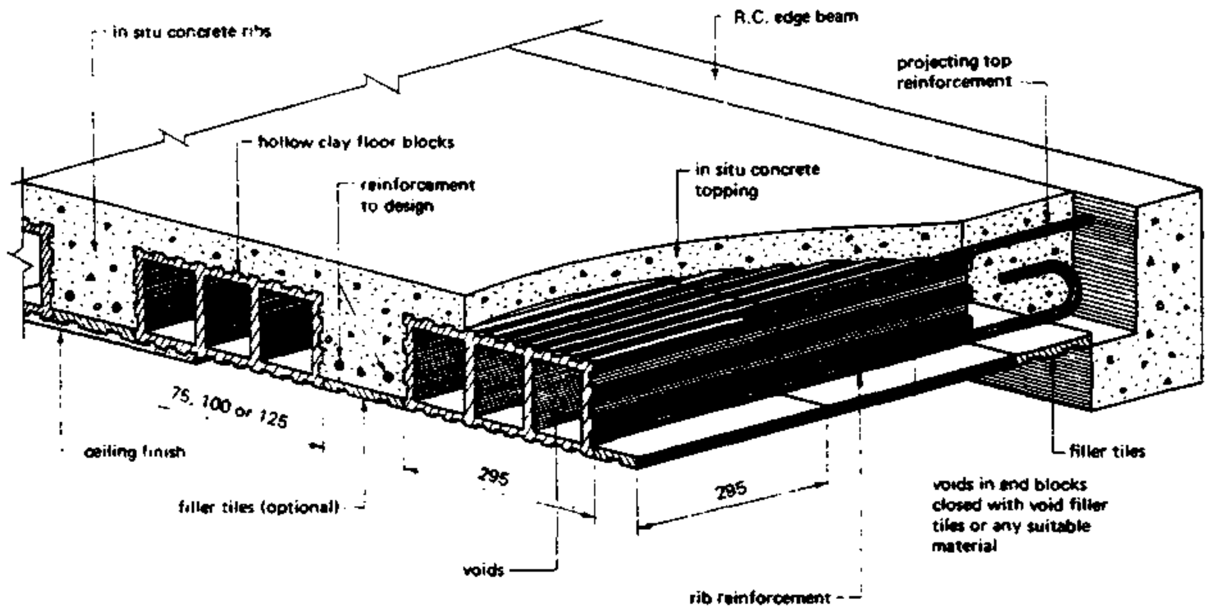
- Precast concrete suspended floors are generally considered to be for light to medium loadings spanning in one direction.
  HOLLOW BLOCK (or hollow pot) and WAFFLE (or honeycomb) FLOORS can be used as an alternative to the single spanning precast floor since they can be designed to carry heavier loadings.
  They are in fact RIBBED FLOORS consisting of closely spaced narrow and shallow beams giving an overall reduction in depth of the conventional reinforced concrete monolithic beam and slab floor.

- HOLLOW BLOCK FLOORS

- These are formed by laying over conventional floor soffit formwork a series of hollow light weight clay blocks (or pots) in parallel rows with a space between these rows to form the ribs.
- The blocks act as permanent formwork giving a flat soffit suitable for plaster application and impact to the floor good thermal insulation and fire resistance.

- The ribs formed between the blocks can be reinforced to suit the loading concitions of the floor.

- The main advantages are:
  its light weight
  its relatively low cost.



WAFFLE or HONEYCOMB floors

. WAFFLE FLOORS

- These are mainly used as an alternative to an in situ flat slab or a beam and slab suspended floor, since it requires less concrete, less reinforcement and can be used to reduce the number of beams and colums required.
- The honeycomb pattern on the underside can add to the visual aspect of the ceiling by casting attractive shadow pattern.
- The floor is cast over light weight moulds or pans made of glass fibre, poly-propylen or steel forming a TWO DIRECTIONAL FLOOR.
- The reinforcement in the ribs is laid in two directions to resist both consitudinal and transverse bending moments in the slab.
- It is advisable to allow for a floor screed to be applied to the in situ topping at a later stage in the contract prior to the fixing of the applied finish.

FLOOR FINISHES

7.5 Floor finishes

- Floor finishes may be classified into four categories:
  1. Jointless floor finishes
  2. slab floor finishes
  3. sheet floor finishes
  4. wood floor finishes
- The choice will depend on many factors; e.g. cost, durability, colour, hardness, slipperness, resistance to oils, acids, heat, sunlight, abrasion, noise and ease of maintenance.

7.51 Jointless floor finishes

7.511 The most common of these is the CEMENT / SAND SCREED. It will give a suitable finish especially for bare feet and sandals.

- There are different ways of construction:

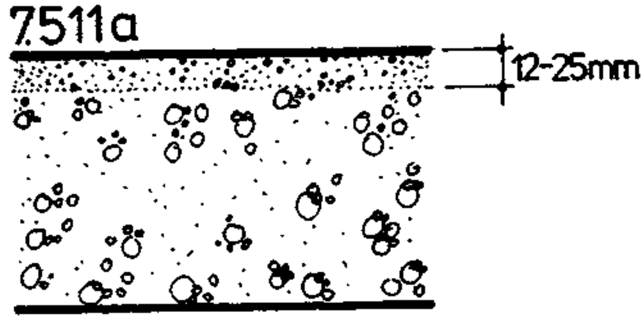
7.511 a Monolithic Construction

The screed is laid on the in situ concrete base within 3 hours (before it has set). In that case, a complete BONDING is obtained

- screed and base shrink together
- Thickness of the screed: only 12 mm necessary, on application thicker than 25mm has to be avoided, in order to restrict shrinkage forces from the SCREED.
- it will be the best solution to eliminate cracking and curling but...
- a proper planning (at the design stage) and complete PROTECTION of the area where screed has been applied is necessary.

JOINTLESS FLOOR FINISHES

7511a



MONOLITHIC CONSTRUCTION

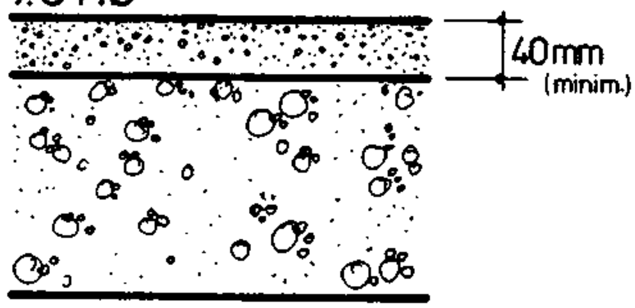
7.511b Seperate Construction

Once the concrete has set, monolithic construction can no longer be used.

- The strength of the bond between screed and base will depend on the way the base has been prepared.

  To achieve a maximum bonding, the base has to be
  - hacked (by mechanical means)
  - cleaned
  - damped (to reduce suction) and
  - grouted (or a bonding agent can be used)
- Minimum thickness : 40 mm.

7511b



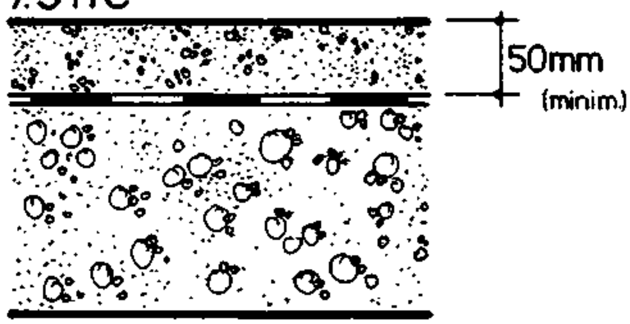
SEPERATE CONSTRUCTION

7.511c Unbonded Construction

If it is not possible to achieve a bond between base and screed (i.e. in case of an screed appli - cation on top of a damp-proof-membrane) the screed layer has to be applied thicker

- Mininum thickness 50 mm.

7511c



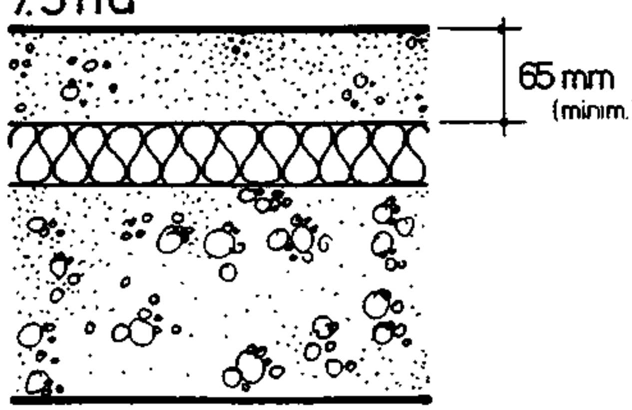
UNBONDED CONSTRUCTION

7.511 d Floating Construction

Is a screed to be laid on compressible layers of thermal or sound insulation, the material should be applied to a

- minimum thickness 65 mm.

7511d



FLOATING CONSTRUCTION

FLOOR SCREEDS

GRANOLITHIC CONCRETE FINISHES

7.511 e <u>Division into bays</u>

In order to avoid cracking and to reduce curling screed should be laid in alternate bays.

- The bay sizes should not be more then 15 m^2.
- The ratio between the sides of the bays may be approxemately 1:1 1/2. - long, narrow bays to be avwoided.
- Expansion joints are required only where similar joints are provided in the main structure.

7.511f <u>Mix designs</u>

- For screeds up to 4o mm, mixtures of 1 : 3 up to 4 1/2 cement / sand are used. (mixes less rich in cement will cause LOWER SHRINKAGE)
- For thicker screeds: FINE CONCRETE of 1 : 1 1/2 : 3 (cement fine aggregate: coarse aggregate) may be applied. The maximum size for coarse aggregate is 10 mm.

7.512 <u>Granolithic concrete finishes</u>

is used where a more durable surface is needed and suitable granite chippings are available.

- It is laid about 30 mm thick in the same way as cement sand (1 part cement : 3 parts granolithic) and trowelled smooth.
- It is used for paved areas, yards, factories, warehouses, and balconies.
- It should be kept damp and protected from hot sun for at least 24 hours after laying and cured for 3 days afterwards.
- Where a non-slip surface is needed, CARBORUNDUM may be spread into the granolithic finish while it is still green.
- Surface hardeners are often applied to granolithic and cement and sand floors. One type of hardener consists of 1 volume of sodium silicate to 4 volumes of water sprayed on after the concrete has set.
- Two applications are usual.
- For heavy industrial floors, especial steel or plastic grids may be inserted which divide up the floor into TILES.
- Synthetic plastics may also be used in place of granite chippings and give a pleasing finish.

TERRAZZO

SLAB FINISHes

7.513 TERAZZO
consists of 2 parts marble chippings of various colours and 1 part (white) Portland cement; laid about 12 mm thick on a screed of cement/sand (1:4).

- Strips of brass or plastic are bedded into the screed and left standing to divide the terrazzo into bays (1-2m^2)
- The floor is ground smooth with a carborundum machine, or by hand, after it has hardened.
- Plastic pellets are also used in place of marble chippings. Synthetic resins and plastics are available in paste form and can be laid 6 mm thick on screeded floors. They have the advantage of being non-slippery when wet.
- It is important that both mixingbays and materials be kept clean and free from soil, otherwise the floor finish will show stains.

7.52 Slab Floors finisehes

- natural stone slabs and slates
- quarry and vitreous tiles

The vitreous types are of better quality than quarry and are produced in brighter colours and patterns. The surface can be smooth or ribbed.

Tiles should be soaked and bedded on to a damp screed and tamped into position with a short straight - edge.
The joints are grouted and the floor cleaned off. It should NOT be used for several days.

- Concrete tiles make a durable floor and are produced in many colours. Even TERAZZO TILES are widely used.
- PVC and vinyl-asbestos tiles

  are light and obtainable in plenty of different colours. The screed is coated with a primer and tiles stuck with adhesive.
  Care must be taken not to lay on too thick a coating of abhesive, because this may ooze through the joints in hot climates and look unsightly.
  As they are grease- and oil - proof, thermoplastic tiles are used in factories, hotels, kitchens and garages.
- Marble mosaic floors can be laid in many patterns: Pieces of marble of varying colours, about 25 mm square, are pushed into a soft screed of mortar to create the pattern.
  This is very highly skilled work. The mosaics can be also sticked to sheets of stiff paper on which the pattern has been drawn. The sheets are cut up, numbered and pressed - TILES DOWNWARDS - into the soft screed.
  When set, the paper is soaked off and the joints are filled with grout.

SHEET FLOOR FINISHES

7.53 Sheet Floor finishes

- Linoleum
- Cork and
- Rubber are satisfactory coverings.
- Plastic floor coverings are now also widely used. PVC flooring takes several forms: it can be supplied in rolls of about 2o m length and a width between 9oo and 18oo mm wide. It is stuck down with a proprietary adhesive.

WOOD FLOOR FINISHES

7.54 <u>Wood floor finishes</u>

- Boarded floor finishes, tounged and grooved flooring boards, 2,5 mm thick and 5 cm to 15 cm wide are nailed on wood bearers.
- Wood-blocks (common measurements are 23x7,6x2,5cm) are laid in numerous patterns and are stuck on to a dry screeded floor with pitch mastic.
- Wood-mosaic consists of strips of hardwood (120 x 2,5 x 10.o cm) arranged in 12 cm squares to form a basket-weave pattern. They are laid similar to wood-blocks, and finished with a sanding maschine.
- Wood pavement is a very durable wood floor finish. The cross-cut end of small wood blocks (6x6x6 cm, 8x8x6, 8x25x6 cm) are exposed to the floor surface and laid in soft asphalt or stuck on to a dry, screeded floor with pitcemastic. For decoration even round sections of wood blocks (up to a diameter of a about 30 cm) are used, the joints are grounted and the surface sanded and polished.

DEPARTMENT

Try to answer the following questions and practice sketching where ever necessary and possible.

1) Local Bylaws
   Local Bylaws demand a certain capability of carrying load according to its destination.
   a) Which minimum load a domestic floor is required to carry?
   b) Which minimum load an industrial floor is required to carry?
2) Solid Ground Floors
   Give explanations (if necessary by sketching) on solid ground floors, particularly on
   a) Site Concrete: - thickness of concr. layers
      - mixtures
   b) Hardcore: - material, which can be used
      - thickness of hardcore bed
      - blinding
   c) Waterproof Membran / DPC
3) Suspended Timber Ground Floors
   a) What are the construction members of susp. timber ground floors?
   b) How to protect susp. timber floors against droughts and dry rot?
   c) Draw a sketch of an air brick
   d) Show in a sketch the minimum dimensions required under B.R.C.4.
   e) Draw the layouts of suspended timber floors with
      - joists, parallel to a fireplace
      - joists, at right angles to a fireplace
   f) Discuss advantages and disadvantages of suspended timber ground floors.
4) Upper Floors
   a) What are the main differences between Ground Floors and Upper Floors?
   b) Sketch and explain the structure of an Upper Floor
   c) List different types of Upper Floors
   d) Explain the term (if necessary by sketching):
      - Common Joist
      - Trimming Joist
      - Trimmer
      - Trimmed Joist

e) Give explanations on "The Spacing of Joists":
   - Commonly used distances between joists
   - Maximum economical span
   - Use of "Double Floor Construction".

f) Sketch different "Strutting Arrangements", such as:
   - Herringbone strutting
   - Solid strutting : in line
   - Solid strutting : staggered

g) Explain three different ways of defining the Size of Floor Joists

h) Sketch and explain different methods of End Support of Floor Joists, such as:
   Built into or
   Supported against loadbearing walls

i) List different sorts of Floor Trimming Joints

j) Write notes on "Monolithic Reinforced Concrete Upper Floors" and describe:
   - Thickness
   - Reinforcement
   - Formwork
   - Advantages and Disadvantages

   if necessary by sketching

k) List and explain different types of "Precast Concrete Upper Floors"

l) Describe (if necessary by sketching) "Hollowblock and Waffle Floors"

6) Floor Finishes:

a) Explain the following terms:
   - Jointless Floor Finish
   - Cement/Sand Screed
   - Monolithic Construction
   - Seperate Construction
   - Unbonded Construction
   - Floating Construction
   - Granolithic Floor Finishes
   - Terrazzo

Use sketches!

b) Give mix - designes

c) Explain different types of "Slab Floor Finishes"

d) List different types of "Sheet Floor Finishes"

e) Write notes on different types of "Wood Floor Finishes"

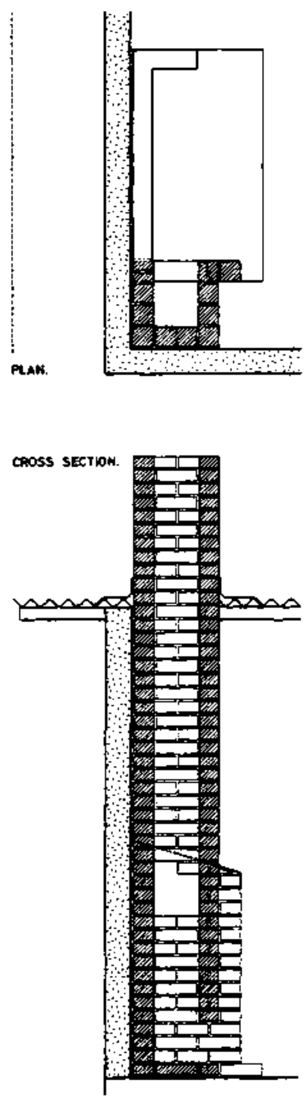
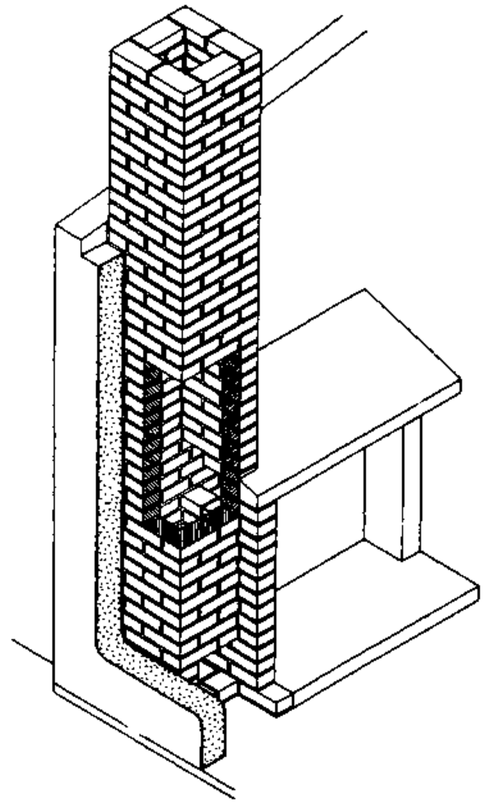
8. FIREPLACES, CHIMNEYS & FLUES

8. FIREPLACES, CHIMNEYS and FLUES.
   - In Tanzania the open fire, burning solid fuel, is still widely used in houses as a means of space heating or for heating water for domestic purposes.





- A FIREPLACE is a space in a wall (or formed in a free-standing position) to accomodate an open fire from which the smoke and gases pass to the open air through a duct or FLUE.

- The structure enclosing a flue (or flues) is called a CHIMNEY.

- Where this rises above the roof it is called a CHIMNEY STACK.

- A projecting part of a wall which a fireplace and flues are constructed is called a CHIMNEY BREAST.

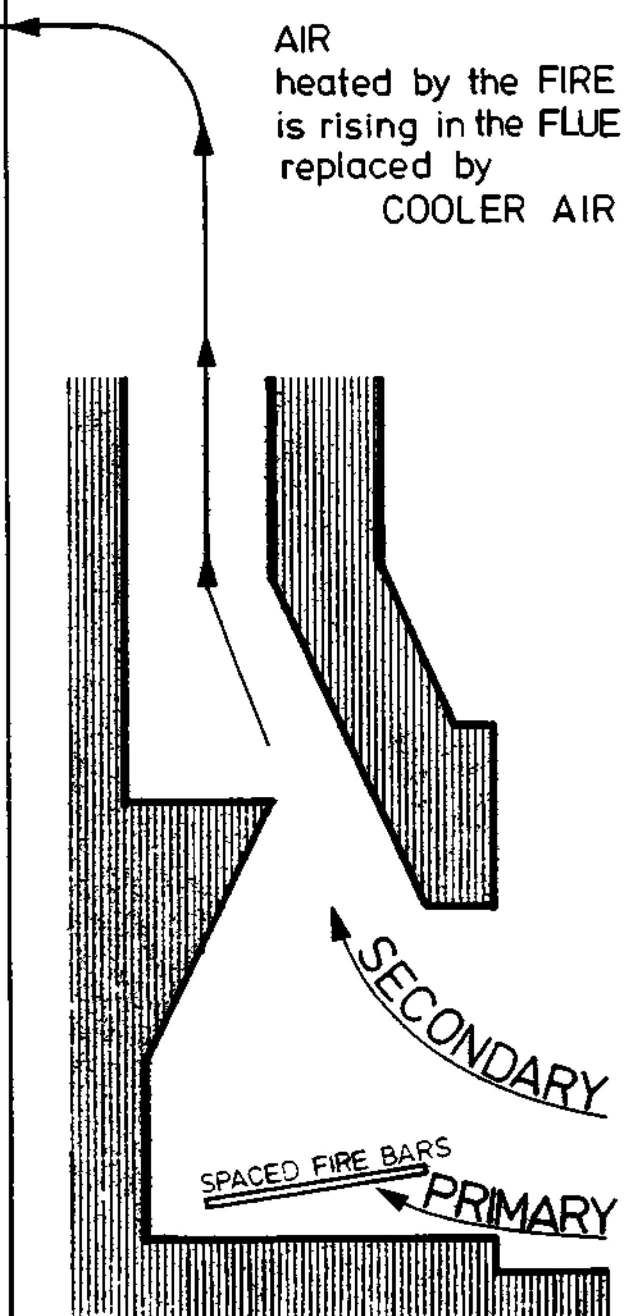
- A tall, freestanding chimney (usually required for large heating plants) is called a CHIMNEY SHAFT.

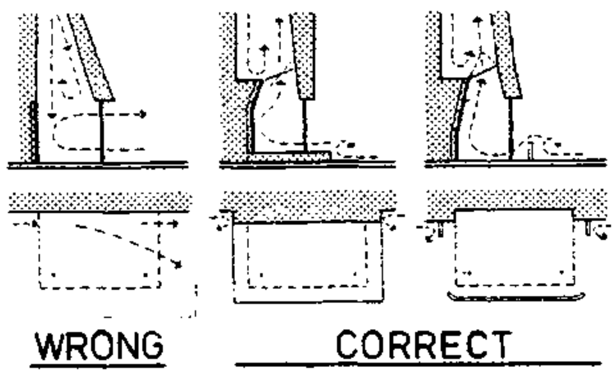
FUNCTION of FIREPLACES and FLUES

8.1 Function of Fireplaces and Flues

- The function of a fireplace is to burn fuel efficiently and safely, and to transfer the effectively the heat generated into the room.
- An adequate supply of air is necessary for the efficient combustion of any fuel. The domestic fire, burning charcoal or timber, relies for its air supply on an upward air movement which is caused by cooler air flowing through and over the fire bed to replace a volume of heated air rising in a flue.
- This cooler air is made up by 2 components:
  . primary and
  . secondary (see fig.).
  The primary air supply is that air which feeds the fire bed and contains the oxygen nessary for combustion.

  The secondary air supply is that required to cause the column of air heated by the fire to rise up the flue carrying away with it the products of combustion.
- An efficient flue promotes this upward air movement, or 'DRAUGHT', and a suitably designed fireplace establishes a proper balance between the primary and secondary supplies so that efficient combustion may occur.
- Since the secondary air must be supplied to the fire via the room, which it enters through crack, windows doors or controlled vents, a measure of air change or ventilation results.





AIRMOVEMENT and AIRSUPPLY along FLOORS and WALLS to be interrupted (SMOKE!)

- THEREFORE:
  The primary function of the flue is to contain the rising warm air and gases above a fire in a manner which will promote a natural upward flow of air (the power of which will depend on the difference in weight between the column of light, warmed air in the flue and a similar column of cool heavier external air.
  The secondary function is to ventilate the room in which the fire is situated.

- In order that fireplaces and flues shall satisfactorily fulfil these functions a chimney and chimney breast (which are also structural parts of the building) must satisfy certain requirements such as:

REQUIREMENTS:

. WEATHER RESISTANCE
The prevention of wind and rain penetration is of particular importance because of the adverse affect on the function of the flue caused by the cooling of the flue gases.
Special care must be taken to prevent damp penetration at the point where a stack passes through a roof and flashings and damp-proof coarses are required at the junctions of the two.

The top part of the stack must also be protected to prevent saturation of the chimney.

WEATHER RESISTANCE

THERMAL INSULATION

. THERMAL INSULATION
Adequate thermal insulation must be provided to the flue by the chimney in order:

1. to avoid the cooling of the flue gases and the cousequent slowing down of the upward air flow or draught;
2. to prevent condensation of flue gases on the walls of the flue which (particularly with slow burning appliances) can cause considerable damage to the chimney.

FIRE RESISTANCE

. FIRE RESISTANCE
The construction of a fireplace and its chimney must be such that combustible materials within and outside the building cannot be ignited by the fire or hot flue gases.

THEREFORE :

Therefore an adequate thickness of noncombustible material around flues and fireplaces must be provided and all combustible materials to be kept away a sufficiant distance from a flue or a fireplace.

- Fireplaces must have a bottom or hearth of noncombustible material and extent on or above which the fire bed will rest.

- The outside surface of a chimney should not become hot enough to iquite timber or other combustible material which may be near it. A temperature of 65°C is considered to be a safe maximum(This is achieved by the use of e.g.100 mm c brickwork or concrete).

- The outlet of a flue should be well above the roof in order to avoid danger from sparks (outside the zones of wind pressure). Building regulations lay down require ments concerning heights of stacks, thickness of materials and proximity of combustible materials to flues and fireplaces.

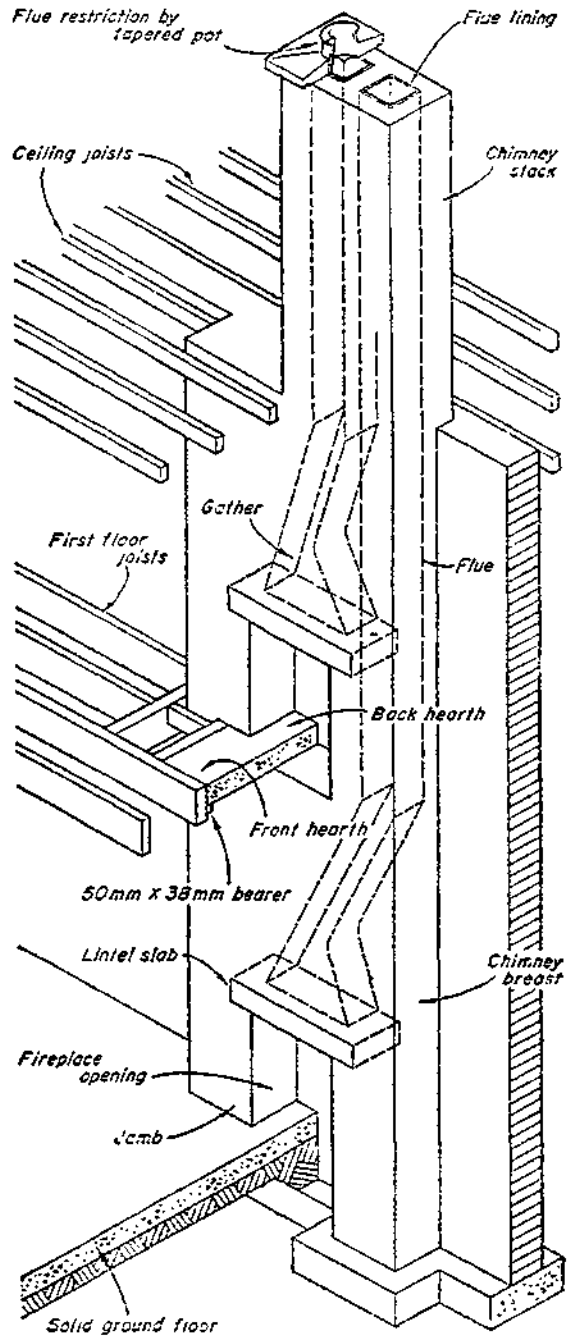
PRINCIPLES OF FIREPLACE DESIGN

8.2. PRINCIPLES OF FIREPLACE DESIGN.

- The shape of the fireplace must be desingned to allow an adequate but not excessive supply of primary air to the fire bed and secondary air to the flue.

- To contain the fire safely and to transfer the heat generated into the room, the fireplace must be constructed of suitable materials, having high fire resistance but capable of storing and radiating heat.

- The fireplace consists basically of a rectangular recess - or FIREPLACE OPENING - of suitable height with means of supporting the chimney breast above and some means of reducing the width of the opening to that of its flue.
The back and sides of the opening are formed of material capable of radiating heat and the base of the opening must be of fire-resisting material extending beyond the opening at front and sides.
A SURROUND around the opening is often incorporated for aesthetic reasons or to increase the effective depth of the fireplace.



DIMENSIONING TABLE for OPEN FIREPLACES

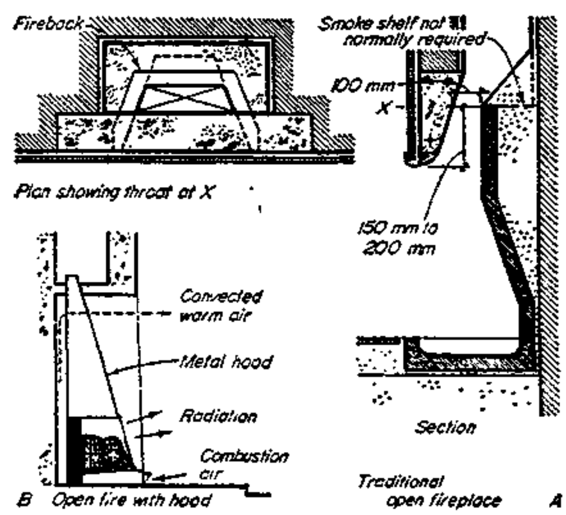
TRADITIONAL OPEN FIREPLACE

8.2.1 TRADITIONAL OPEN FIREPLACE

- Originally fuel was burnt in a simple rectangular recess, but during the course of time scientific principles have been formulated to improve efficiency and reduce smokiness.
  These principles still remain basically sound and involve:
  1.
  The correct design of the junction of fireplace and flue, called the THROAT. This should be 100 mm wide, 200 mm to 250 mm long and 150 mm to 200 mm deep, situated perpendicularly over the fire. The entrance to the throat should be rounded.
  2.
  Splayed sides to the fireplace on plan to obviate eddies of smoke entering the room (This occurs with fireplaces having the back and the front of the opening equal in width.
  3.
  Sufficient depth from the face of the chimney breast to the back of the fireplace to prevent smoking when a draught crosses the opening
  4.
  The fireback sloping foreward to direct radiant heat into the room and raise the temperature of the fire, thus assisting combustion.
  5.
  A smokeshelf level with the top of the throat although research has slown that this can be eleminated if all other features are properly designed and incorporated.



Traditional open fireplace

8. FIRE PLACES	FIREPLACE DESIGN	BUILDING CONSTR.

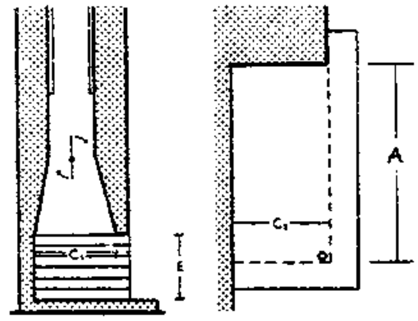
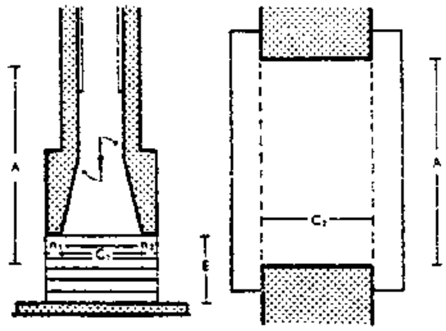
The free arrangement of a fireplace in a room causes often several openings on 1, 2, or 3 sites of the OPEN FIREPLACE.

Dimensions of such fireplaces differ from comon ones with only one opening.

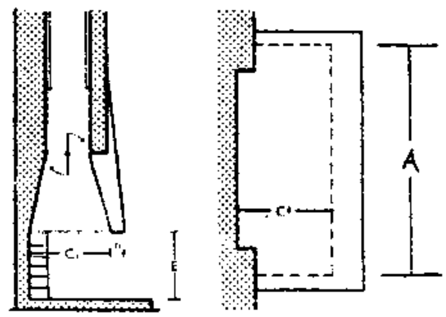
FOR DIMENSIONING REFER TO THE TABLE BELOW



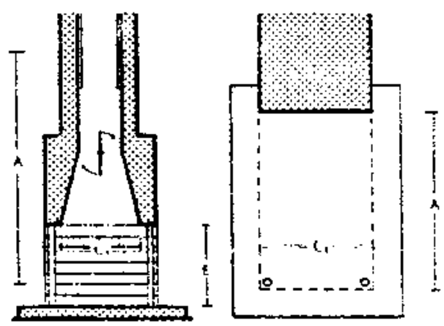
1



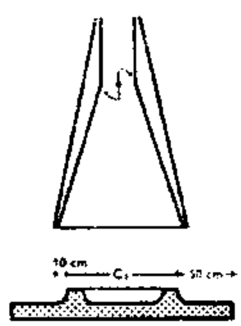
2



3



4



5

- Such fireplaces, however, remain uncontrolled and tend to consume large amount of fuel whilst promoting too large an air change. Control of the secondary air supply can be effected by a hood placed above the fire bed, in which case some heat transfer occurs by way of air circulating round the hot metal forming the hood, or preferably by an adjustable metal throat restrictor.
- When a stool grate to hold the fuel is used some control of the primary air supply to the fire can be effected by selecting a design with a solid front incorporating a variable inlet opening.

IMPROVED SOLID FUEL APPLIANCES ●

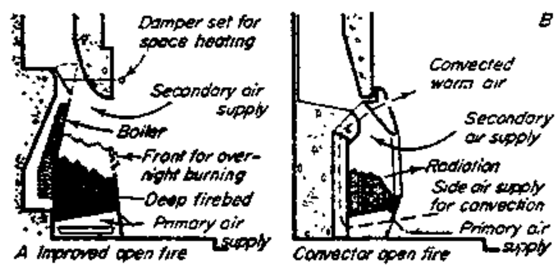
8.22 IMPROVED SOLID FUEL APPLIANCES

- Normal open fires will burn a wide range of fuels including wood, charcoal, coal and peat but they are unsuitable for burning smokeless fuels such as coke and anthracite and they will not burn throughout the night.

- The improved appliances incorporate suitably spaced fire bars and provide increased vertical depth in the fire bed which permits smokeless fuels to be burnt.

- Often BACKBOILERS are incorporated which provide hot water for domestic use or may heat a limited number of radiators situated near the fire. A removable front anables an extra deep firebed to be laid for overnight burning.

- Some improved open fires incorporate a heat exchanger which provides heat by convection in addition to the radiant heat of the fire. They operate by passing air through a convection chamber round a metal fire container and returning the warmed air to the room in which the appliance is situated. These are called CONVECTOR FIRES and may be fitted with back boilers.



Improved solid fuel appliances

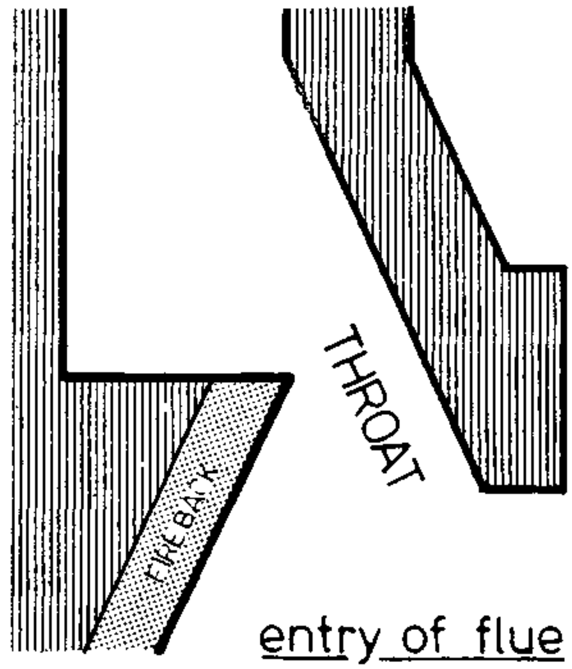
8.3. PRINCIPLES OF FLUE DESIGN

To ensure the proper function of a flue the following factors must be considered in its design:

PRINCIPLES OF FLUE DESIGN

1. SIZE and SHAPE

- Flues to domestic fires should be not less than 3,65m high measured vertically from the outlet of the appliance or fireplace to the top of the flue terminal in order to ensure an adequate difference in weight between the internal flue gases and the external air.
- The entry to the flue should be restricted to increase the inicial velocity of the gases and a further restriction at the flue terminal is desirable to increase the velocity at the outlet (This reduces the danger of down droughts.
- The cross-sectional area of a flue should be not less than 175 mm diameter. The normal 225 x 225 mm brick flue measures about 190 x 190 mm when lined. (For minimum sizes for various appliances refer to table).
- Where rectangular flues are used the longest side should not be more than one- and half times the shorter.
- Flues should be as straight as possible, any bends being near the top rather than just above the fireplace. Unavoidable bends should be at an angle of not less than 45 degrees and preferably not less than 60 degrees to the horizontal.



entry of flue

Appliance	114 mm internal diameter	150 mm internal diameter	225 mm × 225 mm or 175 mm to 200 mm internal diameter
Open and closeable fires, openable heaters, cookers	Heat storage cookers only, burning smokeless fuel	Smokeless fuels (up to 7325 W)	Bituminous fuels (minimum height of flue — 3 65 m)
Domestic boilers	Smokeless fuels (up to 7325 W). Maximum height 9·15m. Sweeping access every 3·0 m	Smokeless fuels (7325–14650 W). Sweeping access every 3·0 m	Bituminous fuels (all outputs). Smokeless fuels (14650–29300 W) — 200 mm diam. minimum

Notes
A closed heater should be provided with a flue of the same size as that of a boiler with the same rate of combustion.
Flues with bends making cleaning difficult should have a minimum diameter of 150 mm.
Smokeless fuels—include coke, anthracite, dry steam coal, coalite, etc.

Minimum flue sizes for solid fuel burning appliances

AIRTIGHTNESS

2. AIRTIGHTNESS

A flue must be airtight in order to maintain the strength of the draught at the fireplace and to prevent the escape of smoke. Air can enter through faulty jointing or faulty withes (controlled entry of air into the flue may however, be an advantage in certain circumstances).

INSULATION

3. INSULATION

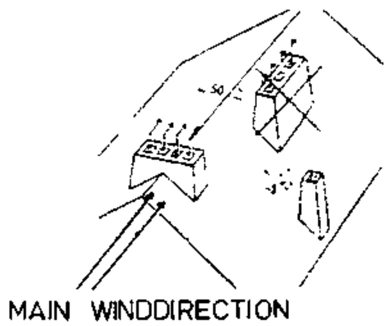
- Care must be taken to prevent the flue gases cooling, which might result in down draught and condensation. This precaution is particularly important where slow burning appliances are used.
- Flues should be constructed with 1/2 brick walls and liners. The use of brick thick walls in place of 1/2-brick thickness does not afford much increase in isulation value and has the disadvantage of offering more surface area to the atmosphere, with consequent cooling of the flue. It also has a high thermal capacity which requires a longer pre heating period before the flue is warm enough to encourage 'drought' action. The greater thickness may, however, be used for any external walls of flues to minimise damp penetration.
- Flues situated internally only need special consideration where they penetrate the roof and become exposed to the weather.

  Thickening of 1/2-brick flue walls to 1-brick thickness can be effected by corbelling out within the roof space, and perticular attention should be paid to the arrangement of the d.p.c. and flashings to the stack.

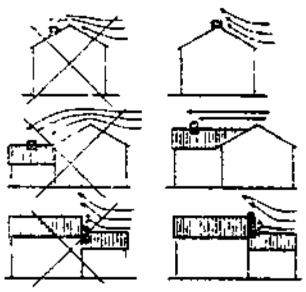
TCA TECHNICAL COLLEGE ARUSHA CHUO CHA UFUNDI ARUSHA — CIVIL ENGINEER. DEPARTMENT

POSITION OF OUTLET

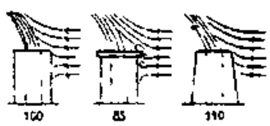
- A suitable capping should be provided to prevent saturation of the chimney.
  A projecting capping, in addition to throwing water clear of the chimney walls, helps to create a zone of low pressure at the flue outlet.



POSITION TO WINDDIRECTION AND RIDGE



EFFECT OF WIND TO THE DRAUGHT



FIGURES COMPARING THE EFFECTIVITY

INFLUENCE OF CHIMNEYHEAD AND AREA ON THE DRAUGHT

4. POSITION OF OUTLET
- For safety in terms of fire the outlet must be at least 1 m above the highest point of intersection of the chimney or flue pipe with the roof.
- The same distance above any adjacent opening light or ventilation opening which is not more than 2,50 m from the outlet, measured horizontally.
- When the chimney passes through the ridge of a pitched roof, or within 0,60 m of it, the outlet may be not less than o,60 m above the ridge.

These dimensions are exclusive of any chimney pot or other terminal.
- If the roof covering is of combustible material the outlet should be at least 1 m above the level of the ridge whatever the position of the stack.

These precautions do not, however, necessarily ensure the efficient functioning of a flue, the outlet of which must be positioned outside any potential zones of high wind pressure.
The positioning of a flue outlet in a potential suction zone will assist in the removal of the smoke and gases, but should occur in a high-pressure zone there is every likelihood of the gases being taken down the flue by air moving from this zone to an area of lower pressure within the room.

CONSTRUCTION OF FIREPLACES

8.4 CONSTRUCTION OF FIREPLACES

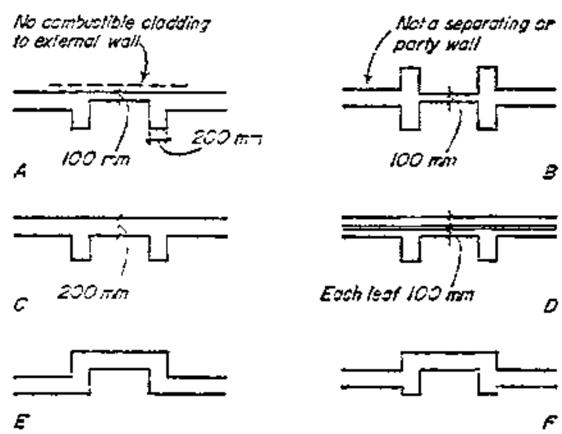
- The normal depth of the opening is 328 mm and the width 578 mm. This will take standard 406 mm and 457 mm wide fires. The height should be 585 mm to 600 mm from the finished hearth level to accommodate a standard 565 mm high fireback. If a projecting surround is to be incorporated this height should be increased to permit the proper formation of a throat.

Minimum thicknesses of material at sides and back of the opening are laid down in building regulations and are indicated in the figure. The jambs are required to be 200 mm thick. The back of the opening may be 100 mm thick when

1. It is set in an external wall and no combustible external cladding is attached behind it (A) or
2. it is common to two fireplaces set back-to back in a wall other than a party or separating wall (B)

In all other cases the back must be 200 mm of solid walling (C) or cavity walling with each leaf not less than 100 mm thick (D). (E) and (F) show alternative ways of setting the chimney breast in the wall of which it forms part.

Where a wide chimney breast is required for sake of appearance the jambs are made wider than 200 mm and where the jamb carries a flue as on an upper floor, a minimum width of 440mm is necessary.

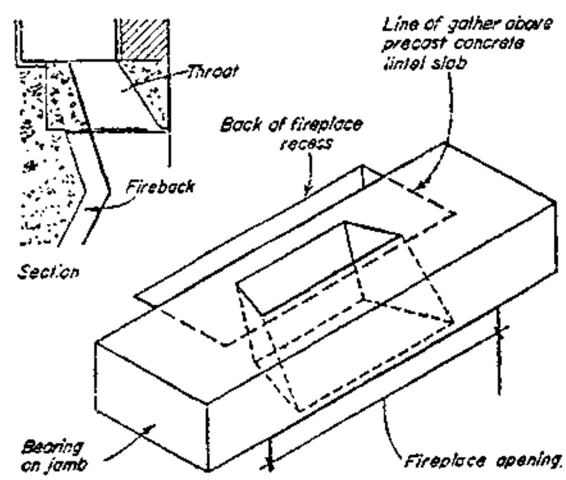


Thickness of material round fireplace openings

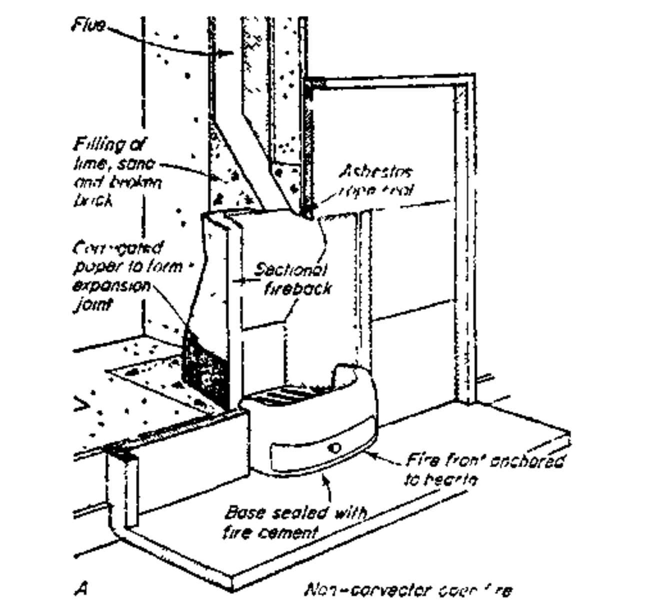
The traditional method of forming the head of the opening was by a segmental rough brick arch but the arch form presents some difficulty in forming a smooth narrow throat and a reinforced concrete lintel is preferable and is now normally used. Alternatively, a precast concrete lintel block or slab may be used in which the throat aperture is formed.

The junction between the relatively wide fireplace opening and the narrow flue is made by corbelling or 'gathering over' the brickwork or stone work of the chimney breast. The funnelshape produced is called the gather and provides a smooth flow from throat to flue.

The base of the fireplace opening is called the hearth.
It is constructed of concrete and building regulations require a minimum thickness of 125 mm. The back hearth, within the recess, bears on the chimney breast. The front hearth must projekt at least 500 mm in front of the breast and 150mm beyond each side of the opening. The full 125 mm thickness of the front hearth must be taken into the recess.
In solid ground floors the floor slab itself forms the hearth of the fireplace. Timber ground floor construction requires the provision of a fender wall. This wall may be 102-5 mm thick, providing support to the floor joists, the space within being filled with hardcore which carries the concrete hearth or it may be 215 mm thick to provide also a bearing for the front and side edges of a reinforced concrete hearth, the back edge of which is supported on the breast.



Precast concrete lintel slab



8.41 NON-CONVECTOR OPEN FIRES

MODERN inset open fires or all-night burners comprise a grate with a front which is sealed into the fireplace opening and invorporates in its design some device for controlling the primary air supply such as a spin wheel or controllable flap. These grates are designed to fit British Standard fire backs which are made of firebrick or refractory concrete (aluminous cement and broken firebrick). The bend or knee at the back should be fairly high to permit the formation of a satisfactory throat (figure).

8.42 CONVECTOR OPEN FIRES

These are freestanding open fires in which the fire is contained in a metal enclosure surrounded by a second metal jacket to form an integral convection chamber. The flue penetrates the outer jacket. The junction of the front of the fire with the fireplace surround must be sealed with soft asbestos rope or string and the appliance must be screwed to the back hearth so that no movement takes place which might break the seal.

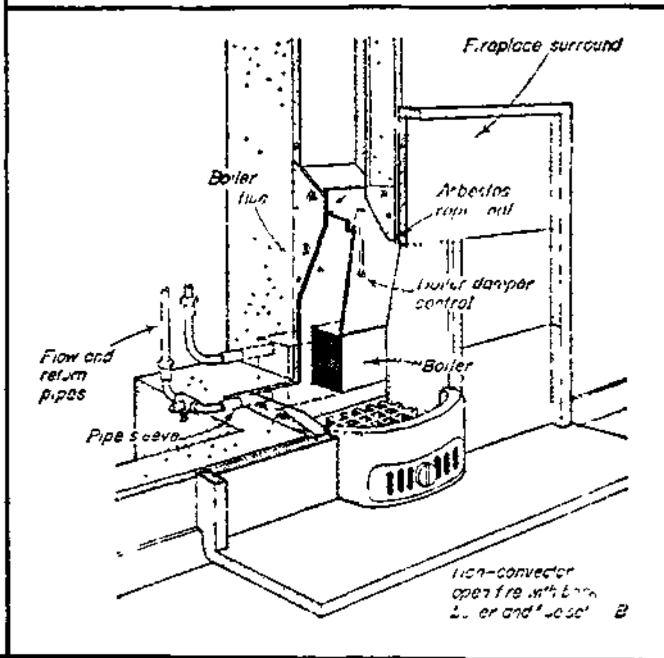
Back boilers

Non-Convector open fires with back boilers are cast iron units incorporating a water container, flue and damper which are installed in place of the normal fire back as shown in the figure. The same general methods of constructing the fireplace already described are used, but the height and depth of fireplace opening may need to be greater than for a normal open fire. Convector fires are also available with back boilers, the boiler being built into the appliances by the manufacturers. Flow and return pipes where they pass through the chimney breast, the gap between being caulked with asbestos string.

NON CONVECTOR OPEN FIRES

CONVECTOR OPEN FIRES

BACK BOILERS



CLEANING

Chimney and flue cleaning

Most open fires are swept through the front. Where adjustable throat restrictors are installed, these are normally removable to allow cleaning brushes to be passed through the remaining opening.

CONSTRUCTION

OF CHIMNEYS

8.5 CONSTRUCTION OF CHIMNEYS

Brick chimneys

Domestic flues are mostly constructed in brickwork, with walls not less than 102-5 mm thick. Bends and slopes in the flue are formed by corbeling

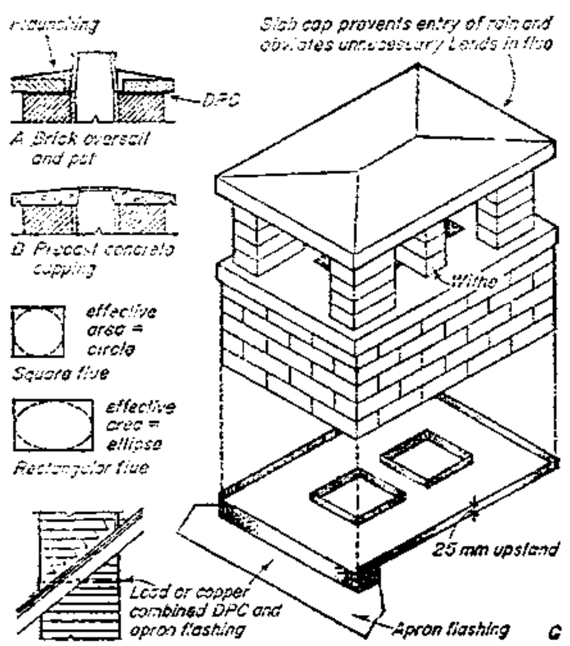
The back of a flue in a party or separating wall, unless back to back with another flue, must be at least 200 mm thick, or be of cavity construction with each leaf not less than 100 mm thick, up to its intersection with the roof.

The chimney breast, immediately above the top ceiling is reduced in width to that required for the stack, allowing for at least 102-5 mm walls and withes, that is the walls between adjacent flues.

For safety in terms of stability the height of a stack, including any chimney pot or other terminal, above the highest point of intersection with the roof must not exceed six times the least horizontal dimension unless the stack is braced in some way or its stability under wind pressure is checked by calculation.

When a chimney breast or stack projects beyond the face of the wall below the total projection of the oversailing brickwork must not exceed the thickness of the wall below with a maximum projection of 50 mm in each course.

BRICK CHIMNEYS

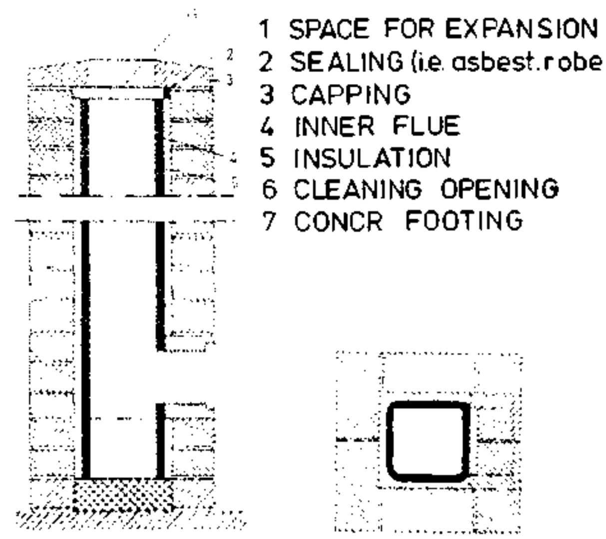


Flues and chimney stacks

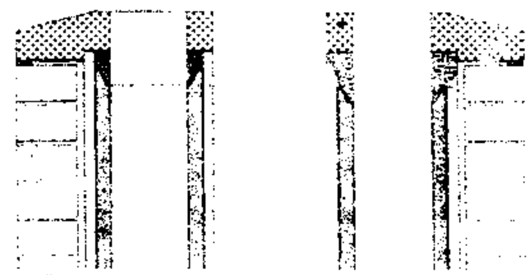
The top of a flue is usually terminated by a cylindrical fireclay pot. Tapering pots provide the slight restriction at the flue outlet to increase the velocity of the rising flue gases. The pot is bedded in one or two courses of brickwork, or other type of capping, and the top of the stack round the pot is flaunched, that is weathered with mortar, to throw off water.

The use of a perforated and weathered stone or precast concrete cap (B) as a terminal has the advantage of dispensing with the need for flaunching which after a time, even with a cement-lime mortar, may crack and permit the penetration of rain.

Any withes should be carried up to the underside of the top slab.
The top twelve courses of a stack should be laid in cement or cement-lime mortar of a strength not less than 1:1:6.
In order to ensure a smooth surface to the flue and to seal possible cracks in the brick joints the flue is parged or lined. Parging is the internal rendering of the flue with a weak cement-lime mortar,1:3:12, mix, not less than 13 mm thick, applied as the stack is built up. Flue liners, as well as ensuring a smooth airtight flue of uniform section, permit added insulation to be provided.
The Building Regulations, 1976, require flues for solid fuel and oil-burning appliances to be lined with rebated or socketed liners and make no provision for parging.
Liners may be made of fireclay, terra-cotta or acid - resisting concrete or they may be in the form of cast iron or vinyl-coated asbestos cement pipes (untreated asbestos cement is liable to disintegrate if heavy condensation accurs)(A,B)



CHIMNEY with PRECAST INNER FORM FLUE

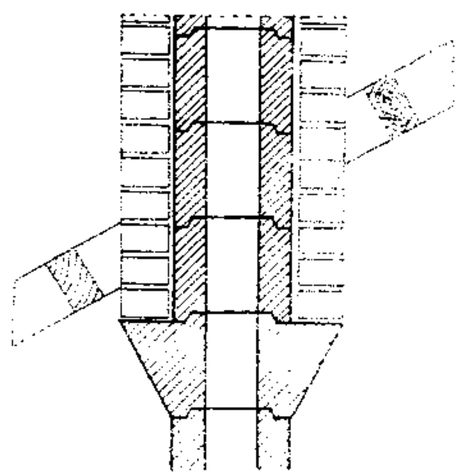


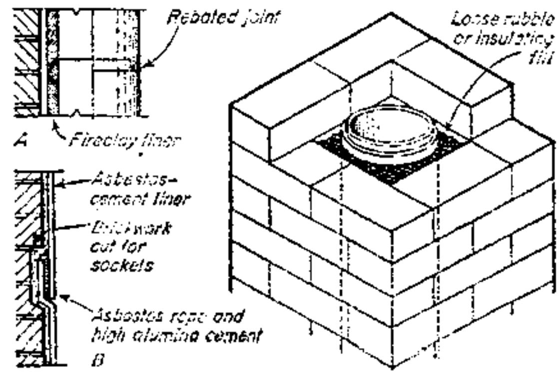
'PLEWA' 'BORA'

CHIMNEYHEAD with INNER FORM DUCT

PRECAST CHIMNEYSTACK

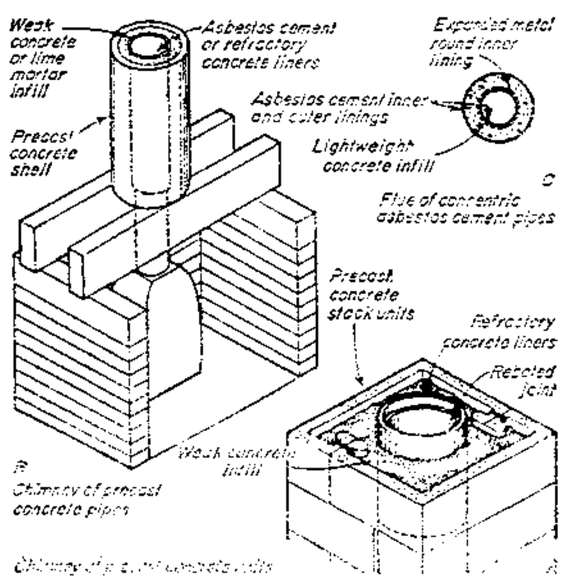
Where pipes are used the sockets should be uppermost and the joints made with asbestos rope and high alumina cement as shown in the figure.
The rope allows expansion and the cement is acid resistant.
The space between the lining and the chimney is usually filled with loose rubble flushed up with concrete or with an insulating material such as light weight concrete (C). Alternatively, the space may be left unfilled but sealed at top and bottom to provide an insulating barrier of still air.
The gathering over of the flue above the fireplace opening, referred to under Fireplace construction, should be steep, not flat, with the entry to the flue itself, that is the top of the 'funnel' more ore less central with the fireplace unless the flue has to pass to one side in order to clear an upper fireplace. A 'dog-leg' bend once always formed in the gather is no longer considered essential.





Flue linings

STONE CHIMNEYS



Chimney construction

Stone chimneys

The temperatures encountered in a domestic flue are not likely to damage a good building stone, except in the immediate vicinity of the fire and in this position sandstone should be used or protection given by firebricks. The flue walls should be at least 215mm thick and if the stone is bakked with brick or concrete this should be maintained as the minimum overall thickness.
Coursed masonry may be corbelled out to a total projection not exceeding the thickness of the wall below. Each course may project a distance equal to half the thickness of the wall below it, provided the corbel stone is bonded into the wall a distance equal to twice its projection. Stone chimneys must be protected by liners.

Concrete chimneys

Concrete chimneys can be constructed in three ways:

1 With in situ concrete
2 With precast concrete units
3 By a combination of 1 + 2

Concrete for in situ work may be either plain or reinforced and where in contact with the flue gases should be of an acid-resisting refractory type. Lightweight concrete made with foamed slag or expanded clay aggregates, or no fines concrete, can also be used, provided protection is given by flue liners. The mix for dense concrete should not be too rich in order to reduce shrinkage and to resist the effects of heat satisfactorily crushed brick, slag, clinker or crushed limestone should be used as aggregate.

The concrete should be at least 100 mm thick and unless increased to at least 150 mm where penetrating the roof should be rendered to provide adequate protection against damp penetration.

Up to a height of seven times its least horizontal dimension the effect of wind pressure on a plain, dense concrete chimney need not be considered. Oversailing projections should form an angle of not less than 60 degrees with the horizontal unless the projection is reinforced. The height of in situ lightweight or no-fines concrete chimneys should be limited to four times their least horizontal dimension and all oversailing or projecting parts should be formed with dense concrete, reinforced as necessary. The open-textured internal surface of such chimneys should always be lined and the external surfaces should be rendered. With cast in situ chimneys of all types liners are invariably used as they form permanent shuttering.

Dampproof courses are not generally required if the outside is rendered and there are flue liners.
A veriety of precast units of dense or lightweight concrete are available for forming chimneys. There are two approaches to the construction of chimneys in this form:
One by precast blocks bonded to form the walls and the withes of the chimney as normal masonry,
another by forming the internal and external surfaces of the chimney with precast units and filling the intervening cavity with lightweight concrete.

Dense vibrated concrete blocks will generally withstand damp penetration without rendering the external surfaces, and such constructions automatically provide a sufficiently smooth surface to the flue.

As with in situ cas flues of lightweight concrete flue liners are exxential with lightweight blocks, and these are incorporated in the manufacture.

METAL and ASBESTOS CEMENT FLUEs

Metal and asbestos cement flues

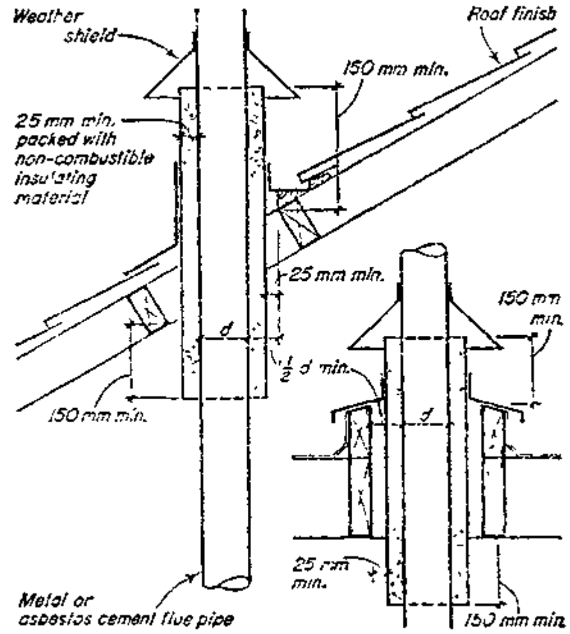
These materials have poor thermal insulation value and are not really suitable for external use unless insulated. They should generally be used only for flues within the room containing the appliance. Metal flues can be made of steel or cast iron. Asbestos cement flues are of heavy quality pipes. The pipes should be frequently supported, usually at every joint or at intervals not exceeding sixteen times the internal diameter.

The joints should be airtight and allowance should be made for the expansion and contraction of the pipes at the joints and at the supports.

Asbestos cement flues are not recommended for open fires or appliances using bituminous coal nor in situations where the internal flue temperature is likely to exceed 260°C since the material cracks when exposed to high temperatures or to flames impinging on its sureface. They must, therefore, be protected form flames by using a 1.8 m length of metal flue immediately above the fire.

Greater strength and insulation can be achieved by using asbestos cement pipes concentrically and filling the intervening cavity with lightweight insulating filling.

All combustible material in a roof or external wall through which the pipe passes must



Metal and asbestos cement flues

1. be kept a minimum distance of three times its external diameter away from the pipe,

or

2. be separated from the pipe by 200 mm of solid non-combustible material (300 mm if the combustible material is in an external wall above the pipe) or

3. the pipe must be enclosed with a sleeve of metal or asbestos cement. Such pipes must pass into a normal chimney within the same room or directly through an external wall or a roof structure, but not through a roof space, floor or internal wall.

•REPETITION••exercises•REPETITION•••

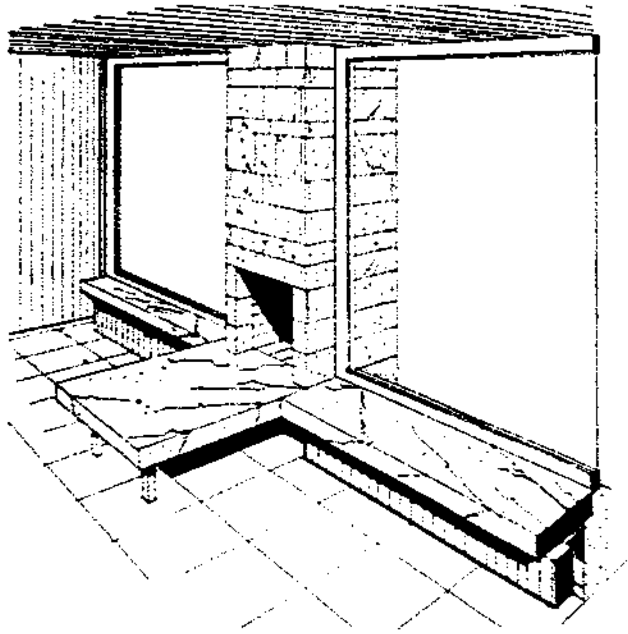
Try to answer the following questions and practice sketching wherever necessary and possible:

1. Define briefly the term "FIREPLACE"
2. Name the structural members of a CHIMNEY
3. Describe briefly the function of Fireplaces and flues
4. Explain by means of sketches the PRIMARY and the SECONDARY AIR SUPPLY in a Fireplace and describe the differences.
5. A chimney and chimney breast must satisfy certain requirements, such as:
   - Weather Resistence
   - Thermal Installation and
   - Fire Resistance

   Write notes on the above listed requirements.
6. Describe the principles of a traditional OPEN FIREPLACE and use sketches for illustration.
7. What are the characteristics of IMPROVED SOLID FUEL APPLIANCES? (use sketches for illustration)
8. Designing a flue properly the following factors must be considered.
   a Size and Shape
   b Airtightness
   c Insulation
   d Position of outlet

   Write notes on the above listed factors.
9. Draw a sketch, indicating depth, width and height of the opening of an open fireplace as well as the thickness of material at sides and back of the opening.
10. What is the traditional method of forming the head of the opening of a fire place?
11. What is an alternative to the traditional method?
12. Describe briefly (by using sketches for illustration)
    a How the junction between the fire place - opening and the flue is made (or HEARTH)
    b How the base (or HEARTH) of the fireplace opening is ctructed?

REPITITION ••exercises• REPITITION



13. Explain briefly the terms:
    - Non-convector fires
    - Convector fires
    - Back boilers

    and use sketches for illustration
14. List different types of chimneys (according to their building materials used for construction) and describe briefly (by means of heat sketches) the methods used for construction.

9. ROOFS

FUNCTIONAL REQUIREMENTS

9. R O O F S

9.1 Functional Requirements

- The main function of a ROOF is to enclose space and to protect the space it coveres from the elements:
  RAIN
  WIND
  HEAT
- To fulfil its functions efficiently the roof normally must satisfy the same requirements as the walls:
  STRENGTH and STABILITY
  WEATHER RESISTANCE
  THERMAL INSULATION
  FIRE RESISTANCE
  SOUND INSULATION

STRENGTH and STABILITY

9.1.1 STRENGTH AND STABILITY are provided by the roof structure and a major consideration in the design and choice of the structure is that of a SPAN.
The wide variety of roof types in different materials which have been developed is - in main - the result of the search for the most economic means of <u>carrying the roof structure and its load over spans of varying degrees</u>.

DEAD WEIGHT

In all types of structures it is necessary to keep the DEAD WEIGHT to a minimum, so that the imposed loads can be carried with the greatest econom y of materials.

The degree of efficiency - in this respect - is indicated by the DEAD/LIVE LOAD RATIO, expressed in the terms of
<u>Loads per square metre of area covered</u>
or
<u>per metre run of roof structure</u>

DEAD / LIVE LOAD RATIO

The structural problem in the design of WIDE SPAN ROOF STRUCTURES is - therefore - primarily that of achieving a DEAD/ LIVE LOAD RATIO as low as possible.

In solving this problem, two factors are important:
1) The characteristics of the materials to be used,
2) The form or shape of the roof

CHARACTERISTICS of MATERIALS

- STRONG
- STIFF
- LIGHT

- if materials are <u>STRONG</u> less material is required to resist given forces.
- if materials are <u>STIFF</u>, they will deform little under load and the structure may be of minimum depth
- if materials are <u>LIGHT</u>, the self - weight of the structure will be small.

ALL OF THESE CONTRIBUTE TO A STRUCTURE OF SMALL DEAD WEIG

EFFECTS of WIND

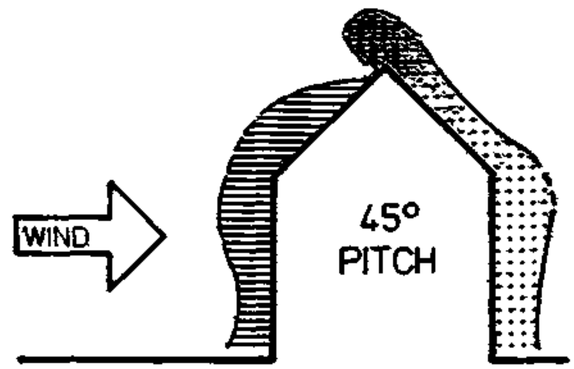
In addition to the dead load and the superimposed loads, the roof must resist the EFFECTS OF WIND.

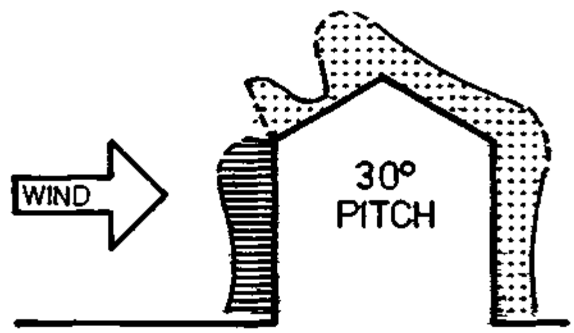
The pressure of wind varies with
- its velocity
- the height of the building, and
- the locality of the building.

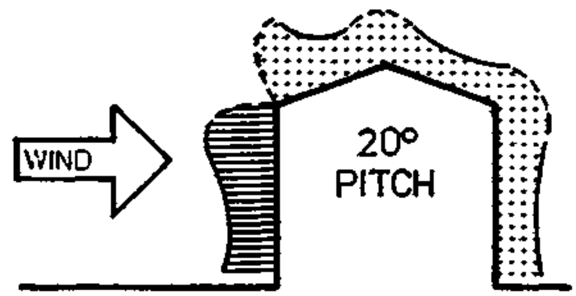
Wind may exert COMPRESSION on some parts of the roof and SUCTION on others, both in varying degrees at different points according to the pitch of the roof.

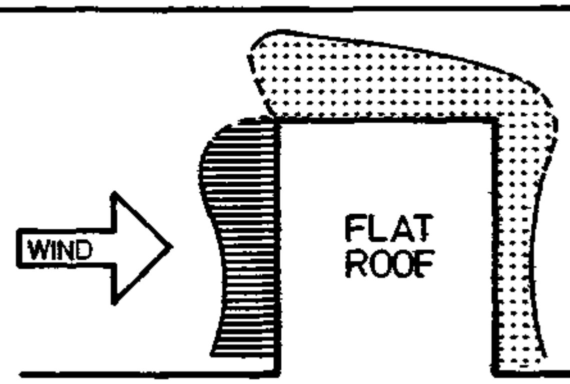
Higher suctions and compressions occure
- at the edges of the roof
- on flat roofs and
- on low pitched roofs the suction over the windward side can be considerable.

LIGHT ROOF COVERINGS: (alu-, g.c.i.-, asbestos sheets)
The supporting structure tends to be light and the weight of the cladding and roof structure as a whole may not be heavy enough to withstand the uplift of excessive suction during short periods of very high wind.
Therefore proper fastenings to the claddings and fixing of the roof structure to frames or walls are necessary to prevent them being stripped off.









9.1.2 WEATHER RESISTANCE
is provided by the roof coverings and the nature of these will effect the form and some details of the roof structure.

WEATHER RESISTANCE

THERMAL INSULATION

9.1.3 THERMAL INSULATION
In most buildings thermal insulation in the roof is either essential or increases the comfort
- <u>in hot areas</u> thermal insulation keeps the heat out of the building
- <u>in cold areas</u> thermal insulation prevents the building from greater heat loss.

Thermal insulation, however, is rarely a factor affecting the choice of the roof type, since the normal methods of providing it are generally applicable to all forms of roofs.
These methods vary and involve
- flexible
  or
- stiff insulation materials.

in or under the roof cladding or structure or the use of self-supporting insulation materials such as
- wood wool
- compressed straw slabs

which are strong enough to act as substructure to the covering.
In the case of concrete surface structurs, light weight aggregate concrete may be used (either fully or partly).

FIRE RESISTANCE

9.1.4 FIRE RESISTANCE

Adequate fire resistance is necessary in order to give protection against the spread of fire from and to any adjacent buildings and to prevent early collaps of the roof.
These matters will be discussed later under the topic"Fire protection".

SOUND INSULATION

9.1.5 SOUND INSULATION
Most forms of roof construction provide for the majority of buildings an adequate degree of insulation against sound from extern. Sources. Only in special cases, such as concert halls in noisy localities or hospitals along highways with heavy traffic, precautions might be necessary and might also affect the choice and design of the roof structure.

The fact, that weight and discontinuity of structure are important factors in sound insulating construction, makes this problem difficult in the case of roofs.

TYPES of ROOF STRUCTURES

9.2. TYPES OF ROOF STRUCTURS

- The area of the roof together with the roof coverings (which may be defined as the 'SKIN' of the roof and which can be constructed in many different ways) are carried by the ROOF STRUCTURE

- In order to drain the rainwater properly the 'SKIN' has to be more or less inclined.

- The better the 'SKIN' of the roof is able to protect the roof structures and the space enclosed from rain and wind, the flatter the roof can be constructed.

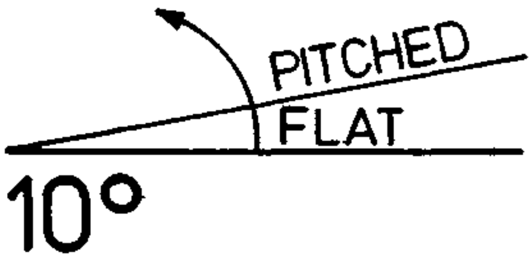
- The different types of roofs may be broadly classified in three ways:
  according to the
  1) shape of the roof
  2) structure of the roof
     (+building materials + span)
  3) coverings of the roof
     (+angle of in clination)

- shape, materials and colour of the 'skin' of the roof are most important for the appearance of the building.
  Therefore shape, degree of inclination as well als the covering material should be in accordance with local envirement.

9.2.1 FLAT AND PITCHED ROOFS

- Flat roof:
  outer surface horizontal or inclined at an angle not exceeding 10°.
- Pitched roof
  outer surface sloping in one or more directions at an angle more than 10°.

FLAT and PITCHED ROOFS



Climat and covering materials affect the choice between a flat or pitched roof.

- In hot, dry areas the flat roof is common (because there are no heavy rainfalls and the roof may form a useful out-of-door living room)
- In areas of heavy rainfalls, a steeply pitched roof quickly drains off rain.

Covering for roofs consist of

- unit materials, such as tiles and slates laid closed to and overlapping each other and
- membrane or sheet materials, such as asphalt, bitumious felt or metal sheeting, whith sealed or specially formed watertight joints.

STRUCTURE of the ROOF

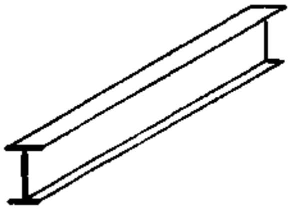
9.2.2 STRUCTURE OF THE ROOF

From a structural point of view roof structures may be conside-red broadly as

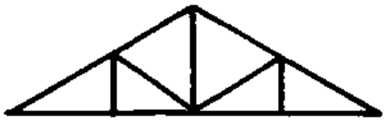
- two - or
- three - dimensional forms.

- Two - dimensional structures for practical purpose have LENGTH and DEPTH only and all forces are resolved in two dimensions with in a single vertical plane (only SPANNING FUNCTION).
- Three-dimensional structures have LENGTH, DEPTH and BREADTH, and forces are resolved in three dimensions within the structure. These forms can fulfil a COVERING and ENCLOSING FUNKTION as well als that of SPANNING. The general term is SPACE STRUCTURES.

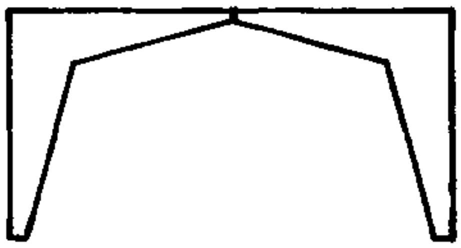
TWO-DIMENSIONAL ROOFS include :



BEAMS



TRUSSES

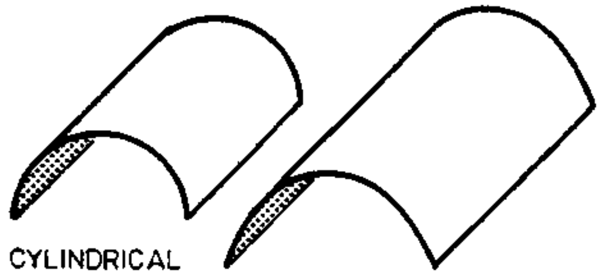


RIGID FRAMES

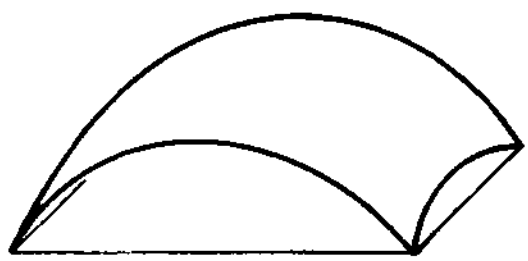
- beams
- trusses
- rigid frames of all types, including arch ribs

THREE DIMENSIONAL ROOFS include :

- cylindrical and parabolical shells and shell domes

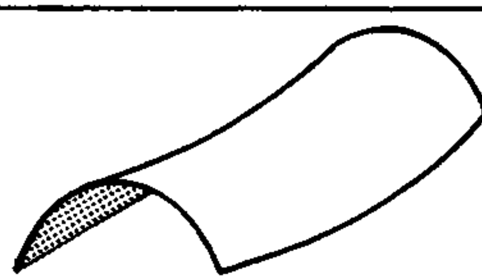


CYLINDRICAL SHELLS PARABOLICAL SHELLS



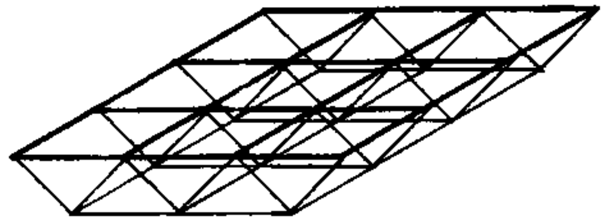
SHELL DOMES

- doubly curved slabs, such as hyperbolic paraboloids and hyperboloids of revolution

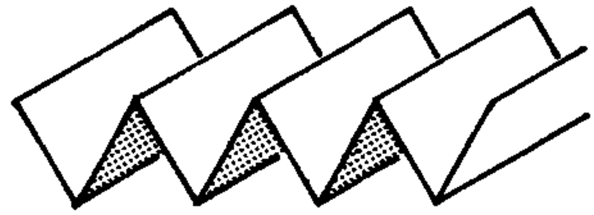


HYPERBOLIC PARABOLOIDS

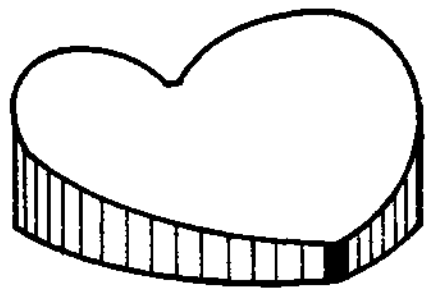
- grid structures, such as space frames, space grids, grid domes and barrel vaults

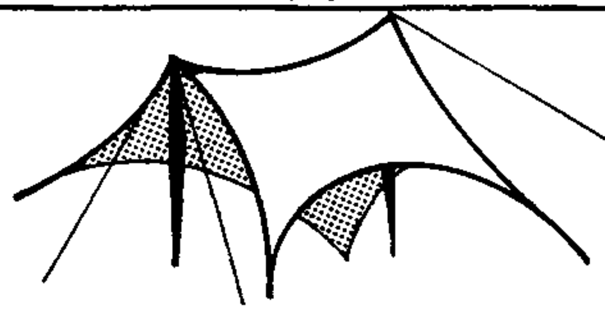


- folded slabs and prismatic shells



- suspended or tension roof structures.





SINGLE DOUBLE & TRIPLE ROOFS

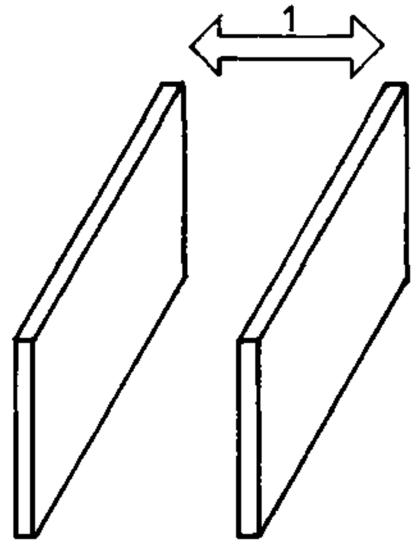
Roofs, constructed of two - dimensional members are classified as

- single
- double and
- triple rooefs

according to the number of horizontal stages necessary economically to transfer the loads to the supports.

SINGLE

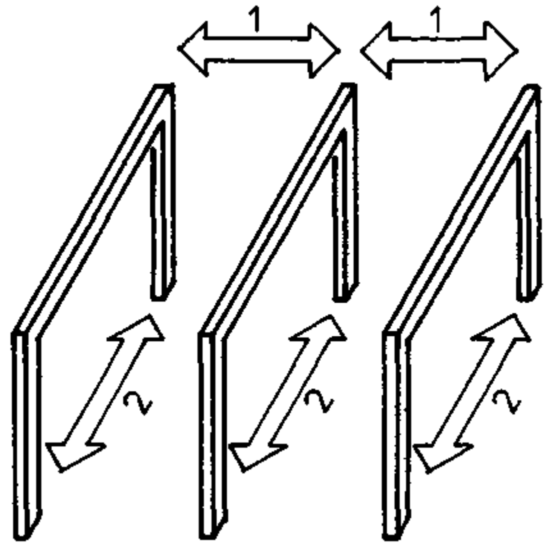
- in single roof construction the roofing system is carried directly by one set of primary members, spanning between the main supports



SINGLE ROOF

DOUBLE

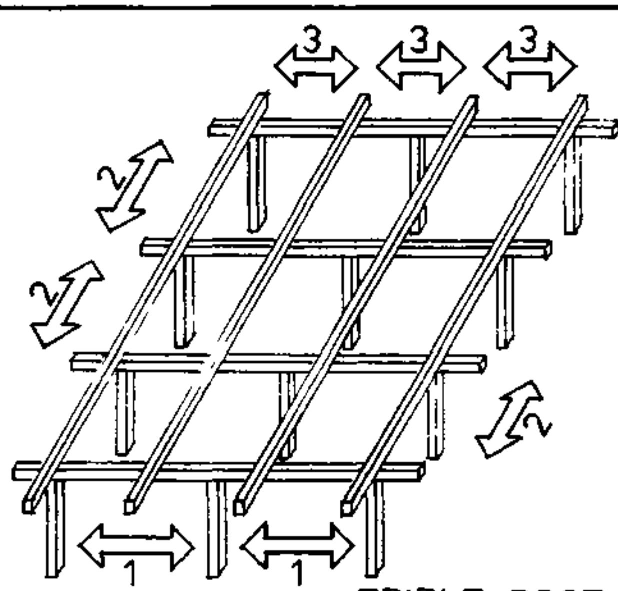
- As the span of the primary members increases a point is reached at which it becomes more economical to use larger members spaced further apart to support secondary members to carry the roofing system. This is known as double Roof Construction



DOUBLE ROOF

TRIPLE

- In some circumstances spans are such that three sets of members are required to produce an economic structure, resulting in three stages of support
  This is called Triple Roof Construction.
- This classification is applied to both flat and pitched roofs (as well as to floor construction).



TRIPLE ROOF

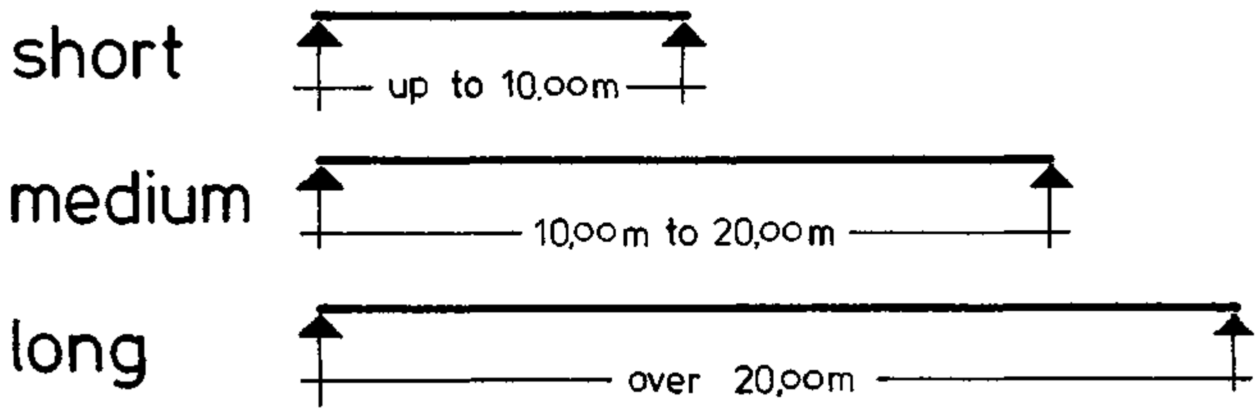
TCA TECHNICAL COLLEGE ARUSHA CHUO CHA UFUNDI ARUSHA	CIVIL ENGINEER. DEPARTMENT	10

LONG and SHORT SPAN ROOFS



9.2.3 LONG AND SHORT SPAN ROOFS

Roof structures are classified in terms of span as

- short span (up to 10.oom)
- medium span (10,oo to 20.oom)
- long span (over 20.oom)

- Short span construction will usually be cheapest
- As an increase in the distance between supports usually results in an increase in the cost - comparible with requirements of clear floor area should always be adopted in design.
- Three dimensional structures are normally <u>not</u> economic over <u>short</u> spans.

N.B.

N.B. All types of roof structures, which are introduced in the following, refer to the SHORT SPAN CONSTRUCTION only.

FLAT ROOFS

9.3 FLAT ROOFS

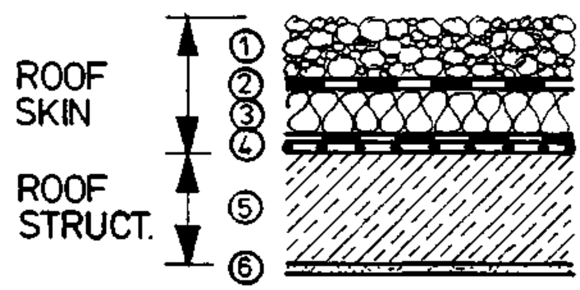
9.31 PHYSICAL AND STRUCTURAL PROB LEMS.

To design a building having a FLAT ROOF, seems to be very simple, because in a drawing using a scale of 1 : 100 or 1 : 200, it is just indicated as a double line and does not show the physical and structural problems behind. Plenty of flat roofs (in Arusha and all over TAN) are leaking, because of

- insufficient (or wrong) construction, and
- lack of adequate building materials (expecially for thermal insulation and waterproof membranes).

9.32 STRUCTURE OF A FLAT ROOF

STRUCTURE of a FLAT ROOF



① PROTECTION OF THE SKIN
② WATERPROOF MEMBRANE
③ THERMAL INSULATION
④ VENT. VAPOUR BARRIERE
⑤ ROOF STRUCTURE
i.e. REINF. CONCRETE
⑥ CEILING

Flat roofs have to be drained through rainwateroutlets, such as:

- central internal rainwater inlet (special gully)
- tapering gutter discharging to an external rainwater downpipe or
- water spouts

THERMAL INSULATION MATERIALS

9.33 THERMAL INSULATION MATERIALS
For most types of roofs (especially for flat roofs) thermal insulation is provided by NON-STRUCTURAL materials of two types with:
1) Low thermal conductivity
2) high thermal reflectivity.

Materials of low thermal conductivity have a <u>high percentage volume</u> of GAS or AIR VOIDS, which retard the transmission of heat.

Most efficient are materials with a CLOSED AIR or GAS CELL STRUCTURE, such as EXPANDET PLASTICS, used in board or granule form, a few mm thickness of which give insulation eaqual to a substantial thickness of brickwork, dense concrete or stone.

Typical of this class of insulators are :

QUILTS

a) QUILTS: consisting of
- glass fibre
- rock wool or slag wool (classified as MINERAL WOOL)

SLABS

b) SLABS : of
- wood wool
- straw boarded
- fibre boarded
- expanded plastics
- cork
- semi rigid glass fibre
- foamed glass
- thick, lowdensity soft wood strips (preferably 50 mm and above)

GRANULATED or NODULATED materials

c) GRANULATED or NODULATED materials used as loose fills, in layers on ceilings or fills in cavities:
- pelleted slag wool
- exfoliated vermicolite (a naturally occuring micaceous material which expands when its constained water is vaporized by heat).

FOAMED PLASTICS

d) PLASTICS FOAMED in - SITU and injected into cavities to fill them.
(note: The FOAM stabilizes the insulating air in the cavity by incorporating it as millions of very small cells within the materials.)

AIR or GAS CELLS

e) AIR or GAS CELLS within a basically highdensity material, as in foamed concrete or screed.

LIGHTWEIGHT AGGREGATES

f) LIGHTWEIGHT - AGGREGATE concrete and screeds which, to be effective, must be of adequate thickness, dried out and kept dry.

SPRAYED INSULATION

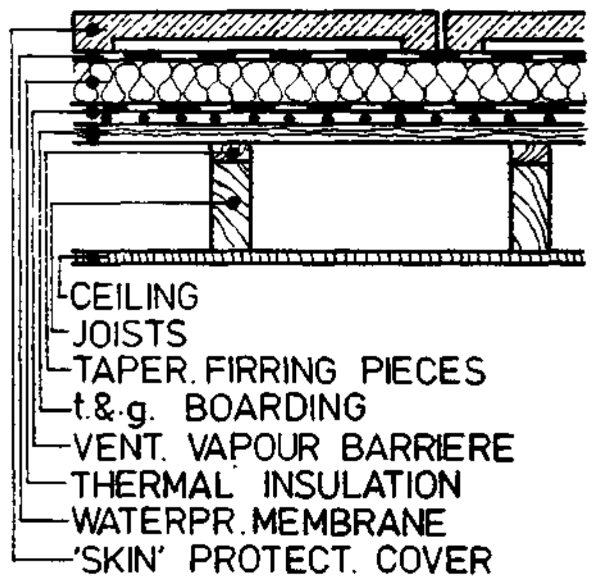
g) SPRAYED INSULATION, of asbestos fibre with water-activated binders, or lightweight plasters, applied to a thickness of 12 mm or more, on exposed protected internal surfaces.

NOTE: The presence of MOISTURE in an insulation material will REDUCE its efficiency.

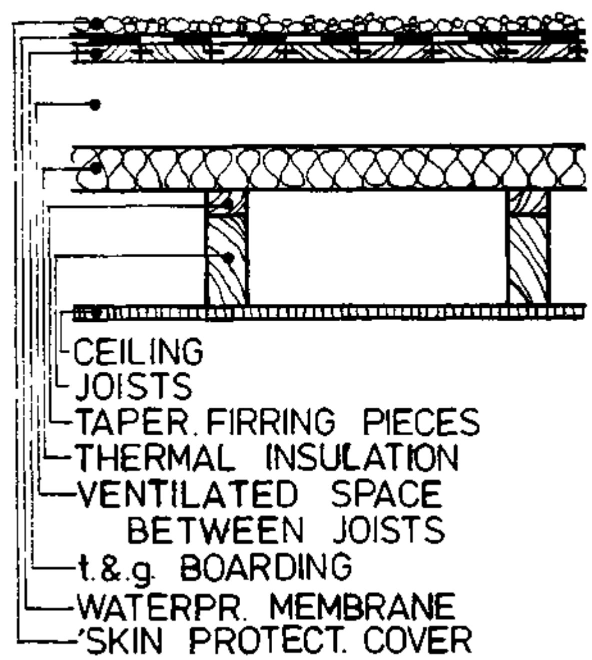
9.34 SINGLE AND DOUBLE FLAT ROOF CONSTRUCTION

The construction of a FLAT ROOF (in timber as well as in reinf. concr.) is comparable with that of an UPPER FLOOR.

SINGLE FLAT ROOF



DOUBLE FLAT ROOF



ASPHALT COVERED FLAT ROOFS

Is widely used but insufficient, because the roof skin is not properly ventilated and there is no protection cover against drying out of the asphalt by the sun. (ref. Fig.)

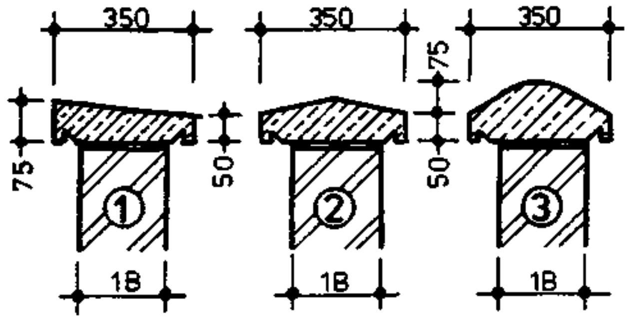
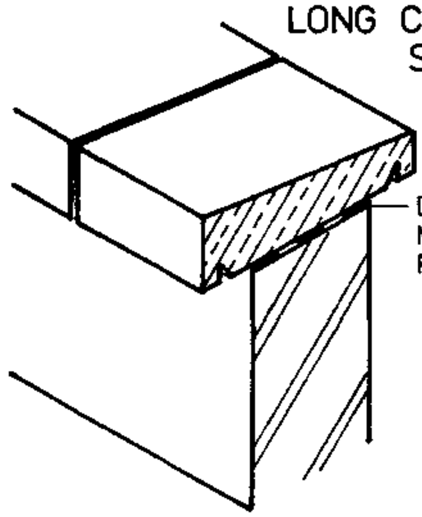
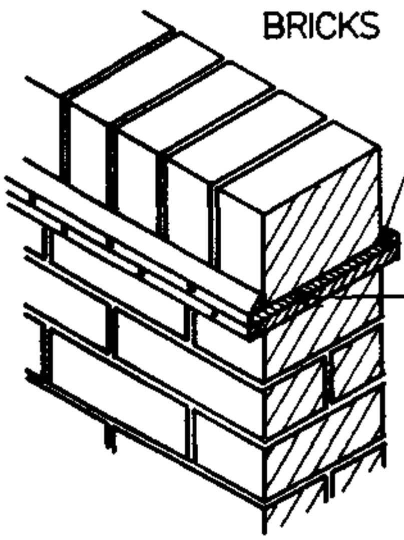
PARAPET WALLS



①
②
③





9.35 PARAPET WALLS

External walls of buildings are raised above the level of the roof as PARAPET WALLS for the sake of appearance of the building as a whole.

Parapet walls are <u>exposed</u> on all faces to driving rain and wind and are much more liable to damage than external walls below eaves level.

Parapet walls are <u>not weighted down</u> by floors and roofs and it is generally accepted that they should not be built above roof level higher than six times the least thickness of the parapet wall.

Parapet walls to be <u>covered or capped</u> with some non-absorbent material such as:

- natural stone (protective and decorative)
- artificial stone: Stones are made with a core of concrete faced with a mixture of crushed stone particles and cement.
- brick capping: Bricks are laid - on - edge on top of two coarses of creasing tiles laid-breaking joint-in cement mortar.
- D.P.C. beneath coping stones within the Parapet walls.

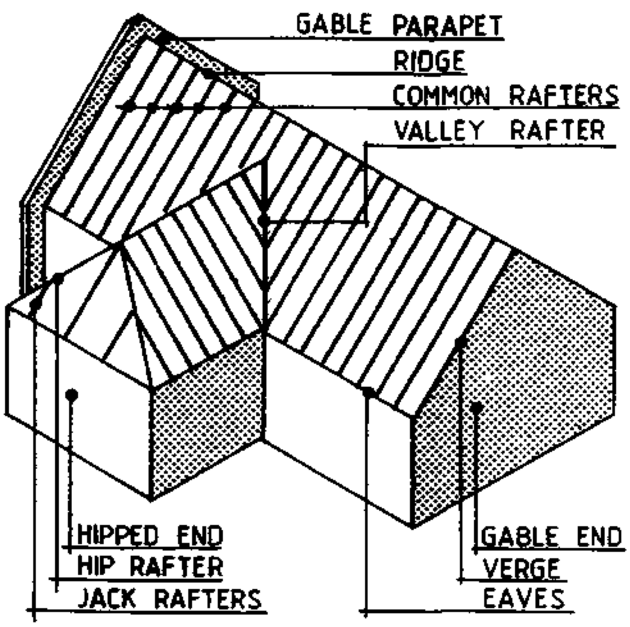
TENT ROOF

ROOFING TERMINOLOGY



9.42 TERMS

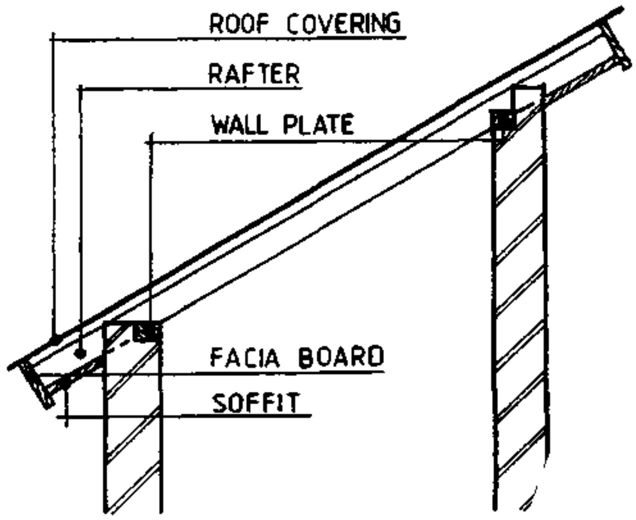
9.43 TYPES OF PITCHED ROOFS IN TIMBER (STRUCTURES)

1.

MONOPICHED ROOF

I. Mono-(single) pitched Roof:

Constructed similar to a timber flat roof or a timper upper floor (joists = rafters). Because of the pitch of the roof a BIRDS MOUTH at the end of the rafters has to be provided to avoid sliding off the wall plate. (ref. fig.)

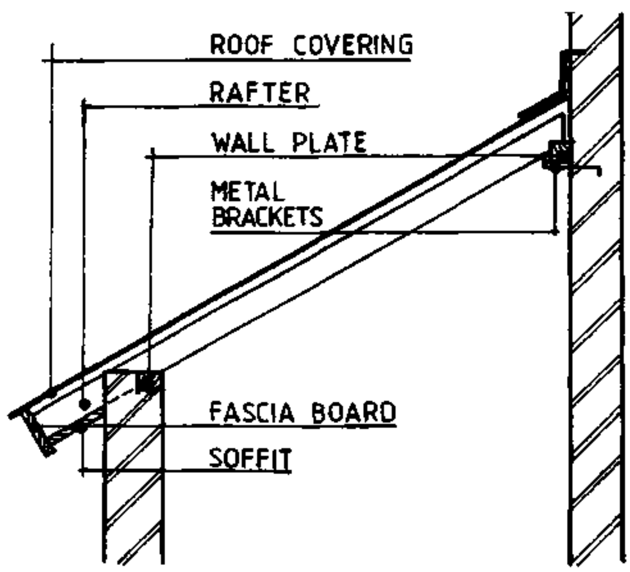


2.

LEAN-TO-ROOF

II. LEAN - TO ROOF

Is a monopitch roof of which the tops of the rafters are pitched against a wall. The feet of the rafters are birds mouthed over a wall plate as for a monopitched roof, and the upper ends over a plate supported on the wall by corbel brackets or by any means of supporting floor joists.



III. COUPLE ROOF

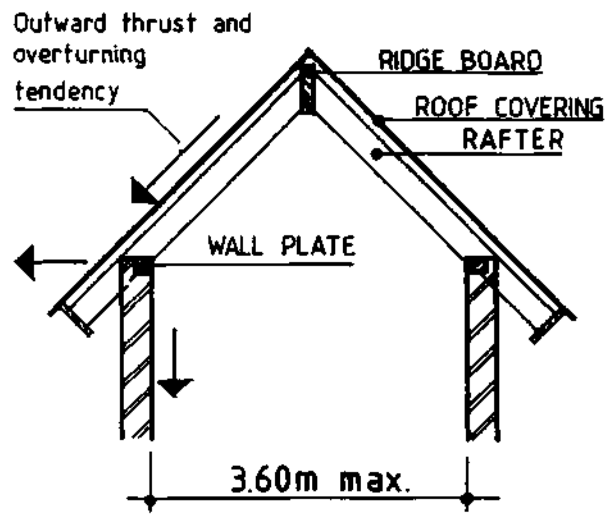
This ist the simplest, but not necessarily the most economic form of ridge roof sloping down in two directions from a central apex or ridge as it is technically termed. It consists of pairs, or couples, of rafters pitched against each other at their heads with their feet bearing on opposite walls.

When two spanning members are arranged in this way the junction at the ridge forms a mutual support so that the span of each is the distance between this point and its lower support. The depth of the rafters in a couple roof may, therefore, be considerably less than that of those in a flat or monopitch roof of the same overall span. This is an advantage from the point of view of economy of rafter material, but the arrangement of rafters results in a tendency for the ridge to drop under the roof load with a resultant outward spread of the rafter feet. In order to keep the roof stable this outward spread or thrust must be resisted by sufficiently heavy supporting walls. If the walls are tall they will, therefore, be thick and expensive. For 215 mm solid or 250 mm cavity walls of normal height the roof must be limited to a maximum clear span of about 3.oo m to keep the thrust within acceptable limits. The clear roof space given by this roof can, however, be used with advantage over wider spans than this if the roof pitch is steep and the eaves are low. This has the effect (1) of reducing the outward tnust of the rafters and (2) of reducing the height of any supporting walls and, therefore, their tendency to overturn, so that their thickness may be kept to a minimum.

The feet of the rafters are birdsmouthed over wallplates and the upper ends butt against a flat board called a ridge piece or board, to which they are nailed. This board facilitates fixing of the rafters and keeps them in position lateraly.

3.

COUPLE ROOF



IV. CLOSE COUPLE ROOF

This roof results from the introduction of horizontal members to tie together the feet of each pair of rafters and prevent their outward spread. This forms a simple triangulated structure and produces vertical loads on the supports with no tendency to overturn the walls so that their thickness need take no account of this. These members, known as ties, are spiked to the feet of the rafters at plate level and if they are used to support a ceiling, as commonly is the case, they are called ceiling joists. The maximum economic span of this roof is about 6.10m, this being limited not by the spread of the rafters but by the economic sizes of the roof members. It is generally found most economic to restrict the depths of rafters to about 100 mm and, depending on the weight of the roof covering and the pitch and spacing of the rafters, this depth can be used over spans of about 4.60 m to 5,20 m

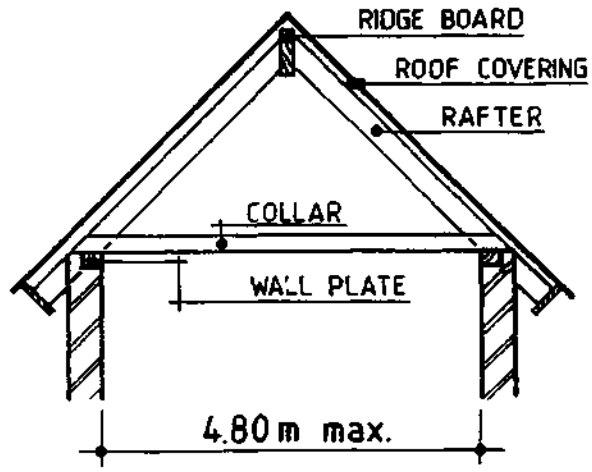
The function of ceiling joists as ties can be fulfilled by quite small sections but, as they act also as beams supporting their own weight and that of the ceiling, they tend to sag or deflect and they must be large enough to keep this within acceptable limits. For spans of the order given above quite large ceiling joists would be necessary and it is found more economic to reduce their effective span by suspending them from the ridge.

The longitudinal 75mmx50mm binder or runner skew nailed to the joists permits the hangers to be fixed to it at every third or fourth joist spacing rather than to each joist, thus economising in timber.

Fixing of hangers to runners should be deferred until the roof covering has been laid in order to avoid deflection of the ceiling joists due to the transfer through the hangers of any slight movement of the roof structure as it takes up the load.

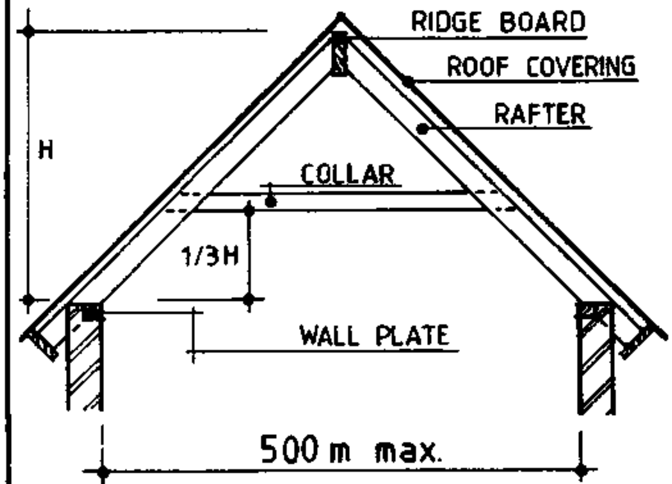
4.

CLOSE COUPLE ROOF



5.

COLLAR ROOF



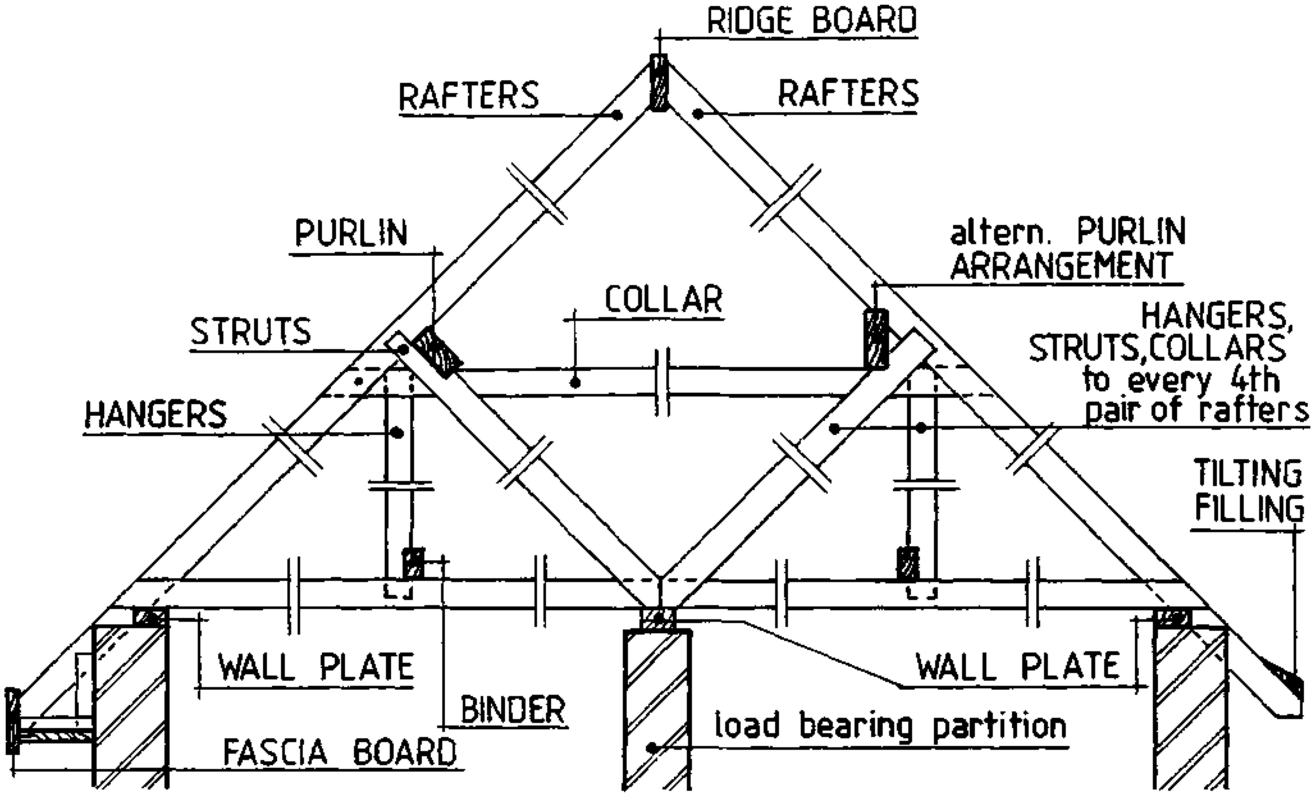
V. COLLAR ROOF

In this roof tie members are used but at a higher level than the feet of the rafters and they are called collars. It can be used for short spans not exceeding 4.90 m when it is desired to economise in walling, since the cailing will be raised and the roof may, therefore, be lowered on the walls to the same extent for a given height of room. The influence of the collar on the spread of the rafters is less marked the higher it is placed and half the rise of the roof is the maximum height at which it should be fixed. The size of the collars is the same as for close couple ties of an equivalent span. In the past a dovetail halved joint at the junction of collars and rafters was normal but this involves considerable labour and it is cheaper and stronger to use a bolt and timber connector.

6.

DOUBLE or PURLIN ROOF

for spans up to 7.20 m



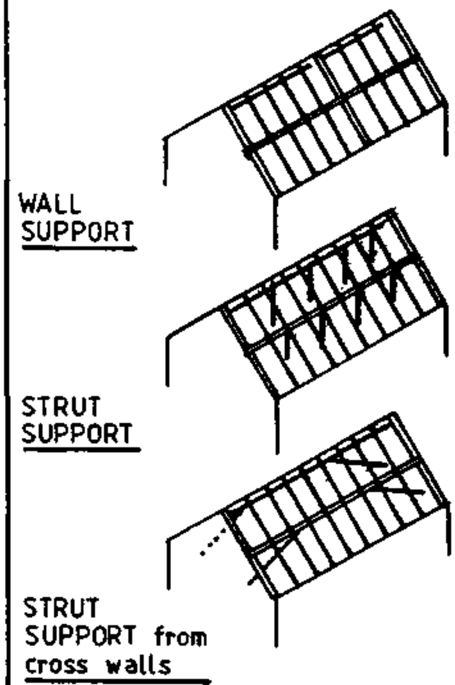
VI. DOUBLE OR PURLIN ROOF

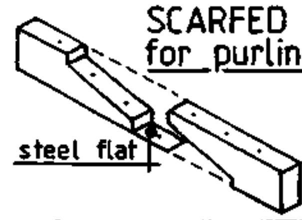
When the span of a roof is more than 6.10 m and requires in a couple type roof rafters much greater than 100 mm in depth it is cheaper to introduce some support to the rafters along their length, thus reducing their effective span, rather than to use large rafters. This support could be in the form of a strut to the centre of every rafter resting on a suitable bearing below, such as a partition or wall but, as in the case of ceiling joist hangers referred to above, it is more economical in timber to introduce a longitudinal beam on which all the rafters bear and to support this member at intervals greater than the rafter spacing. The introduction of this beam, or purlin as it is called, as a second stage of support brings the structure into the double roof classification. Although this introduces extra members into the construction the total cube of timber in the roof (and the weight of the roof) rises less with increase in span than if the rafters were increased in size.

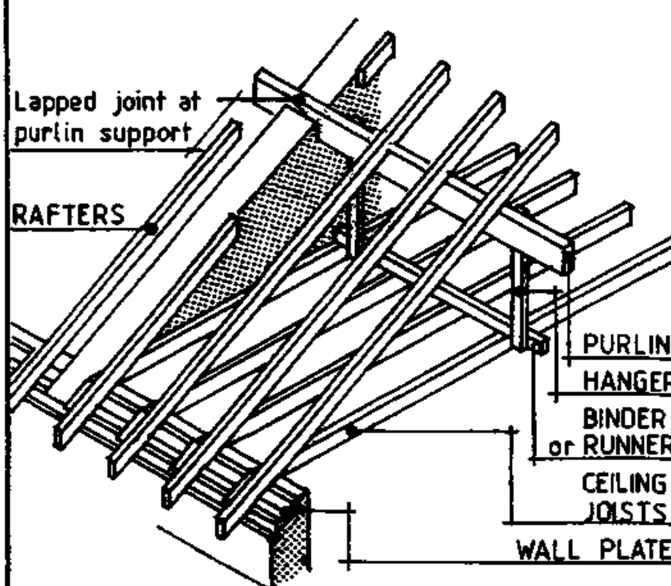
The purlins may be supported directly by cross walls or partitions at sufficiently close spacing along the length of the purlins or by struts off any suitably placed walls partitions or chimneys. The size of the purlins will be governed by the weight of the roofing system, the spacing of the purlins (if the length of rafter supported) and their span. As with rafters an increase in span results in increased size and cost of purlins and the span should, therefore, be kept within economic limits. Depending on the combination of weight and rafter length a 225 mm x 75 mm purlin will span from about 2.5o m to 3.7o m. If the spacing of available supports is such that purlins much larger than this are required it may be better to select an alternative method of construction.

Purlins may be placed vertically or normal to the rafters. The former ist preferable when the purlin bearing is directly on walls or on vertical struts, the latter is sometimes more convenient when inclined struts are used, which is the case when supports do not occur immediately under the purlins. Where possible inclined struts should be paired so that those to opposite purlins meet at the same point and bear against each other over the support. If this should result in struts at

PURLIN ROOF





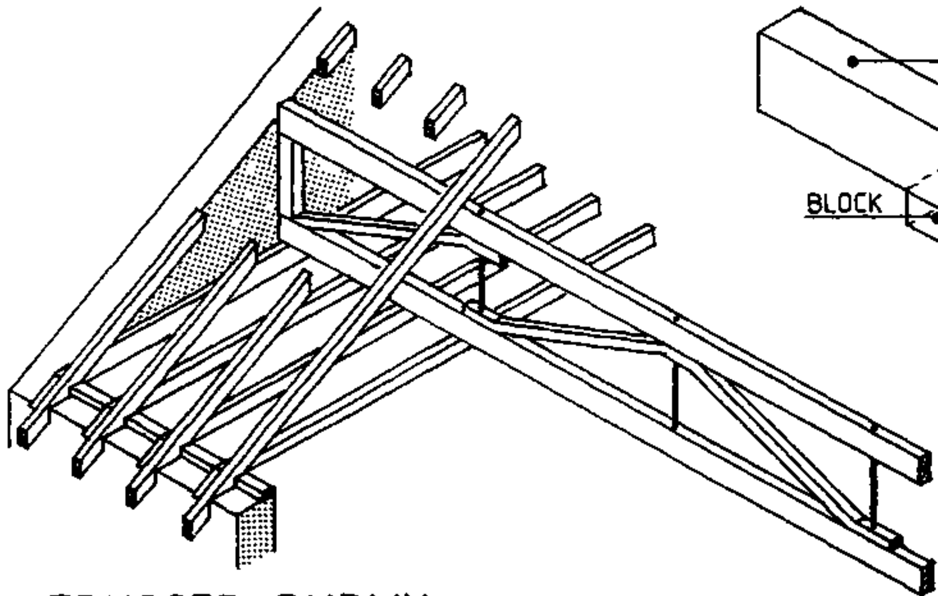


an excessively low angle a spreader piece nailed to the top of a ceiling joist may be used to increase the angle of the struts.

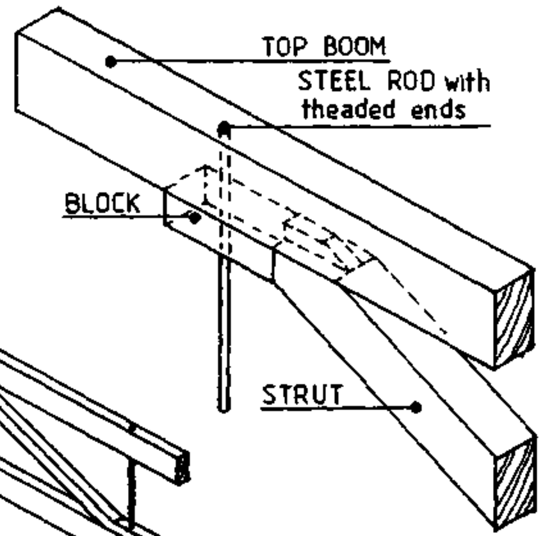
Joints required in the purlins should be made over supports wherever possible in the form of a lapped joint. Where joints must occ ur at points between bearings a stronger joint is necessary and a splayed scarf joint must be adopted.

As the span of the roof increases the size of the ceiling joists can be kept within economic limits by increasing the number of points of support and in a purlin roof hangers carrying binders can be suspended from the purlins. When the purlins are normal to the rafters the hangers are fixed to a rafter face immediately above the purlin.
Where no supports exist at intervals over which solid timber purlins of an economie size can span, but where suitable widely spaced cross walls exist, then deep beam purlins may be used. The maximum span over which they may be used in these circumstances depends to a large extent on the depth available for the beam. Two types are discussed below.

TRUSSED PURLIN



TRUSSED PURLIN



DETAIL of CONNECTION

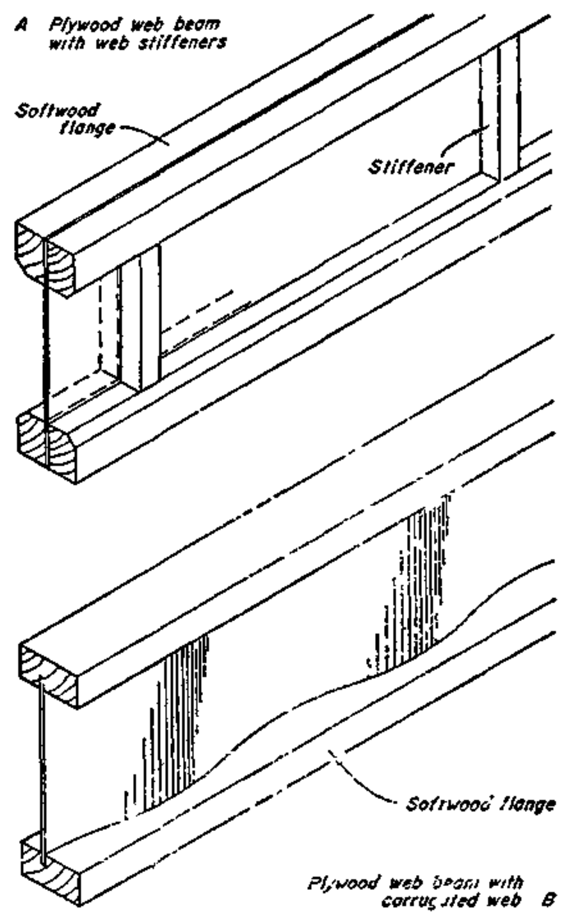
Trussed purlin

This ist a trussed, lattice or framed beam or girder all of which are synonymous terms for a beam built up of triangulated members. For a given load and span as the depth of a beam increases the bending stresses at top and bottom decrease and less material is required in the beam. This economy of material can be developed further by concentrating the majority of the material in the beam at the top and bottom where bending stresses are at a maximum. In the trussed beam structural depth is obtained with a minimum of material at the centre or web by means of relatively thin triangulating members which connect the top and bottom flanges or booms. For maximum economy bending stresses in the members should be avoided as far as possible

To this end the members should be arranged on the 'centre line' principle as far as is practicable that is to say at each junction of members their centre lines should intersect at one point. For the same reason loads should be applied only at the node points With trussed purlins however, the rafters are closely spaced along the top boom and do not all bear at a node point; some bending therefore occurs and the boom size must take account of this.

PURLIN BEAM

Purlin beam
The alternative to a trussed purlin is the thinwebbed timber beam, which may be specially fabricated or of which there are a number of mass-produced types on the market. This consists of a plywood web rebatted into and glued to top and bottom booms or glued at top and bottom between two timbers to form the booms. In deep beams of this type some stiffening against buckling of the thin web is required in the form of vertical stiffeners glued at intervals on each side of the web. In one proprietory beam this stiffening is obtained by using a vertically corrugated ply web instead of applied stiffeners.
A trussed purlin invariably makes use of the full depth between rafters and ceiling joists as shown, to provide direct support to the latter without hangers but when ply-webbed purlin beams are used they are unlikely to be as deep as this, exept in very low-pitched roofs, and hangers for the ceiling joists would be required.



135 Purlin beams

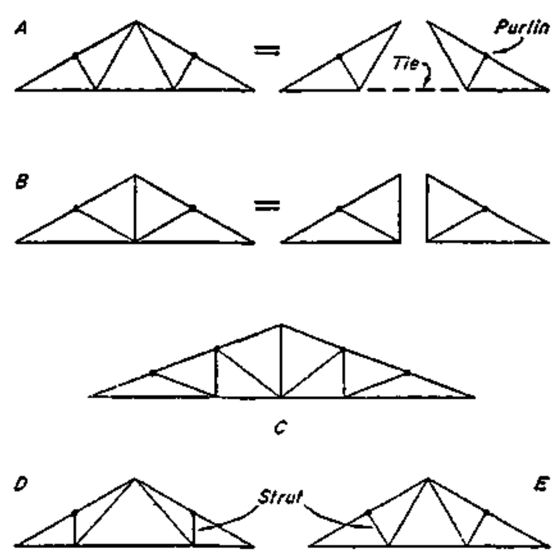
7. TRIPPLE or TRUSSED ROOFS

VII. TRIPPLE or TRUSSED ROOFS

The use of purlins as just described presupposes the presence of supporting elements at appropriate spacings. Where these do not exist or where, for some reason, this form of construction may not be suitable, for example, when the roof span is large and multiple purlins are necessary, an alternative method of supporting purlins is by structural members spanning the width of the roof at intervals along its length, the tops of which follow the pitch of the roof. These may be in the form of either a triangulated structure known as a roof truss or of deep rafters fixed at their feet rigidly to a pair of supporting columns to form one structural component. The latter are called rigid frames.

A ROOF TRUSS consists essentially of a pair of RAFTERS (or a single rafter in a monopitched roof) triangulated to provide support for the purlins, preferably at the node points.

For short span roofs two rafters lying in the same plane as their neighbours may be triangulated to carry purlins which are fixed immediately under them, so that the purlins are in the same relative position to the other rafters which they in fact support. These trusses are placed at relatively close centres. For wider spans resulting in large loads on the truss members, the size of a normal rafter is usually to small to be used in the truss and separate rafters are triangulated and carry the purlins on their backs. These rafters, therefore, lie below the level of the normal rafters and do not directly support the roof covering.
The rafters of the truss are called the PRINCIPAL rafters and the normal rafters the COMMON rafters.



TRUSS CONSTRUCTION in TIMBER

Truss construction in timber

- A roof truss must carry, via the purlins, the loads on a number of adjacent rafters.
- The forces on the joints between its members are, therefore, greater than those on the joints in a single or double roof structure and the use of one or two nails commonly used to secure members in the latter is insufficient in a truss.
- The detailed construction of a truss depends largely on the method adopted for joining the parts.
- Earlier methods involving mortice and tenon joints,necessitated relatively large amounts of timber at the junctions and, therefore, large heavy members (often larger than justified by the stresses in them) and the incorporation of large metal straps particularly at the tension points since the mortice and tenon joint is efficient only in compression.
- This type of truss is exemplified by the traditional king-post and queen-post trusses which, for these reasons, are now absolete.

- There are three modern methodes of joining the members:
  1 nailed joints
  2 bolt and connector joints
  3 glued joints and sometimes a combination of two.

- These methods require the members to be laid one against the other, or LAPPED as it is termed, to make the joint or - alternatively - require the use of cover plates, or GUSSETS, when the members butt one against the other.
- If two members lap, the joint is called SINGLE LAP JOINT If one member lappes by two other members, it is called a DOUBLE LAP JOINT (also known as SANDWITCH CONSTRUCTION).
- In a single lap joint the joint is under eccentric loading. For small span trusses carrying light loads this is not significant but when the joints carry large loads eccentricity should be avoided by the use of double lap joints. Double members are also used in order to obtain a satisfactory arrangement of members in the truss as a whole for jointing purposes.

(1) NAILED TRUSSES:

(1) NAILED TRUSSES:

Jointing by nails is the least efficient of the three methods - but a traditional and simple method.
By preboring nail holes and using wide, thin members to provide ample fixing area, efficient structures may be obtained, particularly where light - weight roof coverings are used.
The arrangement of nails to be calculated.

An example of the application of nailing in this manner is shown in the figure, where sandwich construction is used to carry corrugated asbestos cement sheeting over spans up to 6.1om. The principal rafters and horizontal tie are each formed by two boards, 32 mm thick, and the struts and secondary ties are 100 mm x 50 mm seantlings sandwiched between, the joints at these points being made by direct nailing between the members. As the rafter und tie members lie in the same plane and butt against each other at the feet of the truss it is necessary to use gussets to effect a joint at these points. The gussets here are formed by 25 mm boards on each side set normal to the rafters and securely nailed to each member . The extension of the gusset by two vertical boards increases the rigidity of the whole truss.
The double members at the feet are blocked apart by 5o mm pakking pieces and at the ridge the rafters are secured to each other by a 25 mm board on each side.

NAILED TRUSSES

Struts and secondary ties project beyond the rafters and 5o mm cleats are fixed at the intermediate purlin position to form seatings for the purlins. By joining them together the struts and cleats also serve to stiffen the thin rafter members which, being in compression are liable to buckle.
These trusses would be spaced 3.oo m to 3.6o m apart depending on the weight of the roof covering and the size of the purlins used. The point loads from the truss at its bearings are spread on to the walls by steel bearing plates as shown or by concrete templates built into the brickwork.

The purlin spacings shown in this exemplare are for small section corrugated sheeting. The intermediate purlins impose a point load on the rafters and, therefore, induce bending stresses. Since, however, the roof covering is light these stresses will be small and it is more economic to allow for them in the size of the rafters rather than to form hodes at these points by extra bracing members.

When self-supporting coverings such as these sheets are used they are laid directly on the purlins as in this example, but when the roofing requires a base such as battens, boarding or other roof decking needing support at closer intervals it is then cheaper to support the base on common rafters at the required spacings carried in the traditional way on purlins at the node positions only. This usually results in less timber content than if the porlins are placed at very close intervals.

When loading and span conditions require thicker members and where lapped joints do not provide sufficient nailing area, single thickness construction with gussets throughout may be used. By this means larger areas are available for nailing and all joints may be laid out on the 'centre line' principle.

(2) BOLTED AND CONNECTORED TRUSSES

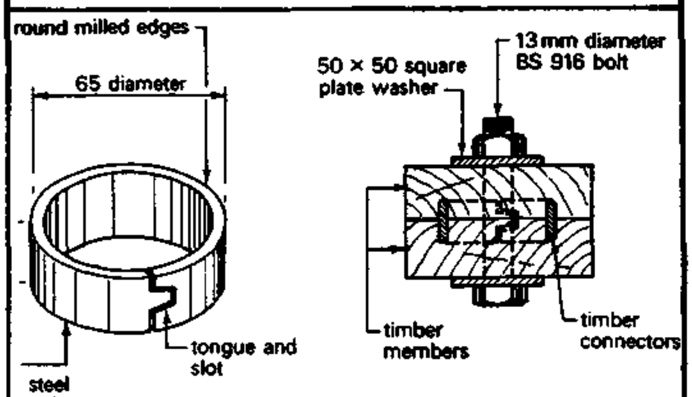
Timber connectors are metal rings or toothed plates used to increase the efficiency of bolted joints. They are embedded half in each of the adjecent members and transmit load from one to the other. There are many different types, of which the most commonly used for li_ght structures is the toothed plate connector, a mild steel plate cut and stamped to form triangular teeth projecting on each side which embed in the surfaces of the members on tightening the bolt which passes through the joint. For greater loads split ring connectors are used, but these require accurately cut grooves to be formed in each piece of timber.

Jointing by connectors and bolts permits thicker timber to be used and its application is illustrated in the figure. This truss is for a span of 7.6o m and is designed to be spaced at 3.9o m centres and to carry large section corrugated asbestos cement sheeting, which is self-supporting over a span of 1.4o m and a ceiling.

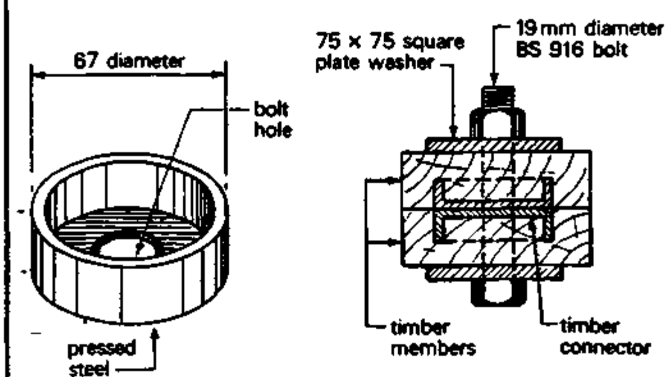
Rafters and horizontal tie are of double members with single member secondary ties sandwiched between. Struts are of double members placed on the outside of rafters and tie. This arrangement permits 'center line' setting out at all joints where three members meet. It also permits a single bolt to effect the joint.

Gussets are required at feet and ridge, firstly because the main members do not overlap and, secondly, in order to obtain a greater fixing area for the number of bolts required at these joints.

(2) BOLTED and CONNECTORED TRUSSES



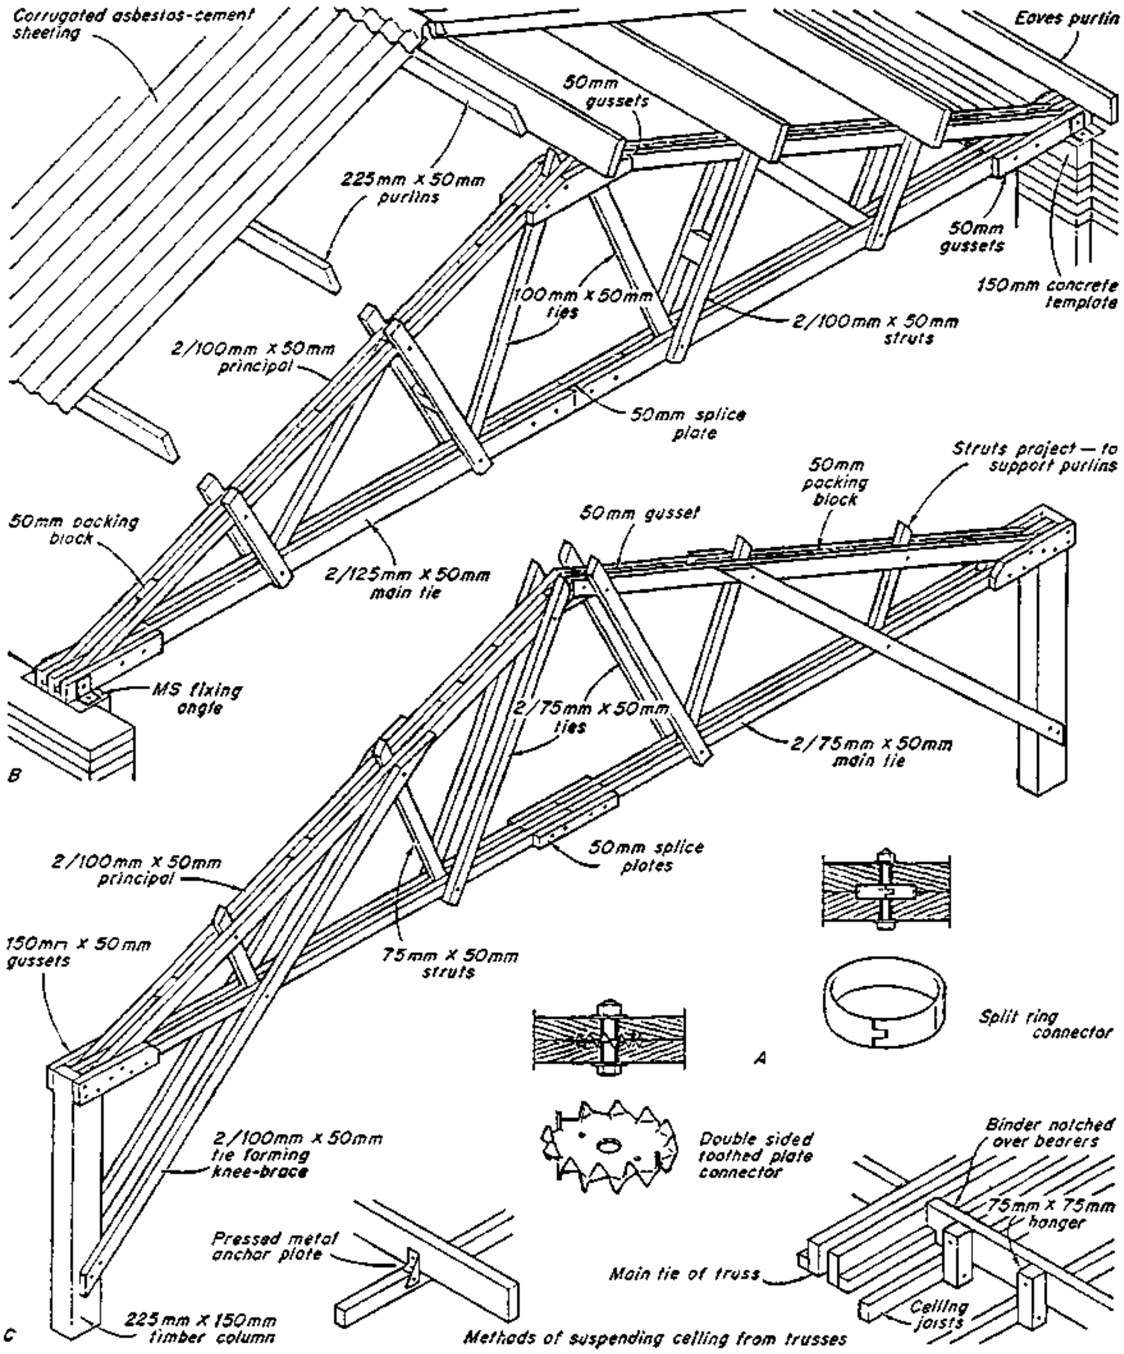
Parallel side split ring connector



Shear plate connectors

BOLTED and CONNECTORED TRUSSES

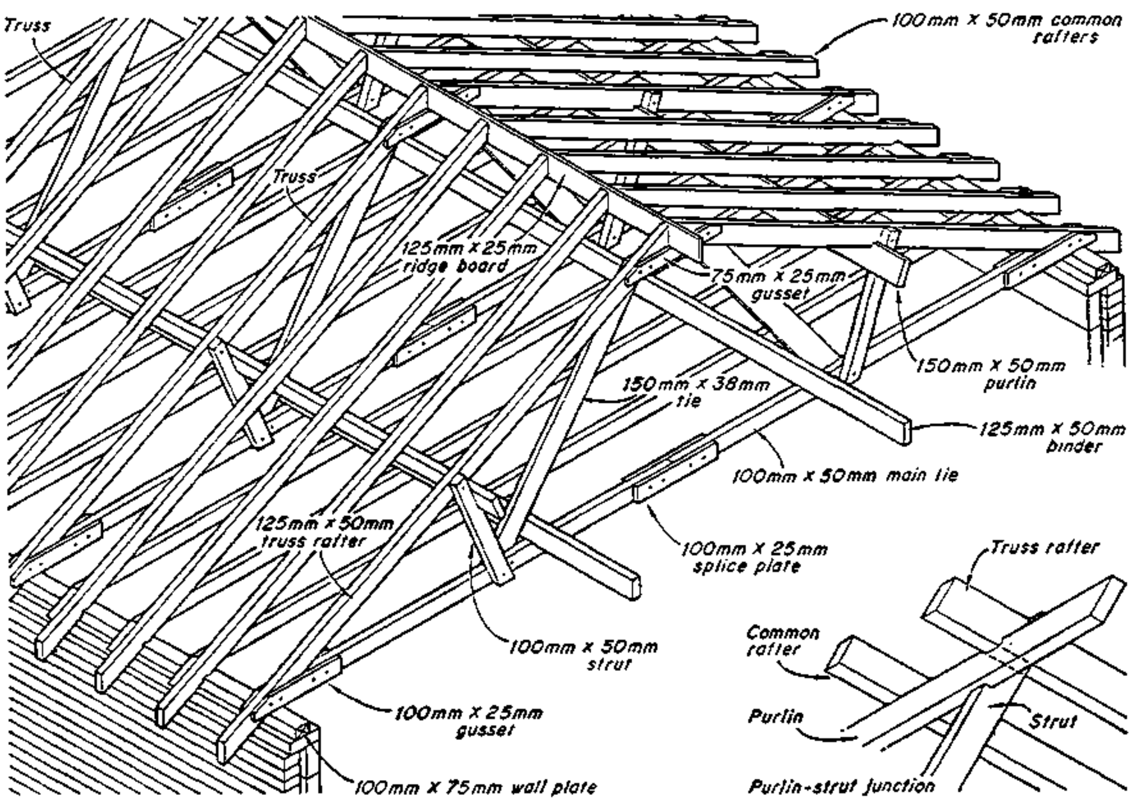
Since only one bolt is required at the foot of the rafter the gusset here need be no deeper than the tie, with a packing piece of the same size in the central space. To avoid the use of very long timbers the members of the main tie are joined or spliced at the centre using a central splice plate and four sets of bolts and connectors.



BOLTED and CONNECTORED TRUSSES

The joints in this truss are made with split ring connectors at each interface on 13 mm diameter bolts, with 5o mm square washers under bolt head and nut to prevent them sinking into the wood when the nuts are tightened. The projecting ends of struts and ties are necessary in order to obtain the minimum end distances beyond the connectors. It will be noted that the double members in the rafters and the long struts, which are compression members, are stiffened between the node points by 50 mm packing blocks securely spiked in position.

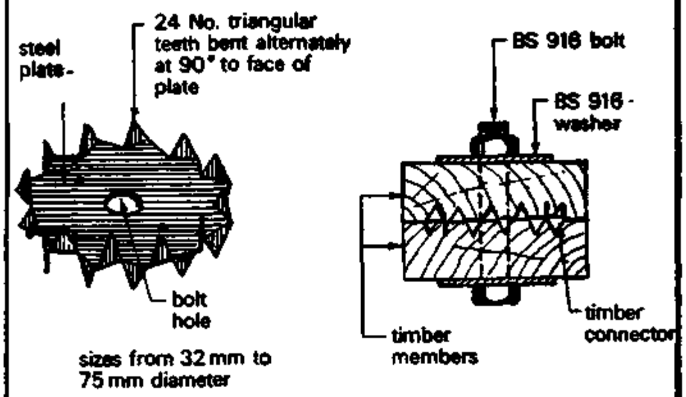
A variation of this type of truss is shown. This ist designed to be supported by columns the connection with which is stiffened against lateral movement by the triangulated and, therefore, stiff junction created by a knee-brace joining truss and column head. This is formed by extending the lower secondary tie to connect with the column some distance below the truss bearing thus rigidly uniting the two. In order to obtain a satisfactory junction with the column and to provide the necessary cross-sectional area for the knee-brace the secondary ties in this example are



made of double members placed on the outside faces of the truss, and the struts are single members. As this truss is not designed to take a ceiling load the struts and ties are smaller, except those forming the knee-braces which must resist wind stresses. To provide for the grater number of bolts required at the feet, due to wind loads transferred to the truss, larger gussets are necessary at these points. A single central gusset is provided at the ridge which also acts as a packing between the rafter members.

The two previous examples of bolted and connectored trusses are designed for self-supporting sheet coverings. Tiles, slates and similar coverings commonly used in domestic work require a substructure of battens supported by common rafters at 400 mm to 450 mm centres. A form of connectored truss for this type of work developed by the Timber Research and Development Association is illustrated and is essentially a pair of framed common rafters thus eliminating the need for separate principal rafters. The rafters of the truss therefore lie in the same plane as the adjacent rafters and the purlins, as a result of this, lie below the truss rafters and not on their backs as in a normal truss.

BOLTED and CONNECTORED TRUSSES



Double sided round toothed plate connectors

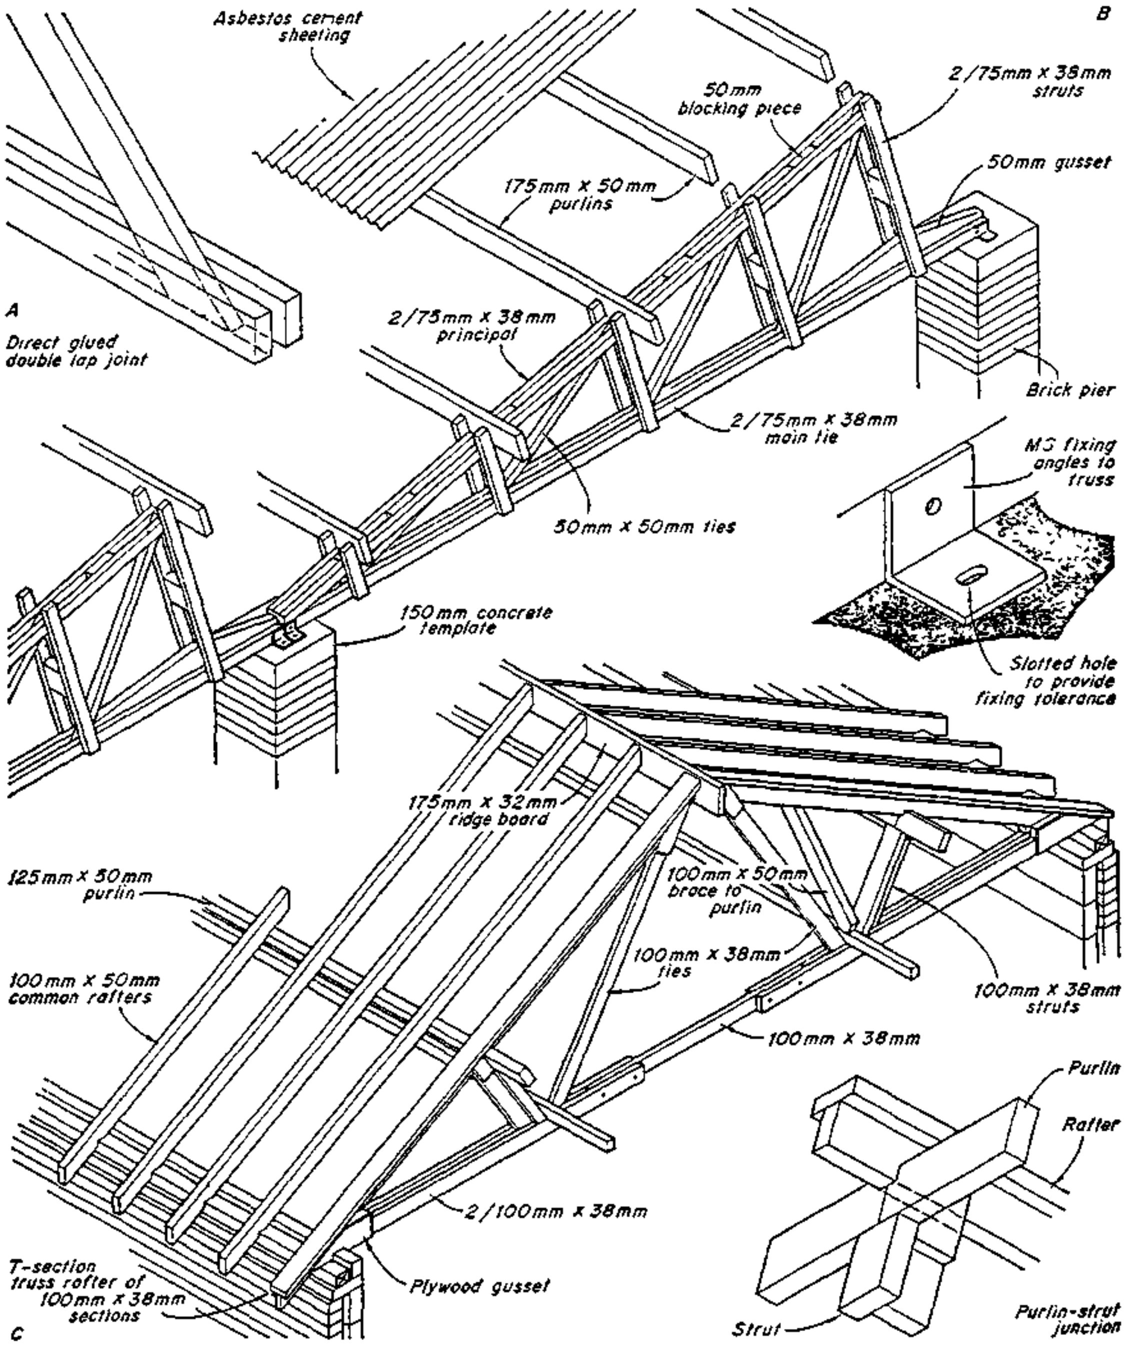
The truss is fabricated from single members, the joint between the rafters and main tie, which lie in the same plane, being made with gussets and the other joints by lapping the members. Binders to support the ceiling joists bear on the main tie near the lower nodes.

The trusses are designed to be placed not more than 1.8o m apart, that is at every fourth rafter where these are at 450 mm centres. The reactions at the feet are, therefore, not excessive and can be transferred adequately to the wall by the normal wall plate without a template or thickening of the wall. The example shown is for a span of 6.oo m.

(3) GLUED TRUSSES

(3) GLUED TRUSSES

Glues made from synthetic resins produce the most efficient form of joint, as strong as or even stronger than the timber joined, and many are immune to attack by dampness and decay. With this type of joint it is necessary to plane smooth all contact surfaces, and the necessary pressure during setting of the glue is provided by cramps or by bolts or nails which act as cramps. These are usually left in position.



GLUED TRUSSES

The members may be glued directly to each other using lapped joints or single thickness construction may be used by the adoption of gussets. As with nailed joints, in certain cases lapped members may not provide sufficient gluing area even with double lapped joints and gussets mast then be used to provide this.

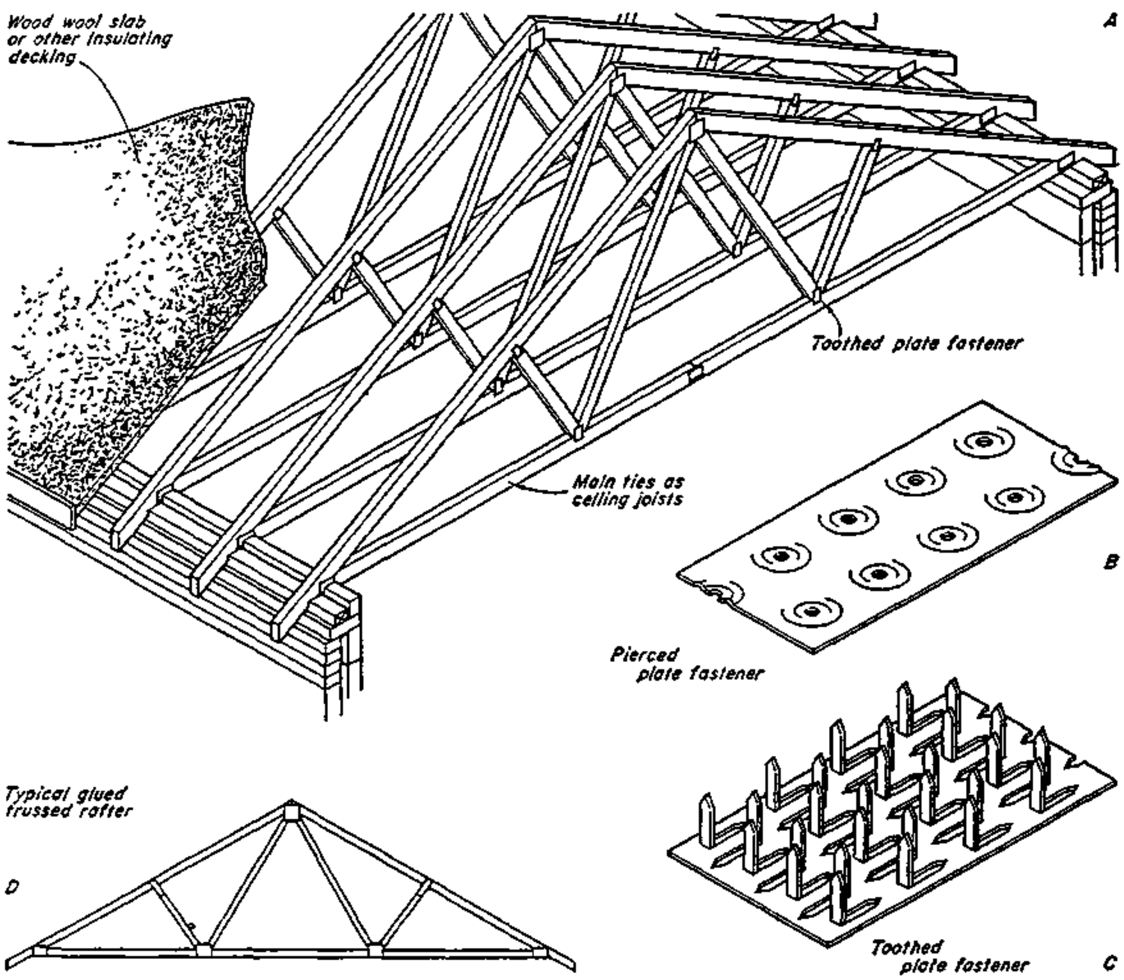
An example of direct gluing is shown in the small 'northli ght' truss of 5.2o m span in figure in which single diagonal ties are sandwiched between double rafter and main tie members and the struts are formed by two thin members glued on the outside faces of the truss. This enables 'centre line' set-out of the members to be adopted. It should be noted that the two longest struts are packed out at the middle point to give increased stiffness to these compression members. Three nails driven in prebored holes act as cramps to each joint during setting of the glue.
Gluing not only produces very strong joints which result in quite small members, but also a very rigid structure which makes the truss easy to handle in transporting and fixing.

An example of a glued and gusseted truss is shown. This is a factory made, standardised truss framed from 38 mm thick members, fabricated in two halves and requiring only site bolding of the main tie and site nailing to the ridge board. Rafters, struts and diagonal ties are single members joined by gussets, the compression members being formed into T-sections to stiffen them against buckling by the addition of 38 mm 'tables' glued and nailed on. Those to the struts form seatings for the purlins which lie below the rafters, so that the latter act also as common rafters.
The main tie is partially of double members between which struts and diagonal ties are sandwiched and secured by direct gluing. To provide greater gluing area the lapped joints between rafter feet and tie are packed out to allow the application of plywood gussets on each side.
These trusses bear on the normal wall plate and are designed to be spaced up to 3.90 m apart for spans from 4.5 m to 9.om

8. TRUSSED RAFTERS

VIII TRUSSED RAFTERS

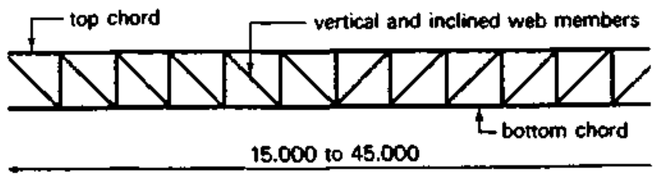
In recent years in domestic work there has developed the practice of triangulating or trussing every pair of rafters in roofs over spans which would normally require purlin construction, thus dispensing with purlins. There are a number of reasons for this, not the least of which has been the development of factory production for this type of component and the simplicity and speed with which this form of roof can be erected. The economic value of trussing every pair of rafters rests on these considerations together with the fact that many newer forms of roof coverings permit low pitches resulting in short bracing members and the fact that the use of insulating dekking such as wood wool or compressed straw slabs, or larger tiling or slating battens, permits the rafters to be placed



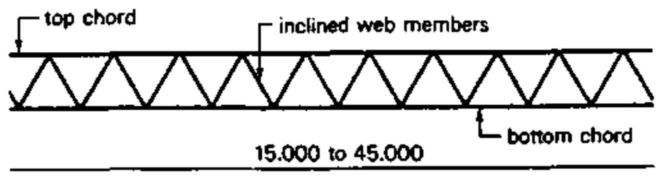
at 600 mm centres rather than the traditional 400 mm. This, together with the elimination of purlins and ridge board, reduces the timber content of the whole roof structure. These members are known as trussed rafters. It should be noted that since there are no purlins such a roof is a single roof construction.

Trussed rafters are fabricated from single thickness members jointed by gluing or nailing, using plywood or, in the case of nailing, punched metal plate gussets. Punched metal plate fasteners as they are usually called, fall into two groups.

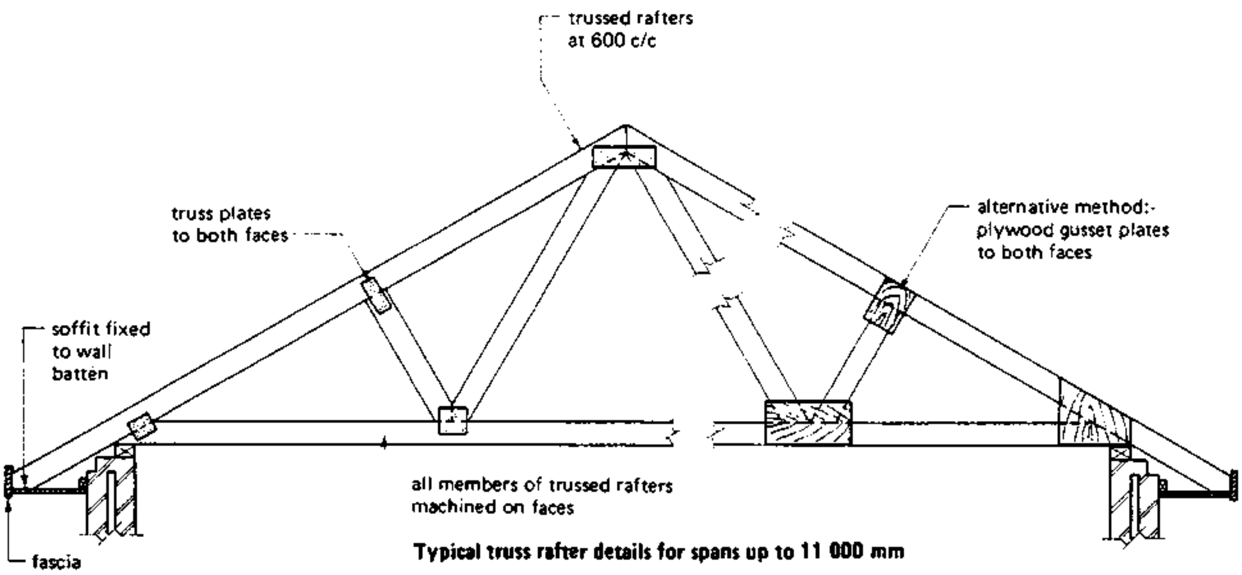
TRUSSED RAFTERS



Typical 'N' or Pratt truss



Typical Warren girder



Typical truss rafter details for spans up to 11 000 mm

The use of low pitches, lightweight roof coverings and lightweight roof structures such as trussed rafters, by reducing the weight of the roof increases the danger of wind uplift and in these types of roof the necessity of adequate auchorages should be considered.

TRUSSED RAFTERS

Firstly, a thin - gauge plate with holes punched regularly over its surface to receive nails, called a pierced plate fastener. Secondly a similar plate with teeth punched from the plate and bent over 90 degrees, called a toothed plate fastener, or connector. The latter, in which the teeth are an integral part of the plate, must be driven in by a hydraulic press or roller and are used in factory production since they are not suitable for site fabrication. The essential difference between a TRUSSED RAFTER and a ROOF TRUSS is that the former carries its own propartion of roof load directly on itself and only that load, wherease a truss carries the loads from a number of adjacent rafters via the purlins.

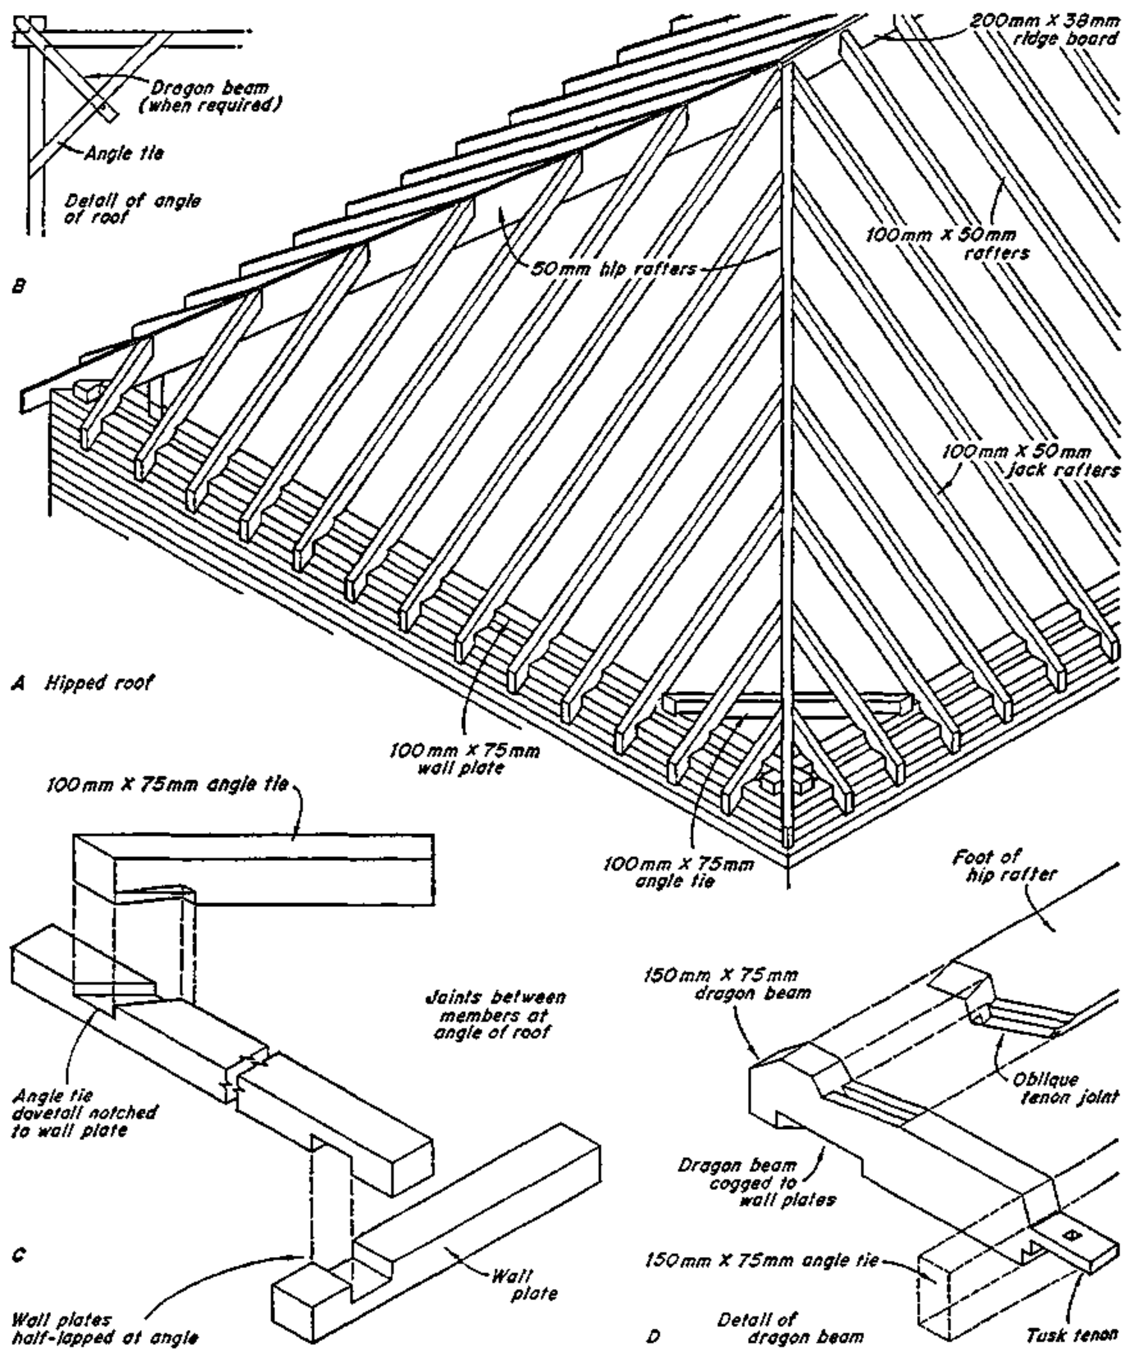
HIPPED ROOFS

IX HIPPED ROOFS

A Hipped Roof is more complicated in its construction than a Gable Roof, necessiating SPLAY and SKEW cutting of all the shortened rafters at the intersections (called JACK RAFTERS) and the provision of a deep HIP RAFTER running from ridge



HIPPED ROOFS

to wall plate to carry their top ends (see fig.). The hip rafter transfers their loads to the wall plate and will, therefore, be 225 mm to 28o mm deep, depending upon its span and the depth of the rafters, and 38 mm to 5o mm thick. If the roof has purlins their ends will also be carried by the hip rafters which may then need to be 75 mm thick.

The tendency of the inclined thrust of the hip rafter to push out the walls at the quoin is overcome by tying together the two wall plates on which it bears by an angle tie dove-tail notched or bolted to the plates (fig.). The foot of the hip rafter ist notched over the wall plates which are half-lapped to each other. If the rafter carries purlins causing a greater thrust more resistance to this is provided by the introduction of a dragon-beam as shown in the fig. linking the ends of the wall plates to the angle tie, which would be larger in size. The dragon-beam is cogged over the plates and tusk-tenoned to the tie. A dragon-beam will in any case be necessary to provide a bearing for the hip rafter when the eaves are sprocketed and the feet of the rafters terminate on the wall plate.

VALLEY

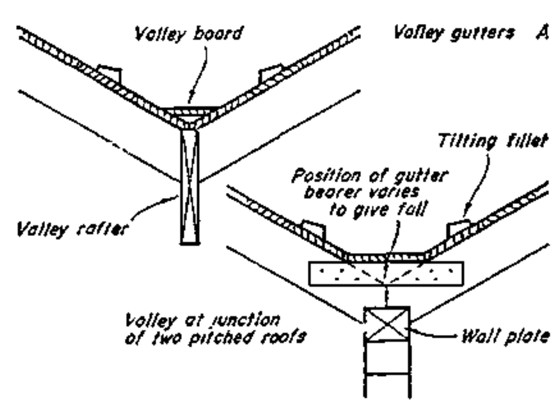
9.44 VALLEY

when the plan shape of the building breaks out or returns the intersection of the roof surfaces results in a junction having an external angle less than 180 degrees which is called a valley (the hip has an external angle greater than 180 degrees) As at a hip jack rafters occur. These run from ridge to valley and their feet are nailed to deep valley rafters the function and size of which are the same as those of the hip rafters

If returns and projections produce roof spans equal to that of the main roof the valley rafters will extend to the ridge where they will gain support as in. If, however, a projection is less in span the valleys will not meet the main ridge, and a support to the tops of the valley rafters and the lower ridge board must be provided in the roof space. If the width of the projection is small valley rafters may be omitted and all the rafters of the main roof be carried down full length on to a suitable bearing with boards laid on them to take the end of the ridge board and the feet of the jack rafters to the projection.

A valley is finished with a triangular timber fillet or a valley board, as shown in the fig. depending on the width required by the nature of the junction between the roof covering on the two slopes.

It will be seen that the plan shape greatly affects the roof construction and when designing a building which is to be covered with a pitched roof the implications of the plan in this respect must be borne in mind. The simple rectangular plan results in simple and relatively cheap roof construction; one in which breaks and returns accur, especially if they are numerous, may result in most expensive construction. This applies not only to the structure itself but also to the roof covereing



EAVES TREATMENT

As with a monopitch roof, unless the roof is set behind a parapet. the eaves of a ridge roof may finish flush with or may project beyond the wall face, the former producing some economy in roof covering and timber, the latter providing some protection to the walls. Detailing of construction varies widely according to the pitch of the roof, the effect desired by the architect and whether an external or a hidden gutter is used. It is, therefore, possible to illustrate only some typical examples.

Examples of open projecting caves are shown in the figeres. With tile or slate coverings of any type the fascia projects as shown 19 mm oder so above the roofing battens in order to tilt the caves courses. Where no fascia is used as at a batten of greater depth than the boarding or battens, called a tilting - fillet, is used at this point. Also closed projecting eaves are shown in the figure. The variation in detailing necessiated by increased projection can be seen. The ends of the rafters are cut horizontally to provide some fixing for the soffit boards (C), but as a considerable portion of the boarding is not supported by the rafter, soffit bearers are fixed to the rafter ends as shown.

The back of the fascia should be grooved to take the edge of the soffit. Greater projections necessitat longer soffit bearers and brackets are then required to support heir inner ends as shown in (D). When plywood or asbestos cement sheet is used for the soffit, as is quite common, the fascia must be grooved to take the front edge and the back edge should be given continuous support by a fillet secured to the wall (E). In this case the soffit bearers can be fixed to this rather than to brackets from the rafters. If the roof pitch is not too great the soffit can be fixed direct to the rafters and, with a gable roof and projecting barge board, can continue up as the verge soffit. In this particular case the barge-board will be slightly less in depth than the fascia, but with a horizontal eaves soffit it must be deeper in order to cover the end of the eaves, in which case the outer and cantilever rafters which support it must be deeper than the common rafters or a thicker bargeboard must be used.

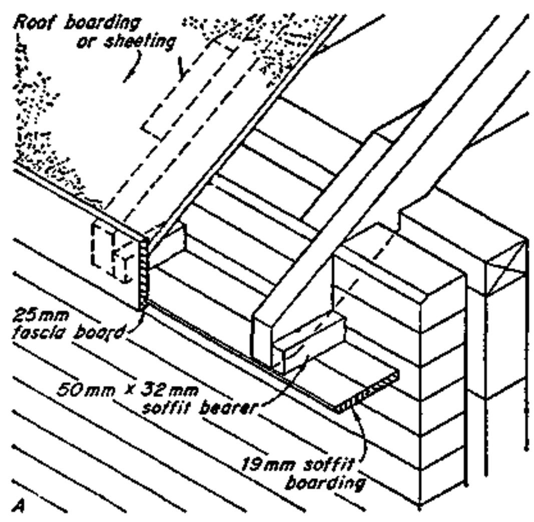
EAVES TREATMENT

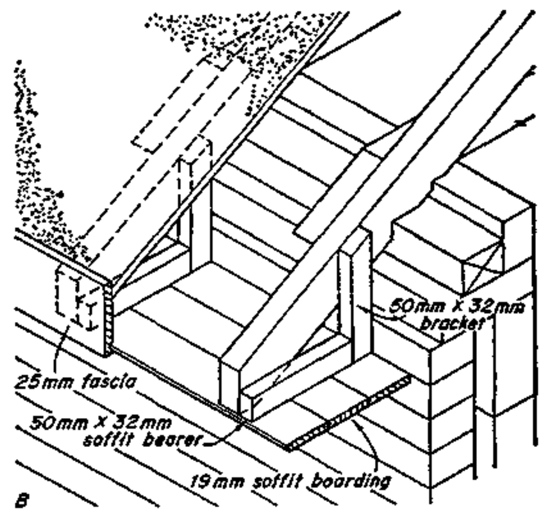
If a clear fascia, unobstructed by an external gutter, is desired an internal gutter may be formed. It is essential that the front edge of this type of gutter be at such a level that in the event of blockage of the outlet water will drain over the front rather than seep back into the roof structure and possibly into the building.

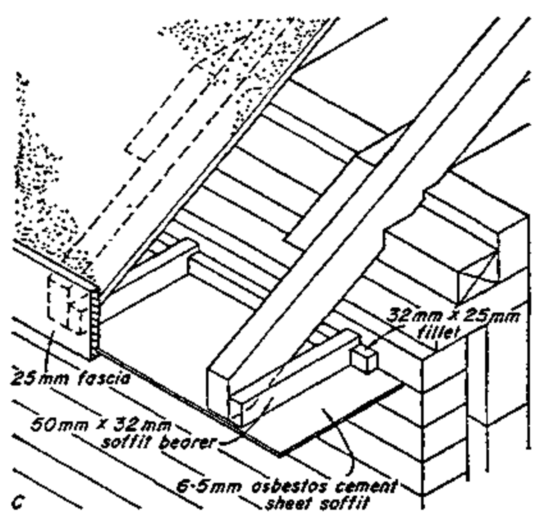
Roof ventilation should be ensured through closed eaves.

When a gable roof finishes with a plain verge, that is with no barge-board, the end of any form of closed projecting eaves must be boxed-in or be closed by the gable wall supported either on corbelling or on a springer. If the gable continues up as a parapet this is usually corbelled out for this purpose.

On wide, steeply pitched roofs the pitch may be reduced at the eaves in order to reduce the velocity of water during heavy rainfall and prevent overshooting of the gutter. This is done by means of sprockets which are short lengths of timber the same size as the rafters, fixed to the sides of the rafter feet as shown in figure   or to the backs of the rafters if the latter run over the wall plate.



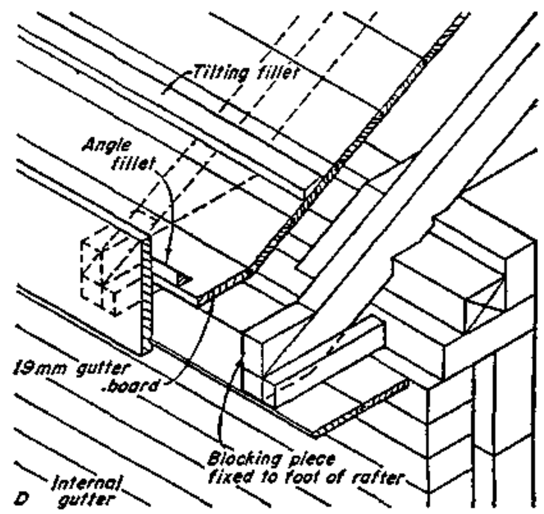


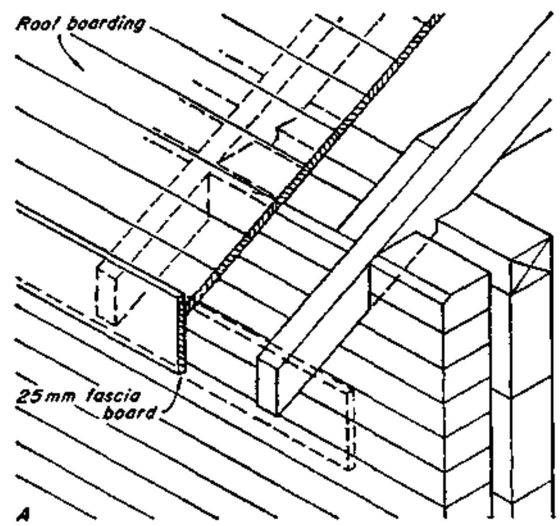


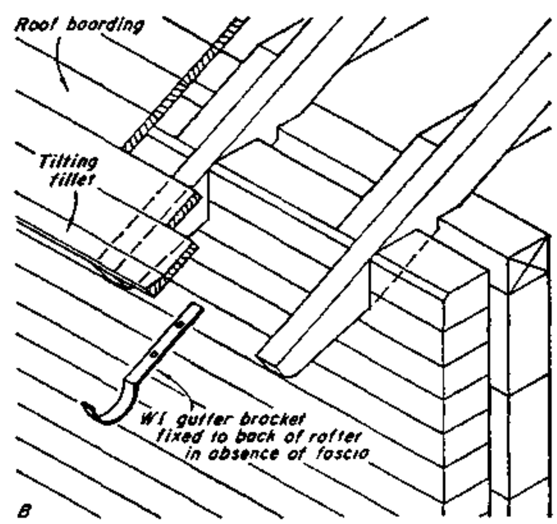
EAVES TREATMENT

The reduced pitch must, of course, not be less than the minimum angle necessary for the particular roof covering.

As an alternative to framing up a projecting eaves in the ways described above proprietary precast concrete eaves or gutter units may be used as for flat roofs, bedded on the head of the external walls. The shape of the unit spreads the roof load over both leaves of a cavity wall and over openings of limited span a back recess may be filled with concrete, together with reinforcing bars, to form a lintel. Behind a parapet wall a parapet gutter is framed up as shown in the figure by means of gutter bearers nailed to the rafters and carrying the gutter boards. The bearers are fixed at different levels along the wall to produce a fall to the gutter and as the level rises up the roof slope this results in a gutter which tapers in width on plan from a maximum at the highest point and is, therefore, termed a tapered gutter in contrast to the parallel or box gutter.





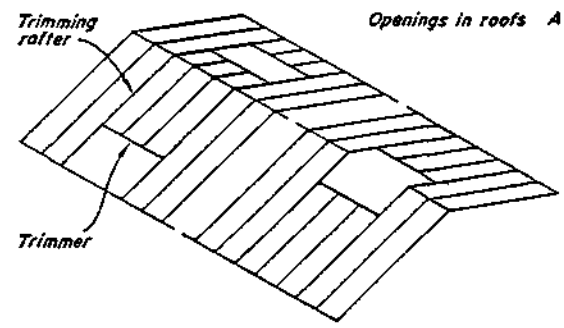


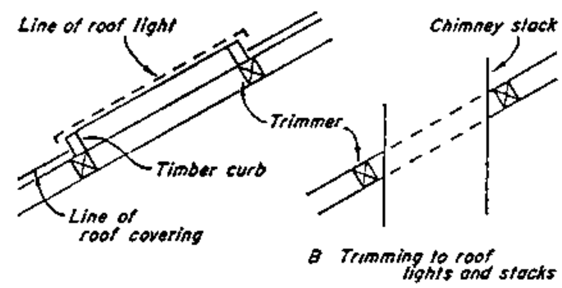
9.46 OPENINGS IN TIMBER ROOFS

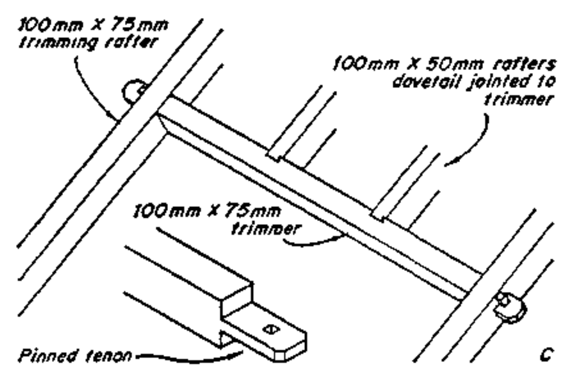
OPENINGS IN TIMBER ROOFS

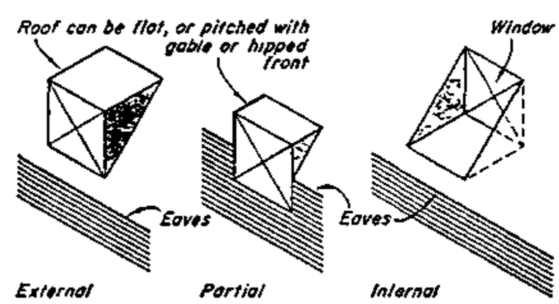
Roofs may be penetrated by chimney stacks and various forms of roof lights and, in pitched roofs, by dormer windows, for all of which openings in the roof must be formed. As in the case of floors and in a similar manner the roof is framed or trimmed to form such openings. Details of trimming to flat roofs are normally identical with those for floors.
In pitched roofs openings may be required at any point between eaves and ridge, or at the ridge, as shown in the figure. For stacks and skylights the trimmers are placed normal to the roof slope and are fixed to the trimming rafters by pinned tenons. This joint has an extended tenon and is secured with a wedge. The trimmed rafters are fixed to the trimmers by any of the methods described for floors.

Openings for roof lights are finished with a timber upstand or CURB as indicated in the figute which in a pitched roof, raises the light above the level of the roof covering and permits a watertight junction to be formed all round, and in a flat roof provides for a 150 mm upturn of the roof finish.









DORMER WINDOWS

The positioning of trimmers for dormer windows varies according to framing requirements and is descussed below.

DORMER WINDOWS

The dormer window is a vertical window set in the slope of a roof as distinct from a skylight which is parallel to the slope. It may take various forms as shown in the figure. The internal dormer which avoids a projection above the roof slope is less common and involves a small flat roofed area in front of the window.

For external dormer windows the lower or cill trimmer is fixed vertically to provide a seating for the dormer framework and window and to raise the window cill clear of the roof covering. It is 75 mm or 100 mm wide and its depth will vary with the roof pitch and the tape of roof covering. The top or head trimmer may be fixed vertically or normal to the slope. If the dor-

DEPARTMENT

mer roof is flat a vertical trimmer provides a fixing surface for the boarding or other decking; if it is pitched a trimmer normal to the slope may be used and this simplifies jointing to the trimming rafters. The sill trimmer is oblique notched over the trimming rafters and nailed in position.
The vertical head trimmer is oblique notched and tenoned to them, the tenon being necessary here in order to resist the thrust from the feet of the upper trimmed rafters. In the case of a partial dormer there is no sill trimmer since the window sits directly on the wall below.

The traditional method of forming the dormer front was to frame up 100 mm by 75 mm side posts and head on the cill trimmer, the posts being tenoned or dowelled to the trimmer, and within this to set the window. Nowadays, unless the dormer is large, it is usual to make the head and mullions of the window frame large enough to act structurally to support the dormer roof and cheeks as shown in the figure. The cheecks are formed by a 75 mm x 75 mm side head running from the dormer front back to the trimming rafter against which it is splay

DORMER WINDOWS

cut and nailed, the spandrels thus formed being filled with 75 mm x 50 mm studs to which 19 mm t and g boarding is fixed externally. If the cheek is small studs can be omitted, the spandrel being covered with 25 mm boarding nailed to corner post and side head, running parallel with the roof slope.
The framing of an internal dormer varies slightly from this. The lower trimmer would be set vertically to form a front bearing for the flat roof below the window and the top trimmer set similarly to form a head over the window. Since neither may be notched over the trimming rafters, in order not to obstruct the roof covering, both must be tenoned into them. Two posts under the bearings of the top trimmer and running from floor to trimming rafters would support a cross bearer carrying the window and the members forming the flat roof.

9.5 ROOF COVERINGS

9.51 FUNCTION OF ROOF COVERINGS

ROOF COVERINGS

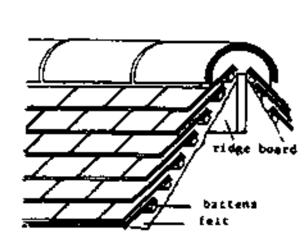
The function of the Roof Covering is that of a 'SKIN' - protection against weather.
In addition to that function the Roof covering has to be fire resistant and has to provide an adequate thermal insulation.

9.52 TYPES OF ROOF COVERINGS

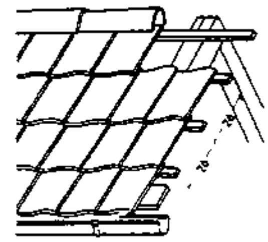
In accordance with the structure of the roof and the above mentioned functions there are different types of Roof Coverings.
A broad classification, comprising 5 groups, is:

1 Roof sealing
2 Table covering
3 Sheet covering
4 Scalloped covering
5 Thatch covering

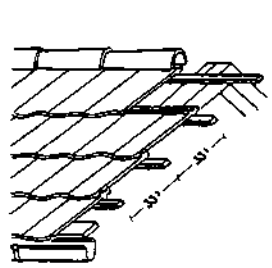
Depending on the SLOPE of the roof the type of Roof Covering has to be choosen. The above mentioned types of Roof coverings are comprising the following material:



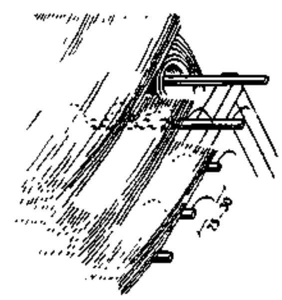
(5) Plain tile roof



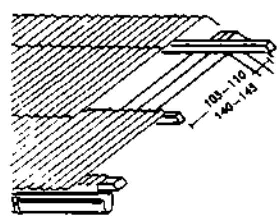
(6) Pantile roof (clay) 43 kg/m²



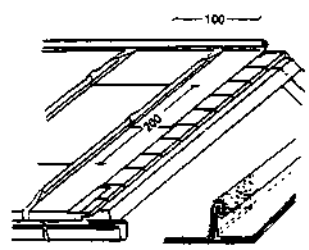
(7) Interlocking tile roof 42 kg/m²



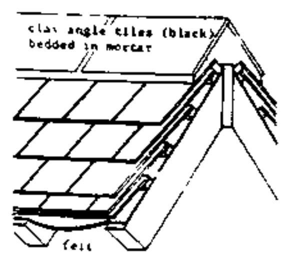
(8) Thatch roof 10 kg/m²



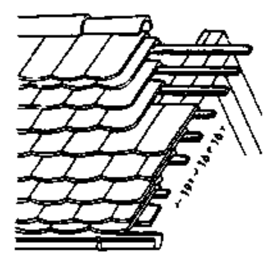
(9) Corrugated Eternit roof 17 kg/m²



(10) Metal roof 3.5-6.5 kg/m² (aluminium 2-3 kg/m²)



(11) Slate roof



(12) Double roof ('Doppeldach') 63 kg/m²

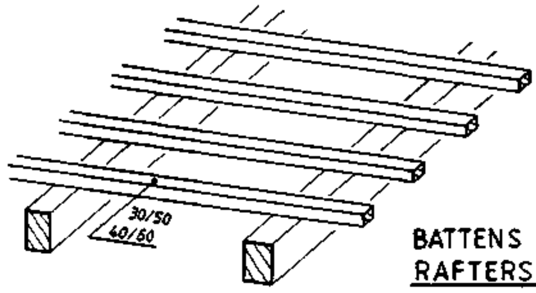
1 Roof sealing: - heat sealed plastic foils; - roofing felts, glued in different layers, sealed with bitumious paints. - reinforced with metal fails, etc.	**ROOF SEALING**
2 Table covering: - asphaltic or bitumious felts, glued or nailed in 1,2,or 3 layers. They are colled according to the weight of the raw-materials (333 g/m^2 or 500 g/m^2). The raw-felt is soaked with tar or bitumen and coated. Sand or chippings may be pressed on the surface of the felt as protection against mechanical loads and weather.	**TABLE COVERING**
3 Sheet covering: - Sheet metal (coated or galvanized) - galvanized corrugated iron sheets - corrugated aluminium sheets - corrugated asbestos sheets.	**SHEET COVERING**
4 Scalloped coverings: - Roofing (clay) tiles - Concrete tiles - Slates - Asbestos plain tiles (in different forms and shapes) - shingles.	**SCALLOPED COVERING**
5 Thatch coverings: - straw - dry grass, or hey - reed	**THATCH COVERING**

SUBSTRUCTURES

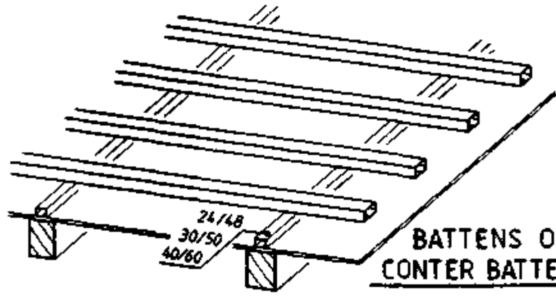
9.53 SUBSTRUCTURES

The Roof covering - 'the SKIN' - has to have an adequate substructure and has to be fixed on it, in order to avoid sliding or being taken away by the wind.

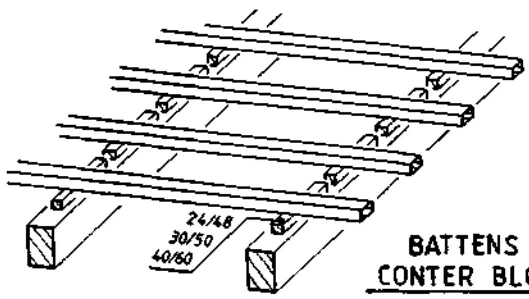
There are different types of substructures depending on the 'SKIN', covering the roof:



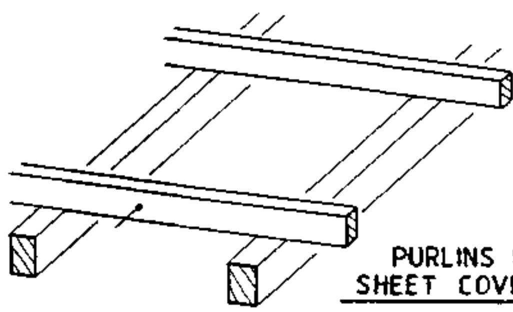
BATTENS ON RAFTERS



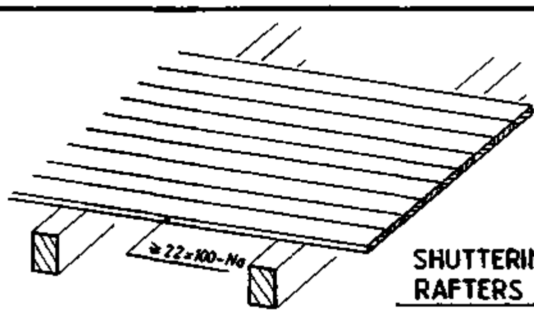
BATTENS ON CONTER BATTENS



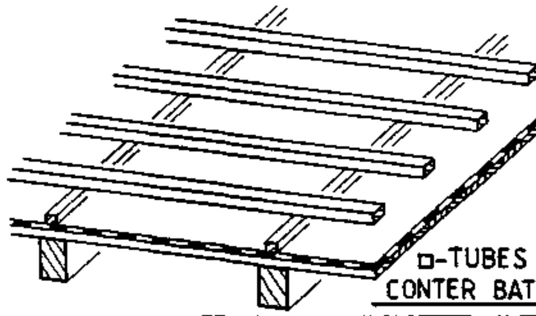
BATTENS ON CONTER BLOCKS



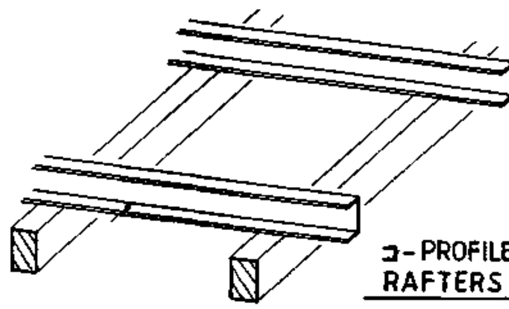
PURLINS FOR SHEET COVERINGS



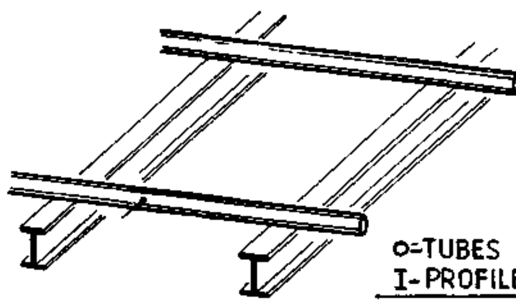
SHUTTERING ON RAFTERS



□-TUBES ON CONTER BATTENS



⊐-PROFILES ON RAFTERS

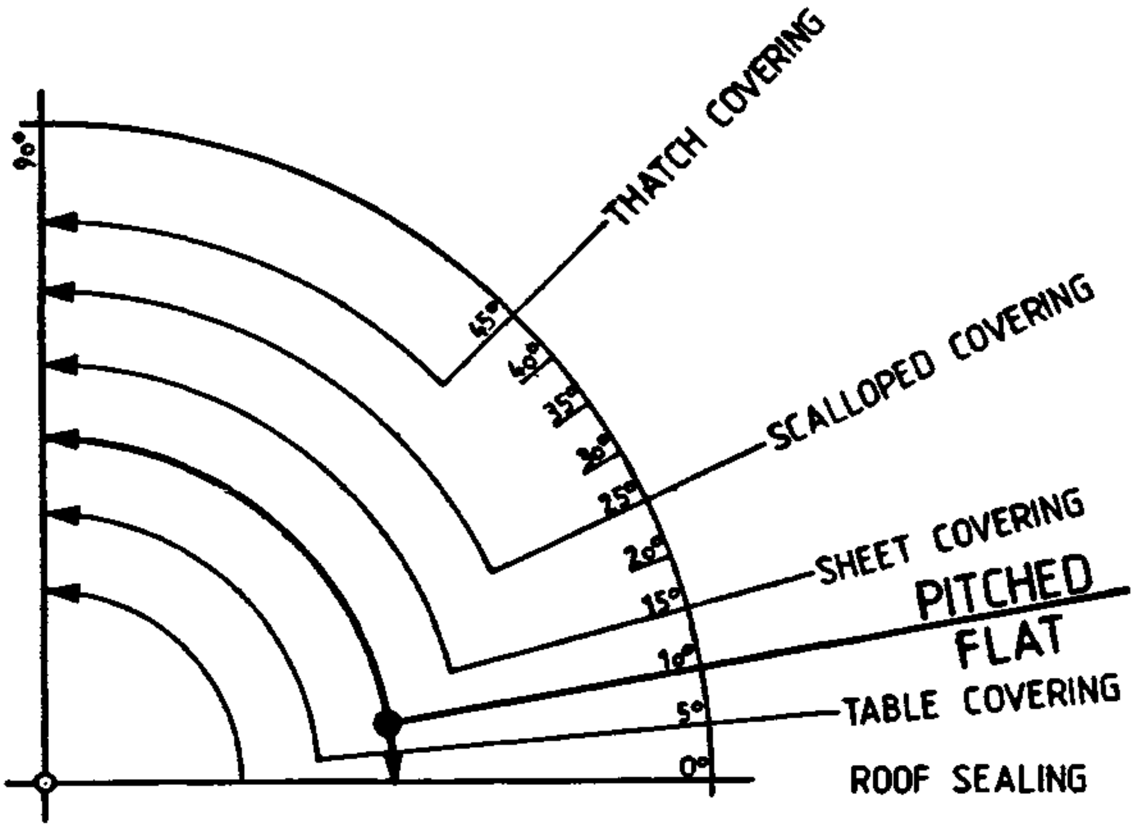


○-TUBES ON I-PROFILES

An additional provision to seal flat inclined roofs is the use of fibre-reinforced roofing felt or special plastic foils.

- The overlapp of such materials to be ~ 15 cm
- In order to get a proper cross-ventilation the material should hang loose between the fieleds of the battens.

9.54 CHOICE OF ROOF COVERINGS



9.55 MATERIALS AND COVERING METHODS

- TABLE COVERING :

  ASPHALTIC OR BITUMIOUS FELTS,

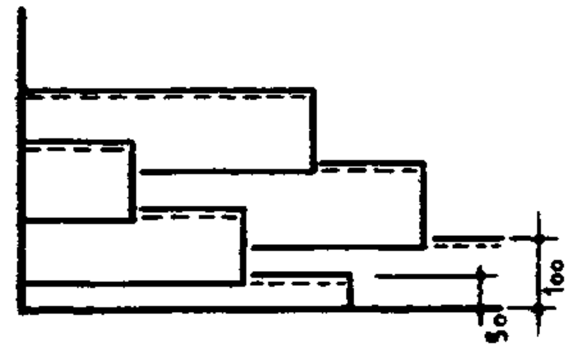
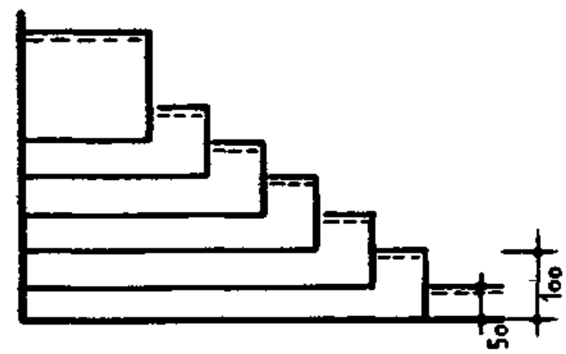
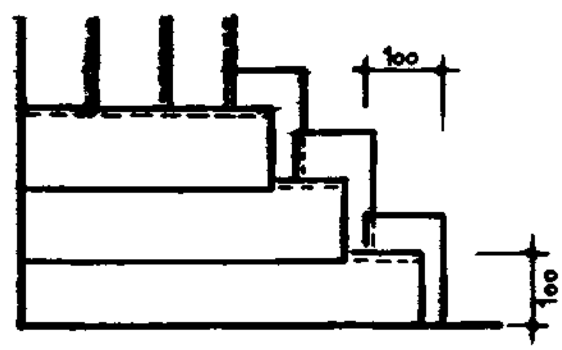
TABLE COVERING

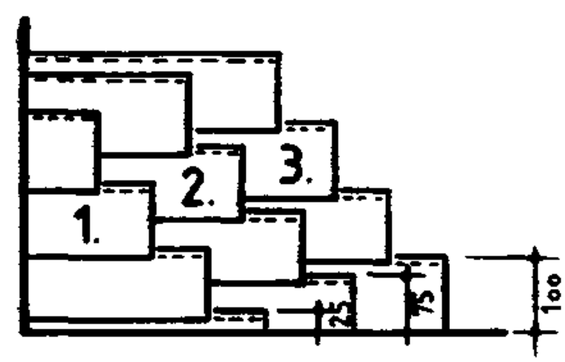
2-LAYER TABLE COVERING







3-LAYER TABLE COVERING



○ SHEET COVERINGS :

SHEET METAL COVERINGS

- Sheet metal coverings provide an excellent protection against wind and rain, is durable and lighter in weight than tiles, slates or asphalts.

Metal roofs are noisy.

Four types of metals are used for sheet coverings:

1 Lead
2 Copper
3 Zinc
4 Aluminium

○ SCALLOPED COVERINGS

- Roofing tiles

a Clay tiles: Hand-made
machine-pressed

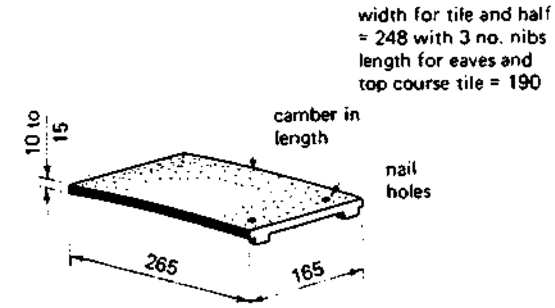
b Plain concrete tiles:(sand/cement/water, compressed in a mould) are uniform in texture, shape and colour.

<u>Nibs:</u>
either projecting nibs at one end of the tiles, or one continous nib, in order to secure the tiles to the sloping surface of the roof.

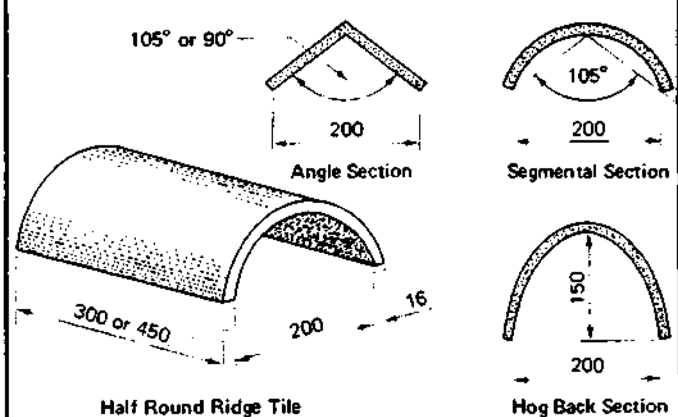
<u>Camber</u>:
the tiles are not perfectly flat, but have a slight rise or CAMBER in the back, to prevent water being drawn up between the tiles by capillary action.

<u>Gauge and Lap</u>:
plain tiles are hung so that at every point on the roof there are at least two thicknesses of a tile.
The sides butt together and these joints are bonded up the slope of the roof.
The tiles in every 4th course are nailed to the battens.
In very exposed positions every tile should be nailed to the battens.

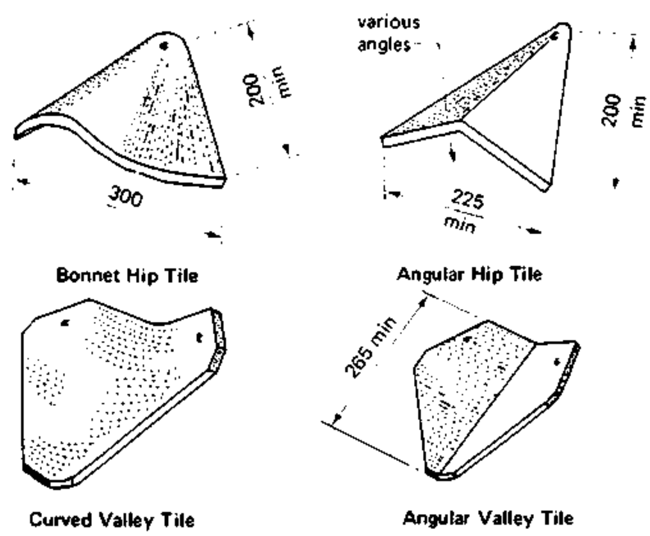
ROOFING TILES



Standard Plain Tiles



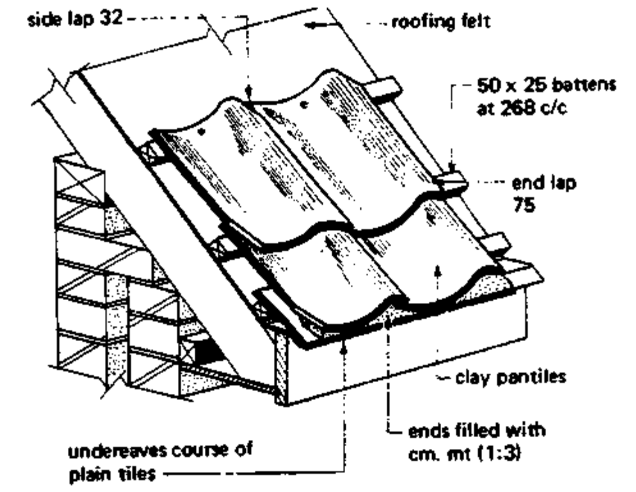
Typical Ridge Tiles



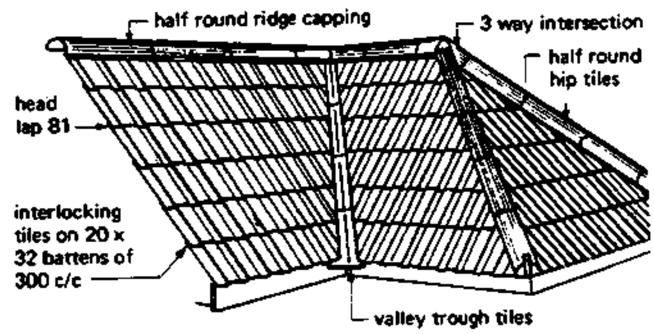
9 ROOFS compiled D VOLKE OCT '79	ROOF COVERINGS	BUILDING CONSTR LECTURE CET 5031/19560

ROOFING TILES

PLAIN TILES ARE LAID TO DOUBLE LAP



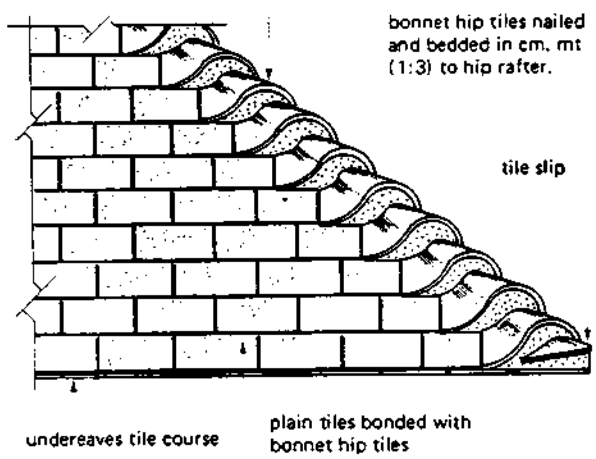
Eaves:
A double coarse overhangs the fascia board some 40 mm.(in order to shed water into the eaves gutter)



Ridge:
There are 4 standard sections of clay ridge tiles.

- Half round ridge tile
- Segmental ridge tile
- Angle ridge tile
- Hog back ridge tile

All ridge tiles have their edges bedded in fillets of cement mortar spread on the back of the top course tiles.



Hips:
May be covered with ridge tiles bedded in exactly the same way as on ridges.
To prevent the tiles from slipping down, a galvanized iron or wrought-iron hip iron is fixed to the hip or fascia.
The tiles next to the hip have to be cut to fit against the side of the hip rafter so that they lie under the hip tiles.

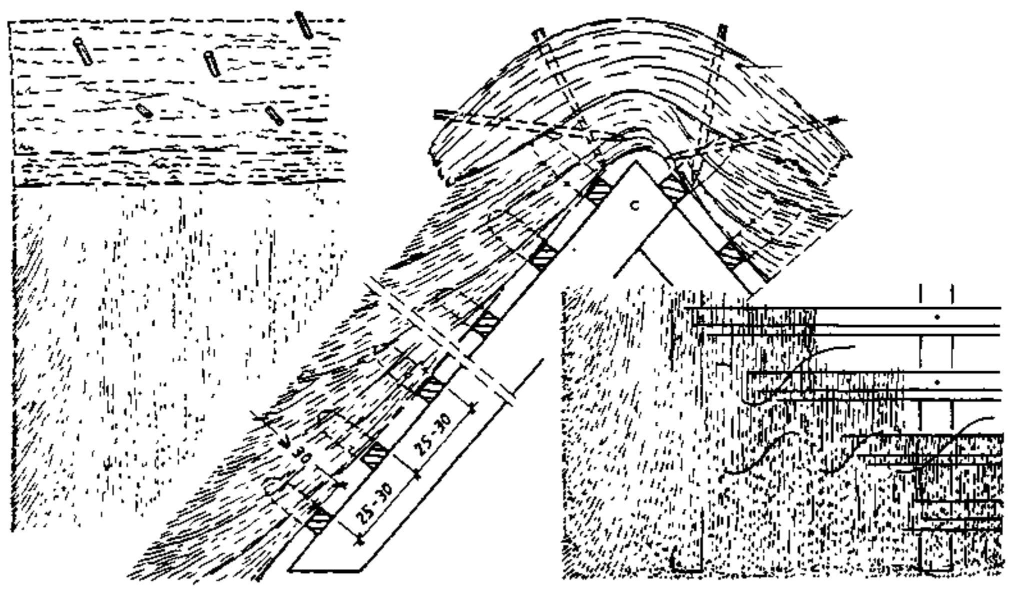
○ THATCH COVERINGS



9 ROOFS compiled : D.VOLKE OCT. '79	ROOF COVERINGS	BUILDING CONSTR. LECTURE CET 5031 / 1 9.565

Try to answer the following questions and use sketches where ever necessary and possible

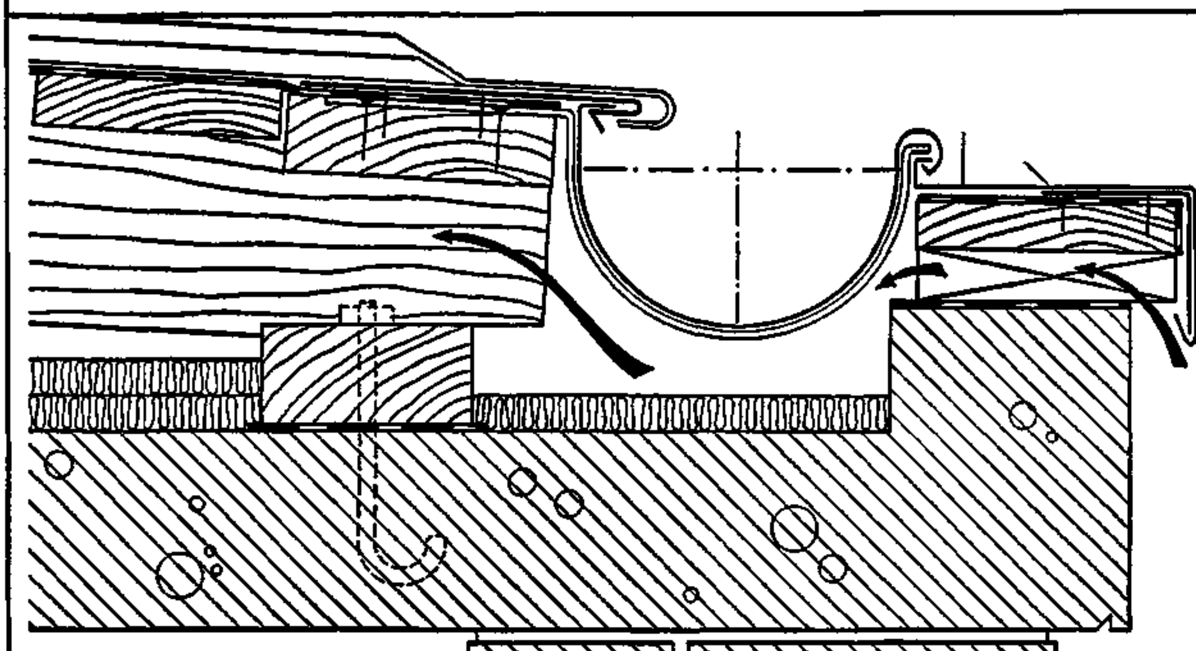
9.1 What are the main functions of a roof?

List the requirements the roof must satisfy to fulfil its functions efficiently and explain briefly the importance of these requirements.

9.2 Explain the terms:
- Roof structure, and
- 'Skin' of the Roof

Classify the different types of roofs in three different ways

Define the following terms:
- Flat roofs
- pitched roofs
- two-dimensional roof structures
- three - dimensional roof structures
- single roof construction
- double roof construction
- triple roof construction
- long span roofs
- medium span roofs
- short span roofs.



9.3 Write notes on Flat Roofs, explaining
- the structure of a flat roof
- thermal insulation materials
- single and double roof construction
- reinforced concrete flat roofs
- timber flat roofs
- parapet walls

and use sketches for illustration.

9.4 Write notes on Pitched Roofs, explaining
- the types of pitched roofs according to the shape of the roof
- the types of pitched roofs according to the structure of the roof

and use sketches for illustration.

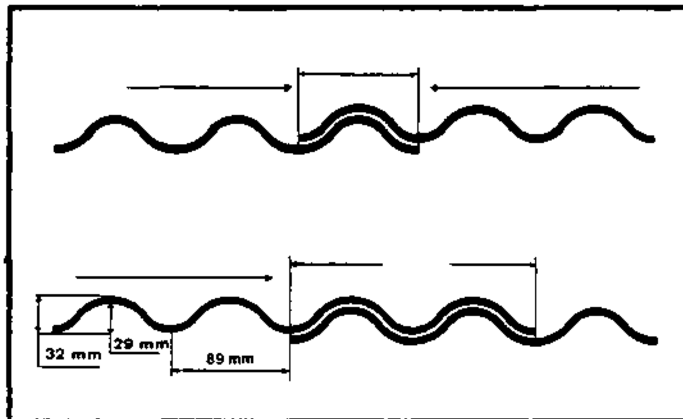
Explain the following terms briefly:
- gable
- gable parapet
- verge
- hip
- hipped end
- vally
- ridge

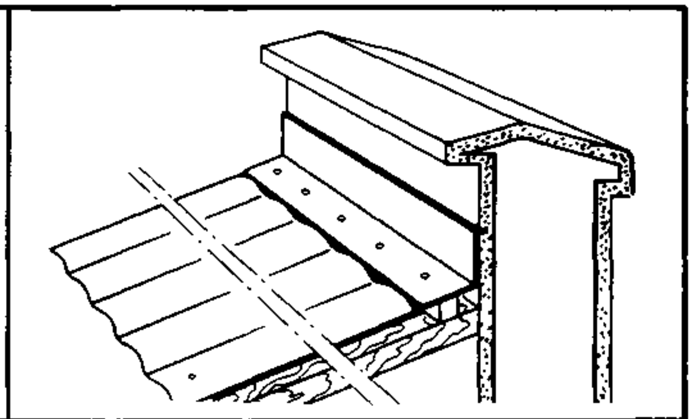
Referring to truss construction in timber, compare the three modern methods of joining the members:
- nailed joints
- bolt and connector joints
- glued joints

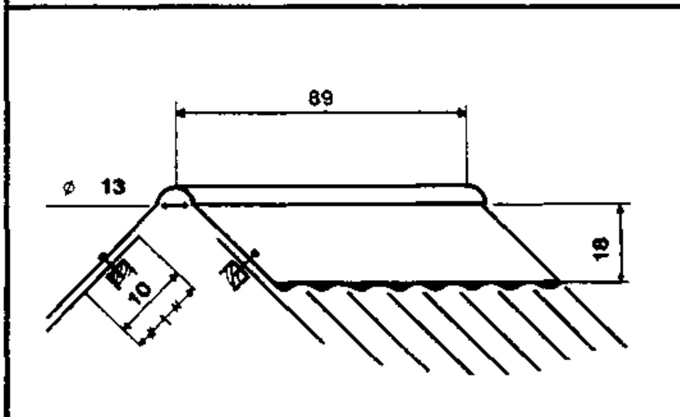
and describe their advantages and disadvantages.

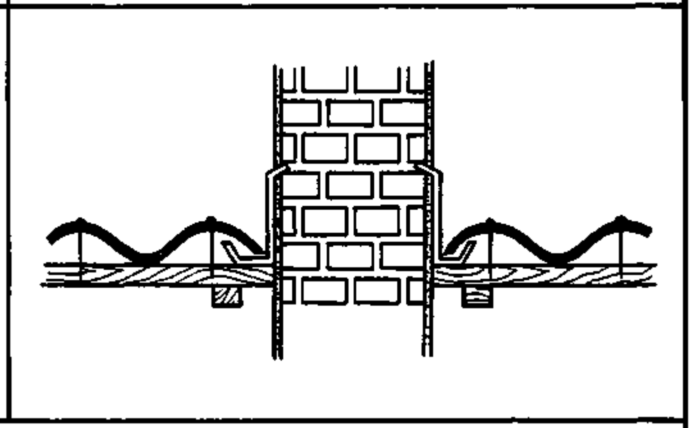
Show by means of neat sketches examples of
- open projecting eaves and
- closed projecting eaves

Write notes on Openings in timber roofs, including DORMER WINDOWS. Use sketches for illustrations.









9.5 Classify the different types of roof coverings
What sort of covering materials may be used for the above listed types of roof coverings?

Explain - by means of sketches - different types of substructures depending on the 'skin' covering the roof.

Write notes on the choice of roof coverings and explain in the form of a diagram the interdependency of the pitch of the roof and the covering material.

Show - by using sketches for illustration - covering methods for different sorts of materials, such as:

- one -, two-, three-, layer table covering
- asbestos sheet covering
- covering with roofing tiles
- covering with slates
- covering with asbestos plain tiles
- covering with shingles
- thatch covering
- sheet metal covering

10.FRAMED STRUCTURES

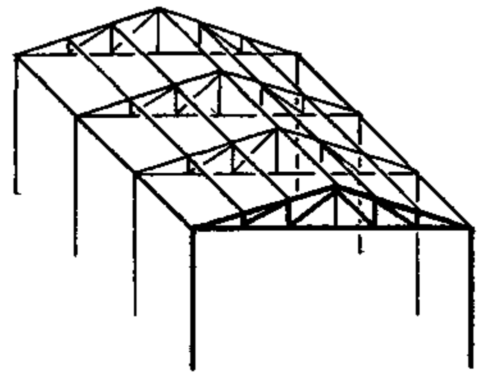
10.1

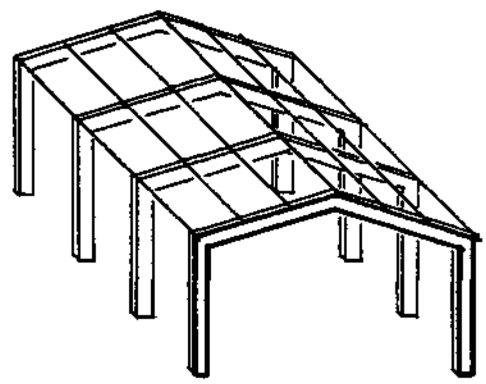
10.1. Structural Concept:

- A framed structure (or skeleton structure) consists essentially of a skeleton or framework which supports all the loads and rsists all the forces acting on the building and through which all loads are transfered to the soil on which the building rests.
- The elements of such framework are pairs of uprights, supoorting some form of spanning members.
  These are spaced apart and tied together by longitudinal members to form the volume of the building.
  They are classified as:
  - BUILDING FRAMES of columns and horizontal beams for single and multi-storey buildings.
  - SHED FRAMES, of columns and roof trusses for single-storey buildings, and
  - PORTAL or RIGID FRAMES, of columns and horizontal or pitched beams for single-storey buildings.
- In these frames the vertical supports are in compression.
  SUSPENDED (or SUSPENSION) STRUCTURES have been developed in which the floos are suspended from the top of the building by vertical supports which are therefore in tension.

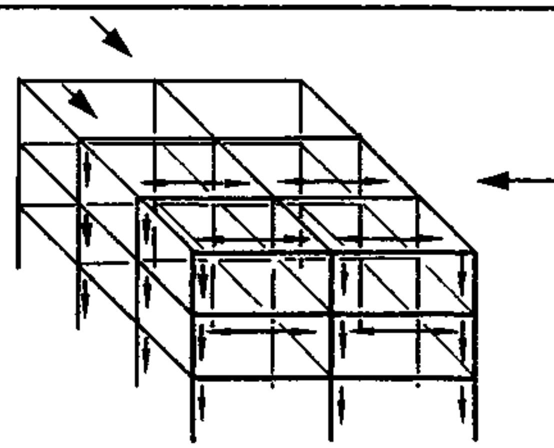
  Other forms of skeleton structures are the frameworks of interconnected members, known as GRID STRUCTURES.
- By its nature the skeleton frame connot enclose the space within it. Therefore other enclosing-elements must be assosiated with it.



SHED FRAME



PORTAL FRAME



BUILDING FRAME

- The significance of this clear destinction between the supporting element and the enclosing element is that the enclosing element can be made relatively light and is not fixed in its position relative to the skeleton frame or may fit into the panels of the frame.

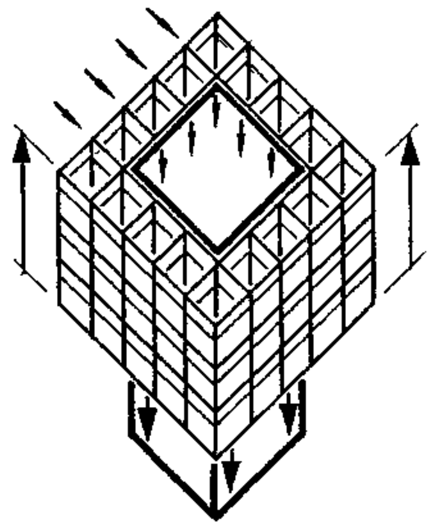
The advantages of framed structures are:

1) Saving in floor space (particularly when internal structural supports must be provided)
2) Flexibility in plan and building operations because of the absence of load bearing walls at any level.
3) Reduction of dead weight.

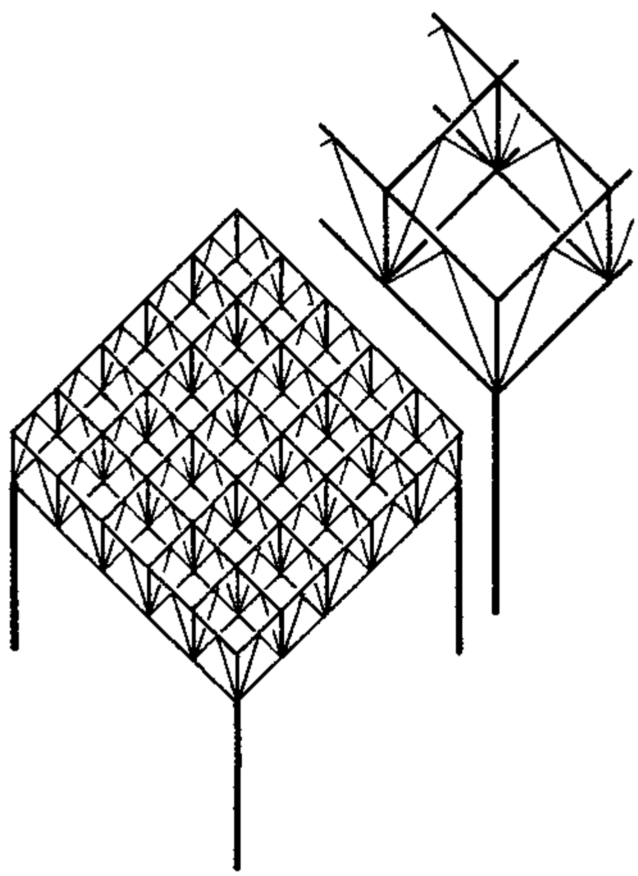
These advantages do not necessarily make a framed structure economically advantageous in every circumstances, i.e. in the case of individual small_scale buildings where the plan area is divided into rooms by walls and partitious.

In general it can be said that framed structures become logical and economical:

1. When the span of roof or floor becomes great enough to necessiate double construction involving beams or truses applying heavy concentrated loads at certain points on the supporting structure.
2. In the case of industrialised system building, the framed structure can be economic even for small-scale building types. (Due to largescale production and to the reduction in erection time and of labour on site which should accompany the use of prefabricated components.



SUSPENSION STRUCTURE



GRID STRUCTURE

10.2 Functional Requirements

Strength and stability: Are ensured by the use of appropiate materials in suitable forms applied with regarding to the manner in which a structure and its parts behave under load.

- Building frames may be classified according to the stiffness or rigidity of the joints between the members, especially between columns and beams.

A NON-RIGID (or pin-jointed) frame is one, in which the nature of the joints is such that the beams are assumed to be simply supported and the joints non-rigid.

Rigidity in the framed structure as a whole is ensured by the inclusion of some stiffing elements in the structure often in the form of triangulating members.
Steel and timber frames are commonly joined together in this manner and sometimes precast concrete frames.

A SEMI-RIGID frame is one in which some (or all) joints are such that some rigidity is obtained. A technique usually limited to steel frames and which effects some saving in materials. In

A FULLY - RIGID frame.all joints rigid. This results in considerable economics in material in the frame.
Depending upon the nature of the structure the joints alone may provide the stiffness necessary to prevent the frame as a whole from deforming under lateral wind pressure, although additional stiffening elements are often required. This type of building frame can be constructed in steel and concrete.

NON-RIGID
SEMI-RIGID
FULLY-RIGID

Fire - resistance: An adequate degree of fire-resistance in the frame is essential in order that its structural integrity may be maintained in the event of fire, either for the full period of a total burn-out or for a period at least long enough to permit any occupants of the building to escape.

- Concrete is highly fire resistent but steel in many circumstance requires the provision of fire-protection, of which a number of forms exist such as en - sure by concrete or by asbestos board. Timber, although a combustable material (which will easily burn in the form of thin boards) burns less readily when in thicknesses greater than about 15 cm. Its combusibility may also be reduced by the application of fire retardants.

10.3 STRUCTURAL MATERIALS

- Materials which are commonly used for framed structures are:
  - Steel
  - Concrete (reinforced or prestressed).
  - Timber
  - Aluminium alloys.
- Material for framed structures - particularly when these are TALL OR WIDE IN SPAN need to be:
  - Strong
  - Stiff.
  - Light in weight.

The stronger the material the smaller the amount which will be required to resist a given force.

The stiffer the material the less will the structure and its members deform under load.

The relationship of the depth of a spanning member or structure to its span is expressed as the DEPTH/SPAN RATIO, and is useful as a basis of comparison of the effects of using material and forms of structure of different degrees of stiffness. A small depth / span ratio indicats the achievement of adequate stiffness with minimum depth of spanning member.

The lighter the material (provided the strength is adequate) the lower the self-weight of the structure. The self or dead weight of a structure, as well as the load which the structure is to carry, contributesto the stresses set up within it.
Low dead weight is an important economic factor (especially in structures carrying light loads)

The smaller the self (or dead) weight of a structure relative to the load to be carried, the more economic the structure.

This relationship is expressed as the DEAD/LIVE LOAD RATIO.

STRONG
STIFF
LIGHT
IN WEIGHT

The raltionship of the weight of a material to its strength provides on indication of its efficiency in terms of the weight required to fulfil the structural function. This is expressed as the STRENGTH/WEIGHT RATIO, a high value indicating high strength with low self weight resulting in a minimum weight of material to fulfil a particular structural purpose.

DEPTH/SPAN RATIO
DEAD/LIVE LOAD RATIO
STRENGTH/WEIGHT RATIO

STEEL

STEEL is a material strong in both: compression and tension, and it is stiff.
A steel structure is therefore relatively economic in material because a small amount can carry a relatively large load and because it is stiff, the structure and its members will not easily deform under load.
It has a high strength/weight ratio. These characteristics make it suitable for both: low-rise and high-rise building frames and roof structures of all spans.

TIMBER

TIMBER varies its bending strength from about 1/28 to 1/23 that of mild steel (according to the specis and to the presence or absence of knots and faults in the timber). Compared with other materials its stiffness is low but in relation to is own weight, which is quite light, it is relatively very stiff. Thus in structural applications compensation for its lack of stiffness can be made without excessive increase in weight of structure.

It has a relatively high strength /weight ratio, and is suitable for lightly or moderately loaded low-rise building frames and for shed and rigid frames (particularly where the span and weight of these are large).

CONCRETE

CONCRETE varies in strength according to mis.
The compressive strength of normal structural concrete is about 1/16 that of steel, but its tensile strength is only about 1/10 of its compressive strength. Its stiffness is low compared with steel and its strength/weight ratio is low.
To overcome this weakness, structural members are REINFORCED in their tension zones with steel bares or PRESTRESSED in the same zones (usually by means of steel wires or cables).

In reinforced form concrete is suitable for SHORT-SPAN low- and high-rise building frames.
In pressed form for wide-span building and rigid frames.
Prestressed concrete may also be applied to shed frames using precast roof trusses.

ALUMINIUM

ALUMINIUM varies in strength according tothe particular alloy, from about 3/4 that of mild steel to strengths somewhat greater than that of steel. Although stiffer than either concrete or timber, aluminium alloys are only about 1/3 as stiff as steel but they are only about 1/3 its weight. These characteristics make them suitable for roof structures (which carry only light imposed loads); particularly those of long span, and less so for normal building frames. The high cost of aluminium usually precludes its structural use for other than very wide span roof structures.

10.4 Layout of Frames

- As a general rule: Space columns as closely as the nature of the building will permit. This resulting in short span beams or trusses will be cheaper than one with widely spaced columns. With smaller spans the beams reduce in size and cost and - similarly - the columns, because of the reduced loads they carry.

- The SPACING of the frames is influenced largely by the economic span of the floor or roofing system which they support and this will vary with the imposed floor or roof loading and the type of floor or roofing system.

In the case of building frames and rigid frames it can be shown, that as the frame beams increase in span (or frame columns increase in height) there comes a point at which it may be more economic to increase the spacing between the frames, rather than to maintain them at the most economic span of particular floor or roofing system.

In the case of shed frames, a close spacing of the frames usually gives the cheapest structure.

The layout of a skeleton structure should be based on a regular structural grid because:

- loads on the structure are transmitted evenly to the foundations (minimising relative settlement and standardising the sizes of foundation slabs).
- It results in regularity in beam depths and column sizes and in the position of columns and beams relative to walls. This avoids the use of 'waste' material to bring beams and columns to similar dimensions either because they are exposed to view or, in the case of reinforced concrete, to standardise formwork. It also standardises the size of dividing and enclosing walls or panels.
- In reinforced concrete work the regular slab and beam spans minimise the variations in rod sizes.
- It permits greater re-use of formwork, both in precast and in situ concrete construction.

10.5 BUILDING FRAMES

- Building frames are basically a series of rectangular frames, placed at right angles to one another so that the loads are transmitted from member to member until they are transferred through the foundations to the subsoil.
- Building frames can be economically constructed of
  - Concrete
  - Steel or a combination of the two and
  - Timber.

10.5.1 Funktions of building frame members

Main beams:
Span between columns and transfer the live and imposed loads placed upon them to the columns.
Secondary beams:
Span between and transfer their loadings to the main beams. Primary function is to reduce the spans of the floors or roof being supported by the frame.
Tie beams:
Internal beams spanning between columns at right angles to the direction of the main beams and have the same function as a main beam.
Edge beams:
As tie beam but spanning between external columns.
Columns:
Vertical members which carry the loads transferred by the beams to the foundations.
Foundation:
The base(s), to which the columns are connected and serve to transfer the loadings to a suitable load-bearing subsoil.

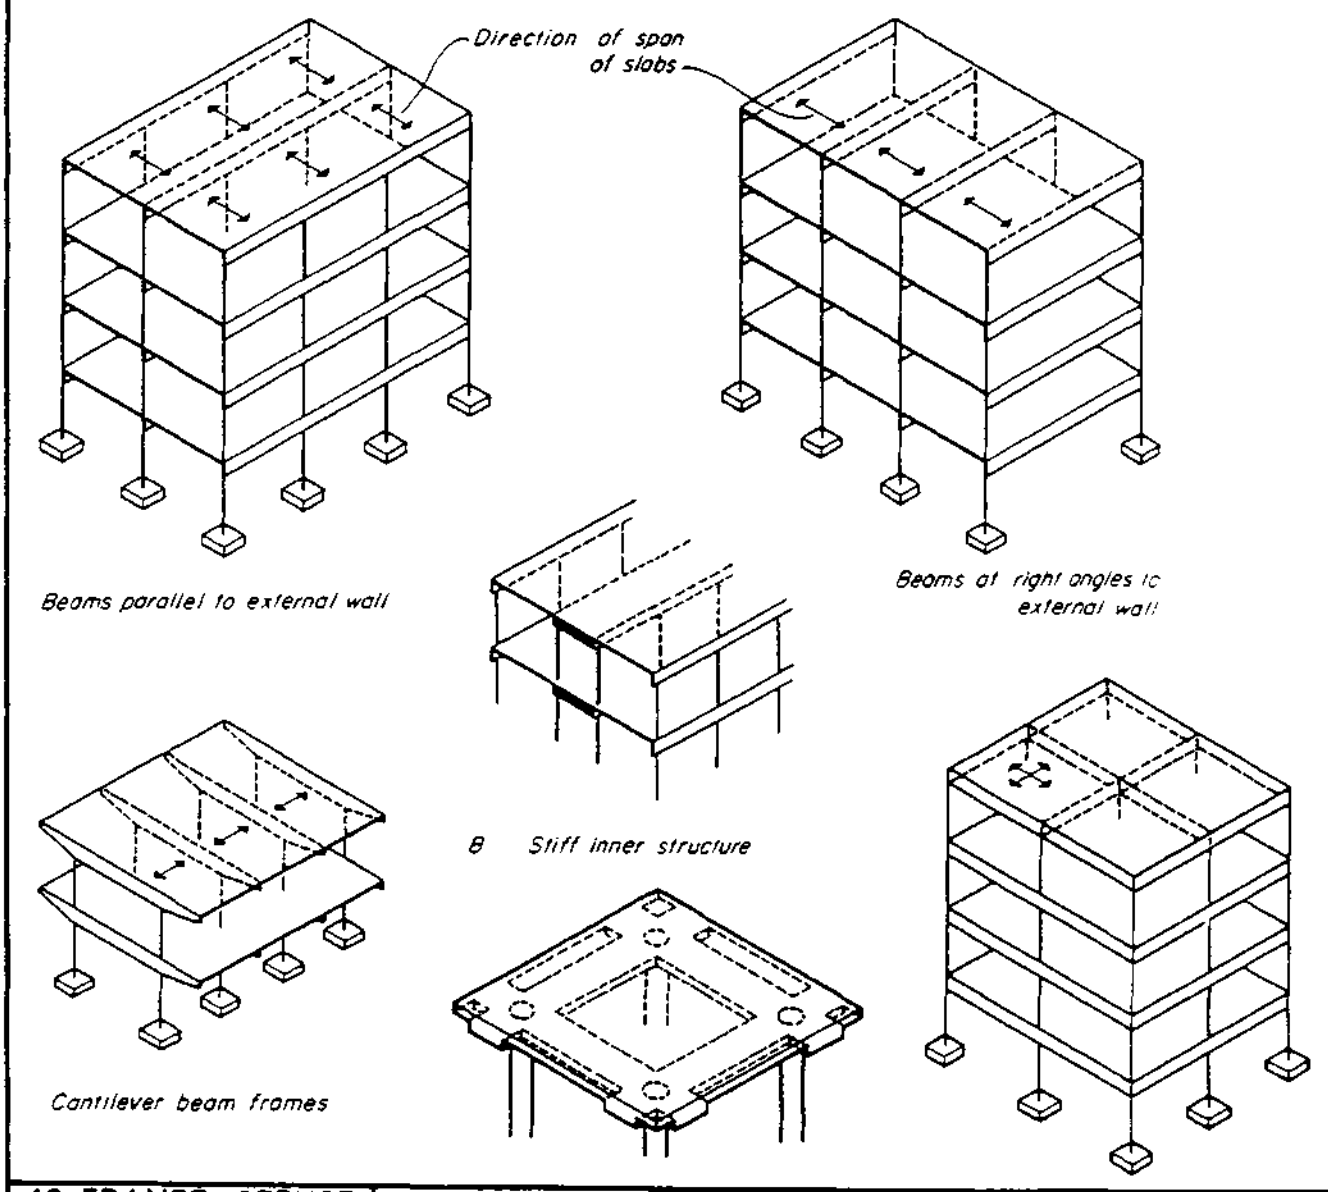
Floors:
May or may not be an integral part of the frame; they provide the platform on which equipment can be placed and on which people can circulate. Besides transmitting these live loads to the supporting beams they may also be required to provide a specific fire resistance, together with a degree of sound and thermal insulation.
Roof:
Similar to floors but its main function is to provide a weather-resistant covering to the upper most floor.
Walls:
The envelope of the structure which provides the resistance to the elements, entry of daylight, natural ventilation, fire resistance, thermal insulation and sound insulation.

REINF. CONCRETE FRAMES

10.5.2 Reinforced concrete frames

Reinforced concrete, because of its particular characteristics, can be formed into walls as well as into beams and columns to form a skeleton frame and the designer's freedom to cast concrete in almost any shape is only limited by the cost of the formwork or shuttering into which the concrete must be poured. This forms a large proportion of the total cost of a reinforced concrete structure as can be seen from the following approximate percentage breakdown:

- Concrete		40%
Materials	28%	
Labour	12%	
- Shuttering incl. errection and stripping		32%
Materials	12%	
Labour	20%	
- Reinforcement		28%
Materials	10%	
Labour	18%	

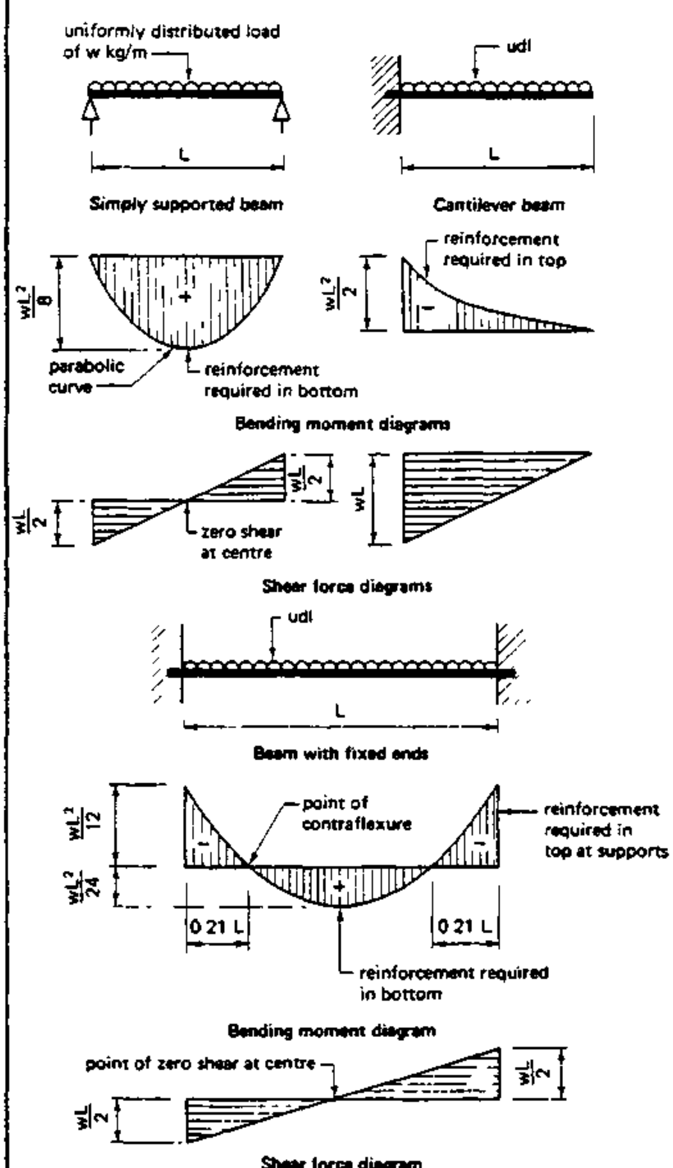


10.5.2.1 Reinforced concrete beams

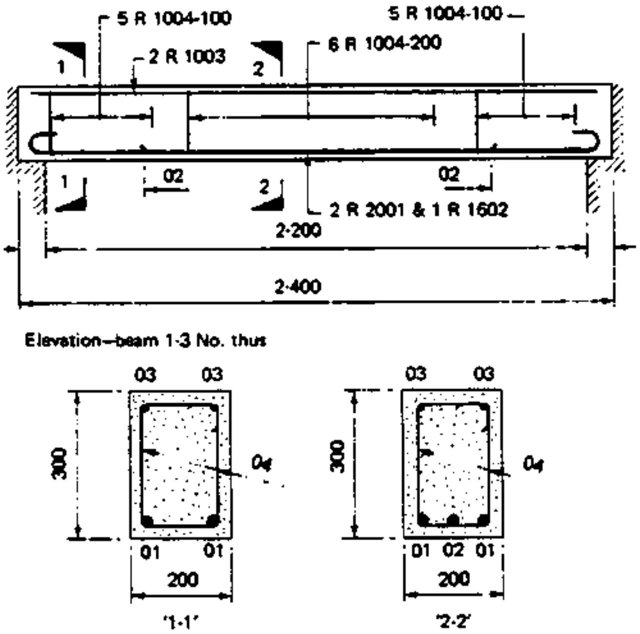
Beams can vary in their complexity of design an reinforcement from the very simple beam formed over an isolated opening to the more common form encountered in frames where the beams transfer their loadings to the columns.
When tension is induced into beam the fibres will lengthen until the ultimate tensile strength is reached, when cracking and subsequent failure will occur.
With a uniformly distributed load the position and value of tensile stress can easily be calculated, but the problem becomes mor complex when heavy point loads are encountered.

The concrete design of a r.c. beam will ensure, that it has sufficient strength to resist both the compression and tensile forces encountered in the outer fibres, but it can still fail in the 'web' connecting the compression and tension areas. This form of failure is called SHEAR failure and is in fact diagonal tension.
Concrete has a limited amount of resistance to shear failure and if this is exceeded reinforcement must be added to provide extra resistance.
Shear occurs at or near the supports as a diagonal failure line at an angle of approximately 45^0 to the horizontal and sloping downwards towards the support (A useful fact to remember is that zero shear occurs at the point of maximum bending.).
Reinforcement to resist shearing force may be either stirrups or inclined bars, or both. The total shearing resistance is the sum of the shearing resistances of the inclined bars and the stirrups, calculatet seperately if both are provided.

Bending moment and shear force diagrams



REINF. CONCRETE BEAMES



Typical R.C. beam details and schedule

Member	Bar mark	Type & size	No. of mbrs	No. in each	Total No.	Length of each bar†	Shape. All dimensions* are in accordance with BS 4466
Beam 1	1	R20	3	2	6	2660	2300
	2	R16	3	1	3	1400	straight
	3	R10	3	2	6	2300	straight
	4	R10	3	16	48	1000	250 150

† specified to nearest 25 mm   * specified to nearest 5 mm

Inclined or bent up bars should be at 45° to the horizontal and positioned to cut the anticipated shear failure plane at right angles. These may be seoarate bars or alternatively main bars from the bottom of the beam which are no longer required to resist tension which can be bent up and carried over or onto the support to provide the shear resistance Stirrups or binders are provided in beams, even where not required for shear resistance, to minimise shrinkage cracking and to form a cage for easy handling. The nominal spacing for stirrups must be such that the spacing dimension used is not greater then the lever arm of the section, which is the depth of the beam from the centre of the compression area to the centre of the tension area or 0.75 times the effective depth of the beam, which is measured from the top of the beam to the centre of the tension reinforcement. If stirrups are spaced at a greater distance than the lever arm it would be possible for a shearing plane to occur between consecutive stirrups, but if the centres of the stirrups are reduced locally about the position at which shear is likely to occur several stirrups may cut the shear plane and therefore the total area of steel crossing the shear plane is increased to offer the tensile resistance to the shearing force.

TCA TECHNICAL COLLEGE ARUSHA CHUO CHA UFUNDI ARUSHA	CIVIL ENGINEER DEPARTMENT	11

10.5.2.2 Reinforced concrete columns

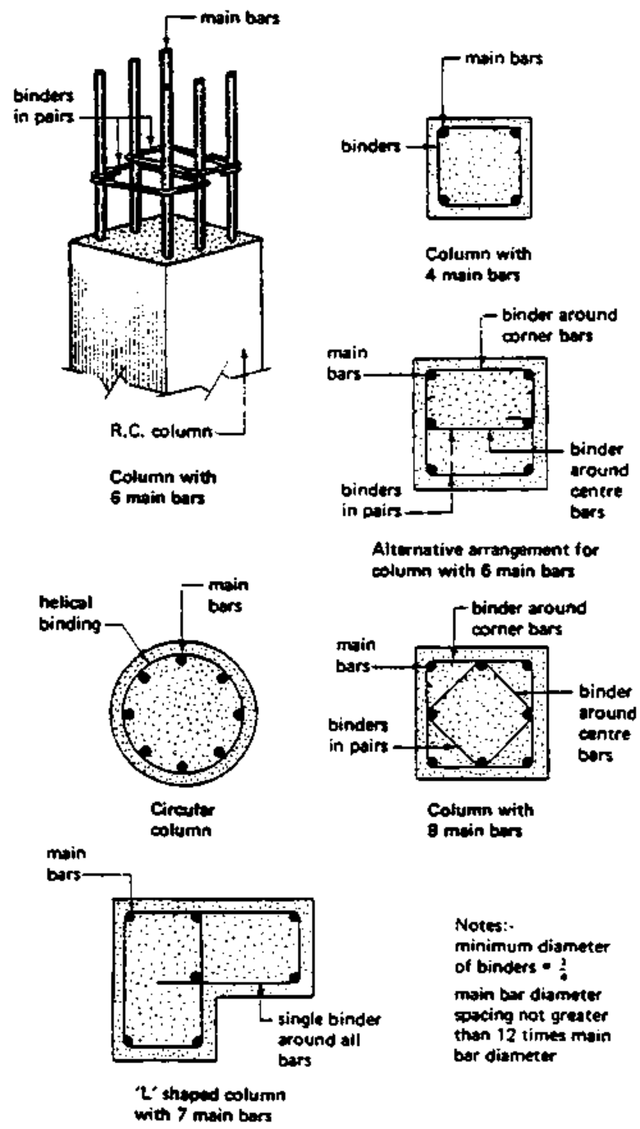
A column is a vertical member carrying the beam and floor loadings to the foundation and is a compression member. Since concrete is strong in compression it may be concluded that provided the compressive strength of the concrete is not exceeded no reinforcement will be required. For this condition to be true the following conditions must exist:
1. Loading must be axial.
2. Column must be short, which can be defined as a column where the ratio of its effective height to its thickness does not exceed 12.
3. Cross section of the column must be large.

These conditions rarely occur in framed buildings, consequently bending is induced and the need for reinforcement to provide tensile strength is apparent. Bending in columns may be induced by one or more of the following conditions:
1. Load coupled with the slenderness of the column; a column is considered to be slender if the ratio of effective height to thickness exceeds 12.
2. Reaction to beams upon the columns, as the beam deflects it tends to pull the column towards itself thus inducing tension in the far face.
3. The reaction of the frame to wind loadings both positive and negative.

The minimum number of main bars in a bolumn should not be less than four for rectangular columns ans six for cicular columns with a total cross section area of not less than 1% of the cross sectional area of the column and a minimum diameter of 12mm. To prevent theslender main bars from buckling and hence causing spalling of the concrete, links or binders are used as a restraint.

REINF. CONCRETE COLUMNS

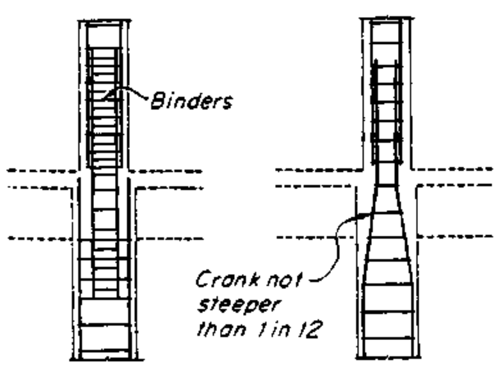
R.C. column binding arrangements



REINF. CONCRETE COLUMNS

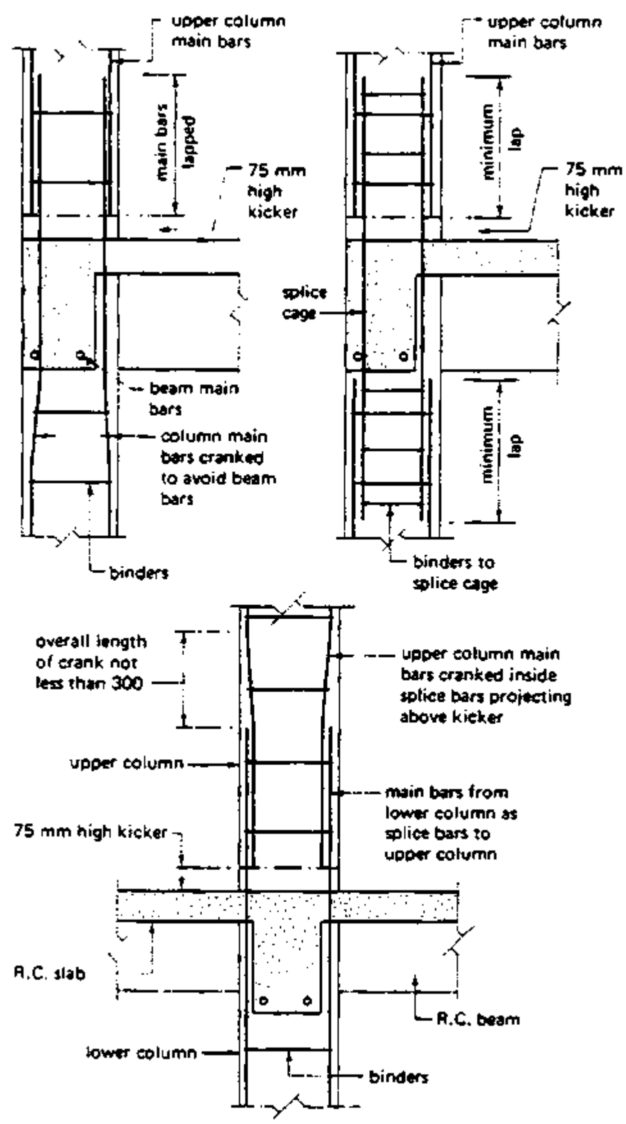
These should be at least one-quarter of the largest main bar diameter and at a pitch or spacing not greater than twelve times the main bar diameter. All bars in compression should be tied by a link passing around the bar in such a way that it tends to move the bar towards the centre of the column.

Where the junction between beams and columns occur there could be a clash of steel since bars from the beam may well be in the same plane as bars in the columns. To avoid this situation one group of bars must be bent or cranked into another plane; it is generally considered that the best practical solution is to crank the column bars to avoid the beam steel.



Alternative column splices

R.C. column and beam junctions



10.5.2.3 Reinforced concrete slabs

A reinforced concrete slab will behave in exactly the same manner as a reinforced concrete beam and it is therefore designed in the same manner. The designer will analyse the loadings, bending moments, shear forces and reinforcement reouirements on a slab strip 1.000 m wide. In pratice the reinforcement will be fabricated to form a continuous mat.For light loadings a mat of welded fabric could be used.

There are three basic forms of reinforced concrete slabs, namely:

1. Flat slab floors or roofs.
2. Beam and slab floors or roofs.
3. Ribbed floors or roofs - see 7. FLOORS.

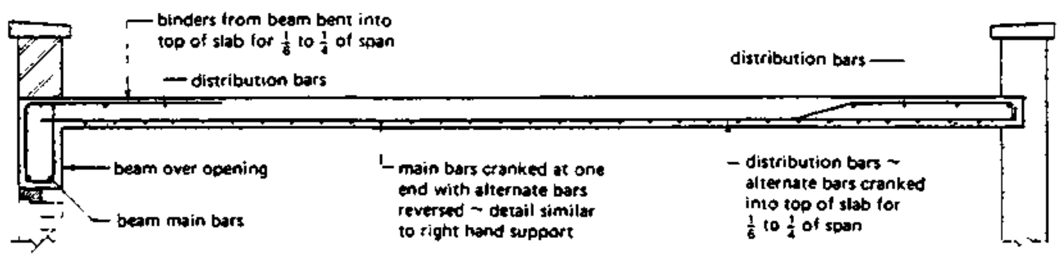
1) Flat slabs

These are basically slabs contained between two plain surfaces and can be either simcle or complex. The design of the complex form is based upon the slab acting as a plate in which the slab is divided into middle and column strips; the reinforcement being concentrated in the latter strips.

Simple flat slabs can be thick and heavy but have the advantage of giving clear ceiling heights since there are no internal beams.

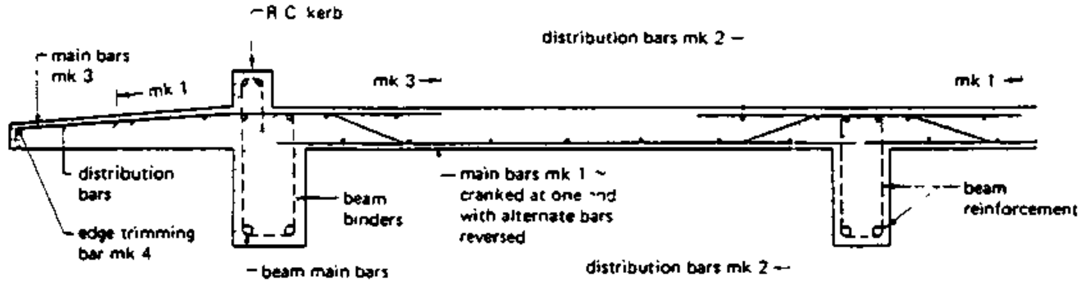
REINF. CONCRETE SLABS

They are generally economic up to spans of approximately 9.000 m and can be designed to span one way, that is across the shortest span, or to span in two directions. These simple slabs are generally designed to be simply supported, that is, there is no theoretical restraint at the edges and therefore tension is not induced and reinforcement is not required. However, it is common practice to provide some top reinforcement at the supports as anti-crack steel should there, in practice, be a small degree of restraint. Generally this steel is 50 % of the main steel requirement and extends into the slab for 0.2 m of the span. An economic method is to crank up 50% of the main steel or every alternate bar over the support since the bending moment would have reduced to such a degree at this point it is no longer required in the bottom of the slab. If there is an edge beam the top steel can also be provided by extending the beam binders into the slab.



Typical R.C. slab details

Typical R.C. flat slab

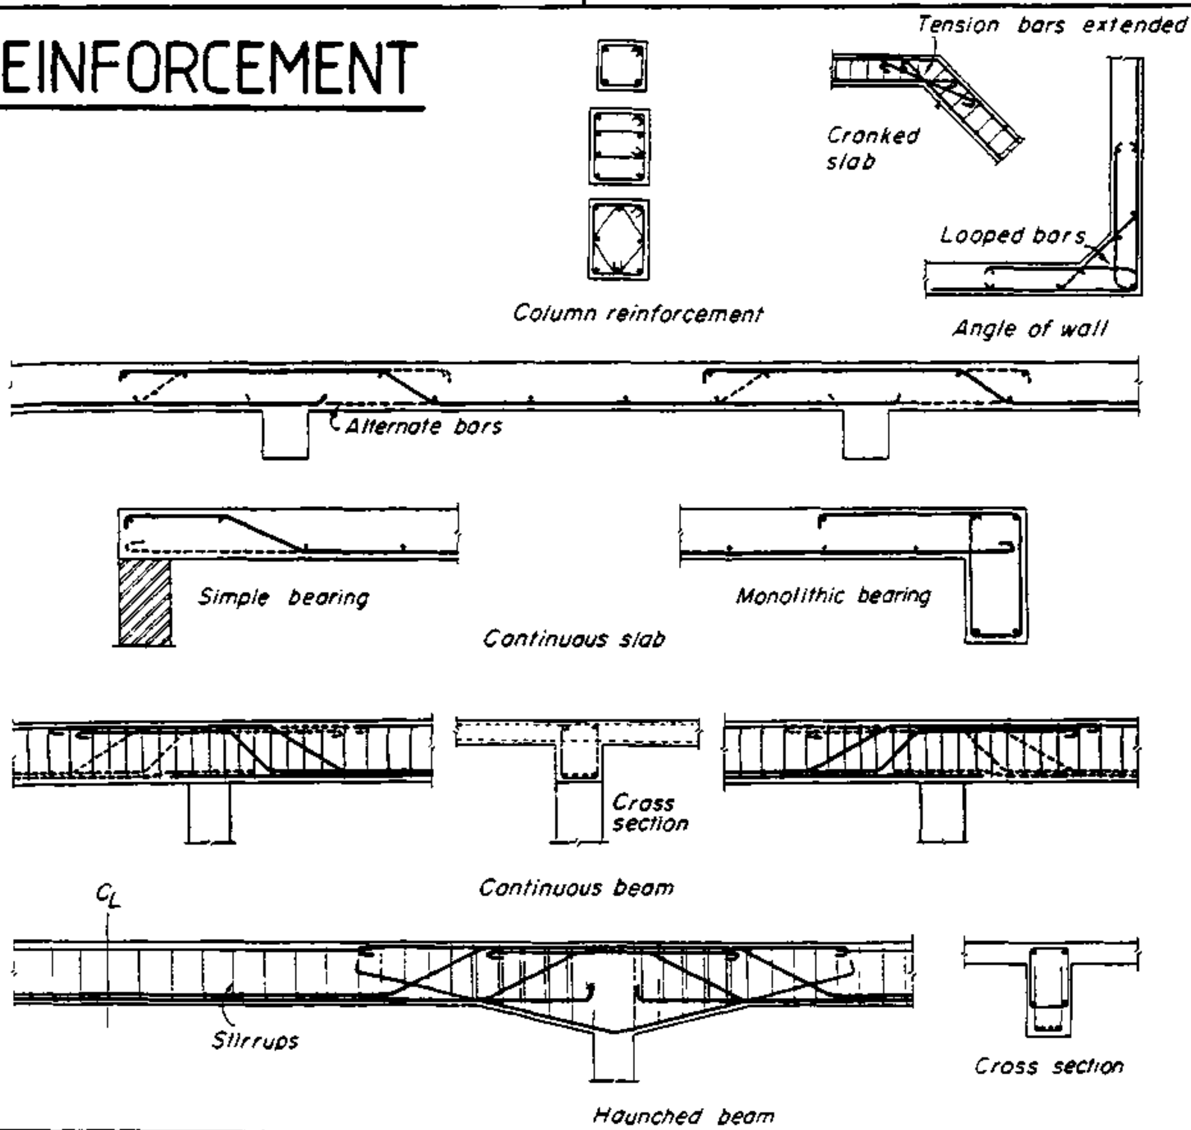


Typical R C beam and slab with cantilever

2) Beam and slab

By adopting this method of design large spans are possible and the reinforcement is generally uncomplicated. A negative moment will occur over the internal suoports necessitating top reinforcement; as with the flat slabs, this can be provided by cranked bars Each bar is in fact cranked but alternate bars are reversed thus simplifying bending and indentification of the bars. Alternatively a separate mat of reinforcement supported on chairs can be used over the supports.

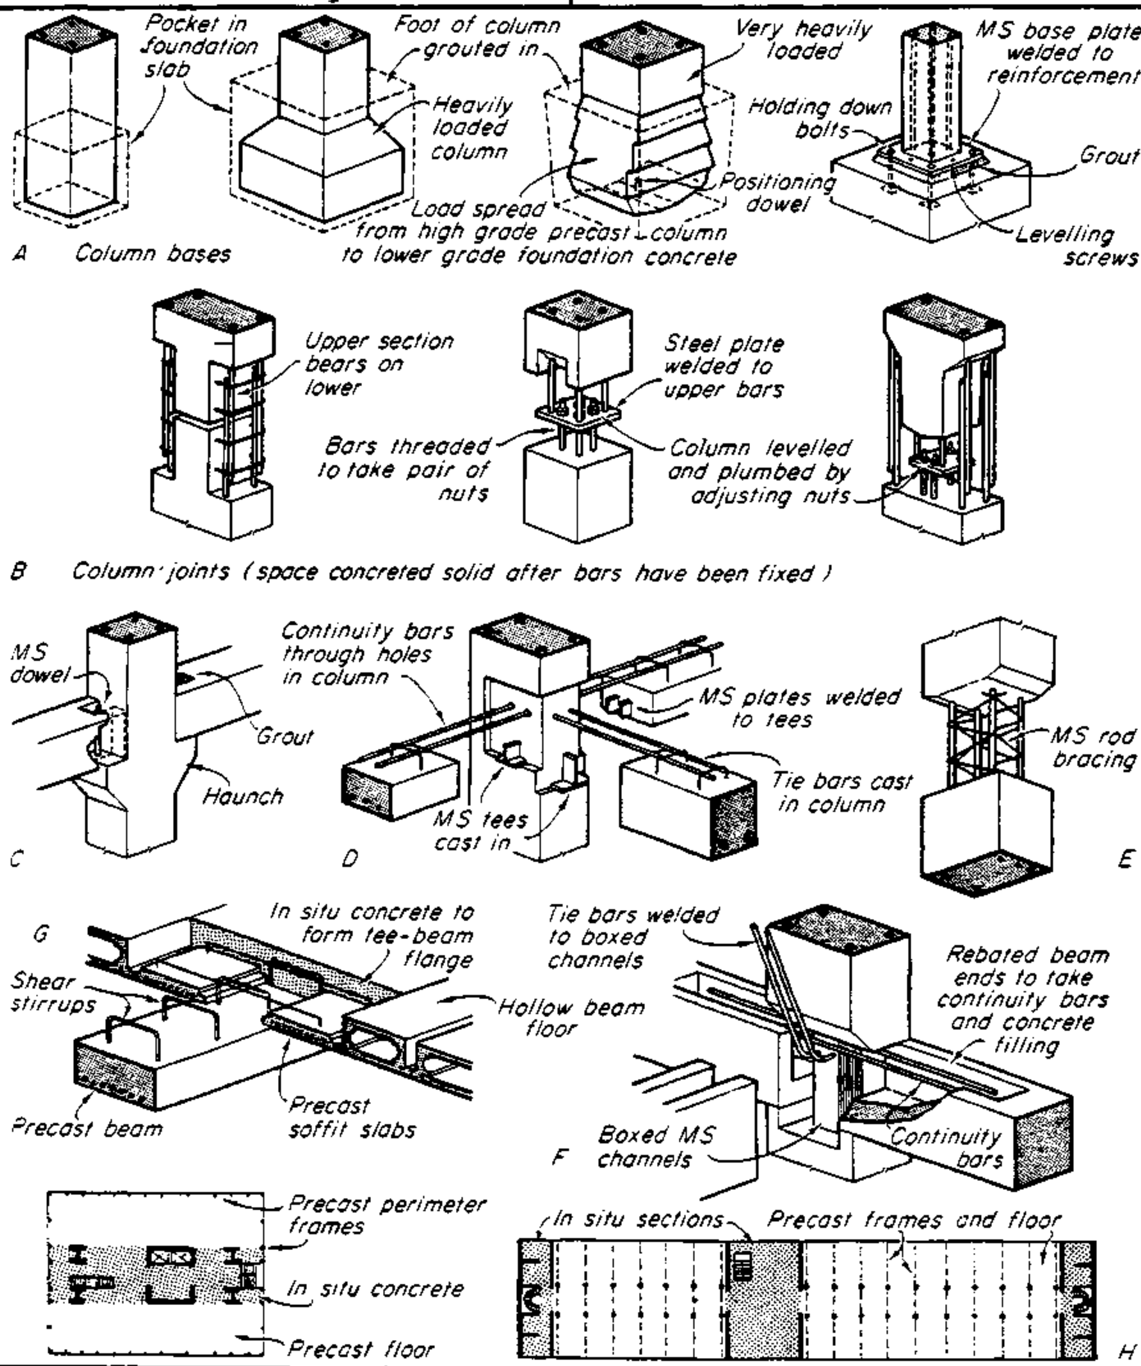
REINFORCEMENT



10.5.3 Precast concrete frames

The overall concept of a precast concrete frame is the same as any other framing material. Single or multi-storey frames can be produced on the skeleton or box frame principle. Single and two-storey buildings can also be produced as portal frames, a method generally reserved for advanced level study. Most precast concrete frames are produced as part of a 'system'building and therefore it is only possible to generalise in an overall study of this method of framing.

PRECAST CONCR FRAMES



Advantages

1. Mixing, placing and curing of the concrete carried out under factory-controlled conditions which results in uniform and accurate units.
   The casting, being an 'off site' activity, will release site space which would have been needed for the storage of cement and aggregates, mixing position, timber store and fabrication area for formwork and the storage, bending and fabrication of the reinforcement.
2. Repetitive standard units reduce costs: it must be appreciated that the moulds used in precast concrete factories are precision made, resulting in high capital costs. These costs must be apportioned over the number of units to be cast.
3. Frames can be assembled on site in cold weather which helps with the planning, programming and progressing of the building operations. This is important to the contractor since delays can result in the monetary penalty clauses, for late completion of the contract, being invoked.
4. In general the frames can be assembled by semi-skilled labour. With the high turnover rate of labour within the building industry operatives can be recruited and quickly trained to carry out these activities.

Disadvantages

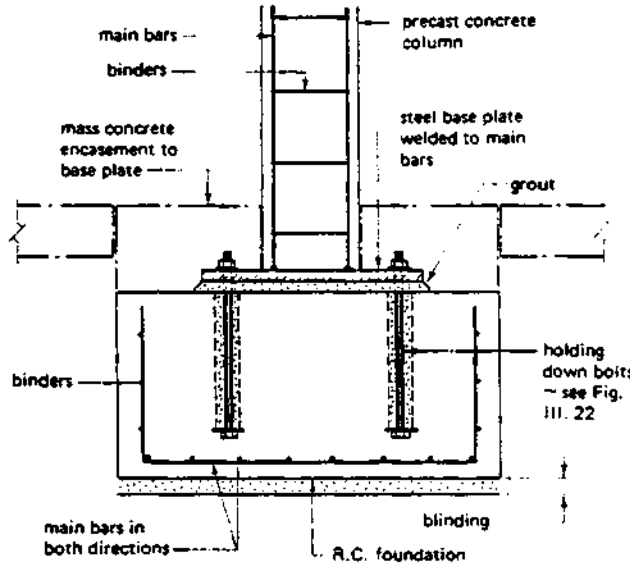
1. System building is less flexible in its design concept than purposemade structures. It must be noted that there is a wide variety of choice of systems available to the designer, so that most design briefs can be fulfilled without too much modification to the original concept.
2. Mechanical lifting plant will be needed to position the units; this can add to the overall contracting costs since generally larger plant is required for precast concrete structures than for in situ concrete structures.
3. Programming may be restricted by controls on delivery and unloading times laid down by the police. Restrictions on deliveries is a point which must be established at the tender period so that the tender programme can be formulated with a degree of accuracy and any overtime payments can be included in the unit rates for pricing.
4. Structural connections between contractual problems. The major points to present both design and contractual problems. The major points to be considered are protection against weather, fire and corrosion, appearance and the method of construction. The latter should be issued as an instruction to site, setting out in detail the sequence, temporary supports required and full details of the joint.

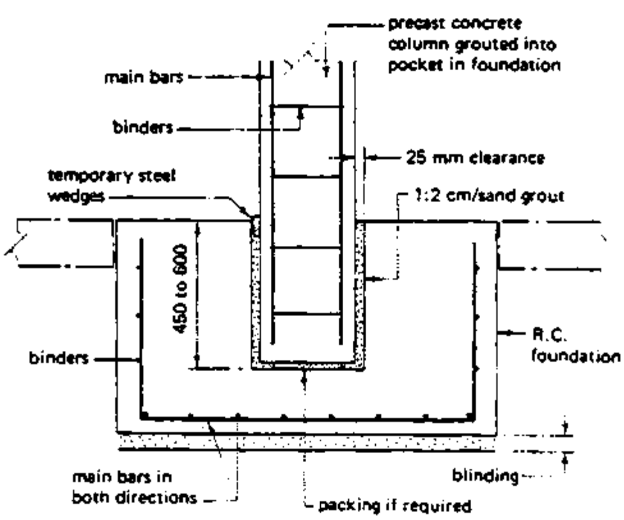
ADVANTAGES | DISADVANTAGES

10.5.3.1 Methods of connections

Foundation connections

Precast columns are connected to their foundations by one of two methods, depending mainly upon the magnitude of the load. For light and medium loads the foot of the column can be placed in a pocket left in the foundation. The column can be plumbed and positioned by fixing a collar around its perimeter and temporarily supporting the column from this collar by using raking adjustable props. Wedges can be used to give added rigidity whilst the column is being grouted into the pocket. The alternative method is to cast or weld on a base plate to the foot of the column and use holding down bolts to secure the column to its foundation in the same manner as described in detail for structural steelwork.





P.C.C. column to foundation connections

Column connections

The main principle involved in making column connections is to ensure continuity and this can be achieved by a variety of methods. In simple connections a direct bearing and grouted dowel joint can be used, the dowel being positioned in the upper or lower column. Where continuity of reinforcement is required the reinforcement from both upper and lower columns left exposed and either lapped or welded together before completing the connection with in situ concrete. A more complex method is to use a stud and plate connection where one set of theaded bars are connected through a steel plate welded to a set of bars projecting from the lower column; again the connection is completed with in situ concrete. Column connections should be made at floor levels but above the beam connections, a common dimension being 600 mm above structural floor level.
The columns can be of single or multi-storey height, the latter having provisions for beam connections at the intermediate floor levels.

METHODS of CONNECTIONS

<u>Beam connections</u>
As with columns, the main emphasis is on continuity within the joint. Three basic methods are used:

1. A projecting concrete haunch is cast on to the column with a locating dowel or stud bolt to fix the beam.
2. A projecting metal corbel is fixed to the column and the beam is bolted to the corbel.
3. Column and beam reinforcement, generally in the form of hooks, are left exposed. The two members are hooked together and covered with in situ concrete to complete the joint.

With most beam to column connections lateral restraint is provided by leaving projecting reinforcement from the beam sides to bond with the floor slab or precast concrete floor units.

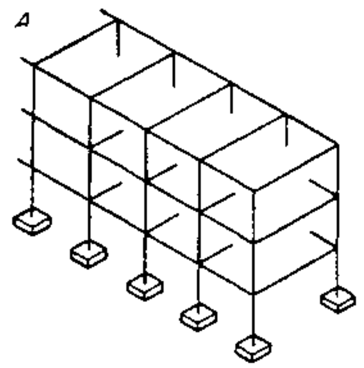
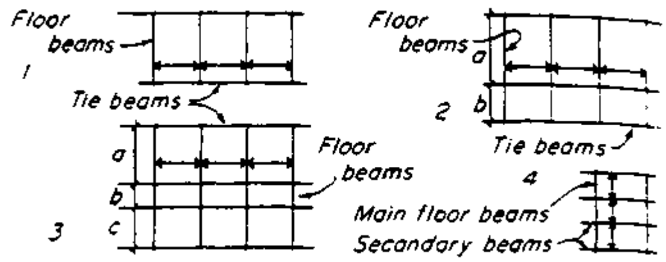
10.5.4 Structural steelwork frames.

STRUCT. STEELWORK FRAMES

Structural steel as a means of constructing a framed building has been used since the beginning of the twentieth century. Structural steel as well as reinforced 'insitu' and precast concrete are used and this means a comparison must be made before any particular framing medium is chosen. The main factors to be considered in making this choice are:



Simple 'cage' frame



Layout	Member	SPANS Practicable range (m)	Economic range (m)
1	Floor beams	3.65 to 15.25	4.25 to 6.00
	Slab	2.40 to 7.30	3.00 to 4.25
2	Floor beams	3.00 to 15.25 for economy 'a' should not be more than 1 1/5 x 'b'	4.25 to 5.50
	Slab	As for 1 above	
3	Floor beams	a c 3 to 15.25 b 1.8 to 15.25 for economy 'b' should be from 1/8 to 2/3 of (a + c)	4.25 to 5.50 2.40 to 3.00
	Slab	As for 1 above	
4	If spacing of floor beams is greater than 5.50 m secondary beams may be used to keep slab span within the economic limits

COSTS :

Site costs:

The use of a steel or precast concrete frame will enable the maximum amount of prefabrication off site, during which time the general contractor can be constructing the foundations in preparation for the erection of the frame. To obtain the maximum utilisation of a site the structure needs to be designed so that the maximum amount of floor area is achieved. Generally prefabricated section sizes are smaller than comparable in situ concrete members, due mainly to the greater control over manufacture obtainable under factory conditions and thus these will occupy less floor area.

Maintenance costs:

These can be considered in the short or long term but it is fair to say that in most framed buildings the costs are generally negligible if the design and workmanship is sound. Steelwork, because of its corrosive properties, will ned some form of protective treatment but since most steel structures have to be given a degree of fire resistance the fire protective method may well perform the dual function.

Construction costs:

The main factors are design considerations, availability of labour, availability of materials and site conditions. Concrete is a flexible material which allows the designer to be more creative than working within the rigid confines of standard steel sections. However, as the complexity of shape and size increases so does the cost of formwork and for the erection of a steel structure skilled labour is required, whereas activities involved with precast concrete structures can be carried out by the more readily available semi-skilled labour working under the direction of a competent person. The availability of materials fluctuates and only a study of current market trends can give an accurate answer to this problem. Site condiditions regarding storage space, fabrication areas and manoeuvrability around and over the site can well influence the framing method chosen.

10.5.4.1 Structural steel frames

The design, fabrication, supply and erection of a structural steel frame is normally placed in the hands of a specialist sub-contractor. The main contractor's task is to provide the foundation bases in the correct positions and to the correct levels with the necessary holding down fixing bolts. The designer will calculate the loadings, stresses and reactions in the same manner as for reinforced concrete and then select a standard steel member whose section properties meet the design requirements. Standard steel sections are given in BS 4, Part 1 and in the Handbook on Structural Steelwork published jointly by the British Constructional Steelwork Association Ltd. and the Constructional Steel Research and Development Organisation, which gives the following section types:

Universal beams: These are a range of sections supplied with tapered or parallel flanges and are designated by their serial size x mass in kilograms per metre run. To facilitate the rolling operation of universal beam sections the inner profile is a constant dimension for any given serial size. The serial size is therefore only an approximate width and breadth and is given in millimetres.

Joists: A range of small size beams which have tapered flanges and are useful for lintels and small frames around openings. In the case of joists the serial size is the overall nominal dimension.

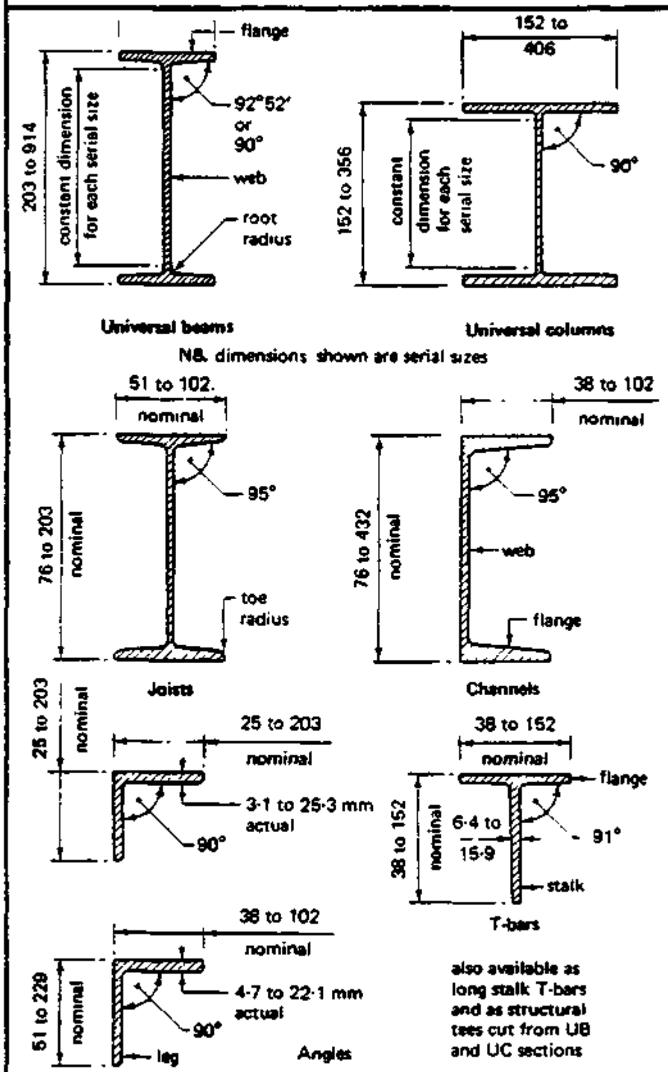
Universal columns: These members are rolled with parallel flanges and are designated in the same manner as universal beams. It is possible to design a column section to act as a beam and conversely a beam section to act as a column.

Channels: Rolled with tapered flanges and designated by their nominal overall dimension x mass per metre run and can be used for trimming and bracing members or as a substitute for joist sections.

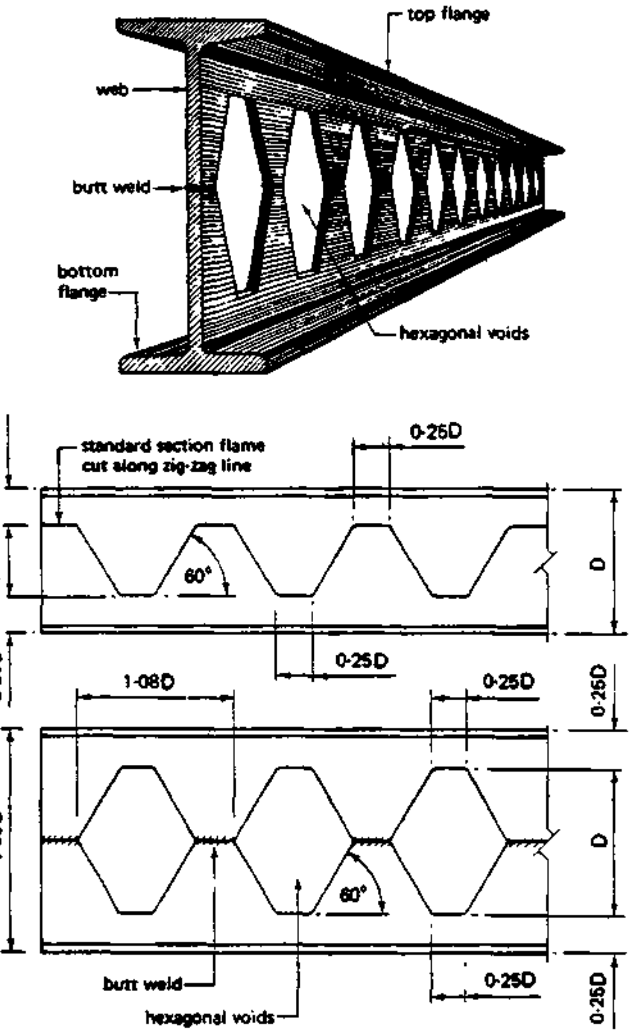
Angles: Light framing and bracing sections with parallel flanges. The flange or leg lengths can be equal or unequal and the sections are designated by the nominal overall leg lengths x nominal thickness of the flange.

T-bars: Used for the same purposes as angles and are available as rolled sections with a short or long stalk or alternatively they can be cut from a standard universal beam or column section. Designation is given by the nominal overall breadth and depth x mass per metre run.

STRUCT. STEEL FRAMES



Castellated beams



NB castellated joists, universal columns and zed sections also available

CASTEL. UNIVERSAL SECTIONS

10.5.4.2 Castellated universal sections

These are formed by flame cutting a standard universal beam or column section along a castellated line; the two halves so produced are welded together to form an open web beam. The resultant section is one and a half times the depth of the section from which it was cut. This increase in depth gives greater resistance to deflection without adding extra weight but will reduce the clear headroom under the beams unless the overall height of the building is increased. Castellated sections are economical when used to support lightly loaded floor or roof slabs and the voids in the web can be used for housing services. With this form of beam the shear stresses at the supports can be greater than the resistance provided by the web; in these cases one or two voids are filled in by welding into the voids metal blanks.

10.5.4.3 Connections

Connections in structural steelwork are classified as either shop connections or site connections and can be made by using bolts, rivets or by welding.

Bolts

Black bolts: The cheapest form of bolt available, the black bolt can be either hot or cold forged, the thread being machined onto the shank. The allowable shear stresses for this type of bolt are low and therefore they should only be used for end connections of secondary beams or in conjunction with a seating cleat which has been designed and fixed to resist all the shear forces involved. The clearance in the hole for this form of bolt is usually specified as 1.6 mm over the diameter of the bolt. The term black bolts does not necessarily indicate the colour but is the term used to indicate the comparatively wide tolerances to which these products are usually made. BS 4190 gives recommendations for black bolts and nuts for a diameter range of 5 to 68 mm inclusive.

Bright bolts: These have a machined shank and are therefore of greater dimensional accura-

cy fitting into a hole with a small clearance allowance. The stresses allowed are similar to those permitted for rivets. Bright bolts are sometimes called turned and fitted bolts.
High strength friction bolts: Manufactured from high tensile steels and are used in conjunction with high tensile steel nuts and tempered washers. These bolts have generally replaced rivets and black bolts for both shop and site connections since fewer bolts are needed and hence the connection size is reduced. The object of this form of bolt is to tighten it to a predetermined shank tension in order that the clamping force thus provided will transfer the loads in the connecting members by friction between the parts and not by shear in or bearing on the bolts. Generally a torque controlled spanner or pneumatic impact wrench is used for tightening; other variations to ensure the correct torque are visual indicators such as a series of pips under the head or washer which are flattened when the correct amount of shank tension has been reached. Nominal standard diameters available are from 12 to 36 mm with lengths ranging from 40 to 500mm, as recommended in BS 4395.

The holes to receive bolts should always be drilled in a position known as the back mark of the section.
The back mark is the position on the flange where the removal of material to form a bolt or rivet hole will have the least effect upon the section properties. Actual dimensions and recommended bolt diameters are given in the Handbook on Structural Steelwork.
Rivets:
Made from mild steel to the recommendations of BS 4620 rivets habe been generally superseded by bolted and welded connections for structural steel frames. Rivets are available as either cold or hot forged with a veriety of head shapes ranging from an almost semi-circular or snap head to a countersunk head for use when the projection of a snap, universal or flat head would create an obstruction. Small diamter rivets can be cold driven but the usual practice is to drive rivets whilst they are hot. Rivets, like bolts, should be positioned on the back mark of the section; typical spacings are 2 1/2 diameters centre to centre and 1 3/4 diameters form the end or edge to the centre line of the first rivet.
Welding:
Primarily considered as a shop connection since the cost together with the need for inspection, which can be difficult on site, generally makes this method uneconomic for site connections.
The basic methods of welding are oxy-acetylene and electric arc. A blowpipe is used for oxy-acetylene which allows the heat from the burning gas mixture to raise the temperature of the surfaces to be joined. A metal filler rod is held in the flame and the molten metal from the filler rod fuses the surfaces together.
In the alternative method an electric arc is struck between a metal rod connected to a suitable low voltage electrical supply and the surface to be joined which must be earthed or resting on an earthed surface. The heat of the arc causes the electrode or metal rod to melt and the molten metal can be deposited in layers to fuse the pieces to be joined together.

With electrical arc welding the temperature rise is confined to the local area being welded whereas oxy-acetylene causes a rise in metal temperature over a general area.
Welds are classified as either fillet or butt welds. Fillet welds are used to the edges and ends of members and forms a triangular fillet of welding material. Butt welds are used on chamfered end to end connections.

STRUCT. STEEL CONNECTIONS

10.5.4.4 Structural steel connections

Base connections:
Are of one or two forms, the slab or bloom base and the gusset base. In both methods a steel base plate is required to spread the load of the column on to the foundation. The end of the column and the upper surface of the base plate should be machined to give a good interface contact when using a bloom base. The base plate and column can be connected together by using cleats or by fillet welding.

The gusset base is composed of a number of members which reduce the thickness of the base plate and can be used to transmit a high bending moment to the foundations. A machined inferface between column and base plate will enable all the components to work in conjunction with one another, but if this method is not adopted the connections must transmit all the load to the base plate. The base is joined to the foundation by holding down bolts which must be designed to resist the uplift and tendency of the column to overturn. The bolt diameter, bolt length and size of plate washer are therefore important. To allow for fixing tolerances the bolts are initially housed in a void or pocket which is

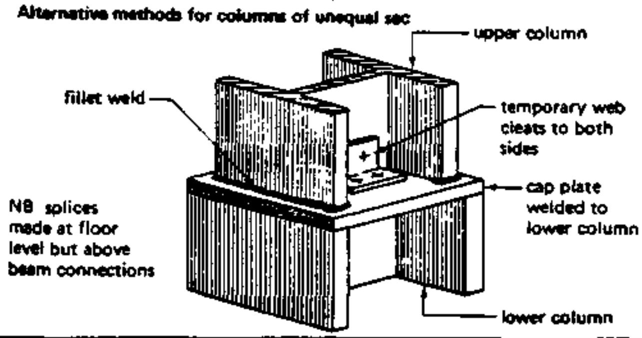
Alternative methods for columns of unequal sec



filled with grout at the same time as the base is grouted on to the foundation. To level and plumb the columns steel wedges are inserted between the underside of the base plate and the top of the foundation.

Beam to column connections:
These can be designed as simple connections where the whole of the load is transmitted to the column through a seating cleat. This is an expensive method requiring heavy sections to overcome deflection problems. The usual method employed is the semi-rigid connection where the load is transmitted from the beam to the column by means of top cleats and/or web cleats; vor ease of assembly an erection cleat on the underside is also included in the connection detail. A fully rigid connection detail, which gives the greatest economy on section sizes, is made by welding the beamt to the column. The uppermost beam connection to the column can be made by the methods described above or alternatively a bearing connection can be used, which consists of a cap plate fixed to the top of the column to which the beams can be fixed either continuously over the cap plate or with a butt joint.

Column splices: These are made at floor levels but above the beam connections. The method used will depend upon the relative column sections.

Beam to beam connections:
The method used will depend upon the relative depths of the beams concerned. Deep beams receiving small secondary beams con have a shelf angle connection whereas other depths will need to be connected by web cleats.

10.5.4.5 Frame erection

This operation will not normally be commenced until all the bases have been cast and checked since the structural steelwork contractor will need a clear site for manoeuvring the steel members into position. The usual procedure is to erect two storeys of steelwork before final plumbing and levelling takes place.
The grouting of the base plates and holding down bolts is usually left until the whole structure has been finally levvelleo and plumbed. The grout is a neat cement or cement/sand mixture depending on the gap to be filled:

12 to 25mm gap - stiff mix of neat cement;
25 to 50mm gap - fluid mx of 1:2 cement/sand and tamped;
over 50mm gap - stiff mix of 1:2 cement/sand and rammed.

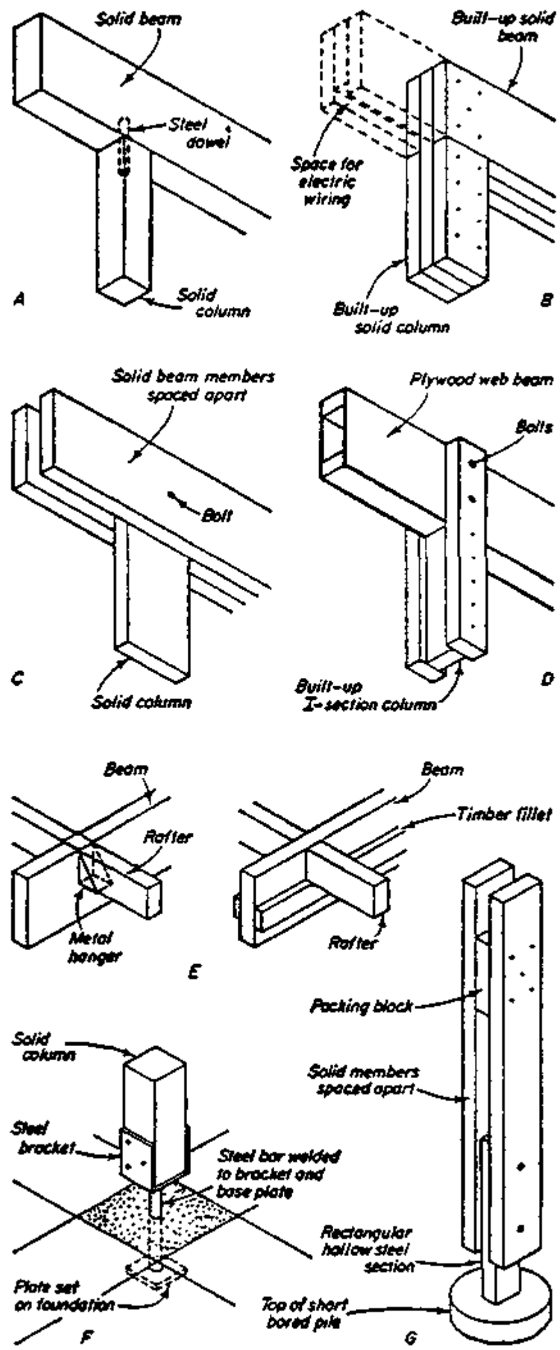
With large base plates a grouting hole is sometimes included but with smaller plates three sides of the base plate are sealed with puddle clay, bricks or formwork and the grout introduced through the open edge on the fourth side. To protect the base from corrosion it should be encased with concrete up to the underside of the floor level giving a minimum concrete cover of 75mm to all the steel components.

10.5.4.6 Fire protection of steelwork

Part E of building regulations together with Schedule 8 gives the minimum fire resistance periods and methods of protection for steel structures according to the purpose group of the building and the function of the member. The traditional method is to encase the steel section with concrete, which requires formwork and adds to the loading of the structure. Many 'dry' techniques are available but not all are suitable for exposed conditions.

10.5.5 Timber frames

Skeleton frames constructed in timber may be fabricated from solid timber sections, built-up sections or glued and laminated sections.



Timber beams and columns

10.5.5.1 Clumns and beams

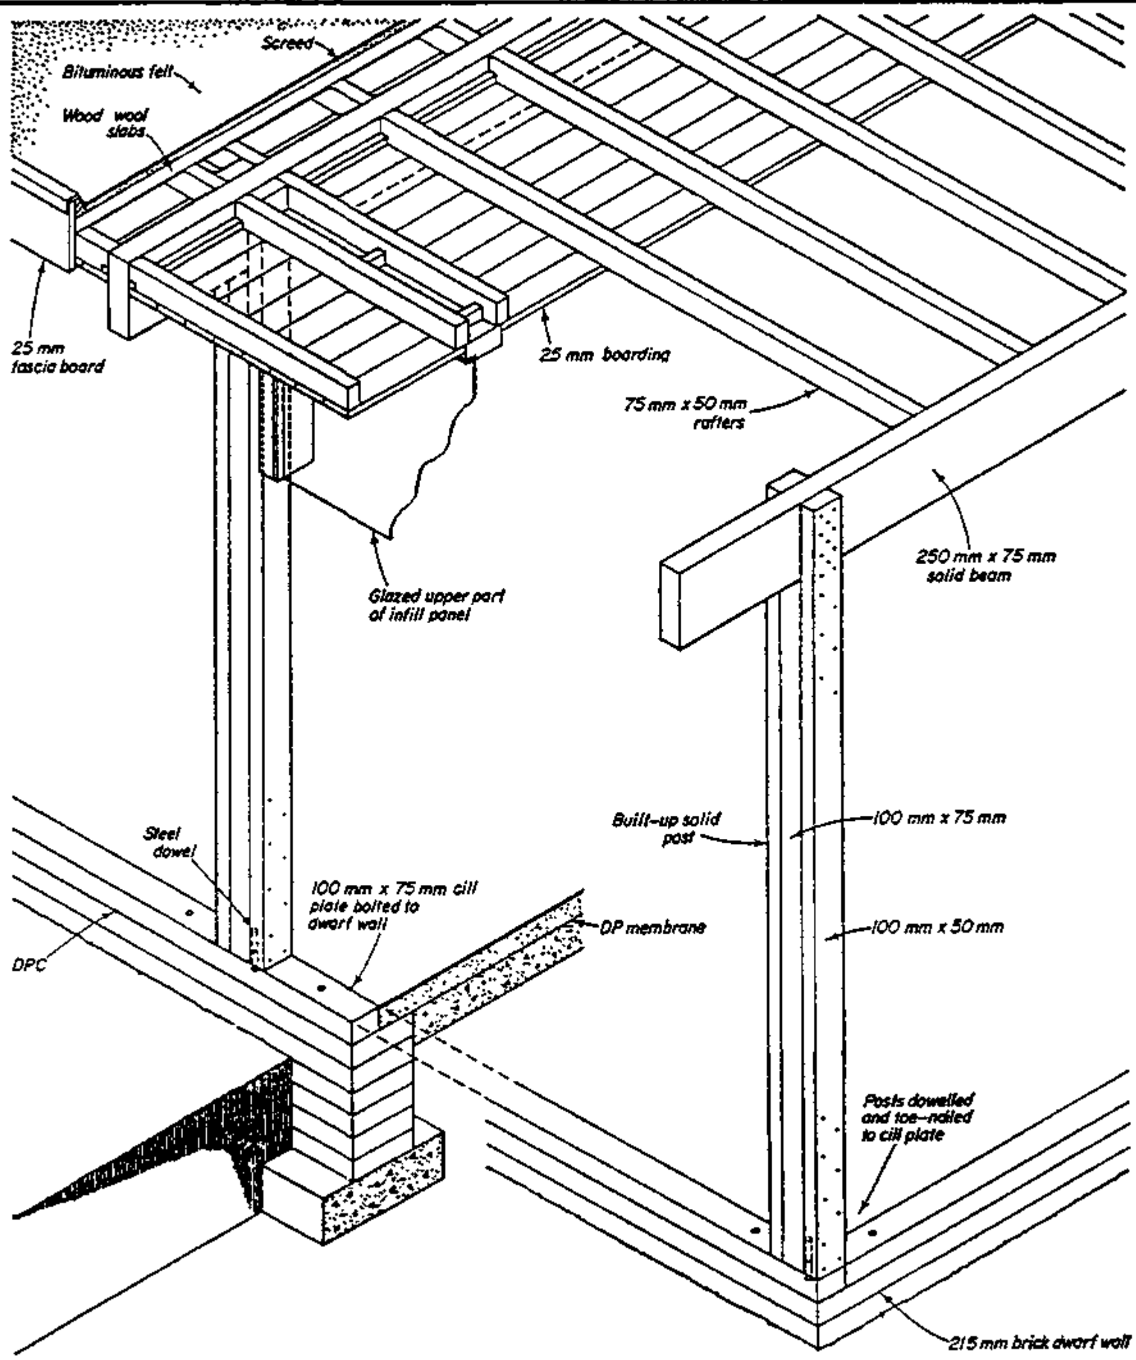
Solid square or rectangular sections are generally the most economical in cost, but where members beyond the available sizes and lengths of solid timber are required it is necessary to form them by combining a number of smaller sections of timber. This may be accomplished by nailing or bolting together several pieces to form built-up solid sections. Apart from obtaining the required sizes for large members there are advantages in building up solid sections from smaller pieces since these are easier to obtain and to season properly without checking and they may be built-up in ways that minimise warping and permit rigid connections between columns and beams.

In the case of built-up column sections involving butt joints in the length it is essential that the abutting faces be carefully machined and the joints staggered. Built-up box and I-sections used as columns are stiffer than a solid section for a given timber content and are particularly suitable for tall columns. Another method of increasing the stiffness of lightly loaded columns is to provide the bearing area in two parallel members spaced apart by packing blocks at intervals and connected by nails, bolts or glue.

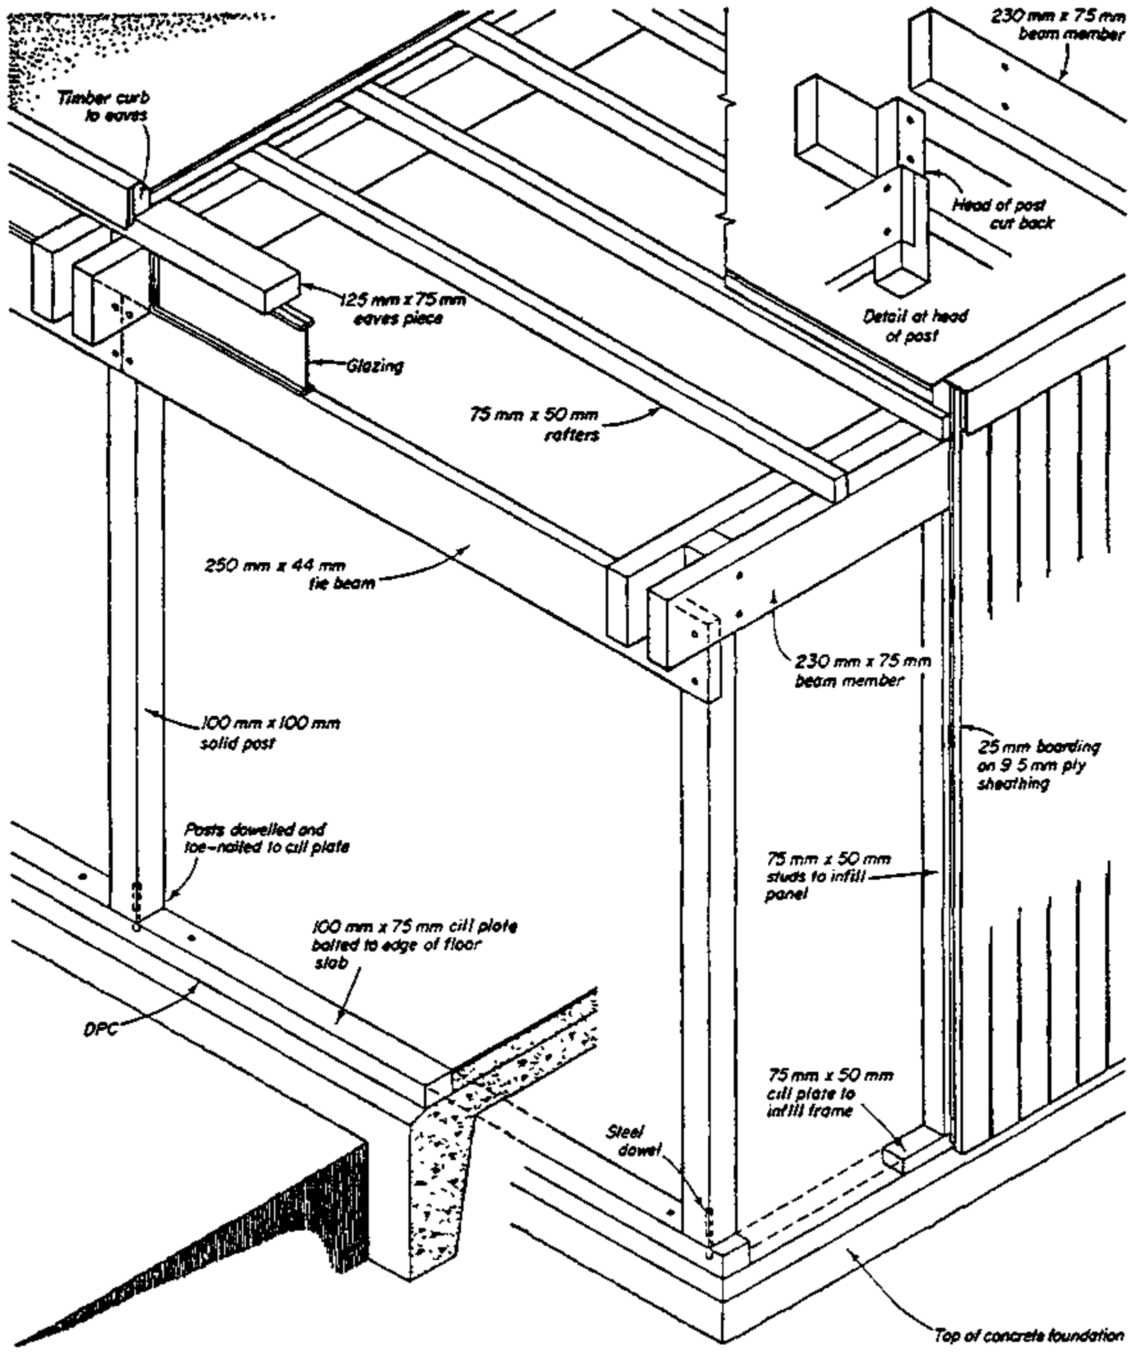
Built-up solid beams are normally built up of vertical pieces nailed or bolted together, nailing being satisfactory for beams up to about 250mm in depth, although these may require the

TIMBER FRAMES

use of bolts at the ends if shear stresses are high. Where the imposed loading is light beams may be built up with solid flanges and plywood webs nailed or glued, or glued and nailed, together. Such web beams, compared with solid beams, are very stiff relative to the amount of timber in them, especially those with two webs forming a box section and result in low dead/live load ratios. The thin webs necessitate stiffeners at intervals along the length of the beam. Increased shear resistance near the supports may be obtained by closer spacing of the stiffeners at the ends of the beam. The fire resistance of



Timber frame with built-up solid posts and solid beams



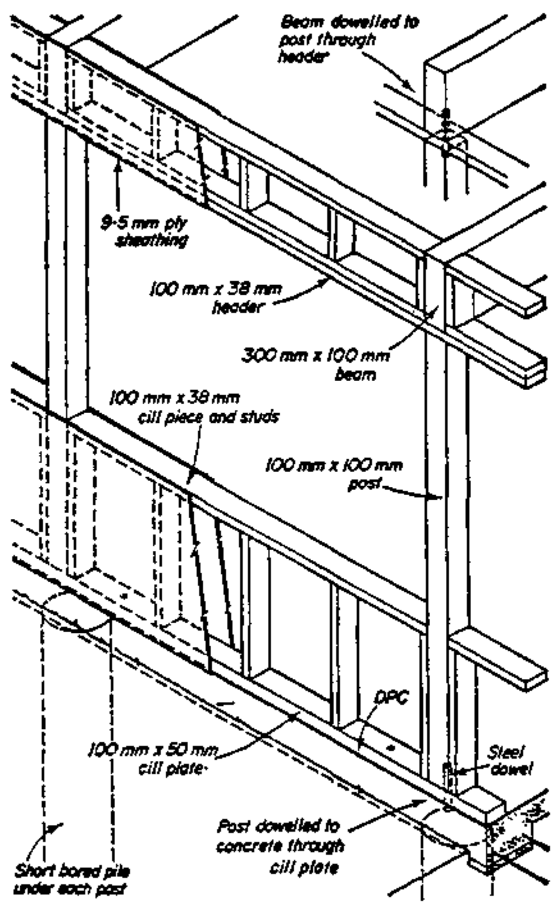
Timber frame with solid posts and spaced solid beams

web beams such as these is very much lower than that of solid or glued and laminated timber beams by reason of the thinness of the parts. If exposed to the weather the surface veneer of the plywood webs of this type of beam tends to check. Glued and laminated sections, commonly called glulam sections, consist of timber laminations glued together to form square or rectangular sections and, for large span beams, I-sections. They are more expensive than solid or built-up sections but permit the use of higher permissible stresses in their design and are, therefore, suitable where loads are great or spans are large.

CONNECTIONS

10.5.5.2 Connections
Connections between beams and columns are made with nails, bolts, dowels and cleats according to the type of members.

Those between solid and glulam beams and columns are made by metal dowels with or without side fixing plates, the latter providing a stiffer connection, or simply by side-nailing the beam to the column. Built-up members are connected by nails, bolts or bolts and timber connectors. Built-up solid sections or spaced solid members permit rigid connections to be made by passing one member, or part of it, through the other.

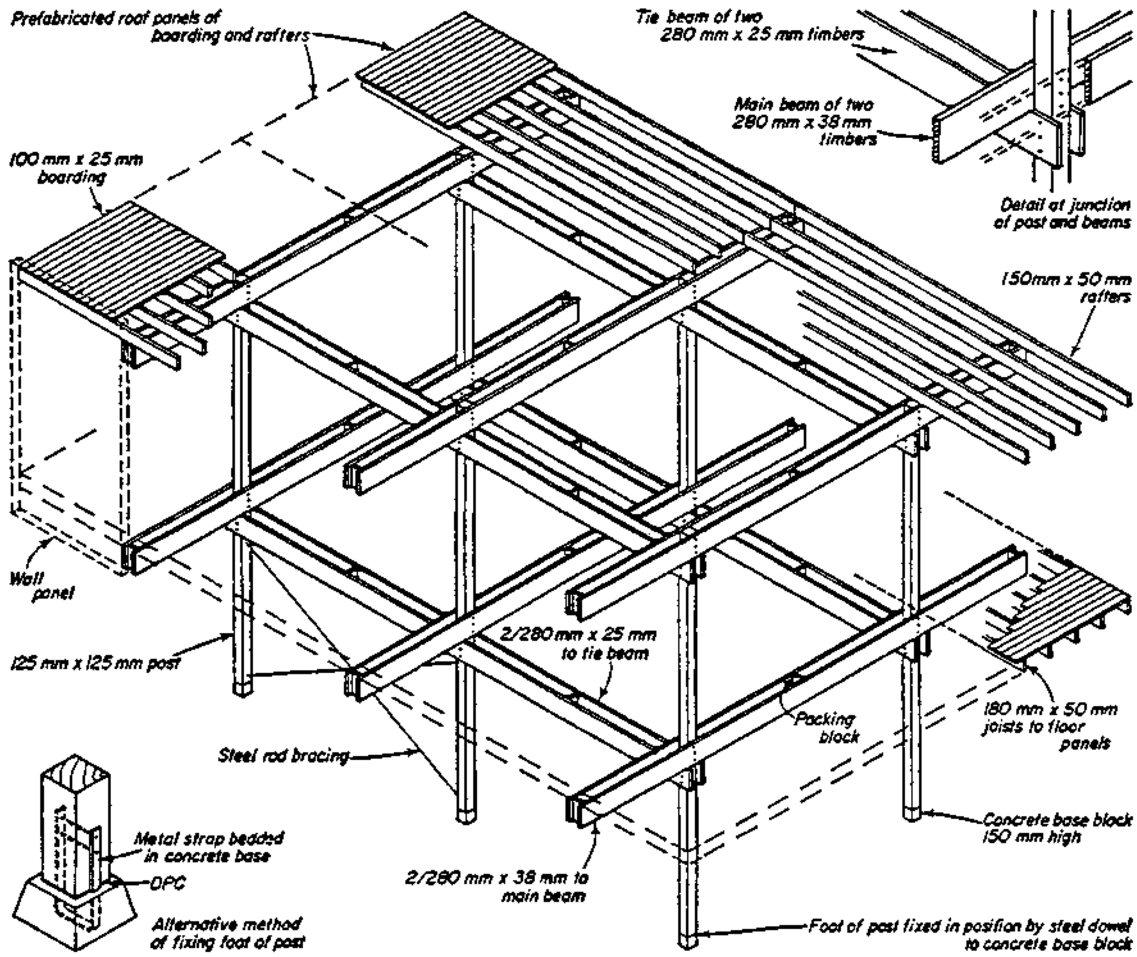


Timber frame with solid posts and beams

Spaced beams permit the use of smaller sections than would be required for a single solid member. The solid built-up beam, however, has the advantage that one piece restrains the warping of the others.
Beam to beam connections are made by means of metal hangers or by metal cleats bolted or screwed to the beams, Rafters and joists may be supported by hangers or timber fillets.
Column base connections are made in various ways depending on the relation of the column to the remainder of the building fabric. Free standing external columns normally are raised of the ground to isolate them from ground moisture. This may be done by means of a concrete stool or block with a damp-proof layer between the timber and concrete, the column being fixed in position by a steel dowel or by straps and bolts. Alternatives to this which isolate the timber from the ground and also fix the column in position are shown in the figure. These three methods also hold the post against wind uplift, the effect of which can be considerable when the roof is flat and the structure is light. External perimeter columns normally bear on a continuous timber cill plate which is bolted to the concrete floor slab or perimeter dwarf wall and which also carries the infilling wall panels. If the loading on the column and the nature of the soil necessitates it a small pier and foundation slab or a short bored pile must be constructed under the column position.
Internal columns usually bear directly on the floor slab, thickened to form a base if necessary, and are secured in position by a metal dowel.

10.5.5.3 Building frames in timber.

Most small-scale timber framed structures take the form of post and beam construction in which resistance to racking distortion of the frame under working load is provided by the infill panels. A proportion of solid or near-solid wall panels is, therefore, necessary to ensure stability and can normally be provided. The choice of connection and form of junction between the members of the frame in most cases thus depends largely on the degree of rigidity required for erection purposes before the panels are fixed.
The figure shows post and beam frames constructed with built-up solid posts and single solid beams, the latter passing between the outer column pieces, to which they are secured by nailing, and bearing on the centre piece. The foot of each post bears on the timber cill plate bolted to the dwarf wall as for frame wall construction. Bearings for the rafters are provided by fillets nailed to the beam sides. The roof extends beyond the wall panels the heads of which are secured to noggings between two closely spaced rafters.
The frames are constructed with solid posts and spaced solid beams. The latter bear on shoulders formed at the head of the posts and are secured by two bolts to produce a rigid connection. In this example some lateral rigidity results from the provision of a deep tie beam immediately below the bearings of the main beams, this also being set into the face of the posts and bolted to them. This tie, together with the substantial member fixed to the paired beams above the glazing and some solid panels under some windows in the wall panels, would provide lateral rigidity to the structure.
Since a dowelled connection does not produce a rigid post to beam junction rigidity must be provided by wall panels parallel to the beams. The header running over the tops of the posts provides some rigidity to the frames during erection and ultimate structural rigidity is provided by the top and bottom solid panels forming an opening for glazing. In this example the foundations are short bored piles placed under each post.
The figure shows a double height house frame with the single floor raised above ground level.
The posts are solid and the main bearing beams and lateral tie beams are formed as spaced beams with pairs of deep but relatively thin solid members. The depth of the junction between posts and beams and the use of three bolts at each connection produces stiff joints and rigidity in both directions. Packing blocks at the ends and centre of all beams provides the necessary stiffening against lateral buckling of the thin members. Further stiffening of the frame would be provided by enclosing one of the ground level bays on all four sides with solid panels.
The floor and roof consist of boarded timber joists and rafters made up into prefabricated panels bearing on top of the beams. Prefabricated wall panels are secured to the edges of roof and floor.



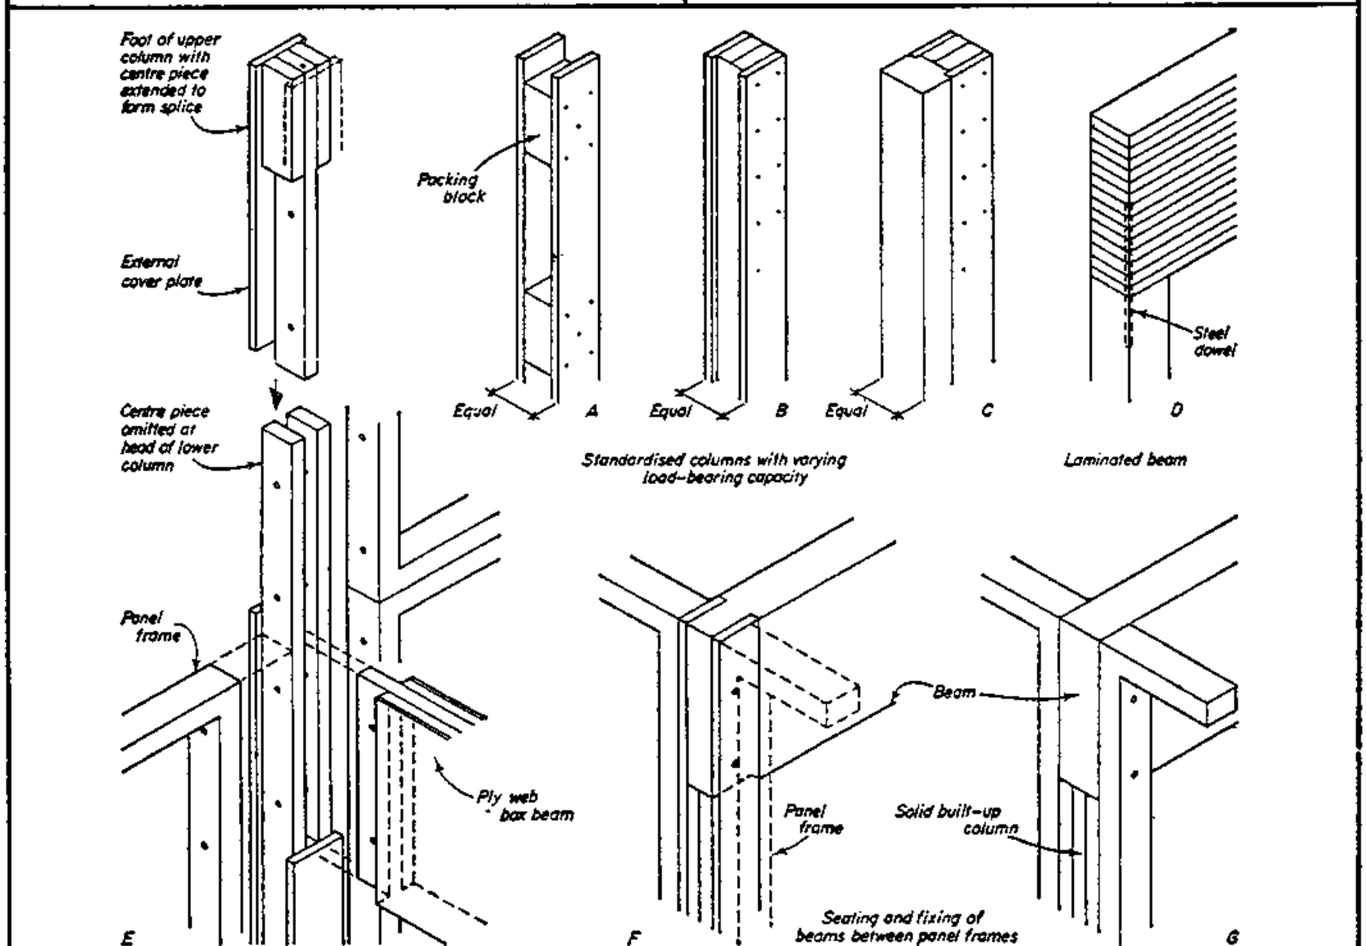
Two-storey timber frame

PREFABRICATION

10.5.5.4 <u>Prefabrication</u>

The design of the last structure and its panel components permits full prefabrication of the parts and assembly by nut-and-bolt is simple and rapid. It is, however, a 'one-off' building. In any form of system building for alarge market provision must be made for the variety of situations produced by arying spans and loading of beams and by single or two-storey buildings, by designing ranges of components with a minimum of variations in construction and dimensions which may be applied to a maximum number of building situations. The figure shows solutions to some aspects of the problem which have been worked out in practice. (A,B, and C) illustrate column types in the same system, all of standard width. (A) is for the light loads and consists of two relatively thin but identical members of sufficient cross-sectional area to take the maximum design load for which they are intended, blocked apart to prevent them buckling. (B) is a built-up solid version with increased bearing area to take greater loads, the outer members and the overall dimensions being the same as in (A). (C) is an extension of (B) to provide further bearing area by the addition of a solid piece glued to (B), to receive which the rebate in the latter is formed. Thus by this means provi-

sion is made for a range of loading conditions by a minimum number of component parts with a standard width dimension.
Variations in span and loading of beams may be met by increased depth and by change of form while maintaining a standard width. Normal timber sizes set a limit to the depth of solid timber beams but deeper beams may be formed as plywood box beams as in (E) where imposed loads are light or by laminating thin boards in glulam construction as in (D).
The three-piece built-up solid column shown in (E) permits a splice connection to be formed for two_story construction, by a simple variation of standard storey-height column components.
The recess to accommodate the beam at the head of a standard column, formed by the omission of the centre piece at that point, is extended by the use of longer outer members. This raceives the splice formed at the foot of the upper column by the use of shorter outer members. In this example the end of the ply box-beam is formed as a deep tenon which is accomodated by the column recess and bears on top of the centre piece. The connection is secured by bolts which pass through the edge members of the infill panels to hold them in position.
In single-storey framed systems the seating and fixing of beams may be accomplished by making the column shorter than the adjacent infill panels and using the latter to fix the beam in position as in (G) which requires the fixing of the panels prior to setting the beam in position. In (F) the built-up column has two thinner outer pieces which carry up the full height and serve to hold the beam in position by nailing until the infill panels are offered up and bolted in position.



Standardised columns with varying load-bearing capacity

Laminated beam

Seating and fixing of beams between panel frames

10.6 PORTAL FRAMES

10.6.1 Theory

- A portal frame may be defined as a continous or rigid frame.
- The basic characteristic is that of a rigid or restrained joint between the supporting member (column) and the spanning member (beam).
- The object of this continuity is to reduce the bending moment in the spanning member by allowing the frame to act as one structural entidy, thus distributing the stresses throughout the frame.
- In a conventional simply supported beam (over a large span) an excessive bending moment occurs at mid-span.

This necessiates a deep heavy beam or a beam shaped to give a large cross section at mid-span. Alternatively a deep cross member of lattice struts and ties could be used. The main advantage of a simply supported frame lies in the fact that the column loading is axial and therefore no bending is induced into the supporting members

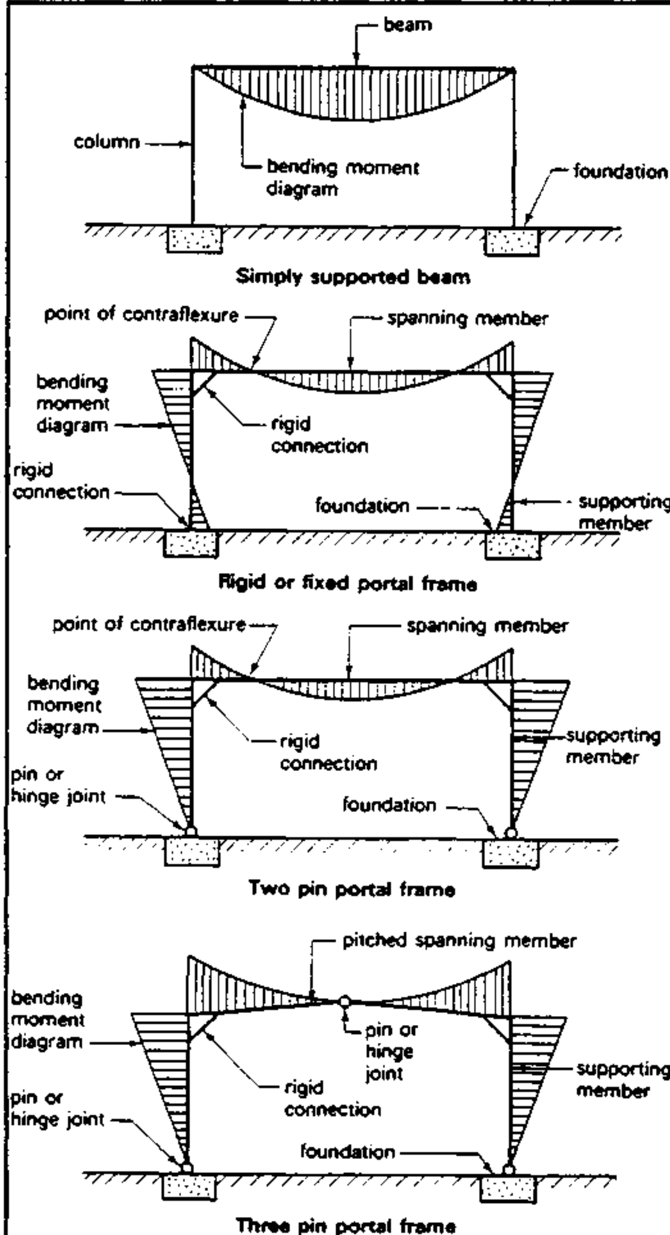
This may ease design problems (since it would be statically determinate), but does not necessarily produce an economic structure.

Furthermore the use of a portal frame eliminates the need for a lattice of struts and ties within the roof space, giving a greater usable volume to the structure and generally a more pleasing internal appearance.

- In a RIGID FRAME the transfer of stresses from the beam to the column will require special care in the design of the joint between the members.

Similarly the horizontal thrust and/or the rotational movement at the foundation connection needs careful consideration. Methods to overcome excessive forces at the foundation are:

1. Reliance on the PASSIVE PRESSURE of the soil surrounding the foundation.
2. Inclined foundations so that the curve of pressure is normal to the upper surface thus tending to induce only compressive forces.
3. A tie bar or beam between opposite foundations.
4. Introducing a hinge or pin joint where the column connects to the foundation.



Portal frames - comparison of bending moments

- HINGES

  Portal frames are usually connected directly to their foundation bases, forming rigid or unrestrained joints.

The rotational movement caused by wind pressures, tending to move the frames and horizontal thrusts of the frame loadings are generally resisted by the size of the base and the passive earth pressures. When the frames start to exceed 4 m in height and 15 m in span the introduction of a hinged or pin joint at the base connection should be considered.

A hinge is a device which will allow free rotation to take place at the point of fixity but at the same time will transmit both load and shear from one member to another.

They are sometimes called: pin joints, unrestrained joints, non-rigid joints.

Since no bending moment is transmitted through a hinged joint the design is simplified by the structural connection becoming statically deteminate.

(In practice it is not always necessary to provide a true PIVOT where a hinge is included but to provide just enough movement to ensure the rigidity at the connection is low enough to overcome the tendency of rotational movement.)

Hinges can be introduced into a portal frame design at the base connections and at the centre or apex of the spanning member, giving three basic forms of portal frames:

1. Fixed or rigid portal frames- all connections between frame members are rigid.
   - The bending moment will be of lower magnitude and more evenly distributed than other forms.
   - Used for small to medium size frames where the moments transfered to the foundations will be excessive.
2. Two pin portal frame - hinges are used at the base connection to eleminate the tendency of the base to rotate.
   - The bending moments resisted by

THEORY

the supporting members will be greater than those in the rigid portal frame.
   - Main use is where high base moments and weak ground conditions are encountered.
3. Three-pin portal frames - this form has hinged joints at the base connections and at the centre of the spanning member.
   - The effect of the third hinge is to reduce the bending moment in the spanning member but to increase deflection.
   - To overcome this latter disadvantage a deeper beam must be used or alternatively the spanning member must be given a pitch to raise the apex wall above the eaves level.

Two other advantages of the three-pin portal frame are that the design is simplified since the frame is statically determinate and on site they are easier to erect, particularly when preformed in sections.

Most portal frames are made under factory controlled conditions - off site - which gives good dimensional and quality control but can create transportation problems.

To lessen this problem and that of site erection splices may be used. These can be positioned at the points of contraflexure, junction between spanning and supporting members and at the crown or apex of the beam.

Portal frames can take the form of the usual roof profiles for single or multispan buildings.

The frames are generally connected over the spanning members with purlines designed to carry lightweight roof coverings or deckings.

The walls can be of similar material fixed to sheeting rails attached to the supporting members or alternatively clad with brick or infill panels.

CONCRETE PORTAL FRAMES

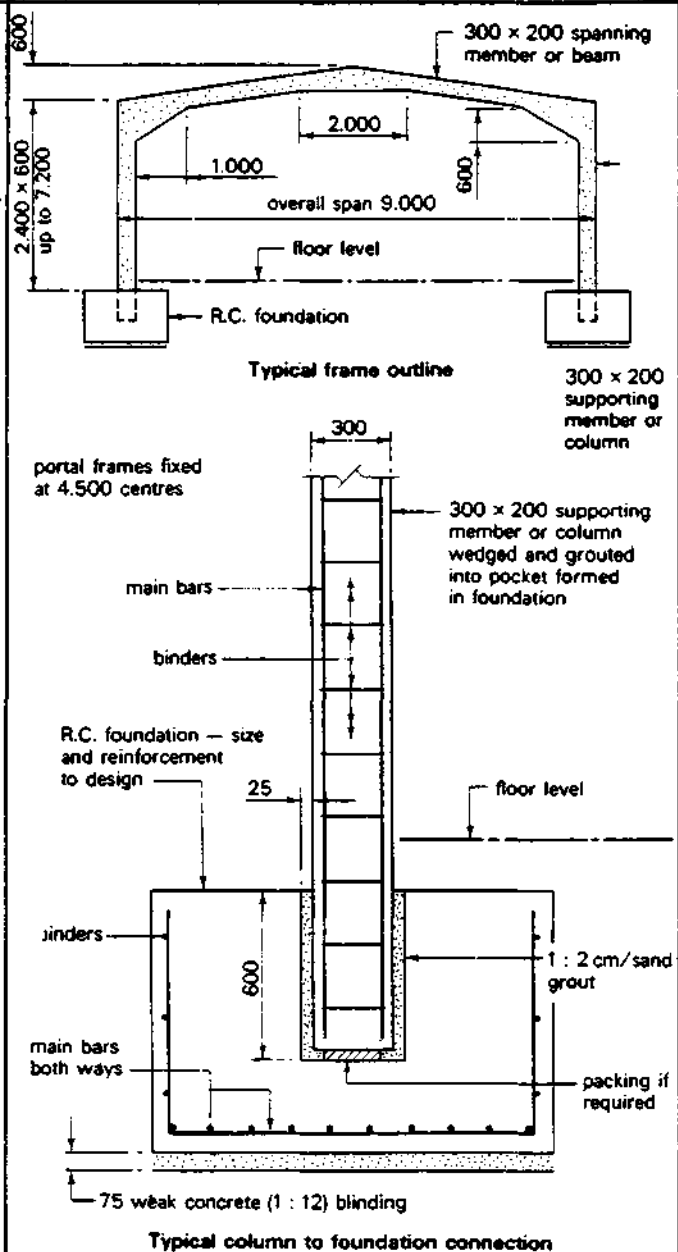
10.6.2 Concrete portal frames

Concrete portal frames are invariably manufactured from high quality precast concrete suitably reinforced.
In the main the use of precast concrete portal frames is confined to low pitch (4^0 to 22 1/2^0) single span frames but two storey and multi-span frames are available, giving a wide range of designs from only a few standard components.

The frames are generally designed to carry a lightweight (34 kg/m^2 maximum) roof sheeting or decking fixed to precast concrete purlins.

Wall finishes can be varied and intermixed since they are non-load bearing and therefore have to provide only the degree of resistance required for fire, thermal and sound insulation, act as a barrier to the elements and resist positive and negative wind pressures. Sheet claddings are fixed in the traditional manner, using hook bolts and purlins, sheet wall claddings are fixed in a similar manner to sheeting rails of precast concrete or steel spanning between or over the supporting members. Brick or block wall panels either of solid or cavity construction can be built off a ground beam constructed between the foundation bases or alternatively they can be built off the ground floor slab. It must be remembered that all such claddings must comply with any relevant Building Regulations.
Foundations and fixings.
The foundations for a precast concrete portal frame usually consist of a reinforced concrete isolated base or pad designed to suit loading and ground bearing conditions. The frame can be connected to the foundations by a variety of methods:

1. Pocket connection -
   the foot of the supporting member is located and housed in a void or pocket formed in the base so that there is an all round clearance of 25 mm to allow for plumbing and final adjustment before the column is grouted into the foundation base.
2. Base plate connection -
   a steel base plate is welded to the main reinforcement of the supporting member, or alternatively it could be cast into the column using fixing



Typical single span pcc frame

lugs welded to the back of the base plate. Holding down bolts are cast into the foundation base; the erection and fixing procedure follows that described for structural steelwork.

3. Pin joint or hinge connection - a special base or bearing plate is bolted to the foundation and the mechanical connection is made when the frames are erected.

CONCRETE PORTAL FRAMES

The choice of connection method depends largely upon the degree of fixity required and the method adopted by the manufacturer for his particular system.

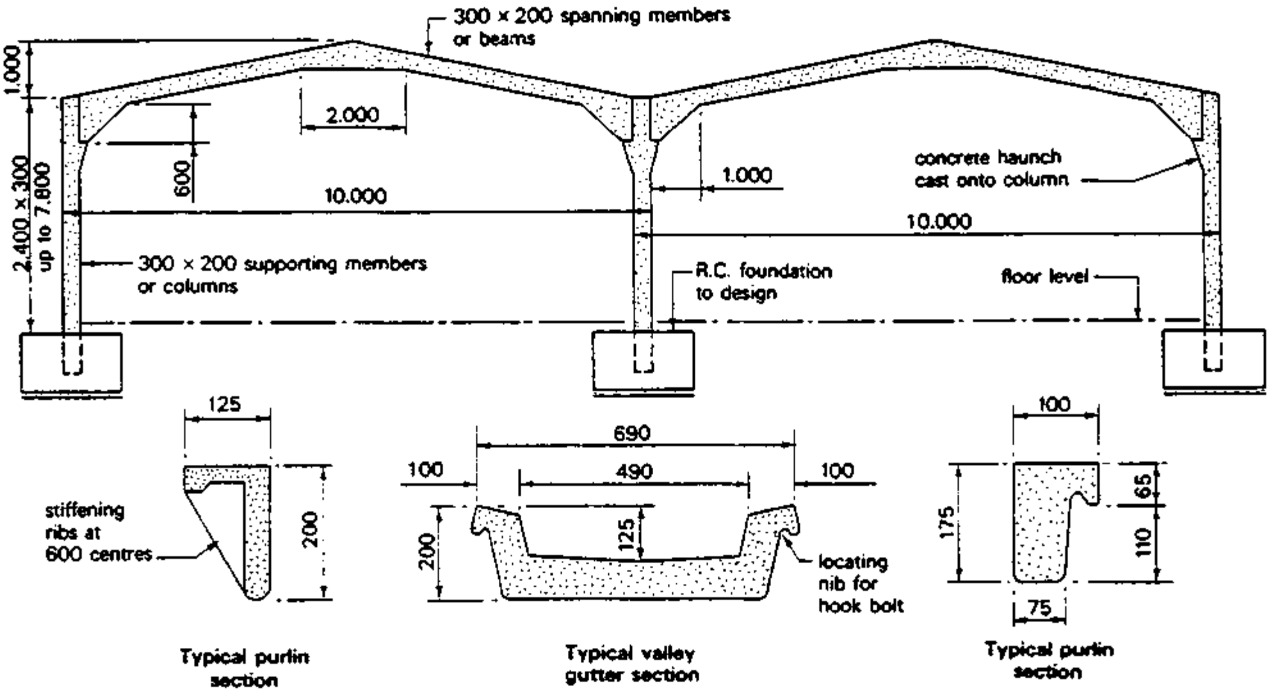


Fig III.3 Typical multi-span precast concrete portal frame

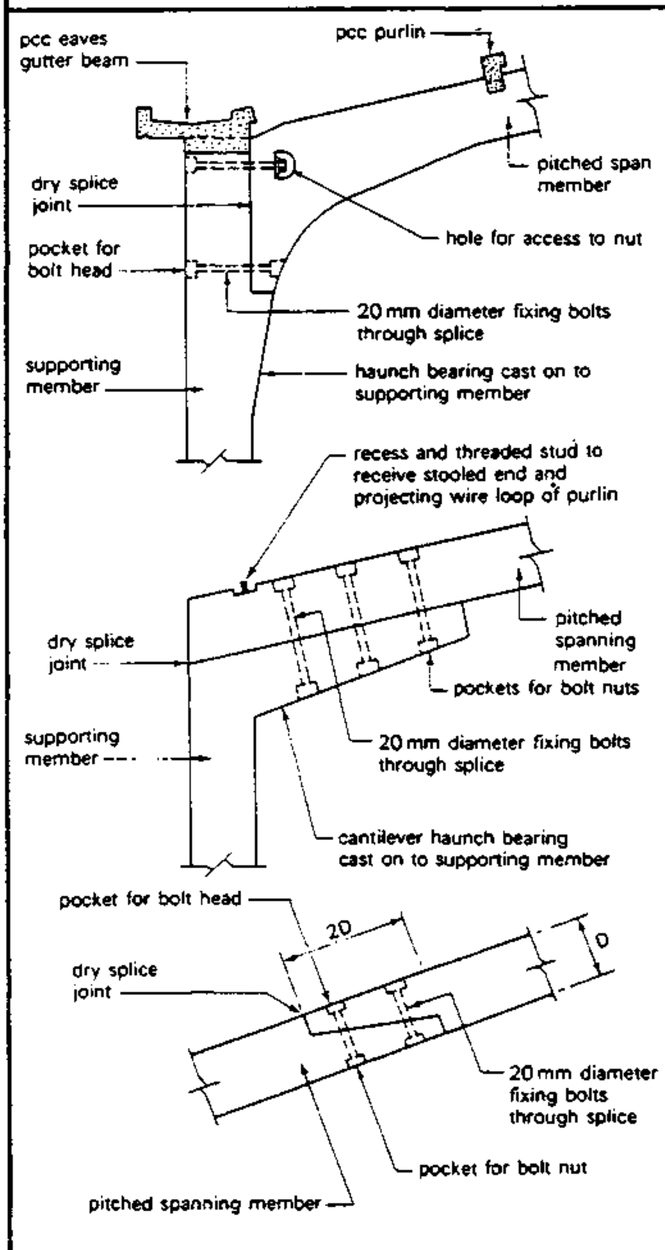
Advantages
The main advantages of using precast concrete portal frames can be enumerated thus:

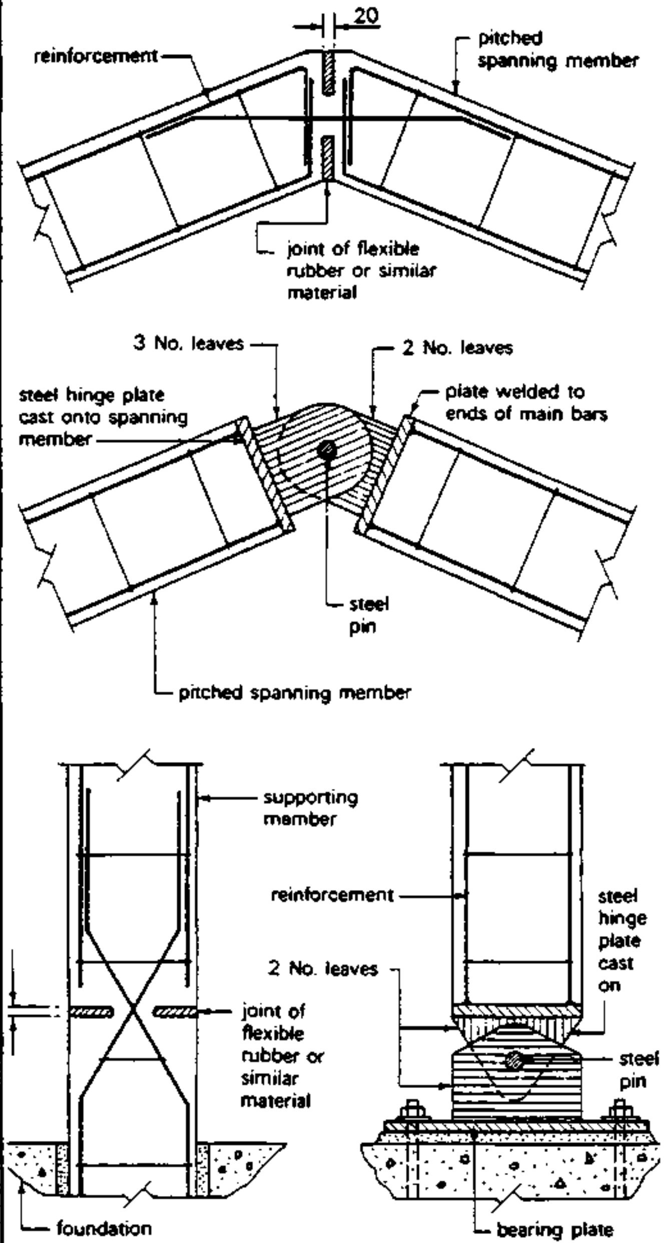
ADVANTAGES

1. Factory production will result in accurate and predictable components since the criteria for design, quality and workmanship recommended in CP 110 can be more accurately controlled under factory conditions than casting components in situ.
2. Most manufacturers produce a standard range of interchangeable components which, within the limitations of their systems, gives a well-balanced and flexible design range covering most roof profiles, single span frames, multi-span frames and lean-to roof attachments. By adopting this limited range of members the producers of precast portal frames can offer their products at competitive rates soupled with reasonable delivery periods.
3. Maintenance of precast concrete frames is not usually required unless the building owner chooses to paint or clad the frames.

4. Precast concrete products have their own built-in natural resistance to fire and therefore no fire-resistant treatment is required. By varying the cover of concrete over the reinforcement most frames up to 24.000 m span are given a 1-hour fire resistance and frames exeeding this span are rated at 2-hour fire resistance.
5. The wind resistance of precast concrete portal frames to both positive and negative pressures is such that wind bracing is not usually required.



Typical splice details for pcc portal frames



Typical hinge details for pcc portal frames

6. Where members of the frame are joined or spliced together the connections are generally mechanical (nut and bolt) and therefore the erection and jointing can be carried out by quickly trained semi-skilled labour.
7. The clean lines of precast concrete portal frames are considered to be aesthetically pleasing.
8. In most cases the foundation design, setting out and construction can be carried out by the portal frame sub-contracting firm.

10.6.3 Steel portal frames

Steel portal frames can be fabricated from standard universal beam, column and box sections. Alternatively a lattice construction of flats, angles or tubulars can be used. Most forms of roof profiles can be designed and constructed giving a competitive range when majority of systems employ welding techniques for the fabrication of alternative system uses special knee joint, apex joint and base joint column sections supplied by the main contractor or by the manufacturer producing the jointing pieces.

The frames are designed to carry lightweight roof coverings of the same loading conditions as those given previously for precast concrete portal frames. Similarly wall claddings can be of the same manner.

Foundations and fixings.

The foundation is usually a reinforced concrete isolated base or pad foundation designed to suit loading and ground bearing conditions. The connection of the frame to the foundation can be by one of three basic methods:

1. Pocket connection - The foot of the supporting member is inserted and grouted into a pocket formed in the concrete foundation as described for precast concrete portal frames. To facilitate levelling some designs have gussets welded to the flanges of the columns.
2. Base plate connection - traditional structural steelwork column to foundation connection using a slab or a gusset base fixed to a reinforced concrete foundation with cast in holding down bolts.
3. Pin or hinge connection - special bearing plates designed to accomodate true pin or rocker devices are fixed by holding down bolts to the concrete foundation to give the required low degree of rigidity at the connection.

Steel portal frames - splices and hinges

ADVANTAGES

Advantages

The main advantages of factory controlled production are: a standard range of manufacturer's systems, a frame of good wind resistance and the ease of site assembly using quickly trained semi-skilled labour attributed to precast concrete portal frames can be equally applied to steel portal frames. A further advantage of steel is that generally the overall dead load of a steel portal frame is less than a comparable precast concrete portal frame. However, steel has the disadvantage of being a corrosive material which will require a long life protection of a patent coating or regular protective maintenance generally by the application of coats of paint. Steel has a lower fire resistance than precast concrete but if the frame is for a single storey building structural fire protection may not be required under the Building Regulations (see Building Regulation E5(4)).

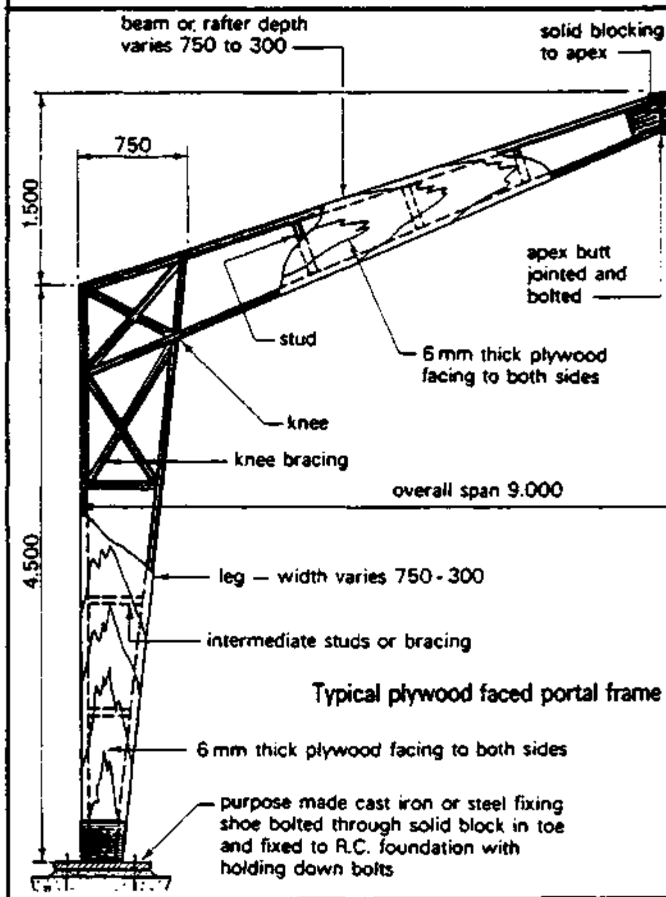
10.6.4 Timber portal frames

Timber portal frames can be manufactured by several methods which produce a light, strong frame of pleasing appearance which renders them suitable for buildings such as churches, halls and gymnasiums where clear space and appearance are important.
The common methods used are glued laminated portal frames, plywood faced portal frames and timber portal frames using solid members connected together with plywood gussets.

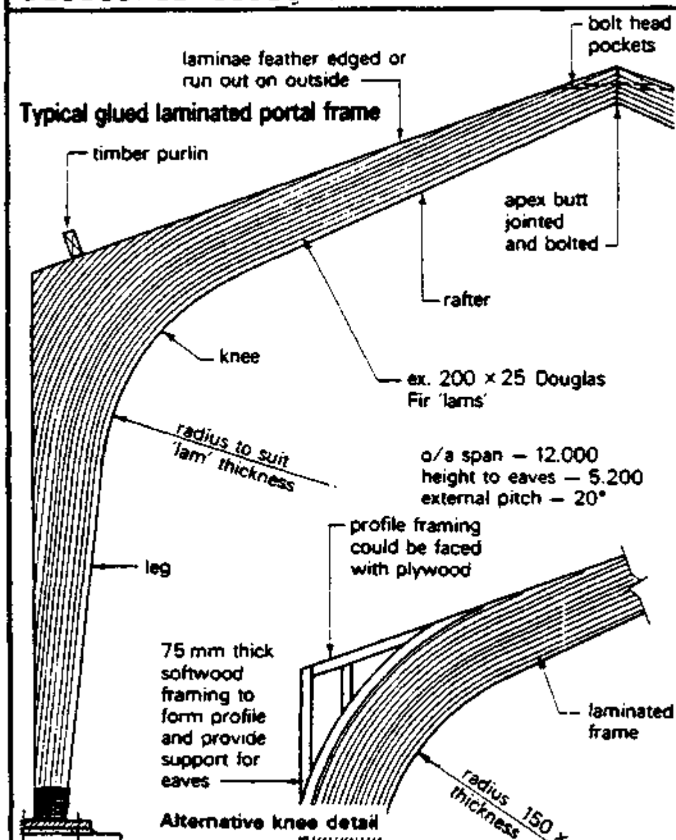
Glued laminated portal frames.

The main objective of forming a laminated member consisting of glued layers of thin section timber members is to obtain an overall increase in strength of the complrete component over that which could be expected from a similar sized solid section of a particular species of timber. This type of portal frame is usually manufactured by a specialist firm since the jigs required would be too costly for small outputs.
The selection of suitable quality softwoods of the right moisture content is also important for a succesful design. In common with other timber portal frames, these can be fully rigid, 2pin or 3 pin structures.
Site work is simple, consisting of connecting the foot of the supporting member to the metal shoe fixing or to a pivot housing bolted to the concrete foundation and connecting the joint at the apex or crown with a bolt fixing or a hinge device. Most glued laminated timber portal frames are fabricated in two halves which eases transportation problems and gives maximum usage of the assembly jigs. The frames can be linked together at roof level with timber purlins and clad with a light-weight sheeting or decking; alternatively, they may be finished with traditional roof coverings.
Any form of walling can be used in conjunction with these frames provided such walling forms comply with any of the applicable Building Regulations.

TIMBER PORTAL FRAMES



Typical plywood faced portal frame



Typical glued laminated portal frame

Plywood faced portal frames.

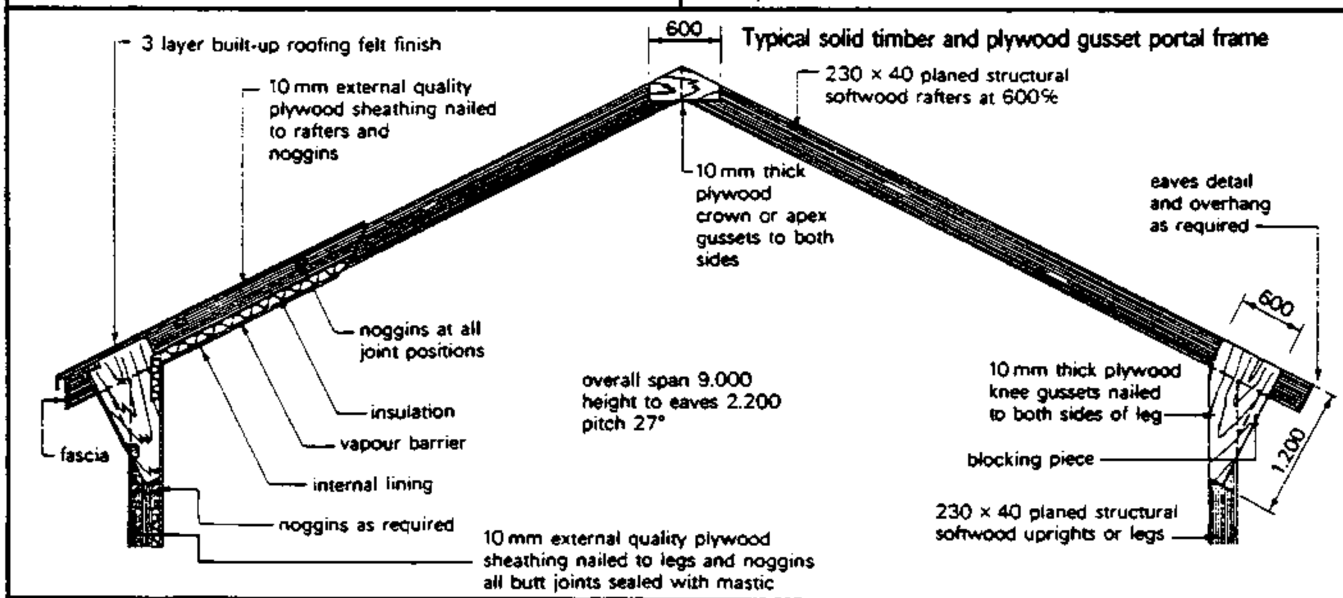
These frames are suitable for small halls, churches and schools with spans in the region of 9.000 m. The portal frames are in essence boxed beams consisting of a skeleton core of softwood members faced on both sides with plywood which takes the bending stresses. The hollow form of the construction enables electrical and other small services to be accommodated within the frame members. Design concepts, fixing and finishes are as given above for glued laminated portal frames.

Solid timber and plywood gussets.

These frames were developed to provide a simple and economic timber portal frame for clear span buildings using ordinary tools and basic skills. The general concept of this form of frame veries from the two types of timber portal frames previously described in that no glueing is used, the frames are spaced close together (600, 900 and 1200 mm centres) and are clad with a plywood sheath so that the finished structure acts as a shell giving a lightweight building which is very rigid and strong. The frames can be supplied in two halves and assembled by fixing the plywood apex gussets on site before erection or alternatively they can be supplied as a complete frame ready for site erection.
The foundations for this form of timber portal frame consists of a ground beam or alternatively the frames can be fixed to the edge of a raft slab. A timber speader or sole plate is used along the entire length of the building to receive and distribute the thrust loads of the frames.

Connection to this spreader plate is made by using standard galvanised steel joists hangers or by using galvanised steel angle cleats. Standard timber windows and doors can be inserted into the side walls by trimming in the conventional way and infilling where necessary with studs, noggins and rafters.
The advantages of all timber portal frame types can be enumerated as follows:

1. Constructed from readily available materials at an economic cost.
2. Light in weight.
3. Easy to transport and erect.
4. Can be trimmed and easily adjusted on site.
5. Protection against fungi and/ or insect attack can be by impregnation, or surface application.
6. Pleasing appearance either as a natural timber finish or painted.



Try to answer the following questions and practice sketching whereever necessary and possible

1) Structural Concept

a) Explain the term FRAMED STRUCTURE, and name the elements of a frame work!

b) Classify different types of FRAMED STRUCTURES! (use sketches for illustration!)

c) When is it logical and economical to use FRAMED STRUCTURES?

2) Functional Requirements

a) Explain the difference between

- Non-rigid frames
- Semi-rigid frames and
- Fully-rigid frames

3) Structural Materials

a) List materials which are commonly used for framed structures!

b) Explain the following terms:

- Depth/span ratio
- Dead/live load ratio
- Strength/weight ratio

4) Layout of frames

a) Write notes on SPACING of frames!

b) Why should the layout of a SKELETON STRUCTURE be based on a regular STRUCTURAL GRID?

5) Building Frames

a) What are BUILDING FRAMES?

b) List different frame members and give brief explainations on each!

c) Write notes on reinforced concrete frames and explain their members:

- reinforced concrete beams
- reinforced concrete columns
- reinforced concrete slabs

(use sketches for illustration!)

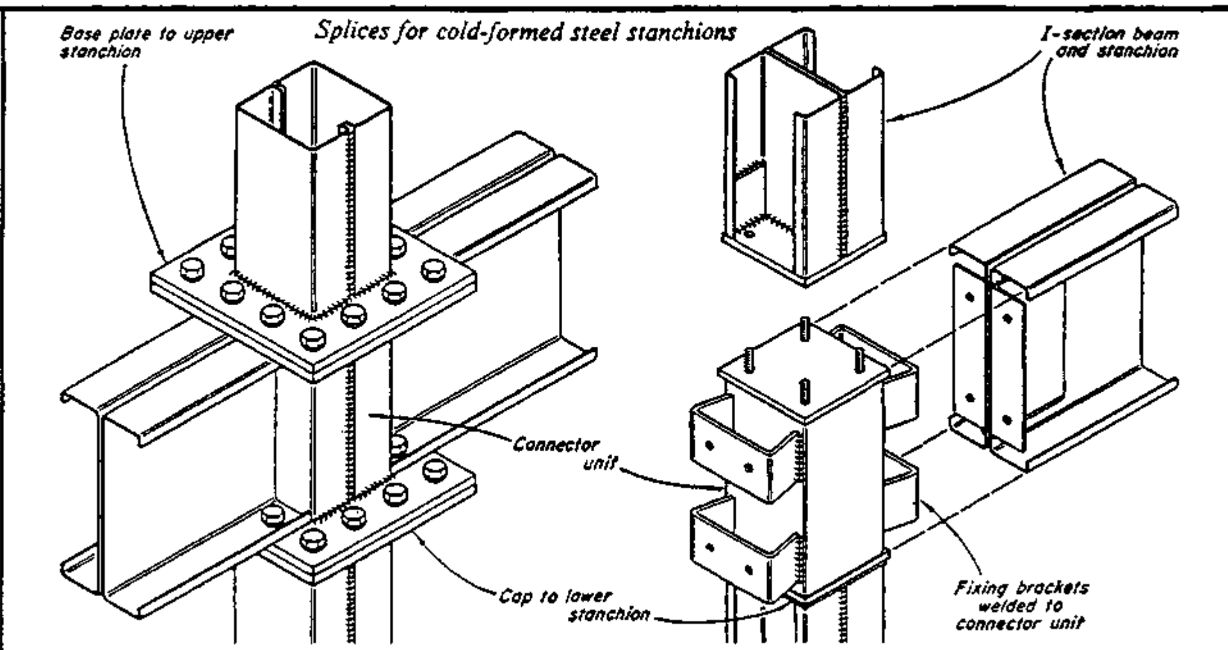
d) Write notes on PRECAST CONCRETE FRAMES and their methods of connections! (use sketches for illustration!)

e) Compare structural steel, reinforced 'in situ' and precast concrete as a material in frame construction!

f) Write notes on STRUCTURAL STEEL FRAMES! (use sketches for illustration!)

g) What are CASTELLATED UNIVERSAL SECTIONs and why are they used?

h) Explain the terms SHOP CONNECTIONS and SITE CONNECTIONS and how they can be made by using bolts, rivets or by welding!



i) Write notes on structural steel connections!

k) Describe the erection of structural steel frames!

l) What do you know about FIRE PROTECTION of STEELWORK?

m) Write notes on TIMBER FRAMES, explaining their members COLUMNS and BEAMS, and their method of CONNECTIONS! (use sketches for illustration!)

n) Explain, by using sketches, the ways of construction of BUILDING FRAMES in TIMBER.

o) What do you know about the PREFABRICATION of timber frames?

6) Portal frames

a) Characterize PORTAL FRAMES

b) What are the methods to overcome excessive forces at the foundation?

c) What are HINGES?

d) Explain the three basic forms of portal frames and show - by using sketches - the position of their hinges.

e) Write notes on CONCRETE PORTAL FRAMES, and their FOUNDATION and FIXINGS! (use sketches for illustration!)

f) What are the ADVANTAGES of concrete portal frames?

g) Write notes on STEEL PORTAL FRAMES, and their FOUNDATIONS and FIXINGS! (use sketches for illustration!)

h) What are the ADVANTAGES of steel portal frames?

i) Write notes on TIMBER PORTAL FRAMES and explain the differences between:

. GLUED LAMINATED PORTAL FRAMES

. PLYWOOD FACED PORTAL FRAMES and

. SOLID TIMBER and PLYWOOD GUSSETS.

(use sketches for illustration!)

k) What are the ADVANTAGES of all timber portal frame types?

11. PROTECTION of BUILDINGS

11. <u>Protection of Buildings</u>

11.1 Exclusion of Water

WATER in its free liquid form must be totally excluded from the interiors of buildings and its presence as VAPOUR in the air or as MOISTURE content of building materials must be controlled to within acceptable limits.

The shrinkage and swelling of soil, the effect of moisture on vegetation, and the water-retaining properties of soils all affect foundation design.

Combinations of soils and water are responsible for the settlement of buildings, cracking, shrinkage, decay, damp disease, chemical attack, subsidence, and landslips.

Moisture in buildings comes from three main sources:

I Precipitation as rain
II Damp rising from the ground through building materials by capillary attraction or as vapour.
III Condensation upon cold surfaces of humidity from the air.

In addition condensed droplets in the air (fog) can be carried by wind to wet the surfaces of the building and to penetrate joints and materials.

The relative humidity of air in buildings can be a critical factor in goverming thermal comfort since it influences the ability of the body to lose heat.

PRECIPITATION

11.1.1 Precipitation.

The frequency of rainfall is well recorded by weather stations every where, and, despite local variations, the designer usually knows what to allow for. In determining open channel and gutter sizes the annual rainfall is not so important as the actual period of the storm and its intensity.

Run-offs can also be hampered by insufficient fall, blockage, damage through traffic, or a sewage system which is simply too small. Soakaways should be large enough to accomodate sudden storms and should also have a seperate drainage system.
The construction of soakaways may be governed by local authorities, who sometimes have a standard layout.
Rainfall statistics in the tropics rarely give an adequate picture of the combined effects of rain, wind, and freak storms. Achieving a perfect match of weather and buildings is not often possible, owing to variations both in exposure and in the performance of the structure itself. These latter may be due to detailing, materials, the size of components, workmanship, and other such factors. And again, rain does not wet walls in the absence of wind. Storms, however, frequently drive rain horizontally and even upwards under balconies and ventilators.

ROOF DRAINAGE

11.1.1.1 Roof Drainage
The most likely source of trouble from water is the roof. Built-up felts, flat roof overflow, rainwater wall streaking, expansion, imperfect flashing, felt blistering inaccurate flow-load calculations incorrect size of large valley gutters, outlets, and r.w.p.s. are common causes of failure. Plastic pipes and gutters also need flexible joints to accomodate thermal movement. Areas subject to sudden storms should have adequate disposal capacity. Ground aprons which take roof discharge direct should have suitable collection channels with sufficient fall, and should be free of blockage and provide easy access to soakaways and drains.

FLOODING

11.1.1.2 Flooding

In coastal areas especially flooding is a common occurence. The extent of damage will depend on the nature of the foundations, the degree of buffeting by the elements, the degree of expansion of soils, erosion, settlement, and crakking. Services, including electricity, may be impaired, plasterboard ruined, timber and plywood split and warped.
After draining or pumping, it may be necessary to punch holes in the lowest areas and remove water trapped in underfloor ducts, pits or cavities. Ventilators and similar openings may have to be cleared of mud. Sea-water flooding can cause erosion of metals, concrete, and lime. Drains should be inspected before use; and one unpleasant effect could be due to backwash, particularly where cesspits and septic tanks are in use. Having cleaned up as well as possible, doors, windows, and vents should be opened and everythin should be done to create maximum air flow through the building.

DROUGHT

11.1.1.3 Drought

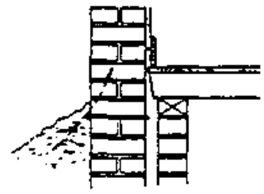
In hot dry climates where living conditions have been adapted to the environment low annual rainfall is not considered as drought. In such circumstances a building is made to combat excessive sunshine, heat, wind, and dust storms. Sanitary services are either designed to be able to cope using the water-supply available, or other means of disposal are used.

Drought in areas of reasonable rainfall and humidity can have serious effects. Shrinkage and settlement, with resulting crakking and bleaching of exposed finishes can occur. The building and its environment will deteriorate where maintanance depends on a supply of water, not to mention the unpleasantness and distress caused by the depletion of the supply. What is sometimes described as a drought is often a decrease in supply resulting from increased demand, particularly in growing towns.

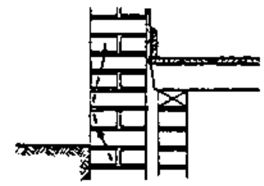
DAMP RISING & . MOIST. MIGRATION

11.1.2 Damp Rising and Moisture Migration.

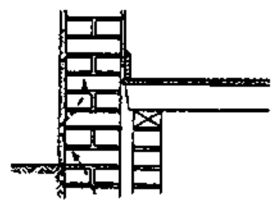
Movement of moisture through the materials of which the building is constructed can occur through capillary attraction or by diffusion of vapour through the pores of the material. The sources of moisture which must be considered in this context include not only precipitation on external surfaces but also damp from the ground floors are not often made in this way. Since, in the case of walls, the exposure to moisture is intermittent it is possible to use thick solid walls of porous materials which absorb moisture into their external faces and then allow it to evaporate without giving rise to serious internal penetration. This type of wall generally has to be very much thicker than is required for structural needs and in modern buildings, means other than thickness have to be used to limit moisture penetration.
Two methods of control are normally employed. Either a barrier of impervious material or an air gap is placed to intercept the movement. Flashings (capillary movement only), damp proof courses, damp proof membranes (capillary vapour diffusion) and vapour barriers (vapour only) are examples of impervious materials bein used as barriers. Cavities, provided that they are not bridged by moisture transmitting features, are a very effective means of arresting capillary movement. They are not necessarily effective against vapour diffusion since unless well ventilated it will be possible for the vapour to pass across. Suspended ground floors formed a good example of a cavity formed to prevent capillary and vapour movement which to be effective in preventing vapour reaching the other side had to be adequately ventilated. This type of construction has now largely gone out of use because of the high heat losses which resulted from the ventilation.
A floor resting solidly on the ground and having a continuous damp proof membrane gives a more satisfactory overall result.



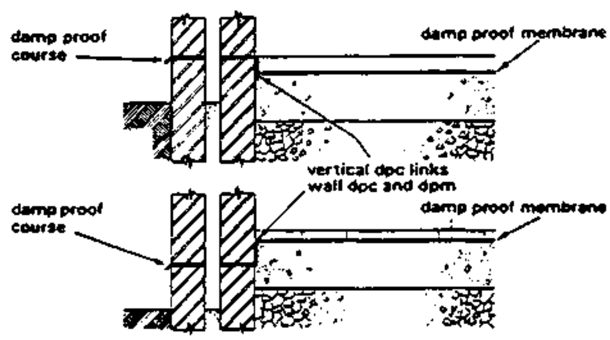
(a) Bridging by earth.



(b) Bridging by mortar pointing.



(c) Bridging by rendering.



11.1.3 Condensation. Condensation arises from the variation with temperature of the capacity of air to hold moisture in the form of water vapour. As temperatures increase the capacity increases. For each temperature, however, there is a saturation level of moisture. When air which has absorbed moisture is cooled to such a temperature that the moisture content exceeds the saturation point, the excess moisture will be deposited as water.

In buildings, the air from outside is taken in and warmed and moisture is addded from occupants and processes. If cold surfaces such as windows, badly insulated walls, or cold metal service pipes exist, they can cool the air immediately adjacent to them so that moisture is deposited on the surface in the form of CONDENSATION: This is both unsightly and likely to cause damage to the contents and finishes of rooms and also to the wall, ceiling and floor materials.

In equatorial coastal climates with little seasonal or diurnal variation in temperature there is not a great deal of heavy condensation. though humidity can be high. Hotels and public buildings are often equipped with air conditioning; if left on for long periods it reverses the process normal to temperate zones, causing heavy condensation to form on the outside of windows and thus spoiling visibility and speeding deterioration of the frames.

Table: Sources and approximate quantities of vapour input to buildings.

Source	Approximate quantity
People: Sedentary Active	0.05kg per person/ 0.2 kg per person/ / per hour
GAS: Cooking or any flueless heaters or appliances	0.81 per m3 of town gas
Paraffin: Flueless heaters	1 kg per litre appr. (1 litre represents approx.4MJ heat output)
Cooking, bathing and showers	0.03to0.06 kg per hour
Clothes washing and drying	Too variable for figure to be given but very substantial quantities of water can be put into the atmosphere and special precautions against general penetration of this moisture into buildings are required.

CONDENSATION

Drying out is mainly a matter of the time taken for water vapour from cellular pores to reach the surface of the material: the rate of evaporation reduces as the temperature falls. Buildings when drying out are thus cooler than the ambient air, and this isthe principle on which the traditional earthenware water cooler works. No rule of thumb on drying out is possible; but premature decoration can be disastrous, especially in damp regions. Dehumididfiers are sometimes used for thies purpose if circumstances warrant it.
The consequences of condensation are, in many modern constructions, more acute than was the case in the past. In masonry and brick constructions significant quantities of water can condense and subsequently evaporate without being apparent or causing serious deterioration.
Risk of condensation can be minimised by increased ventilation. The most effective method, however, is to keep the surface temperature of i.e. walls, windows, cold metal pipes etc. above dewpoint.

Table:
Excess moisture content of air (over outdoor content) for various building types

Building type	Excess content g moisture per kg of dry air
Shops, offices, classrooms, public buildings, dry industrial processes	1,7
Dwellings	3,4
Catering establishments or wet industrial processes	6,8

11.2 THERMAL INSULATION

11.2 Thermal Insulation

11.2.1 Definition

Thermal insulation may be defined as a barrier to the natural flow of heat from an area of high temperature to an area of low temperature. In buildings this flow is generally from the interior to the exterior. During hot seasons however the flow may occur from the exterior to the interior.
Heat is a from of energy consisting of the ceaseless movement of tiny particles of matter called molecules; if these particles are moving fast they collide frequently with one another and the substance becomes hot. Temperature is the measure of hotness and should not be confused with heat.
The transfer of heat can occur in three ways.

Conduction:
Vibrating molecules come into contact with adjoining molecules and set them vibrating faster and hence they become hotter; this process is carried on throughout the substance without appreciable displacement of the particles.

Convection:
Transmission of heat within a gas or fluid caused by the movement of particles which become less dense when heated and rise thus setting up a current or circulation.

Radiation:
Heat is considered to be transmitted by radiation when it passes from one point to another without raising the temperature of the medium through which it travels.

In a building all three methods of heat transfer can take place since the heat will be conducted through the fabric of the building and dissipated on the external surface by convection and/or radiation.
The traditional thick and solid building materials used in the past had a natural resistance to the passage of heat in large quantities, whereas the lighter and thinner materials used today generally have a low resistance to the transfer of heat. Therefore to maintain a comfortable and healthy internal temperature the external fabric of a building must be constructed of a combination of materials which will provide an adequate barrier to the transfer of heat.
Thermal insulation of buildings will give the following advantages:

1. Reduction in the rate of heat loss
2. Lower fuel costs
3. Reduction in the risk of pattern staining.
4. Reduction of condensation and draughts thus improving the comfort of the occupants.

INSULATING MATERIALS

11.2.2 Insulating Materials

When selecting or specifying thermal insulation materials the following must be taken into consideration:

1. Resistance value of the materials.
2. Need for a vapour barrier since insulating materials which become damp or wet, generally due to condensation, rapidly loose their insulation properties; therefore if condensation is likely to occur a suitable vapour barrier should be included in the detail. Vapour barriers should always be located on the warm side of the construction.
3. Availability of material chosen.
4. Ease of fixing or including the material in the general construction
5. Appearance if visible.
6. Cost in relation to the end result and ultimate savings on fuel and/or heating installation.
7. Fire risk - all wall and ceiling surfaces must comply with the requirements of Building Regulation E 15 - restriction of spread of flame over surfaces of walls and ceilings.

Insulating materials are made from a wide variety of materials and are available in a number of forms.

INSULATING CONCRETE

Insulating concrete:
Basically a concrete of low density containing a large number of voids. This can be achieved by using lightweight aggregates such as clinker, foamed slag, expanded clay, sintered pulverised fuel ash, exfoliated vermiculite and expanded perlite, or alternatively an aerated concrete made by the introduction of air or gas into the mix. No fines concrete made by using lightweight or gravel aggregates between 20 and 10 mm size and omitting the fine aggregate is suitable for load bearing walls. Generally light - weight insulating concrete is used in the form of an in situ screed to a structural roof or as lightweight concrete blocks for walls.

LOOSE FILLS

Loose fills:
Materials which can be easily poured from a bag and levelled off between the joists with a shaped template. Materials include exfoliated vermiculite, fine glass fibrewool, mineral wool and cork granules. The depth required to give reasonable results is 25 - 35 mm; care should be taken to indicate, by paint or chalk marks on the sides of the joists, any electrical connections or junctions which have been covered over. Most loose fills are rot and vermin proof as well as being classed as noncombustible.

BOARDS

Boards;
Used mainly as dry linings to walls and ceilings either for self finish or direct decoration. Types include aluminium foil-backed plaster board, woodwool slabs, expanded polystyrene boards, asbestos insulating board and fibreboards. Insulating fibreboards should be conditioned on site before fixing to prevent buckling and distortion after fixing. A suitable method is to expose the boards on all sides so that the air has a free passage around the sheets for at least 24 hours before fixing. During this conditioning period the boards must not be allowed to become wet or damp.

QUILTS

Quilts:
Made from glass fibre or mineral wool bonded or stitched between outer paper coverings for easy handling. The quilts are supplied in rolls from 6.000-13.000 m long and cut to suit standard joist spacings. The are laid over the ceiling boards and can be obtained in two thicknesses, 25mm thick for general use and 50mm-thick for use where a central heating system is installed

REFLECTIVE INSULATION

Reflective insulation:
Used in both ceiling and wall insulation and consists of reinforced aluminium foil which should be used in conjunction with an unventilated cavity of at least 25 mm width.

INSULATING PLASTERS

Insulating plasters:
Factory produced pre-mixed plasters which have lightweight perlite and vermiculite expanded minerals as aggregat4e, and require only the addition of clean water before application. They are only onethird the weight of sanded plasters, have three times the thermal insulation value and are highly resistant to fire.

FOAMED CAVITY FILL

Foamed cavity fill:
A method of improving the thermal insulation properties of an external cavity wall by filling the cavity wall with urea-formaldehyde resin foamed on site. The foam is formed using special apparatus by combining urea-formaldehyde resin, a hardener, a foaming agent and warm water. Careful control with the mixing and application is of paramount importance if a successful result is to be achieved;specialist contractors are normally employed. The foam can be introduced into the cavity by means of 25 mm bore holes spaced 1.000m apart in all directions or by direct introduction into the open end of the cavity. The foam is a white cellular material containing approximately 99% by volume of air with open cells. The foam is considered to be impermeable and therefore unless fissures or cracks have ocurred during the application it will not constitute a bridge of the cavity, in the practical sense, but a relaxation of Building Regulation C9 (2) may be required. In most cases the foam, upon setting, shrinks away from the inner face of the outer leaf enabling any water penetrating the outer leaf to run down the inside face of the external skin.
The most effective method of improving thermal comfort conditions within a building is by fixing insulating materials at the outside position of the surface. Thermal insulation for buildings other than dwellings are covered by separate legislation.

11.3 SOUND INSULATION

11.3. Sound insulation

11.3.1 Definition

Anything that can be heard is a sound, whether it is made by conversation, machinery, or walking on a hard surface. All sounds are produced by a vibrating object which moves rapidly to and fro causing movement of the tiny particles of air surrounding the vibrating source. the displaced air particles collide with adjacent particles setting them in motion and in unison with the vibrating object. Air particles move only to and fro but the sound wave produced travels through the air until at some distance from the source the movement of the particles is so slight that the sound produced is inaudible.
For a sound to be transmitted over a distance a substance, called the sound medium, is required. It can be shown by experiments that sound cannot travel through a vacuum but it can be transmitted through solids and liquids.
Sounds can differ in two important ways, by loudness and by pitch. The loudness of a s ound depends on the distance through which the vibrating object moves to and fro as it vibrates; the greater the movement the louder the sound. The loudness with which a sound is heard depends upon how far away from the source the receiver or ear is. The unit of subjective loudness is a phon whilst the objective unit is called a decibel.

Although the loudness of a sound will vary with the frequency of the note for practical building purposes, the phon and the decibel are considered to be equal over the range of 0 phons, the threshold of hearing, to 130 phons the threshold of painful hearing.
The pitch of a sound depends on the rate at which the vibrating object oscillates. The number of vibrations in a second is called the frequency and the higher the frequency the higher the pitch. The lowest pitched note that the human ear can hear has a frequency of approximately 16 hertz whereas the heighest pitched note which can be heard by the human ear has a frequency of approximately 20.000 hertz or cycles per second.
When a sound is produced within a building three reactions can occur:
1. The pressure or sound waves can come into contact with the walls, floor and cailing and be reflected back into the building.
2. Some of the sound can be absorbed by these surfaces and/or the furnishes. It mustbe noted that sound absorption normally only benefits the occupants of the room in which the sound is generated since its function is to reduce the amount of reflected sound.
3. The sound waves upon reaching the walls, floor and ceiling can set these members vibrating in unison and thus transmit the sound to adjacent rooms.
It must also be noted that sounds can enter a building from external sources such as traffic and low flying aircraft (see fig.)

Sounds may be defined as either impact sounds, caused by direct contact with the structure such as footsteps and hammering on walls which will set that part of the structure vibrating, or they can be termed airborne sounds, such as the conversation or radio which sets the structure vibrating only when the sound waves emitted from the source reach the struc-

tural enclosure.
A noise can be defined as any undesired sound and may have any one of the following four effects on man:

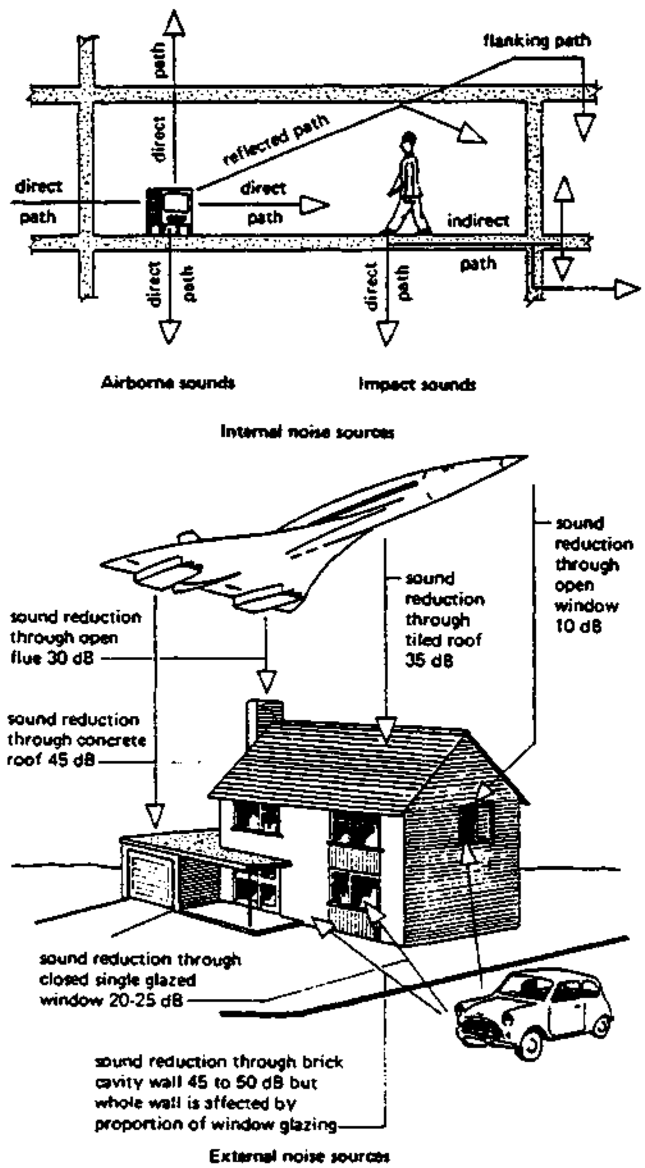
1. Annoyance
2. Distrubance of sleep
3. Interfere with the ability to hold a normal conversation.
4. Damage his hearing.

It is difficult to measure annoyance since it is a subjective attitude and will depend upon the mental and physical well being of the listener, together with the experience of being subjected to such types of noise.
Damage to hearing can be caused by a sudden noise such as a loud explosion or by gradual damage resulting from continual noise over a period of years.
The solution to noise or sound problems can only therefore be reasonable to cater for the average person and conditions.
The approach to solving a noise problem can be three-fold:

1. Reduce the noise emitted at the source by such devices as mufflers and mounting machinery on resilient pads.
2. Provide a reasonable degree of sound insulation to reduce the amount of sound transmitted.
3. Isolate the source and the receiver.

11.3.2 Sound Insulation

The most effective barrier to the passage of sound is a material of high mass. With modern materials and methods this form of construction is both impracticable and uneconomic. Unfortunately modern living with its methods of transportation and entertainment generates a considerable volume of noise and therefore some degree of sound insulation in most buildings is desirable.



Sources of noise within and around buildings

EXTERNAL NOISE

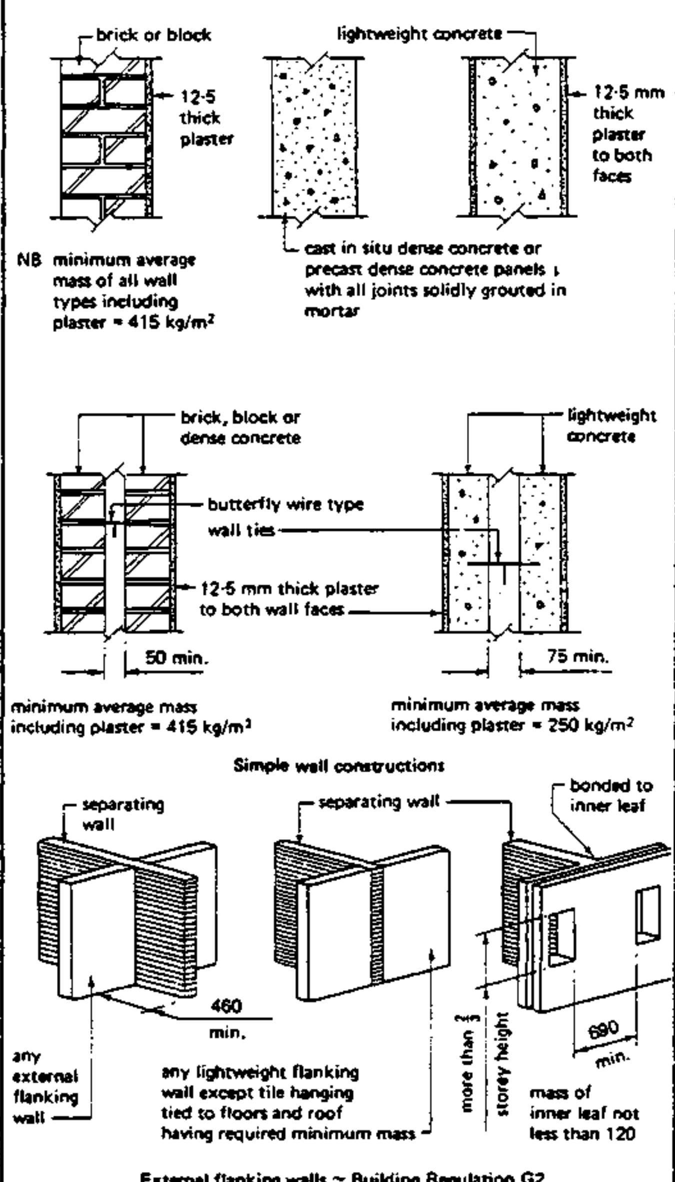
11.3.3 External noise

Another aspect of sound insulation which, although not covered by Building Regulations, requires consideration is insulation against external noise.

The main barrier to external noise is provided by the shell or envelope of the building, the three main factors being:

1. The mass of the enclosing structure.
2. The continuity of the structure.
3. Isolation by double leaf construction when using lightweight materials.

Generally the main problem for the insulation against external noise is the windows, particularly if these can be opened for ventilation purposes. Windows cannot provide the dual function of insulation against noise and ventilation, since the admission of air will also admit noise. Any type of window when opened will give a sound reduction of about 10 decibels as opposed to the 45 -50 decibel reduction of the traditional cavity wall. A closed window containing single glazing will give a reduction of about 20 decibels or approximately half that of the surrounding wall. It is obvious that the window to wall ratio will affect the overall sound reduction of the enclosing structure.



External flanking walls ~ Building Regulation G2

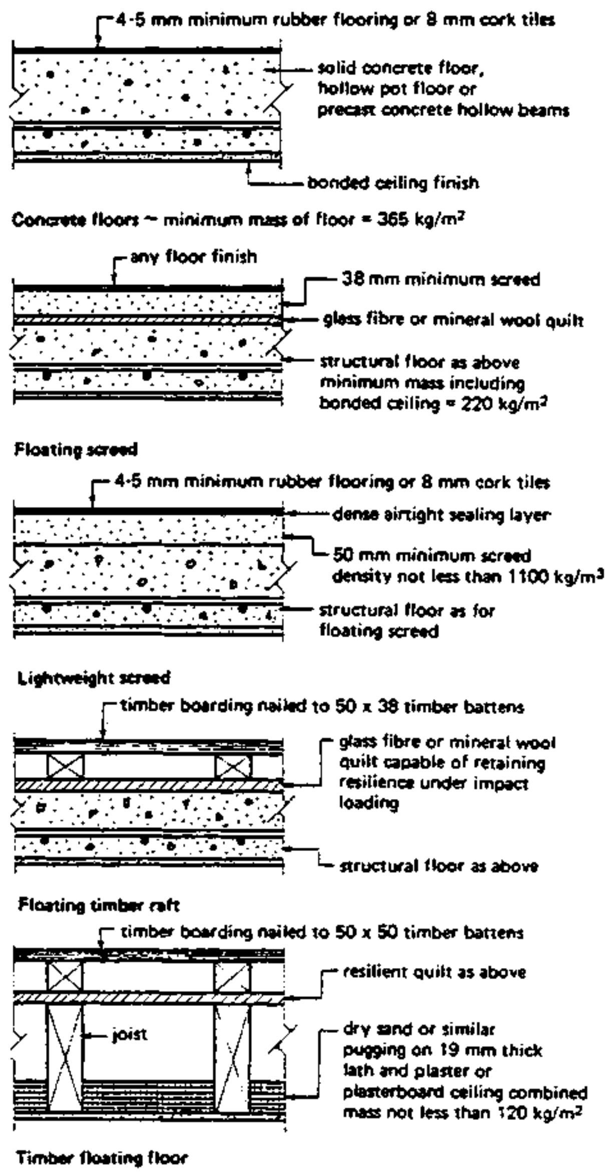
Sound insulation ~ walls

EXTERNAL NOISE

Double glazing can greatly improve the sound insulation properties of windows provided the following points are observed:

1. Sound insulation increases with the distance between the glazed units; for a reduction of 40 decibels the airspace should be 150-200 mm wide.
2. If the double windows are capable of being opened they should be weather-stripped.
3. Sound insulation increases with glass thickness particularly if the windows are fixed; this may mean the use of special ventilators having specific perfomances for ventilation and acoustics.
4. Double glazing designed to improve the thermal properties of a window have no real value for sound insulation.

Roofs of traditional construction and of reinforced concrete generally give an acceptable level of sound insulation, but the inclusion of rooflights can affect the resistance provided by the general roof structure. Lightweight roofing such as corrugated asbestos will provide only a 15-20 decibel reduction but is generally acceptable on industrial buildings where noise is generated internally by the manufacturing processes. The inclusion of rooflights in this type of roof generally has no adverse effects since the sound insulation values of the rooflight materials are similar to those of the coverings.
Modern buildings can be designed to give reasonable sound insulation and consequent comfort to the occupiers but the improvement to existing properties can present problems.



Sound insulation – floors

11.4 FIRE PROTECTION

11.4. Fire Protection

The precautions which can be taken within buildings to prevent a FIRE occuring, or, if it should occur, of containing it within the region of the outbreak, providing a means of escape for people in the immediate vicinity and fighting the fire can be summarized under three headings:

1. Structural fire protection
2. Means of escape in case of fire
3. Fire fighting

FIRE FIGHTING, which is generally integrated with the services of a building, is usually considered in that context and therefore NOT included in this text, as well as MEANS OF ESCAPE IN CASE OF FIRE, which is in the first instance a problem of designing and planning, rather than a problem of building construction.

11.4.1 Structural Fire Protection.

The purpose of structural fire protection is to ensure that during a fire the temperature of structural members or elements does not increase to a figure at which their strength would be adversely affected. It is not practicable or possible to give an element complete protection in terms of time, therefore elements are given a fire resistance for a certain period of time which it is anticipated will give sufficient delay to the spread of fire, ultimate collapse of the structure, time for persons in danger to escape and to enable fire fighting to be commenced.

Before a fire-resistance period can be determined it is necessary to consider certain factors:

1. Fire load of the building.
2. Behaviour of materials under fire conditions.
3. Behaviour of combinations of materials under fire conditions

11.4.1.1 Fire Load

Buildings can be graded as to the amount of overall fire resistance required by taking into account the following.

1. Size of building
2. Use of building
3. Fire load.

The fire load is an assessment of the severity of a fire due to the combustible materials within a building. This load is expressed as the amount of heat which would be generated per unit area by the complete combustion of its contents and combustible members and is given in Joules per square metre. It should be noted that the numerical grade is equivalent to the minimum number of hours fire resistance which should be given to the elements of the structure.

GRADE 1 Low fire load, not more than 1 150 MJ/m2. Typical buildings within this grade are flats, offices, restaurants, hotels hospitals, schools, museums and public libraries.

GRADE 2 Moderate fire load, 1 150to 2 300MJ/m2. Typical examples are retail shops, factories and workshops.

GRADE 4 High fire load, 2 300 to 4 600 MJ/m2. Typical exemples are certain types of workshops and warehouses.

When deciding the grade no account is taken of the effects of any permanent fire protection installations such as sprinkler systems.

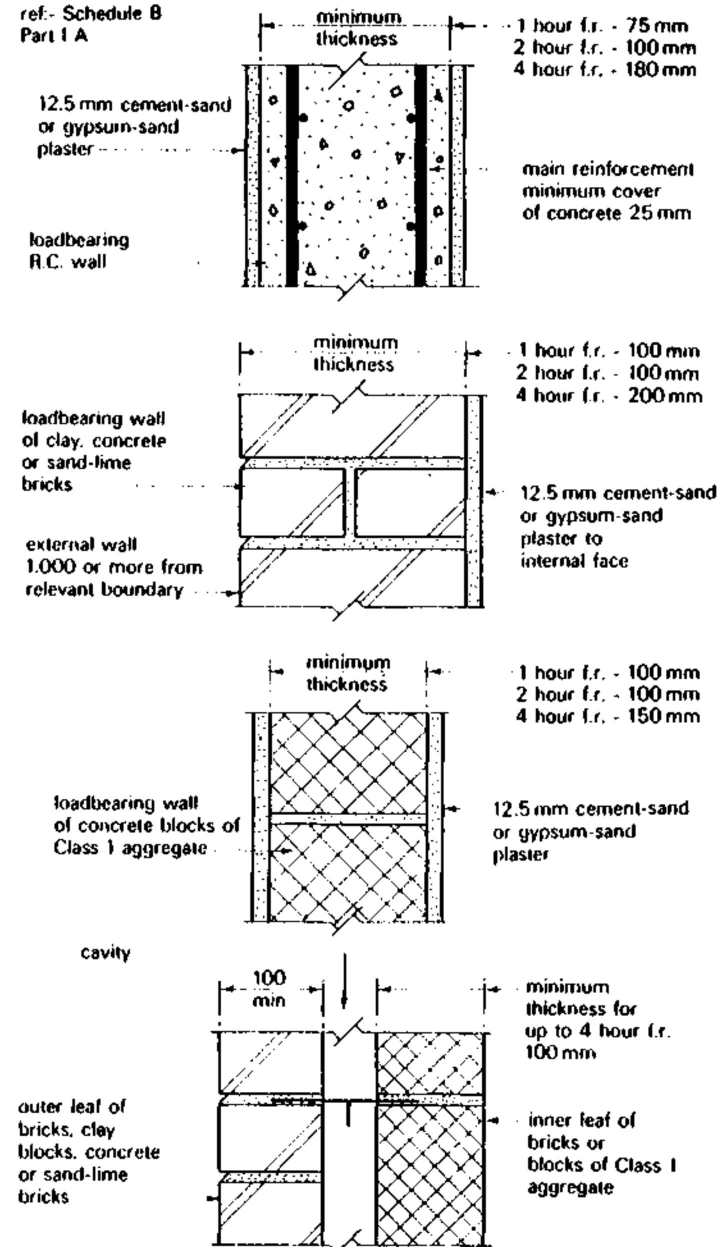
11.4.1.2 Fire Resistance of Material

The materials used in buildings can be studied as separate entities as to their behaviour when subjected to the intense heat encountered during a fire and as to their ability to spread fire over their surfaces. Structural steel is not considered to behave well under fire conditions although its ability to spred fire over its surface is negligible. As the fire progresses and the temperature of steel increases there is an actual gain in the ultimate strength of mild steel . This gain in strength decreases back to normal over the temperature range of 250to 400°C. The decrease in strength continues and by the time the steel temperature has reached 550oC it will have lost most of its useful strength. Since the rise in temperature during the initial stages of a fire is rapid this figure of 550oC can be reached very quickly. If the decrease in strength results in the collapse of a member the stresses it was designed to resist will be redistributed; this could cause other members to be overstressed and progressive collapse could occur. Reinforced concrete structural members have good fire resistance properties, and being noncombustible do not contribute to the spread of flame over their surfaces. It is possible however under the intense and prolonged heat of a fire that the bond between the steel reinforcement and the concrete will be broken. This generally results in spalling of the concrete which decreases both the protective cover of the concrete over the steel and the cross sectional area. Like structural steel members, this can result in a redistribution of stresses leading to overloading of certain members, culminating in progressive collapse. Timber, strange as at may seem, behaves very well structurally under the action of fire. This is due to its slow combustion rate, the strength of its core failure remaining fairly constant. The ignition temperature of timber is low (250-300oC) but during combustion the timber chars at an approximate rate of 0.5 mm per minute, the layer charcoal so formed slows down the combustion rate of the core. Although its structural properties during a fire are good, timber being an organic material and therefore combustible, will spread fire over its surface which makes it unsuitable in most structural situations without some form of treatment.

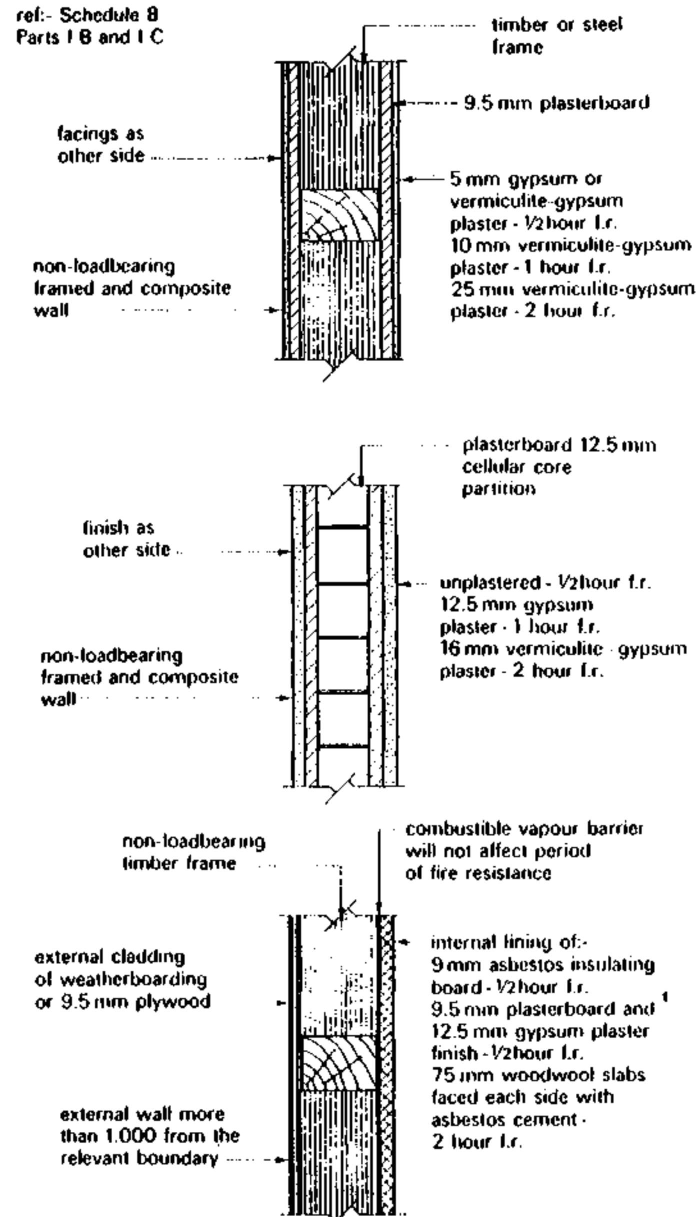
11.4.1.3 Appropriate Types of Construction.

BS 476, Part 8 and Schedule 8 give appropriate types of construction for various notional periods of fire resistance for WALLS, BEAMS, COLUMNS and FLOORS. Schedule 8 of the Building Regulations gives in written and tabulated form various methods of providing the required protection which needs to be translated into working details. The following figures show typical examples taken from this schedules.

WALLS

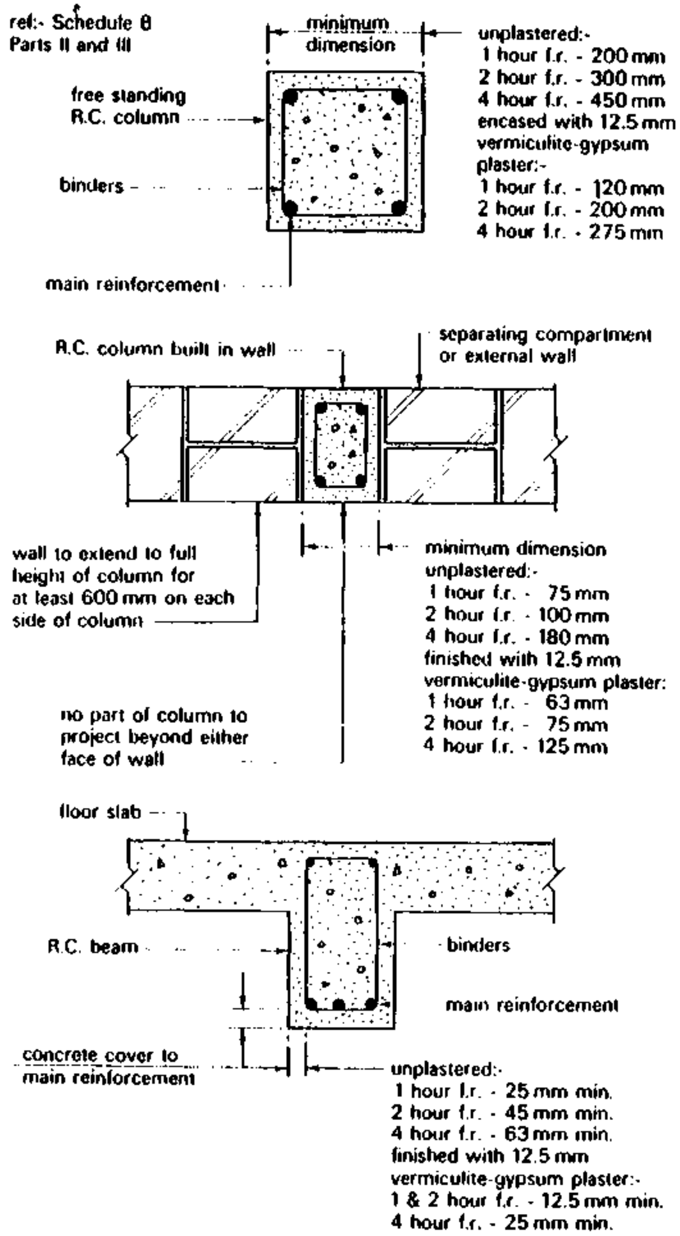


Fire Resistance—walls of masonry construction

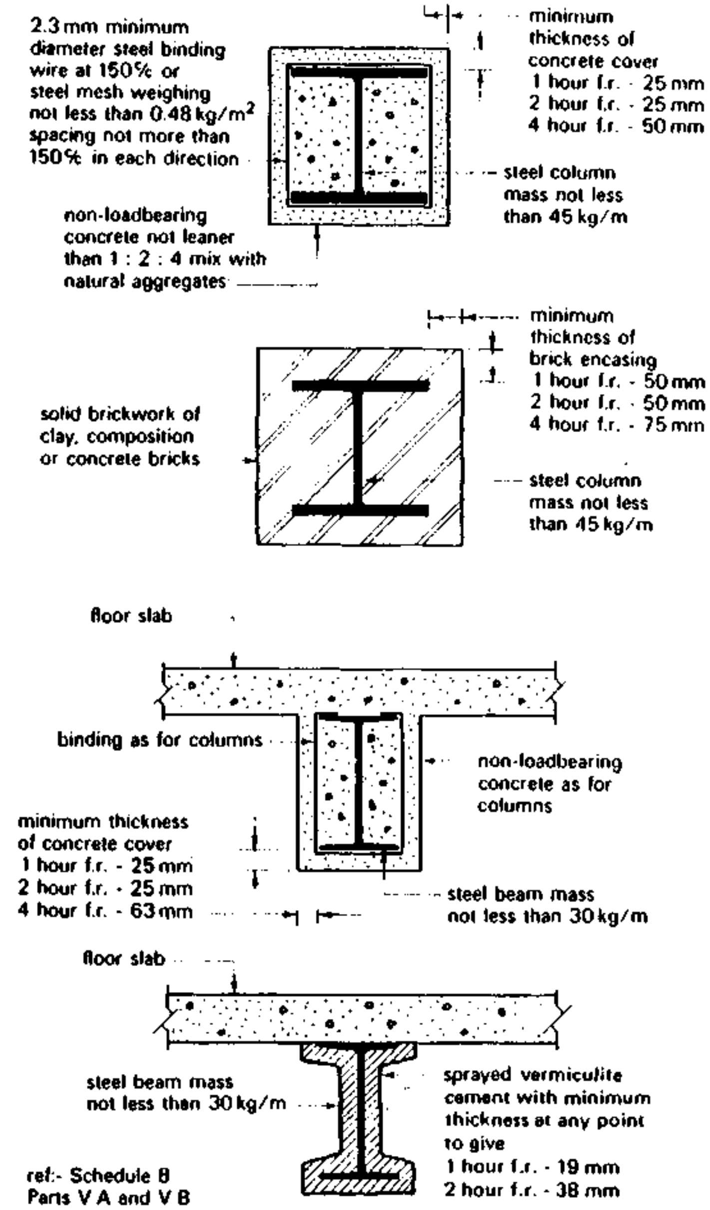


Fire resistance—framed and composite walls

● COLUMNS & BEAMS

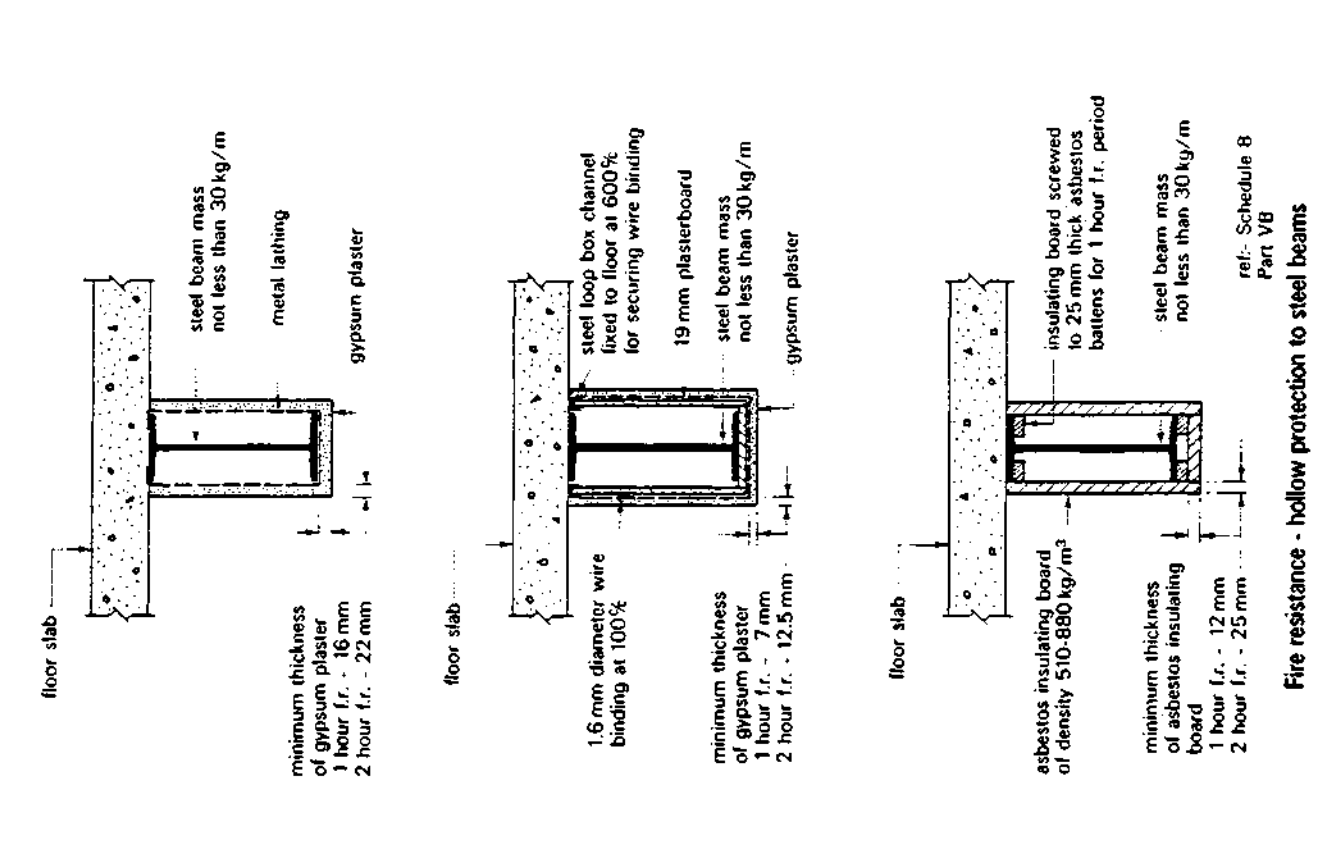


Fire resistance—R.C. columns and beams

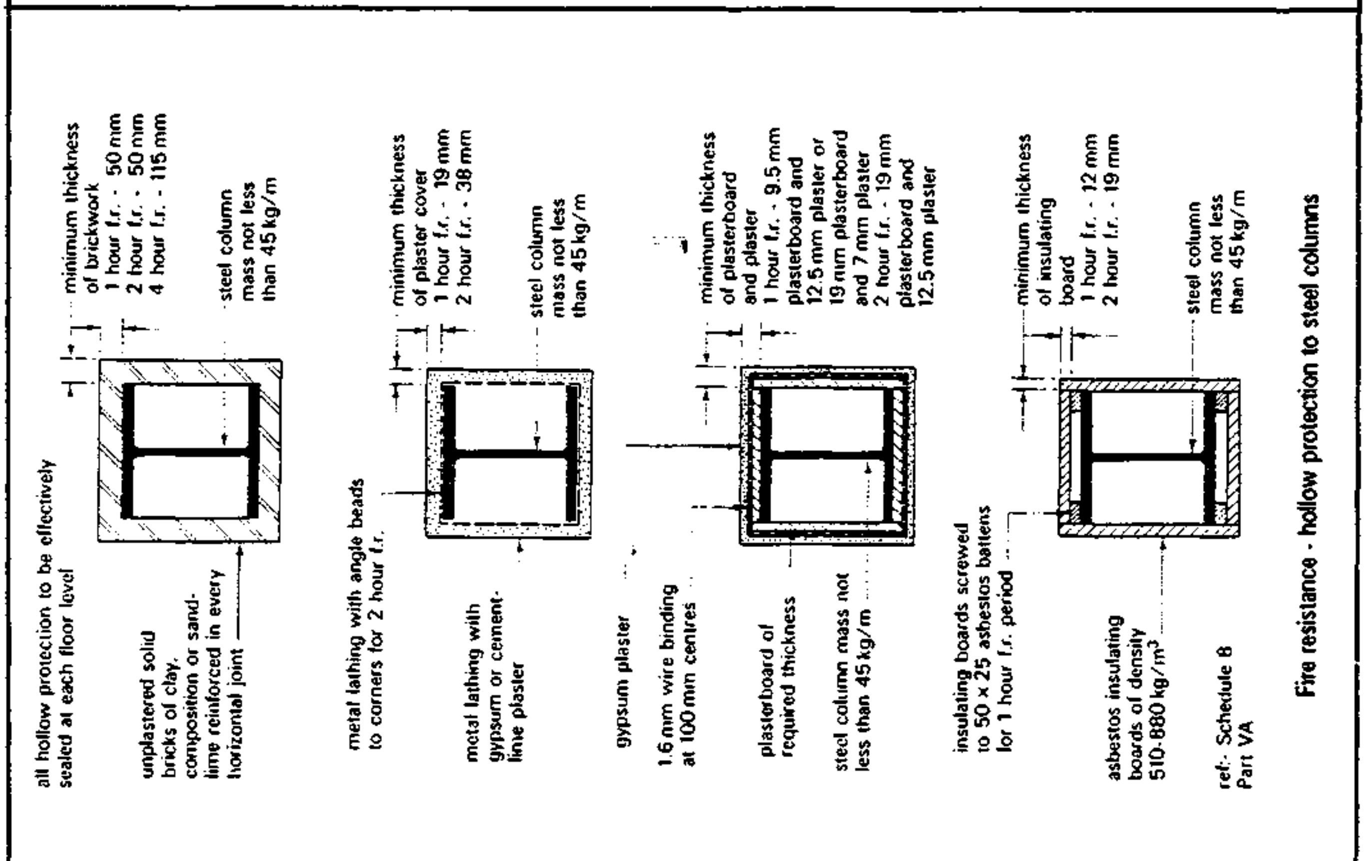


Fire resistance—steel columns and beams

● COLUMNS & BEAMS



Fire resistance - hollow protection to steel beams



Fire resistance - hollow protection to steel columns

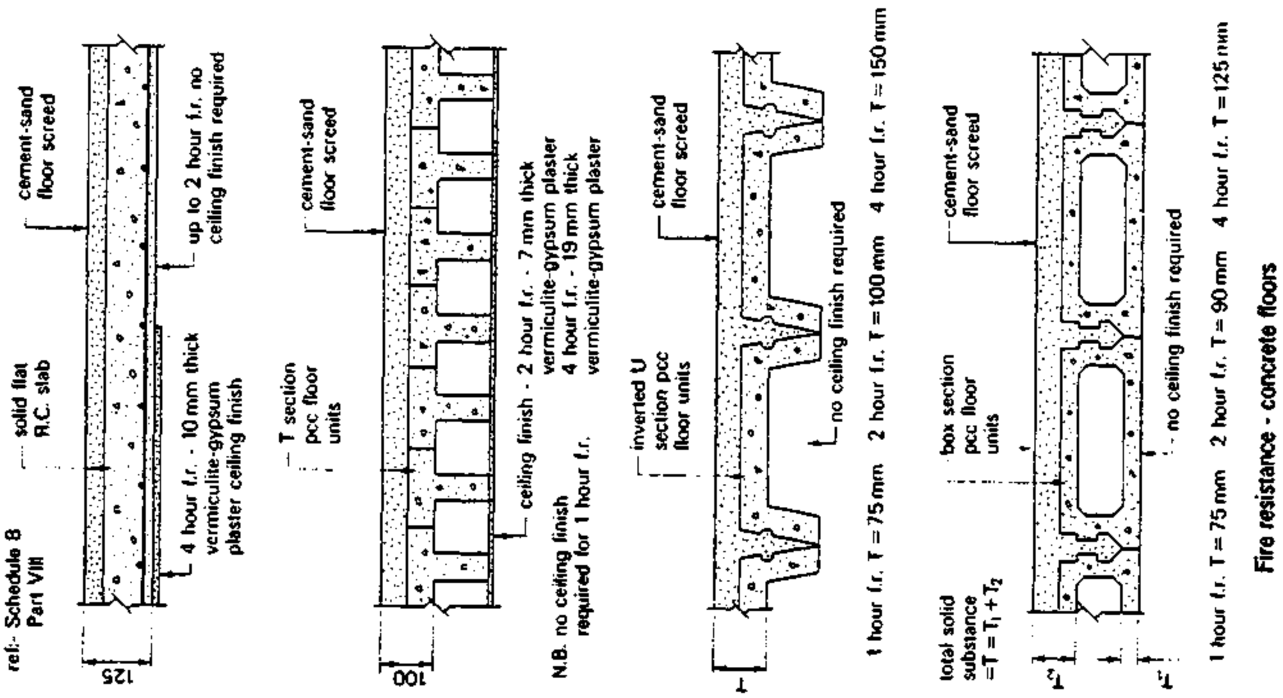
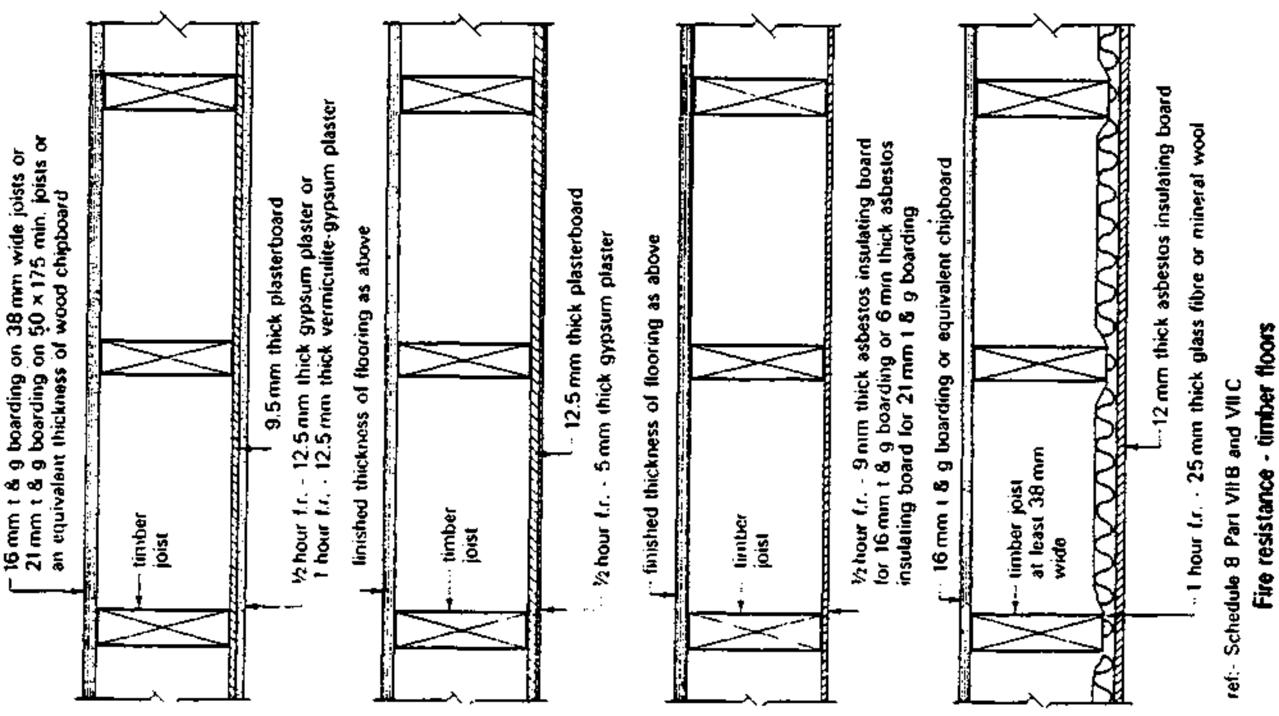
• FLOORS



Fire resistance - concrete floors



Fire resistance - timber floors

●●REPETITION ● exercises ● REPETITION ●●

Try to answer the following QUESTIONS and practice sketching where ever necessary and possible.

1. Exclusion of Water
   - Why must WATER be totally excluded from the interiors of buildings;
   - What are the three main sources of MOISTURE in buildings?
   - Write notes on PRECIPITATION!
   - Describe different ways of ROOF DRAINAGES!
   - Describe damages caused by FLOODING!
   - Where can DROUGHT occur and what does it cause;
   - Which two methods of MOISTURE CONTROL are normally employed?

2. Thermal Insulation
   - Define the term THERMAL INSULATION
   - In which three ways can the TRANSFER OF HEAT occur?
   - What are the ADVANTAGES OF thermal insulation of buildings?
   - Which factors are important in selecting or specifying thermal insulating materials?
   - List and describe different insulating materials

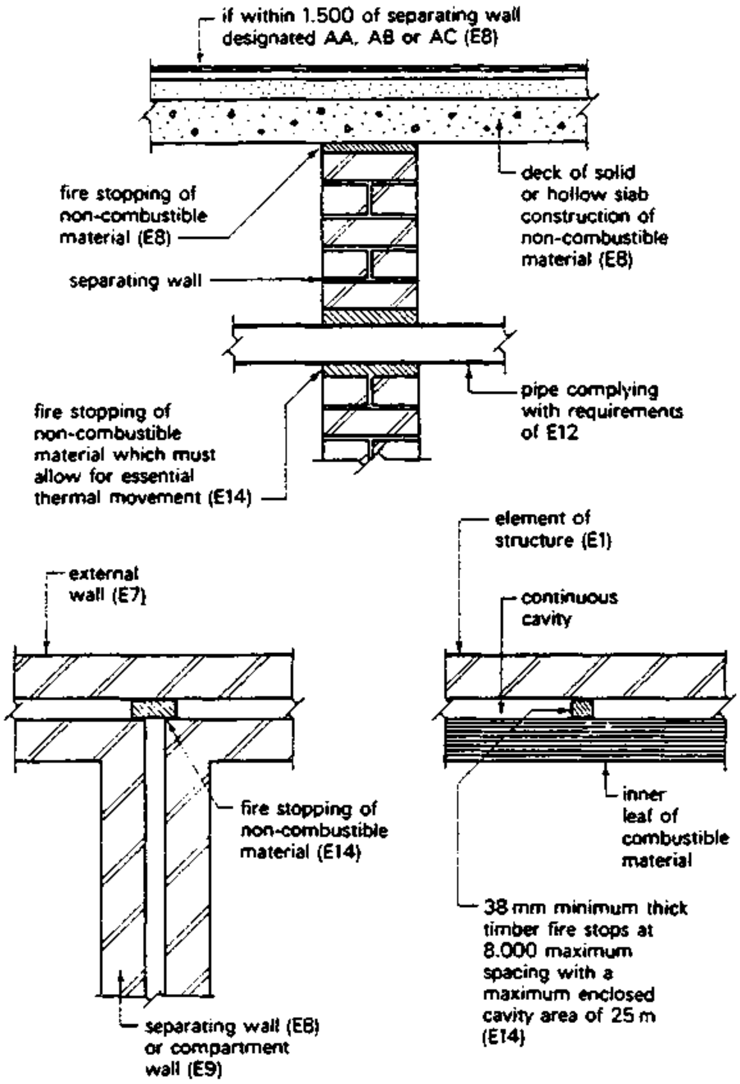
3. Sound Insulation
   - Define the following terms:

. Sound	. internal noise sources
. Pitch	. external noise sources
. Loudness	. airborn sounds
. Frequency	. impact sounds

   - What is the most effective barrier to the passage of sound through materials?
   - Explain in the form of neat sketches examples of Sound insulation in
     a WALLS
     b FLOORS
   - Write notes on EXTERNAL NOISE!

4. Fire Protection
   - What are the three main fields of FIRE PROTECTION?
   - Write notes on STRUCTURAL FIRE PROTECTION!
   - Define the term FIRE LOAD
   - List different building materials and describe their behaviour under intense heat or fire.

Building Reg. E1 — fire stop means a barrier or seal which would prevent or retard the passage of smoke or flame within a cavity, around a pipe where it passes through a wall or floor or at junctions between elements of structure



- Show in the form of neat sketches typical examples of working details for the fire protection of:
  - . Walls of masonry construction
  - . Framed and composite walls
  - . R. C. columns and beams
  - . Steel columns and beams
  - . Hollow protection to steel columns
  - . Hollow protection to steel beams
  - . Timber floors
  - . Concrete floors

12.FINISHING &. FINISHES

12.1 EXTERNAL WALL FINISHES

12.1 EXTERNAL WALL FINISHES

External brickwork with an exposed face of facing bricks is a SELF FINISH and requires no further treatment.

External walls of common bricks or blocks can be treated to give an acceptable appearance by the application of PAINT, an application wall finish such as RENDERING or can be CLAD with boards or tiles.

EXTERNAL RENDERING

12.1.1 External Rendering
This is a form of plastering using a mixture of cement and sand, or cement, lime and sand, applied to the face of a building to give extra protection against the penetration of moisture or to provide a desired texture. It can also be used in the dual capacity of providing protection and appearance.
The rendering must have the properties of
- durability
- moisture resistence
- an acceptable appearance

The sucess of the rendering depends on
- the nature of the background
- the quality of the mix
- the location of the work
- the method of application.

. Good quality brick - or blockwork with raked joints and locked surface will give good results if the wall is wetted to reduce heat and suction.
. SPATTERDASH, i.e. cement and sand slurry 1:3 on concrete walling gives good results in bonding.

. The mix of materials is as important as their quality. Cement and sand mixes will produce a strong moisture resistant rendering but one which is subject to cracking due to high drying shrinkage.(These mixes are used mainly on members which may be vulnerable to impact damage such as columns.)
Cement, lime and sand mixes have a lower drying shrinkage but are more absorbent than cement and sand mixes; they will, however, dry out rapidly after periods of rain and are therefore the mix recommended for general use.

EXTERNAL RENDERING

Two common volume mix ratios are:
a)1:1/2 : 4-4 1/2
cement:lime:sand,
which is used for dense, strong backgrounds of moderate to severe exposure and for application to metal lathing or expanded metal backgrounds.
b)1 : 1 : 6-8
cement : lime : sand
which is for general use.

a) 1:1/2 : 4-4 1/2

b) 1 : 1 : 6-8

- The number of coats required will depend upon the surface condition of the background and the degree of exposure. Generally a TWO COAT application is acceptable, except where the background is very irregular or the building is in a position of severe exposure when a three coat application would be specified.
  The thickness of any one coat should not exceed 15 mm and each subsequent coat is about 5 mm thick.
- Finishes should be floated, not trowelled smooth.
- Various textured surfaces can be obtained on renderings by surface treatments such as scraping the surface with combs, saw blades or similar tools to remove a surface skin of morter. These operations are carried out some three to four hours after the initial application of the rendering and before the final set takes place.

EXTERNAL RENDERING

- Alternative treatments are:

1. ROUGHCAST: a wet plaster mix of 1 part cement : 1/2 part lime : 1 1/2 parts shingle : 3 parts sand, which is thrown on to a porous coat of rendering to give an even distribution.
2. PEBBLEDASH: selected aggregate such as pea shingle is dashed or thrown on to a rendering background before it has set and is tamped into the surface with a wood float to obtain a good bond.
3. SPATTERED FINISHES: these are finishes applied by a machine (which can be hand operated), guns or sprays using special mixes prepared by the machine manufacturers.
4. TYROLEAN FINISH: it consists of 3 coats alltogether.
   1.coat: 1part waterproof cement
   2 parts of sand
   (applied as spatter dash)
   2.coat: 1part of cement
   1part of lime
   8parts of sand
   (15mm thick)
   3.coat: 1part cullamix or snowcrete Tyrolean grade,2 1/2 parts sand applied by a special hand machine, which flips the mix evenly over the wall

   It provides a pleasing and waterproof finish.

MATERIALS

- Quality of materials:
  - sand: should be washed, if dirty and thrown through a sieve.
  - lime: should be well burned and free from unslaked particles.
  - cement: can be a problem, because the quality of local factories is not always in conformity with B.S.
    Therefore the local cement should be tested and compared with B.S. Specifications.
    The most practical test, however, is to lay a sample panel of specified rendering on a wall as soon als the job begins and note the result some month later.

12.1.2 Concrete Finishes

There are a number of methods of finishing concrete walls apart from rendering or painting. The main treatments are to:

- leave it untouched after striking the shuttering
- use formwork other than timber
- use a retarding agent
- make a punched or tooled finish
- make patterns on the formwork.

. The texture of the finish created by the formwork depends on the boards used and the quality of the workmanship.

. Hardwood does not produce the grain effects of soft wood.

. Boards are more difficult to "true up" owing to poor seasoning and warping of timber.

. Tight joints in concrete should be ensured and boards levelled up to the same height.

. Day joints in concrete must be carefully constructed.

. Fins of concrete should be removed immediately the formwork is struck and the whole tubbed down with carborundum.

. Mortar to repair blemishes should be of lighter texture than the concrete it self otherwise it will dry darker. - It should be floated - not trowelled smooth.

. Corrugated metal shuttering is frequently used for effect and comes away easily.

. Plastic-moulded forms produce effects but are expensive.

. Retarding agents are normally brushed on to the formwork before concreting is started, and must be applied evenly. After striking, the concrete surface is brushed to expose the aggregate.

. A tooled finish is normally achieved by electric or pneumatic hammers with special heads. The can be varied to suit the texture required. Bush hammering is a favourite finish. Hand-tooling is done where labour is cheap, or where mechanical hammers could damage corners.

. Care should be taken that tooling does not expose the reinforcement.

CLADDING

12.1.3 Cladding

The term CLADDING is used when thin concrete, stone, granite, marble or slate is employed as a facing in addition to the normal structural requirements. It should not be fixed too tightly to the structure, for some measure of give must be allowed so that the cladding does not bear the strain of the finished construction.

ADVANTAGES

Cladding has several advantages over traditional types of construction.

1. The units can be prepared in a factory, where their production is not hampered by bad weather conditions, and where good quality control can be maintained.

2 They can be produced in readiness for fixing while the framework is being built.

3 The units do not carry any structural loads (other than their own weight) and therefore they may be comparatively thin.

4 A wide variety of surface finishes is available

5 The framework and internal lining can be erected comparatively quickly, so that the internal finishes and services can be put into operation very soon after fixing the external cladding.

Certain points, however, must be observed if failures are to be avoided with this type of construction. Some, of course, are the responsibility of the designer, but the cladding fixer must also play his part by making certain that the fixings are securely made and that all types of joints are constructed in accordance with approved practice.

CLADDING

Important points for the designer:
He should:

1 allow for the thermal movement of the structure
2 allow for movement due to drying shrinkage (The finxing of the slabs should not be started too soon after the main structure. Some time must be allowed for the shrinkage in the framework to take place)
3 allow for elastic deformation particularly with wind loading on tall slender buildings.
4 allow for creep, which is a gradual compression of the structure due to sustained stress. Great care must be, therefore, taken with the compression joints.
5 allow for uneven settlement of the structure
6 avoid the use of a cladding material which is too thin, thus preventing adequate and safe fixing methods from being used
7 provide well designed cramping details
8 ensure that bonder courses or other means of supporting the weight of the cladding are provided at each storey height
9 avoid using slabs of too large an area which would reduce the number of joints and probably absorb movement
10 specify the correct metal for the fising cramps.

Important points for the cladding fixer:
He should:

1 point the joints thoroughly to prevent the percolation of water behind the slabs (This will have a particularly harmful effect in the winter if the water freezes)
2 use the correct type of fixing cramps as specified and not substitute different types or metals

3 make certain that the bonders or supporting nibs are well constructed

4 ensure accurate setting out of the fising holes and slots

5 not use hard mortars for the joints

6 have sufficient thickness of the joints

7 construct expansion and compression joints in accordance with the designer's requirements

8 ensure that the correct gap is maintained at a maximum of 18 mm and a minimum of 6mm. (If these limits are exceeded then the cramps will be either too short or too long and liable to lead to makeshift adaptations)

9 Take precautions against rusting of the reinforcement, which might cause damage to the cladding, if for any reason the concrete structural wall has to be cut back.

for the designer

for the cladding fixer

CLADDING

Cramps and other fixings

These should be made from:

1 non-ferrous metal, for example copper, gun-metal, phosphor bronze

2 stainless steel alloys

3 sherardised steel.

It is preferable that all the fixings on each job are of the same metal to prevent the possibility of electrolytic action taking place between dissimilar metals. This is likely to cause deterioration in at least one of the metals. Iron or steel are not generally suitable for use as cramps or fixings even though they may be coated, as the coating may become damaged and allow the steel to rust and cause staining on the cladding surface, or expansion which is likely to damage the cladding at the joints, or by spalling of the surface.

Cramp holes or mortices.

These should be cut or drilled in the cladding without fracturing or spalling the material immediately surrounding the hole.
Claddings to buildings can be considered under two classifications

1 Claddings fixed to a structural backing

2 Claddings to framed structured.

CLADDINGS fixed to a STRUCTURAL BACKING

12.1.3.1 CLADDINGS FIXED TO A STRUCTURAL BACKING

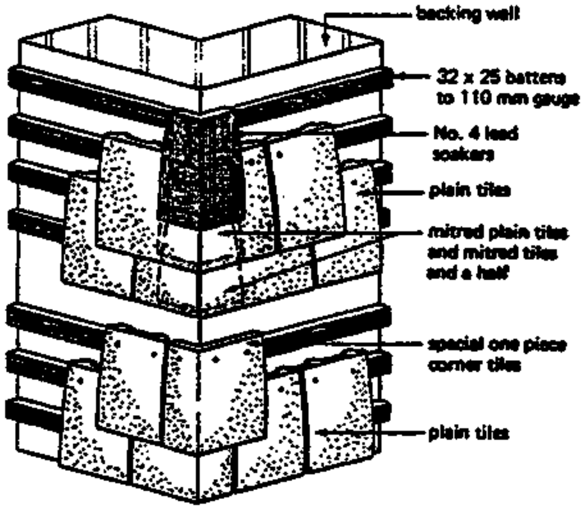
Materials used in this form of cladding are generally considered to be small unit claddings and are applied for one of two reasons. If the structural wall is unable to provide an adequate barrier to the elements a covering of small unit claddings will generally raise the wall's resistance to an acceptable level. Alternatively small unit claddings can be used solely as a decorative feature, possibly to break up the monotony of a large plain area composed of a single material.

The materials used are tiles, slates, shingles, timber boarding, plastic boards and stone facings. The general method of fixing these small units is to secure them to timber battens fixed to the structure backing.

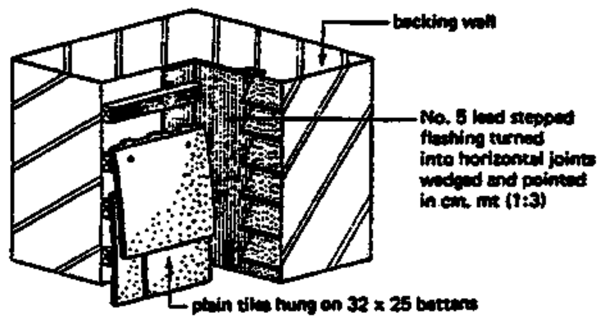
TILE HANGING

- TILE HANGING

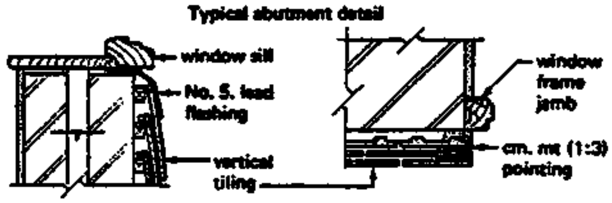
The tiles used in tile hanging can be ordinary plain roofing tiles or alternatively a tile of the same dimensions but having a patterned bottom edge solely for a decorative appearance. The tiles are hung and fixed to tiling battens although nibless tiles fixed directly to the backing wall are sometimes used (see Fig.) The battens should be impregnated to prevent fungi and isect attack so that their anticipated life is comparable to that of the tiles. Each tile should be twice nailed to its support batten with corrosion resistant nails of adequate length.



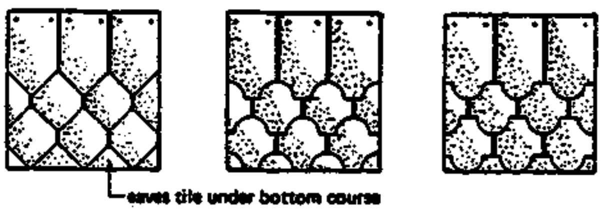
Alternative external angle treatments (internal angles treatments similar)



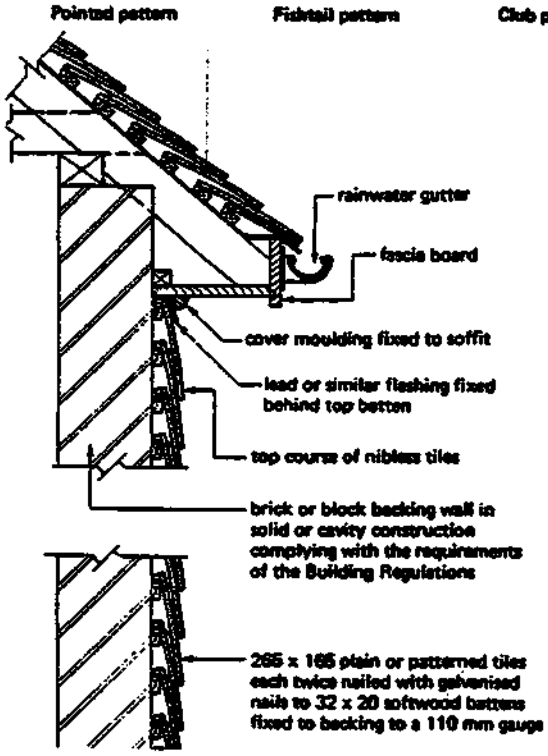
Typical abutment detail



Typical opening details



Pointed pattern — Fishtail pattern — Club pattern



The general principles of tile hanging are similar to those of double lap roof tiling and the gauge is calculated in the same manner. The minimum lap recommended is 40 mm which would give a gauge of 112.5 mm using a standard 265 long tile.

A gauge dimension of 112.5 mm is impracticable and therefore a gauge of 110 mmwould be usual.

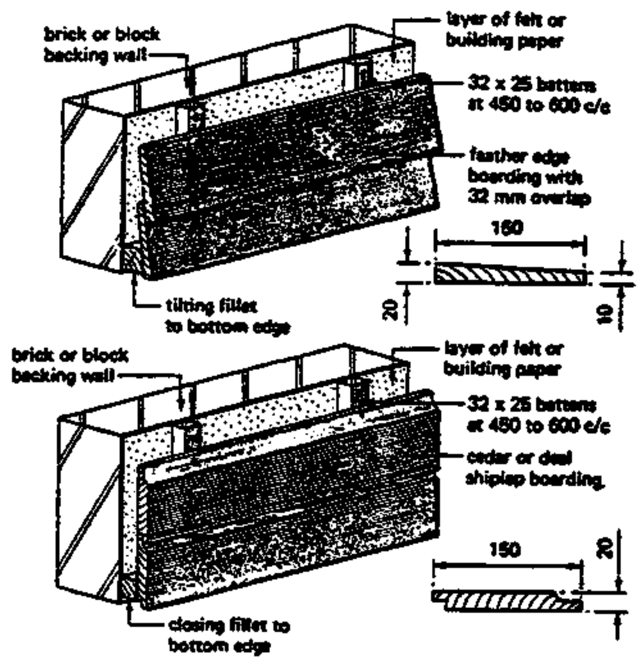
TILE HANGING

Typical details of top edge finishes, bottom edge finishes corners and finishes at windows are shown in the fig.
It should be noted that if the structural backing is of timber framing a layer of impervious felt should be placed over the framing immediately underneath the battens to prevent any moisture which is blown in between the tiles from having adverse effects upon the structure. In this situation building paper is not considered to be a suitable substitute. The application of slates as a small unit hung cladding follows the principles outlined above for tile hanging.

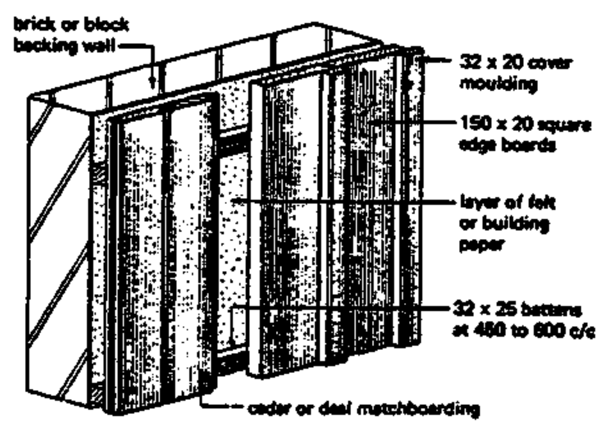
TIMBER CLADDINGS

- TIMBER CLADDINGS

Timber claddings are usually in the form of moulded or shaped boards fixed to battens as either a horizontal or vertical cladding. Timber claddings will require regular maintenance to preserve their resistance to the elements. Softwoods are generally painted and will need repainting at intervals of three to five years according to the exposure. Hardwoods are sometimes treated with a preservative and left to bleach naturally; the preservative treatment needs to be carried out at two-to five-year intervals. Western red cedar is a very popular wood for timber cladding since it has a natural immunity to insect and fungi attack under normal conditions. It also has a pleasing natural red/brown colour which can be maintained if the timber is coated with a clear sealer such as polyurethane, however, it will bleach to a grey/white colour if exposed to the atmosphere. Plastic boards are a substitute for timber and are fixed in a similar manner.



Typical horizontal claddings



Typical vertical cladding

CLADDINGS to FRAMED STRUCTURES

12.1.3.2 CLADDINGS TO FRAMED STRUCTURES

Claddings are a form of masking or infilling a structural frame and can be considered under the following headings:

1 Panel walls with or without attached facings

2 Concrete and similar cladding panels..

3 Light infill panels

4 Curtain walling which can be defined as a sheath cladding which encloses the entire structure

All forms of cladding must fulfil the following functions:

1 Be self supporting between the framing members

2 Provide the necessary resistance to rain penetration.

3 Be capable of resisting both positive and negative wind pressures.

4 Provide the necessary resistance to wind penetration

5 Give the required degree of thermal insulation

6 Provide the required degree of sound insulation to suit the building type.

7 Give the required degree of fire resistance

8 Provide sufficient openings for the admittance of natural daylight and ventilation

9 Be constructed to a suitable size.

BRICK PANEL WALLS

- BRICK PANEL WALLS

These are non-load bearing walls which must fulfil the following requirements:

1 Adequate resistance to the elements

2 Have sufficient strength to support their own self weight plus any attached finishes.

3 Strong enough to resist both positive and negative wind pressures

4 Provide the required thermal and sound insulation.

5 Provide the required fire resistance

6 Have adequate durability

BRICK PANEL WALLS

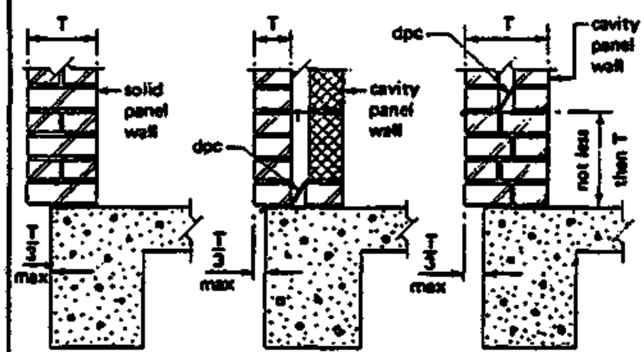
Brick panel walls are constructed in the same manner as ordinary solid or cavity walls and any openings for windows or doors are formed by traditional methods. The panels must be supported at each structural floor level and tied to the structure at the vertical edges. Projection of the panel in front of the structural members is permissible providing such overhangs do not impair the stability of the panel wall; acceptable limits are shown in the fig. The top edge of the panels should not be pinned rigidly to the frame since the effect of brick panel expansion together with frame shrinkage may cause cracking and failure of the brickwork. A compression joint should therefore be formed between the top edge of the panel and the underside of the framing member at each floor level (see fig.)

Two methods of tying the panel to the vertical structural members are in common use:

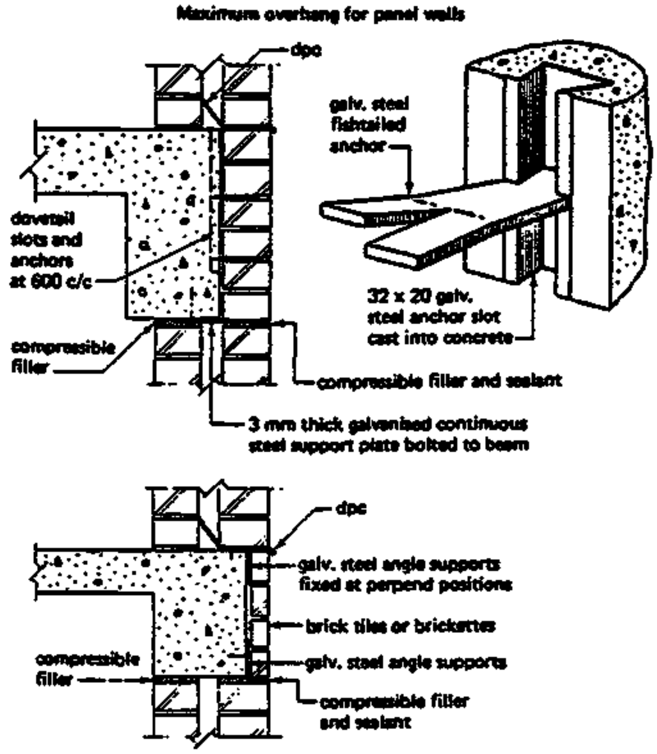
1 Butterfly wall tiles are cast into the column and built into the brick joints at four-course intervals.

2 Galvanised pressed steel dovetail slots are cast into the column and dovetail anchors are used to form the tie (see fig.)

The second method gives greater flexibility with the location and insertion of adequate ties but is higher in cost.



Maximum overhang for panel walls



Typical beam facing details

Brick panel walls

FACINGS

Facings to brick panel walls.

Any panel wall must have an acceptable and durable finish; this can be achieved by using facing bricks with a neat pointed joint or by attaching to the face of a panel of common bricks a stone or similar cladding. Suitable materials are natural stone, artificial stone, reconstructed stone and precast concrete of small units up to 1 m^2 and with a thickness related to the density of the material. Dense materials such as slate and marble need only be 40 mm thick, whereas the softer stones such as sandstone and limestone should be at least 75 mm thick.

Two major considerations must be taken into account when deciding on the method to be used to fix the facings to the brick backing:

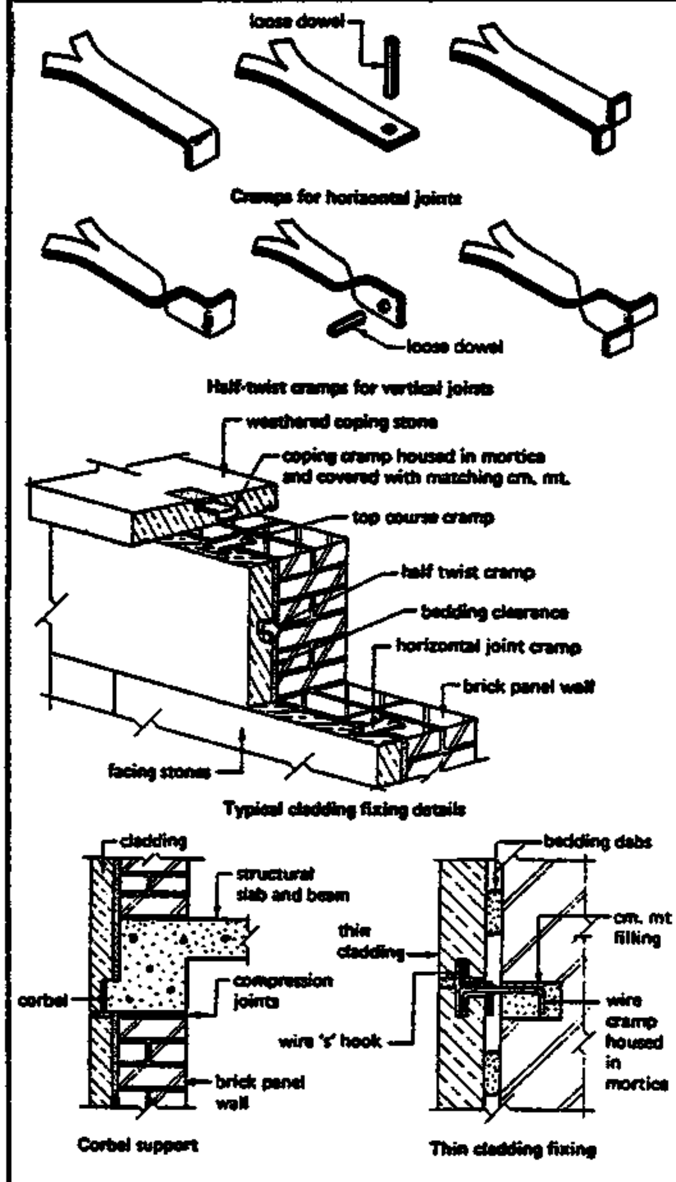
1 Transferring the load to the structure

2 Tying back the facing units.

The load of the facings can be transferred by using bonder stones or support corbels at each floor level, which should have a compression joint incorporated in the detail for the same reasons given above when considering brick panels (see fig.).

The tying back of the facings is carried out by various metal such as gunmetal, copper, phosphor bronze or stainless steel. To avoid the problem of corrosion caused by galvanic action between dissimilar metals a mixture of fixing materials should not be used. Typical examples of fixings and cramps for thick and thin facings are shown in fig.

To provide for plumbing and alignment a bedding space of 12 - 15 mm should be left between the face of the brick panel and the back of the facing. Dense facings such as marble are usually bedded on a series of cement mortar dabs, whereas the more porous facings are usually placed against a solid bed which ensures that any saturation which occurs will be uniform over the entire face.



Cladding fixings

CONCRETE CLADDING PANELS

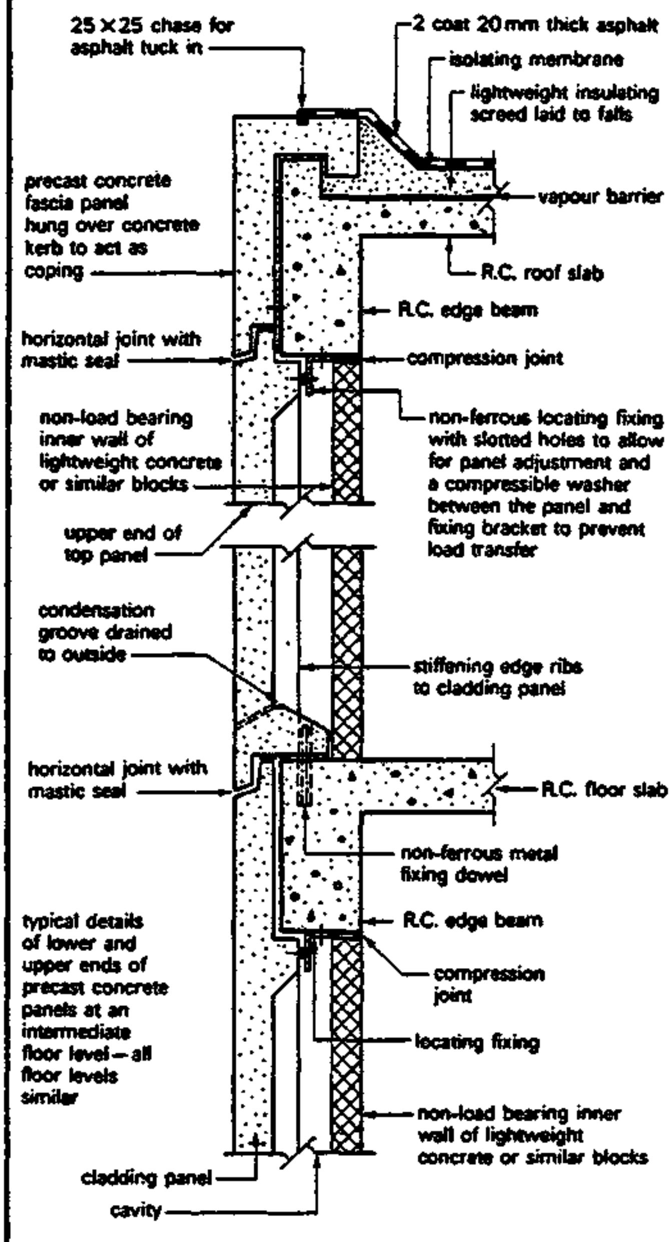
- CONCRETE CLADDING PANELS

These are usually made of precast concrete with a textured face in a storey height or undersill panel format. The storey height panel is designed to span vertically from beam to beam and if constructed to a narrow module will give the illusion of a tall building. Undersill panels span horizontally from column to column and are used where a high wall/window ratio is required. Combinations of both formats are also possible.

Concrete cladding panels should be constructed of a dense concrete mix and suitably reinforced with bar reinforcement or steel welded fabric. The reinforcement should provide the necessary tensile resistance to the stresses induced in the final position and for the stresses set up during transportation and hoisting into position. Lifting lugs, positions or holes should be incorporated into the design to ensure that the panels are hoisted in the correct manner so that unwanted stresses are not induced. The usual specification for cover of concrete over reinforcement is 25 mm minimum. If thin panels are being used the use of galvanised or stainless steel reinforcement should be considered to reduce the risk of corrosion.

When designing or selecting a panel the following must be taken into account:

1 Column or beam spacing
2 Lifting capacities of plant available
3 Jointing method
4 Exposure conditions
5 Any special planning requirements as to finish or texture.



Typical storey height concrete cladding panel

CONCRETE CLADDING PANELS

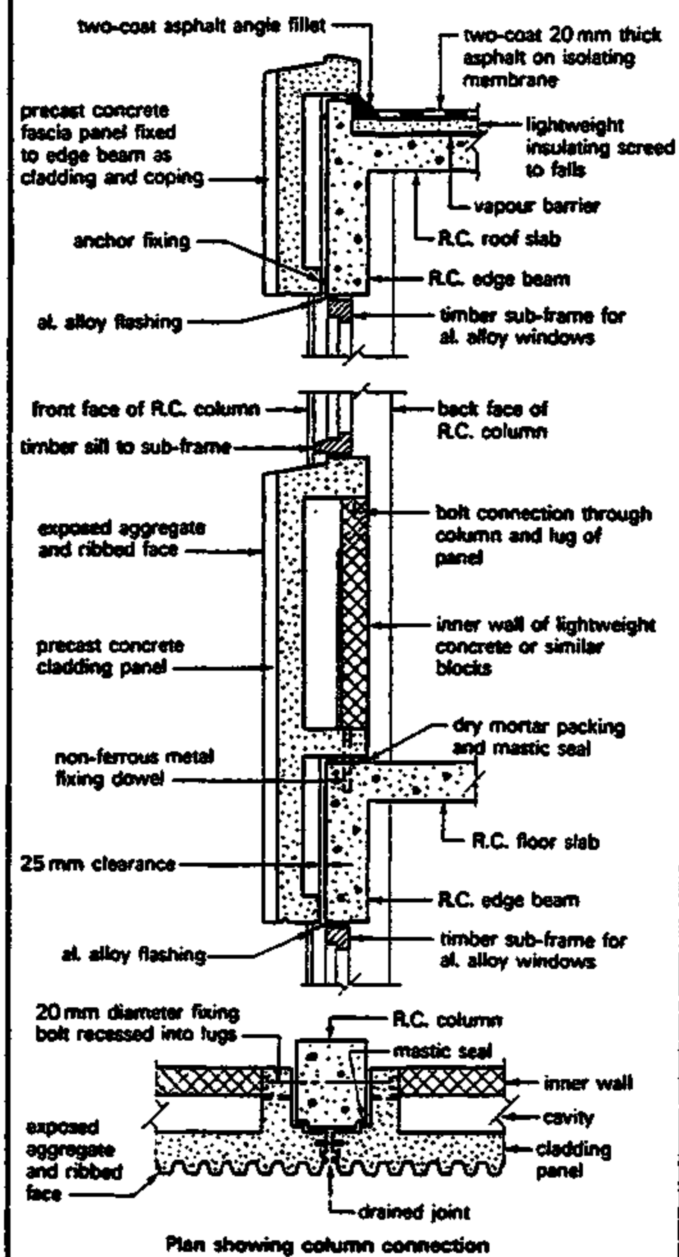
The greatest problem facing the designer and installer of concrete panels is one of jointing to allow for structural and thermal movements and at the same time provide an adequate long term joint - see fig.

Where a stone facing is required to a framed structure, possibly to comply with planning requirements, it may be advantageous to use a composite panel. These panels have the strength and reliability of precast concrete panel design and manufacture but the appearance of traditional stonework. This is achieved by casting a concrete backing to a suitably keyed natural or reconstructed stone facing and fixed to the frame by traditional masonry fixing cramps or by conventional fixings - see fig.

Thermal insulation can be achieved when using precast concrete panes by creating a cavity as shown in the fig.

Concrete cladding panels can be large and consequently heavy. To reduce the weight they are often designed to be relatively thin (50 to 75 mm) across the centre portion and stiffened around the edges with suitably reinforced ribs which usually occur on the back face but can be positioned on the front face as a feature which can also limit the amount of water which can enter the joint.

Another form of cladding material which is beginning to gain popularity and acceptance is glass fibre reinforced plastics (GRP) which consists of pigments and a suitable catalyst as a hardener.

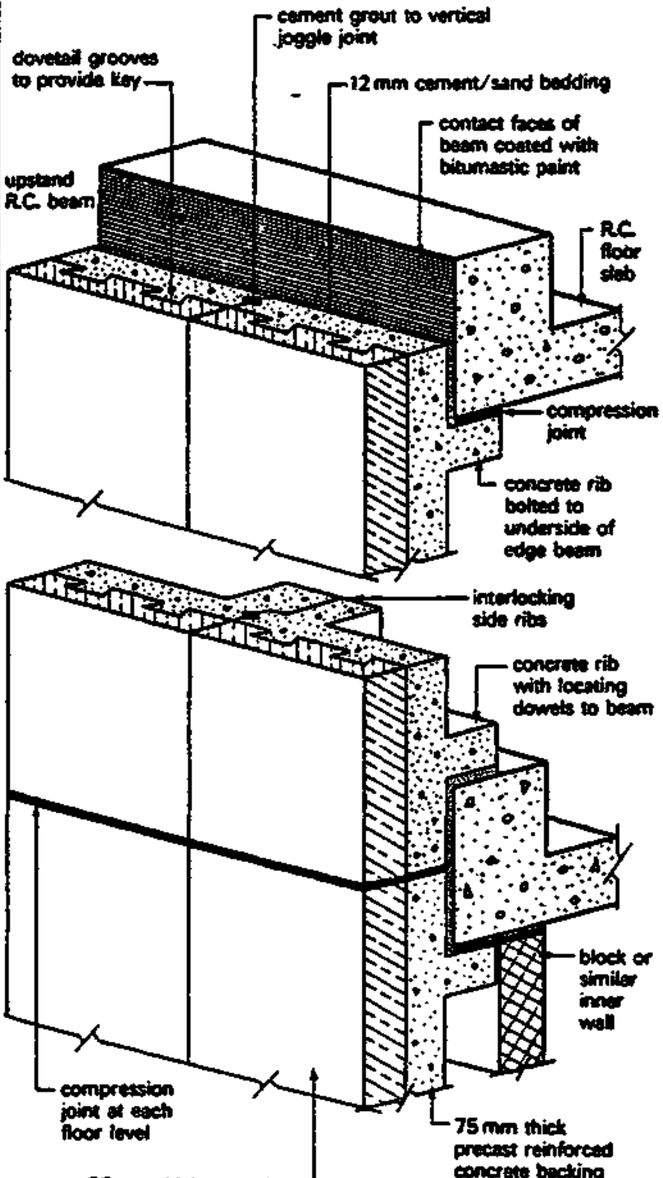


Typical undersill concrete cladding panel

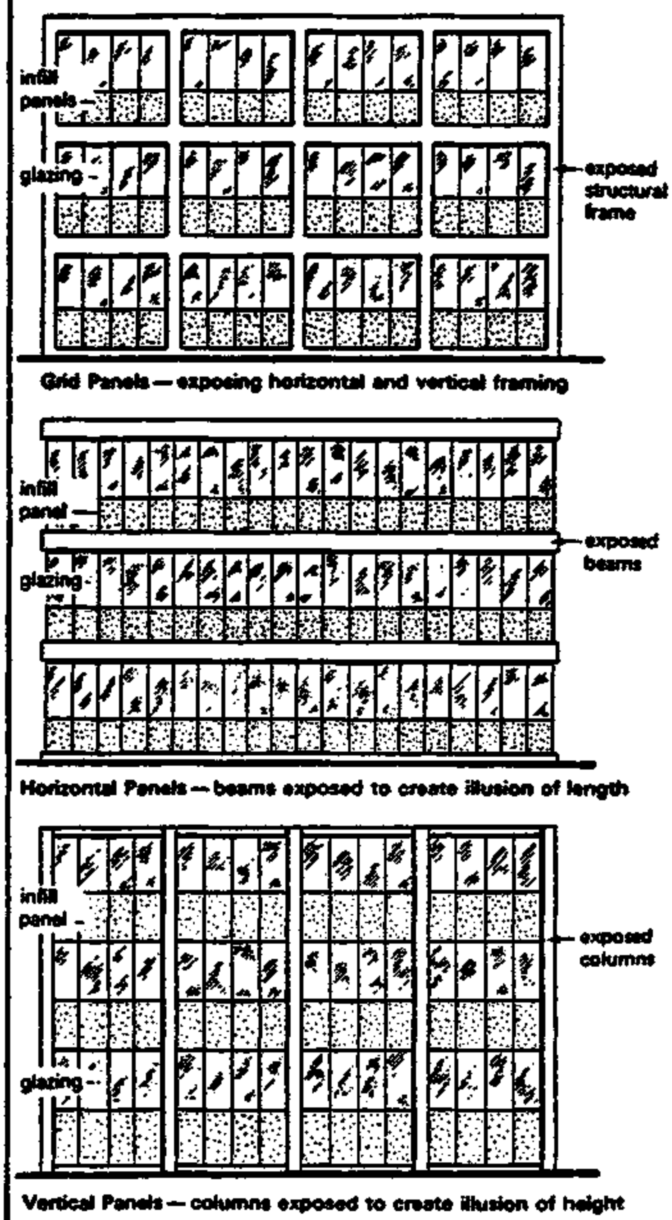
CONCRETE CLADDING PANELS

The resultant panels are lightweight, durable, non-corrosive, have good weather resistance, can be moulded to almost any profile and have good aestetic properties. Students seeking further information are recommended to study the Building Research Establishment Digest 161.

INFILL PANELS



Typical storey height composite panel



Typical infill panel arrangements

INFILL PANELS

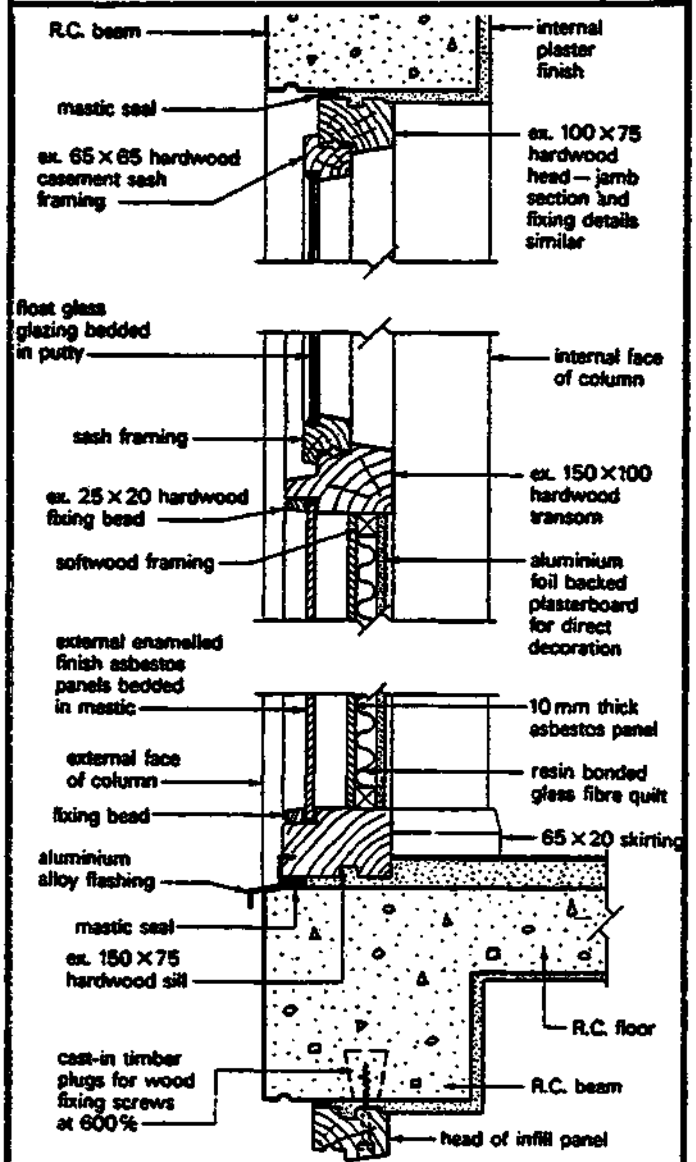
- INFILL PANELS

Infill panels are lightweight and usually glazed to give good internal natural daylighting conditions. The panel layout can be so arranged to expose some or all of the structural members creating various optical impressions. For example, if horizontal panels are used, leaving only the beams exposed, an illusion of extra length and/or reduced height can be created. - see fig.
A wide variety of materials or combinations of materials can be employed such as timber, steel aluminium and plastic. Single and double glazing techniques can be used to achieve the desired sound or thermal insulation. The glazing module should be such that a reasonable thickness of glass can be specified.

The design of the 'solid' panel is of great importance since this panel must provide the necessary resistance to fire, heat loss, sound penetration and interstitial condensation. Most of these panels are of composite or sandwich construction as shown in the fig.

The jointing problem with infill panels occurs mainly at its junction with the structural frame and allowance for moisture or thermal movement is usually achieved by using a suitable mastic or sealant.

Most infill panels are supplied as a manufacturer's system, since purpose-made panels can be uneconomic, but whichever method is chosen the design aims remain constant; that is, to provide a panel which fulfils all the required functions and has a low long term maintenance factor. It should be noted that many of the essentially curtain walling systems are adaptable as infill panels which gives the designer a wide range of systems from which to select the most suitable.
One of the maintenance problems encountered with infill panels and probably to a lesser extent with the concrete claddings is the cleaning of the facade and in particular the glazing. All buildings collect dirt, the effects of which can vary with the material: concrete and masonry tend to accept dirt and weather naturally, whereas impervious materials such as glass do not accept dirt and can corrode or become less efficient.



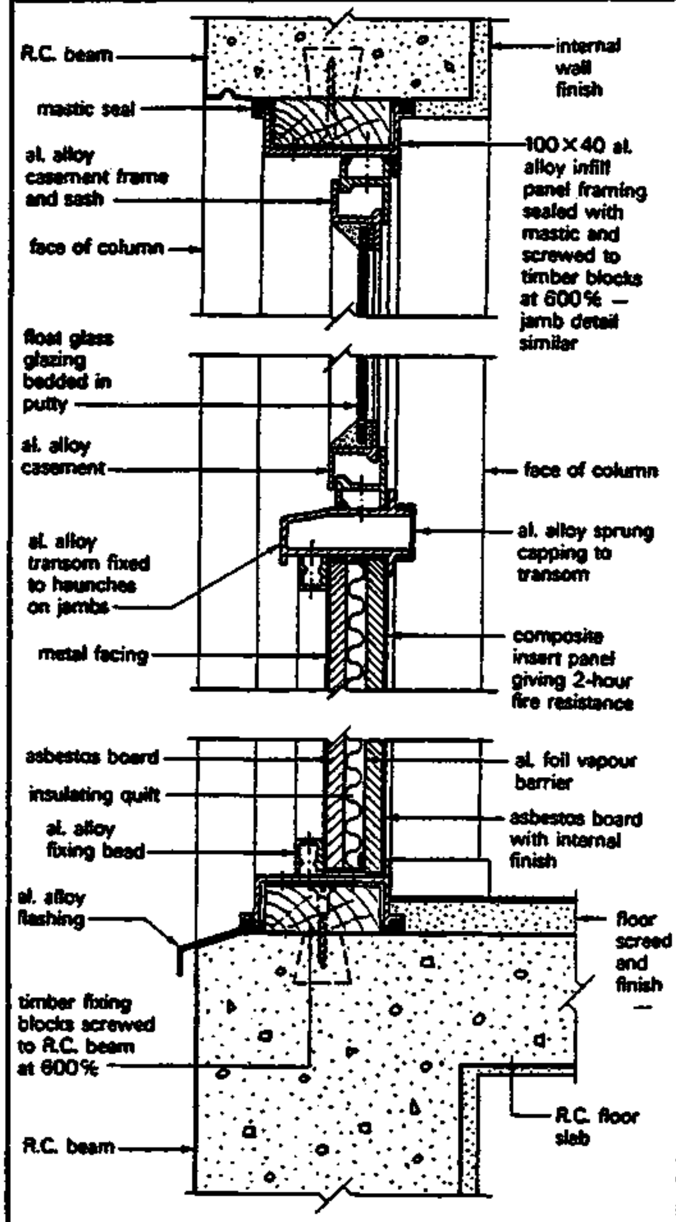
Typical timber infill panel details

INFILL PANELS

If glass is allowed to become coated with dirt its visual appearance is less acceptable, its optical performance lessens since clarity of vision is reduced and the useful penetration of natural daylight diminishes. The number of times that cleaning will be necessary depends largely upon the area, ranging from three-monthly intervals in non-industrial areas to six-weekly intervals in areas with a high pollution factor.

Access for cleaning glazed areas can be external or internal. Windows at ground level present no access problems and present only the question of choice of method such as hand cloth or telescopic poles with squeegee heads. Low and medium rise structures can be reached by ladders or a mobile scaffold tower and usually present very few problems. High rise structures need careful consideration. External access to windows is gained by using a cradle suspended from roof level; this can be in the form of a temporary system consisting of counterweighted cantilevered beams from which the cradle is suspended. Permanent systems, which are incorporated as part of the building design, are more efficient and consist of a track on which a mobile trolley is mounted and from which davit arms can be projected beyond the roof edge to support the cradle. A single track fixed in front of the roof edge could also be considered; these are simple and reasonably efficient but the rail is always visible and can therefore mar the building's appearance.

Internal access for cleaning the external glass face can be achieved by using windows such as reversible sashes, horizontal and vertical sliding sashes, but the designer is restricted in his choice to the reach possible by the average person.
It cannot be over emphasised that such windows can be a very dangerous hazard unless carefully designed so that all parts of the glazed area can be reached by the person cleaning the windows whilst he remains standing firmly on the floor.

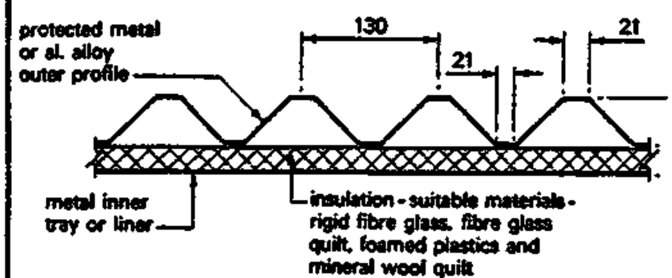


Typical metal infill panel details

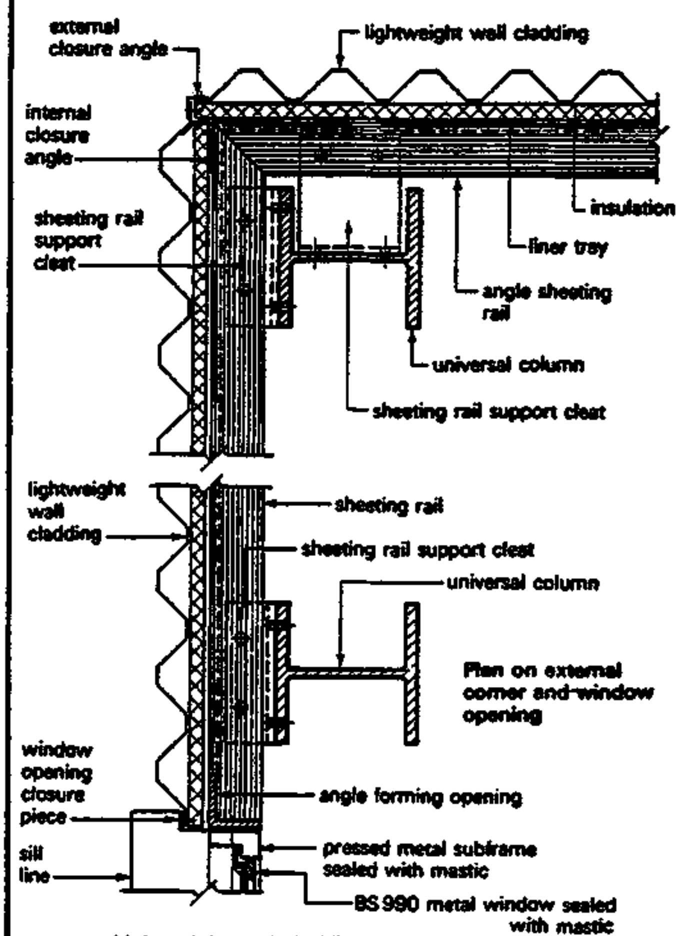
LIGHTWEIGHT WALL CLADDING

- LIGHTWEIGHT WALL CLADDINGS

In common with other cladding methods for framed buildings, lightweight wall claddings do not require high compressive strength since they only have to support their own dead load and any imposed wind loading, which will become more critical as the height and/or exposure increases. Lightweight claddings are usually manufactured from impervious materials which means that the run off of rain water can be high particularly under storm conditions when the discharge per minute could reach 2 litres per square metre of wall area exposed to the rain.
A wide variety of materials can be used as a cladding medium, most being profiled to a corrugated or trough form since the shaping will increase the strength of the material over its flat sheet form. Flat sheet materials are available but are rarely applied to large buildings because of the higher strength obtained from a profiled sheet of similar thickness. Special contoured sheets have been devised by many manufacturers to give the designer a wide range of choice in the context of aesthetic appeal. Claddings of various sandwich construction are also available to provide reasonable degrees of thermal insulation, sound insulation and to combat the condensation hazard which can occur with lightweight claddings of any nature.
The sheets are fixed in a similar manner to that for sheet roof coverings. The support purlins are replaced



Typical cladding profile



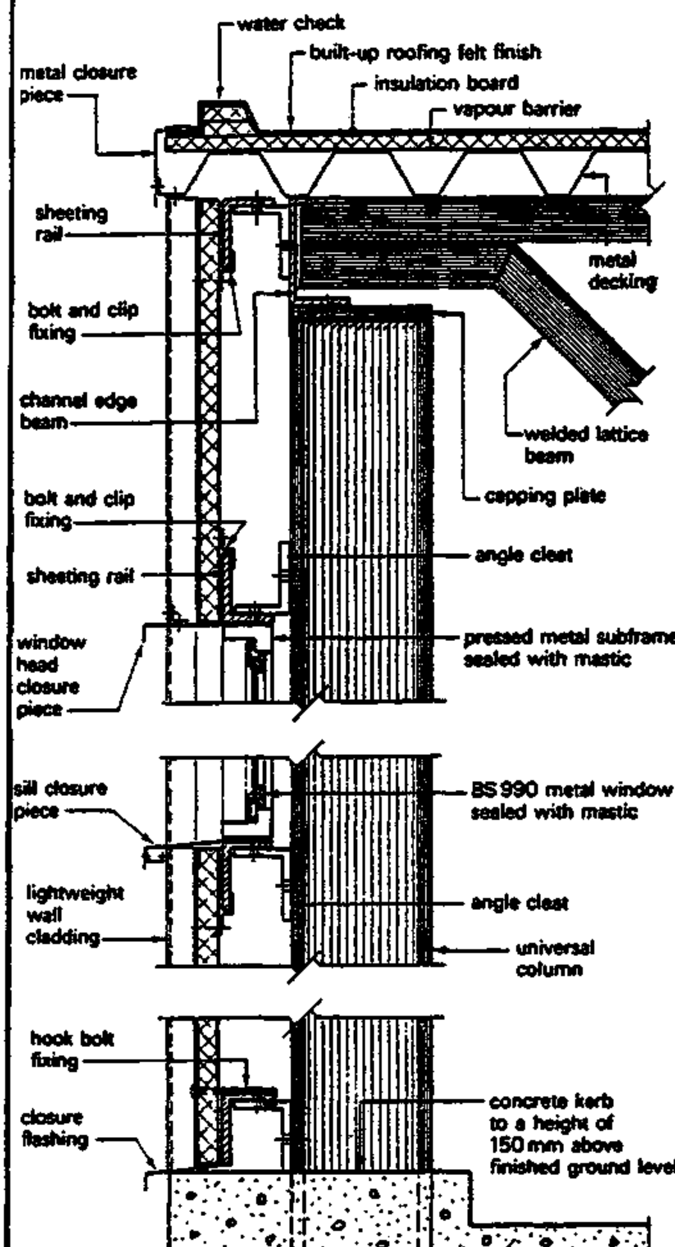
Lightweight wall cladding - typical details 1

LIGHTWEIGHT WALL CLADDING

in walls by a similar member called a sheeting rail which is fixed by cleats to the vertical structural frame members. The major difference occurs with the position of the fixings which in wall claddings are usually specified as being positioned in the trough of the profile as opposed to the crest when fixing roof coverings. This change in fixing detail is to ensure that the wall cladding is pulled tightly up to the sheeting rail or lining tray.

Plastic protective caps for the heads of fixings are available, generally of a colour and texture which will blend with the wall cladding. A full range of fittings and trims are usually obtainable for most materials and profiles to accommodate openings, returns, top edge and bottom edge closing. Typical cladding details are shown in the fig.
Common materials used for lightweight wall claddings are:

1 Asbestos cement
non-combustible material in corrugated and troughed sheets which are generally satisfactory when exposed to the weather but are susceptible to impact damage. Average life is about 20 years which can be increased considerably by paint protection. Unpainted sheets loose their surface finish at the exposed surface by carbonation and become ingrained with dirt. To achieve reasonable thermal insulation standards a lining material will be required, which is normally sandwiched between the cladding and an inner lining tray.



Lightweight wall cladding - typical details 2

LIGHTWEIGHT WALL CLADDING

2 Coated steel sheets non-combustible material with a wide range of profiles produced by various manufacturers. The steel sheet forms the core of the cladding providing its strength and this is covered with various forms of coatings to give weather protection, texture and colour. A typical specification would be a galvanised steel sheet core covered on both sides with a layer of asbestos felt to increase resistance to fire, a layer of bitumen-impregnated felt to act as a barrier to the passage of moisture to the core and on the face surface a coloured and textured coating of plastic. Fixing and the availability of fittings is as described above for asbestos cement.

3 Aluminium alloy sheets non-combustible material in corrugated and troughed profiles which are usually made to the recommendations of BS 2858 and BS 3428 respectively. Other profiles are also available as manufacturers' standards. Durability will depend upon the alloy used but this can be increased by paint applications; if unpainted, regular cleaning may be necessary if its natural bright appearance is to be maintained. Fixing, fittings and the availability of linings is as given for other cladding materials.

4 Polyvinyl chloride sheets generally supplied in a corrugated profile with an embedded wire reinforcement to provide a cladding with a surface spread of flame classification of class 1 in accordance with BS 476: Part7.

The durability of this form of cladding is somewhat lower than those previously considered and the colours available are limited. The usual range of fittings and trims are available.

The importance of adequate design, detail and fixing of all forms of lightweight cladding cannot be overstressed since the primary objective of these claddings is to provide a lightweight envelope to the building giving basic weather protection and internal comfort at a reasonable cost. Claddings which will fulfil these objectives are very susceptible to wind damage unless properly secured to the structural frame.

CURTAIN WALLING

- CURTAIN WALLING

Curtain walls are a form of external lightweight cladding, attached to a framed structure or monolithic walls, forming a complete envelope or sheath around the structural frame.

They are non-load-bearing claddings, which have to support only their own deadweight and any imposed wind loadings which are transferred to the structural frame through connectors which are usually positioned at the floor level.

The basic conception of most curtain walls is a series of <u>vertical</u> MULLIONS spanning from floor to floor interconnected by <u>horizontal</u> TRANSOM S forming openings into which can be fixed panels of glass or infill panels of opaque materials like:
- metal faced insulation materials
- weatherproof blockboard
- plastic materials, etc.

of various thickness built in metal frames.

Most curtain walls are constructed by using a patent or proprietary system produced by metal window manufacturers.

The primary objectives of using curtain walling systems are:

1 Provide an enclosure to the structure which will give the necessary protection against the elements.

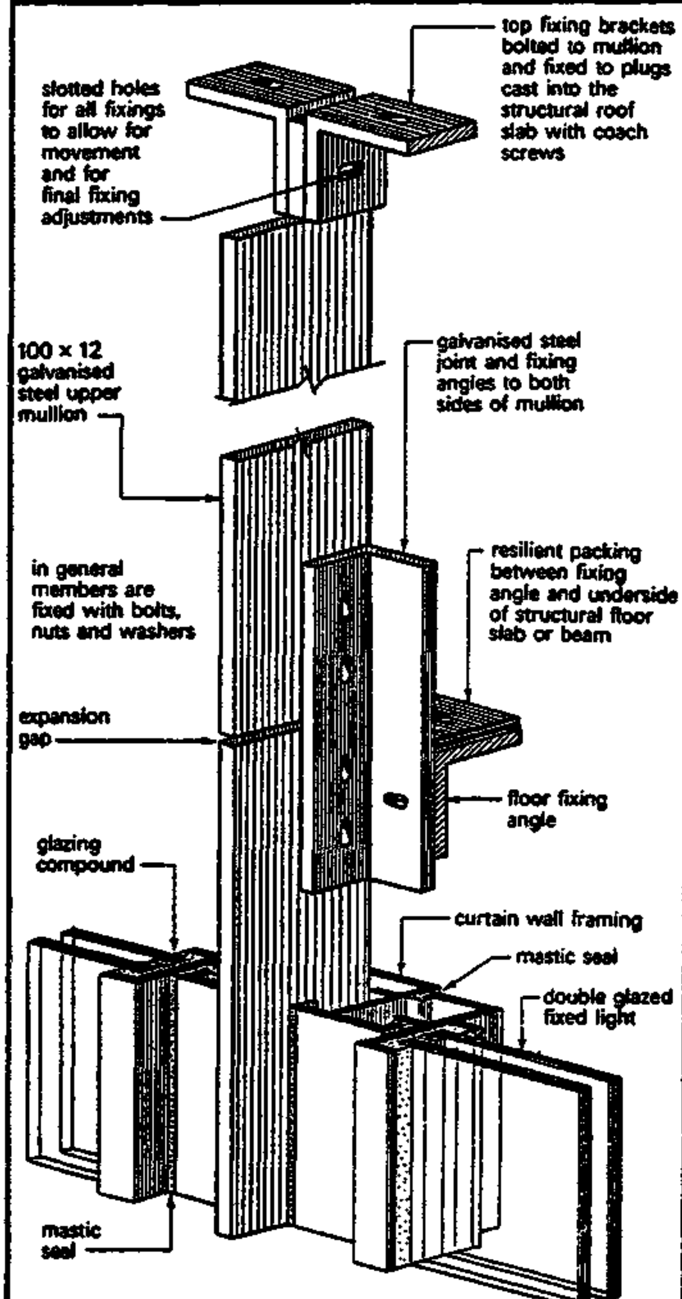
2 Make use of dry construction methods.

3 Impose onto the structural frame the minimum load in the form of claddings.

4 Exploit an architectural feature.

To fulfil its primary functions a curtain wall must meet the following requirements:

1 Resistance to the elements the materials used in curtain walls are usually impervious and in themselves present no problem but by virtue of the way in which they are fabricated a large number of joints occur. These joints must be made as impervious



Typical curtain walling details 1

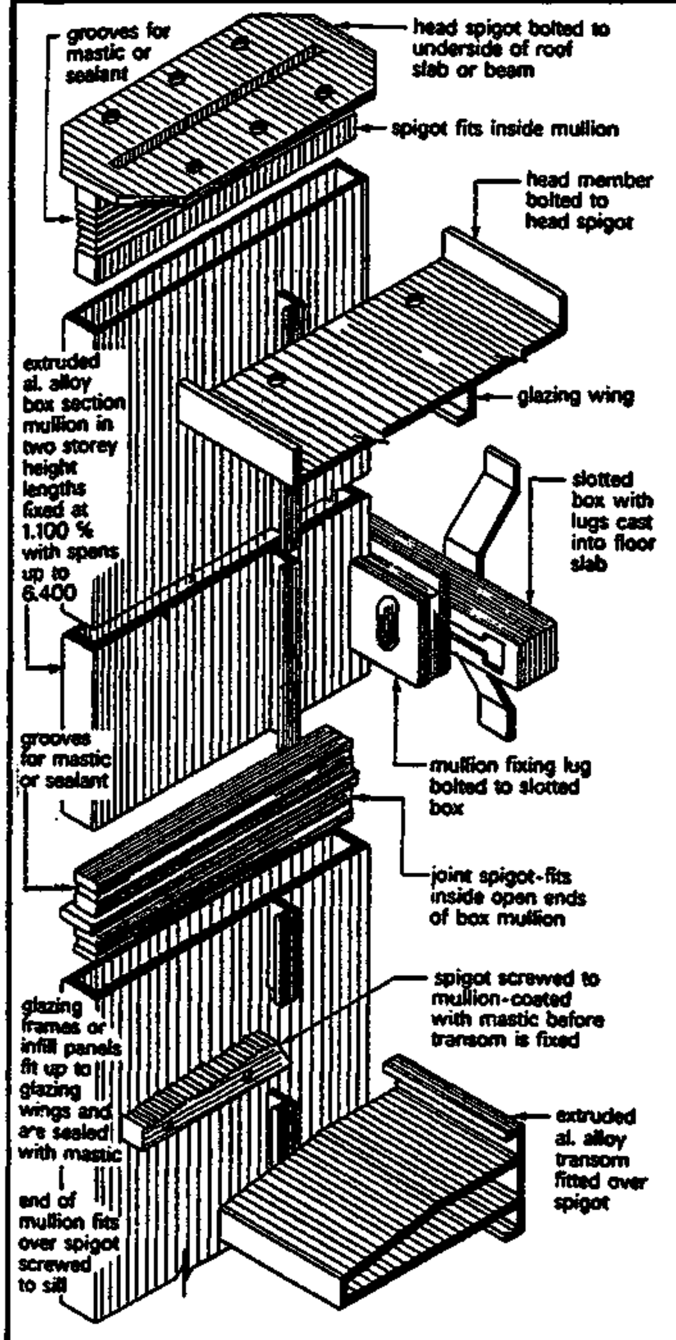
as the surrounding materials or designed as a drained joint. The jointing materials must also allow for any local thermal, structural or moisture movement and generally consist of mastics, sealants and/or preformed gaskets of synthetic rubber or PVC.

2 Assist in maintaining the designed internal temperatures - since curtain walls usually include a large percentage of glass the overall resistance to the transfer of heat is low and therefore preventive measures may have to be incorporated into the design. Another problem with large glazed areas is solar heat gain since glass will allow the short wave radiations from the sun to pass through and consequently warm up the surfaces of internal walls, equipment and furniture. These surfaces will in turn radiate this acquired heat in the form of long wave radiations which cannot pass back through the glazing thus creating an internal heat build-up. Louvres fixed within a curtain walling system will have little effect upon this heat build-up but they will reduce solar glare. A system of non-transparent external louvres will slightly reduce the heat gain by absorbing heat and radiating it back to the external air. The usual methods employed to solve the problem of internal heat gain are:

a Deep recessed windows which could be used in conjunction with external vertical fins.

b Balanced internal heating and ventilation systems

c Use of special solar control glass such as reflective glasses which during manufacture are modified by depositing on the surface of the glass a metallic or dielectric reflective layer. The efficiency of this form of glazing can be increased if the glass is tilted by 5° to 15° to increase the angle of incidence.



Typical curtain walling details 2

damage of the glazed and infill panel areas by enabling these units to move independently of the curtain wall framing.

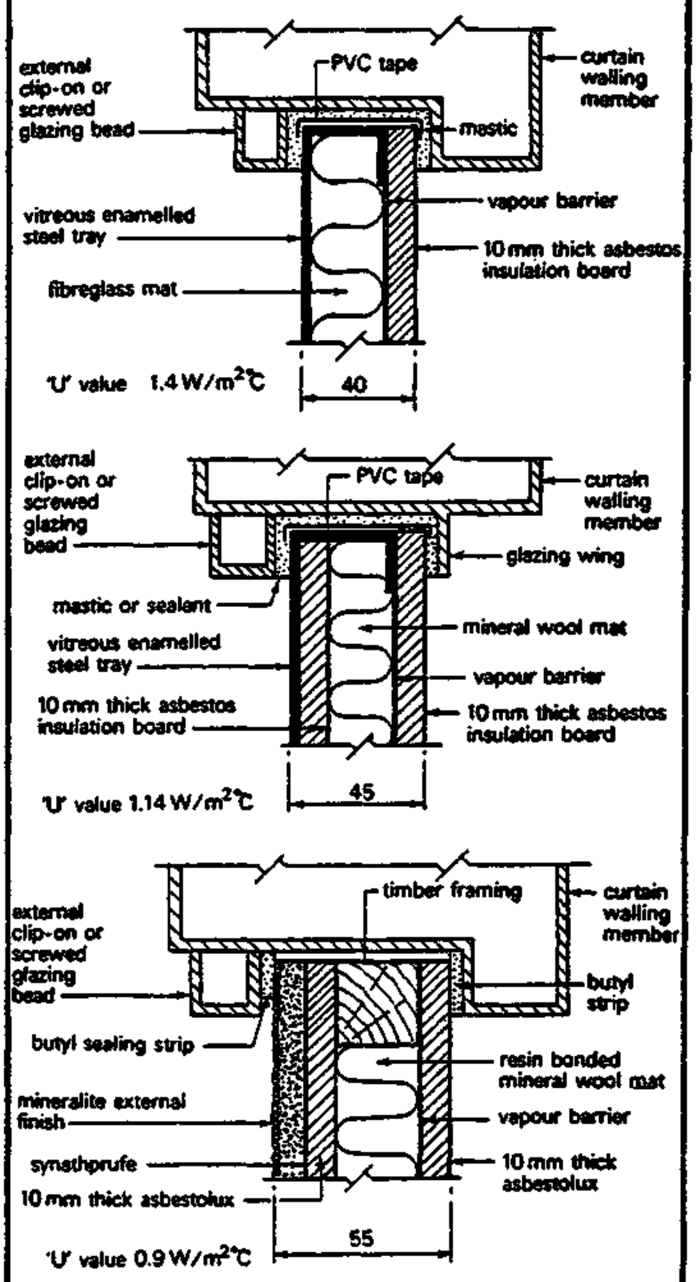
4 Provide required degree of fire resistance - this is probably one of the greatest restrictions encountered when using curtain walling techniques because of the large proportion of unprotected areas as defined in Building Regulation E 1 and by the conditions set out in Building Regulation E 7 and Schedule 9. By using suitable materials or combinations of materials the opaque infill panels can normally achieve the required fire resistance to enable them to be classified as protected areas.

5 Easy to assemble and fix - the principal member of a curtain walling system is usually the mullion which can be a solid or box section which is fixed to the structural frame at floor levels by means of adjustable anchorages or connectors.

3 Adequate strength - although curtain walls are classified as non-load-bearing they must be able to carry their own weight and resist both positive and negative wind loadings. The magnitude of this latter loading will depend upon three basic factors:

a Height of building
b Degree of exposure
c Location of building

The strength of curtain walling relies mainly upon the stiffness of the vertical component or mullion together with its anchorage or fixing to the structural frame. Glazing beads and the use of compressible materials also add to the resistance of possible wind



Typical curtain walling infill panel details

CURTAIN WALLING

The infill framing and panels may be obtained as a series of individual components or as a single prefabricated unit. The main problems are ease of handling, amount of site assembly required and mode of access to the fixing position.

6 Provide required degree of sound insulation - sound originating from within the structure may be transmitted vertically through the curtain walling members. The chief source of this form of structure-borne sound is machinery and this may be reduced by isolating the offending machines by mounting them on resilient pads and/or using resilient connectors in the joints between mullion lengths.

Airborne sound can be troublesome with curtain walling systems since the lightweight cladding has little mass to offer in the form of a sound barrier, the weakest point being the glazed areas. A reduction in the amount of sound transmitted can be achieved by

a Reducing the areas of glazing
b Using sealed windows of increased glass thickness
c Double glazing in the form of inner and outer panes of glass with an air space of 150 to 200 mm between them.

7 Provide for thermal and structural movements - since curtain walling is situated on an external face of the structure it will be more exposed than the structural frame and will therefore be subject to greater amounts of temperature change resulting in high thermal movement. The main frame may also be subjected to greater settlement than the claddings attached to its outer face. These differential movements mean that the curtain walling systems should be so designed, fabricated and fixed that the attached cladding can move independently of the structure. The usual methods of providing for this required movement are to have slotted bolt connections and, to allow for movement within the curtain walling itself, to have spigot connections and/or mastic sealed joints.

EXTERNAL PAINTS and FINISHES

12.1.4 EXTERNAL PAINTS AND FINISHES

The usual colour renderings today are achieved either by use of cement paints, i.e. paints containing coloured cements supplied as powder and mixed with water, or by use of PVA emulsion paints. The former are very popular, especially with Tyrolean finish. The latter are supplied as a thick liquid to which water is added. They are easily applied, require no special skill and form a plastic skin which adheres well to cement rendering. Emulsion paint, however, does fail occasionally because of the alkaline nature of the background. The emulsion paint used must be of external quality.

Oil paints are not greatly used in the tropics on the grounds of their expense, and emulsion paint cannot be applied over them.

Water-bound distemper is still used, as it is cheap and easily applied. It needs frequent renewal.

An expensive but strong and durable surface can be obtained from the use of epoxy resin paint. It is waterproof and adheres well. It is very good for cement screeded floors

Bitumen paints are good, particularly in coastal areas or in damp atmospheres. They are used widely on corrugated iron sheeting and other metals in need of protection from rust. The surfaces must be cleaned before paint is applied. No other kind of paint can be applied over bitumen paint.

Woodwork which is mainly from hardwood does not always receive the preparative treatment which is usual in the case of softwood. Frequently it is not primed. Hardwoods, however, are sometimes subject to rapid decay in external conditions and should be carefully primed before undercoat is applied.

Varnishing of wood used externally although still popular is not always successful on exposed faces. It is quite satisfactory in sheltered areas, under canopies, walkways, etc. but will not stand up to sunlight.

12.2 INTERNAL WALL FINISHES

12.2.1 PLASTERING

A number of factors causes a great variation in the art of plastering from one country to another:
- traditional customs
- religious influences
- the material available
- the tools used
- the background to which it is applied.

Therefore only the main plastering techniques will be dealt with here.

. MATERIALS

The chief materials used for plastering are:
- lime
- cement
- gypsum and
- sand.

LIME

LIME

Lime for plastering is produced by calcining (burning) limestone, mainly chalk, which removes the carbon dioxide. On cooling, the quicklime is stored in a dry place from where it is transported to its destination. Before it can be used, however, the lime must be 'slaked', i.e. water added a week or two before it is needed. Lime for plastering is usually 'fat' lime, i.e. easily slaked and workable as distinct from hydraulic lime which is not, but which has the property of setting under water. Locally burnt lime produced under primitive conditions is rarely of good quality and results in pitting or blowing of the rendering caused by uneven burning.

Modern lime production can be carried out on similar lines to the manufacture of Portland cement. Quicklime is exposed to steam which reduces the lime to a powder. This is bagged for transport in the same way as Portland cement although it is only about half its weight. The lime is usually soaked on site for a short while, say a day, after which it is ready for use.

CEMENT

PORTLAND CEMENT

Where a country has no supply of its own, cement may be imported in 1 cwt (50kg) bags or drums, as explained. There appears to be no reason, however, why the clinker produced by burning, when cooled off, should not be shipped to its destination where it would then be ground into cement. This method would have a number of advantages: it would be cheaper to transport in bulk; it could be freshly ground as required and the clinker would be unaffected by moisture which is an important consideration in humid areas. The grinding process could be incorporated into the full production plant for manufacturing cement when or if it was eventually built.

BUILDING PLASTERS

BUILDING PLASTERS

The bulk of these have a gypsum base, gypsum being a naturally occurring material found in many parts of the world. There are many varieties which, under the BS system are divided into classes.

The main divisions are:

Class A plaster:
This is usually called plaster of Paris. To produce it, gypsum is burnt to a fairly low temperature (160°C) when it loses most of its water of hydration. When the finished plaster is mixed with water, it sets very quickly, within 5 minutes usually. Plaster of Paris is used extensively in plaster casting shops. Here prefabricated panels and mouldings are prepared, reinforced by wood laths and hessian scrim. These are transported to the site and nailed or screwed to wood grounds or bearers which are shaped if necessary. The joints are then neatly filled with gauged plaster. Much fine plaster work is carried out in this way.

Class B plasters.
These are plasters in which the 'set' has been retarded, or the setting time increased. This allows the plasterers time to lay on the material and bring it to a smooth finish. There are three grades of Class B plasters, usually, undercoat, finishing and 'dual purpose', the latter being most widely used, particularly when it has to be imported.

Class C plasters.
These are normally of better quality than those of Class B. They are made by heating gypsum to a higher temperature than 160°C. This causes the plaster to lose its quick-setting power. Accelerators are then added which cause the material to set in enough time to allow the plasterer to obtain a smooth finish.

Class D plasters.
The main plaster in this group is Keene's cement, a high-quality slow-setting plaster giving a smooth marble-like finish. Adhesion of decorative finish on Keene's or Parian cement is very poor unless a coat of sharp oil paint is applied as soon as it has set.

Other types.
Class B,C and D plasters should be applied to backgrounds as undercoats and/or finishes in accordance with the recommendation given in Mixes. Other types of plasters, however, are available which may be applied to any surface including concrete, blockwork or plasterboard. Lightweight plasters are also available with improved acoustical and insulating properties. For further information on these, the reader is referred to M.O.P. B.W. Advisory leaflets, B.R.S. publications, etc.

MIXES

Mixes.
For internal work Cement and Sand is only used, where lime is not available or where a building is designed on an open plan. In most areas in Tanzania all internal renderings are of Portland cement and sand, no other material is used even for the finish coat. This practice is costly in cement and does not provide for a smooth finish, particularly when application and finishing are done with only the aid of a mason's trowal and a straight - edge.

LIME may be added to either Portland cement or gypsum plaster, but Portland Cement must NOT be mixed with gypsum plaster.
Usually Portland cement/lime/sand is reserved for external work and gypsum plasters for internal, although there are many exceptions to this practice.
Gypsum plasters are also used externally in areas of low rainfall and humidity.
The most common mixes are given in the table below.

Background	*Undercoat*	*Finish*
Brickwork or blockwork	(1) Cement/lime/sand 1:2:6	Lime/gypsum Class B 1:¼ (*R*)
	(2) Cement/sand 1:4	Gypsum C neat (*S*)
	(3) Gypsum B/sand 1:3	Lime/gypsum B 1:¼ (*T*)
	(4) Gypsum C/lime/sand 2:1:6	*R*, *S*, or *T* above
Concrete cast *in situ*	As (2) above	As *S* above
	As (3) above	As *T* above
	If none needed	As *S* above
Metal lathing	As (1) above (two coats)	As *R* above
	As (3) above (two coats)	As *T* above
Expanded plastic sheets, plasterboard or fibreboard	None usual (except joints)	As *R* above
Wood-wool slabs	As (1) above	As *R* above
	As (3) above	As *T* above

KEY

FINISHING COAT

Key.
Adhesion of plaster to the background is very important. Concrete should be cleaned free of grease of film and either 'hacked' or painted with an epoxide resin adhesive.
Each coat of plaster should be scratched or grooved the top undercoat only lightly so.

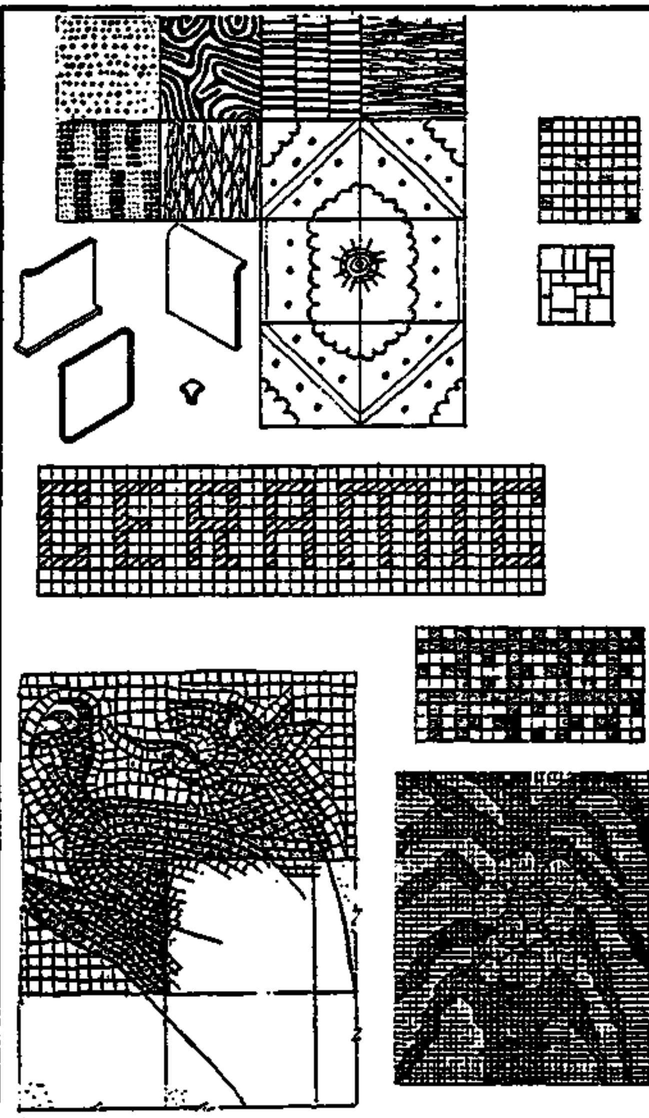
Finishing Coat.
This should not be applied too quickly. One coat 1,5mm to 3 mm is usually sufficient. Undercoat thicknesses vary but 10 to 15 mm is usual.

OTHER INTENAL WALL FINISHES

12.2.2 Other Internal Wall Finishes

There is a wide range of finishes available today and new materials are constantly being introduced. Fashion, ideas, prefabrication, cost and the economic state of the community all effect demand.
Only the basic finishes, therefore, may be listed up to give an idea about the variety of different materials used as internal wall finishes:

- Glazed Tiles
- Decorative Patterned Tiles
- Ceramic Mosaics
- Marble
- Terrazzo
- Mosaic
- PVC Tiles
- Glass,
  i.e. plate glass (coloured)
  glass panels
  patterned glass
  glass blocks
- Dry Lining Techniques etc.



PAINTING

12.2.3 Painting

Protection and decoration are the two important functions of painting.
On interior work, particularly walls and ceilings, the decorative function may be considered more important even though walls may have to withstand washing.

PAINT is a mixture of a liquid or medium and a colouring or pigment. Mediums used in paint manufacture range from thin liquids to stiff jellies and can be composed of linseed oil, drying oils, synthetic resins and water. The various combinations of these materials forms the tape of class of paint. The medium's function is to provide the means of spreading and binding the pigment over the surface to be painted. The pigment provides the body, colour and durability of the paint. White lead is a pigment which gives good durability and moisture resistance but it is poisonous, therefore its use is confined mainly to priming and undercoating paints. Paints containing a lead pigment are required by law to state this fact on the can. The general pigment used for finishing paint is titanium dioxide which gives good obliteration of the undercoating but is not poisonous.

OIL BASED PAINTS

Priming paints:
These are first coat paints used to seal the surface, protect the surface against damp air, act as a barrier to prevent any chemical action between the surface and the finishing coats and to give a smooth surface for the subsequent coats. Priming paints are produced for application to wood, metal and plastered surfaces.

Undercoating paints:
These are used to build up the protective coating and to provide the correct surface for the finishing coat(s). Undercoat paints contain a greater percentage of pigment than finishing paints and as a result have a matt or flat finish. To obtain a good finishing colour it is essential to use an undercoat of the type and colour recommended by the manufacturer.

Finishing paints:
A wide range of colours and finishes including matt, semi-matt, eggshell, satin, gloss and enamel are available. These paints usually contain a synthetic resin which enables them to be easily applied, quick drying and have good adhesive properties. Gloss paints have less pigment than the matt finishes and consequently less obliterating power.

POLYURETHANE PAINTS.
These are quick drying paints based on polyurethane resins giving a hard heat resisting surface. They can be used on timber surfaces as a primer and undercoat but metal surfaces will require a base coat of metal primer, the matt finish with its higher pigment content is best for this 'one paint for all coats' treatment. Other finishes available are gloss and eggshell.

PAINTING

WATER BASED PAINTS.
Most of the water based paints in general use come under a general classification of emulsion paints: they are quick drying and can be obtained in matt, eggshell, semi-gloss and gloss finishes. The water medium has additives such as polyvinyl acetate and alkyd resin to produce the various finishes. Except for application to iron work, which must be primed with a metal primer, emulsion paints can be used for priming, undercoating and as a finishing application. Their general use is for large flat areas such as ceilings and walls.

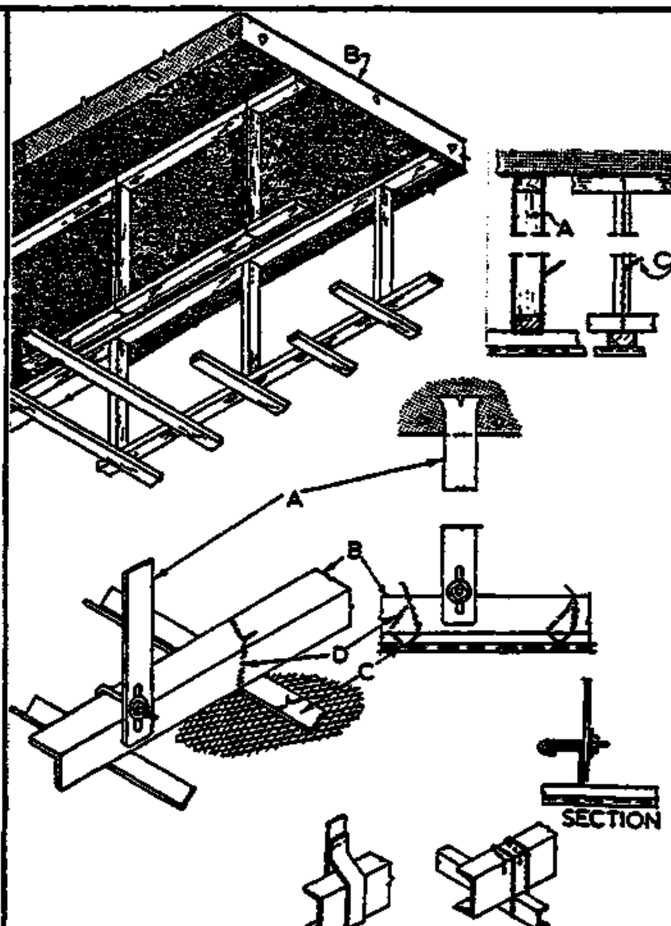
VARNISHES AND STAINS
Varnishes form a clear, glossy or matt, tough film over a surface and are a solution of resin and oil. their application being similar to oil based paints.

The type of resin used, together with the correct ratio of oil content, forms the various durabilities and finishes available. Stains can be used to colour or tone the surface of timber before applying a clear of varnish; they are basically a dye in a spirit and are therefore quick drying.

CEILING FINISHES 12.3

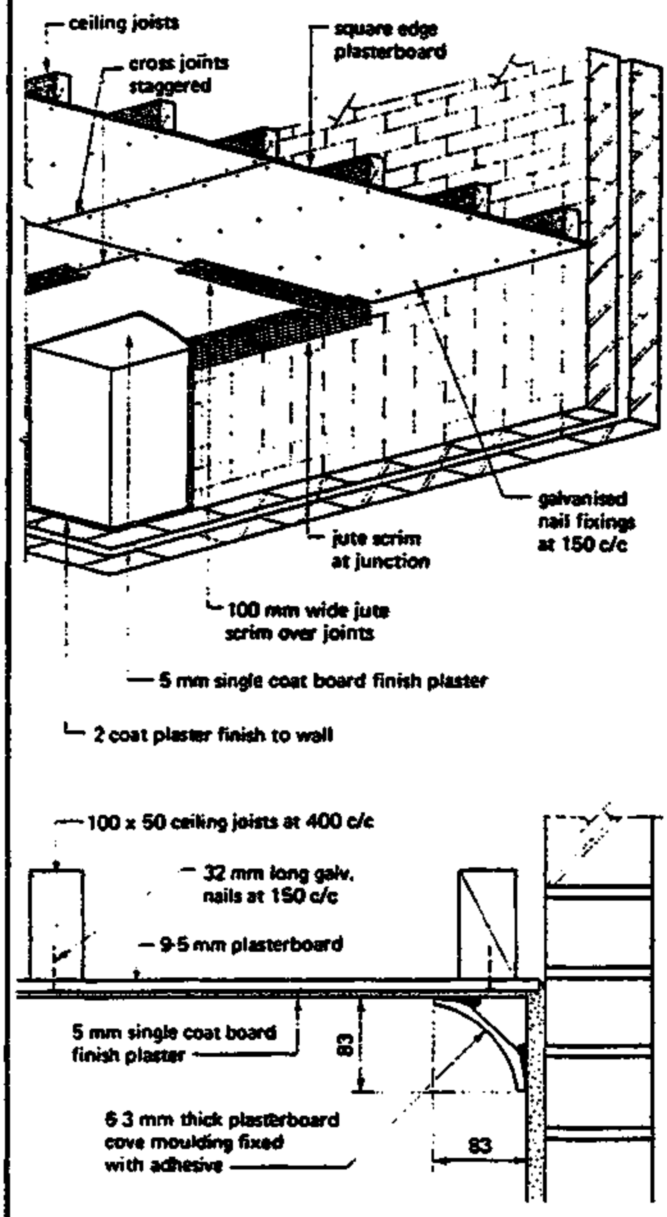
12.3 CEILING FINISHES

Ceilings can be finished by any of the dry lining techniques previously described for walls. The usual method is a plasterboard base with a skim coat of plaster. The plasterboards are secured to the underside of the floor or ceiling joists with galvanised plasterboard nails to reduce the risk of corrosion to the fixings. If square edged plasterboards are used as the base a jute scrim over the joints is essential. The most vulnerable point in a ceiling to cracking is at the junction between the ceiling and wall, this junction should be strengthened with a jute scrim around the internal angle (see fig.) or alternatively the junction can be masked with a decorative plasterboard or polystyrene cove moulding.



CEILING FINISHES

The cove moulding is made in a similar manner to plasterboard and is intended for direct decoration. Plasterboard cove moulding is jointed at internal and external angles with a mitred joint and with a butt joint in the running length. Any clean, dry and rigid background is suitable for the attachment of plasterboard cove which can be fixed in one of two ways. It can be secured by using a special water mixed adhesive applied to the contact edges of the moulding which is pressed into position; any surplus adhesive should be removed from the edges before it sets. Alternatively the cove moulding can be fixed with galvanised steel or brass screws to plugs or battens - fixings to the wall are spaced at 300 mm centres and to the ceiling at 600 mm centres. A typical plasterboard cove detail is shown in the fig. Many forms of ceiling tiles are available for application to a joisted ceiling or solid ceiling with a sheet or solid background. Fixing to joists should be by concealed or secret nailing through the tongued and grooved joint. If the background is solid such as a concrete slab then dabs of a recommended adhesive are used to secure the tiles. Materials available include expanded polystyrene, mineral fibre, fibreboard and glass fibre with a rigid vinyl face. Other forms of finish which may be applied to ceilings are sprayed plasters which can be of a thick or thin coat variety. Spray plasters are usually of a proprietary mixture applied by spraying apparatus directly on to the soffit giving a coarse texture which can be trowelled smooth if required. Various patterned ceiling papers are produced to give a textured finish. These papers are applied directly to the soffit or over a stout lining paper. Some ceiling papers are designed to be a self finish but others require one or more coats of emulsion paint.



Plasterboard ceilings

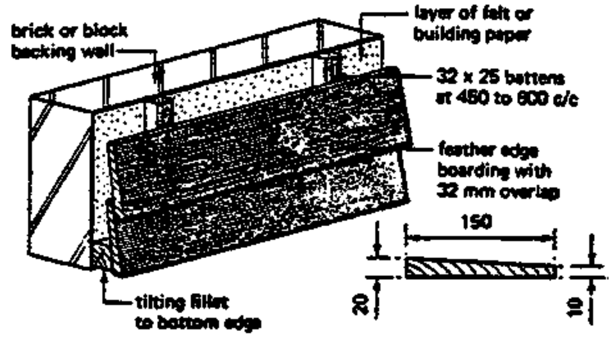
Try to answer the following questions and practice sketching where ever necessary and possible



12.1. External Wall Finishes

- Define the terms: External Rendering
  Spatterdash
  Roughcast
  Pebbledash
  Tyrolean Finish
- What are the properties of the rendering and where does the success of the rendering depend on?
- Give the two common volume mix ratios!
- Write notes on the application of external rendering.
- List and describe methods of finishing concrete walls apart from rendering or painting.
- What are the advantages of cladding over traditional types of construction?
- Which points must a designer keep in mind to prevent failures?
- Which points must a cladding fixer keep in mind?
- Where should cramps and other fixings be made from?
- Write notes on claddings fixed to a structural backing, including Tile Hanging and Timber Claddings. Use sketches for illustration!
- Write notes on claddings to framed structures, including Brick Panel Walls, Concrete Cladding Panels, Infill Panels, Lightweight Wall Claddings and Curtain Walling. Use sketches for illustration.
- Compare the different types of external paints and finishes!

b	314	312	310	306	306	304	302	300	298	296	294	292	290

13. <u>STAIRS</u>

13.1 <u>Introduction</u>

- A STAIR is a number of at least 3 STEPS leading from one level to another, in order to provide means of movement between different levels <u>in</u> and <u>attached</u> to buildings and for predestrian walkways.
- To make STAIRS usable without danger, they have to be designed and constructed carefully:
  - . The type of STAIRS has to be choosen
  - . All measurements have to be calculated
  - . - if necessary - the tapering of the steps has to be designed. etc.
- For the construction of STAIRS different suitable materials can be used, such as
  - . Stone (both natural and artificial)
  - . Concrete
  - . Timber
  - . Steel
- Often you may find different materials combined at the same STAIR (i.e. Steel and Timber or reinforced concrete and Steel)
- The BALLUSTRADE is a part of the STAIR, which is installed for the purpose of SAFETY of the STAIR. Beside that, ballustrades may help to beautify the stair case.

CIVIL ENGINEER. DEPARTMENT

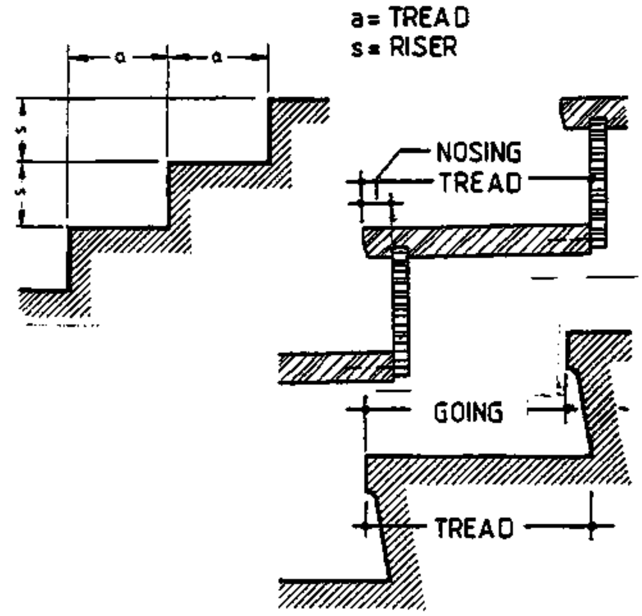
13.2. Definition of Terms

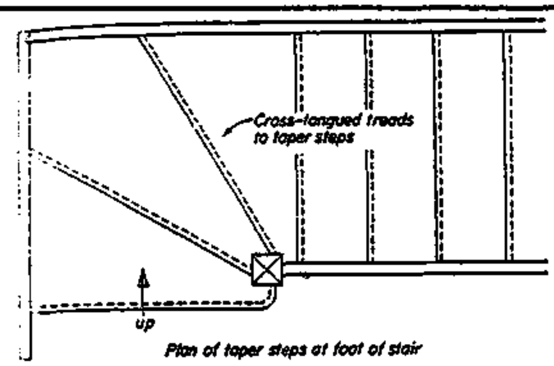
13.2 DEFINITION OF TERMS

- STEP: is a short horizontal surface for the foot to ease ascent from one level to another.
  It consists of an horizontal element called TREAD and a vertical element called RISER.
  The external junction of the tread and riser, or the front edge of the tread (if projects beyond the face of the riser) is called NOSING.
  Special names are given to steps according to their shape on plan:
  - FLIERS are normal parallel steps, uniform in width and rectangular on plan.
  - TAPERED STEPS are steps of which the nosing is not parallel to that of the step above it. There are two forms of tapered steps:

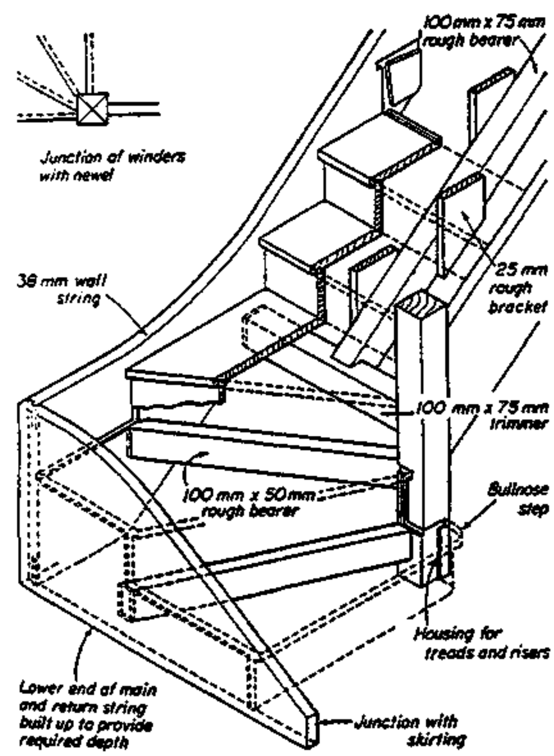
  a) WINDERS - are tapered steps the back and the front edge of which radiate from the centre on a newel post.

  b) DANCING STEPS (or BALANCED STEPS) - are tapered steps the edges of which do not radiate from a common centre. They are built in a way that their narrow end is little narrower than the parallel tread of the straight part of the STAIRS. They are therefore more comfortable to walk on, than a WINDER, in which the nosing radiate from a common centre.



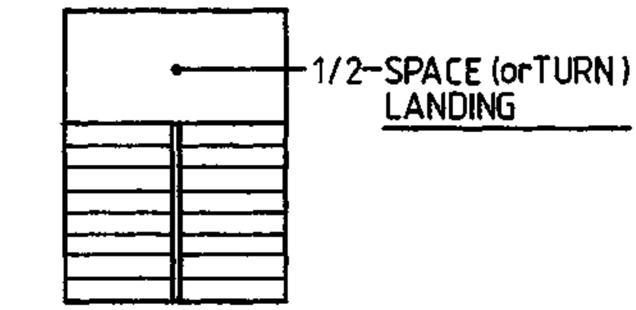


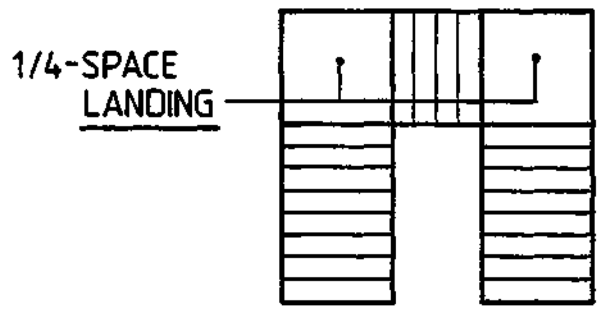
Plan of taper steps at foot of stair

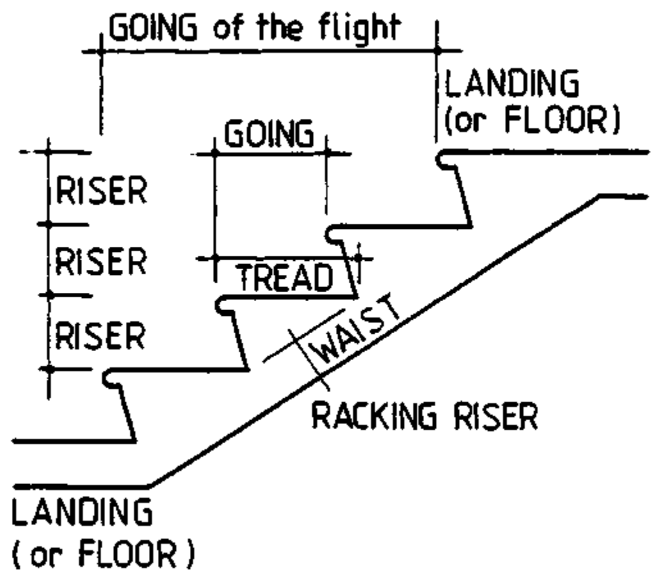


DEFINITION OF TERMS

- FLIGHT : A series of steps between FLOORS and LANDINGS.
- LANDING : A platform between two flights. A landing serves as a <u>rest</u> between flights and also as a means to turn a STAIR.
- . A HALF - SPACE-LANDING extends across the width of two flights and on it a <u>complete half turn</u> is made.
- . A QUARTER-SPACE-LANDING is one on which a <u>quarter turn</u> only is made from the end of one flight to the beginning of the next.
- RISE of a STEP is the vertical distance between the upper surface of 2 consecutive treads and the RISE of a FLIGHT is the total height between the floors or landings i t connects.
- RACKING RISER: A riser which is not vertical and overhangs the tread below, to give more foothold. The tread is bigger than its going.
- GOING (or RUN) of a step is the horizontal distance between the nosings or risers of 2 consecutive steps, and of a flight, the horizontal distance between the top and bottom nosings.
- LINE OF NOSINGS: Is an imaginary inclined line touching the nosings of a flight.
- PITCH or slope: The angle made between the line of nosings and the line of the floor or landing.





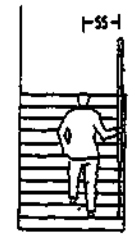


DEFINITION OF TERMS

- WALKING LINE: The average position taking up by a person ascending or descending the stair and generally taken to be 450 mm from the centre of the handrail.
- HEADROOM: The vertical distance between the line of nosings and any obstruction over the stair, usually the soffit of an upper flight or the lower edge of a floor or landing.
- BALUSTRADE: Provides protection on the open side or sides of a stair; it may be either solig or open. An open balustrade consists of vertical bars called BALUSTERS supporting and HANDRAIL.
- STRING or STRINGER: An inclined member which, if fixed to a wall, may act simply as a housing for the steps as in a timber steirs. If it is not feixed to a wall, it then acts as an inclined beam supporting the steps.
- STAIRCASE: This term is applied to a stair together with the part of the building, which encloses it, although it is also commonly used in reference only to the complete assembly of flights, landings and balustrades in a single stair.

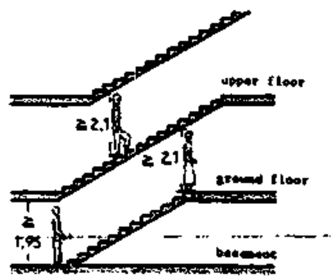
WALKING LINE

If stairs are narrow or curved, distance of walk line from outer string is 350-400 mm (14-16 in)

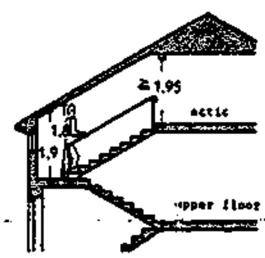


If stairs are wide and straight, distance of walk line from handrail is 550 mm (22 in)

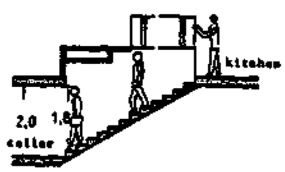
HEADROOM



Stairs correctly placed above each other save space

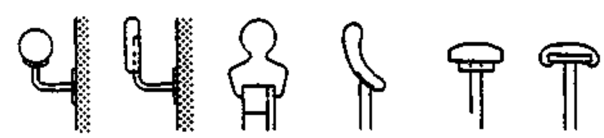


Rafters and joists running parallel to stair save space and costly trimmings



Avoid trap doors and necks to cellars, but combination shown is good and safe

HANDRAILS



HANDRAIL PROFILES

HANDRAILS AT LANDINGS

13.3 TYPES OF STAIRS

13,3 - TYPES OF STAIRS

- The form of a stair depends on the size of the STAIRCASE. Also practical or aesthetical reasons might be taken in to consideration for the choice of the stair.
- Stairs are classified according to: the number of flights, the plan form, the kind of landings, and whether they are RIGHT - HAND or LEFT - HAND - STAIRS.

. According to the number of flights, stairs may be classified as:

a one-flight stairs
b two-flight stairs
c multi-flight stairs

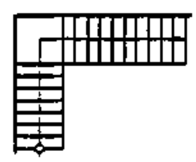
a: one-flight stairs lead without landing from one floor-level to the other

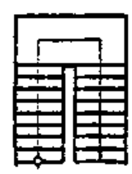
b: two-flight-stairs consist of two flights and a landing in between.

c: in case the difference in level between two floors increases, more than two flights with landings in between might become necessary.
In multi-story buildings, two-or multi-flight stairs are common, in order to make ascent and descent more comfortable.

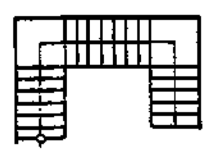
one-flight stairs

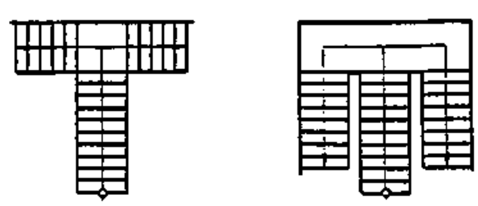
two-flight stairs





multi-flight stairs



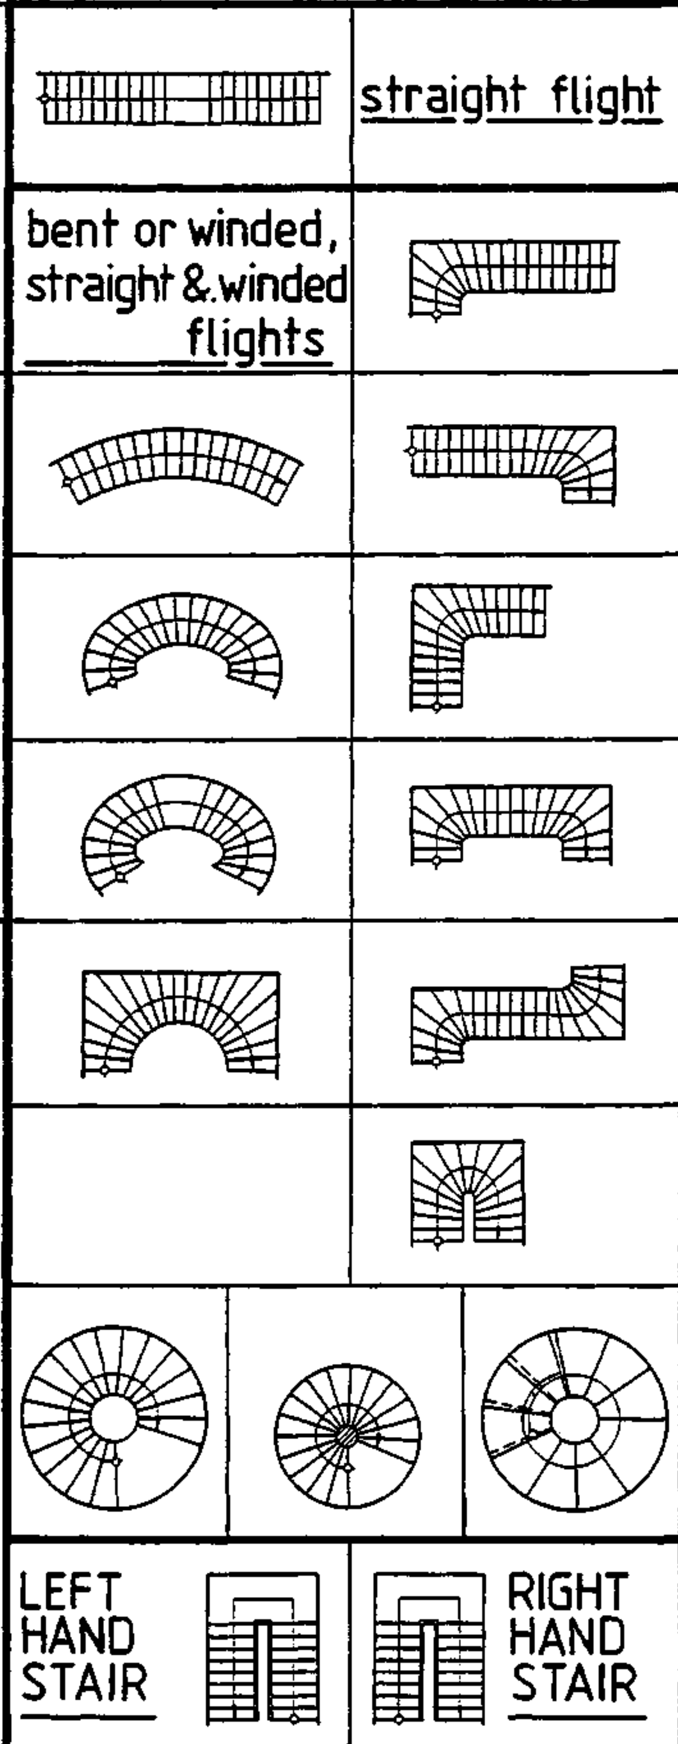


TYPES OF STAIRS

- According to the plan form stairs can be classified as:
  stairs with straight flights
  stairs with bent or circular (winding)flights
  stairs with straight and winding flights.

- According to the kind of landing stairs can be classified as:
  stairs with a half-space-landing and
  stairs with a quarter-space-landing (ref.13.2)

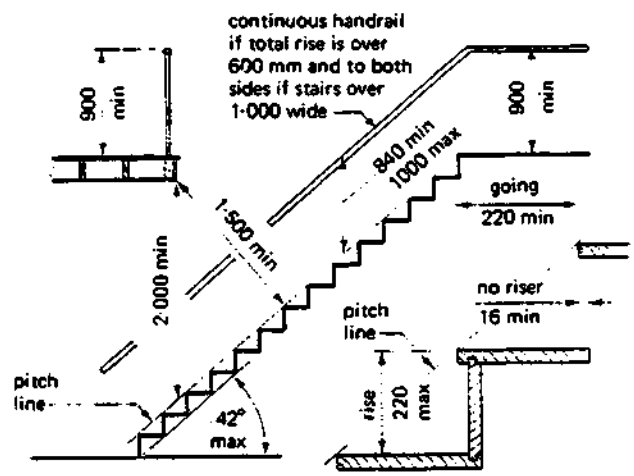
- The term RIGHT-Hand or LEFT-Hand-Stair depends on the open side of the stair:
  Ascending the stair, if you have to hold the handrail with your right hand, it is called a RIGHT HAND STAIR.
  In case of a LEFT HAND STAIR you will find the hand rail on your left hand side.
  Tapered or spiral Stairs are called RIGHT-HAND-STAIRS if the walking direction turns to the right (clockwise) from the straight. Left-hand-stairs turn to the left.



13.4 DESIGN OF STAIRS

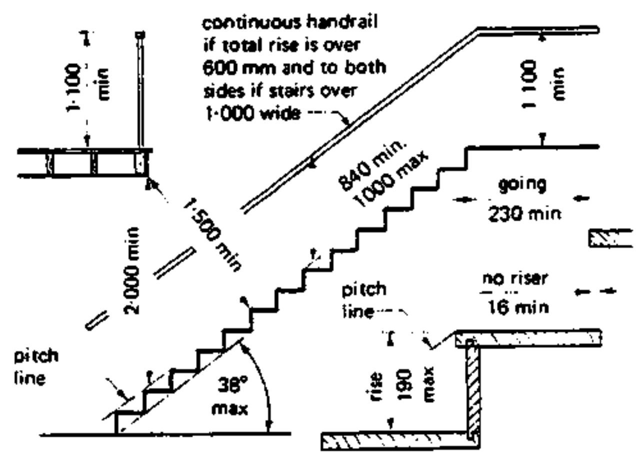
13.4 <u>DESIGN OF STAIRS</u>

- Apart from economic factors, a number of other related to COMFORT and SAFETY in use must be considered in the design of a STAIR. These are concerned with <u>ease of ascent</u> and <u>decent</u> and with protection and support at the sides.
- The dimensions of a STAIR will depend on the VOLUME of TRAFFIC it must carry and also on the NATURE of FURNITURE and EQUIPMENT, which is likely to be carried on it.
- The WIDTH of the flights and landings are important, particulary at the turns. The DIMENSIONS of the TREADS and RISERS should be <u>propor-tioned</u> to give easy ascent and decent.
- STAIRS to be placed correctly within the building.
- MEANS OF ESCAPE
  - Unobstructed egress facilities from big buildings to be provided by ESCAPE ROUTES (I.e.stairs, corridors, balconies and exits) These should be protected by FIRE-RESISTING ENCLOSURES with fire-resisting doors to prevent smoke and fire spread.
  - Tall residential blocks may be planned round a single fire-resistent staircase with access by a common cross ventilated lobby.
  - Office-shop-,factory- and public buildings have special regulations; number, width and position of stairways are related to area and height of these buildings, number of users, and fire risk caused by various activities carried out in them.



sum of going + twice rise = 550 min. to 700 max.
in any flight all risers of equal height and all goings of equal width

Private Stairways

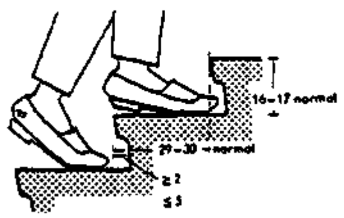


sum of going + twice rise = 550 min. to 700 max.
maximum number of risers in any flight = 16
in any flight all risers of equal height and all goings of equal width.

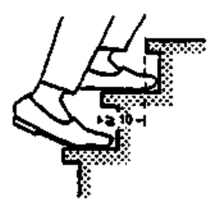
Common Stairways

13.41 RISE - TREAD- PROPORTION

- Comfort in use of a stair depends largely upon the relative dimentions of the rise and going of the steps.
  Rules for determining the proportion are based to some extend upon the assumptions that about <u>twice as much effort is required to ascend than to walk horizontally.</u>
- The average pace of a person walking horizontally measures up to 70 cm. Ascending, the pace will be reduced to 61- up to 65 cm.
- Important for a comfortable and safe use of a stair is the <u>rise</u>.



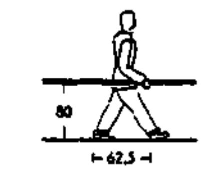
Standard rise of stairs in dwellings and office buildings



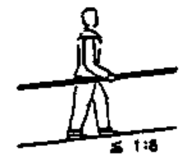
Minimum tread if stairs are curved;

Common rises for different types of stairs	
stair	rise
garden-and open air stairs	12 to 16 cm
stairs in Public Buildings	16 to 18 cm
stairs in flats and dwellings	17 to 19 cm
stair of minor importance	up to 21 cm

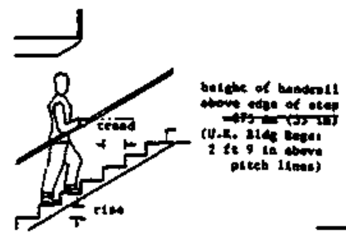
13.41 RISE-TREAD-PROPORTION



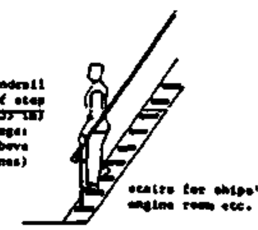
Standard pace of an adult on a horizontal plane



On a ramp the pace is reduced proportionately. Desirable slope 1:10-1:8

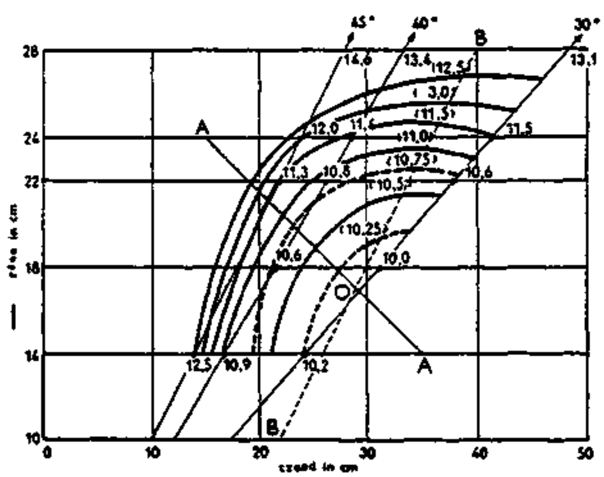


Optimum rise is 2a+1b =625 mm (approx. 23 in; U.K. Bldg Regs 1965)



Ladder stairs with handrails up to 210 x 150 mm (8.4 x 6 in), without handrails up to 250 x 100 mm (10 x 4 in)

- Ascending a stair, one has to step over one tread and two rises.
- All the above mentioned facts result in certain rules which are the base for a good <u>rise-tread proportion</u>.



Relationship between energy required and form of stair (after Dr W.Doll & Dr G.Lehmann)

Figures at the left show the rises, those underneath the treads (both in cm). The figures in the curves show energy in calories per mkg climb-effort. The figures above indicate some pitch angles of stairways. The curves connect all points of equal energy consumption. Therefore all stairs with rise-tread proportions on one of these curves are of equal energy consumption.

Line A + A equals the formula .... 2a + 1b = 630 mm (23 in)
Line B - B equals the formula .... 1b - 1a = 120 mm (4.8 in)

RISE-TREAD-PROPORTION

RULES :

I PACE - RULE:

2 Rises (a) + 1 tread(b) = 61 cm to 65 cm (average 63cm)

- 2a + b = 63 cm

  b = 63 cm - 2a

Example:

The rise-tread-proportion for a stair in a flat has to be calculated:

- rise a - (ref.Table)=17-19cm
- difference of floor levels - h - =2,75 m
- Number of rises - h - = always an integer number.

$$n = \frac{h}{\text{average } a} = \frac{2{,}75}{18} = 18{,}33 \text{ cm}$$

Tread - b- to be expressed in round cm numbers:

I Pace-Rule:

b= 63 cm-2.18,33=26,34 cm

choosen: b=26 cm

proportion:15x18,33/26

II Safety-Rule:

b= 46cm-18,33=27,67cm

choosen: b = 28 cm

proportion 15x18,33/28

III Comfort-Rule:

b= 12 cm + 18,33 =30,33 cm

choosen : b = 30 cm

proportion 15x18,33/30

II SAFETY - RULE:

(For stairs with steep or small pitches)

1 rise (a) + 1 tread(b) = 46 cm

- a + b = 46 cm

  b = 46 cm - a

III COMFORT - RULE:

(relatively wide treads with normal rises of 16-19 cm)

Tread (b) - rise (a) =12cm

- b-a = 12 cm

  b = 12 cm + a

Decision:

either: medium proportion 15x18,33/28

or : according to the space available in the staircase.

- The number of rises is defined as - n- (15 in our case).

Upwards the stair begins with a rise followed by a tread. The last rise is followed by the next floor lavel. There is therefore no tread:

No. of treads = No. of rises - I

= n - I

(= 15 - I = 14)

According to the PLAN the LENGTH of the stair - l - is equal to the sum of the treads:

L = b= (n-I)xb

The length - l - for the example:

I L = (15-I)x26=3,64 m

II L = (15-I)x28=3,92 m

III L = (15-I)x30=4,20 m

13.42 SLOPE OR PITCH

13.42 Slope or Pitch

of a stair should not exceed 45^o nor be less than 25^o.
For stairs in regular use a maximum of 35^o should be taken.
The slope is given for the walking line.

$$\boxed{\text{Pitch} = \frac{\text{rise}}{\text{tread}} = \frac{a}{b}}$$

Example for the proportion 18,33/28 cm:

$$\frac{a}{b} = \frac{18{,}33\ \text{cm}}{28\ \text{cm}}$$

(A) - Pitch as proportion

$a : b = 1 : x$

$x = \frac{1 \times b}{a}$

$a : b = 1 : \frac{b}{a}$

Example for proportion 18,33/28 cm

$a : b = 1 : \frac{b}{a}$

$a : b = 1 : \frac{28\ \text{cm}}{18{,}33\ \text{cm}}$

$a : b = 1 : 1{,}53$

(3) - Angle of the Pitch:

$\tan X = \frac{a}{b}$

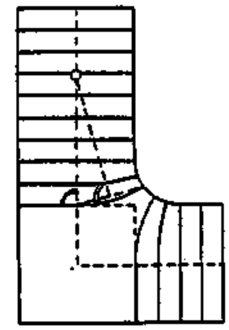
Example for proportion 18,33/28 cm

$\tan X = \frac{18{,}33\ \text{cm}}{28\ \text{cm}}$

$\tan X = 0{,}6546$

$X = 33{,}21^o$

13.43 LANDINGS



Curved steps at landing on a narrow stair save landing space

13,43 - LANDINGS (already defined) ref.to 13.2

(a) Straight landings to be provided at least after 18 rises (as a REST)
Length of the landing:
in accordance with the pace

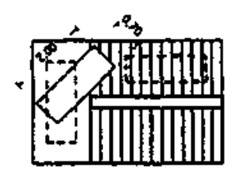
$L = N \times 63\ \text{cm} + 2\ \frac{b}{2}$

(No.of paces)

(b) Landings for turning the direction (half-space or quarter space)
Length of the landing:

$L = 1{,}1 \times \text{width}$ (minimum 1m)

The important factor is the space required for the transportation of large pieces of goods.



Minimum space required to move furniture

13.4.4. WIDTH

13.44 <u>Width</u>

The usable width of a stair has to be measured at the narrowest place of the staircase.

For main stairs the width depends on the use of the stair. (whereby the type of building the number of persons passing each other or the number of people staying in the building are of importance.)

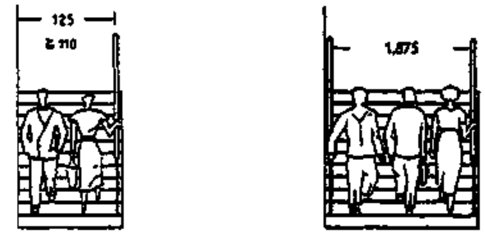
A Common usable width of STAIRS according to the type of building:

TYPE of BUILDING	WIDTH
1-,2-,3-,family flats/ dwelling houses	0.80 — 1.00 m
bigger flats	1.10 — 1.30 m
public buildings	1.30 — 1.90 m

B Usable width of STAIRS according to the number of persons passing each other

No. of PERSONS	WIDTH
2 PERSONS	1.10 — 1.30 m
3 PERSONS	1.80 — 1.90 m

For STAIRS of minor importance (i.e. emergency stairs, stairs in buildings with a lift, etc). the measurements may be reduced, but they have to be in accordance with the rules of the local authorities.



width of stairs allowing two people to pass

8 width of stairs allowing three people to meet and pass

13.45 WALKING LINE

13.45 <u>Walking line</u>: (Definition ref. 13.2)

The representation of the walking line begins with a circle on the nosing of the lowest step and ends with an arrow on the nosing of the next floor level.
The walking line leads always upwards.
In case of all strenght and round flights up to a width of 0.95 m the walking line is always in the centre.
In case of a width exceeding 0.95m the walking line is taken to be generally 45 cm from the centre of the handrail.
On the walking line, the calculated measurements for the treads to be indicated.

13.5 CONSTRUCTION OF STAIRS

13.5 Construction of Stairs

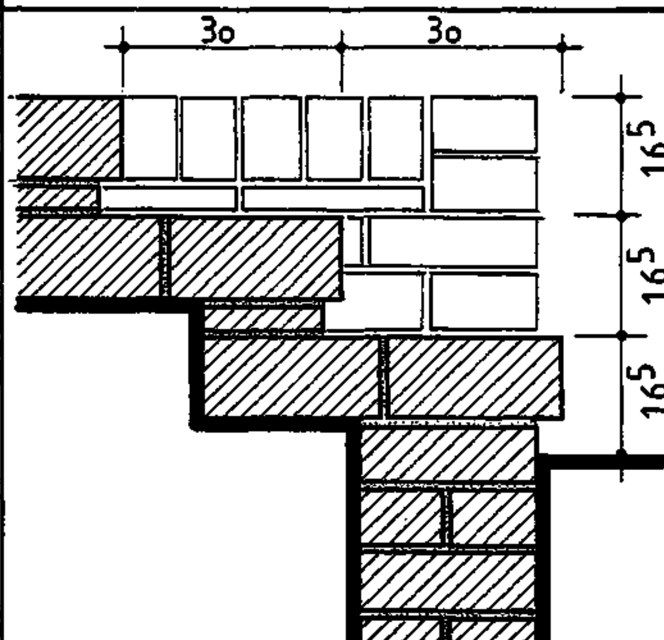
13.51 BRICK STAIRS

Bricks are used for simple external steps and stairs and occasionally for internal use.
The steps must be formed of good hard, square bricks and are bedded in cement mortar on concrete.

If the steps are not built on a natural slope of ground, the deep hardcore filling must be carefully and well consolidated to avoid settlement.

The bonding of the bricks will depend on the dimension of tread and riser and the bricks will normally be laid on edge to expose the face sides and the ends.

13.51 BRICK STAIRS



13.52 STONE STAIRS
are used as external and internal stairs.
In case of external stairs the material has to resist the elements therefore GRANITE, BASALD and hard SANDSTONE are suitable materials.

Stone stairs may be in the form steps simply supported on end walls or as cantilever flights and landings or in the form of a circular newel or turret stair.

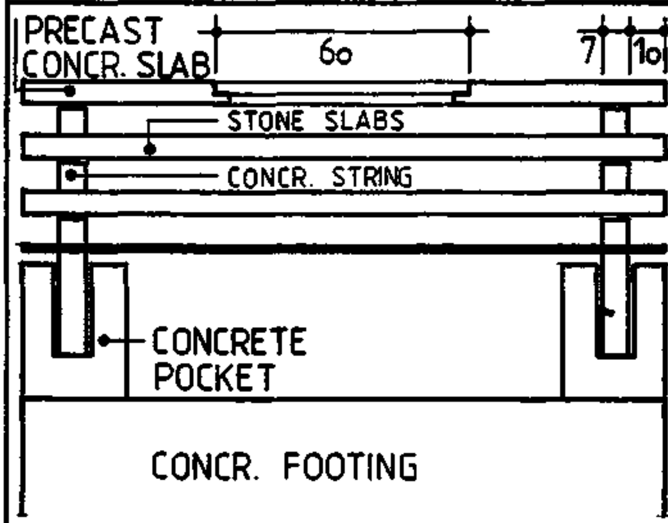
Simply supported or cantilevered steps can be either rectangular blocks giving a stepped soffit or spandrel steps, splayed on the underside to give a smooth soffit.

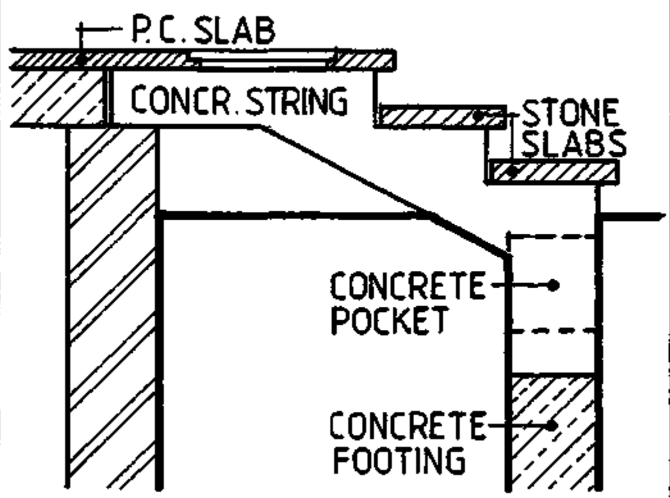
Cantilever stone steps should not usually exceed 1.50m to 1.80m in projection, the safe max. depends upon the type of stone used.

If landings are large, these are made up of a number of slabs with joggeled joints.

The newel stair is similar to the spiral newel stair in precast concrete, but because of the transverse weakness of stone the steps are not to cantilever out from the central newel (where the stone is thinnest); the outer ends are built into the enclosing wall, so that each is a step simply supported on the wall and the newel.

13.52 STONE STAIRS





13.53 CONCRETE STAIRS

13.53 Concrete Stairs

Concrete stairs are widely used in all types of buildings
- They have a high degree of fire resistance,
- are strong, and
- make possible a wide variety of forms.

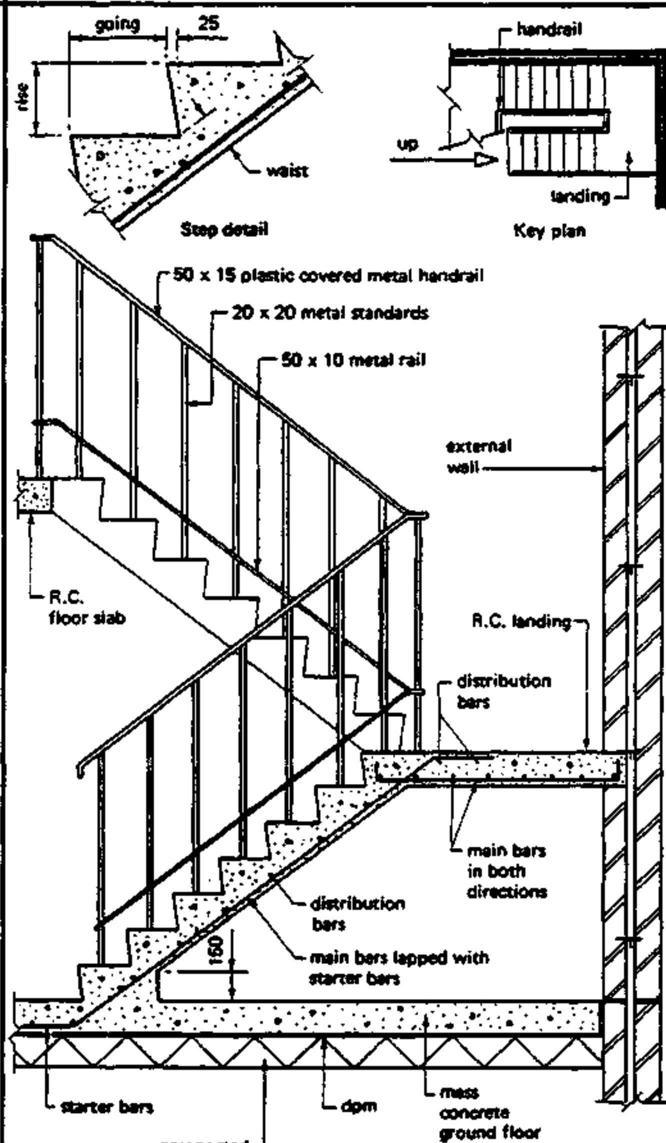
They may be cast in-situ or be precast as whole flights of in seperate parts.

13.531 In Situ Cast R.C.Stairs

- The concrete specification is usually
  - concrete mix 1 : 2 : 4
  - min. cover of concrete over reinforcement : 15 mm (or bar diameter whichever is greater)
  - waist thickness usually between 10 and 25 cm depending on stair type.
  - mild steel or yield steel bars can be used as reinforcement.

    The bars being lapped to starter bars at the ground floor and taken into the landing or floor support slab.

    Number, Diameter and Spacing of the main and distribution reinforcement must always been calculated for each stairway.



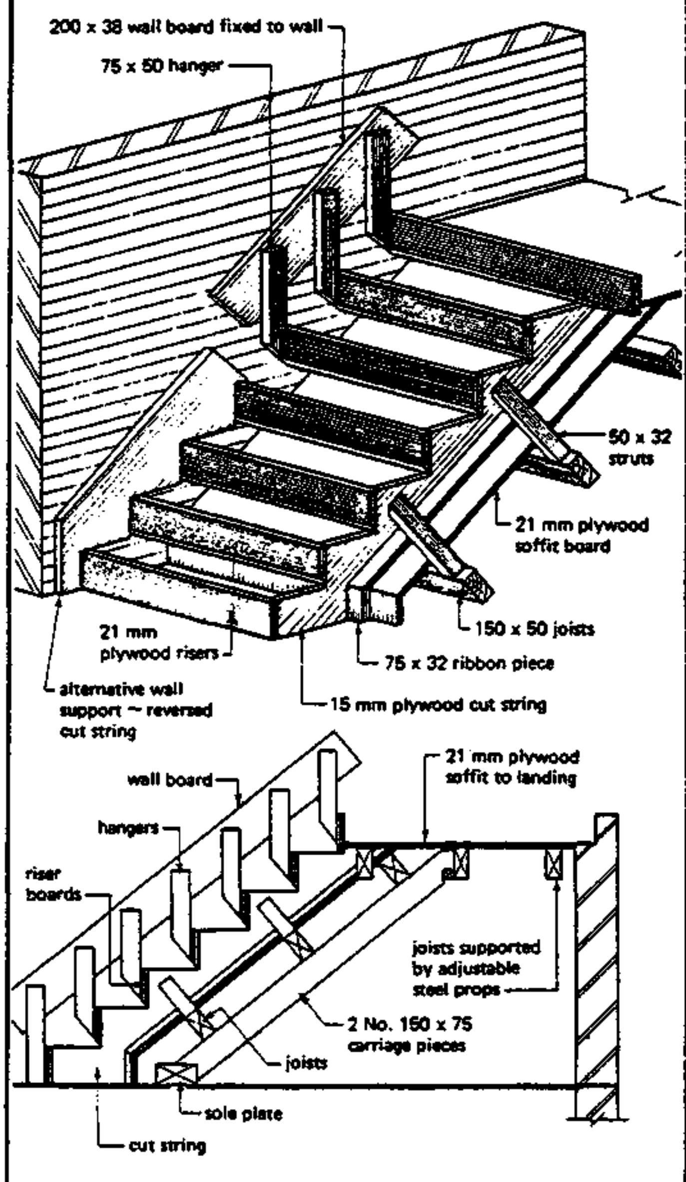
Simple R.C. in situ stairs

CONCRETE STAIRS

- A wide variety of finishes can be applied to the tread surface of the stairs.
- The soffits can be left as struck from the formwork and decorated or finished with a coat of spray plaster or a coat of finishing plaster
- The basic formwork requirements are the same as for formwork to a framed structure.
  - The stair profile is built of an adequately supported soffit of sheet material by using a cut string.
  - Riser boards are used to form the leading face of the steps (these should have a splayed bottom edge to enable complete trowelling of the tread surfaces and to ensure that air is not trapped under the bottom edge of the riser board thus causing voids.
  - If the stair abuts a vertical surface, two methods can be considered to provide the abutment support for the riser boards.

    a) a reversed cut string or

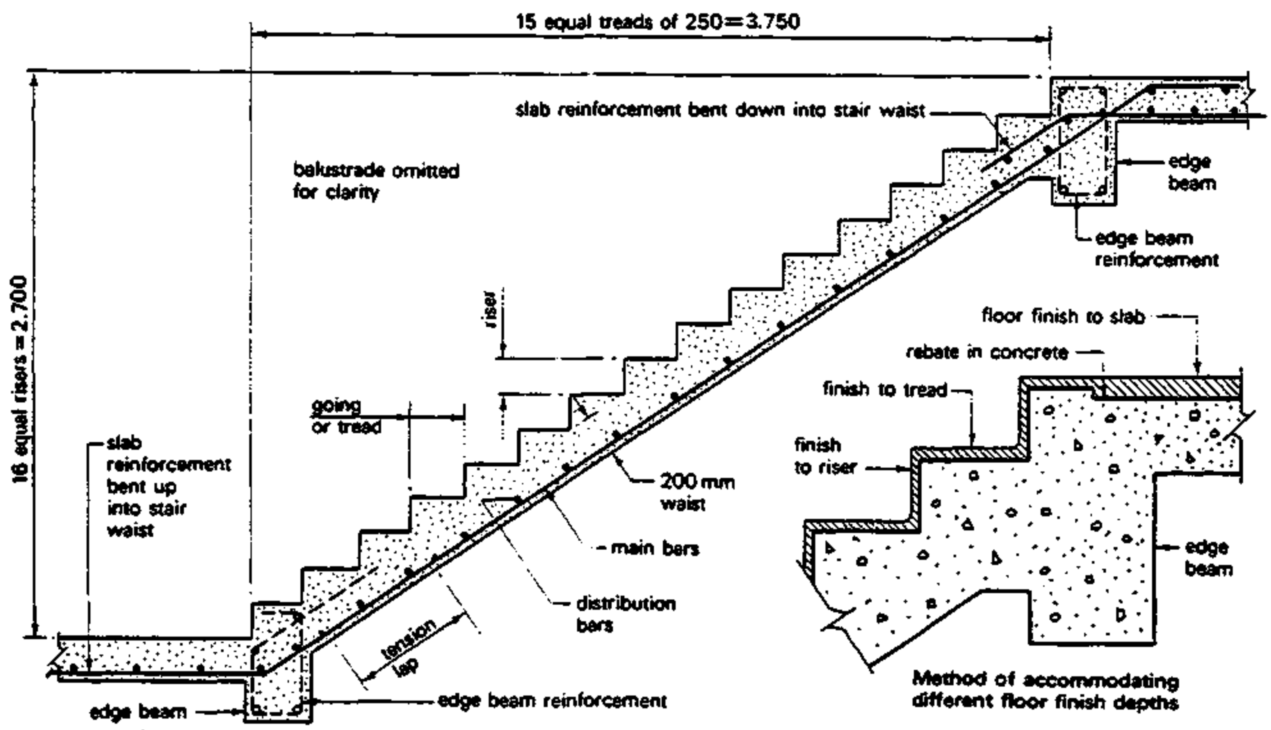
    b) a wall board with hangers.
  - wide stairs can have a reverse cut string as a central support to the riserboards to keep the thickness of these within an ecceptable load limit.



Typical formwork to R.C. in situ stairs

Single flight stairs
- Long and cross spans

- The structural behaviour of a stair flight is very similar to that of a simply supported slab,
  - its effective thickness being its waist. -
- When considering single flights between floors, it should be realised that it is uneconomic to span the flight between landings, since an extra distance of about 1 m at either and of the flight would result in a long span of up to 6 m.
- If downstand beams are provided at the edges of the landings, the effective span may be reduced to 4 m for the same flight which would result in a bending moment reduction of over 50 %.
- The arrangement of reinforcement is shown in figure



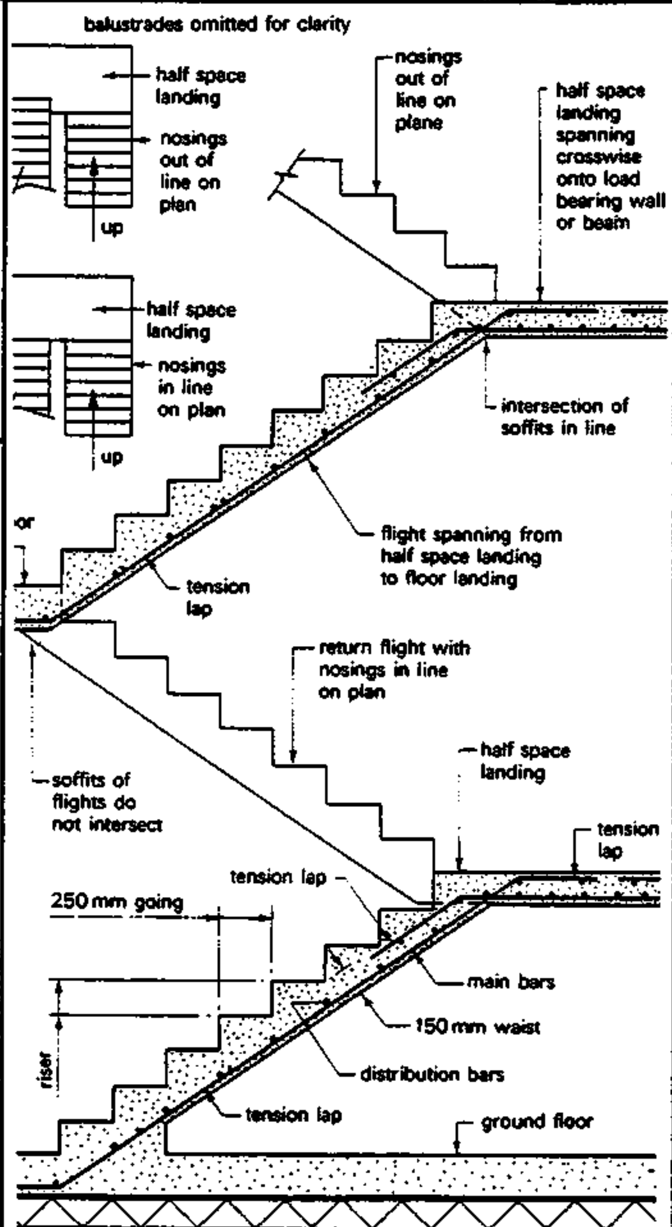
Straight flight concrete stairs

Method of accommodating different floor finish depths

HALF FLIGHTs WITH LANDINGS

Half flights with landings
(inclined slab concr.stair)

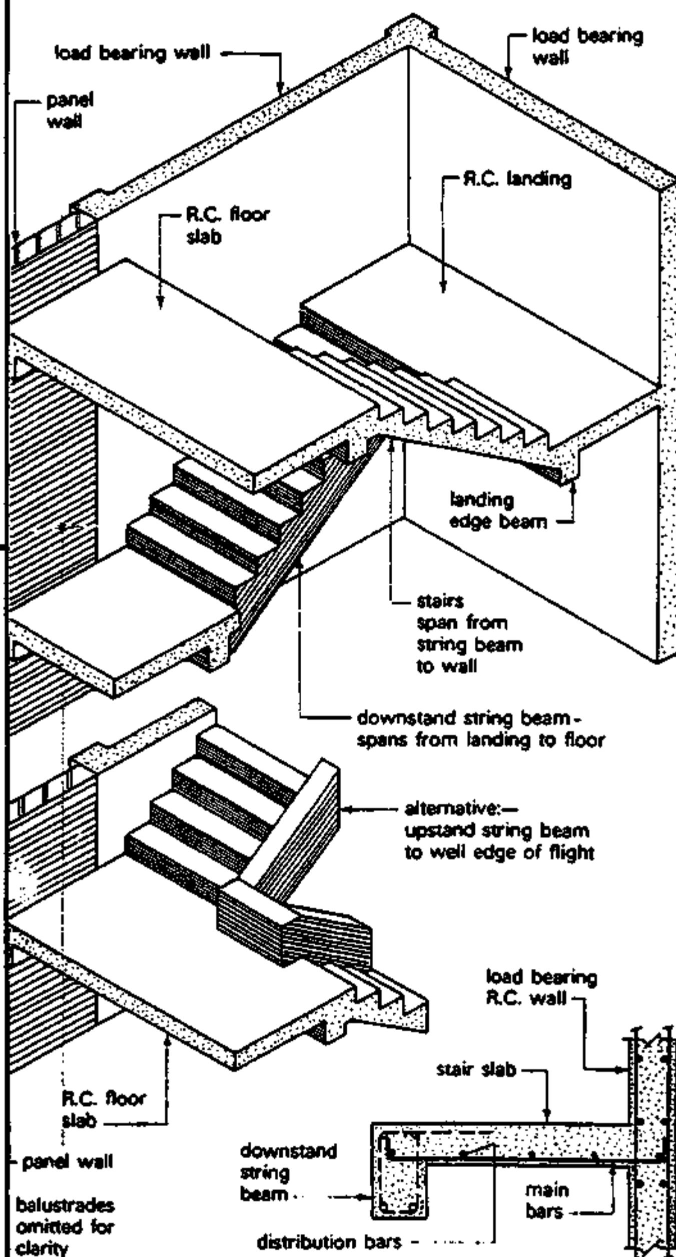
- Where half landings are incorporated it is normal for stairs to span on to the landings with the landings spanning cross ways.
- The arrangement of reinf.bars are shown in the figure. It should be noticed again, that the tension lab is required at the top and bottom of each flight, this is to overcome the tension inducted by the tendency of the external angles of the junctions between stair flights and landings to open out.



Inclined slab concrete stair with half space landings

STRING BEAM STAIRS

String beam stairs
- are an alternative design for the stairs described above. A string or edge beam is used to span from landing to landing to resist the bending moment with the steps spanning crosswise between them;
- this usually results in a thinner waist dimension and an overall saving in the concr. volume required. But this saving in material is usually offset by the extra formwork costs.
- The string beams can be either upstand or downstand in format and to both sides if the stairs are free standing.



String beam concrete stairs

CRANKED SLAB STAIRS

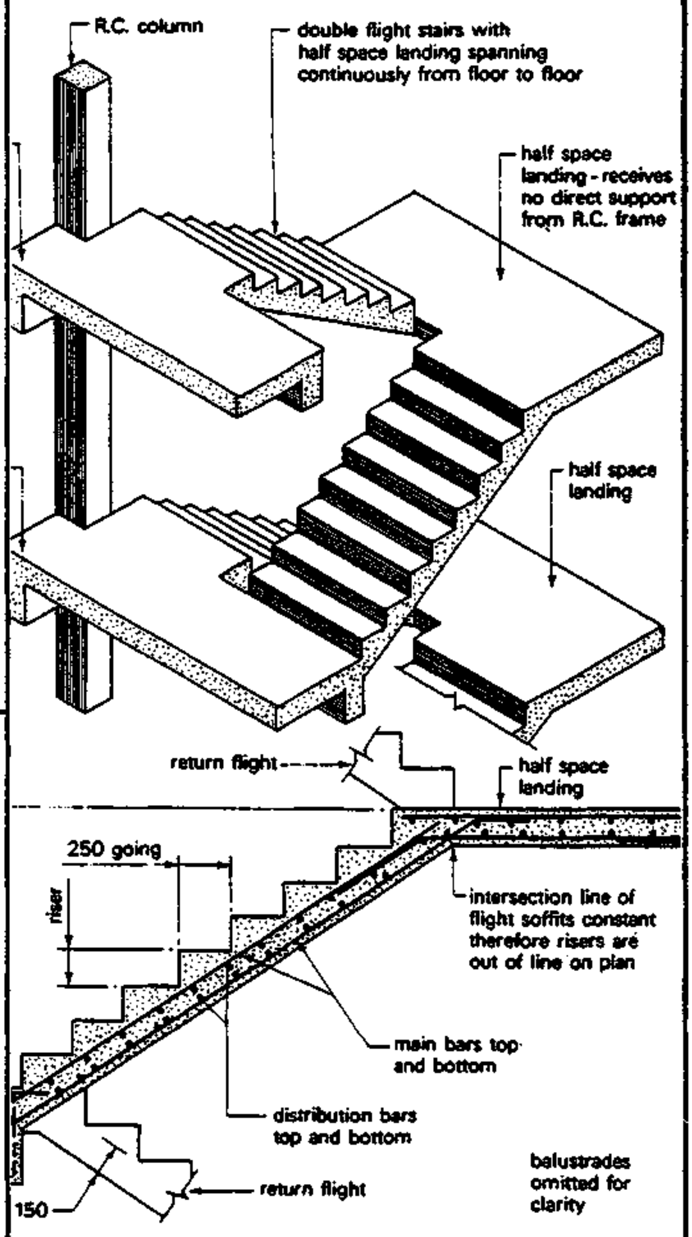
Cranked slab stairs

- are very often used as a special feature, since the half space landing has no visible support being designed as a cantilever slab.
- Bending, buckling and torsions stresses are induced with this form of design.

Creating the need for reinforcement to both, faces of the landing and slab or waist of the flights.

- The amount of reinforcement required can sometimes create site problems with regard to placing and compacting the concrete.

Typical details of a cranked slab stair (which is also known as a continous stair, scissor stair or jack knife stair) are shown in the figure.



Cranked or continuous slab concrete stairs

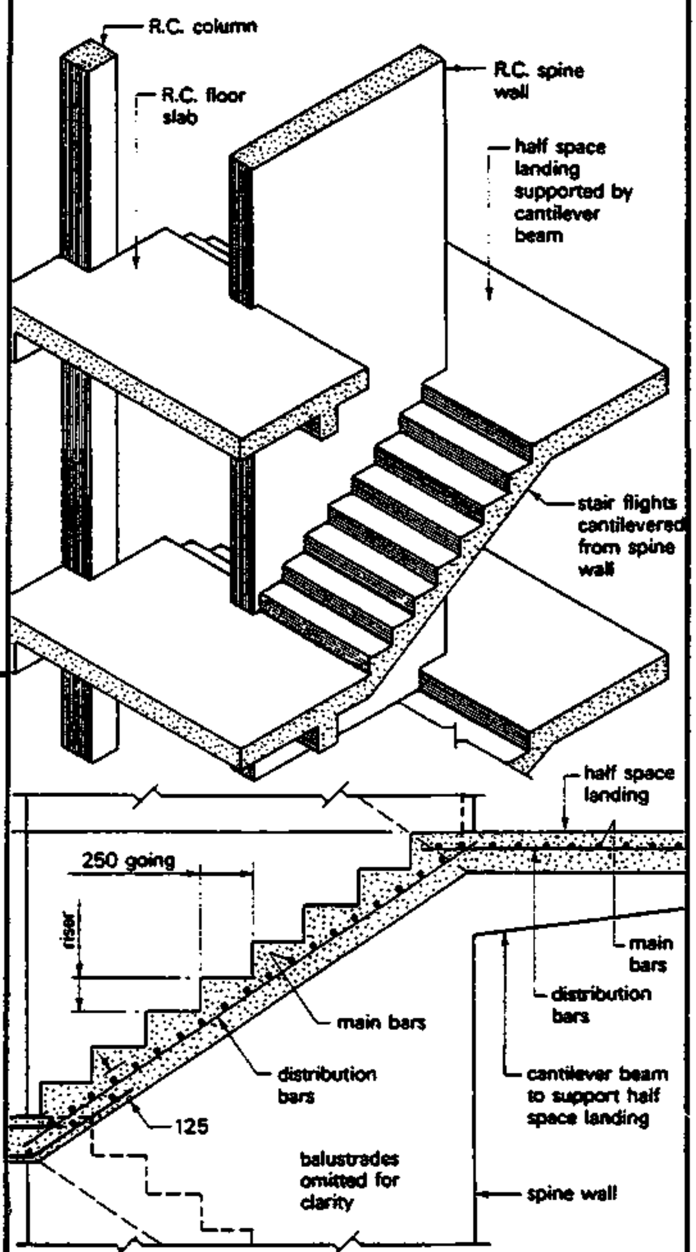
CANTILEVER STAIRS

Cantilever stairs:
(sometimes called spine wall stairs) consist of a central vertical wall from which the flights and half space landings are cantilevered.

- The wall provides a degree of fire resistance between the flights and are therefore mainly used for escape stairs.

Since both flights and landings are cantilevers the reinforcement is placed in the top of the flight slab and in the upper surface of the landing to counteract the induced negative bending moments.

The plan arrangement can be single straight flight or - as is usual - two equal flights with an intermediate half space landing between consecutive stair flights.



Cantilever concrete stairs

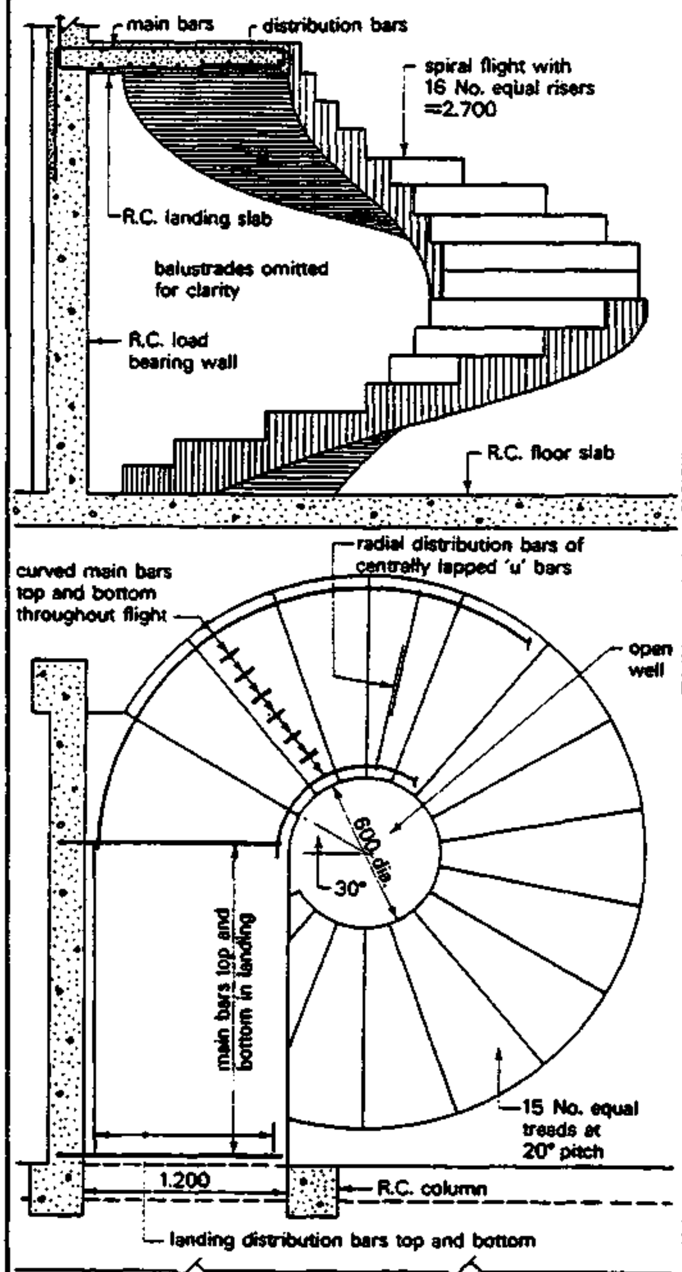
SPIRAL STAIRS

Spiral stairs are used mainly as accomodation stairs in the foyers of prestige buildings such as theatres and banks.

They can be expensive to construct, being normally at least seven times the cost of conventional stairs.

- The plan is generally based on a circle althogh it is possible to design an open spiral stair with an elliptical core.
  The stair can be formed around a central large diameter circular column in a similar manner to that described for cantilivered stairs or - as it is an usual design with a circular open stair well.
  Torsion, Tension and compressive stresses are induced in this form of stair which will require reinforcement to both faces of the slab in the form of radial main bars, bent to the curve of the slab with distribution bares across the width of the flight.

Formwork for spiral stairs consists of a central vertical core or barrel to form the open stair well to which the soffit and riser boards are set out and fixed, the whole arrangement being propped and strutted as required from the floor level in a conventional manner.



Open spiral concrete stairs

13.532 Precast Concrete Stairs

- Most of the concrete stair arrangements previously described can be produced as PRECAST CONCRETE COMPONENTS which can have the following advantages:
  - better quality control of the finished product
  - saving in site space, since formwork storage and fabrication space is no longer necessary
  - stairway enclosing shaft can be utilised as a space for lifting materials dureing the major construction period
  - saving in time
  - can usually be positioned and fixed by semi-skilled labour.
- Like all precast components the stairs must be
  --repetitive and
  --in sufficient quantity
  to justify their use and to be an economic proposition.
- Simple precast concr. stairs spanning between landings can have a simple bearing or, by leaving projecting reinforcement to be grouted into preformed slots in the landings, they can be given a degree of structural continuity.
- Precast concrete stairs, constructed from a series of precast steps are either
  - built into or
  - cantilevered from

  a structural wall.

13.532 PRECAST CONCRETE STAIRS

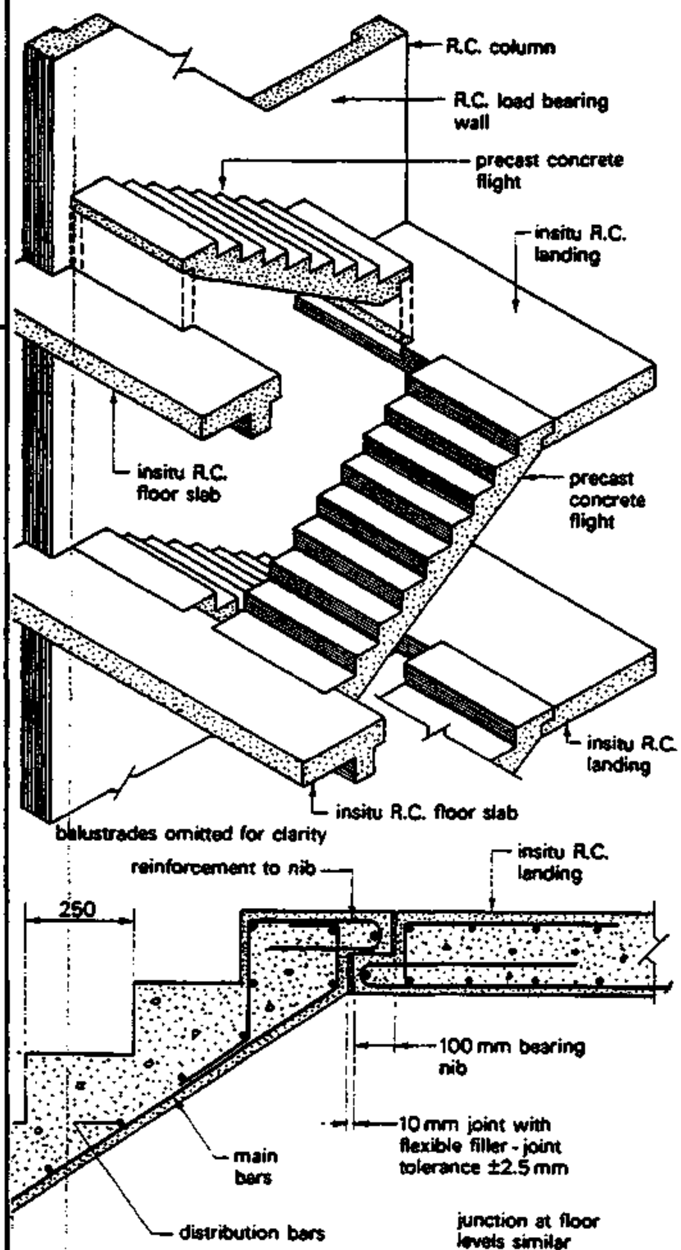
- The use of precaste concr. steps to form a stair way is limited to situations such as
  - short flights between changes in level
  - external stairs to basements

  etc.
  They rely on the load bearing wall for support and if contilevered on the downward load of the wall to provide the necessary reaction.
- The support wall has to provide the necessary load and strength and at the same time it has to be bonded or cut around the stooled and of the steps.
- The steps are usually fabricated in factoris. They consist of a concrete core covered with a facing material (artificial stone).
  To reduce the weight, the steps are often produced as hollow steps.
  It is advisable to protect the edges of the steps.

STRAIGHT FLIGHT PRECAST CONCRETE STAIRS

- Straight flight precast concrete stairs with a simple bearing require only Bottom Reinforcement to the slab and Extra Reinforcement to strengthen the bearing rebate or nib.

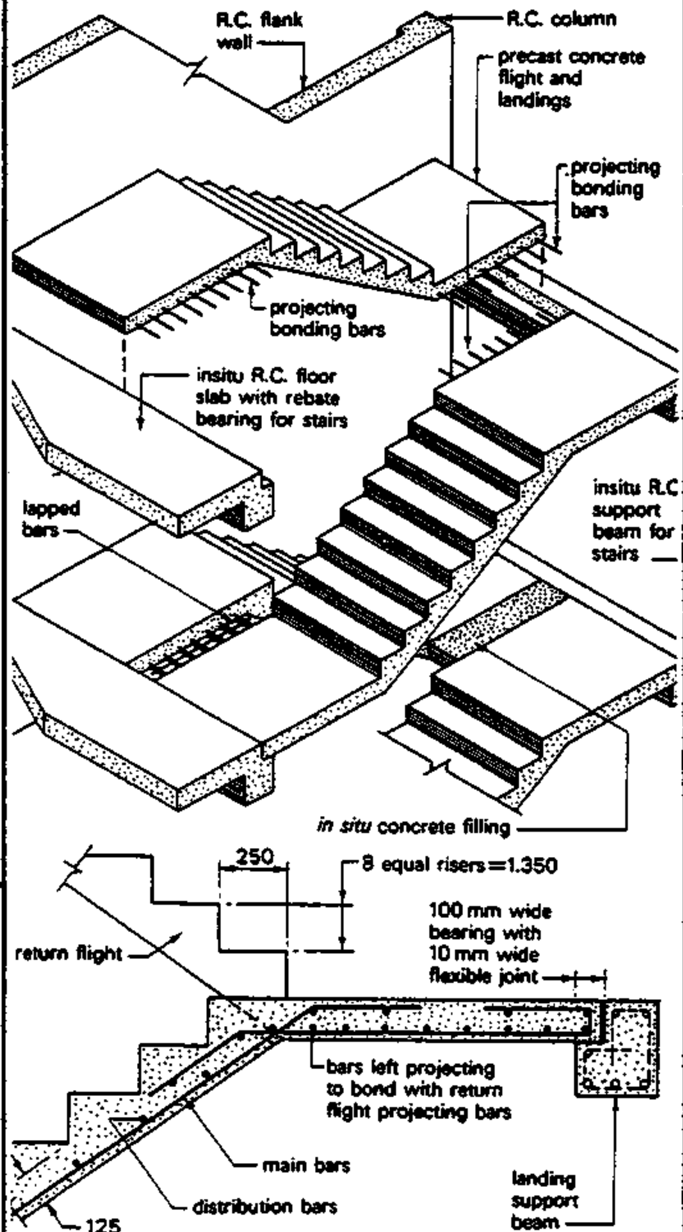
  The bearing location is a rabate cost in the in-situ floor slab or landing, leaving a tolerance gap of 8 to 12 mm which is filled with a compressible material to form a flexible joint.



Precast concrete straight flight stairs

CRANKED SLAB PRECAST CONCRETE STAIRS

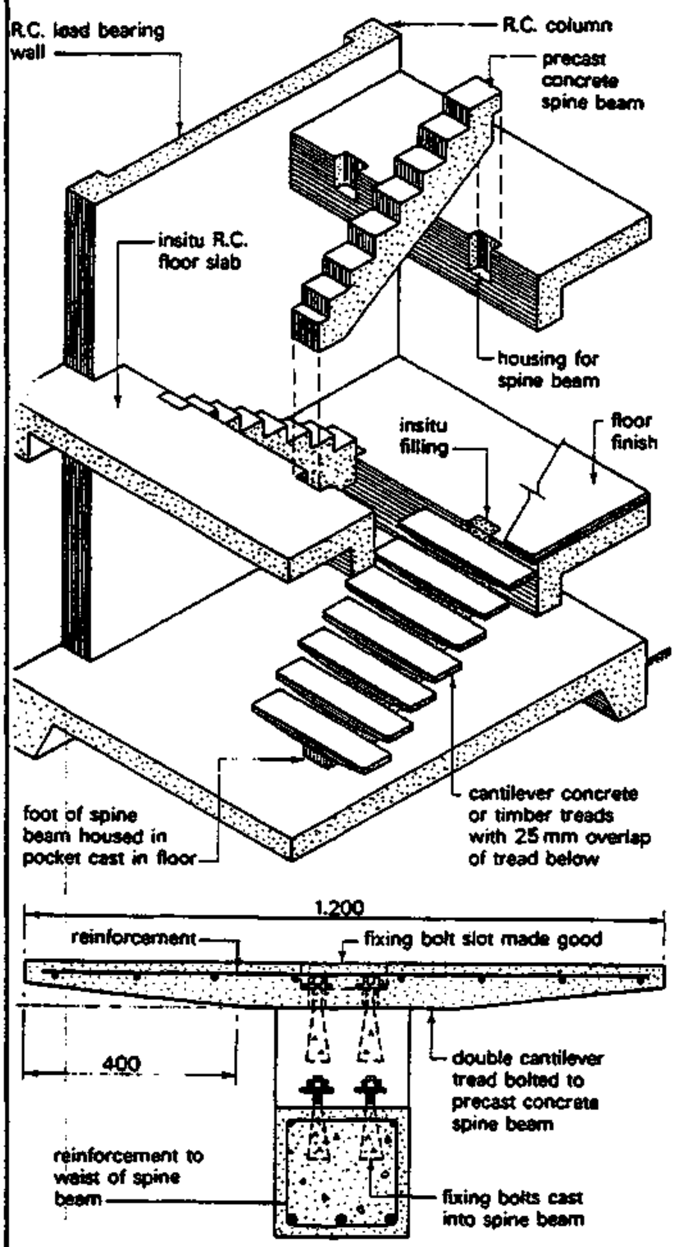
- <u>Cranked slab precast concrete stairs</u>
  are usually formed as an OPEN WELL stair. The bearing for the precast landings to the in situ floor or to the structural frame is usually in the form of a simple bearing.
  The infill can be of in-situ concrete with structural continuity (provided by leaving reinforcement projecting from the inside edge of the landings)
  N.B. when p.c.c. stair flights are hoisted into position,
  different stresses may be inducted from those which will be encountered in the fixed position.
  To overcome this problem the designer can either reinforce the units for both conditions OR - as is more usual - provide definite lifting points in the form of projecting lugs or by utilising any holes cast in to receive the balustrade.



Precast concrete cranked slab stairs

OPEN RISER PRECAST CONCRETE STAIRS

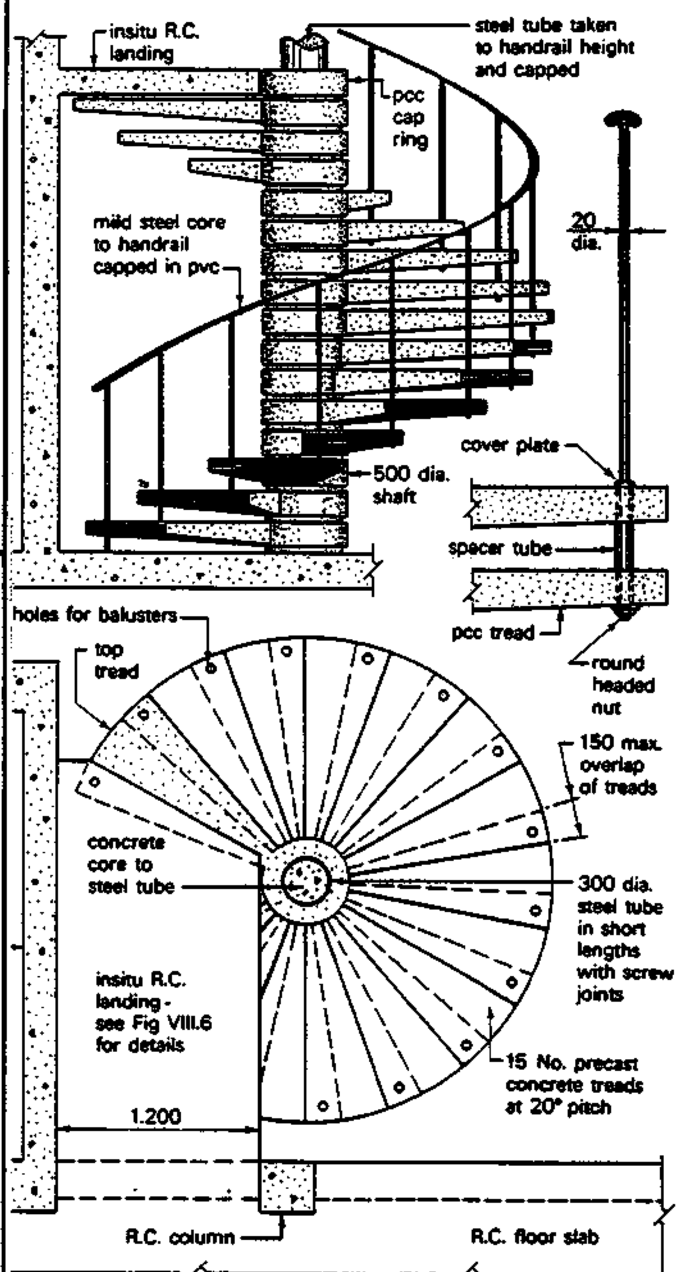
- Precast open riser stairs can be both: economic and attractive - consisting of a central spine beam in the form of a cut string supporting double cantilever treads of timber or precast concrete. The foot of the lowest spine beam is located and grounted into a preformed pocket cast in the floor whereas the support at landing and floor levels is a simple bearing located in a housing cast into the slab edge (ref. Fig.) Provisions for fixings of steps to the beam are given in the figure.
  . Reinforcement to the treads is simply a meshwork of straight bars.
  Spine beam reinforcement to be similar to that of a normal beam.
  . the anchor bolts to be placed sideways rather than lengthways to avoid possible rocking.
  . the finishes are applied after the fixing slots have been grouted up so that no fixings show through.
  . balusters are bolted directly to the treads and holes can be left to provide for these in casting.



Precast concrete open riser stairs

SPIRAL PRECAST CONCRETE STAIRS

- Spiral Stairs
in precast concrete work are based upon the stone stairs found in many historie buildings.
  - They are usually open riser stairs with a r.c. core or (alternatively) a concrete - filled steel tube core.
  - Holes are formed at the extreme ends of the treads, to receive the handrail supports in such a manner that the standard passes through a tread and is fixed to the underside of the tread immediately below. A hollow spacer or distance piece is usually incorporated between the two consecutive treads.



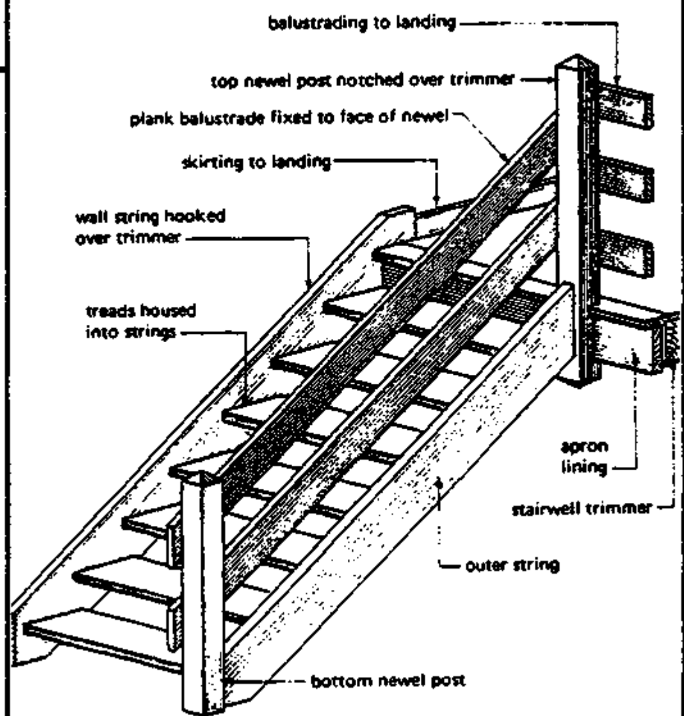
Precast concrete spiral stairs

13.54 TIMBER STAIRS

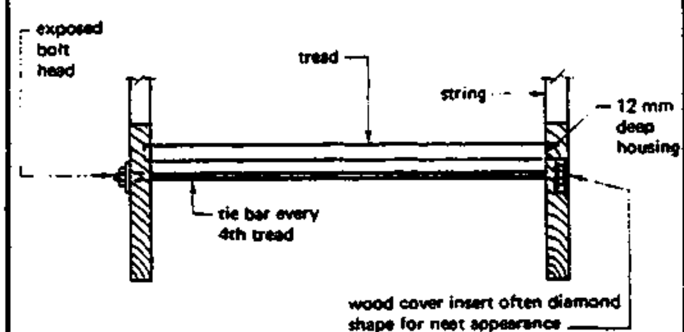
13.54 Timber Stairs

- timber stairs are commonly used in domestic buildings with either
  - . closed or
  - . open rises.
- Due to the position of their supports four basic types of timber stairs may be produced:

CLOSED STRING STAIRS



Typical arrangement



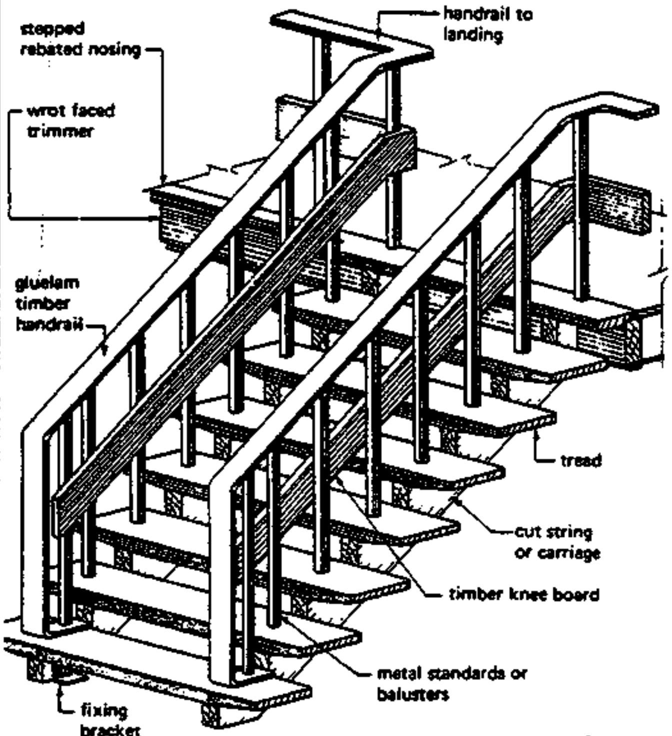
Alternative tie bar arrangements

Closed string open tread stairs

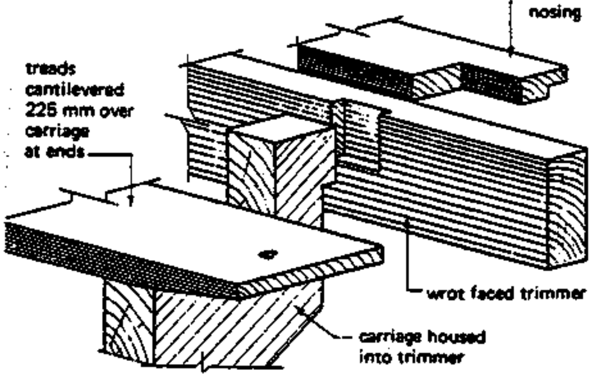
I. Closed string stairs

The treads are tightly housed into the strings which are tied together with long steel tie bars under the first, last and every fourth tread. The nuts and washers can be housed into the strings and covered with timber inserts.

CUT STRINGS or CARRIAGES



Typical arrangement

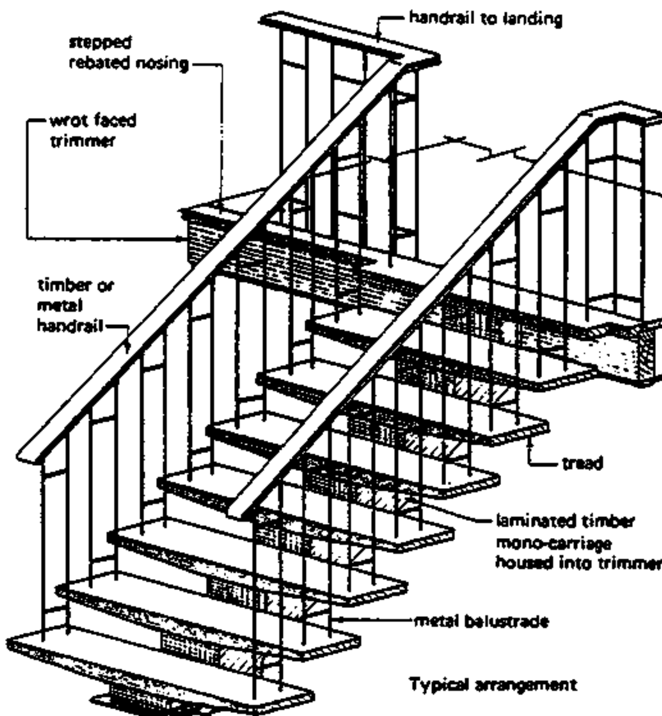


II Cut strings or Carriages

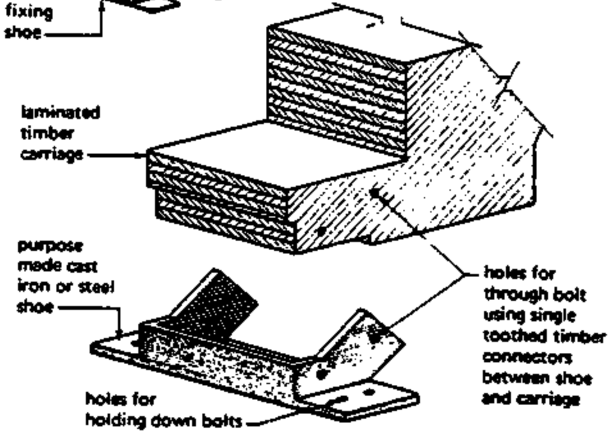
These are used to support cantilever treads and can be worked from the solid or of laminated construction. The upper end of the carrage can be housed into the stairwell trimming-member with possible additional support from metal brackets. The foot of the carriage is housed in a purpose made metal shoe or fixed with metal angle brackets.

III Mono-carriage (or spine beam)

employs a single central carriage with double cantilever treads. The carriage is of laminated construction and very often of a tapered section to reduce the apparent bulky appearence. The foot of the carriage is secured with a purpose made metal shoe in conjunction with timber connectors.



Typical arrangement



MONO CARRIAGE

13. STAIRS	TIMBER STAIRS	BUILDING CONSTR. LECTURE
compiled : D. VOLKE DEC. '82		CET 7031/1 13.528

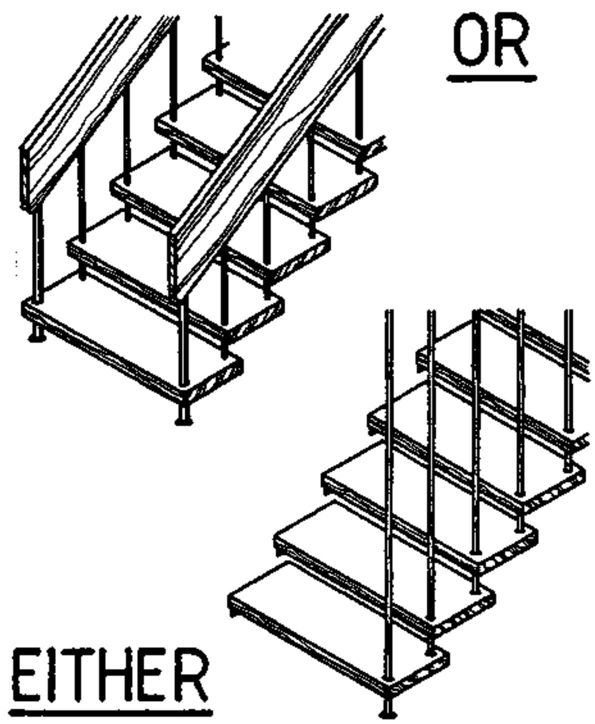
HANGING STAIRS

IV <u>Hanging stairs</u>

consist of treads which are kept in position by tension bars

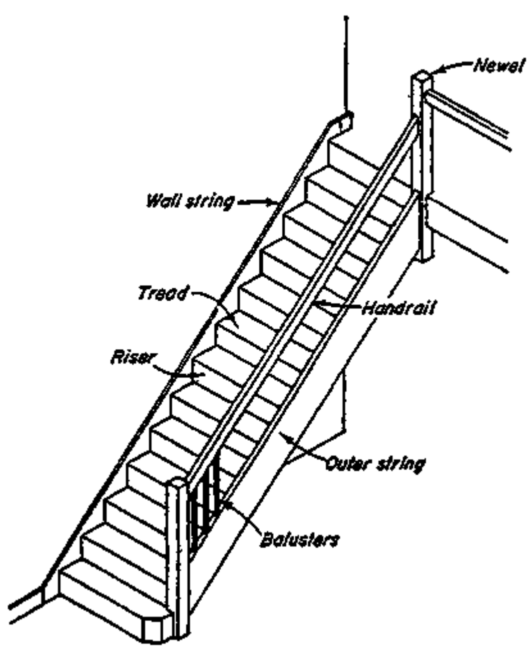
- There are two methods of hanging the treads:

  Either tubular metal balusters, fixed at the ceiling, or a solid hardwood handrail are used as means of support for the treads.
- Cut of the number of different types of staircases, only the construction of newel and ladder type stairs suitable for domestic buildings will be considered



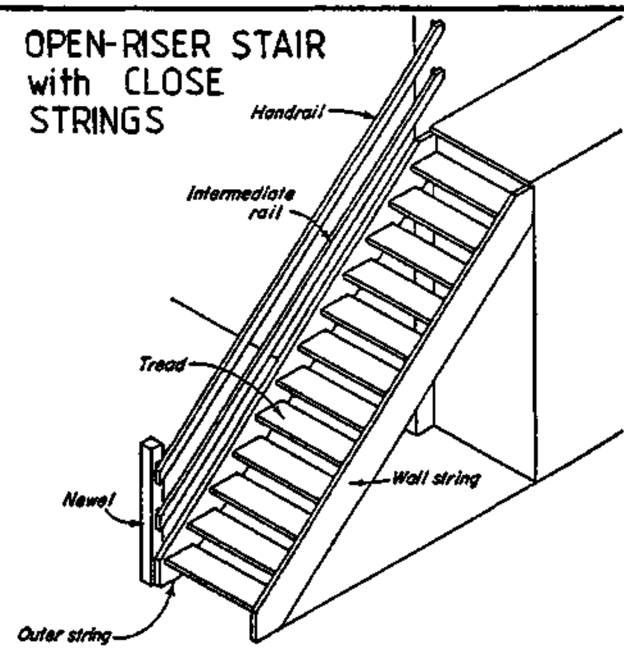
STRAIGHT FLIGHT STAIRS

<u>Straight flight stairs</u>
may be constructed between walls which give it continous support or it may be open on one or both sides.



CLOSED-RISER STAIRS
with CLOSE STRINGS

OPEN-RISER STAIR
with CLOSE
STRINGS



- The sizes of members are not usually calculated, they are determined out of experiance.

  - Treads: 32 mm thick
    (27 mm plained)
  - Risers 25 mm thick
    (21 mm plained)
  - Method of fixing
    The top edge of the riser may be simply butted against the underside of the tread, but the joints should then be covered by a small mould fixed to the tread (to conceal any gap formed by shrinkage)
  - Projection of nosin g: not more then 25 mm. The nosing profile may be square, slightly splayed with rounded top edge or halfround.
  - an alternative 13 mm plywood may be used for the risers (ref. fig.)
  - The ends of the treads and risers are housed into grooves or housings
    - about 12 mm deep - formed in the strings. The housings are wider than thickness of tread and riser. They are tapered so that hardwood wedges, after covering with glue, may be driven behind the treads and risers forcing them tight against the outer faces of the housings.

STRAIGHT FLIGHT STAIRS

Triangular blocks of wood are glued at the junctions of the treads with the risers and strings to give increased rigidity to the whole staircase.

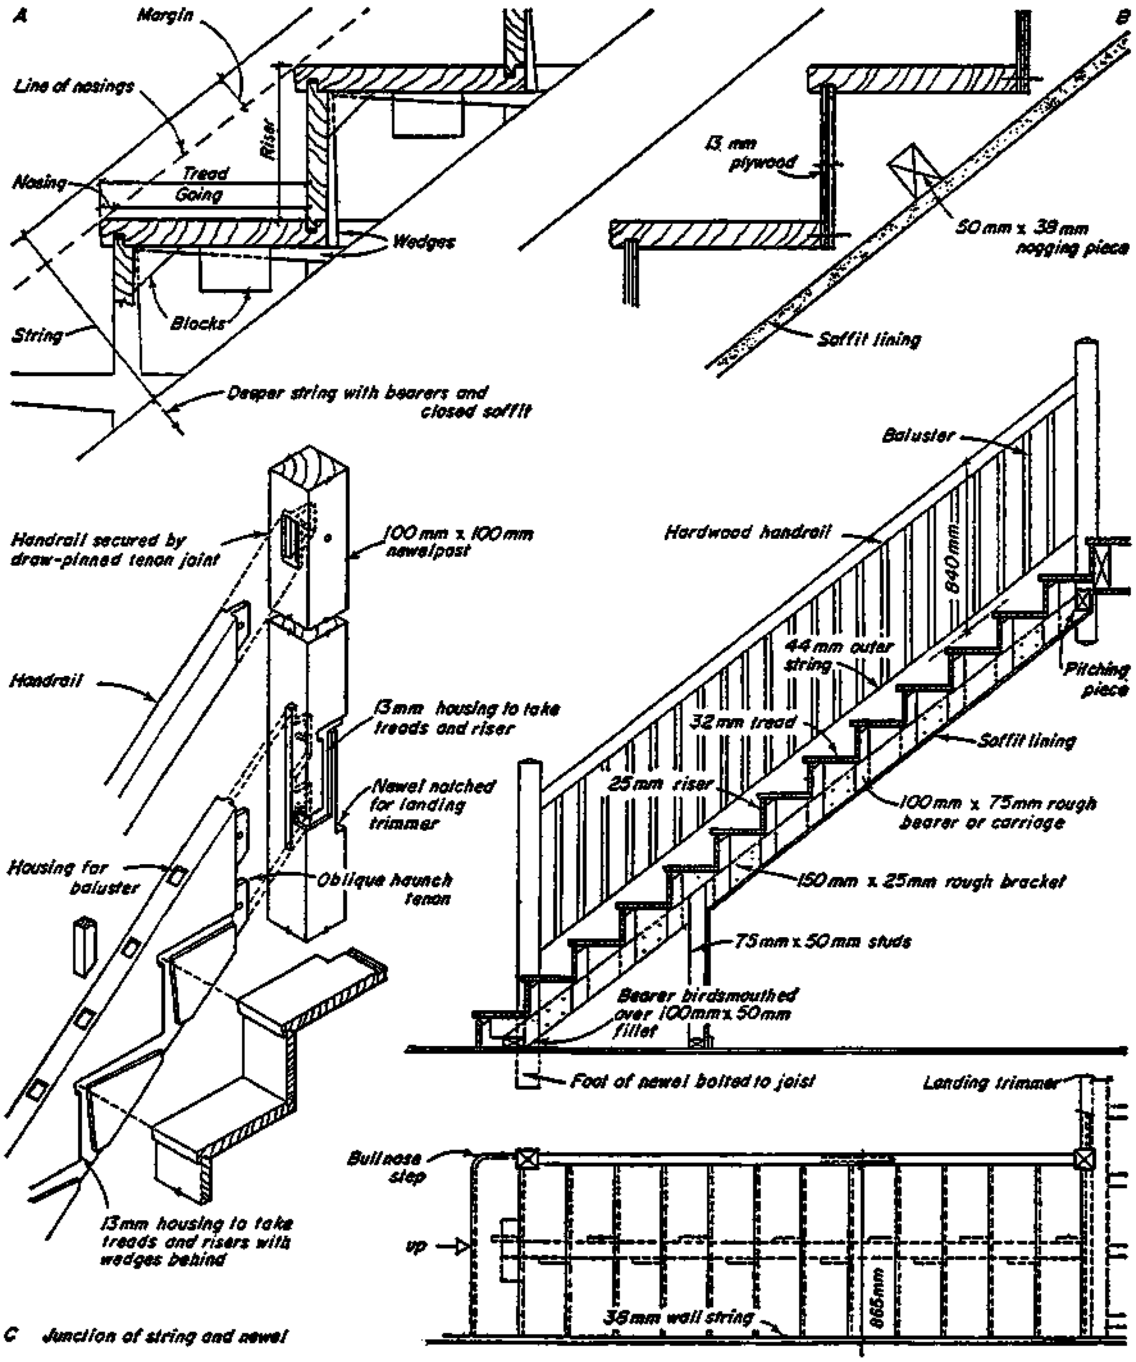
- Wall string: about 38 mm thick
  securely plugged to the wall.
- Outer string 45-50 mm thick
  It must be thicker than the wallstring as it acts

as an inclined beam. (Whereas the former serves as a plate, supported by the wall).

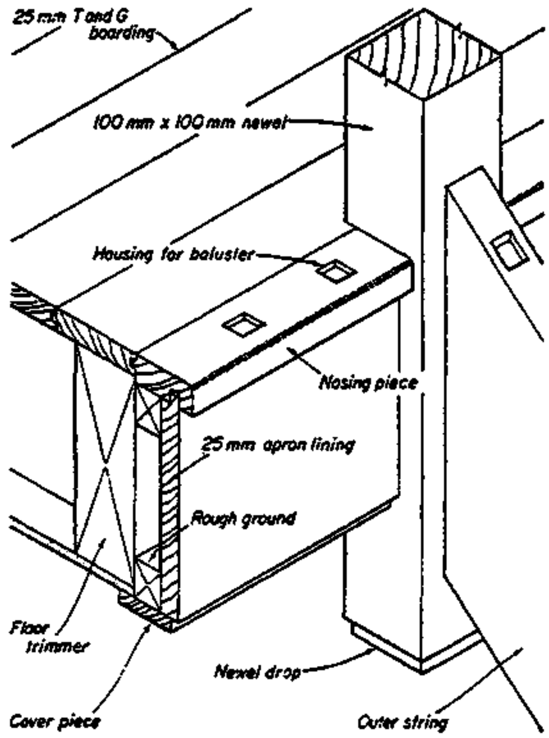
- For stairs wider than 90 cm it is desirable to introduce intermediate support in the form of
  100 x 75 mm or
  100 x 50 mm rough bearers
  or carriages under the steps.

- The outer string is framed in to 100 x 100 mm newels at top and bottom of the flight.
  The strength of newel stairs depends largely on the rigidity of the joint between the string and newelpost. The normal method of joints the two is shown in the figure. This consists of a draw-pinned joint consisting of two obtique haunch tenons on the end of the string fitted into

STRAIGHT FLIGHT STAIRS



mortices formed by the newe
The whole is secured by a slightly tapering hardwood dowel at each tenon.
The newel post - like the strings - is housed to take the treads and risers and is (in addition) notched to fit over the landing trimmer to which it is nailed or - preferably - bolted.
The junction with the lower newel is similar, but the joint is reversed as shown.



Apron lining to landing

STRAIGHT FLIGHT STAIRS

For architectural reasons the newel at the bottom of a stair case is usually set back one (or sometimes two) risers.

- The entry to the stair is less aprupt and may be made slightly from the side as mounting commences.

A specially shaped end to the bottom step (or steps) must be formed as shown in the examples illustrated.

The foot of the lower newel should be taken through the floor and bolted to a convenient joist, to give a fire and secure connection.
The upper newel extends a short way below the string.
This is termed a <u>newel drop</u>.

- Ends of handrails should be housed slightly into the newels and fixed by draw-pinned tenon joints.
- The trimmer to the upper floor landing is faced with an APRON LINING, toungued and grooved at the top to a nosing piece (preferably the same thickness as the stair treads, into which any landing balusters are housed and the floor boards tongued and grooved.

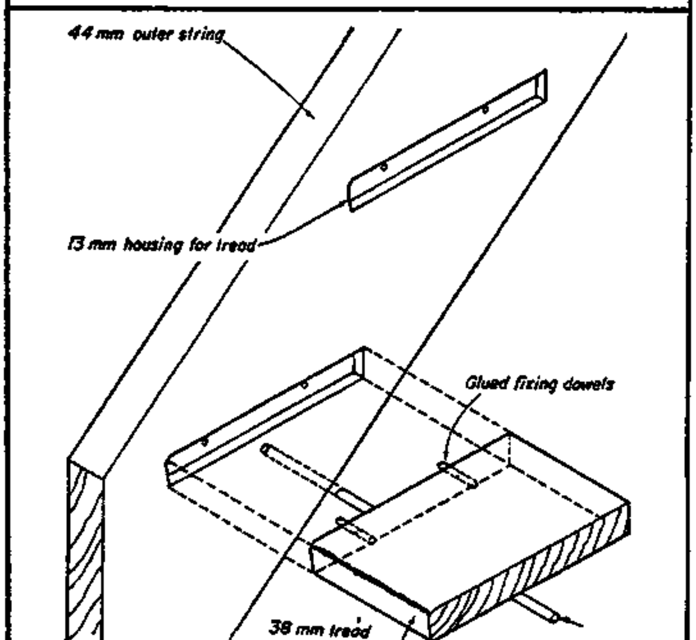
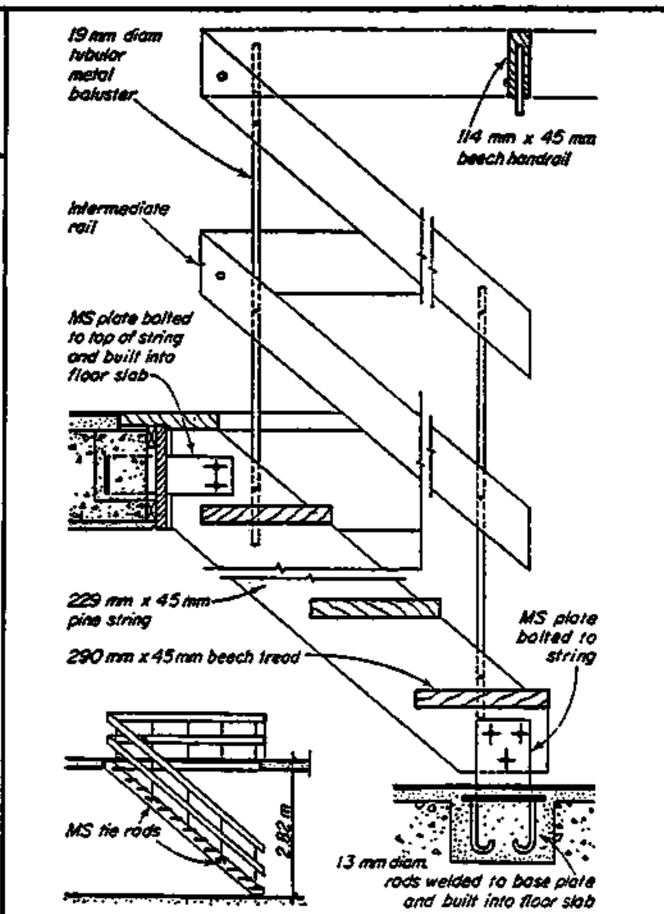
13. STAIRS compiled : D. VOLKE DEC. '82	TIMBER STAIRS	BUILDING CONSTR. LECTURE CET 7031 / 113.5 33
TCA TECHNICAL COLLEGE ARUSHA CHUO CHA UFUNDI ARUSHA	CIVIL ENGINEER. DEPARTMENT	33

OPEN RISER STAIRS

Open-riser or ladder stairs may be constructed with close or cut strings.

- When close strings the connection between the ends of the treads and the strings is not as good as in a closed-riser stair, since there are no wedges or side blocks connecting the two.
  Therefore: The strings should be tied together by 10 mm or 12 mm Ø metal rods with sun and pelleted ends placed under every 4th tread.
- Screw fising: is not very strong as the screws enter the end grain of the tread.
- Glued dowels are better than screws.
- Cut strings are tied together by the treads which rest upon the string and are screwed to it.





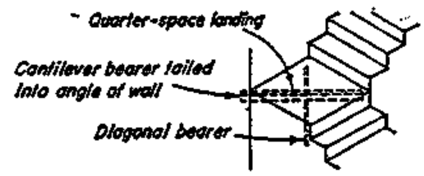
- With open-riser stairs no support is given to the tread by a riser. So the treads should be at least 38to44mm thick.
  The treads are generally of hardwood.
- In case no newels are seen in the stair, this necessiates a direct fixing of the strings to the floors (for example: M.S. plates to which the strings are bolted are cast in the concrete floors.
- Alternative methods of securing the top of an open-riser stair are by fixing the strings directly to the wall face or by fixing to the upper floor by means of a head piece dowelled to the tops of the strings.

DOG LEG STAIR

DOG-LEG STAIR

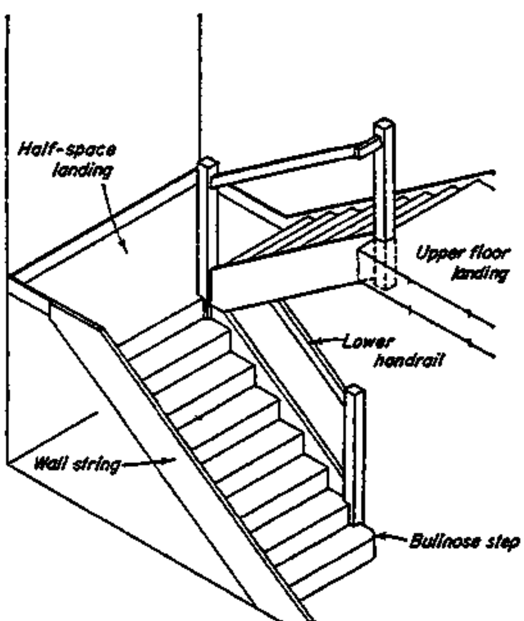
- The use of a single newel at the landing into which both outer strings are framed produces an elevation (the V-junction of strin gs) which gives rise to the name of the stair.
- Constructional details of the flights are identical with those already described for the straight flight stair - exept at certain points at the half - space landing and its newel.

  The latter is usually continued down to the lower floor for the sake of rigidity and fixed at the foot to the floor joist.

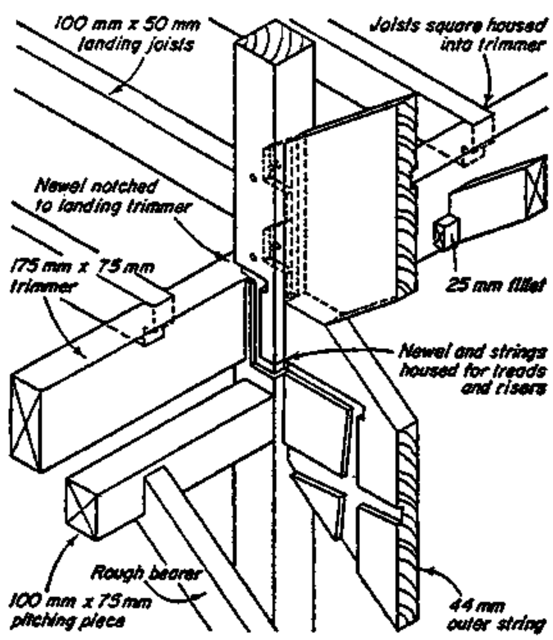


The strings bult against each other on an horizontal line, about 50 mm wide, outside the face of the newel.

The half-space landing, is formed of 100 mm x 50 mm joists supported by the trimmer at one end and by the stair case wall at the other.



Dog-leg stair



OPEN WELL STAIR

gives a better appearance than a dog-leg-stair and a continous handrail up to the landing newel.

All relevant details are similar to those described for the previous stairs.

If the landing is half-space, the landing newels may terminate just below the landing as on the upper floor. The section of landing exposed between the newels is finished with an apron lining.

If a very narrow well is adopted (say 75 to 100 mm), a single newel about 250 mm wide is preferable to avoid an extremly small space between a pair of newels and its accompanying problems at handrail and landing level.

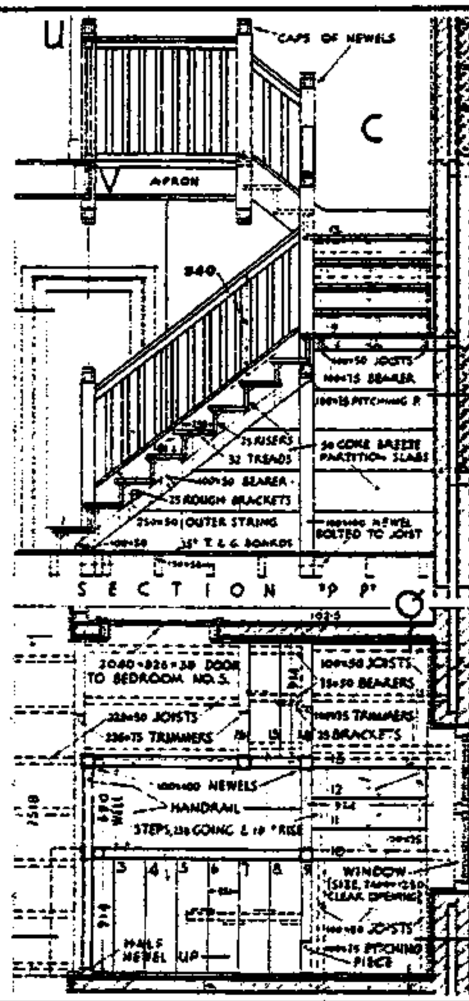
If an intermediate flight is incorporated, quarter-space landings will be formed; in small domestic stairs then landing will support itself (provided the surrounding walls are capable).
In larger stairs it is necessary to provide support to the trimmers of the landings: most simply

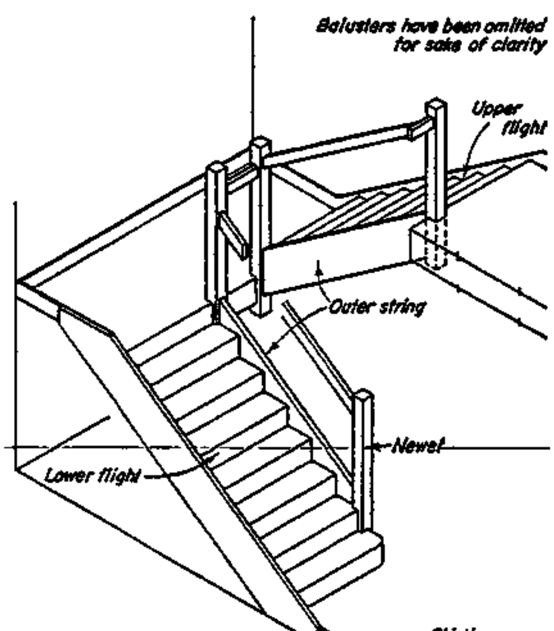
by carring the landing newels down to the floor below

or:

the landing and the newel may be supported on cantilever construction.

OPEN WELL STAIR





Open well stair

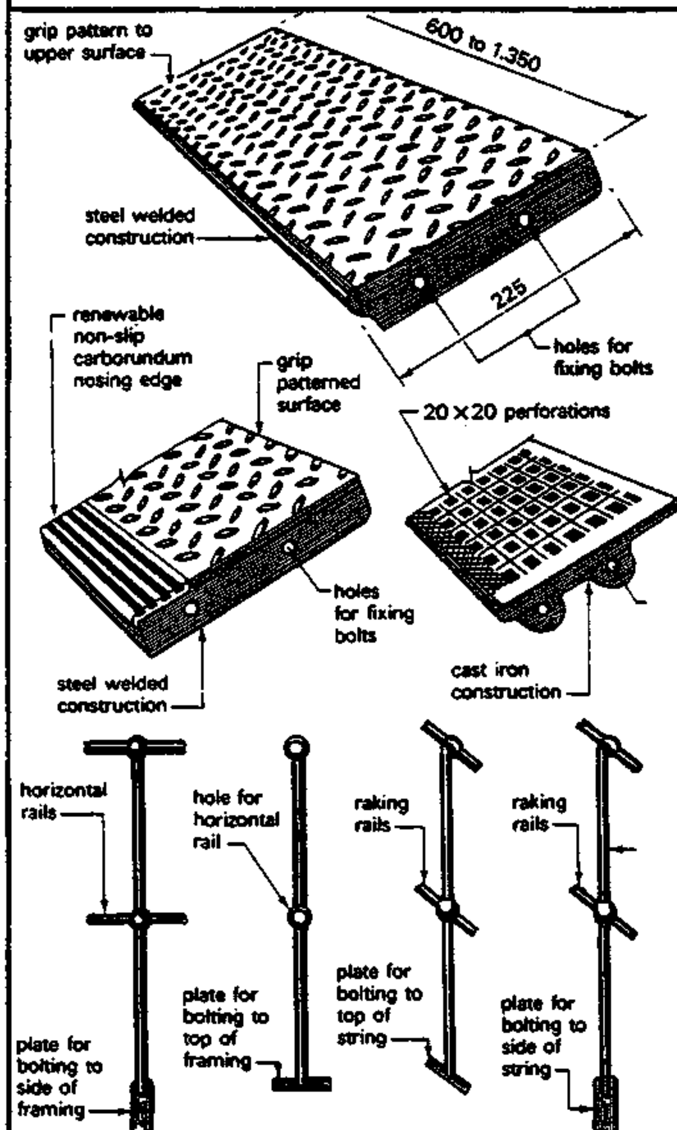
13.55 Metal Stairs
are used as
- escape stairs
- internal accomodation stairs
- external accomodation stairs.

- Most metal stairs are manufactured from mild steel and in straight flights with intermediate half space landings. Spiral stairs in steel are also produced but their use as an escape stair is limited by size and the number of persons likely to use the stairway in the event of a fire. Aluminium alloy stairs are also made and are used almost exclusively as internal accomodation stairs.
- All steel stairs have the common disadvantage of requiring regular maintenance in the form of painting as a protection against corrosion.
- Most metal stairs are supplied in a form which requires some site fabrication and this is usually carried out by the suppliers site erection staff. The main contractor having been supplied with the necessary data as to foundation pads, holding-down bolts, any special cast-in fixings and any pockets to be left in the structural members or floor slabs to enable this preparatory work to be completed before the stairs are ready to be fixed.

13.55 METAL STAIRS

- STEEL ESCAPE STAIRS

The treads of this type of stair are bolted to the strings and can be of a variety of types ranging from perforated cast iron to patterned steel treads with renewable non slip nosings.
Handrail balustrades or standards can be of steel square or tubular sections bolted to the upper surface of a channel string or to the side of a channel or steel plate string.



STEEL SPIRAL STAIRS

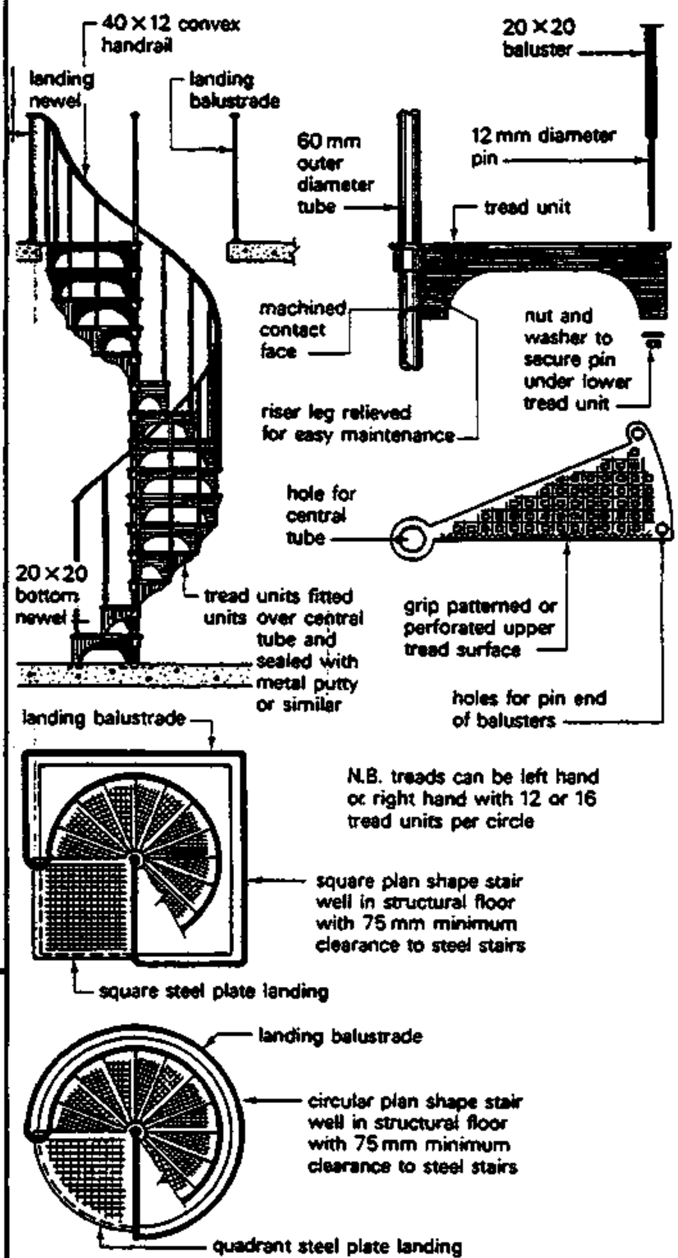
- Steel spiral stairs
are allowed as an internal or external means of escape stairs if they are not for more than 50 persons. The maximum total rise is 9,00 m and the minimum overall diameter is 1,50 m.

- Two basic forms are encountered:
  - a) with treads, which project from the central pole or tube and
  - b) those which have riser legs.

The usual plan format is to have 12 or 16 treads to complete one turn around the central core and terminating at floor level with a quarter circle landing or square landing.

The standards (like those used for precast concrete spiral stairs, pass through one tread and are secured on the underside of the tread below.

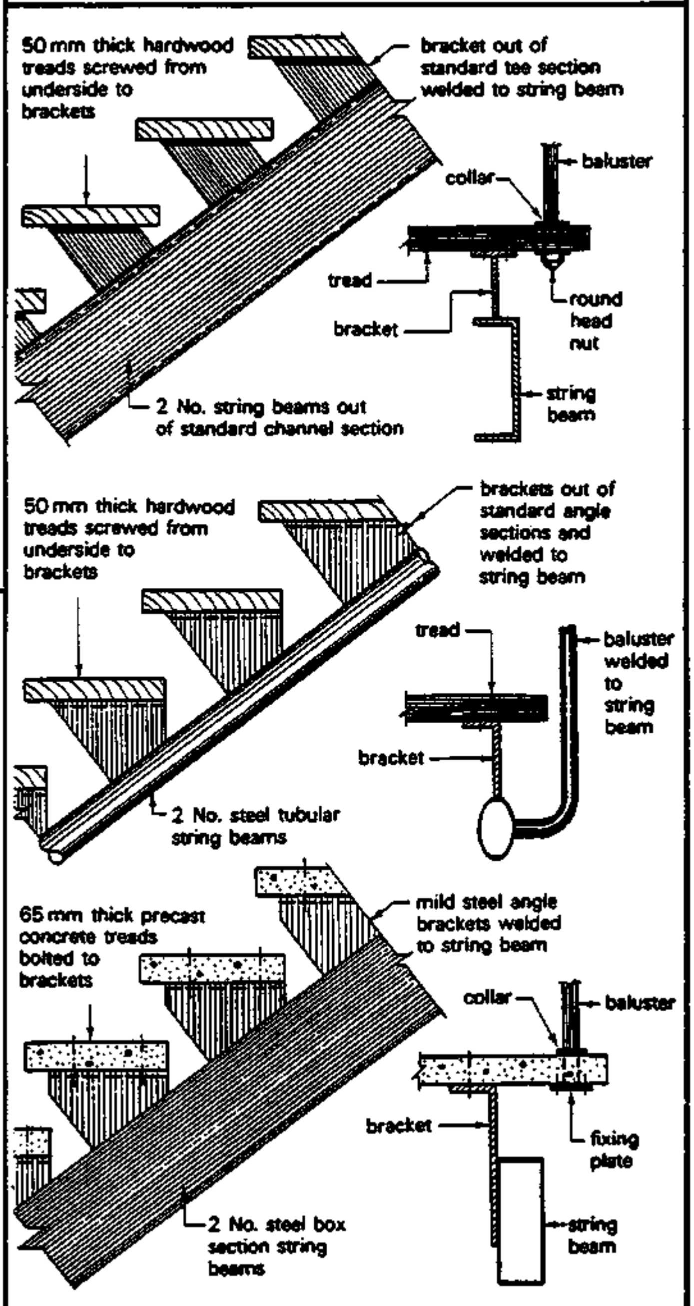
Handrails are continously and usually convex in cross section of polished metal painted metal or plastic covered.



STRING BEAM STEEL STAIRS

- String beam steel stairs

used mainly to form accomodation stairs which need to be light and elegant in appearance. The strings can be of mild steel tubes, steel channels steel boxes or small universal beam sections fixed by brackets to the upper floor surfaces or landing edges to act as inclined beams. The treads, which can be hardwood timber, precast concrete or steel are supported by plate, angle or tube brackets welded to the tup of the string beam. Balustrading can be fixed through the ends of the treads or (alternatively) supported by brackets attached to the outer face of the string beam.



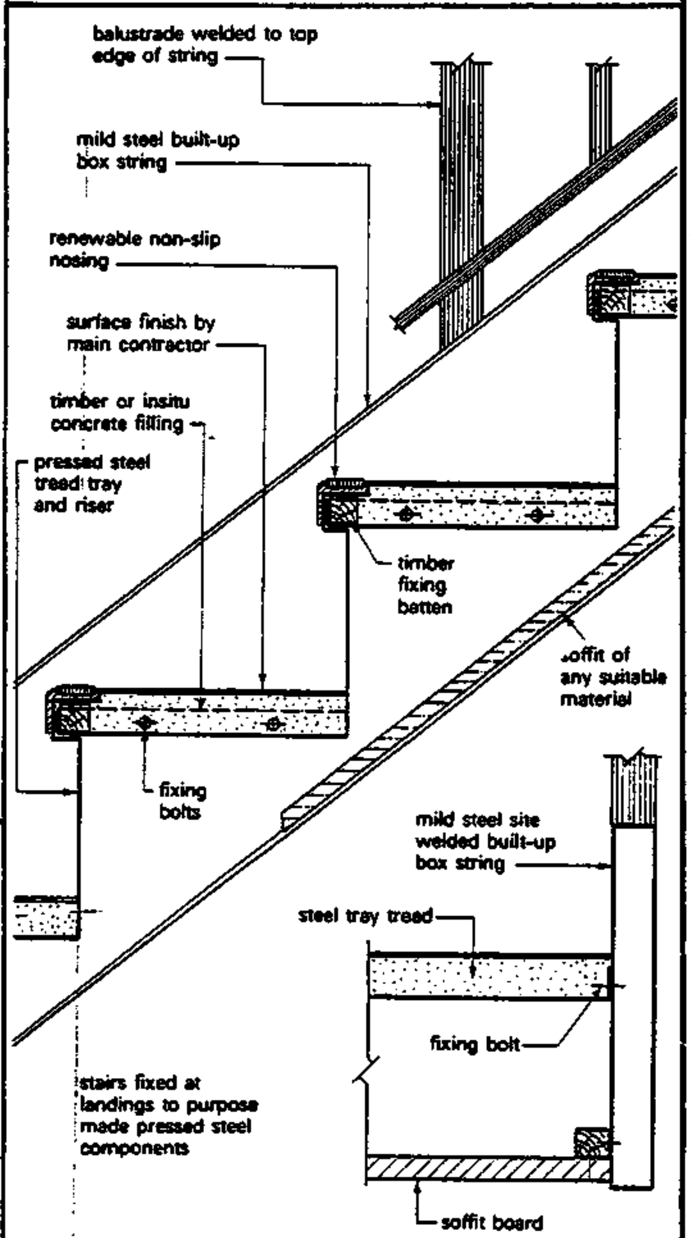
PRESSED STEEL STAIRS

- Pressed steel stairs

accomodation stairs made from light pressed metal such as mild steel.
Each step is usually pressed as one unit with the tread component recessed to receive a filling of concrete, granolithic, terrazzo, timber or any other suitable material.

The strings are very often in two pieces, consisting of a back plate to which the steps are fixed and a cover plate to form a box - section string.

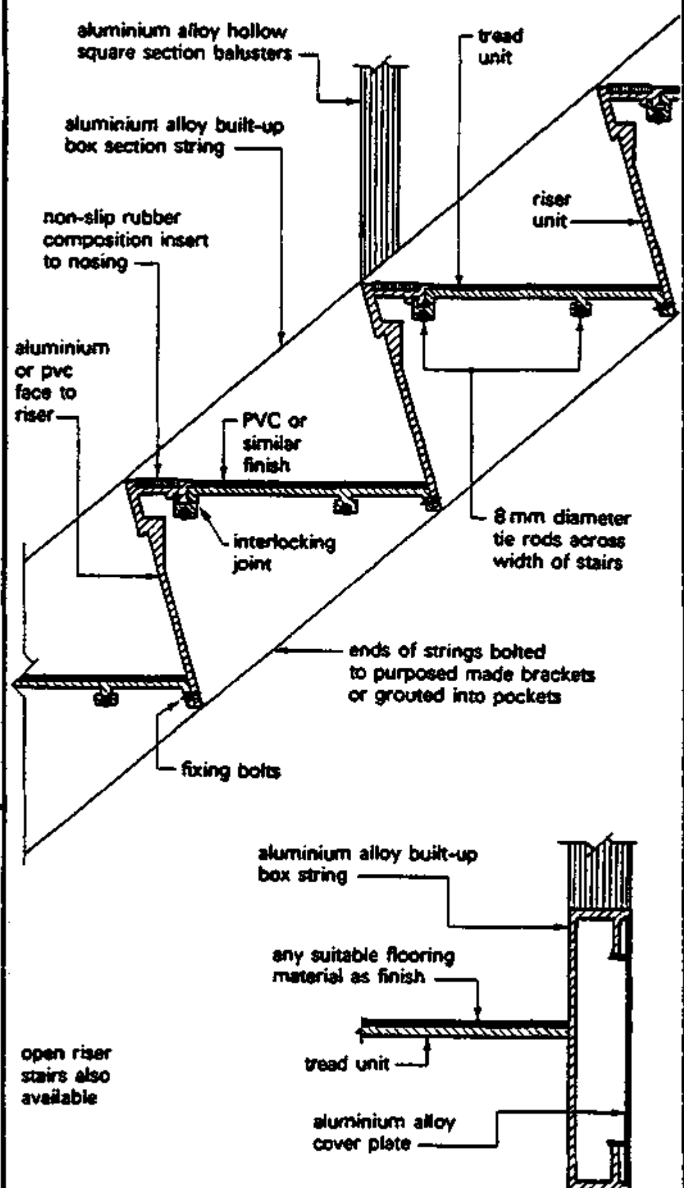
The coverplate to be site-welded.
The complete strings are secured by brackets or built in to the floors or landings and provide the support for the balustrade. Stairs of this nature are generally purpose-made to the required layout and site assembled and fixed by a specialist sub-contructor.



- <u>Aluminium alloy stairs</u>
are suitable for accomodation stairs in public buildings, offices and shops.
The treads have a non-slip nosing with a general tread covering of any suitable floor-finish-material. Format can be open or closed riser.
The two-part box strings support the balustrade and are connected to one another by small diameter tie rods which - in turn - support the tread units.

The flights are secured by screwing to purpose made base plates or brackets fixed to floors and landings or alternatively located in preformed pockets and grou ted in.

When the stairs are assembled they are very light and can usually be lifted and positioned by two men without the need for lifting gear. No decoration or maintenance is required.

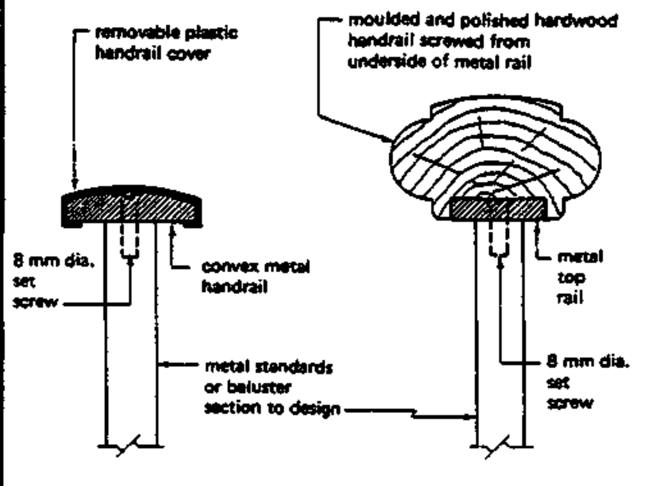


13.61
BALUSTRADES/HANDRAILS

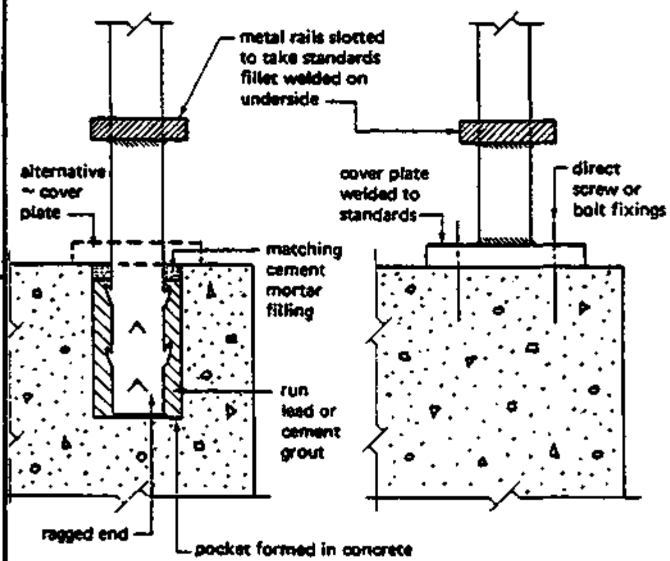
Handrails

Continous handrails of non-combustible materials at a height of between 840 and 915mm above the pitch line (line of nosings) are required to all stairs and to both sides if the stairs width exceeds 1.06 m. The height above the floor to be between 1.07 and 1.09 m.

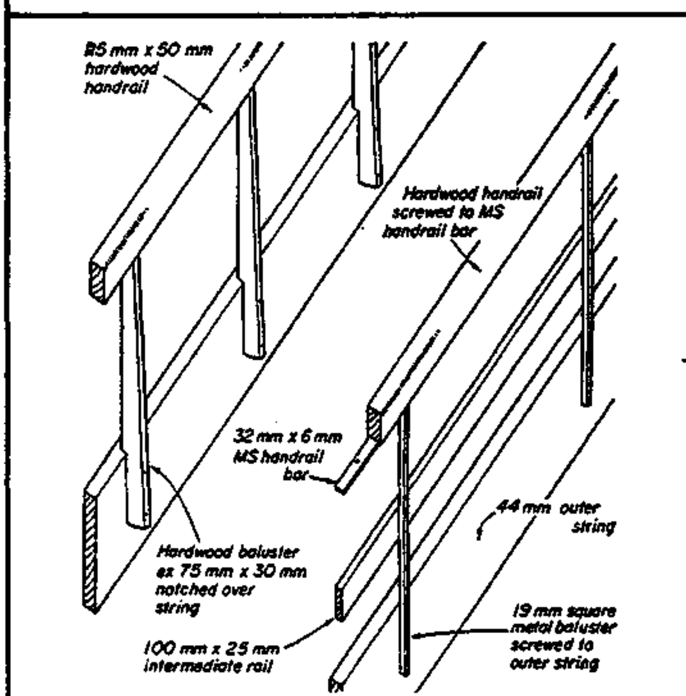
The capping can be of a combustable material such as plastic or timber provided that it is fixed to or over a non-combustible core.



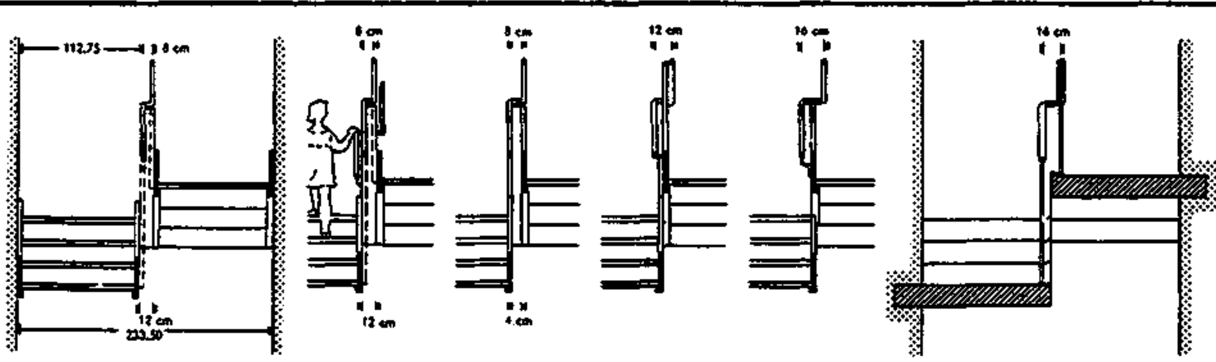
Typical handrails



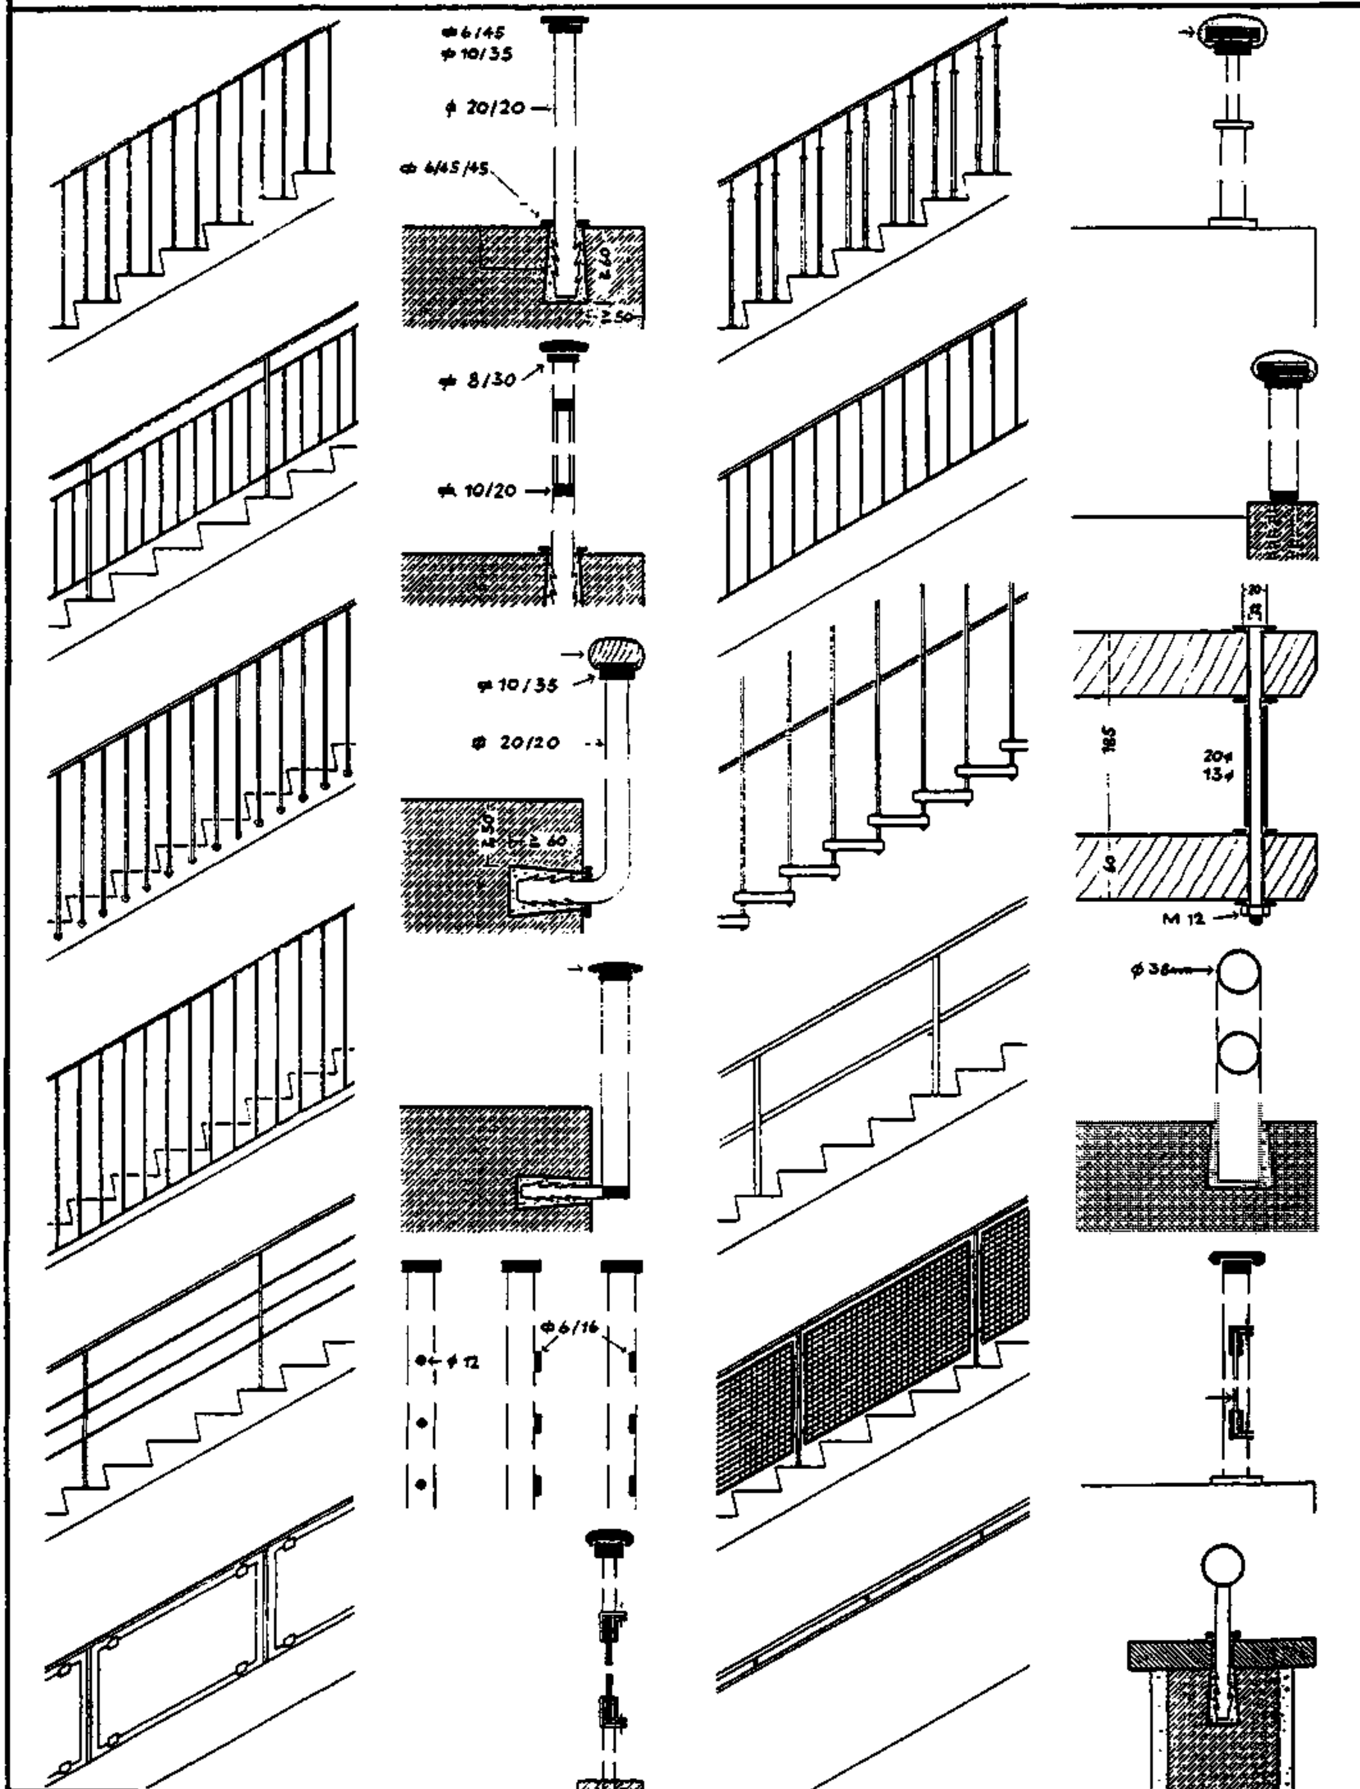
Typical fixing methods



Handrail and string details. Max space is required at hip (handrail) level, but considerably less at foot level. Width at string level therefore reduced to allow more space for stairwell. Staggering of handrail and string also offers better structural fixing of standards to strings, best with handrails 80 mm (3.2 in) apart and space between strings 120 mm (4.7 in). Additional handrail for children, height approx 600 mm (2 ft). Less favourable string and handrail positions, with no space between strings , string above string and stringless r.c. stair without any space between flights

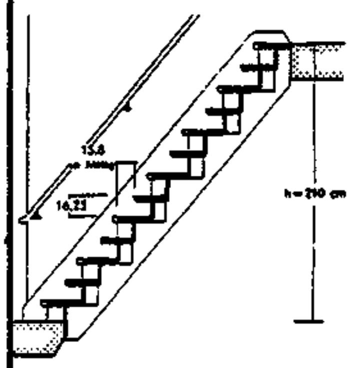


BALUSTRADES and HANDRAIL DETAILS :

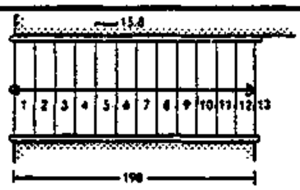


13. STAIRS compiled : D.VOLKE DEC. '82	MISCELLANEOUS	BUILDING CONSTR. LECTURE CET 7031/1 13.6 43
TCA TECHNICAL COLLEGE ARUSHA CHUO CHA UFUNDI ARUSHA	CIVIL ENGINEER. DEPARTMENT	43

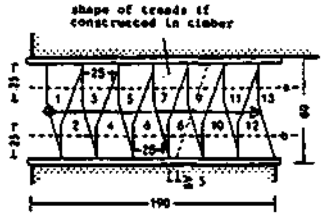
'SAMBA' STAIR; LADDERS; DISAPPEAR. STAIRS; RAMPS



'Samba' stair from timber, section through centre



Normal stair (treads too short)

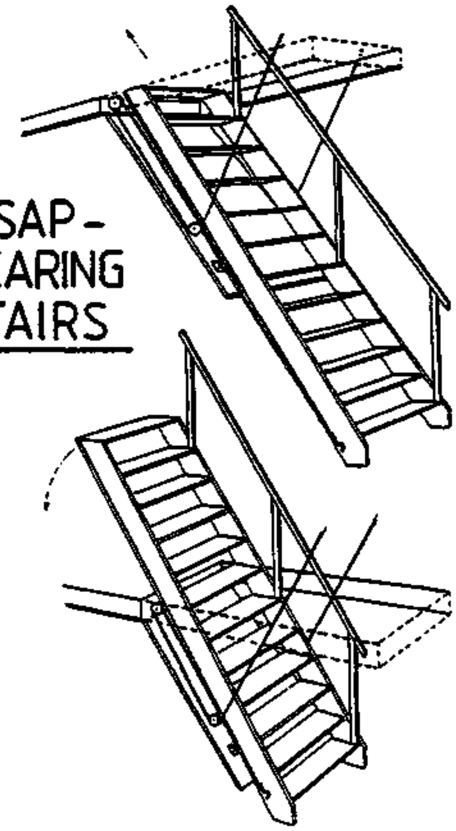


Plan. Tread width at line a and b ≧ 200 mm (8 in)

'Samba' stair

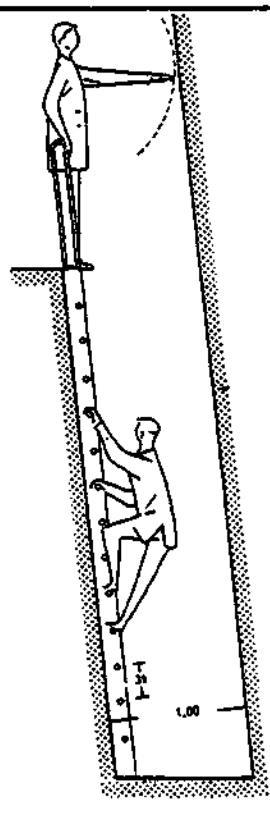
Example. Storey height 2.25 m (7 ft 6 in) = 12 risers = 187.5 mm (7.5 in) per rise; if constructed as a normal stair, a tread of 136 mm (5.4 in) is too small. Therefore steps are curved in such a way that on line a and b tread becomes 250 mm (10 in), fulfilling above requirement: 2 x 187.5 mm (7.5 in) + 1 x 250 mm (10 in) = 625 mm (25 in).

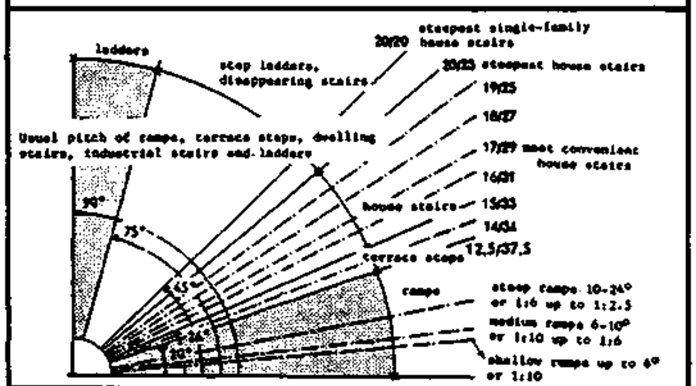
DISAPPEARING STAIRS



CONCEALED CATLADDER

Storey height from F.F.L. to underside of ceiling	Length of opening (width accord-ingly)	Required swivel radius in attic
3,00	1,45	2,30
3,00	1,30	2,45
3,00	1,15	2,60
3,00	1,00	2,75
3,00	0,85	2,90
2,70	1,45	1,95
2,70	1,30	2,10
2,70	1,15	2,25
2,70	1,00	2,40
2,70	0,85	2,55
2,40	1,45	1,65
2,40	1,30	1,80
2,40	1,15	1,95
2,40	1,00	2,10
2,40	0,85	2,25
2,10	1,45	1,30
2,10	1,30	1,45
2,10	1,15	1,60
2,10	1,00	1,75
2,10	0,85	1,90





ramps are divided according to gradient into:

1. Shallow ramps which do not require special non-slip treatment
2. Medium gradient with battens or low rise steps, or at least a rugged non-slip surface
3. Steep ramps requiring battens or low rise steps. Batten distances should be uniform and should conform to normal stride.

Steep stairs at an angle of 38—45° should be used only for short flights and little traffic. The sum of the going + twice its rise should be ≥ 571 mm (22.5 in), ≤ 630 mm (25 in).

Loft ladders, etc, have angle of 45—55°.

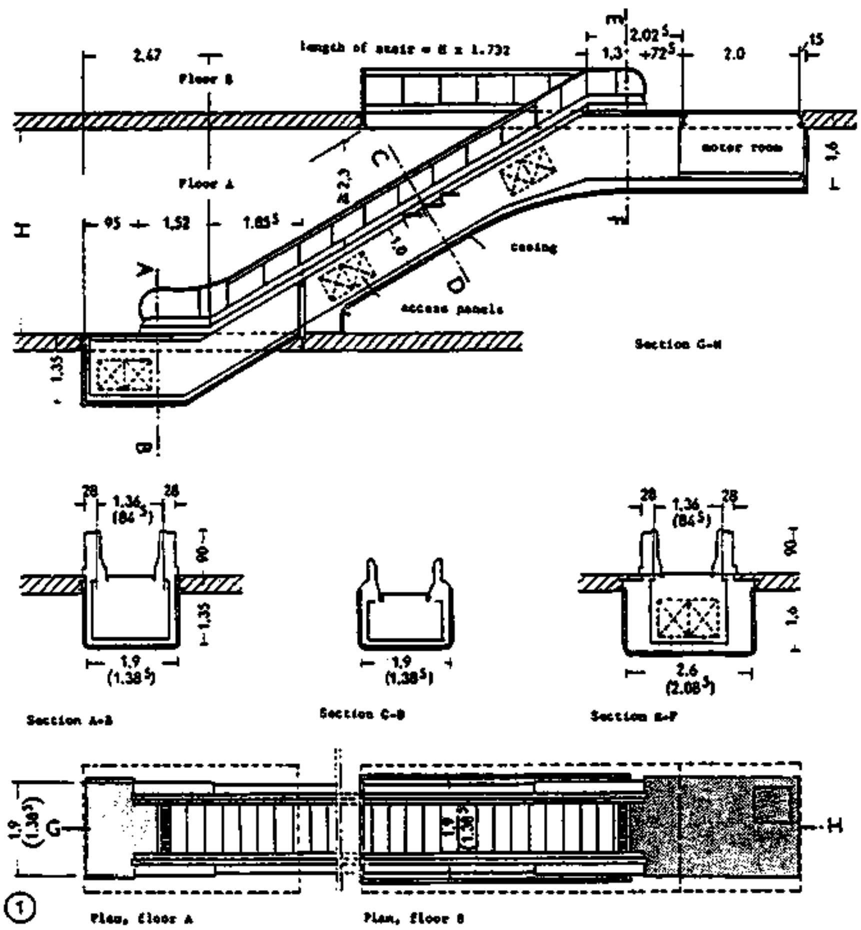
However, if user requirements stipulate a stair-like access (e.g. where loads are carried and available length is too short for flight of normal stairs), then stair with staggered steps, so-called Samba stair, may be designed. Risers for this type of stair should be as few as possible: riser ≤ 200 mm (8 in). Here 'the sum of the going + twice its rise = 630 mm (25 in)' is achieved by shaping the treads; going is measured (staggered) at axes a and b, of right and left foot.

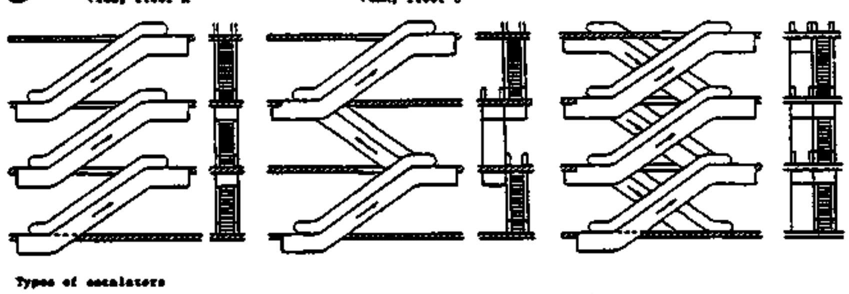
Movable ladders have angles of 65—80°. There are various types including extension ladders.

Fixed ladders have angles of 80°+ and should extend ≥ 750 mm (2 ft 6 in) over platform to be reached if no other precautionary measure against accident is taken. Rung-distance for fixed ladders, 295—315 mm (11.5—12.5 in).

Escalators (1) are required for continuous transport of crowds (requirements of width and distance for means of escape do not take escalators into account). Automatic control by push buttons at top and bottom or through photo-electric cells reduces running times by 40–50%.

Escalators should be evenly distributed throughout all floors, where necessary varying width or speed. To cope with peak traffic a smaller number of escalators at speed of 1 m/sec (3 ft/sec) which move at off-peak times at 0.65 m/sec (2 ft/sec) more economical than larger number of slow moving escalators. However, in UK, max speed 0.75 m/sec (→ BS 2655).





Types of escalators
(2) Superimposed (3) Crossover (4) Double crossover

Stringent requirements (function and security); 30° angle best, going 0.40 m (1 ft 4 in), width of stairs 0.60 m (2 ft) to ≤ 1.00 m (3 ft 4 in), usual 0.80 m (2 ft 8 in). Escalators of 30° angle and 1.00 m stair width permit easy overtaking.

Conveyor belt speed: international about 0.50 m/sec (1 ft 8 in/sec). At change-over from fixed floor to escalator a handrail projection ≥ 0.80 m (2 ft 8 in) is required.

Access and exit with min. 2 horizontal goings, but escalators with larger height dimensions or greater speed ≥ 0.50 m/sec (1 ft 8 in/sec) min 3 horizontal exit goings necessary.

Max capacity/h from steps area and speed

Capacity $M = \frac{Q_1 \times V}{T} \times 3600$

Q_1 = persons/step
T = going depth (m)
v = conveyor speed (m/sec)

Output only 75–80% of M, as steps not used to capacity.

Control: fully automatic through time clock and programme, or intermittent through photo-electric cells, or contact mats.

With working height of ≥ 6.0 m (20 ft) a centre support is normally necessary.

speed	Time per person	Persons/hr transported: 1 person width	2 person width
0.5 m/sec	18 sec	4000	8000
0.9 m/sec	10 sec	7200	14400

Energy consumption: 4 000 person/h: 8 hp AC
8 000 person/h: 15 AC

Length in plan
With 30° escalator: 1.732 x storey height.
With 35° escalator: 1.428 x storey height.
Example: storey height 4.5 m (15 ft), angle 30°. Length in plan = 1.732 x 4.5 = 7.794 m (1.732 x 15 = 26 ft); adding for landings top and bottom, total length approx 9 m (30 ft), allowing about 20 persons to stand in a row.

•REPETITION••exercises••REPETITION•••

Try to answer the following questions and practice sketching where ever necessary and possible.

1) Introduction

a) Explain the term STAIR and list suitable materials, which can be used for the construction of stairs.

2) Definition of Terms

a) Define the following Terms:

- Step
- Tread
- Rise of a step
- Riser
- Racking Riser
- Nosing
- Line of Nosings
- Going
- Fliers
- Tapered Steps
- Winders
- Dancing Steps
- Flight
- Landing
- Width
- Pitch or Slope
- Walking line
- Headroom
- Balustrade
- String or Stringer
- Staircase

3) Types of Stairs

a) How are Stairs classified? Use sketches for illustration!

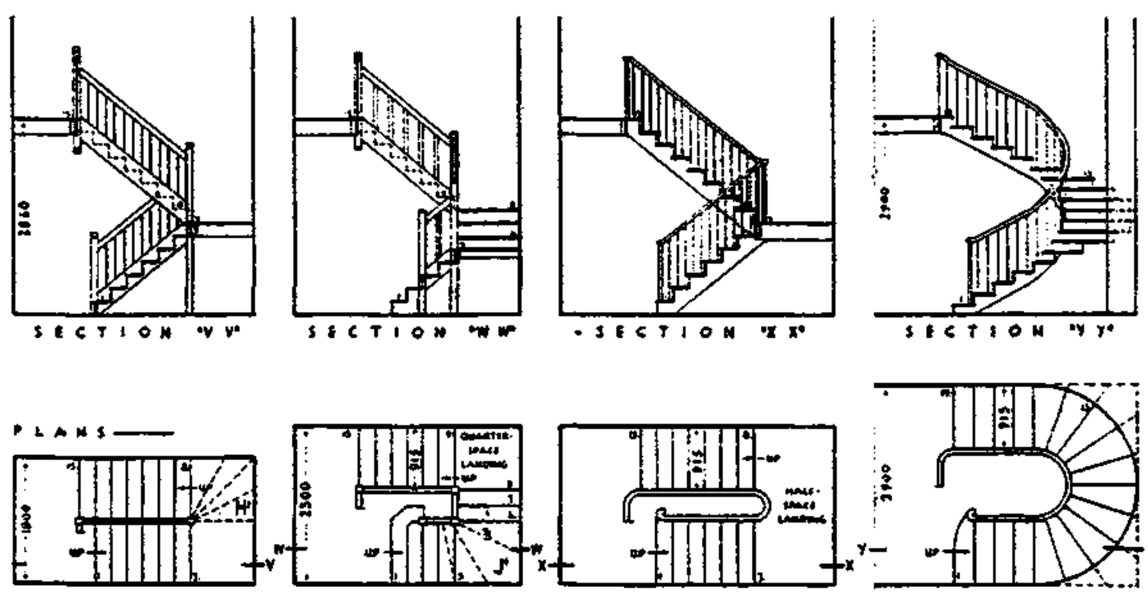
4) Design of Stairs

a) What are the main factors in the design of Stairs?
b) Write notes on the RISE-TREAD-PROPORTION.
c) Calculate a Stair with a rise of 17-19 cm and defference of floor levels - h = 3.00 m, using the I. PACE-RULE
   II. SAFETY - RULE
   III. COMF ORT-RULE

5) Construction of Stairs

a) Explain briefly the construction of BRICK STAIRS. Use sketches for illustration!

b) Explain briefly the construction of STONE STAIRS. Use sketches for illustration!



●REPETITION●●exercises●○○○

c) Explain briefly the construction of 'IN-SITU' CAST R.C. STAIRS and give structural details of:
- single flight concrete stairs
- two-flight concrete stairs with half-space landings
- string beam concrete stairs
- cranked slab concrete stairs
- cantilever concrete stairs
- spiral concrete stairs

Use sketches for illustration!

d) Explain briefly the construction of PRECAST CONCRETE STAIRS and give structural details of
- straight flight p.c. stairs
- cranked slab p.c. stairs
- p.c. open riser stairs
- p.c. spiral stairs

Use sketches for illustration!

e) Explain briefly the construction of TIMBER STAIRS and give structural details of
- straight flight timber stairs
- open-riser or ladder timber stairs
- dog-leg timber stairs
- open well timber stairs

Use sketches for illustration!

f) Explain briefly the construction of METAL STAIRS and give structural details of
- steel escape stairs
- steel spiral stairs
- string beam steel stairs
- pressed steel stairs

Use sketches for illustration!

6) <u>Miscellaneous</u>

a) Describe - by using sketches - different types of balustrades and handrail details.

b) Explain the terms:
- 'samba' stair
- disappearing stair
- ladder
- ramp

by using sketches for illustration!

c) What do you know about ESCALATORS?

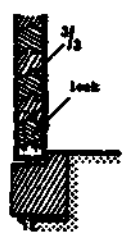
CIVIL ENGINEER.
DEPARTMENT

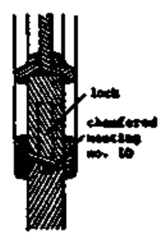
14.1 DOORS

14.1 <u>DOORS</u>

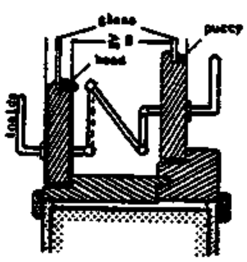
- A door is a screen used to seal an opening into a building or between rooms within a building.
- Doors can be made from
  - wood
  - glass
  - metal
  - plastic
  - felexible rubber
  - or any combination of the above
- They can be designed to
  - swing (side-hung)
  - slide
  - fold (slide and fold)
  - roll
  - shutter
  - or pivot
- They can range in size from tiny cupboard doors to the huge sliding-folding doors of aircraft hangers.
- All doors may be classified by their
  - Position in a building
  - Function
  - or method of Construction.



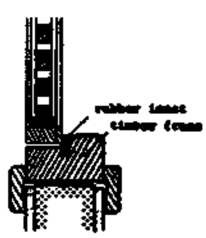
American solid-core door with metal channel profile



Two-leaved framed door with beaded panels



Two coupled doors



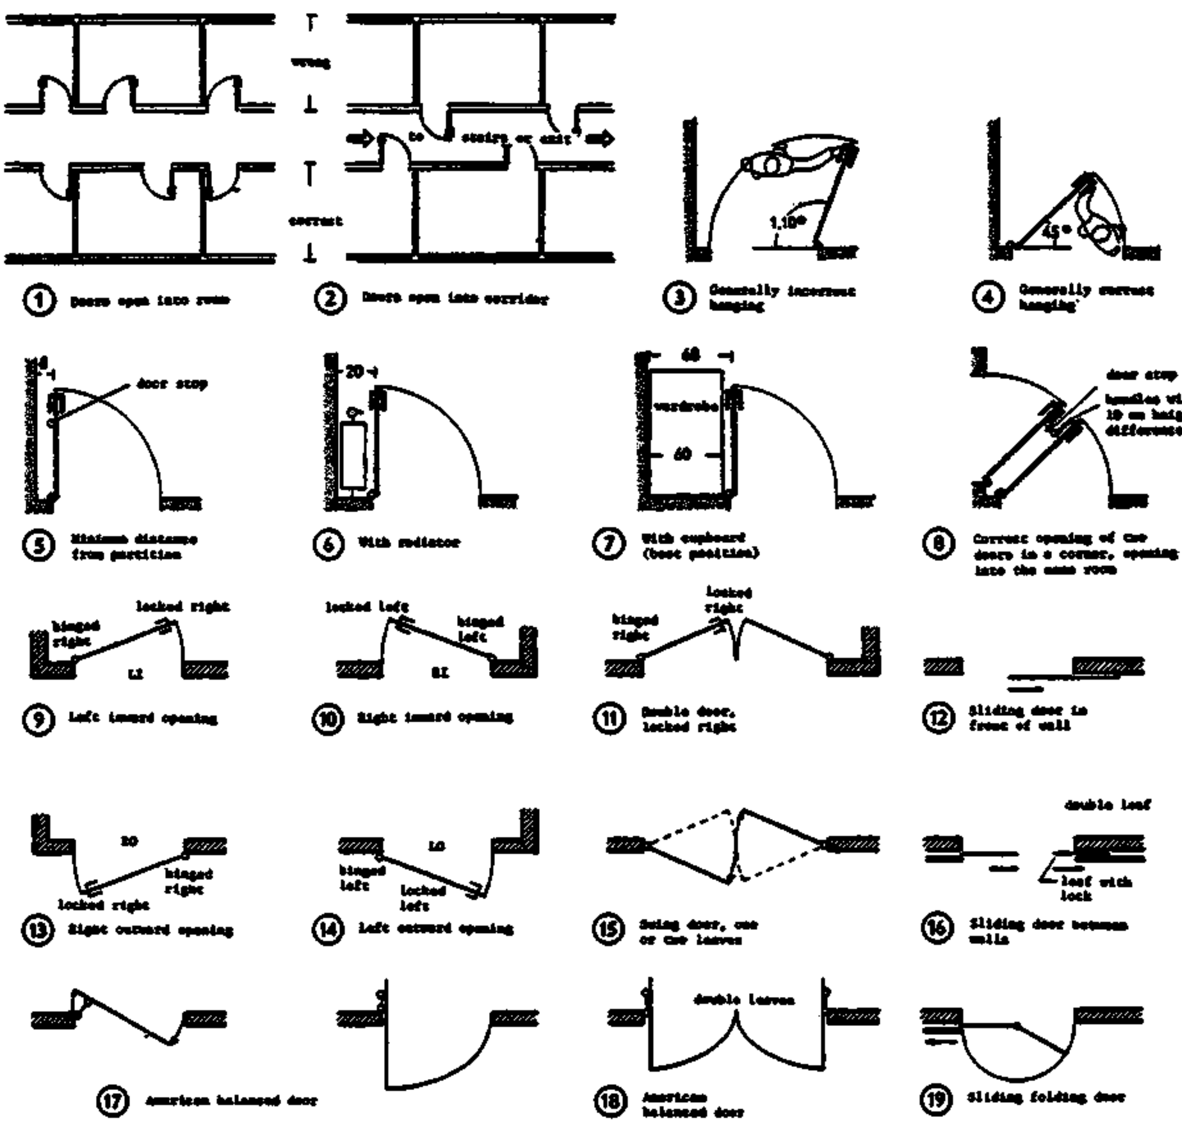
Skeleton-core plywood door

DOORS

Positioning

Correct positioning of doors important for convenient use of rooms, → (1)-(8). For common descriptions of doors in plan, → (9)-(16).

American balanced door, → (17)-(19), requires minimum effort to open and is suitable for passage doors in corridors, draught lobbies, etc.



(1) Doors open into room
(2) Doors open into corridor
(3) Generally incorrect hanging
(4) Generally correct hanging
(5) Minimum distance from partition
(6) With radiator
(7) With cupboard (best position)
(8) Correct opening of two doors in a corner, opening into the same room
(9) Left inward opening
(10) Right inward opening
(11) Double door, locked right
(12) Sliding door in front of wall
(13) Right outward opening
(14) Left outward opening
(15) Swing door, one or two leaves
(16) Sliding door between walls
(17) American balanced door
(18) American balanced door
(19) Sliding folding door

EXTERNAL DOORS

14.1.1 External doors

are built
. to close the access
. to provide security

- They need to be weather resistant, provided by:
  - thickness
  - stability and durability of the construction
  - materials used together with protective coatings of paint or polish
- They should be constructed to maintain the insulation properties of the external walls.
- Standard sizes for external timber doors:
  1981 mm x 762 or 838 mm
  (high) (wide)
  and 45 mm thick
  (which is a metric conversion of the old Imperial door size)

Metric doors are produced so that, together with the door frames, they fit into a modular coordinated opening size and are usually supplied as door sets with the door already attached or hung to/in the frame.

INTERNAL DOORS

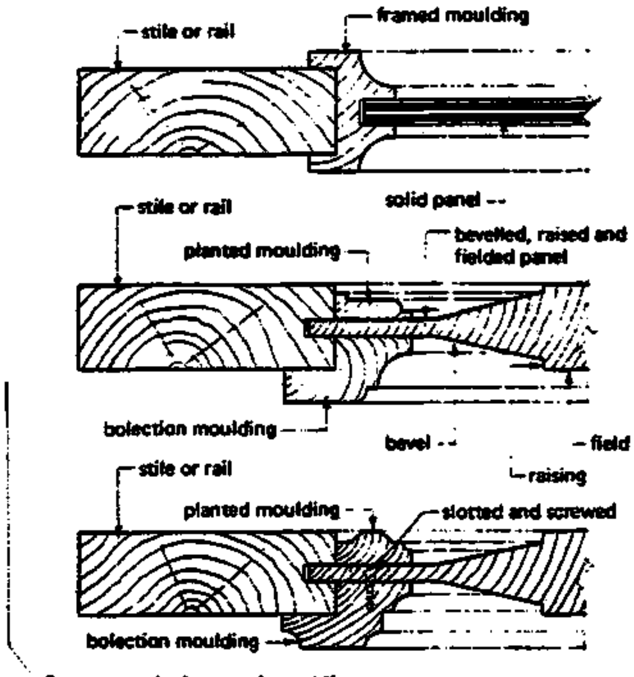
14.1.2 Internal doors

- As with external doors the aim of the design should be to maintain the properties of the wall in which they are housed.
- Generally: internal doors are thinner, standard sizes are similar to external doors, but with a wider range of width to cater for narrow cupboard openings.

PURPOSE MADE DOORS

14.1.3 Purpose made doors.

- The design and construction of these doors is usually based on B.S. 459 for standard doors, but are made to non-standard sizes, shapes or designs.
- They are used mainly for
  . front elevation doors
  . in buildings such as
    banks
    civil buildings
    shops
    theatres
    hotels
    to beautify the external facade or internal decore.



Purpose made doors and mouldings

METHODS OF CONSTRUCTION

14.1.4 Methods of Construction.

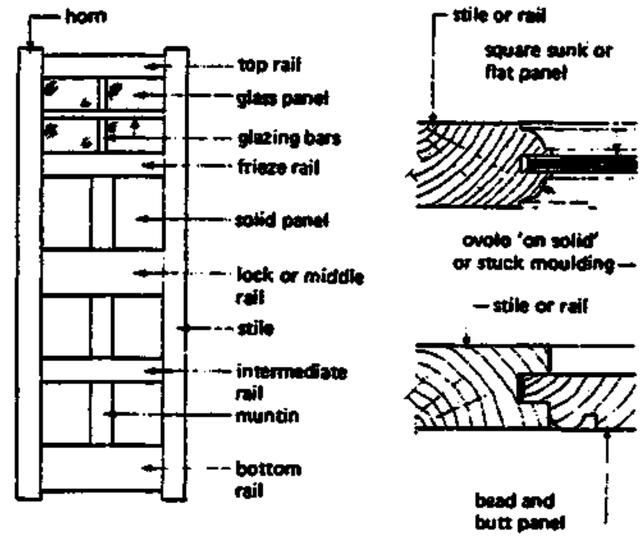
The B.S. for wood doors is divided into four parts, each being a different method of construction:

B.S. 459 Part 1:
Panelled and glazed wood doors
Part 2:
Flush doors
Part 3:
Fire-check doors
Part 4:
Match bearded doors.

Standard doors are used extensively since they are
- mass produced to known requirements
- readily available from stock
- and cheaper than purpose made doors.

DOOR TERMINOLOGY

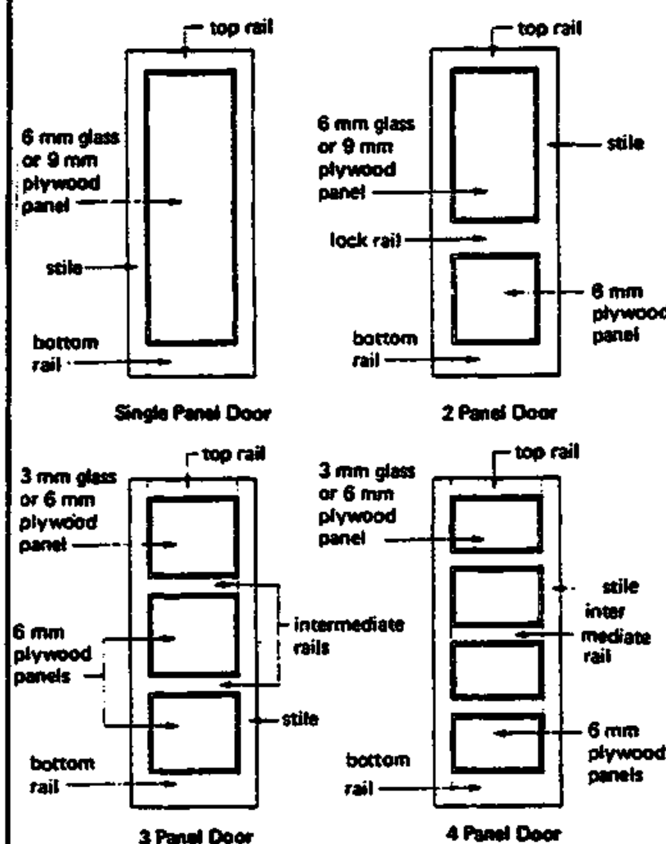
14.1.4.1 Door terminology



PANELLED & GLAZED DOORS

14.1.4.2 Panelled and glazed wood doors

- The wide variety of types is based upon the one/two/three/ or four panel formate.
- They are constructed of timber which should be in accordance with BS 1186 with plywood or class panels.
- The joints used in framing the doors can be a dowelled joint or a mortice and tenon joint. (or double tenon joint)
  - The dowelled joint is considered superior to the mortice and tenon joint, and is cheaper when used in the mass production of standard doors. Bottom and lock rails have 3 dowels, top rails have two. Intermediate rails have a single one.
  - The plywood panels are framed into grooves with closely fitting sides, with a movement allowance within the depth of the groove of 2 mm.

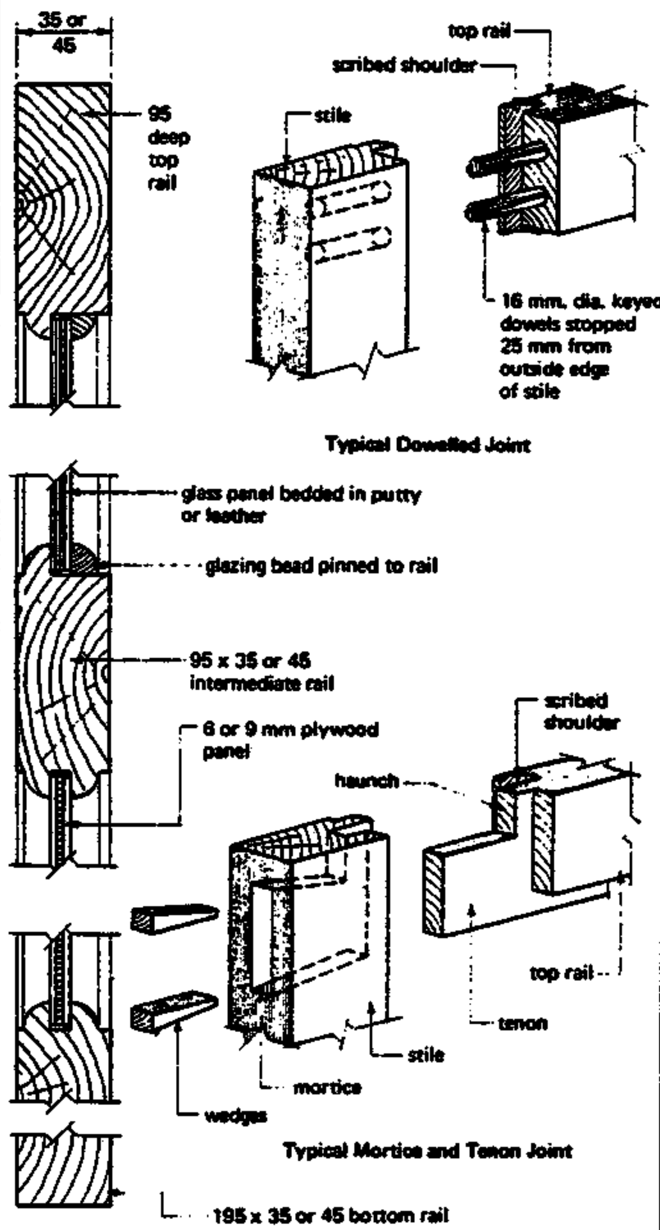


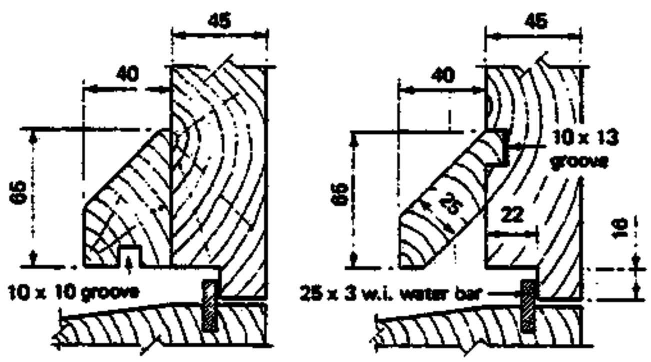
PANELLED&.GLAZED DOORS

- The mouldings at the rail intersections are scribed, where as the loose glazing beads are mitred.
- Weatherboards for use on external doors can be supplied to fit onto the bottom rail of the door which can also be rebated to close over a water bar.

Terms :(Mortice and tenon)joints:

- Haunch
- Mortice: The top and bottom of the mortices are tapered in towards the rails, in order to give space to drive in small wood wedges when tenons are fitted.





Standard Weatherboard

Non-standard Weatherboard

FLUSH DOORS

14.1.4.3 Flush doors

- Is very popular (with both the designer and the occupier)- it has a plain face which is easy to clean and to paint and is also free of the mouldings which collect dust.
- Flush doors can be faced with
  - hardboard
  - plywood or a
  - plastic laminate

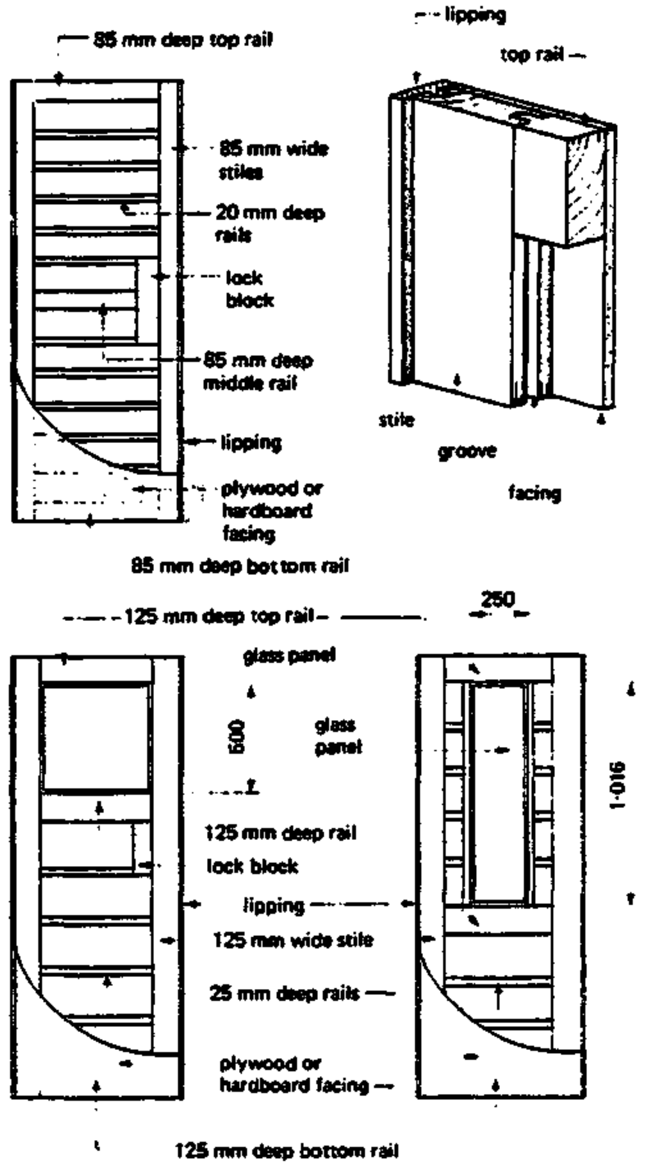
14. DOORS & WINDOWS	DOORS	BUILDING CONSTR.
compiled : D.VOLKE		—LECTURE—
JAN. '83		CET 8031/114.1o6
TCA TECHNICAL COLLEGE ARUSHA CHUO CHA UFUNDI ARUSHA	CIVIL ENGINEER. DEPARTMENT	6

FLUSH DOORS

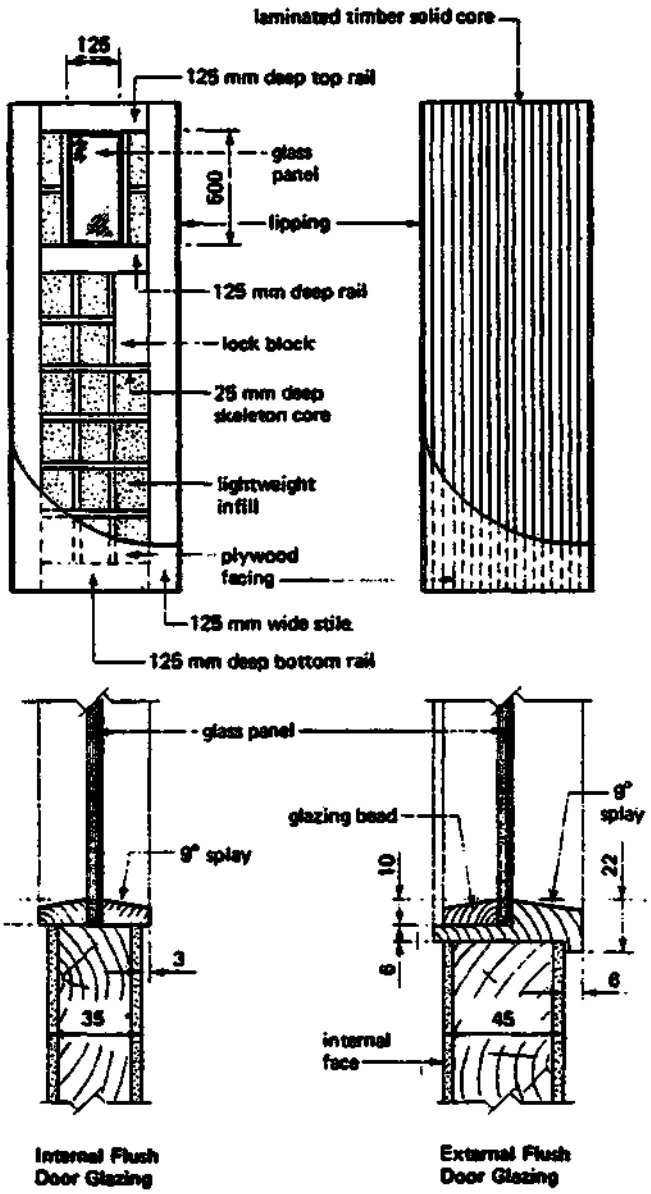
and by using a thin sheet veneer of good quality timber the appearance of high class joinery can be created.

- B.S. specifies the requirements for flush doors but leaves the method of construction to the manufacturer.

therefore: the forms of construction are many and vary, but basically: they can be considered as



Skeleton core flush doors



Solid core doors

-a- skeleton core doors or
-b- solid core doors.

-a- consists of an outer frame with small section intermediate members over which is fixed the facing material. The facing has a tendency to deflect between the core members and this can be very noticeable on the surface especially if the facing is coated with gloss paint.

-b- solid doors of faced block or laminated board are available for
 . internal and
 . external
use.
Another method of construction is to infill the voids (created by a skeleton core) with a light weight material such as foamed plastic which will give support to the facings but will not add much to the weight at the door.

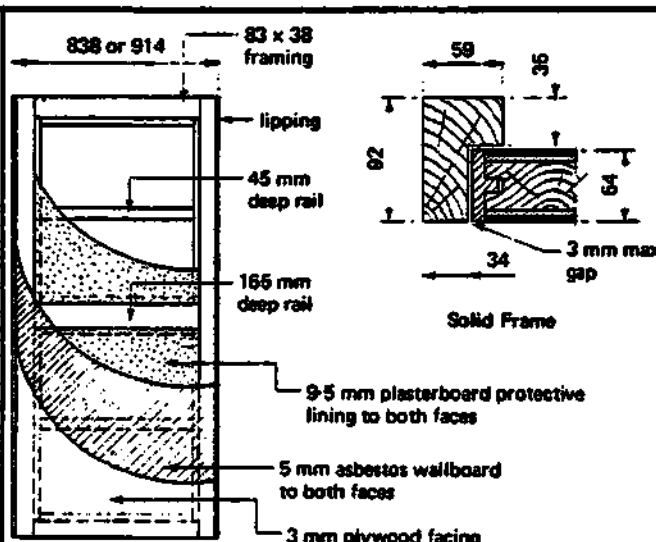
FLUSH DOORS

- The facings can be damaged easyly at the edges, therefore a lipping of solid material should be fixed to at least the vertical edges (good class doors have lippings on all four edges).
- Small glased observation panels can be incorporated in flush doors when the glass panel is secured by loose fixing beads.

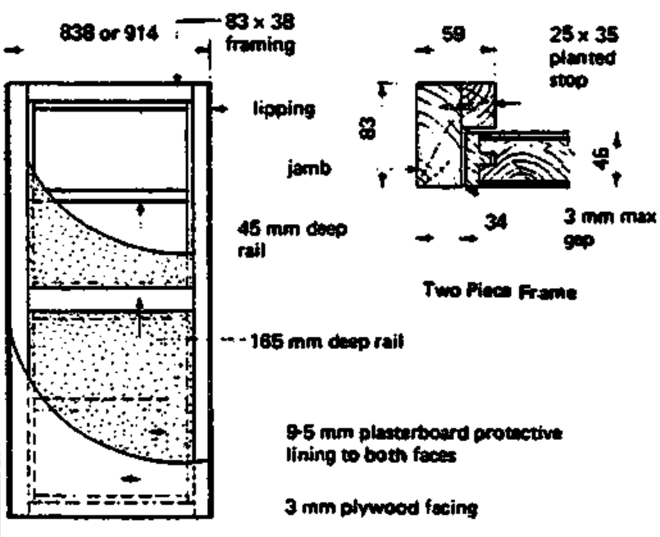
FIRE-CHECK FLUSH DOORS

14.1.4.4 Fire-check flush doors

- Provide an effective barrier to the passage of fire for the time designated by their type - but, to achieve this they must be used in conjunction with the correct frame.



One Hour Type Fire-check Door and Frame



Half-hour Type Fire-check Door and Frame

- Two types are mentioned in BS 459:
 . half-hour resistance
 . one -hour resistance
- This resistance is obtained by placing beneath the ply wood facing a suitably protective lining material (or materials).

Half-hour types are hung using one pair of hinges

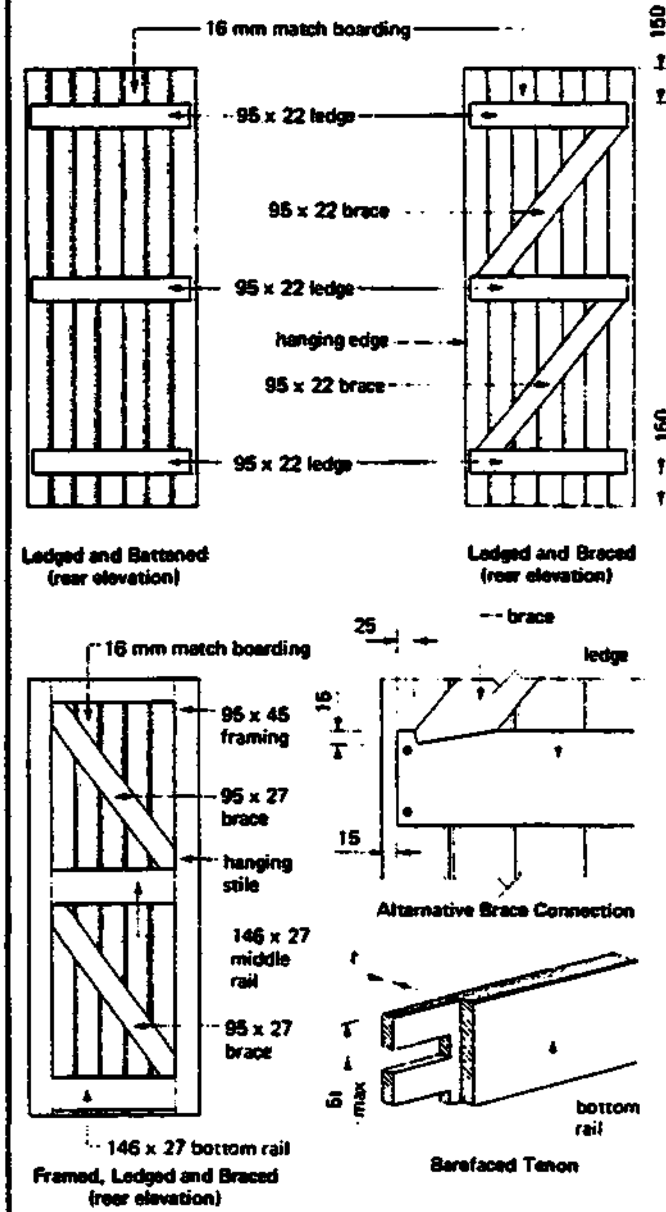
One-Hour types require 1 1/2 pairs of hinges.

MATCHBOARDED DOORS

14.1.4.5 Matchboarded doors

- These doors can be used as
  - external and
  - internal doors.
- There are 2 formes of standard doors:
  - ledged and braced or
  - framed, ledged and braced doors.

  (The latter is the stronger and more attractive version)
- The face is made from tongue and grooved boarding which has edge chamfers on one or both faces. - these form a Vee-joint between the boards.
- 3 horizontal members ('ledges') clamp the boards together - and in this form a non-standard door has been made, called: ledged and battened.
- It is simple and cheap to construct, but it can be easily pulled out of square - the only resistance is that of nails, holding the boards to the ledges.
- The use of that type is limited to buildings such as
  - sheds
  - outhouses etc.
  - In the standard door:
    - Braces are added to resist the tendency to drop out of square.
    - The braces are fixed between the ledges so that they are parallel to one another and slope downwards towards the hanging edge.
  - In the second standard type a mortice and tenoned frame surrounds the match boarded panel giving the door added strength.
  - If wide doors of this form are required the angle of the braces becomes too low to be value as an effective restraint and the brace must therefore be framed as a diagonal between the top and bottom rails. Wide doors of this design are not covered by B.S. but are often used in pairs as garage doors or as wide entrance doors to workshops or similar buildings.

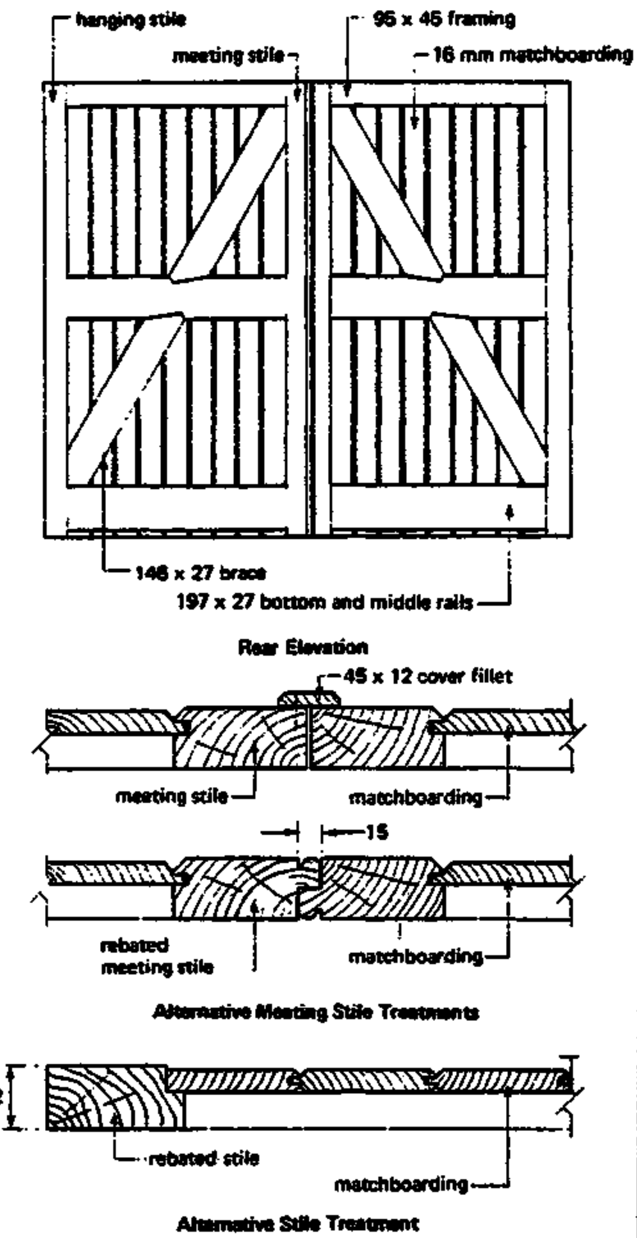


Matchboarded doors

MATCHBOARDED DOORS

- The operation of fixing a door to its frame or lining is termed hanging and entailes.
  - removing the protective horns from the top and bottom of the stiles
  - planing the stiles to reduce the door to a suitable width.
  - cutting and planing the top and bottom to the desired height.
  - marking out and fitting the butts or hinges which attach the door to the frame.
  - fitting any locks and door furniture which is required.
  - The hinges should be positioned 225 mm from the top and bottom of the door and where 1 1/2 pairs are specified for heavy doors the third hinge is positioned midway between the bottom and top hinge.
- A door has to be treated properly during
  - transportation
  - storage
  - after hanging.

+ It should receive a wood priming coat of paint before or immediately after delivery,
+ be stored in the dry and in a flat position (so that it does not twist)
+ receive the finishing coats of paint as soon as practicable after hanging.



Matchboarded double doors

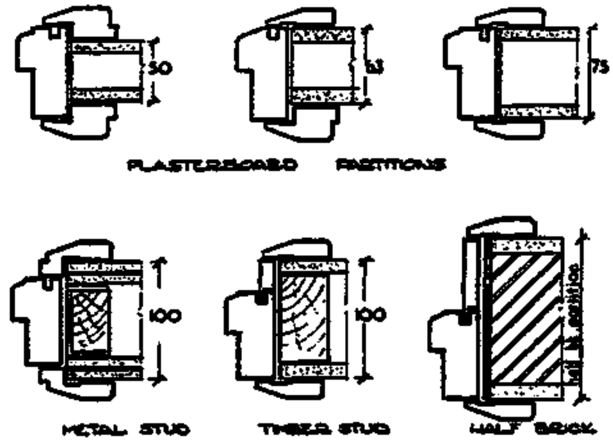
FRAMES and LININGS

14.1.5 Frames and Linings

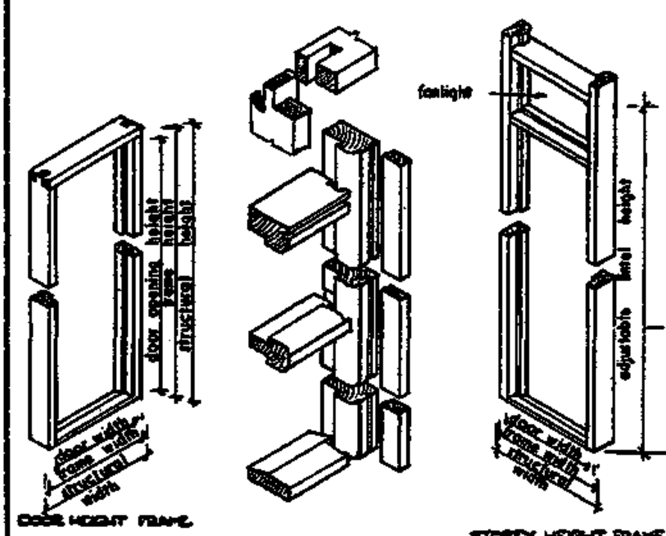
- A door frame or lining is attached to the opening in which a door is to be fitted, it provides a surround for the door and is the member to which a door is fixed or hung.
- Door sets are consisting of a story height frame with a solid or glazed panel over the door head.

14.1.5.1 Timber Door Frames

- Are made from rectangular section timber in which a rebate is formed or to which a planted door stop is fixed to provide the housing for the door.
- Generally a door frame is approximately twice as wide its thickness plus the stop.
- A timber door frame consists of three or four members:
  - . one head
  - . two posts or jambs
  - . one sill or threshold.
- The members can be joined together by
  - . wedged mortice and tenon joints,
  - . combed joints or
  - . mortice and tenon joints pinned with a metal star shaped dowel or a round timber dowel.
- All joints should have either a coating of adhesive or a coating of a lead based paint.
- Door frames which do not have a sill are fitted with mild steel dowels driven into the base of the jambs and cast into the floor slab or alternatively grouted into pre-formed pockets as a means of securing the feet of the frame to the floor.



DOOR
FRAME
COMPONENTS

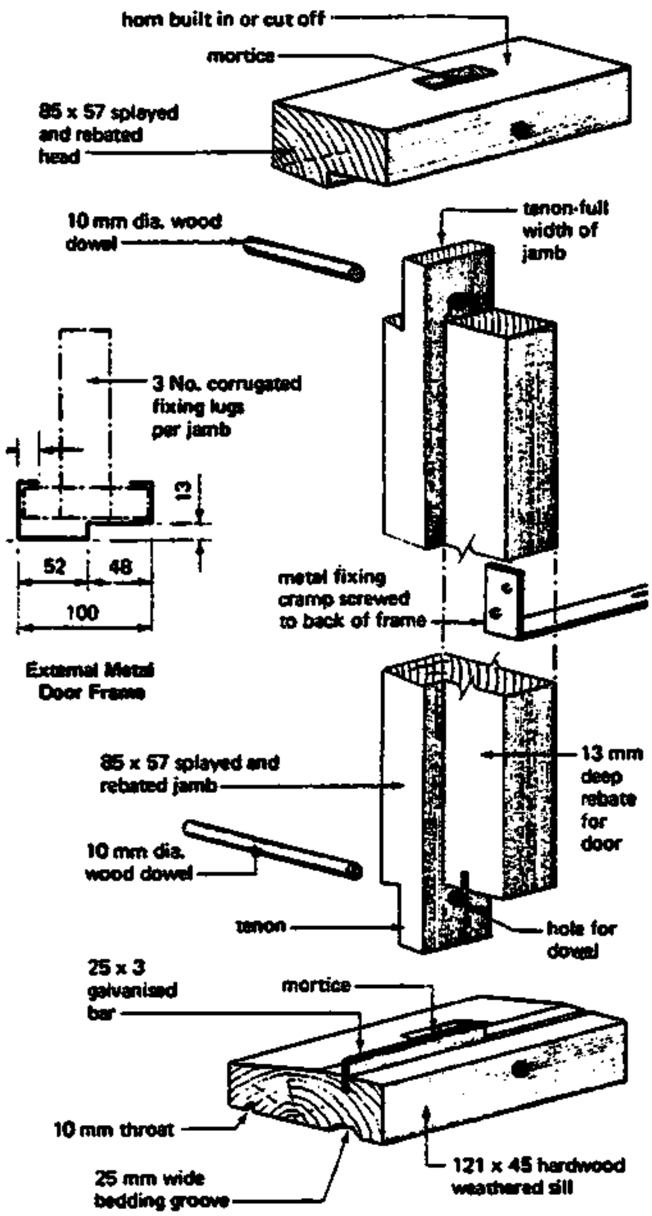


TIMBER DOOR FRAMES

- If the frame is in an exposed position it is advisable to site the feet of the jambs on a damp-proof pad, such as lead or bituminous felt, to prevent moisture soaking into the frame and creating the conditions for fungi attack.
- Door frames fitted with a sill are designed for one of two conditions:
  1. Doors opening out
  2. Doors opening in .

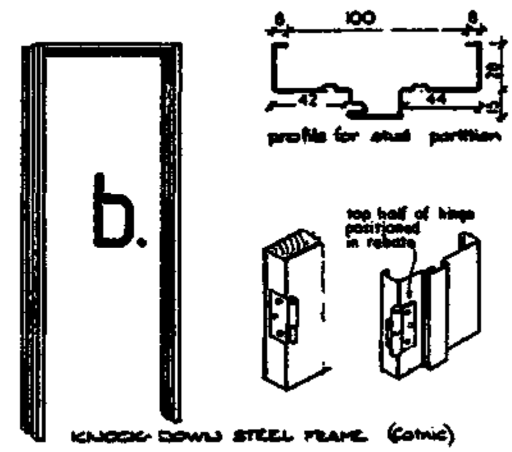
  In both cases the sill must be designed to prevent the entry of rain and wind under the bottom edge of the door.
  - Doors opening out close onto a rebate in the sill
  - Doors opening in have a rebated bottom rail and close over a water bar set into the sill.
- Timberdoor frames can be fixed to a wall by the following methods:
  a) Built into the brick or block wall as the work proceeds by using 'L'shaped ties or cramps.
     The ties are made from galvanised wrought steel with one end turned up 50mm, with 2 holes for wood screws, on the other end being 125 or 225 mm long and fishtailed for building into brick or block bed joints. The ties are fixed to the back of the frame for building in at 450 mm centres.
  b) Fixed into a brick opening at a late stage in the contract to prevent damage to the frame during the construction period.
     This metod is more expensive, but results in a better quality of joinery work.
- The frames are fixed to timber plugs inserted into the reveals with wood screws, whose heads are sunk below the upper surface of the frame.

DOOR FAMES



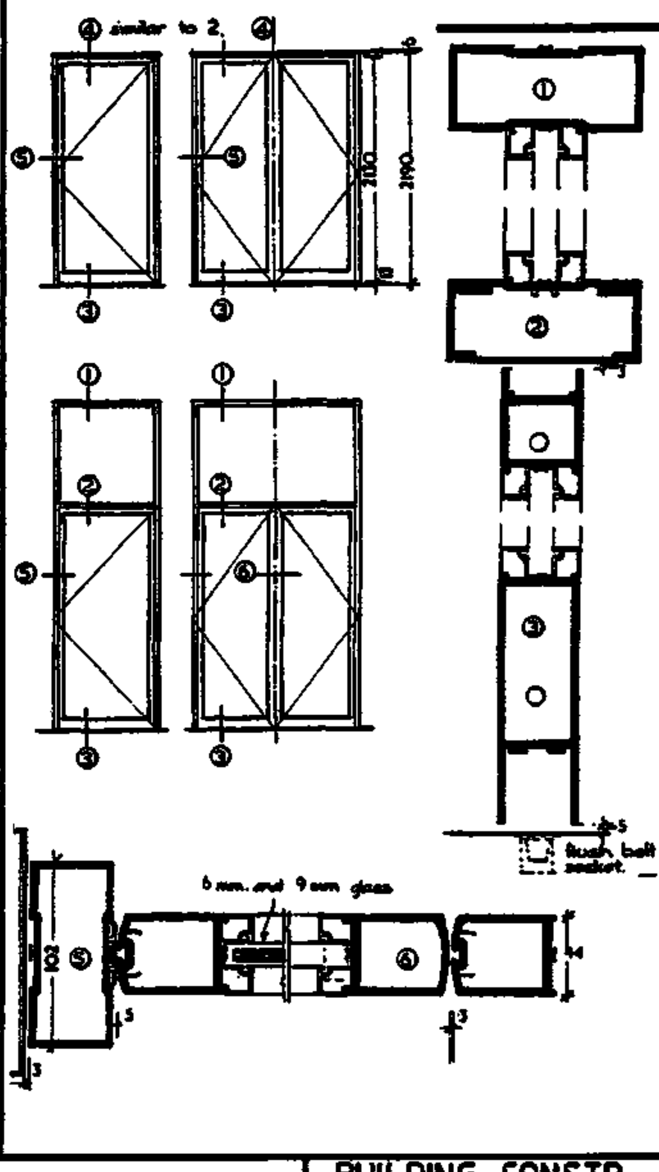
METAL DOOR FRAMES

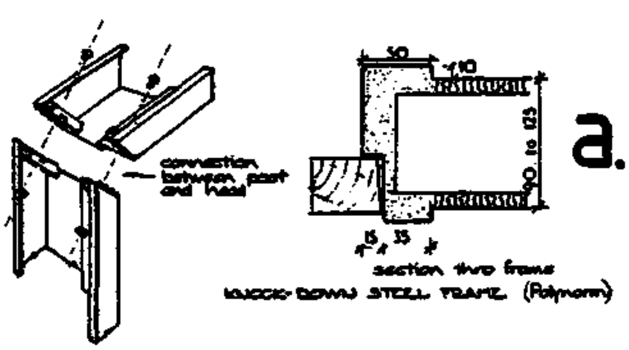
a.) STEEL FRAME 'PolyNORM'
b) STEEL FRAME 'CATNIC'
c.) STAINLESS STEEL FRAME



14.1.5.2 Metal door frames

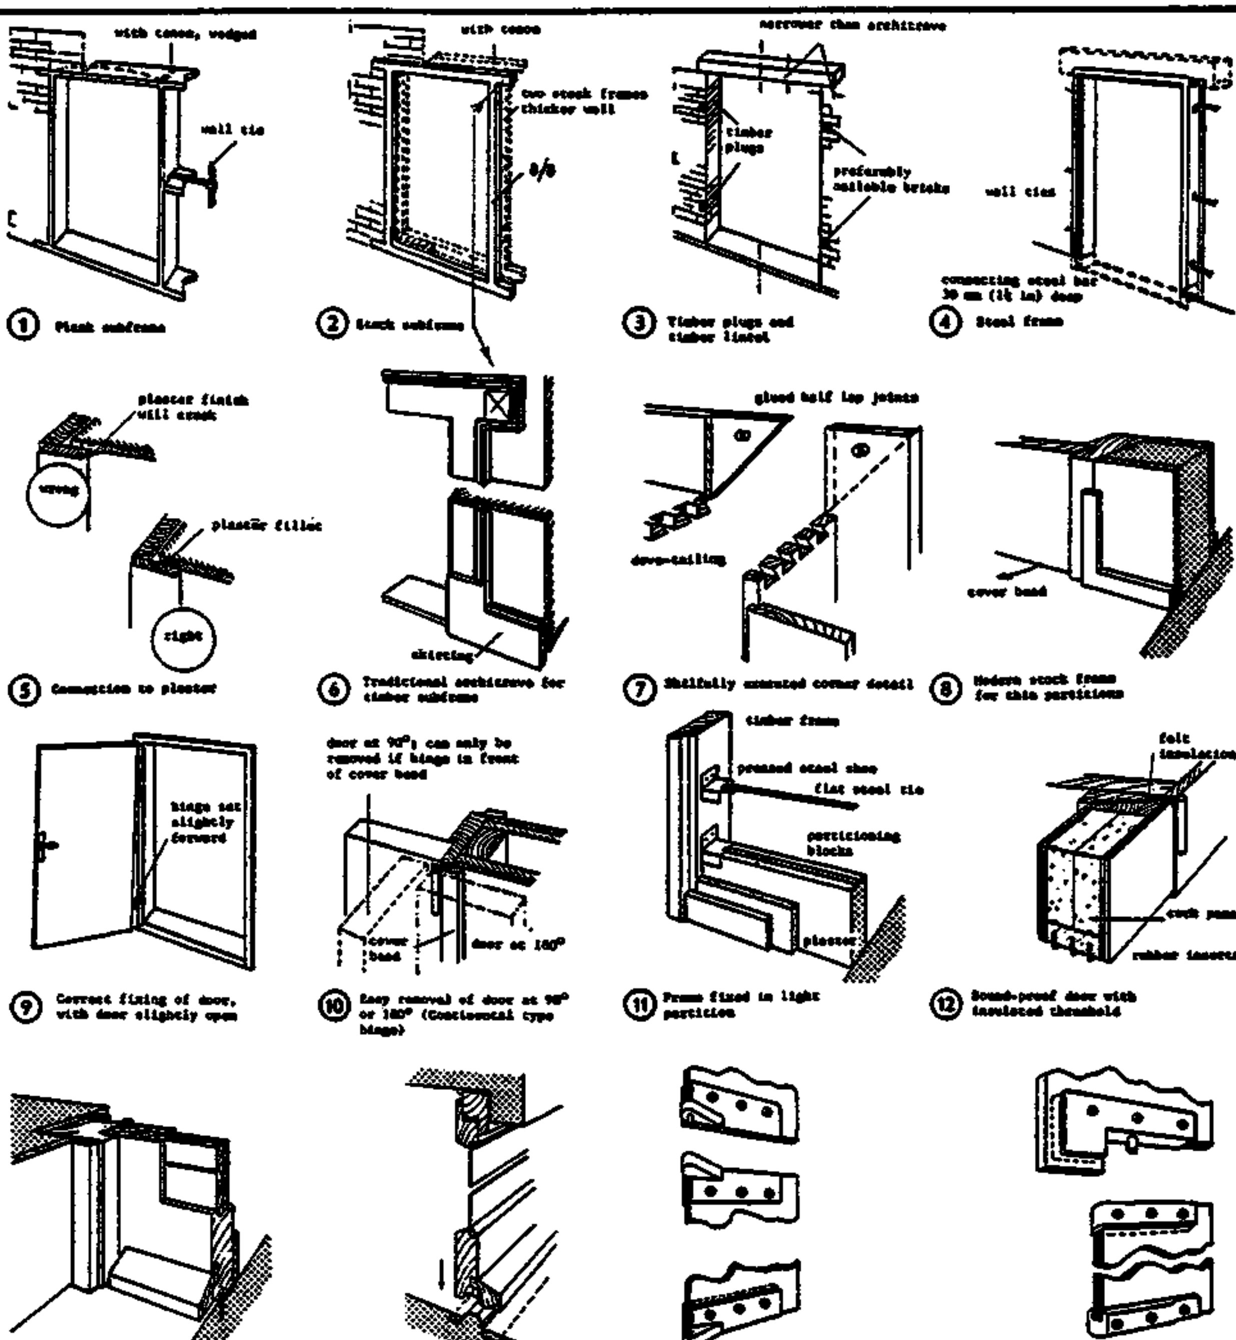
- These are made from mild steel pressed into one of three standard profiles.
- They are suitable for both internal and external positions.
- The hings and striking plates are welded on during manufacture and the whole frame receives a rust-proof treatment before delivery.
- The frames are fixed in a similar manner to timber frames using a tie or lug, which fits into the back of the frame profile and is built into the bed joints of the wall.
- The advantage of this type of frame is that they will not shrink or warp, but they are more expensive than timber ones.





14. DOORS & WINDOWS	DOORS	BUILDING CONSTR.
compiled : D. VOLKE		LECTURE
JAN. '83		CET 8031 / 1 14.1 13

DOOR FRAMES



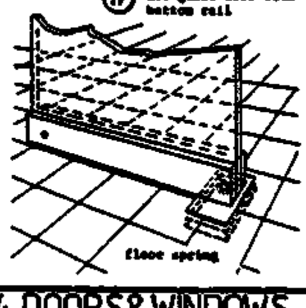
(1) Plank subframe (2) Stock subframe (3) Timber plugs and timber lintel (4) Steel frame

(5) Connection to plaster (6) Traditional architrave for timber subframe (7) Skilfully executed corner detail (8) Modern stock frame for thin partitions

(9) Correct fixing of door, with door slightly open (10) Easy removal of door at 90° or 180° (Continental type hinge) (11) Frame fixed in light partition (12) Sound-proof door with insulated threshold

(13) Entrance door (14) Rising French door (15) One sided hinge for all-glass doors with fan light (16) Swing door hinges for all-glass doors with fan light

(17) All-glass door with bottom rail



Timber subframes and plugs require lining and architrave, which must cover up the plaster.

For the best finish the lining must be dovetailed and the architrave half-mitred, → (7). Planed stock frames for light partitions are also a guide for the plaster finish and are erected before putting up partition blocks, → (8); to avoid damage, doors should be easily removable, → (10).

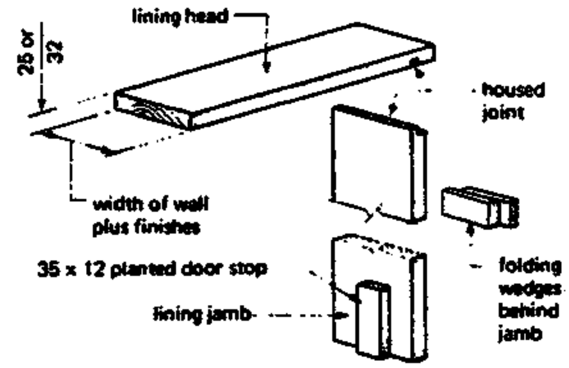
Doors in thin partitions are fixed in steel, → (8), or timber frames with wall tie, → (11). For outside doors plywood must be of external quality; timber doors (weather boarding), steel doors or steel-framed doors with glass panels are preferable. Panels in external doors must overlap, → (13). For French doors on balconies, doors should have rising gear, → (14).

In modern office blocks etc. frameless all-glass doors (armour-plate glass) are used, → (15)-(16), often with automatic electrically-operated opener and floor springs, → (17)

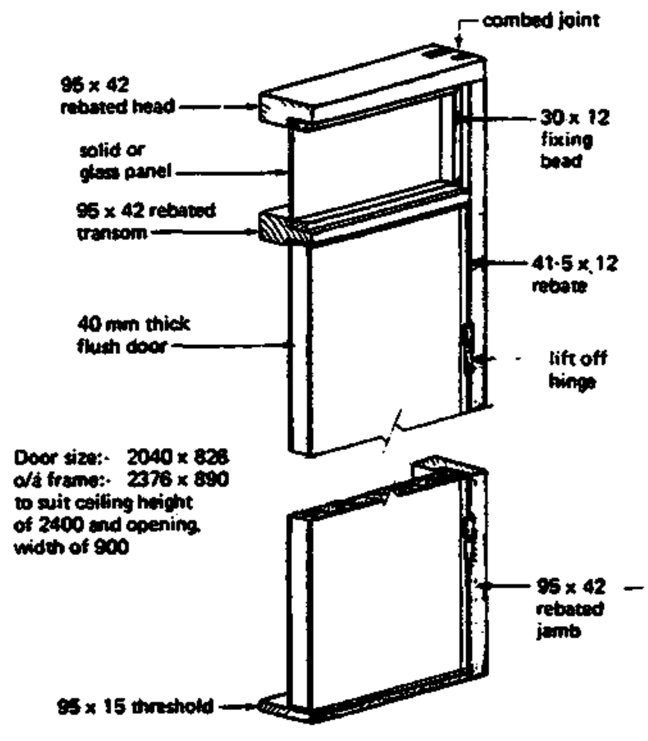
DOOR LININGS

14.1.5.3 Door linings

- These are made from timber board 25 or 35 mm thick and as wide as the wall and any wall finishes.
- They are usually only specified for internal doors.
- Door linings are not built in but are fixed into an opening by nailing or screwing directly into block walls or into plugs in the case of brick walls.
- Timber packing pieces or folding wedges are used to straighten and plumb up the sides or jambs of the linings.



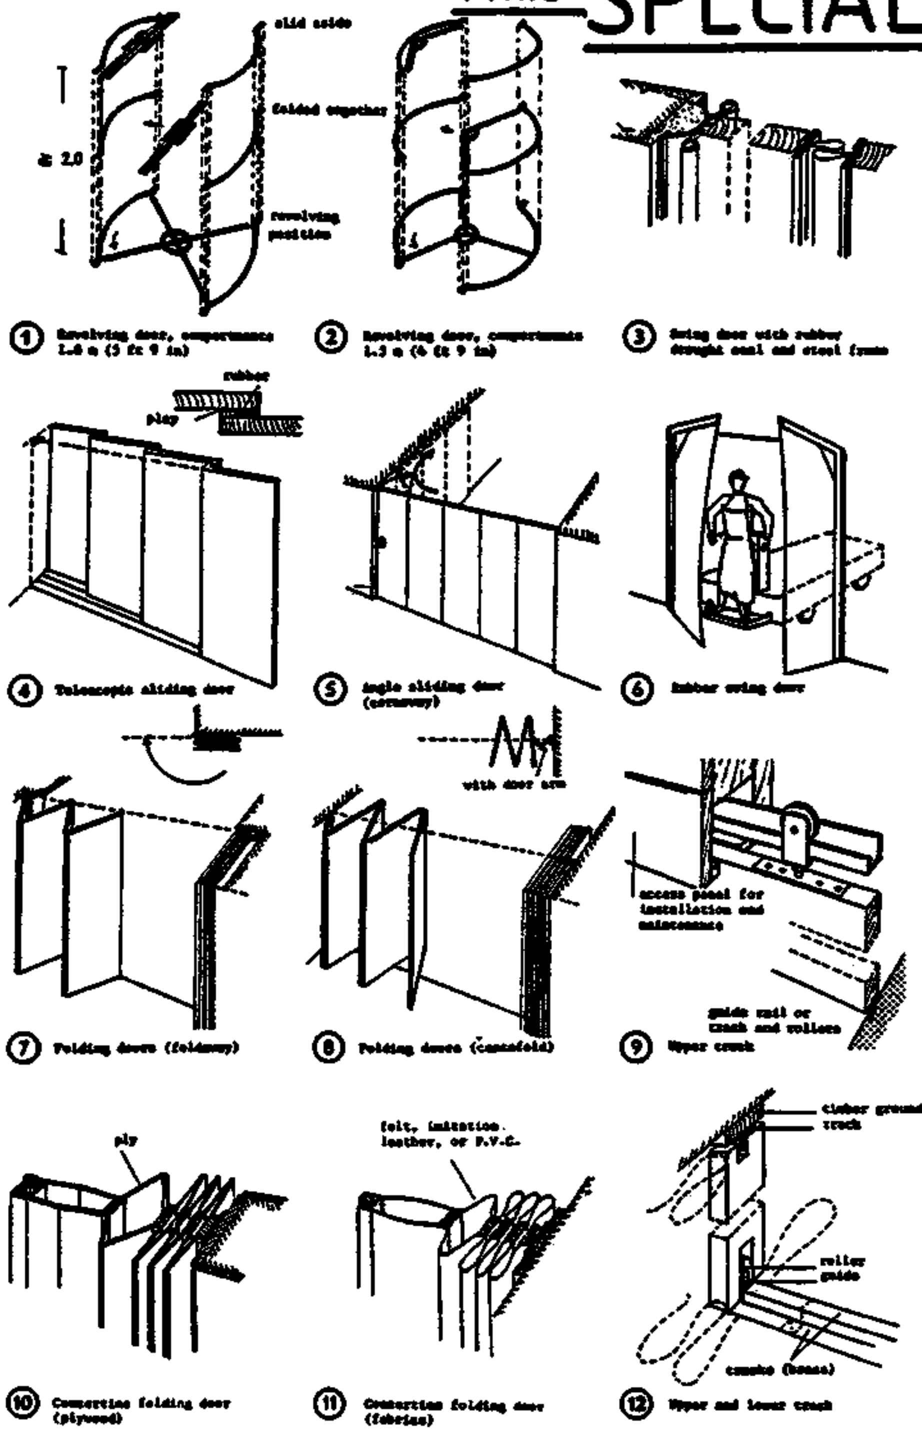
Typical Door Lining



Typical Door Set

Door linings and door sets

14.1.6 SPECIAL DOORS



Revolving doors have wings which may be folded back during peak traffic, especially in summer. Wings are folded away completely if traffic is in one direction only (e.g. at closing time).

Swing doors have spring, check and helical hinges, or shoes and top centres and floor springs. To stop swing and achieve air-tightness, interchangeable draught seals are inserted at meeting styles, → (3).

Large openings (partitions), etc, which cannot be closed by normal swing doors are fitted with special sliding doors, sliding-folding doors, or concertina-folding doors, → (4)-(8). Such doors have hangers (top hung) or rollers (bottom rolling), → (9); rollers, as in lightweight concertina doors, → (12), are infrequently used.

Narrow rooms which provide no space for sliding doors may be closed by overhead doors sliding beneath ceiling, → (13)-(16).

All these doors can be electrically operated and this is especially suitable for large openings with heavy door structures (garages, hangars, etc).

Adjustable fillet rails are necessary at the meeting styles of large doors to cope with temperature fluctuations in steel doors and shrinkage in large timber doors.

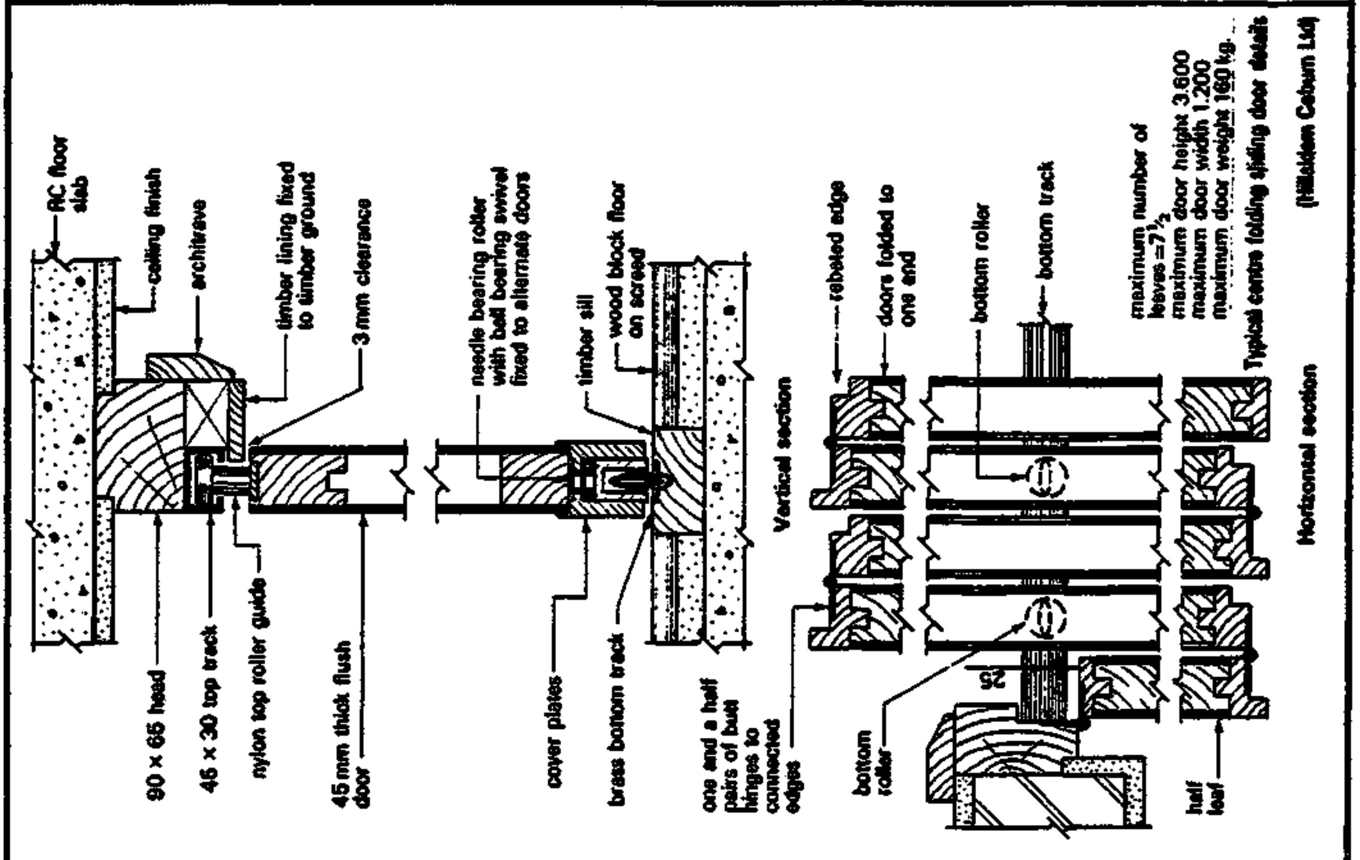
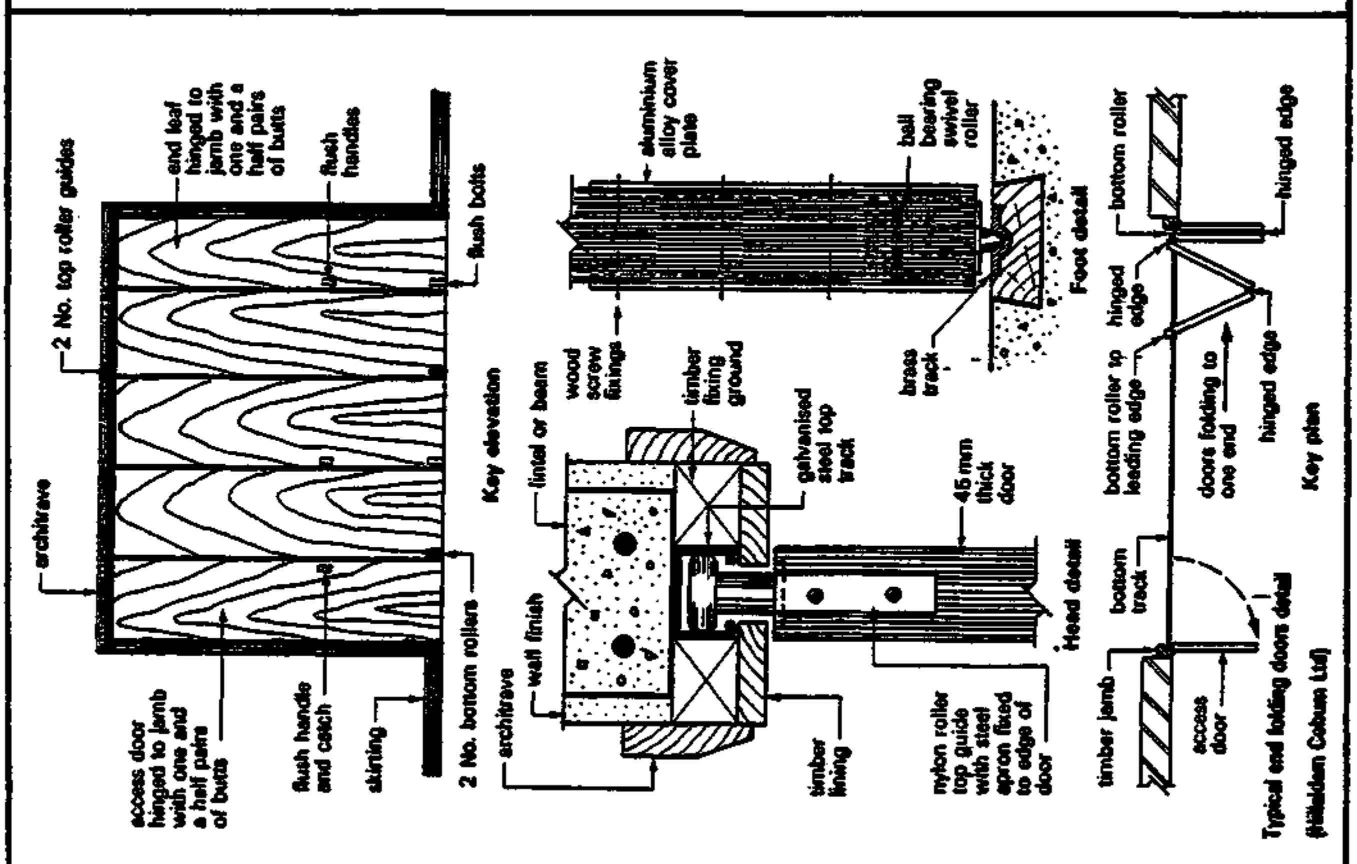
FOLDING DOORS



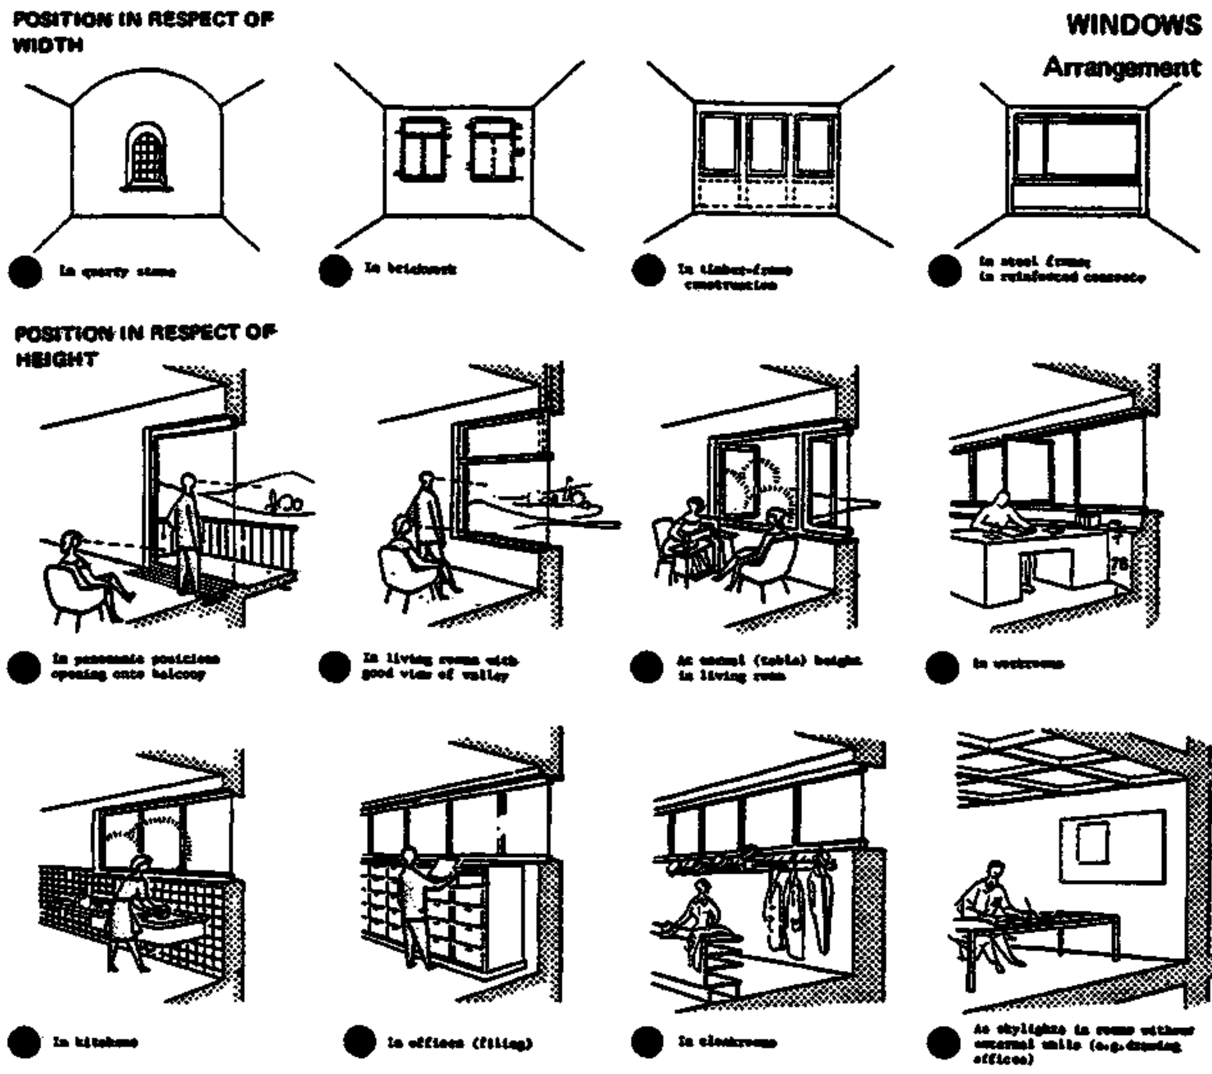


14.2 WINDOWS,GLASS &.GLAZING

PRIMARY FUNCTIONS OF WINDOWS

14.2.0 Primary Functions of Windows:

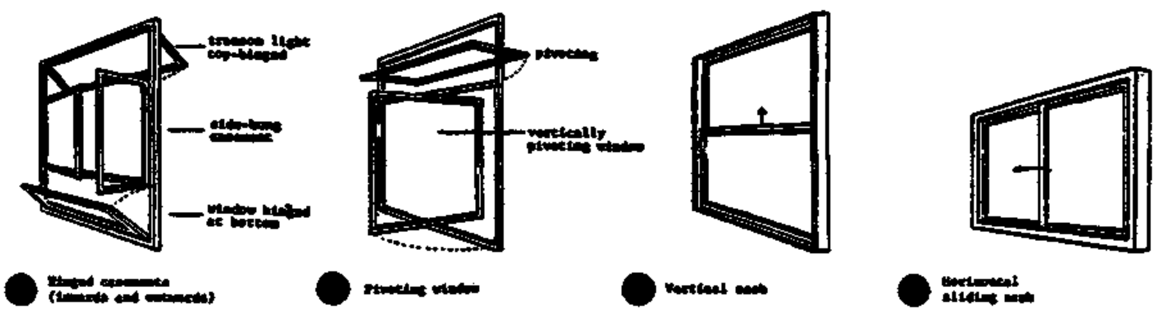
- to provide a means for admission of natural daylight to the interior of a building.
- to provide a means of the necessary ventilation of buildings by including opening lights into the windows.
- A window not only provides daylight and ventilation, also a view at the external surroundings, which is vital for the occupants.



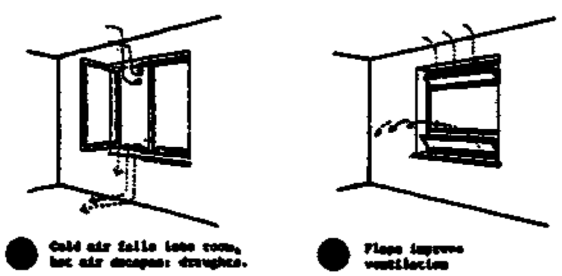
- Windows, like doors, can be made from different materials (or a combination of these such as:
  - timber
  - metal and
  - plastic
- They can also be designed to operate in different ways by arranging for the sashes
  - to slide (vertically or horizontally
  - to pivote (vertically hung, horizontally hung)
  - to swing, by being hung to one of the frame members. This is known as a CASEMENT WINDOW and it is the most widely used type of windows.

PRIMARY FUNCTIONS

TYPES OF OPENING



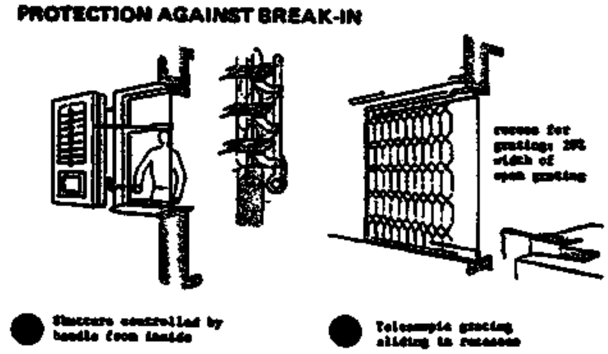
VENTILATION



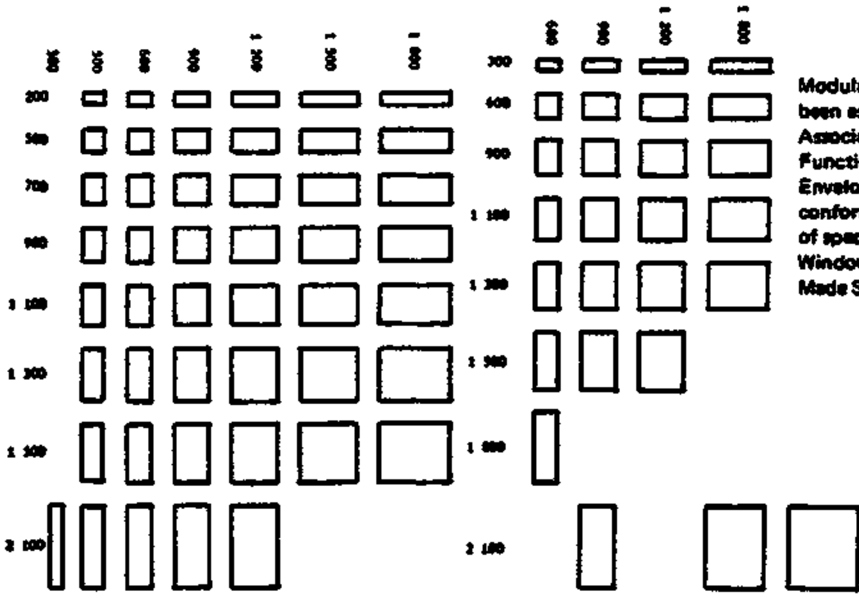
VENTILATION

PROTECTION

PROTECTION AGAINST BREAK-IN



Window spaces



Basic spaces in mm for standard steel windows as issued by the Steel Window Association: (left) Housing (right) Other Building Types (purpose made steel windows).

Modular basic spaces for steel windows have been established for UK by the Steel Window Association from matrices produced by BSI Functional Group Panel B/94/4/2 (External Envelope), with lengths of basic spaces conforming to BS 4011. There are two ranges of space sizes: 1 Housing (Standard Steel Windows): 2 Other Building Types (Purpose Made Steel Windows).

BUILDING REGULATIONS

K1
K2
K3

14.2.1 Building Regulations

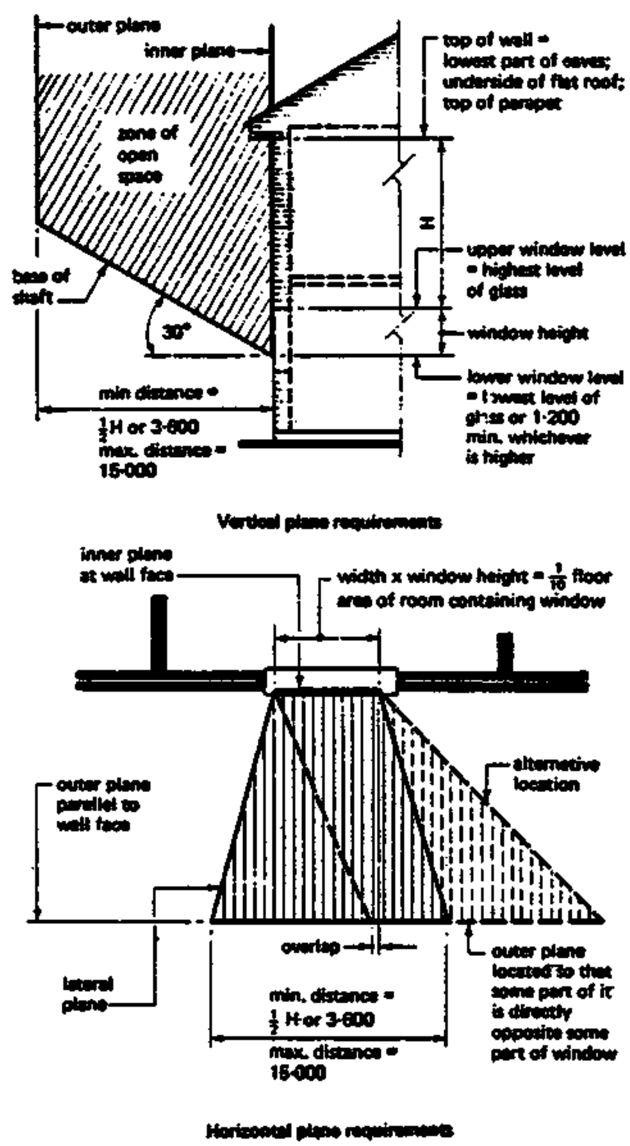
- Regulations K1, K2 and K3 deal with the daylight aspect of the windows.
  - These regulations require for an OPEN SPACE outside windows of habitable rooms (open to the sky and free from obstructions.
  - The minimum size of the open space is related to the height of the wall containing the window.
  - The height is measured from the lower window level (= actual or a min. of 1.20m above the floor to the top of the wall (1. Soffit of a flat roof; 2. lowest part of the eaves for a pitched roof; 3. the top of a parapet, wether the roof is flat or pitched).

K4

- BR K4 deals with the VENTILATION OF HABITABLE ROOMS. (For the purpose of this regulation, a room used i.e. for a kitchen is classified as a habitable room) A HABITABLE ROOM must have ventilation openings (unless it is adequately ventilated by mechanical means.

BUILDING REGULATIONS

- Constructional by - laws require windows equal to at least 1/10th of the area of the floor of the room.
- There is no definition in the B.R. of adequate mechanical means, but it is generally recommended:
  - Three of four air changes per hour would be a reasonable ventilation standard.
- Ventilation opening = any part of a window or hinged panel, adjustable louvre etc. which opens directly to the open air. (excluded are openings assosiated with a mechanically operated system.
  = a door (if it opens directly to the external air) can be defined as a ventilation opening if it has an opening ventilator with an area of not less than 10 000 mm^2 or if it is situated in a room which contains one or more ventilation openings whose total area is not less than 10 000 mm^2.
- The basic requirements for ventilation openings are:
  1. Total area of the ventilation opening (or openings) must exeed 1/20th of the floor area of the room it serves.
  2. Some part of the ventilation opening must be not less than 1,75 m above the floor level.
  3. Rooms with an enclosed veranda must have vent. openings whose total area is not less than 1/20th of the combined floor areas.
  4. Any larder must be ventilated to the external air and if this is achieved by using windows they must have ventilation openings whose total area is not less than 85 000 mm^2 and must be fitted with a durable fly-proof-screen.



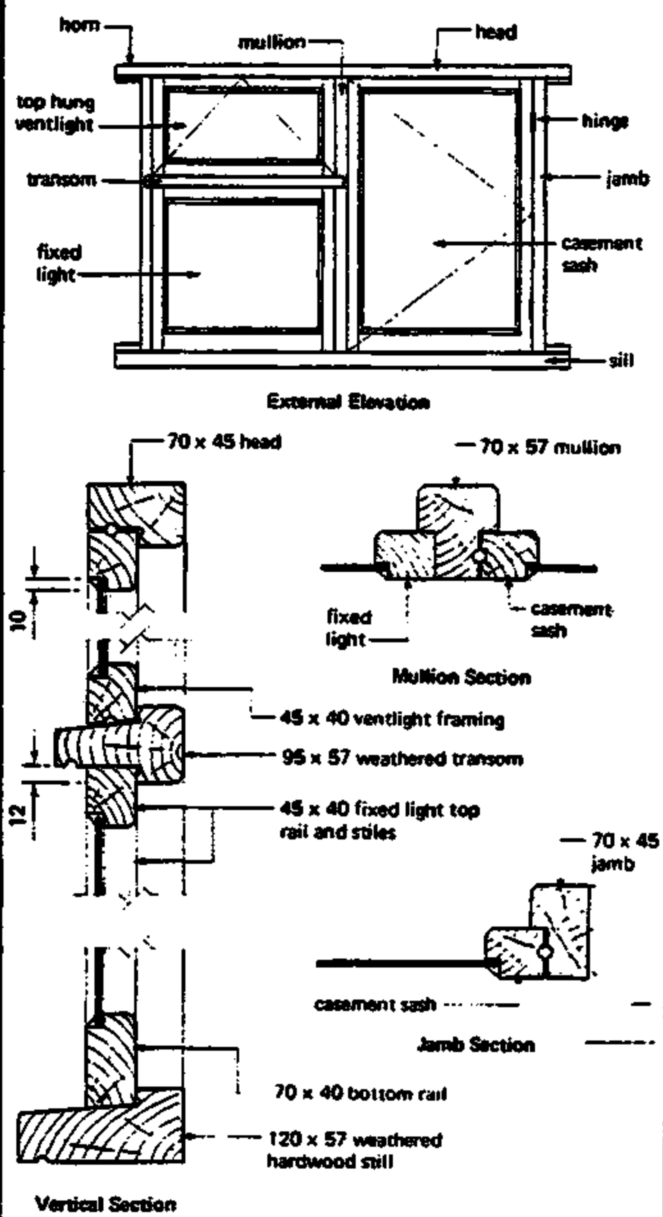
Windows and zones of open space — B. Reg. K1

14 DOORS & WINDOWS compiled : D.VOLKE JAN. '83	WINDOWS	BUILDING CONSTR. LECTURE CET 8031 / 1 14.2.24
TCA TECHNICAL COLLEGE ARUSHA CHUO CHA UFUNDI ARUSHA	CIVIL ENGINEER. DEPARTMENT	24

TRADITIONAL CASEM. WINDOWS

14.2.2 Traditional casement windows.

- A wide range of designes can be produced by using various combinations of the members. A limiting factor is the size of glass pane relevant to its thickness.
- The general arrangement of the framing is important:
  - heads and sills always extend across the full width of the frame (and in many cases have projecting horns for building into the wall)
  - jambs and mullions span between the head and sill; these are joined to than by a wedged or pinned mortise and tenon joint.
- This arrangement gives maximum strength since the vertical members will act as struts. It will also give a simple assembly process.
- The traditional casement window frame has deep rebates to accomodate the full thickness of the sash (= term for the framing of the ventilator). If fixed glazing or lights are required it is necessary to have a sash frame surround to the glass since the depth of rebate in the window frames is too great for direct glazing to the frame.



Traditional timber casement window

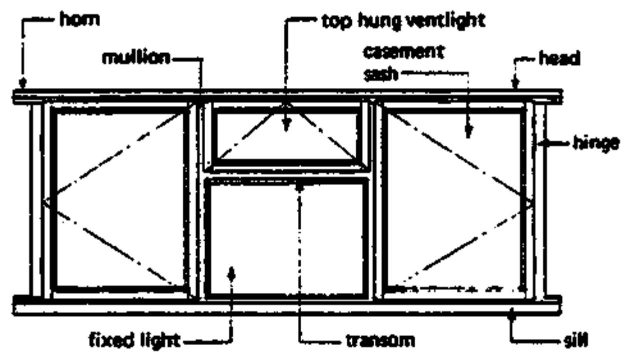
STAND. WOOD CASEM. WINDOWS

14.2.3 Standard Wood Casement Windows.

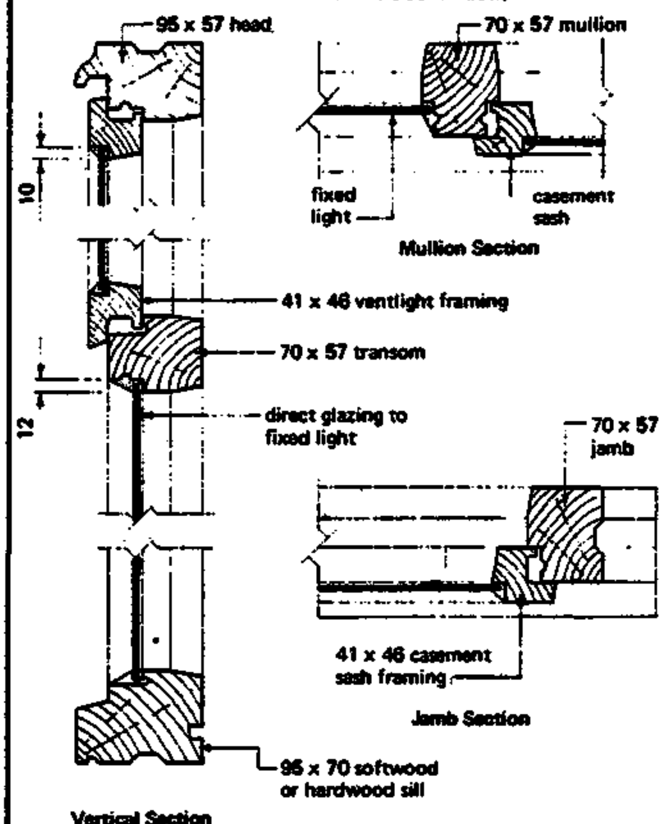
- B.S. 644, Part I, gives details of the
  - quality
  - construction and
  - design

  of a wide range of wood casement windows.
- Frames, sashes and ventlights are made from standard sections of soft wood timbers arranged to give a variety in design and size.
- Sashes and ventlights are designed so that their edges rebate over the external vace of the frame to form a double barrier to the entry of wind and rain.

  The general construction is similar to that described for traditional casement windows and the fixing of the frame into the walls follows that described for door frame.
- Most joinery manufacturers produce a range of modified standard casement windows following the basic priciples set out in BS 644 but with improved head, sill and sash sections.
- The range produced is based on a module for basic spaces of 300 mm giving the following lengths (in mm):
  600; 900; 1200; 1800; 2400
- Frame heights follow the same pattern with the exeption of one half module (in mm):
  600; 900; 1050; 1200; 1500.
- Window types are identified by a notation of figures and letters, i.e.: 4 C V 30 where
  4 = four width modules
  = 4 x 300 mm = 1200 mm
  C = casement
  V = ventlight
  30= three height modules
  = 3 x 300 mm = 900 mm



External Elevation (8 CVC35 window)

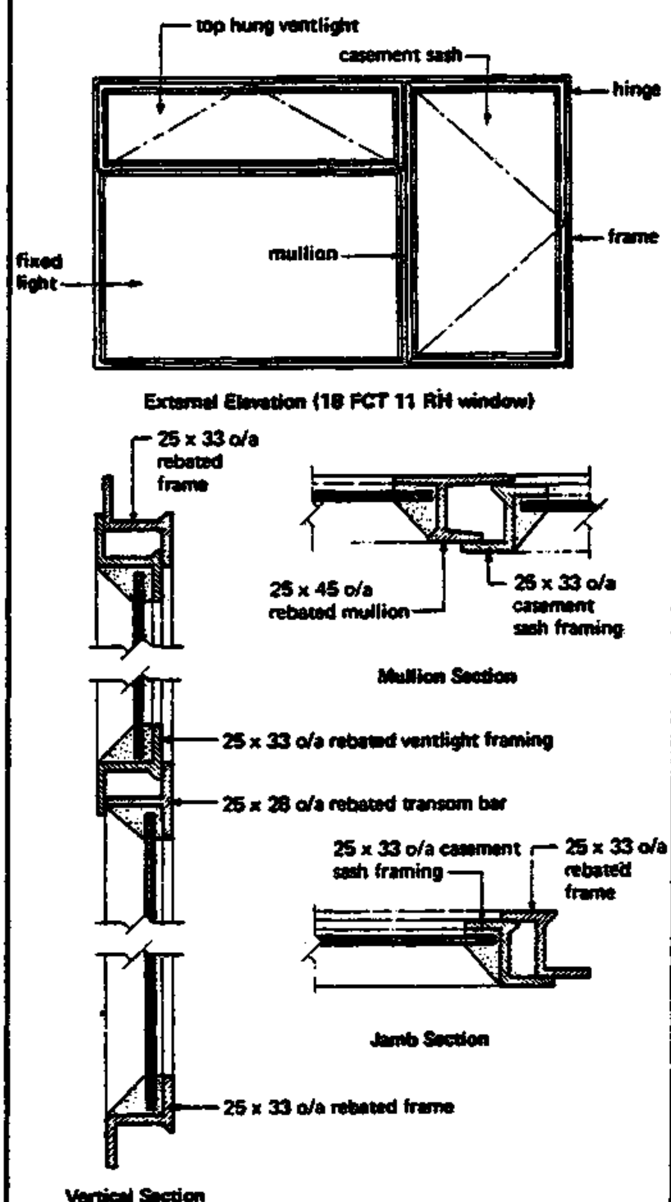


Typical modified BS casement window

STEEL CASEMENT WINDOWS

14.2.4 Steel Casement Windows

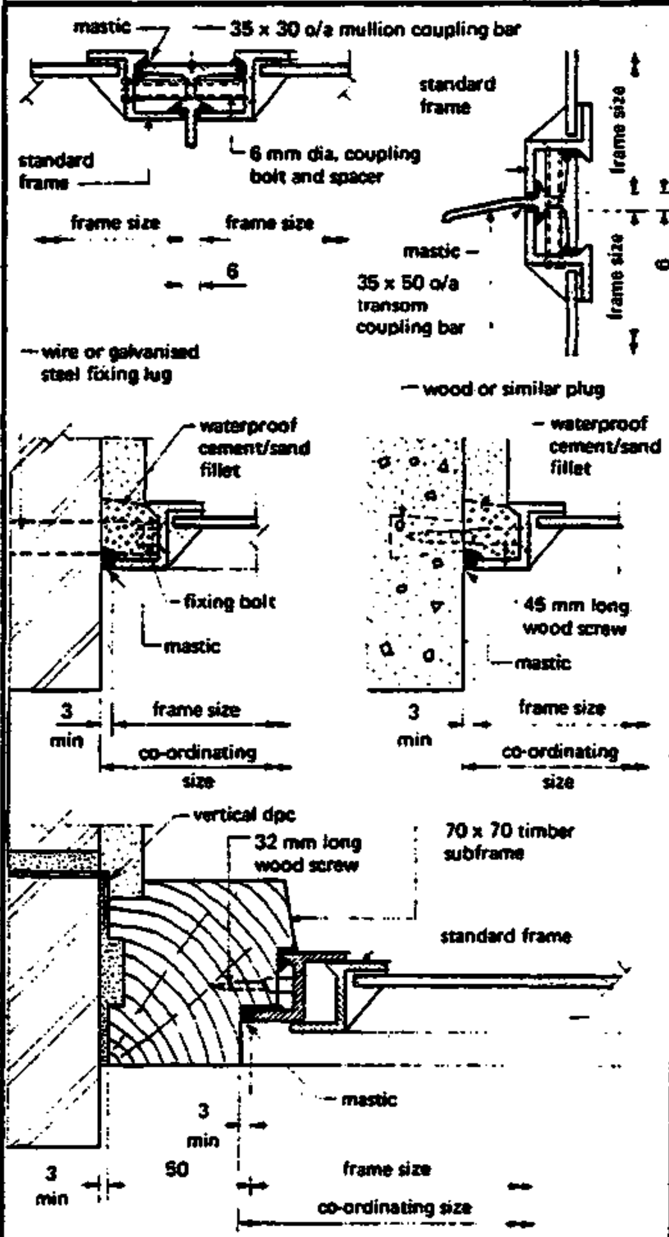
- B.S. 990 gives details of construction, sections, sizes, composites and hardware.
- The standard range coveres
  - fixed lights
  - hung casements
  - pivot casements and
  - doors.
- The lengths, in the main, conform to the basic space first preference of 300 mm giving the following range (in mm) 500; 600; 800; 900; 1200; 1500; 1800.
- Frame heights are based upon basic spaces for the preferred head and sill heights for public sector housing giving the following sizes (in mm): 200; 500; 700; 900; 1100; 1300; 1500.
- Steel windows (like wood windows) are identified by a notation of numbers and letters:
  - Prefix number x 100 = basic space length
  - code letters:
    - F = fixed light
    - C = side hung casement opening out
    - V = top hung casement opening out and extending full width of frame
    - T = top hung casement opening out and extending less than full width of frame.
    - B = bottom casement opening inwards
    - S = fixed sublight
- suffix number: x 100 = basic space height
- suffix code: R.H = right - hand casement as viewed from outside
  L.H = left-hand casement as viewed from outside.



Typical BS 990 steel window

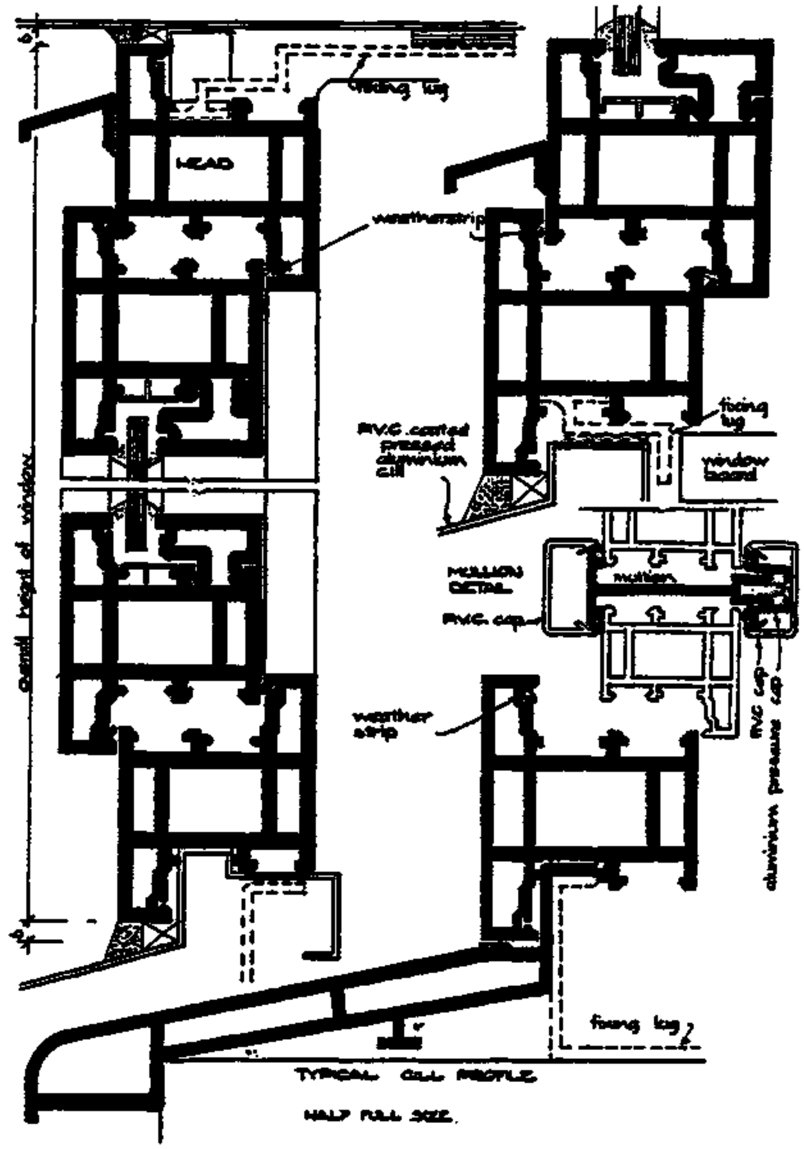
STEEL CASEMENT WINDOWS

- The basic range of steel windows can be coupled together to form composite frames by using TRANSOM and MULLION coupling sections without increasing the basic space module of 100 mm - The actual size of a steel frame can be obtained by deducting the margin-allowance of 6mm from the basic space size.
- All the frames are made from basic rolled steel sections which are mitred and welded at the corners to form right- angles;
  - internal bars are tenoned and rivetted to the outer frame and to each other.
  - the completed frame receives a hot dip galvanised protective finish after manufacture and before delivery.
- Steel windows can be fixed into an opening by a number of methods such as:
  - using a wood surround which is built into reveals and secured with fixing ties or cramps. The wood surround will add 100 or 50 mm to the basic space size in each direction using either a nominal 75 x 75 mm or 50 x 75 mm timber section.
- Advantage of steel windows
  - larges glass area (due to smaller frame sections)
- Disadvantage of steel windows:
  - condensation, which can form on the frames because of the hight conductivity of the metal members.



Steel window couplings and fixings

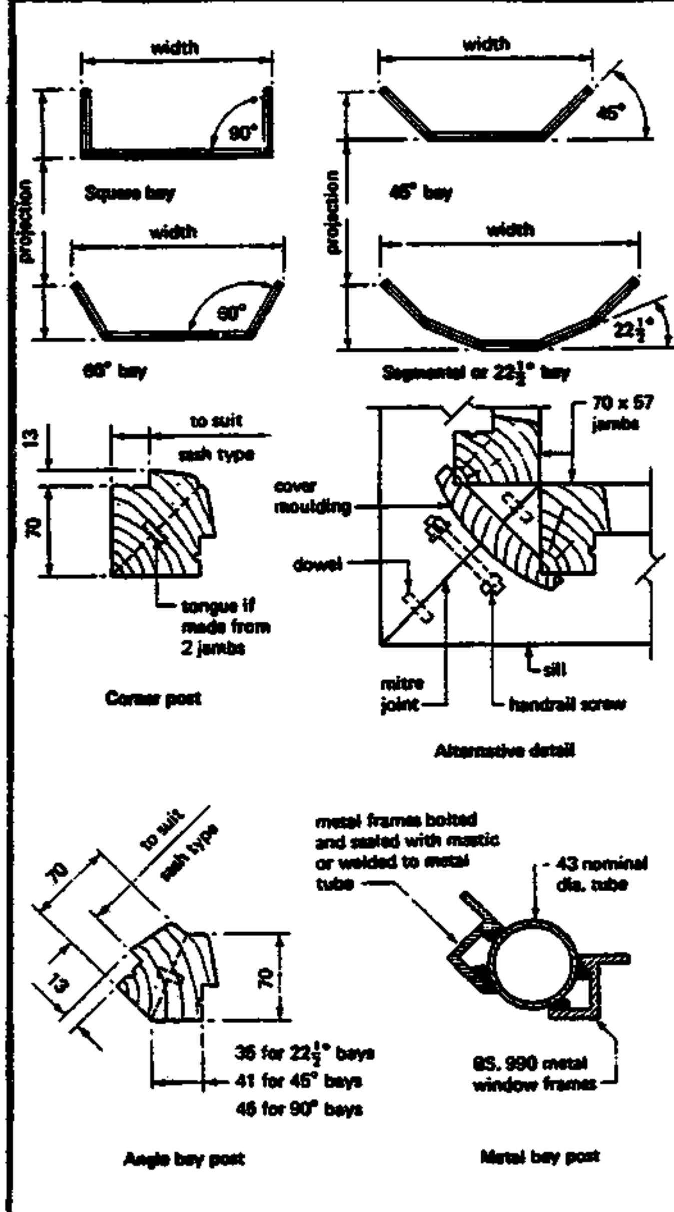
PLASTIC CASEMENT WINDOWS



Plastic windows. Unplasticized polyvinyl chloride (U.P.V.C.) is now in demand for all types, including horizontal and vertical sliders, particularly in modern housing development. Glass is secured in position with rigid P.V.C. slip-on beads. Double-glazing units, up to 24 mm thick, can also be accommodated. Single units can be coupled together using mullions and transoms, as with other types. The profiles are normally supplied in light grey or white, Fig.

Glass-reinforced polyester resin (G.R.P.) is also used in window manufacture. It has excellent weathering properties and is impervious to insect and fungal attack.

BAY WINDOWS

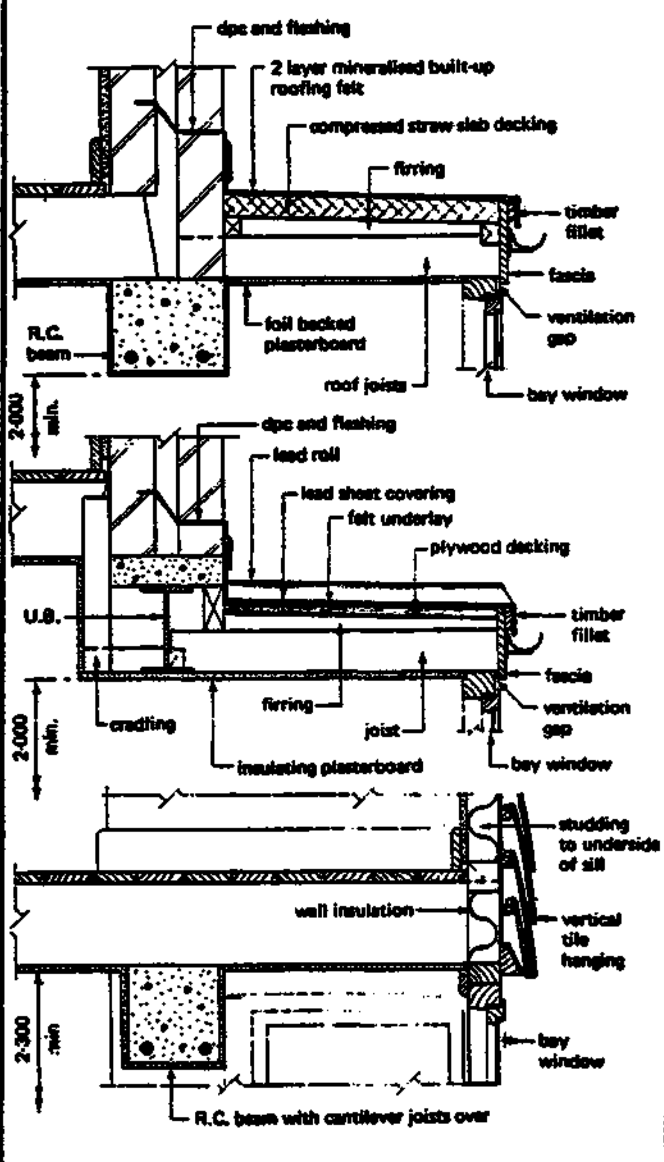


Bay window types and corner posts

- the main difference in detail is the CORNER POST, which can be made from the solid, jointed or masked in the case of timber and tubular for metal windows.
- Any roof treatment can be used to cover in the projection and weather seal it to the main wall

14.2.5 Bay Windows

= any window which prejects in front of the main wall line.
- various names are given to various plain lay layouts (ref. to fig.)
- Bay windows can be constructed of timber, and/or metal and designed with
  - casement or
  - sliding sashes:



Bay window roofs and 2-storey bays

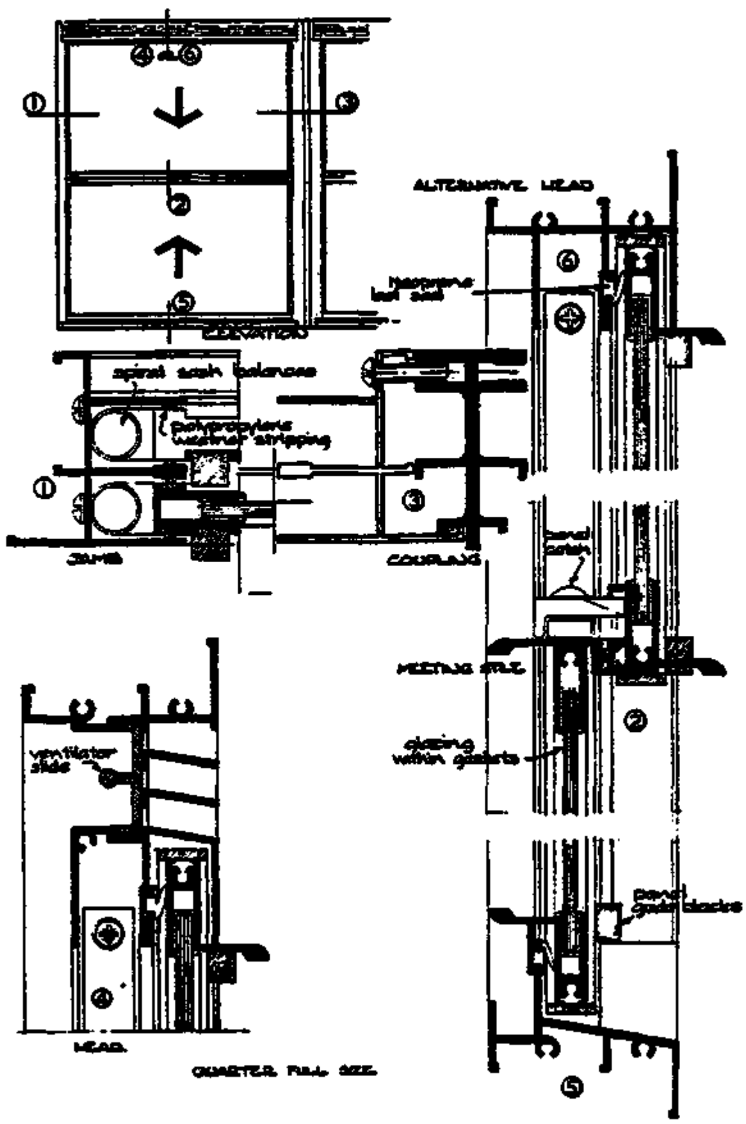
SLIDING SASH WINDOWS

14.2.6 Sliding sash windows:

VERTICAL

14.2.6.1 Vertical sliding windows (also called 'double hung sash windows'

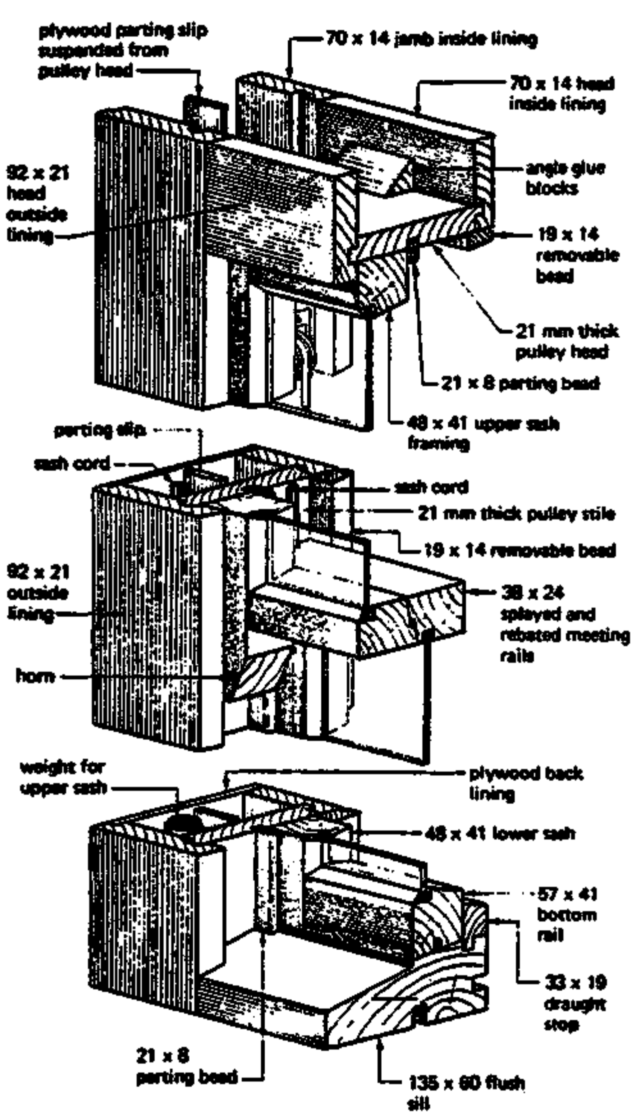
- consist of sashes, sliding vertically over one another.
- Are costly to construct but are more stable than side hung sashes and have better control over the size of ventilation opening, thus reducing the possibility of draughts.



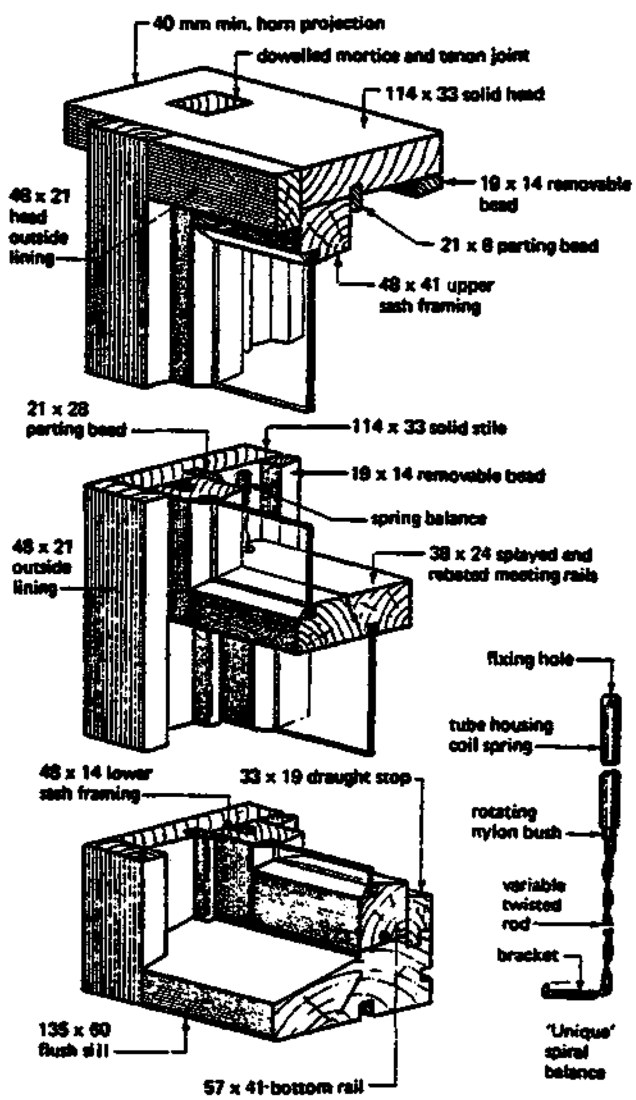
SLIDIND SASH WINDOWS

VERTICAL

- Two main types:
  1. Weight balanced type
  2. Spring balanced type
- No. 1 is the older method. The counter balance weights are suspended by cords and housed in a boxed framed jamb or mullion.
  No. 2 uses solid frames and needs less maintenance.



Double hung weight-balanced sash windows



NB if 114 x 60 solid stiles are used balances can be housed in grooves within the stile thickness

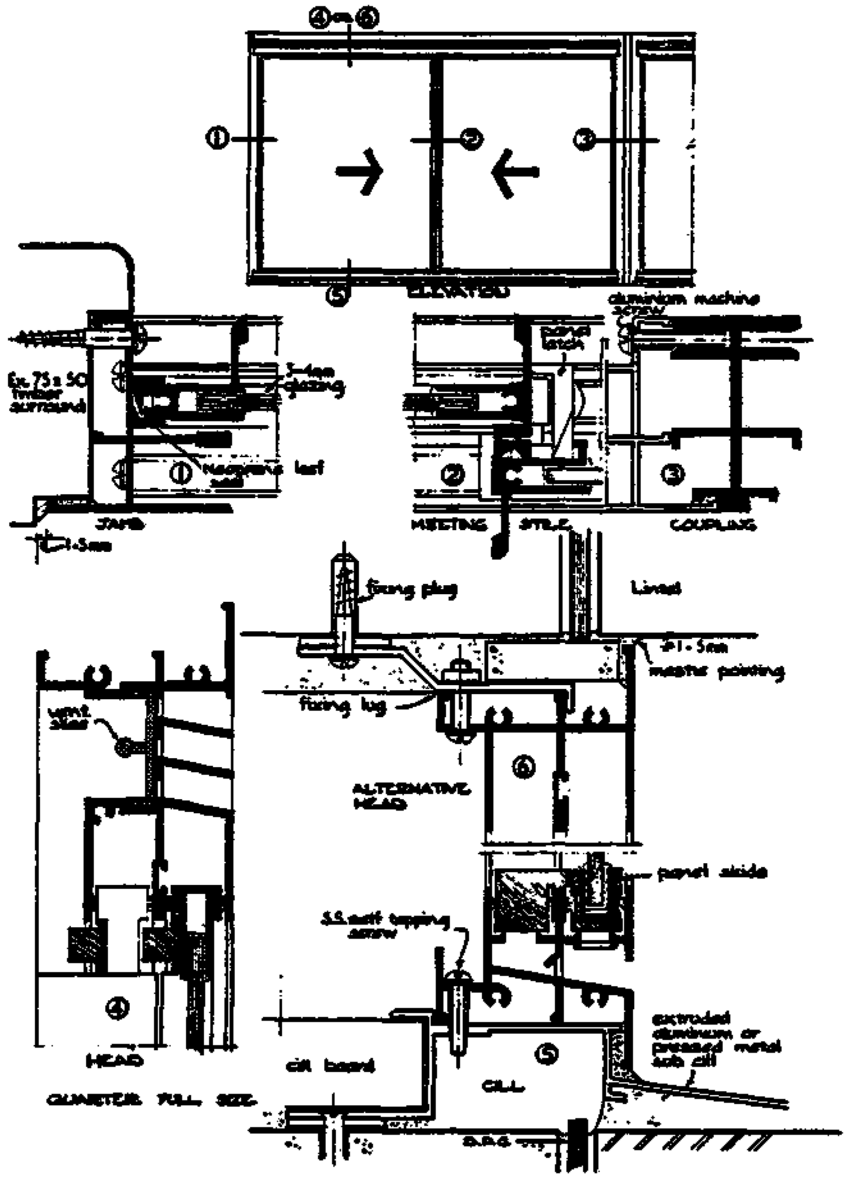
Double hung spring-balanced sash windows

SLIDING SASH WINDOWS

HORIZONTAL

14.2.6.2 Horizontal sliding windows.

- consist of a window frame (wood or metal) with at least 2 sashes. One or both can be opened by sliding horizontally.
- The sashes are made to slide on wood/metal/or compressed fibre runners fixed inside the frame.
- Disadvantage: Sashes tend to jamb in the frame (especially if they are large).



14. DOORS & WINDOWS compiled : D. VOLKE JAN. '83	WINDOWS	BUILDING CONSTR. LECTURE CET 8031/1 14.233

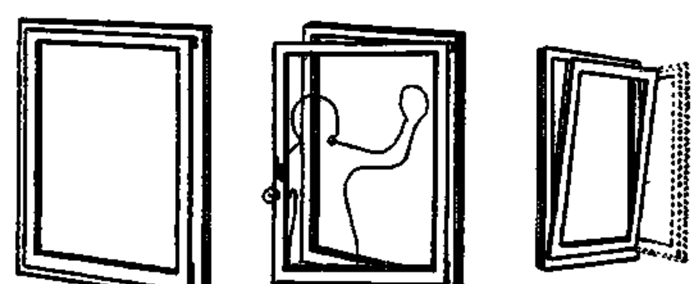
PIVOT WINDOWS

14.2.7 Pivot windows

- The basic construction of the frame and sash is similar to that of a standard casement frame and sash.
- The sash can be arranged to pivot
  - horizontally or
  - vertically

  on friction pivots housed in the jambs or in the sill and head.
- These windows give good adjustment for ventilation purposes.
- Both faces of glazing can be cleaned from the inside of the building.
- Disadvantages:
  - horiz. pivot: Ventilation in high buildings = hot air, which moves upwards along the facade is directed into the rooms.
  - vertic. pivot: (the same as casment windows opening to the inside) restrict the use of the rooms when opend.

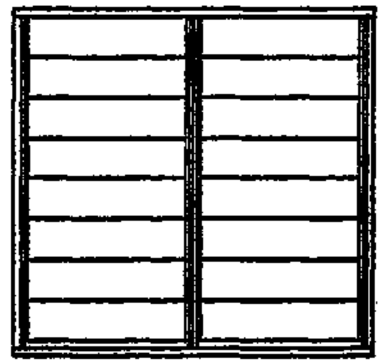
TURN &.TILT WINDOWS

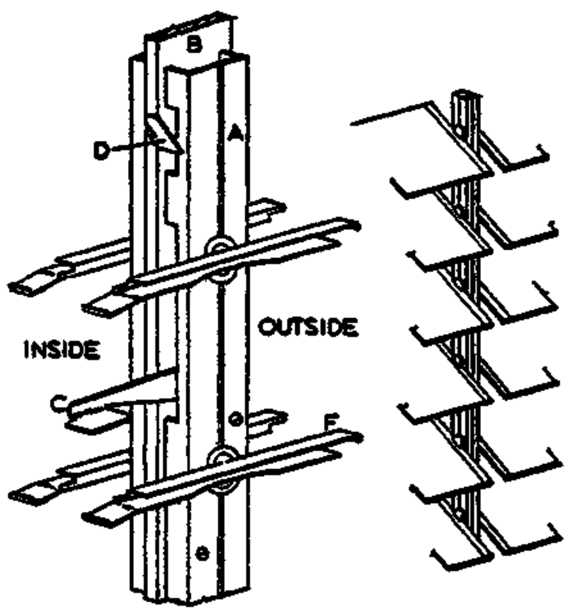


LOUVRES

14.2.8 Louvres

- Adjustable louvres are available in a number of sizes and patterns.
- A louvre blade on a jamb unit is screwed to a galvanized channel surround. The channels and louvres are supplied 'knocked down' and assambled on side.
- another alternative: 'selfmullion' (i.e. 2 jamb units with a spacer bracket between.

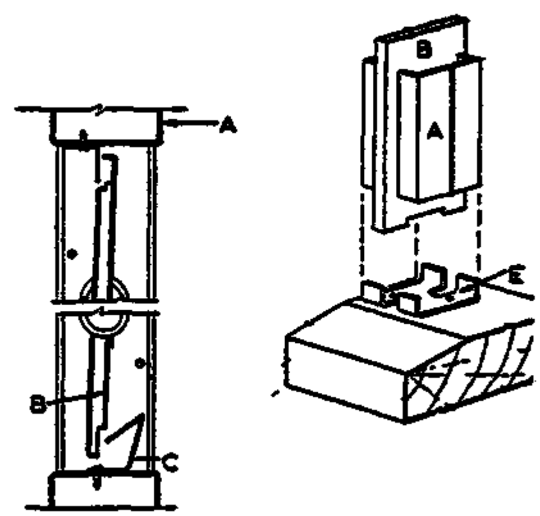




Typical glass louvres in aluminium carriers
A Pressed steel frame
B Glass louvre carrier
C Pressed steel stop

The glass ranges from 3 to 6mm plates depending on the size of the window; but in order to prevent breakage the glass should not be less than 5mm.

- 5mm glass blades should not be longer than 30"(762mm) length
- 6mm glass blades should not be longer than 36"(914mm).



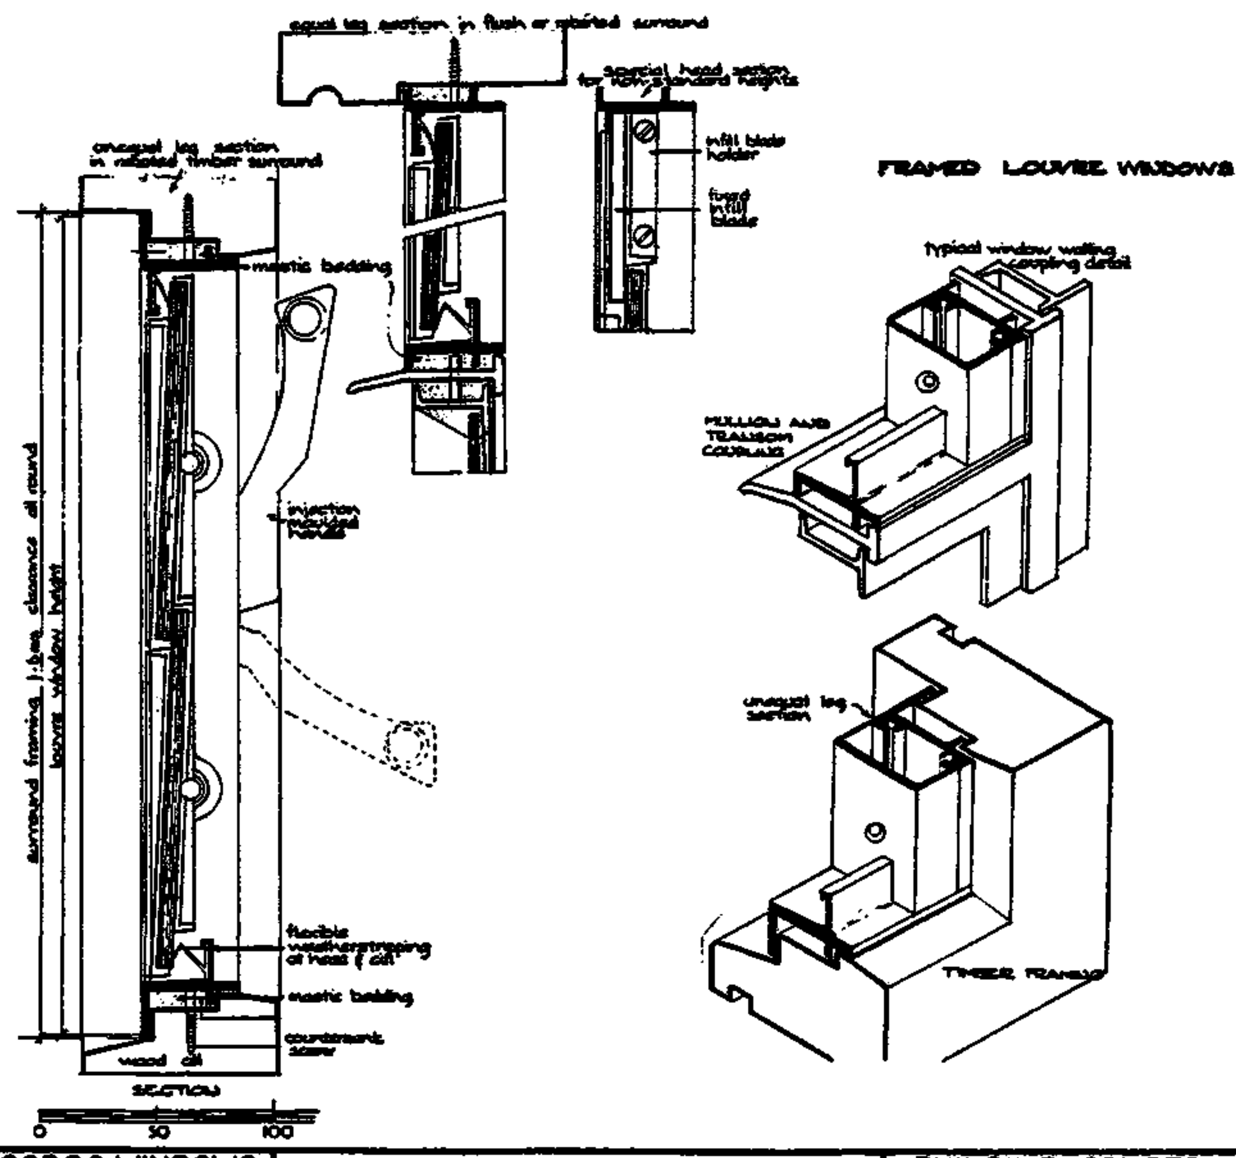
Mullion with steel core

A 1$\frac{3}{4}$ in × $\frac{1}{2}$ in (44 mm × 13 mm) jamb
B 2 in × $\frac{1}{4}$ in (51 mm × 6 mm) steel core
C Operator
D Lock (sometimes combined with the operator)
E Core clip
F Blade carrier

- For high windows, steel mullion strips are available to which the alluminium jamb units may be fixed.
- The glass blades are normally 4" (or 10cm) and 6"(or 15cm) wide, although 9"(23cm) blades are often used.

LOUVRES

This is exceeded in sheltered positions. The lap between 15 cm blades is 12mm and between 23 - 25 mm.
- The height of self-supporting mullion varies according to the length and width of the glass blades (i.e. 6" or 9") and the max wind velocity expected.
- Where the mullion spacing is small (18" or 46 cm) twenty -one louvres with 6" blades may be carried.
  But with a spacing of 4'(1.22m) only fourteen louvres may be carried.



LOUVRES

- With tall windows the jamb units may be easely joined, although care has to be taken to marry the louvres accurately.
- Standard heights of windows for louvres with 15 cm blades range from 12 1/2 in (with 2 blades) to 78 1/2 in (198,4cm) with 14 blades (also with self - mullions, if required)
- Operating handles or 'operators' are usually supplied for every six blades, although this varies with different makes.
- Locking catches may be either seperate (as shown) or incorporated with the operator.

Advantages:
- adaptability to existing openings
- stand. heights to fit any size of opening
- ease of operation
- neat oppearance
- free air flow   etc.

Disadvantages:
- not as secure as fixed wood or metal louvres (glass baldes are easily removed)
- not water tight
- often mullions are not fixed plumb nor the blades are truly horizontal. Poor fixing causes breakage!
- They frequently slip out of their clips.

But there is no doubt, that their advantages far outweight their disadvantages(especially in hot-humid areas like i.e. the coast region in TAN).

GLASS and GLAZING

14.2.9 Glass and Glazing

14.2.9.1 Glass

- Drawn clear sheet glass

- There are 2 principal methods of producing drawn clear sheet glass
  (1) vertical drawing from a pool of molten glass which, when about 1m above the pool level, is rigid enough to be engaged by a series of asbestos rollers, that continue-to draw the ribbon of glass up a tower some 10 m high, after which the ribbon is cut into sheets and washed in a dilute acid to remove surface deposits.
  (2) the glass is initially drawn in the vertical plane but it is turned over a roller so that it is drawn in the horizontal direction for some 60 m and passes into an annealing furnace, at the cold end of which it is cut into sheets.
- it is a transparent glass (85% light transmission) with a fire finished surface, but because the two surfaces are never perfectly flat or parallel there is always some distortion of vision and reflection.

B.S. 952 recommends 3 qualities for sheet glass:
1. Ordinary glazing quality (O.O.) to be used for general glazing purposes.
2. Selected glazing quality (S.G.Q.)for hight grade work (such as cabinets).

- Generally 6 thicknesses are produced(from 2-6 mm thick). The 2 mm thickness is not being recommended for general glazing.

- Float glass

- is a transparent glass (85% light transmission) and is a truly flat glass with undistorted vision.
- it is formed by floating a continuous ribbon of molten glass over a bath of liquid metal at a controlled rate and temperature.
- a general glazing quality and a selected quality are produced in six thicknesses (from 3-12mm).

- Rolled and rough cast glass

- is a flat glass produced by a rolling process
- generally the glass produced in this manner is translucent, which transmits light with varying degrees of diffusion, so that vision is not clear.
- a wired transparent glass with 80% light transmission is produced generally in one thickness of 6mm.
- the glass is made translucent by rolling on to one face a texture or pattern which will give 70-85% light transmission.
- Rough cast glass has an irregular texture to one side.
- wired rough cast glass comes in 2 forms:

  (a) georgian wired (12mm square mash elt.-welded wire reinforcement or
  (b) hexagonally wired which is reinforced with hexagonal wire of approx. 20mm mese.
- rouge cast glass is produced in 5,6 and 10 mm thickness and is made for safety and fire resistante glazing purposes.

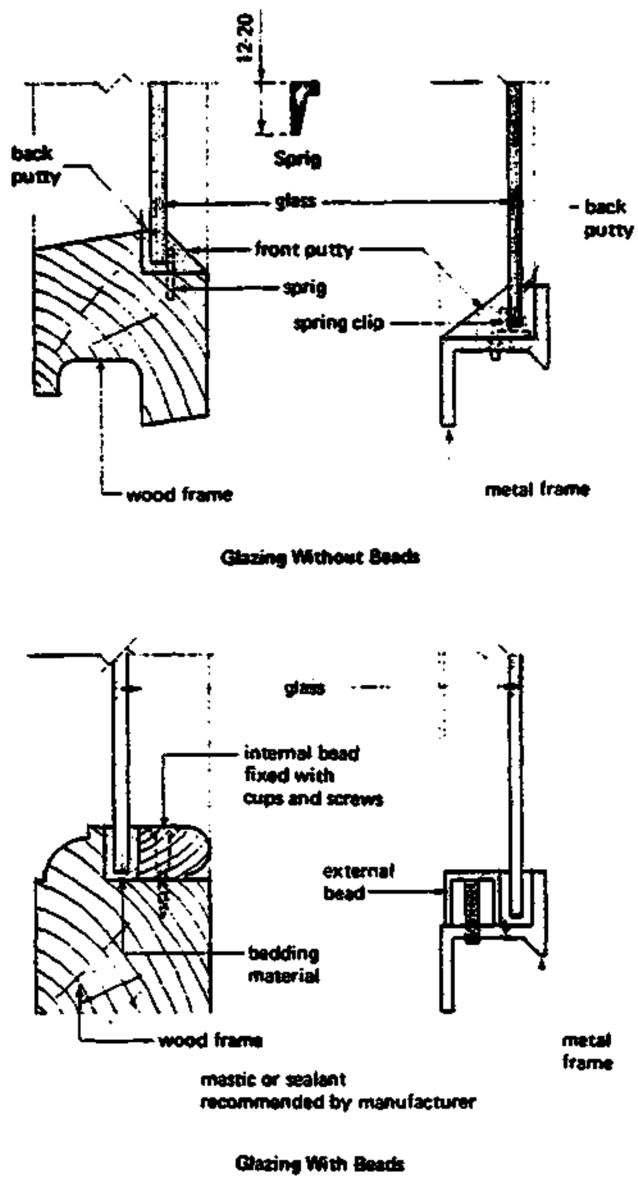
GLASS and GLAZING

14.2.9.2 Glazing

(a) Glazing without BEADS
- is a suitable method for general domestic window and door panes.
- the glass is bedded in a compound and secured with sprigs, pegs or clips and fronted with a weathered surface putty.
- putty is glazing, compound which will require a protective coating of paint as soon as practicable after glazing.
- two kinds of putty are generally used:
  1. Linseed oil putty: for use with primed wood members and is made from linseed oil and whiting.(B.S.544)
  2. Metal casement putty:for use with metal or non-absorbent wood members and is made from refined vegetable drying oils and finely ground chalk.
- The glass pane should be cut to allow a min. clearance of 2 mm all round for both wood and metal frames.
- Sufficient putty is applied to the rebate to give at least 2mm of back putty when the glass is pressed into the rabate, any surplus putty being stripped off level or at an angle above the rabate.
- The glass should be secured with sprigs or clips at not more then 440mm centres and finished off on the front edge with a weathered putty-fillet, so that the top edge of the fillet is at or just below the sight line.

(b) Glazing with BEADS
- is generally applied to good class joinery
- the beads should be secured with
  - panel pins or
  - screws

  for hardwoods it is usual to use cups and screws.
- The glass is bedded in a compound or a suitable glazing felt mainly to prevent damage by vibation to the glass
- Beads are usually mitred at the corners to give continuity of any moulding.
- Beads for metal windows are usually supplied with the sourround or frame, and fixing of glass should follow' the manufacturers instructions.



Glazing details

MOSQUITO SCREENING

14.2.10 Mosquito screening
(Fly screens)

- mass production of copper wire and nylon screens have made complete proofing very common.
- Green-tinted gauze is available which reduces glare considerably.
- Nylon gauze (although cheap) is not as transparent as copper and tends to produce a foggy outlook. Such sceens are not designed to resist damage caused by fly swatting and should be left undisturbed when once in position.
- Fibre glass is an excellent material for screening. It will resist corrosion and rust and will not stain walls and sills.
  This material
  + does not deteriorate in industrial areas,
  + is not affected by mildew
  + resists salt air and
  + will withstand heat up to 150°C before becoming soft.
  + it provides good fire protection.
- When fly screens are inteded for glass-louvre windows, it is necessary to make the window frame wide enough to clear the louvre when fully open (the screen may be fixed direct to the frame).
- removable screens (secured by wing nuts) are used where mosquitos or other pests occur only at certain times of the year.

  A neater solution, however, lies in the use of roll-up insect screens which may be fixed permanently.
  These consist of light alu-frames with fibreglass screens which roll up into a head-box (= 60mm²).
  They may be fixed to either wood or metal frames.

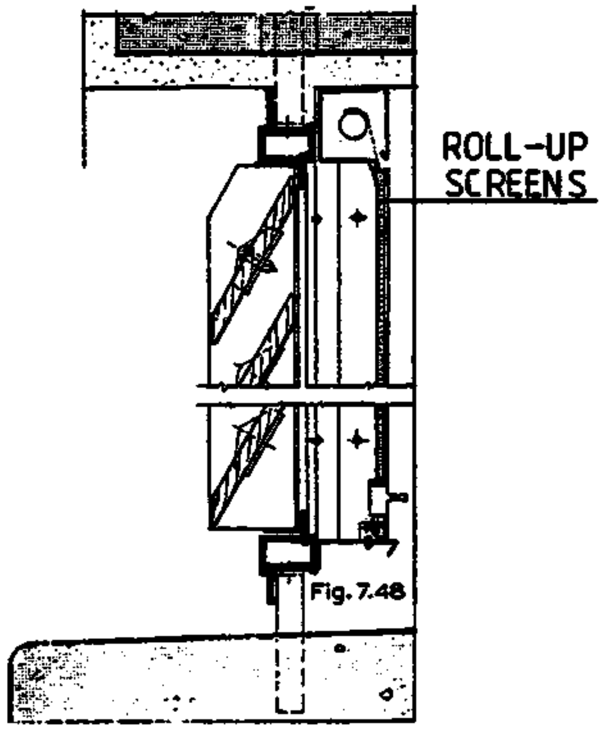


Fig. 7.48

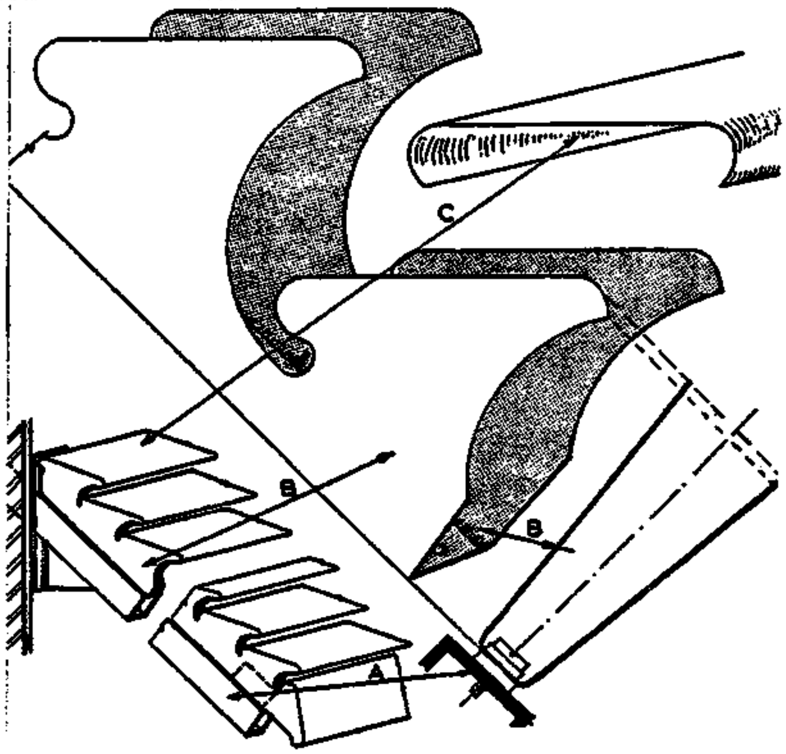
- Flat insect screens in alu-frames are also available
  - fixed
  - hinged or
  - sliding.
- Gauze doors may be made of timber framing or in alu-frames.
  + When such doors are used, they should be arranged to open outward, if possible, otherwise disturbed insects on the screen will tend to fly inwards as the door is opened.
  + The doors may be installed on the face, or in the reveal and should not interfere with the normal door.

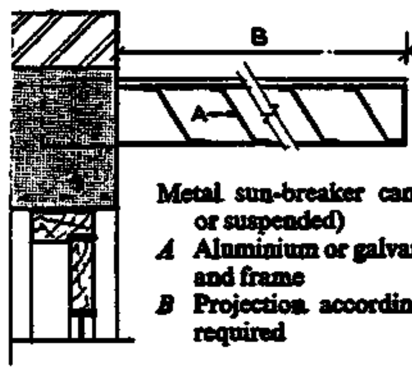
SUN-BREAKERS



Aluminium sun-breakers
A Steel box section (size to suit span)
B Stringer (size and shape to suit climate)
C Aluminium panels (clip-on)

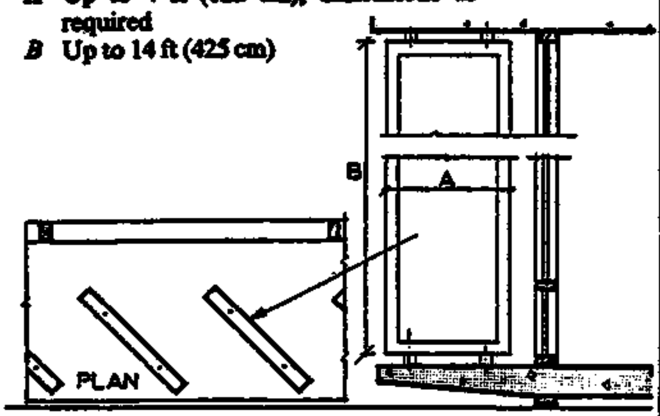
14.2.11 Sun-breakers

- Sun control is frequently necessary and many diff. systems have been developed to effect this, such as
  - pierced panels of brick-work or blockwork
  - overhanging eaves
  - canopies
  - painted or coloured glass
  - metal louvres
  - vertical slats of concrete, extending the full height of the building, arranged at a suitable angle to de-feat direct entry of sun-light.
- Before adequate sun control can be achieved, several fac-tors require consideration:
  - orientation of the buil-ding
  - the latitude of the country
  - the hours of sunlight against which protection is needed
  - the position of the building regarding the prevailing winds and rains.



Metal sun-breaker canopy (cantilevered or suspended)
A Aluminium or galvanized steel blades and frame
B Projection according to shade angle required

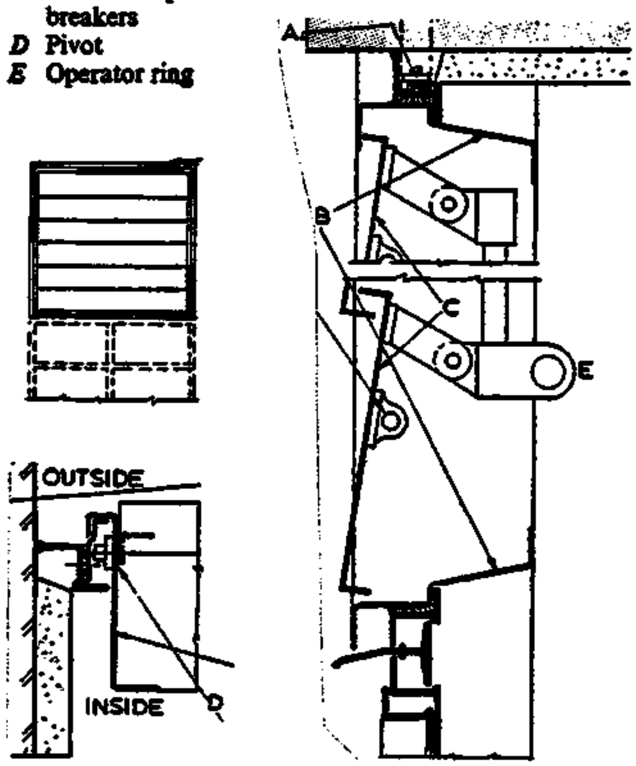
Aluminium fixed sun panels (also in pressed steel)
A Up to 4 ft (122 cm), dimensions as required
B Up to 14 ft (425 cm)



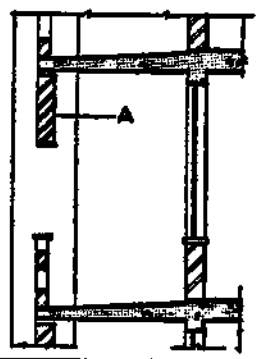
SUN-BREAKERS

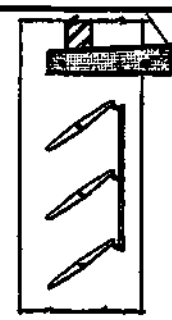
- Sun breakers can be
  either fixed or
  pivoted
  either horizontal or
  vertical
  If pivoted they can be
  either manually or
  mechanically
  operated.
- pivoted sunbreakers are very useful, as the area of sun surface can be considerably reduced. They can also exclude rain.
- For determining the angle and size of sunbreakers various charts and other aids are available (It is advisable to deal with methods of determining shadow angles in building openings in order to design sunbreakers, which are effective at all seasons and any hour of the day.
- Sunbreakers are obtainable in many styles and patterns.
- A common method consists of a V-shaped stringer shaped to take alu-strips. The stringers are produced at diff. angles to suit the required latitude. They are adoptable to a wide variety of uses (including cladding panelling, sun-louvres, canopies, roofs etc).
- Another design is that of pressed steel sunbreakers. A similar section will permit ventilation but is shaped to act as a gutter which prevents the entry of rain.
- A vertical sun panel can be made in a variety of heights, widths and thicknesses. This can be made in pressed steel, or aluminium and is designed to resist high wind. The angle of fixing is designed to give maximum sun protection.

Adaptors for metal sun-breakers
A Standard fixed metal casement
B Adaptor frame of pressed steel
C Ventilated pressed steel movable sun-breakers
D Pivot
E Operator ring



Section through a typical balcony
A Wood-louvred sun-breaker (height and angle of louvre as required)

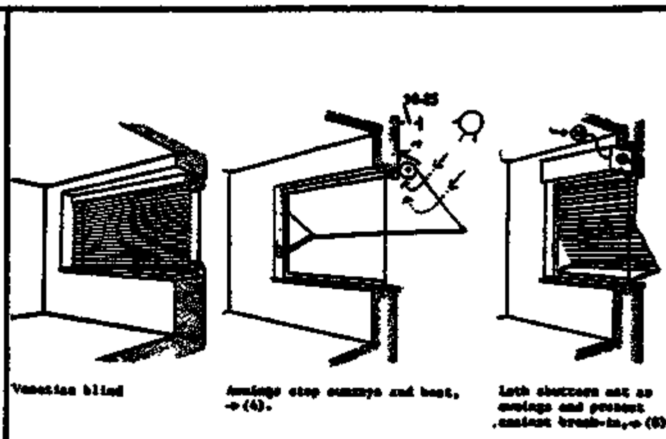


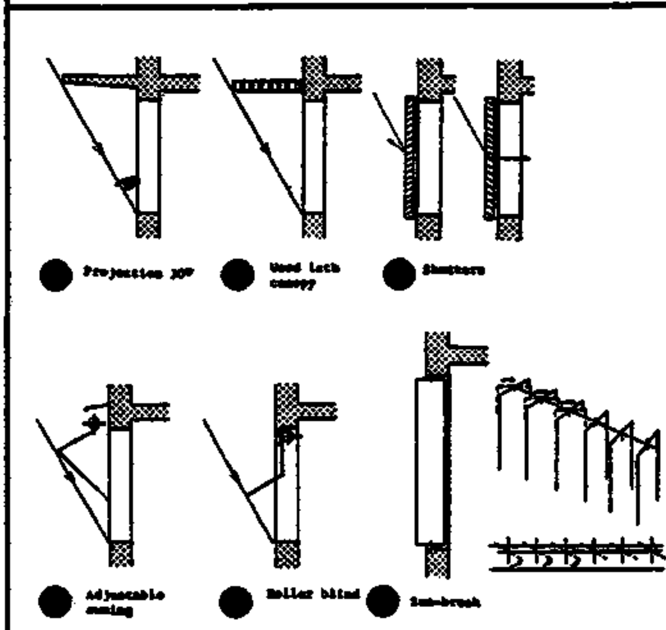


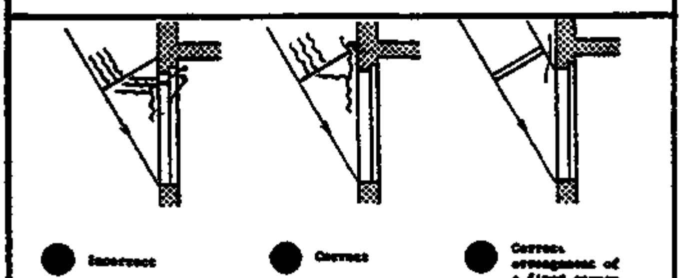
Pivoted aluminium sun-breakers

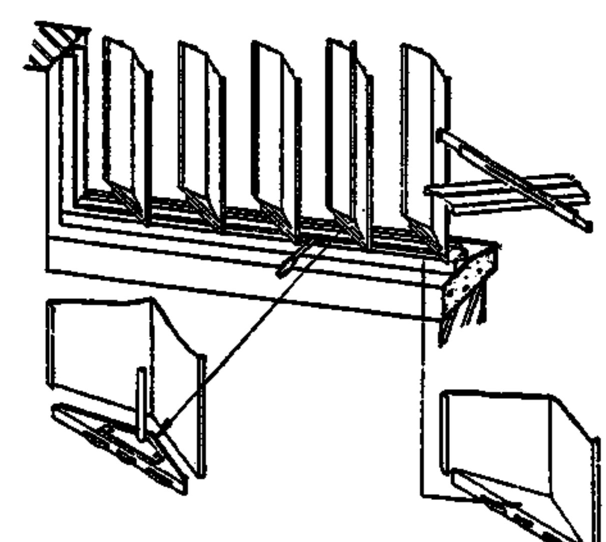
SUN-BREAKERS

- Rolling window shutters are frequently used in some countries.
  These consist of fine slates running vertically in guide channels which themselves can be pivoted to clear the window and let in light and air.
- Sund-blinds of the venetion type are extensively used where no other method is available or where permanent control is not warranted.
- An example showing plan + section of a pressed steel sun-breaker set in a frame, adapted to fit a standard metal window.
  A bank of 6 louvres is pivoted and linked to one operator.
- The normal type of wood louvre in a frame is supported by concrete sun 'fins' at approx. 3 m centres.
- Aerofoils may also be used, although they are more costly. They are insulated and can be pivoted to give maximum protection. They can be made to various dimensions and can be fixed either horizontally or vertically.
  When closed, they also give wind and rain protection.
- Vertical alu-sun-breakers.
  These are designed to fit standard blade carriers by using an adapter.
  In order to prevent twist between the top and bottom blade carriers, a torsion bar is required. This is fixed in the nearest carrier to the operator.









Vertical metal sun-breakers

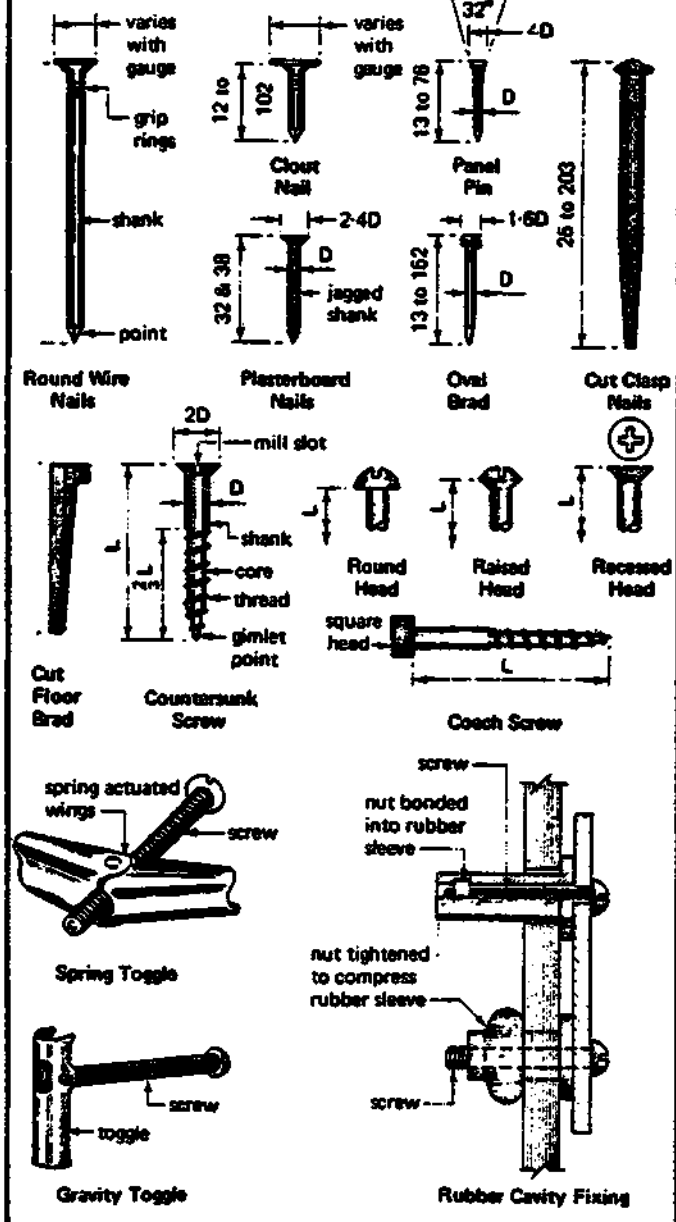
TCA TECHNICAL COLLEGE ARUSHA
CHUO CHA UFUNDI ARUSHA

CIVIL ENGINEER. DEPARTMENT

IRON MONGERY



Nails, screws and cavity fixings

14.3 Iron Mongery

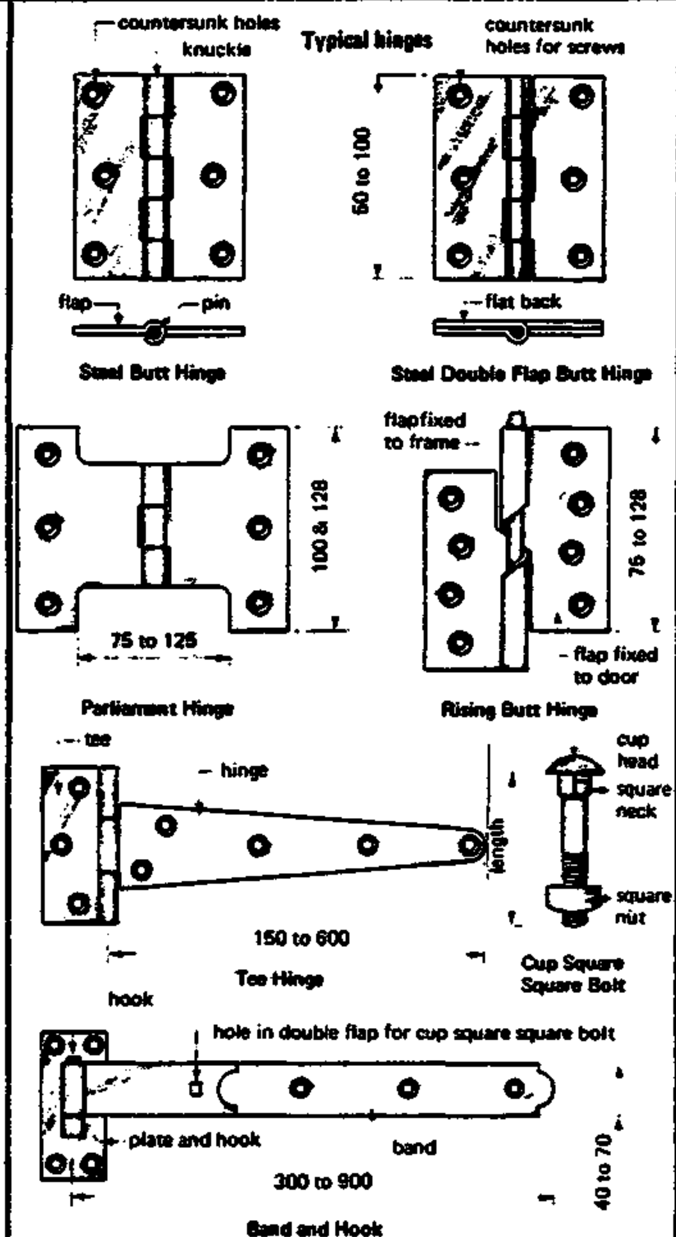
- Iron Mongery or HARDWARE covers a wide field, so that we have to concentrate on those items only which are in common use (in Tanzania) in the field of design and construction, such as:
  14.3.1 Hinges
  14.3.2 Locks and Latches
  14.3.3 Miscellaueous

HINGES

14.3.1 HINGES

are made for hanging doors, casements and ventlights. There are different types available.

- Most commenly used are the cheap <u>pressed steel butt hinges</u> They are made from steel strip which is cut and pressed around a PIN. The PIN is fixed inside the Kunckle.
- <u>Loose pressed steel but hinges</u> have the advantage that by taking out the loose pin the door can be taken off its hinges whereas with standard steel butts a door can only be taken off by unscrewing its hinges from the frame.
- <u>Double pressed steel butt hinges</u> are made of two strips of steel, each folded back on itself around the pin. They are stronger than ordinary steel butt hinges and are used for heavy doors.
- <u>cast iron butt hinges</u> are heavier and more expensive than steel butts of similar size and shape; but have longer useful live, as the bearing surface of the kunckles are more resistand to wear.
- <u>Brass butt hinges</u> are more expensive than steel or cast iron hinges, used mainly for decorative purposes.
- <u>Steel skew butt hinges</u> (rising butt) The bearing surfaces of the kunckles are cut on the skew, so that, as the hinge opens, one butt rises. These hinges are used for hanging doors and are fixed so that the flap screwed to the door rises as the hinge opens.
  <u>Purpose</u>:- To ride over carpets
  - self closing (fire cheded)
- <u>Steel tee hinges</u> consist of a rectangular steel flap and a long tail with knuckles around a pin.



The flap is fixed to the frame and the tail to the door. They are used mainly for matchboarded doors, as they assist in bracing the ledges against sinking.

- <u>Hook and band hinges</u> consist of a rectangular steel plate in which a pin is fixed and a steel band folded around the pin. They are made of heavier steel than tee hinges and are used for hanging heavy doors such as garage and workshop doors.

- Projecting steel windows
  Metal casements are often hung on projecting steel hinges.
  Reason: To make it possible to clean the glass in the casement on both sides from within the building.
- Casements are secured with a single pivoted cock spur type fastener and a peg stay is fixed to the frame and casement so that the casement can be kept open in windy weather.
- Ventlights are hung on ordinary steel hinges and are fitted with a peg stay similar to that used for casements.

HINGES

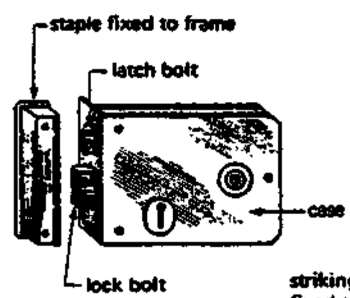
LOCKS and LATCHES

14.3.2 Locks and Latches

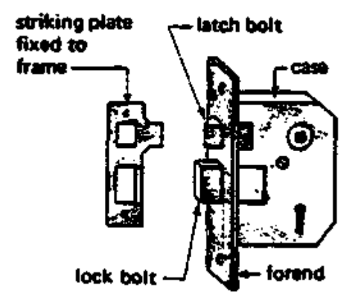
- Lock: any device of wood or metal attached to a door which can be used to keep it closed by the use of a loose key
- Latch: any device of wood or metal attached to a door to keep it closed and which can be opened by the movement of a handle lever or bar.

Mortice Lock
is the mechanism which is most used today. It comprises
a latch and
a bolt.
The former being operated by handles; the latter by means of a loose key.
Mortice locks:
Because they fit in a mortice cut in the door, so that the lock case is hidden.

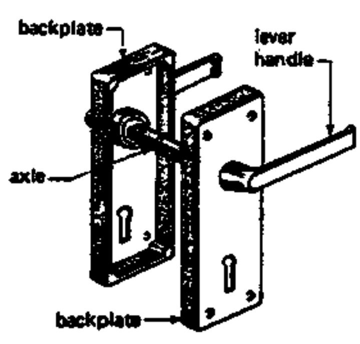
Rim Lock:
is screwed to one face of a door. They are not much in use today, as they spoil the appearance of the door. Sometimes they are used as an additional lock for safety purposes.



Rim Lock



Mortice Lock



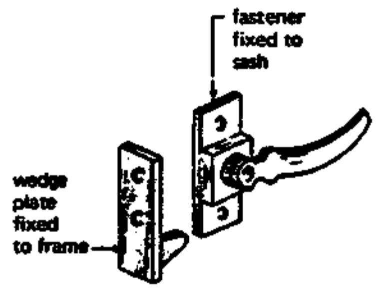
Lever Mortice Furniture

LOCKS and LATCHES

Cylinder night latch:
consists of a metal cylinder which is housed in a metal case which is fixed to the inside face of a door. The cylinder fits in a hole in the door. The latch can be opened by a knob from inside. The levers inside the cylinder are arranged in a way that only the key cut to fit a particular cylinder will open its latch. These latches are commonly used for front doors to houses and flats.

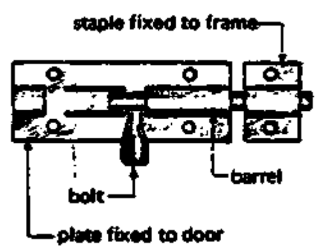
Mortice dead lock:
consists of a case inside which is a single bolt shich can only be operated by a loose key. These locks are fitted to a mortice in the door and the lock bolt shoots into a hole in a lock plate fixed to the door frame. These locks are used in addition to cylinder night latches or locks for entrance doors to houses and flats, because they are more difficult to force or prise open then cylinder night latches.

Cylinder Lock:
has a safety-mechanism which is separate from the lock mechanism. It can be fit in an ordinary mortice or rim lock in order to take over the function of an ordinary loose key.
The functioning of a cylinder lock depends on the principle, that while unlocking with the heavily profiled key, a number of pins (which are under spring-compression) is brought in the only one position, which allows a turn of the cylinder core, on which the lock bit is fixed.
The quality of the cyl.-lock depends on the number of pins (=number of grooves of the key bit). The min. No. should be 5 pins, in order to provide a safe lock.

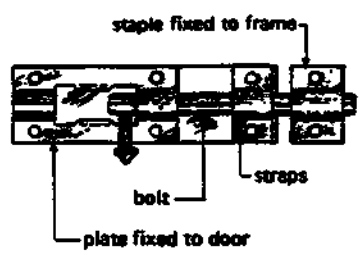


Casement Fastener

Casement Stay



Barrel Bolt



Tower Bolt

•REPETITION•• exercises ••REPETITION•

Try to answer the following questions and use sketches where-ever necessary and possible

14.1 Doors

What is the function of a DOOR?
Which materials may be used for construction?
Which methods may be used for construction?

Compare EXTERNAL DOORS and INTERNAL DOORS and describe the differences!

What are PURPOSE MADE DOORS and where are they mainly used for?

Define the following terms by using sketches for illustration.

- horn
- toprail
- glass panel
- glazing bars
- frieze rail
- solid panel
- lock o middle rail
- stile
- intermediate rail
- muntin
- bottom rail

Explain in the form of sketches the basic types of PANELLED and GLAZED WOOD DOORS.
What are dowelled joints and what are mortice and tenon joints?(use sketches for explanation!)

Explain in the form of sketches methods of construction of FLUSH DOORS.

What are FIRE-CHECK FLUSH DOORS?

Explain in the form of sketches methods of construction of MATCHBOARDED DOORS.

Sketch and explain the construction of TIMBER DOOR FRAMES as well as for METAL DOOR FRAMES and compare their advantages and disadvantages.

Sketch a typical DOOR LINING

14.2 WINDOWS, GLASS and GLAZING

What are the primary functions of WINDOWS?
Which materials may be used for construction?
Which methods may be used for construction?

Where do the regulations K1,K2,K3 and K4 deal with?
What are the basic requirements for ventilation openings?

Sketch an elevation and sections of a TRADITIONAL CASEMENT WINDOW and give brief explanations!

Sketch an elevation and sections of a STANDARD WOOD CASEMENT WINDOW and give brief explanations!

Sketch an elevation and sections of a STEEL CASEME NT WINDOW and give brief explanations!

Explain BAY WINDOWS and describe the main difference in details to casement windows (use sketches for illustration)

REPETITION exercises REPETITION

Write notes on SLIDING SASH WINDOWS and explain (by using sketches for illustration) VERTICAL and HORIZONTAL sliding windows.

What are PIVOT WINDOWS?

Write notes on LOUVRES, compare advantages and disadvantages and use sketches for illustration.

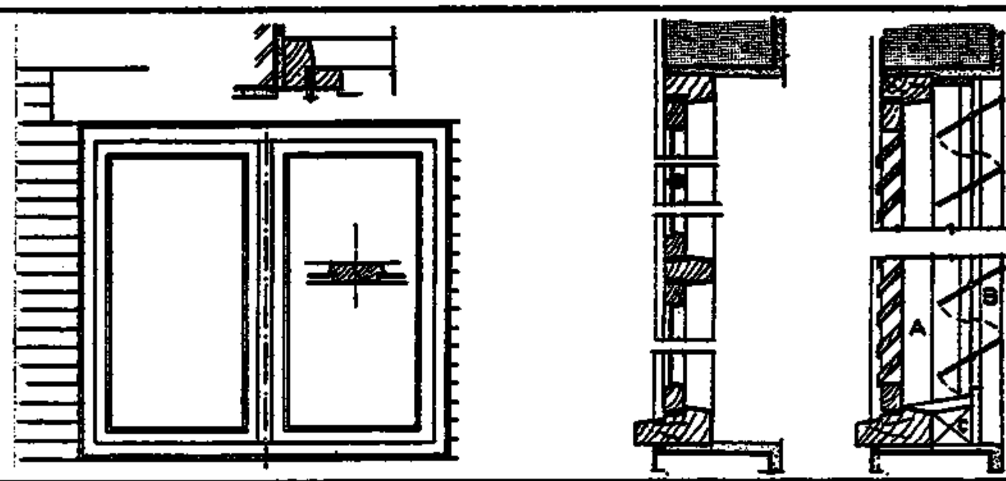
Which methods of producing
- DRAWN CLEAR SHEET GLASS
- FLOAT GLASS
- ROLLED and ROUGH CAST GLASS

do You know?

There are two main ways of GLAZING. Describe both and compare their advantages and disadvantages (use sketches for illustration)

Write notes on MOSQUITO SCREENING

List different SUN-BREAKER systems!
Classify the different types of SUN-BREAKERS and give brief explanations about their construction. (Use sketches for illustration whereever possible!)



14.3 IRON MONGERY

Define the following terms and use sketches for illustration:

- pressed steel butt hinges
- loose pressed steel butt hinges
- double pressed steel butt hinges
- cast iron butt hinges
- brass but hinges
- steel skew butt hinges
- steel tee hinges
- hook and band hinges
- projecting steel windows
- mortice lock
- rim lock
- cylinder night latch
- martice dead lock
- cylinder lock

SMALL ENGINE

1. Fuel system
2. Ignition system
3. Speed control system
4. Valve mechanism
5. Crancshaft mechanism
6. Lubrication system
7. Cooling system
8. Starting system
9. Exaust system

What this Instruction Material wants:	What this Instruction Material does not want:
- to be easy understadable	- to replace a book
- to be job related	- to substitute the teacher
- to support the teacher in his work	- to teach unnecessary subject matter
- to create student activity	

Help to teach and learn efficiently

- o This instructional material is developed by the Thai-German Teaching Aid Centre in cooperation with the Technical College Nongkhai.

- o The student should have preknowledge about the principle of 4-stroke internal combustion engine.

- o The Information, specially about maintenance and repair is based mainly on the Honda engines G 150 - G 200 and GX 120 - GX 160.

- o The teaching method, which should be used, is the "questioning technique". Please do not only lecture!

<u>The Instructional Material Package (IMP) contents the following elements:</u>

1. List of objectives
2. Information sheets
3. Task sheets
4. Job sheets
5. Teaching aids (Transparencies, models, e.g.)
6. Solutions

1. A list of objectives shows the teacher what the student should know after the lesson.

2. Information sheets show pictures with short explanations of the subject matter. These information sheets should be given to the student after the lesson as a summary. Information about repair and maintenance should be given briefly before starting the work prescribed in the Job sheets.

3. Task sheets help the teacher to check the learning progress. They should be used at the end of one period. It is necessary to discuss the solutions with the studends. Please do not use them as a test.

4. The Job sheets are showing the student the right sequence of working steps.
   The Information sheets about maintenance and repair can be used like a manual during work.

5. Teaching aids make the subject matter better understandable and motivate the students.

6. Solutions for the task sheets

Content

The student should be able to ...

Fuel system

1.1 Components of fuel system

1. Name various components and their functions of fuel system
2. Describe about fuel delivery from fuel tank to carburetter

1.2 Fuel tank

3. Tell components of fuel tank
4. Tell function of fuel tank

1.3 Fuel filter

5. Tell components of fuel filter
6. Tell functions of fuel filter

1.4 Air filter

7. Tell various types of air filter
8. Tell features and characteristics of the wet-type air filter
9. Explain principle of the wet-type air filter
10. Tell advantages and disadvantages of the wet-type air filter
11. Tell features and characteristics of the dry-type air filter
12. Explain principle of the dry-type air filter
13. Tell advantages and disadvantages of the dry-type air filter

1.5 Carburetter

14. Explain principle of carburetter
15. Tell various types of carburetter
16. Tell internal construction of the side draft carburetter
17. Tell functions and components of the floating circuit
18. Explain principle of the floating circuit
19. Tell functions and components of the idle circuit
20. Explain principle of idle circuit
21. Tell functions and components of full throttle circuit
22. Explain principle of full throttle circuit
23. Tell functions and components of choke unit
24. Explain principle of choke unit

1.6 Repair and maintenance

25. Inspect any leakage of the fuel tube
26. Clean fuel tank correctly
27. Clean air filter correctly
28. Dismantle and reassemble carburetter correctly
29. Inspect components of carburetter for wear
30. Set the float correctly
31. Adjust the idle mixture correctly
32. Adjust the idle speed correctly

2. Ignition system

2.1 Basic principle

1. Explain basic principle of ignition system used in small engines.
2. Tell various types of ignition system used in small engines

2.2 Contact breaker ignition system

3. Tell name and function of various parts of the contact breaker ignition system.
4. Explain principle of the contact breaker ignition system.

2.3 Capacitor discharge ignition system (CDI)

5. Tell name and function of various parts of the CDI system
6. Explain principle of the CDI system.
7. Tell advantages and disadvantages of the CDI system

2.4 Transistor ignition system

8. Tell name and function of various parts of the transistor ignition system.
9. Explain principle of transistor ignition system.
10. Tell advantages and disadvantages of the transistor ignition system.

2.5 Repair and maintenance

11. Remove and reassemble various parts of ignition system.
12. Check conditions of spark plug.
13. Clean and set electrode gap of spark plug correctly.
14. Check ignition coil correctly.
15. Check CDI and transistor ignition module correctly.
16. Check condenser correctly.
17. Set contacting point gap correctly.
18. Adjust ignition timing correctly.
19. Adjust clearance between ignition coil and magnetic fly-wheel correctly.

3. Speed control system

3.1 Governor

1. Tell the task of a gpverner

3.2 Types and function of governers

2. Tell various types of speed control systems.
3. Explain principle of pneumatic governor.
4. Explain principle of mechanical governor.

3.3 Repair and maintenace

5. Remove/refitting pneumatical and mechanical governer
6. Adjust pneumatical and mechanical governer

4. Valve mechanism

4.1 Functions of valve mechanism

1. Tell functions of valve mechanism.

4.2 Types and principle of valve mechanism

2. Tell various arrangements of valve.
3. Explain principle of overhead valve engine.
4. Tell advantages and disadvantages of the overhead valve engine.
5. Explain principle of side valve engine.
6. Tell advantages and disadvantages of side valve engine.

4.3 Compression-reduction mechanism

7. Tell purpose of compression-reduction mechanism
8. Tell various parts of compression-reduction mechanism.
9. Tell function of various parts of compression-reduction mechanism.
10. Explain principle of compression-reduction mechanism.

4.4 Repair and maintenance

11. Remove-reassemble cylinder head.
12. Remove-reassemble valves.
13. Measure length of valve spring.
14. Check squareness of valve spring.
15. Check strength of valve spring.
16. Measure diameter of valve stem.
17. Check straightness of valve stem.
18. Check valve face, margin and valve stem.
19. Measure width of valve seat.
20. Use valve seat cutter correctly.
21. Grind valve correctly.
22. Measure bore of the valve guide.
23. Remove and refit valve guide.
24. Adjust valve clearance correctly.

5. Crankshaft mechanism

5.1 Components and functions

1. Tell various parts of crankshaft mechanism
2. Tell various types of piston rings.
3. Tell functions of piston rings.
4. Tell functions and components of piston, connecting rod and crankshaft.

5.2 Repair and maintenance

5. Test compression, and tell their specification.
6. Remove and reassemble crancshaft mechanism.
7. Inspect piston, crankshaft and cylinder.
8. Inspect thickness and clearances of piston rings.
9. Arrange piston ring ends.
10. Measure sizes of gudgeon pin, hole and small-end connecting rod.

6. Lubrication system

6.1 Tasks of the lubrication system

1. Tell the Tasks of the lubrication system
2. Tell various parts that need lubrication.

6.2 Splash-type lubrication

3. Tell various parts of the splash-type lubrication.
4. Explain principle of the splash-type lubrication.
5. Tell advantages and disadvantages of the splash-type lubrication.

6.4 Repair and maintenance

6. Check and change oil.

7. Cooling system

1. Tell tasks of the cooling system.
2. Explain principle of air cooling system.
3. Tell components of air cooling system

7.1 Repair and maintenance

4. To remove-reassemble various components of cooling system.
5. To clean blower blade and its cover.

8. Starting system

8.1 Types of starting system

1. Tell types of starting systems.

8.2 Components of starting system

2. Tell components of starting unit.
3. Tell functions of components of starting unit.

8.3 Repair and maintenance

4. To remove/reassemble components of the starting unit.
5. To repair the starting unit.

9. Exhaust system

9.1 Purpose of exhaust system

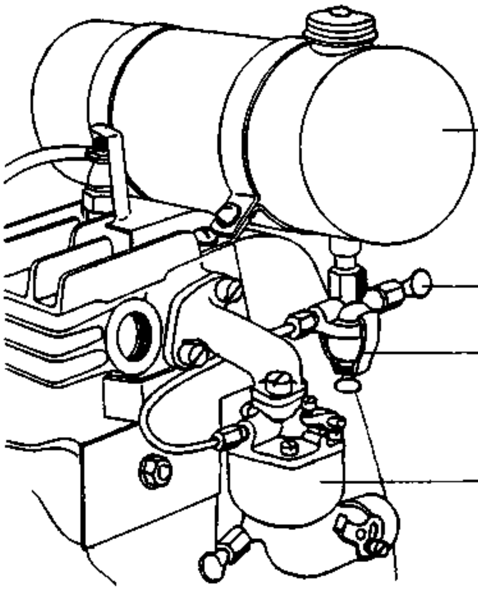
1. Tell purposes of the exhaust system.

9.2 Components of exhaust system

2. Tell components of theexhaust system.
3. Tell functions of the components of the exhaust system.

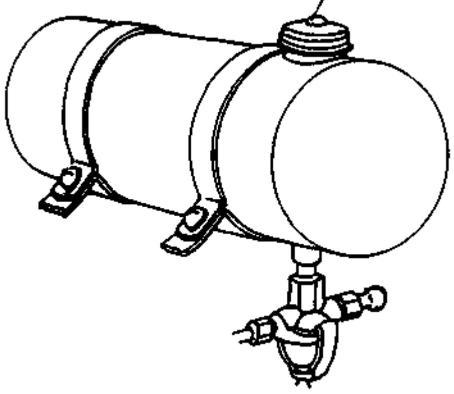
1 Fuel system

1.1 Components of fuel system



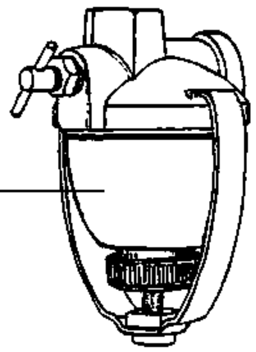
Fuel is delivered from the fuel tank into the carburetter by means of its gravity

1.2 Fuel tank



Vent : When fuel level decreases, air can enter into the fuel tank via the vent and fills up the decreased space of fuel.

1.3 Fuel filter



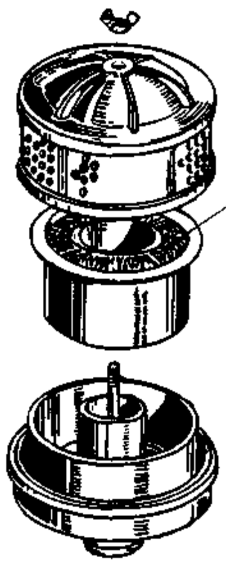
Fuel filter will trap impurities as contained in the fuel before the fuel is delivered into the carburetter.

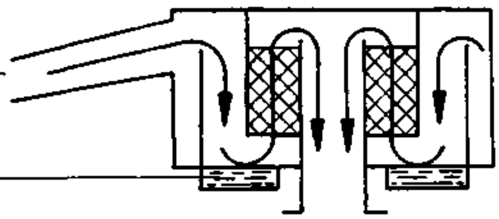
1.4 Air filter

If unfiltered air is entering the combustion cambre, then both, cylinder and piston will be worn rapidly.

1.4.1 Oil bath- or wet-type

Oil will trap dust in the air.



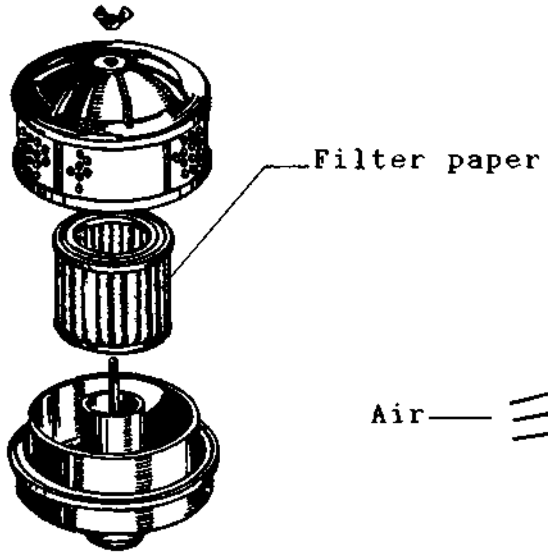


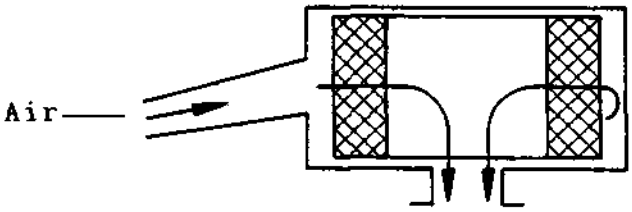
Filtered air to carburetter

Advantage : Filter screen can be washed by benzene

Disadvantage : dirty

1.4.2 Paper element type or dry type





Filtered air to carburetter

Advantage : Easy to use and maintain, most use nowaday

Disadvantage : If the filter gets too dirty, it most be replaced.

1.1 to 1.4 Tank and Filters

Cross the correct statements!

.... 1. Fuel from the fuel tank enters into the carburetter by means of its gravity.

.... 2. In small engines, the fuel tank is mounted below the carburetter.

.... 3. If the fuel tank vent is clogged, then the fuel cannot enter into the carburetter.

.... 4. Fuel filter can trap water as contained in the fuel.

... 5. Engine without fuel filter will shorten life of its piston and piston rings.

.... 6. Air filter can be classified, according to usage, into 2 types: wet and dry.

.... 7. Wet type air filter uses oil to trap dust from intake air.

.... 8. Clogged air filter will cause high fuel consumption.

.... 9. Wet type air filter can be cleaned by benzene.

.... 10. Nowaday, small engines employ the dry type air filter.

1.1 to 1.4 Tank and Filters

Cross the correct statements!

.X. 1. Fuel from the fuel tank enters into the carburetter by means of its gravity.

.... 2. In small engines, the fuel tank is mounted below the carburetter.

.X. 3. If the fuel tank vent is clogged, then the fuel cannot enter into the carburetter.

.... 4. Fuel filter can trap water as contained in the fuel.

... 5. Engine without fuel filter will shorten life of its piston and piston rings.

.X. 6. Air filter can be classified, according to usage, into 2 types: wet and dry.

.X. 7. Wet type air filter uses oil to trap dust from intake air.

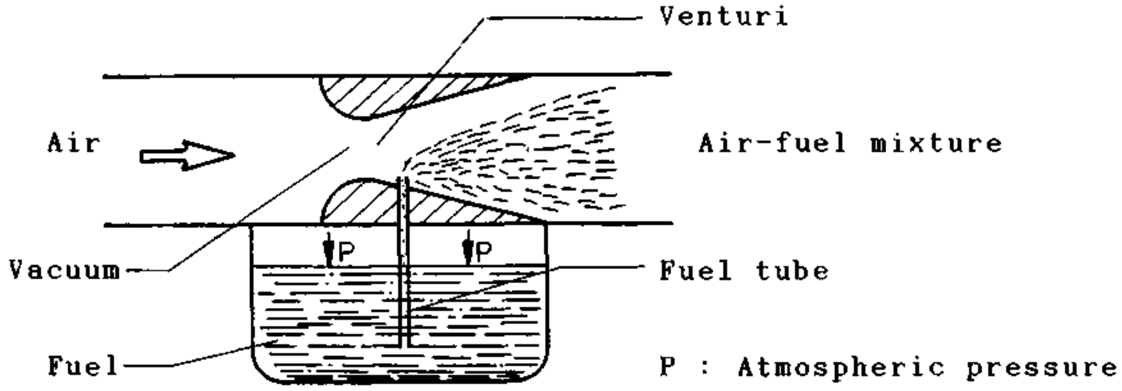
.X. 8. Clogged air filter will cause high fuel consumption.

.X. 9. Wet type air filter can be cleaned by benzene.

.X. 10. Nowaday, small engines employ the dry type air filter.

1.5 Carburetter

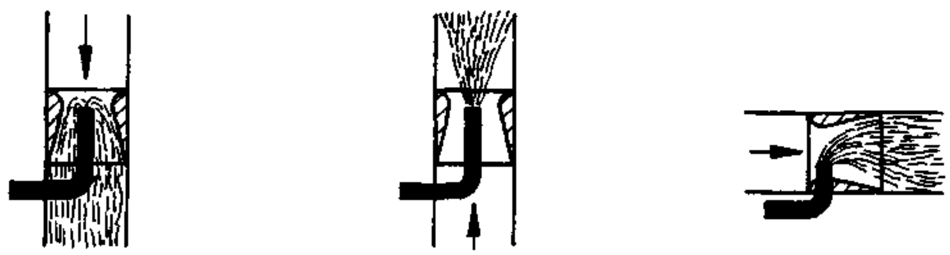
1.5.1 Principle of carburetter



As air rushes through the venturi, it will develop partial vacuum in that area. At the same time, atmospheric pressure will push fuel up by the fuel tube to mix with the rushing air.

1.5.2 Types of carburetter

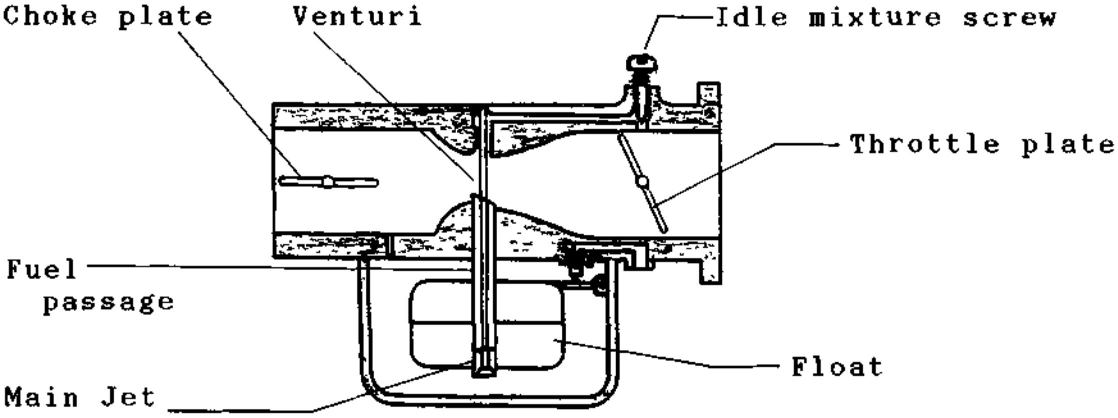
They can be classified into three types according to suction methods:



a) Down draft b) Up draft c) Side draft

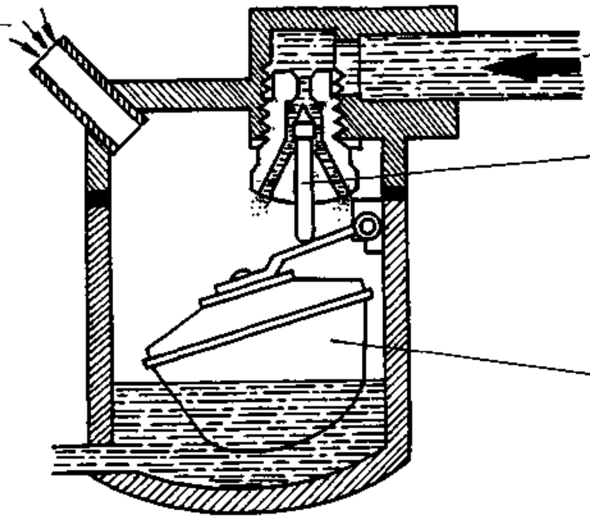
Remark: Most small engines use the side draft carburetters, and next the up draft ones.

1.5.3 Side draft carburetter

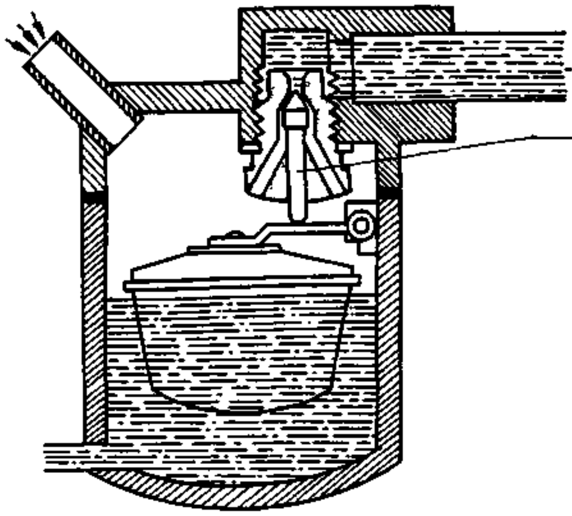


1.5.4 Floating circuit

Floating circuit is to control the amount of fuel entering the float chamber and maintain the fuel level in it.

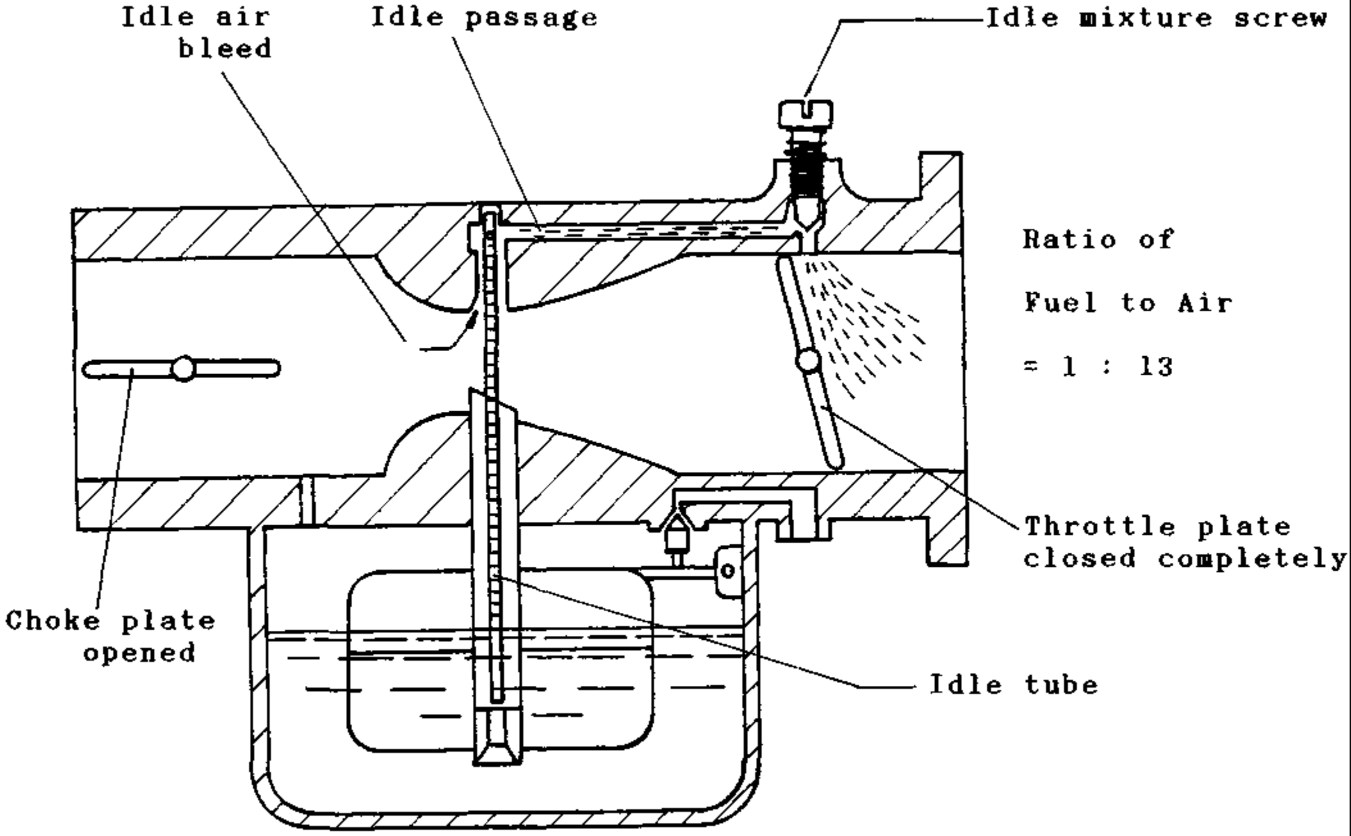


As the engine is running, a certain amount of fuel is used up causing the fuel level to decrease and thereby lowering the float which activates the needle value to allow additional fuel to enter into the float chamber.



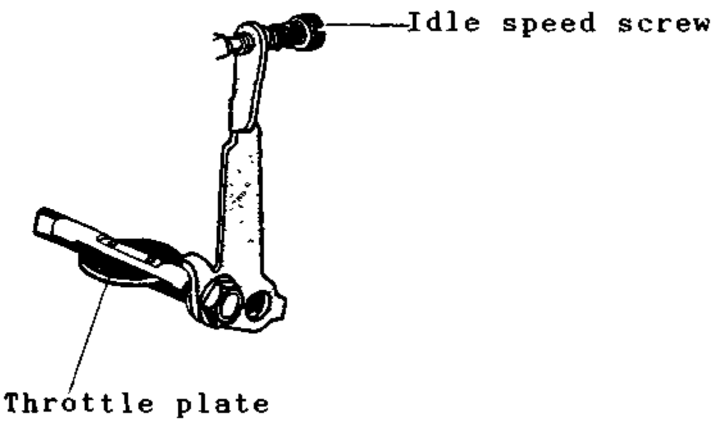
As additional fuel is entering into the float chamber, the float rises until a certain level the needle value closes and fuel flow ceases. In this circumstance, the fuel level is maintained constantly.

1.5.5 Idle circuit



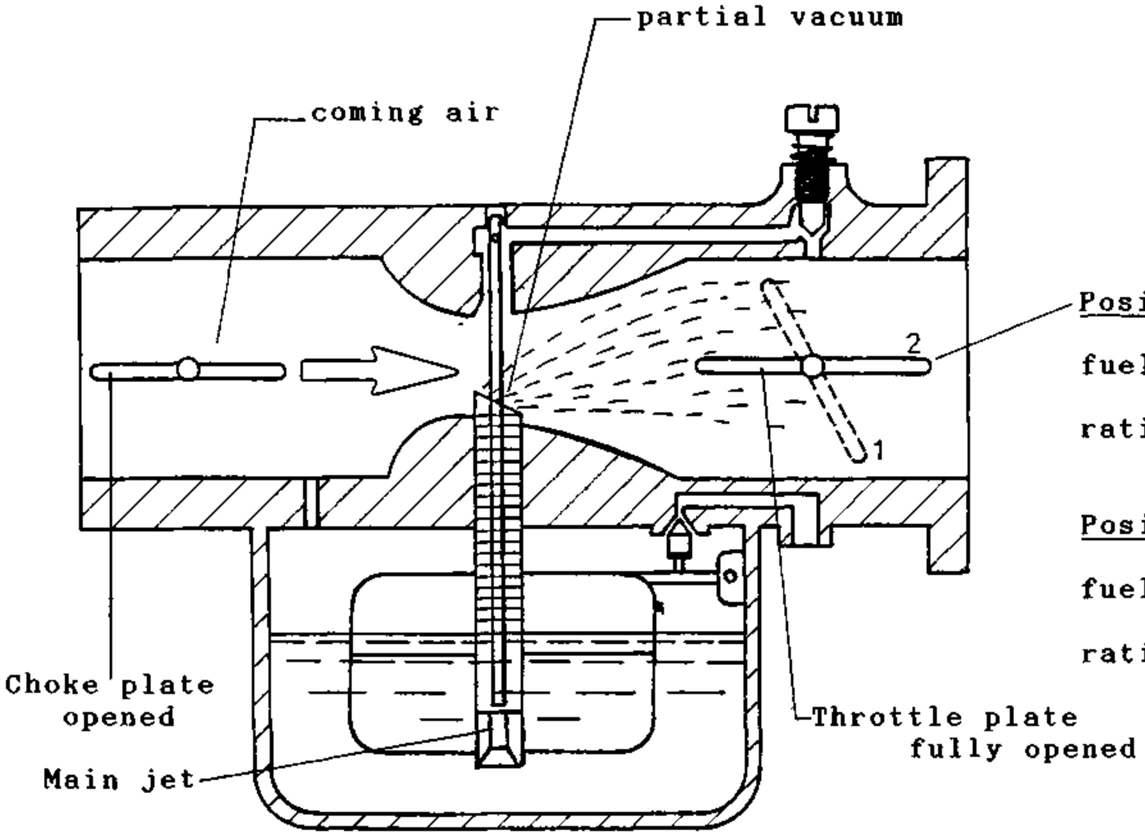
When the throttle plate closes completely, air is sucked via the idle air bleed and thereby sucks fuel from the float blow to mix with it in the idle passage and comes out by the idle port.

Ratio of fuel to air can be adjusted by means of the idle mixture screw. Whereas the idle speed is adjusted by the idle speed screw.



1.5.6 Full throttle circuit

Full throttle circuit is for distributing sufficient amount of air-fuel mixture to the required increasing engine speed.



Position 2: fuel to air ratio 1 : 13

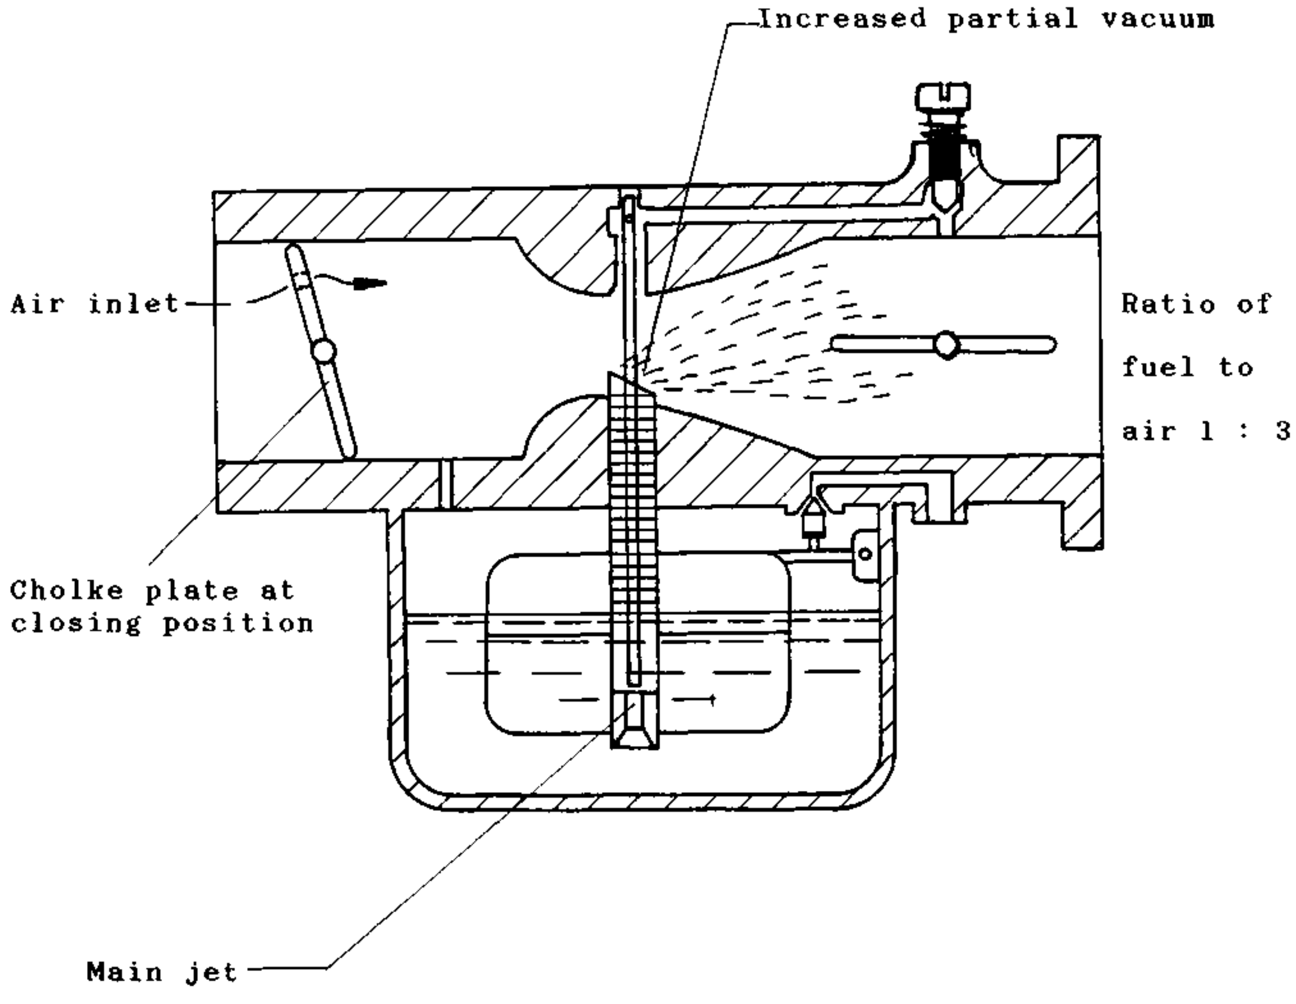
Position 1: fuel to air ratio 1 : 15

Pos. 1 : When the throttle plate opens, air rushes over the venturi increasing the partial vacuum in that aerea and thereby sucks fuel via the main jet - Engine speed is thus increasing.

Pos. 2 : When the throttle plate opens fully, more air rushes over the venturi, thus higher partial vacuum is developed. The fuel is sucked more than in the previous position, thus the engine is running at maximum speed.

1.5.7 Choke Circuit

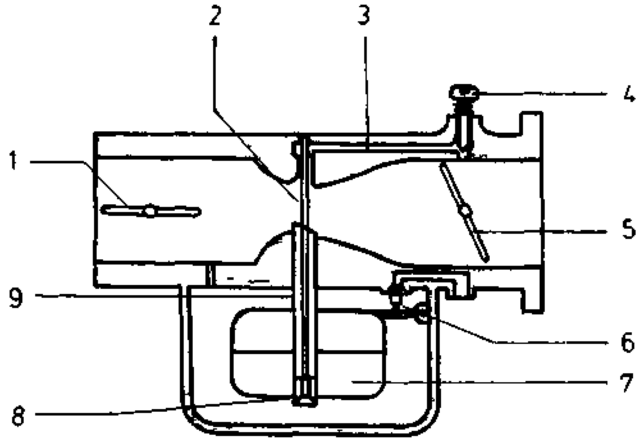
Choke circuit provides richer fuel mixture than normal especially, during the start of the engine.



When the engine is started, its speed is still low. A small amount of air flows through the venturi and suck very limited amount of fuel. Increasing fuel is needed in this case by closing the choke plate which in turn increasing the partial vacuum over the venturi.

1.5 Caburetter (I)

1. Name the parts of the carburetter!



1. ______________________
2. ______________________
3. ______________________
4. ______________________
5. ______________________
6. ______________________
7. ______________________
8. ______________________
9. ______________________

2. As air is flowing through the venturi, the pressure at the venturi is -higher/lower- than the atmopheric pressure.

3. The pressure over the float chamber is -higher/lower- than the pressure at the main jet when air is flowing through the venturi.

4. Carburetters used in small engines can be classified, according to types of drafts, into __ types; i.e. ____________________.

5. The most used carburetter for small engines is _____________.

6. The float circuit is for ________________________________.

7. If the fuel level in the float chamber is dropped, the needle valve will -close/open-.

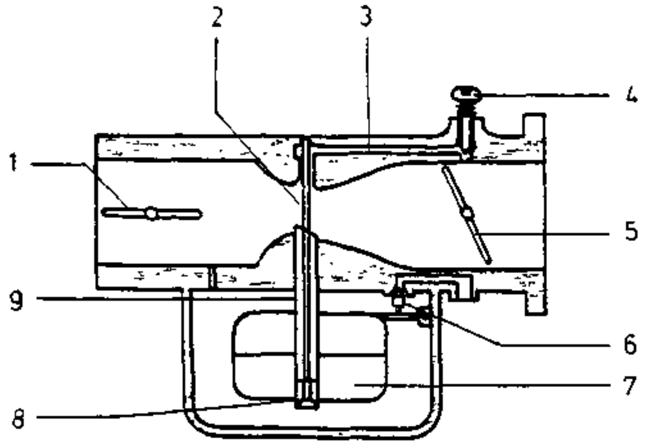
8. The fuel to air ratio of the idle circuit is about ___ : ___.

9. While the engine is idling, the throttle plate will be at -fully closing/fully opening- position.

10. The fuel to air ratio of the idle circuit can be adjusted by ____________________.

1.5 Caburetter (I)

1. Name the parts of the carburetter!



1. Choke plate
2. Venturi
3. Idle passage
4. Idle mixture screw
5. Throttle plate
6. Needle valve
7. Float
8. Main jet
9. Fuel passage

2. As air is flowing through the venturi, the pressure at the venturi is -~~higher~~/lower- than the atmopheric pressure.

3. The pressure over the float chamber is -higher/~~lower~~- than the pressure at the main jet when air is flowing through the venturi.

4. Carburetters used in small engines can be classified, according to types of drafts, into 3 types; i.e. down, up, side.

5. The most used carburetter for small engines is side draft.

6. The float circuit is for control the amount of fuel in the carboretter.

7. If the fuel level in the float chamber is dropped, the needle valve will -~~close~~/open-.

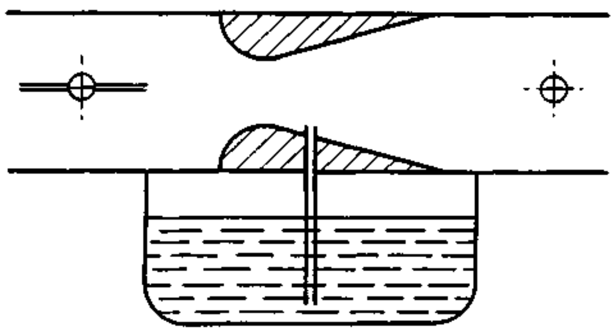
8. The fuel to air ratio of the idle circuit is about 1 : 13.

9. While the engine is idling, the throttle plate will be at -fully closing/~~fully opening~~- position.

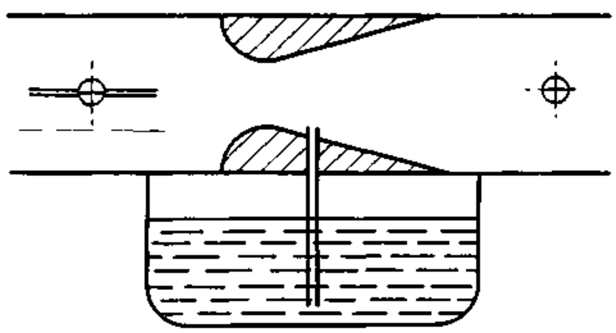
10. The fuel to air ratio of the idle circuit can be adjusted by the idle mixture screw.

1.5 Carburetter (II)

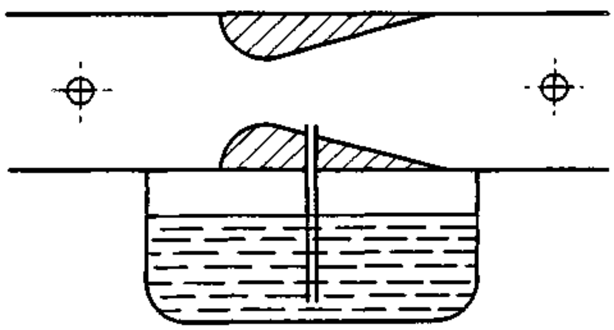
Picture 1: If little fuel is needed by the cylinder, (idle run) what will be the position of the throttle plate? (make a sketch!)



Picture 2: If more fuel is required by the cylinder, what will be the position of the throttle plate ? (make a sketch!)

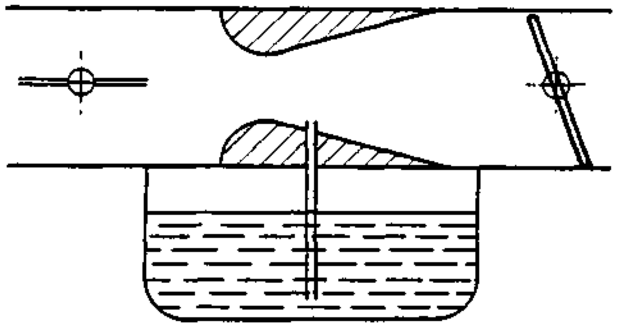


Picture 3: If maximum fuel is needed by the cylinder, what will be the positions of both, the choke plate and the throttle plate ? (make a sketch!)

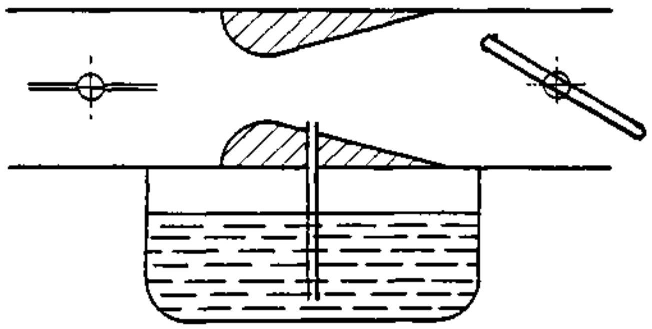


1.5 Carburetter (II)

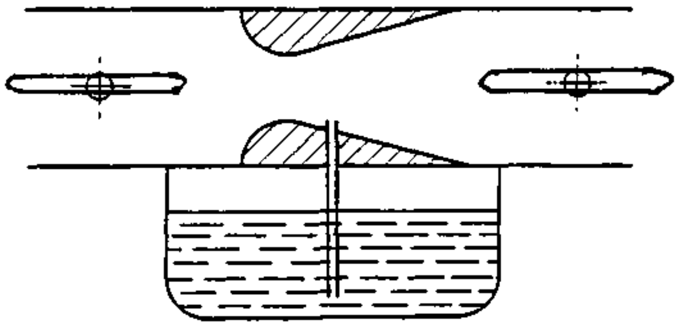
Picture 1: If little fuel is needed by the cylinder, (idle run) what will be the position of the throttle plate? (make a sketch!)



Picture 2: If more fuel is required by the cylinder, what will be the position of the throttle plate ? (make a sketch!)



Picture 3: If maximum fuel is needed by the cylinder, what will be the positions of both, the choke plate and the throttle plate ? (make a sketch!)



1.5 Carburetter (III)

Answer the following questions correctly!

1. In float setting, what will happen if the float is not set to the specified value ?

   1.1 In case the float is too low : ____________________________

   ____

   ____.

   1.2 In case the float is too high ____________________________

   ____

   ____.

2. What will happen if the idle mixture screw is not adjusted to the specified value?

   2.1 In case it is higher than the given standard : ___________

   ____.

   2.2 In case it is lower than the given standard : ____________

   ____.

3. How can the size of the main jet effect the fuel consumption rate ?

   ____

   ____

   ____.

4. What will happen if the needle valve is worn ?

   ____

   ____

   ____.

1.5 Carburetter (III)

Answer the following questions correctly!

1. In float setting, what will happen if the float is not set to the specified value ?

   1.1 In case the float is too low : Fuel is overflowing

   1.2 In case the float is too high : Insufficient fuel

2. What will happen if the idle mixture screw is not adjusted to the specified value?

   2.1 In case it is higher than the given standard : idle speed is to high.

   2.2 In case it is lower than the given standard : idle speed is to low.

3. How can the size of the main jet effect the fuel consumption rate ?

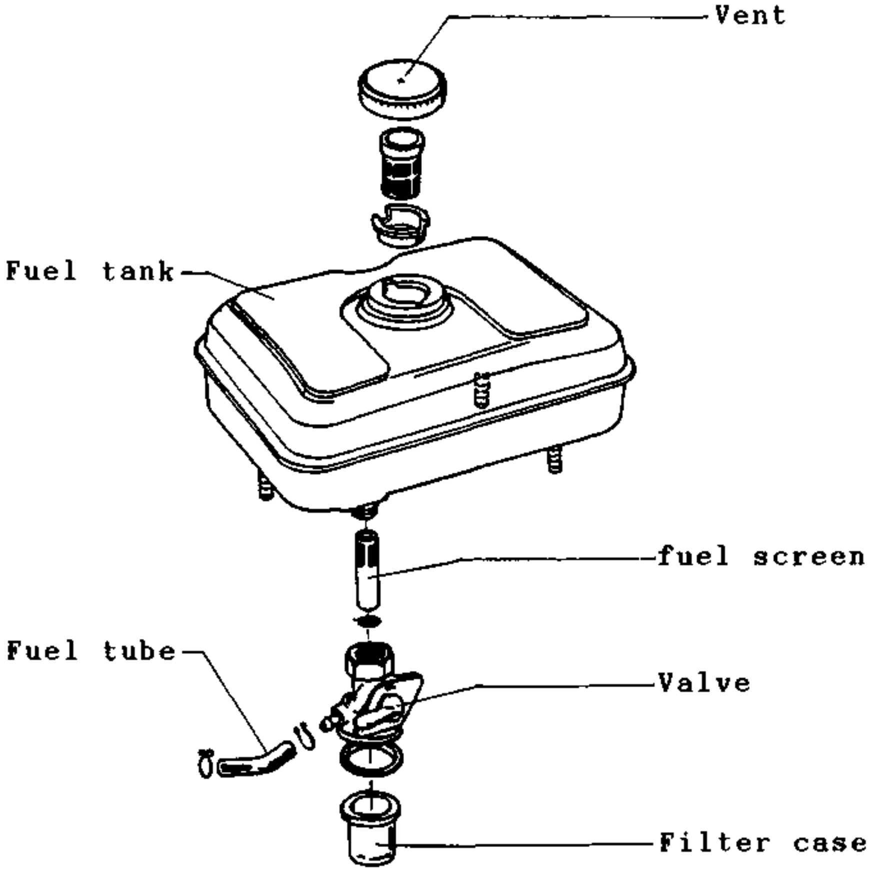
   Big bore → high fuel consumption
   Small bore → low fuel consumption

4. What will happen if the needle valve is worn ?

   The carborctter will leak

1.6 Repair and maintenance

1.6.1 Servicing fuel tank



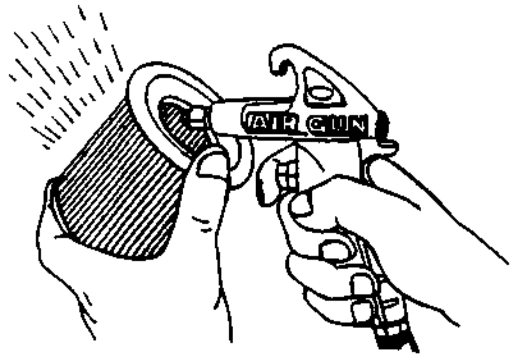
Caution : Fuel must be drained out completely prior removing the fuel tank.

Components	Services
1. Fuel cap	-Inspect the vent, it must be clean and clear. Use air gun to clean it.
2. Fuel tank	-Inspect for any puncture of the fuel tank. Clean inside of the tank.
3. Fuel screen	-Inspect for any blockage or wreckage.
4. Valve	-Clean it.
5. Fuel tube	-Inspect conditions like cracks.
6. Filter cae	Clean the filter case in benzene.

Caution : Be sure that no fuel leakage after reassemble.

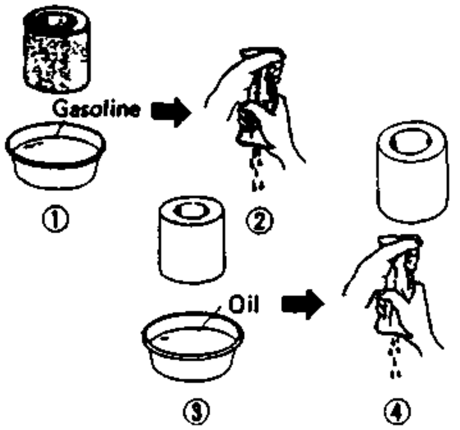
1.6.2 Servicing dry-type air filter

- Filter paper type



- Tap the filter rim gently or brush the paper.
- Blow out dirt from inside the filter with an air gun.

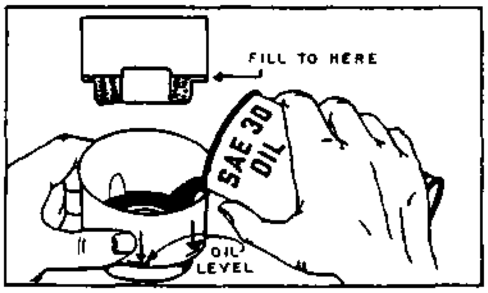
- Filter sponge



- Clean the filter sponge in benzene, squeeze out dirt.
- Dry the filter sponge by squeezing and waving it.
- Dip the filter sponge into the pan of oil and benzene mixture of 1 to 10 ratio.
- Squeeze the sponge until wet dry.

Precaution : Do not twist the filter sponge, otherwise it will be torn off. Replace the damaged or ruin sponge.

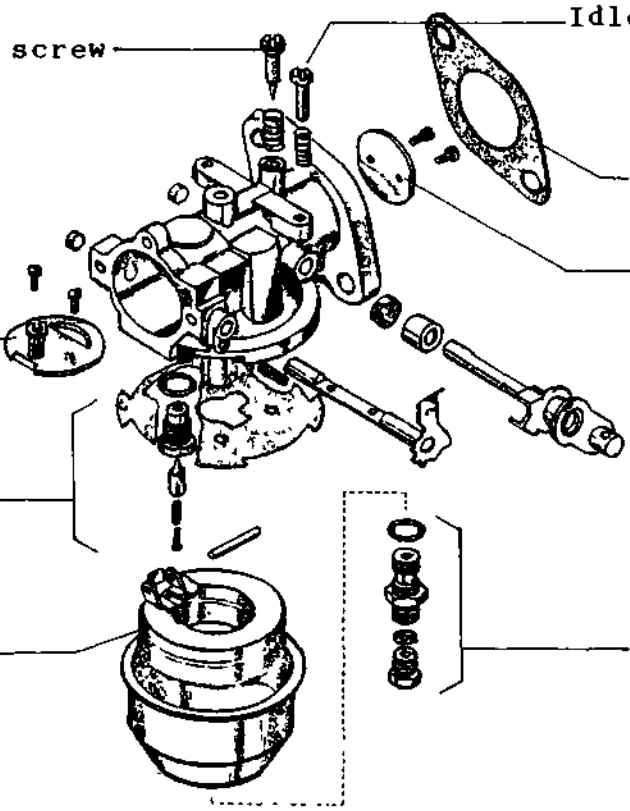
1.6.3 Servicing wet-type filter



- Remove the filter and stir it in a fuel pan.
- Clean the filter inside and outside.
- Refil the oil upto the marked level.

Precaution : Use the correct oil and refil according to the manufacturer's manual.

1.6.4 Dismantling Reassembling carburetter

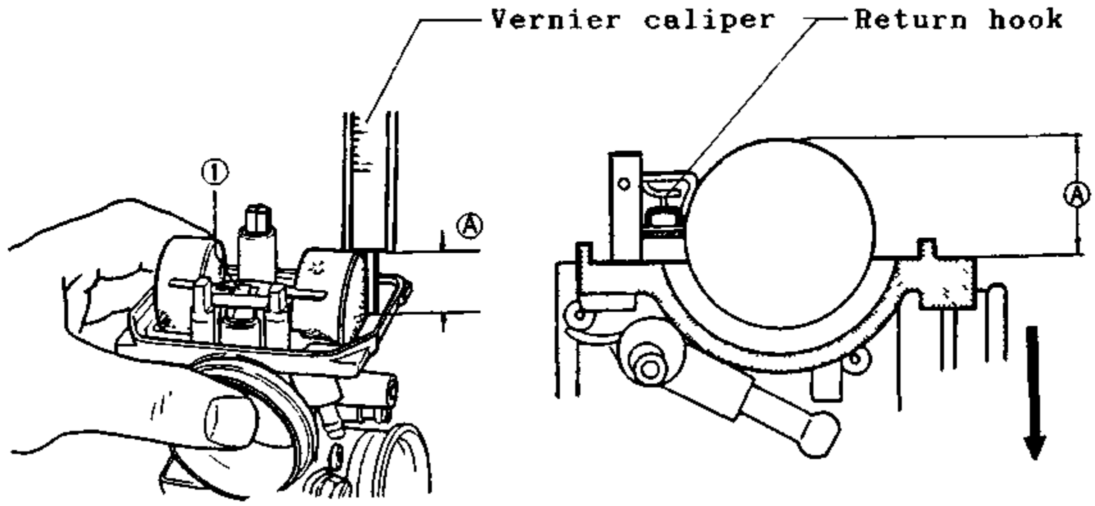


Components	Services
1. Float chamber	- Clean and blow with air gun
2. Float	
3. Main jet	- Blow with air gun
4. Needle	- Inspect for wear
5. Idle mixture screw	- Inspect for wear or damage on cone and thread
6. Carburetter body	- Clean and blow with air gun.

Remarks: - In removing the carburetter assembly, unscrew and remove the float chamber, and drain out fuel residual.

- Before Inspection, clean all parts with benzene and brush, and blow until dry with air gun.

1.6.5 Float Setting



Measuring and setting:

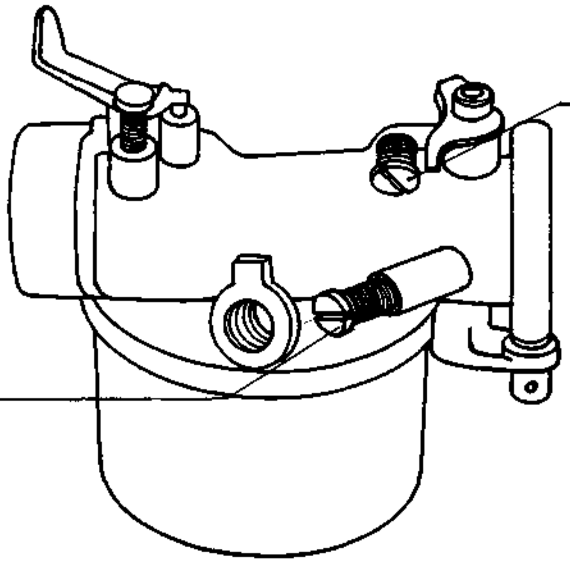
With the float cover placed horizontally, lift the float slowly with a finger (until the return hook is just lifting the float). Measure the height of the float at this position and compare the obtained value with that given in the manual.

If the obtained value is outside the manual value, then resetting is needed.

Example:

Standard value for height of float:	HONDA	G 150	8.2 mm
		G 200	8.0 mm
		GX 120	13.7 mm
		GX 160	13 mm

1.6.6 Idle mixture adjustment



Screw in the idle mixture screw completely and then unscrew it for the specified number of turns as given in the manual.

The specified number of turns of idle mixture screw:	HONDA	G 150	1 3/8 Turns
		G 200	3 1/4 Turns
		G x 120	2 5/8 Turns
		G x 160	2 1/8 Turns

<u>Remark</u>: If the specified number of turns is not known, then assumes for 1 1/2 to 2 turns or observe for the smoothest idling of the engine.

1.6.7 Idle speed setting

- Start the engine and allow it to idle.
- Adjust the idle speed screw inward or outward until the specified number of revolutions is obtained.

Standard idling speed	1,400 rev/min

1.6.8 Fault diagnosis oif engine as due to carburetter failure.

Symptom	Causes	Remedy
1. Wet spark plug	- Fuel flooded - Worn float needle or dirty	- adjust float level - Clean, replace
2. Idle speed too high	- Incorrect idle speed - Clogged idle circuit - Clogged fuel tube of idle circuit	- Readjust idle mixture screw - Clean, blow with air gun
3. Poor acceleration	- Clogged fast idle main jet - Fuel level is too low in the float chamber - Choke unit sticking	- Clean, blow with air gun - Readjust the float level - Dismantle, clean
4. Engine will not start	- Float sticking, no fuelentering - Choke unit sticking - Fuel flooded	- Clean - Dismantle, clean - Readjust the float level

1.2 to 1.4 Tank and Filters (I)

Tools: A set of wrenches, air gun with hose

Equipement: Benzen, Oil, Soft brush, cleaning pan, cloth

Manufacturer .... Model ....

Type of air cleaner ....

Sequence of operations	Inspection
1. Prepare tools and equipment	
2. Close fuel valve and disconnect hoses.	- Condition of fuel valve ☐ Normal ☐ Damaged - Condition of hose ☐ Normal ☐ Damaged
3. Remove fuel tank	
4. Empty the fuel tank	- Condition of fuel ☐ Normal ☐ Deposited ☐ Water contained ☐ Others
5. Remove fuel valve and fuel cap	- Condition of fuel cap ☐ Normal ☐ Blocked vent
6. Clean fuel valve and fuel filter	- Condition of fuel filter ☐ Normal ☐ Clogged ☐ Damaged
7. Clean fuel tank with benzene	- Condition of fuel tank ☐ Normal ☐ Rusty ☐ Leaked
8. Reassemble those components in reverse order.	Remarks: ______________________ ______________________________

1.2 to 1.4 Tank and Filters (II)

Sequence of operations	Inspection
Paper type air cleaner:	
1. Remove the air cleaner unit from the carburetter.	
2. Remove the filter for inspection	- Condition of the filter ☐ Normal ☐ Dirty, clogged ☐ Damaged ☐ Others
3. Blow the filter from inside	
4. Clean the air cleaner body with benzene	
5. Reassemble the air cleaner	Remarks: ....
Sponge type air cleaner:	
1. Remove the air cleaner unit from carburetter.	
2. Remove the filter for inspecting.	- Condition of filter ☐ Normal ☐ Dirty, clogged ☐ Damaged ☐ Others
3. Clean the filter with benzene	
4. Squeeze and wave the filter.	
5. Dip the filter in the fuel oil mixture (1 : 10 ratio)	
6. Reassemble the air cleaner	Remarks: ....

1.2 to 1.4 Tank and Filters (III)

Sequence of operations	Inspection
Wet type air cleaner:	
1. Remove the air cleaner unit.	
2. Remove the filter for inspecting	- Condition of the filter ☐ Normal ☐ Dirty, clogged ☐ Damaged ☐ Others
3. Clean the filter and the air cleaner body.	
4. Refil oil into the air cleaner body upto the marked level.	- Amount of refil oil ...... ccm Oil number ....
5. Reassemble the filter and the air cleaner.	
6. Clean and store tools and equipment used.	Remarks ....

1.5 Carburetter (I)

Tools: A set of wrenches, air gun with hose

Equipement: Benzen, soft brush, cleaning pan, cloth

Manufacturer .... Model ....

Type of carburetter .... Model ....

Standard float height ..... mm

Standard number of
turns of idle mixture screw ....

Standard idling speed .... rev/min

Standard number of main jet ....

Sequence of operation	Inspection
1. Prepare tools and equipment.	
2. Remove air cleaner.	- Type of filter
3. Close fuel valve and disconnect hose.	
4. Remove carburetter and related linkage and spring. Remark : Memorize linkages before removing.	
5. Clean outside of carburetter.	- Condition of leakage ☐ Nil ☐ leaked
6. Remove carburetter cover and empty fuel residual. Caution : Gasket may be torn off	- Condition of float chamber ☐ Normal ☐ Dirty - Condition of fuel ☐ Normal ☐ Di ty ☐ Water contained ☐ Others

1.5 Carburetter (II)

Sequence of operaations	Inspection
7. Remove float and needle for inspection.	- Condition of float ☐ Normal ☐ Damaged - Condition of needle ☐ Normal ☐ Dirty ☐ Worn ☐ Others ....
8. Remove main jet assembly	- Condition of main jet bore ☐ Normal ☐ Blocked ☐ Worn Number of main jet .... ☐ Original main jet ☐ New main jet
9. Remove idle mixture screw	- Condition of idle mixture screw ☐ Normal ☐ Dirty ☐ Worn ☐ Others ....
10. Clean all components with benzene and dry with air gun.	
11. Set the height of float according to the manual.	- Height of float Obtained value .... mm ☐ Normal ☐ Resetting
12. Reassemble the carburetter in reverse order.	

1.5 Carburetter (III)

Sequence of operations	Inspection
13. Adjust the idle mixture screw according to the manual as specified.	- Number of turns ......
14. Start the engine and allow to idle.	- Performance of the engine ☐ Normal ☐ Abnormal
15. Adjust the idle speed screw according to manual.	- Idling speed as specified .... rev/min
16. Stop the engine	
17. clean tools and equipement and store it.	

Remarks:...

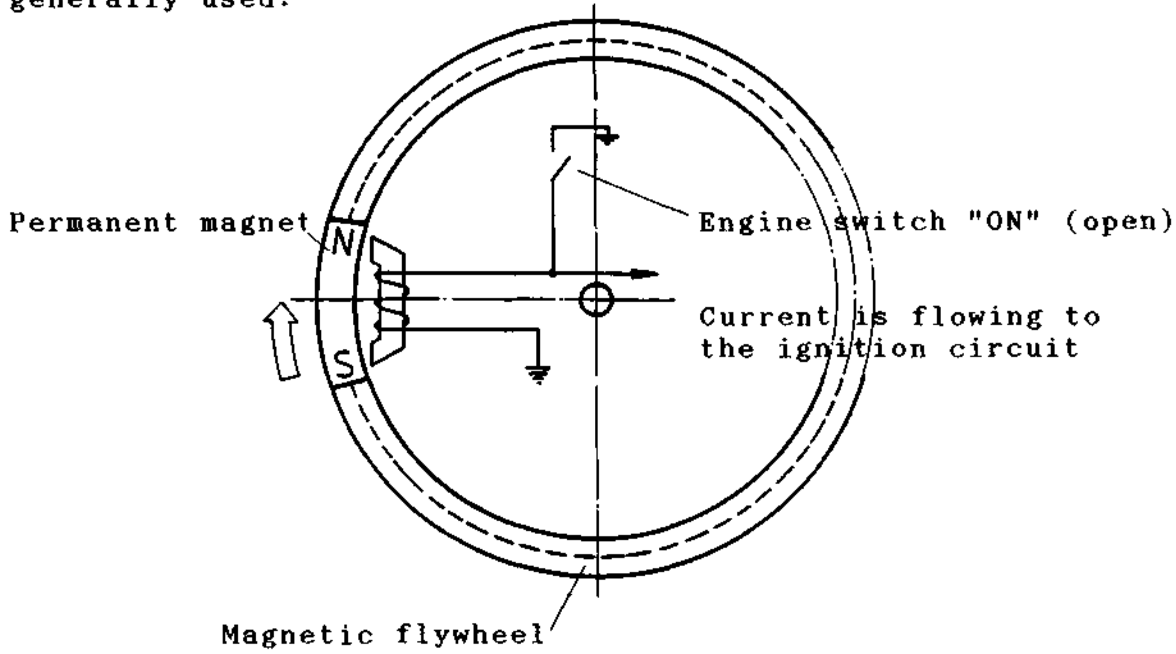
2. Ignition system

2.1 Basic principle

For small gasoline engines, magneto ignition system is generally used.



- The magnetic field of the permanent magnet, which rotates over the coil will generate current in the coil circuit.

- If the engine switch is at "OFF" position (closed), the generated current flows to the ground and cause no current flows in the ignition circuit.

Magneto ignition system can be classified into 3 types:

1. Contact point ignition system.

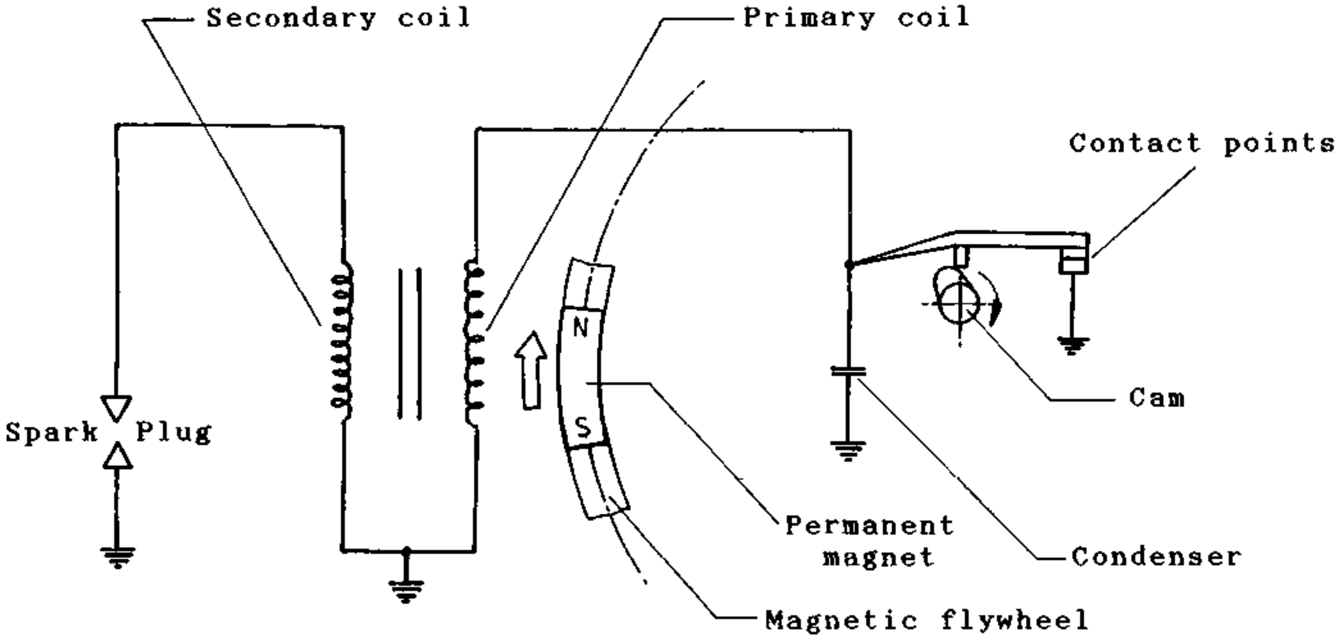
2. Transistor ignition system

3. Capacitive discharge ignition system.

On the following pages the function of these systems is shown.

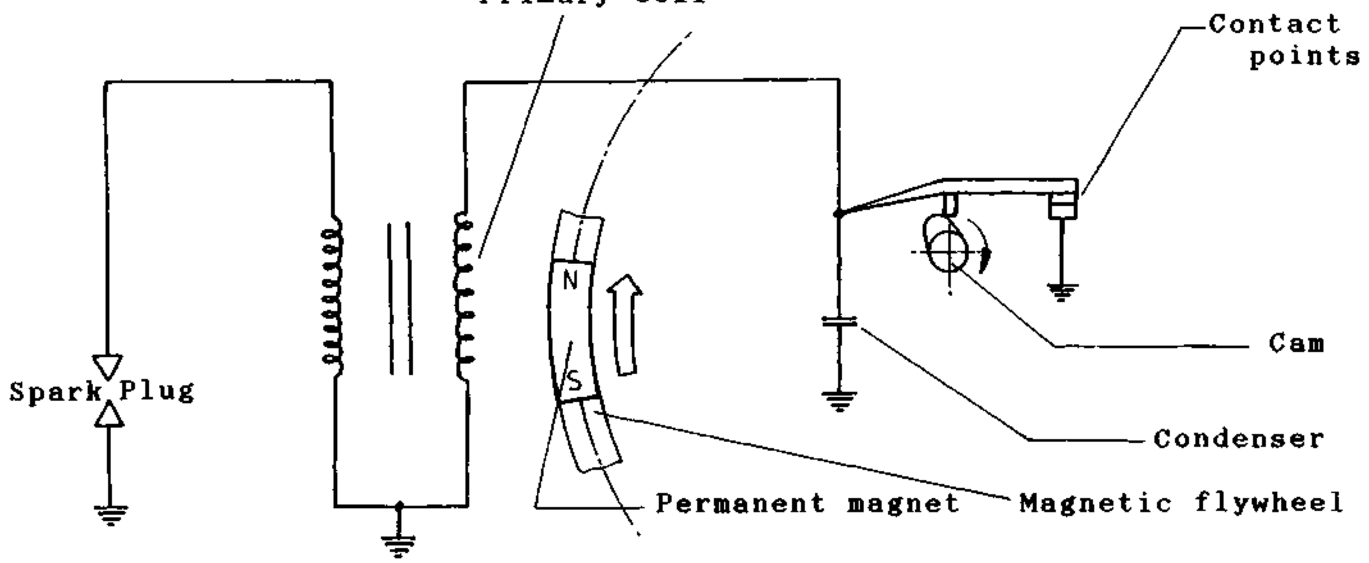
2.2 Contact point ignition system

2.2.1 Components of contact point ignition system and their function

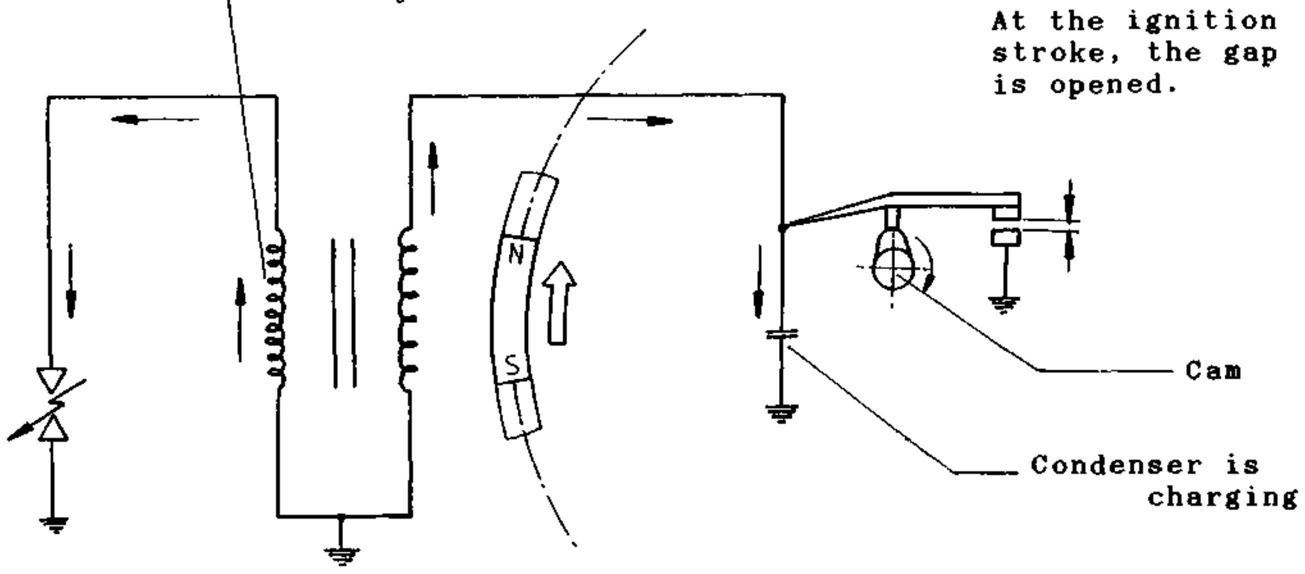


Components	Functions
1. Magnetic fly wheel	- makes the permanent magnet rotates around the coil and thereby produces the current in the ignition circuit
2. Contact point	- switches on and off the current flowing from the primary coil
3. Cam	- open/closes the contact point at correct timing.
4. Condenser	- charges/discharges the current and to prevent arcing between the two contact points.
5. Ignition coil	- converts low current voltage to high current voltage, sufficient for arcing the spark plug.
6.Spark plug	- produces arcing and ignite the fuel mixture in cylinder.

2.2.2 Function of contact point ignition system



- When the engine is starting, the magnetic flywheel rotates causing the magnetic field of permanent magnet to cut the primary coil, and thereby generates current flowing in the primary coil.
  As the gap of contact point is closed, the generated current is flowing to the ground by the contact points.

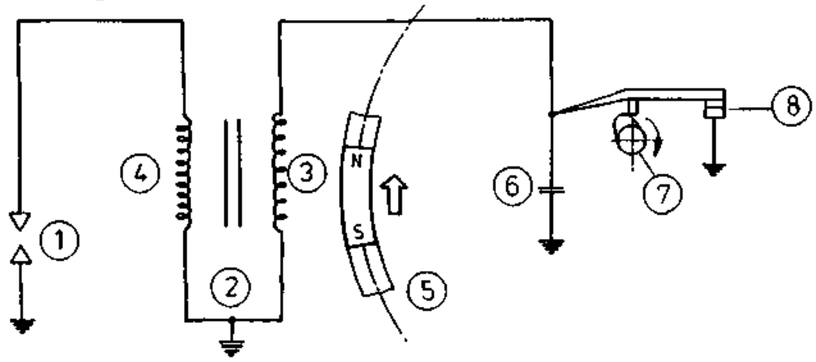


- At the ignition stroke, the cam mounted on the magnetic flywheel opens the gap of contact points. The current flowing to ground is impossible. The condenser is charging by the time the gap is opening. This will prevent arcing between contact points.
- A sudden interruption of current flowing in the primary coil causes the magnetic field to collapse and cut the secondary coil.
- Thus, the high current voltage is generated in the secondary coil and enable arcing between the electrodes of the spark plug.

2.2 Contact point ignition system

Complete the sentences or underline the correct options.

1. Ignition system generally used in small gasoline engine is -battery/magneto type.
2. Current which flows in the ignition circuit is generated by ___________________ .
3. Magneto ignition system is classified into _____ types, they are ____ .
4. Please name all parts of the ignition system.



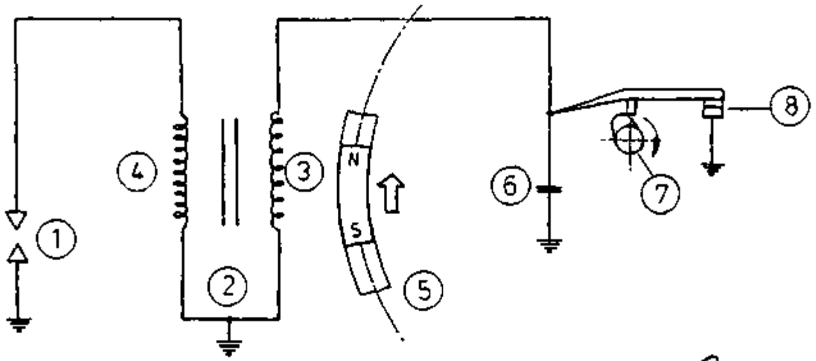
1.	5. ....
2.	6. ....
3.	7. ....
4.	8. ....

5. Contact point is for _______________________________________ .
6. The device that opens/closes the contact point is __________ .
7. Condenser/Ignition coil is for converting low current voltage to high current voltage.
8. The primary coil will be induced when the gap of contact point is closed/opened.
9. When the current flowing in the primary coil is interrupted suddenly, the magnetic field will _________________________ .
10. The secondary coil shall generate high current voltage for the spark plug when the gap of contact is beginning to open/close.

2 Contact point ignition system

Complete the sentences or underline the correct options.

1. Ignition system generally used in small gasoline engine is ~~battery~~/magneto type.
2. Current which flows in the ignition circuit is generated by magnetic flywheel .
3. Magneto ignition system is classified into 3 types, they are Contact point, Transistor and CDI .
4. Please name all parts of the ignition system.

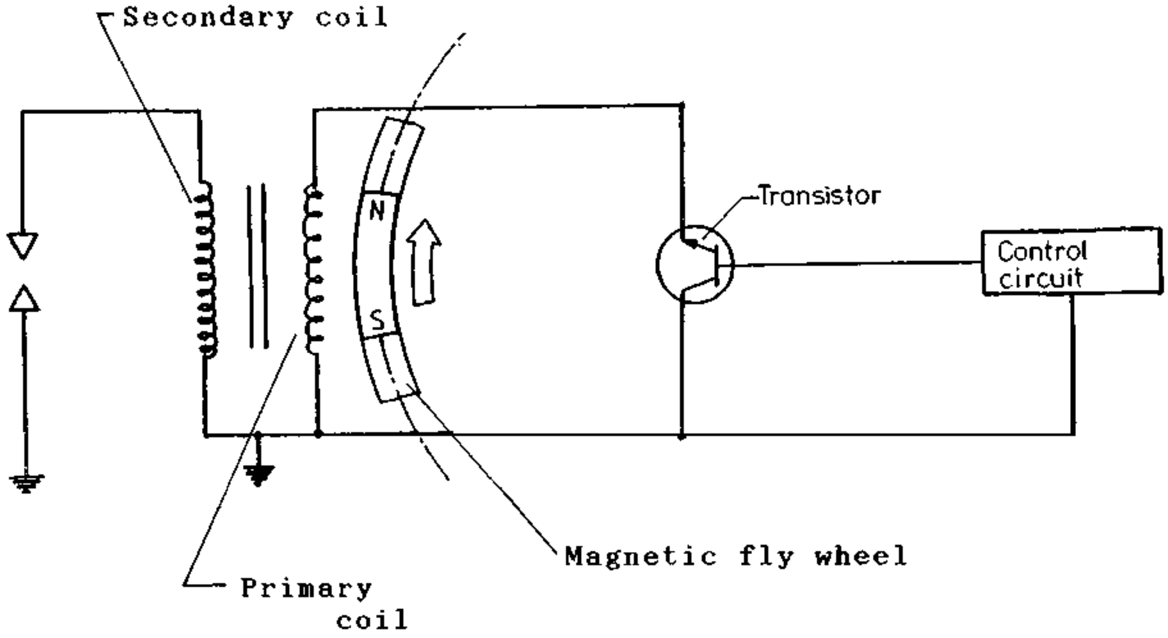


1. Spark plug
2. Ignition coils
3. Primary coil
4. Secondary coil
5. Magnetic flywheel
6. Condenser
7. Cam
8. Contact points

5. Contact point is for interrupting current flow in primary coil.
6. The device that opens/closes the contact point is the cam .
7. ~~Condenser~~/Ignition coil is for converting low current voltage to high current voltage.
8. The primary coil will be induced when the gap of contact point is closed/~~opened~~.
9. When the current flowing in the primary coil is interrupted suddenly, the magnetic field will collapse .
10. The secondary coil shall generate high current voltage for the spark plug when the gap of contact is beginning to open/~~close~~.

2.3 Transistor ignition system

2.3.1 Components of transistor ignition system and their function



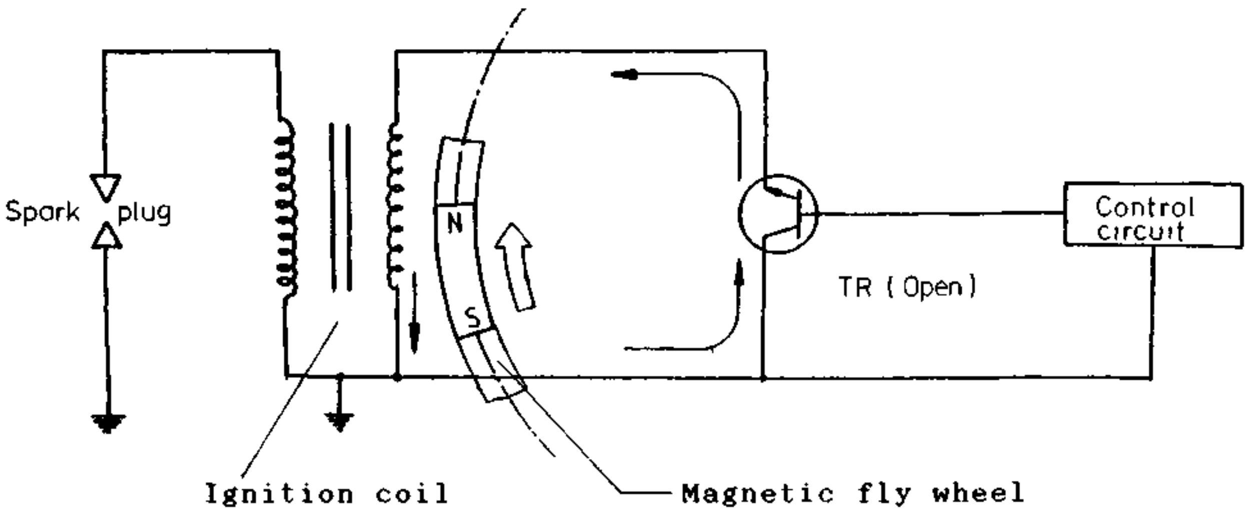
Transistor (TR)

- acts as on/off switch, like the contact points. But, a transistor can do the task contact-free.

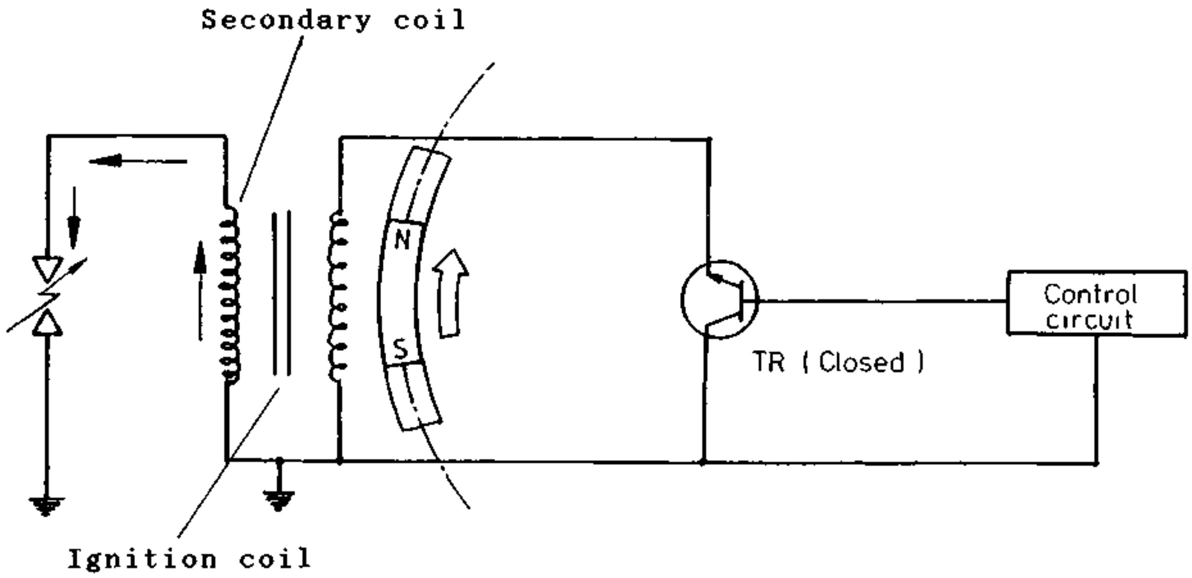
Control circuit

- acts like the cam in opening-closing the contact points, it controls the opening/closing of the transistor.

2.3.2 Function of transistor ignition system



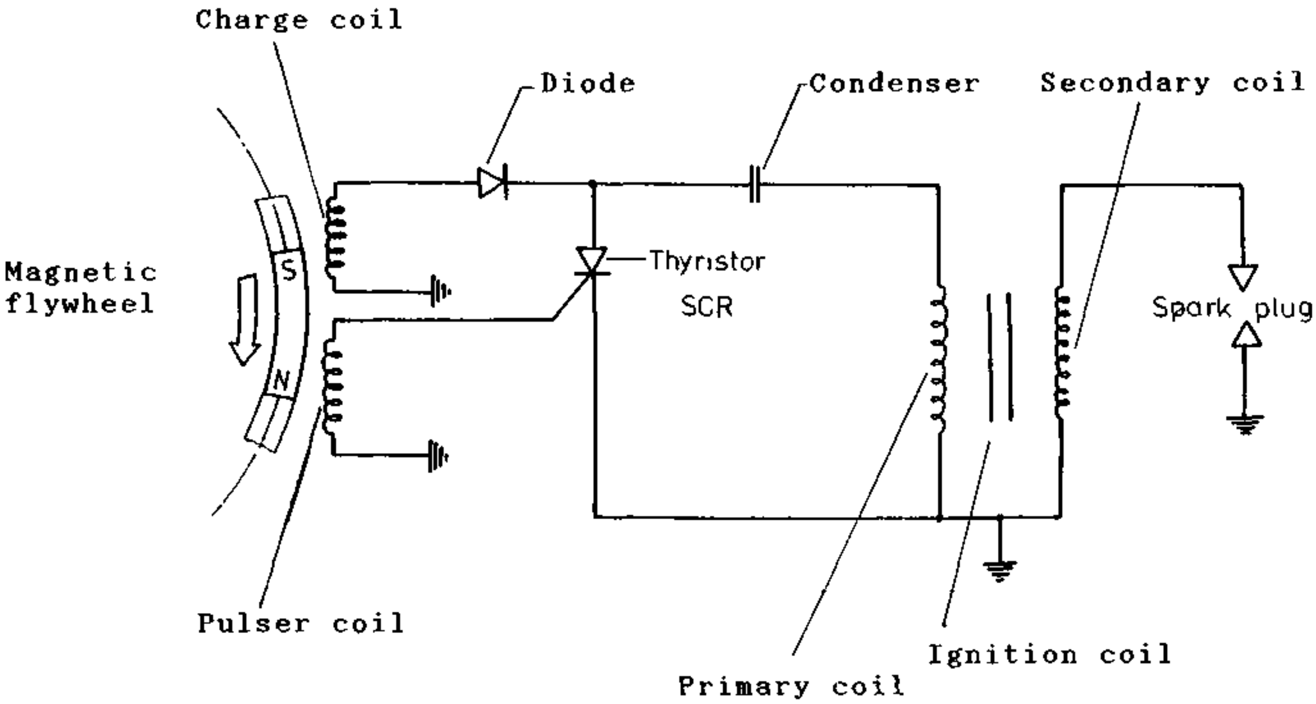
When starting the engine, magnetic fly wheel will rotate. As the magnetic field of permanent magnet is approaching the primary coil, current is induced and flowing through the transistor and thereby coming back to the primary coil, generating a magnetic field.



As the magnetic fly wheel turns until the ignition stroke, the induced voltage is increasing sufficiently for the control circuit to activate the Transistor to cut the flow of current to the primary coil. The magnetic field in the coil is, thus, collapsing and thereby inducing the high voltage current in the secondary coil, to flow to the spark plug.

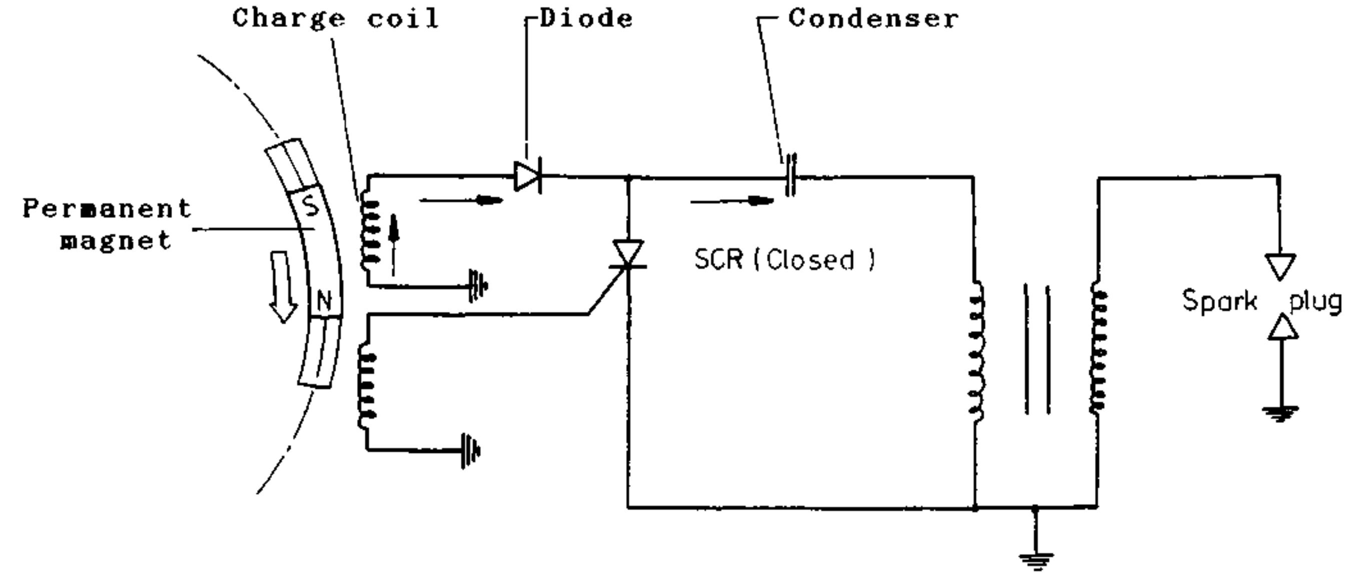
2.4 Capacitive discharge ignition system (CDI)

2.4.1 Components of capacitive discharge ignition system and their function

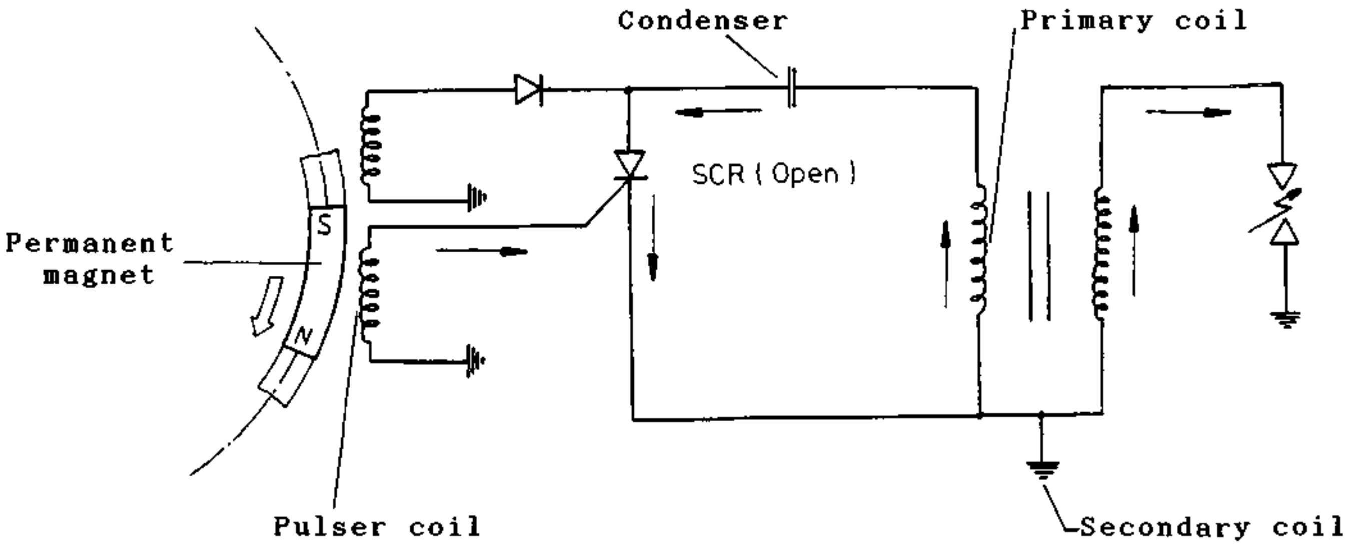


Components	Functions
1. Primary coil	- generates alternating current
2. Diode	- converts alternating current to direct current
3. Condenser	- charges and discharges current
4. Thyristor or SCR SCR = Silicon Control Rectifier	- closes/opens the circuit, acts like the contact points of the contact point ignition system. The current can flow from A to K only when G is activated.
5. Pulser coil	- generates a current to activate the SCR to open the circuit.

2.4.2 Function of CDI ignition system



When starting the engine, the magnetic flywheel will rotate.
As the magnetic field of the permanent magnet cuts the charge coil, alternating current is induced and flows to the diode. The diode will rectify it into direct current and the condenser will store it.



As the magnetic flywheel turns until the ignition stroke, its magnetic field cuts the pulser coil and current is generated.
The generated current will trig the SCR, causing the condenser to discharge its stored current to flow through SCR and through the primary coil to ground. This will induce the high current voltage in the secondary coil which flows to the spark plug causing arcing between the electrodes of the spark plug.

2.5 Advantages and disadvantages of CDI and transistor ignition systems

Advantages:

1. Reduced maintenance, no need of adjustment
2. Prolong life of a spark plug
3. No wearing of contact points
4. Easy starting, because higher ignition voltage
7. Constant high performance over the working life.

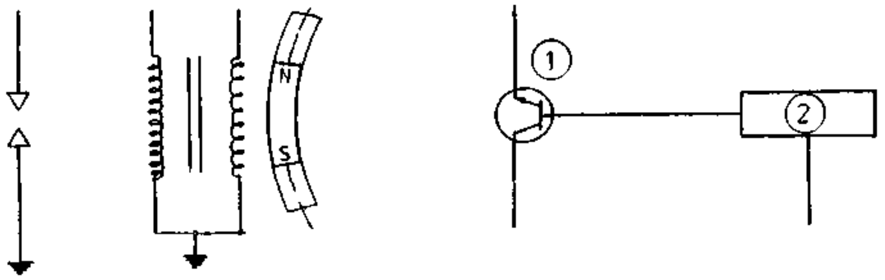
Disadvantages:

1. Expensive.
2. Electronic devices are not repairable.

2.3 and 2.4 Transistor and CDI ignition systems

Fill in the blanks and underline the correct answers.

1. Name various parts and complete the circuit diagramme of the transistor ignition system.



1. ....
2. ....

2. The Transistor is for ....

3. In a Transistor ignition system, the device which is

   equivalent to the cam is ....

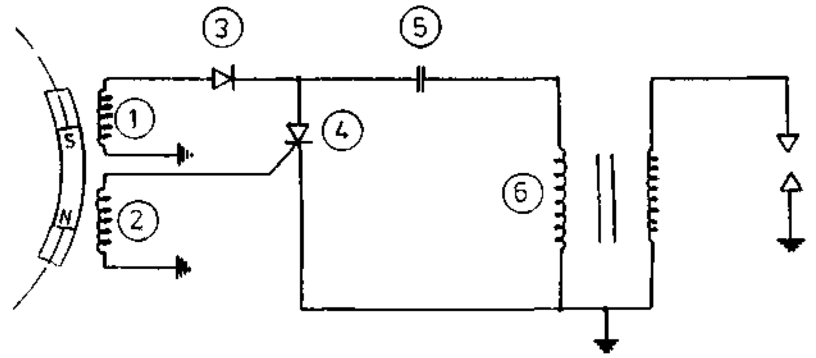
4. The Control circuit will activate the Transistor to cut the current flow when the voltage is increasing/decreasing.

5. What happens, when the Transistor cuts the current flow to

   the primary coil? ....

   ....

6. Name the parts of the CDI system.

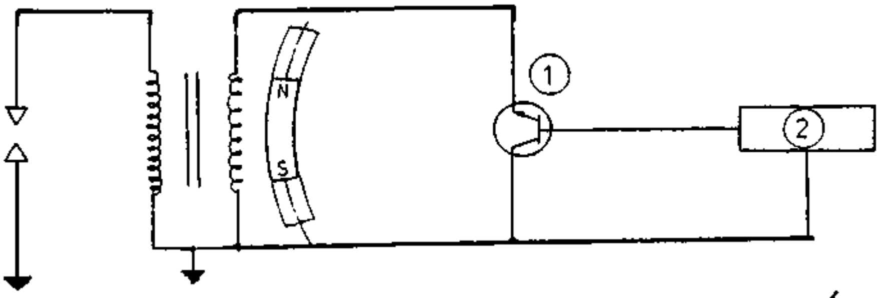


1	4 ....
2	5 ....
3	6 ....

2.3 and 2.4 Transistor and CDI ignition systems

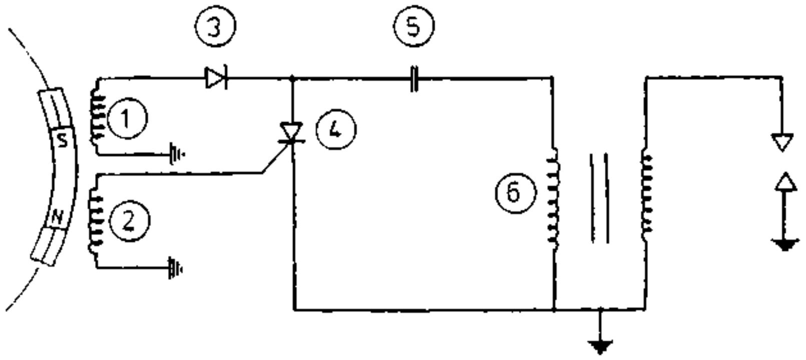
Fill in the blanks and underline the correct answers.

1. Name various parts and complete the circuit diagramme of the transistor ignition system.



1. Transistor........
2. Control unit......

2. The Transistor is for opening/closing the current flow of primary coil
3. In a Transistor ignition system, the device which is equivalent to the cam is the Control unit..............
4. The Control circuit will activate the Transistor to cut the current flow when the voltage is increasing/~~decreasing~~.
5. What happens, when the Transistor cuts the current flow to the primary coil? The magnetic field is collapsing and generating high voltage in the secondary coil......
6. Name the parts of the CDI system.



1 Charge coil.....
2 Pulser coil........
3 Diode.............
4 Thyristor (SRC)
5 Condenser.......
6 Primary coil.....

7. The device in the CDI system, which performs the same function as the contact points is ....

8. The Pulser coil/Charge coil is producing the current that triggers the SCR to open the circuit.

9. From the circuit of item 6:

   As the permanent magnet is moving past the coil 1, -alternating/direct- current will be generated and flowing through the diode by which it is changed into -alternating/ direct- current and storing in ....

10. When the SCR opens the circuit, the current as released by the condenser will flow through ....

11. High voltage current will flow to the spark plug when the magnetic wheel is cutting- the charge coil/the pulser coil.

12. Advantages of both the CDI and transistor ignition systems are:

    1. .... 3. ....

    2. .... 4. ....

13. Disadvantages of both the CDI and transistor ignition systems are:

    1. ....

    2. ....

7. The device in the CDI system, which performs the same function as the contact points is the Transistor...

8. The Pulser coil/~~Charge coil~~ is producing the current that triggers the SCR to open the circuit.

9. From the circuit of item 6:

   As the permanent magnet is moving past the coil 1,

   -alternating/~~direct~~- current will be generated and flowing through the diode by which it is changed into -~~alternating~~/ direct- current and storing in the condenser............

10. When the SCR opens the circuit, the current as released by the condenser will flow through the primary coil..............

11. High voltage current will flow to the spark plug when the magnetic wheel is cutting- ~~the charge coil~~/the pulser coil.

12. Advantages of both the CDI and transistor ignition systems are:

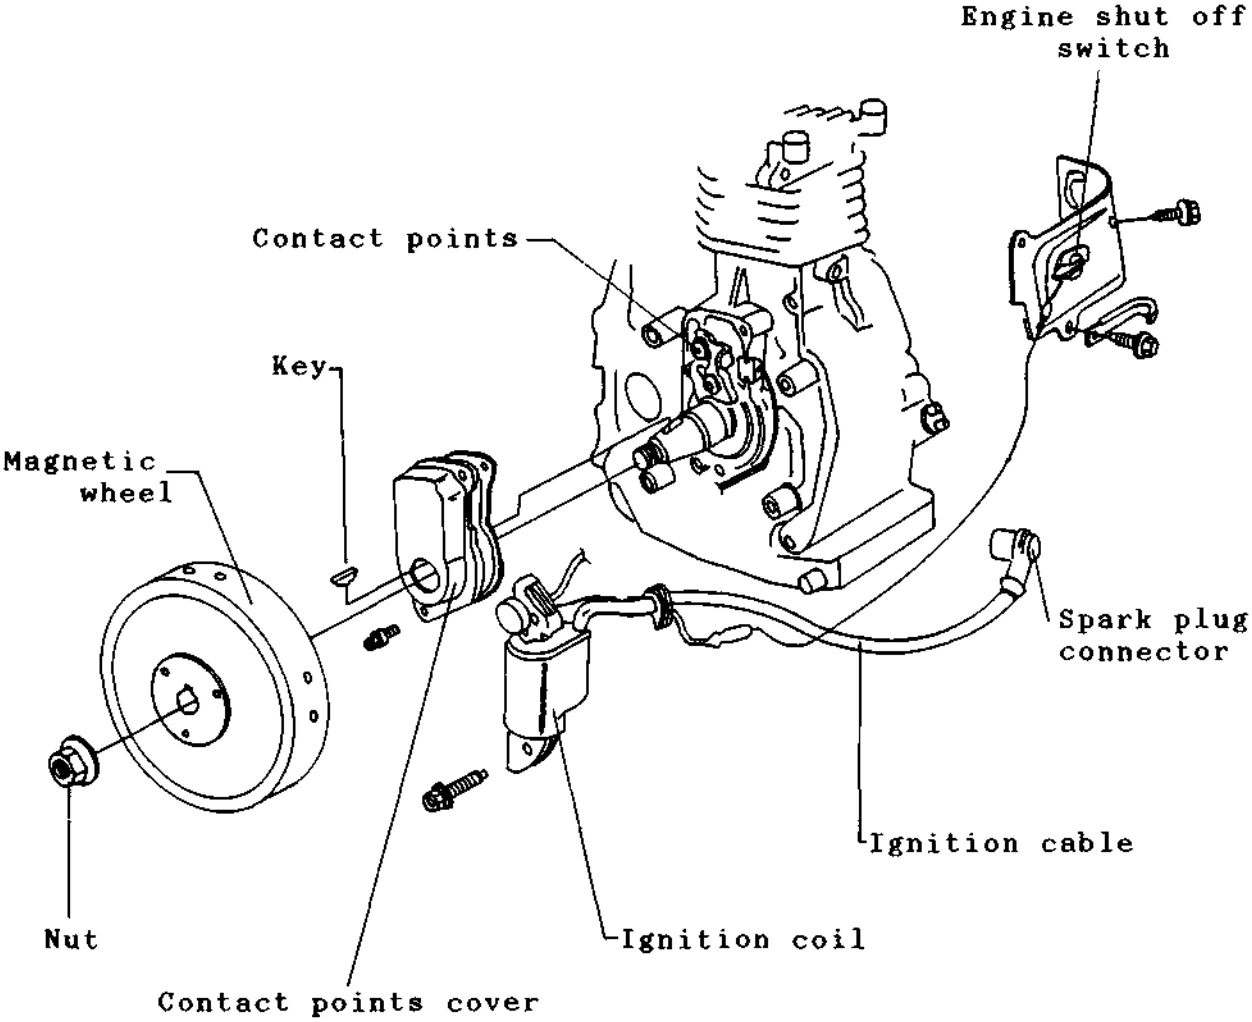
    1. Reduced maintenance..
    2. Longer live of spark plug
    3. No wearing of contact points
    4. Easy starting.........

13. Disadvantages of both the CDI and transistor ignition systems are:

    1. Expencive..
    2. Electronic devices ...not repairable.........

2.6 Maintenance and repair

2.6.1 Assemble and disassemble the ignition system



Removing:
- Special tool should be used to remove the magnetic wheel.
- Do not hammer the magnetic wheel, otherwise it will be damaged or spoiled.

Refitting:
- Clean the magnetic wheel completely before refitting.

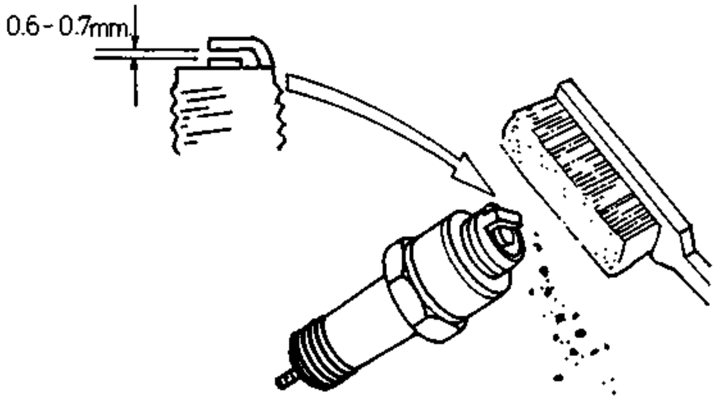
Remark:
- The magnetic wheel nut must be tighten with a torque wrench at the correct torque according to the manufacture's manual.
- The specified torque = 6.0 - 7.0 kgm

2.6.2 Inspect, clean and adjust spark plugs

Inspecting conditions of a spark plug:

Conditions of electrodes	Cause	Remedy
dry and light brown	- normal engine operation	
dry and black	- fuel mixture too rich	- readjust the idle mixture screw - inspect choke and air filter
	- wrong heat range	- switch to hotter plug, e.g. from BP 7 ES to BP 6 ES
wet and black	- Oil leaking into the combustion chamber may be caused by worn piston rings or others	- inspect and repair piston rings, piston and cylinder
burned and eroded	- wrong heat range	- switch to colder plug, e.g. from BP 6 ES to BP 7 ES
white spot deposit	- aditive deposits from leaded fuel	- switch to hotter plug

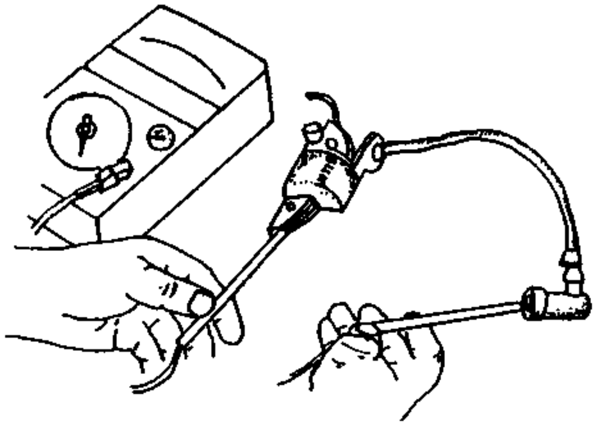
Cleaning and adjusting a spark plug:



- clean the electrodes with a steel brush.
- adjust the spark plug gap according to manual

  (Standard spark plug gap = 0.6 - 0.7 mm)

2.6.3 Inspect the ignition coil



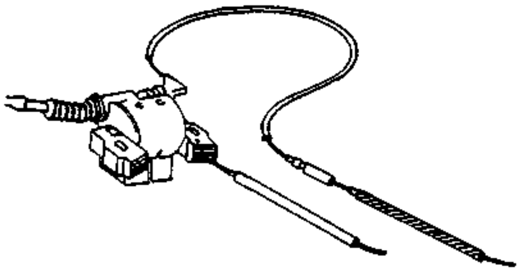
- disconnect the spark plug connector
- measure between the spark plug connector and the ignition ciol base with an ohmmeter

  standard resistance = 6.6 KΩ

Condition of ignition coil	Causes
Resistance of the primary coil is too low	- short circuit in coil
Resistance of the primary coil is too high	- dirty coil
Resistance of the secondary coil is too low	- short circuit in coil
Resistance of the secondary coil is too high	- dirty terminal

2.6.4 Inspect CDI and transistor ignition system

Primary coil:

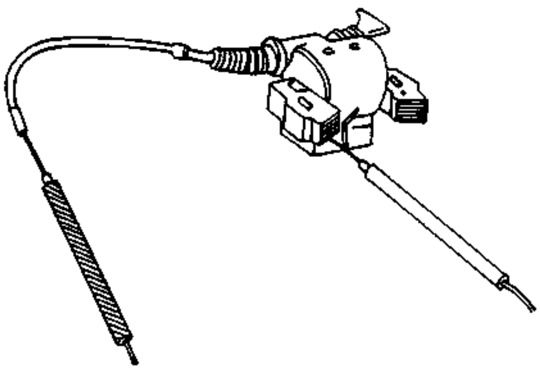


Use ohmmeter to check between the black cable (engine stop) and the core.

Standard resistance of primary coil:

for HONDA Model GX 110, 120, 140, 160	= 1.2 - 0.2 Ω
For HONDA Model GX 240, 340	= 0.7 - 0.9 Ω

Secondary coil:

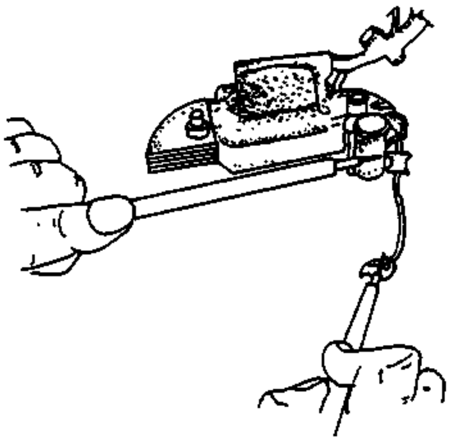


- Remove the spark plug lead
- Use ohmmeter to check between the spark plug lea and the core.

Standard resistance of secondary coil:

for HONDA Model GX 110, 140	= 12 - 2 KΩ
for HONDA Model GX 120, 160	= 6.5 - 8 KΩ
for HONDA Model GX 240, 340	= 6.3 - 7.7 KΩ

2.6.5 Inspect condenser



- measure the resistance of the condenser between positive and negative terminals
- if the indicater rises a little and falls back, the condenser is alright
- if the indicater does not rise or fall, it is damaged

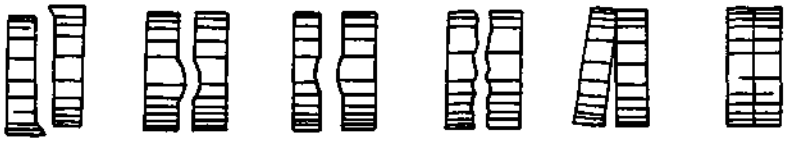
Standard capacitive = 0.24 μF

Remark: If the contact points wear abnormally, then the condenser must be replaced.

Conditions of condenser	Faults
Too large capacitive	- Contact points are eroded
Too small capacitiv	- Contact points are eroded

2.6.6 Inspect and adjust contact points

Conditions of contact points:



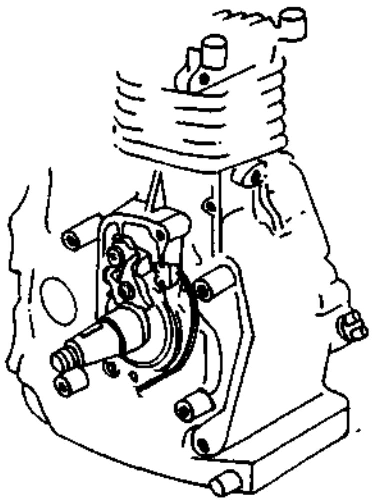
- Light gray contact points are normal.

- If burned, eroded or pitted, contact points must be replaced.

- If colour is normal and worn a little, then file them smooth.

Adjusting the contact points:

- Insufficient gap will cause contact points arcing and burning.
- Excessive gap will reduce the dwell angle of the contact points and thereby ceasing the ignition at high-speed.



Operating steps:

- Turn the crank shaft until the cam opens the contact points fully.

- Measure the gap by using feeler gauge.

- Readjust the gap if it is not correct according to the manual.

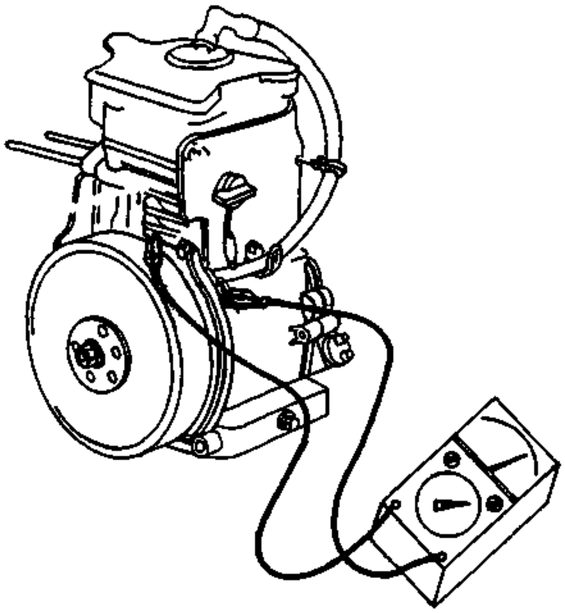
(Standard contact point gap = 0.4 - 0.5 mm)

2.6.7 Adjust the ignition timing

Ignition timing	Faults
1. Advanced ignition	- Engine is knocking
	- Engine runs back
2. Retarded ignition	- Difficult to start
	- Engine lacks power
	- Engine is overheated

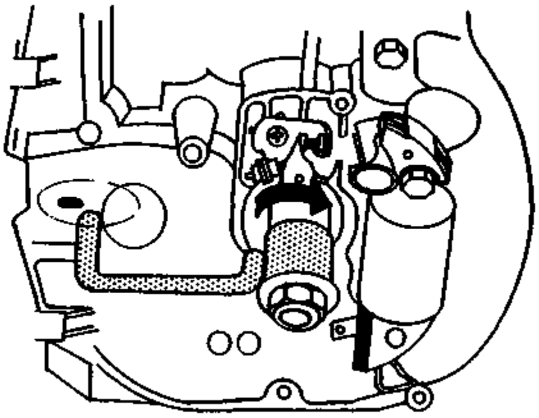
Adjusting the ignition timing:

a) by using timing tester



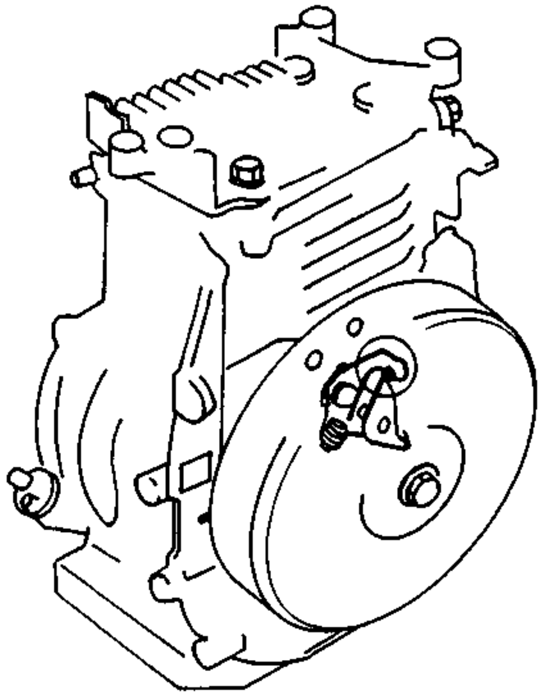
- Connect one lead of the timing tester to ground.
- Connect another lead of the timing tester to contact point terminal (ignition terminal of switch key)
- When the timing tester is switched on, sound should be heard if the contact points open, or vice versa.
- The position at which the contact points open, must be inlined with F, otherwise readjusting the ignition timing is needed.

b) by using special tool to identify the "F" mark



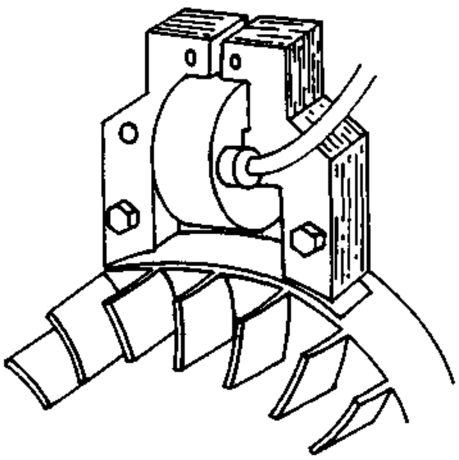
- Remove the magnetic wheel and the cover of contact points.
- Install the special tools to the crank shaft and tighten the nut.
- Turn the engine clockwise.
- At the position where the contact points open, the mark on the special tool must be inlined with the F mark.
- If it is out of inlined, then loosen the screw of the contact point base, and readjust it according to the mark.

c) Without using a special tool



- Remove the magnetic wheel and the contact point cover, then reassemble the magnetic wheel temporarily to its position.
- Now the opening - closing of the contact points can be seen.
- Turn the magnetic wheel clockwise, at the point where the contact points are opening, the F mark on the magnetic wheel must be inlined with the mark of the engine.

2.6.8 Adjust gap between ignition coil and magnetic wheel



- Turn the engine until the permanent magnet is underneath the ignition coil
- Measure the gap by feeler gauge.

Standard gap = 0.4 - 0.2 mm.

If it is outside the standard value, then loosen the screw of the ignition coil and readjust the ignition coil up or down until the required gap is obtained.

2.6.9 Trouble shooting

Fault	Possible causes	Remedy
Engine cranks normally,but will not start	1. Low voltage circuit is broken.	- Inspect connections of ignition coil and contact points.
	2. Contact points sticking.	- Readjust.
	3. Burned contact points.	- Clean or replace.
	4. Incorrect ignition timing.	- Inspect and readjust the ignition timing.
	5. Damaged condenser.	- Replace the condenser.
	6. Damaged ignition coil	- Replace the ignition coil.
	7.	- Inspect ignition coil and spark plug cable.
	8. Foulded spark plug	- Clean and readjust or replace.
Engine lacks power	1. Incorrect ignition timing	- Inspect and readjust the ignition timing.
Engine is overheated	1. Retarded ignition timing	- Readjust the ignition timing.
Engine is back fired	1. Incorrect ignition timing	- Readjust the ignition timing.
	2. Wrong heat range of spark plug	- Use correct heat range.
Engine is knocking or pinging	1. Incorrect ignition timing	- Readjust the ignition timing.
	2. Incorrect contact point gap	- Readjust the contact points gap.

Tools: A set of wrenches, special tool for removing magnetic fly-wheel, Torque wrench, Filler gauge, Ohmmeter, Smooth file, Timing tester, a special tool for setting the position F, Air gun with hose

Equipement: Steel brush, Brass brush, Cleaning pan, Cloth

Manufacturer: .... Model ....

Type of ignition system : ....

Standard torque for magnetic flywheel : .... Nm

Standard resistance of ignition coil : ....

Standard inspection for C.D.I and transistor module :

- Primary coil : ....
- Secondary coil : ....

Standard capacitive of condenser : .... µF

Standard gap between ignition coil and magnetic flywheel .... mm

Standard gap between contact points .... mm

Sequence of operations	Inspection
1. Prepare tools and equipment	Condition of spark plug.
2. Remove spark plug.	☐ Normal ☐ Damaged
3. Clean spark plug.	☐ Use steel brush
4. Check and adjust electrode.	Obtained electrode gap
5. Remove starting unit.	☐ Normal
6. Remove blower cover and other obstruction.	☐ To be readjusted
7. Remove magnetic flywheel.	Use of tools.
	☐ Use special tools
	☐ Others ....
8. Remove all parts of ignition system.	Conditions of general parts.

3. Speed control system

3.1 Task of governor

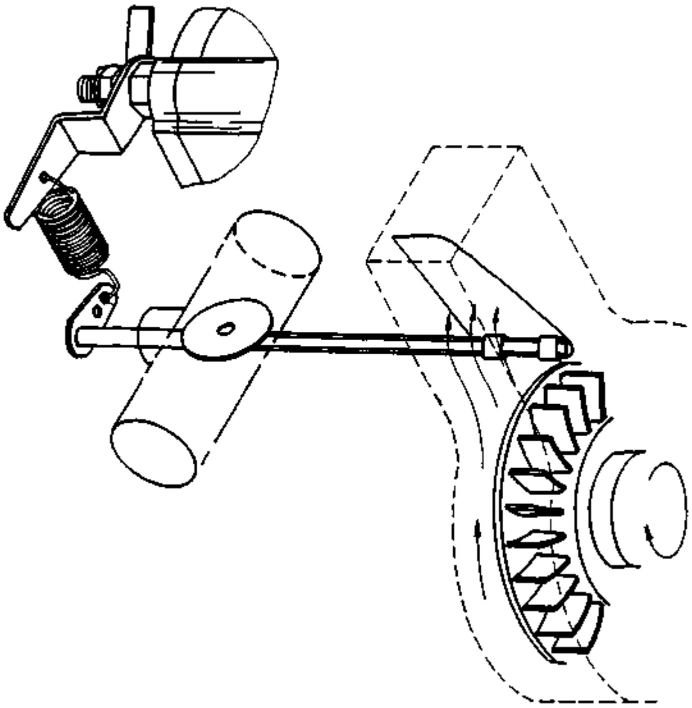
- to maintain constant engine speeds during running under varying loads.

3.2 Types and function of governor

Governors can be classified into 2 types:

3.2.1 Pneumatic governor

Constant engine speed is controlled by means of air flowing from the blower upon the blade of governor, which is connected to throttle plate mechanism.

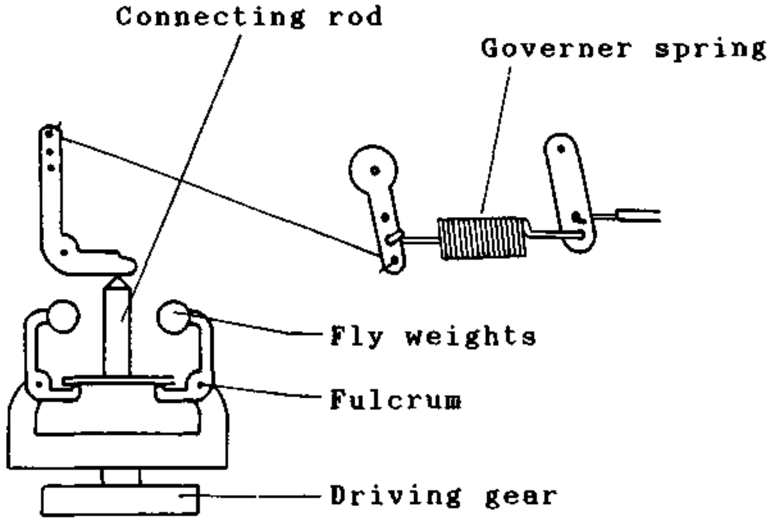


- As the engine speed increases, the flow of air is also increasing accordingly, and thereby turning the governor blade to turn the throttle plate in the direction to which the engine speed decreases until the throttle plat spring balances the force on the governor blade.

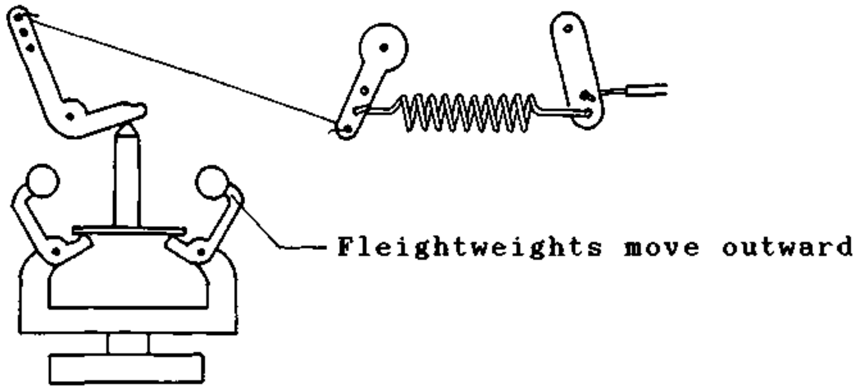
- When the engine is subjected to increasing load its spee will be decreasing. Thus, the air-force on the governor blade is also decreasing relatively, and surrendering to the force of throttle plate spring.
Therefore, the engine speed will be maintained constantl at every changing load.

3.2.2 Mechanical governor

This type of governor is operated by means of centrifugal force of the fly weights.



- As the engine speed decreases, the centrifugal forces of the flyweights are also decreasing, and thereby opens the linkgage of the throttle plate further. Thus, the engine speed increases to match a particular load.



- As the engine speed increases, the fly weights move away further and thereby reducing the opening of the throttle plate. Thus, the engine speed is coming down. Therefore, the engine speed will be maintained constantly at every changing load.

Fill in the blanks and underline the correct answer.

1. Governor is for ....

2. Governor is classified into ..... types, i.e. ....

   ....

3. At the engine stops, the position of the throttle plate will be -fully opened/ fully closed-.

4. The tensioning force of spring will tend to -increase/decrease- the engine speed.

5. Governor that has fly weights is of the .... type.

6. As the engine speed is on the increase, the flyweights will be -retracted/expanded-.

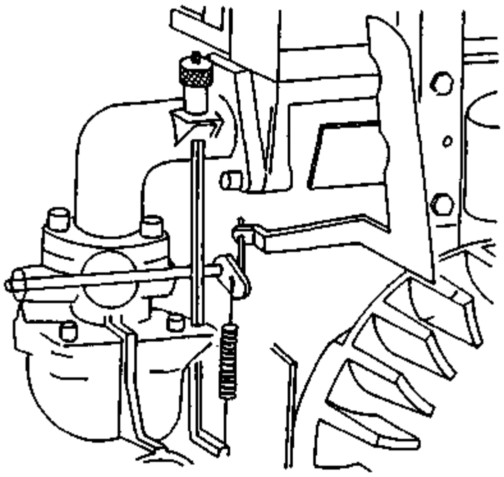
7. When the centrifugal forces of the flyweights are reducing, the throttle plate will be progressively -opened/closed-.

Fill in the blanks and underline the correct answer.

1. Governor is for maintaining constant engine speed.......
2. Governor is classified into .2.. types, i.e. Pneumatic.. governor a. Mechanical governor.......................
3. At the engine stops, the position of the throttle plate will be -~~fully opened~~/ fully closed-.
4. The tensioning force of spring will tend to -increase/~~decrease~~- the engine speed.
5. Governor that has fly weights is of the mechanial type.
6. As the engine speed is on the increase, the flyweights will be -~~retracted~~/expanded-.
7. When the centrifugal forces of the flyweights are reducing, the throttle plate will be progressively -opened/~~closed~~-.

3.3 Repair and maintenance

3.3.1 Adjusting the pneumatic governor

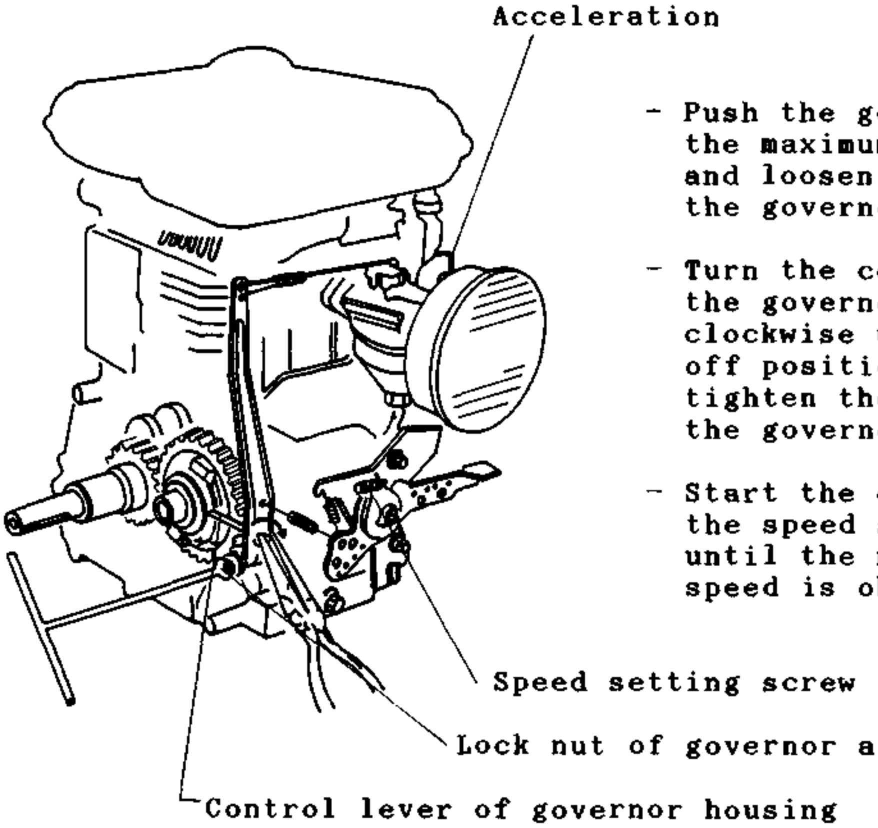


Sequence of operations:

1. Screw on the governor spring fully.
2. Start the engine.
3. Unscrew the governor spring gradually until the required engine speed is obtained.

Remark: - The further the screw is tightened the lower the engine speed.
- The further the screw is loosened the higher the engine speed.

3.3.2 Adjusting the mechanical governor



- Push the governor arm to the maximum speed position and loosen the lock nut of the governor arm.
- Turn the control lever of the governor housing clockwise until stop (shut off position), then tighten the lock nut of the governor arm.
- Start the engine; adjust the speed setting screw until the maximum engine speed is obtained.

Standard maximum speed 4000 rev/min.

Tools: a set of wrenches, air gun with hose
Equipement: Benzene, oil can, cleaaning tray, cloth

a) Pneumatic governer

Manufacturer .... Model ....

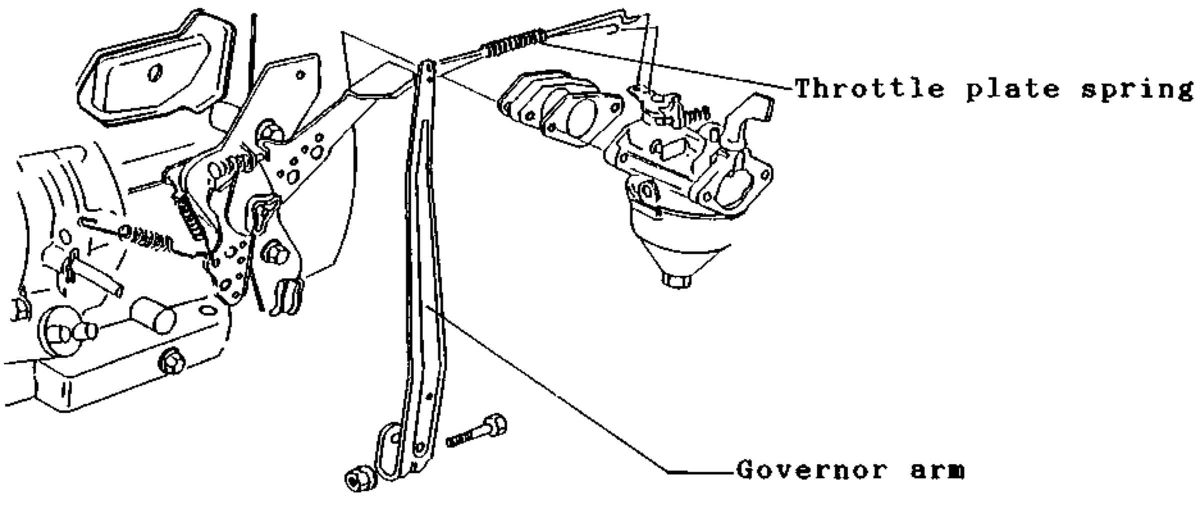
Sequence of operations	Inspection
1. Remove the blower cover.	- Condition of blower cover
2. Remove the governor unit. Caution : Be aware of mixing up positions of governor mechanism	- Condition of governor spring Normal Weakened Others ....
3. Reassemble in reverse order.	

b) Mechanical governer

Manufacturer .... Model ....

Sequence of operations	Inspection
1. Remove carburetter and governor arm. Caution beware of benzene	- Tension of the throttle plate spring. Normal Weakened
2. Remove governor unit from the carburetter.	- Straighteness of the governor arm Normal Bent
3. Reassemble in reverse order	

Remember: The short end of the throttle plate spring is on the carburetter side.



4. Valve mechanism

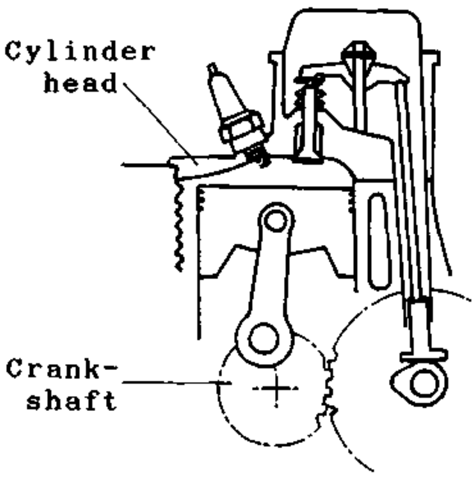
4.1 Task of valve mechanism

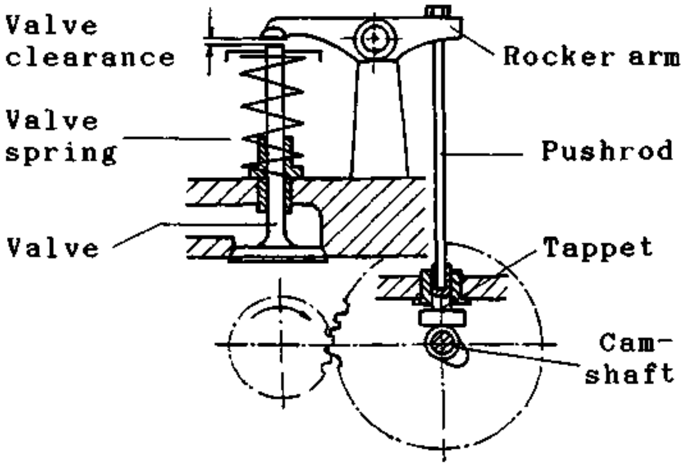
to open/close intake air-fuel mixture and exhaust gas in and out the cylinder, according to various strokes of engine.

4.2 Types and function

Valve mechanism is classified into 2 types:

4.2.1 Overhead valve





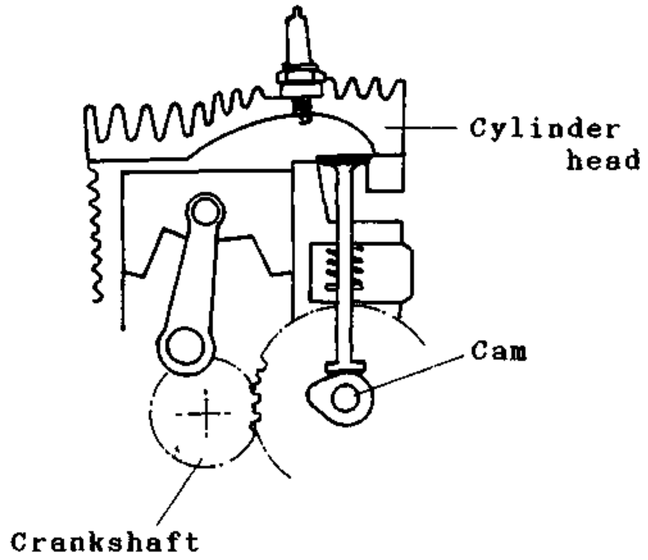
Crankshaft speed : Camshaft speed = 2 : 1

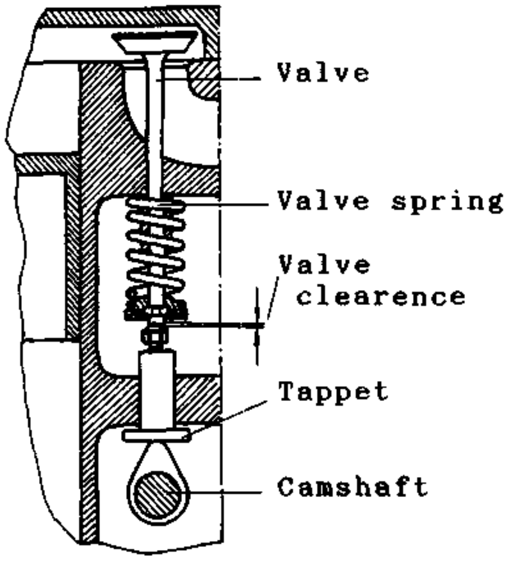
As the camshaft is driven by the crankshaft gear, the tappet is left and thereby the push rod pushes the rocker arm. The valve is, thus, opened as the pushing force of the rocker arm prevails that of the spring. When the cam turns beyond its lift the valve is closed under the force of valve spring.

Opening/Closing of valves is timed according to various strokes of the engine.

Advantages	Disadvantages
1. Low intake flow resistance.	- Complicated cylinder head.
2. Improved engine power.	- Engine is tall.
3. Valve servicing is easy.	- High number of parts of valve mechanism.

4.2.2 Side Valve





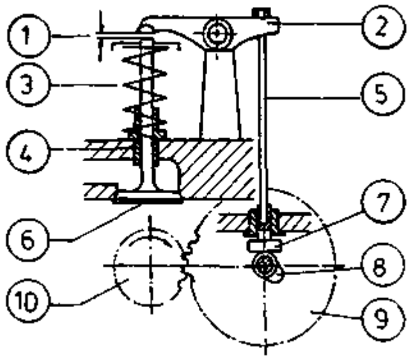
- As the camshaft is driven by the crankshaft gear, the valve is pushed to open by the cam via the tappet.

Advantages	Disadvantages
1. Valve arrangement is easy.	- High intake and exhaust flow resistance.
2. Small number of parts of valve mechanism.	- Cambustion chamber is not compact.
	- Inefficient engine power.

Complete the statements.

1. Valve arrangement for 4 stroke small engines can be accomplished in ..... ways, that is ....

2. Name various parts of the valve mechanism.



1 .... 6..................

2 .... 7 ....

3 .... 8 ....

4 .... 9 ....

5 ....10 ....

3. Crankshaft speed : camshaft speed = ... : .....

4. As the engine makes 1 complete turn, the intake valve will open and close for ..... time whereas the exhaust valve does the same for ..... time.

5. Both intake and exhaust valves can be opened or closed by means of ....

6. The advantages of the overhead valve engine are :

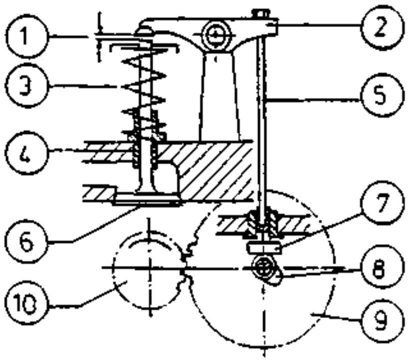
   1. ....
   2. ....
   3. ....

7. The advantages of the side valve engine are :

   1. ....
   2. ....

Complete the statements.

1. Valve arrangement for 4 stroke small engines can be accomplished in 2 ways, that is Side valve and Overhead valve
2. Name various parts of the valve mechanism.



1 Valve clearance
2 Rocker arm
3 Valve spring
4 Valve guidance
5 Pushrod
6 Valve
7 Tappet
8 Cam
9 Timing gear (cam)
10 Timing gear (crankshaft)

3. Crankshaft speed : camshaft speed = 2 : 1
4. As the engine makes 1 complete turn, the intake valve will open and close for 1 time whereas the exhaust valve does the same for 1 time.
5. Both intake and exhaust valves can be opened or closed by means of Cam, Tappet, Pushrod and Rockerarm.
6. The advantages of the overhead valve engine are :
   1. Low intake flow resistance
   2. Improved engine power
   3. Valve service is easy
7. The advantages of the side valve engine are :
   1. Valve arrangement is easy
   2. Small number of parts

4.3 Compression reduction mechanism

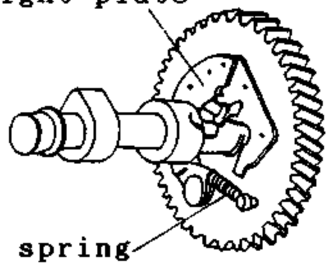
4.3.1 Purpose of compression reduction mechanism

To reduce compression in the cylinder during engine starting, thus, the power to start the engine is at minimum..

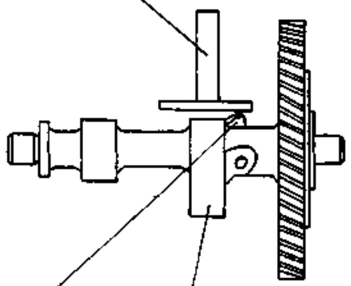
4.3.2 Components and function

This mechanism will open the exhaust valve during the starting string is pulled out.

a) When starting the engine



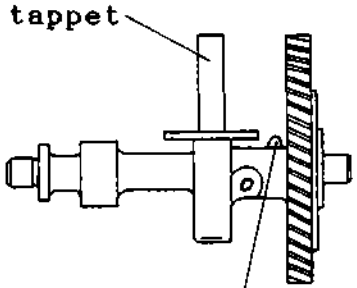
When the engine is at rest, the counter weight plate is kept in its original position by means of the retracting spring.



The compression reduction cam is on its peak which is above the heel of the cam.

When the starting string is pulled out, the compression reduction cam will slightly raise the valve tappet to reduce compression. This arrangement will ease the stert of the engine due to the engine can run fast.

b) During engine running



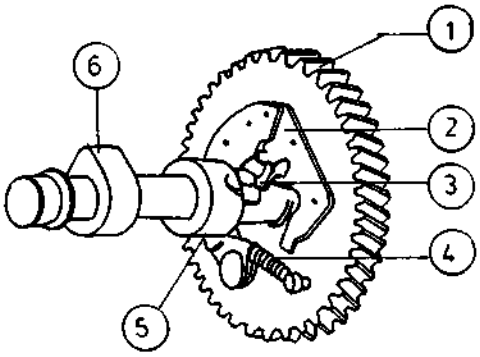
When the engine is running at the speed of 800 rev/min, the counterweight plate is forced outward by the centrifugal force.

The compression reduction cam is thereby pulled down and away from the valve tappet.

4.3 Compression reduction mechanism

Complete the statements or underline the correct answers.

1. The purpose of compression-reduction is ....
   ....
2. Compression -reduction can be accomplished by -opening/closing- the .... valve.
3. Name various parts of the compression-reduction mechanism.



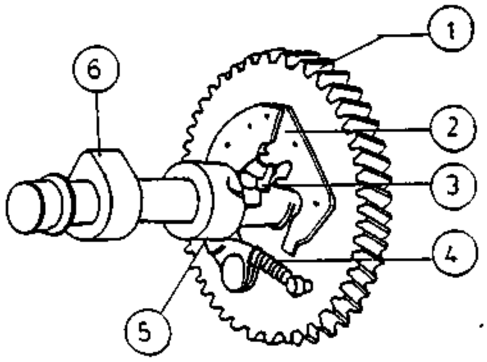
1. ....
2. ....
3. ....
4. ....
5. ....
6. ....

4. When the starting string is pulled, the .... will lift the tappet and the .... is opened to allow the exhaust gas to escape.
5. As the engine is running, the centrifugal force of the counter-weights will be -increasing/decreasing- and causing them to -expand/retract.

4.3 Compression reduction mechanism

Complete the statements or underline the correct answers.

1. The purpose of compression-reduction is to reduce compression in the cylinder during engine start.
2. Compression -reduction can be accomplished by -opening/closing- the exhaust....... valve.
3. Name various parts of the compression-reduction mechanism.

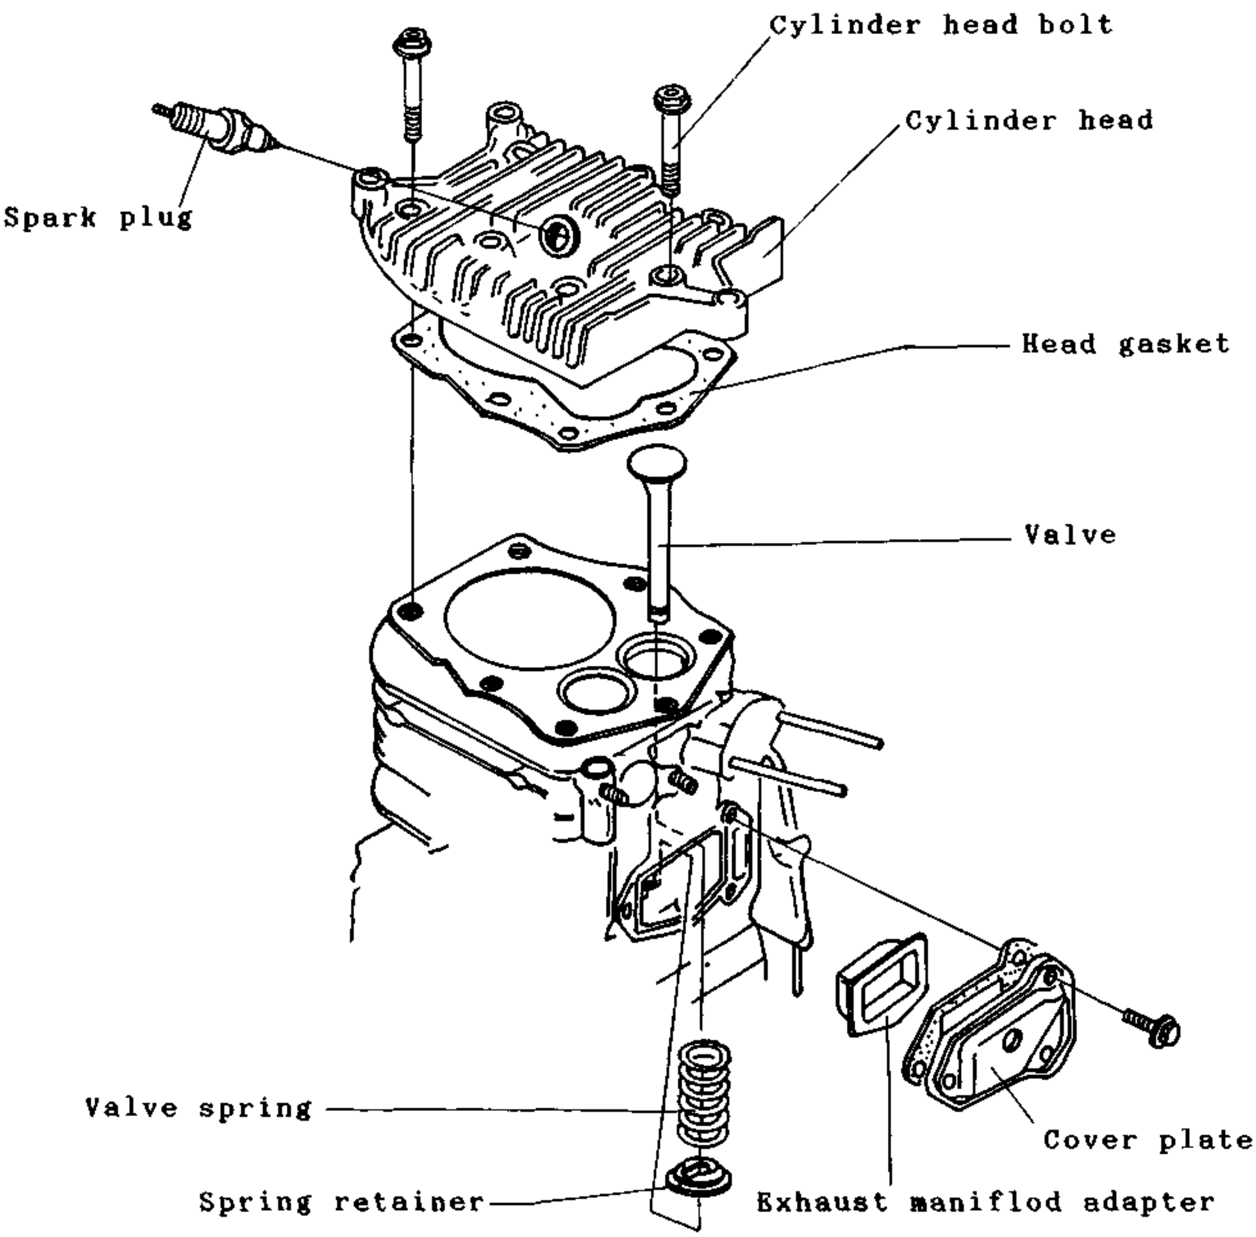


1. Timing gear
2. Counter weight plate
3. Compression reduction cam
4. Retracting spring
5. Cam for exhaust valve
6. Cam for intake valve

4. When the starting string is pulled, the compression redc. will lift the tappet and the exhaust valve. is opened to allow the exhaust gas to escape.
5. As the engine is running, the centrifugal force of the counter-weights will be -increasing/~~decreasing~~- and causing them to -~~expand~~/retract.

4.4 Repair and maintenance

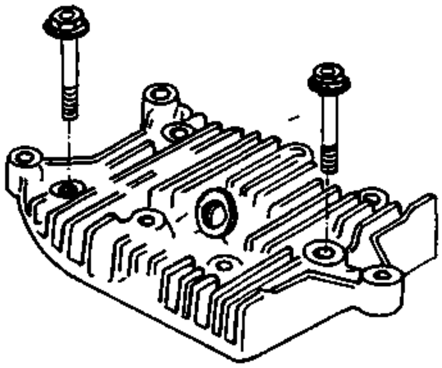
4.4.1 Removal and refitting of valve mechanism



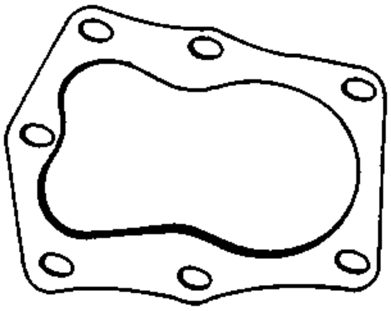
Remark : For valve mechanism removal, cylinder head and valves must be removed accordingly to the specified numbers and reassembled in their reverse order.

4.4.2 Removal/Reassemble of the cylinder head

a) Removing cylinder head

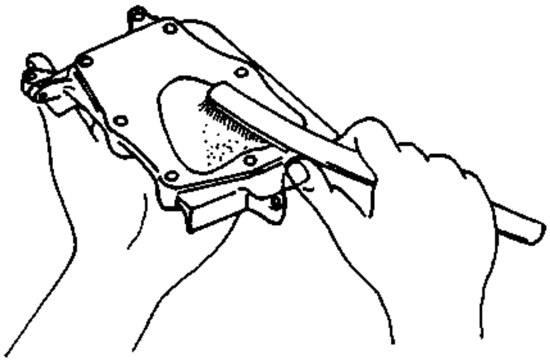


- Loosen all bolts in reverse order
- During loosening, gradual torque settings must be distributed over each bolt.



- Mating surface of the gasket, between the cylinder head and the cylinder block, must be cleaned and of no traces.

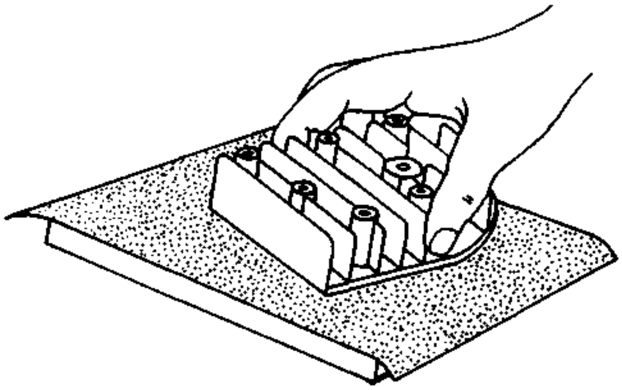
b) Cleaning cylinder head



- Decarbonize the combustion chamber and clean with benzene and dry with air gun.

Remark:

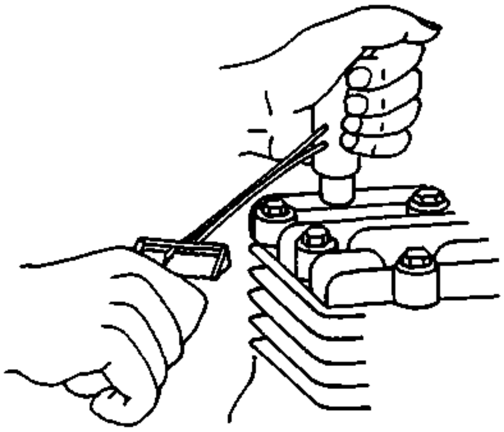
In removing carbon deposits, a broken piece of saw blade which is ground unsharp may be used.



- In case, the cylinder head is distorted or bent, then grind its mating surface with fine grain sand paper (No. 400), which places on a smooth, flat surface level.

Remarks:
- Contaminated dirt on fins of the cylinder head causes poor heat dissipation.
- After scraping and cleaning the fins, the cylinder head must be cleaned with benzene and dried with air gun.

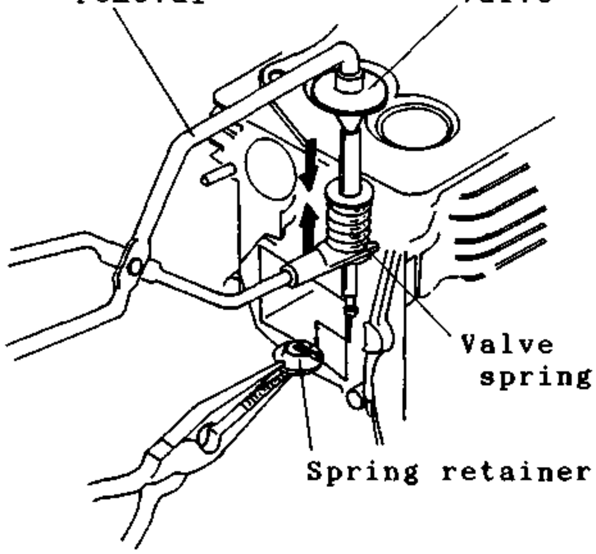
c) Refitting the cylinder head



- Tighten the cylinder head bolts in their reverse sequence by using the torgue wrench.
- The required tightening torque must be distributed gradually over successive settings.

  Remark: Required tightening torque 24 - 26 Nm

4.4.3 Removal/Reassemble of the valves



Removal:

Press the valve spring with pliers and remove the spring retainer, then release the pliers and remove valve and valve spring.

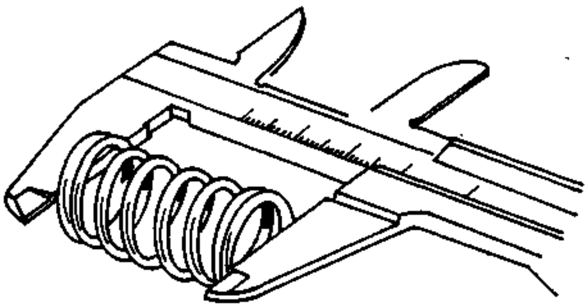
Reassemble:

Insert valve and valve spring, press the spring with pliers and insert the valve retainer.

Caution: Check, if the spring retainer is in the right position!

4.4.4 Valve spring

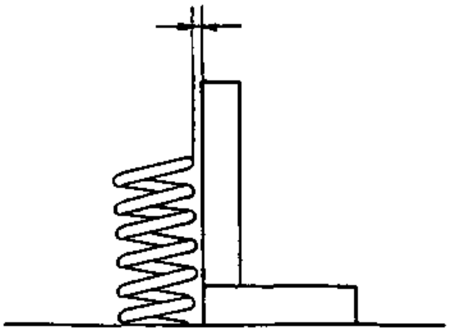
a) Measuring length of valve spring



- If the length of spring is shorter than the specification then the spring is weakened.

Standard lenght	36.7 mm
Minimum length	35.2 mm

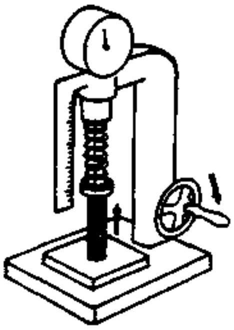
a) Checking squareness



- Turn the spring around itself against the square and observe any diviation.

  Remark: Deviation should not exceed 2 mm

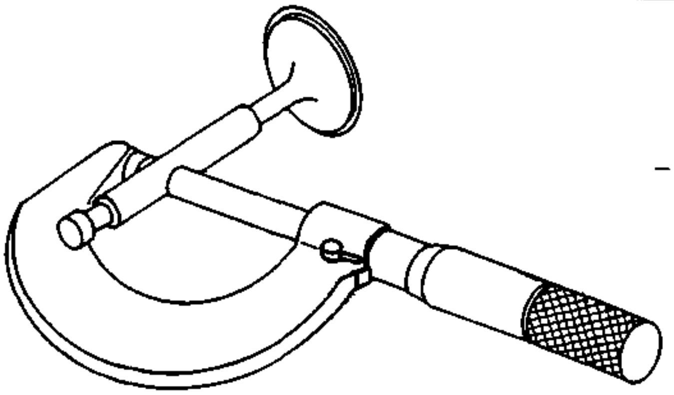
c) Checking strength of spring



- Set the height of the tester to the specification and read the obtained valve on the dial

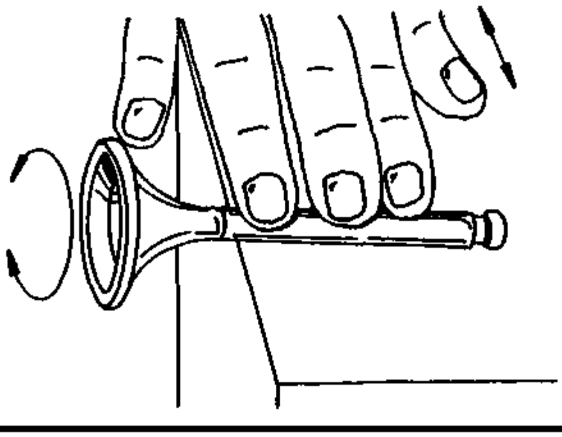
4.4.5 Valve

a) Measuring diameter of valve stem



- Compare the obtained reading with that of the manual.

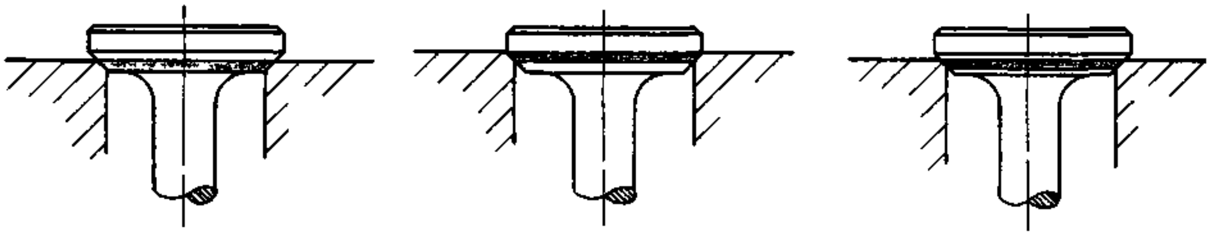
b) Checking straightness of the valve stem



- Roll the valve stem over the surface level, notice for any bending. Replace if it is bented.

c) Checking valve face, margin, and valve stem

Valve margin ...

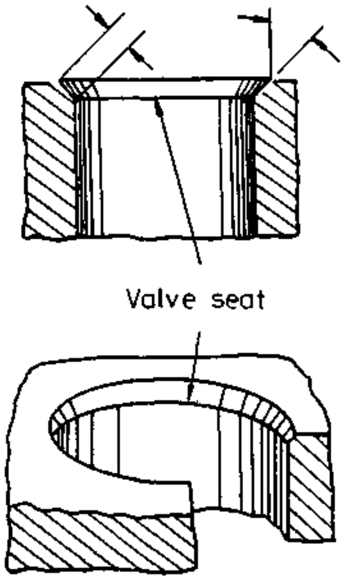


- to high
- to low
- correct

If valve foot is not smooth, then grind it with oil stone.

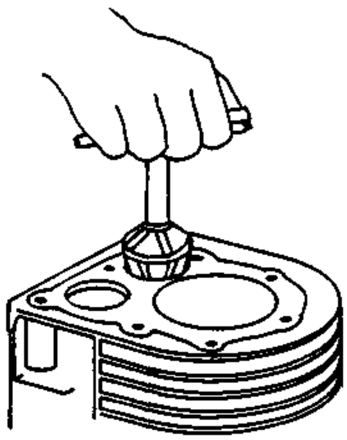
4.4.6 Valve seat

a) Measuring width of valve seat



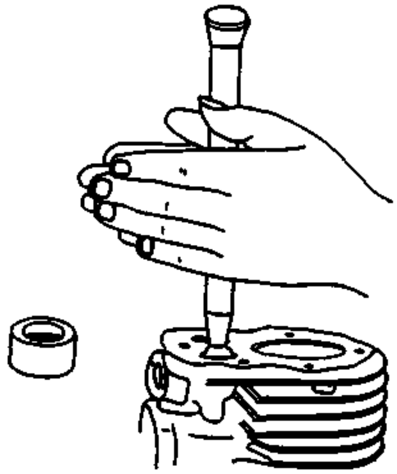
- Measure width of valve seat with vernier caliper.
- Recut the valve seat with the valve seat cutter, if its widt is less than that of the specification.

a) Valve cutting



- cut the valve seat with 90 valve seat cutter.
- Recut the valve seat with the smooth cutter.
- Final cut with the 90 valve seat cutter.

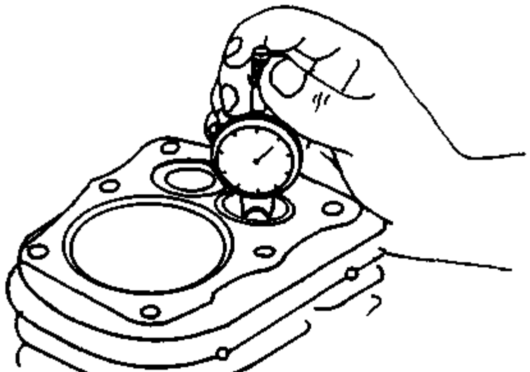
b) Valve grinding



- Smear the vlave seat lightly with carborundum paste.
- Hold the valve by the rubber of the grinding tool. Turn the grinding tool to tub the valve face against valve seat.
- Clean the ground valve seat and valve face.

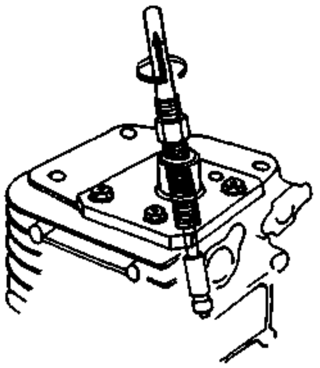
4.4.7 Valve guide

a) Measuring bore of the valve guide



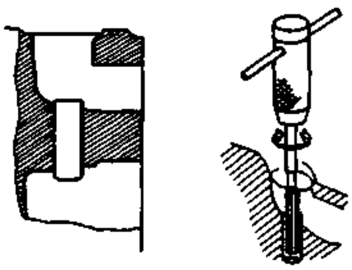
- Measure the bore with the dial indicator.
- Replace the valve guide if the obtained reading is beyond that of the specification.

b) Removing valve guide



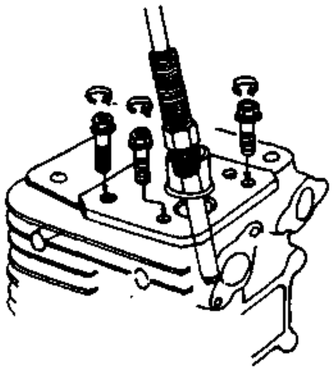
- Mount the special tool to the cylinder head by tightening 3 nuts.
- Screw in the valve guide extractor and screw on the nut underneath the valve guide.
- Unscrew the valve guide extractor until the valve guide is out.

c) Guide and its bore



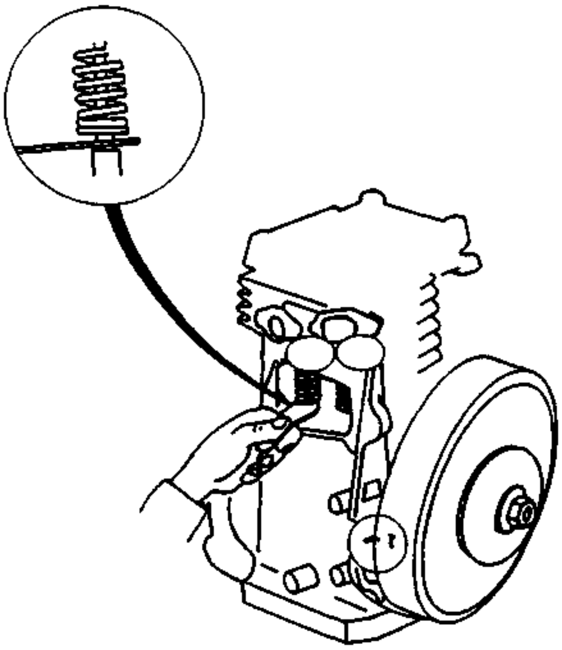
- Screw in the extractor to pull the valve guide.
- The valve guide must be pulled in and positioned correctly.
- Remove the nut and the extractor.

d) Reassembling valve guide



- Reverse the valve guide extractor.
- Fix the flange to the cylinder head and screw on the nut tightly.
- Insert the valve guide onto the extractor and hold it with the nut.
- Oil must be applied to the valve guide and its bore before reassembling.

4.4.8 Valve adjustment



- Turn the engine until the piston is at the top of compression stroke.
- Measure the valve clearance by the feeler gauge.
- Adjust the valve clearance to the specification.

Valve clearance specification 0.04-0.12 mm

- Excessive valve clearance : change valve or tappet
- Insufficient valve clearnace : grind valve stem with oil stone.

Tools: a set of wrenches, Spark plug wrench, Torque wrench, Socket wrench and handle, Feeler gauge, Vernier caliper, Spring strength tester, dial indicater

Eqwuipement: Benzene, Oil caan, Cleaning pan, Cloth, Brass brush, Sand paper (400), broken saw blade, Oil stone

Manufacturer .... Model ....

Type of valve arrangement ....

Compression-reduction mechanism ☐ Yes ☐ No

Torque for cylinder head hold-down screw ....Nm

Standard lenght of valve spring .... mm

Limited deviation of valve spring squareness .... mm

Standard strength of valve spring ....

Standard diameter of valve stem .... mm

Standard width of valve seat .... mm

Standard bore of valve guide .... mm

Standard valve clearance .... mm

Sequence of operations	Inspection
1. Prepare tools and equipment.	
2. Close fuel valve and disconnect fuel hose.	
3. Remove fuel tank.	
4. Remove blower cover and any obstruction.	
5. Remove cylinder head by loosening from the outmost screw toward center.	
6. Remove head gasket.	- Condition of head gasket ☐ Normal ☐ Damaged
7. Clean cylinder head. Remark: If the cylinder head is bent or distorted, grind it with sand paper over the surface level.	- Condition of cylinder head ☐ Normal ☐ Dirty ☐ Craked ☐ Bent, disorted

Sequence of operation	Inspection
8. Remove carburetter.	
9. Remove side cover plate.	
10. Remove valve springs.	
11. Remove vlaves.	
12. Clean valve unit and valve seats and arrange them in good order.	
13. Check length of valve spring.	- Obtained reading .... mm. ☐ Normal ☐ Damaged
14. Check squareness of valve spring.	- Obtained reading .... mm. ☐ Normal ☐ Damaged
15. Check strength of valve spring.	- Correct to specification
16. Measure diameter of valve	- Obtained reading .... mm. ☐ Normal ☐ Worn
17. Check straightness of valve	☐ Normal ☐ Distorted, bent
18. Check valve face.	☐ Normal ☐ Worn
19. Check margin of valve seat.	- Obtained reading .... mm. ☐ Normal ☐ Worn
20. Check width of valve seat.	- Obtained reading .... mm. ☐ Normal ☐ Worn

Remark: If excessive wear on valve seats, then recut the valve seats and regrind it.

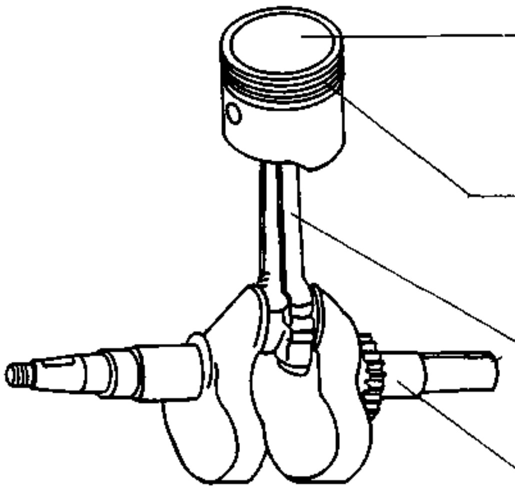
21. Check bore of valve guide.	- Obtained reading .... mm. ☐ Normal ☐ Worn

Remark: If excessive wear on valve guides then remove and replace the valve guides by using the special tool. I

22. Reassemble all components in their reverse order.	Reassembling ☐ Complete ☐ Incomplete
23. Adjust valve clearance.	- Standard valve clearance .... mm.
24. Clean and store all tools and equipment.	Note: ....

5. Crankshaft mechanism

5.1 Components and functions of crankshaft mechanism



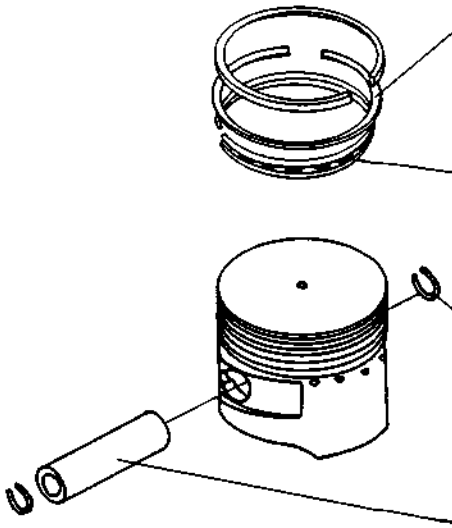
Piston:
Moving up-down in the cylinder according to various engine strokes.

Piston rings:
A series of seals to prevent leakage of combustion gas and scrape oil in cylinder.

Connecting rod:
Transmitting force from piston to crankshaft.

Crankshaft:
Converting reciprocating force into rotating force.

5.1.1 Piston and piston rings



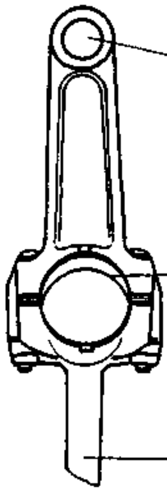
Compression rings:
Are acting like seals to prevent leakage of combustion gases. There are 2 of them.

Oil control ring:
Scrapes excess oil from entering into the combustion chamber. There is 1 ring.

Lock ring:
Keep the gudgeon pin centered in the connecting rod.

Gudgeon pin:
Links the piston to the connecting rod.

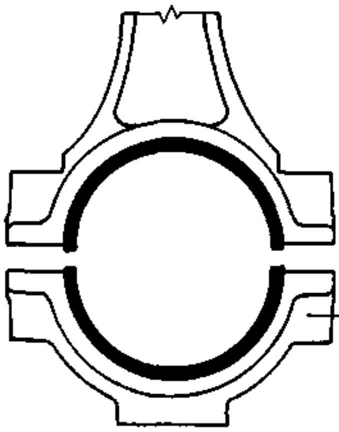
5.1.2 Connecting rod and connecting rod bearings



Small-end bearing:
The upper end of connecting rod has a bush bearing for connecting with the gudgeon pin.

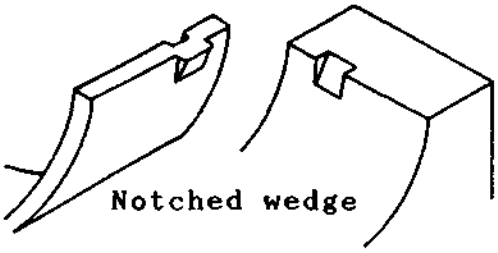
Big-end bearing:
The lower end of connecting rod has bearing shells for connecting with the crankshaft.

Oil splasher



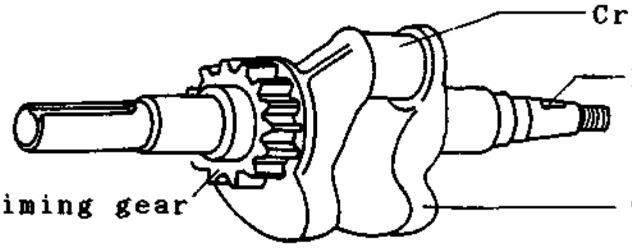
The big-end bearing shells split in two halves. The upper shell fixes with the connecting rod, the lower one with the connecting rod cap.

Connecting rod cap



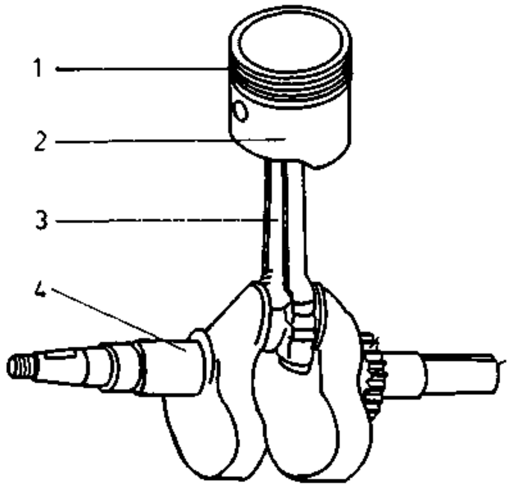
The bearing shells are positioned by the notched wedges and grooves on the connecting rod and connecting rod cap.

5.1.3 Crankshaft



- Crankpin journal is for connecting with the connecting rod.
- Timing gear is for driving the camshaft.
- Key way is for connecting with the magnetic wheel.
- Counterweight is for damping the engine vibration.

1. Name the parts of the crankshaft mechanism.



1. ....
2. ....
3. ....
4. ....

2. Make a cross in front of the correct statements

... 1. The part of the piston that bears the impact force mostly is the piston skirt.

... 2. Piston rings act as a series of seals to prevent leakage of combustion gases.

... 3. Compression rings and oil control ring are exchangeable.

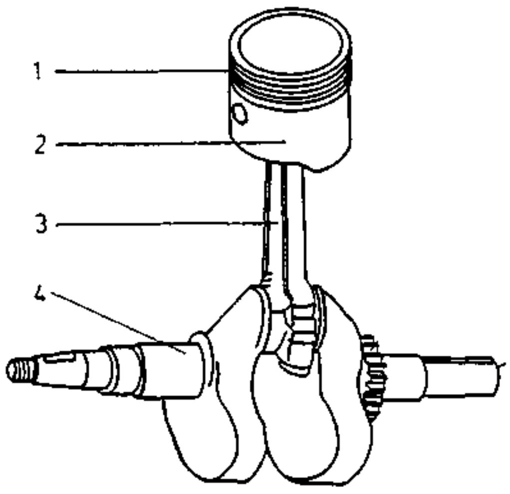
... 4. Connecting rod transfers the force from piston to crankshaft.

... 5. Big-end bearing shells can be inserted to connecting rod with regardless of their pisitions.

... 6. Crankshaft converts reciprocating motion into rotary motion.

... 7. Timing gear of the crankshaft is for setting the ignition timing.

1. Name the parts of the crankshaft mechanism.



1. Piston rings..........
2. Piston................
3. Connecting rod.......
4. Crankshaft..........

2. Make a cross in front of the correct statements

... 1. The part of the piston that bears the impact force mostly is the piston skirt.

.X. 2. Piston rings act as a series of seals to prevent leakage of combustion gases.

... 3. Compression rings and oil control ring are exchangeable.

.X. 4. Connecting rod transfers the force from piston to crankshaft.

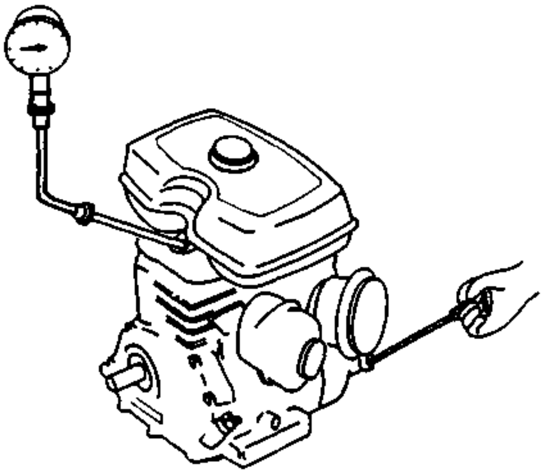
... 5. Big-end bearing shells can be inserted to connecting rod with regardless of their pisitions.

X. 6. Crankshaft converts reciprocating motion into rotary motion.

... 7. Timing gear of the crankshaft is for setting the ignition timing.

5.2 Repair and maintenance

5.2.1 Testing the compression



Sequence of operations:

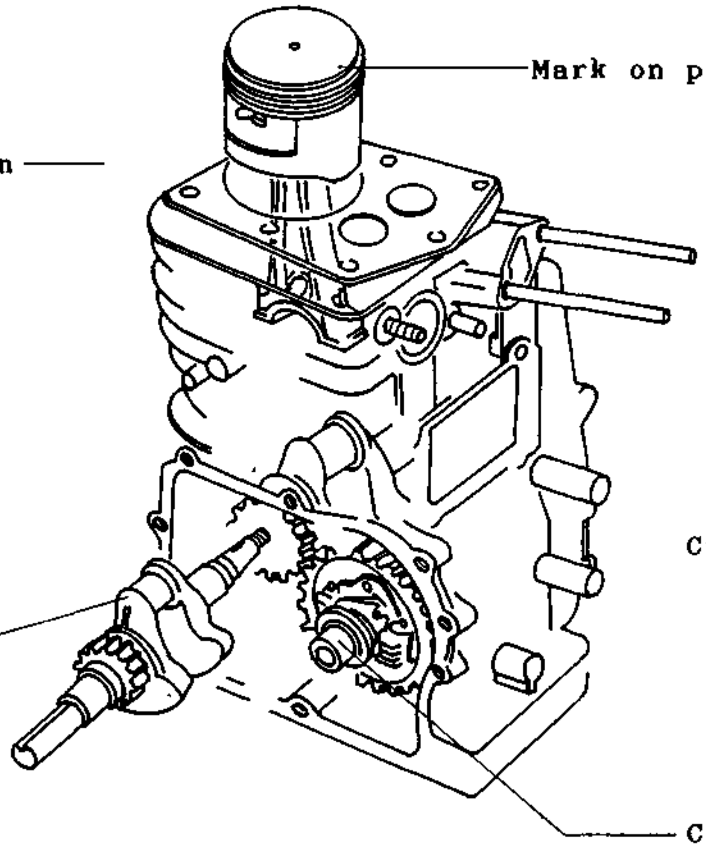
- Remove the spark plug.
- Install the pressure gauge in the spark plug hole.
- Pull the string to crank the engine hardly for several times, and read the pressure.

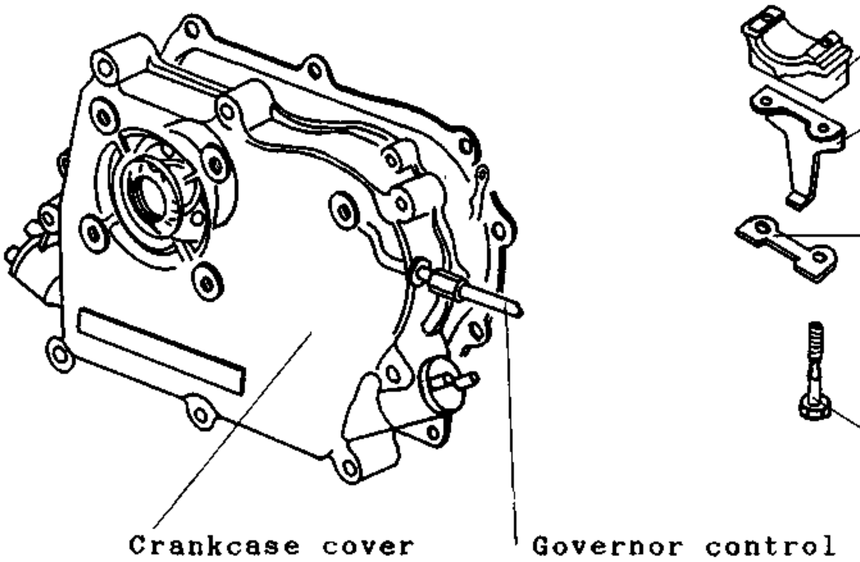
Standard minimum compression = 6 bar

Caution:

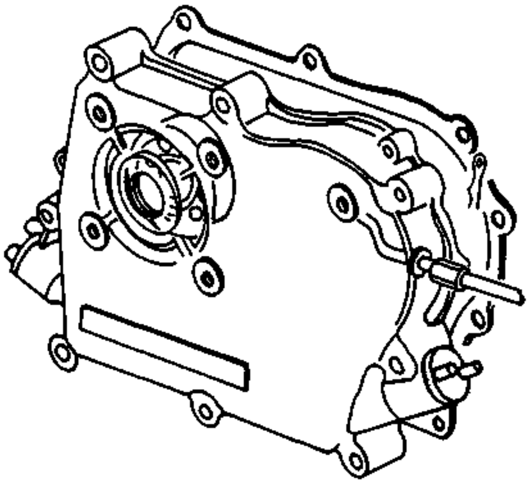
- During spark plug removal, be aware of dust falling into the cylinder.
- Pressure gauge should be cleaned before installing.

5.2.1 Dismantling-Reassembling components of engine





a) Crankcase cover

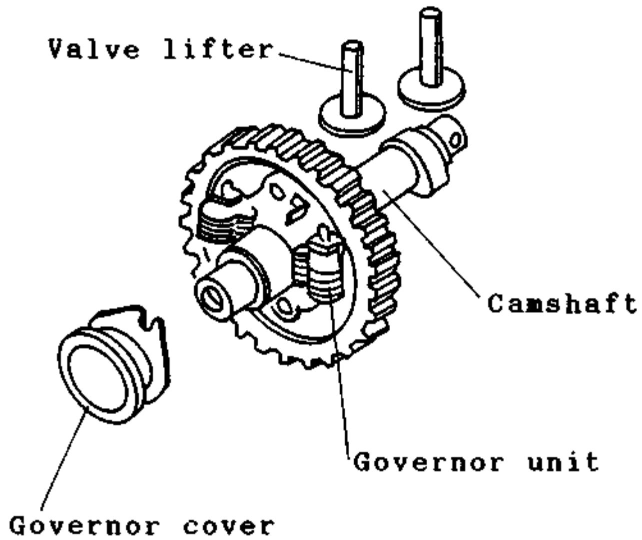


Removal:

1. Remove key on crankshaft if any.
2. Remove all screws of crankcase cover.
3. Tap the crankcase cover around gently with a plastic head hamer.
4. Remove the crankcase cover slowly.

Caution: Gasket may tear off and seal be damaged.

b) Camshaft

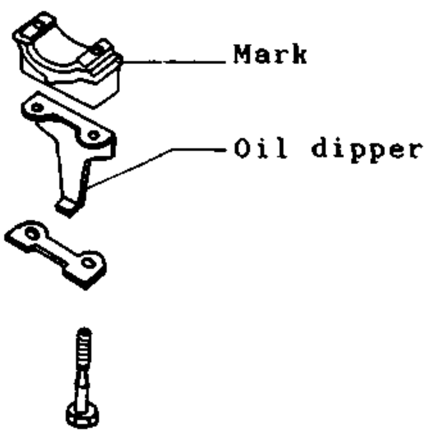


Removal:

1. Turn the crankshaft until the piston is at the top of the compression stroke.
2. Pull the camshaft assembly out.
3. Remove the valve lifters.

Remark: Governor unit is fixed to the camshaft assembly.

c) Connecting-rod cap



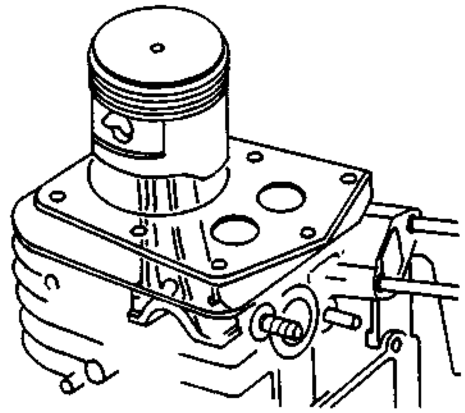
1. Make a mark onto the connecting-rod cap to prevent mixing up.
2. Unscrew the connecting rod bolts after flatten the cap washer.

Caution: position of oil dipper

3. Remove the connecting rod and cap.

Standard torque	9 - 11 Nm

d) Piston unit



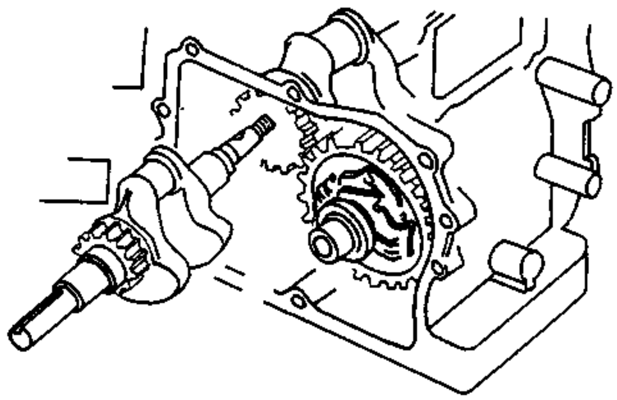
Removal:

Push the piston assembly upward

Reassemble:

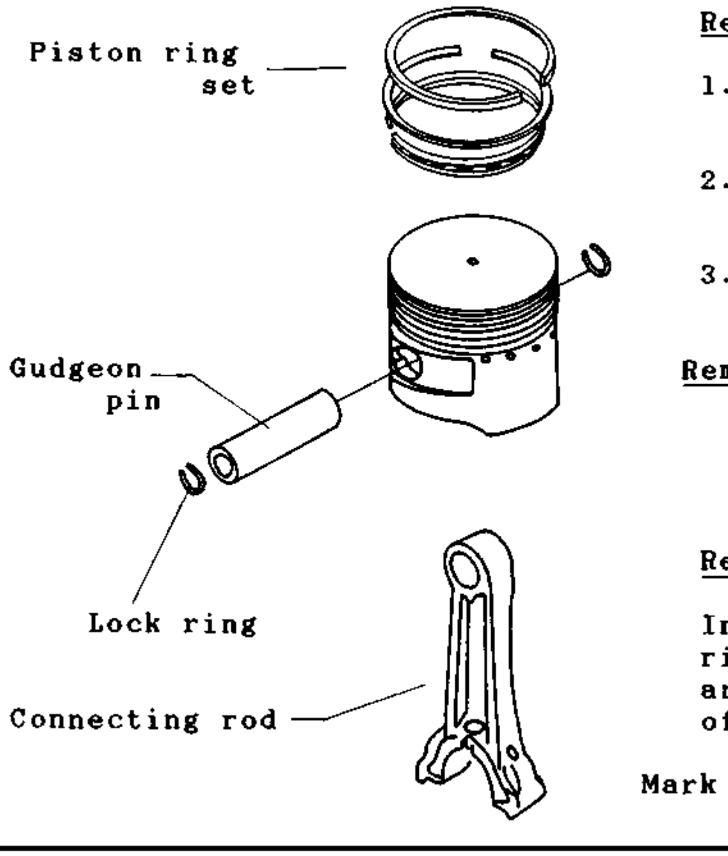
The arrow mark must be directed toward the valves.

e) Crankshaft unit



Caution: Do not drop the crankshaft.

f) Piston rings and gudgeon pin



Removal:

1. Remove piston rings with a special tool.
2. Take out one of the loc ring.
3. Push out the gudgeon pin by hand or with hammer.

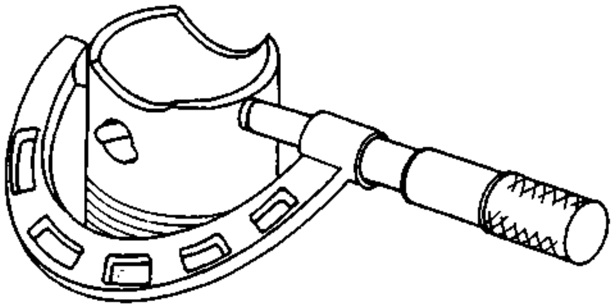
Remark: Remove piston rings before the gudgeon pin, otherwise, piston ring may brake

Reassembling:

Install piston Gudgeon pin rings in correct order and arrange their ends at 120 offset.

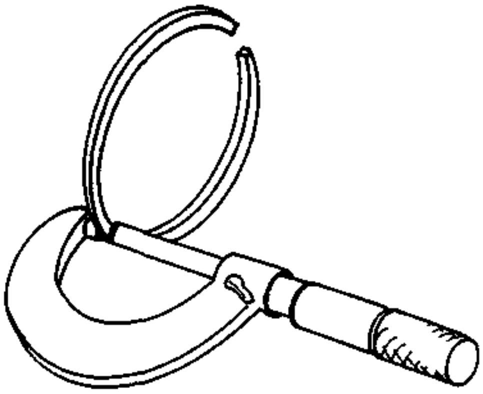
5.2.3 Inspecting the piston and piston rings

a) Measure diameter of the piston skirt



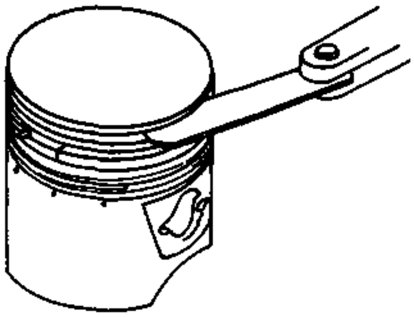
Model	Nom. size	Limited size
G150	64 mm	68.88 mm
G200	67 mm	66.88 mm

b) Measure thickness of compression rings and oil control ring



Nominal size	Limited size
Top compression ring 2 mm	1.87 mm
Second compr. ring 2mm	1.87 mm
Oil control ring 2mm	2.87 mm

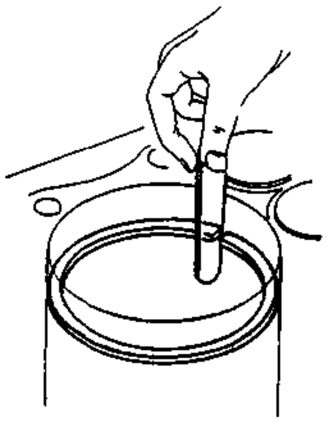
c) Measure side clearance of piston ring



All piston rings must be installed correctly before measuring.

Nominal size	Limited size
all rings 0.01-0.05 mm	0.15 mm

d) Check piston ring end gaps with feeler gauge

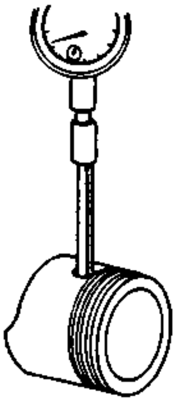


Insert all piston rings into the cylinder before measuring.

Nominal size	Limited size
all rings 0.2-0.4 mm	1 mm

5.2.4 Checking gudgeon pin and gudgeon-pin hole

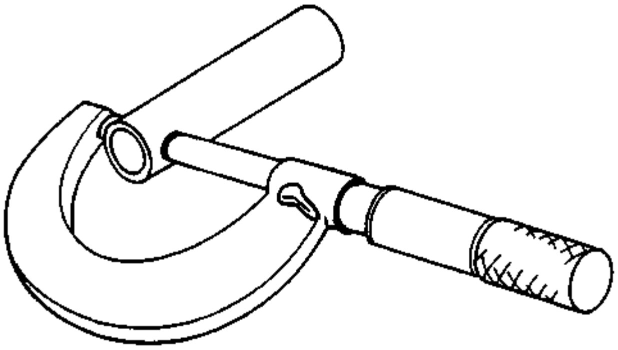
a) Check gudgeon-pin hole



Inside micrometer

Nominal size	Limited size
15 mm	15.04 mm

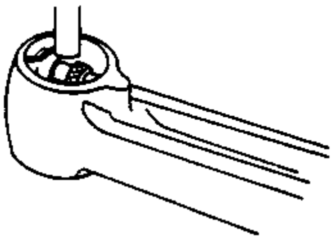
b) Measure diameter of the gudgeon pin



Nominal size	Limited size
15 mm	14.954 mm

c) Measure bore of the small-end connecting rod

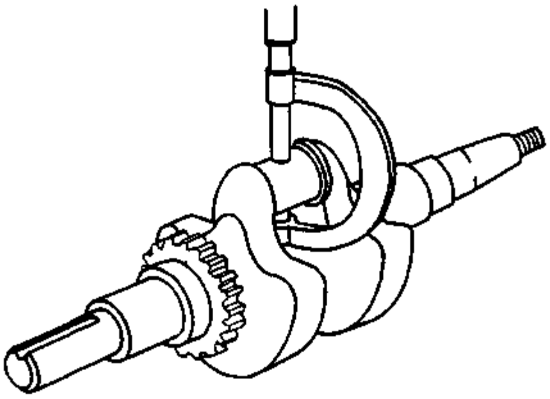
Inside micrometer



Nominal size	Limited size
15 mm	15.07 mm

5.2.5 Checking crankshaft and crankshaft bearings

a) Measure diameter of crankpin journal

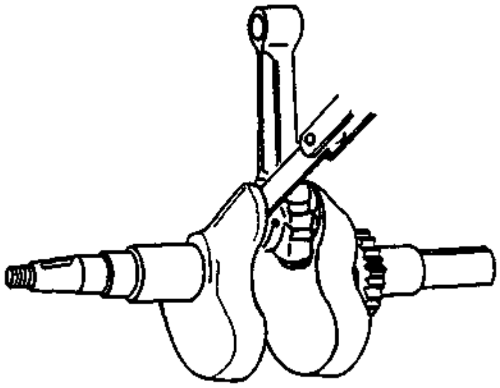


Nominal size	Limited size
26 mm	25.917 mm

b) Inspect surface conditions of both, crankshaft and seals with eyes.

c) Inspect condition of the big-end bearing shells with eyes for any sign of wear.

d) Measure connecting rod side clearence with feeler gauge.

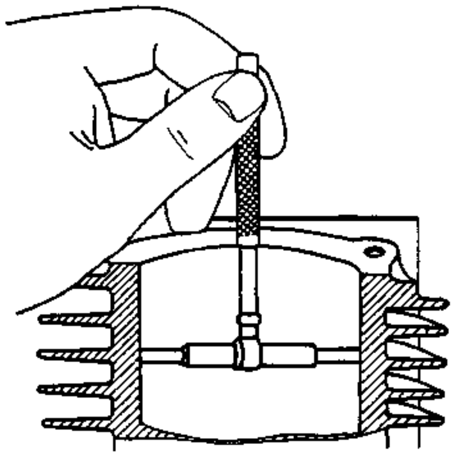


Nominal size	Limited size
0.1-0.8 mm	1.2 mm

Remark: Any parts of beyond the limited size it must be replaced.

5.2.6 Checking the cylinder

Measure diameter of cylinder with inside micrometer.



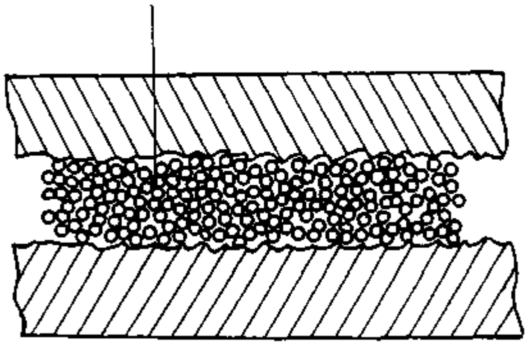
Nominal size		Limited size
G150	64.0 mm	64.165 mm
G200	67.0 mm	67.165 mm

Remark: Measuring should be carried out in several locations

6. Lubrication system

6.1 Tasks of the lubrication system

Lubrication system will supply oil to various moving parts of an engine, in order to ...

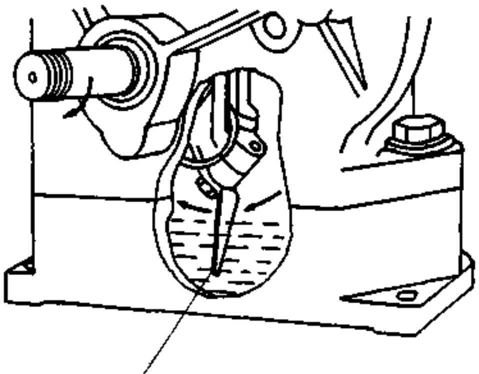


- reduce friction between moving parts,
- dissipate heat from various parts,
- absorb shock load between shaft and bush bearing,
- act like a sealing between piston rings and cylinder,
- act as cleaning agent.

6.2 Splash-type lubrication

This type of lubrication is mostly used in small engines, due to its simple construction and the simplest lubricating method.

6.2.1 Components and their function



- Oil dipper will splash oil from the sump during the downward rotation of the crankshaft, to the cylinder wall and other parts.

Advantage:

- Small number of parts and simple construction

Disadvantage:

- Insufficient lubrication may occur to various part in case there is inadequate amount of oil in the sump.

Complete the statements!

1. Lubrication means ....

2. The tasks of the lubrication systems are:

   1. ....

   2. ....

   3. ....

   4. ....

   5. ....

3. Parts of small engine which need lubrication are ....

   ....

4. Most used lubrication system in small engines is the ..... type,

   because ....

5. Disadvantage of the lubrication system used in small engines;

   ....

   ....

Complete the statements!

1. Lubrication means Supply oil to the moving parts of the engine.

2. The tasks of the lubrication systems are:
   1. reduce friction between moving parts
   2. dissipate heat from various parts
   3. absorb shock load between shaft and bush bearing
   4. act like a sealing between pistonrings and cylinder
   5. act as cleaning agent

3. Parts of small engine which need lubrication are crankshaft mechanism, valve mechanism and cylinder

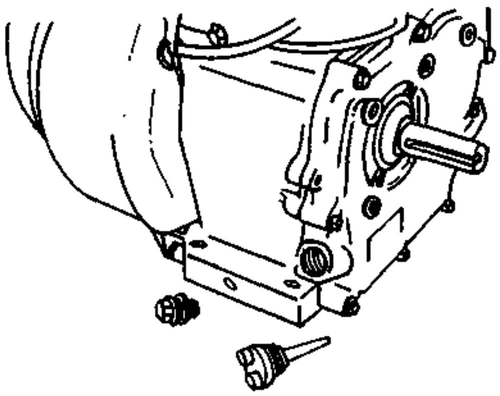
4. Most used lubrication system in small engines is the splash type, because due simple construction.

5. Disadvantage of the lubrication system used in small engines:

   Insufficient lubrication when there is inadequate amount of oil in the sump.

6.3 Repair and maintenance

Inspecting/changing oil:

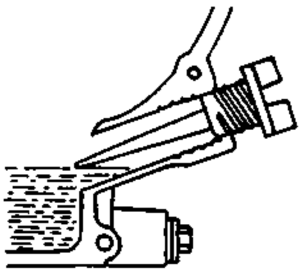


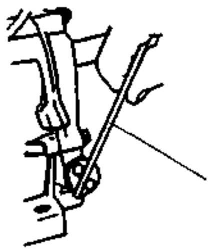
- Unscrew both the drain plug and oil refil screw plug to drain out old oil.
- Screw in the drain plug and refil with new oil upto the specified level.

Capacity of oil sump 0.7 litre

Recommended oil: SAE 2100 W-30

- The engine must be in horizontal position when checking oil level.
- Close the screw plug tightly with the aid of screw driver.





Tools: A set of wrenches

Equipement: Equipement tray, Cloth, Oil, Oil pan

Manufacturer .... Model ....

Oil grade ....

Capacity .... litre

Sequence of operation	Inspection
1. Prepare tools and equipment.	
2. Run the engine for 5 minutes.	
3. Stop the engine and drain oil.	- Condition of oil ....
4. Refil new oil upto the specified level.	- Capacity of oil .... litre - Grade ....
5. Start the engine and observe for oil leakage.	☐ Leakage ☐ No leakage
6. Stop the engine and recheck oil level.	- Oil level ☐ Correct ☐ Incorrect
7. Clean and store tools and equipment.	- Tools ☐ Complete ☐ Incomplete

Note : ....

....

....

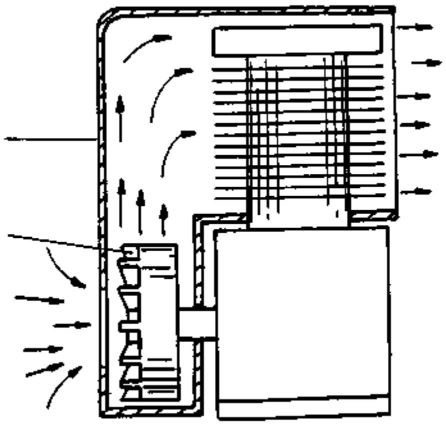
....

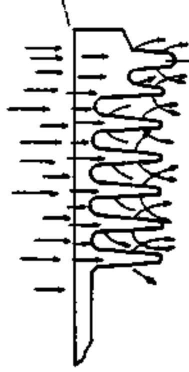
7. Cooling system

Air cooling system....

is the most used system in small engines because it is easy to place, light in weight, has asmall number of parts and low production costs.
Its tasks are:

- to dissipate heat as generated by friction
- to control dissipating heat within certain range of working teperature for efficient engine performance





- The system uses air as a cooling medium to transfer heat from engine to surrounding air which has lower temperature.
- For engine with air cooling system, the exterior of cylinder will be in forms of fins and spaces which increases area of air contact.
- To be of efficient the blower cover is used to direct air blowing.
- As the engine runs, the blower blade attached on the flywheel will suck in cool air and blow it along the cover to cool down the cylinder wall.

Complete the statements!

1. The tasks of the cooling system are:

   1. ....

   2. ....

2. Small gasoline engines generally use .... cooling system, because ....

3. Small gasoline engines generally have their cylinder head and cylinder block made in the forms of .... This is for ....

4. Components of cooling system of most small gasoline engines consist of ....

5. Blower cover is used for ....

Complete the statements!

1. The tasks of the cooling system are:
   1. To dissipate heat as generated by friction.......
   2. To control temperature within a certain range...

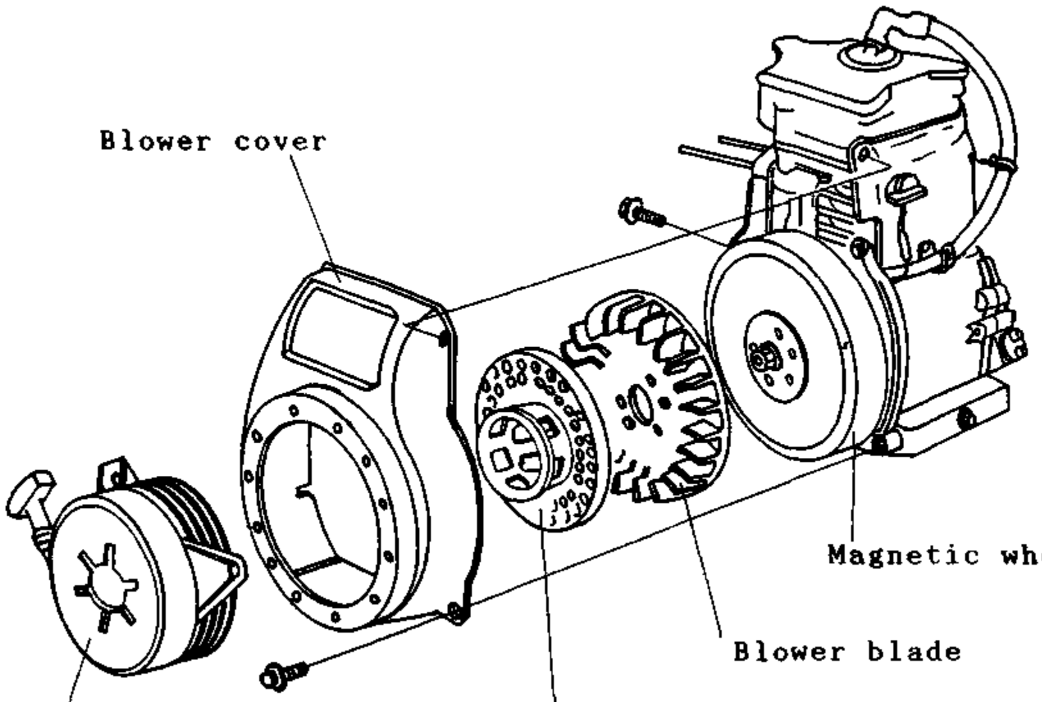
2. Small gasoline engines generally use .air.... cooling system, because it is easy to place, light in weight, has a small number of parts and low production costs.

3. Small gasoline engines generally have their cylinder head and cylinder block made in the forms of ..fins and spaces..... This is for increasing the area of air contact.....

4. Components of cooling system of most small gasoline engines consist of . lover,. lower-cover and fins..............

5. Blower cover is used ~~for~~ to guide the air...............

7.1 Repair and maintenance



- The starting unit must be cleaned before assembling the blower cover.

- The blower blade must be fixed to the magnetic wheel at the correct position which is guided by the pilot pin of the magnetic wheel. Be aware of cracking the blower blade.

Tools: A set of wrenches

Equipement: Tray, cloth, benzene

Manufacturer.......................... Model ....

Type of cooling system ....

Sequence of operations	Inspection
1. Prepare tools and equipment.	
2. Close fuel valve, disconnect fuel hose and remove fuel tank.	
3. Remove starting unit. Remark: Notice the position of starting unit.	
4. Remove blower cover.	- Condition of blower cover ☐ Normal ☐ Damaged
5. Remove starting pulley. Remark: Notice the position of starting pulley.	
6. Remove blower blade.	- Condition of blower blade ☐ Normal ☐ Damaged
7. Clean blower blade, fins of cylinder head and cylinder block, and blowe cover.	
8. Reassemble those components	
9. Clean and store tools and equipment.	- Tools-equipment ☐ Complete ☐ Incomplete

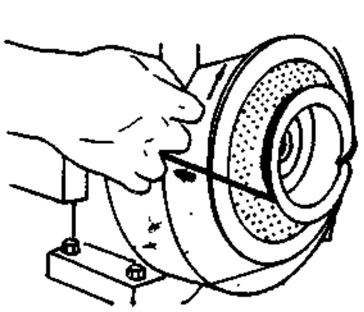
Note : ....

....

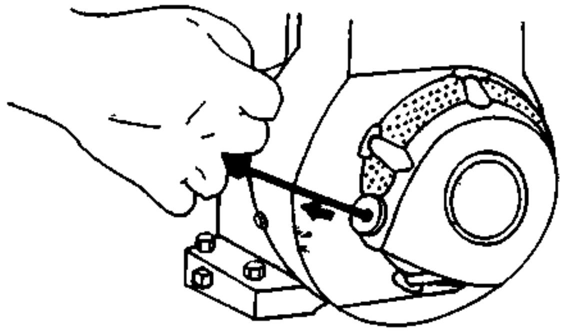
....

8. Starting system

8.1 Types of starting systems



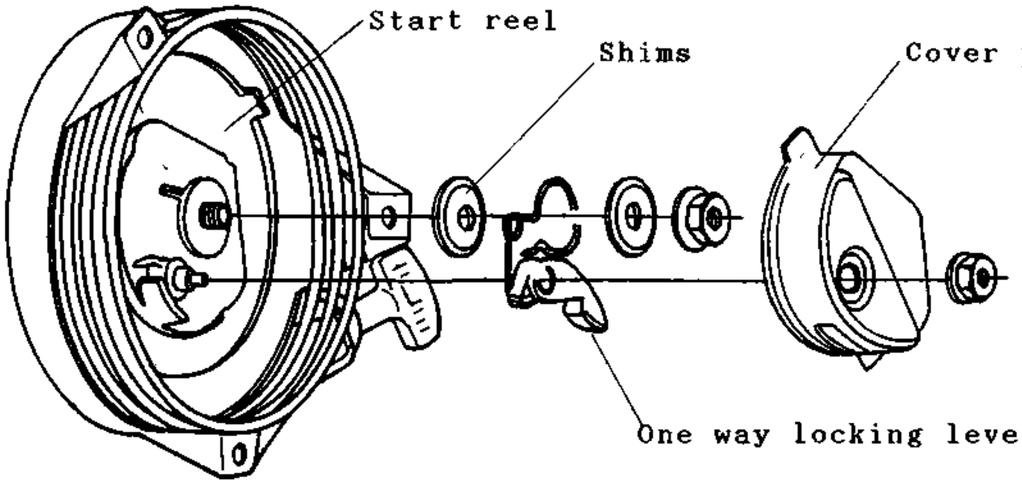
Conventional type



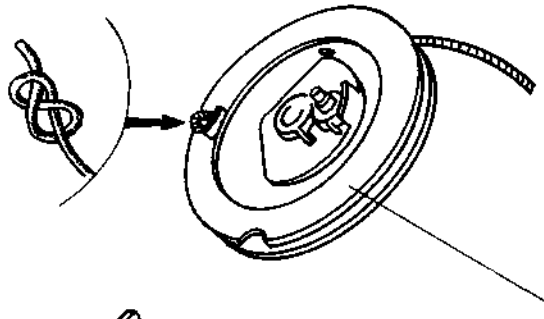
Built in starting unit

8.2 Repair and maintenance

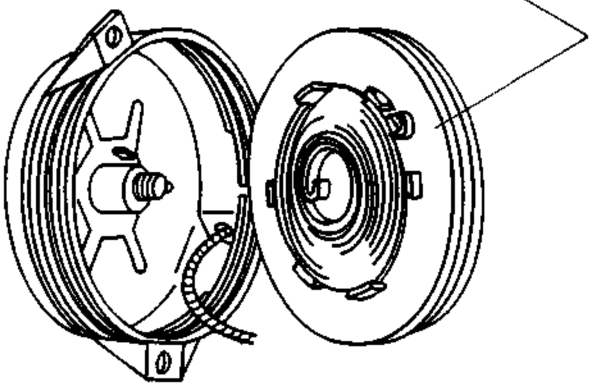
a) Removal and reassemble starting unit



b) Assembling starting string

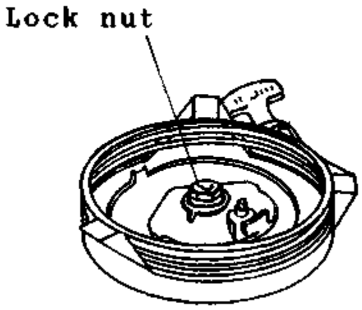


- Thread one end of the string through the hole of the start reel and make a knot.



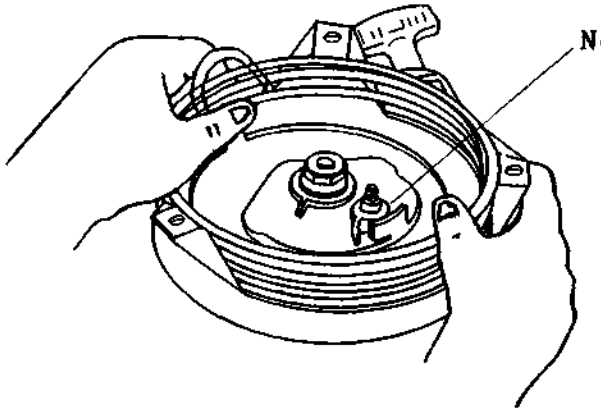
- Wind the string on the start reel (in the direction of spring). Thread the other end of string through the spring housing. Refit the start reel to the spring housing.

Starting spring housing

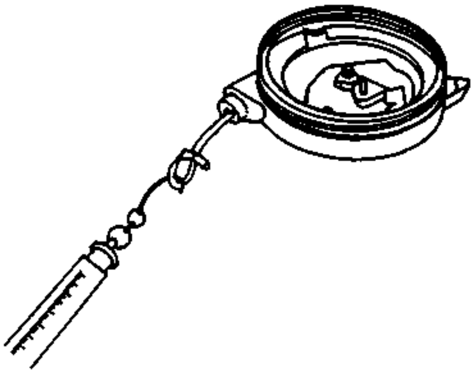


- Reassemble the spring plate and screw on the lack nut. Tighten it to the specified torque.

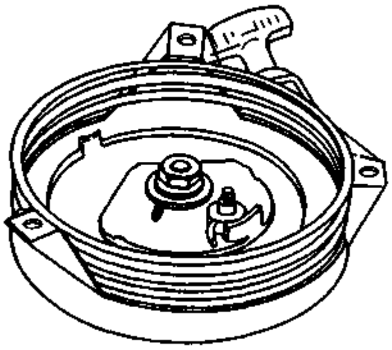
Spring plate



- Turn the start reel for about 1 1/2 turns to wind up the rest of string from the notch of the start reel.



- Check tensioning of the starting string by using a spring scale. The reading should be about 0.6–1.4 kg. Adjustment of tension can be accomplished by tightening or loosening the start reel.



- Refit the handle to the starting string and tie it. Assemble the spring to the ratchet of the start reel. Inspect function of the ratchet.

- Reinstall the start reel cover.

Tools: A set of wrenches

Equipement: Tray, cloth, grease

Manufacturer .... Model ....

Type of starting system ....

Sequence of operations	Inspection
1. Prepare tools and equipment.	
2. Remove starting unit from blower cover.	
3. Dismantle components of starting unit.	- check/repalce parts
4. Clean all parts of the starting unit.	- grease moving parts
5. Reassemble components of the starting unit.	
6. Refit the starting unit	- check performance
7. Inspect its function	
8. Clean and store tools and equipment.	

Note : ....

....

....

....

9. Exhaust system

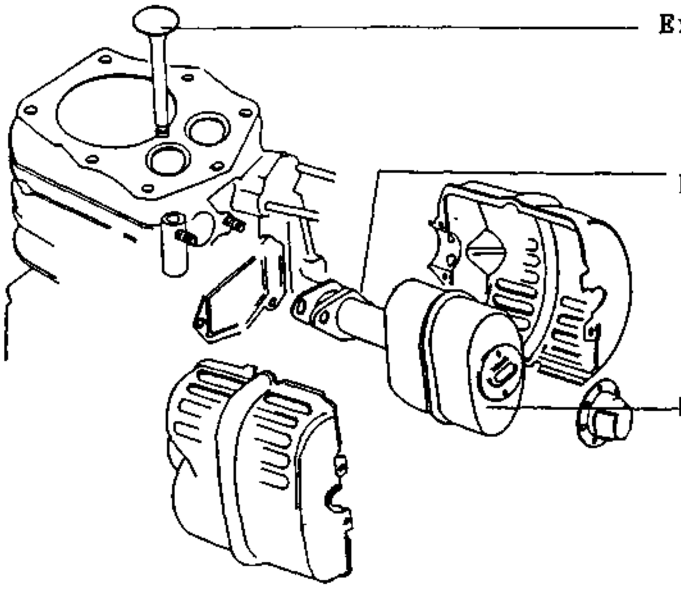
9.1 Purposes of exhaust system

a) To relief exhaust gas from the combustion chamber.

b) To improve engine power.

c) To reduce expanding noise of exhaust gas.

9.2 Components and their function



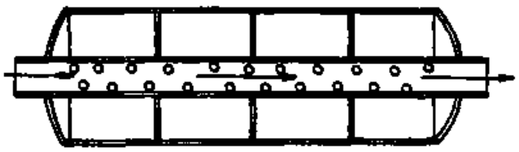
Exhaust valve:
Controles the flow of exhaust gas according to the strokes of the engine.

Exhaust manifold:
Acts as passage for the exhaust gas.

Muffler:
- Reduces noise of the exhaust gas.
- Smoothes the flow of exhaust gas.

There are two kinds of mufflers:

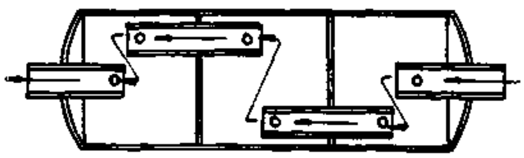
a) Straight-through muffler



The exhaust gas flows like a stream both inside and outside the muffler, causing turbulence.

Hard flow of exhaust gas will reduce engine power.

b) Reverse-flow muffler



The exhaust gas will expand inside each compartment of the muffler as it flows. This wil minimize the level of noise considerably when it comes out to the atmosphere.

Turbulence of exhaust gas is reduced, thus, noise is also reduced.

Complete the statements!

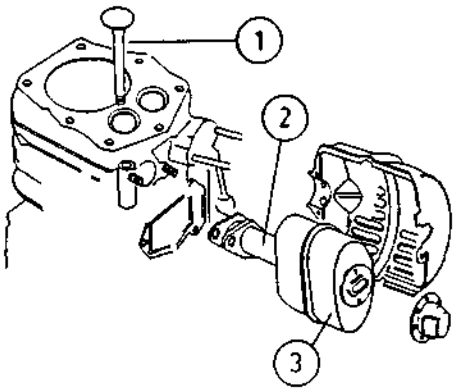
1. Purposes of exhaust system are :

   a) ....

   b) ....

   c) ....

2. Name various parts of the exhaust system.



1. ....
2. ....
3. ....

3. The muflfer can reduce noise of exhaust gas, due to ....

   ....

4. There are .... muffler-designs, which are ....

   ....

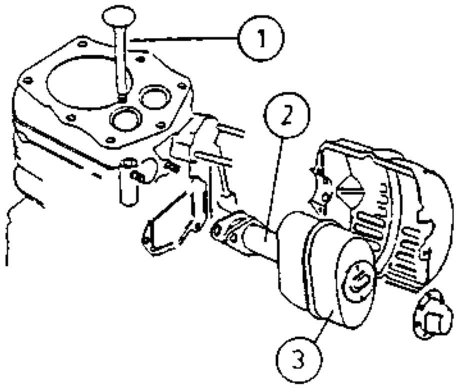
5. Small gasoline engines generally use the ....muffler-type

   because ....

Complete the statements!

1. Purposes of exhaust system are :
   a) To relief exhaust gas from the combustion chambre
   b) To improove engine power
   c) To reduce expanding noise of exhaust gas

2. Name various parts of the exhaust system.



1. Exhaust valve
2. Exhaust manifold
3. Muffler

3. The muflfer can reduce noise of exhaust gas, due to turbulence and expansion

4. There are 2 muffler-designs, which are Straight-through and Reverse-flow muffler.

5. Small gasoline engines generally use the Reverse muffler-type, because noise is reduced and engine power improoved.

Foreword

Children come to school with rich knowledge about their environment. They gained this knowledge through observation and imitation. For example, they know how to construct toy cars by perfectly applying the physical laws. They also know how to carry a heavy load on the head and how to lift a heavy stone. They can do all this without studying Physics. Through such learning by doing they absorb easily the knowledge needed to solve everyday problems.

Science and Physics for that matter is borne in the nature around us. Scientists observe, explain and formulate the results into abstract laws for further investigation of other problems. We are all born with the ability to be investigators, however, we have to learn how to do it. This learning should start with phenomena the child is familiar with and not with abstract definitions what science is.

The rich practical knowledge of the students can be used as a springboard for teaching science not only to beginners by getting the pupils to have a critical look at and ask analytical questions about their environment. This requires a practical approach in teaching. By this approach students learn to be investigators by finding the applied principles in the things around them. Students should learn to see the daily environment with the eyes of an analytical scientist. This makes them also aware of the resources to be found in their country.

Physics as a natural science deals with the investigation of matter. However, the investigation of matter can be done by using a practical approach only.

Children are eager to talk or ask questions about things they are familiar with rather than about abstract theoretical knowledge taken from books.

Furthermore, the teaching of science with locally available materials makes learning by doing accessible, even when conditions for teaching are not conducive.

This is the message of this book. It shows that the most common materials are often sufficient for stimulating experimental lessons. Experimenting is a difficult job for a less experienced teacher. However it can also be fun for him. Most of the experiments described in this book can be performed in a very short time and without long sessions of preparation.

The described experiments are not only for school purposes, but also for other people interested in this subject.

It is my sincere hope that this book will contribute to the building up of a broad line of people in our country who are interested in learning more about Physics.

LET US ENJOY PHYSICS BY DOING
L.K. MSAKI
Acting Commissioner for Education

Preface

This source book is addressed to people who are concerned with teaching Science at the Junior Secondary School level. This includes Teachers, Teacher Training College Tutors and University Lecturers. Nevertheless, the book can be useful to Science Club Masters and Students who want to experiment on their own. The main audience are the teachers and tutors who work in inadequate teaching and learning conditions trying to encourage students to develop capabilities to master and use science in their daily life.

This source book contains therefore experiments and activities which can be performed in any classroom and in a very short time with a few low or even no cost materials. Moreover, these practicals do not require a long preparation time.

Such easy to carry out experiments for and through beginners have a long standing tradition in the history of teaching science. They are called *handy experiments* because they can be performed "by hands" only without any difficulties.

You will find in this source book ideas and suggestions which are not normally found in textbooks. We assume that the teachers know most of the traditional experiments which are found in the usual textbooks. Therefore there is no need to repeat them here. The reader will welcome the ideas on how to modernize his teaching since this book provides him not only with the "how to do it" but also with the "what to do" information.

Going through this book, the reader will find that many traditional experiments can be performed as handy experiments too. They are more illustrative and more appealing to students than "black box experiments" with sophisticated equipment. They encourage the students' creativity to invent other experiments and stimulate their natural curiosity to understand the physics behind the experiments.

The suggestions of this source book are stimulants to modern teaching and learning, i.e. *teaching and learning by doing.* They should be supplemented with the teachers' own ideas, students' ideas and ideas from other sources. This source book is a result of a workshop which drew participants from Uganda, Kenya, Germany and Tanzania.

We acknowledge with gratitude the professional, technical and financial assistance of all who have contributed to publish this source book particularly to the Ministry of Culture of the State of Hessen (Germany) and the Goethe-Institute for sponsoring the workshop.

Last but not least, we thank Morogoro Secondary School for hosting the workshop from which the source book resulted.

A.S. NDEKI
Chairman of the Executive Committee
Mzumbe Book Project

Contents

How to Use This Book

This source book may be used in connection with the series of textbooks called "Enjoy Physics", volume I and II, produced by the same publishers, the MZUMBE BOOK PROJECT. These books have been written with great emphasis on the use of materials which can easily be obtained from our environment. However, this source book may be also used without these textbooks.

Many students think that Physics is a very tough subject and they actually fear it. If you as a Physics teacher use the approach suggested in this source book, you can be quite sure that your students will lose their fear. They will become interested and creative in Physics. They will like and even enjoy your Physics lessons. This way they will be able to develop those talents which are needed for real development to take place.

Being a Physics teacher, this book will help you to master the simple techniques described in order to be able to make simple apparatus, models and other teaching aids. After this you may want to transfer the skills to your pupils so that they may help you in making the required items.

The experiments described in this book are simple and can be carried out even in the absence of a Physics laboratory. The Physics kit described in the appendix is meant to be self-contained. However, first you may select only a few experiments from each section. Therefore, we have listed the materials needed for each single experiment in the appendix. Of course, each kit needs all the *materials* listed on p.111 and these were omitted in the list of materials of the various experiments (see p.112).

Perhaps your students might become interested to prepare the materials for further experiments described in this source book. Thus, after some time you might be able to carry out most of the experiments suggested.

For heating purposes an improved, sootless kerosene burner has been developed which any "fundi", who makes normal "vibatari", is able to produce, see p. 109.

Being a Student, this book may also help you in the designing and carrying out of physics projects. If you produce your own Physics kit, this will provide you with a kind of minilab at home.

Using it, you can train yourself on the practical and investigating aspects of Physics. Therefore, you will enjoy Physics and develop your talents in this subject. This way, Physics may contribute to self-substained development by improving the daily life of the people.

An experiment has several important phases which we have usually outlined in this source book. The symbols are as follows:

P: The *procedure:* what and how to perform the experiment and/or how to build the apparatus.

Q: *Questions* which the investigator may ask himself or a teacher may ask his students in order to guide them to the proper observations and explanations.

At this stage the dedicated investigator or student should stop reading and try to answer the questions himself after carrying out the experiment. If he/she has the self-discipline needed to do this, he/she will certainly gain a lot.

O: The *observations* are described here. So you may check *after* you have made your own observations if you did not miss an important point.

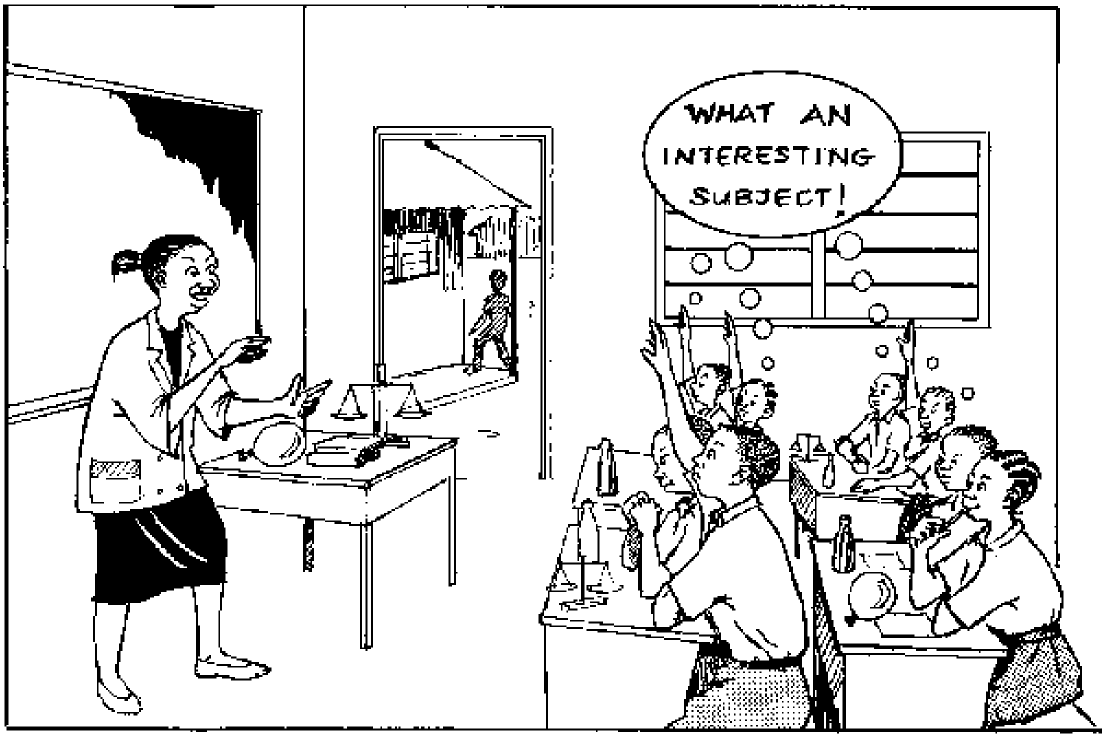
E: The *explanation* of the observations is outlined here. Physics always aims for explaining observations. Only if he can explain his observation, the scientist usually will be able to predict the outcome of other experiments. This leads to the knowledge of the laws of physics. Then he/she may also become creative enough to apply a certain physical law in a machine or an apparatus which he/she invents. This way development takes place.

A: Some *applications* of the phenomenon under investigation in the respective experiment may be given here. Thus, the interested student will easily recognise and appreciate the close relationship between Physics and Technology. The latter cannot exist without the former.

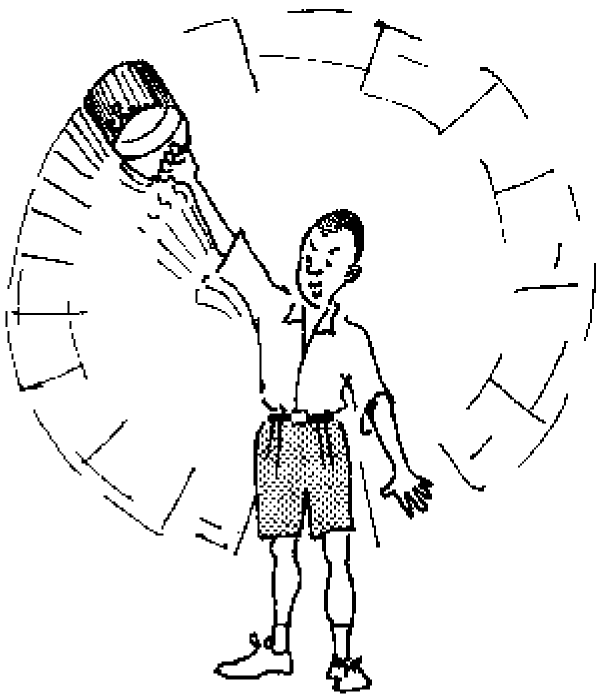
We warmly welcome your criticism, suggestions and opinions about this book. Please, fill in the questionnaire at the end of this volume and send it to us. Please write to us to improve future editions of this book:

Team of the source book and "Enjoy Physics"

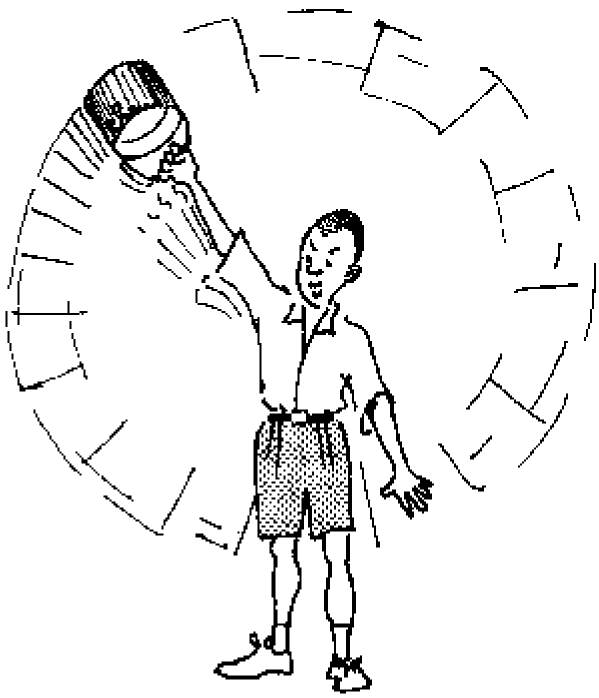
Mzumbe Book Project
P.O. Box 19,
Mzumbe - Morogoro
Tanzania.



1. What is Physics?



1.1 What is Physics?



A bucket of water is sufficient to start investigating the effect of centripetal forces. Fill the bucket with various quantities of water and you will learn even more by doing. Increase the number of revolutions of the bucket.

Physics must not be a boring, tough subject, just good for exams and to be understood by a few "experts" (nly. Physics should not happen in books only. It is everywhere where things are. The teaching of science without experiments is just like a ngoma without dancers.

Pupils learn more and better by doing. Stimulate them to investigate their environment through easy to carry out experiments. Ask the pupils to make a list of physical phenomena which can be observed in their environment. Let the pupils enjoy physics. This sourcebook shows how this can be achieved.

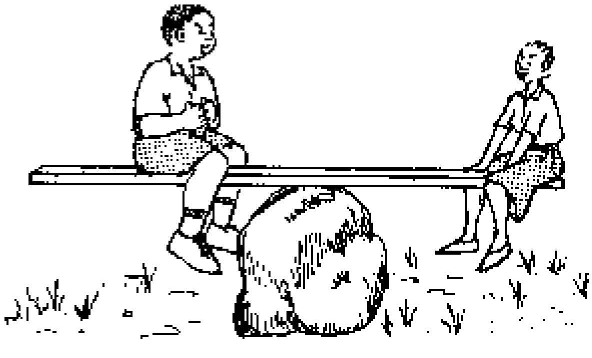
1.2 Laboratory Techniques

Imagine you would buy different kinds and different quantities of meat. The butcher will have to weigh and then calculate the price for each kind of meat and produce the total bill. Thus, measuring and the collection of data happen nearly everyday in our life.

The tailor takes the measurements of his customer and of the material needed for a suit. The milkman measures the volume of the milk sold. The technician measures with a calliper the diameter of a screw and even at school the time of each period is measured. Especially in engineering precise measurements are indispensable.

Therefore physics as a subject has to introduce even beginners to the principles of measuring and data collection. "I have no measuring instruments in my school," you may say. Really? Let the students enjoy physics starting with measurements which are easy to carry out and the construction of measuring instruments. For a lot of hints see chapter 2.

1.3 Basic Mechanics

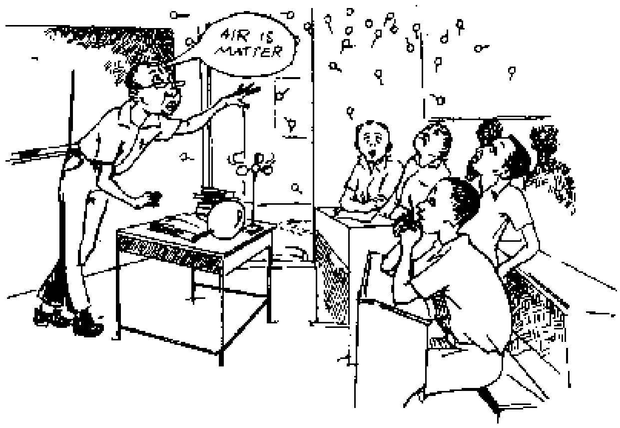


Have you observed children balancing a plank like a seesaw? They know how a big and a small child can balance although they are of different weight.

Usually they do not know what a fulcrum, a load distance and a moment of force is. However, such basic mechanics dominate an essential part of our daily life. We encounter motion, friction, inertia, work and power almost every day. We also learn in a practical way about density, pressure of fluids or gases. Work, energy, power and other physical phenomena look very abstract in books but happen every day. Also the movement of earth, moon and the planets which determines the lengths of our days, months and years, has to do with basic mechanics such as motion, mass attraction and centripetal forces.

Ask the students to discuss where such basic mechanics phenomena can be observed. Discussing only? No! There are plenty of meaningful experiments. For these, see chapter 3.

1.4 Matter

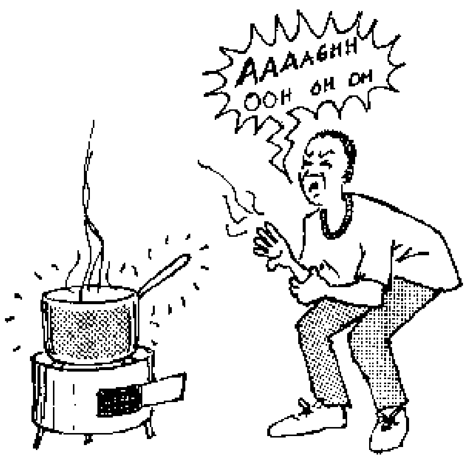


A chair can be touched. Water in a bucket also. But air? Can you imagine that while you are reading these lines your nose is punched more than 100 billion times by air molecules?

The environment around us, whether in solid, liquid or gaseous state is made up of billions of tiny particles which are either molecules or atoms. These particles which constitute air are so tiny, that we cannot see them even by a powerful microscope. However, the students can be given an idea of the particle structure of matter by indirect evidence.

Discuss with the students from which evidence we can conclude the existence of particles and ask them to write an essay about this. You may think, there are no experiments possible about states of matter, diffusion, molecular forces and other properties of matter? Failed! For details see chapter 4.

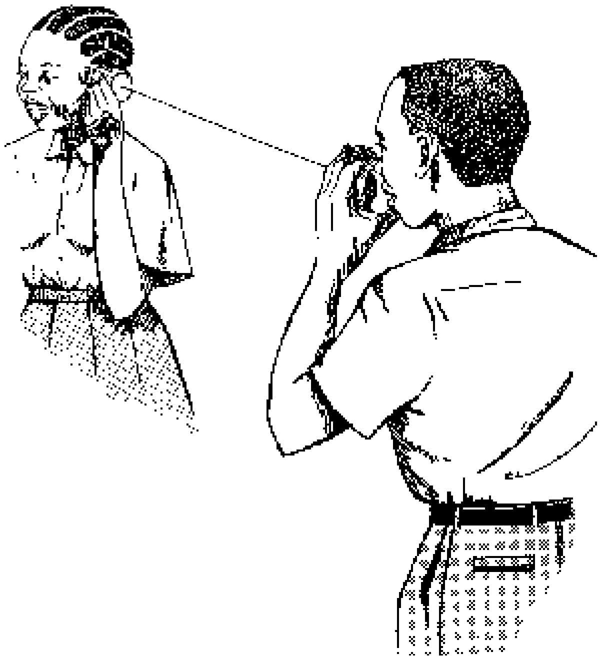
1.5 Thermal Physics



Would you ever touch the handle of a hot pan? Not me. Would you put margarine just aside of the pot? Not me. Would you hold your hand right above the hot water? Not me. This is because, we know a lot about thermal physics by daily experience. But we do not always relate this knowledge with what we learn at school about heat conduction, heat radiation or heat convection as is the case in the examples mentioned above.

Thermal physics has also to do with thermal energy and the measurement of temperatures, with calorimetry, change of states, expansion, etc. Ask the students to talk about everyday thermal phenomena and to write about these. Why should we teach this topic by talk and chalk only, if there are illustrative experiments which do not require a lot of equipment and which are not time consuming in their preparation and performance? See chapter 5.

1.6 Wave Motion



Communication through spoken words has to do with the transport of waves. Telephone and radio are well known. But do we think about waves when we hear a music band, when a craw is croaking or when children are playing with a string telephone?

However, children know how to construct a good string telephone. Two tin cans are needed, also a string which is tied with a knot in a hole at each can. The string should be stretched and not be slack. It should not be heavy. All this is everyday knowledge about the transport of sound waves.

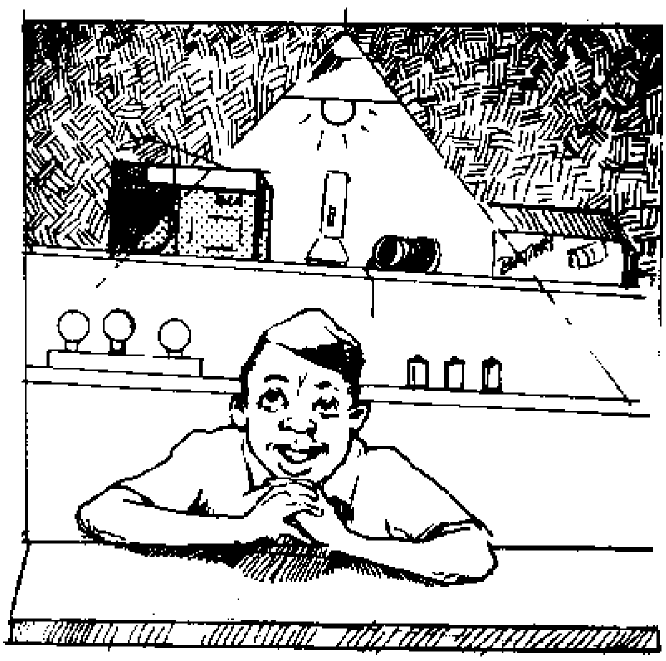
But teaching about waves does not mean only sound waves. We already have mentioned electromagnetic waves. Water waves we notice in a water puddle as well as in a cup of tea.

Produce waves in physics not only by talking. Meaningful and simple experiments are possible on many themes of this topic. No time? Hand experiments are always brief, illustrative and can be carried out with everyday things. Get ideas by reading chapter 6.

1.7 Geometrical Optics

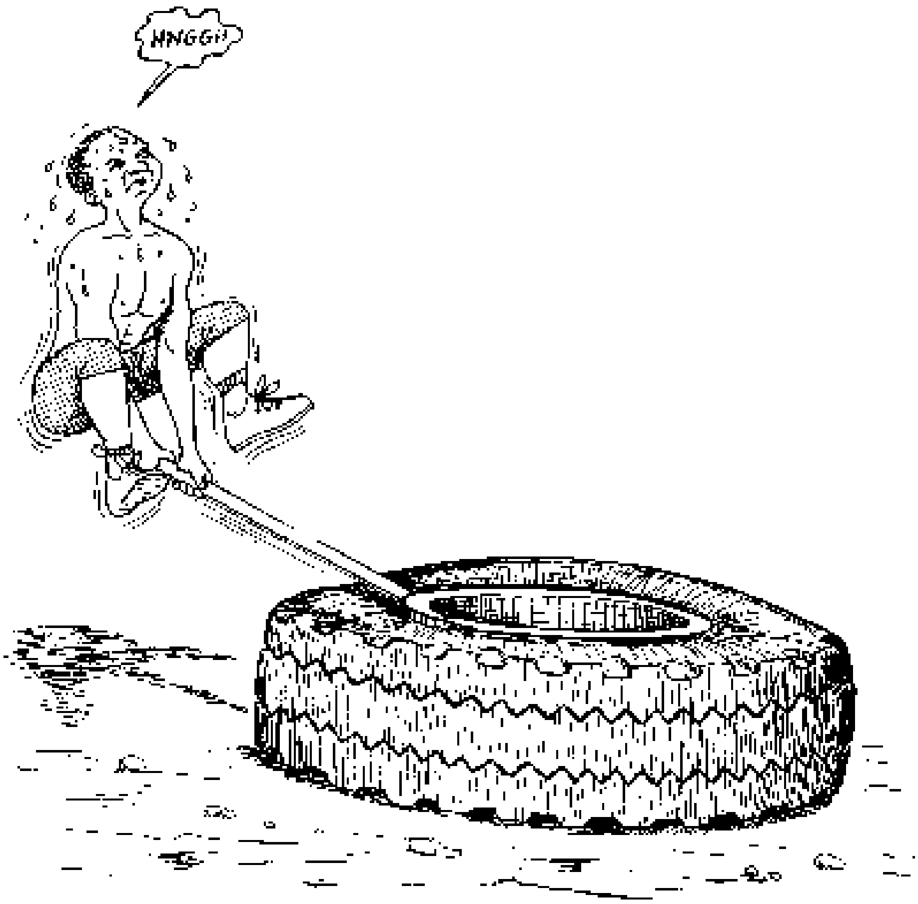
When we hear about optics, the optician, eye glasses and lenses come into our mind. But that is not all what optics is about. Optics is also about the reflection of an image in a mirror or in a water puddle. The water surface is like a mirror. The image to be seen is inverted and it seems to be as far behind the water surface as the object is in front of it. Perhaps there are no curved mirrors at your school to teach about concave and convex mirrors. No problem. Take a polished spherical spoon and you will be able to perform an interesting lesson. If you have no equipment for an introduction to the principles of how lenses work, this is no problem too. Take a fused and water filled transparent bulb and you can be sure about the admiration of your students about your creativity in teaching physics by doing. Certainly not all themes can be taught by simple qualitative hand experiments only. But you may be astonished to see how many there are for eye catching demonstrations. For details, see chapter 7.

1.8 Electricity and Magnetism



Effects of electricity can be observed nowadays nearly everywhere. A light bulb lights the room, a radio enchants our ears and a torch helps to find our way in the darkness and last but not least we do owe a cool soft drink to a refrigerator. The understanding on how electric apparatus work is essential nowadays.

But electricity does not only mean a current flows in a circuit. It means also static electricity or a lightning during a thunderstorm. The topic electricity is closely related to magnetism. Without magnets electric motors would not work. Loudspeakers work with magnets and even a simple bicycle dynamo has one. In harbours you can see how "attractive" magnets can be to lift heavy loads. Do you think that the teaching of electricity by doing is difficult, needs a lot of equipment and is even dangerous? Brief and attention attracting experiments wanted? Only look on chapter 8.

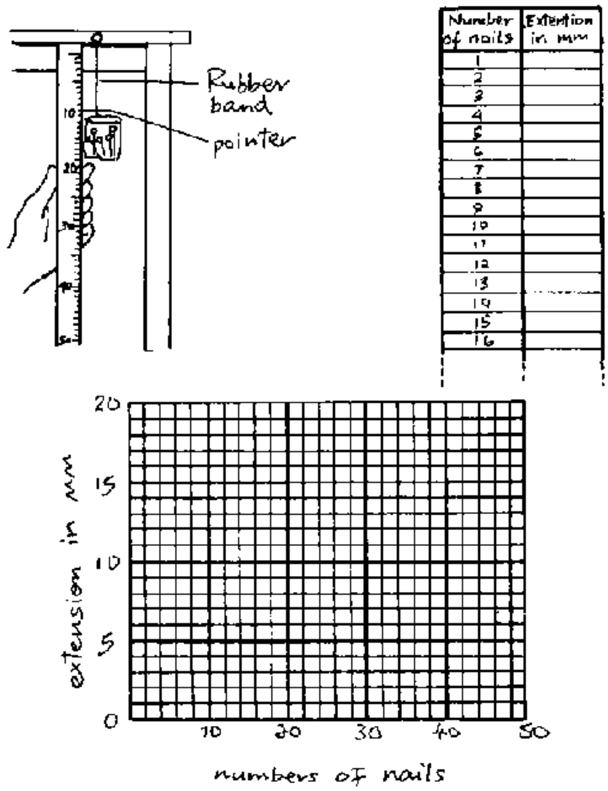


2. Laboratory Techniques

2.1 Collection of Data

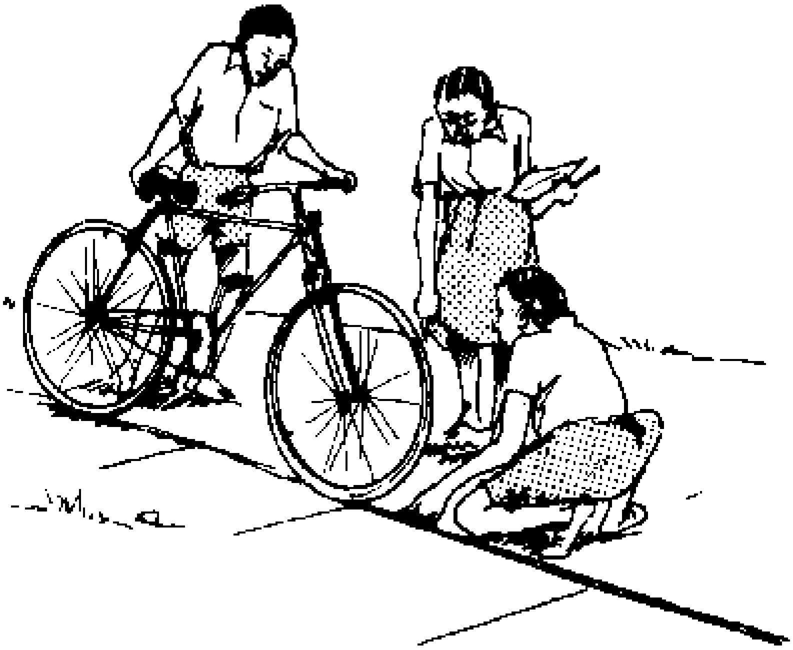
Man's progress is due, in large part, to his ability to measure and hence collect data with greater and greater precision. Young pupils should learn, generally, about how to obtain data by carrying out simple experiments. They should be introduced to the basic measurements of mass, distance and time. They should be trained in recording and in graphical analysis of data.

2.1.1 Data on Weighing



A rubber band is fixed at one end and is attached both to a wire hook at the other end (which serves as a pointer) and a small plastic bag (e.g. for wrapping groundnuts). Fill the bag with nails in succesive small numbers (which you count) or other objects of similar weights. Let the pupils measure the extension of the rubber band, each time they add more nails, record the readings and ask them to draw a graph (see the figure).

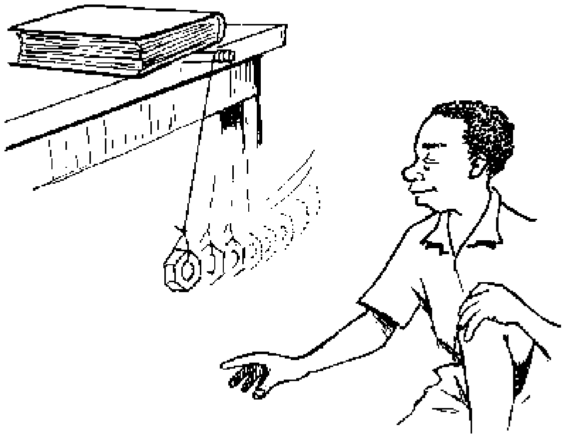
2.1.2 Data on Distance



TURNS	DISTANCE

Make a mark on the tyre of a bicycle or a car at a point just next to the surface of the pavement. Turn the tyre to move straight forward along the pavement and measure and record the length of one turn. This is the distance covered when the mark is about to make contact with the pavement again. Let the pupils repeat the experiment several times in each case with the tyre allowed to roll a few more turns. The distance is calculated in each case and a graph is drawn.

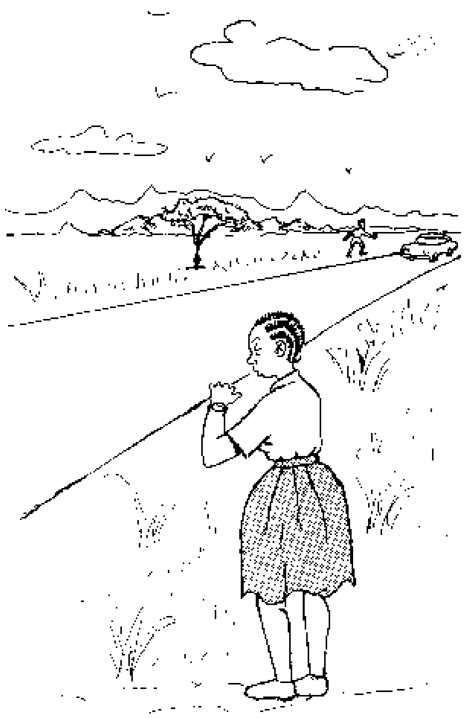
2.1.3 Data on Time



LENGTH OF PENDULUM	SWINGS		
	5 CM	10 CM	15 CM
50 cm			
75 cm			
100 CM			

Fix a thin thread somewhat off the edge of a table and hang e.g. a nut at a distance of 50 cm on it. You have made a pendulum. Hold the (nut) pendulum and pull it to one side, so that it is horizontally displaced by 5 cm. Start counting the number of oscillations (back and forth) that take place in one minute. Record your result as shown. Repeat the experiment by horizontally displacing the nut by 10 cm and 15 cm consecutively. Try to find out the length of a pendulum which happens to oscillate just 60 times in one minute.

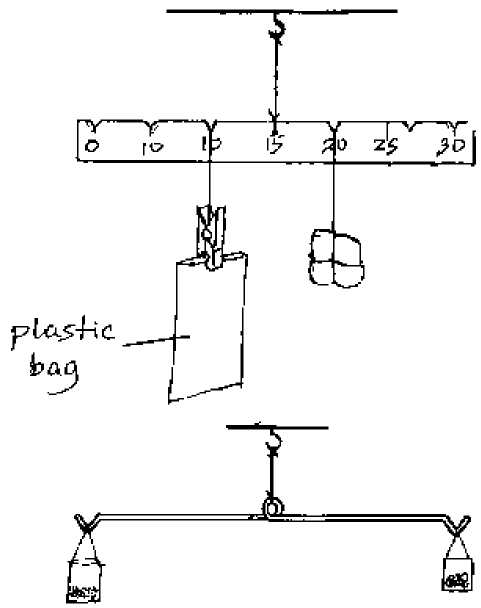
2.1.4 Data on Velocity



Mark a distance of 100 metres along a nearby road or playground. Note the time taken for a car, a bicycle or a sprinter to cover the distance as follows. One pupil waves down his hand as either the car, bicycle or sprinter crosses the 0 metres mark. Another pupil with a watch, starts timing at the same time. A third pupil at the 100 metre mark waves down his hand as the moving object crosses the 100 metre mark and at this instant the timekeeper stops his watch.

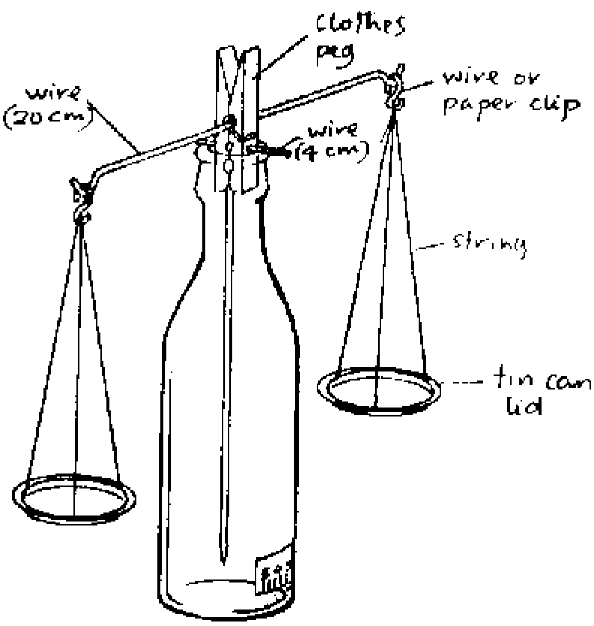
Pupils record the time taken for each case and figure out the respective velocities.

2.1.5 Simple Beam Balances



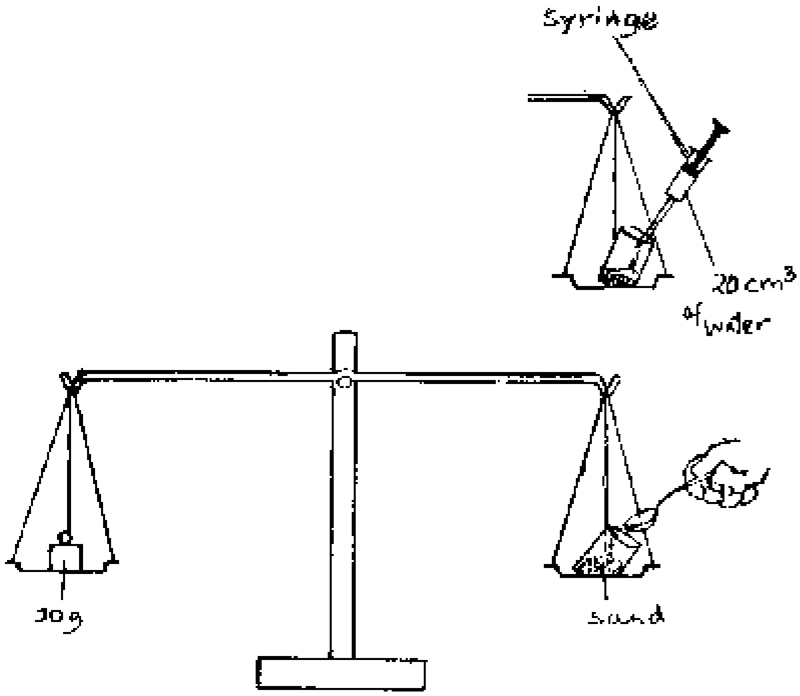
A balance for teaching moments and equilibrium can be made from a ruler or a thin wooden bar. A balance for introducing equilibrium consists of a wire with a loop for hanging in the centre and with two hooks at the ends.

2.1.6 Sensitive Laboratory Balance



Drill a hole through a clothes peg below the spring for a wire or nail to pass through. Fix a wire right in the spring as a balance beam, and another one in the mouth of the peg as a pointer. (The shorter the pointer, the more sensitive the balance). Fit the arrangement in a wide mouth glass bottle or a plastic bottle marked with a scale.

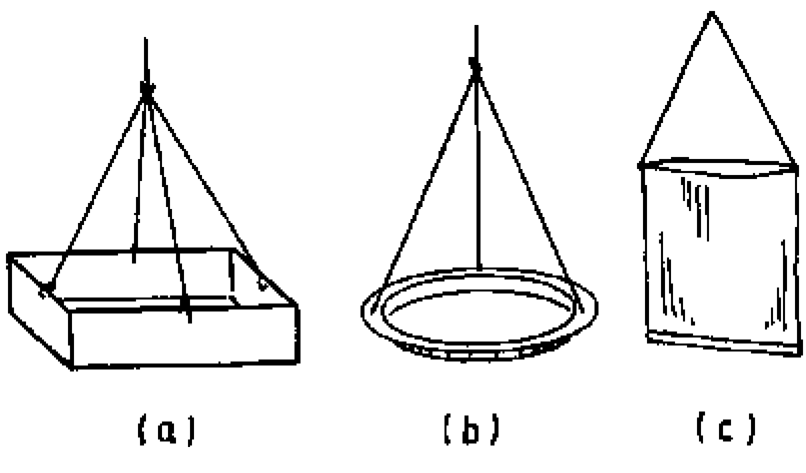
2.1.7 Weights



(a) Fill small plastic bags with sand or small stones and compare them with standard weights. Label and seal the bags with a small flame.

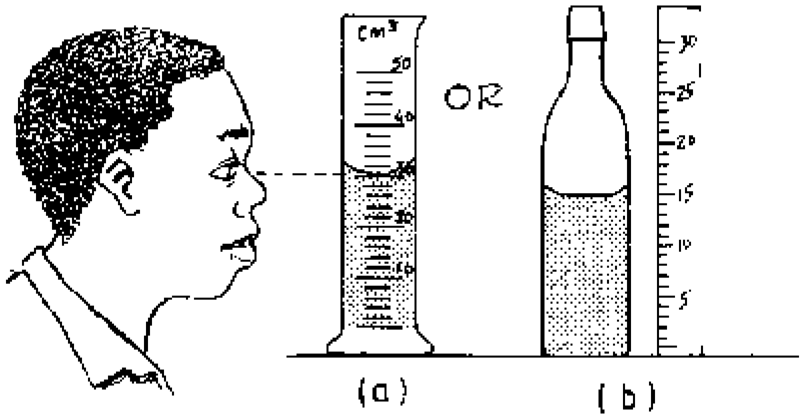
(b) Where there are no standard weights, use syringes or measuring cylinders to fill plastic bags with equal amounts of water. Use the fact that 1 cm^3 of water has a mass of 1 gram.

2.1.8 Weighing Pans



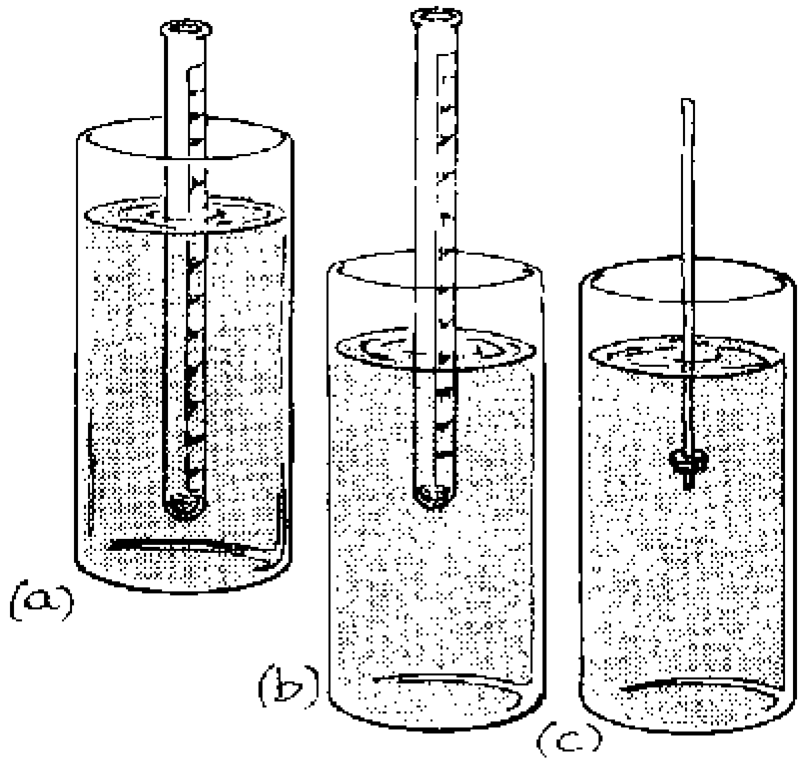
Weighing pans can be made from match boxes (a), plastic lids (b), or even small plastic bags (c) as used for wrapping ground nuts.

2.1.9 Measuring Liquids



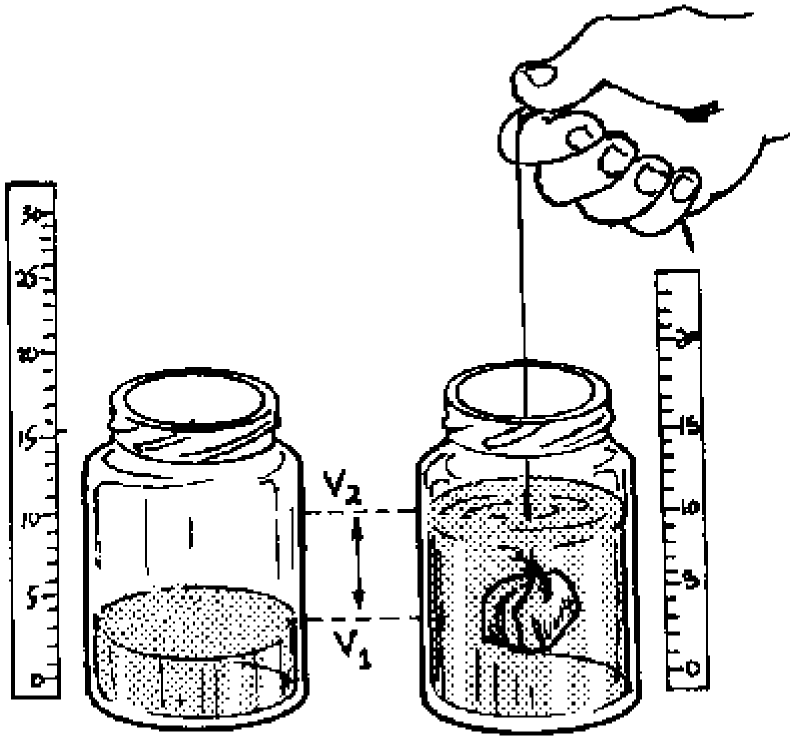
The volume of liquids can be measured by accurately reading the meniscus (a). The principle can be taught with a transparent bottle and a ruler (b).

2.1.10 Measuring Different Densities



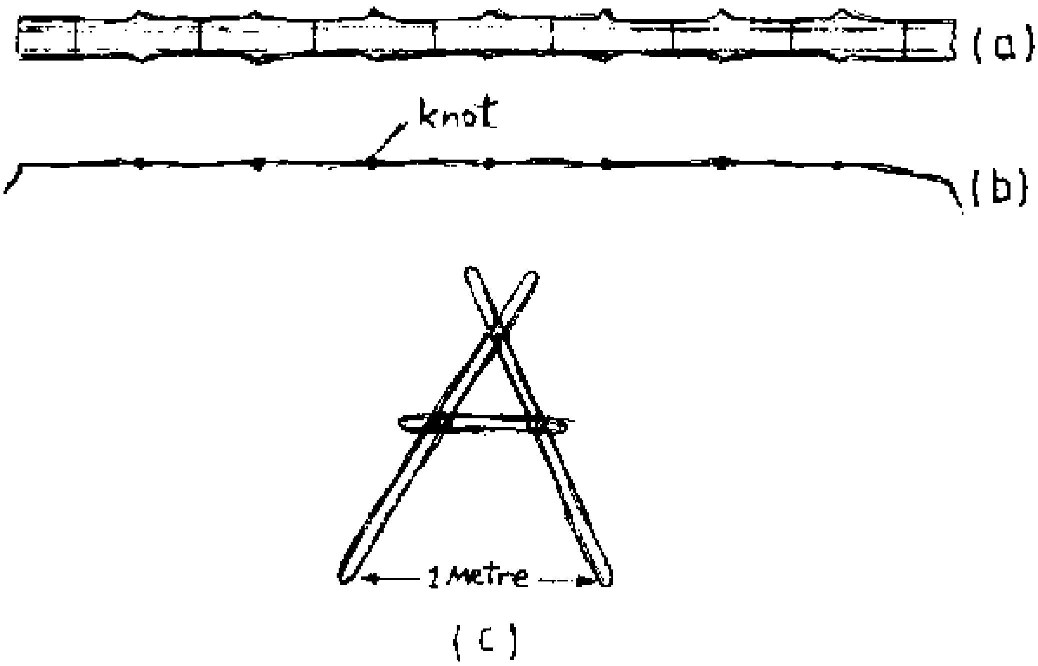
Fill a test tube with sand to keep it upright in water (b). Place a paper scale inside or fix a nut or a stone at one end of a wooden stick. Make regular marks (scale) along the wooden stick (a). Dip the tube or wooden stick in water (b), oil (a), (or kerosene, ethanol, etc.) and record in each case the extent to which the device sinks.

2.1.11 Measuring Irregular Bodies



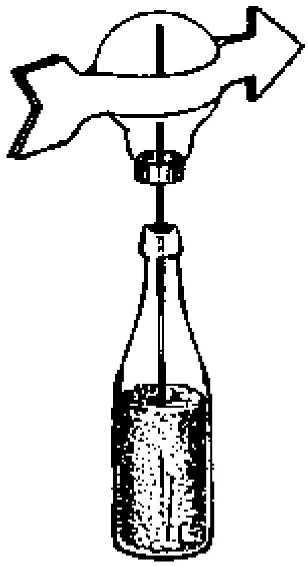
The volume of an irregular body (stone) can be measured by hanging it on a thin thread and dipping it completely in a measuring cylinder containing water. The difference in the volumes of the water read before and after completely submerging the irregular body is its volume. Only the principle is shown here.

2.1.12 Measuring Long Distances



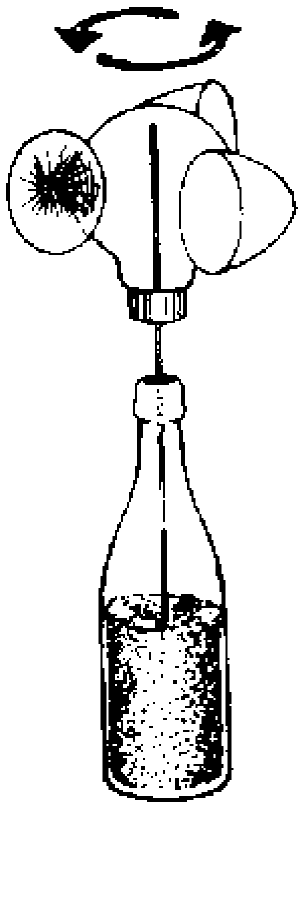
Measuring devices can be made from wooden sticks (a,c) or from strings by making knots at definite intervals (b). The sticks can be arranged closely together in succession to measure distances on uneven ground.

2.1.13 Wind Direction



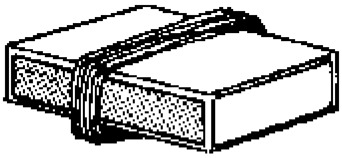
Take an opened fused bulb (for opening see appendix), place a piece of stiff wire so that the bulb turns with low friction on the tip of the wire. Fix two paper arrows folded around the bulb. Dip the wire in a sand filled bottle as a support. The device works excellently.

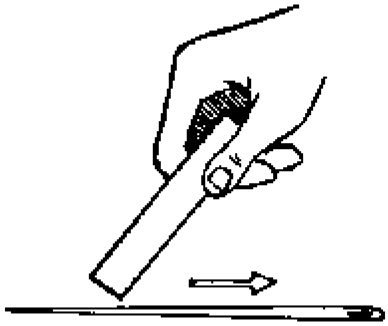
2.1.14 Wind Speed

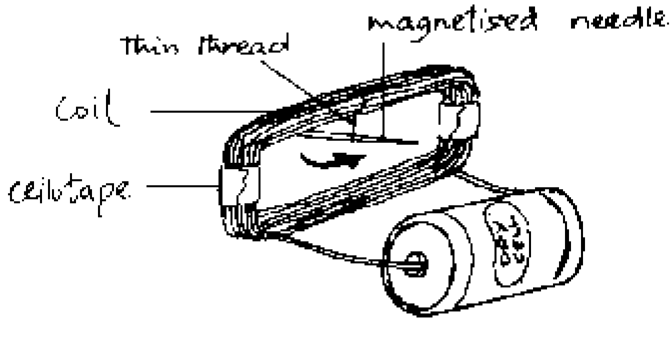


Fold 3 cones from round paper disks (preferably from cement bags or other resistant paper). One cone should be painted outside in a different colour for a better counting of the number of revolutions. Glue the cones to the bulb. Insert a piece of stiff wire which can be dipped in a sand filled bottle as a support (see experiment 2.1.13).

2.1.15 A Simple Current Indicator

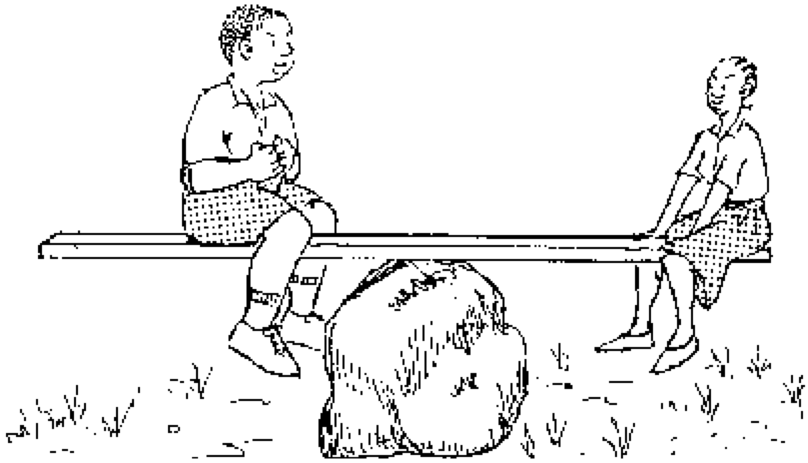






Wrap about 10 turns or more of insulated wire (from a used motor coil or as used for electric bells) round a match-box in order to get the required shape of the coil. Suspend a magnetised steel needle (or a magnetised piece of a bicycle spoke) with a thin thread inside the coil. You can magnetise the needle with a magnet (taken from the loudspeaker of an old radio) by moving it along for about 30 times always in the same direction. When a current flows through the coil, it deflects the needle. A change of the poles changes the deflection.

3. Basic Mechanics



3.1 Rectilinear Motion

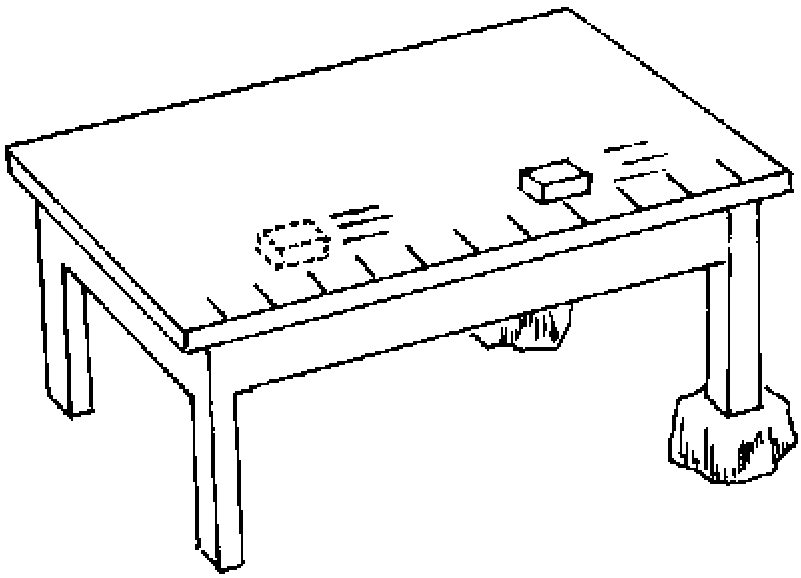
This section introduces the uniform and the accelerated rectilinear motions, i.e. those having constant velocity and constant acceleration.

Definitions:

Displacement = distance measured along a straight line
Velocity = displacement ÷ time taken
Acceleration = change in velocity ÷ time taken

Uniform and accelerated motions play an important role in the movement of cars, buses, trains, ships and aeroplanes.

3.1.1 Uniform Motion



P: Place chalk marks along the long side of a smooth table or plank at an equal distance of 10 cm. Then tilt it so that a matchbox loaded with a stone will just not start to move. Then give the box a little push so that it will move.

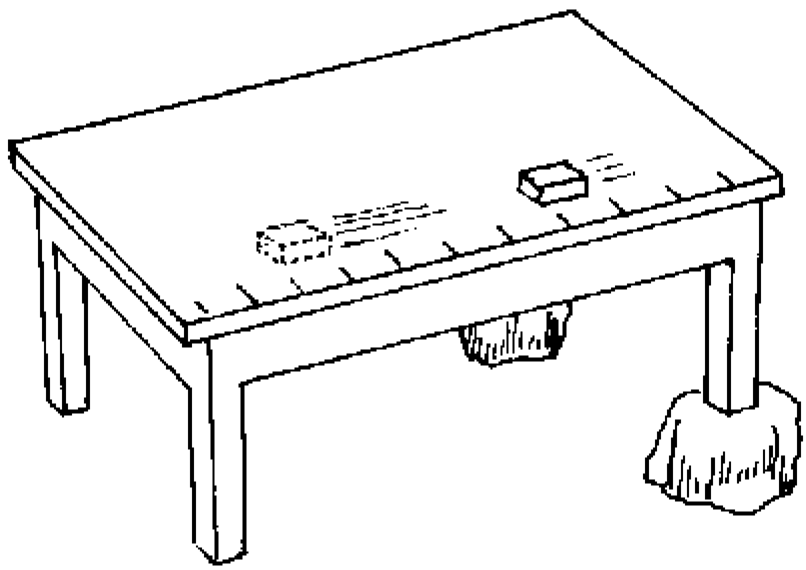
Q: Does it need always the same time from one mark to the next?

O: If not, change the inclination of the table or plank until it does.

E: If so, this is a *uniform* rectilinear motion: the velocity is constant, there is no change in velocity, thus the acceleration is zero.

A: Where does this motion occur in daily life? **-** For example, a bus, a train or a boat going at constant speed on a straight line path.

3.1.2 Accelerated Motion



P: Tilt the smooth table or plank more than in experiment 3.1.1.

Q: How is the time which the matchbox needs to cover the distance between two marks? Is this time getting shorter when the box moves down?

E: If so, this is an *accelerated* motion. Its velocity changes as the box moves down. Its velocity *increases.* Thus, it is an accelerated rectilinear motion.

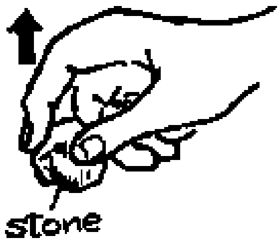
A: Where do such motions occur in daily life? - For example, a stone falling down; a bus accelerating after the stop; a bus breaking before a stop.

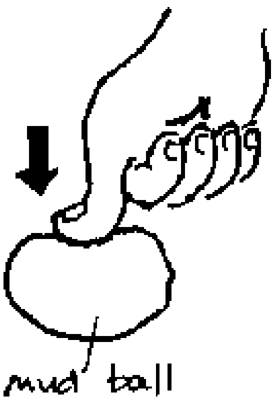
3.2 Forces

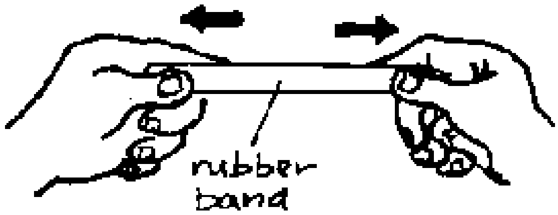
What is a force? *A force is a push or a pull on a body.* It can be recognised by its effects on a body which are:

Change in velocity of a body (accelerating, breaking, changing the direction of the movement); Deformation of a body (changing its shape or size).

3.2.1 The Effects of Forces







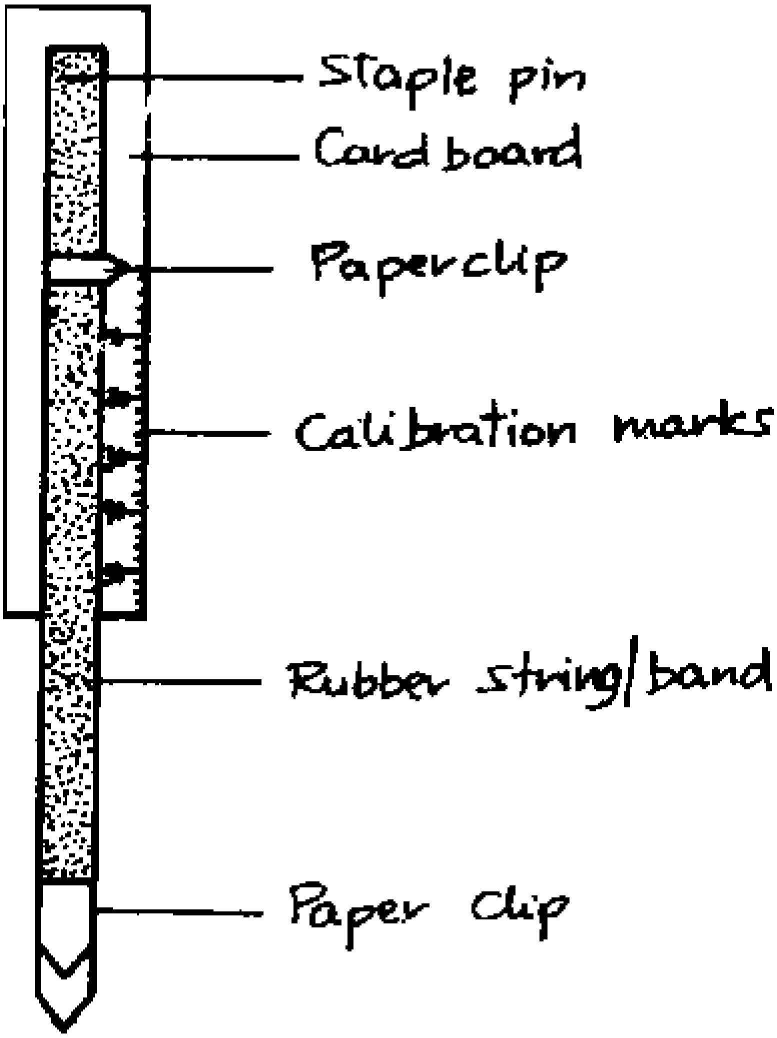
P: Show the effects of forces by pushing, pulling, lifting, turning a stone; by stretching a rubber band.

Q: How can you group these effects of force?

E: Pushing, pulling, lifting, turning *change the velocity of a body.* - Compressing and stretching *change the shape or size of a body.*

A force changes the velocity or the shape of a body.

3.2.2 Making a Newton Balance



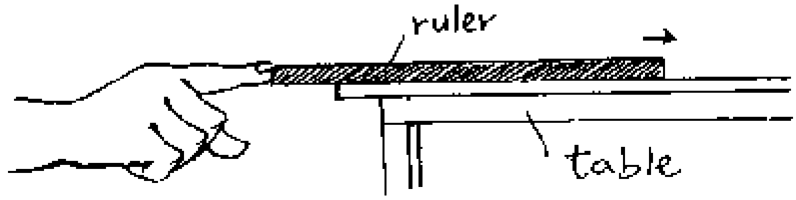
Forces are measured with a Newton balance.

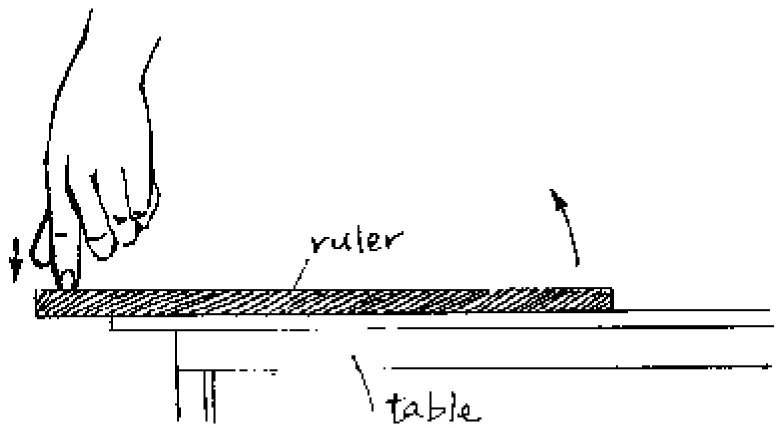
P: Take a strip of card board or a wooden lath. Using incisions or a nail fix a rubber band on it. (The stronger the rubber band, the larger the force you can measure.) Attach one paper clip as a pointer as shown in the figure. Then fix some paper clips as a hook at the bottom end of the rubber band.

Now *calibrate* the balance in *newtons* using either a standard set of weights (e.g. borrowed from the lab of a well equipped school) or another Newton balance: a weighing piece of 1 g mass has a weight of 0.01 N; one of 10 g mass has a weight of 0.1 N; one of 100 g mass has a weight of 1 N and so on. Draw marks accordingly on the scale of the balance.

H: Never apply such a big force that the pointer does not go back to the zero mark when the force ceases.

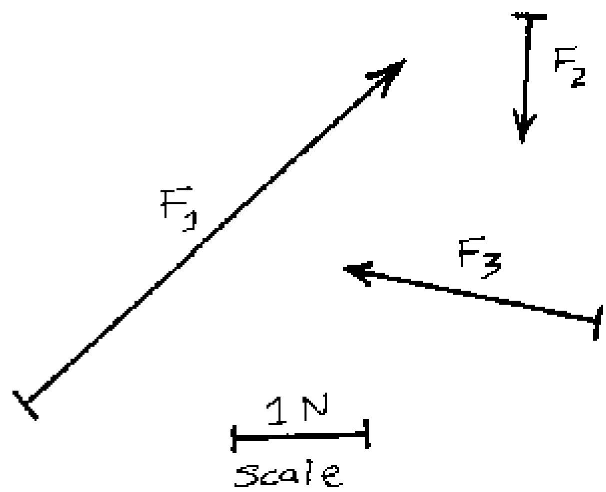
3.2.3 Direction of Forces





P: Show that the direction of a force is important for the effect of a force by applying a force on a stick in various directions, see the figure.

3.2.4 Forces as Vectors



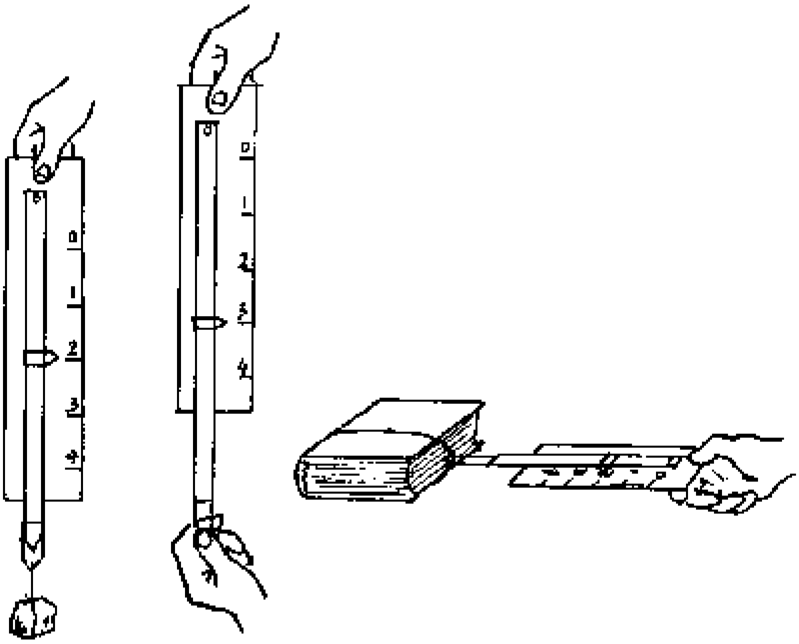
Quantities which have both direction and magnitude are called vectors.

Thus, for example, force, displacement, velocity and acceleration are vectors.

Vectors are drawn as arrows whose length gives the magnitude.

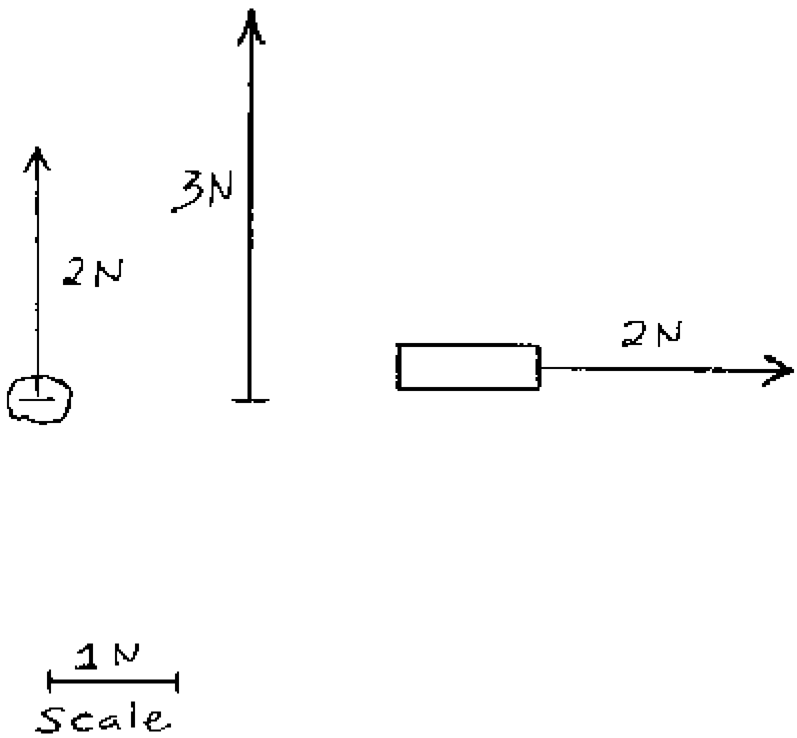
Draw some forces like those in the above figure and a scale on the blackboard and ask the students to give the direction and magnitude of these forces.

3.2.5 Measuring Forces



P: Using your Newton balance measure various forces like the force needed to lift different stones, the force needed to pull a book sliding over your desk, the force to stretch a spring, etc.

3.2.6 Drawing Forces



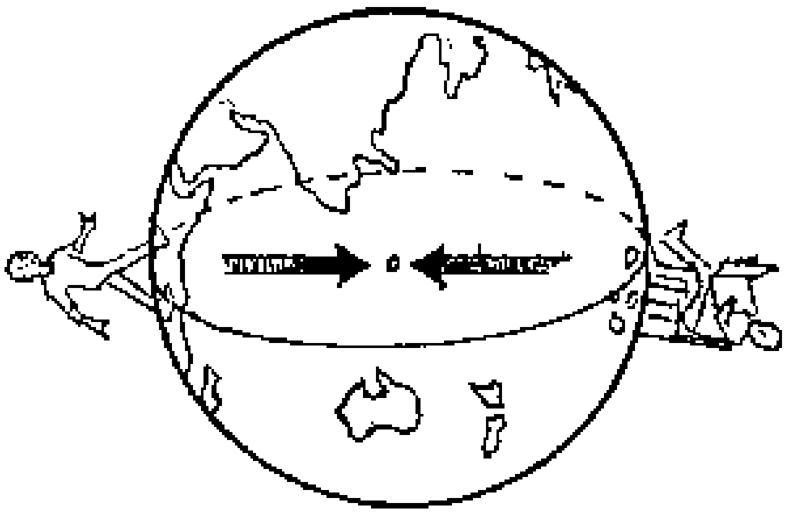
P: Ask the students to draw all the forces which you have measured in experiment 3.2.5 as vectors in their notebook.

3.3 Weight and Mass

The *weight* of a body is the pull of the earth on it. Thus, weight is a *force* measured in newtons. It is a *vector* directed to the centre of the earth. It is measured by the Newton (spring) balance.

The *mass* of a body is a measure for the quantity of matter in that body. Thus, it is a *scalar* which *stays everywhere the same* while the weight of body will decrease when its distance to the centre of the earth increases. It is measured by the beam balance.

3.3.1 Weight as the Pull of the Earth



P: Hold a stone at the level of a table plate and release it.

Q: What do you observe?

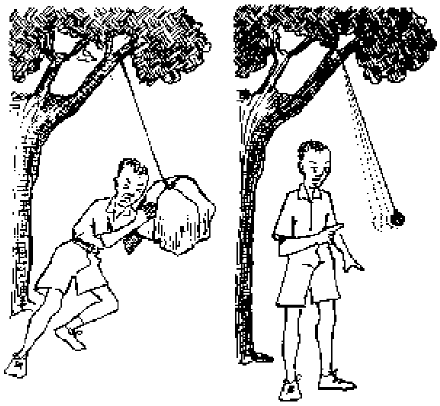
O: It will fall down to the floor.

E: It changes its velocity, i.e. a *force* must act on it. This force is the pull of the earth on the stone. This pull is always directed to the centre of the earth. Thus, the weight has magnitude and direction. It is a *vector.*

Hence, as the figure shows, the weight of people in different regions of the world has different directions. However, it is *always directed to the centre of the earth.*

The *magnitude* of the weight of the same body is *not* everywhere the same. The further away from the centre of the earth the body will be, the less its weight will become.

3.3.2 Mass as the Quantity of Matter



P: (a) Suspend a large and a small stone using long pieces of string (e.g. from a branch of a tree). Try to push the two stones. Then try to stop them.

Q: Which stone is harder to push? Which is harder to stop?

P: (b) Take a ball and a stone or brick of similar size. Throw both.

Q: Which is harder to throw?

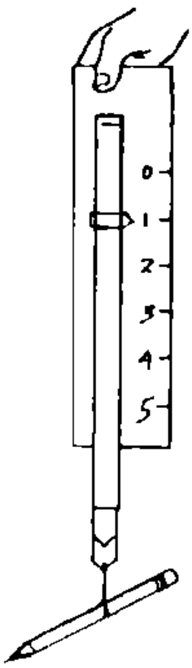
O: (a) The larger stone is harder to push and to stop than the small stone.

(b) The stone or brick is harder to throw than the ball.

E: The greater the mass of a body, the more it resists to any change in its velocity. We say, the greater the mass of a body, the greater its *inertia.*

The quantity of matter of the same body, and hence its mass, is everywhere (e.g. on the earth, on the moon, etc) the same. Mass has no direction, thus it is a *scalar.*

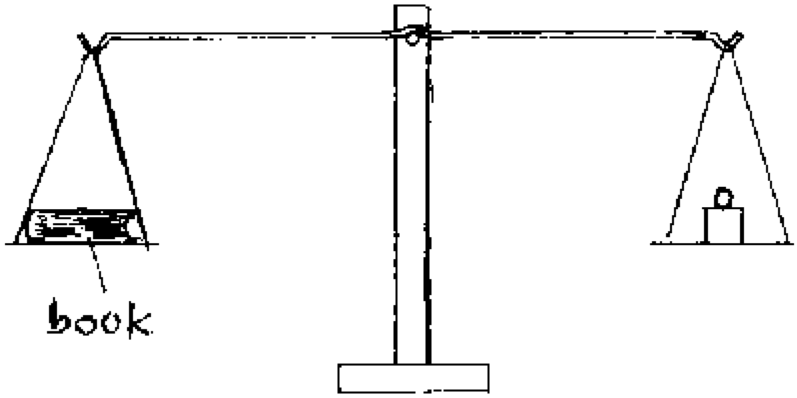
3.3.3 Weight is Measured by the Newton (Spring) Balance



Since weight is a force, it is measured by the Newton (or spring) balance.

P: Take a Newton balance (see p. 15) and measure the weight of a pencil, a book, etc. in newtons.

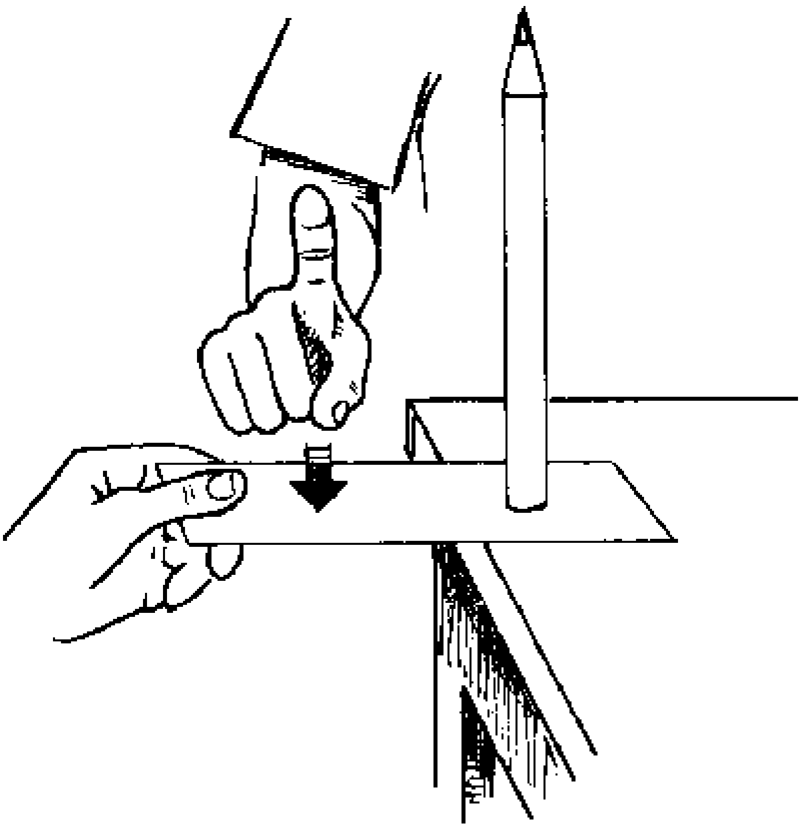
3.3.4 Mass is Measured by the Beam Balance



The mass of a body is measured by the beam balance.

P: Take a beam balance and a set of weighing pieces (see p. 10) and measure the mass of a pencil, a book, etc. in grams (g).

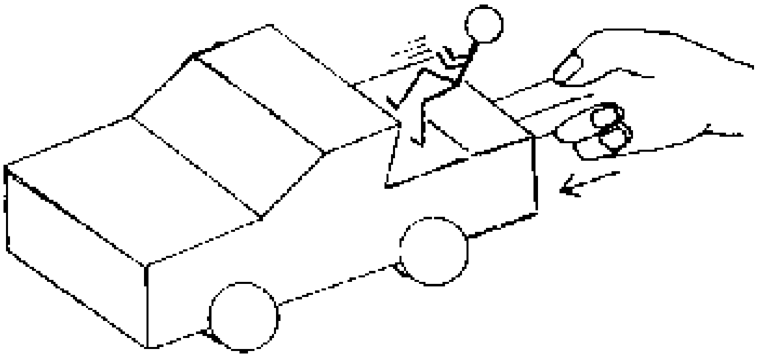
3.3.5 The Surprising Pencil



P: Stand a pencil upright on a strip of paper near the edge of a table. At once hit the strip with your finger so that it leaves the table, see the figure.

Q: What happens? How do you explain this?

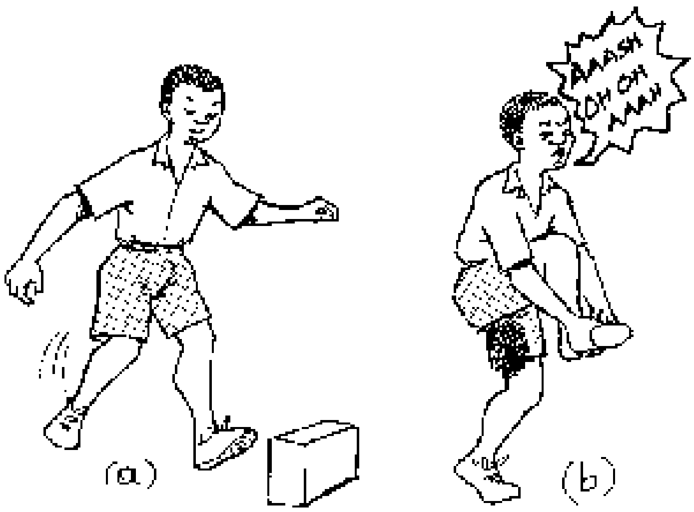
3.3.6 The Standing Passenger in the Pick-up



P: Take a toy pick-up or a box (representing a pick-up) and place a *freely standing* passenger (made of card or wood) in it. Strongly accelerate the pick-up. Make it turn a corner. Finally slop the pick-up suddenly.

Q: What happens to the standing passenger in each case? Why?

3.3.7 Kicking a Brick

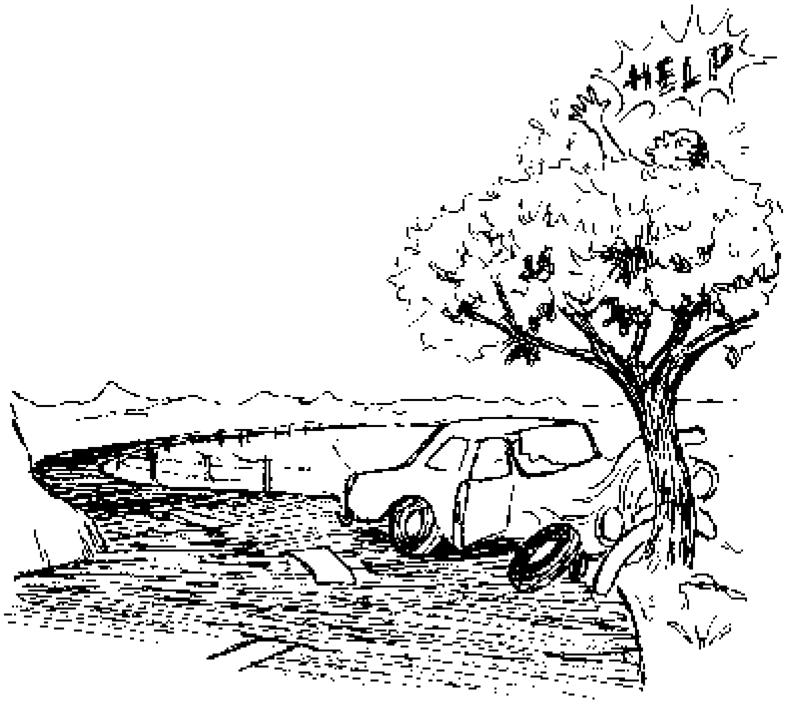


P: Ask students to draw the figure on a display chart.

Q: Why does the student feel great pain after he kicked the brick? Would the same happen, if he kicked the same brick on the moon?

E: He feels pain because the brick has a greater mass, and hence a greater inertia than a football. The same would happen at the moon, because the mass, and hence the inertia of the brick, is the same on the moon.

3.3.8 Car Crash

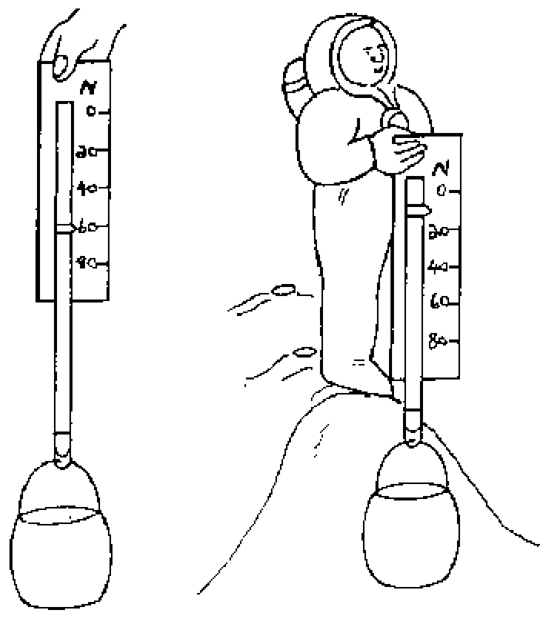


P: Make a display chart of the figure.

Q: Why did this car get so badly damaged?

E: The big mass of the car has great inertia. Thus, a great force exerted by the tree was needed to stop it suddenly. This force deformed the car.

3.3.9 The Weight Changes



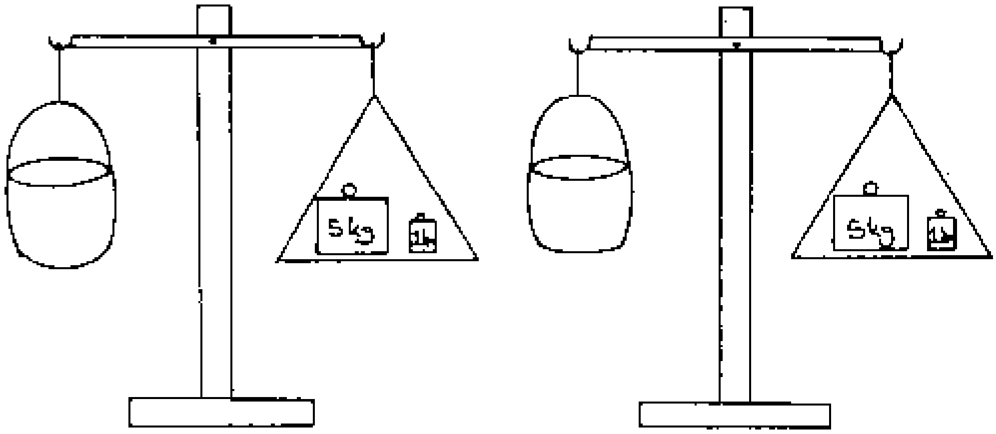
(a) On the earth (b) On the moon

P: Make a display chart of the figure.

Q: Why is the weight of the same bucket of sand less on the moon than on the earth?

E: The weight of a body depends on the place where the body is. It is *not* everywhere the same.

3.3.10 The Mass Stays the Same



(a) On the earth (b) On the moon

P: Make a display chart of the figure.

Q: Why is the mass of the bucket of sand the same on the earth and on the moon?

E: The quantity of matter of the bucket has not changed, hence its mass has not changed.

3.4 Centre of Gravity and Stability

This section deals with the moment of a force, the centre of gravity (centre of mass) and stability.

Moment of a force = force x perpendicular distance from the pivot

In equilibrium: total clockwise moment = total anti-clockwise moment

The *centre of gravity* (centre of mass) *is the point in which the total weight of the body seems to act.*

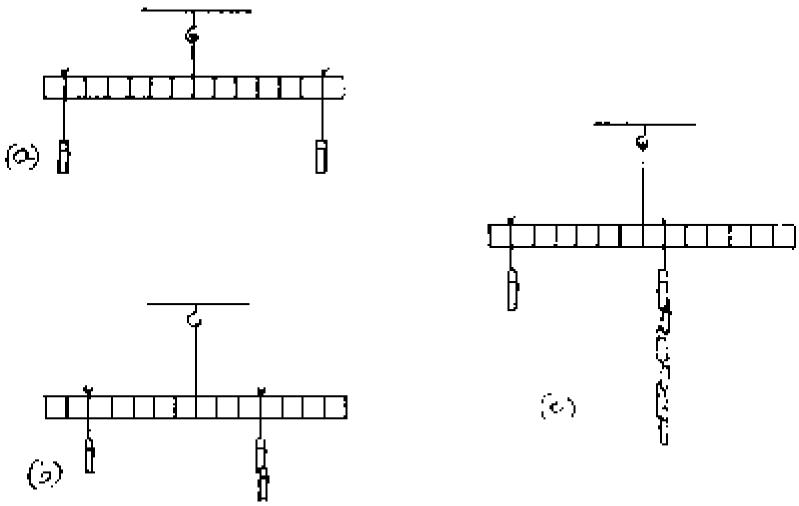
The stability of a body depends on the position of its centre of gravity (COG).

A body is in *stable* equilibrium if a small movement would rise its COG.

A body is in *unstable* equilibrium if a small movement would lower its COG.

A body is in *indifferent* equilibrium if a small movement would keep the COG at the same level.

3.4.1 Moment of a Force



P: Cut a piece of cardboard 40 cm x 3 cm and attach a supporting string exactly at the middle of it in a hole near the top (see figure). Mark six 3 cm spaces on each side of this middle point *(fulcrum).* Suspend this balance e.g. from the back of a chair and balance it by cutting off a little from the heavier side. Tie pieces of thread of about 20 cm length into loops about 7 cm long to support the weights. Use e.g. *equal* clothes-pegs as weights and balance them in many ways (see fig.).

Multiply weight x distance (from the fulcrum) for each side of the balanced beam.

Q: Prepare a table for several weights and distances from the fulcrum.

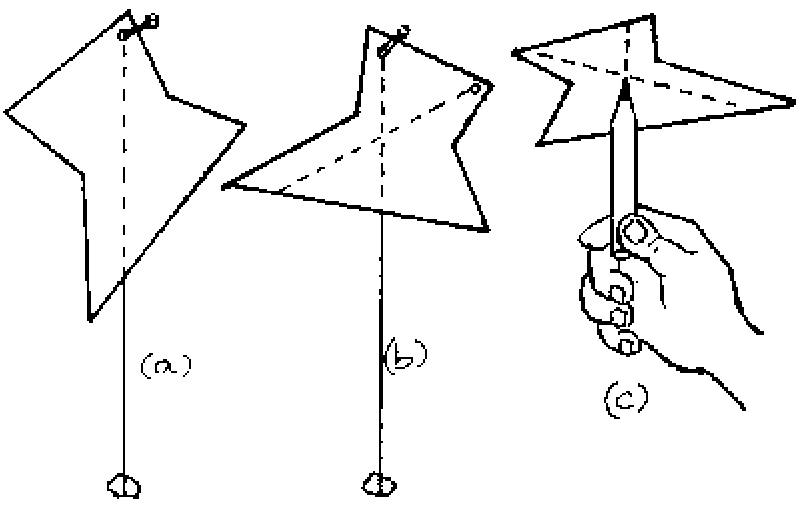
E: A force acting at a distance from a fulcrum has a *turning* effect which is called *moment* or torque. It can be calculated:

Moment = force x perpendicular distance (from the force to the fulcrum)

Our table shows that *the clockwise moment must be equal to the anti-clockwise moment in order to achieve equilibrium.*

A: The beam balance (see p. 10), the roman steelyard and other levers (see section 3.10).

3.4.2 Centre of Gravity (COG)



P: (a) Cut a piece of card into an odd shape (see fig.(a)). Suspend it from a nail and attach a string with a stone. Mark the position of the string using two crosses. Join these using a ruler to form a pencil line.

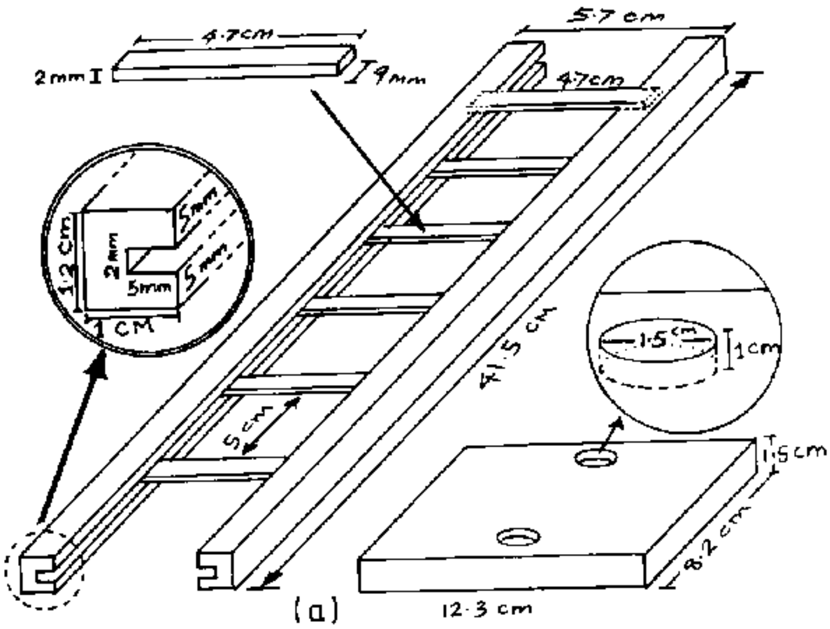
(b) Repeat (a) but fix the nail in another position on the card (see fig.(b)). Where the two pencil lines meet is the *centre of gravity* of the card.

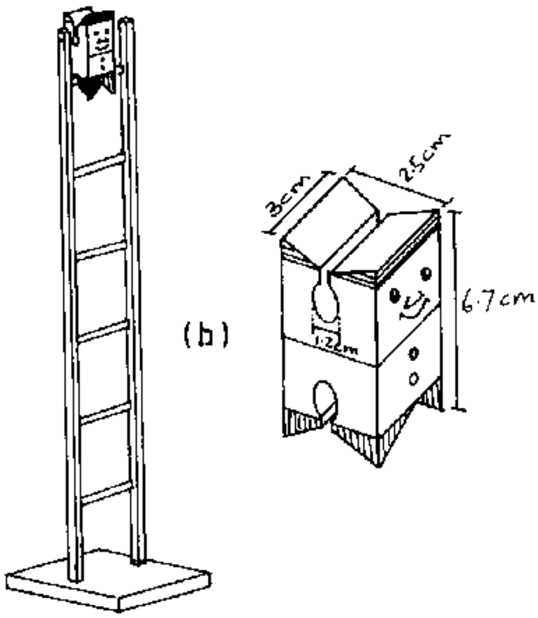
(c) Now support the card with the tip of a pencil below the centre of gravity.

Q: What do you notice about the stability of the position of the card?

E: The position of the card remains stable as long as it is supported in the centre of gravity because now all the moments of the weights of all the mass particles of the card balance.

3.4.3 The Funny Jumper





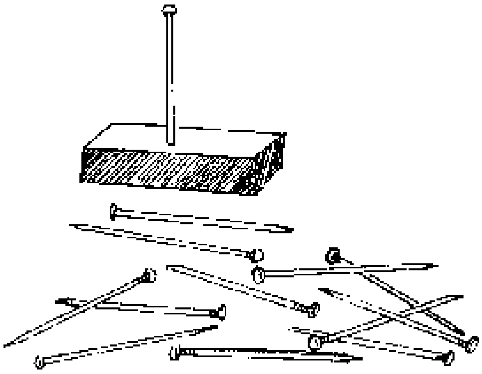
P: Ask a carpenter to make the funny jumper according to fig.(a) and (b). Place the jumper *feet down* on the uppermost step of the ladder.

Q: What happens? Why?

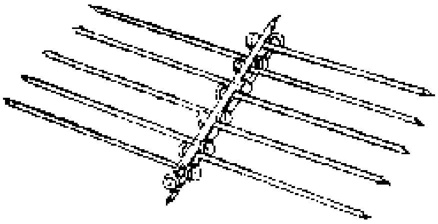
O: The jumper jumps from one step to the next down the whole ladder.

E: First the centre of gravity of the jumper is above a step of the ladder. This is an *unstable equilibrium since* the COG is lowered when the jumper turns round to hang on that step. However, due to the slot it has, it then falls down to be *above* the next step. Thus, the process is repeated until the jumper meets the ground level.

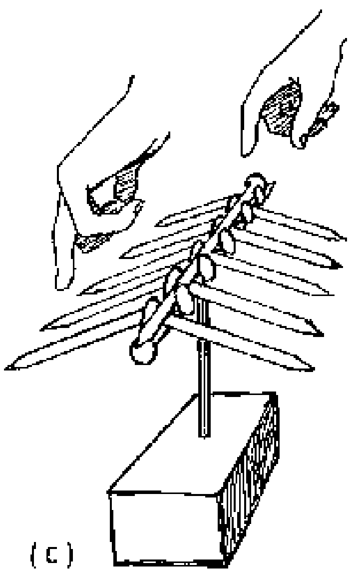
3.4.4 Balancing Nails



(a)



(b)



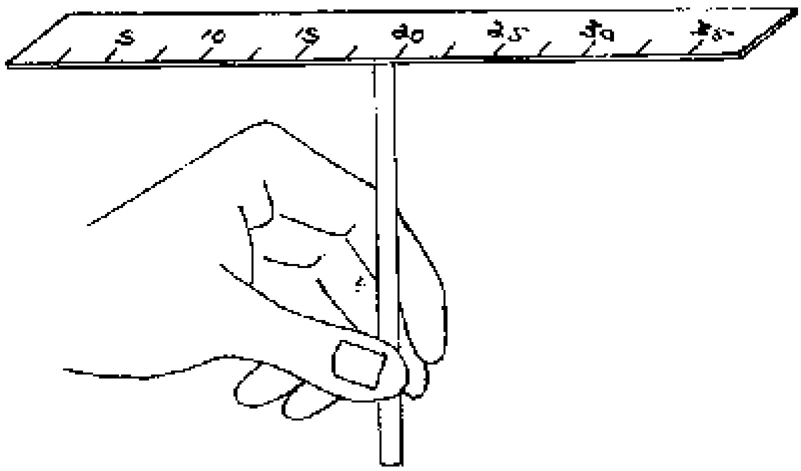
(c)

P: Give the students 2 inch nails (see fig.(a)) and ask them to balance them all on top of the nail which was fixed on the piece of wood. In doing this, the nails must neither be bent nor glued together etc.

This may be a challenging riddle for the students!

E: This riddle can be solved by arranging the nails according to fig.(b) when lying on the table. Then lift this arrangement carefully to the top of the first nail and balance it there. The COG is now lower than the supporting head of the first nail. Thus, a *stable equilibrium* is reached.

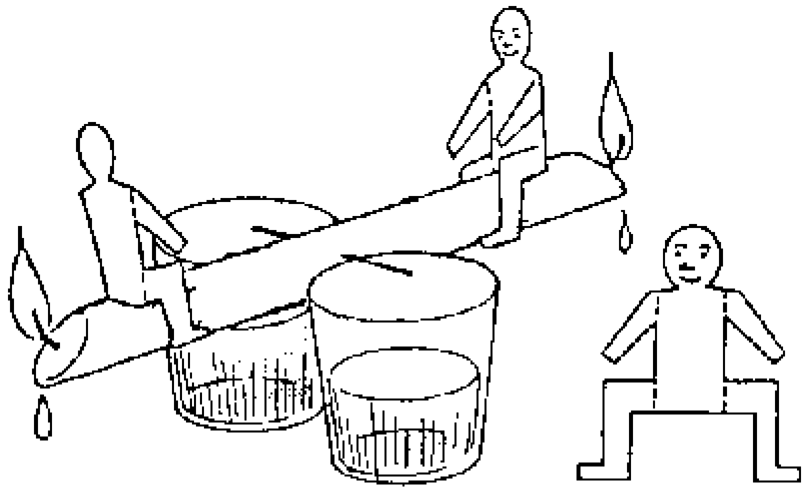
3.4.5 The COG of a Ruler



P: Find the centre of gravity of a ruler by balancing it on the tip of a pencil.

Q: Where does the COG of the ruler lie? Why?

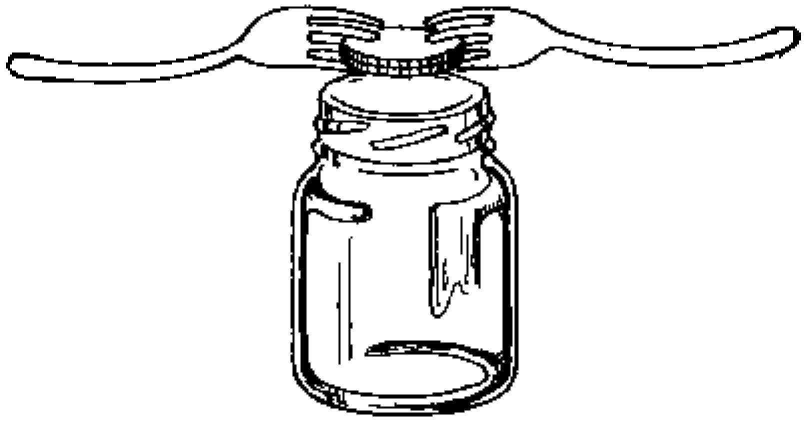
3.4.6 Candle Balance



P: Construct a candle balance as shown in the figure.

Q: What happens? Why?

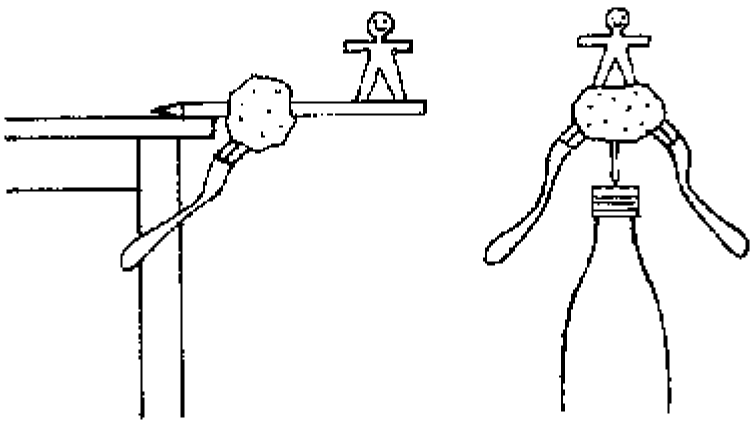
3.4.7 Balancing Coins



P: Take two coins and attach two forks to them as shown in the figure. Balance this arrangement on the rim of a jam glass.

Q: Why do the coins not fall down?

3.4.8 Riddles



P: Produce the arrangements shown in the figures (a) and (b).

Q: Why do they not fall down?

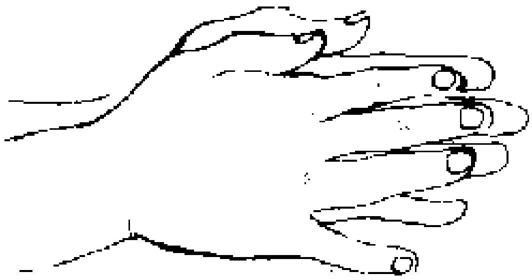
3.5 The Force of Friction

The force of friction always opposes motion. Friction may be reduced by lubrication. Rolling friction is less than sliding friction. The rougher a surface, the greater the force of friction.

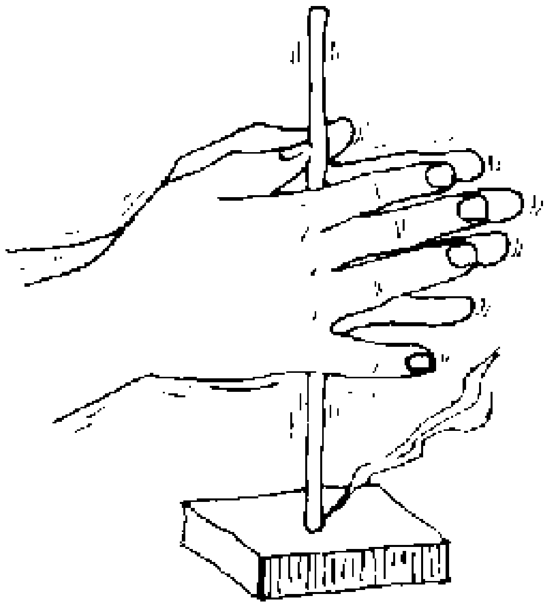
Friction plays an important role in daily life. Without friction we would be unable to start walking.

Any woven material would decompose because it is held together by friction of the threads only. However, we have to reduce friction in the bearings of moving parts of vehicles and other machines in order to save fuel.

3.5.1 Friction Produces Heat



(a)



(b)

P: Rub your hands.

Turn a stick very quickly between your hands and press its tip onto a piece of wood.

Q: What do you feel on your hands?

What do you observe on the piece of wood?

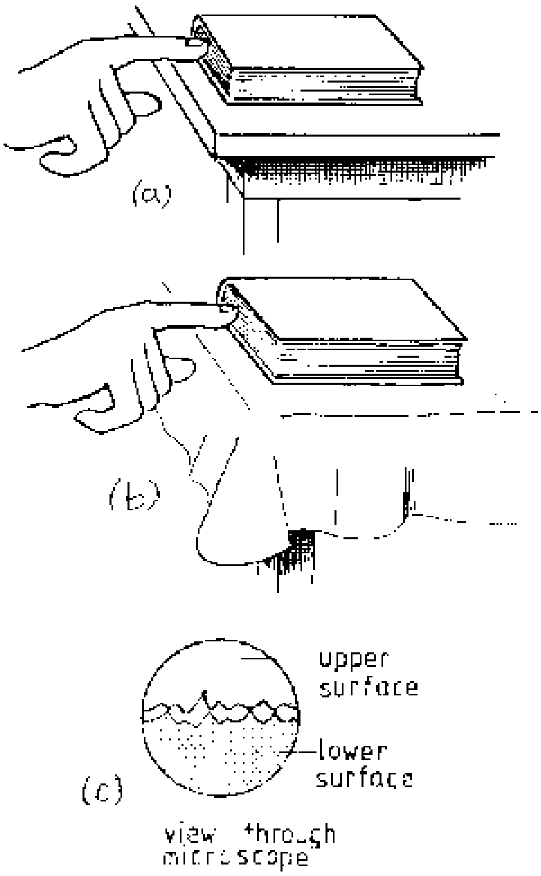
How do you explain this?

O: The hands become warm, the piece of wood starts smoking and finally burning.

E: Friction produces heat which can light wood if great enough.

A: Lighting a fire without matches.

3.5.2 Friction and the Kind of Surface



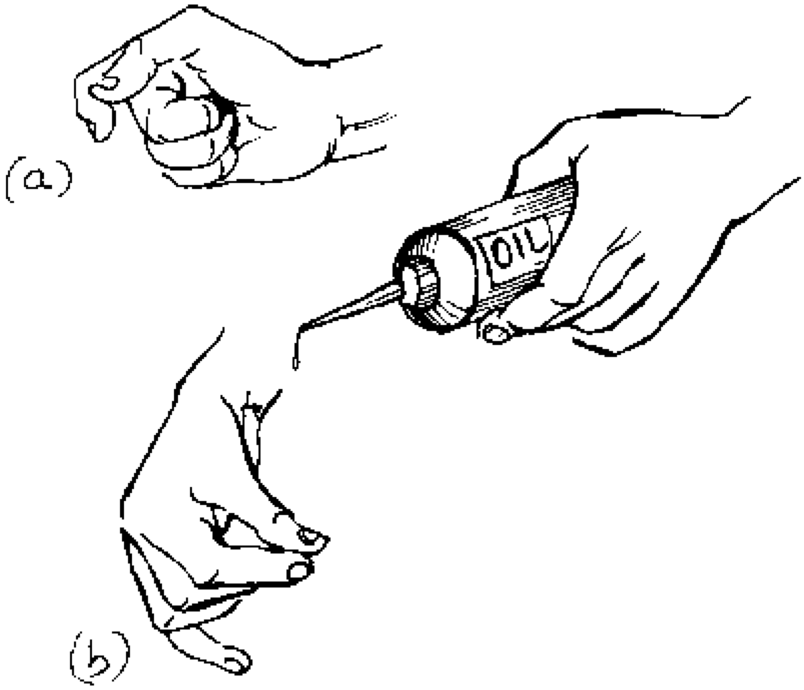
P: Pull a book on a bare table surface and then on a piece of cloth.

Q: On which surface is it harder to pull? How docs the force of friction compare on the two surfaces? How can we explain friction?

O: It is harder to pull the book on the cloth than on the bare surface of the table.

E: The rougher the surfaces are which slide on each other, the greater the force of friction is. The "mountains" and "valleys" of the surfaces tooth and hence cause the force of friction, see figure (c).

3.5.3 Lubrication

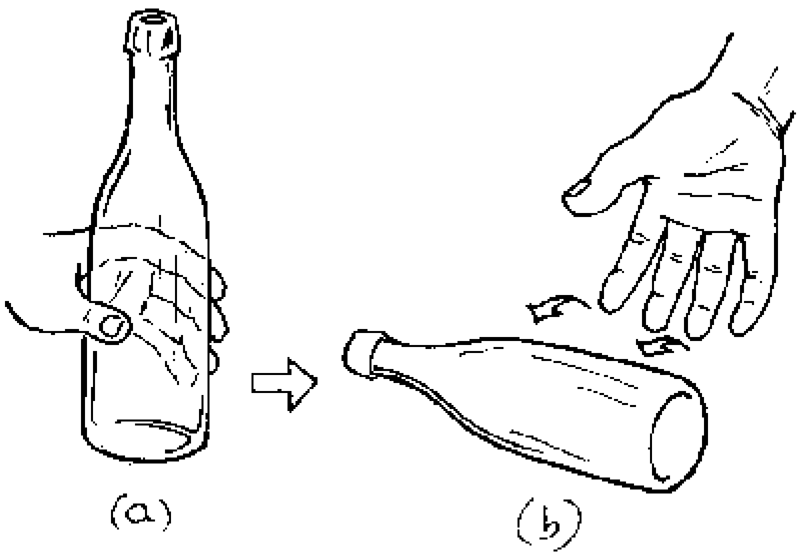


P: Rub your thumb and a finger together. Then place a drop of cooking oil or margarine on your thumb and repeat rubbing.

Q: How do the forces of friction (needed for the rubbing) compare in the two cases? Hence, what can be done to reduce friction?

A: Lubrication of bearings etc. to reduce friction.

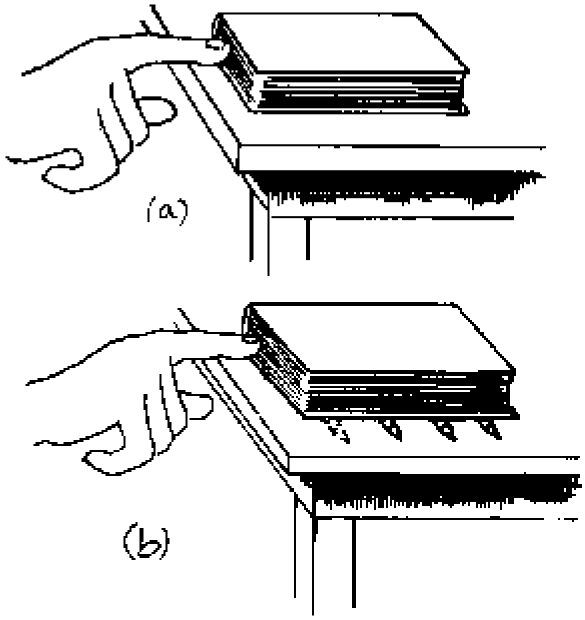
3.5.4 Rolling and Sliding Friction



P: Slide a bottle or tin and roll it.

Q: How are the forces of friction in each case?

3.5.5 Rolling Friction

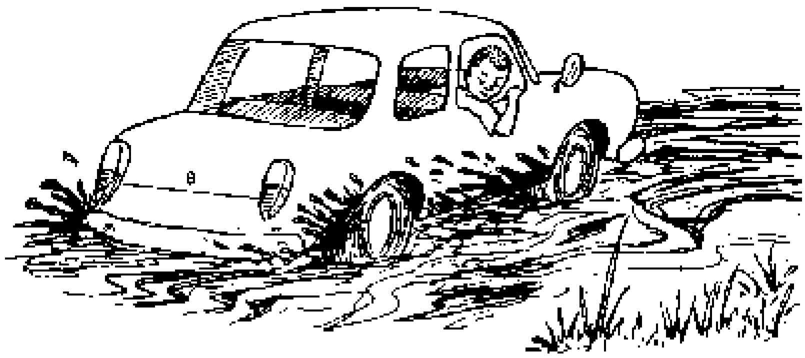


P: Pull a book over a table. Put some round pencils or drinking straws between the book and the table.

Q: How do the forces of friction compare now?

A: Roller bearings, ball bearings.

3.5.6 Where Friction is Needed



P: Ask students to draw the figure on a display chart.

Q: Why does the car *not* move even though the wheels turn?

E: There is not enough friction between the tyres and the road to get the car moving.

3.6 Density

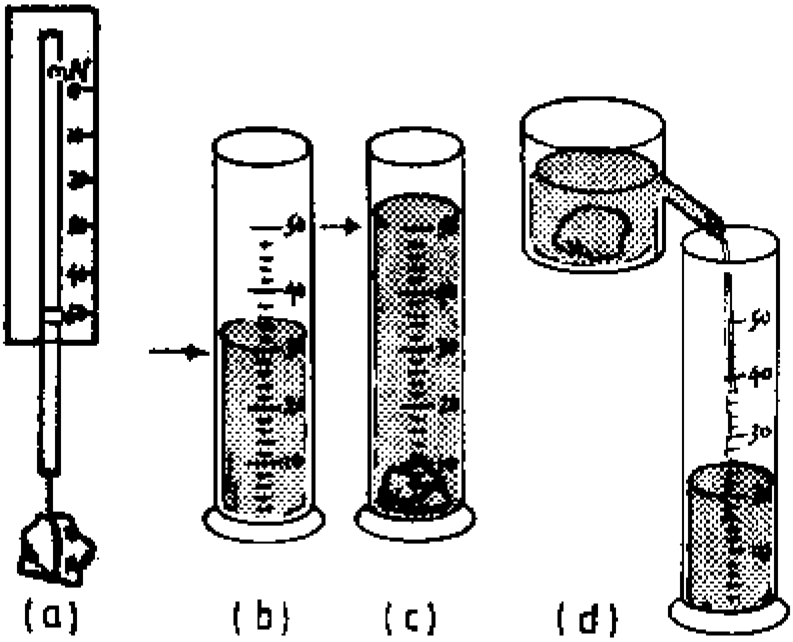
The density of a substance tells us which mass the unit volume of that substance has got. Thus, it is defined as follows:

Density = mass + volume.

For any pure substance the density is constant at constant temperature and pressure.

Hence, density may be used to identify substances.

3.6.1 The Density of a Solid



P: Attach a stone to a thread and determine the weight of the stone using a Newton balance, see fig.(a). Calculate the mass of the stone. Fill a measuring cylinder partly with water and record the volume, see fig.(b). Now immerse the stone fully in the water and record the new volume, see fig.(c). The difference in volume gives the volume of the stone. Alternatively, you can produce an overflow can from a tin using aluminium foil to make the overflow pipe, see fig.(d). Make the joint of pipe and tin water-tight using glue. Now calculate the density of the stone.

E: Assume that the stone has a weight of 0.5 N. Then its mass is

$$0.5 \text{ N} \div 10 \text{ N/kg} = 0.05 \text{ kg} = 50 \text{ g}$$

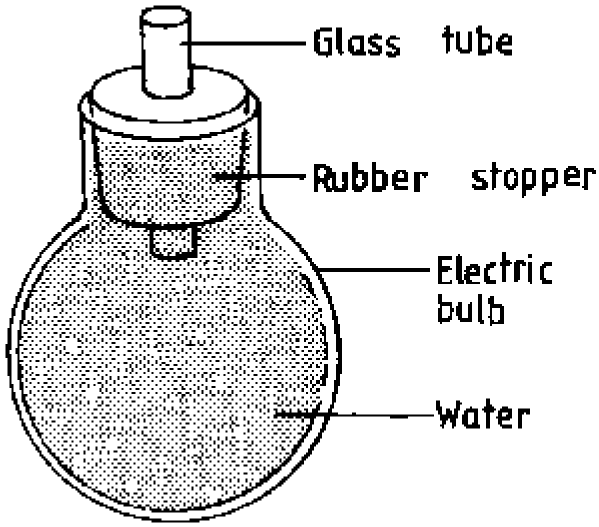
(Of course, the mass could be measured using a beam balance.)

Assume that the volume of the water displaced by the stone is 20 cm^3. Then the density of the stone is

$$50 \text{ g} \div 20 \text{ cm}^3 = 2.5 \text{ g/cm}^3$$

A: The determination of density can help to identify a certain substance, e.g. to answer the question: "Is a certain ring really made of gold?"

3.6.2 The Density of a Liquid



P: Prepare a density bottle from a worn out electric bulb fitted with a rubber stopper. Weigh the bulb with its stopper in air, then weigh it when filled with water and then when filled with liquid A, whose density is required. Determine the respective masses. You may use the beam balance described on p. 10.

Q: Determine the mass of the water and of the liquid. Calculate the volume of the density bottle and the density of liquid A.

E: E.g: Mass of empty density bottle = 15 g

Mass of density bottle with water = 68 g

Mass of density bottle with liquid A = 45 g

Then: Mass of the water = 68 g - 15 g = 53 g

Thus: Volume of density bottle = 53 cm^3

Mass of liquid A = 45 g - 15 g = 30 g

Thus: Density of A = 30 g ÷ 53 cm^3 = 0.56 g/cm^3

H: Be very careful when opening the worn out bulb, see appendix.

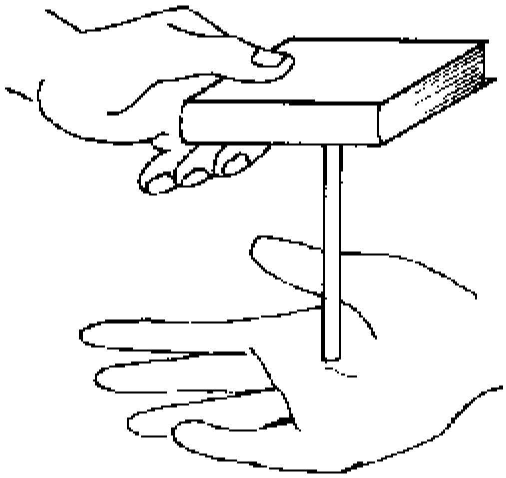
3.7 Pressure in Liquids and Gases

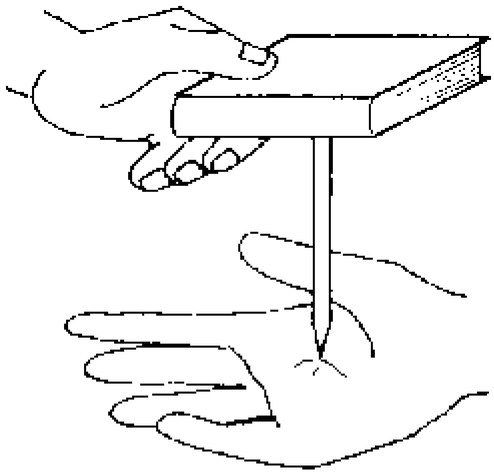
The pressure in liquids and gases is caused by their weight. It is defined as follows:

Pressure = force ÷ area

The laws of pressure govern many technical devices like barometers, manometers, pumps, etc.

3.7.1 What is Pressure?





P: Ask a student to support a book as shown in figure (a). Then turn the pencil upside down as shown in figure (b).

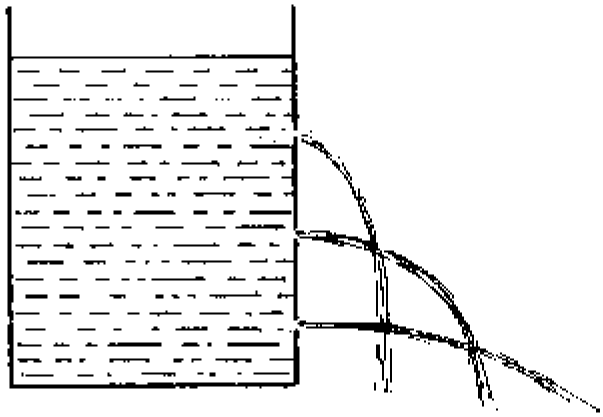
Q: What will the student feel? Why?

O: In case (b) the student will feel pain on the hand supporting the pencil.

E: In case (b) the force with which the pencil acts on the hand is the same (equal to the weight of book plus pencil) as in case (a) but the pressure on the hand has increased very much since the area on which the pencil touches the hand has decreased so much. Hence, the students will understand that pressure = force ÷ area.

A: Large area feet of elephants; wide tyres of tractors; wide chains of caterpillar machines.

3.7.2 Liquid Pressure Increases with Depth



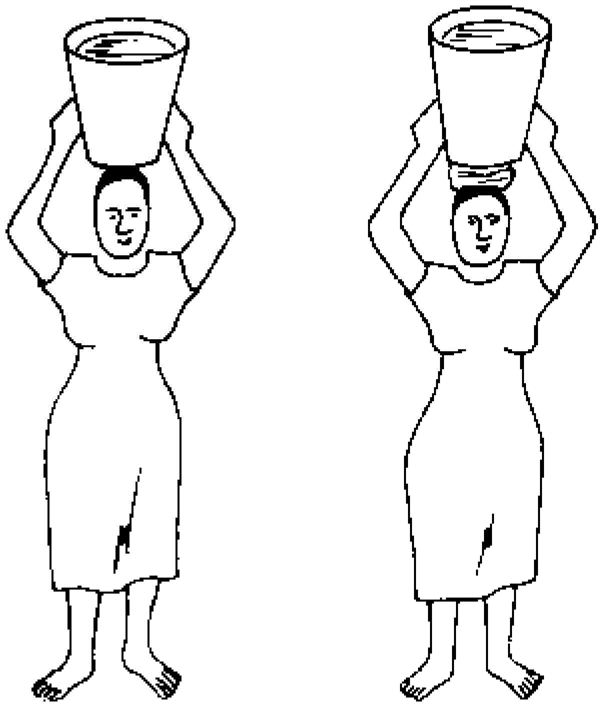
P: Pinch 3 holes into a tin according to the figure. Fill the tin with water up to its rim. What do you observe?

Q: How does the pressure change with the depth of the water? Why?

O: The water shoots the faster out of a hole, the greater the depth of that hole from the surface of the water in the tin.

E: The increasing speed of the water from the top to the bottom holes shows that the water pressure increases with the depth of the water. This is so because the weight of the water on top of a certain water particle acts on that particle causing pressure.

3.7.3 Carrying a Load on the Head

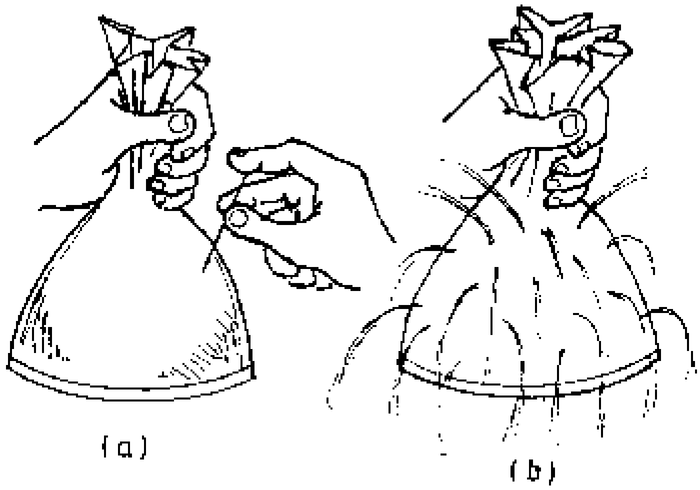


(a) (b)

P: Carry a bucket of water on your head without (fig. a) and with a "ngata" (fig. b).

Q: What difference do you feel? Why?

3.7.4 Liquid Pressure Acts in All Directions



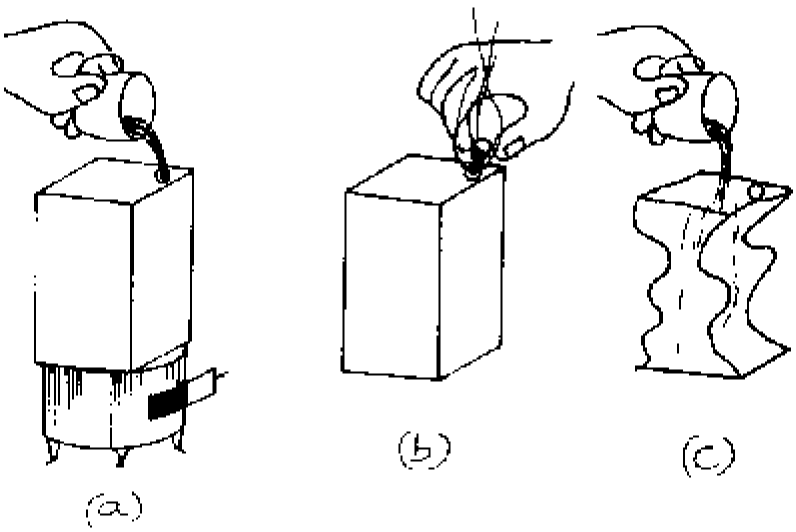
P: Pinch some small holes into a plastic bag using a needle. Fill it with water and squeeze the bag gently.

Q: In which directions does the pressure of the water act? Why?

O: The pressure acts in all directions.

E: The particles of a liquid can easily move behind each other while those of a solid are in fixed positions (see chapter 4.2).

3.7.5 Air Pressure: The Crashing Can



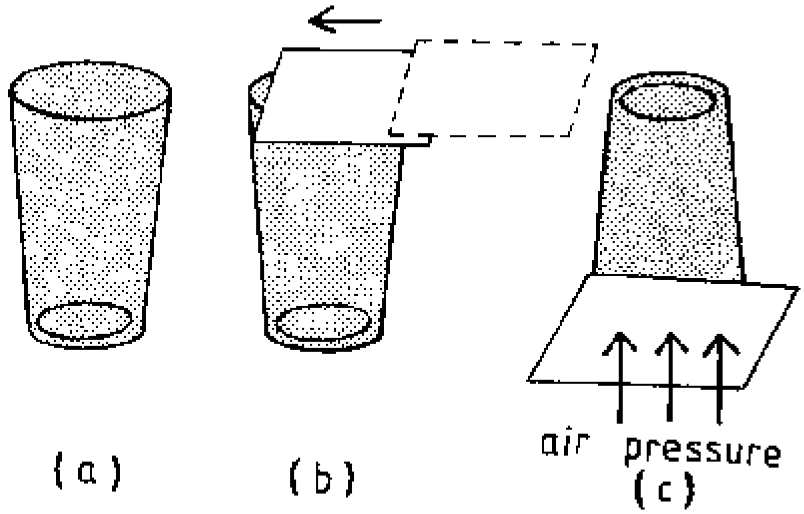
P: (a) Fill one cup of water into the large tin can. Then heat the *open* can to boiling.

(b) Remove the can from the fire and close it *immediately* air-tight.

(c) Now pour cold water on the can.

Q: What happens? Why?

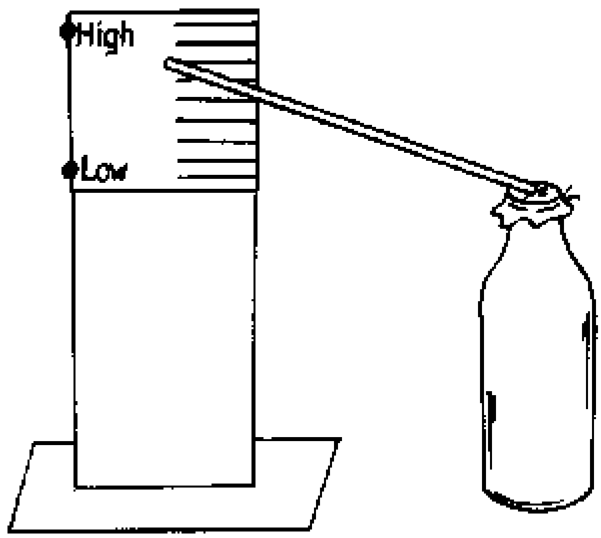
3.7.6 Air Pressure



P: Fill a drinking glass up to the rim with water. Then push a smooth card or a sheet of smooth plastic from the side to close the glass so that no air bubbles are included. Then turn the glass upside down.

Q: Why will the card not fall off?

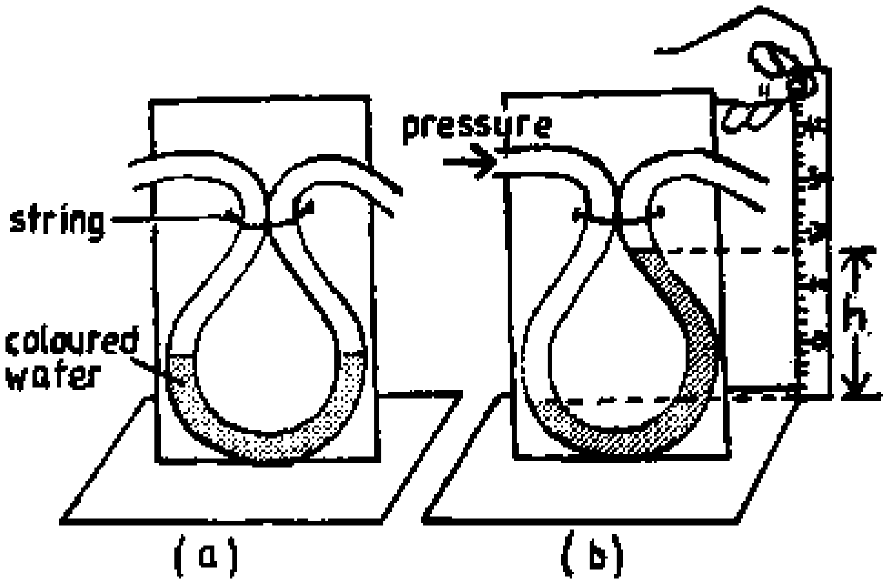
3.7.7 A Barometer



P: Assemble a barometer by closing a bottle *air-tight* by using a piece of plastic bag and a string. Glue the strow onto the middle of the piece of plastic and point the straw to a scale (see fig.)

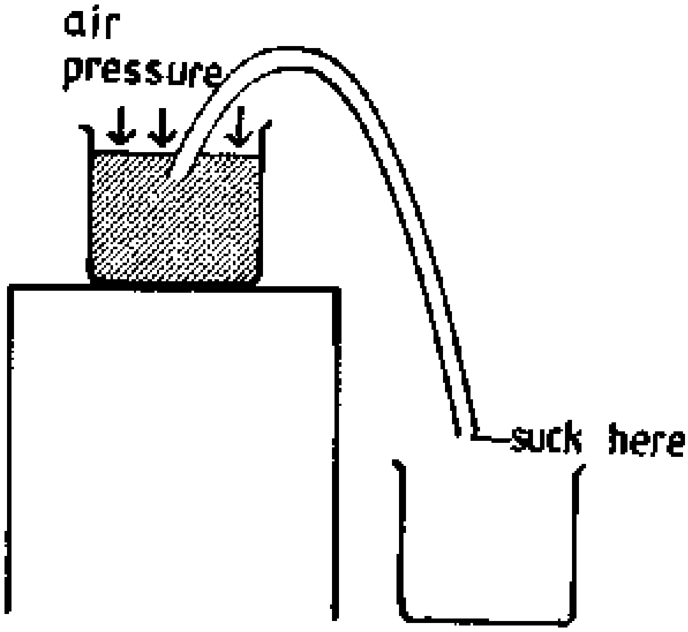
Q: How does this barometer work, when the air pressure increases or decreases respectively?

3.7.8 A Manometer



P: Make a manometer according to the figure. Use it to measure the water pressure at various depths of the tin of experiment 3.7.2, see p.26.

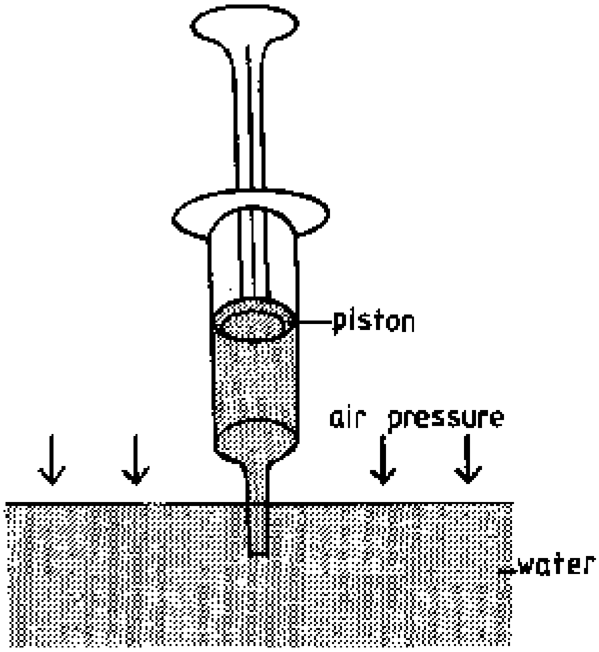
3.7.9 The Siphon



P: Arrange two glasses and a plastic or rubber tube as shown in the figure. Suck at the lower end of the tube.

Q: What happens? Why?

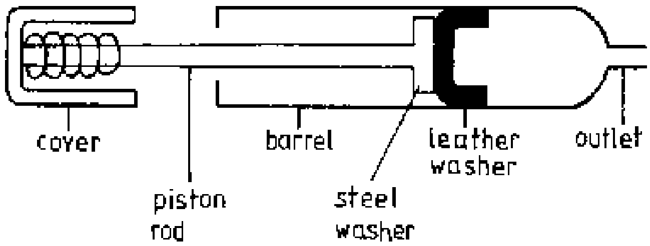
3.7.10 The Syringe



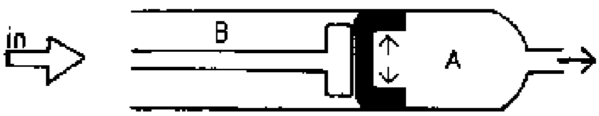
P: Obtain a one-way-syringe from a hospital. Suck water in as shown in the figure.

Q: Why does the water rise in the syringe?

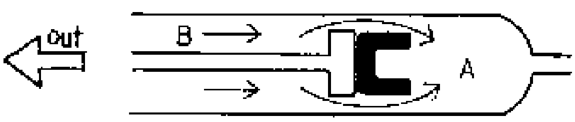
3.7.11 The Bicycle Pump



(a)



(b)



(c)

P: Using a bicycle pump, pump air into a bicycle tyre. Ask students to draw a display chart of the above figure.

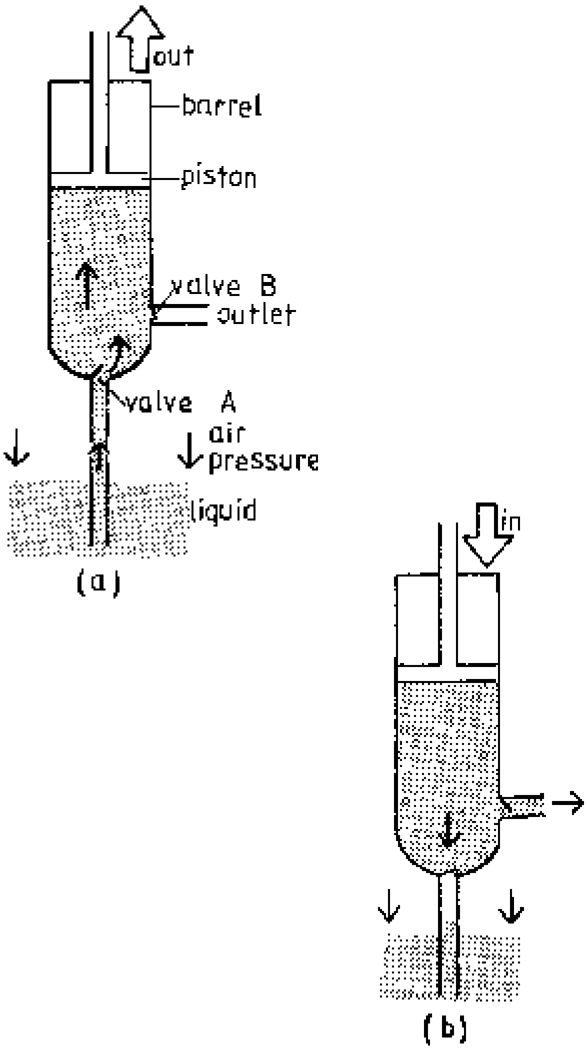
Q: Which stroke is easier, the inward or outward one? Why? Explain what happens in these strokes.

O: The outward stroke is easier than the inward.

E: *Inward stroke* (see fig. b): The air in region A will be compressed, and in turn it will press the leather washer against the barrel to make it air tight. Consequently air will be forced into the tube.

Outward stroke (see fig. c): The air in A decreases in pressure. Atmospheric air from B pushes the leather washer inwards and hence enters region A.

3.7.12 The Force Pump



P: Ask students to draw a display chart of the force pump according to the above figure.

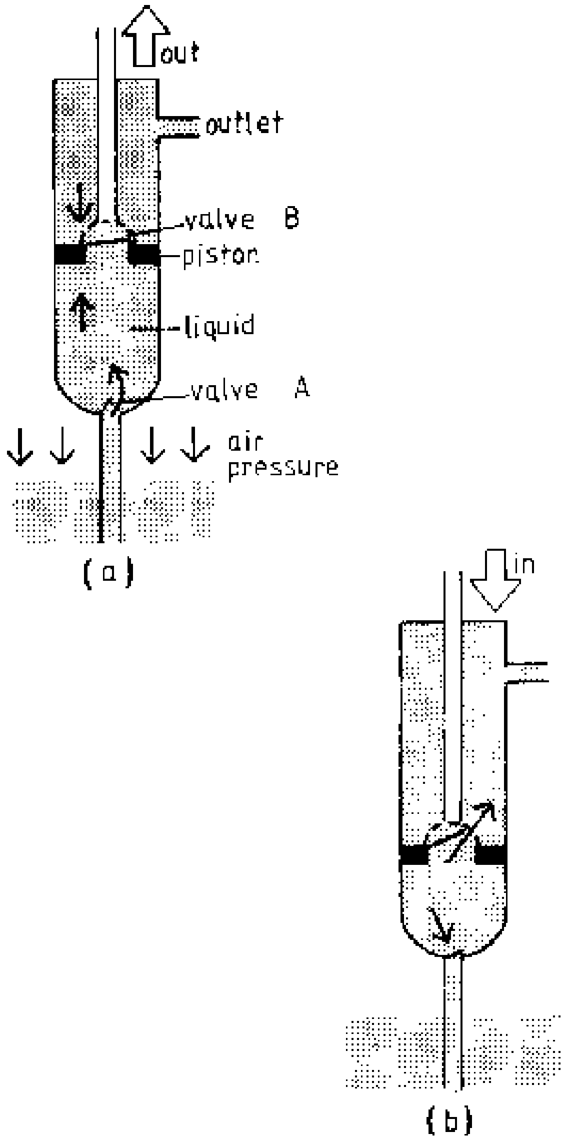
Q: Explain how the force pump works using the display chart.

E: *Outward stroke* (see fig. a). When the piston is raised, the liquid pressure in the barrel becomes less than the air pressure. Hence, the air pressure opens valve A and pushes the liquid up into the barrel. It closes valve B.

Inward stroke (see fig. b). When the piston is lowered, valve A closes and valve B opens because of the higher pressure of the liquid in the barrel. Consequently the liquid is forced through valve B to the outlet.

A: Force pumps are used to pump water from shallow wells in villages. Since the air pressure pushes the water up, the maximum depth from which the water can be lifted is less than 10 m

3.7.13 The Lift Pump



P: Ask the students to draw a display chart of the lift pump (see the above figure).

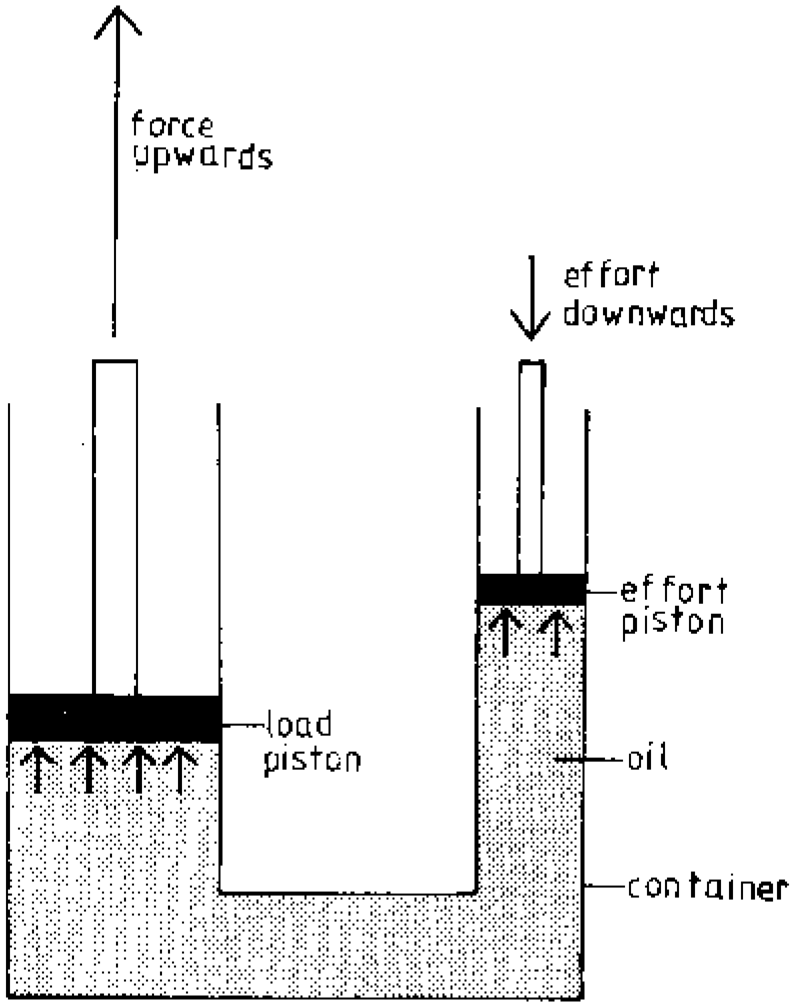
Q: Explain how the lift pump works using the display chart.

E: *Outward stroke* (see fig. a): The rising piston pushes the water on its upper side out of the outlet since valve B (on the piston) is closed. At the same time the air pressure pushes the water through the open valve A up the barrel.

Inward stroke (see fig. b): When the piston goes down, valve B opens and water flows from below to the top of the piston, while valve A is closed.

A: The lift pump is used to raise liquids from containers, e.g. tanks of kerosene etc.

3.7.14 The Hydraulic Press



P: Ask the students to draw a display chart of the hydraulic press according to the above figure.

Q: Explain - using the display chart - how the hydraulic press works.

E: A hydraulic press consists of a container which has one end wider than the other. Load and effort pistons are fitted in its ends respectively. Note that the load piston has a larger surface area than the effort piston.

When the effort piston is forced downwards, the pressure of the liquid, e.g. oil, is transmitted equally in all directions in the whole liquid.

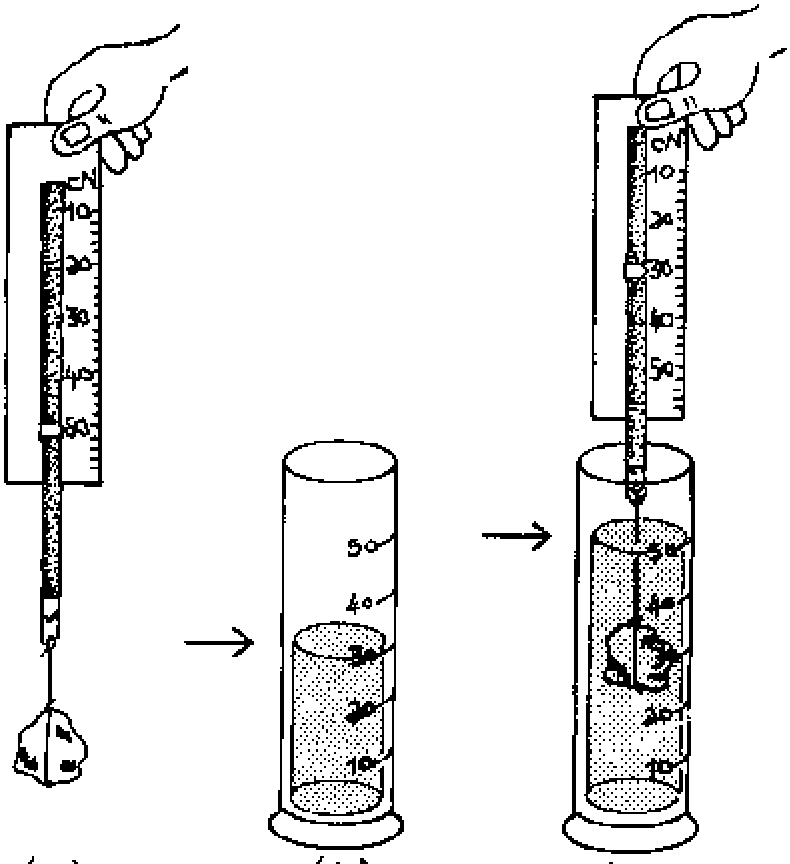
Therefore, the pressure at the load piston is the same as that one at the effort piston. Yet, since force = pressure x area and the area of the load piston is greater than that of the effort piston, the force at the load piston is greater than that at the effort piston. Thus, *small effort will raise a big bad.* However, the distance moved by the effort will be larger than that moved by the load.

A: Hydraulic systems are used in brakes, pressing bales of cotton, lifting heavy loads (e.g. vehicles in garages), etc.

3.8 Archimedes' Principle and the Law of Floatation

Archimedes' principle states that the *upthrust* (buoyancy) of a body immersed in a liquid is *equal to the weight of the liquid displaced* by the body. When a body *floats* then *the weight of the liquid displaced is equal to the weight of the body* (Law of floatation).

3.8.1 Upthrust



(a) (b) (c)

P: (a) Attach a stone to a thread, and fix it on a Newton balance (see p. 15). Note the weight of the stone.

(b) Fill a measuring cylinder partly with water and record the reading.

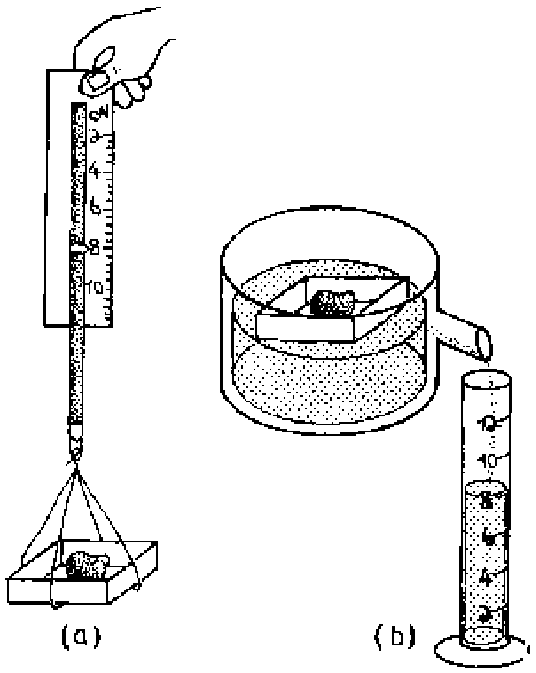
(c) Immerse the stone fully into the water (without touching the bottom of the cylinder) and record the reading of the spring balance. Record the reading of the water level too.

Q: How much is the volume of the stone? What is the weight of the water displaced, if 1 cm^3 of water weighs 0.01 N? By how much did the weight of the stone decrease when it was immersed in the water? What can you conclude about the upthrust?

O: For example, let the weight be 0.2 N. You observe that the decrease in weight when the stone is immersed is also 0.2 N, which is equal to the upthrust.

E: Thus, you have verified *Archimedes' principle.*

3.8.2 The Law of Floatation



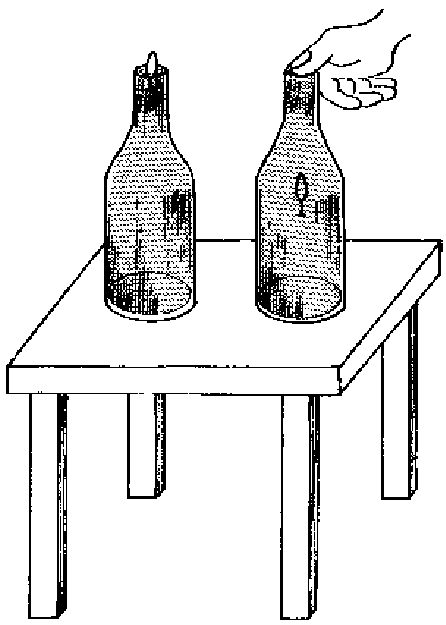
P: Load a matchbox with a small stone so that it still floats in water. Weigh the matchbox and . stone using a Newton balance to obtain its weight (see p. 15).

Fill the overflow can (see p.25) with water and allow the matchbox with stone to float on it. Let the overflow run into a measuring cylinder. From the volume of the overflow find its weight.

O: For example, the weight of stone and matchbox be 0.08 N. Then you will observe that the weight of the overflow will also be 0.08 N.

E: Thus, you have verified the *law of floatation.*

3.8.3 The Cartesian Diver



P: Fill a bottle to the rim with water. Load a small piece of styrofoam with a small nail so that it just floats in the bottle. This is the "diver". Close the bottle with your thumb airtight and apply pressure.

Q: What do you observe? Why?

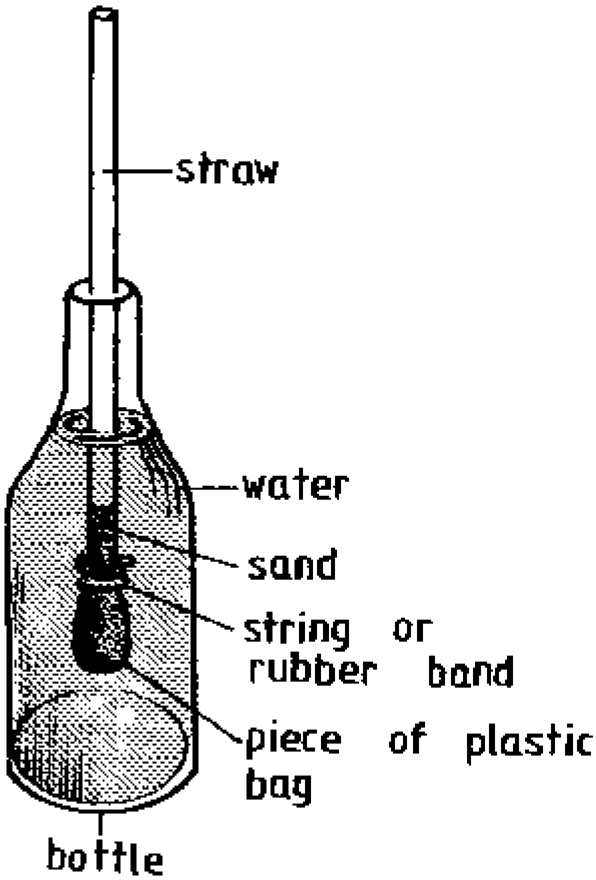
O: According to the pressure exerted by your thumb, the diver will sink or rise.

E: Styrofoam has very many tiny pores which are full of air. Thus, when the pressure of the water increases, the air is compressed, its volume decreases, but its mass remains constant Hence, its density increases, the diver sinks.

When the pressure is released, the air expands, its density decreases, the diver rises.

H: Do not allow the diver to stay for a long time in the water. Always remove it immediately from the water when your experiment is finished. Otherwise it will suck in water (since the styrofoam contains capillaries; see exp. 4.4.6, page 51) and sink even without the application of pressure.

3.8.4 The Hydrometer



P: Prepare a hydrometer by using a drinking straw. Close one end of the straw by wrapping it with a piece of a plastic bag water-tight using a rubber band or a thread.

Fill clean sand into it until it floats in a vertical position in fresh water. Mark the water level on the straw. Label it 1.0 (since water has a density of 1.0 g/cm^3). Take the distance of this mark from the bottom of the straw to be x cm. Now you may put marks for liquids with other densities by calculating their distance 1 cm from the bottom of the straw by using the formula:

$$1 = x \div (\text{density of liquid})$$

For example, if x = 9.4 cm, you calculate the position of the mark for a density of 0.9 g/cm^3:

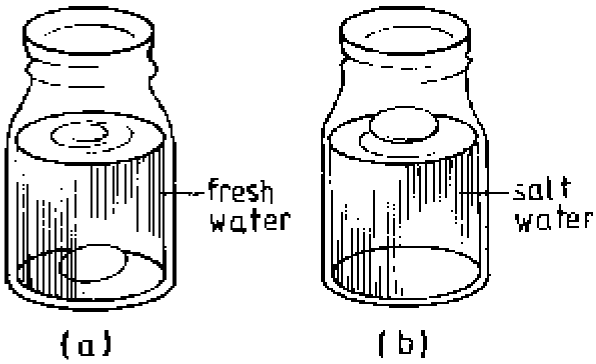
$$1 = 9.4 \text{ cm} \div 0.9 = 10.4 \text{ cm}$$

i.e. you place the 0.9g/cm^3 mark at the distance of 10.4 cm from the bottom of the straw, and so on. Place marks from 0.6 to 1.2 g/cm^3.

H: You might have to compress the sand at the bottom of the straw using a stick (or put a nail inside) in order to make it float vertically.

A: Use the hydrometer to measure the density of e.g. kerosene, sea water and pure milk. Thus you can discover the wateringdown of milk by measuring its density using the hydrometer.

3.8.5 An Egg in Water

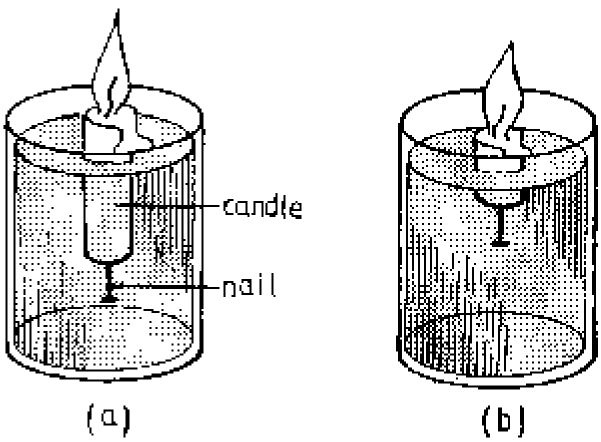


P: Place a fresh egg in water. Observe. Now dissolve salt in the water while stirring until the egg floats.

Q: Why does the egg float in the salt water?

E: The density of salt water is higher than that of fresh water. Thus, the weight of the displaced salt water becomes equal to the weight of the egg. Hence, the egg floats in salt water of a sufficient salt content.

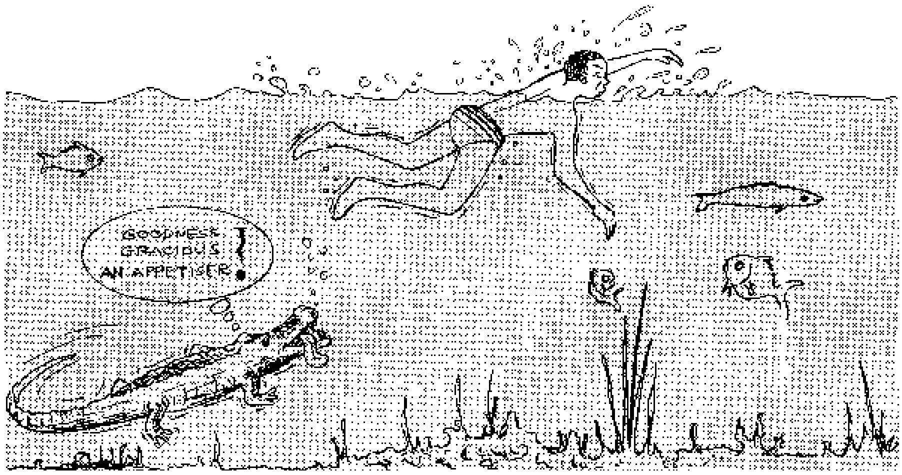
3.8.6 The Floating Candle



P: Put a nail into the bottom end of a candle so that the candle just floats with its top a bit above the surface of the water.

Light the candle and watch it as it burns up.

Q: Why does the candle continue to float even though it constantly loses weight as it burns up?



3.9 Work, Energy and Power

To pull a heavy cart is tiring work. In physics *work* is defined as follows:

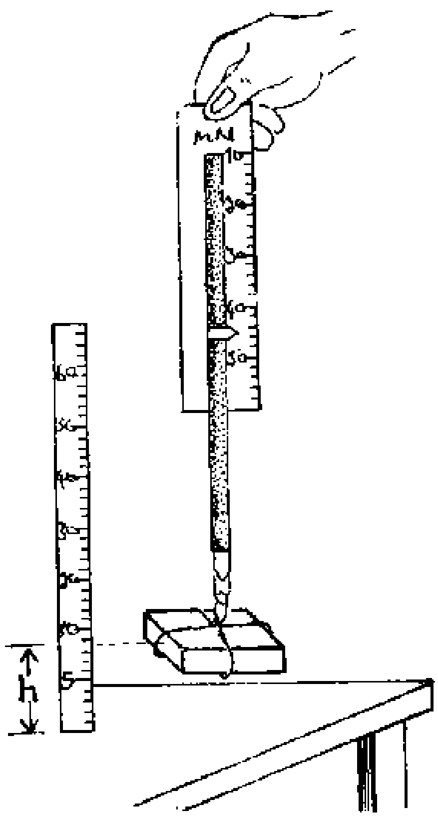
Work done = force x distance moved in the direction of the force.

Unit: 1 N x m = 1 J (joule)

Energy is the ability of doing work. Hence, its unit is also 1J.

Power is the rate of doing work, i.e. work per unit time. Its unit is 1 joule/second = 1 watt (1 W)

3.9.1 Work Done by Lifting



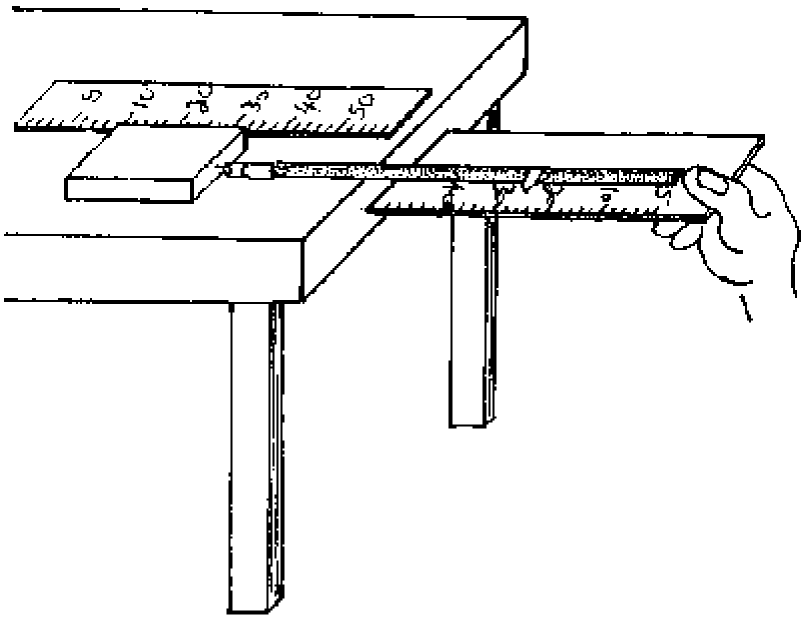
P: Raise a block of wood from the table using a Newton balance (see p. 15). Read the balance when you lift the block at *constant* velocity, not when starting or stopping. Compare this force with the weight of the block. Measure the vertical distance the block is raised.

Q: Calculate the work done when the block was raised by the vertical distance h.

E: The force which lifts the block at constant velocity is equal to its weight in magnitude but has the opposite direction. Thus, the *work done by lifting* is

Work done = weight x vertical distance

3.9.2 Work Done by Friction



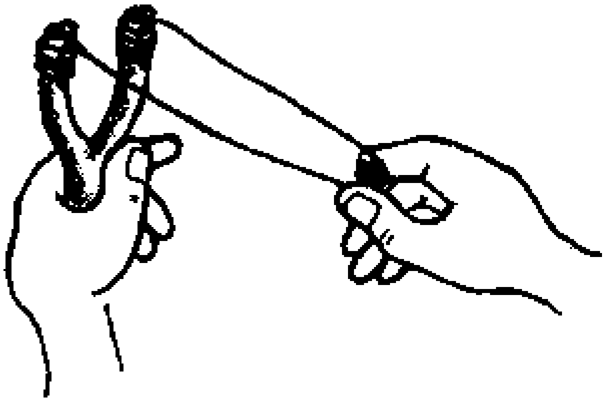
P: Place a block of wood on a table. Pull it with constant velocity using a Newton balance. Measure the distance moved by the block.

Q: Calculate the work done from the reading of the balance and the distance measured.

E: The force which pulls the block at constant velocity is equal to the force of friction in magnitude but has the opposite direction. Thus, the *work done by friction* is

Work done = force of friction x distance moved

3.9.3 A Catapult



P: Tie a rubber band to the ends of a branched stick. Place a stone in the middle of the rubber band and stretch the band by pulling the stone towards you. Then release it.

H: Be very careful that nobody will be hit by the stone!

Q: What do you observe?

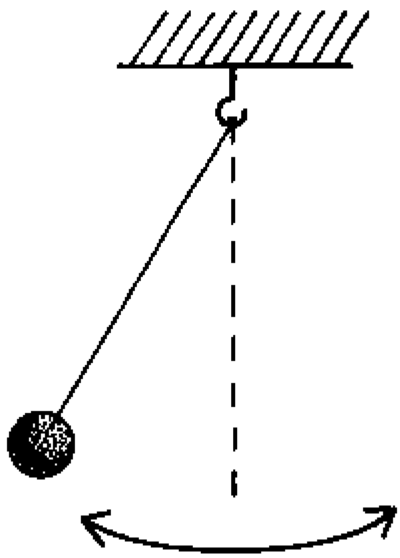
What kind of energy does the stretched rubber band, what the flying stone possess?

3.9.4 The Principle of a Steam Engine

P: Fill some water into an opened electric bulb (see appendix) and close it *slightly* by a stopper. Then holding it with a strip of paper heat it using e.g. a kerosene burner until the water boils.

Q: What happens to the stopper? What energy changes take place?

3.9.5 A Pendulum

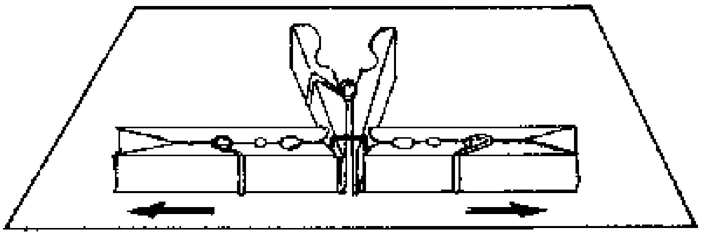


P: Suspend a stone on a long string. Displace it sidewards.

Q: What do you observe? What changes in energy take place?

E: When the pendulum is displaced sidewards by your hand, *chemical energy* of your food is changed into *potential energy* of the pendulum. When the pendulum swings back, it converts the latter into *kinetic energy* which is changed again into *potential energy* on the other side of the oscillation and so on.

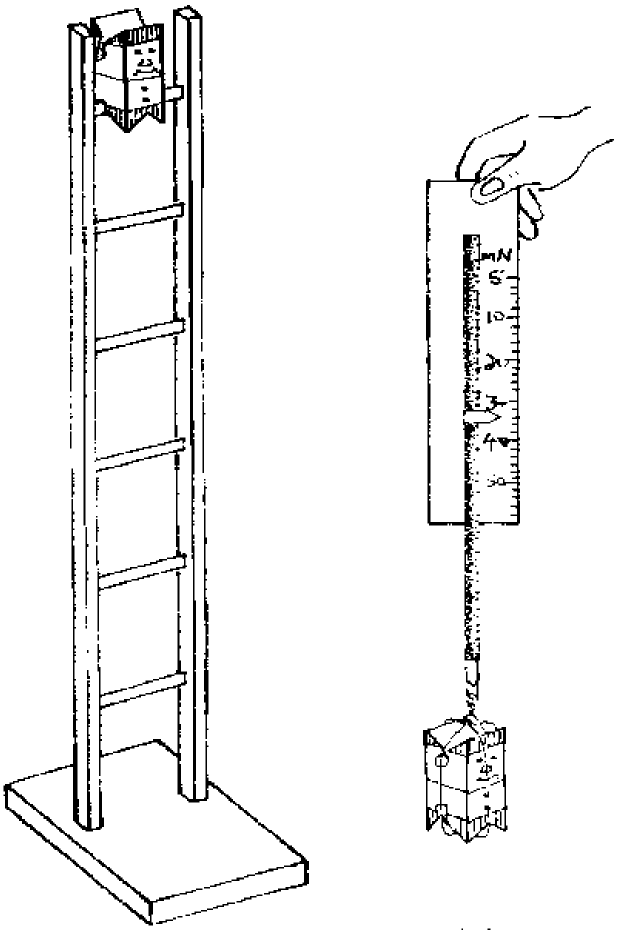
3.9.6 Potential Energy in a Clothes-Peg



P: Tie the handles of a spring clothes-peg together with *one* loop of thread. Place this peg at the middle of a smooth table and place two other pegs beside it, one against each end of each handle. Bum the thread.

Q: What do you observe? What changes in energy take place?

3.9.7 Energy and the Funny Jumper



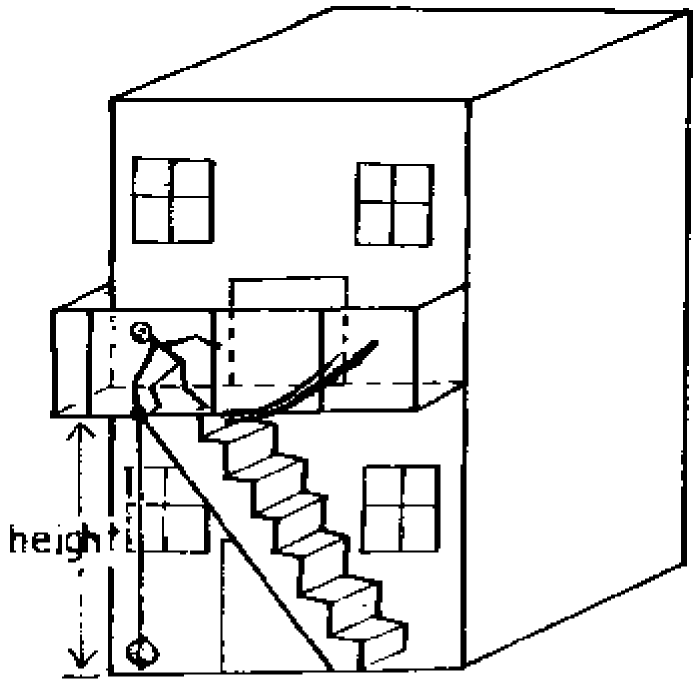
(a) (b)

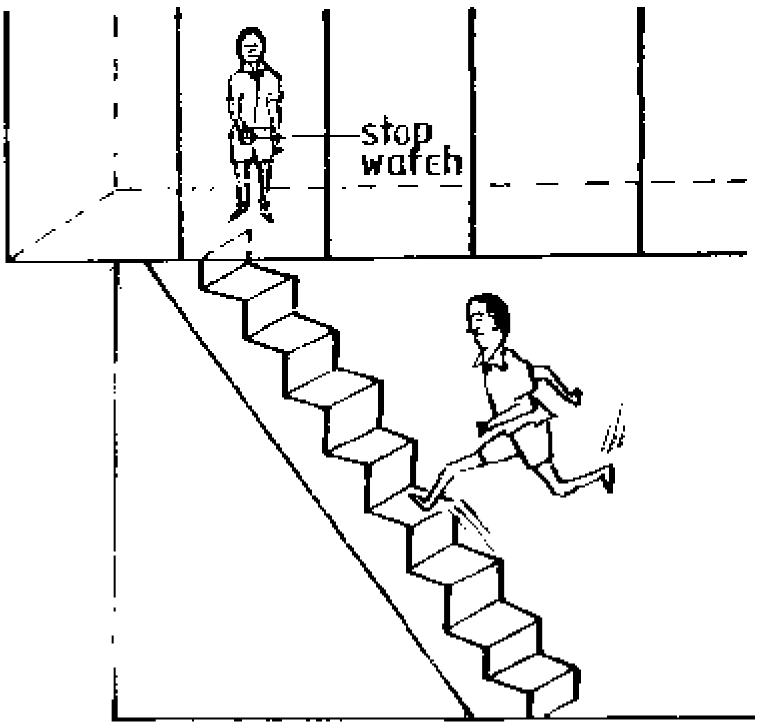
P: Set up the funny jumper (see p.21). Weigh the jumper using a Newton balance.

Q: Calculate the potential energy of the jumper when it is on the uppermost step of the ladder. Where does this energy go when it jumps down step by step?

E: The *potential energy* of the jumper is equal to its weight times the height of the uppermost step above ground. As the jumper jumps down, this energy is converted into *kinetic energy* (energy of motion) which in turn is converted into *heat* by friction.

3.9.8 Power





P: Measure the vertical height above ground of the first floor of a storey building. Run up to that floor as fast as you can while your friend times you with a watch. Take your weight (probably in a hospital).

Q: Calculate your maximum power.

E: Using your weight and the height of the first floor above ground, first calculate the potential energy (PE) of your body when it is on the first floor:

PE = weight x height

This is the energy which you had to give out in order to raise your body to that height.

Now calculate your power by dividing that energy by the time (in seconds) you needed for running up.

3.10 Simple Machines

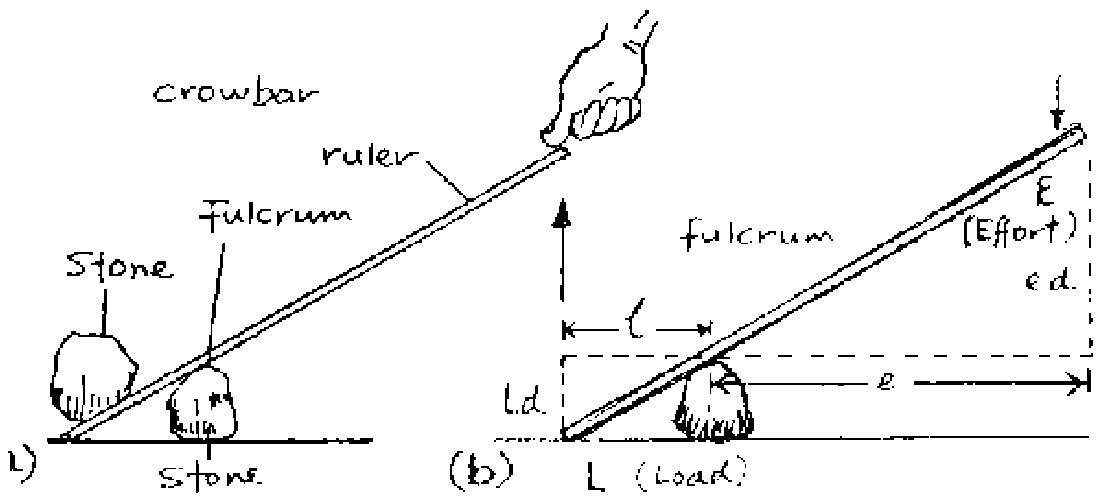
Simple machines use the principles of Physics to give us mechanical advantage, e.g. to *lift a heavy load using a small effort.* Examples are levers, wheel and axle, pulleys, the inclined plane etc.

Mechanical advantage (MA) = load ÷ effort. It depends on friction.

Velocity ratio (VR) = distance moved by effort ÷ distance moved by load. It does not depend on friction.

Efficiency = output ÷ input - work done on the load ÷ work done by the effort = MA ÷ VR. It depends on friction.

3.10.1 Levers



P: Make a lever using your ruler and a tipped stone. Use it to lift a heavy stone or brick.

Q: Do you feel the mechanical advantage? Derive a simple formula for MA (assuming there is no friction) using moments of forces (see p.20).

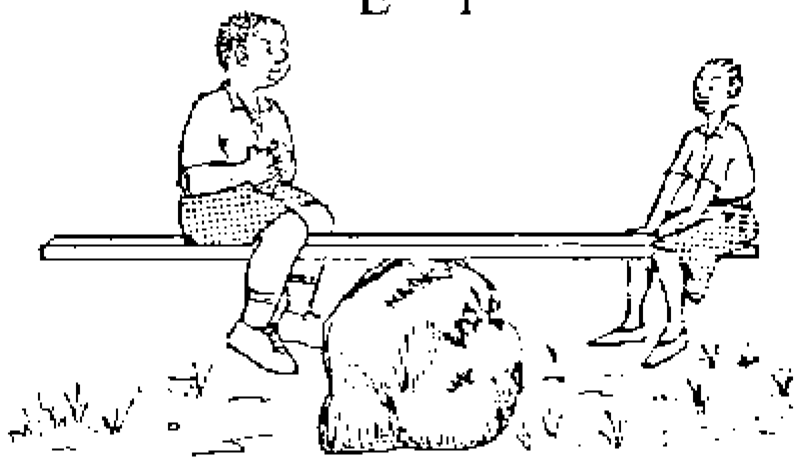
O: The effort is less than the load but the distance moved by the effort (d.e.) is longer than the distance moved by the load (d.l.).

E: Taking moments of forces (see fig. b) we obtain (neglecting friction):

$$L \times 1 = E \times e$$

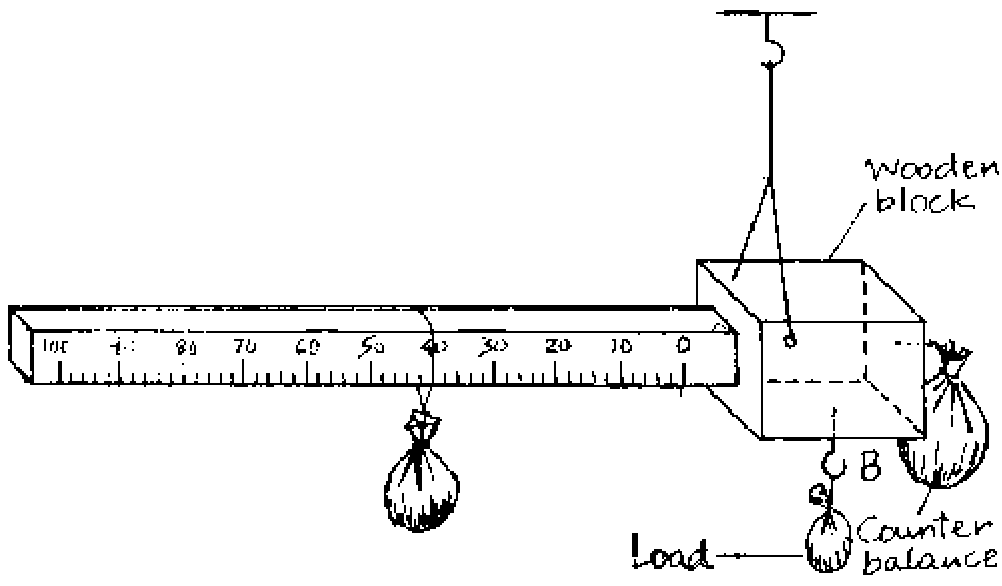
A:

$$\frac{L}{E} = \frac{e}{l}$$



The seesaw, pliers, the wheelbarrow, tweezers, the bottle opener, the forearm, the roman steelyard, etc. are all levers.

3.10.2 The Roman Steelyard



P: Make a roman steelyard according to the figure using wood.

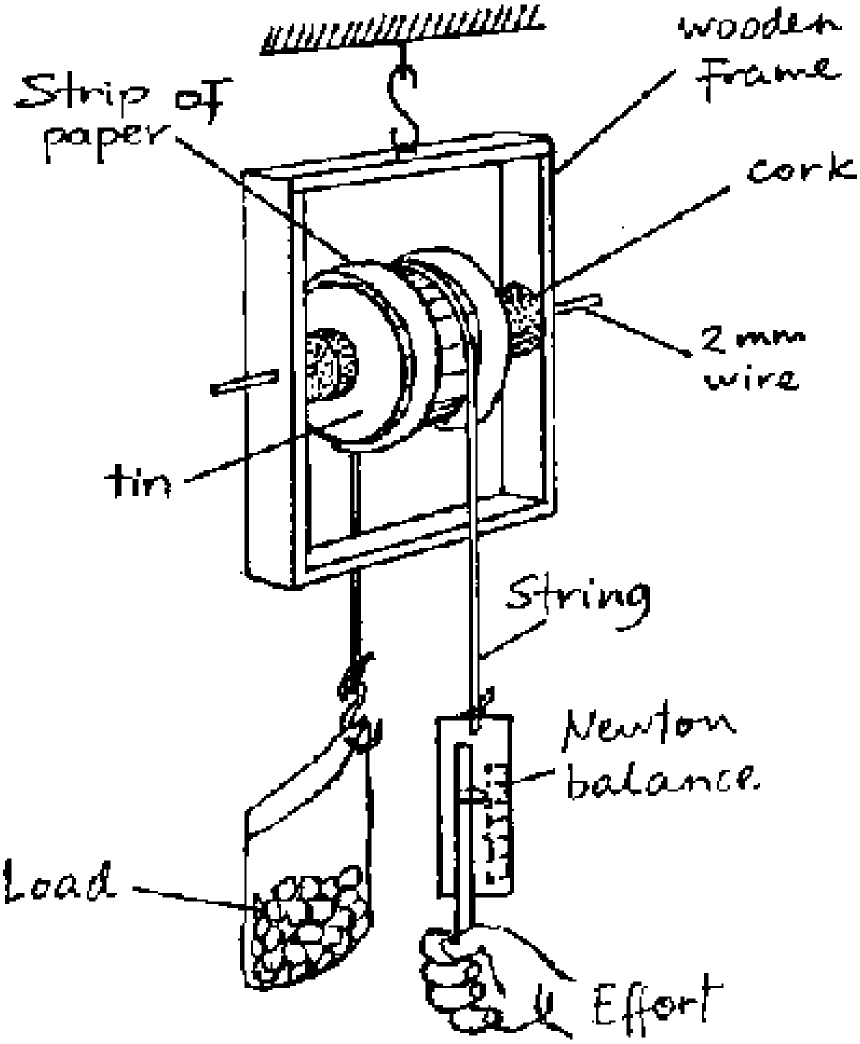
Calibration: Suspend the roman steelyard in air. Then suspend e.g. a 100 g mass on the assumed zero mark. Hang a counterbalance mass on the other side (as shown) so that the whole system balances horizontally. Then hang a standard mass, e.g. 50 g on B and adjust the 100 g along the rod so that the whole system balances horizontally. Mark this point for the standard mass used (e.g. 50 g). Repeat this procedure for other masses (e.g. 100, 150, 200 g, ...).

How to measure an unknown mass (load): Suspend the load (whose mass you want to determine) from B. Then adjust the 100 g mass along the beam so that the whole system balances horizontally. Read and record the mass of load.

H: The whole system should be suspended freely in air and it must be balanced *horizontally* in each step.

A: Used in weighing cotton, bags of coffee etc.

3.10.3 The Single Pulley

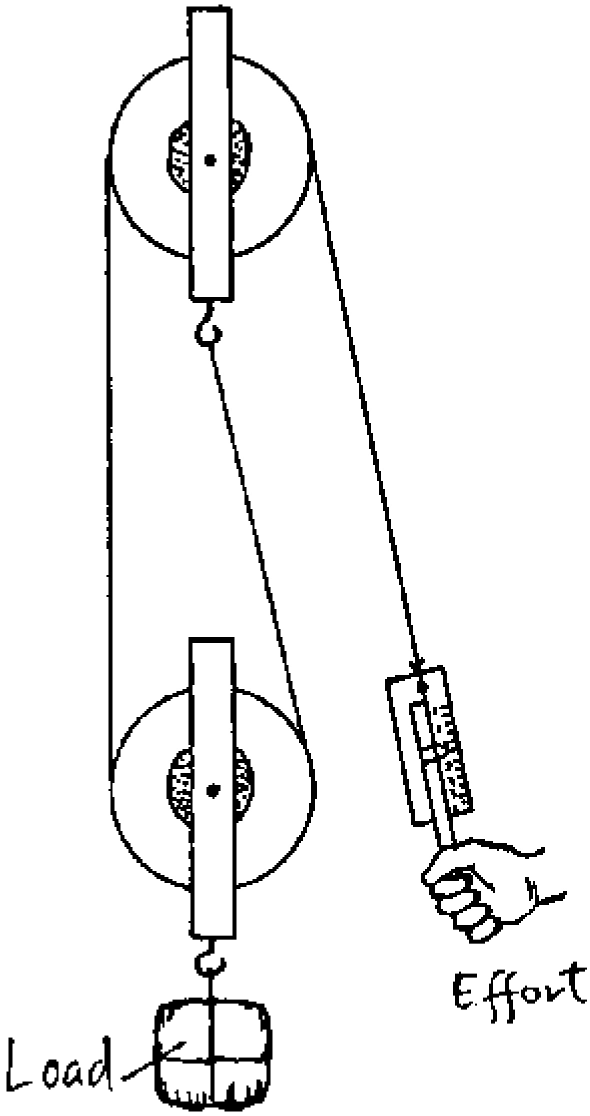


P: Produce a pulley by boring holes in the centre of the top and the bottom of a small tin. Take a wire of 2 mm diameter as an axle and fix it in a wooden frame as shown in the figure. Attach strings and use it to lift a load (which should be much heavier than the pulley). Use a Newton balance to measure load and effort.

Q: What is the MA of the simple pulley? What is the advantage of it?

E: A single pulley has an MA of 1, i.e. the effort is as big as the load is (including friction it is even bigger). Yet, the advantage is that the pulley *changes the direction* of the force. You can easier lift a heavy load by pulling downwards (assisted by your weight) than by pulling upwards.

3.10.4 The Two Pulley System



The two pulley system is the simplest *block and tackle* which gives a real MA when used to lift heavy loads.

P: Connect two single pulleys as shown in the above figure. Use this system to lift the same load as in experiment 3.10.3. Measure the effort using a Newton balance.

Q: What do you feel when lifting the load directly and when using this pulley system? How is the MA now (if you neglect friction and the weight of the lower pulley)? How far does the effort move, when the load moves, e.g. a distance of 20 cm?

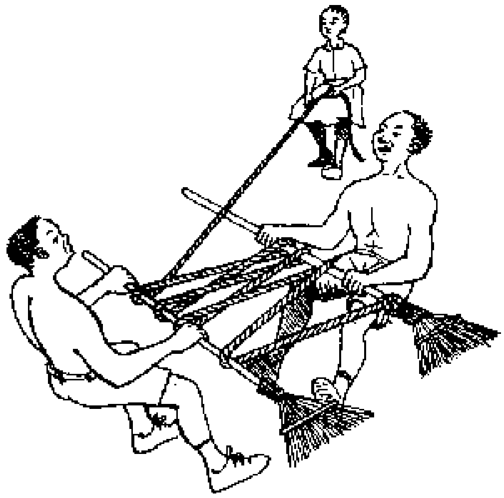
O: It is easier to lift the load using this system: the effort is smaller.

E: Neglecting friction and the weight of the lower pulley, the MA will be 2, i.e. the load is twice the effort. However, in practice it is less due to the factors mentioned.

The effort moves 40 cm when the load moves 20 cm.

A: Cranes (e.g. in harbours) use (even more complex) pulley systems to lift very heavy loads.

3.10.5 A Riddle



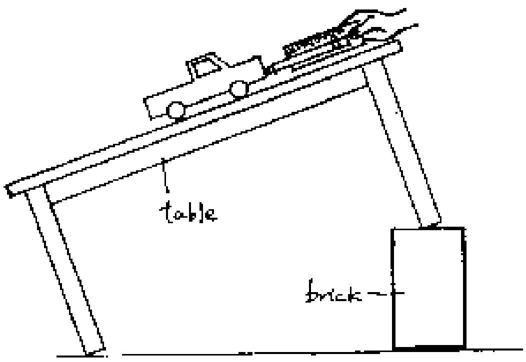
P: Ask two strong boys and a girl to take two (broom) sticks and a rope and to arrange themselves as shown in the figure.

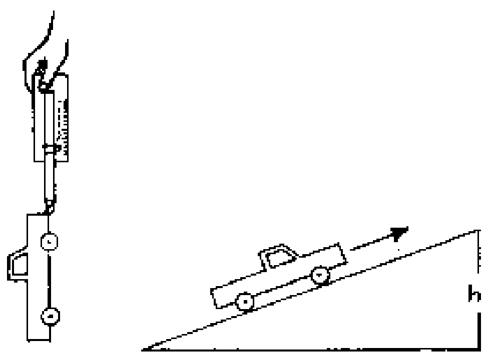
Q: Will the girl be able to pull the two strong boys together or can the boys resist the pull of the girl?

O: The girl wins. Why?

E: This is an arrangement of "broomstick pulleys". Thus, the girl needs much less effort to pull the heavy loads of the two boys! However, the girl will have to move farther than the boys do.

3.10.6 The Inclined Plane





P: Tilt a smooth table by placing bricks underneath its legs on one end of the table (see fig. a). Ask students to bring their toy cars.

Weigh a toy car using a Newton balance. Now pull this toy car up the inclined plane of the table using a Newton balance to measure the effort.

Q: Is the effort smaller than the load (weight of the toy car)? How is the velocity ratio = (distance moved by effort along the slope) ÷ (distance moved by the load *vertically*)?

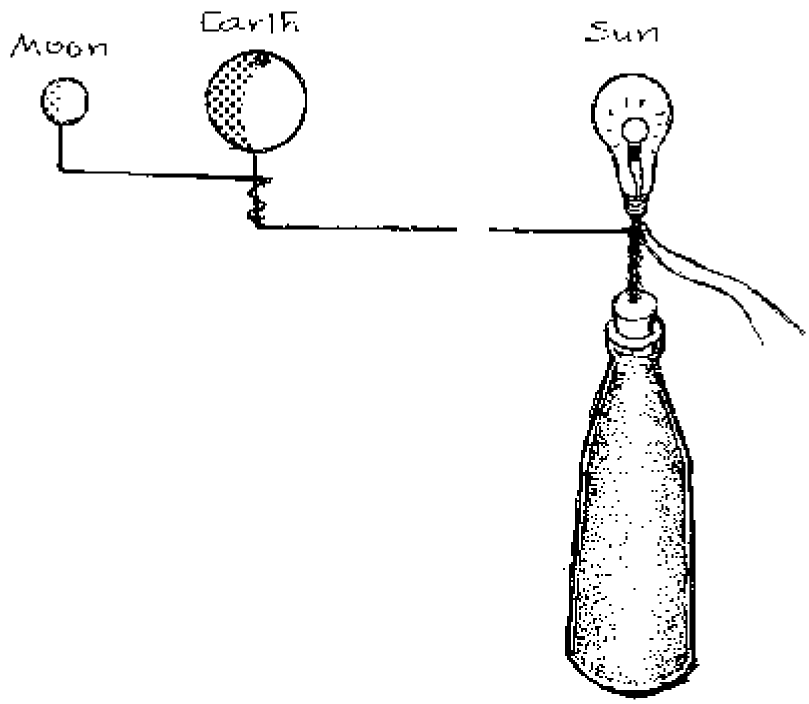
E: The effort is smaller than the load. The MA depends on the inclination of the plane as does the VR which is greater than 1.

A: Hills, slopes and ramps are examples of inclined planes, screws apply the same principle. The Egyptians used inclined planes do build their pyramids as people do sometimes nowadays to carry the building materials when building a two or three storey house.

3.11 Astronomy - The Solar System

Astronomy is the study of bodies in the universe and of their motion, e.g. the study of the solar system. The sun has nine planets going around it. The planets differ in size and relative distances from the sun. They are kept in their almost circular paths by the *gravitational force* of the sun which acts as *centripetal force.*

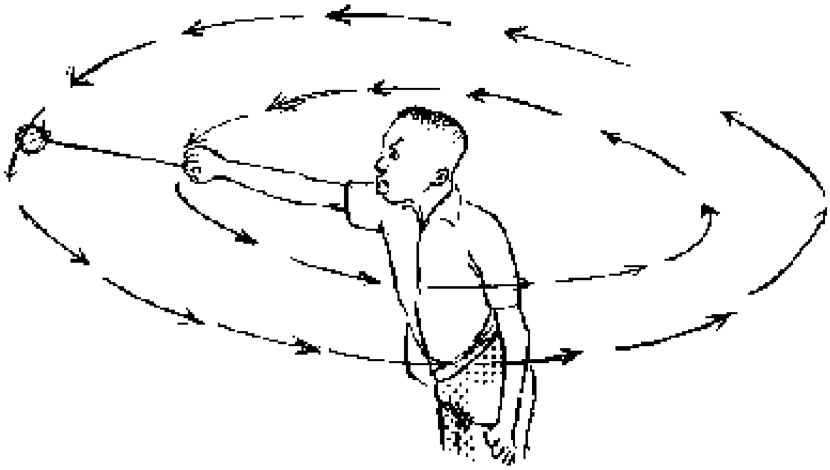
3.11.1 Model of Sun-Earth-Moon

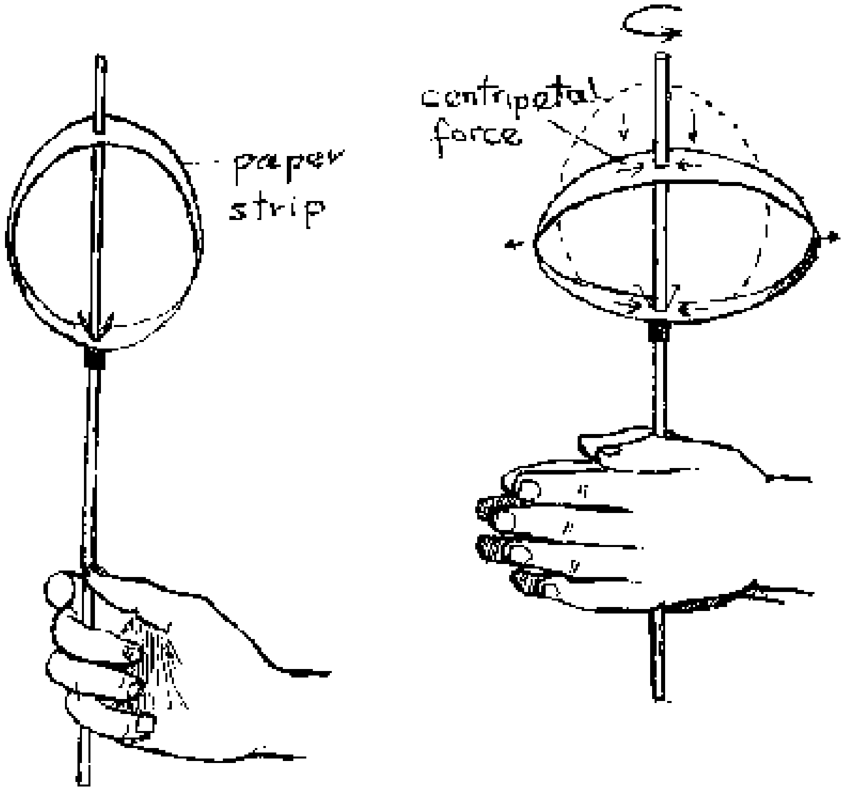


P: Pierce a seed and a small fruit with wires. Join an opened bulb (see appendix) to a bottle filled with sand using a wire. Join the three wires so that they allow rotation. The seed, fruit and bulb represent moon, earth and sun respectively. The bulb may be lit using a torch bulb and battery.

E: The model can be used to show the movement of the earth and the moon around the sun and earth respectively. It can also show the eclipse of the moon and the sun, when the earth shades the moon or the moon shades a part of the earth respectively.

3.11.2 Centripetal Force





Due to its inertia a body will move along a straight line when *no* force acts on it. What force keeps the planets on their circular paths?

P: Tie a ball or stone to a thread and whirl it around as shown in the above figure.

Q: What force keeps the stone on its circular track?

E: There acts a force along the thread (which you feel in your hand) called the *centripetal force* which forces the stone to the circular path. Thus, a centripetal force must also act on each planet to keep it on its circular path.

3.11.3 Demonstrating the Solar System

P: Place a chair at the centre of the football field of your school to represent the sun. Now ask nine students to go around the chair in circles to represent the planets. The radius of each circle should correspond to the distance of the respective planet from the sun.

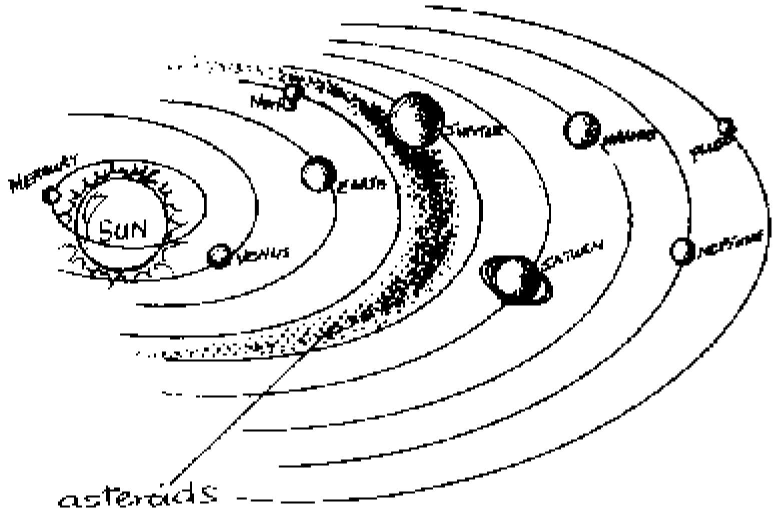
For example, if you use a scale of 1 cm representing a distance of 1 million km from the sun, then (see the table below) the radius of the mercury path must be 58 cm, that of the venus 107 cm, that of the earth 149 cm and so on. (Of course, in this scale, the sun would be a ball of 2 cm diameter, the earth only a grain of sand).

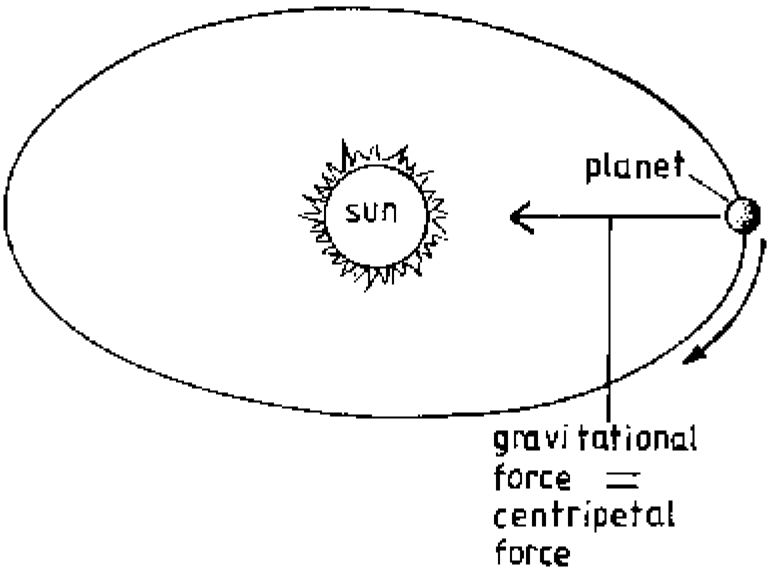
Q: What will be the radii of the paths of Jupiter, Uranus and Pluto respectively in this model?

E: They will be 7.8 m, 28.5 m and 58.7 m respectively.

Planet	Distance in millions of km from sun
Mercury	58
Venus	107
Earth	149
Mars	227
Jupiter	773
Saturn	1418
Uranus	2853
Neptune	4469
Pluto	5866

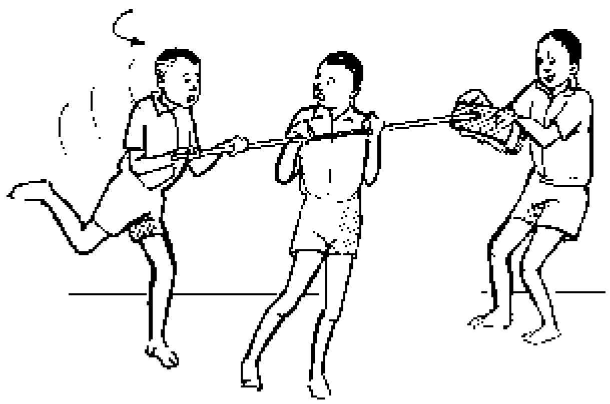
3.11.4 Gravitational Force

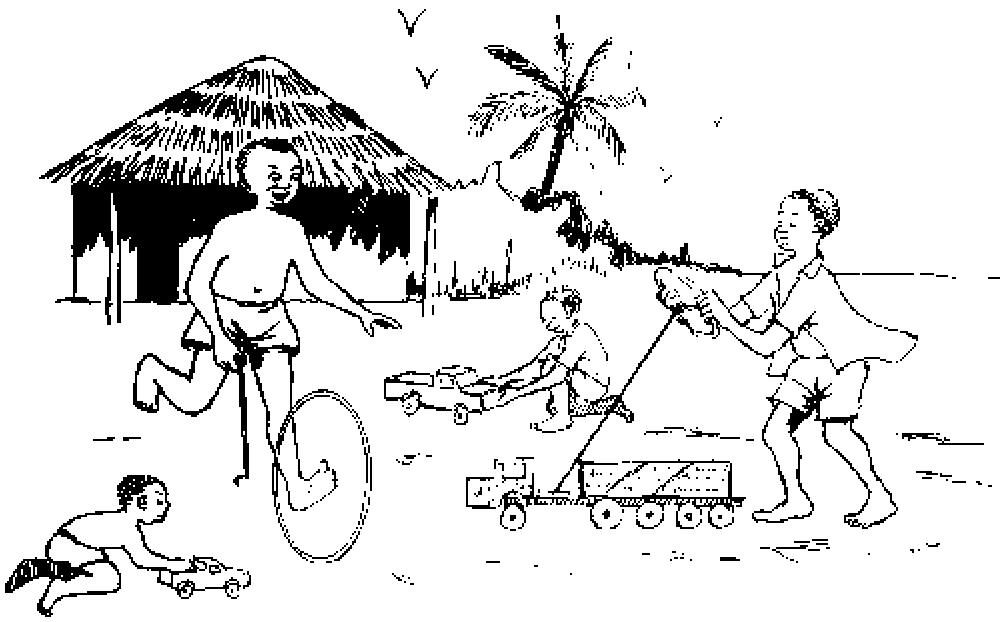




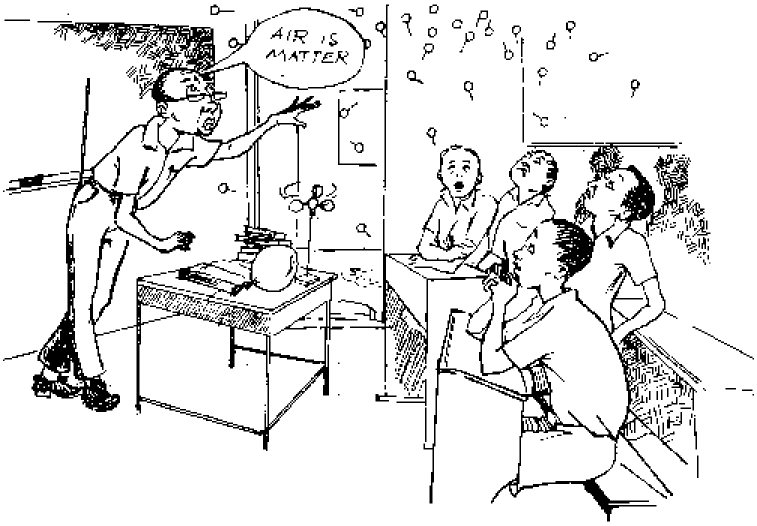
How do we call the force which acts as the centripetal force for the planets? Obviously, the planets are not tied to the sun by a string as the stone in experiment 3.11.2 is tied to your hand.

There must be a force acting through the empty space tying the planets to the sun. This force is the pull of the mass of the sun on the mass of the respective planet. It is a force of attraction between the two masses which we call *gravitational force.* Thus, the gravitational force between the sun and a planet acts as centripetal force (always directed towards the sun) to keep the planet in its circular path. (You can feel the gravitational force of the earth causing the *weight* of a body on the earth. Due to this gravitational pull of the earth, e.g. a stone falls down to the earth where released.)





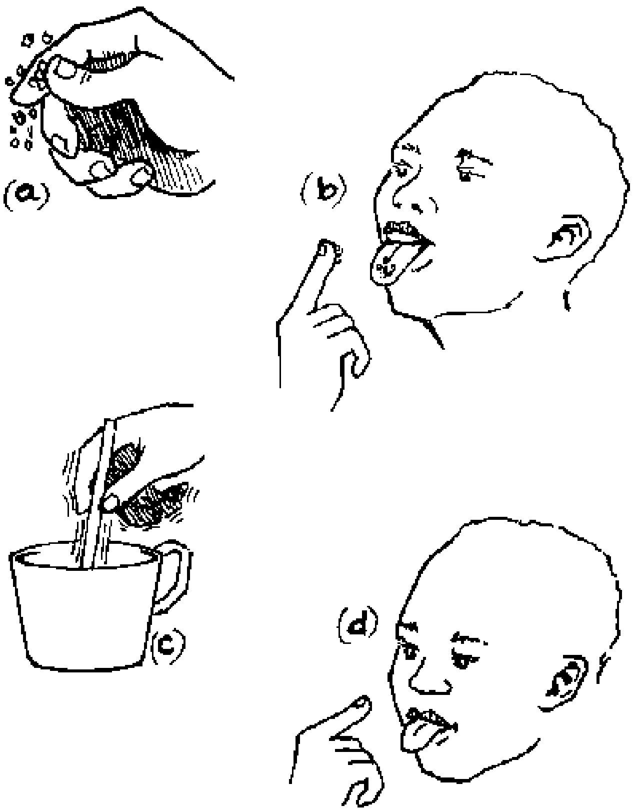
4. Matter



4.1 The Particle Model of Matter

Matter is anything which occupies space and has mass. It consists of very *small* particles called atoms or molecules which take part in chemical reactions. The particles possess kinetic energy. Therefore they are in constant vibration. The energy content increases with the increase in temperature. Hence, the motion of the particles increases with the temperature. Forces exist which hold the particles strongly together in *solids,* while they can easily move past each other in *liquids* and *gases.*

4.1.1 Salt is Made of Particles



P: Take some salt (or sugar) crystals and roll them between your fingers in order to feel their hardness. Taste the crystals.

Take a small amount of boiled water and taste it.

Put salt (or sugar) crystals into the water and shake. What happens? Taste again.

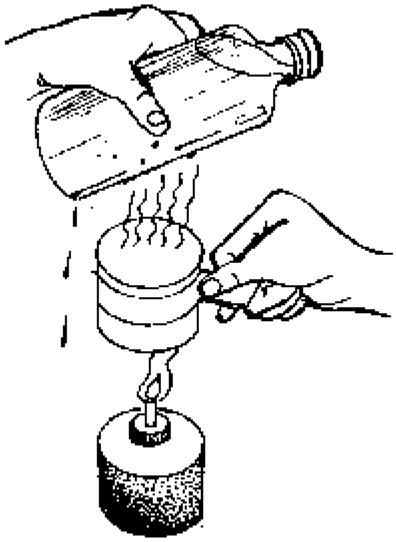
Q: Describe and explain your observations.

O: Salt crystals are often of cubical shape. They are quite hard.

The crystals dissolve in water. The solution tastes like salt (or sugar).

E: Sugar or salt in water exists as very tiny invisible particles that can be identified by tasting.

4.1.2 Water is Made up of Particles



P: Pour a small amount of water into a tin can and heat it until it boils. Fill a bottle with cool water and hold it above the tin can.

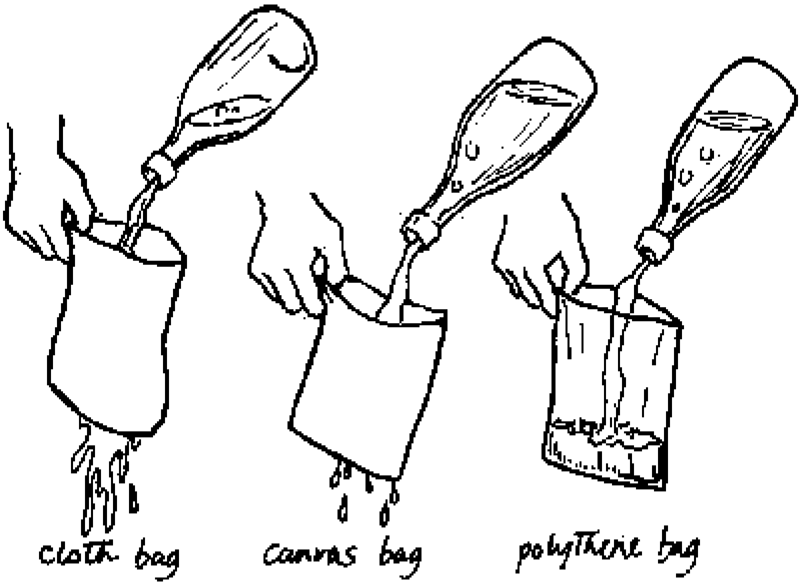
Q: What do you observe?

O: Water drops form on the outside of the cool bottle wherever it is touched by the steam of the boiling water.

E: Water particles escape from the boiling water as vapour and condense on the lower surface of the bottle to form water droplets.

The formation of drops from vapour is an indirect evidence that water is made up of small particles.

4.1.3 Size of Particles

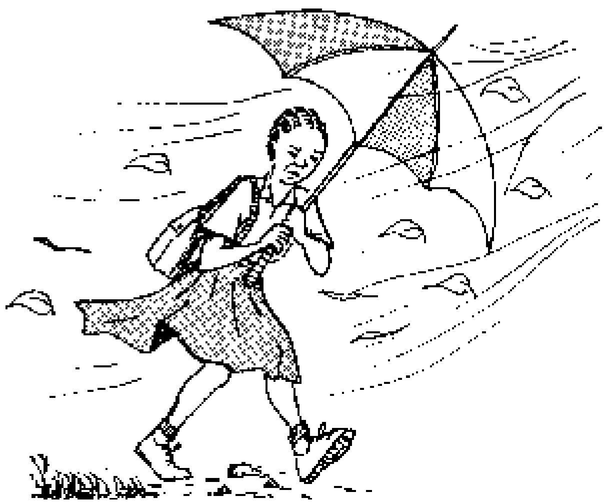


P: Make bags from cotton cloth, canvas cloth and polythene sheet Fill water into the bags.

Q: What do you observe?

E: Water passes through cotton and canvas but not through polythene. This is because polythene has too small pores to allow water particles to pass through.

4.1.4 Feeling Particles

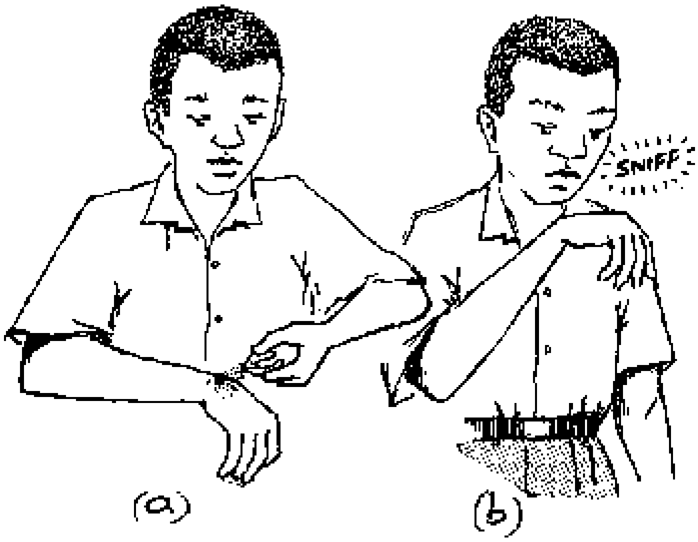


P: A wind is blowing vigorously towards a student carrying an open umbrella.

Q: What will she feel?

E: The umbrella is forced down by the wind pressure. This is due to the current of air particles (wind).

4.1.5 Smelling Particles

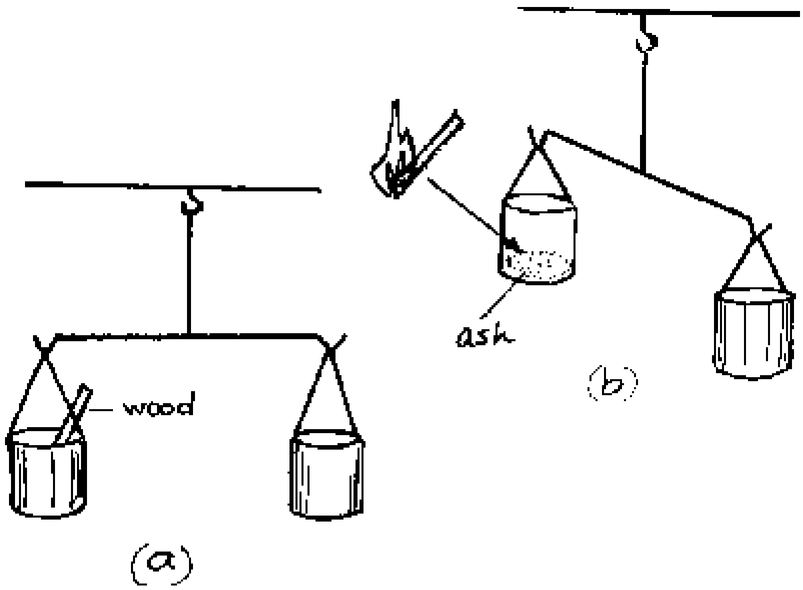


P: Let a student squeeze an orange peel.

Q: What can he sense?

E: He smells the orange, because invisibly tiny particles from the orange peel spread by diffusion to his nose.

4.1.6 Weighing Particles



P: Ask students to weigh pieces of wood. Record the weight. Burn the pieces of wood and weigh the ash.

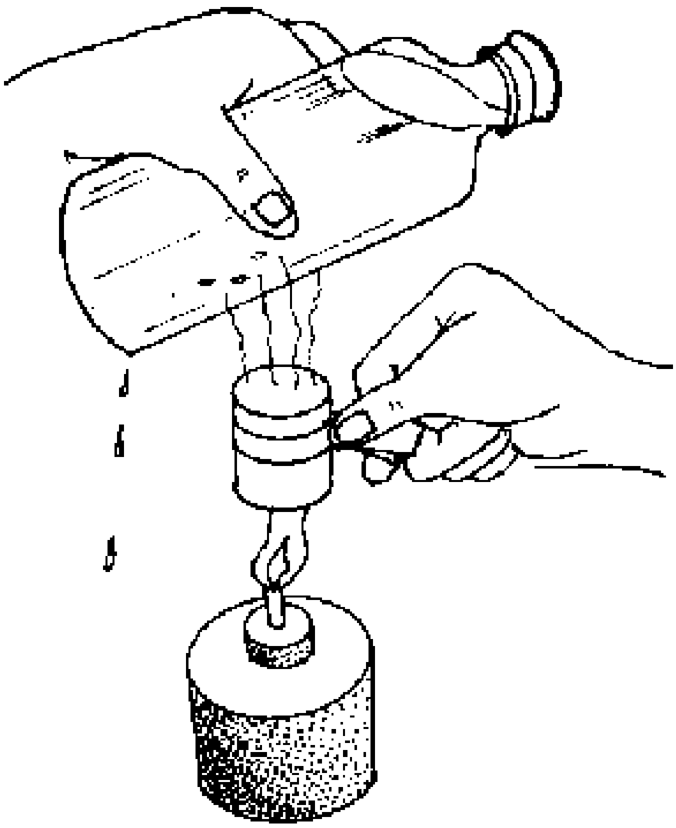
Q: Is there any difference between the weight of the wood and the ash?

E: The weight of ash is less than that of wood. The loss in weight is due to particles which escaped as soot and gas.

4.2 States of Matter

Matter exists in three states namely: solid, liquid and gas. The three states can be converted into one another by heating and cooling. In *solids* the particles are very close together and have a definite order. In *liquids* the particles are slightly farther apart than in solids and can move past each other. In *gases* the particles are in fast random motion. The three states differ mainly in the thermal energy each contains and as a consequence in the volume which equal masses of the same substance occupy.

4.2.1 Changes of State

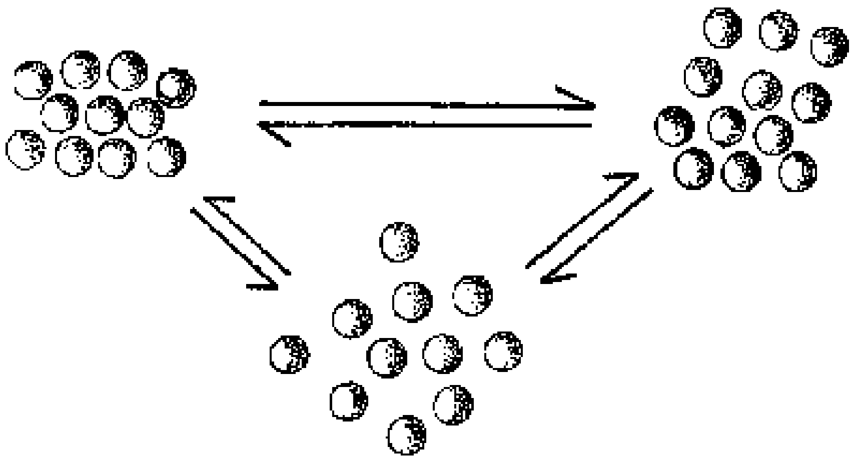


P: Heat pieces of candle wax carefully in a spoon or in a tin and hold a glass filled with cold water above it.

Q: What do you observe?

O: On heating, the solid melts to form a liquid and then by further heating the liquid evaporates as a vapour which is in gaseous state. The gas then condenses at the cold surface. This is similar to experiments performed with water (see 4.1.2, 5.3.1 and 5.3.2).

4.2.2 Explaining the States of Matter



P: The three states of matter can be explained by simple models as shown in the figures above.

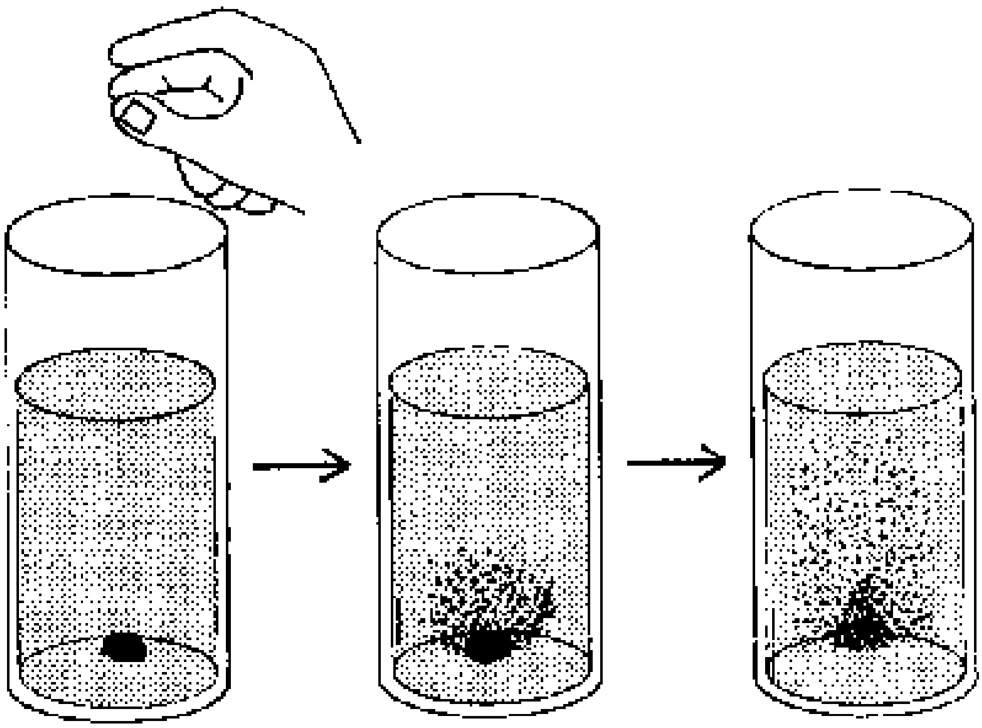
Q: What do the pictures represent?

E: Very close pupils or balls represent the particles in the *solid* state. Farther apart pupils or balls represent the particles in the *liquid* state. They move past each other. Fast and randomly moving pupils or balls represent the particles in the *gaseous* state.

4.3 Motion of Particles

Particles are in random motion. However, they cannot be seen. How do we get to know about their motion? The existence of the molecular motion can be deduced by indirect evidence through observation of *diffusion.* The movement of one kind of substance through a volume already occupied by another substance is known as diffusion. More direct evidence for molecular movement in gases or liquids comes from *Brownian movement.* Small visible particles can be seen in an irregular movement. From this we conlude that rapidly moving invisible gas molecules collide with them.

4.3.1 Diffusion in Liquids



P: Put a crystal of potassium manganate (VII) (permanganate) into a jar containing water. Set the jar and observe.

Q: What do you observe?

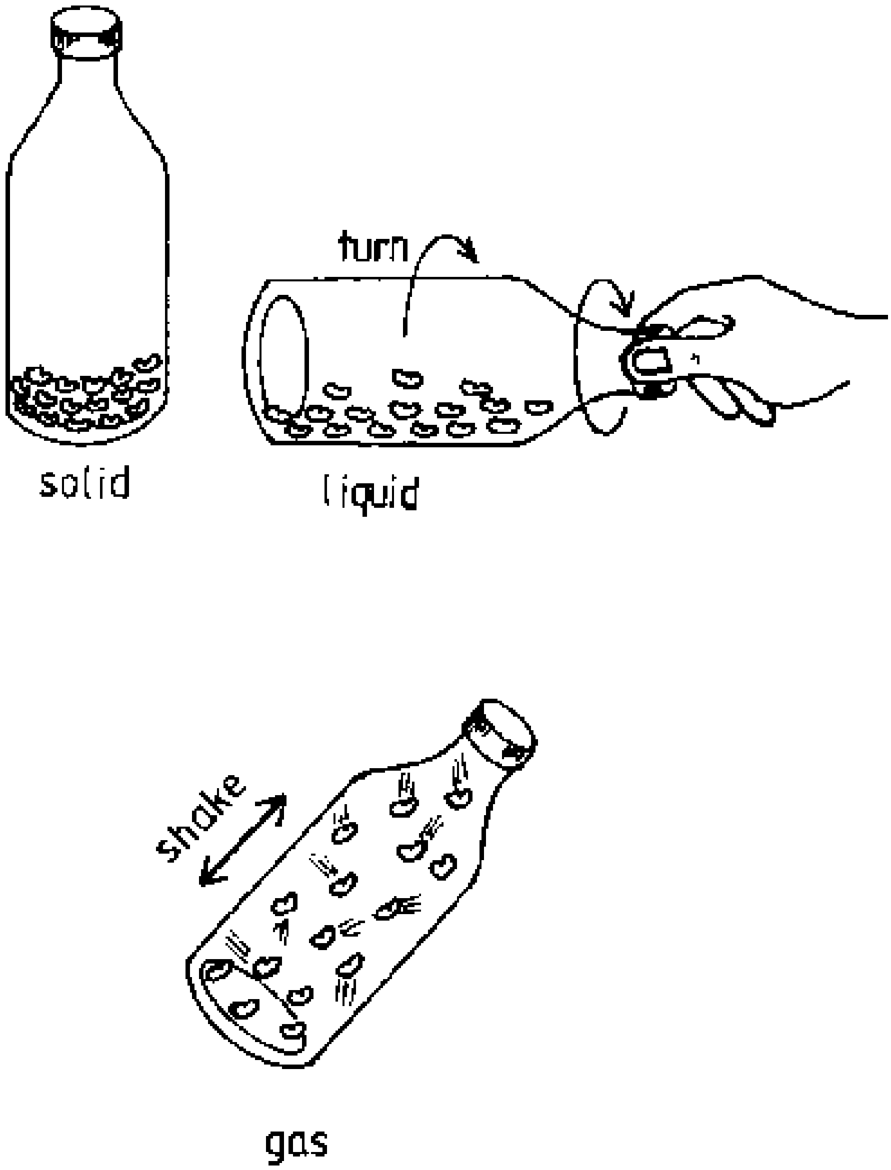
O: The purple colour of potassium manganate(VII) (permanganate) will be found to spread gradually throughout the water.

E: This spreading out is due to the motion of the particles of potassium manganate(VII).

This process is called *diffusion.*

H: This is a slow process. Therefore allow the jar to stand for same days.

4.3.2 A Model on Motion

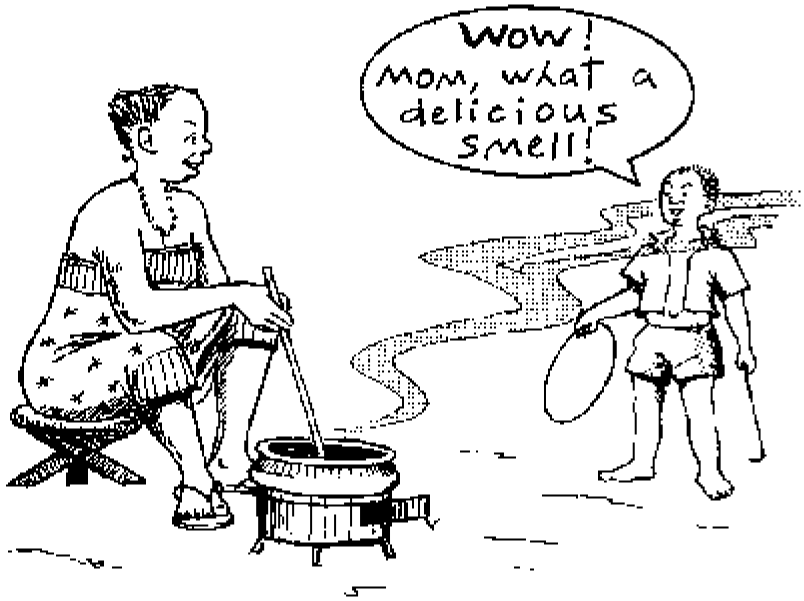


P: Put some dry beans, rice or stones in a transparent bottle. Hold the bottle still (a), then turn it (b). Then shake it vigorously (c).

Q: Which activity corresponds to which state of matter?

E: The movement of particles in *solids* is small and hence the particles are in a fixed order. In *liquids* the particles move past each other and have lost the stiff order. In *gases* the particles move very fast and randomly. They have now no order at all anymore. Hence, the observations in (a), (b) and (c) represent solid, liquid and gaseous state respectively.

4.3.3 Diffusion in Daily Life



P: Pass near a place where people are roasting meat or cooking.

Q: What do you smell? Why?

E: The smell is sensed even at a distance, because the particles which produce the smell spread by *diffusion.*

4.3.4 Diffusion and Pollution

P: Pass near a polluted area (e.g. latrine, burning heaps of litter, a filling station).

Q: What do you smell?

E: Many hazardeous substances spread to the environment by *diffusion.* (Hazardeous substances in any state of matter in our environment mean *pollution.*)

4.3.5 Brownian Motion

P: Observe a beam of light through dust in a dark room.

Q: What do you observe? Why?

E: The dust particles can be seen moving randomly. This demonstrates *Brownian motion.* What is seen is the consequence of the bombardment of the dust particles by invisible air particles. This is an indirect evidence for the existence of particles in the air.

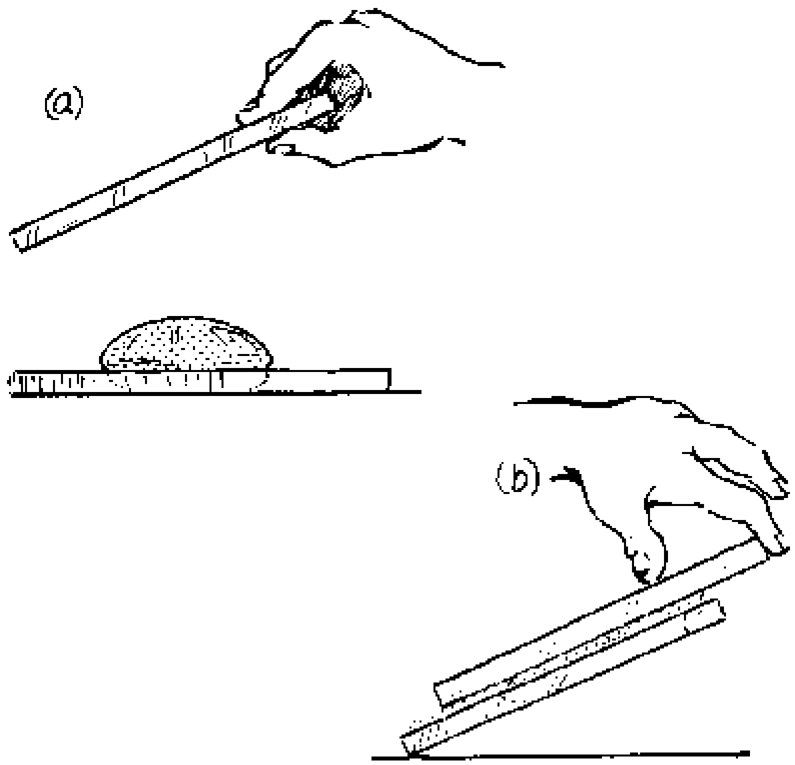
4.3.6 Model on Brownian Movement

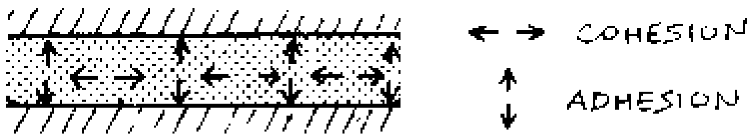
Imagine there would be standing a tall adult person around whom small children are in a continuous random movement. The tall person would be punched permanently by the children and hence would be jerkily moved.

4.4 Cohesion and Adhesion

There are two types of *forces between particles.* Forces between particles of the same material are called *cohesive forces* while those between particles of different materials are called *adhesive forces.* Cohesive forces hold the molecules in a water drop together. Nevertheless they are weak, so that the molecules can be easily separated, for example, when we jump into water or when it is heated. Paints and all kinds of glues are based on the effects of adhesive forces.

4.4.1 Exploring Cohesion and Adhesion





P: Drip water on a clean glass sheet (a).

Q: What happens?

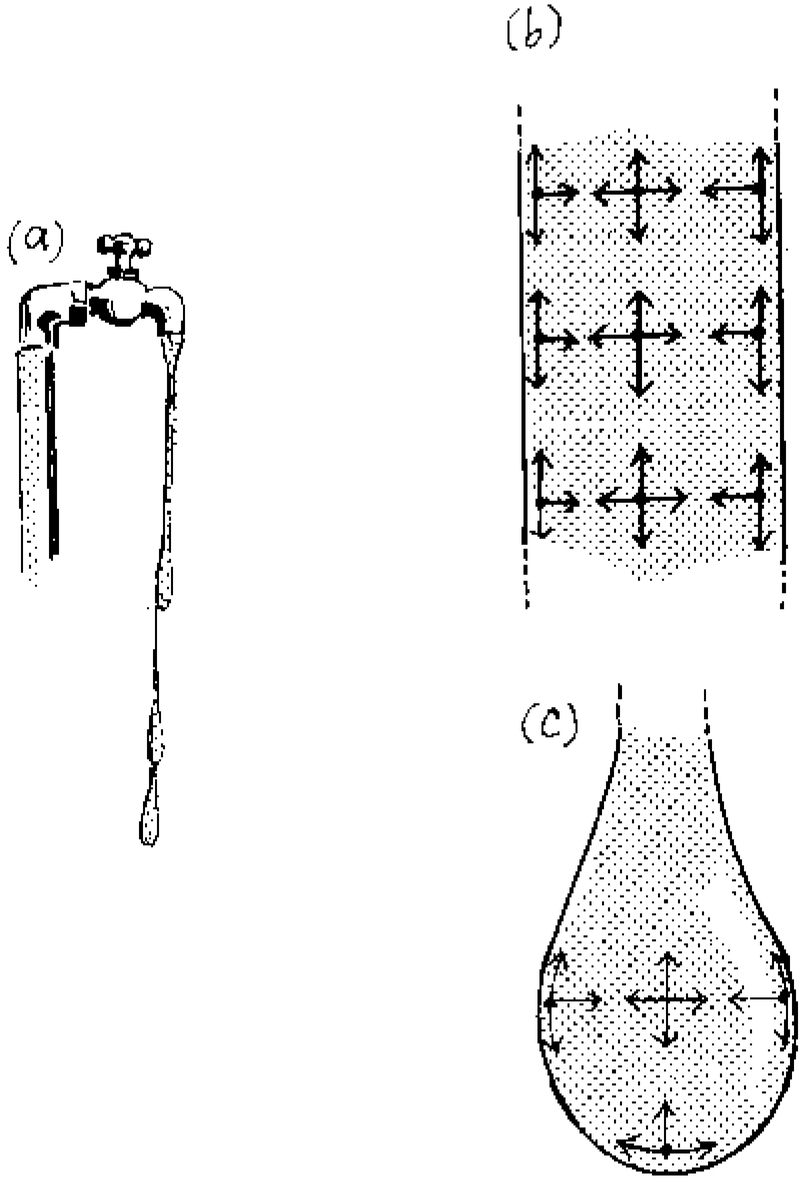
P: Place a second glass sheet on the wet first sheet and try to lift it, see fig.(b).

Q: What do you notice?

E: (a) Water spreads to form a patch on the first glass surface because *adhesive forces* attract water molecules to the glass surface.

(b) A strong force is applied to separate the two glass sheets because the adhesive forces between glass and water are large.

4.4.2 Water Drops from the Tap



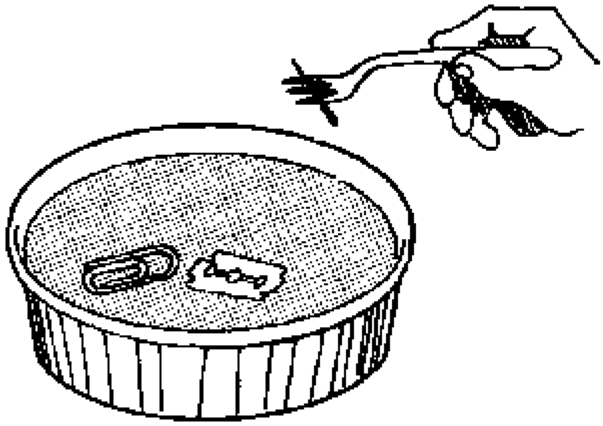
P: Let a thin stream of water flow from a water tap.

Q: What happens?

O: The water stream grows thinner and thinner as it moves further down and finally breaks to form drops.

E: Considerably strong *cohesive forces* exist as the stream starts to flow, but as the stream grows thinner the cohesive forces are overcome by the accelerating force of gravity and hence the stream is breaking down to drops. The molecules of the resulting drops are still held together by cohesive forces.

4.4.3 Surface Forces



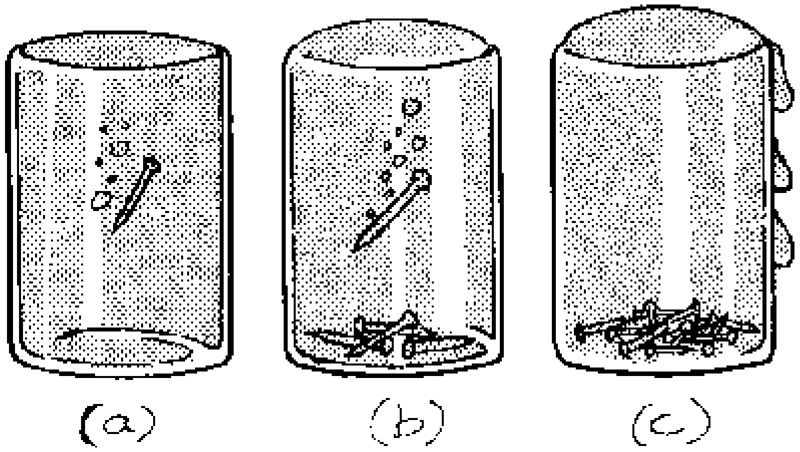
P: Carefully float a needle, a razor blade, a clip and a pin on a water surface as shown.

P: What do you observe?

E: The surface of water behaves like a thin elastic membrane. This is due to forces of cohesion called *surface tension.*

H: The pin can be easily floated with the help of a fork.

4.4.4 More on Surface Forces

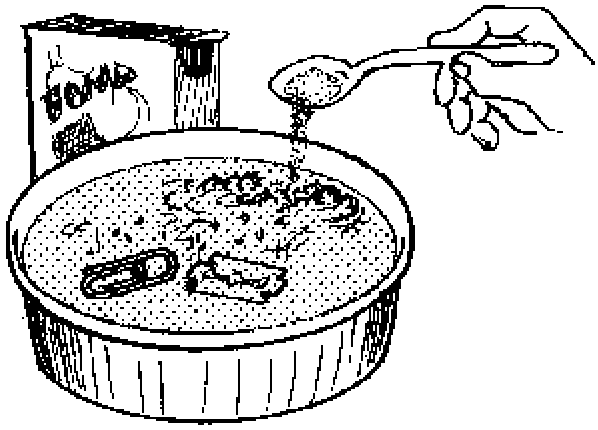


P: Carefully fill a transparent glass vessel with water to the rim. Add nails, one at a time, to the water and count the number of nails sunk just as water begins to spill over.

Q: Explain your observations.

E: The water surface bulges out but does not break immediately because of strong *cohesion forces* between the water particles.

4.4.5 Affecting Surface Tension

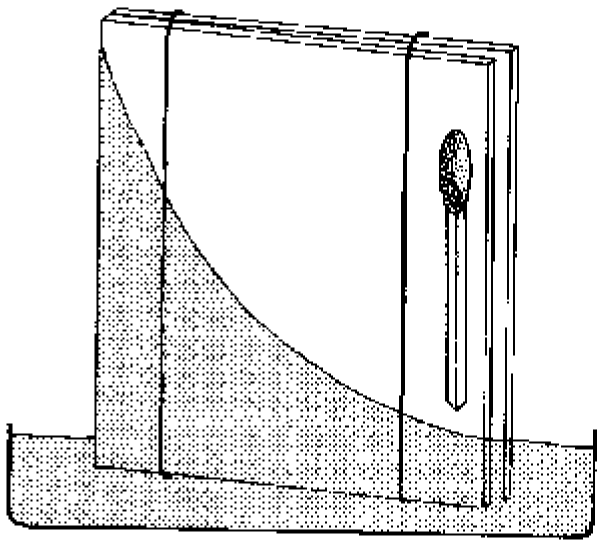


P: Repeat experiment 4.4.3 using detergent or soap solution instead of water.

Q: What do you observe?

E: Soap lowers the *surface tension* of water and therefore the bodies sink.

4.4.6 Capillary Rise

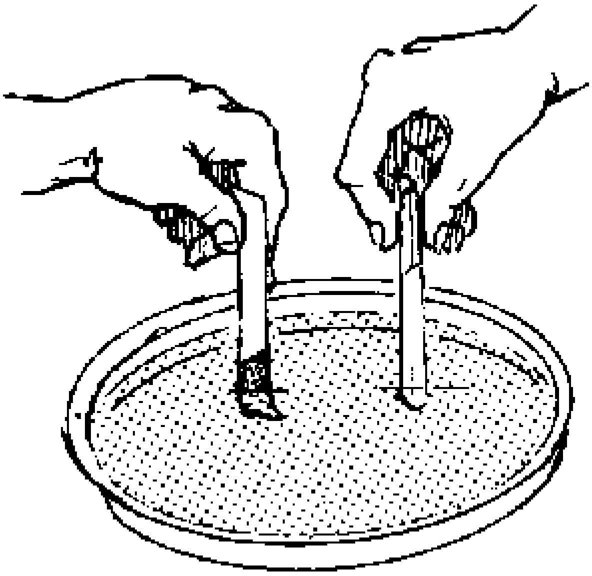


P: With the help of a rubber band and a matchstick, arrange two clean glass sheets as shown in the diagram. Place the arrangement in a plate containing some water.

Q: What do you observe?

E: Water rises to different heights along and between the glass sheets. This is *capillary action.* Water rises more where the glass sheets are closer together (see also 4.4.7).

4.4.7 Measuring Capillary Rise



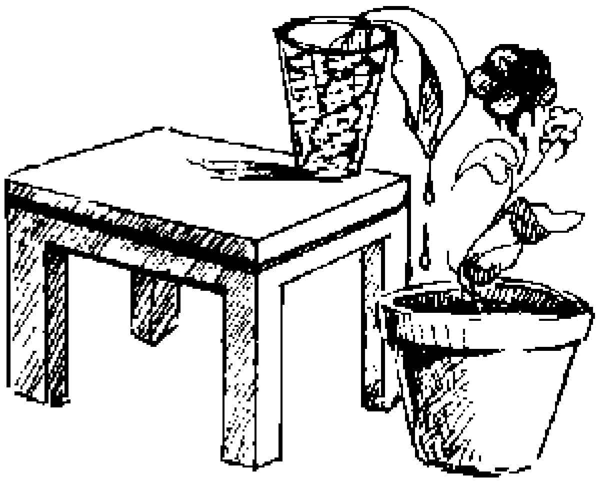
P: Hang a strip of newspaper and place a chalk-stick in a vessel containing water. Leave the arrangement for some time and measure the capillary rise in each with a ruler.

Q: Explain the causes of the differences in capillary rise.

E: Due to smaller capillaries water rises faster in the chalk-stick than in the paper.

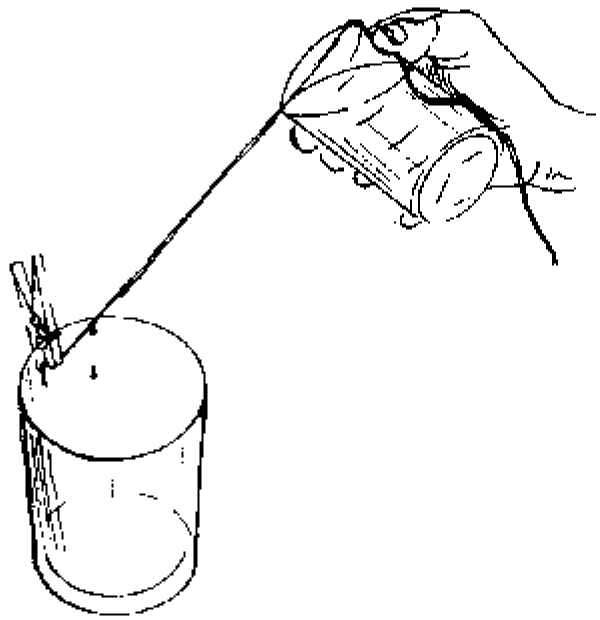
H: Test other substances too.

4.4.8 Automatic Irrigation



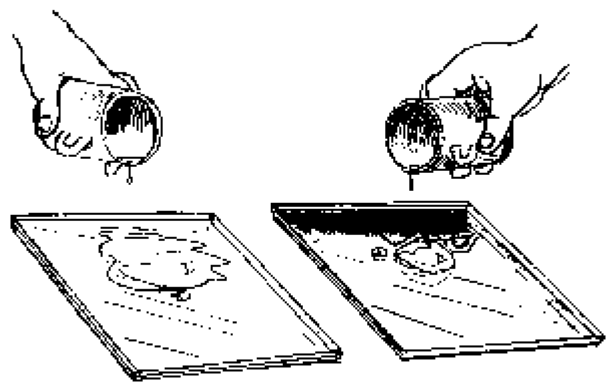
P: The knowledge of capillarity can be used to provide an automatic irrigation. Students can perform irrigation by dipping a porous material such as paper or cotton cloth in water.

4.4.9 Inclined Water Transport



E: When *adhesive forces* are greater than *cohesive forces,* drops of water can be made to move down along an inclined thread.

4.4.10 Weak Adhesion



P: Put a few drops of water on a clear glass surface (a) and on a sooty or greasy surface (b).

Q: What do you observe?

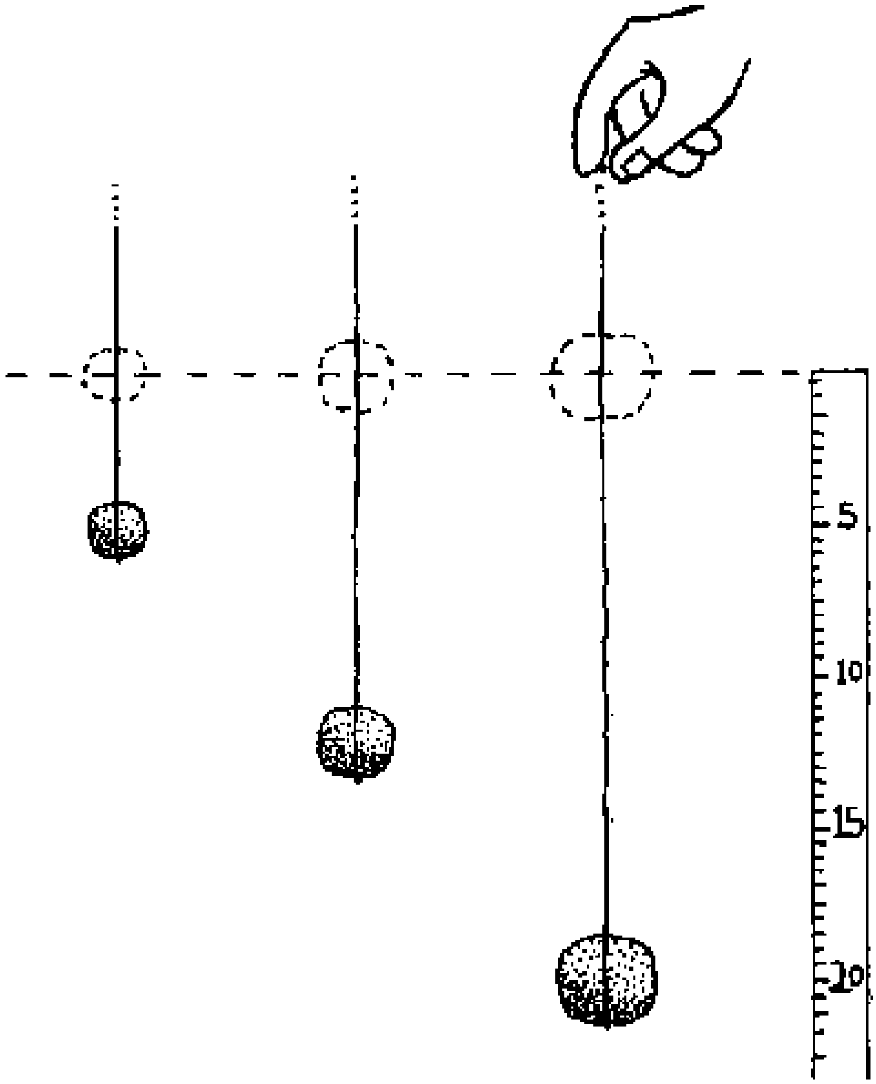
E: The shiny surface gets wet because the *adhesive forces* between water and glass are very great. The sooty or greasy surface does not get wet because adhesive forces between water and these surfaces are very weak.

4.5 Elasticity and Viscosity

Elasticity is the ability of a substance to recover its original shape after a distorting force is removed. *Hooke's law* on elasticity states that the extension of a spring is directly proportional to the load applied provided the elastic limit is not exceeded. Most materials are elastic. It is important to know the behaviour of a material when acted by forces before we can use it for a particular job.

Viscosity is the frictional force exerted by a fluid. The flow of liquids is influenced by this force. Where the frictional force is greater, the liquid flows less readily and is said to be more viscous and vice versa.

4.5.1 Elasticity in Solids



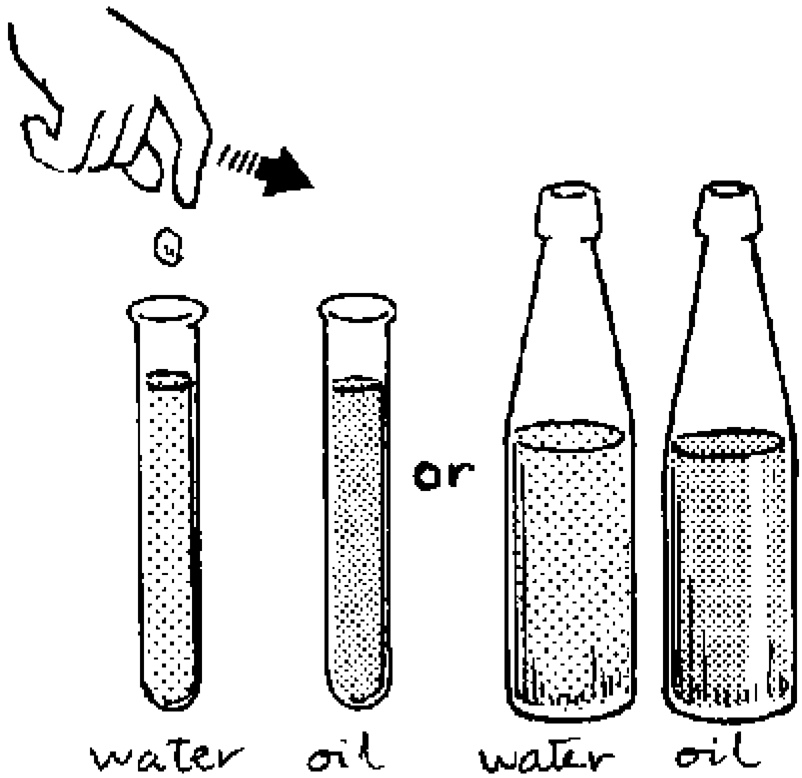
P: Attach various masses (e.g. 1 g, 2 g, 3 g) to a rubber band or a spring and measure the extension for each mass attached. Remove the masses in succession and record the corresponding readings.

Q: What happens when the masses are removed one after the other?

Plot a graph of extension (y-axis) against mass (x-axis).

E: The graph obtained shows that the extension is proportional to the mass which is *Hooke's Law.*

4.5.2 Viscosity in Liquids

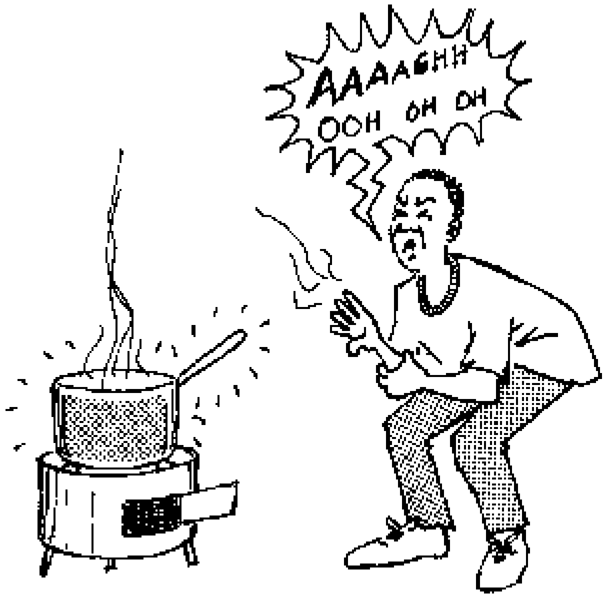


P: Fill one test-tube or a tall bottle with water and another with oil, both to the rim. Put a small stone into the water and record the time taken by the stone to reach the bottom. Repeat the experiment using oil.

Q: In which liquid does the stone take longer to reach the bottom?

E: The stone takes longer to reach the bottom in the vessel containing oil because oil has a higher *viscosity* than water.

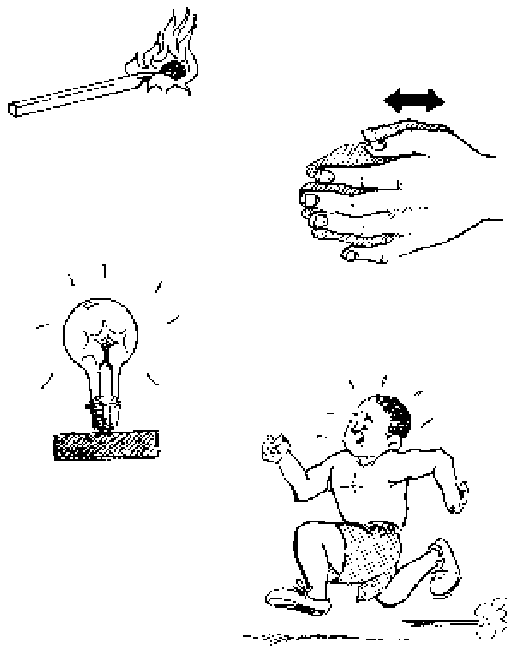
5. Thermal Physics



5.1 Thermal Energy and Temperature

Thermal energy is a form of energy which can easily be produced by converting other forms of energy. Thermal energy is commonly called *heat.* The quantity of heat absorbed by a body generally causes an increase in its temperature. The *upper fixed point* of a thermometer is the temperature of the steam of pure water boiling at standard atmospheric pressure. It is 100°C. The *lower fixed point* is the temperature of pure melting ice at standard atmospheric pressure. It is 0°C. *Absolute zero* is the coldest possible temperature which is -273°C. This corresponds to the zero degree on the kelvin scale.

5.1.1 Sources of Thermal Energy



P: Ignite a match stick. Rub your hands very vigorously. Switch on an electric bulb. Run as fast as you can a certain distance or up a staircase.

Q: Which forms of energy are converted to thermal energy in each case?

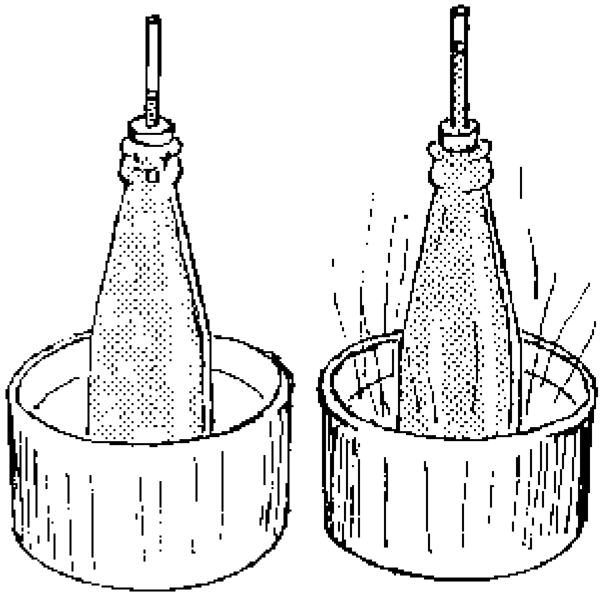
E: (a) A match stick burns converting *chemical energy* into *thermal energy.*

(b) An electric bulb gets heated because *electric energy* is converted to *thermal energy.*

(c) The hands get hot, because *mechanical energy* is converted to thermal energy.

(d) We feel hot, because our body converts the *chemical energy* of the food partially to *thermal energy.*

5.1.2 Principle of a Thermometer



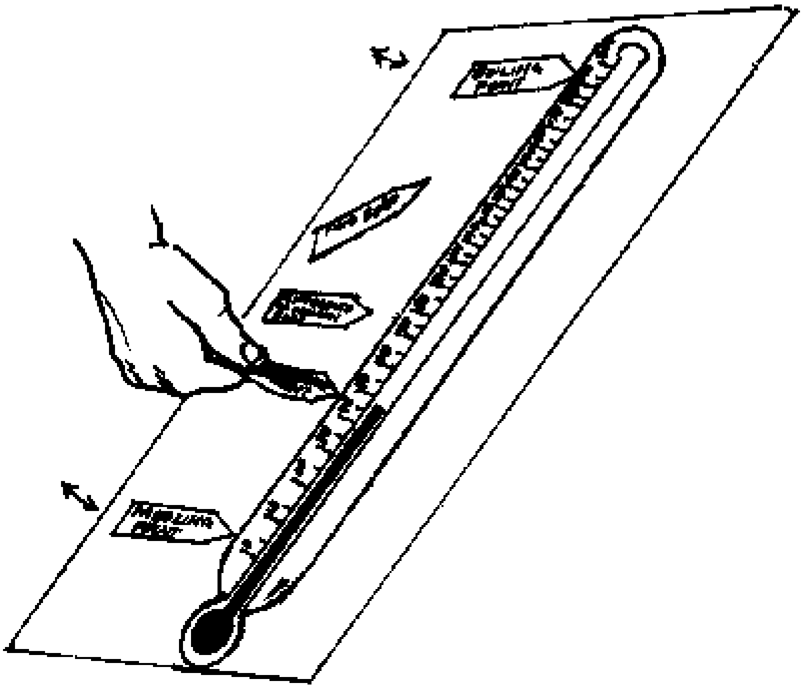
P: Fill a small bottle (about 0.5 litre) with coloured water up to the rim. Tightly fix a stopper which is carrying a narrow transparent tube (e.g. an empty ball pen tube) into the mouth of the bottle. The liquid level should be just visible above the stopper. Then put the bottle into hot water or heat it gently.

Q: What happens to the liquid level in the tube? Why?

E: The liquid level rises, because the liquid is expanding on being heated.

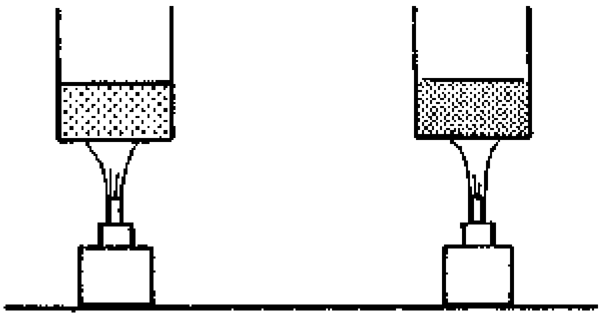
A: The principle of expansion of liquid is used in clinical thermometers. In the clinical thermometer the expansion of mercury is used to measure the body temperature. Obtain a clinical thermometer and discuss its scale. Ask the students to draw a diagram of the thermometer. Some out-door thermometers contain coloured alcohol instead of mercury. The expansion of alcohol is six times greater than that of mercury. Mercury is often used in thermometers for measuring higher temperatures than alcohol because it has a higher boiling point than alcohol.

__5.1.3 Fixed Points__



P: Draw a large diagram (a display chart) of a thermometer on a paper (paper from cement bags is suitable). Cut out paper arrows for indicating the characteristic fixed points for water and other substances. The pupils can be asked to indicate (using the arrows) the appropriate fixed points on the diagram.

__5.1.4 Specific Heat Capacity of Liquids__

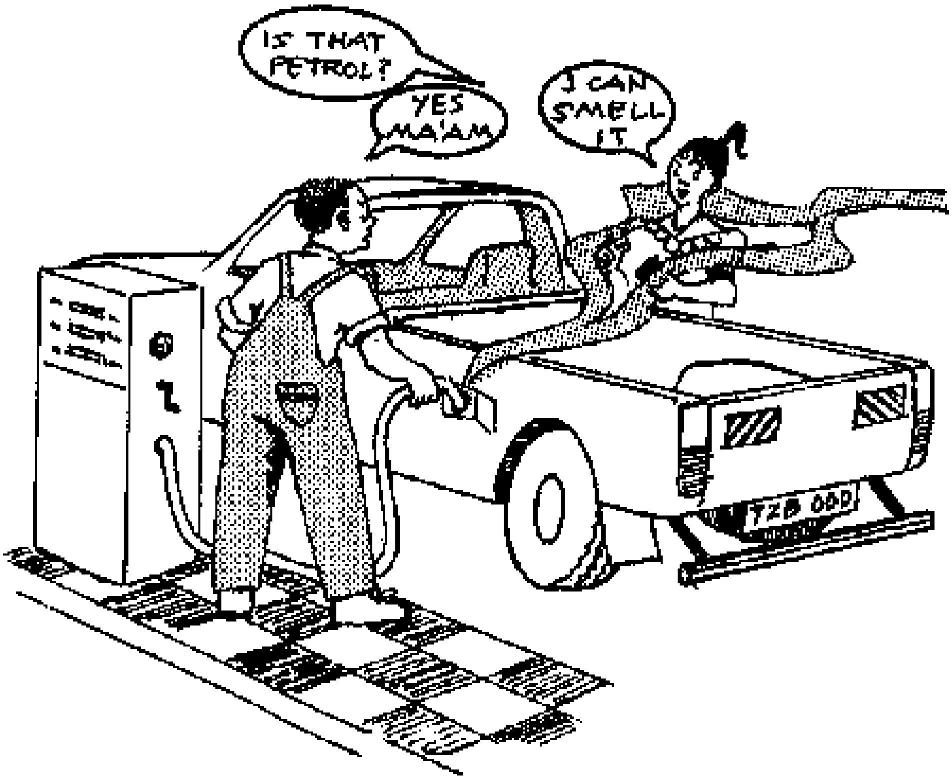


P: Heat equal masses of different liquids (e.g. water and oil) in two identical containers using a "kibatari" (kerosine lamp) for the same length of time.

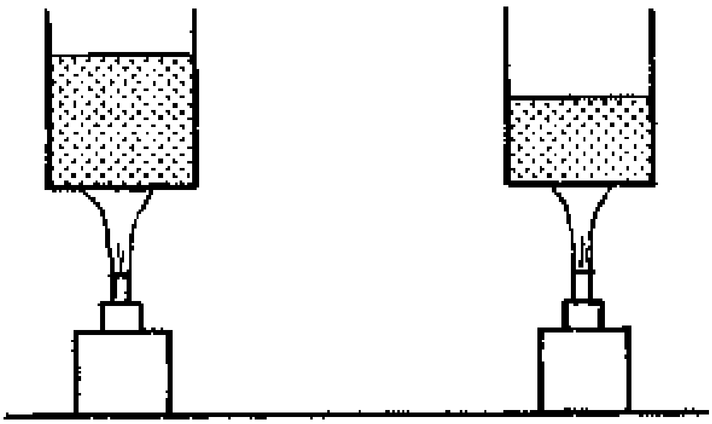
Q: What difference in temperature can you feel with your finger?

E: The temperature of the oil is higher, because it needs less energy to raise the temperature of one gram of oil by 1°C than that of water. Thus, using the same amount of heat and mass, the temperature of oil must be higher.

H: Great care must be taken when heating oil, for it can catch fire (and you should not put your finger in it, if you have heated it for a long time).



5.1.5 Thermal Energy



P: Heat different quantities of water using a "kibatari" (kerosine lamp) in two identical containers (e.g. tin cans) for the same length of time. Dip your finger into the two containers of water.

Q: What differences in temperature can you feel?

E: The temperature of the smaller quantity of water is higher, because it received more thermal energy per gram of its mass than the larger quantity. So for the same heat input the temperature rise of the smaller quantity of water will be greater.

5.1.6 Application of Specific Heat Capacity

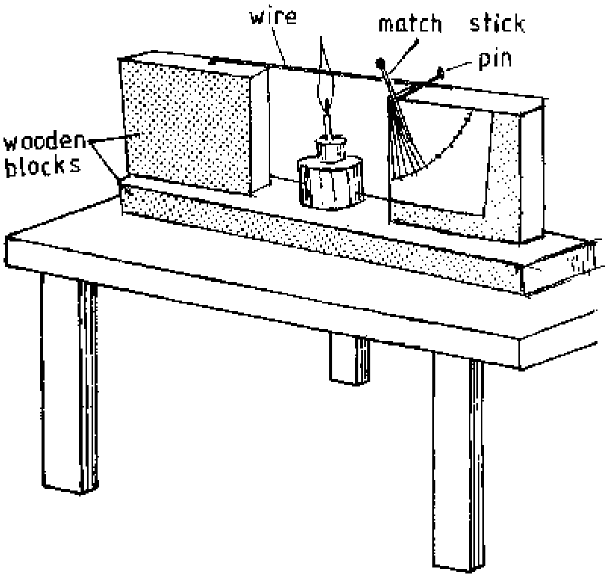
P: Using your hand find out how fast a water puddle and a heap of sand warm up during the day. Find out again how fast they cool during the night.

E: A heap of sand heats up faster during the daytime and cools down faster during night, because sand has a lower specific heat capacity than water. (Specific heat capacity of water = 4200 J/kg°C; of sand = 800 J/kg°C).

5.2 Thermal Expansion

Solids, liquids and gases expand when heated and contract when cooled. Expansion and contraction occur in all directions. The kinetic theory explanation is, that the particles vibrate with large amplitudes when heated, forcing each other a little further apart. Cooling reduces the amplitude of vibration and brings the particles closer together. *Water* has an anomalous expansion. Its highest density is at 4°C. Therefore in cold regions water at this temperature always sinks to the bottom of lakes. This is why in cold regions the water at the bottom of the lakes does not freeze.

5.2.1 Expansion Apparatus

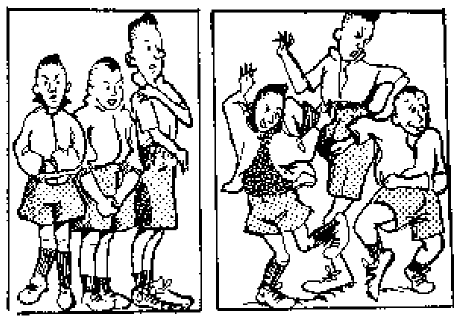


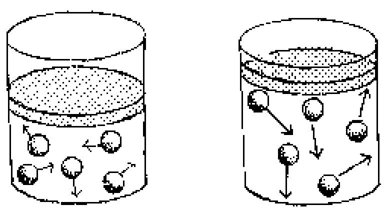
P: Place a metal rod horizontally with one end fixed firmly on a wooden block. Insert the pin through a match stick and place it under the rod as. shown in the figure. Heat the rod from below with a candle or a "kibatari" (kerosine burner).

Q: What do you observe?

E: The match stick turns in the clockwise direction, because the rod expands causing the pin to roll forward and the match stick to turn. H: For the best results the pin should lie on a smooth surface. A wire of 2 mm diameter or a bicycle spoke can be used for the metal rod.

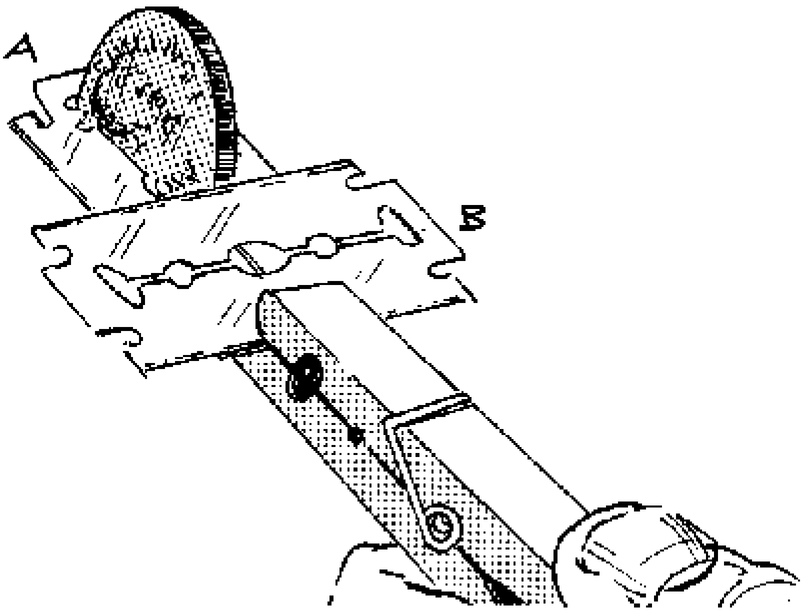
5.2.2 A Simple Model for Explaining Expansion





P: Expansion can be explained by a simple human model: When a group of pupils stands still, they are close together and they do not need much space. But if they start to dance or even to run about, each of them needs more space and the group as a whole takes more space. The particles in a body are like the pupils in the group, they only move far apart when they are heated and hence need more space.

5.2.3 Expansion of a Coin

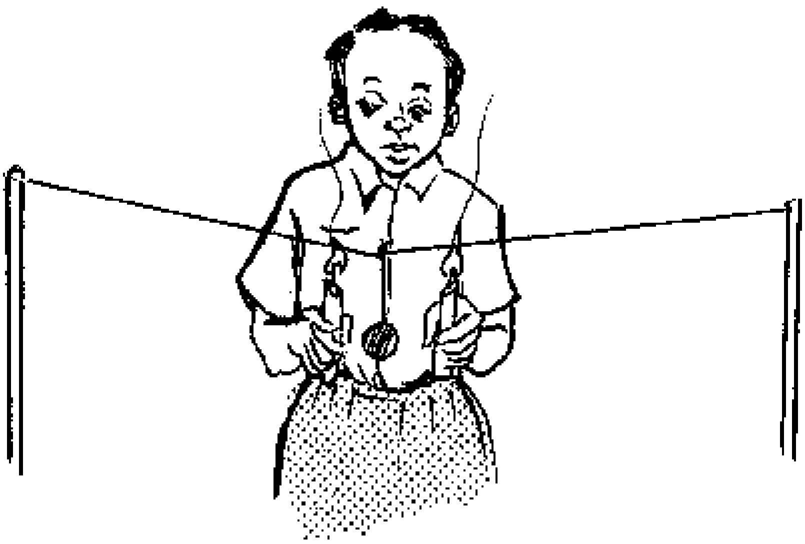


P: Place a coin into the slit of a razor blade A. Slide a second blade B so that the coin just passes through the slit. Firmly clamp the blades together with pegs or clips. Now remove the coin and heat it in a flame and try to pass it through the slit again.

Q: What happens?

E: The coin does not pass through, because it has expanded due to heating.

5.2.4 Expansion of a Wire

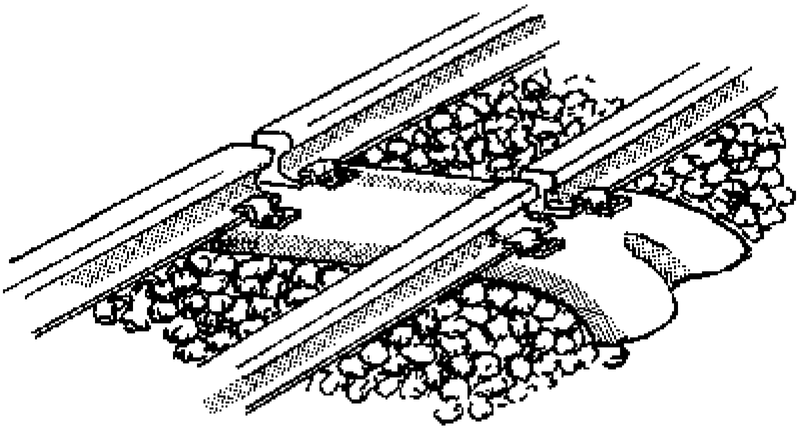


P: A thin copper wire is firmly fixed between two chairs and a weight is hung in the middle to stretch the wire. Then heat the wire along its length.

Q: What happens to the weight?

E: The weight sags further down, because the heated wire expands and hence increases in length.

5.2.5 Applied Expansion

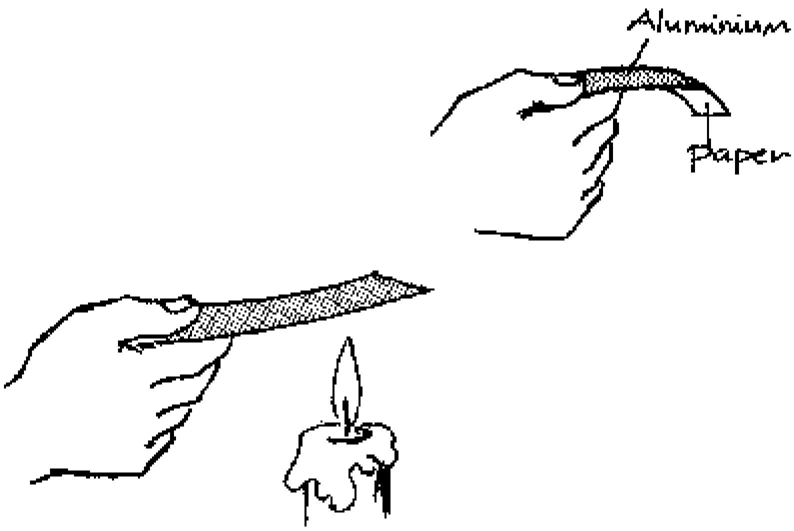


Steel railway lines have gaps at the end of each length of rail. Clicks can be heard as the wheels go over them.

Q: Why are the gaps necessary?

E: The gaps are needed to allow the rails to expand without bending during hot days. The gaps are called *expansion gaps.*

5.2.6 Bimetal Principle

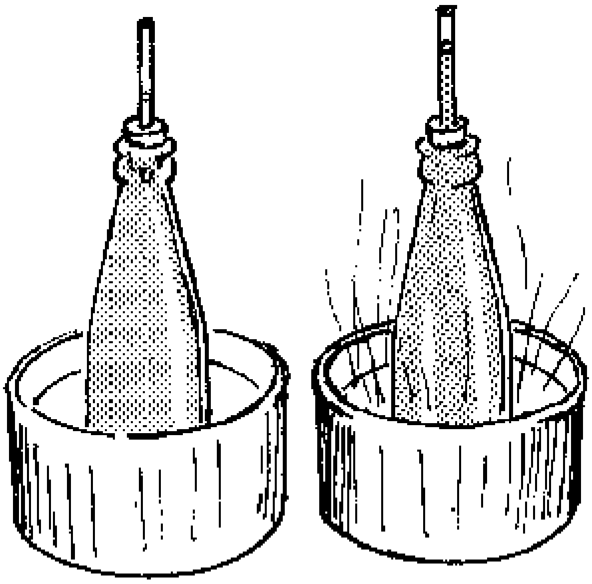


P: A bimetallic strip is made of two different metal strips like iron and brass or iron and aluminium joined together. To show the principle of a bimetallic strip, cut a one centimeter strip of aluminium paper from a cigarette packet and hold it close to a flame.

Q: What happens?

E: The strip bends towards the paper side, because aluminium expands more than paper.

5.2.7 Expansion of a Liquid

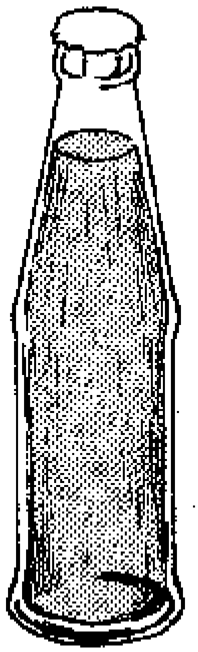


P: Fill a bottle up to the rim with coloured water. Tightly fix a cork bearing a transparent plastic tube (an empty ball point pen tube). Place the bottle into hot water.

Q: What happens?

E: The liquid rises along the tube, because it is heated by the hot water and expands along the tube.

5.2.8 Allowing for Liquid Expansion

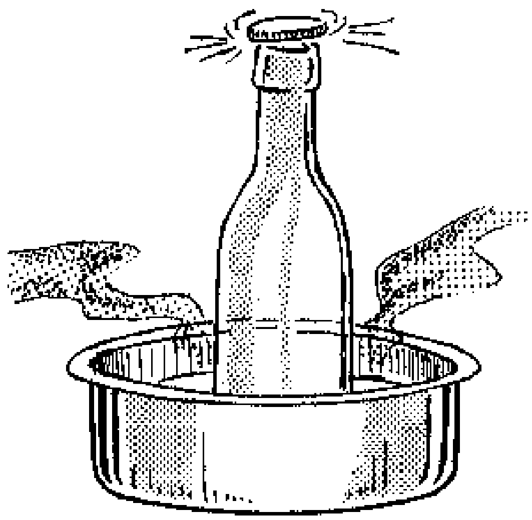


P: Observe the top of soda or beer in a corked bottle.

Q: Why does the bottle contain a small amount of gas trapped above the soda or beer?

E: The space is to allow the expansion of soda or beer when the bottle is stored in a warm place.

5.2.9 The Jumping Coin

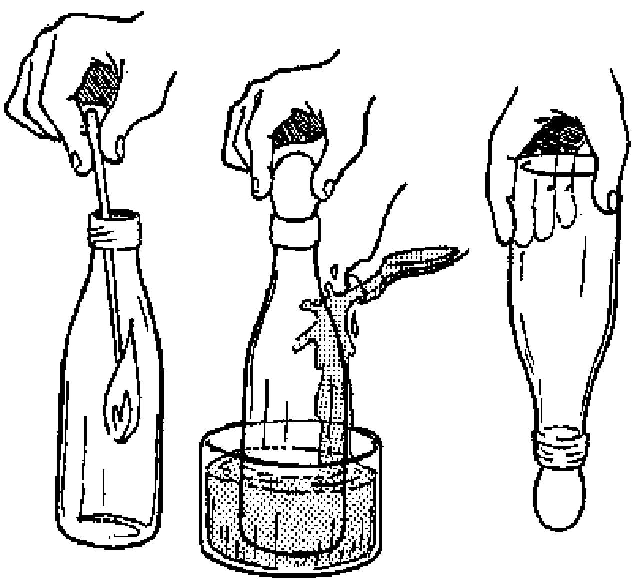


P: Wet the rim of a bottle with water and cover it with a coin (e.g. a shilling coin). Place the bottle into a hot water bath.

Q: What happens to the coin after a short time?

E: The coin vibrates opening and closing the bottle. This is because when the air inside the bottle expands, it pushes up the coin and when the air escapes, the pressure inside drops and the atmospheric pressure pushes down the coin.

5.2.10 Contraction of Air



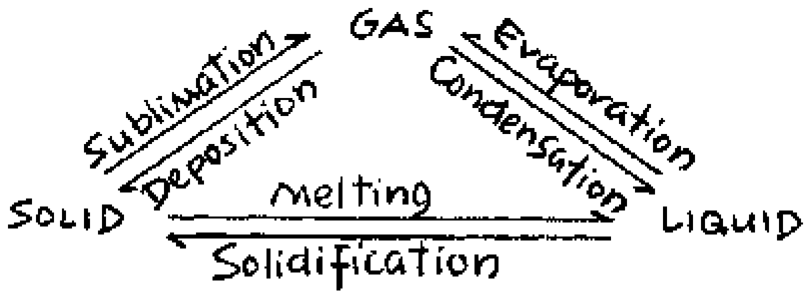
P: Place an "empty" bottle into a hot water . bath or burn some paper or a wooden stick in it. After it has warmed up, close the bottle either with your thumb or a boiled and peeled egg. Now immerse the bottle in cold water.

Q: What do you observe?

E: The thumb or egg will be held by the bottle, because on cooling the bottle the air inside contracts and creates a lower air pressure inside.

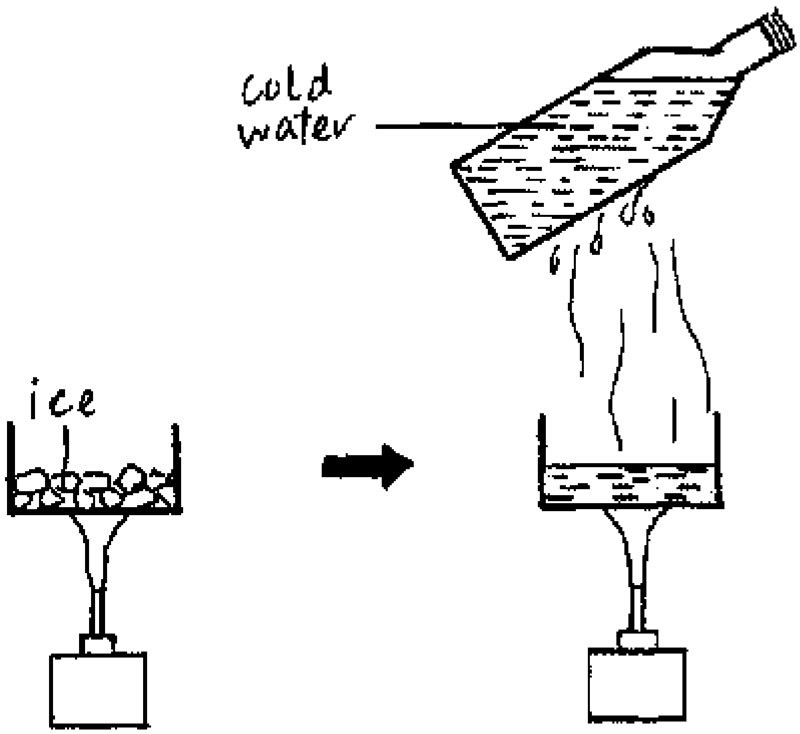
5.3 Changes of State

There are three states of matter, *solid, liquid* and *gas.* Matter can be converted from one state to another:



Every pure substance has *characteristic fixed points* at which one state changes into another one. That depends on the temperature. The water cycle in the atmosphere illustrates the change of state of water.

5.3.1 Changes of State of Water

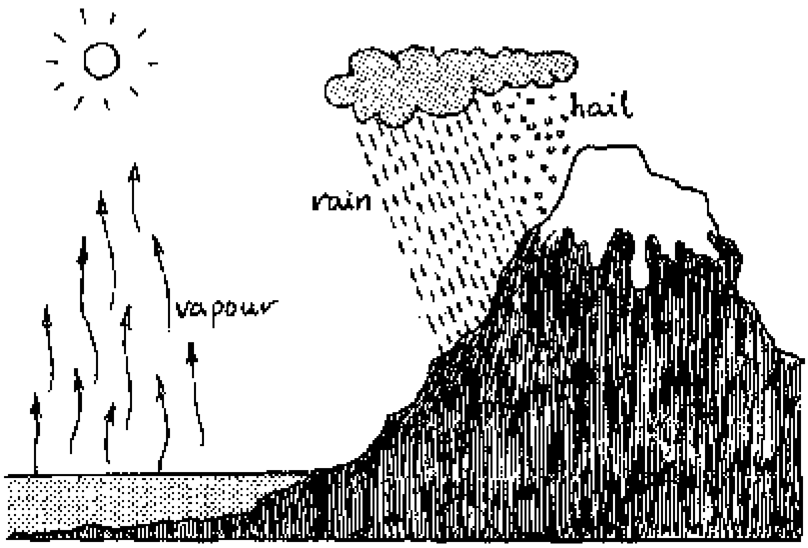


P: Heat ice in an open can for a few minutes and hold a glass bottle filled with cold water above the can.

Q: Which changes of state can you observe?

E: The ice changes from solid to liquid *(melting)* in the can. The liquid changes to gas *(boiling)* and the steam changes to liquid on the cold surface of the cold bottle *(condensation).*

5.3.2 Rain and Hailstone Formation



P: Rainfall is a common occurence all over the country and sometimes the rain is accompanied by hailstones which destroy our crops.

Q: Can you explain how rain and hailstones are formed?

E: The sun heats the sea and lakes. The water evaporates and rises up in the air. The vapour cools and condenses into water droplets forming a part of the clouds. At higher altitudes where temperatures are very low, bigger drops of water are formed which fall as rain. At times bigger drops of water turn into ice (solid) and fall as hailstones.

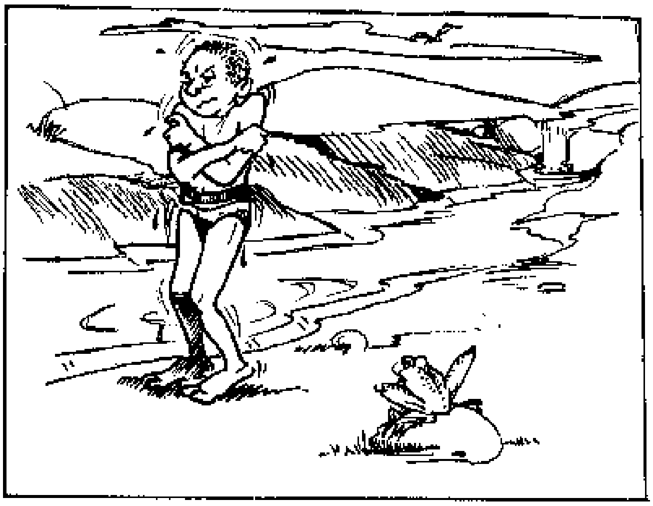
5.3.3 Evaporation

P: Pour some spirit or petrol on the back of your hand.

Q: Explain what you feel as the spirit evaporates.

E: The back of the hand feels cold, because evaporation of the spirit needs energy which it absorbs from the skin.

5.3.4 Evaporation



P: A boy plunges himself into a pool of water and then gets out.

Q: Explain the change of the temperature of his body.

E: He feels very cold (chilly) because the evaporation of water from his body absorbs heat from his skin making him feel cold. This explains why we feel very cold when we stand in a draught of air after sweating.

5.3.5 Cooling Water

P: Touch the blackboard with a wet hand.

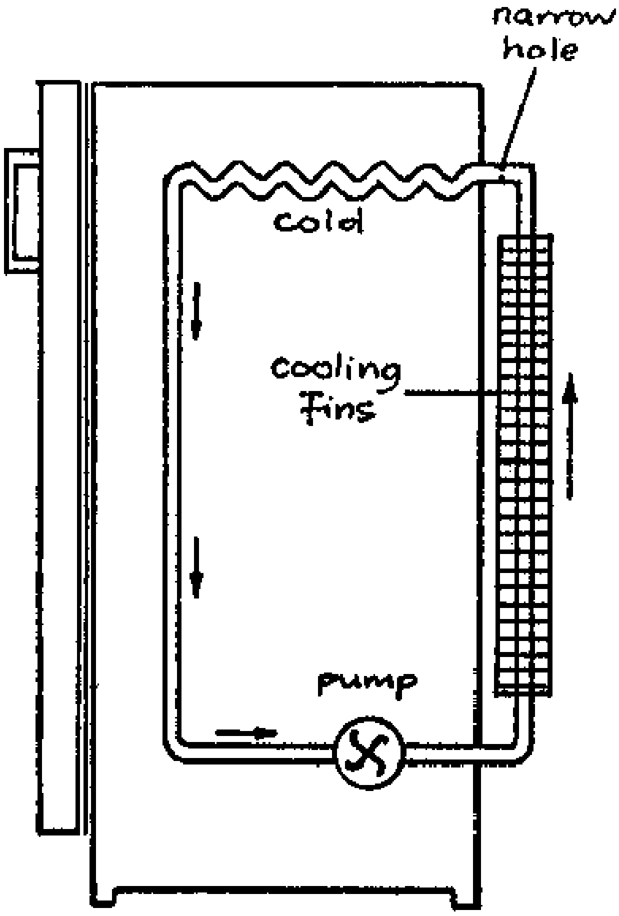
Q: Observe the trace for some minutes.

P: In many houses water is kept in fired clay pots *(chungu).* Water pots have very tiny pores through which minute amounts of water ooze out.

Q: Explain how water is cooled in these clay pots.

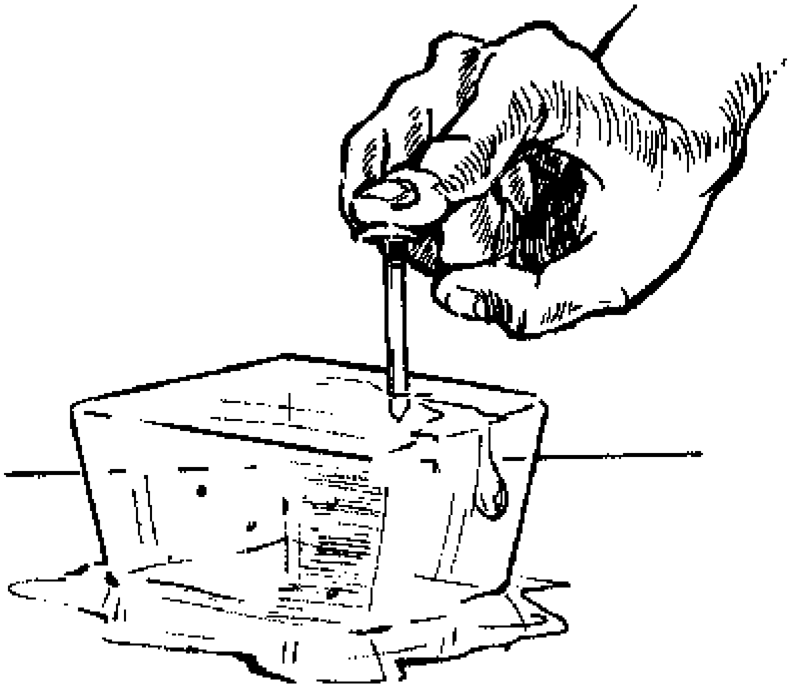
E: Some water passes through the tiny pores and evaporates. The energy needed for the evaporation is taken from the pot and water and hence the water cools down.

5.3.6 The Refrigerator



E: Some urban households have got refrigerators. In the refrigerator a special liquid is circulated through a pipe. In one portion of the pipe the liquid evaporates at a low pressure. The energy for the evaporation is taken from the pipe which cools the inner part of the refrigerator. In the pipe at the back the vapour condenses to a liquid under high pressure, thus giving out heat. Therefore cooling fins on the outside have to transmit this heat to the air.

5.3.7 Pressure and Melting Point

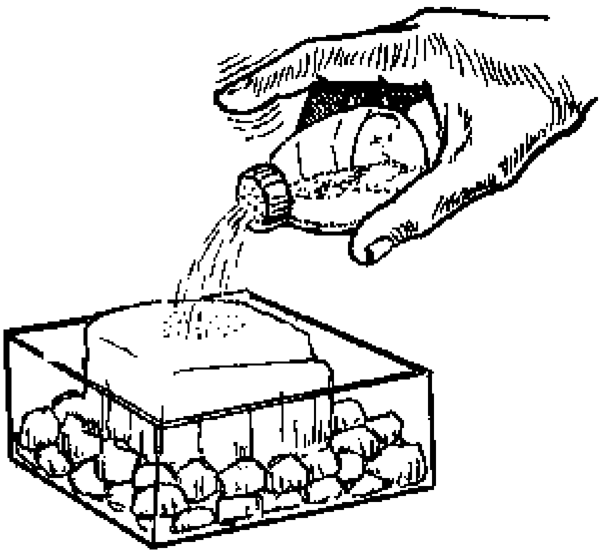


P: Steadily press a nail or a screw into a block of ice without heating it.

Q: What happens?

E: The nail penetrates into the ice because the pressure causes the ice at the tip of the nail to melt. (This is so, because water has less volume than the same mass of ice.) But when you release the pressure on the nail the water freezes again and "glues" the nail into the block of ice.

5.3.8 Impurities and Melting Point



P: Place some pieces of ice in a glass container and sprinkle some salt on the ice. Stir the mixture and measure the temperature.

Q: What do you observe?

E: The ice pieces melt at a lower temperature than 0°C. *Impurities* (e.g. salt) *lower the melting point of ice.*

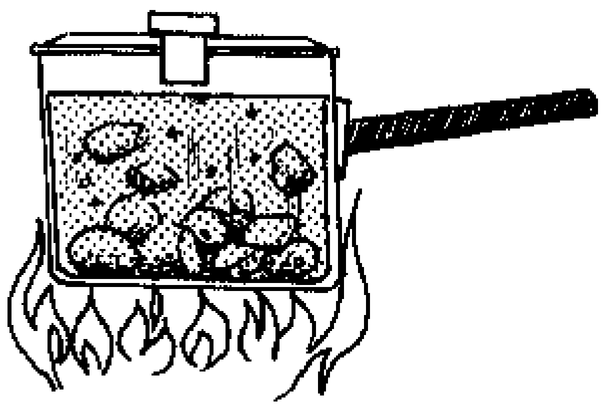
5.3.9 Pressure and Boiling Point

P: Some people who go for mountain climbing expeditions take pressure cookers with them for cooking on the peak of a mountain.

Q: Can you explain why?

E: The air pressure decreases with the altitude and water will boil at a lower temperature on the peak of a mountain. Generally, *the lower the pressure on the water, the lower its boiling point.* Thus, food would need a very long time to be cooked e.g. on the top of Mount Kilimanjaro. So for food to cook faster we need to use a pressure cooker so that the temperature inside increases to cook the food faster.

5.3.10 The Pressure Cooker



P: Demonstrate how a pressure cooker works.

Q: Explain how it helps to save energy costs.

E: Under the high pressure in such a pot the water boils at a higher temperature of about 120°C. At this temperature food like beans need only about one hour (instead of 3 hours in a normal pot) to cook and become soft. Therefore the pressure cooker uses less fuel to cook and hence saves fuel.

5.4 Transfer of Thermal Energy

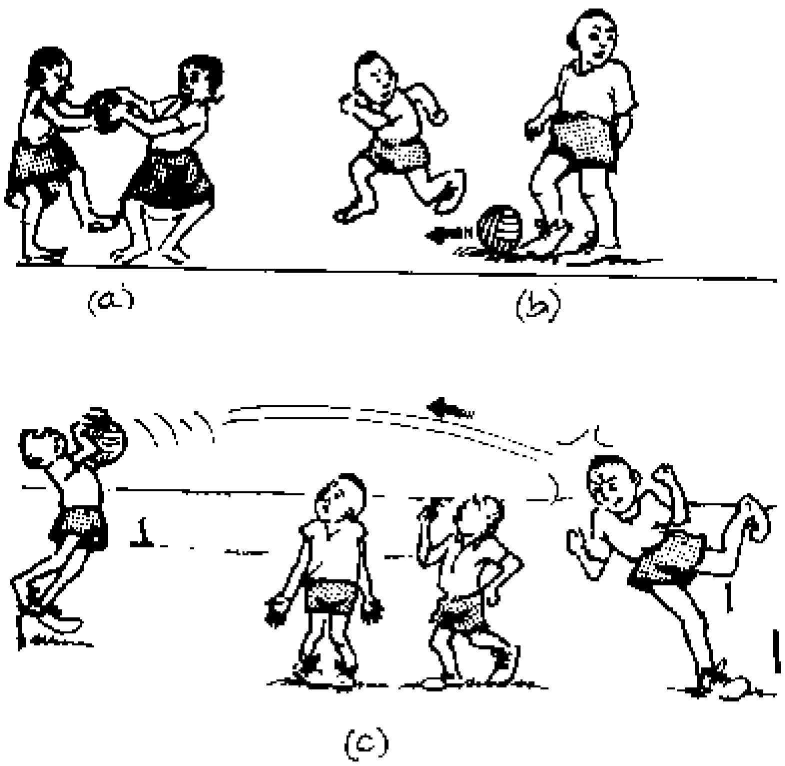
Heat can be transfered in three ways:

Conduction of heat is the transfer of heat through a material from one point to another, whenever there is a temperature difference between the two points.

Convection of heat is the transfer of heat energy due to the movement of the material particles of the medium.

Radiation of heat is the transfer of heat energy from one place to another without the use of any material medium.

5.4.1 The Football Model Of Thermal Energy

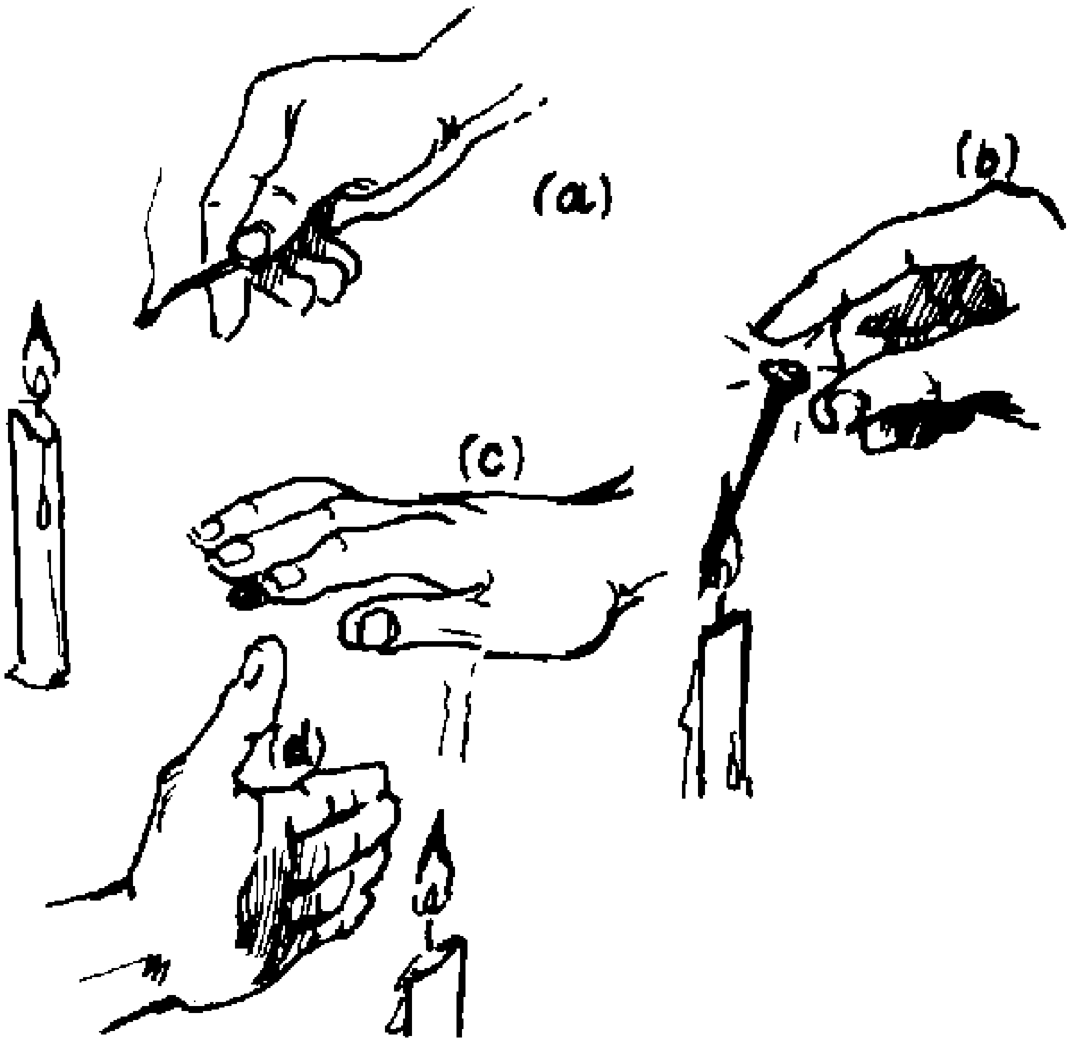


Heat conduction is likened to a football being passed from one player to another just as heat passes from one molecule to another in conduction of heat as shown in figure (a).

Convection is likened to a football being taken by one player from one point of the playground to another one just as heat in a gas or liquid is transported by a particle from one point to another in convection of heat as in figure (b).

Radiation is likened to a football being kicked by one player from one point at the playground to another one without the use of intervening players just as heat is transmitted from a hot object to another without any medium by radiation of heat as in figure (c).

5.4.2 Candle Flame and Heat Transfer



P: (a) Light a candle and demonstrate three ways of heat transfer by a simple hand experiment.

(b) *Conduction:* Stick one end of a nail into the flame.

Q: What do you feel?

(c) Convection: Place your hand at a distance above the flame.

Q: What do you feel?

(d) Radiation: Place your hand at the same distance on the side of the flame.

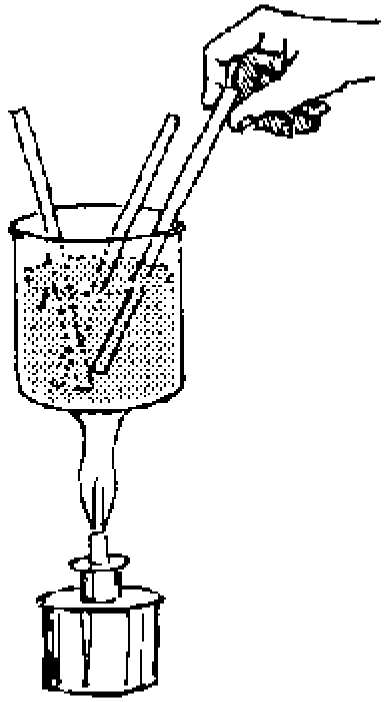
Q: What do you feel?

O: In each case heat is transmitted to your hand.

P: To check the *amount of heat transfered per unit time* by convection and radiation, hold a new match stick above and on the side of the flame and find out how long it takes to ignite the match stick in each case.

H: Any burner can be used instead of the candle. Non-luminous flames will produce the best results.

5.4.3 Solids as Conductors



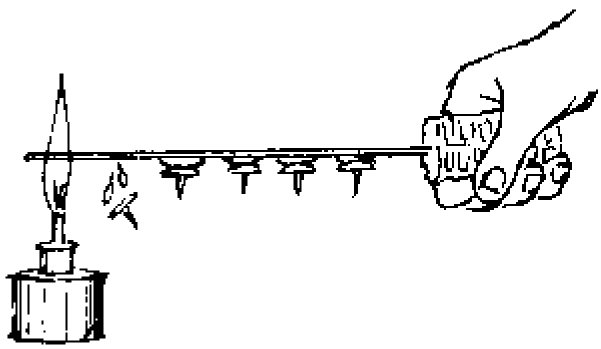
P: Heat water in a container until it is about to boil. Place metal, wooden and plastic rods of the same dimensions vertically into the water. Touch the exposed ends of the rods after 3, 4 and 5 minutes.

Q: What do you conclude about the conductivity of each rod?

E: The metal rod is a good conductor but the plastic and wood arc bad conductors.

A: Plastics and wood are used as handles of saucepans; the saucepans and other cooking pots arc best made of good conductors of heat e.g. metals.

5.4.4 Conduction by a Metal Rod

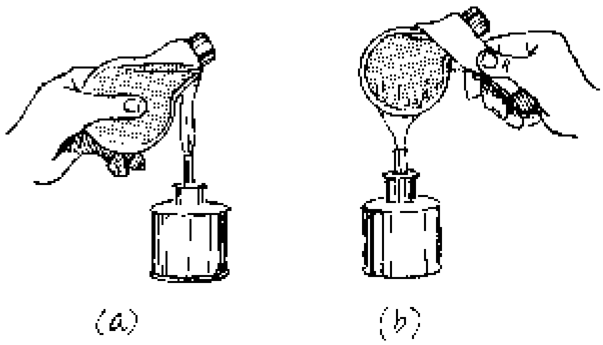


P: Fix several small stones with molten candle wax along a metal rod at a regular interval. Heat one end of the rod.

Q: What do you observe?

E: The stones will fall off one after another starting from the end being heated, because heat is conducted slowly along the rod from the heated end.

5.4.5 Liquids as Conductors



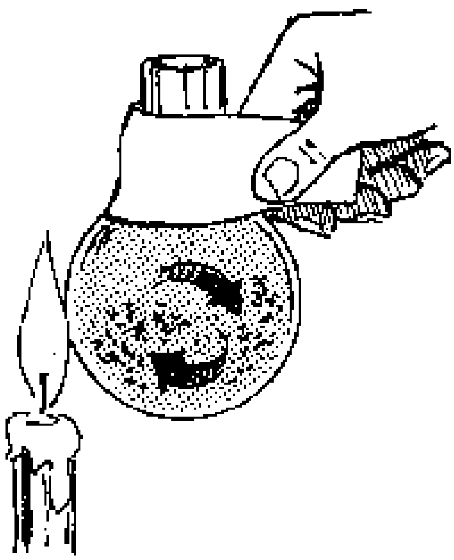
P: Fill a test tube or an opened bulb (see appendix) with water. Heat the water just below the top. Feel the bottom of the test tube with your hand, see figure (a).

Q: Explain what you feel.

E: The bottom of the test tube stays cold because water is a bad conductor and does not conduct the heat to the bottom.

Q: What would happen if you held the test tube at the top and heat it at the bottom? (see figure (b)).

5.4.6 Convection of Heat

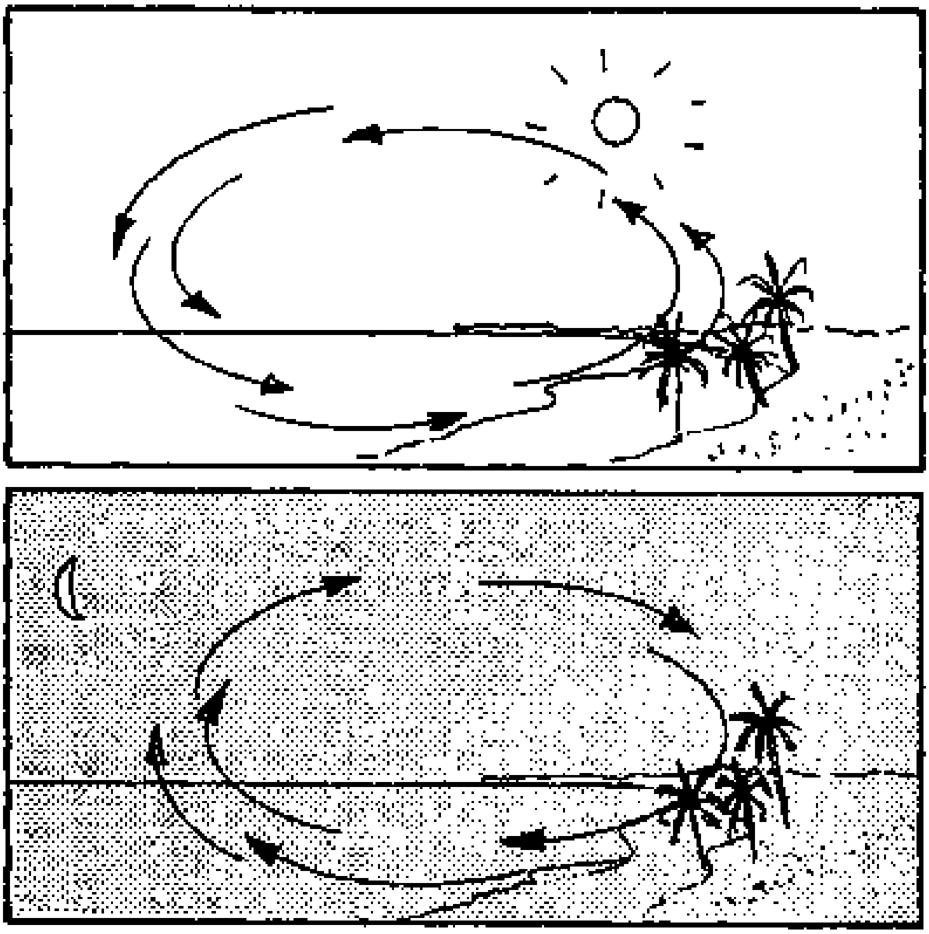


P: Fill a round flask or opened bulb (see appendix) up to the neck with water. Sprinkle a pinch of fine saw dust on the water. Heat one side of the flask only.

Q: What do you observe in the flask?

E: You will see a *convection current* being formed in the flask. The warm water rises and the cooler water sinks down to the bottom as seen by the movement of the saw dust.

5.4.7 Breeze as a Convection Current

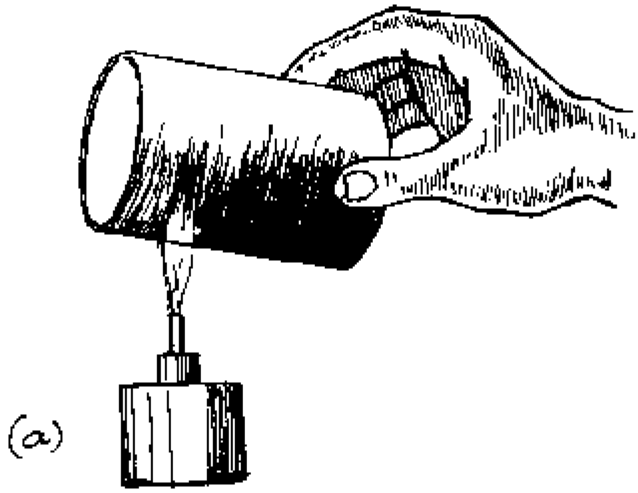


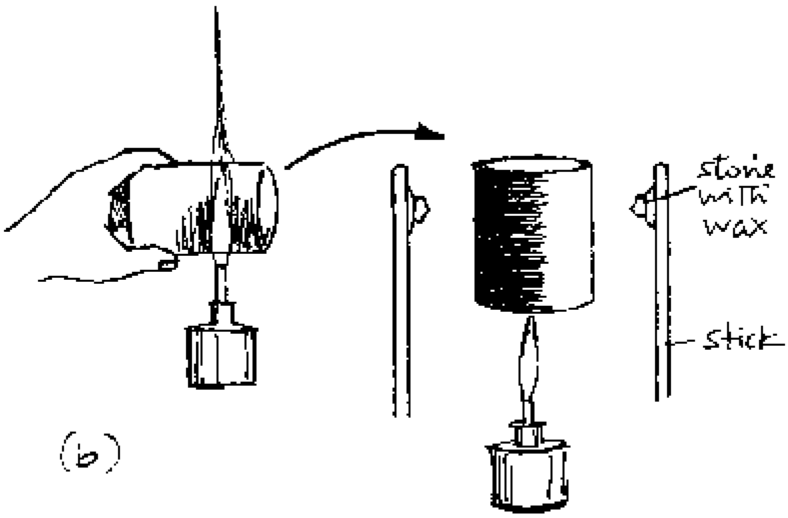
O: At the coast and on lake shores a gentle air stream (breeze) always blows. The direction of the breeze during the day is different from that at night.

Q: How can you explain this?

E: *During daytime* the land warms up faster than the sea. The warm air rises over the land and colder air from the sea flows to the land. This creates a breeze from the sea to the land. *During night,* the water stays warmer than the land, air over the water rises, colder air from the land flows to the sea. This creates a breeze from the land to the sea. The general effect is that the breeze from the sea keeps the daytime temperature on the land lower than expected from the hot sun, whereas the breeze from the land makes the night temperatures cooler than expected.

5.4.8 Good and Bad Radiators





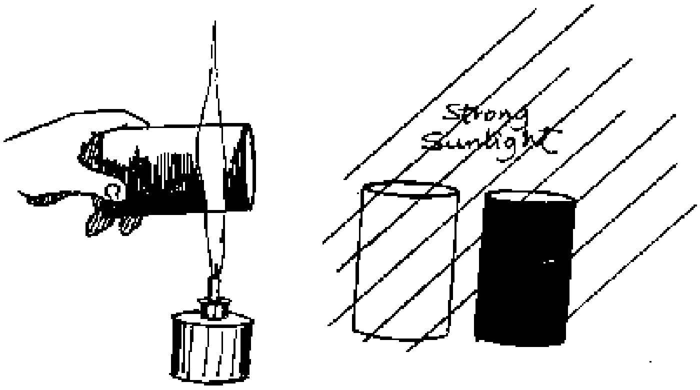
P: Paint one half of the outside of an open can black and leave the other half shiny (see figure (a)). Place a wooden stick near each side of the can. Stick a small stone with candle wax on each stick. Heat the bottom of the can.

Q: What do you observe?

E: The candle wax opposite the blackened surface begins to melt earlier than the wax opposite the shiny surface. This shows that *a black surface is a better radiator than a shiny surface.*

H: Soot and black shoe polish will do for the black paint.

5.4.9 Good and Bad Heat Absorbers



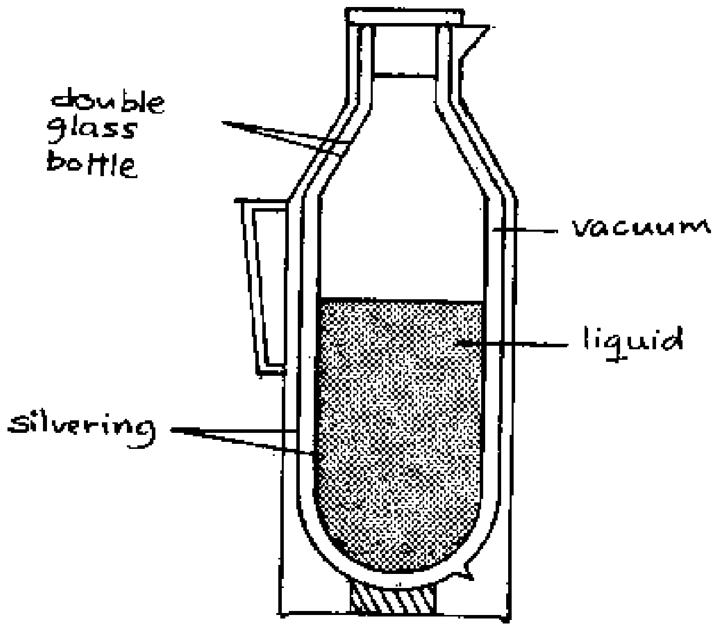
P: Take two shiny and identical cans and paint the outside of one black (soot can do). Place both of them in the sun or place them at equal distances from a fire for some time (about half an hour). Then find out how hot each can feels.

Q: Which can heats up more quickly?

E: The can with a *black surface absorbes heat more quickly than* the one with *a shiny surface.*

A: It is wiser for people in hot areas to wear bright clothes and paint their houses white - so that they absorb less heat. What colour should a petrol tank be painted? Give your reasons.

5.4.10 The Thermos Flask

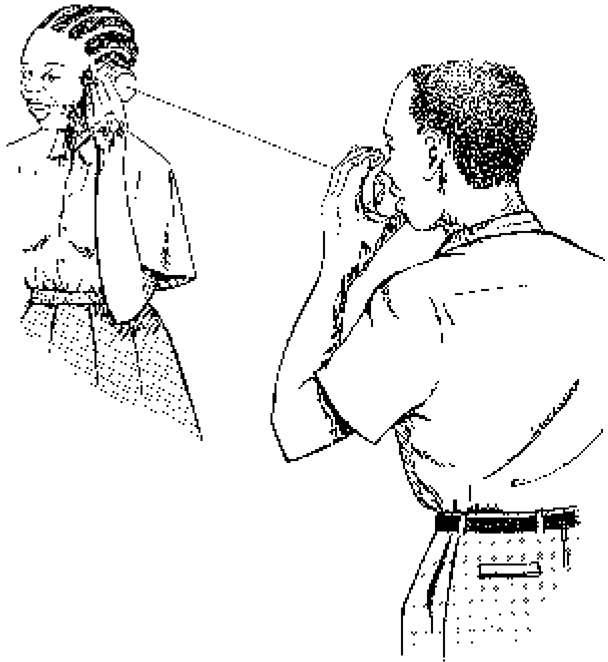


P: The thermos flask is a double walled glass bottle with a vacuum between the walls. Both the inner and outer surfaces of the walls are silvered so that they are shiny.

Q: How does the flask keep hot tea hot or cold water cold?

E: A vacuum is a bad conductor of heat and does not allow convection of heat The vacuum prevents heat loss or gain by conduction and convection. The silvery walls reduce heat absorption and heat loss by radiation.

6. Wave Motion



6.1. Production of Waves

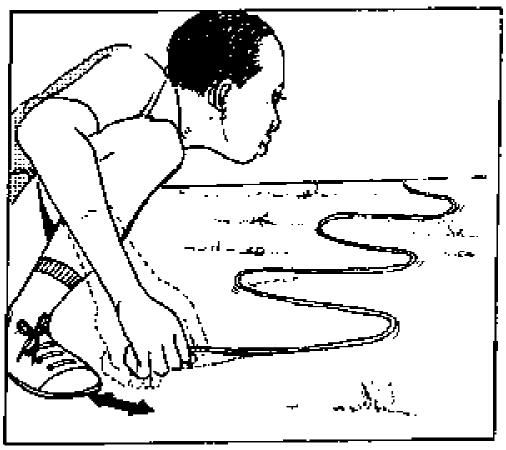
If a stone is dropped in a still pool of water, concentric circles spread out from the point where the stone enters the water. These concentric circles are an example of a travelling disturbance. A travelling disturbance is called a *wave.*

In *transverse waves* (e.g. water waves) the vibration of the particles is *perpendicular* to the direction of the propagation of the waves. In *longitudinal waves* (e.g. sound waves) the vibration of the particles is *in the direction* of the propagation of the waves.

Only *energy is transported by a wave.* The oscillating particles of the medium, which transmits the wave, do *not* travel with the wave.

The *frequency* gives the *number of oscillations per unit time.*

6.1.1 Transverse Wave Using a Rope

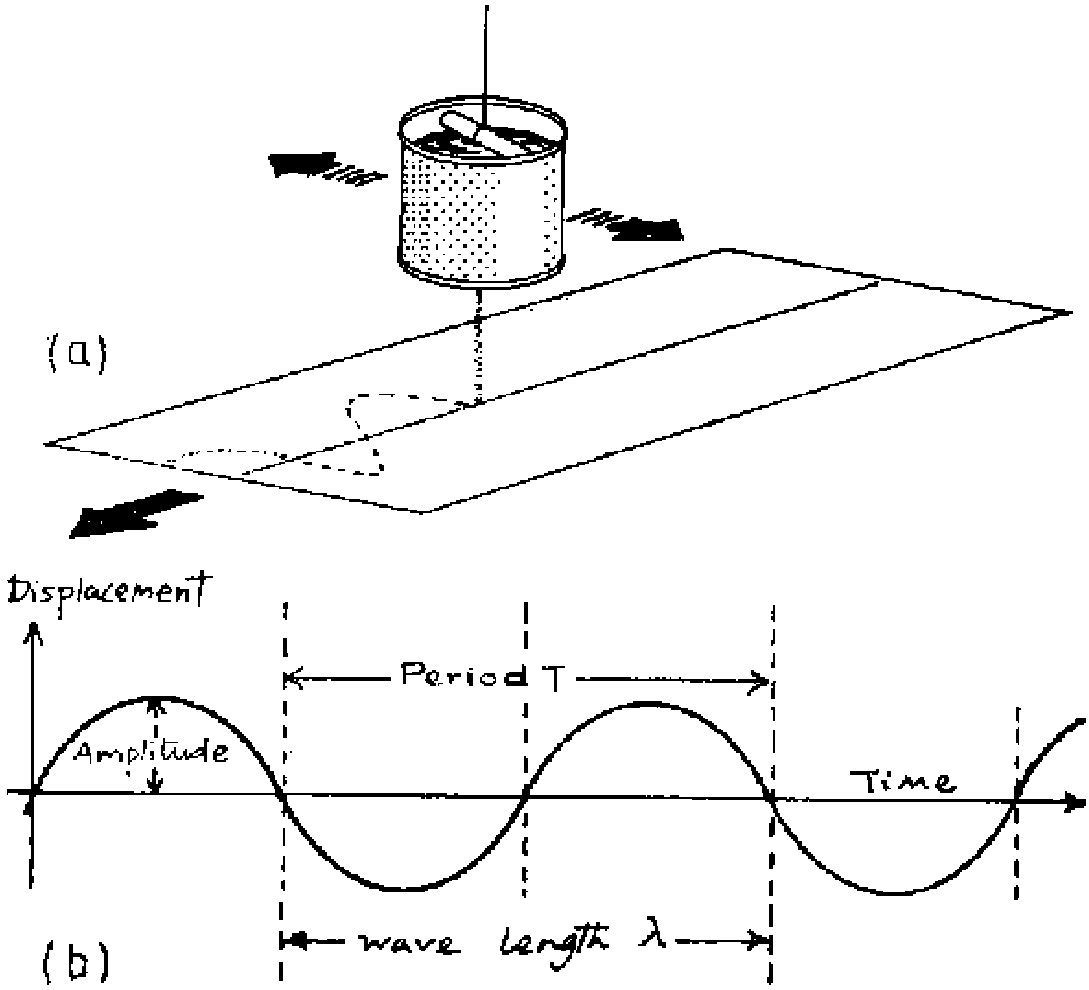


P: Take a piece of rope of about 6 m length. Hold it at one end and jerk it sideways.

Q: What do you observe? Draw a sketch.

E: The disturbance produced by jerking travels along the rope making *crests* and *troughs.* The jerking of the rope acts as a source of disturbance which travels along the rope. The direction of motion of the wave is *perpendicular* to the direction of jerking. Thus is a *transverse wave.*

6.1.2 Tracing a Wave Using a Pendulum Container

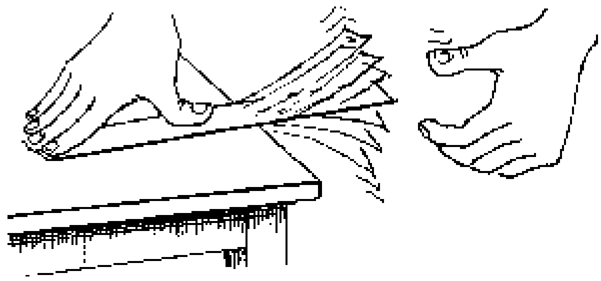


P: Take an empty tin opened at one end. Make a small hole at the other end using a sharp nail. Suspend it using a string so that the bored end faces downwards. By gluing or pinning prepare a 30 x 200 cm sheet of an old newspaper. Fill the suspended tin with coloured water (e.g. using ink) or fine sand (dry). Pull the tin to one side and leave it to oscillate freely. While it is oscillating steadily, pull the paper under the tin with *constant velocity.*

Q: What do you observe? Draw a sketch.

E: When the tin is pulled sidewards, it tries to go back to the equilibrium position and overshoots. As it oscillates the jet from the tin draws a sinus trace on the paper passing underneath it. The resulting trace shows a *transverse wave.*

6.1.3 Sound from a Ruler

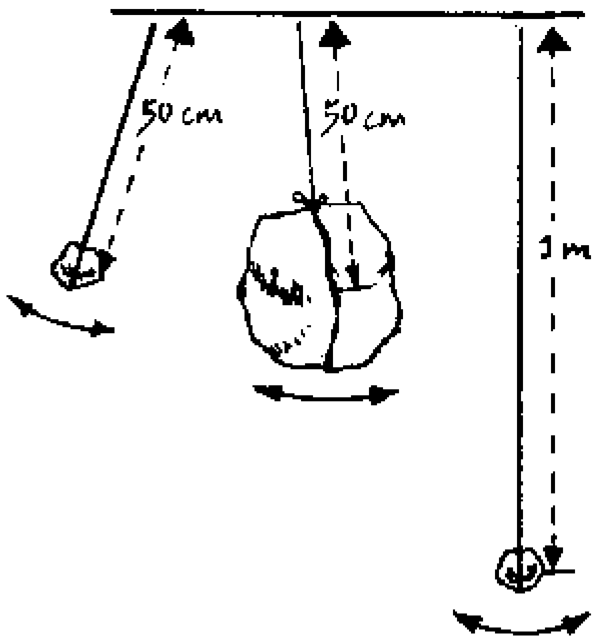


P: Clamp a ruler on a table with its free end protruding. Cause the free length to vibrate and listen to the sound. Repeat this for different protruding lengths of the ruler. Four different lengths are enough.

Q: How does the sound and vibration relate to the protruding length of the ruler?

E: When the vibrating length is reduced, a higher pitch sound is heard and the vibrations become faster and faster. When the vibrating length is increased, a lower pitch sound is heard and large masses of air are set into vibration with large amplitude. Consequently a loud sound is heard. Conversely, short lengths cause small masses of air to vibrate with small amplitudes producing a low sound.

6.1.4 A Transverse Pendulum

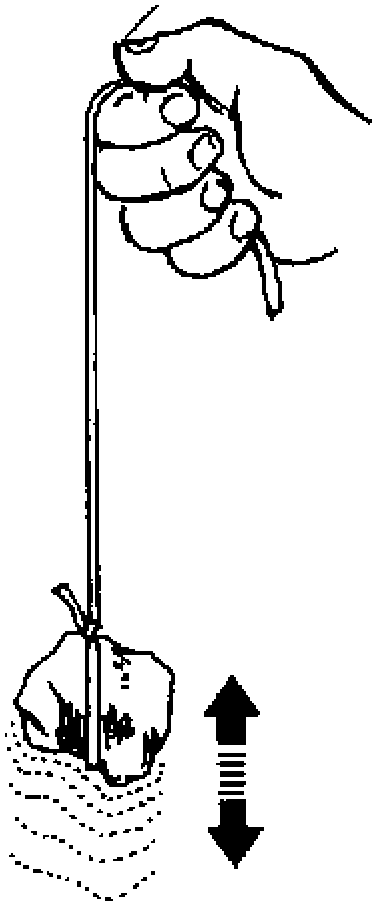


P: Tie a stone to one end of a thread of 50 cm length. Fix the other end of the thread and cause the pendulum to oscillate. Make sure that the displacement is not more than 10°. Record the time for 20 oscillations and find the frequency. (Frequency = number of oscillations ÷ time taken). Change the stone to a heavier one and repeat the procedure. Change the length of the thread to 100 cm and repeat the procedure.

Q: What do you find?

E: The frequency is independent of the mass, but depends on the length of the thread.

6.1.5 A Longitudinal Pendulum



P: Tie a stone to one end of a rubber band and hold the other hand as shown above. Lift the stone up and release it so that it oscillates. Record the time for 20 oscillations. Find the frequency. Repeat the procedure by varying the length of the rubber band and the mass of the stone.

Q: What do you observe?

E: The frequency is independent of the mass but depends on the length.

6.1.6 Sound Vibrations

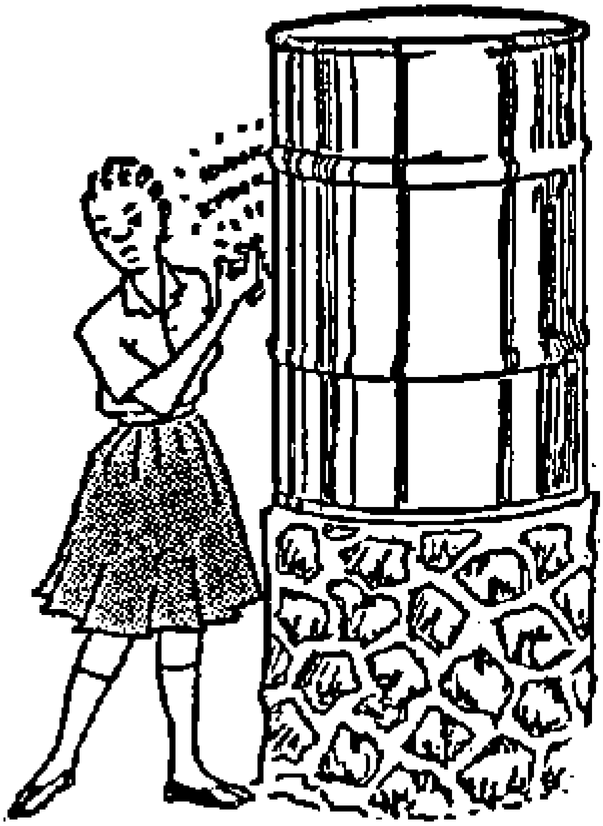
P: Cover one end of an open tin with a membrane (paper). Fasten it using a string. Spread fine dry sand on the membrane. Speak a soft and a loud sound from the bottom into the tin while your friend is watching the sand.

Q: What does he/she observe?

O: The louder the sound, the larger the amplitude of the vibrations.

E: The air underneath the membrane has been disturbed by the sound waves which in turn disturb the membrane and make it vibrate. This experiment shows that sound travels as a vibration.

6.1.7 Knocking a Water Tank



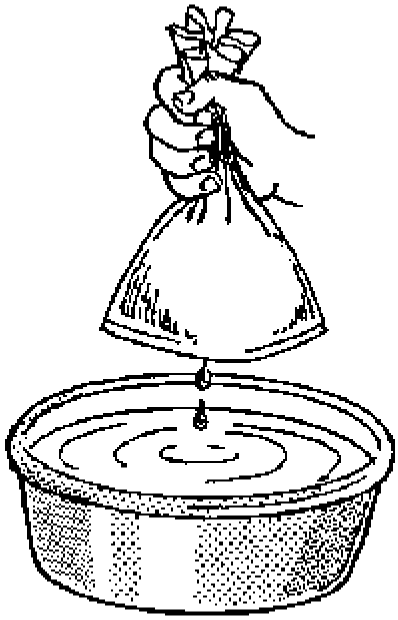
P: Gently knock the side of a wa(...)um from the top downwards to the bottom and listen to the tones (see the figure).

Q: What do you hear?

O: The knock causes the drum to vibrate. At the top, the knocking sets air inside the drum into vibrations giving a loud sound; at the bottom the knocking sets water inside the drum into vibrations giving a soft sound.

A: This can be used to check the presence of liquids in tanks or larger containers.

6.1.8 Waves on a Water Surface

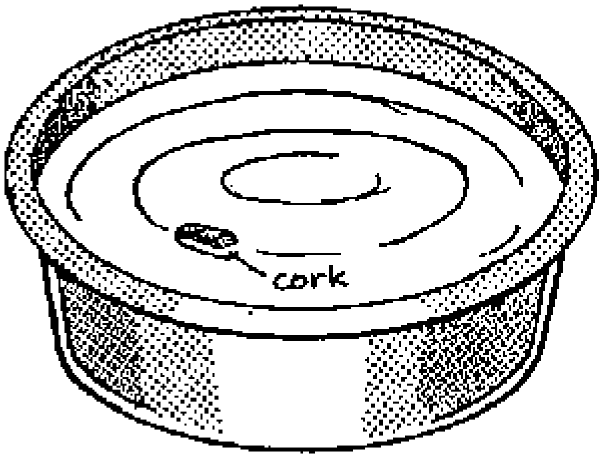


P: Allow the surface of coloured water in a bucket to come to rest. (Ink can be used to colour the water.) Fill a plastic bag with water and make a small hole at its bottom. Raise the bag so that drops of water fall on the surface of the coloured water.

Q: What do you observe?

O: You will see circular waves spreading out rapidly. The drops disturb the water. The disturbance spreads out in concentric circles from the centre. The concentric circles observed are water waves.

6.1.9 Transfer of Energy



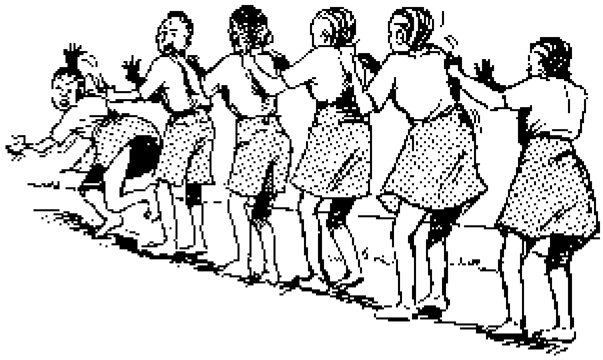
P: Put a small piece of light material (e.g. light wood, polystyrene) on the surface of water in a bowl. With a dropper (see 6.1.8) release a few drops of water onto the centre of the water surface. Avoid wind.

Q: What do you observe?

O: You will see water waves moving from the centre outwards but the pieces of light materia will not travel with the waves.

E: Energy travels with the wave. However, the particles of the wave-transmitting medium (e.g water) do *not* travel with the wave, they only oscillate up and down.

6.1.10 Transfer of Energy



P: Line up a group of students and ask each student to place his/her hands on the shoulder of the student in front with the elbows kept bent. Tell the last student to push forward.

Q: What do you observe when one after the other student pushes?

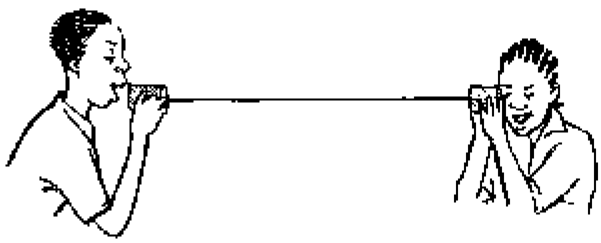
O: A longitudinal wave moves through the queue.

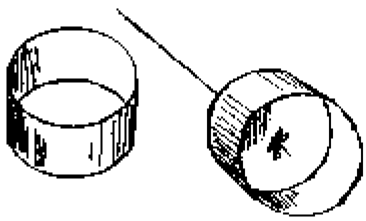
6.2 Propagation of Waves

Sound does not travel through a vacuum but it requires a *medium* for its propagation. Denser media are better transmitters of sound than less dense media.

Thus, sound travels faster and better in water, wood or strings of various materials than in air.

6.2.1 The String Telephone



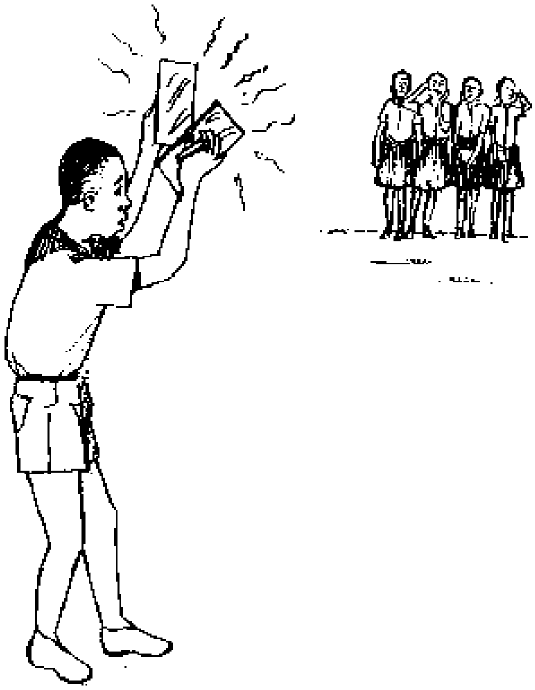


P: Punch a small hole at the centre of the bottom of each of the two empty cans. Connect the cans with a long string knotted inside each can. Hold the cans so that the string is stretched. Talk into one can while your friend is listening (he/she may close the other ear with a finger). Ask your friend to talk to you also and listen to him.

Q: What do you hear?

O: You will hear each other distinctly. Sound has travelled through the string (as a medium) from one can to the other.

6.2.2 Sound Waves in Air

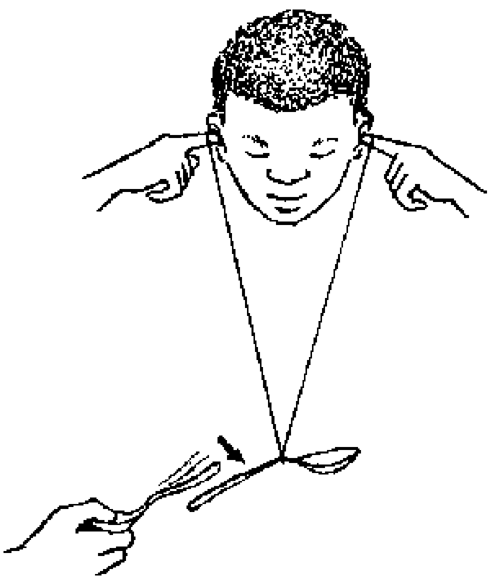


P: One student is standing about 100 m from the class and making sound by clapping two metal pieces (two lids) together.

Q: What do you hear?

O: You will hear a sound. The sound you hear has been transmitted from the source to you by air as a medium.

6.2.3 Sound in a String

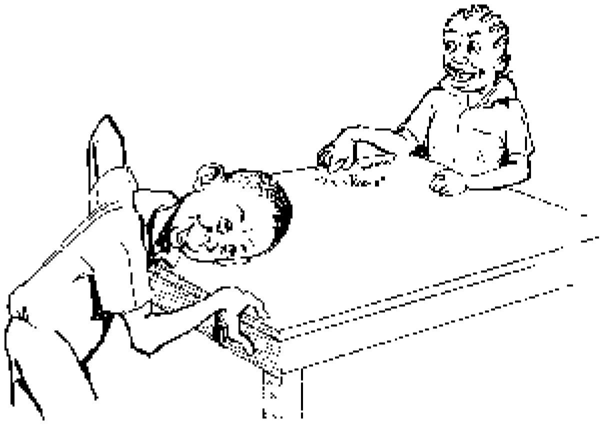


P: Tie a metallic teaspoon at the middle of a one metre long cotton thread. Wind each end of the thread around a fingertip (see figure). Press the fingertips into your ears. Bend down so that the string and the spoon hang freely. Let someone hit the spoon slightly with a nail or another spoon. Listen to the sound.

O: You will hear a chime sound like that of a church bell.

E: Sound travels through the string to your ears. Sound travels better in strings than in air.

6.2.4 Sound in Wood



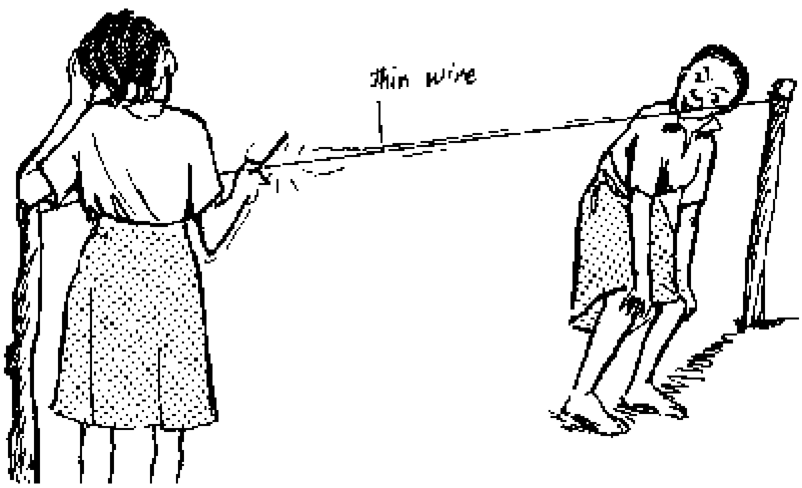
P: Place your ear against one edge of a table while your fiend is knocking the opposite edge slightly. Repeat the experiment by scratching the table slightly. Listen to the sound through air and the sound through the table.

Q: Describe what you hear.

O: The sound travelling through the table is heard more distinctly than when heard through the air.

E: Hence sound travels better in wood than in air.

6.2.5 Sound in Metal



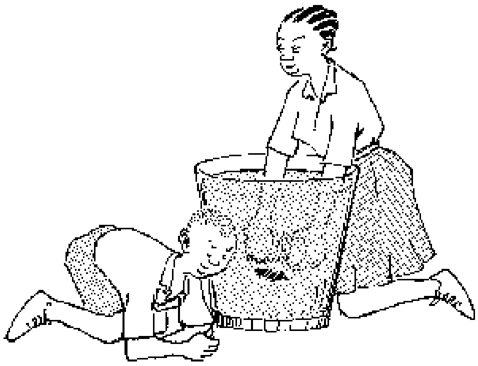
P: Take a long thin wire and fix it to two posts placed about 5 m apart. Tell your friend to be at one end. Then scratch the other end of the wire. Scratch the wire again while your friend has placed his/her ear against the wire on his/her side.

Q: Ask your friend what he/she hears.

O: Your friend will hear nothing unless he/she places his/her ear against the wire.

E: Sound travels better in metal than it does in air.

6.2.6 Sound in Water



P: Fill a plastic bucket with water. Take two stones and knock them against each other *in the water,* while another person has put his/her ear close to the bucket.

Q: What does he/she hear?

O: He/she will hear the sound coming through the water more loudly.

E: Sound travels better in water than in air.

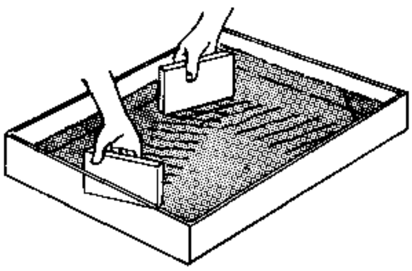
6.3 Reflection of Waves

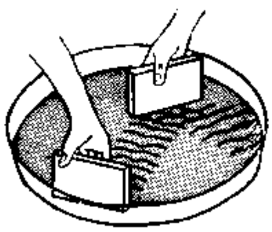
When a travelling wave meets a smooth barrier it is reflected. When a wave is reflected, the angle of incidence is equal to *the angle of reflection.*

When a wave is constantly reflected the same way back as it comes to the obstacle (e.g. a wave reflected on the fixed end of a string), a *standing wave* is produced.

Reflected sound is called an *echo.* Ships use *echo-sounding* to determine the depth of the ocean.

6.3.1 Reflection of Water Waves





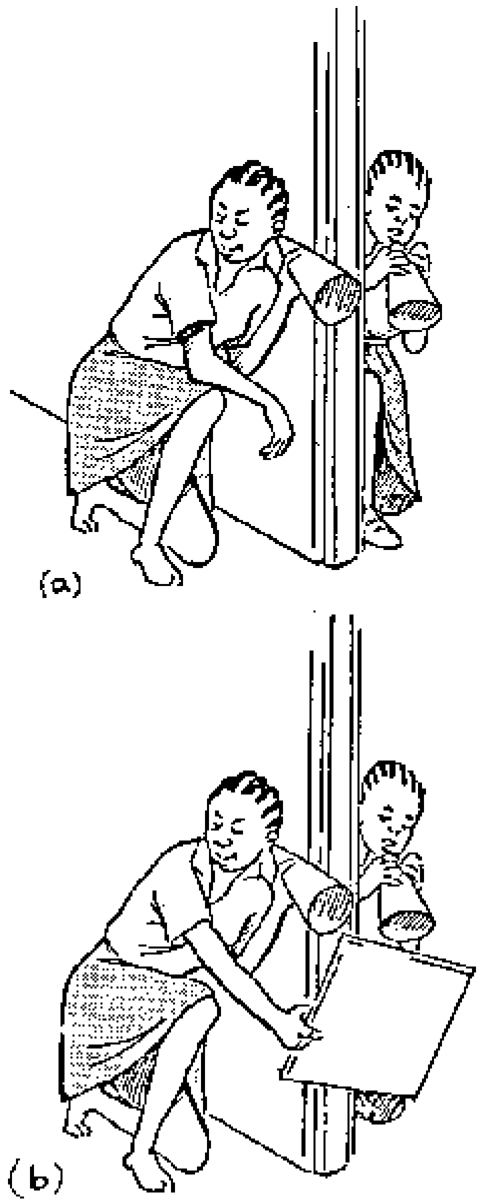
P: Place a straight metal or plastic barrier in the dish containing coloured water. Touch the surface of the water with a rectangular block of wood repeatedly in equal time intervals.

Q: What do you observe?

O: Parallel waves move across the dish and rebound from the barrier.

E: This behaviour is known as *reflection of waves.* When the angle of inclination of the barrier is changed, the angle of reflection remains the same as the angle of incidence. The barrier is acting as a reflector just as a mirror is a reflector of light.

6.3.2 Reflection of Sound Waves



P: You and your friend should stand on both sides of a wall beside an opened door. Ask your friend to whisper into a cone and listen through the other cone, see figure (a).

Q: Do you hear anything?

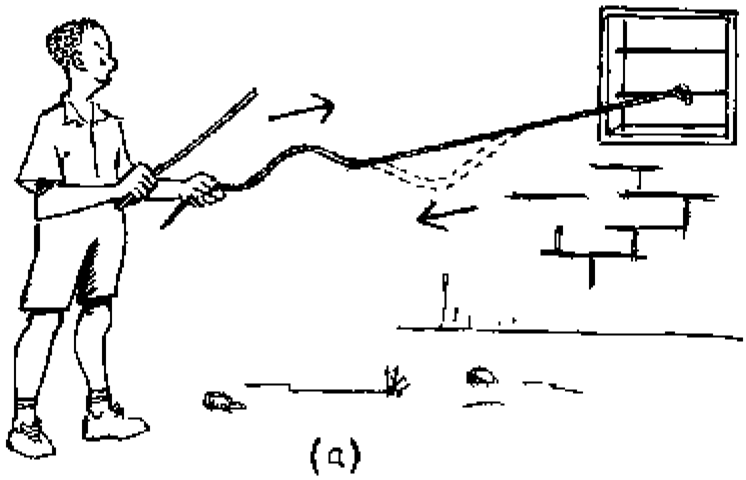
O: No sound is heard.

P: Repeat the above procedure while holding a smooth cardboard as shown in figure (b). Change the position of the smooth cardboard.

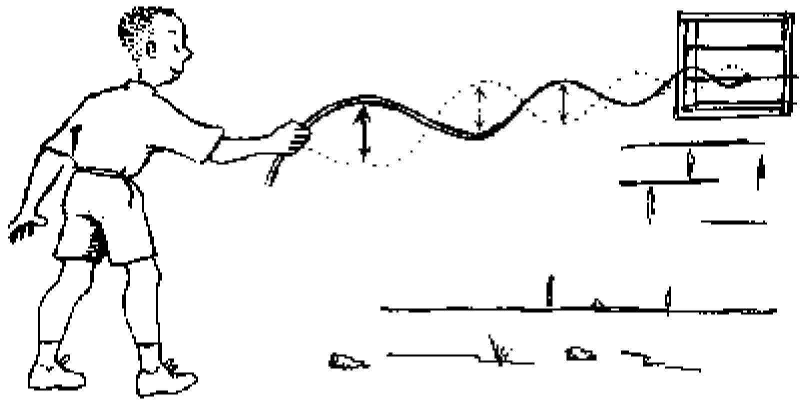
Q: What do you hear?

O: Distinct sound is heard. This is because the whispered sound has been reflected by the smooth cardboard towards the listener.

6.3.3 Reflection in a Rope



(a)



(b)

P: Tie a rope of about 4 metres length on a fixed bar of a window as shown in the diagram. Hit the rope by a stick.

Q: What do you observe?

P: Repeat the procedure above by jerking the rope up and down.

Q: What do you observe now?

O: (a) An impulse travels along the rope and comes back.

E: When the impulse hits the fixed end of the rope, it bounces off and comes back again as shown by the dotted line in the diagram. The reflected impulse has the same shape as the incident impulse, but is inverted, see figure (a). ? Thus, when a wave is reflected on the fixed end of the rope, a *standing wave* is produced, see figure (b).

6.3.4 Reflection in a Hose Pipe

P: Take a long piece of an empty garden hose pipe. Listen at one end of the pipe while your friend is whispering into the other end of the pipe.

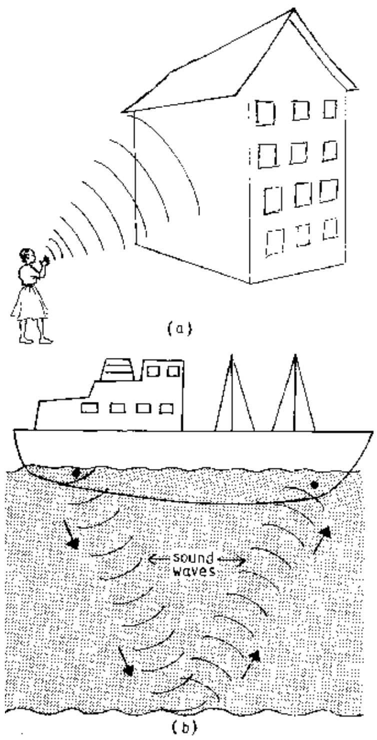
Q: What do you hear?

O: The sound is heard more distinctly.

E: When your friend is whispering,, he is sending sound waves into the pipe which are reflected on the walls of the hose pipe. These waves are directed to the other end of the hose pipe where they can be heard.

A: Similarly light can be reflected in a glass fibre. Thus, light pulses may be transmitted by glass fibres. This is used for telephone television etc.

6.3.5 Reflection of Sound Waves: Echoes



P: Stand near a tall building and call out loudly, see figure (a).

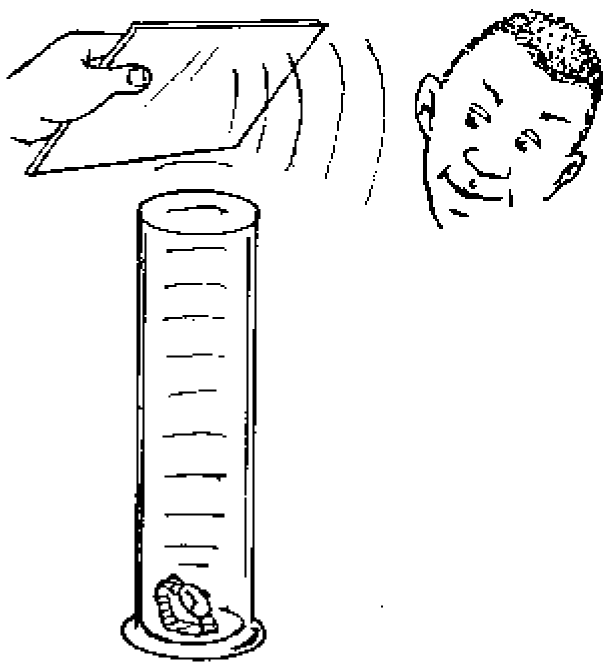
Q: What do you hear?

O: After a short time, the call is heard again.

E: The sound waves have been reflected from the wall of the building. The reflected sound which is heard is called an *echo.*

A: Echoes are used by bats in (ultra sound) navigation. Also echoes are used to determine shoals of fish and the depth of oceans, a phenomenon called *echo-sounding* see figure (b).

6.3.6 Reflection of Sound Waves



P: Take a tall cylindrical container and put a mechanical clock in it. Place your ear close to the side of the container. Listen to the sound from the clock. Then place a cardboard at slant position about 5 cm on top of the container and listen again (change the position of the board).

Q: What do you hear?

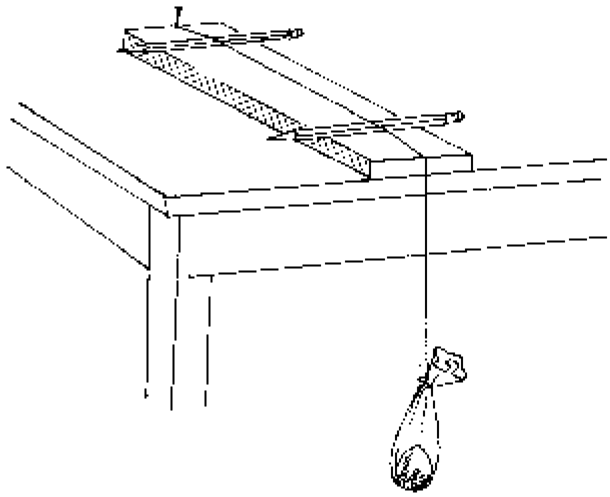
O: In the absence of the cardboard no sound is heard. But in the presence of the cardboard the tick-tack sound is heard.

E: This is because the sound from the clock travels vertically up and is reflected by the cardboard towards the observer.

6.4 Music and Musical Instruments

The human voice is produced by the vibration of the vocal cords. Changes in tension and length produce changes in pitch or tone of the voice. *The less the length and the higher the tension of a cord, the higher the pitch of the tone produced.* The same principle is used to produce music with a *guitar* or a *violin.* The *marimba* and the *xylophone* use sticks or bars of various length or thickness to produce tones of different pitch. The *flute,* the *bottle orchestra* and the *organ* use air columns of various length.

6.4.1 Sonometer (One - String Guitar)



P: Place a soft board on a table. Fix a string with a nail to one end of the soft board. Tie the heavy mass of a stone to the other end of the thread so that the mass hangs below the edge of the table. Insert two pencils under the thread so as to raise the thread off the board. Pluck the thread between the two pencils. Vary

(a) the distance between the two pencils;
(b) the mass hanging.

Q: What do you hear?

O: (a) A higher tone is produced if the distance between the two pencils is reduced.

(b) A higher tone is produced if the mass is increased.

E: The tone which is produced by the vibrating string depends on its vibrating length and the tension of the string.

6.4.2 Bottle Orchestra

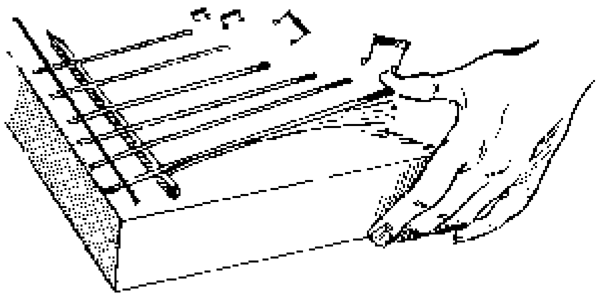
P: Take four equal bottles. Leave the first bottle empty. Fill the second bottle a quarter of its volume, the third a half, and the fourth three quarters of its volume with water and blow into the bottles one after another and listen to the tones produced.

Q: Do you notice any difference in sound?

O: The shorter the air column the higher the tones.

A: The organ (used in some churches); the flute.

6.4.3 Marimba



P: Cut bicycle spokes into different lengths. Arrange them on a piece of wood and fix them to it by putting another spoke across them as shown in the figure. Lift the fixed spokes by inserting a pencil under them to raise the free ends of the spokes off the wood. Pluck the free ends one after another and listen to the tones produced.

Q: What do you notice?

O: The plucking causes the spokes to vibrate and produce sound. The longer the spoke, the lower the tone.

A: Grand pianos produce lower notes than normal ones.

6.4.4 Simple Flute (Bamboo Flute)

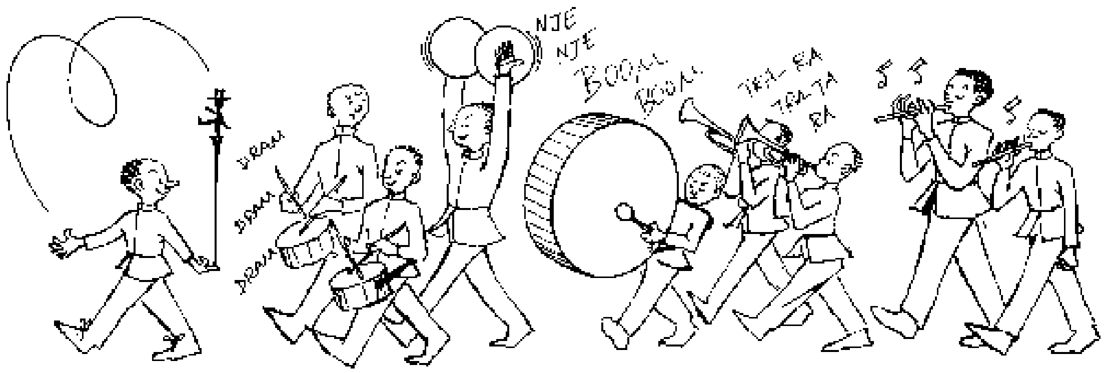
P: Take a straight bamboo tube of about 1.5 cm diameter and 30 cm length. Clean the knots inside. Dry it until its colour changes to yellowish-brown. Make a mouth-piece and a row of holes as shown in the figure. Blow air into the mouth-piece while closing some of the holes with your fingers.

Q: What do you hear?

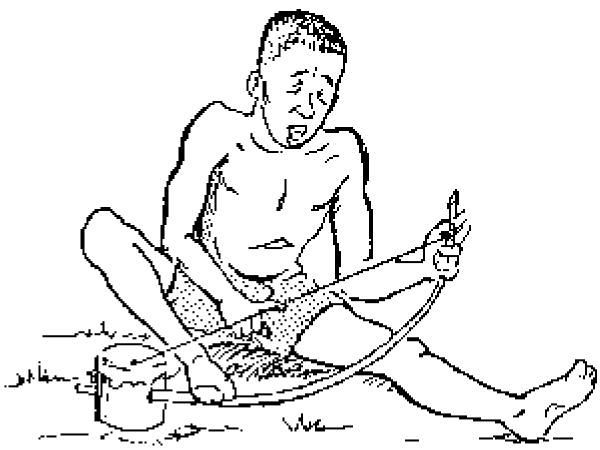
O: Different tones are produced by the flute as you remove fingers from different holes.

The pitch of the tones depends on the distance of the first open hole from the mouthpiece, i.e. the closer the hole is to the mouth-piece, the higher the tone produced.

E: Thus, the tone produced is determined by the vibration of air in the column between the mouth-piece and the first uncovered hole.



6.4.5 The Violin



P: Make two holes diametrically opposite each other near the upper open end of a tin and then pass a flexible wooden stick through them so that it just protrudes from the can on one side. Bore a small hole at the centre of the bottom of the can. Fix one end of a string at the hole and tie the other end to the end of the stick which is bent into a bow as shown in the diagram. Make the string tight. Pluck the string repeatedly with a finger as if playing a guitar.

(a) Change the tension by further lightening the string.

(b) Change the length of the vibrating portion of the string by touching the upper end with your finger.

Q: What do you hear?

O: (a) The pitch of the tone produced increases with the tension of the string.

(b) The pitch of the tone produced increases with the decrease of the length of the string.

H: Knotting the string on a nail held horizontally in the bottom of the can helps to anchor the string.

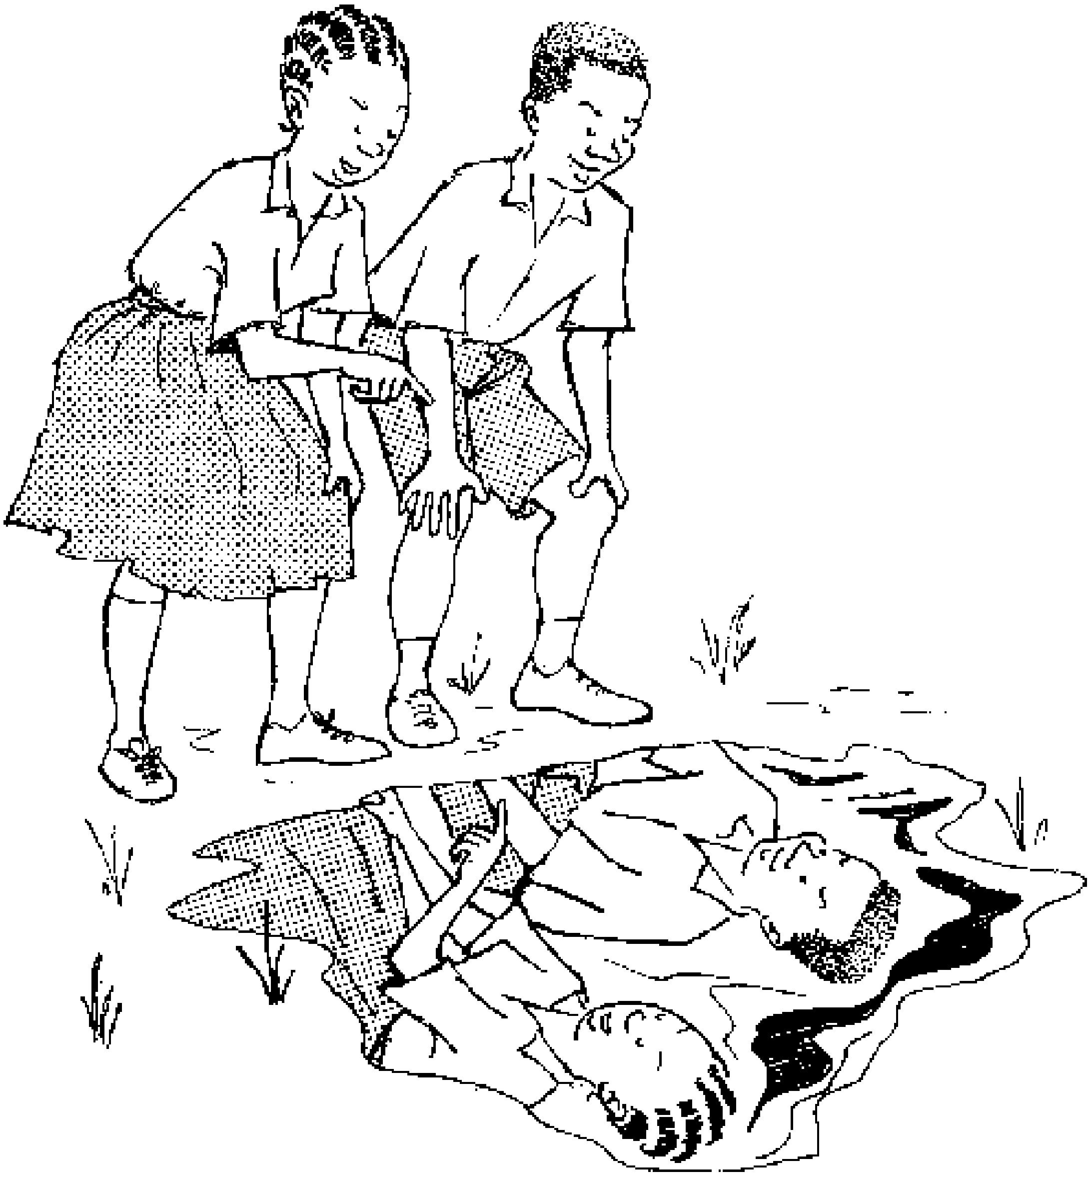
6.4.6 The Xylophone

P: Make a wooden box with the bottom and the top side open. Take timber bars of different types and thickness. Drill four holes into each bar and pass two strings to hold all the bars together on the top of the open box. Beat the bars in turn by using two sticks.

Q: What do you hear?

O: Different sizes of bars give different tones and different types of materials of the same thickness give different tones.

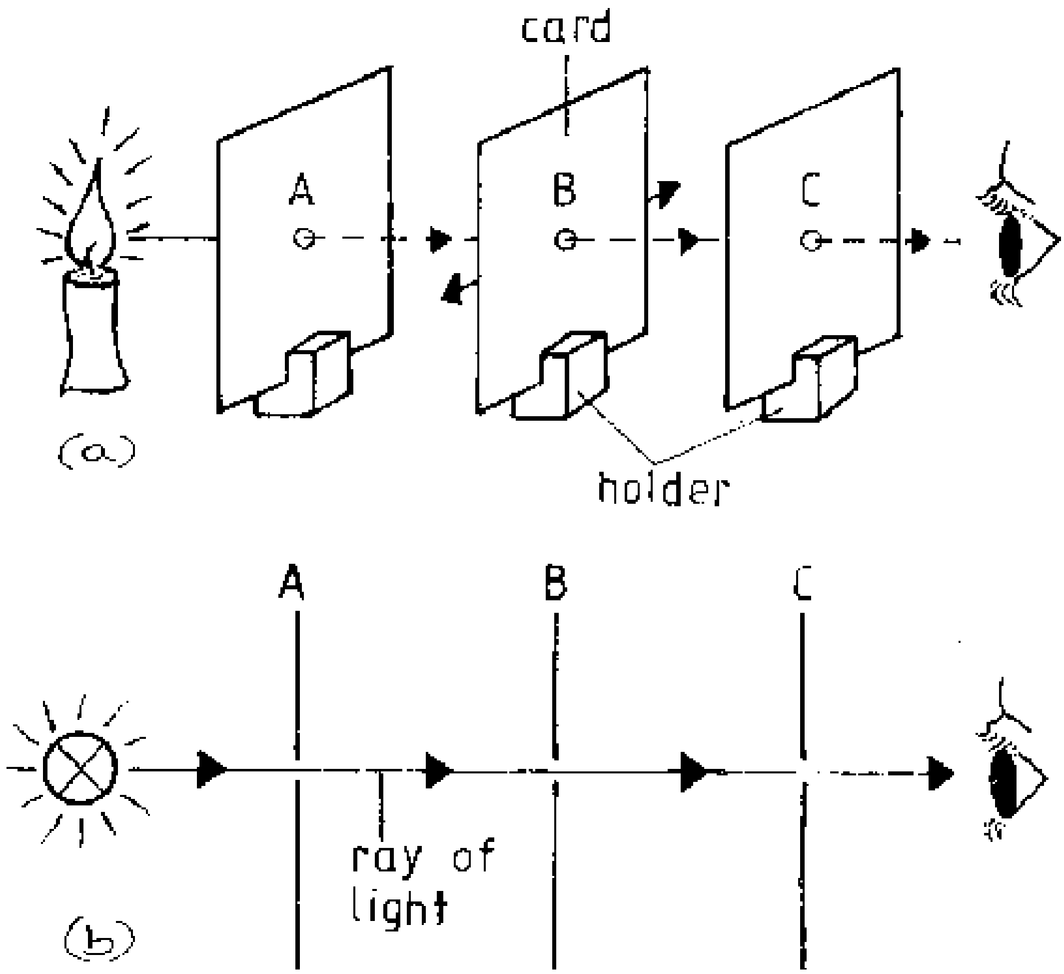
7. Geometrical Optics



7.1 Nature and Propagation of Light

Light is the energy which is given off by very hot bodies in the form of electromagnetic waves and makes objects visible to our eyes. Light travels in straight lines. Thus, we may use *ray diagrams* in order to explain the *formation of the image in the pinhole camera* or the *formation of shadows* of an object.

7.1.1 Light Travels in Straight Lines



P: Make small holes on pieces of cardboard A, B and C. Place them in front of a source of light as shown. Pass a thread through the holes and pull it at both ends to make it taut. Adjust the cardboards so that all the three holes are in line. Remove the thread. Bring a candle near card A and look through the hole in card C. Record your observations.

Displace anyone of the cards so that the holes are not in alignment.

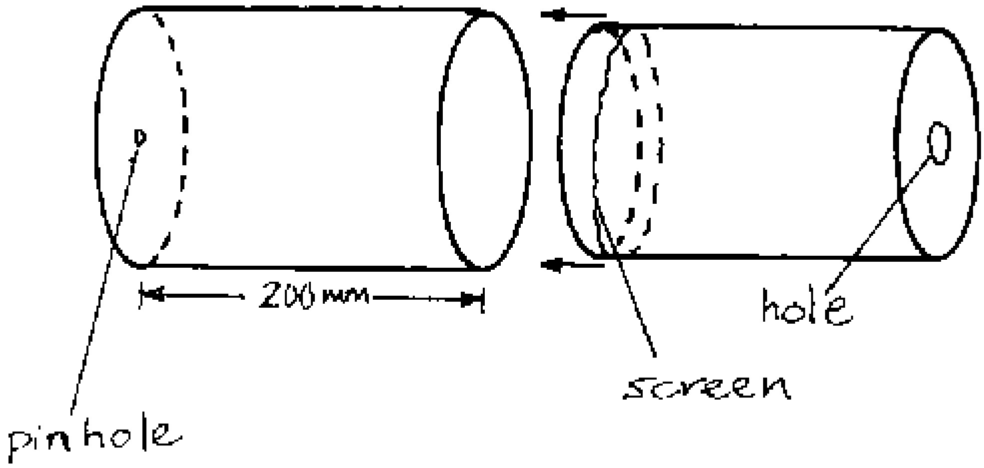
Q: What do you observe? How can you explain this?

E: The light can be seen from end C only if all the three holes are in line. Displacing any of the cards obscures the ray of light and hence you cannot see the ray as you look from card C.

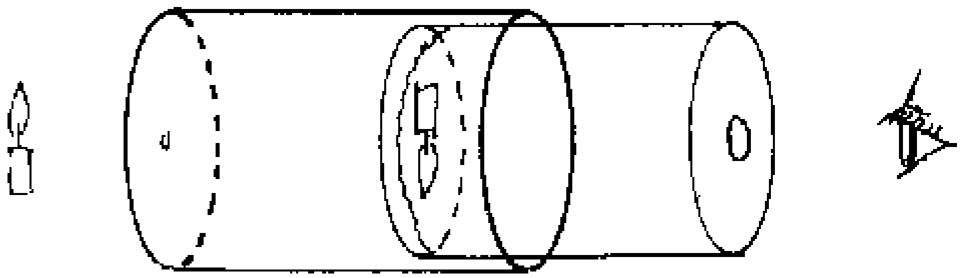
Hence *light travels in the straight lines.*

Figure (b) shows the same arrangement as figure (a) using symbols which are like the cross-section of the actual apparatus. We call such a figure a *ray diagram.*

7.1.2 The Pinhole Camera



(a)

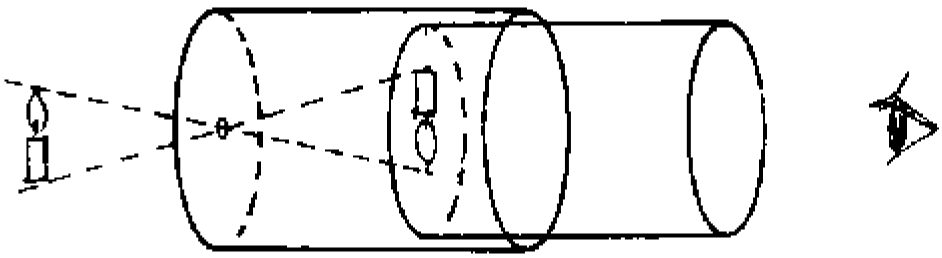


(b)

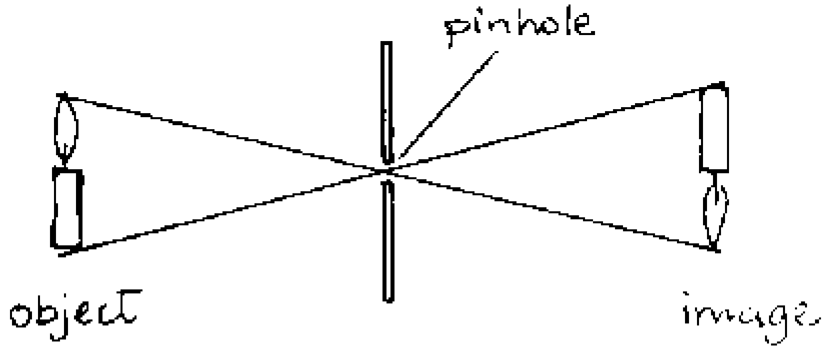
The pinhole camera is a camera made by using a tin or box with a pinhole at one end.

P: Roll a piece of manila card to make a cylinder. Glue a circular piece of card on one open end of the cylinder and puncture a hole at its centre using a pin. Make a second cylinder which fits tightly into the first cylinder. Cover one end of the second cylinder with a plain paper. The paper acts as a screen for the image which will be formed. Close the other end of this cylinder with a card. At the centre of the card produce a hole of about 2 cm diameter. Through this hole you will observe the image. The card prevents light to enter from this side because the image may be too dim to be seen, if light enters from the side of the observer.

7.1.3 Using a Pinhole Camera



(a)



(b)

P: (a) Observe a burning candle using the pinhole camera. Adjust the pinhole-screen distance in order to get a clear, sharp image of the candle.

(b) Change the distance between the screen and the pinhole by steadily pulling the inner cylinder. Observe what happens to the image.

(c) Move the camera slowly away from the candle, and observe what happens to the image.

(d) Make the hole wider. Observe the image.

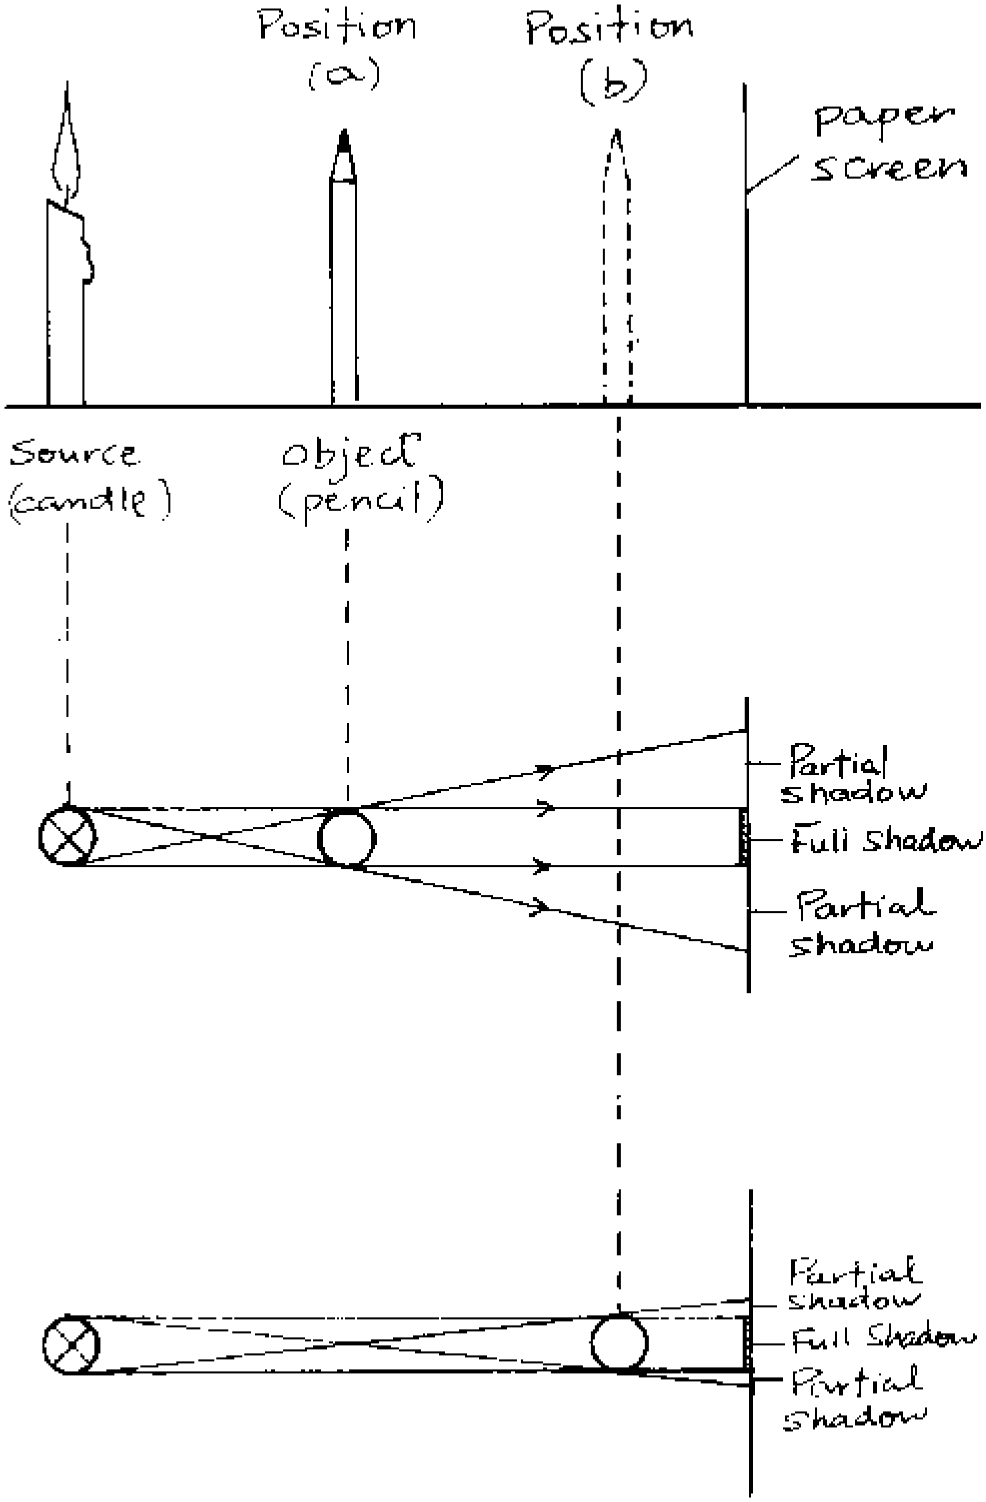
E: (a) The cone of rays reaching the pinhole from the object (candle) decreases with the distance of the hole from the object. Thus, the image becomes smaller and less bright. It is always an *inversed and real image. An image is real if it can be caught by a screen, since the rays really meet in the various point of the image.*

(b) When the distance between screen and pinhole is increased the image on the screen becomes larger and more blurred.

(c) The image becomes larger and more blurred when the object is closer to the hole and becomes smaller and sharper when the object recedes.

(d) When the hole is made larger the image on the screen becomes larger and more blurred. Generally, *an optical image is sharp when all the rays, coming from one point of the object* to the screen, *meet at one point of the image.* If the rays, coming from one point of the object to the screen, hit several points of the screen, the image is blurred.

7.1.4 Shadows Using one Light Source



P: Hold a pencil between a source of light (e.g. candle) and a white paper. Observe the shadow formed on the paper (screen).

Gradually move the pencil closer to the screen and observe the change in the shadow.

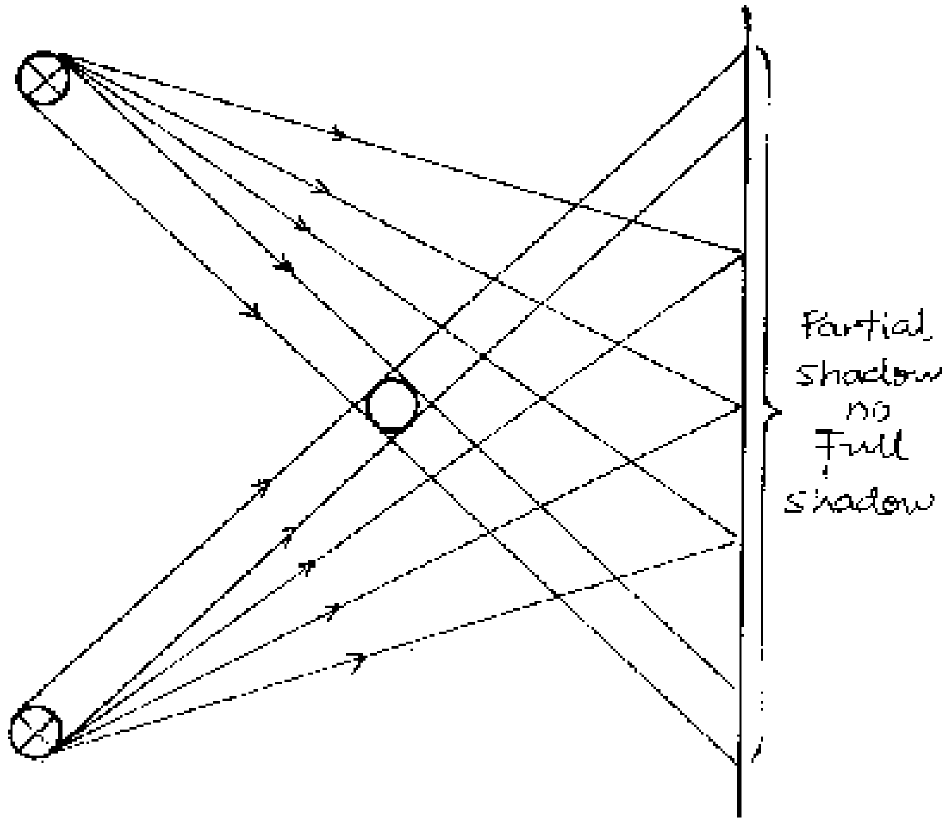
Q: How does the shadow change?

Explain this with the use of ray diagrams.

E: The shadow becomes sharper as the obstacle (pencil) approaches the screen.

The figures show that *full shade* exists only on those points of the screen, which are *not hit at all by rays* coming from any light source. Wherever points of the screen receive rays from a *part* of the light source only (but *not* from the whole source), there is *partial shade.*

7.1.5 Shadows Using two Light Sources

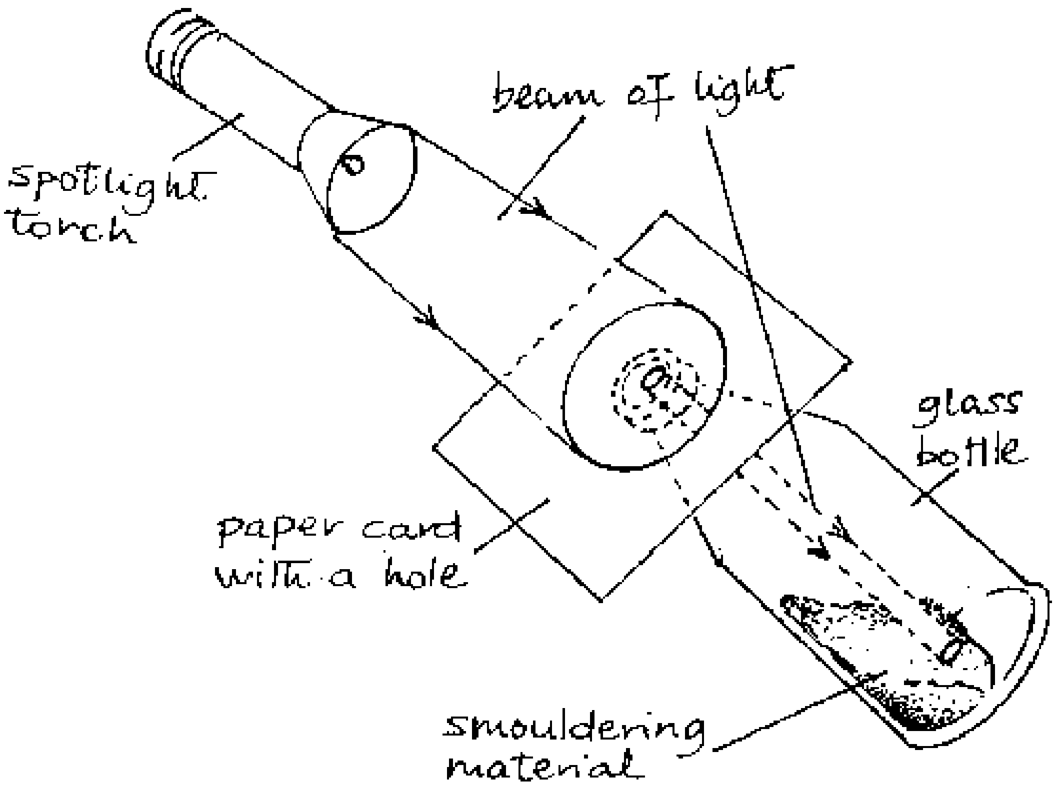


P: Repeat the above experiment using two candles and one pencil. Observe the shadows formed.

Q: Explain the results and discuss the formation of shadows by a point source and extended source of light.

E: The figure shows that all the points of the screen which do *not* receive rays from candle 1, *do receive* rays from candle 2 and vice versa. Thus, full shade does not exist in this experiment (except the object is brought very close to the screen).

7.1.6 Rays in the Smoke Box



P: Make a smoke box using a glass bottle and some smouldering material e.g. damp paper, cotton wool etc., as shown in the figure.

Produce parallel and divergent beams of light by using small and larger holes in the papercard covering the mouth of the bottle. In a dusty room, parallel, convergent and divergent beams of light can be visible when the floor is swept.

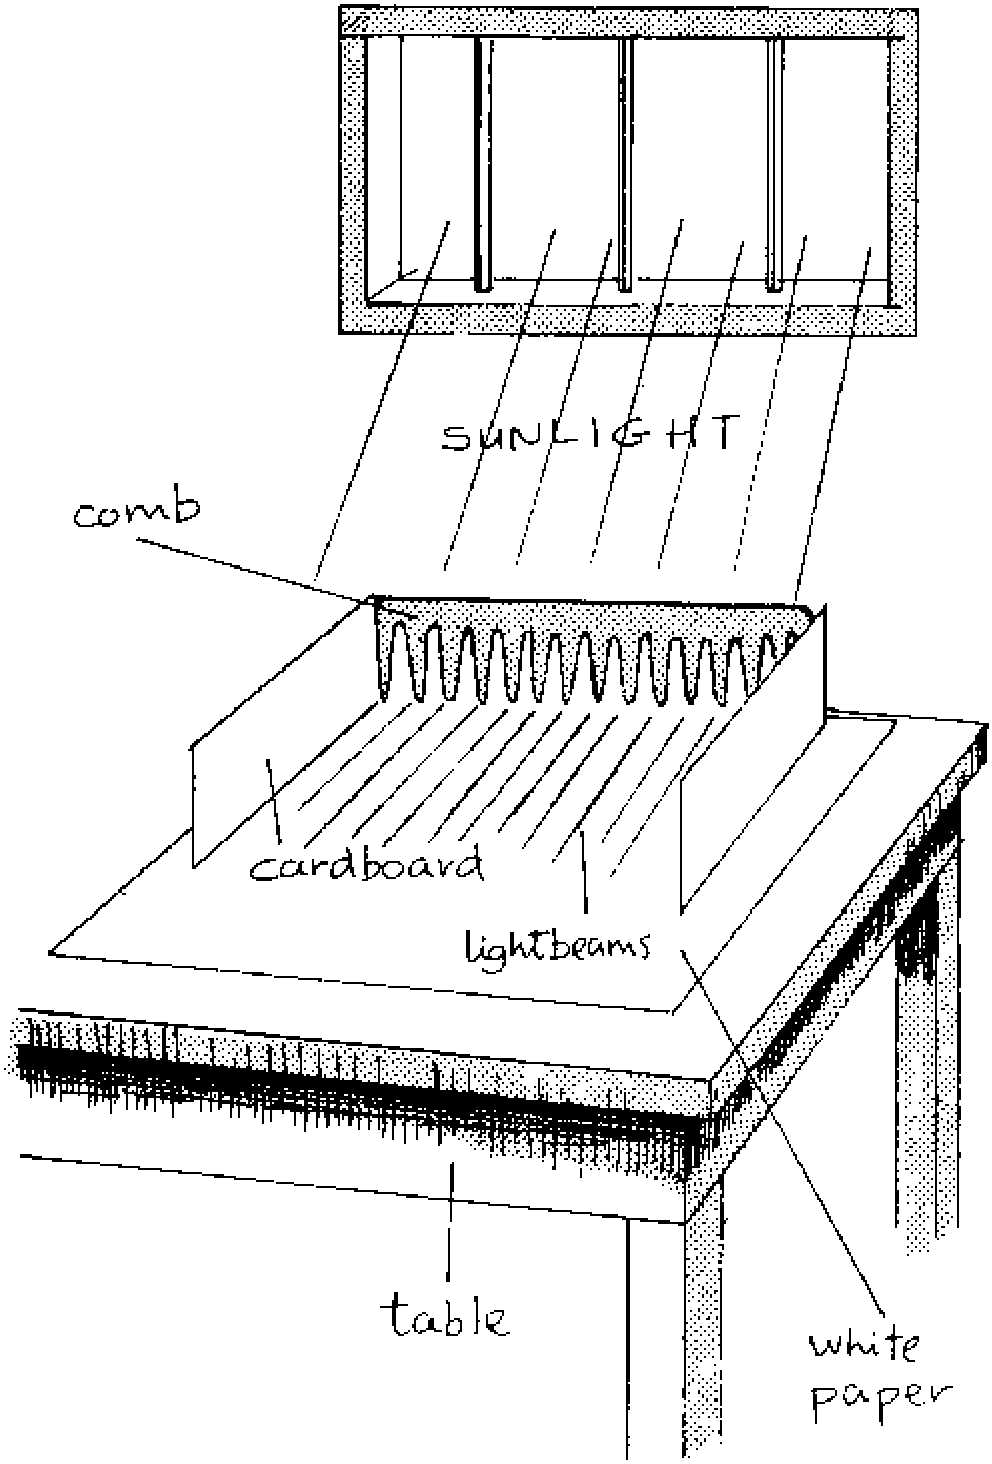
Sunlight or torchlight may be used as a source of light.

Q: How is it possible for smoke or dust to make beams of light visible? Why are sunlight rays parallel?

E: The smoke particles reflect some of the light in all directions and hence make it visible.

Sunlight rays are parallel when they reach the earth, because the earth is 150 million km away from the sun.

7.1.7 Beams of Light



P: Hold a comb on a white paper placed on a table. Place pieces of cardboards by the sides of the comb (see diagram).

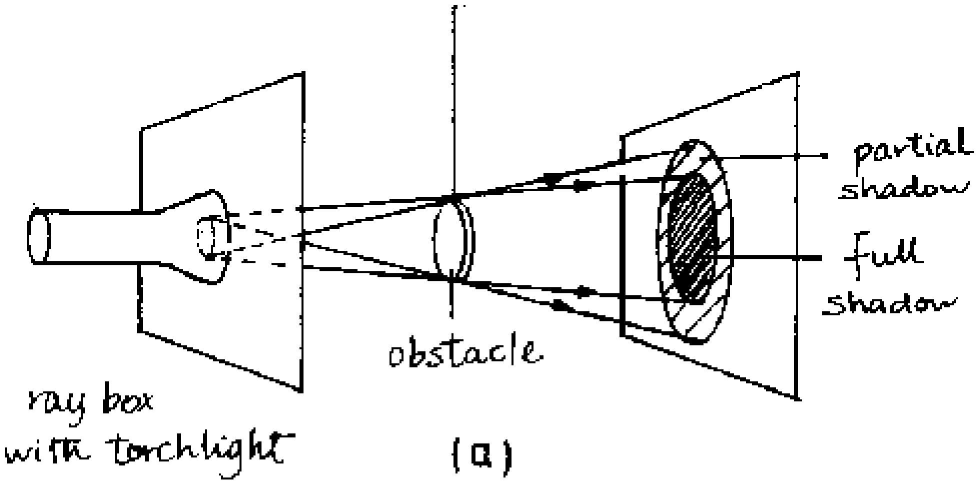
Q: What do you observe on this white paper? Explain.

Trace the beams of light which become visible on the white paper. Explain what is meant by the words "rays" and beam of light.

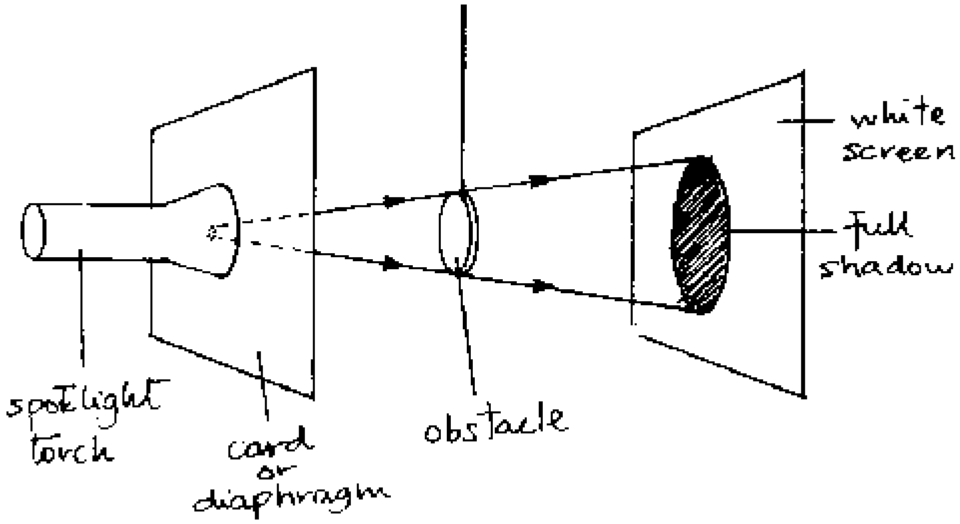
E: A *ray* is the direction of the path taken by light. A collection of rays forms a *beam.*

Since the sunlight consists of parallel rays, *parallel* beames of light will be observed on the white paper.

7.1.8 Shadow Formation by Point and Extended Sources of Light



(a)



(b)

P: Place a torch light behind a cardboard with a hole in it. The assembly is called a *ray box.* Observe the shadow formed by an obstacle placed in the light from a ray box with a large hole (see fig. a).

Change the hole of the ray box to a very small size and note the shadow formed by the same obstacle on the same screen (see fig. b).

Repeat the above experiments with sunlight.

Q: In which case do you get

(i) full and partial shadow?
(ii) full shadow only?
(iii) Sharper shadows?

Explain why the shadows formed by sunlight are not typical of your results in these experiments.

What do these experiments suggest about the way light travels?

E: All the experiments give evidence that light travels in straight lines.

Single *extended light sources* give partial and full shadows.

Single *point sources* give mainly full shadows. Sharper shadows are obtained when an obstacle intercepts parallel rays, i.e. rays from a distant source. Though the sun is an extended source, its rays reach the earth parallel and therefore produce sharp shadows.

7.2 Reflection of Light

When light strikes a surface separating two different media, part of it is thrown back to the original medium. This phenomenon is called *reflection.*

If the surface is smooth, reflection is regular, otherwise it is diffuse. The position of the object determines the position and attribute of the image.

The *law of reflection* states:

The *angle of incidence is always equal to the angle of reflection.* These angles are always measured *against the normal* of the reflecting surface.

This is sufficient to construct *ray diagrams* for plane mirrors. For *spherical mirrors* the following rules are helpful for the construction of ray diagrams:

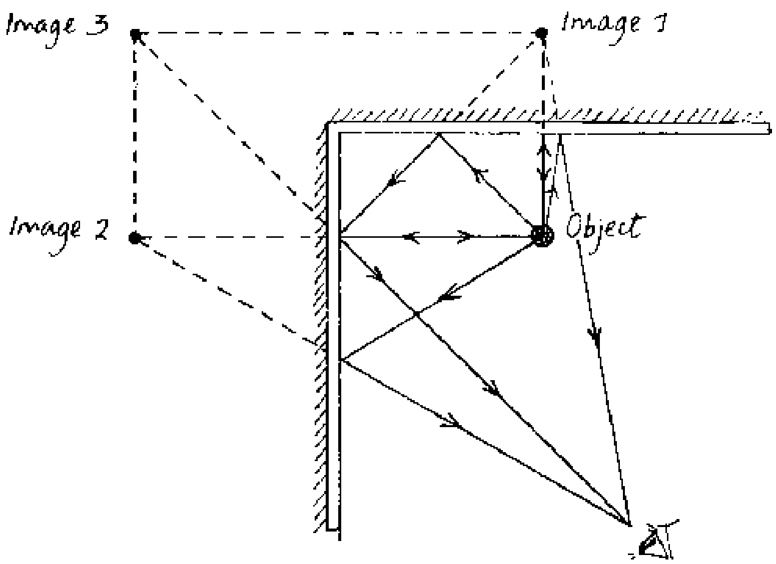
(i) *Rays parallel to the axis are always reflected through the principal focus* F.

(ii) *Rays passing through C* (the centre of curvature of the mirror) *are reflected back along their own path.*

(iii) *Rays passing through the principal focus* F *are reflected parallel.* (Reverse light path of (i).)

The distance of F from the mirror surface is called the *focal length* f. For spherical mirrors the *radius of curvature* r is always equal to 2f: r = 2f.

7.2.1 The Kaleidoscope (Inclined Mirrors)



P: Arrange two plane mirrors to meet each other at right angles as shown. Confirm that three images of one object (candle) can be seen simultaneously. Refer to figure.

Repeat the experiment with mirrors at angles of 60° and 30° to each other.

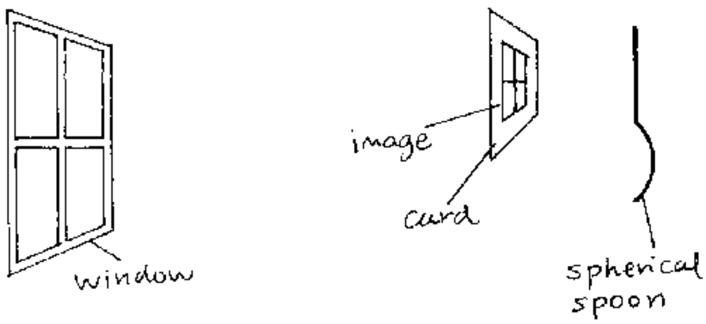
Q: How many images can be seen in each case?

O: When mirrors are at 60° to each other, five images are seen, at 30° eleven images are observed. When the mirrors are parallel to each other, there is a large number of images.

H: Note that the number of images = (360° ÷ angle between the mirrors) - 1

A: The kaleidoscope arrangement is used in shops and pavillions to display items.

7.2.2 The Focus of a Concave Spherical Mirror

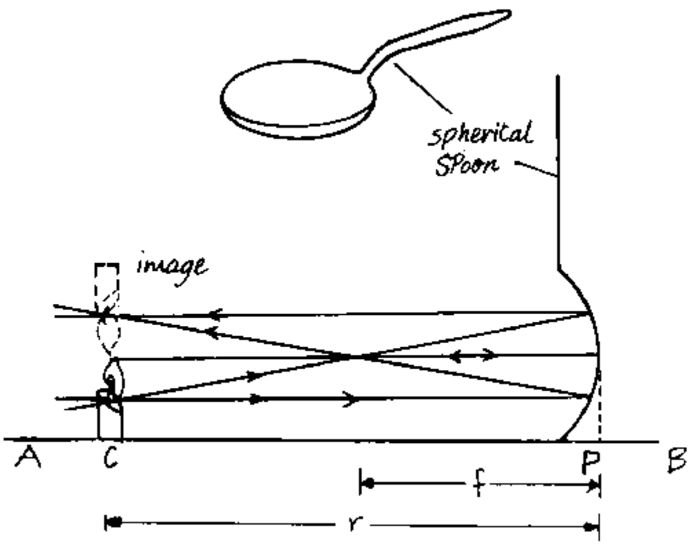


P: A simple concave mirror is the face of a shiny spherical spoon. Hold the curved mirror and a white card in front of the mirror as shown in the figure. Point it towards a distant window, so that it throws the image of the window on the white card. Move the mirror back and forth to find a position where it gives you a clear image on the white card. Note the image distance (the distance from the mirror to the card).

Q: Draw a ray diagram for this experiment. How are the rays coming from the distant window? What does the image distance give in this case?

E: Since the window is distant, its rays meet the mirror parallel. Hence, they are reflected through F. Thus, the image distance recorded give f, the focal length of the mirror.

7.2.3 The Radius of Curvature of a Concave Spherical Mirror



P: Draw a line AB on a white sheet of paper. Place a concave mirror on the paper with its centre vertical above point P. Light a candle and place it in front of the mirror on line AB, see in the figure.

Move the candle back and forth along line AB to get a point C on AB, where the inverted image of the candle coincides with the object candle. Point C is a *point of no parallax* because when you move your head slightly to the left or right, the object and image remain inseparable.

Q: Measure the radius of curvature CP = r. Compare your values of f and r. What do you find out?

Draw ray diagrams to show how the mirror forms images of an object placed at different positions. How would the mirror work best as a shaving mirror?

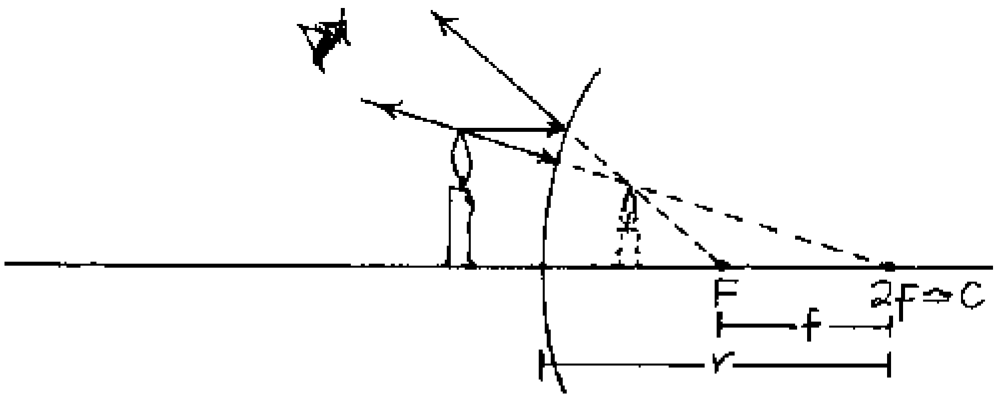
E: The ray diagram shows that C is the centre of curvature and hence r = 2f.

Ray diagrams show that (i) the *concave mirror* produces a real, inverse and magnified image, if the object is farther away than F from the mirror.

(ii) If the object is nearer to the mirror than F, the image appears to be behind the mirror and is hence virtual. However, it is erect and magnified. In the latter case the mirror works best as a shaving mirror.

A: Shaving mirror, dentist's mirror, floodlight (case (ii)); if the object (bulb) distance = f: torch, car headlight.

7.2.4 Convex Spherical Mirror



Arrange the back of a spherical spoon (a convex spherical mirror) and a lighted candle on a white sheet of paper. Locate the image formed by use of a needle or a lighted candle held behind the mirror. The image position is the point of no parallax (see 7.2.3) between the image and the locating needle or candle.

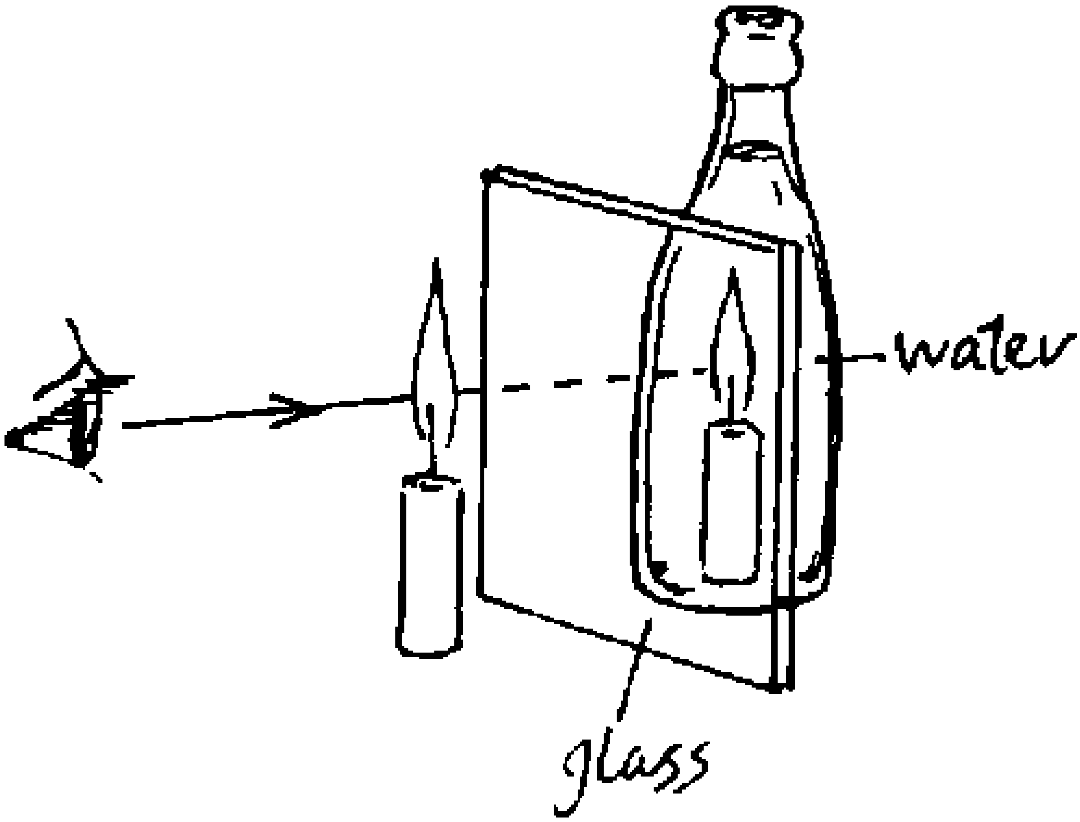
Mark the position of the object, the mirror and the image. Measure the object size, the object distance and the image distance.

Draw the ray diagram to show how the convex mirror forms an image (see the figure).

E: The image seen is always virtual, erect and reduced in size.

A: The convex spherical mirror is used as a rearview mirror in cars because it gives a broad field of view.

7.2.5 Candle in Water Experiment



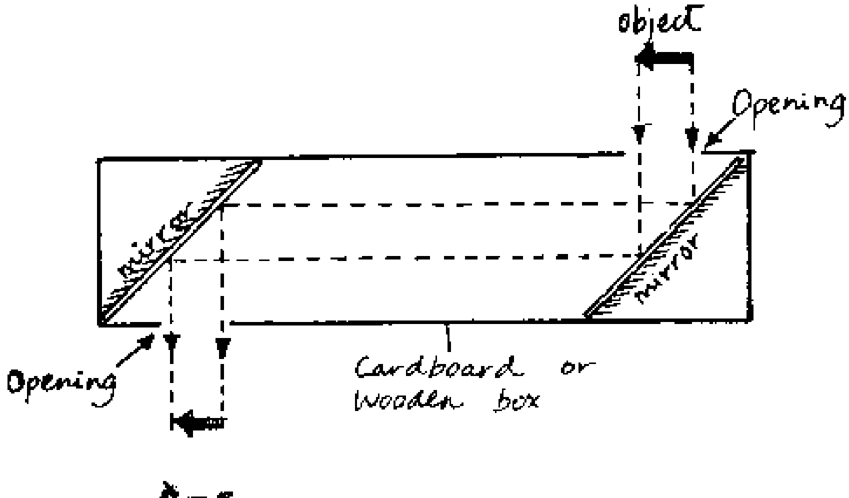
P: Place a transparent glass-pane mid-way between a lighted candle and bottle full of water. View the bottle through the glass-pane from the side of the candle.

Q: At what position do you see the image of the burning candle?

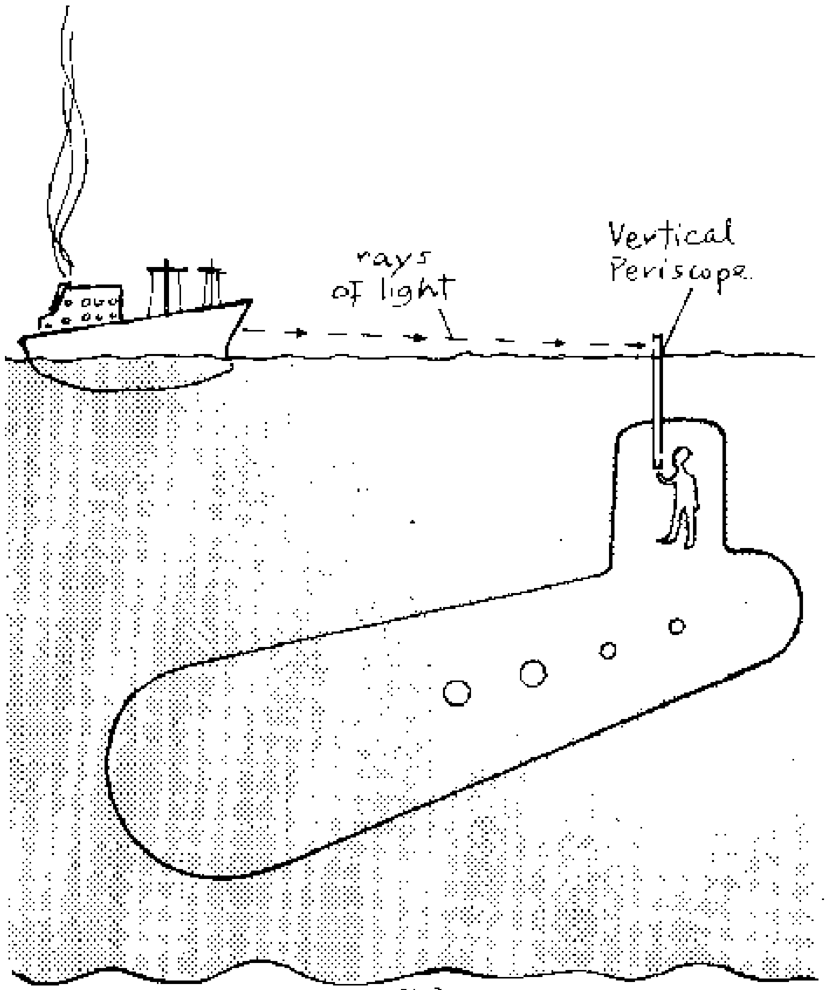
O: The candle appears to bum in the water in the bottle.

Explain this observation using a ray diagrams.

7.2.6 The Periscope



(a)



(b)

P: Arrange two mirrors in a rectangular box as shown in figure (a). This instrument is called a *periscope* and allows to observe objects behind corners.

Q: Observe objects placed behind obstacles.

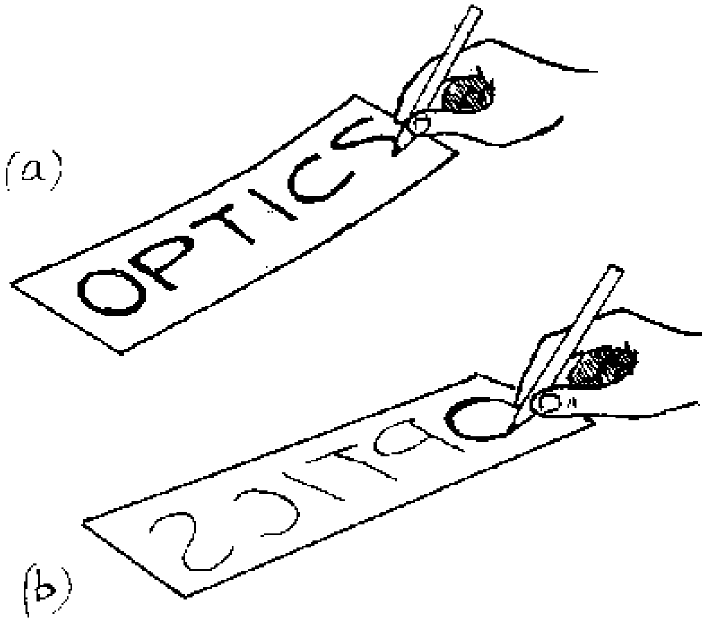
How do they appear?

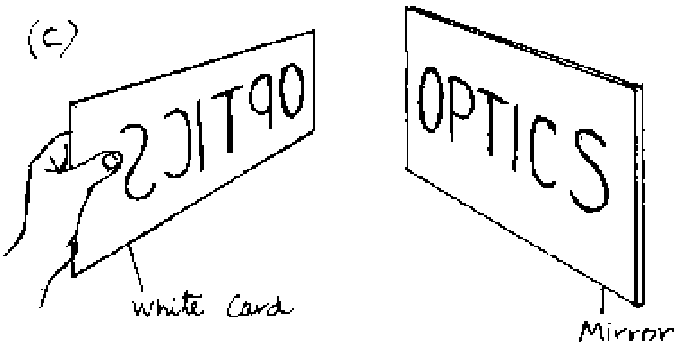
Write the word OPTICS on a paper and use it as an object. How does the image appear?

Compare your observations with experiment 7.2.7.

A: The periscope is used in dived submarines to see what is above the water surface, see figure (b).

7.2.7 Reversed Image





P: Write the word OPTICS on an ordinary piece of paper, see figure (a). Turn the piece of paper and retrace the faint word appearing on its back, see figure (b). You will obtain the *mirror-writing* of the word OPTICS. The latter is a reversed image of the former.

Place the piece of paper in front of a plane mirror (see figure (c)).

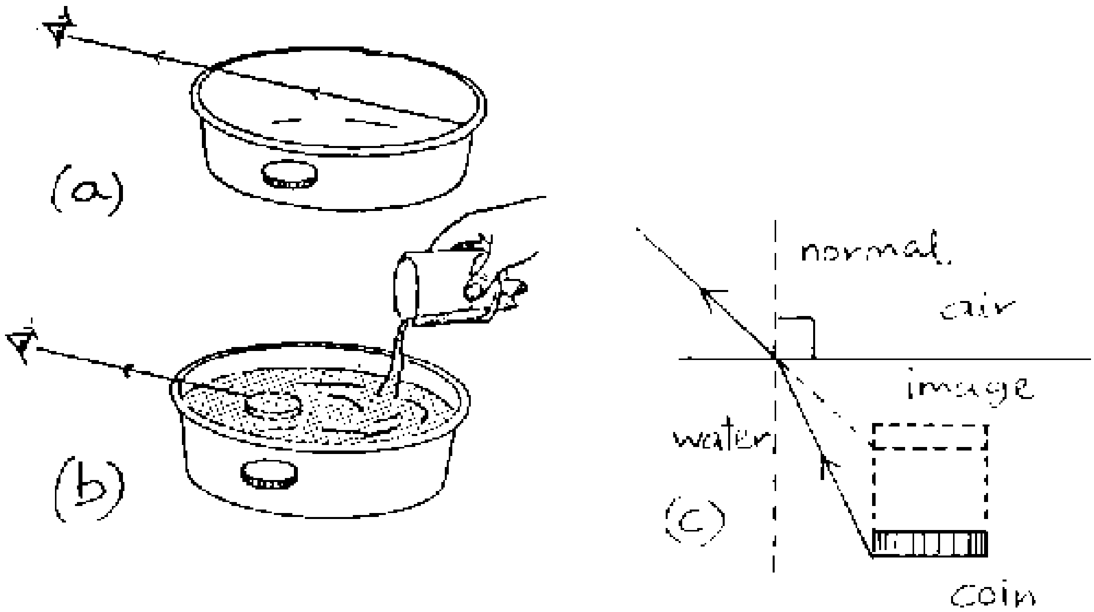
Q: What do you see? Repeat using the word at the back side of the paper. What do you see? Compare your observations with those under section 7.2.6. What do you conclude about the mirror image?

E: Mirror images are reversed images, i.e. the left and right side of the object are interchanged.

7.3 Refraction of Light

Refraction is the change in direction of light as it passes from one medium into another of different density. Refraction is used in lenses to produce images in cameras, microscopes, telescopes, etc. *Total internal reflection* takes place on the boundary between an optically denser medium (e.g. glass) and an optically less dense medium (e.g. air), when the angle of incidence in the denser medium is greater than the *critical angle.*

7.3.1 The Rising Coin



P: Put a coin in the lid of a jam jar.

Hold the lid up to almost level of your eye, until you just cannot see the coin in the bottom of the lid. Gently pour water in the lid to cover. the coin completely. The coin will be visible to you again, see figures (a) and (b).

Q: Explain your observation with the use of a ray diagram.

E: The ray diagram of figure (c) shows that we can only see the coin because the light rays coming from it are deflected at the water surface away from the normal of the water surface.

P: Lower the lid and look at the water vertically from above

Q: Where does the coin appear now?

Explain the observation.

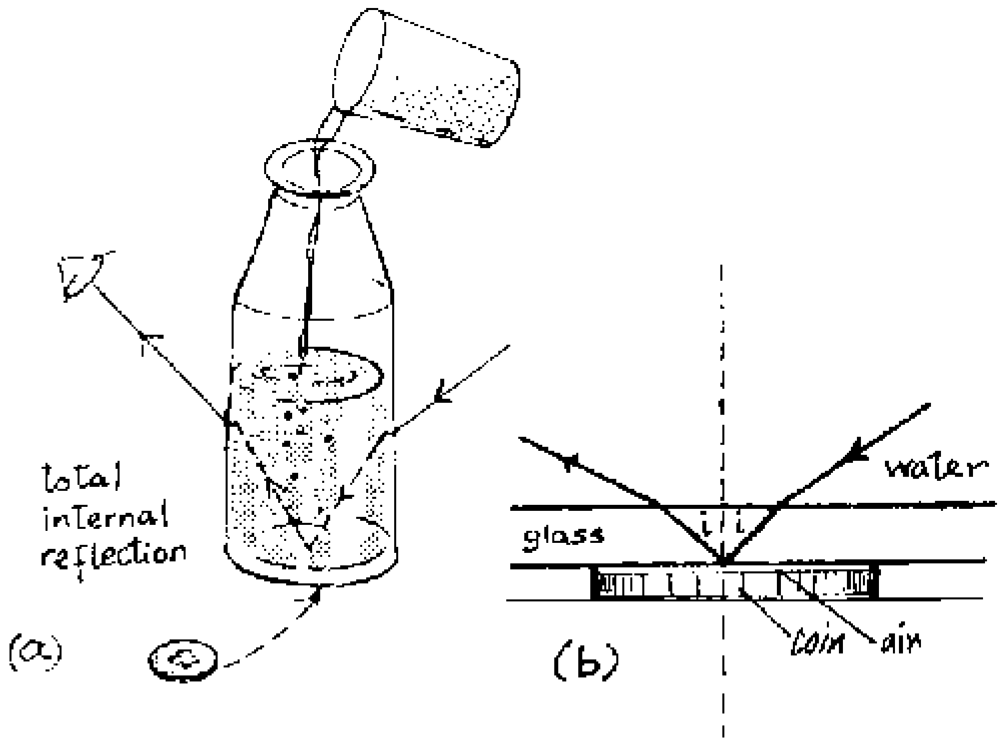
O: When viewed vertically from above the coin appears to be at the bottom of the lid. However, the bottom seems to have rised because of the refraction of those rays which reach the water surface under an angle of incidence different from 0°.

P: View the coin from different directions.

Q: How does its position seem to change?

E: When viewed at an angle from the vertical the coin appears to be raised above the bottom of the lid, therefore as the viewer changes position the coins position also seems to change because of the refraction.

7.3.2 Total Internal Reflection

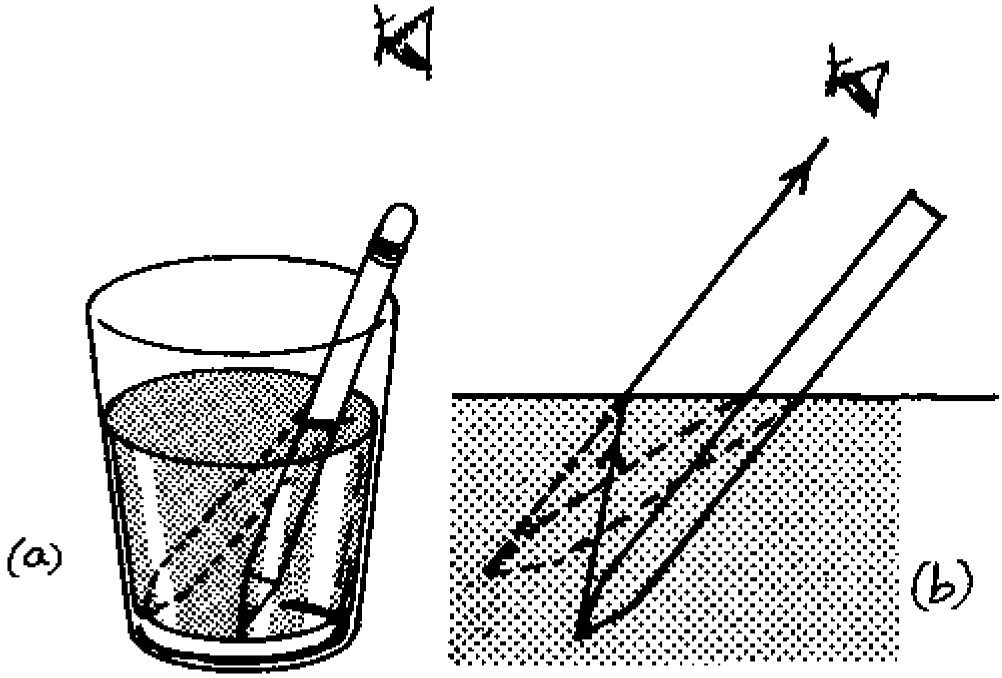


Place a transparent bottle on a coin and look at the coin from above at an angle from the normal. The coin can be seen. Pour water into the bottle slowly. There is a level at which, when you look at the coin, it disappears from sight, see figure (a).

This phenomenon is called *total internal reflection.* It is a special type of refraction. In our experiment, it takes place at the bottom of the bottle where the glass borders the air (above the coin). Total reflection only takes place on a boundary between an optically denser (e.g. glass) and an optically less dense medium (e.g. air) when the angle of incidence in the denser medium is greater than the *critical angle.* In our case the light rays coming from the right side into the glass of the bottom of the bottle are totally reflected and then coming to your eye, see figure (b). These rays are *not* refracted to the air outside the bottom of the bottle because their angle of incidence i is larger than the critical angle for a glass/air boundary which is 42°. These totally reflected rays are so strong that they completely cover the relatively weak rays coming from the coin. Hence, the coin cannot be seen any longer.

A: Prisms in binoculars, etc., see 7.3.6.

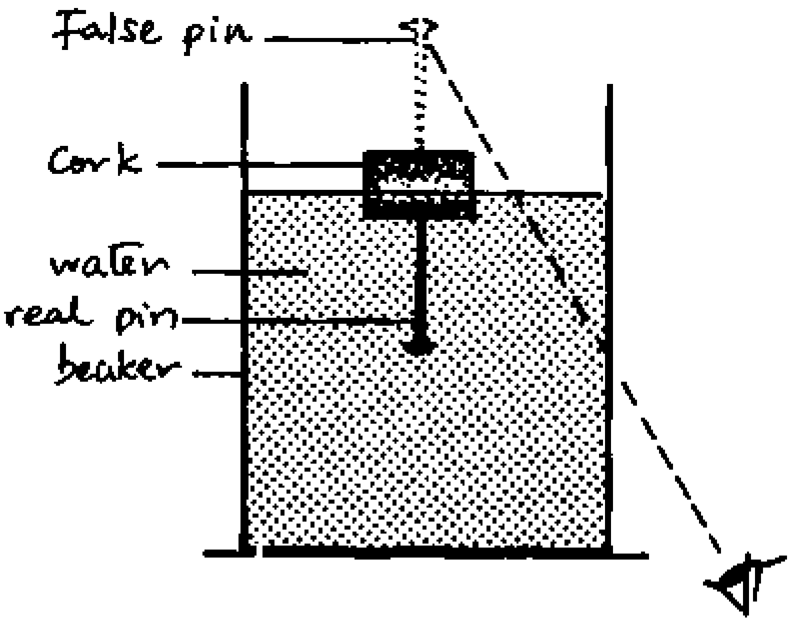
7.3.3 Bending a Pencil with Water



P: Pour water in a glass. Place a pencil in the water at a slant position, see figure (a). Look at the pencil through the surface of the water sidewise along its length and note what you see. Explain your observation by using a ray diagram.

E: Figure (b) gives the ray diagram which explains the observation that the pencil seems to be bent by refraction.

7.3.4 The False Pin



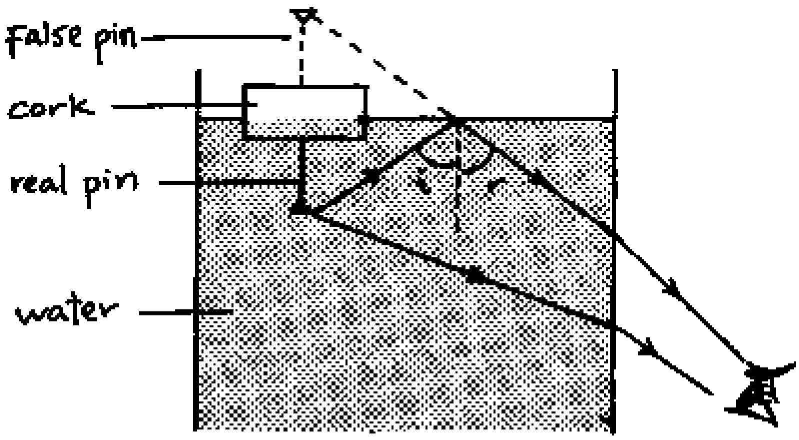
P: Stick a pin (office pin) into the underside of a small cork and allow it to float in a beaker full of water.

Hold the beaker above your head and look up through the side of the beaker at an angle from the vertical.

Q: What do you see?

O: You will see the real pin below the cork and a fake pin above the cork.

7.3.5 Explaining the False Pin



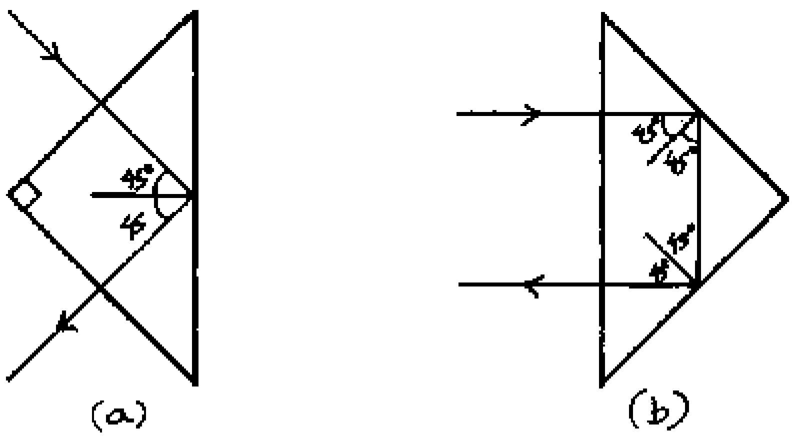
Draw a ray diagram and explain how the false pin appears on top of the cork.

E: Some rays from the pin towards the eye are refracted at the glass-air boundary making the pin visible to the eye.

Other rays from the pin undergo total internal reflection at the water-air boundery. The reflected rays are refracted at the glass-air boundary before they reach the eye. Hence the eye sees a virtual image of the pin on top of the cork as shown in the figure.

Hence both the real pin and the false pin can be seen by the observer.

7.3.6 Total Internal Reflection in Prisms



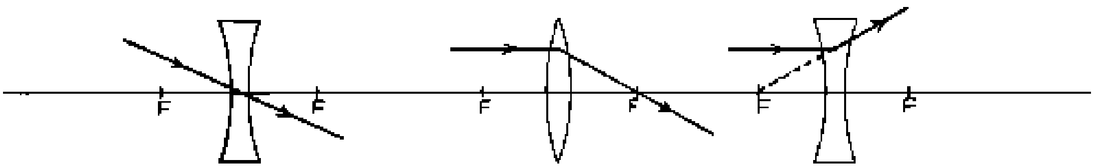
P: Total internal reflection occurs when light falls on a glass prism with angles of 45°, 45° and 90°. This is because a ray falling normally on any face of such a prism hits the inside face at 45°, and this is greater than the critical angle of glass/air (about 42°). In figure (a) the ray is turned through 90° and in figure (b) through 180°.

A: Totally reflecting prisms are used in periscopes (instead of mirrors) and in binoculars.

7.4 Lenses and Optical Instruments

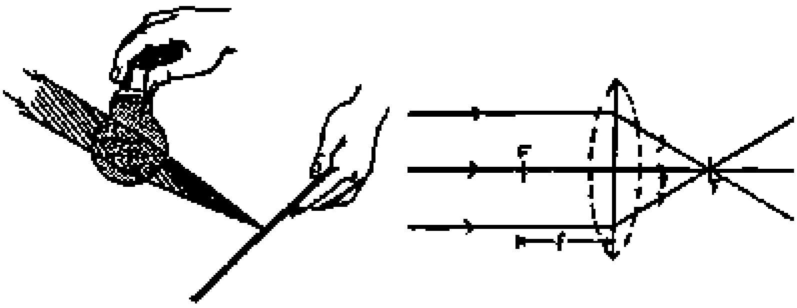
Any transparent material bounded by at least one curved surface acts as a lens. Common examples of lenses are made of glass. By their action on rays of light lenses can be put into two groups: the converging and the diverging lenses. *A converging (convex) lens* is thickest at its centre whereas this is where the *diverging (concave) lens* is thinnest. The action of a lense is due to the refraction of the rays on its curved boundaries. For the construction of *ray diagrams* for *thin* lenses the following rules are helpful:

> *For both types of lenses: rays passing through the centre of the lens travel straight on,* see figure (a).
>
> *For convex (converging) lenses: rays parallel to the axis are refracted through the principal focus* F, see figure (b).
>
> *For concave (diverging) lenses: rays parallel to the axis are refracted away from the nearer principal focus* F, see figure (c).



(a) (b) (c)

7.4.1 Action of a Convex Lens on Parallel Rays



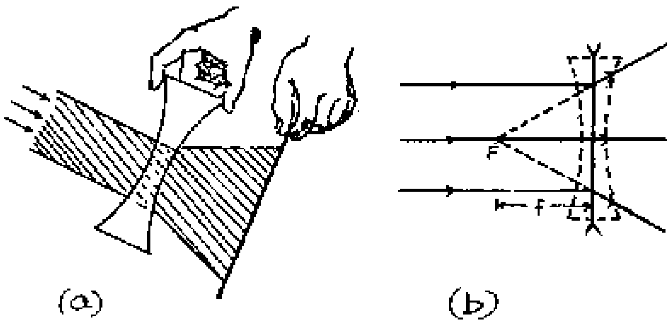
(a) (b)

P: Hold a water filled opened bulb (see appendix) or a concave lens into the direct sunlight and focus the light on one spot of a paper.

E: The distance between the centre of the bulb or lens and that spot on the paper is called the *focal length* f. We can draw a ray diagram for this experiment, see figure (b). The focal points are denoted as F. The action of the lens or bulb on the rays is explained by refraction of the rays on its curved surfaces.

H: The bulb is *not* a *thin* lens. Hence the focus is not as sharp as with a thin lense.

7.4.2 Action of a Concave Lens on Parallel Rays



P: Try to repeat experiment 7.4.1 using a concave lens. If that is not available, the base of a soda bottle or a thin film of water on a wire loop also can serve as a concave lens.

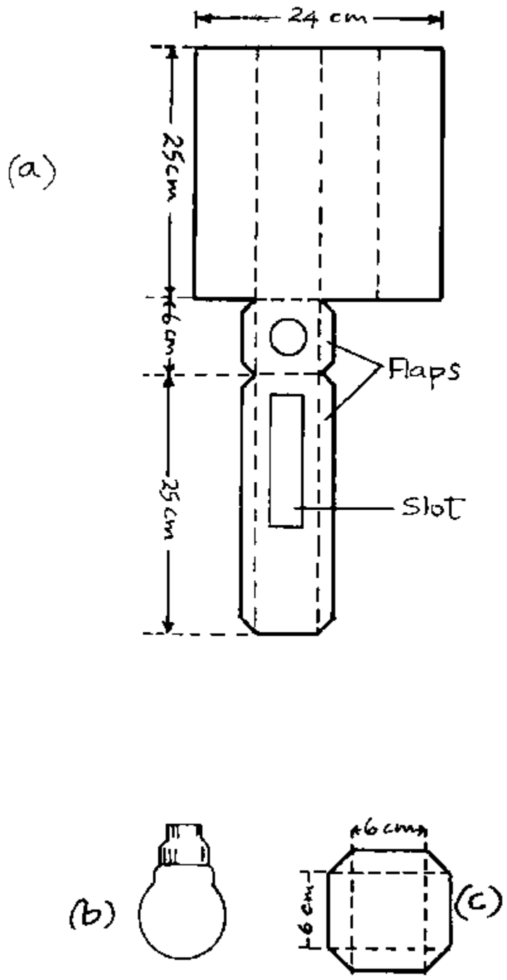
Q: What do you observe? Do you find a focal point?

O: No focal point can be found.

E: This lens *diverges* the light and hence no real focus exists.

However, the ray diagram (see fig. b) shows that a *virtual* focal point can be found on the same side of the lens on which the light source is.

7.4.3 How to Construct a Simple Box Camera



P: (i) Cut a piece of manila sheet according to the plan of a rectangular box in figure (a).

(ii) Open the bulb seal of a transparent used up electric bulb and remove the filament. Then fill it with water to make the water lens (see appendix).

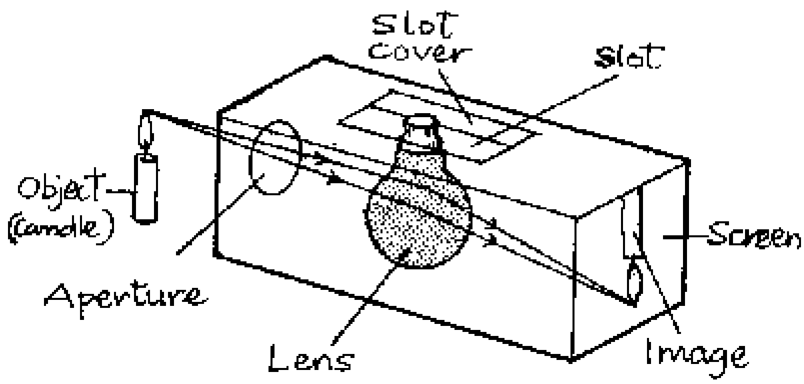
(iii) Fold the manila sheet cutting (figure (a)) along the dotted lines. Fit the water lens on the slot and close the box by gluing the flaps.

(iv) Cover the open end with a piece of plain paper or (better) parchment paper as a screen using glue (see figure c).

(v) Close the slot using a sliding manila sheet cover, having dimensions of 6 cm by 30 cm with a hole to fit the bulb at its centre.

H: Make sure that the box is light-tight (light-proof).

7.4.4 Using the Simple Box Camera



P: Use the simple box camera to produce images of illuminated objects like a candle, a window etc. Change the position of the lens (bulb) so that you obtain a sharp image on the screen.

(i) Find the focal length f of the lens (bulb) by focussing a distant object (e.g. a distant window) on the screen. Then the image distance v is equal to f. Measure the image distance v on top of the camera from the centre of the bulbs neck to the screen.

(ii) Choose a large object distance u of a lit candle (the distance between the centre of the lense (bulb neck) and the candle) and adjust the lens so that you obtain a sharp image on the screen.

(iii) Now decrease the object distance by moving the camera towards the object and adjust the image distance each time.

(iv) Note u and v at which the image size becomes larger than the object size.

Q: Why is v = f in case (i)? How is the image distance v in each case? How is the size of the image (e.g. of the candle flame) as compared with the size of the object in each case? What kind of image do you obtain?

E: (i) v = f because the rays coming from a distant object are parallel.

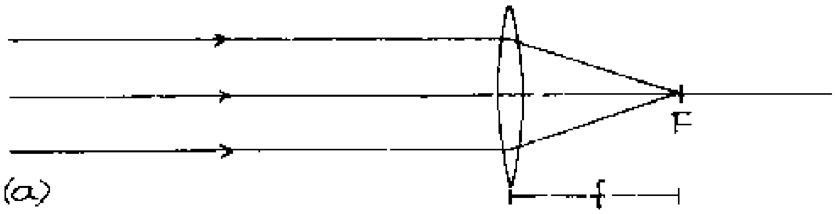
(ii), (iii) The size of the image grows larger as the object distance u decreases. First the image size is smaller than the object size. When u = 2f, then the image size is equal to the object size. All images are *real* because they appear on a *screen.*

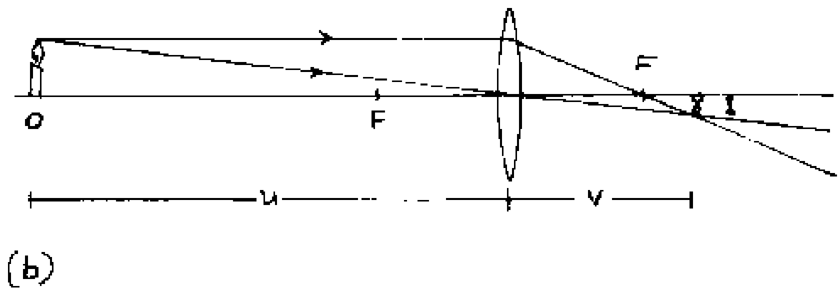
(iv) When 2f > u > f, then the image size is larger than the object size. When u < f, no *real* image can be observed.

H: The bulb is no thin lens hence the image will not be as sharp as with a thin lens which may be obtained from TAN OPTICS, P.O.B. 1929 Moshi, Tanzania.

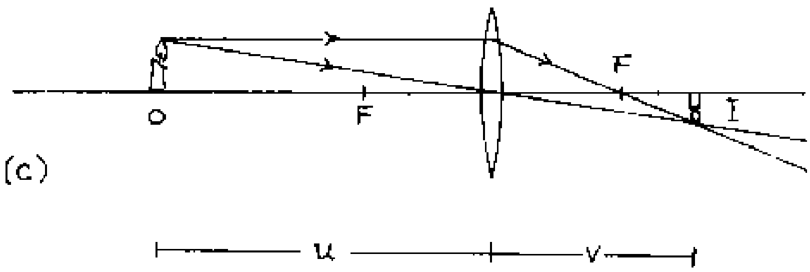
A: (iii) Photographic cameras, (iv) projectors for movies and slides.

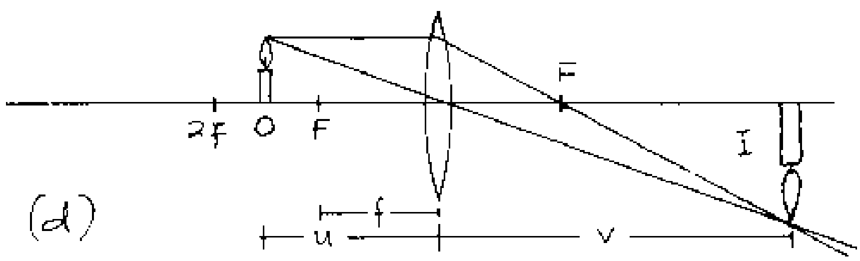
7.4.5 Ray Diagrams for the Box Camera





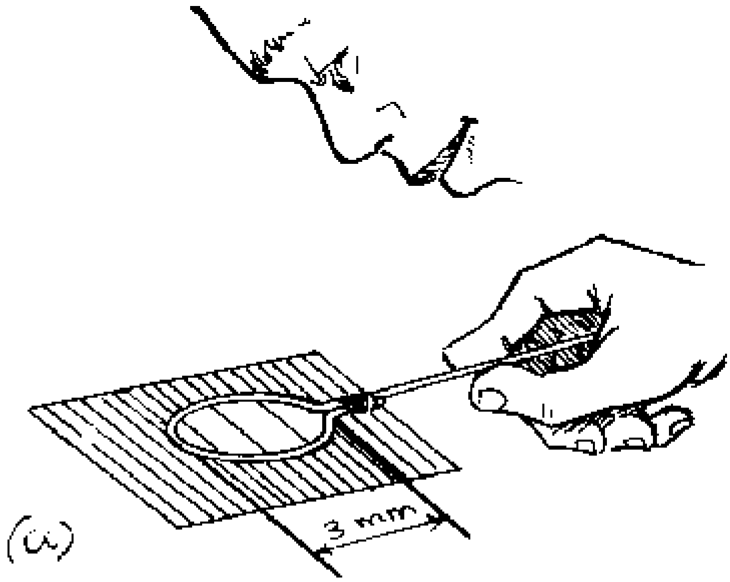
P: Ask the students to draw ray diagrams using thin converging (convex) lenses for the cases (i) to (iv) of experiment 7.4.4.

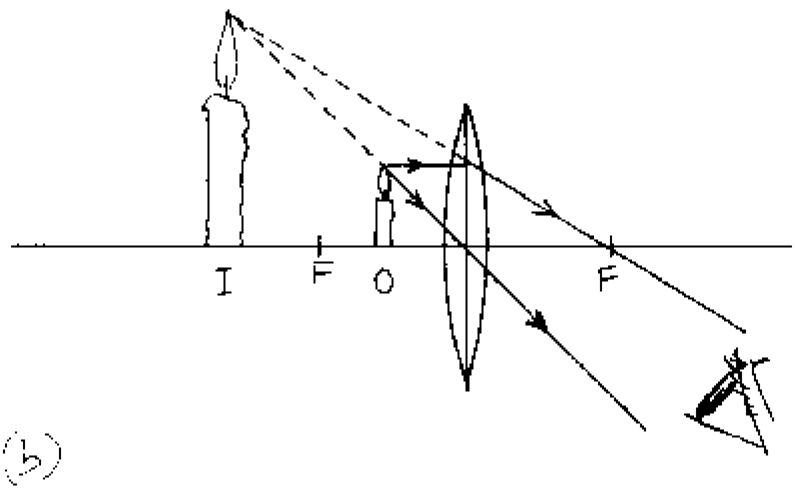




E: See figures (a) to (d) which correspond to the cases (i) to (iv) of experiment 7.4.4.

7.4.6 Magnification





P: Produce a magnifying glass by making a loop as shown in figure (a) using paper clip wire (e.g. winding it around the tip of a ball point pen). Dip this loop in. water and use it as a magnifying glass by observing letters in a book etc. Thus, this water drop lens acts as a convex lens.

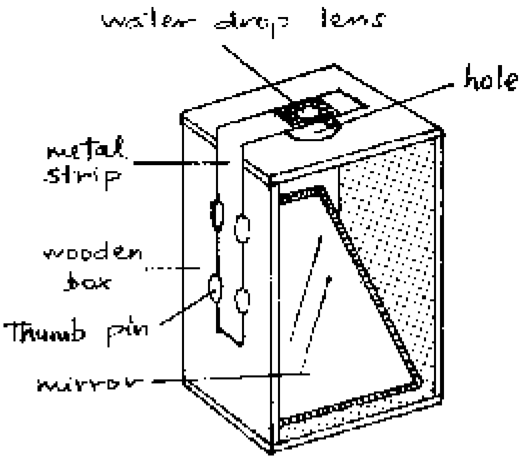
Q: Explain the magnification by drawing a ray diagram. What kind of image is formed?

E: See fig. (b), the image is larger than the object. However, this image is *virtual* because it cannot be obtained on a screen. In a virtual image the light rays do not meet really in the image point. They only seem to meet there because the eye and brain of the observer are accustomed the assume that the light rays travel in straight lines only. Yet the real rays were refracted by the lens which causes the image to appear in the eye of the observer. The object distance u must be less than f: u < f.

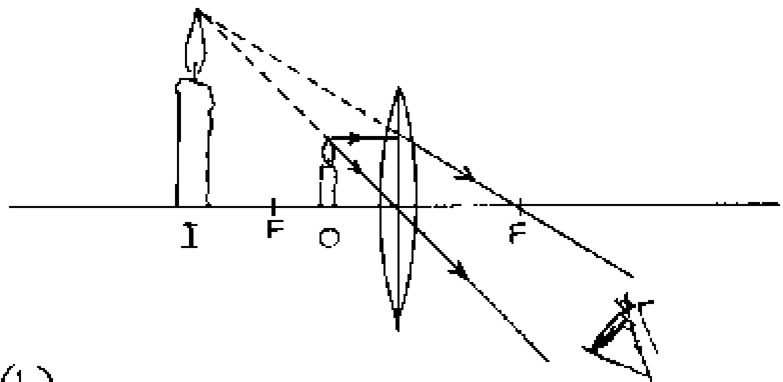
H: A bulb filled with water can also be used.

A: Magnifying glass, eye lens of compound microscopes, telescopes etc.

7.4.7 Simple Microscope



(a)



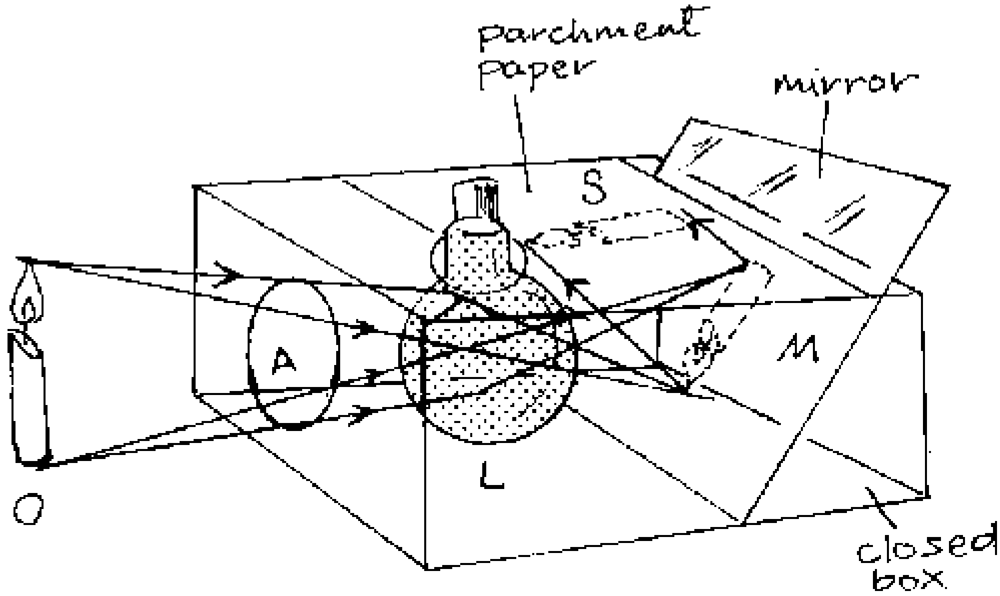
(b)

P: Produce a simple microscope according to the above figure. Adjust the mirror so that sun rays will be reflected to the hole below the lens. Place a transparent object (e.g. wing of a fly) on the hole and adjust the metal strip so that the water drop lens has less distance from the object than its focal length.

Q: How does the lens act here? What happens when you bring it even nearer to the object? Draw a ray diagram.

E: The lens acts here as a magnifying glass. When the object distance decreases further, the magnification will increase. The ray diagram is the same as in the last experiment.

7.4.8 Mirror Reflex Camera

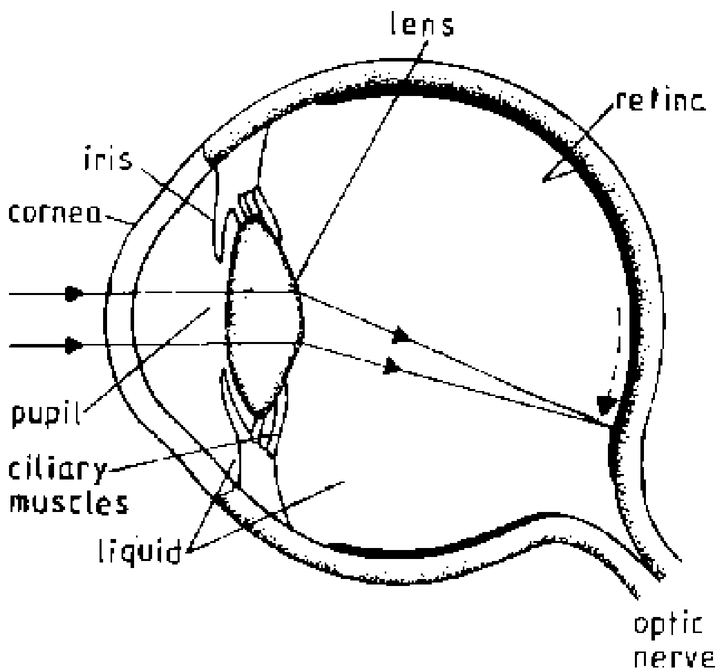


P: Modify the box camera (see p.90) according to the above figure using a mirror and another sheet of parchment paper to provide the top screen. Now this camera can serve as a model of a mirror reflex camera.

Q: Explain how a mirror reflex camera works.

E: In the mirror reflex camera the film is there where the screen is in the box camera (see p.90). The screen on top is just to view the same image (and to focus it) which will be produced on the film when the mirror has been removed. Thus, when taking a snap with the mirror reflex camera, the mirror is turned so that the image falls on the film instead on the top screen.

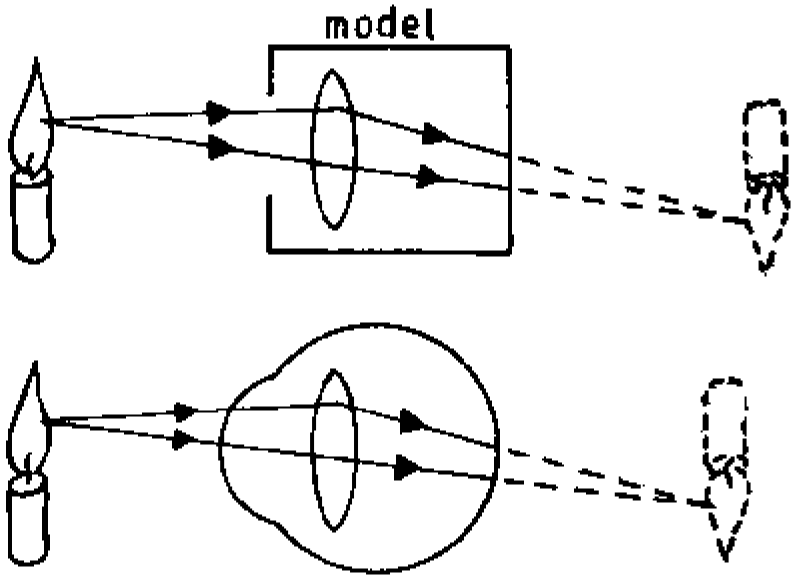
7.4.9 Display Chart of the Eye



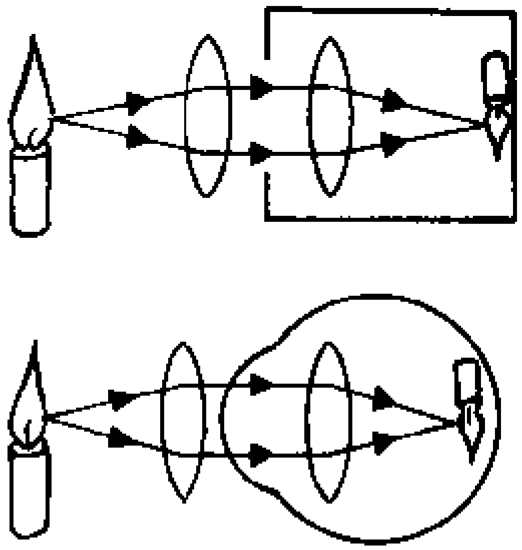
The eye possesses an convex lens which focusses the light on a sensitive membrane (called retina). In difference to the camera the eye lense changes its curvature and hence its focal length in order to focus the light from objects of different object distance. The focal length varies according to object distance while the image distance is kept constant and is roughly equal to the diameter of the eye, see the figure.

P: Draw a display chart of the above figure.

7.4.10 The Long-Sighted Eye



(a)



(b)

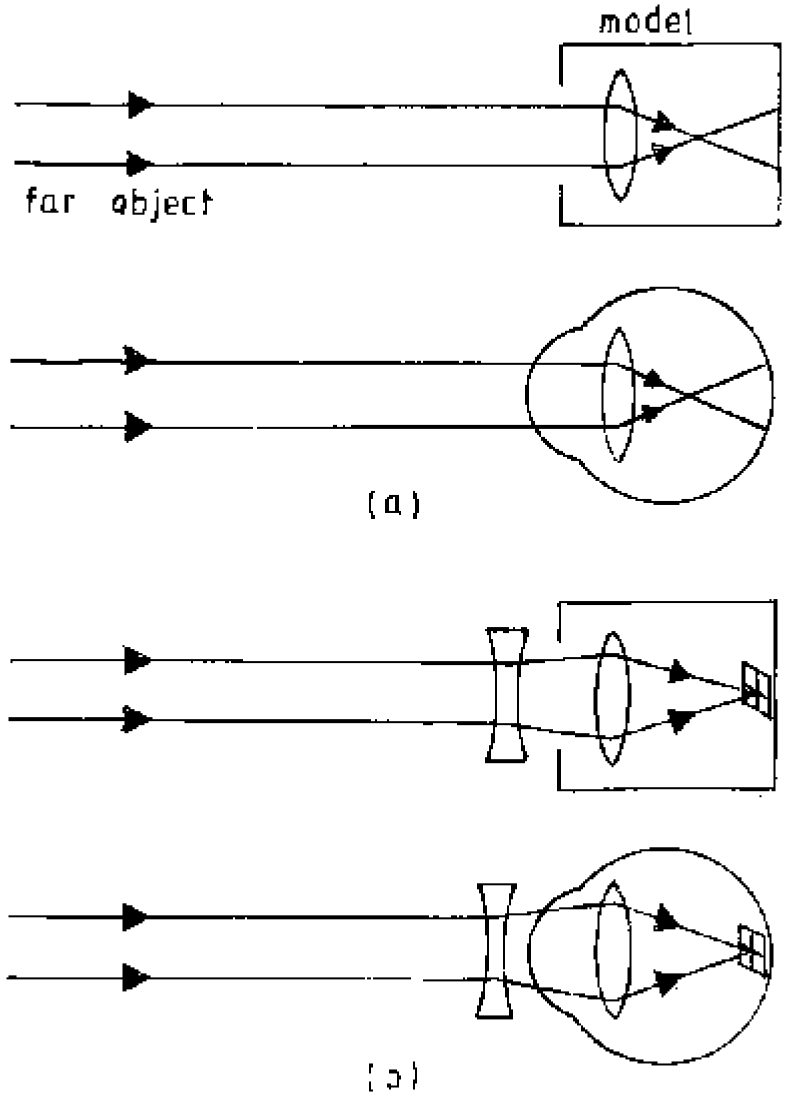
The long-sighted eye cannot focus near objects. The rays from a near object are focused *behind* the retina, see figure (a).

P: Make a *model of the long-sighted eye* by fixing the lens of the box camera (see p.90) so that it focusses a near candle *behind* the screen.

Q: How can you amend this sight defect in your model (without changing the image distance because that is *constant* in the eye)?

E: You need to place a convex lens of suitable focal length in front of the eye model in order to focus the near candle on the screen (retina), see figure (b). Thus, a long-sighted person needs spectacles having converging lenses.

7.4.11 The Short-Sighted Eye



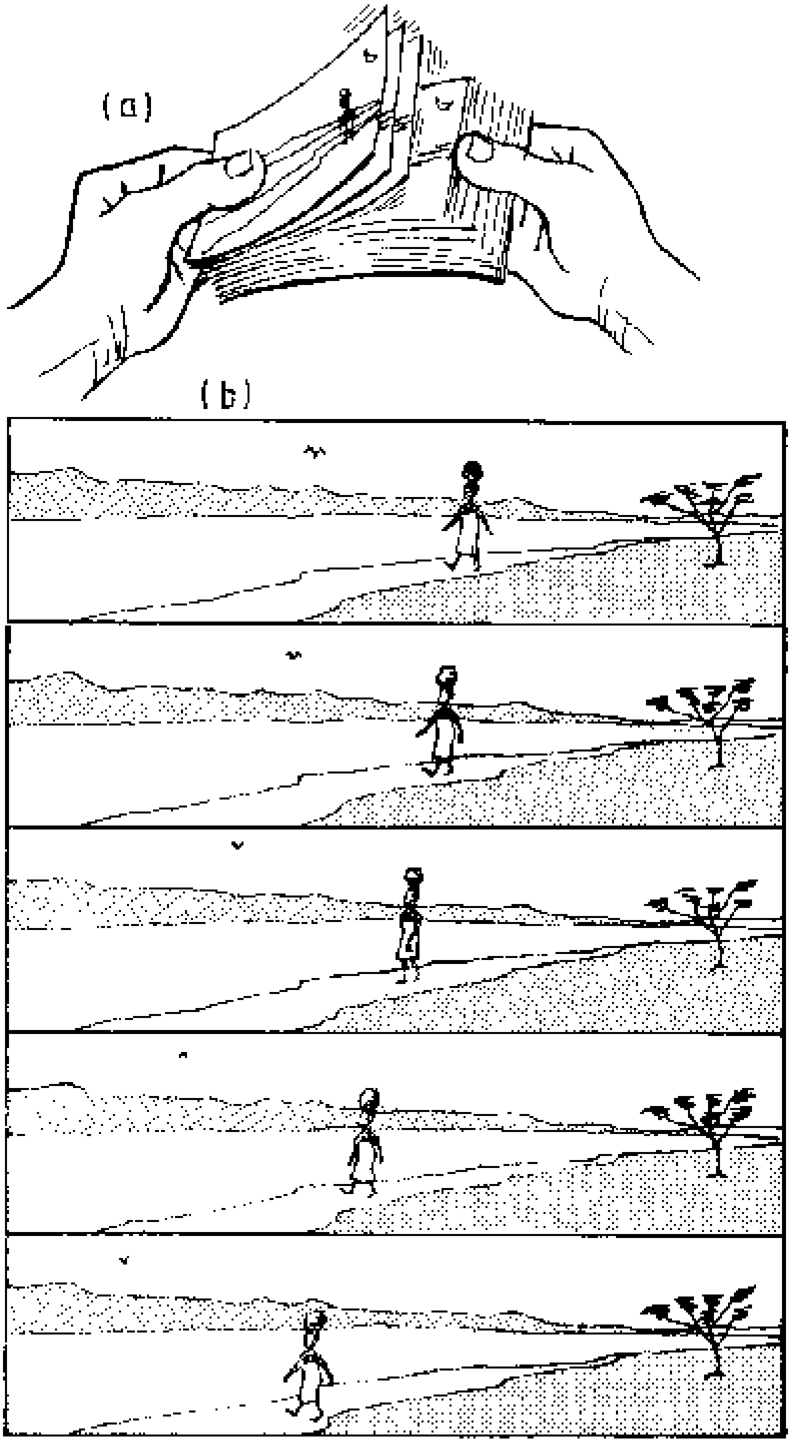
The short-sighted eye cannot focus distant objects. They are focussed *in front* of the retina, see figure (a).

P: Make *a model of the short-sighted eye* by fixing the lens of the box camera (see p.90) so that it focusses a distant candle *in front* of the screen.

Q: How can you amend this sight defect in your model (without changing the image distance because that is constant in the eye)?

E: You need to place a concave lens of suitable focal length in front of the eye model in order to focus the distant candle on the screen (retina), see figure (b). Thus, a shortsighted person needs spectacles having diverging lenses.

7.4.12 Persistence of Vision



An image lasts on the retina for about one tenth of a second after the object has disappeared as can be shown by flipping cards having motion pictures as shown in figure (a).

A: The effect makes possible the production of motion pictures. 24 separate pictures each slightly different from the previous one, are projected on to the screen per second and give the impression of continuity.

P: Make eight motion pictures of a walking woman as shown in figure (b). Arrange them subsequently and hold them so that each picture comes to vision after the previous one within a short time.

Q: What do you observe?

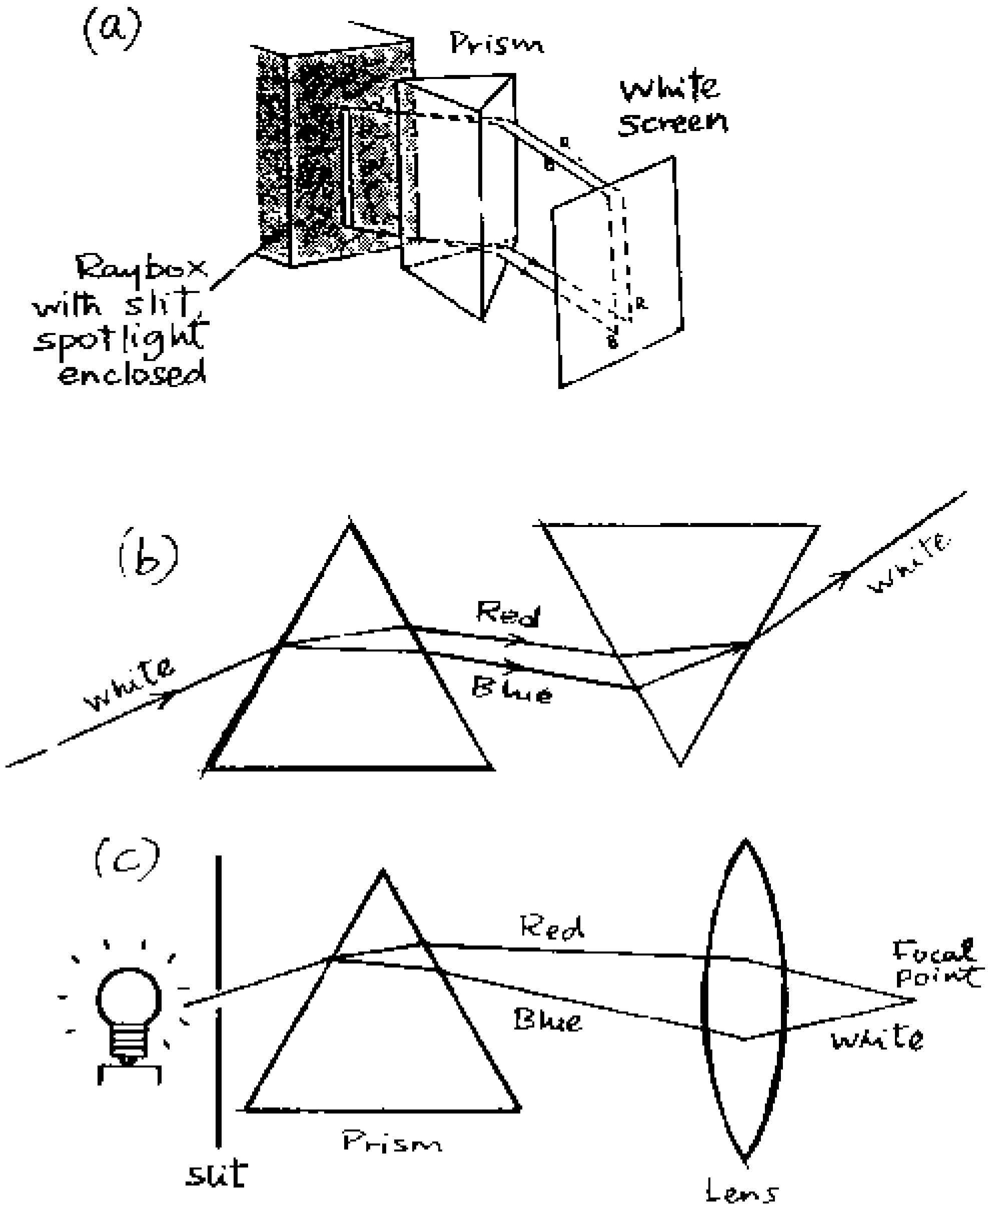
E: The woman appears to walk.

A: Movies, television, videos.

7.5 Dispersion and Colours

The separation of white light into its component colours is called *dispersion.* Each colour has a particular value of refractive index. Hence by passing light through a glass prism, each colour is refracted through different angles.

7.5.1 Dispersion by a Glass Prism



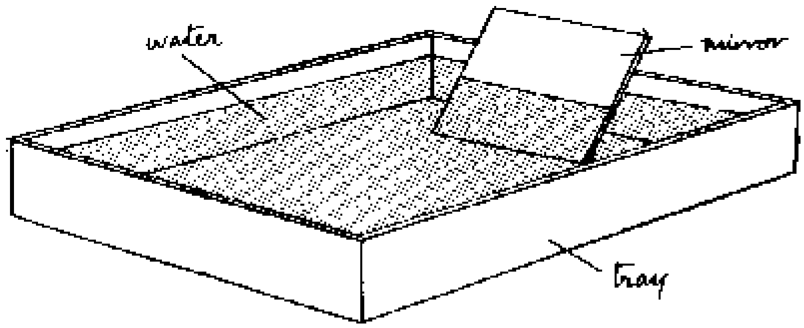
P: Arrange a glass prism, a narrow source of white light and a screen as shown in figure (a). Adjust the angle at which the ray hits the prism and the screen so that you catch the dispersion colours *(spectrum)*

Q: Which colour of light is most refracted by the prism? Which colour is least refracted by the prism?

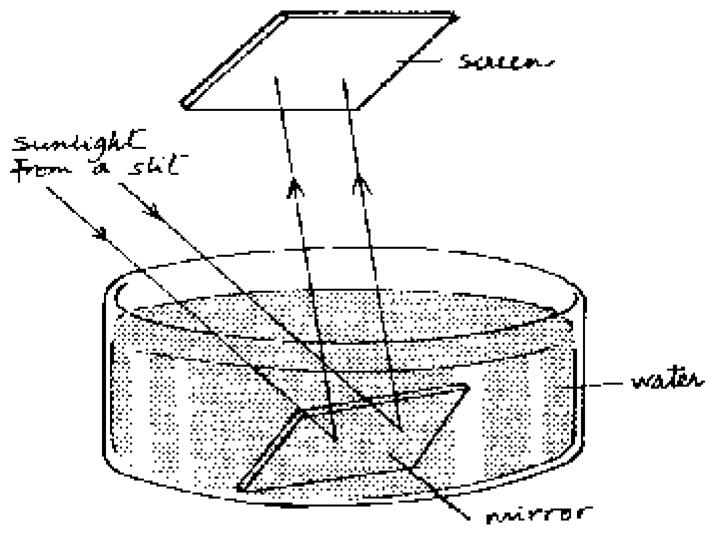
E: The prism splits white light into its component colours. Blue light is refracted most and is observed nearest to the base of the prism. Red light is least refracted.

With the use of a second prism or a converging lens the separated light colours can be recombined to form white light, see figures (b) and (c).

7.5.2 Dispersion with a Mirror in Water



(a)



(b)

P: Place an inclined mirror in a container half full of water. Allow a light to strike at the slanted face of the mirror. Look through the submerged portion of the mirror, see figure (a).

Q: What do you observe?

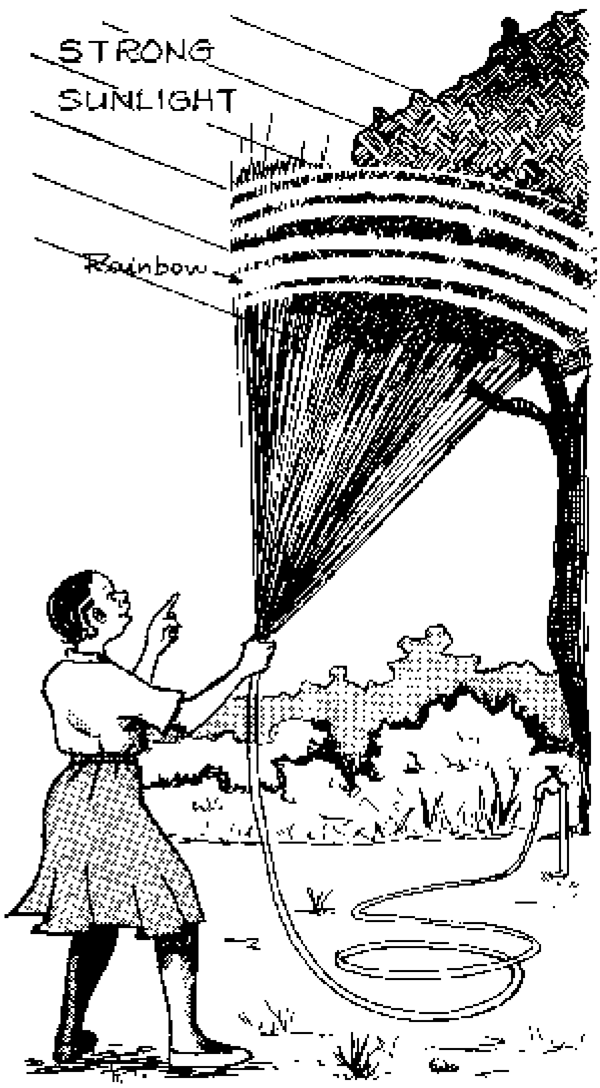
O: The dispersion colours (spectrum).

P: Use the arrangement of figure (b) to obtain the spectrum on a screen.

Q: How do you explain the formation of this spectrum?

E: The refraction of the incident colours on the surface of the water and of the reflected rays again makes the water act as a "water prism".

7.5.3 Rainbow Colours from a Water Hose



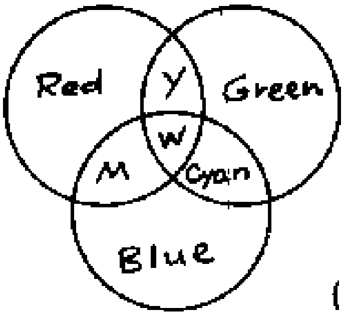
P: Early in the morning or late in the afternoon of a bright sunny day spray water from a hose pipe against a dark background of trees with your back towards the sun, see the figure.

Q: What do you see? How can it be explained?

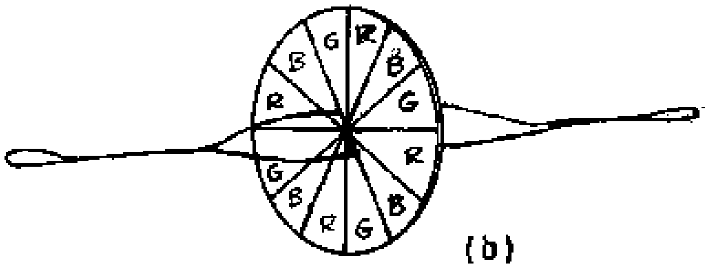
O: You will observe the colours of the rainbow in the spray from the hose.

E: The rainbow is a result of the dispersion of light rays striking water droplets.

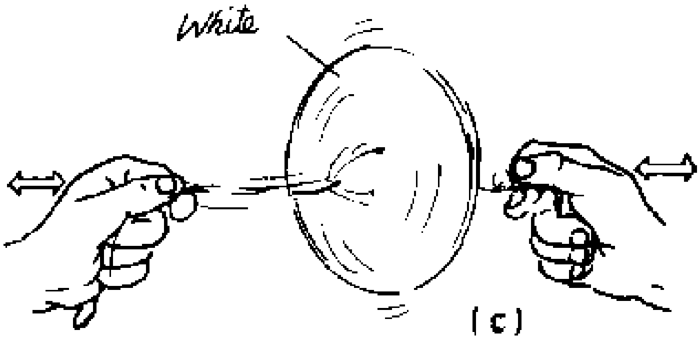
7.5.4 Colour Mixing: Newton's Disk



(a)



(b)



(c)

There are colours of light which when mixed in varying intensities will produce all other colours, but they themselves cannot be produced by mixing other colours. When mixed in appropriate intensities, they will also produce white light. These are the *primary colours* of light. The three primary colours of white light are *blue, green and red.* Hence BLUE + GREEN + RED = WHITE, see figure (a).

Y = yellow, M = Magenta and W = White.

Secondary colours are formed by adding two primary colours, e.g. Red + Green = Yellow.

So yellow is a secondary colour of red and green.

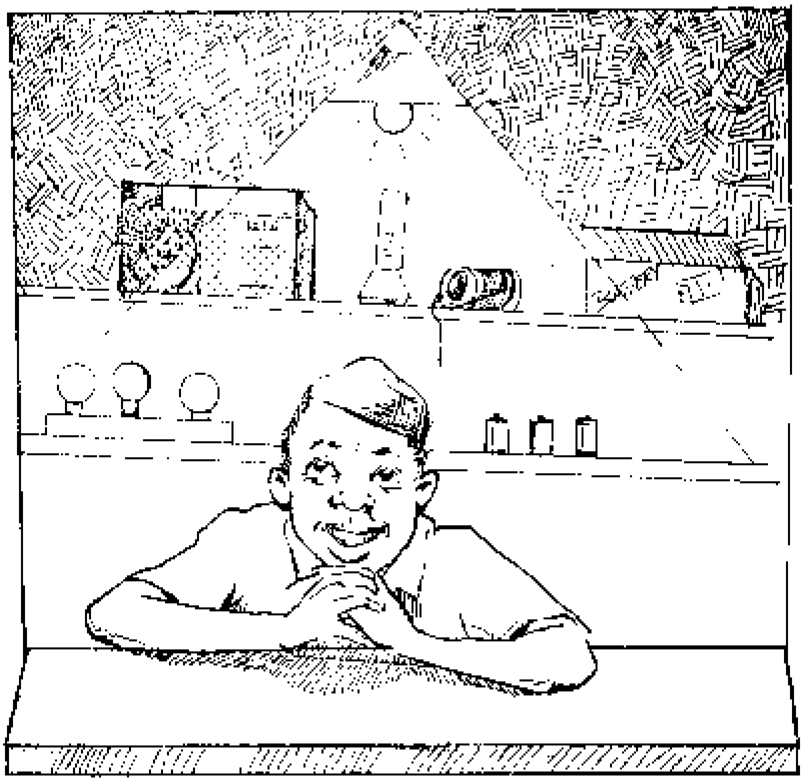
P: Paint twelve equal sectors of a disk made from white cardboard with red, green and blue colours arranged in that order, see figure (b). Tie a string through the two holes around the centre of disk. Swing and pull the string ends with both hands, see figure (c). The disk will start spinning to and forth.

Q: What do you observe on the disk?

O: The spinning disk appears whitish.

E: The colours of the light reaching the eye at short time intervals mix to white light due to the *persistence of vision.*

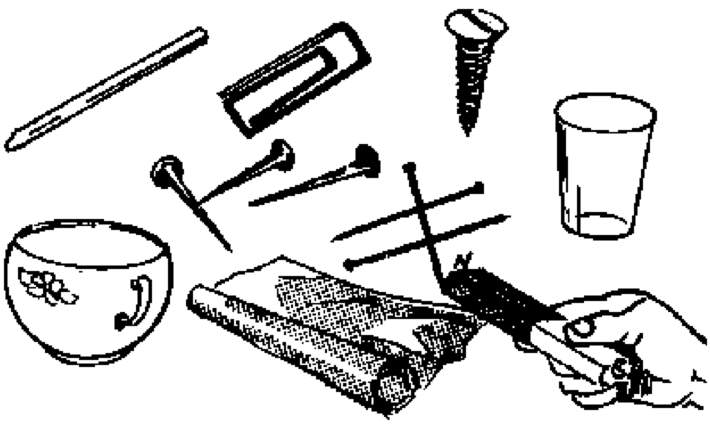
8. Magnetism and Electricity



8.1 Magnetism

There are some materials which can attract iron. These kind of materials are said to have *magnetic properties.* The earth is a very weak magnet. Hence, a freely suspended magnet can be used as a *compass.* The end of a magnet pointing to the north is called the north (N-) pole, the end pointing to the south is called south (S-) pole. Thus, each magnet has a N-pole and a S-pole. Magnets can be found, for example, in loudspeakers and bicycle dynamos. Magnets are remarkable because they exert a force on iron or other magnets at a distance without any medium being in between. *Unlike poles attract each other, like poles repel each other.*

8.1.1 Distinction of Magnetic and Non-Magnetic Materials



P: Arrange the materials shown in the diagram above on a table. Bring a magnet close to each material.

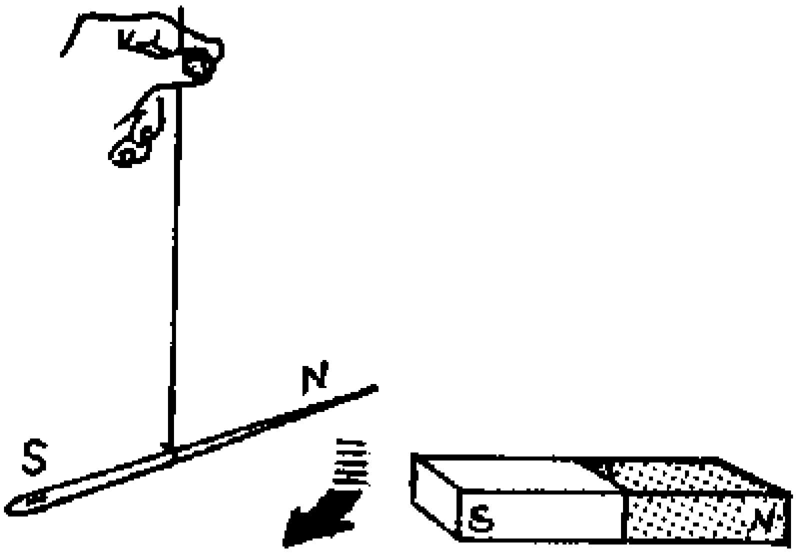
Q: What happens to each material?

E: Those materials which are attracted by a magnet are called magnetic substances. Those which are not attracted are called non-magnetic substances.

A: One can use a magnet to distinguish magnetic materials from non-magnetic materials. For example, you can find out if dry sand collected from outside contains magnetic materials by pushing a magnet through the sand.

H: The materials used in this experiment should include copper, iron, aluminium, plastic, porcelain, wood, nickel etc. if ever possible.

8.1.2 Interaction between Magnets



P: Suspend a magnetized steel needle (see experiment 8.1.3) and a bar magnet, one at a time. In each case mark the end pointing to the north as N-pole, and the end pointing to the south as S-pole.

Bring the N-pole of the magnet near the S-pole of the suspended needle.

Bring the S-pole of the magnet near the S-pole of the needle.

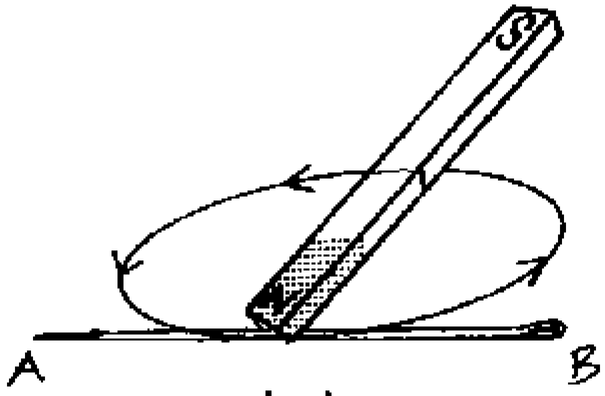
Now bring the N-pole of the magnet near the N-pole of the needle.

Q: What do you observe in each case?

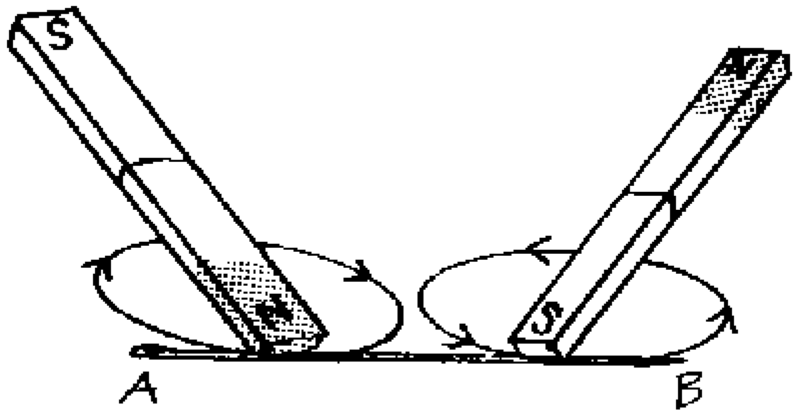
O: You will observe that the N-pole of the magnet attracts the S-pole of the needle; the S-pole of the magnet repels the S-pole of the needle; and the N-pole of the magnet repels the N-pole of the needle. So we say *unlike poles of magnets attract each other and like poles repel each other.*

H: In case bar magnets are not available a magnetised piece of steel can be used instead of a bar magnet, see experiment 8.1.3.

8.1.3 Magnetisation by Single and Double Touch Method



(a)



(b)

P: Move one pole of a bar magnet many times along the needle as shown in figure (a).

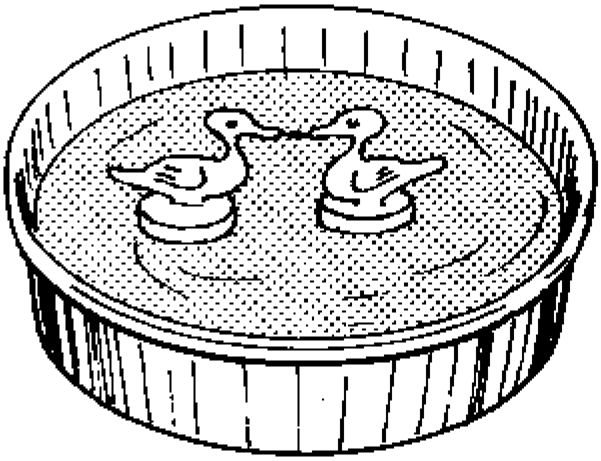
Now move the magnet along another needle as shown in figure (b). Do this several times, each time starting from the middle of the needle.

Q: Are the two needles magnetized? If so what are the poles of the needles?

O: Both needles are magnetised. The end A of the first needle is a N-pole and end B is a S-pole. The end A of the second needle is S-pole while end B is a N-pole.

H: The first needle has been magnetised by the single touch method and the second one has been magnetised by the double touch method.

8.1.4 Magnetic Ducks



P: Magnetize one pin (or needle). Fix the pin or needle on the beak of one the paper ducks. Fix an unmagnetised pin on the beak of the second duck. Place the ducks to float in a bowl of water.

Q: What do you observe?

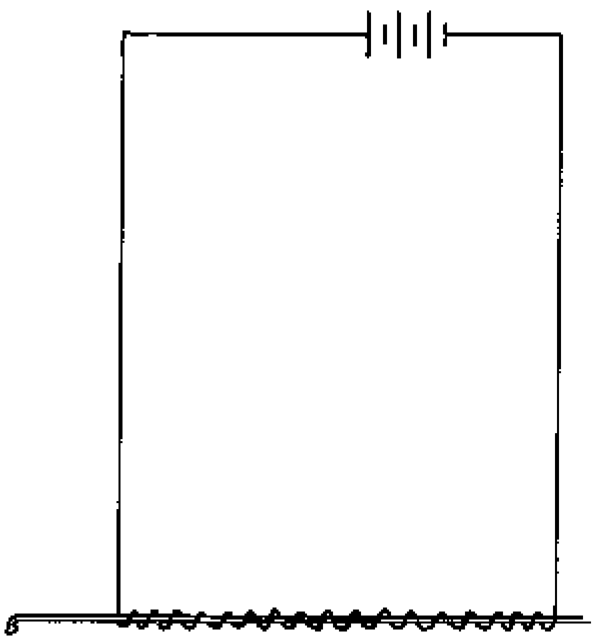
O: The beaks of the ducks come together as if they were kissing each other.

E: This is because the end of the magnetised pin in the beak of one duck attracts the end of the unmagnetized pin in the beak of the second duck.

H: To make the ducks, cut four pieces of paper in the shape of a duck and stick two of them together to make a duck. Fix each duck on a piece of wood so that it can float.

P: Magnetise both pins which are inserted into the beaks of the ducks and observe what happens.

8.1.5 Magnetisation by Electric Current



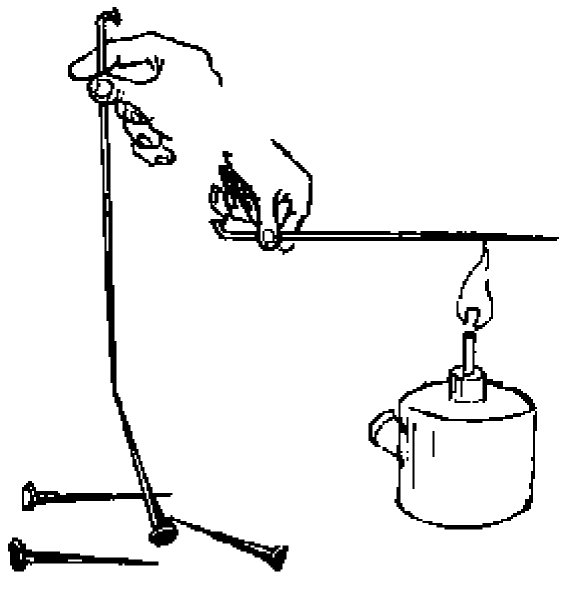
P: Make a coil by winding about fifty turns of isolated wire around a bicycle spoke. Connect the coil to two or three radio cells, see the figure. After a few minutes disconnect the battery and remove the spoke from the coil. Dip the spoke into iron filings.

Q: What do you observe?

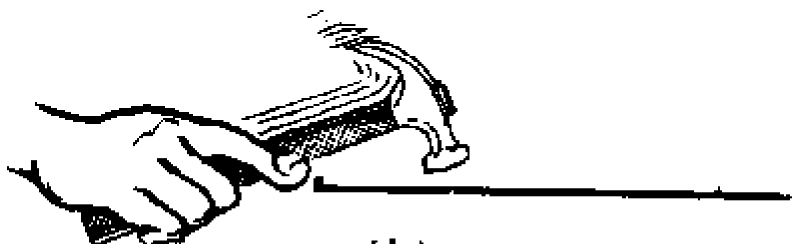
E: The iron filings are attracted by the end of the spoke. The electric current in the coil has magnetized the spoke.

H: Steel can be magnetized by this method but soft iron *cannot.*

8.1.6 Demagnetisation of a Magnet



(a)



(b)

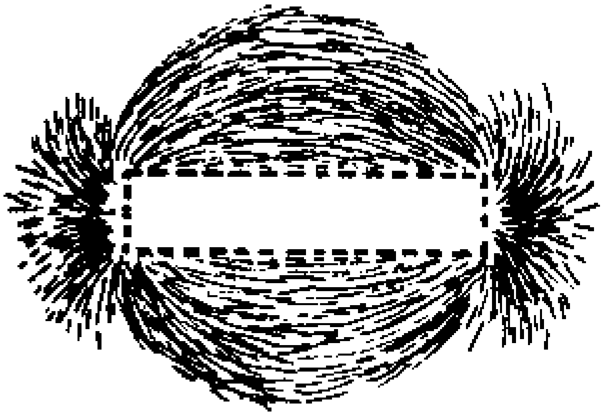
P: Magnetise a bicycle spoke and check if it attracts small nails or iron filings. Heat the spoke in a flame as in figure (a) and check again if it attracts the nails. Get another magnetised spoke and hammer it several times as shown in figure (b). Check if the spokes still retain their magnetism.

Q: What has happened to the spokes?

E: Heating and hammering of the spokes has destroyed the magnetism of the spokes.

H: Magnets should not be kept in hot places or dropped otherwise they may lose their magnetism.

8.1.7 Magnetic Field Pattern



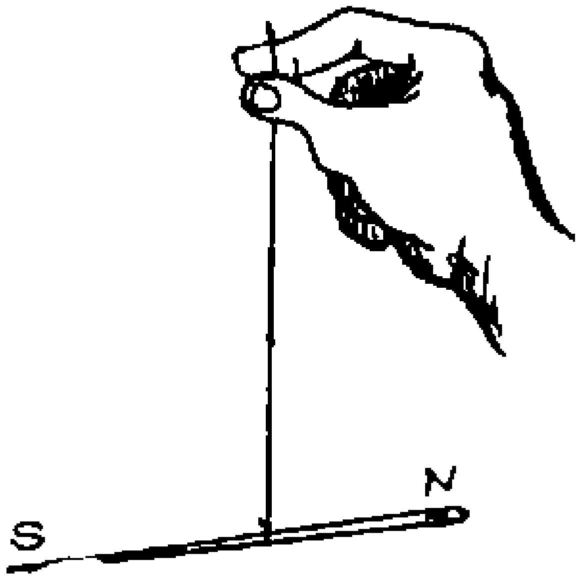
P: Place a cardboard on top of a permanent magnet Sprinkle iron filings on the cardboard. Tap the cardboard gently several times.

Q: What pattern do you observe being formed by the iron filings? Draw a sketch diagram of the pattern formed.

O: The iron filings form a pattern as shown in the figure above. The iron filings are aligned along lines called *magnetic field lines* or lines of magnetic force.

H: Instead of iron filings small bits of iron wool may be used.

8.1.8 Making a Simple Compass Using a Knitting Needle



P: Suspend a magnetized knitting needle using a cotton thread. Allow the needle to settle and lable the N-pole and S-pole of the needle.

Turn the suspended needle through various angles and release it.

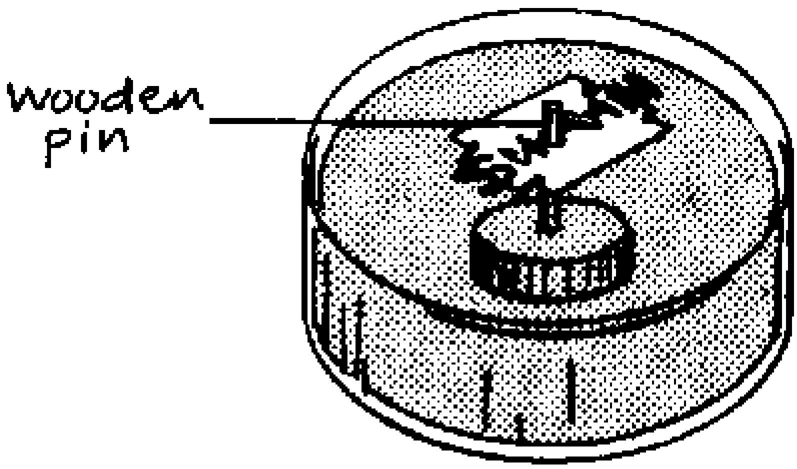
Q: What do you observe?

E: You will notice that the needle will always return to settle in the N-S direction.

The suspended magnetised needle can act as a simple divice to find the north-south direction.

A: Such a divice which shows the N-S direction is called a *compass.*

8.1.9 Making a Simple Compass Using a Razor Blade



P: Fix a wooden pin vertically in a bowl of water. Slip a magnetised razor blade along the pin and carefully place it on the surface of the water so that it can rotate using the pin as an axle. Allow the blade to come to rest and mark its N-pole and S-pole.

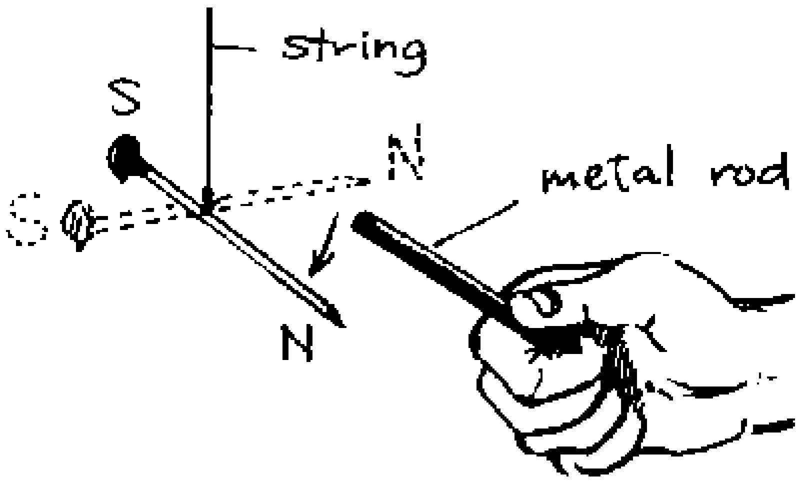
First gently rotate the bowl. Then rotate the blade through any angle and leave it

Q: What do you observe in each case?

O: In the first case the blade will continue to lie in the N-S direction. After the blade has been rotated, it returns to lie in the N-S direction.

A: This arrangement can be used as a simple compass.

8.1.10 Testing for Magnets



P: Bring the first end of a metal rod close to one pole of a suspended magnetized steel nail. Bring the second end of the metal rod close to the same pole of the suspended steel nail.

Repeat the above procedure with an iron rod which is magnetized.

Q: What do you observe with the magnetised and with the unmagnetised rod respectively?

O: With the unmagnetised rod both ends are attracted by the pole of the suspended magnet With the magnetised iron rod, one of its ends will be repelled. This follows from the fact that like poles repel and unlike poles attract.

A: This is used to distinguish magnets from unmagnetised iron.

8.2 Electrostatics

When plastic materials, e.g. plastic pens, combs and rulers are rubbed with fur, woolen clothes, or hair, they acquire negative *electric charges.*

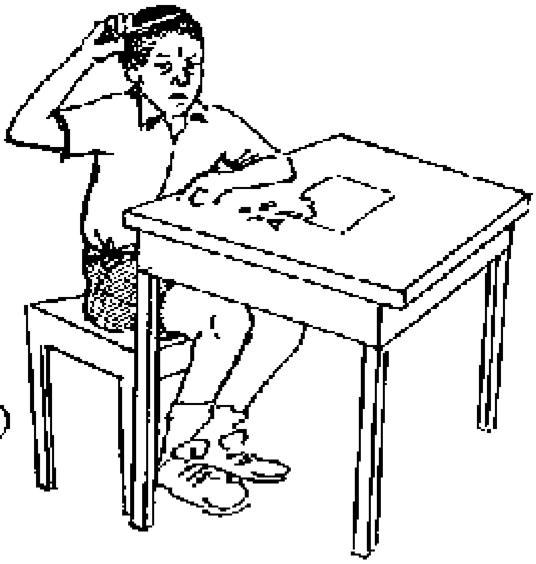
When materials made of glass are rubbed with silk or polyester clothes, they acquire positive charges.

The charges acquired are stationary (static). The study of stationary electric charges is known as *electrostatics.*

Like electric charges repel each other, unlike charges attract each other.

8.2.1 Charging by Rubbing (Friction)

(a)



(b)

P: Rub a plastic pen on your hair, on woolen or synthetic clothes and bring it near small pieces of paper or pieces of thread.

Repeat the experiment by rubbing a glass bottle with a piece of "baibui" (made of silk) or polyester.

Q: What do you observe?

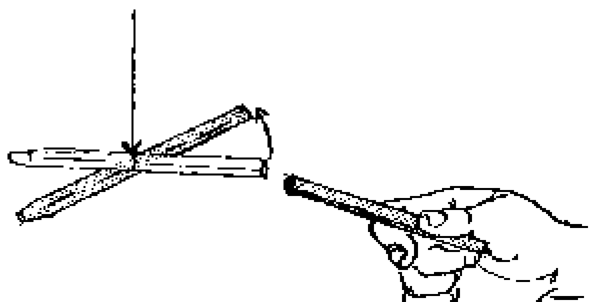
O: The plastic pen or glass bottle picks up small pieces of paper or thread.

E: The plastic pen becomes negatively charged and the bottle becomes positively charged. Thus they both attract pieces of paper.

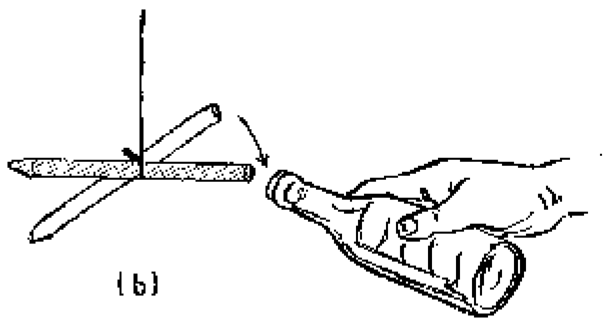
A: The roller in a photocopying machine is charged positively. It attracts the paper which is being photocopied. Thus the paper sticks on the roller.

H: Changing by rubbing is more effective if you use dry materials during a dry day. Most of the time, electrostatic experiments won't work on a humid day.

8.2.2 Laws of Electrostatics



(a)



(b)

P: Rub a plastic pen on your hair or on a woolen or synthetic cloth and bring it near a suspended plastic pen (also charged by rubbing it on your hair).

Repeat the experiment by bringing a glass bottle charged by rubbing with silk or polyester material near the freely suspended *charged* plastic pen.

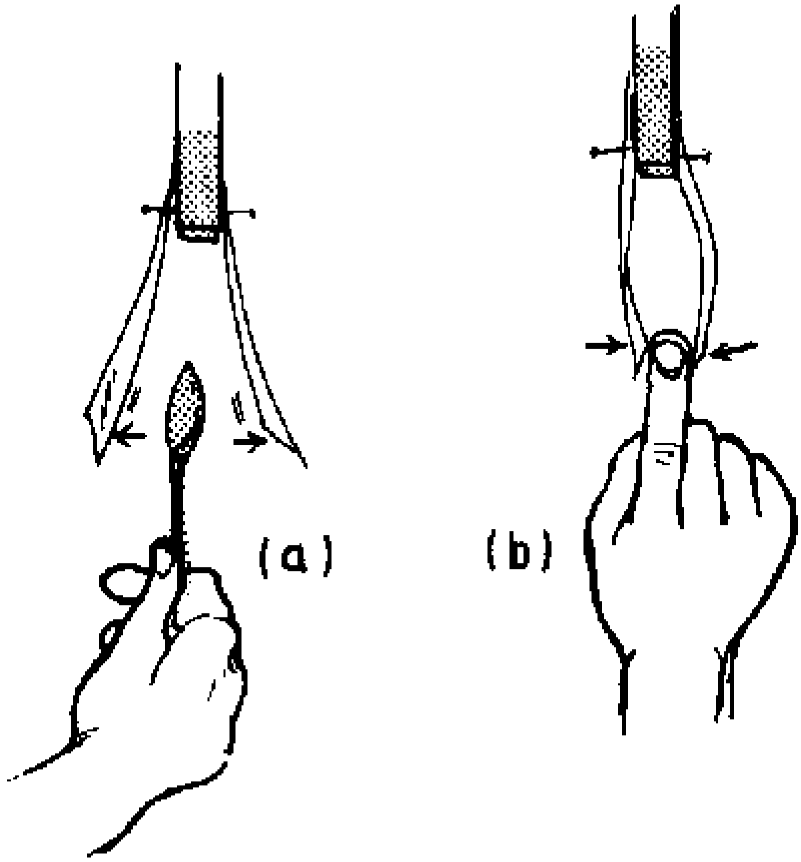
Q: What do you observe in both cases?

O: In the first experiment the two plastic pens repel each other; and in the second experiment, the plastic pen is attracted by the glass bottle.

E: The existence of the same types of charges (negative) on the plastic pens causes repulsion. When the positively charged bottle (glass) is brought near the plastic pen, attraction occurs.

This experiment demonstrates the electrostatic law: *like charges repel and unlike charges attract each other.*

8.2.3 Simple Electroscope



P: Cut two strips of polythene sheet. Fix the strips to a piece of wood as shown in the figure. Charge the strips by rubbing them with a clean duster.

(a) Introduce a charged plastic spoon between the charged strips.

(b) Introduce your finger between the charged strips.

Q: What happens to the strips?

O: The charged polythene strips repel each other.

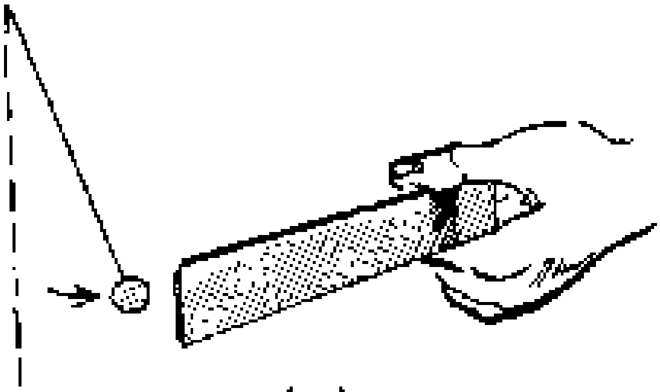
(a) The strips are repelled further with the charged plastic spoon between them.

(b) The finger attracts the strips because the body is earthed. So it becomes positively charged relative to the two strips.

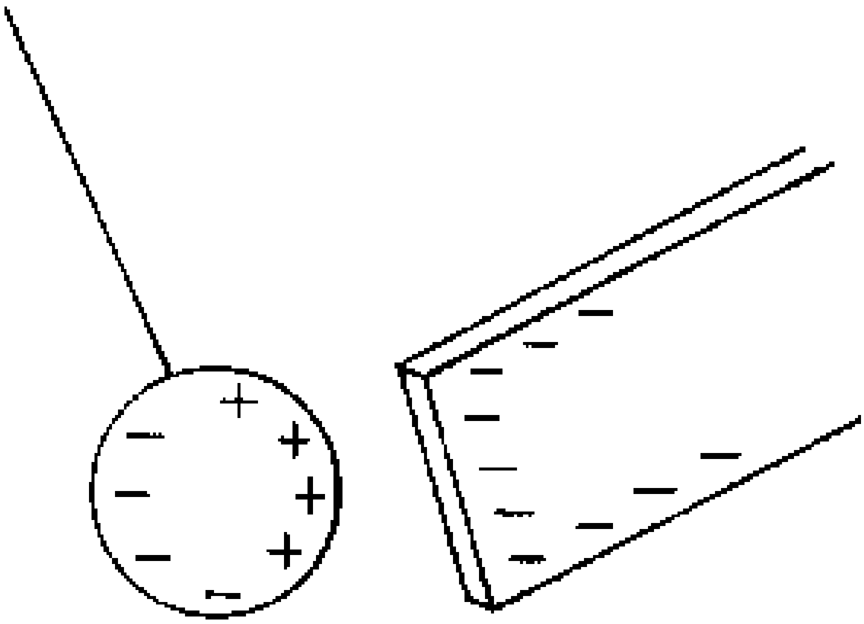
H: The polythene strips can be obtained from the transparent covering of a cigaratte package.

A: The electroscope.

8.2.4 Electrostatic Induction



(a)



(b)

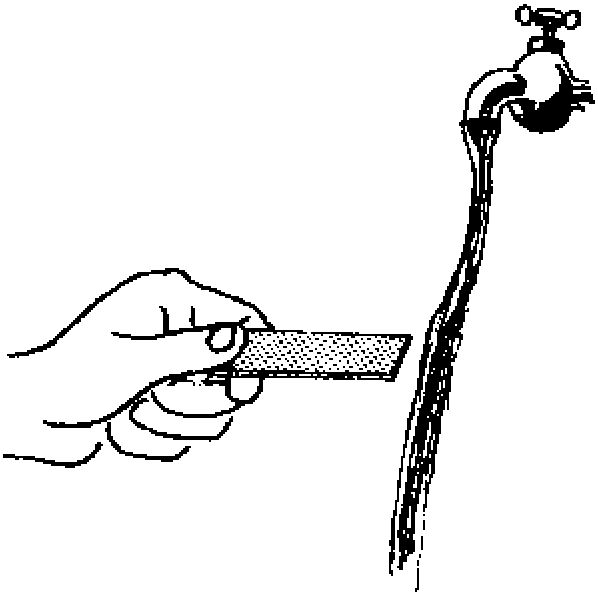
P: Make an aluminium ball (by using aluminium foil) and suspend it freely using a cotton thread. Bring a charged plastic ruler (negatively charged) near the aluminium ball without touching it.

Q: What do you observe?

O: The aluminium ball is attracted by the charged plastic ruler.

E: The force of attraction occurs due to the fact that the negative charge on the plastic ruler repels some of the electrons in the aluminium ball away from the side of the spherical surface near the ruler. Therefore the surface near the ruler gets positive charges and so the aluminium ball is attracted by the plastic. The other side of the aluminium ball becomes negatively charged, see figure (b). The process taking place in the aluminium sphere is called *electrostatic induction.*

8.2.5 Attraction of a Thin Stream of Water by a Plastic Object



P: Charge a plastic object rubbing it on a woolen cloth. Then hold it near (but not touching) a thin stream of water from a tap.

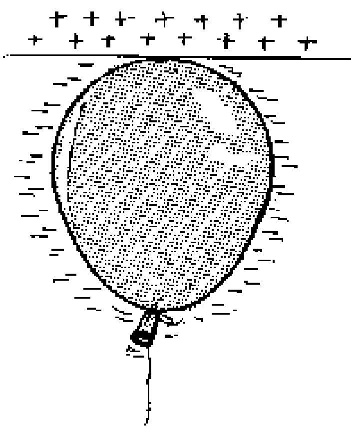
Q: What happens?

O: The thin stream of water *is attracted by the plastic object.*

E: The negative charge on the plastic object causes the water stream to be attracted.

(For teachers only: The water is *not* charged. This effect is due to the dipole nature of the water molecules. The pupils cannot understand this yet in form one or two. Since the *water molecules* are *dipoles,* they have a positively and negatively charged end, yet the total charge of the molecules is zero since the two charges balance. When the charged object comes near the water stream, the oppositely charged end of the water molecules is attracted, the other end repelled. Thus, the molecules turn so that the attracted end gels nearer to the charged object than the repelled end. Since the electrostatic forces become weaker with the increase in distance to the charged object, the attracted end of the water molecules is more attracted by the charged object than the other end is repelled. Hence, the water molecules are always attracted. It does not matter whether the object is positively or negatively charged).

8.2.6 Charged Air Balloon



P: Rub a balloon on a woolen or synthetic cloth or hair and then place it against the ceiling.

Q: What do you observe?

O: The charged air balloon sticks to the ceiling.

E: This happens because the negative charge on the balloon repels some of the electrons in the ceiling away from the surface. This leaves the surface positively charged and so the negative balloon is attracted by the ceiling,

H: The experiment should be carried out during dry weather. Otherwise moisture in the air will neutralize the charges and the balloon will not stick to the ceiling. Holding the balloon with bare hands may also neutralize the charge. Try using dry paper.

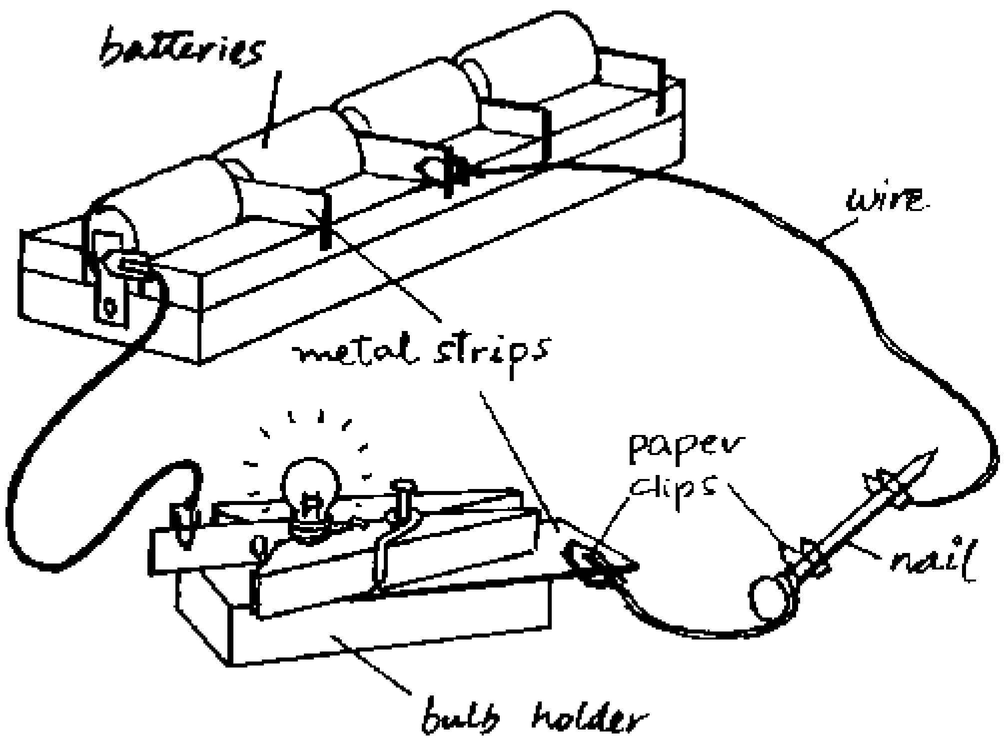
A: Why do gramophone records tend to gather a lot of dust?

8.3 Electric Current

When electrons flow through a conductor they may, for example, light a bulb, heat a wire and produce a magnetic field. The flow of electrons in such a conductor is called an *electric current.* Materials, which allow a current to pass, are called *conductors.* Materials which do not allow a current to pass, are called *insulators.*

Note: If your house or school has got electricity, *never use the mains for performing the following experiments. The voltage there is quite high and could easily kill you.*

8.3.1 Conductors and Insulators



P: Connect a nail, a bulb and two cells with wires as shown in the figure. Successively replace the nail with cotton thread, a plastic spoon (or any plastic material), wood, aluminium foil (from a cigarette packet), paper and a piece of graphite from a pencil.

Q: What happens to the bulb in each case?

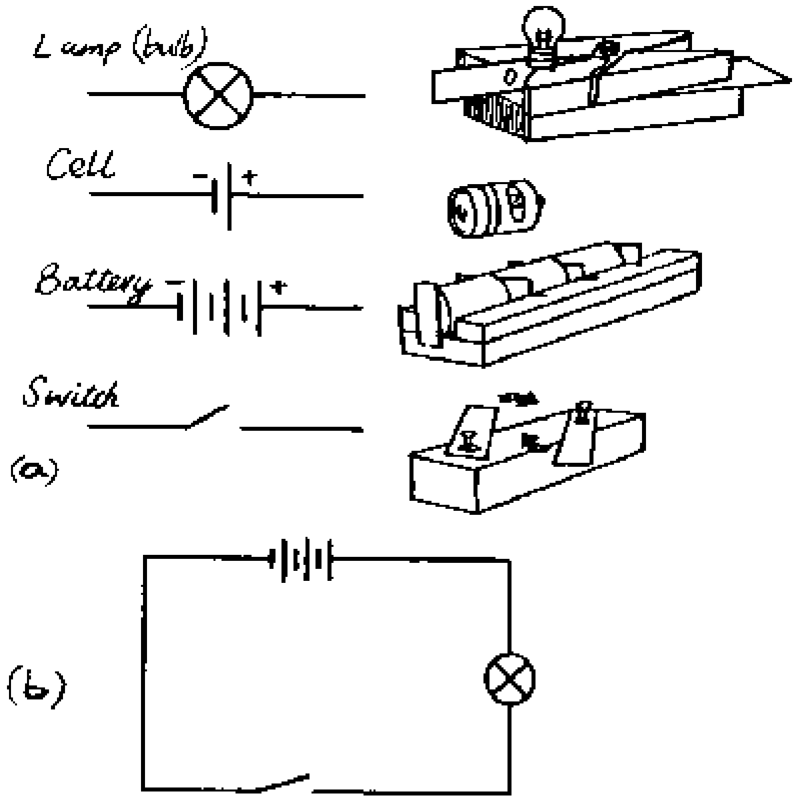
O: The bulb lights for some materials and does not light for others.

E: The bulb lights when current is allowed to flow through it and does not light when no current passes. The materials, which allow current to pass are called good *conductors* and those, which do not allow current to pass, are called poor conductors *(insulators).*

H: How to construct the bulb holder and the cell holder, refer to the figure. Note that metal plates are fixed at the end of the cells as a cell holder. For the lamp holder the metal plates are fixed on the side of the bulb and under the bulb.

Metals like copper, aluminium, iron etc. are used for connecting electric circuits. Plastics, wood, porcelain, etc. are used as insulators.

8.3.2 The Electric Circuit

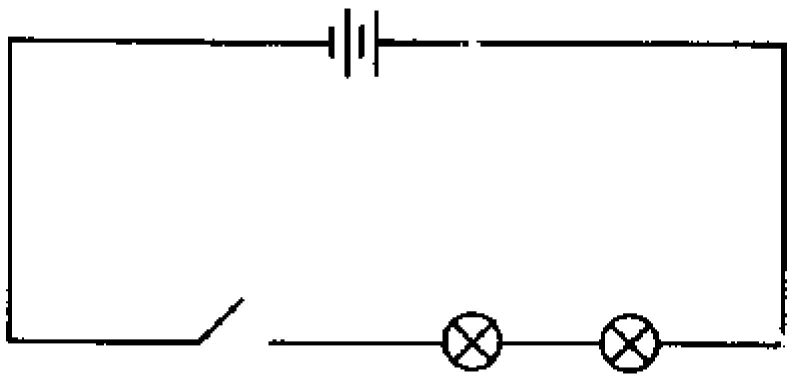


P: On the left side of diagram (a) we have placed the symbols used for a bulb, a cell, a battery of three cells, a switch. Connect a battery of three cells, a switch and a bulb with wires as shown in the circuit diagram (b). Close the switch.

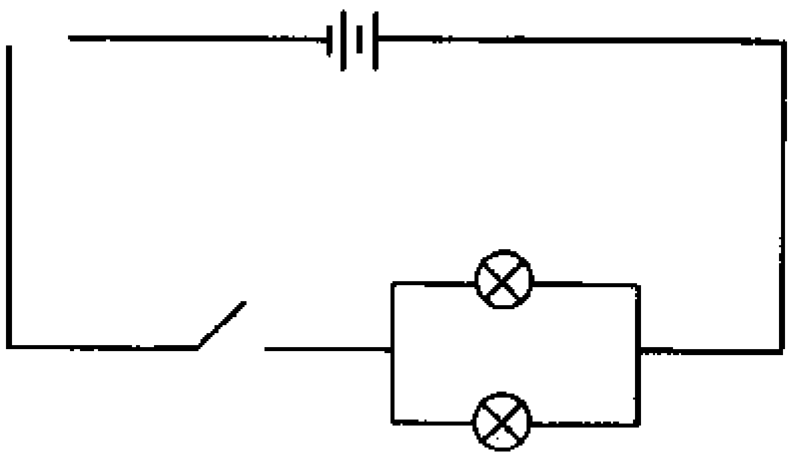
Q: What do you observe at the bulb when the switch is closed?

E: When the switch is closed, the current flows through the bulb from the positive terminal of the battery to the negative terminal. Note, that this is *the conventional* current which flows from the positive to the negative terminal.(Of course, actually *electrons* flow in the wires from the negative to the positive terminal.) The switch makes a continuous path possible and hence the current can flow. This continuous path is called an electric circuit. In an *electric circuit diagram* we always use symbols. Every component of the circuit has its own symbol.

8.3.3 Bulbs in Series and Parallel



(a)



(b)

P: Connect two bulbs as shown in circuit diagram (a) so that they are in one line (series). Close the switch and observe the brightness of the bulbs. Now connect the bulbs side by side (parallel) as shown in circuit diagram (b). Close the switch and observe the brightness of the bulbs.

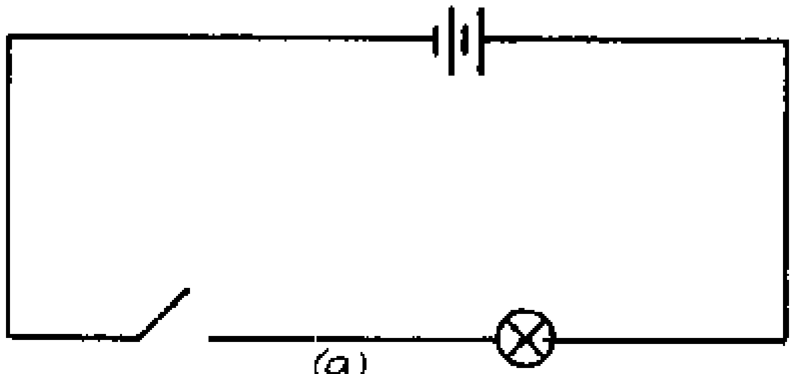
Q: What difference do you observe in the brightness of the bulbs when they are connected in series and when they are parallel? Explain your observations.

O: The bulbs are brighter when they are parallel than when they are in series.

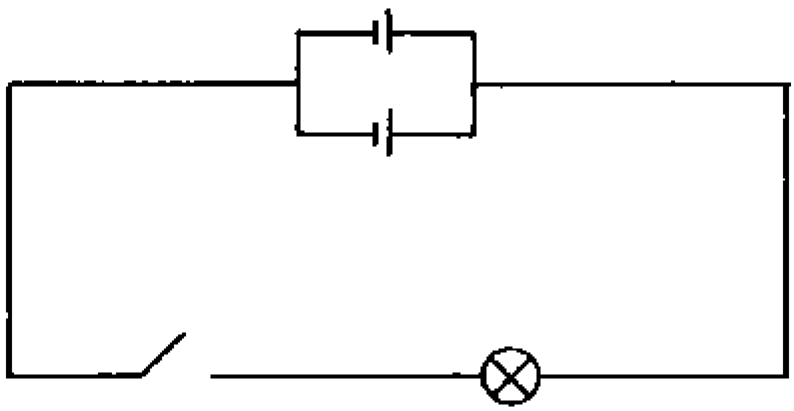
E: More current passes through each bulb when they are parallel than when they are in series. The reason is that the full voltage of the battery lies on each bulb when the bulbs are connected parallel. When they are in series only half the voltage of the battery lies on each bulb.

A: In domestic wiring bulbs are connected parallel so that they obtain the right voltage.

8.3.4 Cells In Series and Parallel



(a)



(b)

P: Connect two dry cells in series, that is the positive terminal of one to the negative terminal of the next as shown in circuit diagram (a). Connect the two cells parallel, that is the positive terminal of one to the positive terminal of the other and the negative terminal of one to the negative terminal of the other as shown in circuit diagram (b).

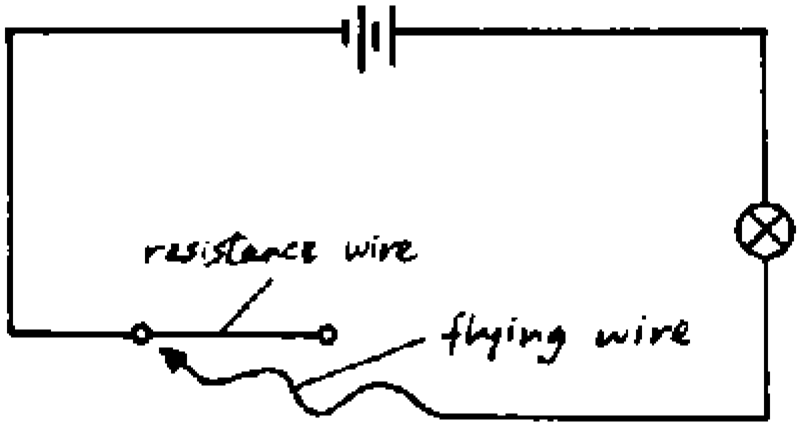
Q: What difference do you observe in the brightness of the bulb when the cells are connected in series as in circuit (a) and when they are connected parallel as in circuit (b)? Explain your observations.

O: The bulb is brighter when the cells are connected in series than when they are connected parallel.

E: More current passes through the bulb when the cells are connected in series than when they are connected parallel. The reason is that the *voltage* of the two cells add when they are in series. When they are parallel, the voltage stays the same as that of one cell.

A: In torches and car batteries cells are connected in series to get the required voltage. In cars 12 volts are needed, thus 6 cells are connected in series since one car cell has only 2 volts.

8.3.5 Ohm's Law: Increasing the Resistance



P: Connect the circuit as shown in the diagram. Slide the free end of the flying wire along the resistance wire.

Q: What happens to the brightness of the bulb?

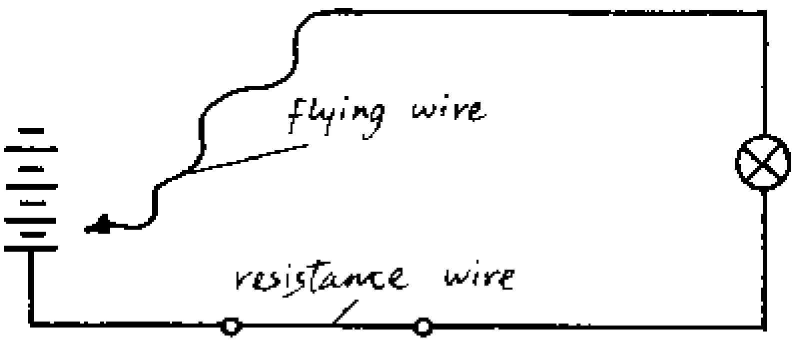
O: The bulb becomes dim when the flying wire is placed at the free end of the resistance wire.

E: As the length of the resistance wire increases, the brightness of the bulb decreases. The current passing through the bulb decreases as the length of the wire increases, since the resistance of the wire increases.

A: Rheostats are long coiled wires used to vary the current in circuits.

H: For the resistance wire you can use a long steel wire from steel wool.

8.3.6 Ohm's Law: Increasing the Voltage



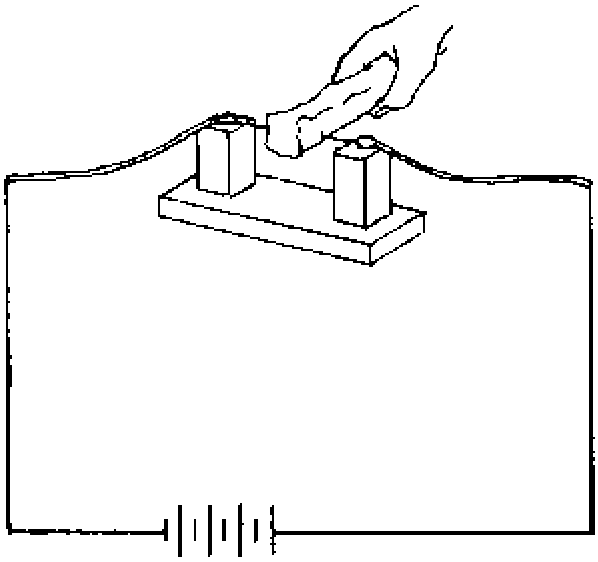
P: Connect the circuit above. Starting with the free end of the flying wire connected to one cell, successively increase the number of the cells.

Q: What difference in brightness of the bulb do you observe as the number of cells connected are increased?

O: The bulb becomes brighter when more cells are used than when one cell is used. The brightness increases with increase in the number of cells.

E: The current passing through a circuit increases with increase in the number of cells since the voltage increases accordingly.

8.3.7 Heating Effect of an Electric Current



P: Set up the circuit as shown. Press a piece of styrofoam (polystyrene) gently across the steel wire.

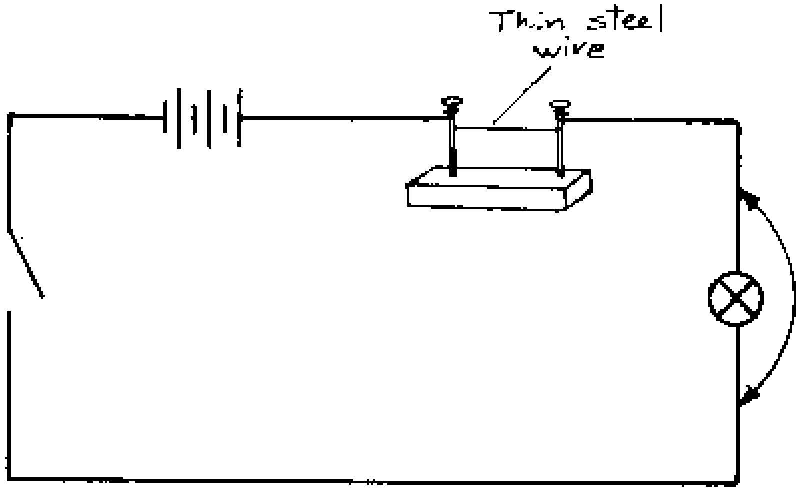
Q: What happens to the styrofoam?

O: The styrofoam piece is easily cut.

E: The electrical energy has been converted to . heat energy which melts the styrofoam.

A: Electric iron, electric kettle, electric cooker etc.

8.3.8 The Fuse



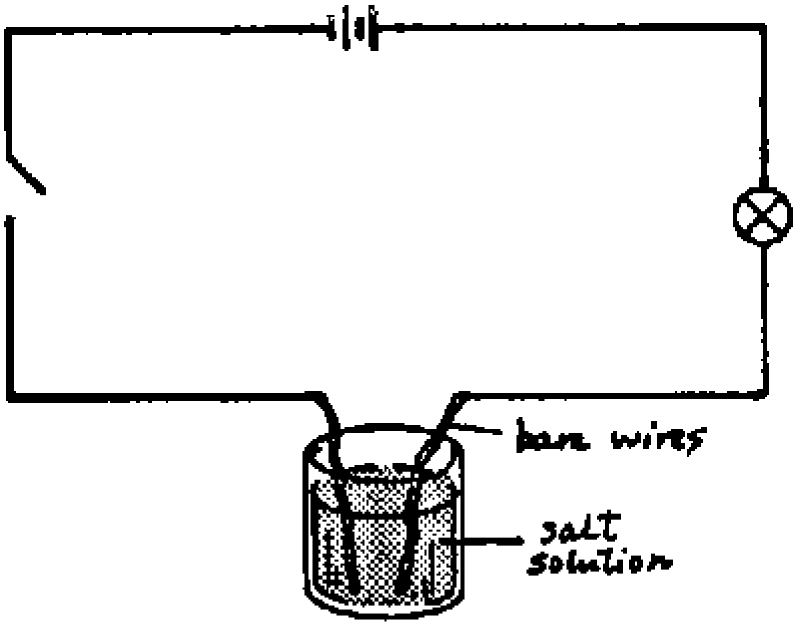
P: Connect the circuit as shown in the diagram. Close the switch. Make a short circuit by connecting a copper wire across the bulb.

Q: What happens to the thin steel wire connected across the nails?

O: The steel wire melts (fuses) and the bulb stops lighting. This is because a large current passes through the thin steel wire. The wire acts as a fuse.

A: A fuse is used in electrical appliances and domestic wiring to cut off large currents in electric circuits which could start fires.

8.3.9 Chemical Effect of an Electric Current



P: Connect the circuit shown in the diagram and close the switch so that an electric current passes through the salt solution.

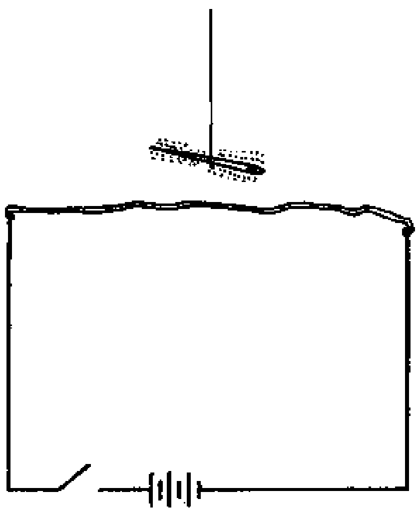
Q: What do you observe in the salt solution?

O: Bubbles are produced on the bare wires in the salt solution.

E: When electricity is passed through a liquid like a salt solution, a chemical reaction takes place which gives off gas bubbles. This process is known as *electrolysis.*

A: Electrolysis is used in electroplating and coating of iron with different metals.

8.3.10 Magnetic Effect



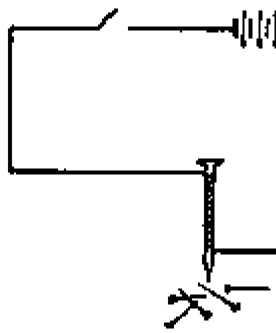
P: Connect the electric circuit as shown in the figure. Suspend a magnetized needle with a piece of cotton thread just above the wire. Close the switch *only for a very short time.*

Q: What happens to the magnetised needle?

E: The magnetised needle is deflected, because the wire has produced a magnetic field.

A: Electromagnets.

8.3.11 An Electromagnet



P: Wind about fifty turns of insulated wire around a nail. Connect the ends of the wire to the cells. Place one end of the nail close to office pins lying on the table and close the switch. After a while open the switch.

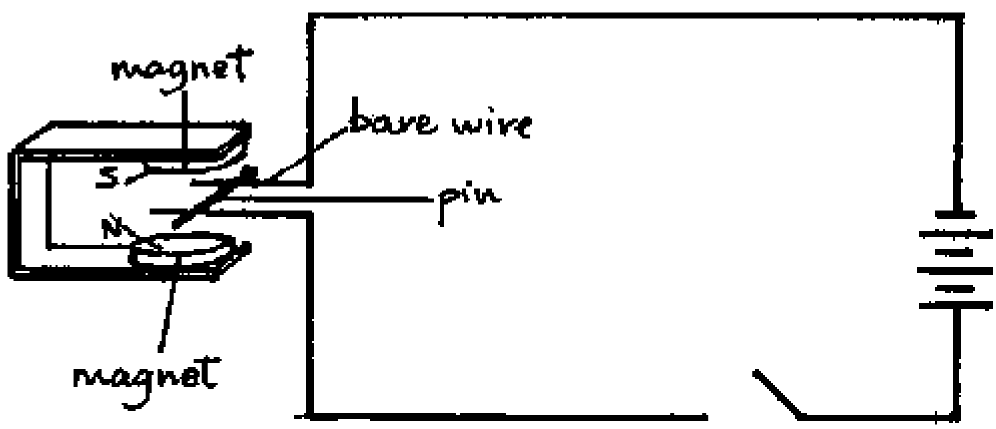
Q: What happens to the pins?

O: The pins are attracted to the nail, when the switch is closed, and fall off when the switch is opened.

E: When the switch is closed the current flows through the coil and magnetizes the nail. The magnet formed is known as *electromagnet.* The nail is made of soft iron. Thus it loses the magnetism when the current is switched off.

A: Used in harbours for lifting heavy loads with iron containers. In electric motors.

8.3.12 The Force on a Current in a Magnetic Field



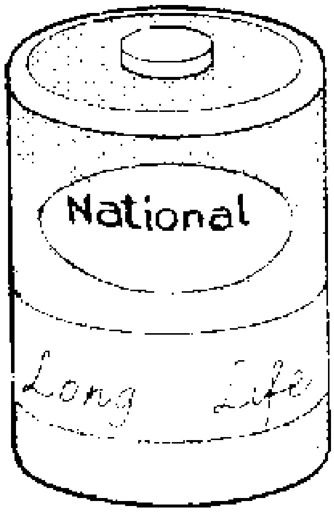
P: Connect the circuit as shown in the diagram. Place a nail across the straight bare wires between poles of the magnet and close the switch, *for a short time only,*

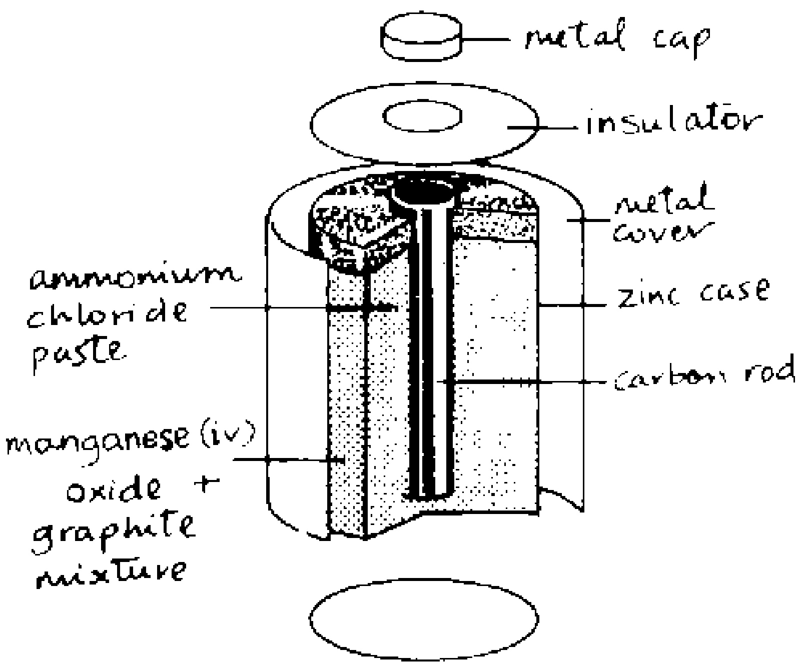
Q: What happens to the nail?

O: The nail rolls along the straight wires, because a force is produced on the current in the nail by the magnetic field.

A: Electric motors and loudspeakers.

8.3.13 Opening a Dry Cell





P: Open a dry cell. Examine it carefully.

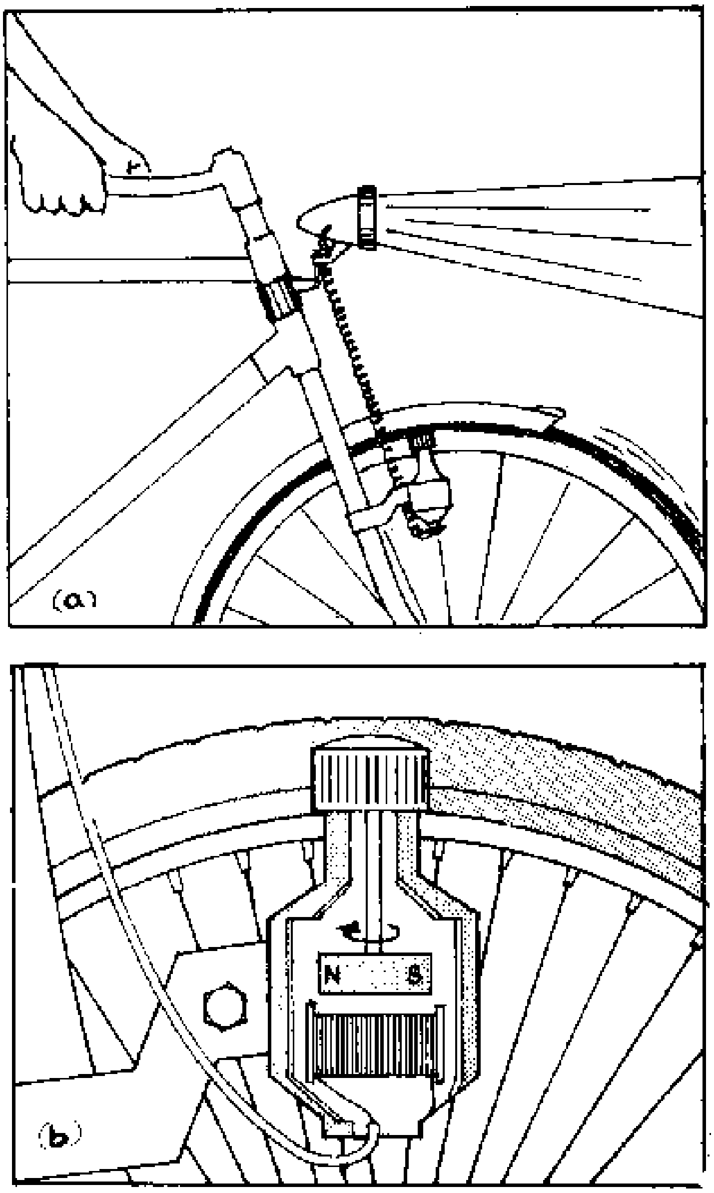
Q: What do you see in the broken dry cell?

O: You will see a black rod at the centre of the cell surrounded by a black substance covered by eaten up zinc.

E: The black rod at the centre is a carbon rod (graphite). The black substance contains manganese(IV) oxide and ammonium chloride paste.

The electrical energy is produced by a chemical reaction between the zinc and the ammonium chloride paste.

8.3.14 The Bicycle Dynamo



P: Connect a bulb to a bicycle dynamo by using connecting wires. Turn the wheel of the bicycle very fast and then slowly.

Q: What do you see when the wheel is turned very fast and when it is turned slowly?

O: When the wheel is turned very fast, the bulb gives a bright light, and when it is turned slowly, the bulb gives a dim light.

E: Inside a dynamo there is a magnet and a coil, see figure (b). When the wheel is turned, it makes the magnet rotate. The rotation of the magnet near the coil produces a current in the coil. The amount of current produced increases with the speed of rotation of the magnet.

A: Electric Generators.

Appendix

A Sootless Kerosene Burner

Spirit for burners is not always available, but kerosene can be purchased nearly everywhere. For the heating of tins or other things a sootless *kibatari* (kerosene burner) will do.

With a simple and cheap additional device which the same 'fundi' can make who produces the normal *kibatari,* you can get a nearly sootless flame. The principle behind is to improve the draft of the air stream in order to obtain a *more complete combustion* of the kerosene. The flame of the kibatari should bum in contact with a metal wall, which acts as a catalyst.

The basic device consists of 4 parts:

(a) A *perforated inner chimney* is made from a tin which is about 1.3 cm wide and 7 cm long. If the diameter of this tube is too small, the flame will not burn; if it is too wide the effect will be small. The holes can be made with a nail and should have a diameter of 2 mm. There should be 3-4 holes per square centimetre.

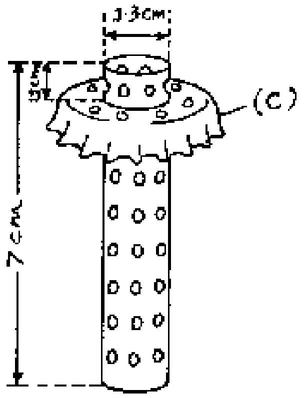
(b) An *outer chimney* which serves at the same time as a wind shield. The holes below are about 5 mm in diameter.

(c) Both chimneys fit together in a *per forated soda bottle cap* as shown.

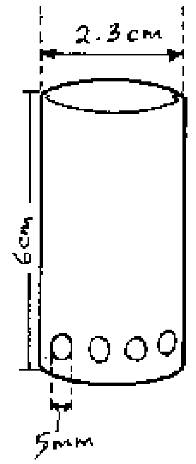
(d) Ask the fundi to solder another soda bottle cap around the *wick holder (d).* This holds the chimneys better.

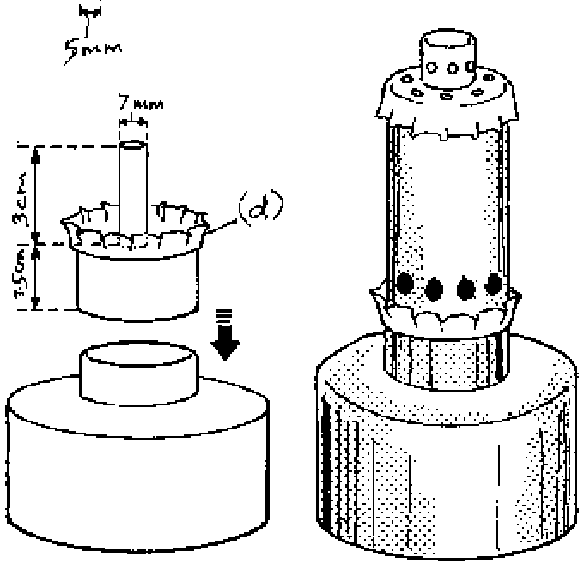
The flame is optimized by adjusting the length and shape of the wick: it should have contact with the perforated tube. With this burner temperatures of about 650°C can be achieved.

(a)



(b)



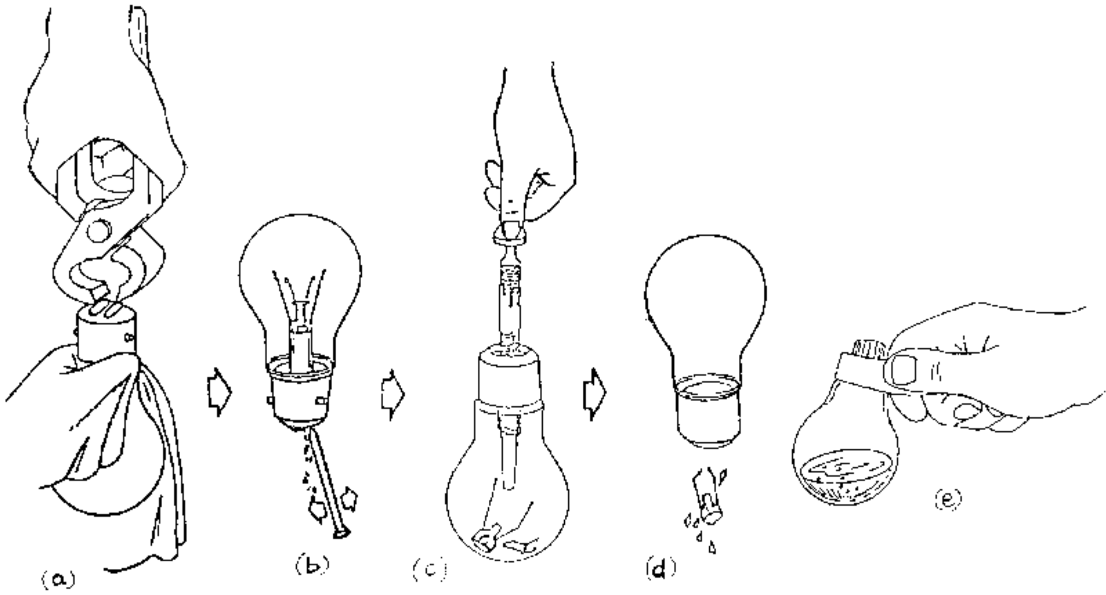


Test Tubes and Flasks

A cheap substitute for expensive test tubes and reaction flasks are opened worn out electric bulbs. They resist the temperature of an alcohol or kerosene burner, but *not* the temperature of a bunsen burner. Heat the bulbs carefully and do *not* use them for aggressive substances like *concentrated* acids and hydroxides.

Bulbs can be opened with pliers and a round file or even with a pointed long nail. Wrap your hand with a piece of cloth. Never hold the bulb to be opened at its glass, hold it only at its socket, see figure (a).

Special clamps are not needed. Fold a sheet of paper and you have the cheapest test tube or bulb clamp, see figures (c).



List of Materials

This is the list of materials needed for a workshop on "Teaching Physics to Beginners with Locally Available Materials."

It is assumed that the organisers will bring the materials which are needed for each kit and the tools listed below. These, therefore, are not mentioned especially under the numbered experiments below. Common materials like water, etc. are not mentioned.

The materials listed allow to produce the *Physics kit* with which the experiments described in this book can be performed. Each participant of a workshop should produce his/her own kit according to the experiments he/she selects.

Materials (needed for each kit)

Matches
Wooden rulers
Opened (transparent) bulbs (and if possible some test tubes)
Some vibatari (kerosene lamps; if possible with chimneys for a sootless flame).
Cement bag or similar paper
Nails of different diameters
Thumb pins
Office pins
Paper clips
Small and medium size tins for heating
Some transparent bottles with smooth surface
Some transparent glass jars
2-3 candles
Glue

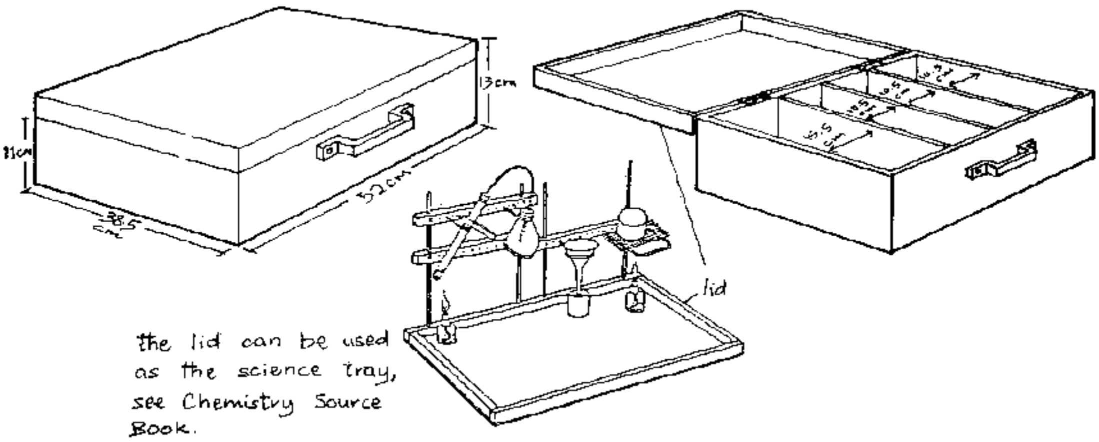
Tools etc. (needed only once)

1 sharp knife
1 combination plier
1 hammer
1 set of weights
1 balance (see p. 10)
1 measuring cylinder

1 magnet (e.g. from a discarded loudspeaker)
1 drill borer for 2-3 mm holes
1 tin opener
1 pair of plate-shears
1 pair of scissors

To be done by craftsmen:

Chimney for sootless kibatari (see p. 109)
Funny jumper (see p.21)
Box with lid and handle for physics kit, sec the figure below



In addition to the materials listed above you need the following materials according to the experiments you choose:

2.1.1 Rubber band, thin wire, small plastic bags (groundnuts)
2.1.2 Bicycle, meter band
2.1.3 Thread, nut or small stone
2.1.4 Watch, meter band (better 10 m thread)
2.1.5 Thread, wooden ruler, small plastic bags, thin wire
2.1.6 Clothes-peg, wire (2 mm), thread
2.1.7 Plastic bags (groundnuts)
2.1.8 Small plastic bags (groundnuts)
2.1.9 -
2.1.10 Wooden stick, kerosene
2.1.11 -
2.1.12 5 m string
2.1.13 -
2.1.14 -
2.1.15 Sewing needle (or a piece of bicycle spoke), insulated wire, 1.5 V dry cell
3.1.1 Matchbox, smooth table or plank, some bricks, a small stone
3.1.2 The same as 3.1.1
3.2.1 A stone, a rubber band, a ball of mud
3.2.2 Card board or wooden lath, rubber band
3.2.3 -
3.2.4 -
3.2.5 Newton balance, see p. 15
3.2.6 -
3.3.1 Stone
3.3.2 A large and a small stone, string, ball
3.3.3 Newton balance, see p. 15
3.3.4 Beam balance, weights, see p. 10
3.3.5 A pencil, a strip of paper, (table)
3.3.6 A toy pick-up or an open box, some card
3.3.7 A large paper

3.3.8 A large paper
3.3.9 A large paper
3.3.10 A large paper
3.4.1 Sheet of cardboard, thread, 7 equal clothes-pegs
3.4.1 Sheet of cardboard, stone, string, pencil
3.4.3 -
3.4.4 14 nails of 2-inch length, piece of wood
3.4.5 Pencil
3.4.6 A candle, some card
3.4.7 A coin, 2 forks
3.4.8 A potato, 2 forks, pencil, bottle, some card, string
3.5.1 Wooden stick, a flat piece of wood
3.5.2 Book, table, piece of cloth
3.5.3 Oil or margarine
3.5.4 -
3.5.5 Book, about five round pencils or drinking straws
3.5.6 Large paper
3.6.1 Stone, thread, Newton balance (see p. 15), measuring cylinder
3.6.2 Rubber stopper, piece of glass or transparent plastic tubing, beam balance, (see p. 10
3.7.1 Book, pencil
3.7.2 -
3.7.3 Bucket, a 'ngata'
3.7.4 Plastic bag
3.7.5 Large tin with air-tight lid, e.g. a charcoal stove, small tin or cup
3.7.6 Drinking glass or jam glass, smooth card or plastic sheet
3.7.7 Bottle, plastic bag, string, straw
3.7.8 A piece of transparent plastic tubing, string
3.7.9 Plastic or rubber tube
3.7.10 One way syringe from a hospital
3.7.11 Bicycle pump, large paper
3.7.12 Large paper
3.7.13 Large paper
3.7.14 Large paper
3.8.1 Stone, thread, Newton balance, measuring cylinder
3.8.2 Matchbox, small stone, Newton balance, overflow can (see p.25), measuring cylinder
3.8.3 Bottle, small piece of styrofoam
3.8.4 Drinking straw, a piece from a plastic bag, thread, bottle or test tube
3.8.5 Salt, egg
3.8.6 Candle
3.9.1 Wooden block, Newton balance, thread
3.9.2 Like 3.9.1
3.9.3 Rubber band, stone, branched stick
3.9.4 Stopper, used bulb, paper, burner
3.9.5 Stone, string
3.9.6 3 clothes-pegs, thread, matches
3.9.7 Funny jumper (see p.21)
3.9.8 String (to measure height), stone, watch
3.10.1 Heavy stone, tipped stone
3.10.2 Wooden block and bar, some weights (see p. 10), string
3.10.3 Wooden lath, wire (diameter 2 mm), 1 cork, card, string
3.10.4 Two pulleys (see 3.10.3), string, Newton balance
3.10.5 Two broomsticks, rope of about 5 m length
3.10.6 Table or plank, some bricks, toy car, string, Newton balance
3.11.1 Wire (2 mm), thin wire, 1 seed, 1 small fruit, 1 bulb (1 torch bulb, battery, connecting wires), 1 bottle
3.11.2 Stone, string
3.11.3 Long string for measuring distances
3.11.4 -
4.1.1 Some salt
4.1.2 -

4.1.3 Pieces of cotton, canvas cloth, small polythene bag
4.2.4 Orange peels
4.2.5 Umbrella or big plastic sheet
4.1.6 Simple balance (see 2.1.5)
4.2.1 -
4.2.2 -
4.3.1 Some potassium manganate(VII) (permanganate; or other solid colouring agents)
4.3.2 -
4.3.3 -
4.3.4 -
4.3.5 -
4.3.6 -
4.4.1 2 clean glass pieces (of a broken window)
4.4.2 -
4.4.3 Razor blade, fork
4.4.4 -
4.4.5 Some detergent or soap
4.4.6 2 glass sheets of about 10 cm x 10 cm, rubber bands or string
4.4.7 Stick of chalk, plotting paper or newspaper
4.4.8 Piece of cloth
4.4.9 Thread
4.4.10 -
4.5.1 Rubber band, plastic bags (groundnuts)
4.5.2 2 tall small bottles (or test tubes)
5.1.1 -
5.1.2 Small bottle, cork stopper, empty ball point tube
5.1.3 Large sheet of paper, ruler, writing facilities
5.1.4 Some oil
5.1.5 -
5.1.6 -
5.2.1 2 Wooden blocks, 30 cm wire (about 2 mm diameter), pin needle
5.2.2 -
5.2.3 2 razor blades, 1 clothes-peg
5.2.4 Thin copper wire (from used motor coil)
5.2.5 -
5.2.6 Aluminium paper from cigarette packages
5.2.7 The same as 5.1.2
5.2.8 -
5.2.9 Soda or beer bottle
5.2.10 The same as 5.2.9, plus tin for a water bath
5.3.1 Some ice
5.3.2 -
5.3.3 Some spirit or petrol
5.3.4 -
5.3.5 -
5.3.6 -
5.3.7 Piece of ice
5.3.8 Some salt, piece of ice, plastic dish (or plate)
5.3.9 -
5.3.10 -
5.4.1 A ball (from children)
5.4.2 -
5.4.3 Wire, plastic rod, wooden rod (all of similar size)
5.4.4 30 cm wire (2 mm diameter)
5.4.5 -
5.4.6 Saw dust
5.4.7 -
5.4.8 Shiny tin, 2 wooden sticks
5.4.9 2 identical shiny tins
5.4.10 -

6.1.1 A rope of about 6 m length
6.1.2 Tin, string, some newspaper, glue, ink or fine sand
6.1.3 Table or chair
6.1.4 Thread, stones of different masses, watch
6.1.5 Rubber band, stones of different masses, watch
6.1.6 Tin, paper, string
6.1.7 Water tank, etc
6.1.8 Ink or potassium manganate(VII) (permanganate), a plate, plastic bag
6.1.9 Piece of cork, light wood or polystyrene, dropper (see 6.1.8), plate
6.1.10 -
6.2.1 2 empty tins, string
6.2.2 2 pieces of metal
6.2.3 2 spoons, string
6.2.4 Table
6.2.5 Some metres of a thin wire, two poles
6.2.6 Plastic bucket, 2 stones
6.3.1 Plate or tray, straight metal, plastic or wood barrier, rectangular block
6.3.2 Wall or door, 2 paper cones, a sheet of cardboard
6.3.3 A window with burglar bars, rope of about 5 m length, a stick
6.3.4 A garden hose pipe
6.3.5 Tall building or wall
6.3.6 Tall tin or jar, a clock, a sheet of cardboard
6.4.1 A soft board, thread, 2 pencils, various stones
6.4.2 4 equal soft drink bottles
6.4.3 A wooden block (better: a box), bicycle spokes
6.4.4 A bamboo tube (1.5 cm x 30 cm)
6.4.5 Empty tin with lid, wooden stick, string
6.4.6 Wooden box, timber bars of different wood and thickness, 2 sticks
7.1.1 Wooden blocks as stands, cardboard, candle
7.1.2 Manila sheet, string
7.1.3 Candle, pinhole camera (see 7.1.2)
7.1.4 Pencil, candle, white paper
7.1.5 2 candles, otherwise like 7.1.4
7.1.6 Glass bottle, damp paper etc., (torch), some cards
7.1.7 Comb, white paper, piece of cardboard
7.1.8 Torch, piece of card, piece of white card or paper as screen, pencil
7.2.1 2 plane mirrors, candle
7.2.2 Spherical spoon or concave mirror, white card, candle, sheet of white paper
7.2.3 Like 7.2.2 plus candle, sheet of white paper
7.2.4 Spherical spoon or convex mirror, candle, white paper, needle
7.2.5 Transparent glass-pane, candle, bottle
7.2.6 2 mirrors, rectangular box
7.2.7 Paper, plane mirror
7.3.1 Coin, lid of a jam jar
7.3.2 Transparent bottle, coin
7.3.3 Glass or jam jar, pencil
7.3.4 Pin or needle, cork, glass or jam jar
7.3.5 -
7.3.6 -
7.4.1 Convex lens or opened bulb (see p. 110), paper
7.4.2 Concave lens or soda bottle bottom or wire loop of 8-10 mm diameter
7.4.3 Manila sheet, opened bulb (see p. 110) or convex lens, parchment paper
7.4.4 Simple box camera (see 7.4.3), window or candle
7.4.5 -
7.4.6 Thin wire or opened bulb (see p. 110)
7.4.7 Wooden box, metal strip, plane mirror, thin wire loop of 3 mm diameter
7.4.8 Box camera (see p.90), plane mirror, parchment paper
7.4.9 Large sheet of paper
7.4.10 Box camera (see p.90), convex lens
7.4.11 Box camera (see p.90), concave lens

7.4.12 Some paper
7.5.1 Glass prism, white paper as screen, second glass prism or convex lens
7.5.2 Plane mirror, dish, white paper as screen
7.5.3 Hose pipe
7.5.4 White card, blue, green and red pencils or felt pens, string
8.1.1 Magnet (e.g. from discarded loudspeaker) plus materials listed on p.98
8.1.2 Magnet, magnetised steel needle (see 8.1.3), thread
8.1.3 Needle, magnet
8.1.4 Needle, magnetised pin or needle (see 8.1.3), paper, small pieces of wood or cork
8.1.5 Bicycle spoke, thin insulated copper wire (from old motor coil), 3 radio batteries, insulated wire, iron filings or bits of steel wool
8.1.6 The same as in 8.1.5 plus burner
8.1.7 Paper, bar magnet or magnetised steel needle, iron filings or bits of steel wool
8.1.8 Magnetised knitting needle (see 8.1.3), thread
8.1.9 Wooden pin, bowl, magnetised razor blade
8.1.10 Metal rod or needle, 2 magnetised needles or steel nails, thread
8.2.1 Plastic pen, piece of paper
8.2.2 2 plastic pens, thread, glass bottle, silk (e.g. baibui) or polyester material
8.2.3 Polythene sheets from transparent covering of a cigarette package or a plastic bag, piece of wood
8.2.4 Small piece of aluminium foil, cotton thread, plastic ruler or pen
8.2.5 Tap with water, plastic pen, woolen cloth
8.2.6 Balloon, wooden or synthetic cloth
8.3.1 2 radio cells, torch bulb, connecting wires, 2 metal strips, clothes-peg, plus materials listed on p. 104
8.3.2 Torch bulb, 8 metal strips, 3 radio cells, insulated wire for connecting
8.3.3 2 radio cells, 2 bulbs, 2 bulbholders (see 8.3.1), switch (see 8.3.2), insulated wire
8.3.4 2 radio cells, bulb holder (see 8.3.1), switch (see 8.3.2), insulated wire
8.3.5 2 radio cells, bulb, bulb holder, resistance wire or long wire from steel wool, insulated wire for connections
8.3.6 4 radio cells, insulated wire, torch bulb, cell holder, bulb holder
8.3.7 Styrofoam, 8 cm steel wire (from steel wool), insulated wires, 4 radio cells, some pieces of wood
8.3.8 3 radio cells, very thin steel wire (from steel wool), torch bulb, switch, insulated wire, piece of wood
8.3.9 2 radio cells, bulb, bare copper wire, insulated wire, switch, salt
8.3.10 3 radio cells, switch, 1-2 mm copper wire, insulated wire, needle, thread
8.3.11 3 radio cells, switch (see 8.3.2), insulated wire, thin insulated wire (e.g. from a motor coil)
8.3.12 4 radio cells, switch, insulated wire, 2 magnets or U-magnet, wooden stand for the magnets
8.3.13 Worn out radio cell
8.3.14 Bicycle with dynamo and headlight

This book .....

• emphasizes learning Physics by doing without which no scientific development can take place.

• describes how to make a Physics Kit which is a minilab by itself. It can be used to equip schools which luck laboratory equipment for Physics with locally available materials.

• Students can even make their own Physics Kit and use it as a home lab to promote their talents in Physics.

• promotes creativity and shows that creative Physics lessons can take place in any scientific development.

• tries to make teachers and students aware of the resources available in heir environment which may be used for the teaching and learning of Physics and other science subjects.

Foreword

Biology is about the living world. It concerns the structure and organization of living things and how they work. It is becoming increasingly obvious that such a knowledge is essential in order to derive the maximum benefit from our environment without damaging it for ever. Debates on such issues now range from local to global level, and increasing public awareness and media coverage of environmental matters has served to focus attention on the importance of Biology more than ever before.

In the past, Biology as a subject was often regarded as academically inferior to and intellectually less demanding than the other pure sciences. However, recent advances in areas such as biotechnology and genetic engineering have shown this to be totally untrue. Even at its simplest levels, Biology is a fascinating subject, dealing as it does with ourselves, our surroundings, the complex interaction between physical and chemical processes.

Biology is essentially a practical subject based on enquiry, observation and experimentation. This book follows that theme throughout, whilst also drawing on the natural curiosity of the young person. By emphasizing the use of locally available materials, the text becomes a starting point for a learning process, which is easily related to the familiar surroundings of the pupil! Thus Biology ceases to be an abstract topic and becomes relevant to everyday life. Another major feature of this approach is "learning by doing," that is the active involvement of the pupils, and a movement away from traditional and considerably less effective teaching strategies such as the familiar "chalk and talk education". This book is intended to provide a stimulating source of ideas for both teacher and pupil and above all to make Biology enjoyable. For that reason, the environmental approach can be justified on both psychological and educational grounds. The simplicity of some of the activities and of the local materials used, should not be seen as an inferior substitute for complicated investigations involving expensive and sophisticated scientific equipment. Rather it is an acknowledgment that science is more about developing an enquiring mind, than memorizing facts (following the pattern from the simple to the complex, from the familiar to the unknown). Furthermore the science of Biology is all around us, and so, even more than in other sciences, its teaching should not be restricted to the classroom. The shamba, the village or the school compound can provide fruitful areas of study and rich sources of material. For this reason many of the activities can be done by the pupils without assistance, even at home.

It is hoped that this book will have a wide appeal to pupils, teachers, student teachers and teacher trainers, and its use will contribute not only to the improved teaching and learning of Biology but to a general awareness of the importance of Biological issues in every aspect of modern life.

L.K. MSAKI
Commissioner for Education

Preface

This sourcebook is addresssed to all those who are concerned with the teaching of Science at the Junior Secondary School level. This includes the Teachers, Teacher Training College Tutors and University Lecturers. Nevertheless, the book will also be useful to Science Club Organisers, the Student or Anyone who wants to experiment on their own. The main audience is the teacher and tutor who work in inadequate teaching and learning conditions trying to encourage students to develop skills to understand, control and wisely use science in their daily life.

This sourcebook is the result of an International Workshop which drew participants from Uganda, Tanzania, Germany and Great Britain.

This participants developed and tested ideas, experiments and activities which can be quickly performed in any classroom using a few low or even no cost materials. Moreover, these practicals do not require a great deal of preparation.

Such easy and enjoyable activities and experiments have a long standing tradition in the history of teaching science. They are often called "hand experiments" because most can be performed without commercial equipment but by hands alone.

You will find ideas and suggestions which are not normally found in science textbooks. We assume that teachers are familiar with most of the traditional experiments which are found in the set textbooks. Therefore we feel there is no need to repeat all of them here. The reader will welcome the ideas on how to bring teaching up to date, since this book provides not only "how to do it" and "what to do", but "why" with clear, simple explanations.

Going through this book, the reader will find that many traditional experiments can be performed as "hand experiments" too. They are more illustrative and more appealing to the students than "black-box experiments" with sophisticated commercial equipment. They encourage the students' creativity to invent other experiments and activities and stimulate their natural curiosity to understand the biology of everyday life.

The suggestions in this sourcebook are stimulants to modern teaching and learning i.e. *teaching and learning by doing.* They should be supplemented with the teachers' own ideas, the students' ideas and ideas from other sources.

We acknowledge with gratitude the professional, technical and financial assistance of all who have contributed to publish this sourcebook particularly to the Ministry of Education and Culture of the State of Hessen (Germany) and the Goethe-Institut for sponsoring the workshop.

Last but not least, we thank Morogoro Secondary School for hosting the workshop from which this source book resulted.

A.S. NDEKI

Chairman of the Executive Committee

Mzumbe Book Project

How to Use This Book

This source book may be used with any Biology textbook. It offers such as variety of ideas that any teacher should find something that fits into their own pattern of teaching. Teaching is such a personal art, that it would be wrong to suggest one simple approach to teaching Biology. To enrich Biology learning we must consider *how* to teach the subject as well as *what* we teach.

This book incorporates a selection of activities for lower secondary level (Form 1 and 2) most of which can be carried out with materials to be found around the school and home. These activities do not require a lot of materials and in many cases none. Wherever possible we selected low cost or no cost materials.

With a basic tool kit of just ten items most of the suggested activities and models can be performed or constructed. These ten tools are all available locally (see appendix).

Time is also a limiting factor for many teachers. The preparation for and carrying out of activities may seem to use up the time available for covering the syllabus. For this reason we have, especially selected so called "hand experiments" which can be done in a very short time and with a minimum of preparation or even with none! So the editorial team has considered the reality of daily school life, to overcome difficulties imposed by lack of time and facilities.

It should not be forgotten that work done outside school time is an essential and integral part of biology as is the classroom teaching. The suggested activities can be carried out and enjoyed by science clubs and individuals. However it should be noted that some of these activities need the guidance and supervision of an experienced adult in order to avoid any risk and to derive the utmost benefit. A pupil may not be aware of the risks of a harmless looking experiment. For this reason our book is not directly addressed to the unsupervised pupil.

P: The *procedure* describes what is needed and how to carry out the activity.

Q: These are suggested *questions,* which the teacher may ask themself or the student. A guide to proper observation and explanation.

O: Possible *observations* are described.

E: The *explanation* of the observation is outlined. The teacher should insist that all observations be discussed and as far as possible, explained. This is an integral part of scientific working.

I: Some activities give *additional information.* Important safety precautions are printed in italics.

We warmly welcome your opinions, suggestions and constructive criticisms of the content and layout of this sourcebook. Please fill in the questionnaire at the back of this volume and send it to us. With your help we can improve the future editions of this book.

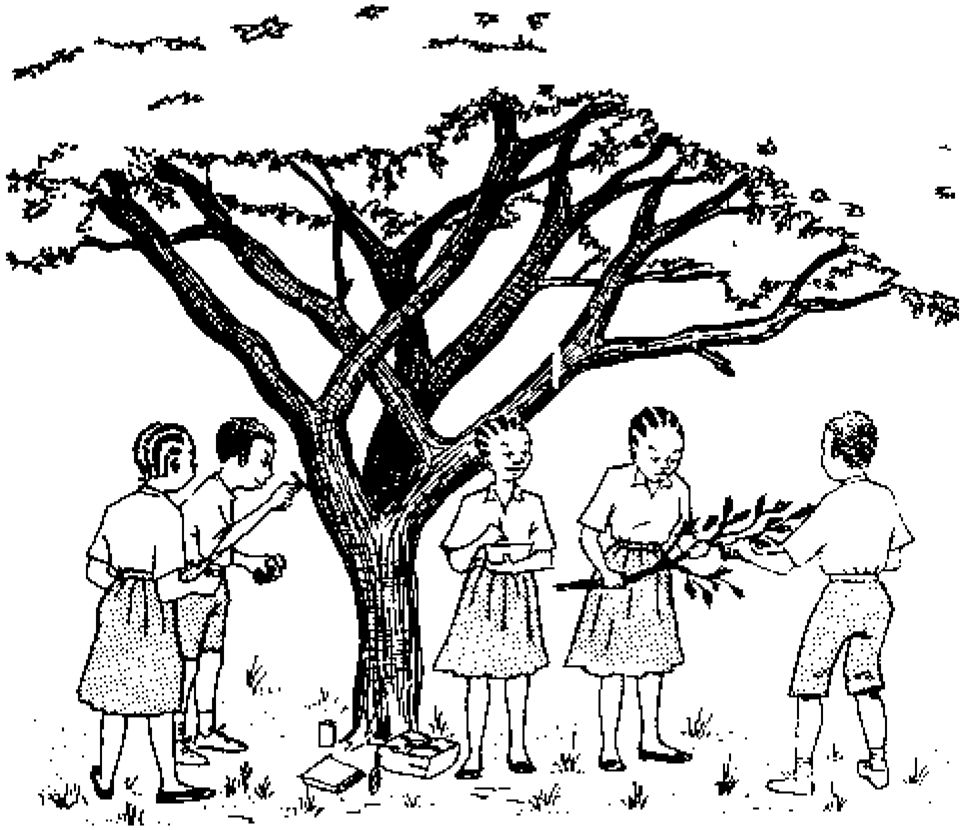
1. Introduction to Biology



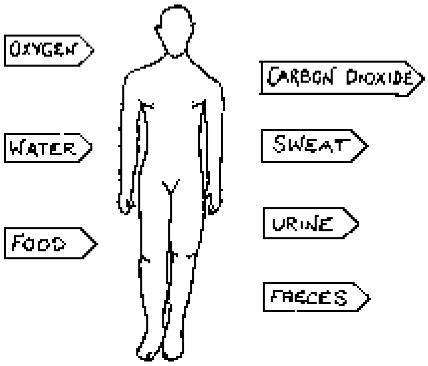
1.1. Characteristics of Living Things

The study of living organisms is called *Biology.* All living things have certain characteristics in common with each other. They are in dynamic equilibrium with their surroundings, constantly taking in some substances and giving out others;. While inside the organism many of these substances undergo changes. This process is called *metabolism* and it enables the organism to maintain a constant internal environment, regardless of external changes. Maintaining such an internal equilibrium is called *homeostasis.*

Seven specific characteristics can be identified, which are shown by all living organisms at some stage during their life. These are growth, respiration, response to stimuli, movement, nutrition, excretion, and reproduction.

Some of these characteristics can be shown by non-living things, but only living organisms carry out all seven of them. In addition living organisms are controlled by a programme of instructions contained in their genes, which can be passed on from one generation to the next. The smallest biological structure which is capable of showing all these characteristics of life is the cell. It can therefore be thought of as the basic unit of life.

1.1.1 Metabolism

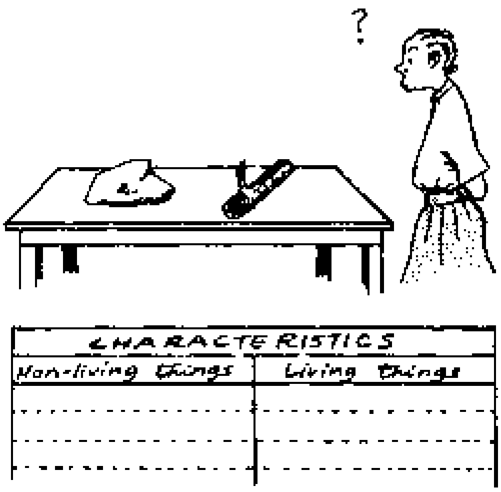


P: Draw an outline sketch of a human being, and make a list of the main substances taken into and given out from the body.

Q: Why are the substances taken in different from those given out?

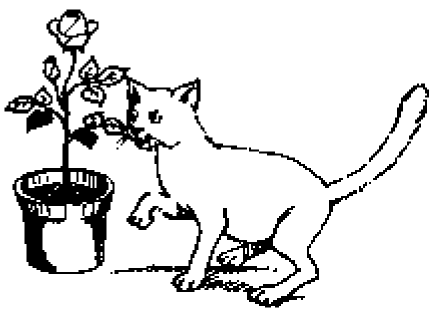
E: Changes to these substances occur as a result of metabolism. Useful substances are retained by the body while useless ones are removed.

1.1.2 Obvious Characteristics of Living Things



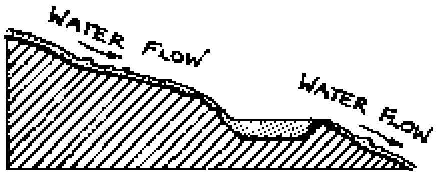
P: Display some non-living things such as a stone, piece of wood, glass of water etc., and list any obvious differences between these things and a living organism (i.e. man). Produce a table from the whole class response.

1.1.3 Other Characteristics of Living Things



P: Display a potted flowering plant and identify the main characteristics of life. Note that many of these are less obvious in plants than in animals.

1.1.4 Equilibrium in Non-living Things



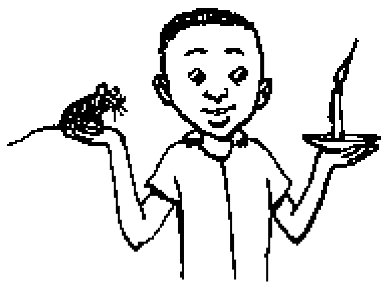
P: Construct a small pond on the school compound with an inlet and an outlet for the water.

Q: What do you observe about the water flow and the water level in the pond?

O: Although the water flows constantly, the level remains the same.

E: Such a phenomenon is called a dynamic equilibrium. Other examples are the flame of a candle and living organisms.

1.1.5 Is a Candle Flame Living?



P: Look at a burning candle. The candle flame can be considered as an example of a process in a state of dynamic equilibrium.

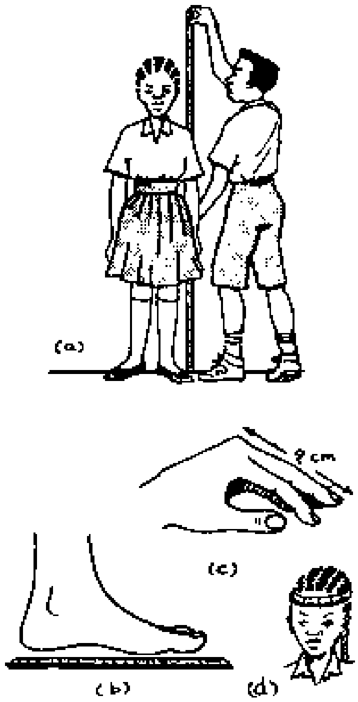
Q: What are the similarities and differences between a candle flame and a living organism.?

E: A candle flame is the result of a metabolic process. The candle wax is burnt to carbon (soot) and other gaseous substances. The shape, colour and brightness of the flame remains fairly constant, but only as long as there is a supply of wax and air. The flame is not self-sustained and cannot reproduce itself.

1.2. Variation in Living Things

In Science we are constantly concerned with measuring things in order to make observations and collect data. However, it is a feature of living things that they vary. When we talk about typical features these are based on average data taken from many observations. The differences between individuals determine how they are grouped together or classified. For instance the differences between separate species will be greater than that normally occuring within the same species. These differences are the result of variation, which can be investigated by observing and measuring various examples of "typical features".

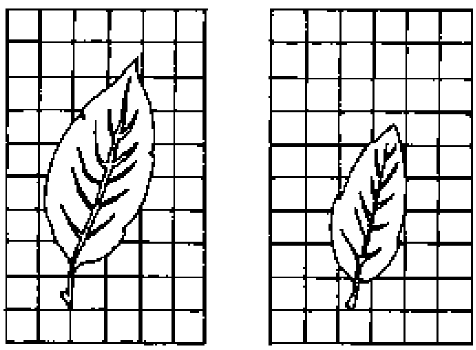
1.2.1 Variation in Humans



P: Using adults measure (a) their height, (b) length of middle finger, (c) length of foot, (d) circumference of head (taken just above the eyebrows). Adults should be used, since in children, variation will be due to different stages of growth.

Q: What is the range of values (maximum and minimum) and the average values for each measurement taken?

1.2.2 Variation in Leaves



P: Take some leaves from the same plant (or from a plant of the same species) choosing some in the sun and some in the shadow. Measure the surface area of each leaf by placing on squared paper. Count only the squares which are more than half covered. Calculate the average leaf area for each type (i.e. shade leaves and sun leaves).

Q: What are your results?

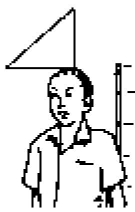
O: Shade leaves are normally bigger than sun leaves.

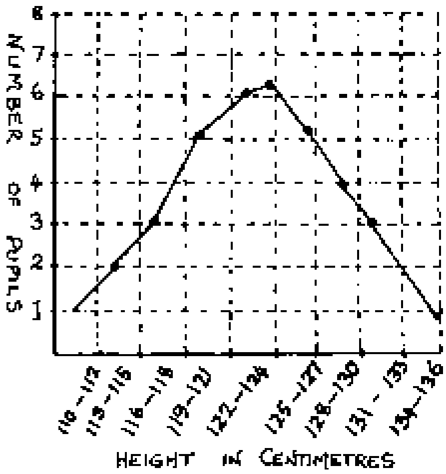
E: Shade leaves get less light, so in order to absorb sufficient light for photosynthesis, the surface area is usually larger.

1.3. Collecting and Recording Data

Human progress is due largely to his ability to measure and collect data with ever greater precision and accuracy. Pupils should be taught general skills in obtaining data by carrying out simple experiments. They should be introduced to basic measuring techniques and encouraged to develop skills in the recording and graphical analysis of data. It should be stressed that data be compiled from as many measurements as possible in order to improve their validity.

1.3.1 Data on Height





P: Obtain the heights of all the student in the class (in centimetres). Use these heights to divide the students into groups (i.e. 110-112 cms, 113-115 cms etc). Count the number of pupils in each group. Plot a graph of height against numbers.

Q: What does the graph look like and what does this show?

O: A normal distribution curve is obtained showing that a few students are very tall, a few are short, but most of them come somewhere between these extremes.

E: Members of a species can vary in size between a maximum and a minimum value, but most individuals are near the middle of this range.

1.3.2 Analysis of Pulse Rate

	STRESS					REST					
MINUTES	0	2	4	6	8	10	12	14	16	18	20
FIRST GIRL											
SECOND GIRL											

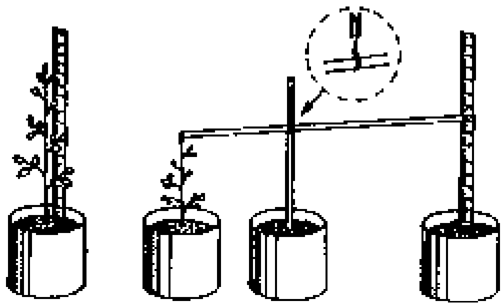
P: Take the resting pulse rate of ten students, then ask them to run around the school compound for two minutes. Take the pulse of each student at two minute intervals until the pulse returns to normal. For each student plot a graph of pulse rate against time.

Q: Which pulse rate was the highest and which pulse returned to normal most quickly?

O: Each curve of pulse rate will be slightly different

E: This is due to differences in levels of physical fitness of each student. The less fit ones generally reach a higher pulse rate, which takes longer to return to normal.

1.3.3 Growth Measurement



P: Take a seedling in a pot (or use a plant in its natural environment) and attach a fine thread to a light stick (as shown above). Alternatively use the simple method for measuring growth. Make measurements at fixed intervals (say 2 or 3 days). Devise a method of presenting your data graphically.

1.3.4 Weight Increase by Germinating Seeds

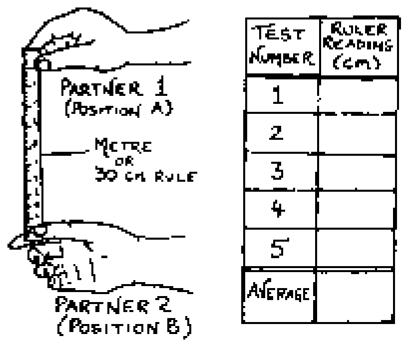
P: Place 10 bean seeds between pieces of wet newspaper. Place a second group of 10 beans between dry paper. Measure the weight of each group of beans at daily intervals, and also record any observations.

Q: What are the differences in weight between the two groups of seeds?

O: The soaked beans swell and the weight increases. No change occurs in the beans on dry paper.

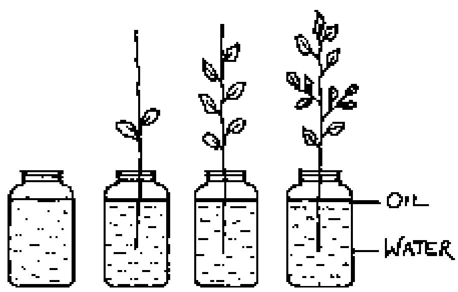
E: The beans on the wet paper have absorbed water and started germinating. The dry beans did not.

1.3.5 Obtaining Averages



P: Hold a ruler or strip of wood as shown. Ask your friend to place a thumb and forefinger on either side of the ruler at mark O, but without touching it. Release the ruler. Your friend should try to catch it as quickly as possible. Note where the ruler was caught and measure the distance of the point from mark O. Repeat 5 times and take the average.

1.3.6 Keeping a Written Record



P: Pick branches with different numbers of leaves and place each one in containers with the same volume of water (To avoid loss by evaporation pour some oil on the surface). Record the daily loss of water in each container

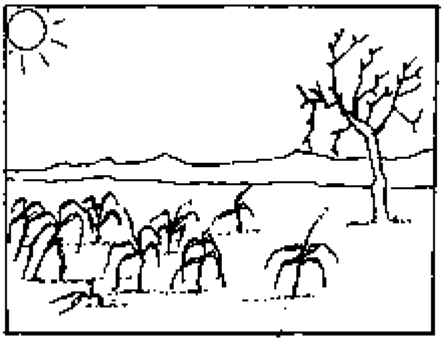
O: The more leaves on the branch, the greater the loss of water.

E: Leaves are the organs where most water is lost by the plant

1.4. Scientific Method

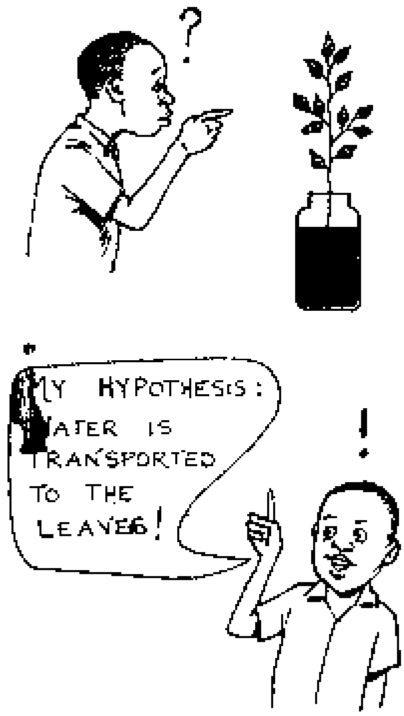
Being a scientist is not just a matter of learning a lot of facts. It is more a way of thinking. Being scientific means first making careful observations of objects, organisms or events and then suggesting possible explanations. This explanation is called an *hypothesis.* This should then be tested by designing a suitable experiment or series of investigations. If it does not turn out to be true then a new hypothesis must be proposed and tested by a different set of experiments. As soon as an hypothesis is found to be true it can be applied to other, similar situations.

1.4.1 From Observation to Application



Observation - Without water from rain or by irrigation, the soil around plants eventually becomes dry. This is particularly obvious when plants are grown in pots or other containers. In extreme cases the soil gets so dry that the plant dies.

Hypothesis - the plant requires water, which it absorbs from the soil through its roots. This water is then transported through the plant.

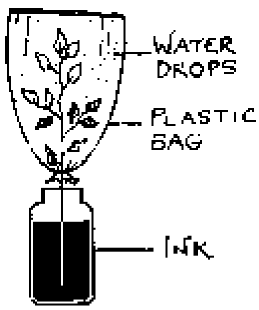


Experiment 1: Place a branch of a non woody plant in a solution of coloured ink.

Observation: After some time the coloured ink is seen in the stem and leaves of the plant. (Also in the petals of the flowers - if they are present). A lot of liquid has been absorbed.

Conclusion: The plant transports water upwards through the stem to the leaves where most of it is probably lost.

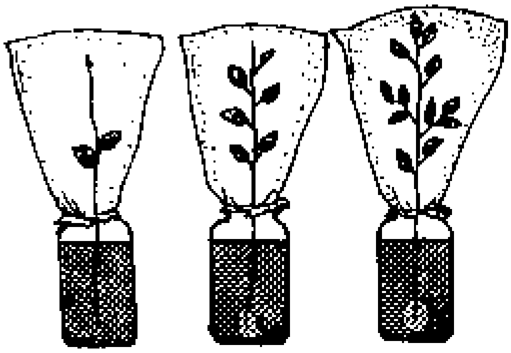
Hypothesis: Water is transported to the leaves where it is lost.



Experiment 2: Using the same materials, as experiment 1, place a plastic bag around one of the branches and tie it tightly to the stem with string or rubber bands.

Observation: Clear (uncoloured) water collects in the plastic bag.

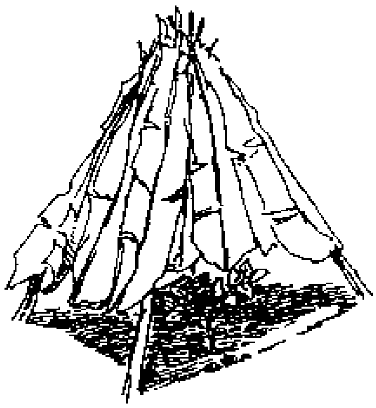
Conclusion: Water evaporates from the leaves and condenses in the plastic bag. The dissolved materials (the colour in the ink) remain in the plant.

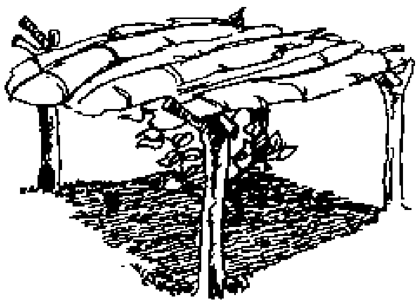


Experiment 3: Using the same materials, place one plastic bag around a single leaf and another around a branch with many leaves.

Observation: More water collects in the bag enclosing the larger number of leaves.

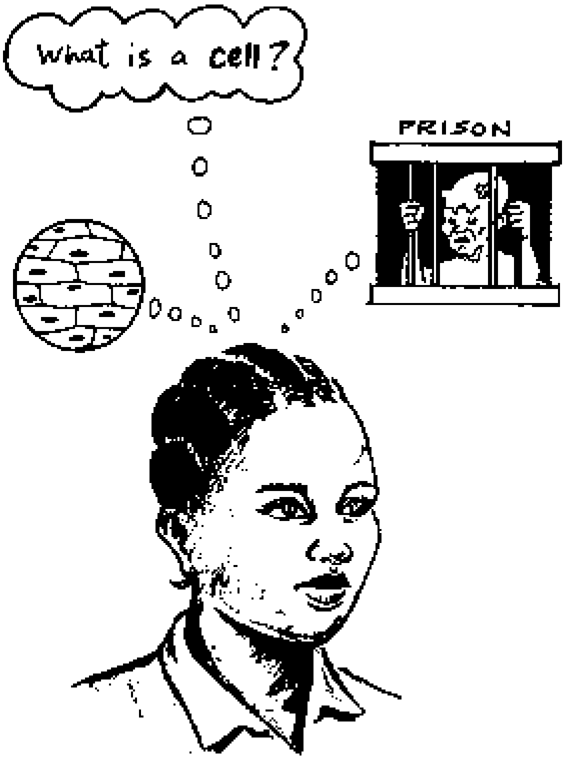
Conclusion: Since water is lost from the leaves of a plant, the larger the number of leaves, the greater the amount of water lost.





Application. For better growth, plants need to be Supplied with an adequate amount of water. To reduce excessive water losses by transpiration, special methods of cultivation are used. Can you match the above pictures to these methods?

2. Cell Structure and Organisation

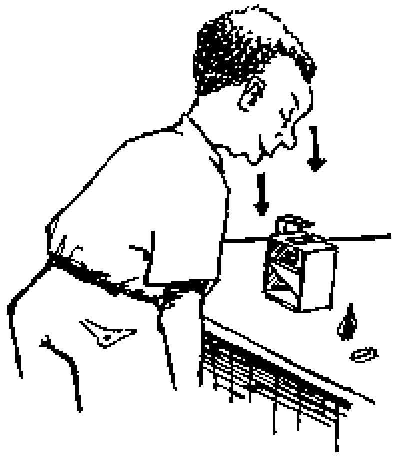


2.1. Cells - Tissues - Organs

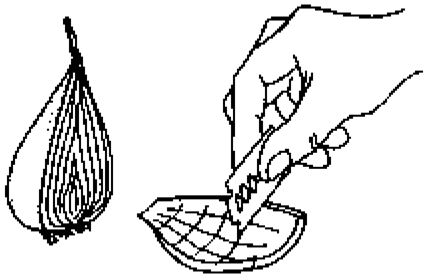
Cells are the basic units of all organisms. Some organisms, e.g. protozoa, are composed of only one cell (unicellular), but most consist of very many cells (multicellular). Certain features like cell membranes, cytoplasm and nucleus are common to all cells. Most cells are specially adapted in their size, shape and chemistry to carry out particular functions (for example animal and plant cells). There is a constant movement of substances into and out of cells which is controlled by the membrane. Almost all cells are too small to be seen with the unaided eye, and so a microscope is needed to observe them.

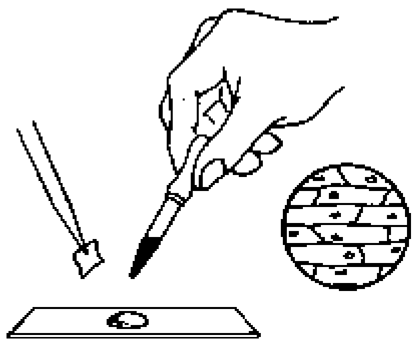
Cells of the same function group together to form tissues. Different tissues form organs and different organs form organ systems. All organ systems together make up the complete organism.

2.1.1 Looking at Onion Cells



P: Slice an onion into two, lengthways and take out one of the thick leaves from inside it. Cut the inner thin surface of the leaf into squares of 2 x 2 mm. With a pin or needle place one of these squares in a drop of water on a slide or any small piece of window glass. Lower a cover slip carefully on to it and examine the cells with a microscope as described in the appendix. Make a drawing of what you see.



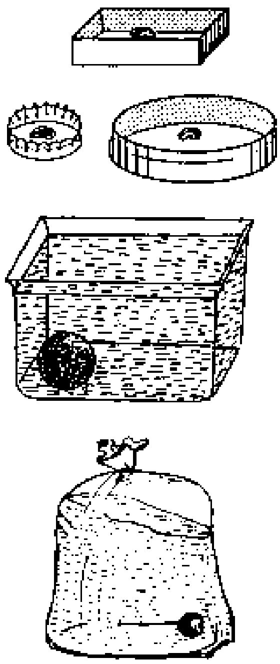


Q: What do the cells look like?

O: Onion cells appear with a dark line around them (the cell wall) and with a dark oval body inside (the nucleus). They are usually packed closely together.

I: The cells can be seen more clearly if a drop of iodine is added to the slide.

2.1.2 Simple Models of Cells

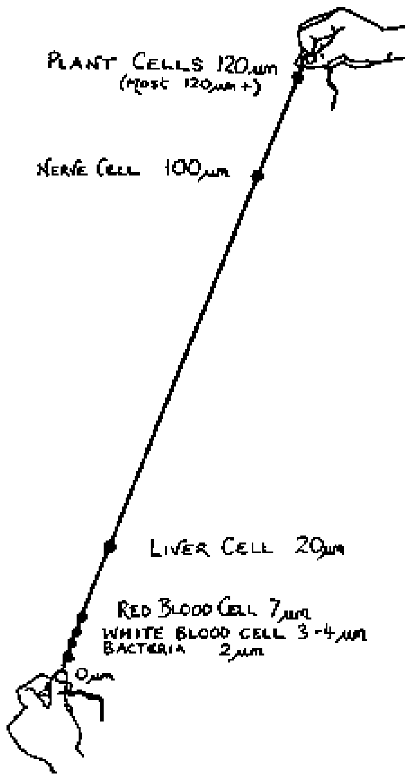


P: Take a small stone or seed and place it in the tray of an empty match box, in a soda bottle top or in any other small container. Prepare a water filled container or plastic bag with seed or stone to represent a nucleus.

Q: What do the sides of the containers, the seed and the space between them represent?

E: The sides represent the cell membrane, the seed, the nucleus and the space between shows the cytoplasm.

2.1.3 Size of Cells



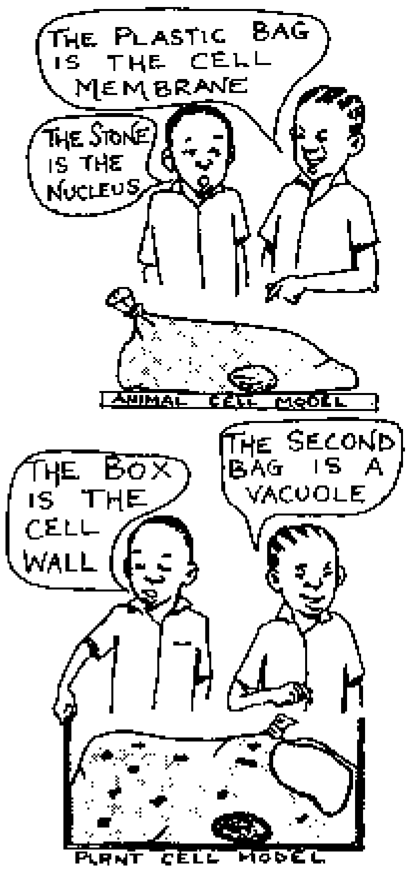
P: Take a piece of string (or chalk a line on the ground) about 60 cm long. Mark distances as shown in the diagram above. The lengths represent the sizes of different types of cells enlarged one thousand times.

Q: How many times bigger is a plant stem cell than a blood cell?

E: 50 times.

I: Although almost all cells are too small to be seen with the unaided eye, they show a wide range of sizes (about the same range as a mouse and an elephant).

2.1.4 Animal and Plant Cells

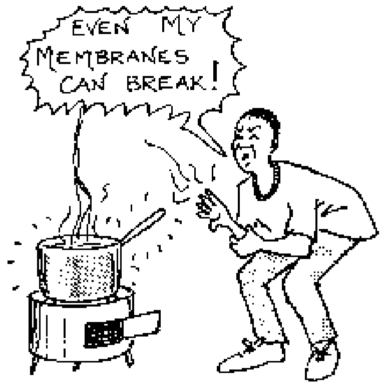


P: Use a plastic bag to represent the cell membrane, a large seed or a stone to show the nucleus and water in the bag for the cytoplasm. For the plant cell place the bag into a cardboard box to show the cell wall. Trapped air or a small air filled plastic bag will act as vacuoles. Small cuttings of leaves can represent the chloroplasts.

Q: What are the main differences between an animal and a plant cell?

E: Plant cells have chloroplasts, cell wall and a large vacuole whereas animal cells do not. Also plant cells are usually larger and have a more definite shape than animal cells.

2.1.5 Breaking Membranes



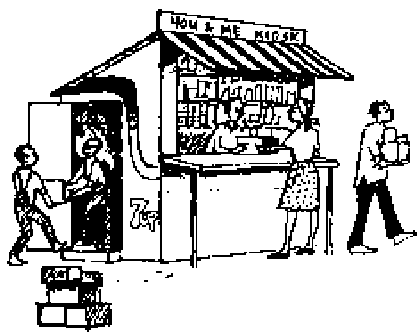
P: (a) Put a grape or an uncut segment of orange in your mouth. Leave it for a few moments without moving your mouth, then chew it slowly. (b) Heat a deep coloured fruit, flower, leaf etc. in water.

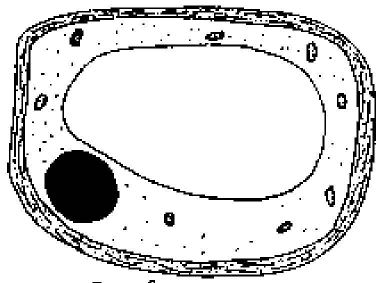
Q: Do you taste the fruit before or after chewing? What can you observe about the colour after heating?

O: The fruit can be tasted after chewing and colour is found in the water after heating.

E: The juices containing sugar and other chemicals, which give the fruit its particular flavour, are found inside the cells. They are only released when the membranes are broken, for instance by mechanical forces like chewing and heating.

2.1.6 "Kioski" as a Cell





PLANT CELL

P: Observe what happens at a kiosk where goods are sold.

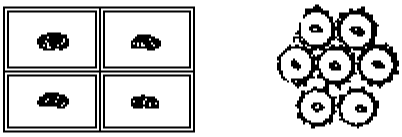
Q: How does the activity at a kiosk compare with a living cell?

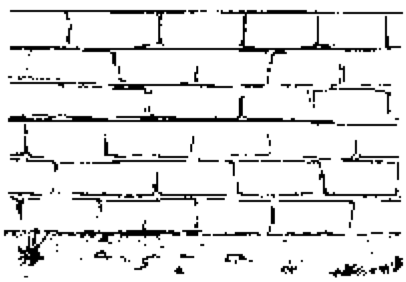
E: A kiosk is partly like a cell because

- in a kiosk only specific things move in and out.
- things are taken in and passed out at different rates.
- different types of kiosk sell different goods (just as different cells carry out different functions).

Unlike a cell, the kiosk is not self sustaining and the things given out are the same as those taken in.

2.1.7 Models of Tissues



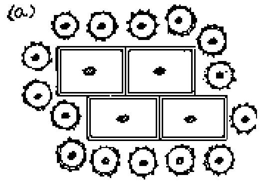


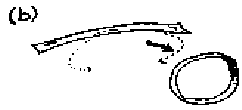
P: Group match box "cells" and bottle tops (see 2.1.2) together to form tissues. Cells and tissues can also be demonstrated by bubbling air through a soap solution with a drinking straw.

Q: How are cells arranged to form tissues?

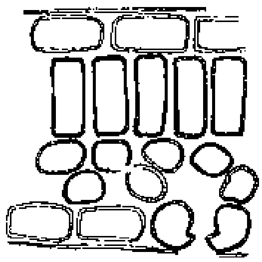
E: In tissues the cells are all of the same type and are closely packed together like bricks in a wall.

2.1.8 Models of Organs





PAPER STRIP MODEL

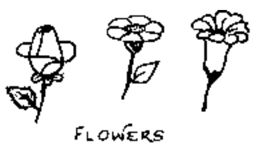


P: Arrange different types of tissues together to form the basic structure of an organ. This can be done by using the tissues formed from match boxes and soda bottle tops (a).

Q: How are tissues arranged to form organs?

I: A model of an actual organ (like a leaf) can be constructed from strips of paper, to show the different types of cells and tissues present (b).

2.1.9 Display of Organs



FLOWERS

FRUITS

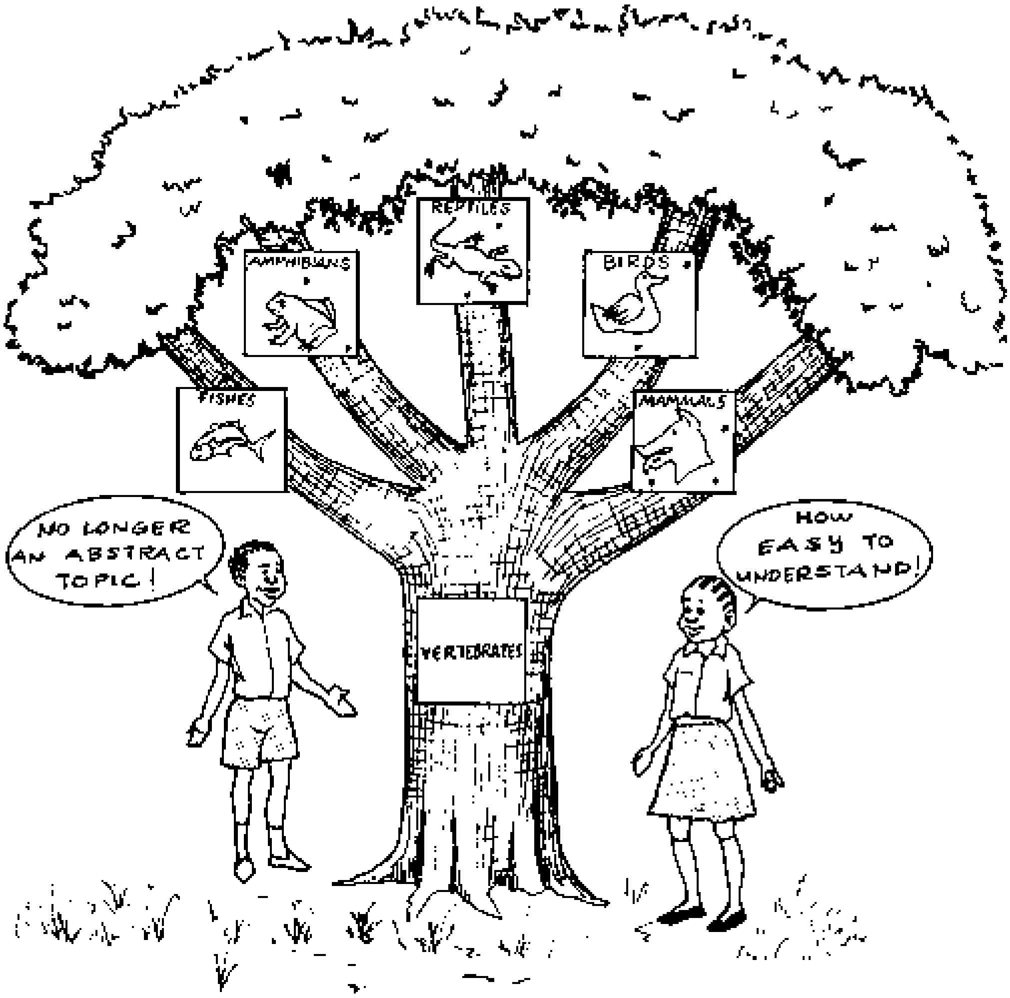
LEAVES

P: Collect leaves, flowers, seeds and roots from different plants and arrange them in a display. List the function of each structure.

Q: What are the structural similarities between organs performing the same functions?

E: Organs carrying out similar functions are similar in structure, i.e. food storage organs are swollen, leaves are thin and flat, flowers are coloured etc.

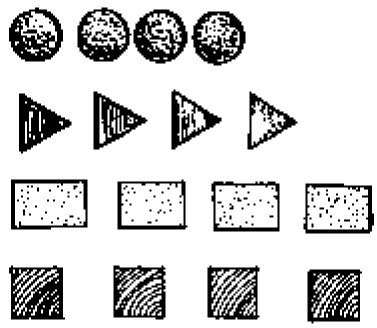
3. Classification of Living Things

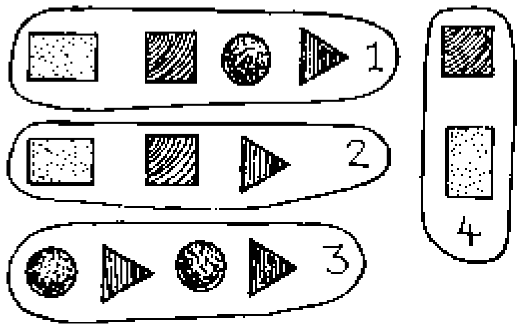


3.1. Biological Classification

Classification is the sorting of things into separate groups in such a way that all items in the same group have certain features in common. Books in a library, types of goods in a shop, vegetables in a market and notes in a bank are all examples of a simple system of classification. Biological classification is more complicated because of the large numbers and diversity of living things, but the general principle is the same. Organisms are placed into groups according to their structure, appearance and the way they live, based on similarities and differences between them. Organisms are first placed into large groups, whose members may only have a few common features, then into increasingly smaller groups where the members have a greater number of similarities. The smallest such group is called a *species.* Organisms of the same species can usually be recognised because they look very similar to each other. Human Beings all belong to the same species. Other examples of a species include a lion, a chicken, a mango tree or a cassava plant. Classifying organisms in this way allows us to recognise them, to study them more easily and to investigate the relationships between them.

3.1.1 Arranging Shapes



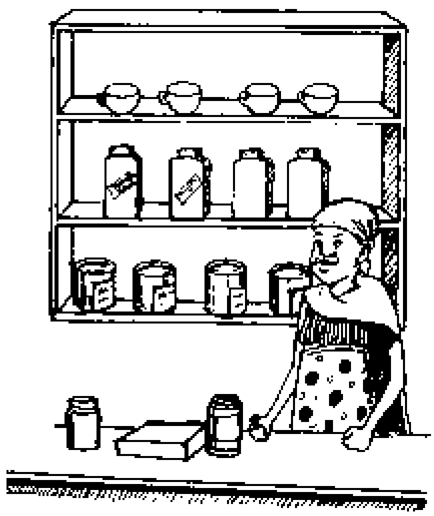


P: Make four of each of the following shapes: squares (3 cm x 3 cm) triangle (3 cm sides) rectangles (3 x 4 cm) circles (3 cm diameter). Mix the shapes and then sort them according to a chosen feature.

Q: How many different ways can you find of grouping the shapes?

O: At least 4 can be found.

3.1.2 Classification at the Duka



P: Observe how the goods at the local shop are arranged on the shelves

Q: Can you find a pattern in the arrangements on the shelves?

E: The goods will be arranged firstly in large groups, ie. foodstuffs, non-food stuffs (medicines etc.), and then into smaller groups such as foods in tins, foods in bottles, etc..

3.1.3 Find a Missing Person

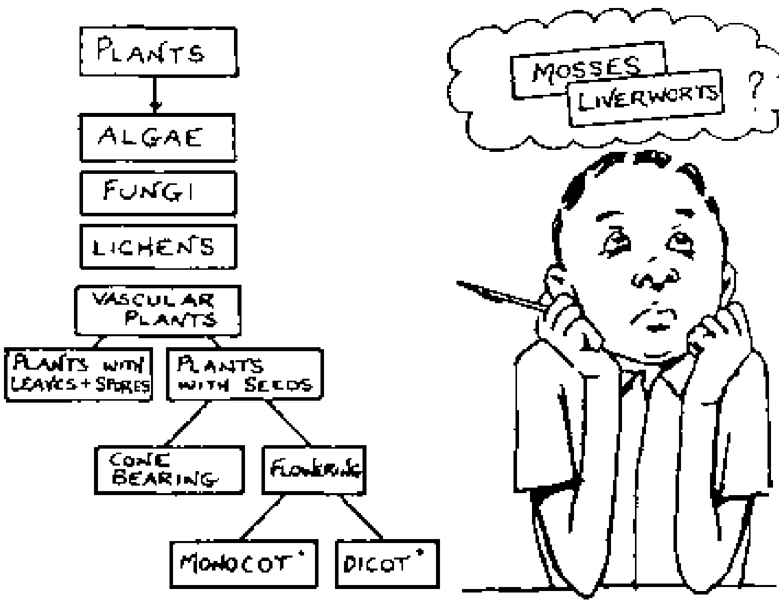
P: Imagine that you have been asked to find one particular person on earth.

Q: What information would you require?

O: Continent, country, region, district, ten cell block, house, name of person.

E: This procedure can be compared to the process of classifying organisms, firstly in large groups. (equivalent to a continent) then smaller groups (equivalent to country, region etc).

3.1.4 Classification Charts

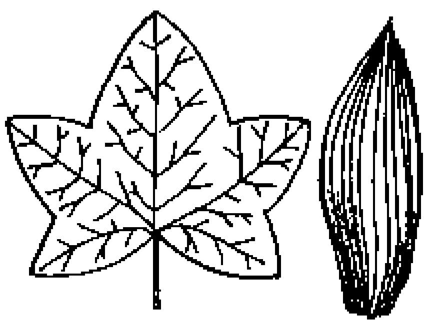


P: Prepare cards giving the names of the main groups of living organisms. Arrange them to show how the living world can be classified into kingdoms, phyla and so on.

E: Kingdoms can be arranged horizontally, phyla vertically.

I: Pictures from magazines or newspapers can be used to illustrate the cards. After mixing use the cards for oral assessment.

3.1.5 Classifying Leaves

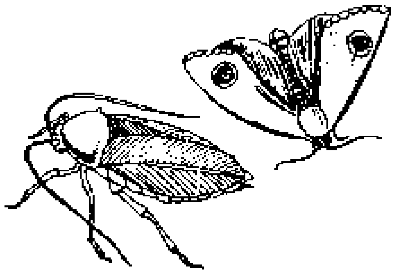


P: Collect leaves from different plants. Make large groups and small groups using as many different characteristics as possible.

Q: How many ways did you find to group the leaves?

E: Characteristics like shape, colour, vein pattern, leaf margin etc. can all be used.

3.1.6 Variety in Insects



P: Collect at least 5 different types of insect. Identify the obvious external characteristics of each specimen.

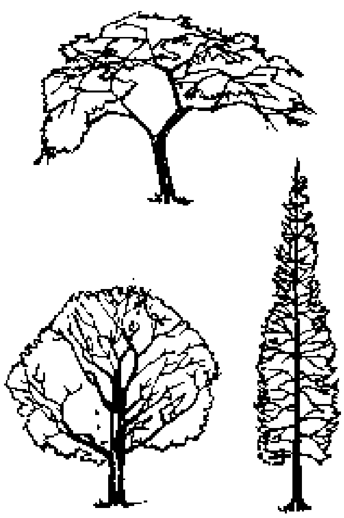
Q: What features are common to all insects, and which ones are found only in one particular type?

O: Features like jointed legs, external skeleton, wings and three body regions are found in all insects. Features such as number of wings, shape of wings, shape of body etc., are specific to one type.

3.2. Looking at the Diversity of Organisms

The concept of classification should not be learned by memorising long lists of complicated names, or attempting time - consuming and difficult identification exercises. The diversity of living organisms and the complex interactions between them, should be studied by field work wherever possible. The school compound can provide a rich source of material which is readily accessible. When necessary specimens can be collected and further investigation carried out in the classroom. Please note, however, that removing of organisms from their natural habitat should be restricted to common types and any disturbance of the environment kept to a minimum.

3.2.1 Identifying Trees

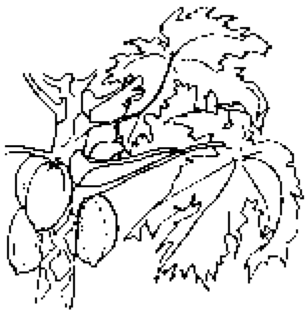


P: Try to find as many different types of trees as possible in the school compound. Make a note of their particular characteristics, such as overall shape, the arrangement of branches, colour of trunk, colour and shape of leaves etc.. Record the names of any trees which you recognise.

Q: Which characteristics are most useful for identifying the trees and which are the least useful?

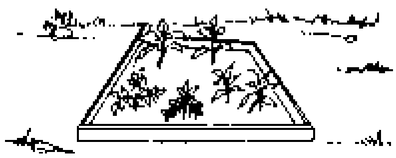
E: Best features are shape of leaves, types of fruit and flowers. Arrangement of branches, bark colour and size are less useful as they are more variable.

3.2.2 Food Plants



P: Take a walk around your local shambas and record all the types of food plant you see. Make a brief description of each plant. Exchange your description with a friend and see if they can identify the plants you have seen.

3.2.3 Sampling with Squares



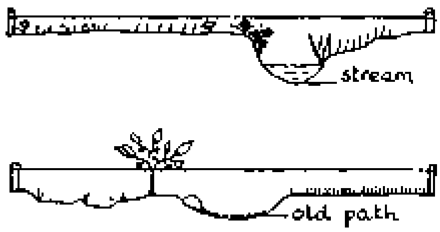
P: Construct a square with 1 m sides from sticks or thin pieces of wood. Choose an overgrown piece of ground on the school compound and place the square on it. Record the names or descriptions of organisms found inside the square.

Q: What differences do you find in the organisms found in different places?

E: The differences will depend on various factors, such as whether the ground is cultivated or not, if it is flat or on a slope, dry or wet and so on.

I: This method can also be used to compare the numbers of organisms found in different habitats. Squares used for sampling are called *quadrats.*

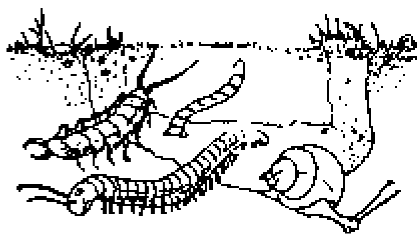
3.2.4 Sampling with Lines



P: Take a piece of string 20m long and divided into 1 m lengths by tying knots. Stretch the string over a piece of ground between two sticks. Working from one end, record all the organisms which the line touches and their distance from the beginning.

E: The organisms found will vary according to the ground over which the string passes. By choosing a site which shows variation, more differences will be found. This technique is called a *line transect.*

3.2.5 Life under a Stone



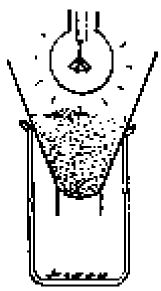
P: Choose a large stone which has not been disturbed for some time. Lift it and record all the organisms you find there.

Q: Can you explain why there are no plants present?

E: No plants will be found since there is no light under the stone. This means this is a very specialised habitat and only certain organisms can live there.

I: Compare the organisms under the stone with those living on top of it (i.e. mosses, lichens and other small plants.)

3.2.6 Life in the Soil



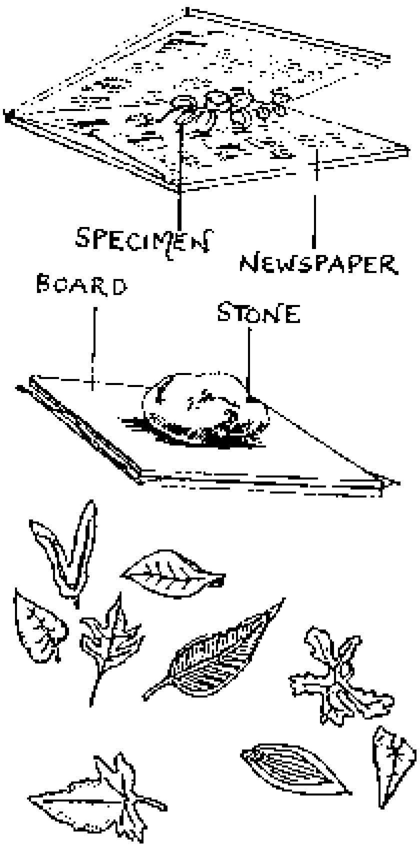
P: Collect about 250g of fresh soil and place in a funnel with a piece of gauze across the neck. Arrange a lamp directly above the funnel and a small container below.

O: Small organisms from the soil collect in the container.

E: Soil organisms usually prefer dark, damp and cool conditions, so the heat and light from the lamp drives them downwards until they drop out of the funnel. The organisms collected can be used to show the range of organisms found in the soil.

3.3. Collecting and Displaying Specimens

3.3.1 Simple Plant Press



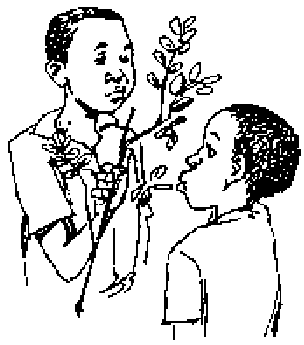
P: Cut two pieces of stiff cardboard, hardboard or thin wood about 30 cm square. Place layers of newspaper between the squares, and arrange the plant specimens between the sheets of paper. Tie together with string or put a heavy weight like a brick or stone on top and leave until the plants are dry.

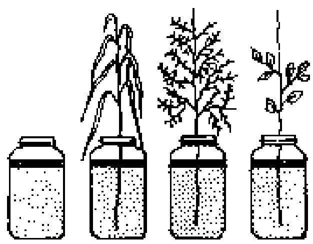
I: The newspaper may need to be replaced with dry paper to dry the specimens completely.

3.3.2 Making an Herbarium

P: An herbarium is a collection of plant leaves or flowers. After drying in a press they can be fixed to paper with sellotape or glue. Thick paper in a loose leaf file is best, but exercise books can be used instead. Whenever possible give the name of the specimens in English. The place where it was collected and the date should be included. The work of individual pupils can be built into a reference collection or used as a display.

3.3.3 Making a Species Collection

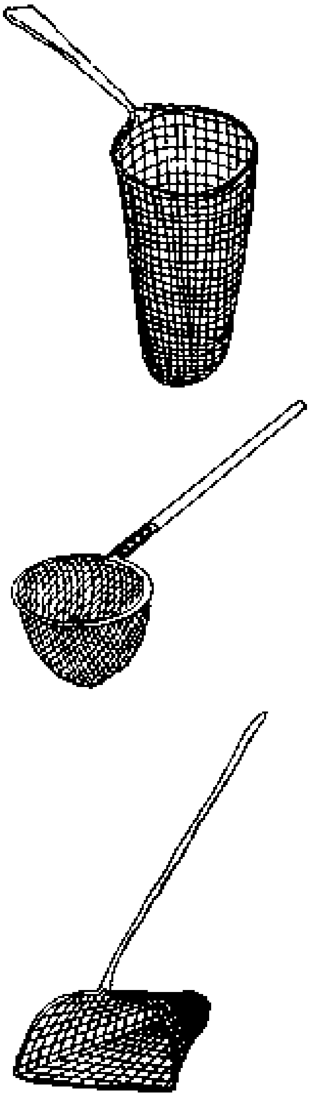




P: Plants which cannot be pressed or other specimens, such as branches of trees, seeds, fruits and small animals can be displayed on a science table or science corner. Many such specimens can be allowed to dry, but if this causes too many changes, they can be kept in jars of water for short periods or in spirit for longer periods.

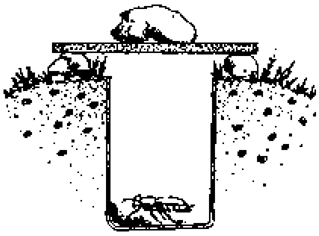
I: A few drops of domestic bleach in the water will reduce rotting of the specimen by fungi or bacteria. Make sure all specimens are properly labelled and arranged in a systematic and logical way, with a clear indication of what the display is intended to show. This could be organisms in a pond, plants by the roadside, insects found in the home etc.

3.3.4 Collecting Nets



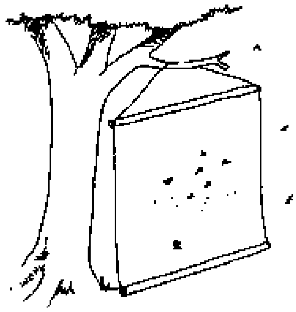
P: A wide mouthed sweep net can be made easily from a stick, some wire and mosquito netting. With this net insects can be knocked off plants. Wire netting is more suitable for water sweep nets.

3.3.5 Pitfall Traps



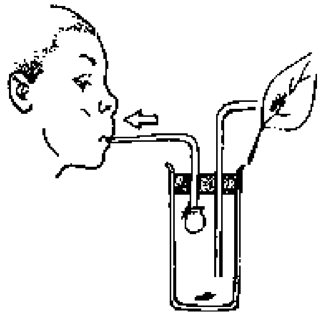
P: A jam jar or tin can be buried in the soil with the rim at ground level. Punch a few holes in the bottom of the tin to let water escape. Cover the tin with wood or a stone to keep rain out. Some fresh food will attract insects.

3.3.6 Sticky Paper Trap



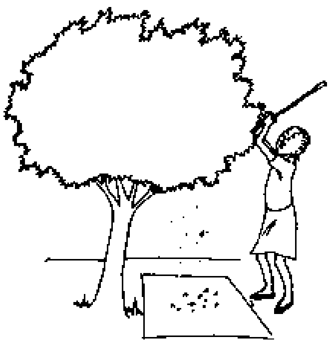
P: Coat a piece of stiff paper with honey, jam or a strong sugar solution. Hang it from a tree. Small flying insects will become stuck to the paper.

3.3.7 Pooter



P: A pooter for collecting small animals can be constructed as shown above, from a variety of jars or tins. Cover the tube through which air is sucked with net or cloth to avoid the specimen being sucked into the mouth!

3.3.8 Beating with a Stick



P: Place a white cloth or sheet of newspaper under a tree or bush. Beat the branches with a long stick and the insects fall onto the sheet.

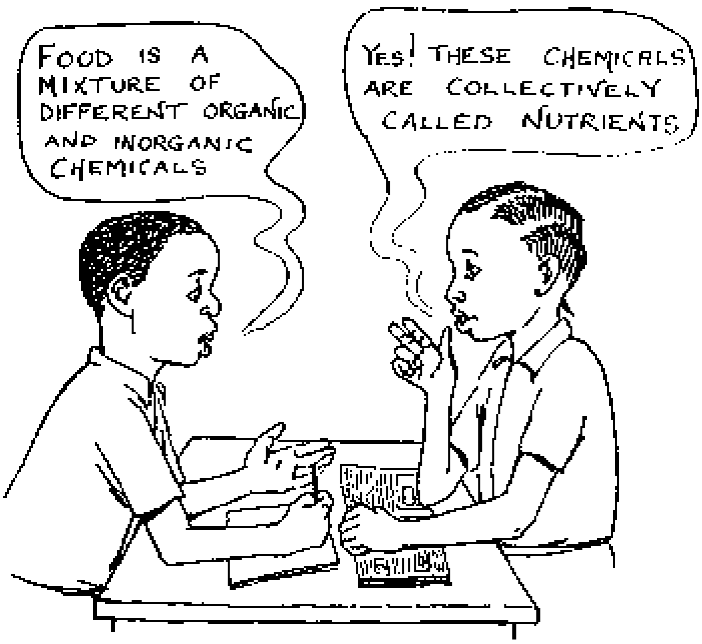
4. Nutrition

4.1. Organic and Inorganic Food Substances

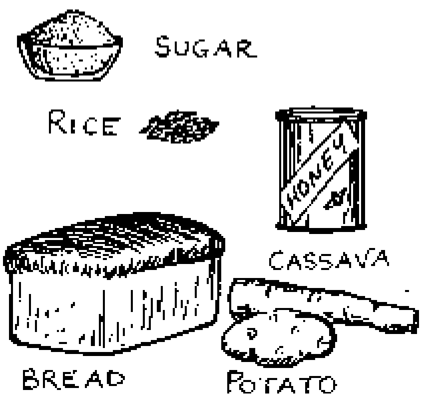
Foods are a mixture of different organic and inorganic chemicals, collectively called *nutrients.* These provide the body with (i) energy (ii) materials for growth and repair (iii) substances for regulating metabolic processes. The main classes of nutrients are carbohydrates, lipids (fats and oils), proteins, vitamins and minerals. Carbohydrates contain the elements carbon (C), hydrogen (H) and oxygen (O), and include sugars, starch and cellulose. With the exception of cellulose, the tough fibrous material found in plant cell walls, they usually provide energy.

Lipids also contain C, H and O, but in different proportions to the carbohydrates. Their main function is storage of energy but they are also important for insulation, protection, formation of hormones and synthesis of cell membranes. Proteins contain C, H and O, but also very importantly the element nitrogen. (They sometimes contain sulphur and phosphorous as well). Proteins are very large and complex molecules, composed of long chains of smaller molecules called amino acids. These provide materials for growth and repair of tissues.

Vitamins are a diverse group of organic compounds which are involved in cell metabolism. They are only required in very small amounts but they are vital for good health. Minerals are small, inorganic ions such as calcium (found in bones), iron (found in red blood cells) and iodine (a component of the hormone thyroxine). Although not really a nutrient, water forms an essential constituent of food. It performs so many functions that life would not be possible without it.

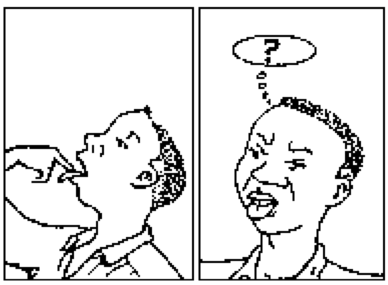


4.1.1 Carbohydrate Collection



P: Make a collection of food-stuff: containing carbohydrates and display these in a science corner of the classroom. Clearly label all specimens.

4.1.2 Tasting Carbohydrates



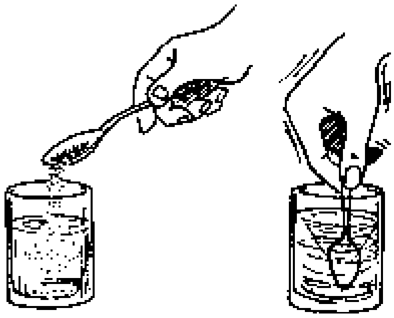
P: Place a little starch on the tongue and note the taste. Next place a little sugar on the tongue and also note its taste.

Q: Describe the taste of starch and sugar

O: Starch is tasteless while sugar tastes sweet.

E: Sugar molecules are small and soluble. They can be detected by the taste buds, to produce a sweet taste. Starch molecules are large and insoluble and cannot be tasted.

4.1.3 Carbohydrate Solubility

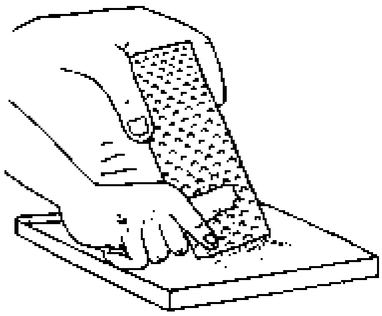


P: Place a teaspoon of sugar in a glass of water and stir. Repeat the experiment using a teaspoon of starch in a glass of water.

Q: What happens to sugar and starch?

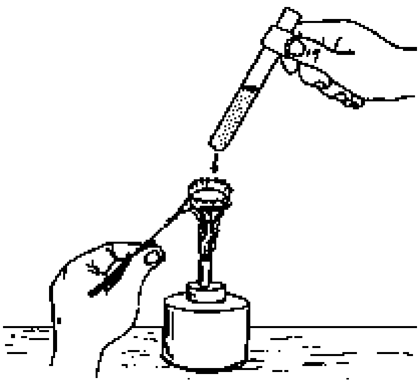
O: Sugar dissolves in water while starch does not.

4.1.4 Preparation of Starch from Cassava



P: Grate the cassava and soak the resulting material in water mixing thoroughly. Strain the liquid from the fibres. Leave the liquid to settle and the starch can be easily seen at the bottom of the container. Decant off the water. Starch could then be dried and stored for future use.

4.1.5 Heating Carbohydrates



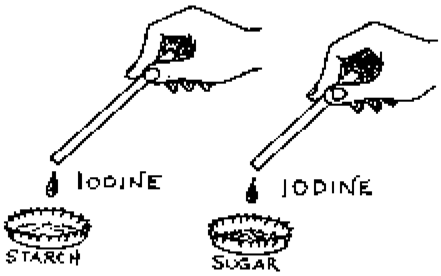
P: Place a small amount of sugar in a bottle cap and heat as shown. Hold a water filled test tube or glass over the vapour from the cap. Repeat the experiment using starch.

Q: What do you observe?

O: Water will condense on the tube and black carbon will remain in the cap.

E: Carbon and water are produced when carbohydrates like sugar and starch break down.

4.1.6 Iodine Test



P: Place a small amount of sugar in a bottle cap and a small amount of starch in another. Drop a little iodine into each cap.

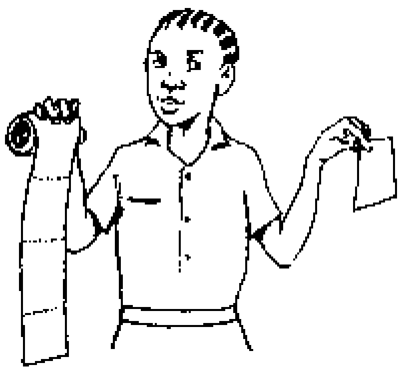
O: The starch and iodine produces a blue black colour while there is no colour change with sugar and iodine.

I: Test other foods such as bread, potatoes etc..

4.1.7 Simple Sugars in Plants

P: Plants contain mono and disaccharides. Sucrose (cane sugar or table sugar) is formed from joining together of a fructose molecule and a glucose molecule. Grapes contain glucose. Simple tasting of fruits will confirm the presence of simple sugars by sweetness. Try heating fruits in water to obtain extract.

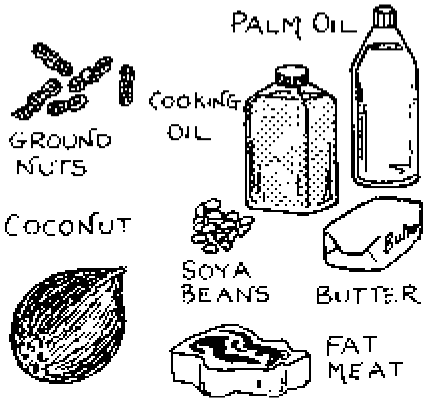
4.1.8 Simple Sugar Model



P: To illustrate the long chain structure of polysaccharides use strings of beads, toilet roll or a chain of pupils. Each long chain is formed by smaller units which represent simple sugars.

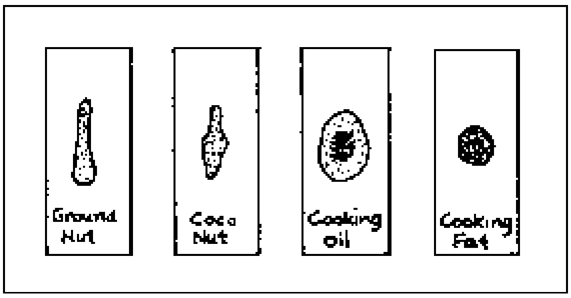
Can you think of any other simple examples using bottle caps, beans, seeds and stones?

4.1.9 Foods Rich in Fats and Oils



P: Make a collection of foods rich in fats or oils. These could be butter, margarine, animal fat, milk, egg yolk, palm oil, groundnut oil, cod-liver oil and coconut oil

4.1.10 Effect of Fats and Oils on Paper



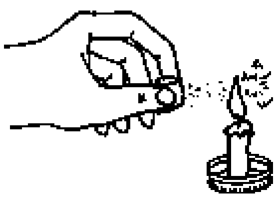
P: Press or rub groundnuts, coconut, cooking oil, milk, butter and cooking fat onto paper.

Q: What happens to the paper?

O: The substances make a grease mark which is transluscent when held up to the light, but looks dark when placed on a desk.

E: The grease marks show the presence of fats and oils in the food items. Simple carbohydrates manufactured by plants can be changed into oils for storage purposes in fruits and seeds.

4.1.11 Orange Peel Oils



P: Squeeze a fresh orange or orange peel near a flame.

Q: What happens?

O: The spray from the peel burns with bright flashes

E: The peel of oranges contains volatile oils. These do not make a lasting grease spot.

4.1.12 Solubility of Fats and Oils

P: Mix fats or oil with water. Then in a separate container mix fats or oils with a small amount of petrol.

Q: Look through the two liquids is there a difference?

O: Oils and fats dissolve in organic solvents such as petrol or alcohol, but not in water. However, vigorous shaking with water will produce a cloudy or milky emulsion of suspended fat droplets.

4.1.13 Stable and Unstable Emulsions

P: To demonstrate stable and unstable emulsions, add oil to water and shake. In another container add oil and a little soap solution to water and shake.

Q: What is the difference between the two samples?

O: Oil forms a suspension with water which separates later into two layers, while a milky suspension in soap and water persists longer.

E: The soap acts as an emulsifier breaking down the oil into smaller droplets. In human digestion bile acts in a similar way by emulsifying fats and oils.

4.1.14 Dangerous Oils

THIS IS DANGEROUS!

P: Mineral oils are not edible and can be dangerous. Heat carefully small samples of mineral oils.

Q: What do you notice about the smell?

I: *It is dangerous to inhale petrol or mineral oil fumes?*

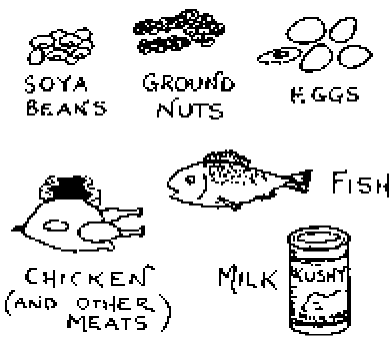
4.1.15 Hot Oils

P: Hot oils are dangerous. Never add water to hot oil (which boils at 300 degrees C).

Q: Why does adding water make the oil spit?

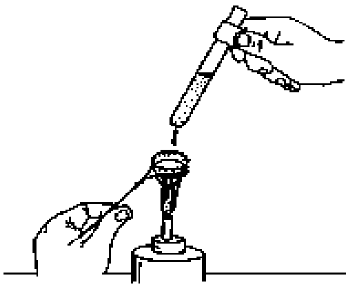
E: *Water in the oil evaporates so quickly that the vapour causes fat to spit out with it and this may catch fire.*

4.1.16 Protein Collection



P: All plants contain a certain amount of protein, but some have a high concentration particularly seeds like cow pea, groundnut, soya bean. Collect samples of plant food stuffs and make a display or drawings for the science corner.

4.1.17 Carbon and Water in Protein



P: Heat pieces of egg-white in a bottle cap. Hold a water filled test-tube over the vapour.

Q: Is carbon present in egg-white? Is water present in egg-white?

O: Water condenses on the test tube. Black carbon deposit will be left in the bottle cap.

E: Protein in egg-white, contains water which evaporates on heating and condenses on the test tube. Carbon remains in the bottle cup.

4.1.18 Protein Contains Other Elements

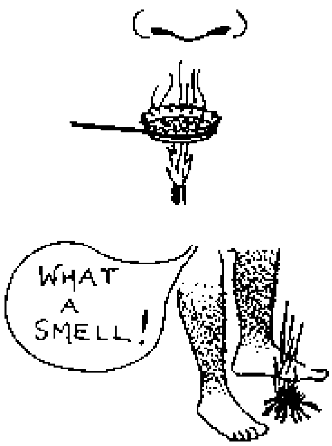
P: Heat pieces of the white of egg with some limestone (or basic substance).

Q: What do you notice about the smell?

O: A pungent smell is produced.

E: On heating, nitrogen in the egg-white combines with hydrogen to produce ammonia. This has a pungent smell.

4.1.19 Burning Hair and Horn



P: Heat some samples of hair and horn over a flame.

O: A pungent smell is produced.

4.1.20 Straightening Hair

P: Some Tanzanian women use a hot comb to straighten their hair.

Q: Why can't we use a cold comb?

E: The protein keratin, which is present in hair, has sulphur bonds between protein chains. Combing the hair with a hot comb can break these bonds temporarily and thus straighten the hair. The bonds soon rejoin and the hair becomes kinky again.

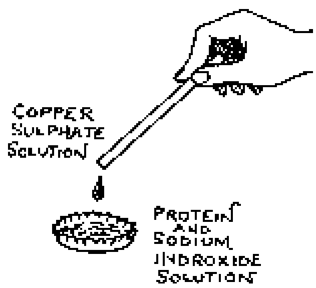
4.1.21 Coagulated Protein

P: Examine an egg before and after cooking. Place a small amount of egg-white in a bottle cap and heat.

Q: The jelly like egg-white turns into a white solid mass.

E: Amino acids and proteins are very sensitive to certain physical changes such as temperature. When heated, protein molecules lose their special properties and become denatured.

4.1.22 Biuret Test for Protein



P: Mix a little protein solution with the same amount of 10 per cent sodium hydroxide solution. Add a few drops of 0.5 per cent copper sulphate solution drop by drop, shaking well after each drop.

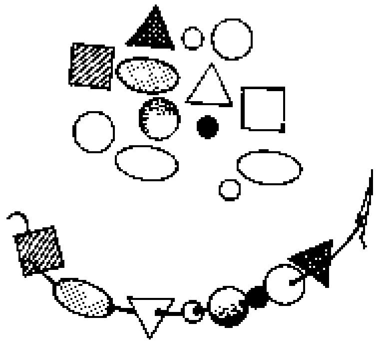
Q: What colour change do you see?

O: The solution turns purple.

E: Purple colour confirms the presence of protein.

I: Test other foods for protein.

4.1.23 Models of Proteins

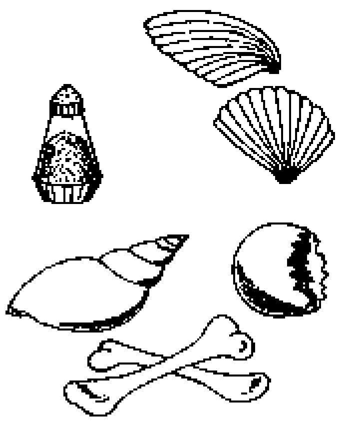


P: Using different types of beads or seeds to represent the different amino acids, string together simple models of protein chains.

Q: How could this also show protein digestion?

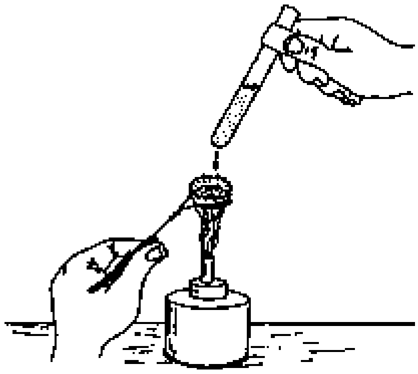
E: A pair of scissors could be used to represent an enzyme breaking down protein into amino acids.

4.1.24 Mineral Collection



P: Make a collection of sea shells, snail shells, bones, egg shells and other materials from living things rich in mineral salts.

4.1.25 Heating Items rich in Mineral Salts



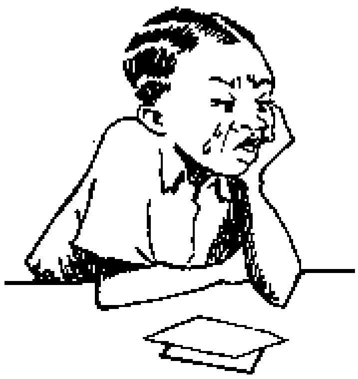
P: Heat some samples of living things rich in mineral salts.

Q: What happens if egg shell is heated?

O: The shell does not burst into flames although burning may occur on the inner surface of the shell where organic membrane is present

E: Calcium present in the egg shell is inorganic and so it does not burn.

4.1.26 Sweat and Tears



P: Taste your sweat or tears.

Q: What does it taste like?

O: They taste salty.

E: The mineral salts dissolved in these fluids give a distinctive taste.

I: When you have cut yourself what did blood taste of?

4.1.27 Mineral Salts in Wood Ash

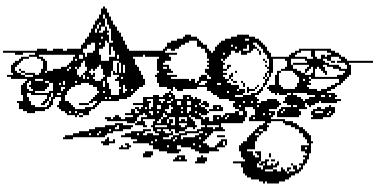
P: Mix some ash from plants (wood etc.) with water and heat. Then filter and evaporate off the water.

Q: What is left in the test tube?

O: Salt crystals can be seen

E: Plant materials contain salts which are left in the ash when the organic material burns off.

4.1.28 Foods containing Vitamins

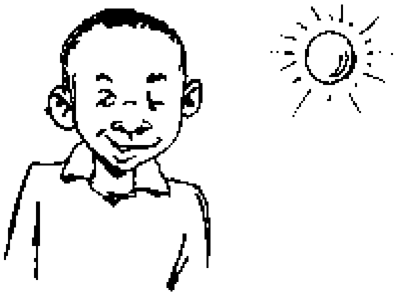


P: Make a collection of foods containing vitamins. These could include eggs, milk, beans and peas, groundnuts and citrus fruits. A vitamin is an organic substance which an animal must obtain in order to be healthy. Vitamins are only needed in small amounts, and part of the need may be synthesized by an animal, although this does not often happen. Different animals require different vitamins. Every vitamin is available from another plant or animal and many can be synthesized in factories.

4.1.29 Baby's Milk

P: Babies fed from a bottle on modified cow's milk need extra vitamin C (e.g. from orange juice) because the vitamin C in milk is destroyed by boiling. All babies need extra vitamin C as they grow (e.g. from cod-liver oil). Proprietary brands of baby milk powders may be harmful if they are mixed unhygienically or in the wrong proportions.

4.1.30 Sunlight Vitamin



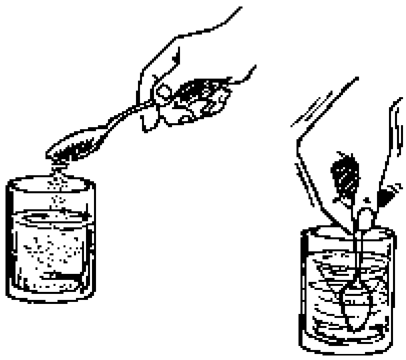
P: Small amounts of Vitamin D can be produced by the body in sunlight. Other sources are milk, eggs and liver. Vitamin D deficiency causes rickets in babies and young children and bone softening in adults. Vitamin D maintains the level of calcium in the blood to form strong bones and teeth.

4.1.31 Vitamin B Group

Q: What happens if our diet is deficient in B group vitamins?

E: Lack of energy is a major symptom of Beri-beri (nerve and muscle wasting) and Pellagra (skin, gut and nerve disorders).

4.1.32 Water as a Solvent



P: Mix a little salt (or sugar) in water.

Q: What happens?

O: The salt dissolves.

E: Mineral Salts and other body nutrients dissolve in water for transport and absorption.

4.1.33 Wilting Plants

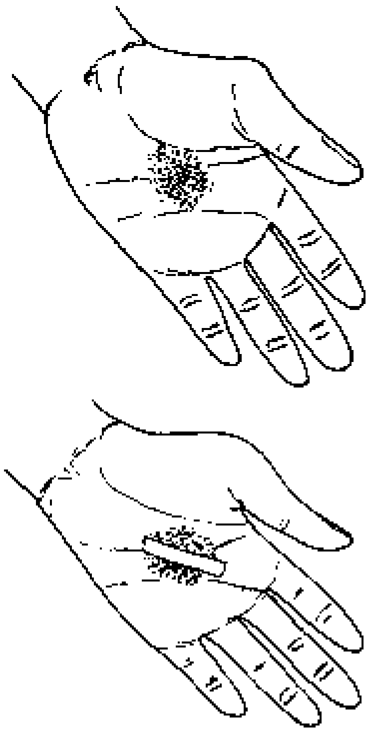
P: Look at plants during the dry season or unwatered seedlings after transplanting.

Q: What happens to the plants?

O: The plants and seedlings wilt or droop until supplied with water.

E: Water is essential in maintaining cell turgor and thus plant structure.

4.1.34 Water and Sweat



P: Rub iodine solution on to the palm of the hand. Allow this to dry. Place a piece of dry starch paper on to the iodine stained skin. Hold in position for 1-2 minutes. Remove the starch paper and examine it.

Q: What has happened to the starch paper?

O: Dark dots of blue black colour appear on the paper.

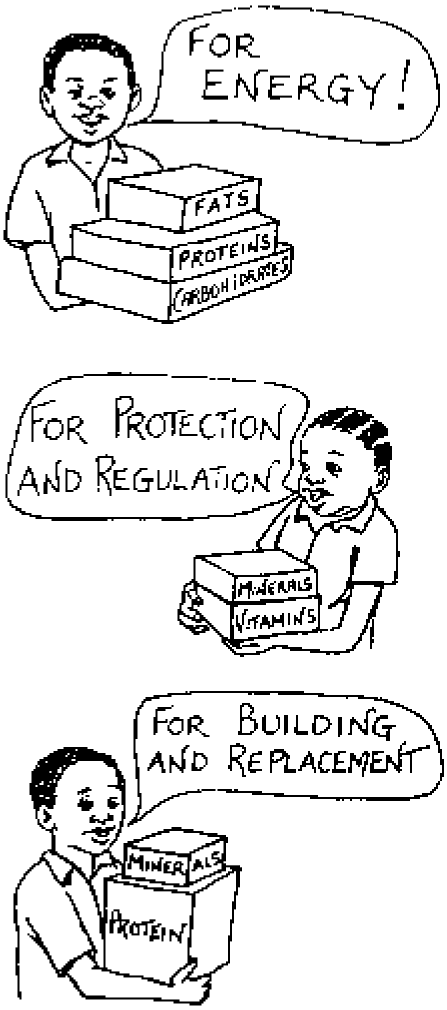
E: Dry iodine and dry starch do not react to produce a colour change. Only when water is present does the colour appear.

I: Repeat this experiment after vigorous exercise. Compare the marks with the first test. What can you deduce about and output of sweat by the skin?

4.2. Balanced Diet

Living organisms could be described as machines doing work, the fuel being the food. In addition, like machines, our bodies must first be built up and then have worn out parts replaced. In order to function properly the body needs a balanced diet. A balanced diet should contain adequate amounts of carbohydrates, proteins, fats and oils, mineral salts and vitamins. Although not a nutrient, water is also an essential constituent of food.

4.2.1 Functions of Nutrients

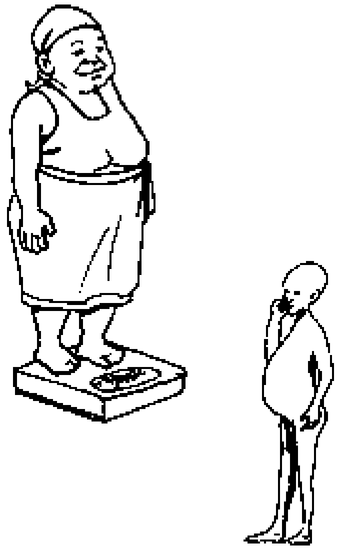


P: Use boxes or containers to represent the five components of food.

Q: Which foods appear under two headings?

E: Proteins and minerals appear under two function headings.

4.2.2 Malnutrition



P: Learn how to identify some of the signs of malnutrition (both under and over nutrition)

E: Our food should contain an adequate total amount of nutrients. If it does not, then we suffer from *under nutrition* or perhaps *starvation.* Our diets should contain the correct amount of each nutrient, but if they do not, we suffer from malnutrition. The person who becomes fat because of eating more carbohydrates in the form of sweets and cakes than are needed by the body suffers from malnutrition, that is *over nutrition.*

4.2.3 Reasons For Deficiency Disease

P: Ask the pupils to give reasons why a person may not get a balanced diet

Q: Give three reasons why some people may be malnourished

E: The pupils should be able to state that

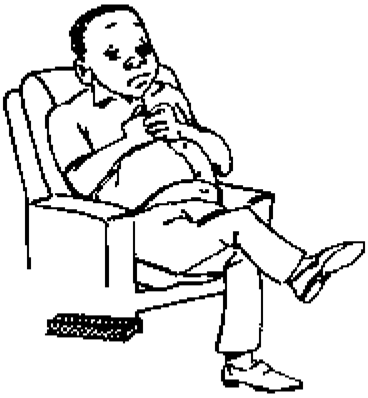
a) A shortage of the right kinds of food (such as protein) in certain areas means the normal diet consists of mainly cereals or starchy foods.

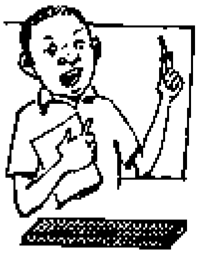
b) The low income of some families means that they may be too poor to buy the right kinds of food, such as protein-rich meats, eggs etc..

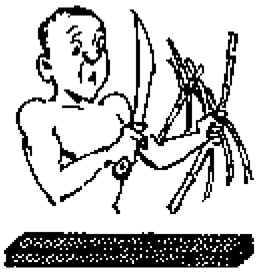
c) Superstitition and lack of education on concepts of a balanced diet. Local customs can dictate what is eaten and even if suitable foods are available, people may be unwilling to try them. In the past some traditions dictated that pregnant women should not eat eggs even though the protein would help the growing baby's development. Other foods were considered to possess magical properties and to eat them would bring bad luck.

I: Are there any traditional food customs in your area which may affect having a balanced diet?

4.2.4 Daily Energy Needs







P: Make an illustrated bar chart with paper strips, to show the different energy needs of a sedentary person, a moderately active person and a very active person for an 8 hours working day.

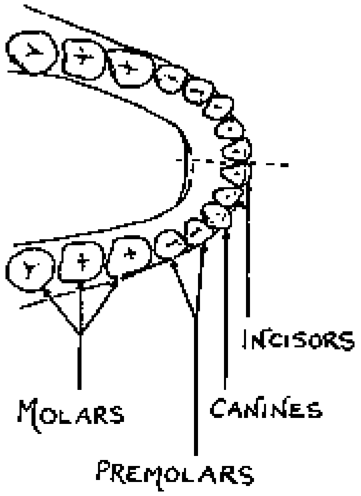
Q: Can you clearly show the different energy needs of different occupations?

E: The very active person needs more energy than a moderately active person who in turn needs more than a sedentary person.

4.3. Digestion in Mammals

Digestion is carried out in the alimentary canal. The alimentary canal is a very long tube which begins at the *mouth* and ends at the *anus.* It has several parts namely buccal cavity, oesohagus, stomach, duodenum, ileum, caecum, appendix, colon and rectum. Each of these parts is modified for specific functions. Associated with the canal are various glands. Food undergoes physical and chemical digestion as it moves along the canal.

4.3.1 Four Types of Teeth



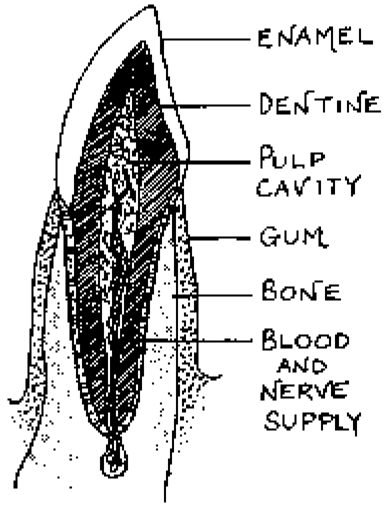
P: Look into a friend's mouth. Examine the teeth and differentiate between them. Count the number of each type present. Try to identify the function of each.

Q: How many are there altogether of each type?

O: There are four types of teeth in the buccal cavity 32 teeth in all.

E: The four different types of teeth perform different functions. The front ones, the incisors, are used for cutting. The canines are used for tearing. The premolars may have one or more points for cutting, or flat surfaces for grinding. Behind the premolars are the molars with flat surfaces for grinding. Molars are not present in young children.

4.3.2 Tooth Models



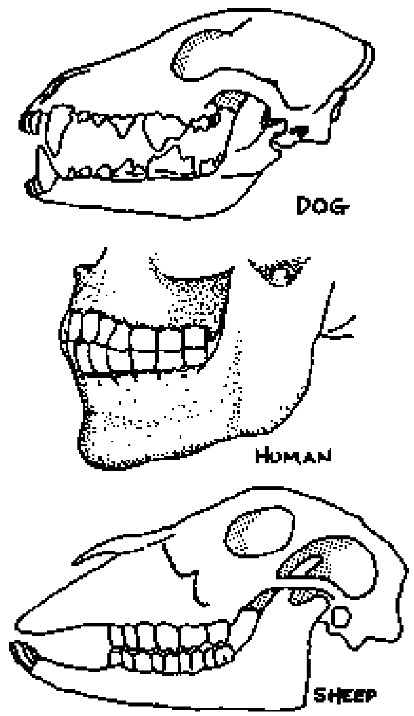
P: Split different types of teeth longitudinally with a sharp knife or tool. Identify the different parts. Using modelling clay or paper mache (soaked paper pieces and paste) make a model using the tooth and text book diagrams as a guide.

Q: Does the tooth cross section exactly match the text book drawing?

O: No. Each tooth is unique.

I: Label your model for display. Try models of different tooth types. Each tooth consists of the *crown,* the *neck* and the *root. A* longitudinal section of the tooth shows the *enamel, dentine* and the *pulp cavity* (which contains nerves and blood vessels). The tooth is cemented to the jaw bone which is covered by the gum.

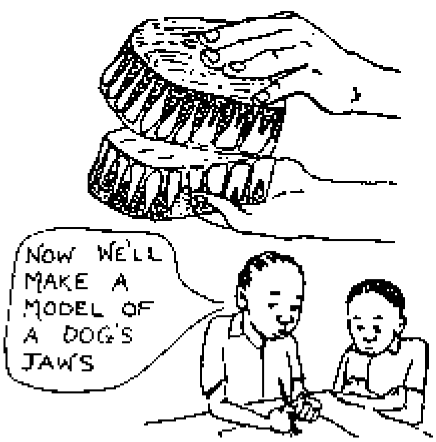
4.3.3 Dentition in Mammals



P: Collect examples of dentures and teeth from different animals. Display these to show the dental formulae of omnivores, carnivores and herbivores. Dental formulae of different animal differ with the type of food they eat.

O: Carnivorous mammals are flesh eaters and must be able to kill, tear up and slice the prey, prior to swallowing it. Large fang-like canines and sharp ridges on other teeth act like scissor blades to slice flesh. Herbivorous mammals must be able to crop and grind the tough vegetation. The incisors in the lower jaw are large and chisel shaped. The upper incisors and canines are replaced by a horny pad; the lower incisors and canines act against the pad to crop grass. A gap separates newly cropped grass from that being ground by the premolars and molars.

4.3.4 Human Dentition Model



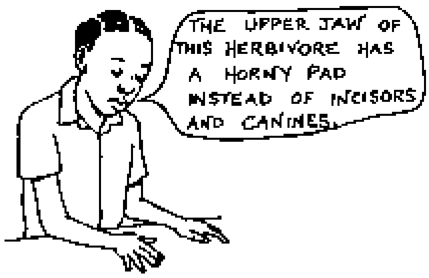
P: Prepare two shaped pieces of wood or cardboard to represent the upper and lower jaw. Make a hinge of rubber on the straight edge between the pieces. Paint, draw or stick a drawing of the teeth around the edge of the wooden shapes.

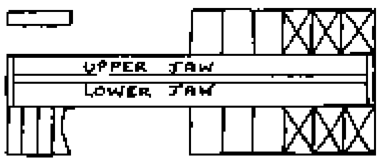
4.3.5 Dental Formulae Game

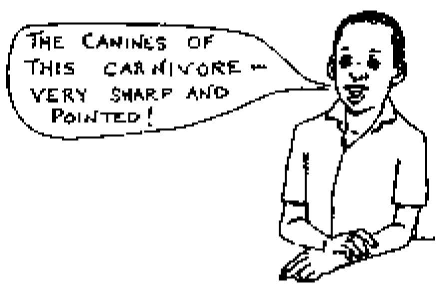
MAMMALIAN DENTITION		INCISOR	CANINE	PREMOLAR	MOLAR
CARNIVORE (DOG)	1/2 UPPER JAW	3	1	4	2
	1/2 LOWER JAW	3	1	4	3
OMNIVORE (HUMAN)	1/2 UPPER	2	1	2	3
	1/2 LOWER	2	1	2	3
HERBIVORE (SHEEP)	1/2 UPPER	0	0	3	3
	1/2 LOWER	3	1	3	3

P: Make a table comparing the different dental formulae. Prepare movable cards corresponding to the types of teeth in each dental formula. Mix-up the cards and try to place the correct numbers in the appropriate square. As the numbers are written on movable cards it is easy to correct errors and find the correct solution.

4.3.6 Dental Formulae Cut-Outs







P: Using the illustration in 4.3.3 make large card or paper cut-outs of the teeth shapes of a dog and goat and arrange them along a ruler.

Q: What do you notice?

O: Teeth arrangement in the mouth of a dog and a goat are different.

4.3.7 Functions of Teeth

P: Bite off a small piece of bread and chew it.

Q: In what order are the teeth used?

O: First the front incisors bit off a piece of bread and then the premolars and molars do the chewing.

E: Different teeth have different functions.

I: Try biting off a piece of meat or sugar cane. Are the same teeth involved?

4.3.8 Dental Hygiene

P: Demonstrate the correct way to clean the teeth using a stick or brush.

Q: What errors do some people make when cleaning their teeth?

E: There are many different ways to clean the teeth. A vertical movement of the teeth brush removes food from between teeth and encourages blood flow in the gums.

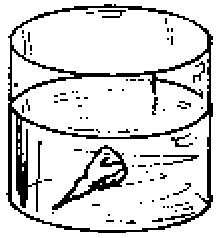
4.3.9 Tooth Decay

P: Try and obtain a human tooth which has been subject to decay. Boil it in water to sterilise.

Q: How does it differ from a healthy tooth?

O: It may have holes in the enamel, or show signs of bacterial attack in the pulp cavity.

4.3.10 Decaying Tooth



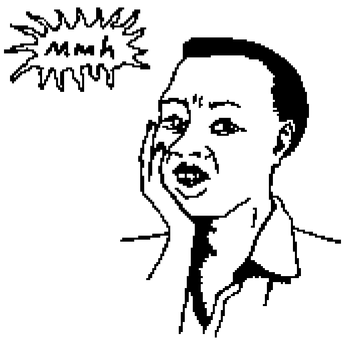
P: Take a mammalian tooth and examine it closely. Then place it in dilute hydrochloric acid for two or three days. Put a similar tooth in an empty container for comparison.

Q: What do you notice about the teeth?

E: The hydrochloric acid has reacted with the tooth enamel digesting part of it.

I: When a person fails to brush their teeth properly, the food that remains on the teeth is acted upon by the bacteria producing acids. These acids eat away the enamel and dentine causing tooth decay.

4.3.11 Nerves in Teeth



P: Watch someone who has toothache.

Q: What do you observe?

O: They are often in great pain

E: The nerves of the tooth have been attacked making the tooth sensitive.

4.3.12 Licking Lips

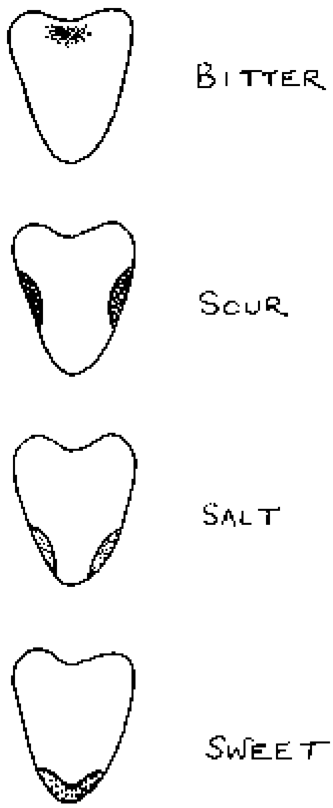
P: Try chewing dry biscuits,

Q: How many dry biscuits can you chew *without* licking your lips?

O: It is often hard to prevent the tongue automatically licking the lip's.

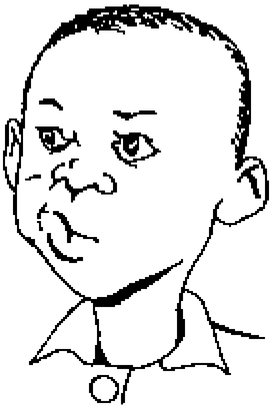
E: The tongue is used for ingestion and helps to spread saliva lubricating the lips.

4.3.13 Taste Map



P: Prepare four solutions (sugar/salt/bitter/sour). The bitter solution may contain chloroquine, lemon peel, strong cold tea or coffee. The sour solution may be vinegar or lemon/lime juice. The subject shuts their eyes and holds out their tongue. Using a dropper or matchstick put drops of each solution on different areas of the tongue. The mouth should be rinsed after every test. Each of the four solutions is felt strongly at a specific place on the tongue, where specific taste buds are present. Draw a large map and mark the appropriate strong taste zones.

4.3.14 Tongue and Chewing

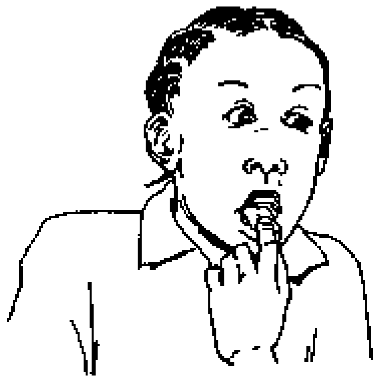


P: Chew some hard seeds or nuts.

Q: What do you notice about the action and position of the tongue?

O: The tongue moves the nuts and pieces of nuts around the mouth to positions where the teeth can break them down.

4.3.15 Multi-purpose Tongue

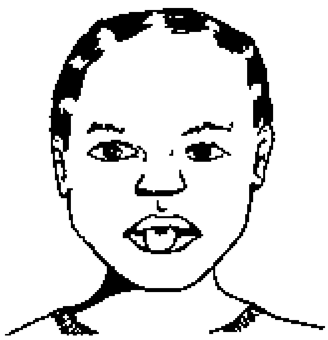


P: Try holding the tip of your tongue and say, "The tongue is used for speaking". Then say each letter of the alphabet and see which sound the same as normal.

Q: Which letters sound different?

E: The tongue moves inside the mouth to form many of our spoken words.

4.3.16 Tongue Rolling



P: Try to roll your tongue as shown in the diagram.

Q: Can everyone in the class roll their tongue?

O: Not everyone will be able to roll the tongue.

E: The ability is inherited. Can your parents, brothers, sisters and relatives roll their tongues?

4.3.17 Production of Saliva

P: Hold up your tongue and look for the ducts of the sub-lingual glands. Squeeze some lemon juice on the tongue.

Q: What do you notice after squeezing lemon juice on the tongue.

O: The lemon juice stimulates the production of saliva.

E: There are three saliva glands in the buccal cavity.

4.3.18 Stimulation of Saliva Production

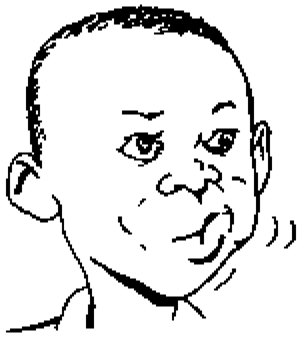
P: Pass near a place where food is cooking and there is a nice smell.

Q: What happens in your mouth?

O: Saliva is produced.

E: Smell and even the thought of food can stimulate saliva production.

4.3.19 Enzymes in Saliva



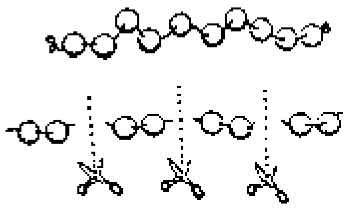
P: Try chewing a piece of dry bread crust *without* swallowing.

Q: What happens to the bread and the taste in your mouth?

O: The bread becomes softer, wetter and sweeter.

E: Saliva breaks down the chains of saccharides (starch) in the bread to form simple saccharides (sugars) which taste sweet.

4.3.20 Action of Salivary Amylase



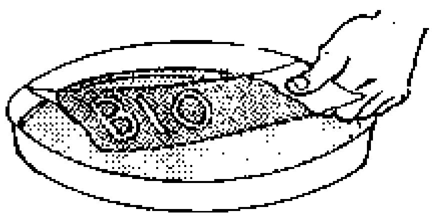
P: The model of starch in 4.1.8 uses a string of beads or seeds to represent simple sugars joined in a long chain. Use scissors to cut up the chain.

Q: What action does cutting with scissors represent?

E: The scissor action represents the action of salivary amylase as it breaks down the long starch chain to simple sugars (maltose).

I: A chain of paper clips or toilet paper could be used as a substitute to a strip of beads.

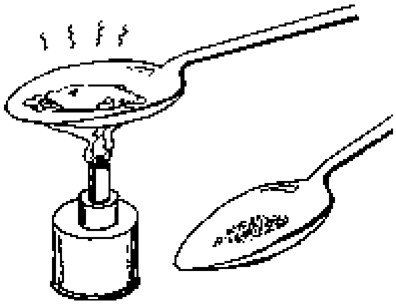
4.3.21 Invisible Saliva Ink



P: Prepare a starch suspension by adding about a teaspoon of maize/cassava flour to half a cup of water. Bring to the boil, then allow to cool and filter (clearer) liquid through a cloth. Soak filter (blotting, news or toilet) paper in the starch suspension and allow to dry. Write your name using saliva on a matchstick. Allow the paper to dry. "Develop" to reveal the hidden writing by dipping in very dilute iodine solution.

E: The saliva digests the starch where it touches the paper.

4.3.22 Salts in Saliva



P: Gently heat some saliva on a clean shiny tin or spoon until it is dry.

Q: What do you observe?

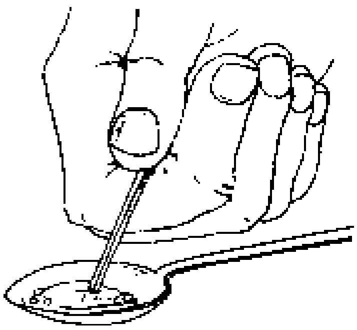
O: A white residue is left.

P: Test this residue with a little dilute hydrochloric acid.

O: Bubbles of carbon dioxide are given off.

E: Calcium carbonate is the residue and this reacts with the hydrochloric acid to produce carbon dioxide.

4.3.23 Saliva and Air



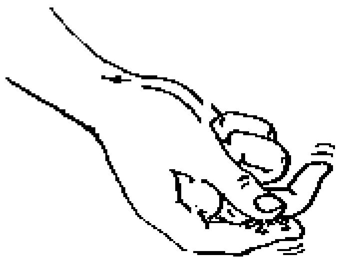
P: Mix some saliva with air on a spoon. Stir gently with a matchstick.

Q: What happens?

O: It goes opaque

E: Hydrogen carbonates (bicarbonates) in the saliva form a precipitate when they come into contact with carbon dioxide in the air.

4.3.24 Saliva as a Lubricant



P: Take a sample of saliva and compare it with water for stickness.

Q: How do they compare?

O: Saliva mucus is; slippery

E: Saliva is used to moisten and lubricate food for ease of swallowing.

4.3.25 Touch Reflex

P: Try to touch the soft palate (at the back of the mouth) with your finger.

Q: What happens?

O: The mouth tries to eject the finger as in vomiting.

E: This is a reflex action to remove a foreign body and prevent it entering the oesophagus.

4.3.26 Epiglottis and Palate

P: Use a spoon to press down the tongue and let another student observe the activity of the epiglottis and soft palate during swallowing.

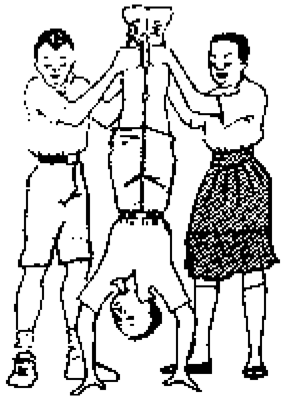
Q: What happens?

O: The epiglottis and soft palate are both open.

E: During swallowing both epiglottis and soft palate close, preventing food entering the trachea and nose.

I: Why is it useful to hold the tongue down while swallowing?

4.3.27 Swallowing Upside Down



P: Drink a mouth full of water from a cup and swallow it. Then fill your mouth again, (without swallowing) and with the help of two friends do a handstand. Then swallow while upside down.

E: You are able to swallow while upside down, but not as easily. The peristalsis of the oesophagus works against the forces of gravity.

4.3.28 Swallowing with Open Mouth

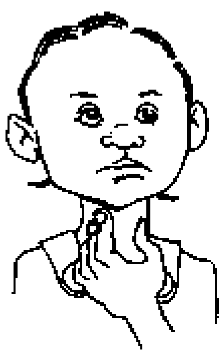
P: Try to swallow food with an open mouth.

Q: Is it easy?

O: No, liquid may escape from the front

E: The mouth is usually shut and the tongue pressed up when swallowing occurs.

4.3.29 Larynx Movement

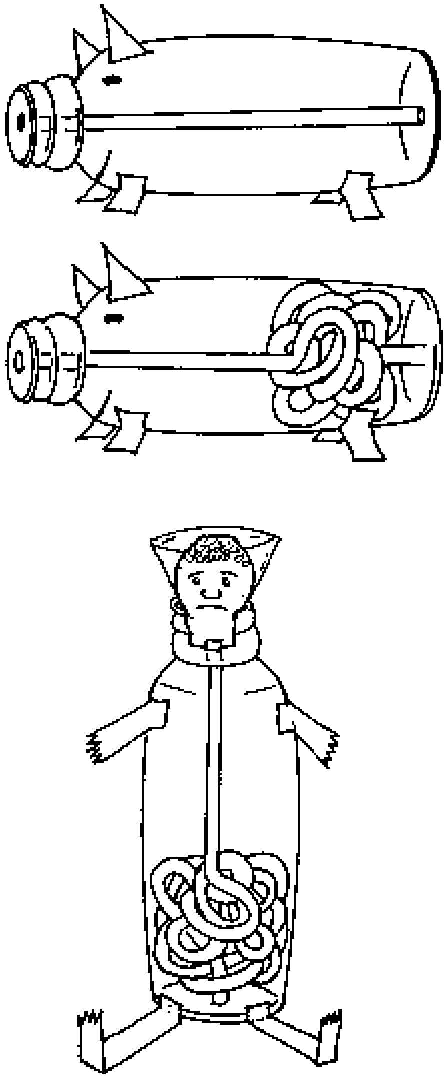


P: Hold your larynx with the fingers of one hand and swallow. Then hold the larynx and breathe in and out

Q: Is there any difference?

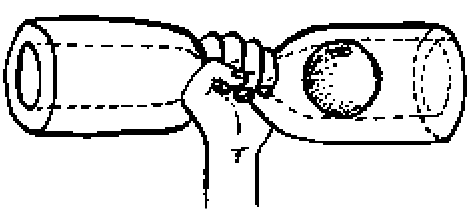
E: During swallowing there is more movement around the larynx because of the passing wave action of the muscles.

4.3.30 Food Tube Journey



P: Using a bottle and tube construct the model as shown in the diagram. Pour water into the funnel and see how long it takes to pass through the alimentary canal tube.

4.3.31 Peristalsis Model



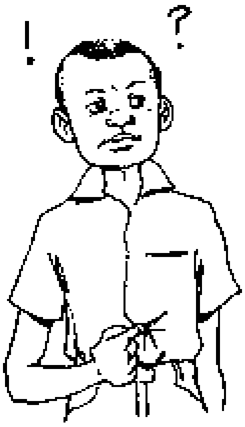
P: Demonstrate peristalsis by pushing a marble or stone down a piece of bicycle inner tubing or a self prepared tube made from plastic bags.

Q: How does this show peristalsis?

O: The tube bulges as the marble moves down its length

E: Circular muscles in the oesophagus wall, (behind the food) contract and relax and so propel the food bolus in a wave like motion to the stomach.

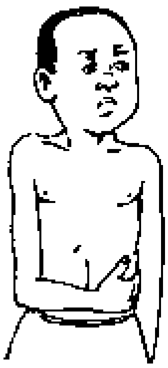
4.3.32 My Stomach is?



P: Use a finger to point to the approximate position of your stomach and intestines. Move your hands around and point to other organs?

E: By using themselves as a learning aid students can more easily relate the information in the text book to real life.

4.3.33 Indigestion



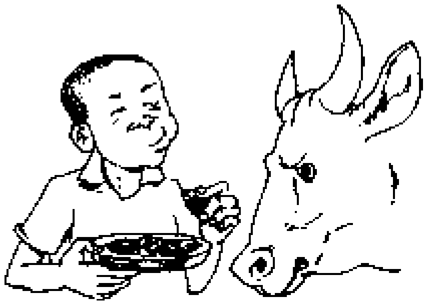
Q: How does it feel to have indigestion?

O: Indigestion can be a pain behind or just below the ribs, or just feeling sick.

E: It may be caused by bacteria from foods not hygienically stored or warmed, too much fat or eating too much.

I: Always cook foods thoroughly, cover from flies and keep stored foods cool

4.3.34 Digestion Question?

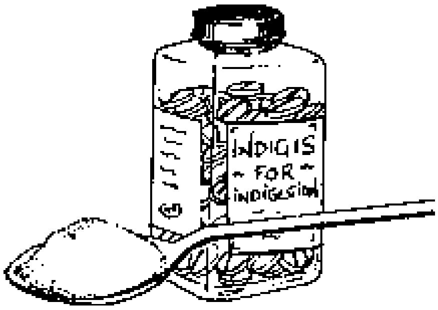


P: Eat a piece of cooked cow's stomach or intestine meat.

Q: I can eat and digest cow's stomach, why don't the acids digest my own?

E: The stomach wall produces mucus - a slimy thin, watery jelly which lines the stomach and protects its walls from it's own digestive juices.

4.3.35 Indigestion Powders



P: A person with acid indigestion will take stomach powder.

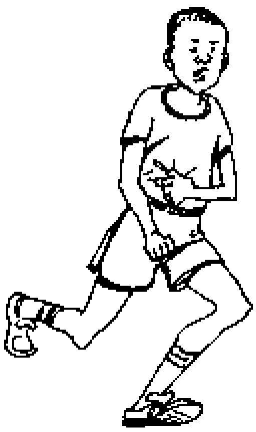
Q: How does this help digestion?

O: Sodium bicarbonate (soda) helps ease indigestion problems.

E: Sodium bicarbonate neutralises the acid.

I: Milk or thick soup also help.

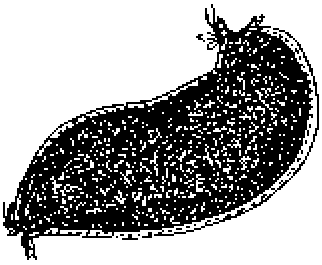
4.3.36 Sloshing Stomach



Q: Why do I sometimes hear a sloshing noise from my stomach as I run?

E: This means there is hot gas in your stomach. A burp to release trapped gases helps.

4.3.37 Plastic Stomach Model

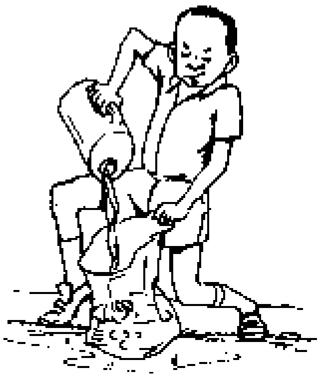


P: Draw the shape of the stomach on a transparent plastic sheet. Cut out four pieces of human stomach shape. Stitch, glue or staple the edges together to make two stomachs. Stuff one stomach model with cotton wool or crumpled up paper.

Q: Observe the size of the two models.

E: The empty model represents an empty stomach and the stuffed model represents a full stomach.

4.3.38 Stomach Volume



P: Fill a large plastic bag or bucket with 2.5 litres of water. Note the space occupied by the 2.5 litres of water. The human stomach bulges to about this volume to accommodate the water and food. The stomach stores food, mixes it and starts digestion.

4.3.39 Acid Heartburn

Q: What is heartburn?

O: A burning sensation in the oesophagus which is near the heart.

E: Acid in your stomach kills off bacteria in your food and helps digestion of food. The stomach makes mucus (a slimy, thin, watery jelly) which lines and protects the stomach from its own digestive juices. Heartburn is caused as acid splashes up and burns the oesophagus.

4.3.40 Intestine Investigating

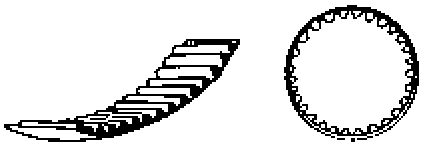
P: Ask the pupils to bring parts of the intestine of small animals and investigate the surface which is like soft cloth.

Q: Why is the surface inside the intestine soft?

O: The surface is covered with small villi and microvilli.

E: The small intestine is well adapted for absorption. It has a very large surface area because of its considerable length, its folded walls and its inner surface which consists of numerous finger like projections called *villi.* The surface area is further increased by the epithelial cells (microvilli) covering the villi.

4.3.41 Corrugated Cardboard Villi Model

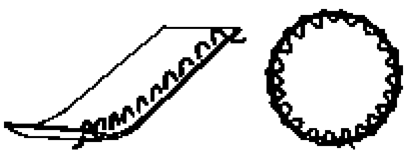


P: Cut a piece of corrugated cardboard approximately 2 cm by 20 cm. Roll it up with the corrugated surface inside.

Q: What is the relationship of the corrugations to the villi?

O: The folds of the corrugated surface correspond to the villi of the ileum. They increase the surface area for absorption of nutrients.

4.3.42 String Villi Model



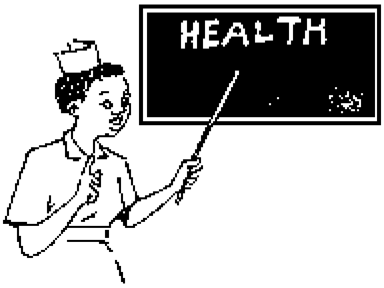
P: Take a strip of cardboard (approx 4 cm x 24 cm). Punch holes through it as shown every 2 cm. Loop some thread through the holes and pull it loosely to form loops on one surface. Roll the cardboard so the loops are inside.

Q: How long is the string forming the loops?

O: The string's length is far longer than the inner circumference of the cardboard. Pull it put and see.

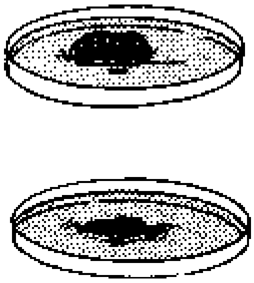
E: This shows how the villi increase surface area for nutrient absorption.

4.3.43 Healthy Eating



P: Ask a doctor, nurse or health officer to give a talk on medical issues related to the digestive system. Students could make a list of questions which may be given to the doctor before the visit. Medical professionals may bring new insights into your lessons.

4.3.44 Paw Paw Enzymes



P: Cut two pieces of meat. Place one in a dish with water and another in a dish of paw paw or pineapple juice.

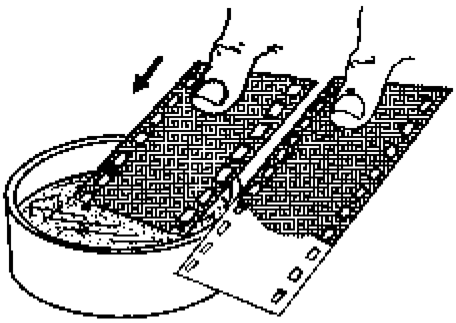
Q: What happens?

O: The meat with juice seems more tender and soft.

E: Enzymes in the paw paw juce denature meat protein and aid digestion.

H: Paw paw is used as a meat tenderiser.

4.3.45 Enzyme Action



P: Cut two strips of exposed photographic film. Place one in a little water and the other one in the juice of paw paw or pineapple.

O: The film in the juice has lost its coating.

E: The enzymes in the juice digest the gelatin containing the silver salts and the plastic is left clean.

H: Would this affect film storage?

4.3.46 Chewing Cud

P: When a cow eats grass it does not seem to chew before it swallows.

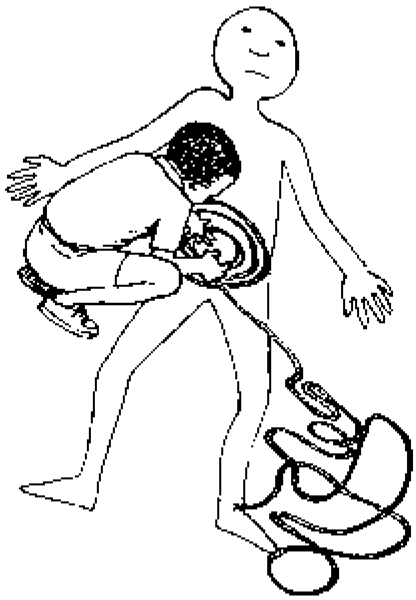
Q: When does a cow chew its food?

O: A cow lies down quietly and chews cud.

E: The cow swallows grass immediately after cutting and then returns it to the mouth by antiperistalsis and grinds it between the back teeth by a side to side movement of the jaw.

H: Sheep and goats also chew cud.

4.3.47 Length of Intestine



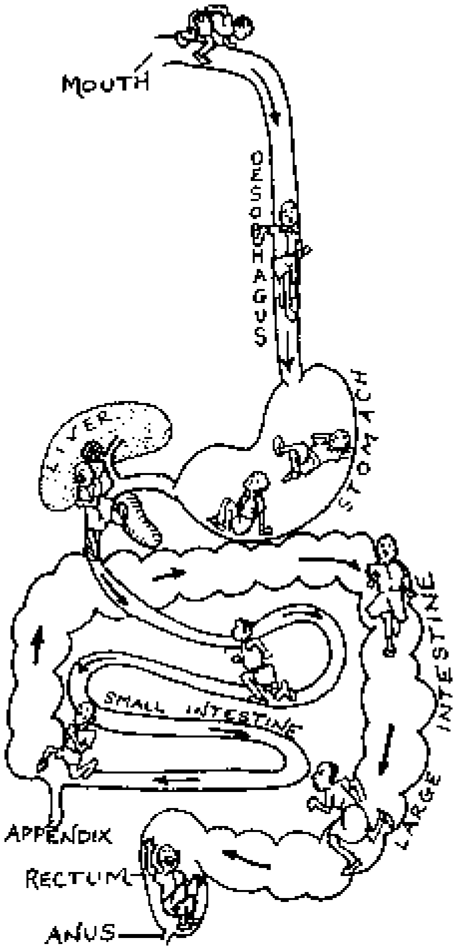
P: Ask pupils to draw on the ground the shapes of different animals. Rabbit, man, cat/dog, pig, cow. Try to draw them life size. Then coil string or strips of paper inside the abdominal cavity area of the animal shape. Here are approximate lengths of intestine: rabbit (1 m) cat/dog (2 - 5 m), pig (24 m), horse (30 m), cow (50 m).

Q: Suggest the reason for the difference in length of the intestine in different animals.

O: Observers may be suprised at the length of some animal intestines.

E: Length of intestine corresponds to the type of diet an animal eats. Herbivores have longer intestines than carnivores while that of omnivores is intermediate in length.

4.3.48 Digestion Game

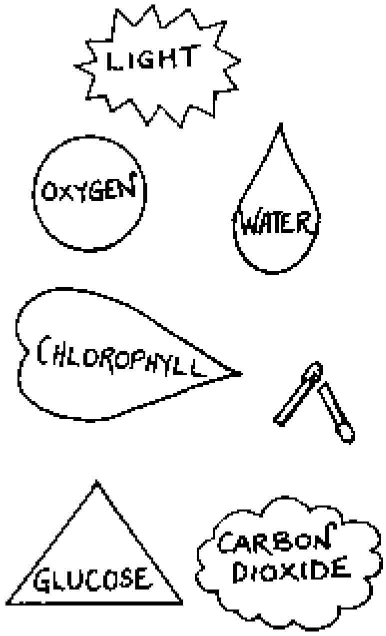


P: Draw a large outline of the digestive system on the classroom floor or mark it out on the playing field, with string and pegs or use stones. Ask the pupil to walk through the outline and describe what happens at the various places. Labels may be added before or during the activity.

4.4. Plant Nutrition

Plants obtain their food by making their own. This type of feeding is known as *autotrophic nutrition.* The process by which plants do this requires water, carbon dioxide, light and a green substance found in plants called chlorophyll. This process is called *photosynthesis.* The first substances manufactured by photosynthesis are simple sugars. These can be converted to starch, cellulose, fats, proteins or any other organic compound needed by the plant. For some of these compounds, additional elements are required, which are obtained as mineral salts from the soil. As well as providing essential compounds for the plant, photosynthessis converts the energy. This can then be used directly by plants themselves, or indirectly by all other living organisms.

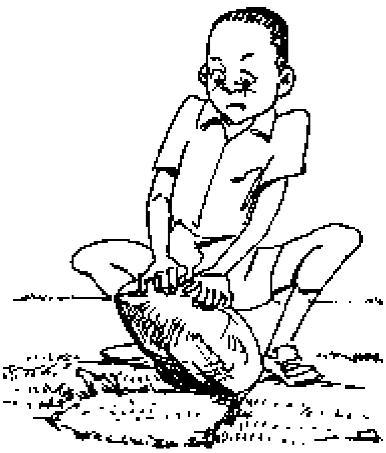
4.4.1 Photosynthesis is a Chemical Process



P: Draw and cut out the symbols shown above. Then arrange them in the correct order to show the chemical equation for photosynthesis. Use matchsticks for arrows and + symbols.

I: Repeat the above procedure but replace the words in the shapes with the chemical formulae of the substances involved. These may be written on the reverse side of the first set of cards.

4.4.2 Do Plants Need Light?



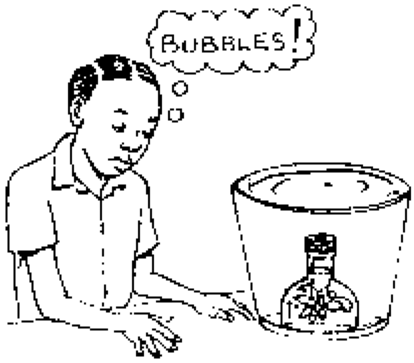
P: Cover an area of grass with a large flat brick or stone or with a black plastic bag so that no light reaches the plants. Examine the grass after a few days. An alternative is to place a black plastic bag over green leaves at the end of a branch and seal it by using string, tape or wire.

Q: What changes take place in the appearance of the leaves?

O: The plants and leaves become pale green or yellow in colour and die eventually.

E: Plants need light for photosynthesis. When they lose their green chlorophyll no more light can be absorbed and they die.

4.4.3 Photosynthesis Produces a Gas



P: Cut the neck from a plastic bottle, leaving the screw cap in place. Place in a large container of water making sure the bottle is completely filled with water. Place some aquatic plants under the bottle and leave for a few days in sunlight.

O: The water level goes down. Oxygen produced by photosynthesis forms as bubbles on the leaves, which rise and collect in the bottle neck.

4.4.4 Chrorophyll Extract

P: Pick about 5, large soft green leaves. Cut these into small pieces and grind with a stone. Add a little water to the pulp and pour the mixture into a glass jar or test tune. Leave to settle.

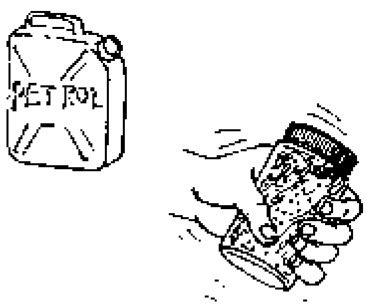
Q: What do you observe?

O: The solid material settles out, leaving a green solution.

E: The green substance in the water is chlorophyll, which has been released from the cells by mechanical breaking of the cell membranes by grinding.

I: The extraction of chlorophyll works better in alcohol or spirit.

4.4.5 Leaf Pigments



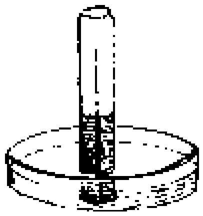
P: Take some chlorophyll extract (see 4.5.4) and mix it with an equal volume of colourless petrol. Shake well.

Q: What do you notice about the colour of the liquid?

O: Some colour from the extract dissolves in petrol leaving it yellow

E: The green colour of leaves is a mixture of several pigments including chlorophyll (green) and xanthophyll (yellow). The yellow colour is more soluble in petrol than in water.

4.4.6 Chromatography

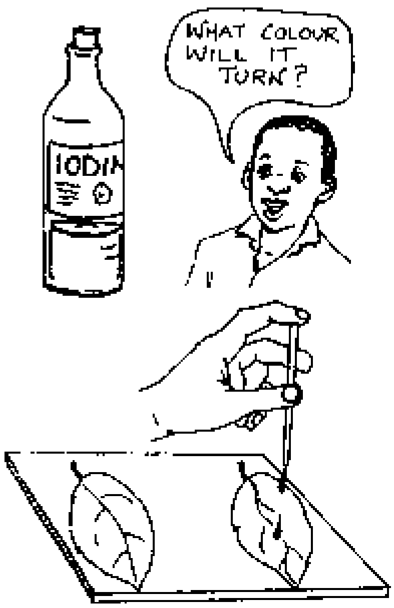


P: Place a few cm 3 of chlorophyll extract (see 4.5.4) in a shallow container. Stand a stick of dry blackboard chalk upright in the extract.

O: The extract rises up the chalk and two colour bands (one yellow and one green) can be seen.

E: By capillary rise leaf pigments are transported with different velocity and thus the green chlorophyll can be separated from the yellow xanthophyll: This process is called chromatography.

4.4.7 Plants make Starch during Photosynthesis



P: Take two plants grown in pots and place one in sunlight and the other in a dark cupboard for 2 days. Pick a leaf from each, but keep them separate. Heat each leaf in some surgical spirit for about 5 minutes to remove some of the green colour. Take each leaf out and lay it on a flat surface. Add a few drops of iodine solution.

Q: What is the result?

O: The leaf from the plant grown in the light became a blue-black colour, whereas the one from the dark was the pale brown colour of iodine.

E: When a leaf is exposed to light, photosynthesis occurs producing sugar, which is then converted to starch for storage. This gives the blue/black colour with iodine. In the dark, no photosynthesis can take place, so no starch is produced.

I: *Never heat spirit directly with a flame or it will catch fire. Place the spirit container in another one filled with water and heat the water container.*

4.4.8 Nutrients from Soil

P: Fill one container (i.e. 250g Tan Bond tin) with pieces of card board or foam packing cut into very small pieces. Fill another container with fertile soil and plant a few seeds (peas, beans or maize) in each one. Water each container with distilled water (prepared by condensing steam from a kettle) or rain water collected in clean jars. Use this water to keep the containers damp throughout the experiments. Examine daily.

Q: What differences do you see in the seedlings in the two containers?

O: Seedlings grown in the container without soil are smaller and less healthy with yellow leaves.

E: As well as water, carbon dioxide and sunlight plants require mineral salts in order to grow and remain healthy. The seedlings grown without soil get only water and so are lacking these salts.

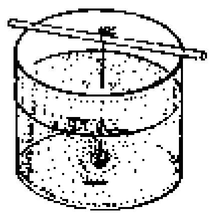
5. Transportation of Materials in Organisms

5.1. Basic Principles of Transportation

Transport is the movement, circulation or flow of substances within living organisms. This can either be with or without a system of tubes (vascular system). The blood circulatory system in animals, and the xylem and phloem in plants are examples of transport systems.

In an individual cell, substances generally move into and out by *diffusion, osmosis* or *active transport.* Diffusion is the free movement of molecules of a substance from regions of high concentration to regions of lower concentration. Osmosis is the diffusion of water molecules through a semi-permeable membrane from a weak solution to a strong solution. Active transport is an energy consuming process, which moves substances through a membrane from a region of low concentration to a region of higher concentration (i.e. the opposite direction to diffusion).

5.1.1 Diffusion in Liquids



P: Carefully, put a crystal of potassium permanganate at the bottom of a jar containing water. Leave undisturbed and observe at 20 minute intervals. Alternatively, knot a piece of string four or five times to make a compact ball. Wax or grease the string above the knot and soak the knot in iodine solution. Hang it in a jar of water and observe at intervals. Starch solution could be used instead of water in the case of the iodine experiment, thus producing a blue-black colour as a result of diffusion.

Q: What happens to the colour of the water or the starch solution?

O: In both cases the colour of potassium permanganate and iodine spread slowly throughout the solutions.

E: Molecules of potassium permanganate or iodine move from where they are more concentrated to the where they are not found at all, until the concentration in both areas is the same. This is diffusion.

5.1.2 Simple Diffusion Model

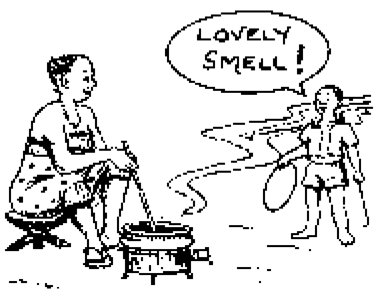
P: Arrange two or three different types of seeds or beads in layers in a container. Cover and shake thoroughly.

Q: What do you observe about the distribution of seeds or beads?

O: They are all mixed together.

E: Since they are free to move, the seeds or beads become evenly distributed. This is similar to the process of diffusion.

5.1.3 Diffusion in Daily Life



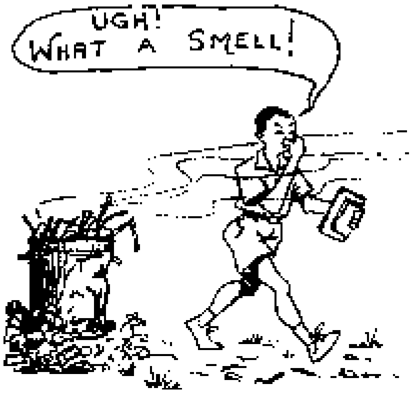
P: Pass near a place where meat is being roasted or food is being cooked.

Q: What do you sense?

O: The smell of cooking food

E: The smell from the food can be sensed even at a distance, because the particles producing the smell spread out into the air by diffusion normally by the joint effect of diffusion and wind.

5.1.4 Diffusion and Pollution



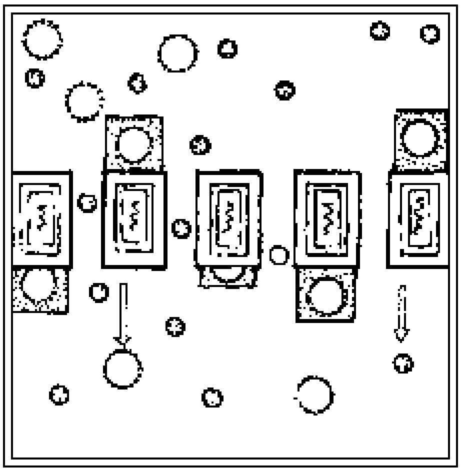
P: Pass near a polluted area (e.g. burning heap of litter, filling station, latrine)

Q: What do you smell?

O: The smell in each case is often unpleasant.

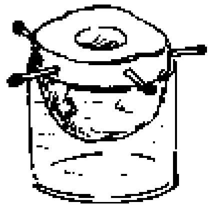
E: See 5.1.3

5.1.5 Osmosis and Active Transport Model



P: Construct the above model using a small cardboard or plastic tray and some matchboxes. The gaps between the boxes should allow small objects to pass (i.e. peas) but prevent movement of larger ones (soda bottle caps). Place ten soda bottle caps and ten peas in one side of the tray and twenty peas in the other side. Shake the tray gently ten times. Count the peas in each side. The matchboxes and the space between them represent a selectively permeable membrane; the peas represent water molecules and the soda caps represent large solute molecules such as glucose. The water molecules can move freely, whereas the glucose molecules cannot. This represents *osmosis.* The process of *active transport* can be demonstrated by placing a soda cap in a matchbox tray and pushing it through the matchbox "membrane". Thus it illustrates that active transport requires energy and is selective for certain substances, since only bodies which fit in the matchbox tray can be carried across.

5.1.6 Osmosis in Plant Cells



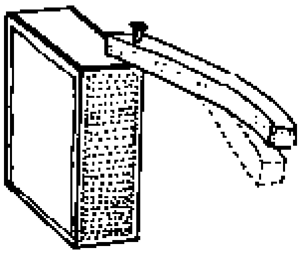
P: Cut a piece of potato or a piece of carrot. Make a shallow hole in the cut surface, and support the potato in a cup or jar. Place a small amount of sugar or salt in the hole. Leave for 3 or 4 hours.

Q: What happens to the sugar or salt in the hole?

O: Water gradually collects in the hole and sugar or salt dissolves.

E: Water is drawn out of the plant cells by osmosis and into the hole. This is because the solution in the cells (the cytoplasm) is weaker than the sugar or salt solution in the hole.

5.1.7 Osmosis and Turgidity



P: Cut some strips of irish or sweet potato about 50 mm long and 5 mm square. Place some in a strong sugar solution (2 or 3 spoonfuls of sugar in half a cup of water) and some in plain water.

Q: What is the difference between the strips?

O: The strip from the sugar solution has lost water by osmosis and so is soft (flaccid). The one in water has not lost water and so remains rigid (turgid).

5.1.8 Changing the Size of an Egg

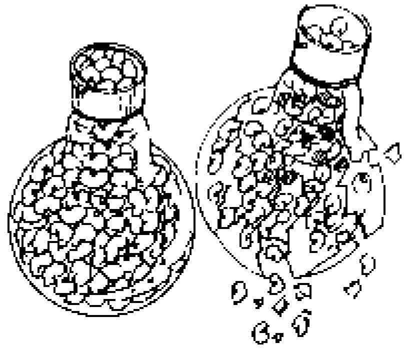
P: Take two eggs and place them in dilute hydrochloric acid until their shells dissolve (about 12 hours). Find the volume of each egg by submerging in a container of water. Place one egg in distilled water and the other in strong salt solution. After several days remove the eggs and find their respective volumes.

Q: What can you say about the volumes of the eggs at the end of the experiment.

O: The egg in distilled water increases in volume whereas the egg in salt solution decreases in volume.

E: The concentration of the liquid inside the egg is higher than water so water moves in by osmosis. However when placed in salt solution the external solution is now stronger so water moves out of the egg by osmosis.

5.1.9 Bursting Osmosis Box



P: Tightly pack a matchbox with dried beans or seeds. Place in a container of water and leave overnight

Q: What do you observe?

O: The seeds swell and burst the box open.

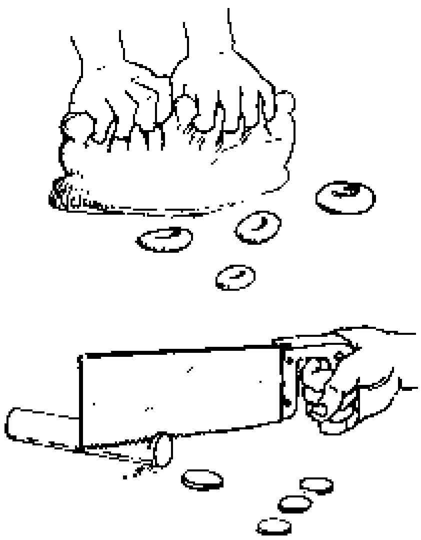
E: Dormant seeds have a low water content. When they start to germinate they take in water by osmosis and increase in size. The forces involved are enough to burst the box.

I: The swelling seeds will even break the glass of a fused bulb.

5.2. Blood and Blood Groups

Blood is a fluid tissue of animals consisting of several different types of cell suspended in a fluid called plasma. The cells include red blood cells, white blood cells and platelets. Blood transports substances from one part of the body to another, helps defend the body against disease and keeps conditions right for the working of our cells.

5.2.1 Red Blood Cell Models



P: (a) Use a modelling material like clay or plastercine to shape red blood cells.

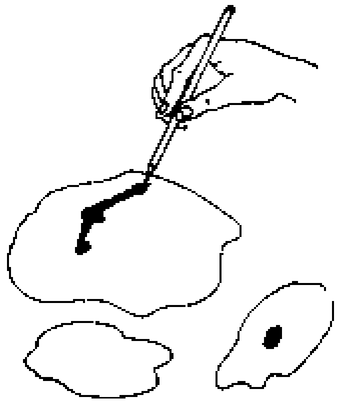
(b) Cut slices of wood from a round straight stick. Use a knife to carve out the concave areas. Paint if necessary.

(c) Cut out circles of thick card board and shade to show concave area.

E: Red blood cells are biconcave discs approximately circular and 7.2 micrometre in diameter. They have no nucleus.

H: Platelet models can be made by cutting red cell models into pieces.

5.2.2 White Blood Cell Models



P: (a) Fill a plastic bag with a little water and add a stone or seed to represent the nucleus of the white cell.

(b) Cut the white blood cell from a thin sheet of sponge rubber. Draw on a nucleus.

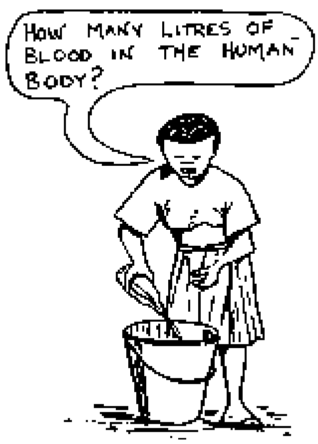
(c) Cut the shape of the white cell from cardboard or plastic sheet and draw on a nucleus.

Q: Compare these blood cells with red blood cells.

O: White blood cells have no fixed shape are transluscent and are much larger than red blood cells.

E: Their large size helps them to secrete a lot of antibodies and to engulf bacteria or foreign bodies.

5.2.3 How much Blood?

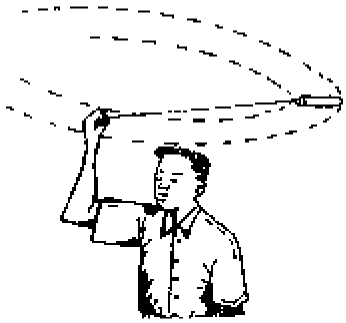


P: Take a bucket full of water and an empty bucket.

Q: Let the student estimate how many litres would represent the amount of blood in the human body?

O: You would need about 5 litres.

5.2.4 Simple Centrifuge



P: Attach a short string to a test tube neck. Half fill the tube with animal blood and seal securely. Spin the tube very quickly around your head. Shorten the string to make the tube circle faster.

E: The red blood cells being heavier than plasma are pushed to the bottom by centrifugal force.

I: *For safety reasons make sure that both seal and string are attached securely and noone will be hurt.*

5.2.5 Red Blood Cell Factory

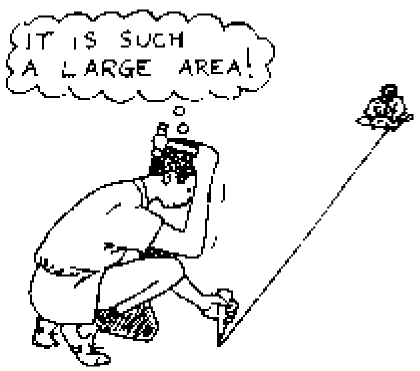
P: Saw or crack open a fresh bone.

Q: What do you notice about the colour?

O: The ends of the bones may look bright red.

E: Red blood cells are' made in the red bone marrow of short bones such as the sternum and vertebrae.

5.2.6 Blood and Football



P: Measure out an area 50 metres by 25 metres on the football field or school compound.

Q: What has this to do with blood?

E: This is the area that could be covered if the body's red blood cells were placed side by side one cell deep! (A quarter of the area of a full size pitch).

5.2.7 Around the World

P: Imagine if all the red blood cells in your body were placed side by side in a line.

Q: How far would the line stretch?

O: The line of red blood cells would stretch over four times round the world.

E: Over 20 billion red cells are present in the blood of an teenage human.

5.2.8 Anaemia

P: Pull down your lower eyelid to expose the surface next to the eyeball. Using a mirror observe its colour. If there is no mirror let your neighbour check the colour.

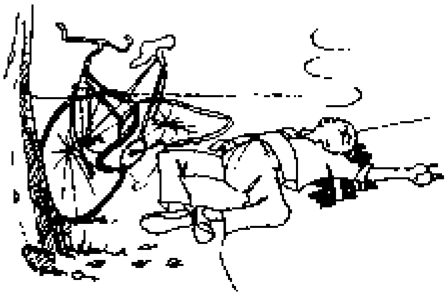
O: The lower side of the eyelid may be pale or red coloured.

E: The paleness indicates that a person is anaemic and they do not have enough red blood cells. The oxygen carrying capacity is reduced causing tiredness. The most common kind of anaemia happens when women and girls lose blood during menstruation and do not eat enough iron-containing foods.

5.2.9 Engulfing Model

P: Use a white handkerchief to represent a white blood cell and a seed or fruit as an invading foreign body. Shape the handkerchief so that it has two arms representing pseudopoda and then bring those arms around the seed or fruit. White blood cells swarm to a site of infection and devour bacteria by engulfing (phagocytosis).

5.2.10 Blood Loss



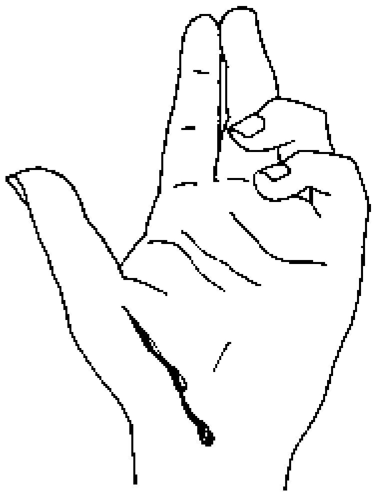
P: In an accident a person may lose blood.

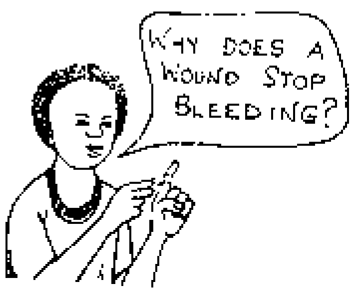
Q: What happens if we lose a lot of blood?

O: We lose consciousness.

E: Death may occur because blood pressure falls, and this slows down the flow of blood around the body. The number of red blood cells falls, so the oxygen-carrying ability of the blood is reduced.

5.2.11 Blood Clotting



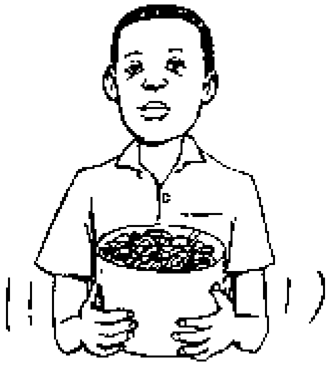


P: When you cut yourself the wound will bleed for a few minutes and then begin to clot.

Q: Why does it stop bleeding?

E: Blood clotting is brought about by a series of reactions. *Platelets* release a substance that converts *prothrombin* to *thrombin. Thrombin* converts *fibrinogen* in plasma into *fibrin* a mesh or network of fine threads. Blood corpuscles are entangled in the network that covers the wound. The resulting clot blocks the wound, prevents bleeding and stops germs entering the body, while white blood cells in the network attack bacteria already present.

5.2.12 Blood Clot Model



P: Place some red and white beans in a container to represent red and white blood cells. Move them around by gently shaking. Mix thin strips of grass or paper with the beans and repeat the shaking action. The beans are packed more securely by the strips. The strips represent the fibrin network (see 5.2.11)

5.2.13 The Healing Battle

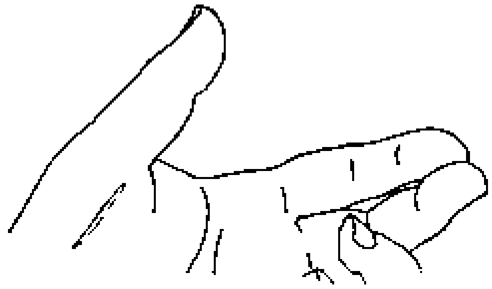
P: Examine a wound a few hours after it occurred.

Q: What do you notice?

O: The area of the wound has swollen in size, it looks red and causes pain.

E: The body is mending and defending itself against the invasion of foreign germs. Heat is produced during these activities and swelling helps to immobilise the wounded area. Pain warns the brain to take care of the wound.

5.2.14 After the Battle



P: A few weeks after cutting your hand or knee the scab (network of fibrin and cells) comes away

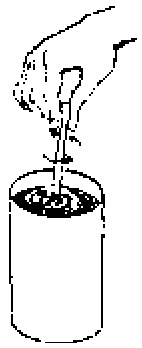
Q: What does the wound look like now?

O: The skin of the wound looks healed but a little tender. There may be some clear fluid behind the scab.

E: The skin under a scab may not have a protective layer of dead cells on it. The fluid is plasma serum.

I: If the scab comes off too early the new skin will pull away and bleeding will result.

5.2.15 Slowing Blood Clotting



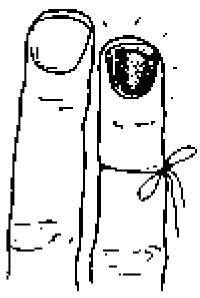
P: Animal blood tends to start clotting soon after leaving the animal. Stir the blood with a rod or stick for 4-5 minutes.

Q: Why do these actions stop Hood clotting?

E: Fibrin collects around the stick

I: Chemicals such as sodium oblate or sodium citrate or heparin also prevent blood clotting.

5.2.16 Finger Nail Indicator



P: Tie a cord or band around your thumb or finger. Examine the nail colour.

Wait for a minute.

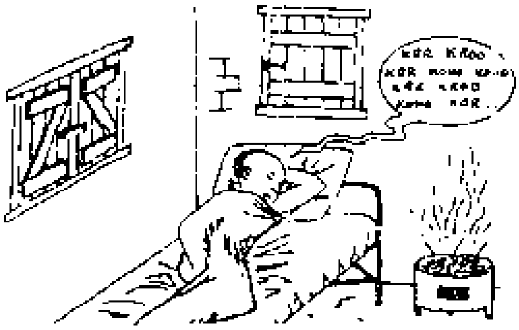
Q: Has the nail colour changed?

O: Yes, It has gone a blue-red colour.

E: The oxygen in the end of the finger is gradually being used up giving the blood a blue tint.

I: *Do not leave the cord on your finger too long*!

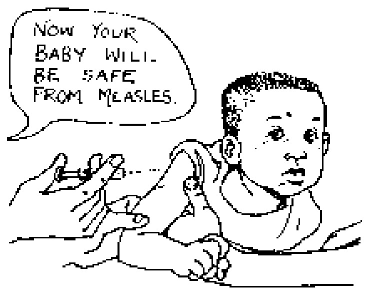
5.2.17 Haemoglobin's Favourite



P: Sleeping in a room with a charcoal stove on while the windows are closed may lead to carbon monoxide poisoning.

E: Carbon monoxide is the odourless, colourless, killer component of combustion. Often it is produced when a fuel burning appliance does not work efficiently. Haemoglobin has an even greater liking for carbon monoxide than for oxygen. It combines 300 times more readily than with oxygen. If we breathe it in, less oxygen can combine with the blood, so the tissues are starved of oxygen. Small amounts of CO are found in cigarette smoke.

5.2.18 Immunity

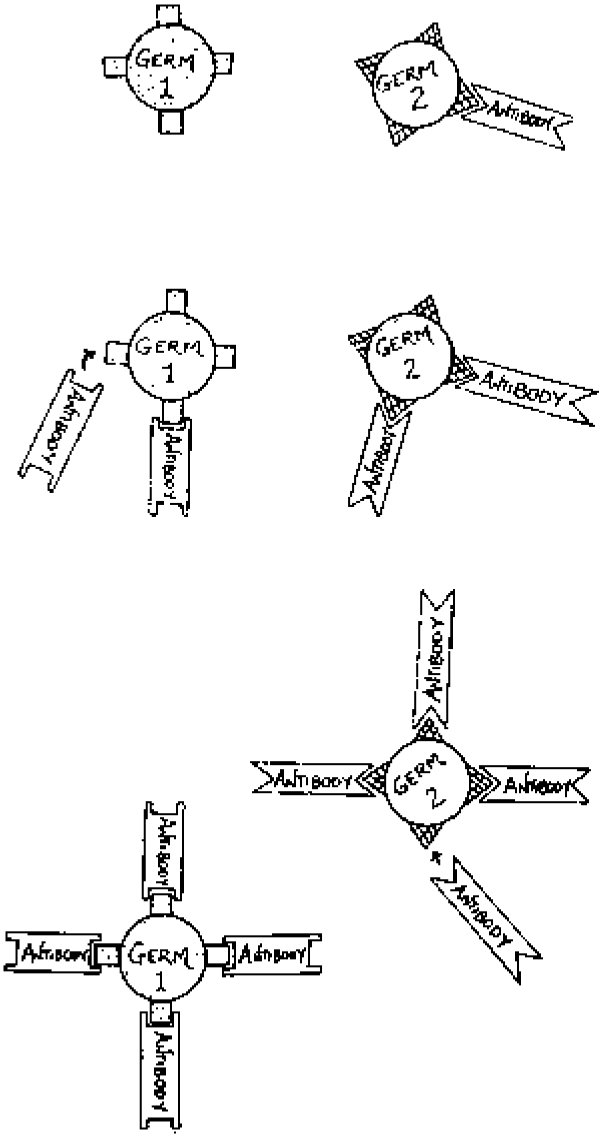


P: Inoculation into the body of a vaccine (which may consist of an old strain of the disease; or the dead organisms or live micro-organism) gives immunity.

Q: What is immunity?

E: The inoculation causes the build up of antibodies which may remain in the body for several years. These antibodies are ready to fight infection by the microorganism at any time.

5.2.19 Antibody and Antigen Reaction

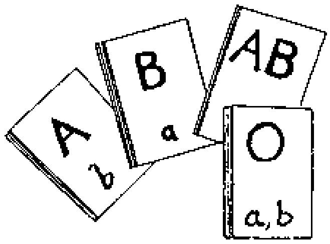


P: Prepare circles of card with different shapes on their edges as shown in the diagram. The circles represent the *germ* and the edge shapes their *antigens.* Now cut strips of card and alter one end of each so it matches the edge shapes of the "germ circles".

Q: How would you use these?

E: The strips of card represent the antibodies produced by the body to combat the antigens of the germs. The antibodes will be able to act on a specific antigen.

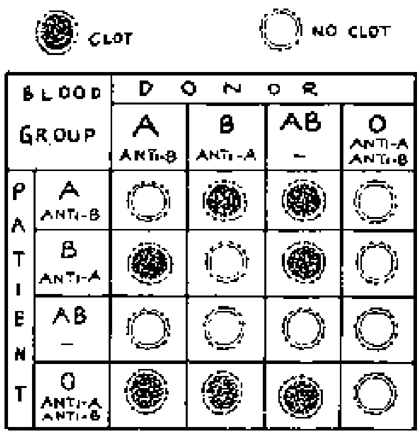
5.2.20 Transfusion Card Game



P: Cut out twenty rectangles of card and label five cards for each blood group as shown above. The game is played in the following way: The dealer shuffles the cards and places the pile face down on the table. One card is turned face upwards on the table between two or more players. This card denotes the *patient's* blood group. The next card turned over denotes the *donor's* blood group. Every time a transfusion is possible, the players must call out 'safe'. When the transfusion would be dangerous they call out 'clot'. The first to shout the correct term wins the cards and adds them to their pile. At the end of the game the player with the most cards wins.

5.2.21 Transfusion Checkers

BLOOD GROUP		DONOR A ANTI-B	DONOR B ANTI-A	DONOR AB –	DONOR O ANTI-A ANTI-B
PATIENT	A ANTI-B				
	B ANTI-A				
	AB –				
	O ANTI-A ANTI-B				



P: Draw out a grid as shown in the diagram. Prepare two types of bottle tops: one type to represent a clot and the other to represent a safe transfusion.

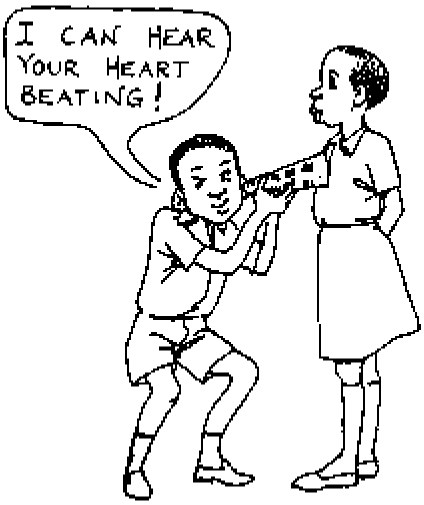
Q: Can you place the tops on the right square to show which blood groups are compatible? Which ones aren't?

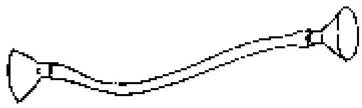
E: The main red blood cells contain antigens, classified as blood groups A, B or AB. Blood group O cells do not have antigens. Antibodies in plasma clump blood cells together.

5.3. Blood Circulation

Blood circulation is the continuous flow of blood round the body initiated by the pumping action of the heart. As the heart pumps blood, pulsations can be felt at some points in the body such as wrists and temples. From the heart, blood moves through thick-walled vessels called *arteries,* into very small thin-walled *capillaries* and back through veins. Some animals, such as mammals have a double circulation where blood goes through the heart twice before completing the cycle. As blood moves it carries useful substances such as oxygen from the lungs and food from the intestines to the body tissues. It also removes waste substances like carbon dioxide from the body tissues. Blood is prevented from flowing back by structures called *valves.*

5.3.1 Newspaper Stethoscope





P: Roll a newspaper up into a hollow tube. Place one end of tube against another students rib cage (in the area of the heart).

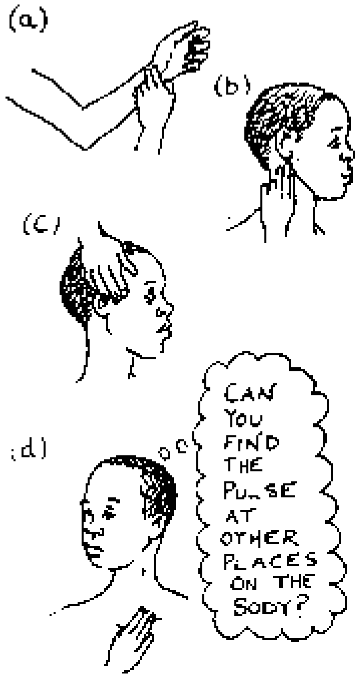
Q: What do you hear?

O: One can hear the heart beats.

E: A doctor uses a stethoscope to focus the sound from the heart. Another stethoscope idea could use funnels and plastic tube.

I: Try listening after vigorous exercise.

5.3.2 Taking the Pulse

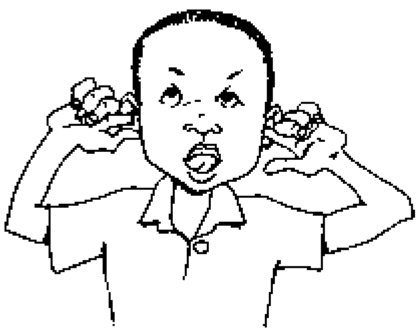


P: There are various places on the body where the pulse may be taken for example (a) at the wrists, (b) under the ear beside the, angle of the jaw, (c) at the temple, (d) above the collar bone.

Q: Can you find the pulse at the various locations?

E: Sometimes you may have to move your finger tips around the area to find the exact location of the pulse or apply a little more pressure.

5.3.3 Listening to Blood Flow



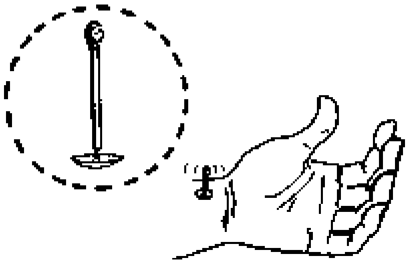
P: Place your index fingers carefully into your ears. This cuts out most external sound. Listen.

Q: What do you hear?

O: A muffled rhythmic beat can be heard.

E: By cutting out external sounds the ears can sense the inner pulse beat of the heart.

5.3.4 Pulse Indicator



P: Attach a matchstick to a drawing pin and place on the wrist where the pulse is strongest. Chewing gum, clay or a small piece of wood may be used if no drawing pin is available.

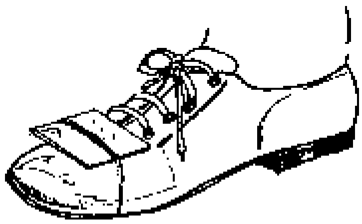
Q: What happens to the matchstick?

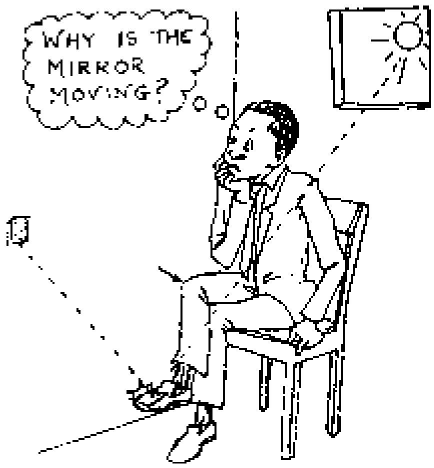
O: The matchstick moves from side to side

E: The matchstick moves every time a pulse beat passes under the pin.

I: Try using the pulse indicator after vigorous exercise.

5.3.5 Pulse Mirror





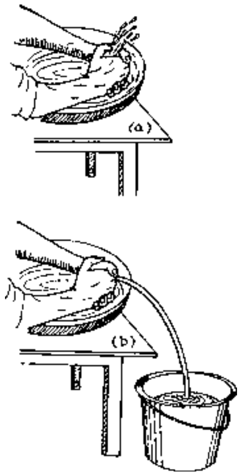
P: Cross your legs as shown above. Attach a small mirror to the shoe of the crossed limb, so that window light or the light of a torch, is reflected by the mirror onto a wall. Sit with crossed legs for a while and observe the patch of reflected light on the wall.

Q: What do you notice about the light reflected onto the wall?

O: The reflected light patch begins to move rhythmically.

E: The crossed leg tends to press on the leg artery and the pulse causes a rhythmic rocking of the lower leg, thus moving the foot and moving the mirror.

5.3.6 Pumping Heart Action



P: (a) Half fill a basin or bucket with water. Place your hands in the water. Open and close your palms pivoting them at the fingers.

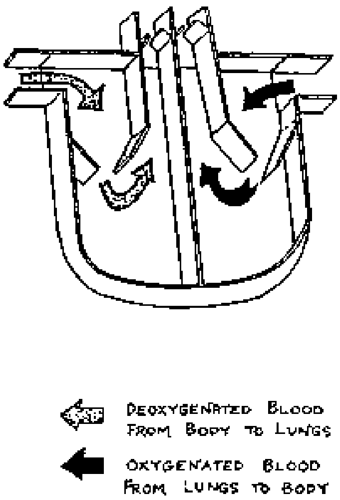
(b) Grip your hands and hold a rubber tube in position as shown in the diagram. Open and close your palms again.

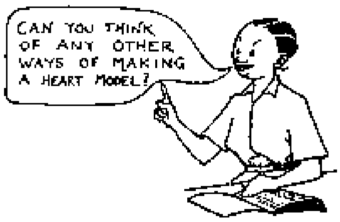
Q: What do you observe at the open end of the hands and at the free end of the tube?

O: When the palms are open, water fills the palm cavity and when closed, water is forced out through the rubber tubing.

E: The opening and closing of the palms represent the relaxation and contraction of the heart muscles. Blood enters the chambers of the heart when the muscles relax and is forced out into the vessels as they contract.

5.3.7 Heart Model



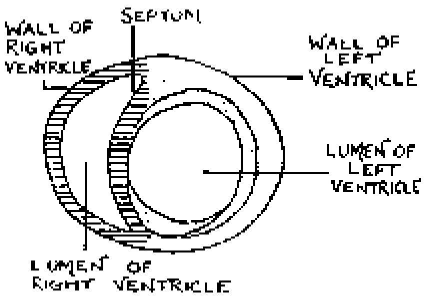


P: Draw a vertical section of the human heart on a piece of hardboard. Cut strips of thick cardboard or stiff paper and glue them on to the board to make a model heart as shown in the diagram. Add arrows. Clay or wood may be used instead of thick paper.

E: The heart is a four-chambered muscular organ. The upper chambers, are thin walled *atria,* which receive blood from the veins. The lower two chambers are the thick-walled *ventricles* which pump blood into arteries.

I: Examine the heart of a large mammal such as a cow or goat.

5.3.8 Ventricle Cross Section



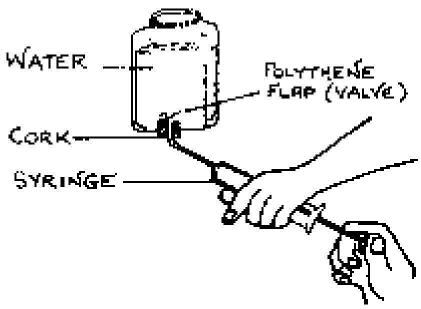
P: Draw and cut out a cross-section though the ventricles from stiff paper.

Q: Are there any differences between the two ventricles?

O: The left ventricle has a thicker wall and larger lumen than the right ventricle.

E: The reason for the difference is that, pumping blood to the nearby lungs, by the right ventricle, takes much less effort than pumping blood to the rest of the body by the left ventricle.

5.3.9 Valves



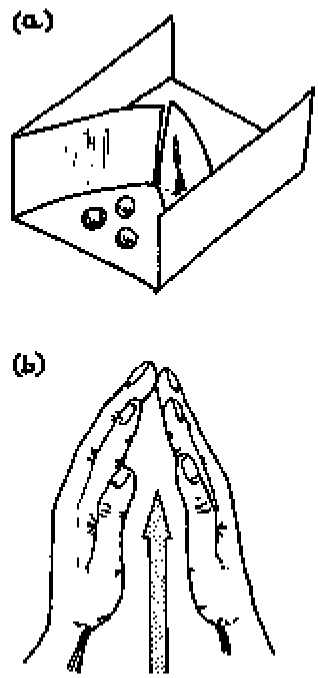
P: Set up the apparatus as shown above. Push in the syringe plunger, then pull it back.

Q: What do you observe?

O: When the plunger is pushed in, the flap opens allowing water into the plastic container. When it is pulled back, the flap closes preventing water from flowing back.

E: The polythene flap acts as a valve allowing forward flow of blood and preventing its back flow.

5.3.10 Valve Models



P: Using a card or paper, make a model valve as shown in the diagram (a). Use pebbles or pieces of chalk to show the flow through the valve in the direction shown. Tilt the model backwards.

Q: What do you observe about the flow?

O: The pebbles pass through the valve, but the valve closed preventing the flow going in the opposite direction when the model is tilted backwards.

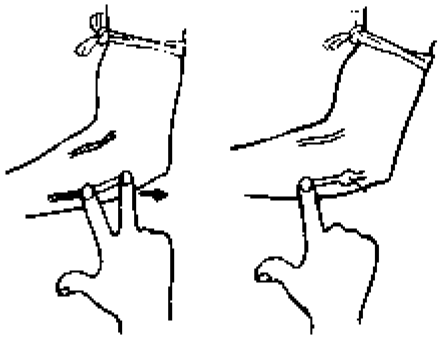
E: The valves allow flow of blood in one direction only.

I: The action of valves can also be illustrated using touching hands as in diagram (b). Let your neighbour push their hand through the touching fingers in the direction of the arrow.

5.3.11 Pulse Rate and Heartbeat

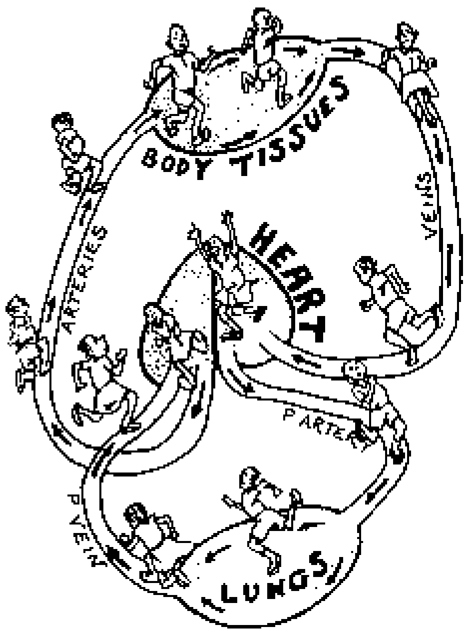
P: See 1.3.2 and 5.3.2.

5.3.12 Harvey's Experiment



P: Carefully tie a piece of cloth round the upper arm. *Keep this tied for only a short time.* Surface veins fill with blood. Harvey found he could empty a vessel by placing a finger on the raised vessel and pushing the blood out and up the arm with another finger. When he released the finger nearest the heart, the blood did not fill up the vessel again.

5.3.13 Circulatory System Game



P: Mark out a model of the circulatory system on the ground using stones, string or chalk. Put pieces of red flowers or paper in the area marked *lungs* and pieces of blue flowers or paper in the area marked *body tissues.* To begin the game two or three pupils pick up blue petals at the body tissues and follow the arrows through to the *heart* and on to the *lungs.* At the lungs the pupils drop the blue flowers and pick up the red and return to the body tissues via the other side of the heart.

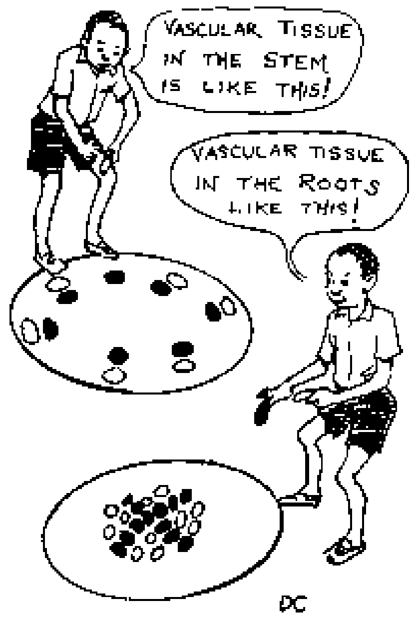
Q: What do the pupils represent?

E: The pupils represent the flow of blood in the body. They must go through the heart twice before completing the cycle of *double circulation.* As blood flows it transports substances such as oxygen (red flowers), carbon dioxide (blue flowers) and food materials. Pupils can also act as *heart valves.*

5.4. Transport in Plants

Most plants, like animals, have a transport system, although its structure and arrangement are quite different. One type of tissue, the *xylem,* forms a system of open tubes which carries absorbed water and mineral salts from the roots, through the stem to the leaves. Another type of tissue, the *phloem,* consists of living cells, which can transport large molecules such as food Substances in either direction, between any parts of the plant. Water moves up through the xylem by a process called the *transpiration stream* and evaporates from the leaf surface by *transpiration.* Movement of materials through the phloem is called *translocation.*

5.4.1 Plant Vascular Tissues

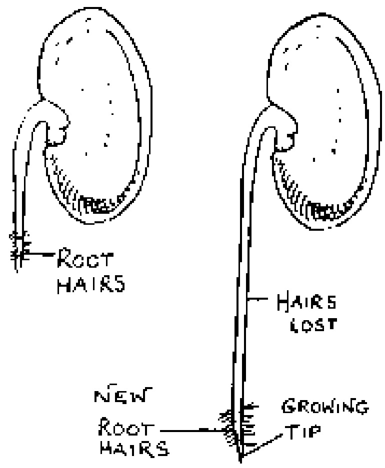


P: Chalk two circles on the floor. Each about one metre in diameter. Cut out 20 discs of newspaper, card or exercise book paper. Colour 10 discs to represent the xylem, the other ten uncoloured discs represent the phloem. Place the different coloured discs of paper in the chalked circles to show the arrangement of the tissues in a stem, and the arrangement in a root.

Q: What are the differences in arrangement between stem and root?

E: Vascular tissue forms a ring of bundles in the stem but a central column in the root.

5.4.2 Root Hairs



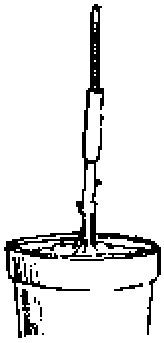
P: Germinate some peas or bean seeds on a damp cloth or newspaper. Leave them until the young root (radicle) emerges. Observe the root tip. (This can be assisted using a simple magnifier).

Q: What is the appearance of the root?

O: A fine covering of thin hair-like structures can be seen, just behind the root tip.

E: A root develops hairs just behind the growing tip. As the root gets older and larger the root hairs are lost. Root hairs increase the surface area of the root for absorption of water and mineral salts.

5.4.3 Root Pressure



P: Cut the stem of a well grown potted plant about 5 cms above soil level. Place a tight fitting piece of tubing over the stem and insert a narrower tube (of glass or plastic) inside. Seal all joints with vaseline.

O: Water collects in the tube and the water level gradually rises.

E: Root pressure is one of the forces which helps water to move up the stem. It is the force which causes the water to rise up the tube.

5.4.4 The Plant as a Straw

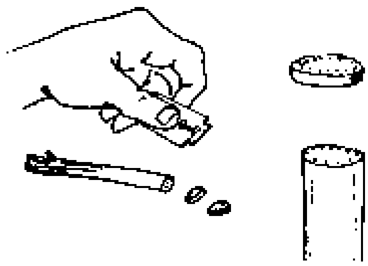
P: Set up the materials as shown. Make sure the clay forms a complete air-tight seal. Suck air through the straw from the air space at the top of the bottle.

E: The plant has a system of tubes (xylem) running from the roots through the stem to the leaves. These tubes end in spaces in the leaf which open to the air through tiny holes called stomata. By sucking, air is drawn in through the stomata and along the xylem tubes to the cut end of the stem and bubbles form.

5.4.5 Movement of Water in a Plant

P: Take a young plant, such as Balsam, which has a semi-transparent stem (Zinnia). Wash the roots well and place in a diluted solution of red or blue ink. Leave for two hours. Coloured ink can be seen moving up the stem and into leaves.

5.4.6 Which parts of the Stem carry Water?



P: Take a plant stem which has been placed in coloured ink or dye. Cut very thin sections with a sharp razor blade. Examine the sections by holding them up to the light on the end of a pin or by using a simple microscope.

O: The colour is located as small dots forming a circle towards the outside of the stem.

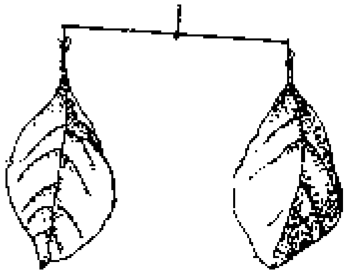
E: Water and the dye are carried in xylem tissue which is found grouped together as separate vascular bundles.

5.4.7 Leaf Transport System

P: Spray or dust paint (or ink) onto the leaf surface. Place a piece of paper on the painted surface, press under a weight. Remove the paper to reveal print.

E: Monocot and dicot leaves of flowering plants have vascular bundles which can be seen as veins in the leaves when holding the leaves to the sun. The veins run parallel to each other in monocots and form a network in dicot leaves.

5.4.8 Transpiration -Weight Loss



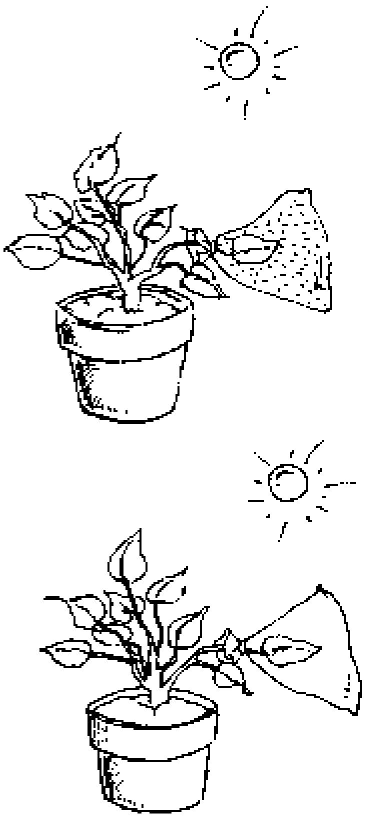
P: Take two leaves of the same size and type. Grease one leaf on both surfaces, then hang each one at opposite ends of a thin stick. Suspend the stick by a thread so that it is balanced

Q: What happens to the balance of the stick?

O: The end of the stick on which the ungreased leaf is hung moves upwards.

E: Leaves lose water by transpiration. This can be prevented by applying a layer of grease. The ungeased leaf loses water and becomes lighter.

5.4.9 Transpiration -Water Loss



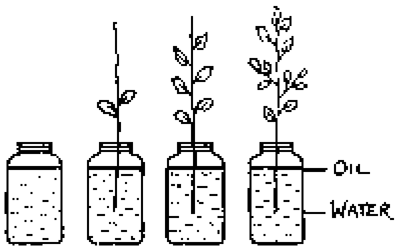
P: Place a polythene bag over the leaf of a living plant. Secure the bag to the stem with a thread. Repeat the experiment with a greased leaf of the same size.

Q: What can you see on the inside surface of the bags?

O: Water droplets appear on the inside of the bag placed over the ungreased leaf. Very little or no water collects in the other bag.

E: Water, which is absorbed from the soil by the plant, is lost through the pores (stomata) of the leaf. This is transpiration. There is no water loss from the greased leaf because the grease blocks the pores.

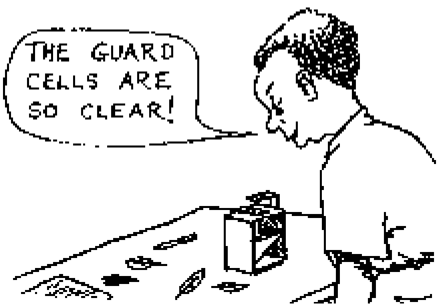
5.4.10 Leaf Number and Water Loss



P: Take branches of the same plant with a different number of leaves. Take containers and put an equal volume of water in each. Place a few drops of cooking oil or kerosene on the surface of the water in order to avoid evaporation. Measure the volume of water in each container every day.

E: Water is lost through stomata. The larger the number of leaves the more stomata and the more water lost into the air.

5.4.11 Looking at Stomata



P: Take a leaf of comelina, zebrina or similar. Snap it in half to obtain a ragged edge. With forceps peel off a small portion of lower epidermis. Place this in a drop of water on a glass slide, add one drop of dilute iodine and cover with a coverslip. Examine using a simple microscope (see appendix). The irregular, rounded cells of the epidermis can be seen and scattered through these are curved guard cells found in pairs around the stomatal pore.

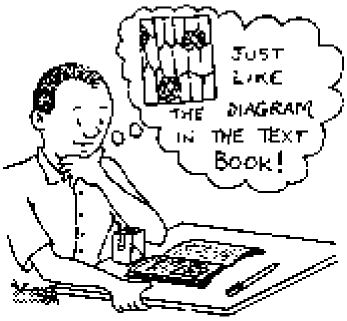
5.4.12 Distribution of Stomata

P: Put a leaf into very hot water and observe the changes on it. Repeat the experiment with various types of leaves (monocots and dicots).

O: Bubbles come from the stomata due to the expansion of the air in the leaf. Dicot leaves show bubbles mainly on the lower surface, but monocot leaves show bubbles on both surfaces.

E: Stomata are found mainly on the lower surface of dicot leaves whereas they are equally distributed on both surfaces of monocot leaves.

5.4.13 Stomata Skin



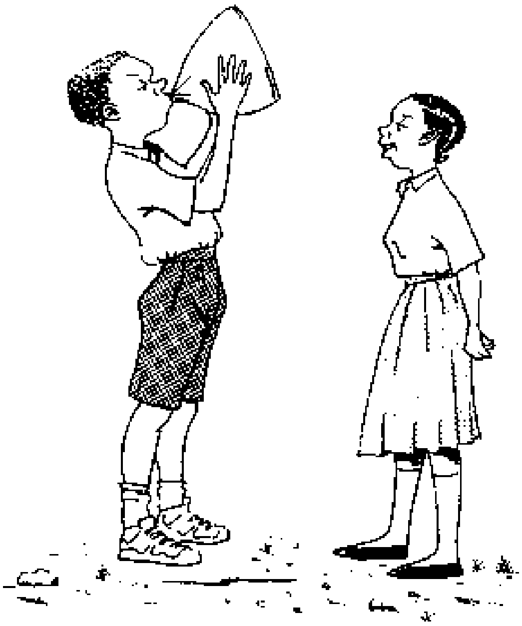
P: Lightly coat the underside of a leaf with clear nail varnish. Allow the varnish to dry then peel it off. Examine the varnish 'skin' under a simple microscope (see appendix).

Q: What do you observe on the varnish 'skin'?

E: Small curved cells are visible around the pores. These are the guard cells of stomata.

I: Try using this technique to examine other surfaces.

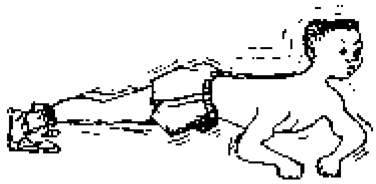
6. Gaseous Exchange and Respiration

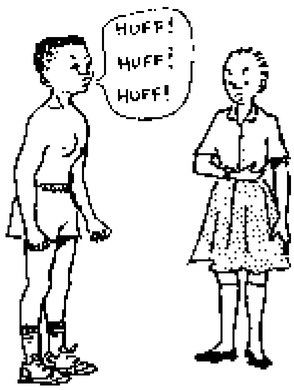


6.1. Ventilation in Vertebrates

Living things use air (oxygen) for the production of energy which is required for carrying out life processes such as movement, growth etc.. *Respiration* is the breakdown of organic substances within cells to release energy (cell respiration). Gaseous exchange of carbon dioxide for oxygen. Gaseous exchange needs a flow of air over a respiratory surface a process called ventilation (or breathing).

6.1.1 Data on Breathing and Fitness





P: Count the number of breaths (on inspiration or expiration) per minute of a number of people a) while sitting, b) while standing and c) after exercise. Tabulate the results and compare. How can you explain the differences?

6.1.2 Air is Not Always Clean
